**Background:** Gradual bone loss is expected with advancing age and gender differences were reported in the rate of annual loss of bone. Ideally, the decision to introduce interventions designed to prevent bone loss would be informed by reliable algorithms to identify fast bone losers. However, these are not readily available.

**Objectives:** In this analysis of 14 years prospective population-based data, we aim to identify predictors of the bone mineral density (BMD) loss in the perimenopausal and elderly population.

**Methods:** This study included members of the general population aged 40+years from the longitudinal cohort SAOL (individuals aged 18+years randomly selected from a local county of Coimbra, Portugal). The included individuals answered validated self-reported questionnaires at baseline (1997–2000) comprising questions on osteoporosis risk factors and medication use and underwent a Dual-energy x-ray absorptiometry (DXA) of the proximal femur (PF) and lumbar spine (LS). These procedures were repeated at follow-up (2011–2014). Demographic characteristics and DXA BMD details were descriptively summarised at baseline.

Annual percentage changes of total BMD ( $\text{g}/\text{cm}^2$ ) in the PF and LS were computed (annual  $\Delta\text{BMD}$ ). The relationship between annual  $\Delta\text{BMD}$  and potential predictors was assessed by independent-samples t-test or Pearson correlations, according to the categorical or continuous nature of the independent variable. The baseline independent variables included were: age (years); gender; body mass index ( $\text{kg}/\text{m}^2$ ); smoking, alcohol intake, rheumatoid arthritis, glucocorticoid treatment and secondary osteoporosis according to FRAX algorithm definitions. The follow-up reported calcium/vitamin D supplementation and treatment with bisphosphonates, for at least 1 year (yes/no), were also considered as independent variables. We used linear regression models (enter method) to estimate the possible association between socio-demographic/clinical variables and the BMD changes of PF and LS. The predictor variables included in the model were selected *a priori* based on variables that were associated with annual  $\Delta\text{BMD}$  on univariate analysis. Results were considered significant when  $p < 0.05$ .

**Results:** This analysis included data from 636 individuals (mean ( $\pm\text{SD}$ ) age of 53  $\pm 8$  years, 76% female). The mean ( $\pm\text{SD}$ ) follow-up period was 13.6  $\pm 1.1$  years. Baseline mean ( $\pm\text{SD}$ ) BMD of the PF and LS were 0.77  $\pm 0.004$  and 0.94  $\pm 0.132$ , respectively. The mean ( $\pm\text{SD}$ ) percentage of annual bone loss was: -0.19  $\pm 1.02$  for PF and -0.06  $\pm 0.84$  for LS. On univariate analysis,  $\Delta\text{BMD}$  at both the PF and LS was significantly associated with gender ( $p < 0.001$ ). Annual  $\Delta\text{BMD}$  was also associated with vitamin D supplements ( $p = 0.014$ ) at PF, and with calcium supplements ( $p = 0.002$ ) and bisphosphonate treatment ( $p = 0.027$ ) at LS. On multiple linear regression analysis, female gender persisted as a predictor of faster BMD loss in both PF ( $p < 0.001$ ) and LS ( $p = 0.006$ ). While bisphosphonate treatment didn't predict the annual bone loss, vitamin D and calcium supplementation persisted as predictors of lower annual  $\Delta\text{BMD}$  at PF ( $p = 0.034$ ) and LS ( $p = 0.033$ ), respectively.

**Conclusions:** Our results confirm that the rate of BMD loss at PF and LS over 14 years is significantly associated with gender. Vitamin D and calcium supplementation appeared to have a role in the prevention of bone loss in this general population cohort.

#### THU0492 PRELIMINARY STUDY OF THE BONE MASS IN LUNG TRANSPLANTED PATIENTS IN TREATMENT WITH DENOSUMAB

M. Barceló-Bru, B. Rodríguez-Diez. *Rheumatology Unit, Hospital Universitari Vall d'Hebron, Barcelona, Spain*

**Background:** Osteoporosis (OP) is a known complication before and after a lung transplant. In addition to altering bone mass, treatment with glucocorticoids alters the bone microarchitecture, conditioning an increased risk of fracture in these patients. Denosumab (Dmab) is a monoclonal antibody approved for the treatment of postmenopausal OP and its use for corticoid OP is pending approval.

**Objectives:** To describe the subcohort of lung transplant patients who have been treated with Dmab. To study the evolution of bone mass in patients with lung transplantation, with OP induced by glucocorticoids, treated with Dmab.

**Methods:** We included 19 lung transplant patients between 1995 and 2017 controlled in rheumatology for OP and in treatment with Dmab. Of these 19 patients, the evolution of bone mass of the 9 patients who have completed a minimum of 12 months of treatment is shown. Bone densitometry (DXA) was performed on a General Electric Healthcare Lunar Prodigy Advance 15 version densitometer, before and after treatment with Dmab. Demographic data of the patients were collected, the diagnosis of the disease that motivated the transplant, the glucocorticoid doses before and after the transplant, as well as the immunosuppressive treatment. In the 9 patients with DXA follow-up, the 3D-SHAPER software was applied in the DXA before and after the transplant.

**Results:** We included 19 patients (10 women) with a mean age of 58.6 years  $\pm 11.4$ . The diagnosis of the disease that led to the transplant was in 4 COPD patients, 6 patients with pulmonary fibrosis or diffuse interstitial disease, 2 with bronchiectasis, 2 patients with cystic fibrosis, 1 with histiocytosis X, 2 with lymphangioleiomyomatosis, 1 with bronchiolitis obliterans and 1 patient with pulmonary hypertension. Before transplantation, 8 patients (42.1%) had required high doses of glucocorticoids. The prevalence of OP prior to start Dmab treatment in the 19 lung transplant patients was 94.7%. The means of BMD in  $\text{g}/\text{cm}^2$  and T-score before treatment with Dmab and the results of the 3D-SHAPER are shown in table 1.

	DMO $\text{g}/\text{cm}^2$	T-score
Lumbar spine	0,909 $\pm 0,13$	-2,40 $\pm 1,08$
Femoral Neck	0,708 $\pm 0,94$	-2,50 $\pm 0,77$
Total Hip	0,702 $\pm 0,86$	-2,73 $\pm 0,59$
Cortical Density ( $\text{g}/\text{cm}^2$ )	109,3 $\pm 7,7$	-2,9 $\pm 0,3$ ‡
Trabecular vBMD ( $\text{g}/\text{cm}^3$ )	85,7 $\pm 21,4$	-2,9 $\pm 0,8$ ‡
Integral vBMD ( $\text{g}/\text{cm}^3$ )	198,7 $\pm 19$	-3,3 $\pm 0,5$ ‡

The mean time in which the DXA was performed prior to the treatment with Dmab with respect to the transplant date was 4.31  $\pm 5.83$  years. The mean time in which the DXA was performed after the start of Dmab was 19  $\pm 4.17$  months. The results of the evolutionary BMD, the 3D-SHAPER study and its percentage of change are shown in table 2. Of these 9 patients, 88.9% had received osteoactive treatment before Dmab, 5 with oral bisphosphonates and 3 with endovenous bisphosphonates. The mean time of treatment with bisphosphonates until the onset of Dmab was 5.4 years. There were no significant differences in BMD evolution between patients treated for OP prior to Dmab and those not treated, nor for 3D-SHAPER.

		Tx (9)	
OP pre-Dmab		8 (88,9%)	
OP post-Dmab		8 (88,9%)	
DMO post-Dmab (mean)		$\text{g}/\text{cm}^2$	T-score
-	L1-L4	0,949 $\pm 0,13$	-2,05 $\pm 1,07$
-	CF	0,722 $\pm 0,12$	-1,86 $\pm 2,22$
-	FT	0,696 $\pm 0,06$	-2,76 $\pm 0,49$
% change DMO			
-	L1-L4	8,42 $\pm 6,64$ *	
-	CF	2,21 $\pm 6,55$ *	
-	FT	2,80 $\pm 3,56$ *	
High GC dose pre-Transplant		2 (22,2%)	
3D-SHAPER (mean):			
-	Cortical Density ( $\text{g}/\text{cm}^2$ )	113,7 $\pm 10$	
-	Trabecular vBMD ( $\text{g}/\text{cm}^3$ )	88,5 $\pm 23,7$	
-	Integral vBMD ( $\text{g}/\text{cm}^3$ )	203,7 $\pm 24,4$	
% change 3D-SHAPER:			
-	Cortical Density	4,13 $\pm 4,5$	
-	Trabecular vBMD	3,4 $\pm 10,9$	
-	Integral vBMD	2,6 $\pm 7,7$	

**Conclusions:** All patients who started treatment with Dmab had a diagnosis of OP except one patient with osteopenia. The mean increase in BMD in patients treated with Dmab was significant in all the regions assessed, being higher in the lumbar spine. There was an increase in cortical density, trabecular volumetric BMD and integral volumetric BMD after Dmab treatment, although this increase was not significant for any of the three parameters.

#### THU0493 ARE BISPHOSPHONATES SOLELY RESPONSIBLE FOR ATYPICAL FEMORAL FRACTURES? A CASE SERIES

M.S. Jamal, C. Cockill, S. knights. *Rheumatology, YDH, Yeovil, UK*

**Background:** Atypical femoral fracture (AFF) is an uncommon but important type of fracture. It is concerning because of the associated morbidity, bilateral nature of the condition and delay in healing which has significant implications on the health of the patients.

**Objectives:** To identify other risk factors contributing to development of atypical femoral fractures in our cohort of patients presenting to the fracture liaison service.

**Methods:** We identified a case series of 18 cases were retrospectively from June 2006 to January 2018 through the cohort of patients presenting to the fracture liaison service at Yeovil District Hospital NHS foundation trust, with features suggestive of Atypical femoral fractures. Individual patient cases were evaluated and notes and images reviewed. Atypical femoral fractures were diagnosed according to the 2013 American society of mineral and bone research (ASMBR) criteria. Demographic and co morbidity status was investigated from case notes. Blood results and dual energy x-ray absorptiometry (DEXA) images were accessed through electronic patient records. The results were compiled with Microsoft excel.

**Results:** There were total 22 patient episodes, of which 4 patients had bilateral symptoms. Female to male ratio was 21:1. Median age of presentation was 71. The incidence of AFF was more in shaft fractures. 54% cases had prodromal symptoms lasting from 1-3 months. 9 cases had radiographic evidence of stress fractures of whom 6 were not identified until they fractured. 86% cases had either concurrent or previous bisphosphonate therapy. Duration of Bisphosphonate therapy was variable from 12 months to 30 years. 54% were taking Proton pump inhibitors and 41% were on long term glucocorticoids. 9% were active smokers. 50% episodes were in patients having two or more risk factors. 3 patients had no risk factors identified.

Conclusions: Exposure to Bisphosphonates remains a major risk factor for development of AFF but our case series has shown that other risk factors do play an important part eg. prolonged courses of glucocorticoids and Proton pump inhibitor therapy. It is plausible that bisphosphonates are given for prolonged courses in patients on glucocorticoids and this combination seems to be a particular risk. The risk appears to be greater with multiple risk factors. The temporal relationship of fractures with relation to bisphosphonate therapy cannot be determined as it can happen even after the cessation of therapy. Further longitudinal and larger studies are required to identify whether Bisphosphonate would play a role to reduce the risk of Atypical Femoral fractures.

#### THU0494 THE EFFICACY OF DENOSUMAB IN GLUCOCORTICOID-INDUCED OSTEOPOROSIS DID NOT DEPEND ON PRIOR TREATMENT BUT WAS AFFECTED BY THE DOSAGE OF GLUCOCORTICOID

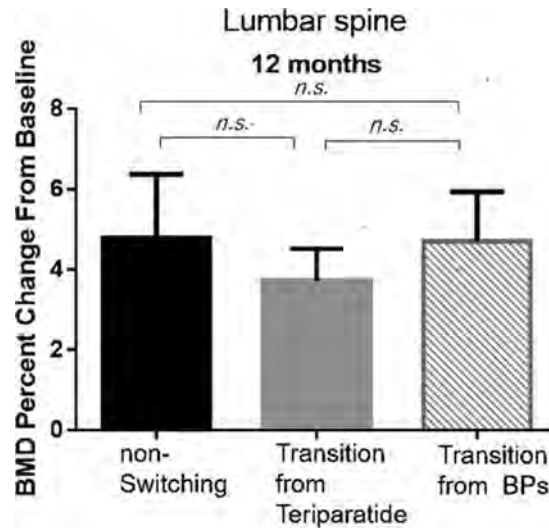

N. Iwamoto<sup>1</sup>, Y. Ueki<sup>2</sup>, T. Aramaki<sup>2</sup>, K. Ichinose<sup>1</sup>, K. Eguchi<sup>2</sup>, A. Kawakami<sup>1</sup>.  
<sup>1</sup>Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki; <sup>2</sup>Department of Rheumatology, Sasebo Chuo Hospital, Sasebo, Japan

**Background:** Despite of the good clinical efficacy of denosumab for primary osteoporosis, 2017 American College of Rheumatology guideline for treatment of glucocorticoid-induced osteoporosis (GIOP) placed denosumab as second-line treatment because of lack of clinical experiences with concomitantly use of immunosuppressive agents. Moreover, recently large phase 3 study in primary osteoporosis revealed that transition from teriparatide to denosumab continuously increased bone mineral density (BMD)<sup>1</sup> However, there is still remain unclear whether prior treatment affect to the efficacy of denosumab in GIOP.

**Objectives:** The aim of this study is to compare the therapeutic effect of denosumab in GIOP between previous anti-osteoporotic treatments, and to investigate the factor that influence the efficacy of denosumab in GIOP.

**Methods:** Sixty-six patients for whom treated by denosumab, were enrolled. All patients were receiving several dosages of prednisolone (PSL) (2–20 mg) for RA and connective tissue diseases at initiation of denosumab. 23 patients had been treated with daily teriparatide and 27 patients had been treated with bisphosphonate (BPs) prior to denosumab. The rest 16 patients had not been treated by anti-osteoporosis medication at initiation of denosumab. We evaluated BMD at lumbar spine and bone turnover markers (NTX, BAP and P1NP) every 6 months for 12 months. The changes in BMD was compared among these 3 groups at 6 months and at 12 months. To assess the factors which influences clinical response of denosumab in GIOP, univariate and multivariable ordinal logistic regression analyses were used.

**Results:** Mean percentage change in BMD of lumbar spine from baseline to 6 and 12 months were significant (2.85% increased;  $p < 0.0001$  and 4.40% increased;  $p < 0.0001$ , respectively) Gains higher than 3% were observed in 68.2%. Whereas, the subjects who showed decrement of BMD at 12 months were few (16.67%). All bone turnover markers determined in this study were decreased at 6 months. Transition from BPs to denosumab further increase BMD at 12 months as compared to transition from teriparatide to denosumab (4.71% increased, 3.71% increased, respectively). However, difference among these 2 groups was not significant and furthermore, the changes in BMD in patients who did no transition from anti-osteoporosis medication to denosumab also showed no significant difference (figure 1). Univariate analysis showed that dosage/duration of PSL, body weight and gender were associated with BMD increase higher than 3% at 12 months. Among these candidates, multivariable logistic analysis showed that dose of PSL was independently associated with clinical response of denosumab (OR 1.36, 95% CI 1.045–1.761  $P < 0.01$ ). No hypocalcemia and osteonecrosis of the jaw was observed during the study period.

**Conclusions:** Our present study demonstrated that denosumab increased BMD in GIOP regardless of prior anti-osteoporotic treatment in 'real-world' settings. We should consider denosumab treatment for GIOP, especially who are treated by much dose of glucocorticoids or at the time when the efficacy of BPs is diminished.

#### THU0495 INDICES OF VERTEBRAL PAIN SYNDROME, PHYSICAL PERFORMANCE AND QUALITY OF LIFE IN OLDER AGE WOMEN WITH VERTEBRAL FRACTURES DEPENDING ON THEIR QUANTITY AND LOCALIZATION

N. Grygorieva, V. Povronyuk, O. Rybina. State Institution «Institute of Gerontology Named after D. F. Chebotarev of Nams Ukraine», Kyiv, Ukraine

**Background:** Nowadays, vertebral fractures (VF) are one of the frequent and severe complications of systemic osteoporosis, which lead to severe spine pain, restriction of physical activity, increased disability and mortality, however, the data about their particularities depending on their quantity and localization are limited. The purpose was to study the indices of vertebral pain syndrome, physical performance, disability and quality of life in women of older age groups with VF depending on their number and localization.

**Objectives:** We examined 230 women aged 50–89 years old, which were divided into 2 groups: I – patients without any history of osteoporotic fractures (n=151), II – women with VF at thoracic and/or lumbar spine (n=79). Subsequently, the persons of the second group were divided into subgroups depending on the number (1 or 2 and more) and localization (thoracic, lumbar spine or combined) VF.

**Methods:** The presence and intensity of pain in the thoracic and lumbar spine were evaluated using the 11-component visual analogue scale (VAS), the level of physical performance was evaluated using static and dynamic functional tests (FT) (Thomayer, Schober tests, chest excursion, lateral trunk lean, 3-, 4-, 15-metre tests, "stand up from the chair", static balancing); disturbance of life was determined using Roland-Morris questionnaire, quality of life - EuroQol-5D questionnaire.

**Results:** It was demonstrated that the intensity of vertebral pain (pain at the time of investigation, the most common level of pain, pain in the best periods of the disease) is significantly worse in women with VF than corresponding parameters in persons without fractures. It was found that women with 2 and more VF have worse values of majority of measured FT (results of Schober test, lateral trunk lean, chest excursion, breath holding, hand grip strength, 15-metre test) in comparison with control group, while in women with 1 VF only results of Schober test and breath holding were significantly worse than same ones in control group. It was shown that for women with VF at the thoracic spine, results of breath holding

and 15-metre tests were significantly worse compared with control, whereas in persons with VF at lumbar spine results of Schober index, lateral trunk lean, hand grip strength and test "stand up from the chair" were worse. In patients with combined VF most of the FT (lateral trunk lean, chest excursion, hand grip strength and 15-metre test) were significantly worse in comparison with control group. The Roland-Morris questionnaire score was significantly higher in women with 2 or more VF compared to controls, unlike the women with 1 VF. We did not find any differences in EQ-5D questionnaire score depending on the number and location of VF.

**Conclusions:** Indices of pain assessment and physical performance in women of older age groups have own peculiarities depending on the number and location of VF, which should be taken into account while assessing of physical abilities and developing of rehabilitation programs for people with VF.

**Acknowledgements:** We are grateful for the collaboration of the group of scientists of «Institute of Gerontology named after D. F. Chebotarev of NAMS Ukraine» (Kyiv, Ukraine) who performed clinical examination, pain assessment and physical performance.

#### THU0496 SKELETAL DEFICIT DUE TO ALTERED BONE QUALITY IN TYPE 1 DIABETES MELLITUS

S. Mohsin, J.J. Sunny, K. Menon, S. Kaimala, on behalf of CMHS, UAEU. Anatomy, United Arab Emirates University, Al Ain, United Arab Emirates

**Background:** Diabetes mellitus (DM) is associated with osteoporosis and increase fracture risk<sup>1</sup>. Increase fractures in type 1 DM are linked to decrease bone mineral density (BMD) but BMD alone does not explain the increase fracture rate seen in diabetics. Alterations in bone quality which entails bone microarchitecture, material and composition of bone tissue also contributes to diabetic osteopathy<sup>2</sup>. Chronic state of hyperglycaemia, hypoinsulinemia, inflammation, low levels of insulin growth factor-1 (IGF-1), increased marrow adiposity, altered adipokine and endocrine factors, increased cell death and accumulation of advanced glycation products that compromise matrix properties impairs normal bone metabolism in type 1 DM<sup>3</sup>. While BMD is detected clinically using a dual-energy X-ray absorptiometry (DEXA) scan, methods to detect changes in bone quality are limited. Estimating bone markers in serum and urine are used in assessing bone quality. An imbalance in bone remodelling as measured by various bone markers is observed in type I DM. But due to discrepancy in results of various studies the exact mechanisms is still elusive.

**Objectives:** To investigate the underlying mechanism of altered bone quality in type 1 diabetes:

1. By measuring the bone formations and resorption markers.
2. By measuring the advanced glycation end products.
3. By analysing the changes at cellular level in type I diabetes

**Methods:** Experimental diabetes mellitus was induced in 24 Wistar rats by injecting streptozotocin 60 mg/kg body weight intraperitoneally. Rats were sacrificed at 6th, 8th and 12th week of developing diabetes. Blood and bone specimens were collected. Serum levels of osteocalcin, bone alkaline phosphatase, C-terminal cross-linked telopeptide of type-I collagen (CTX) and pentosidine were measured using ELISA to investigate bone turnover in type I DM. The bone specimens were fixed, processed, sectioned and stained for bone histomorphometry<sup>3</sup>. Histological analysis was carried out using an 'Olympus Research Inverted Microscope Model IX53' complete with fluorescent attachment equipped with a DP73 camera (Olympus). Statistical analysis was carried out using sigmastat 4.0.

**Results:** Low levels of osteocalcin and bone alkaline phosphatase and increased levels of pentosidine and CTx levels in serum were found in 6th and 12th week duration of diabetes. Additionally increase number of mast cells  $p < 0.05$  were observed in diabetic bones as compared to control specimens

**Conclusions:** Chronic hyperglycaemic state in type I DM impairs bone remodelling by decreasing bone formation and increasing bone resorption. Increase in advanced glycation end products and mast cells also contribute to diabetic osteopathy.

#### THU0497 IS THE SECONDARY OSTEOPOROSIS SOMETHING SECONDARY? EXPERIENCE OF A SECONDARY OSTEOPOROSIS CONSULTATION

S. García-Carazo, P. Aguado Acin, L. Nuño, A. Villalba, A. Balsa. *Rheumatology, La Paz University Hospital, Madrid, Spain*

**Background:** There are many pathologies and drugs that favour the development of Osteoporosis (OP). Although the prevalence of this secondary OP is very high, sometimes assuming a high risk of fracture, it remains an underdiagnosed and undertreated pathology.

**Objectives:** To assess the characteristics of the patients and bone metabolic pathology referred to a secondary OP consultation.

**Methods:** In order to optimise the management of bone metabolic pathology associated with Rheumatoid Arthritis (RA) and other inflammatory articular diseases, an inflammatory op consultation was founded in april/2012. Faced with the growing demand from other medical specialities, it became a secondary OP Consultation in 2014, 2 days per week. Sociodemographic, clinical, biochemical and densitometric data were collected.

**Results:** 418 patients with a mean age of 58.7±11.3 years were evaluated, 78.9% were women, 15.4% premenopausal. 57.4% of patients had densitometric OP and 25.8% Osteopenia. 22.4% had a fragility fracture (60.6% vertebral, 26.5% peripheral, 1.1% hip, 8.5% peripheral/vertebral). Vitamin D level was deficient in 71% of patients.

The most frequent medical specialities who referred patients to our consultation were Rheumatology (18.9% from early RA Unit and 18.2% from Consultation or Rheumatol. Day Hospital), Gynaecology (12.7%) and Neumology (11.2%). But also, there were patient from Oncology, Endocrinology, Nephrology, Haematology and several more medical specialities.

The most frequent underlying diseases were: breast cancer (22.5%), 77.6% in treatment with aromatase inhibitors, early RA (12.4%) and pulmonary disease (11.5%), 41.6% of them were sarcoidosis, other diseases are shown in table 1.

The glucocorticoid-induced OP represented 30.1% of the sample, with a main age of 60.2±11.4 years, being 73% women, 20.6% premenopausal. The most frequent reasons for the use of corticosteroids were: early RA and pulmonary disease (23% respectively), rheumatic diseases (autoimmune dis.(13.5%), established RA (12%), other inflammatory articular disease(7.9%), multifactorial (8.7%), haematological conditions and kidney transplantation(4% respectively). 42.8% of these patients had densitometric OP and 29.3% osteopenia We found 33 fragility fractures (26.1% of patients), 25 were vertebral (75.7%), peripheral 5 (15.1%) and 3 (9.1%) vertebral and peripheral. In 21.2% of cases, these fractures presented with BMD in the osteopenic range and in 6% with a normal BMD.

DISORDER	N (%)
Breast Cancer	94 (22.5%)
Early RA	52 (12.4%)
Endocrinopathies	31 (7.4%)
Pulmonary dis.	48 (11.5%)
Other inflamm. articular dis.	28 (6.7%)
Autoimmune dis.	27 (6.4%)
Multifactorial	27 (6.4%)
Stablished RA	25 (6%)
Digestive dis.	22 (5.3%)
Haematological condition	17 (4%)
Kidney transpl.	12 (2.9%)
Abnormal bone architecture	6 (1.4%)
Nutritional dis.	5 (1.2%)
Prostate Cancer androgenic supp.	5 (1.2%)
Other (HIV, neurological dis,...)	19 (4.5%)

**Conclusions:** There are multiple processes that can associate bone metabolic pathology or a secondary OP, with a high prevalence of fragility fracture in these patients, being the rheumatologist a reference for the management of this comorbidity. A monographic consultation of secondary OP has been useful for other medical specialities and to optimise the management of OP associated with inflammatory/autoimmune diseases in Rheumatology

THU0498

### CORE ENDURANCE AND POSTURAL STABILITY IMPAIRMENTS IN OSTEOPOROTIC WOMEN: A CASE-CONTROL STUDY

S. Toprak Celenay<sup>1</sup>, D. Ozer Kaya<sup>2</sup>. <sup>1</sup>Physiotherapy and Rehabilitation, Ankara Yildirim Beyazıt University; <sup>2</sup>Physiotherapy and Rehabilitation, Izmir Katip Celebi University, Ankara, Turkey

**Background:** Crosstalk between bone and muscle has been focused, lately.<sup>1</sup> Any impairment in bone quality may affect core muscle endurance and whole postural control.<sup>2,3</sup>

**Objectives:** This study aimed to compare core muscle endurance and postural stability in women with and without osteoporosis.

**Methods:** Women with (n: 40, age: 59.16±6.83 years, body mass index (BMI): 31.46±5.44 kg/m<sup>2</sup>) and without osteoporosis (Controls, n: 36, age: 56.10±7.17 years, BMI: 33.81±5.32 kg/m<sup>2</sup>) were recruited. Core endurance was assessed with McGill's trunk muscle endurance tests in seconds.<sup>4</sup> Postural stability were evaluated with Biodex Balance System SD in static-dynamic, eyes-open and closed conditions. Independent sample *t* and Mann Whitney U tests were used for analysis.

**Results:** The ages and BMI of the groups were similar (*p*>0.05). The following scores were found respectively in osteoporotic women and controls: the endurance of trunk flexor [15.0 (20.0)/17.5 (15.2) s]; back extensor [9.0 (16.0)/12.5 (22.2) s], right lateral [0.0 (7.0)/6.5 (20.0) s] and left lateral muscles [0.0 (8.0)/5.0 (20.0) s], static eyes-open [1.93±0.80/1.44±0.86] and eyes-closed [2.46±1.71/1.68±0.73], dynamic eyes-open [3.08±1.95/2.86±1.39] and eyes-closed [6.31±2.31/5.40±1.24] postural stability. Lateral trunk muscle endurance decreased, static and dynamic eyes-closed instability increased in women with osteoporosis in comparison to women without osteoporosis (*p*<0.05). No differences were found in trunk flexor and back extensor muscle endurance, and static and dynamic eyes open stability scores (*p*>0.05).

**Conclusions:** Lateral core muscle endurance and static and dynamic eyes-closed postural stability impairments were observed in osteoporotic women. It might be appropriate to be aware of these deficits for prevention programs.

### THE EFFECT OF CONCOMITANT TYPE OF VITAMIN D, BIOLOGICAL DMARDS AND DISEASE ACTIVITY FOR THERAPEUTIC EFFECT OF DENOSUMAB IN OSTEOPOROTIC PATIENTS WITH RHEUMATOID ARTHRITIS

S. Anno<sup>1</sup>, K. Inui<sup>2</sup>, T. Okano<sup>2</sup>, K. Mamoto<sup>2</sup>, Y. Sugioka<sup>3</sup>, M. Tada<sup>4</sup>, T. Koike<sup>3,5</sup>, H. Nakamura<sup>2</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Yodogawa Christian Hospital; <sup>2</sup>Department of Orthopaedic Surgery; <sup>3</sup>Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine; <sup>4</sup>Department of Orthopaedic Surgery, Osaka City General Hospital; <sup>5</sup>Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Osaka, Japan

**Background:** Osteoporosis is one of the major comorbidity in patients with rheumatoid arthritis (RA). There are a lot of evidence that denosumab increase bone mineral density (BMD) in patients with osteoporosis. However, there are few reports investigated the influence of denosumab in patients with RA.

**Objectives:** We evaluated the BMD change in patients with RA treated denosumab and assessed the effect of various factors, such as the type of vitamin D, biological disease-modifying anti-rheumatic drugs (bDMARDs) use, and disease activity.

**Methods:** This study included 100 RA patients (96 female, mean age 69.9±9.3 years) treated with denosumab. BMD at the lumbar spine and proximal femoral were evaluated by dual energy X-ray absorptiometry (DXA) at baseline and

1 year after treatment. We evaluated the influence of the type of vitamin D, bDMARDs and disease activity for BMD change.

**Results:** In all patients, BMD at the lumbar spine, proximal femoral and femoral neck were significantly increased in one years (6.2%: *p*<0.01, 4.0%: *p*<0.01, 2.2%: *p*=0.04, respectively). There were no significant differences in improvement ratio of BMD between 10 patients taking active form vitamin D and 71 patients taking native form vitamin D (7.7 vs 4.4%: *p*=0.55, 4.3 vs 4.0%: *p*=0.83, 1.4 vs 4.2%: *p*=0.52), between 30 patients treated with bDMARDs and 57 patients treated without bDMARDs (6.4 vs 6.2%: *p*=0.3, 2.7 vs 4.5%: *p*=0.95, 1.1 vs 2.5%: *p*=0.2), between 61 patients in remission or low disease activity and 26 patients in moderate or high disease activity (7.2 vs 4.0%: *p*=0.25, 3.3 vs 5.0%: *p*=0.87, 1.6 vs 3.8%: *p*=0.98) (figure 1).

Figure 1. BMD change

**Conclusions:** Denosumab improved BMD in patients with RA independently regardless of the type of vitamin D, bDMARDs use, disease activity.

THU0500

### EFFECTS OF LONG-TERM USE OF UNFRACTIONATED HEPARIN (UFH) OR LOW-MOLECULAR-WEIGHT HEPARIN (LMWH) ON BONE MINERAL DENSITY (BMD) IN PATIENTS WITH NEPHROTIC SYNDROME

S.V. Monov<sup>1</sup>, D. Monova<sup>2</sup>, R. Shumnalieva<sup>1</sup>. <sup>1</sup>Department of Rheumatic Diseases, Medical University; <sup>2</sup>Department of Internal Medicine, Medical University, Medical Institute, Sofia, Bulgaria

**Background:** Osteoporosis is a systemic skeletal disease characterised by decreased bone mass and micro- and macroarchitectural tissue alterations, resulting in bone fragility and increased fracture risk. Generalised osteoporosis is a result of different causes and pathogenic mechanisms, which often combine forces to become clinically relevant. Among the different exogenous factors, several drugs have been associated with increased risk of osteoporosis, when used chronically.

**Objectives:** The aim of this study is to determine the effects of UFH or LMWH therapy of at least 1 year duration on bone mineral density BMD in patients with nephrotic syndrome (NS).

**Methods:** All patients undergoing native renal biopsy for NS between 2006 and 2017 yielding a diagnosis of primary glomerulonephritis were identified. Baseline serum albumin, proteinuria, estimated glomerular filtration rate, date of biopsy and histological diagnosis were recorded. 465 (238 male, 227 female) patients with nephrotic syndrome received the prophylactic anticoagulation regimen were included. Mean age at biopsy was 43,8±19,2 years. Median follow-up was 5,3±2,4 years. In addition to the prophylactic anticoagulation regimen, patients received treatment for their underlying glomerulopathy. This included optimising blood pressure control, renin-angiotensin system blockade, and prescribing immunosuppressive therapy if indicated. Patients received corticosteroid treatment or with renal failure were excluded from the study. 312 patients (67,1%) received treatment with UFH and 153 - with LMWH at some point in the course of their disease. There was no difference in mean age, sex, or disease duration between both groups. 276 patients were switched from UFH or LMWH to acenocoumarol as a result of protracted hypoalbuminemia (serum albumin <2.0 g/dl) at a median time of 24,3±9,3 weeks' treatment. The anticoagulant control achieved in these patients was good. Bone mineral density (BMD) was measured at the lumbar spine and total hip region with dual x-ray absorptiometry.

**Results:** Results of Poisson regression analysis showed that LMWH therapy was associated with a lower risk of osteoporosis compared with UFH (0,7 vs 1,1 per 100 person-years). No statistically significant increase in the risk of fractures at 12 months was found for patients (RR = 1, 03; 95% CI: 0,27-3,34). UFH for 24

months decreased mean BMD by 2.6–3.5% (depending on the BMD site) compared to mean BMD decreases of 1.9–2.9% with LMWH. BMD of the spine and hip is significantly lower in patients with LMWH therapy than in subjects with UFH therapy, which is independent of age, sex, menopause, low BMI and altered body composition.

**Conclusions:** LMWH most likely have less effect on bone turnover when compared to UFH. LMWH for 6 months may not increase the risk of osteoporosis, but longer exposure for up to 24 months may adversely affect BMD. Clinicians should consider monitoring BMD in adults on long-term heparin therapy who are at increased risk of bone loss or fracture.

#### THU0501 WHAT DOES TRABECULAR BONE SCORE CONTRIBUTE TO A FRACTURE LIAISON SERVICE?

S. Ojeda<sup>1</sup>, A. Naranjo<sup>1</sup>, A. Saavedra<sup>1</sup>, F. Santana<sup>1</sup>, A. Molina<sup>1</sup>, T. Marrero<sup>2</sup>, O. Suarez<sup>2</sup>, C. Rodriguez-Lozano<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Hospital Univ. Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain

**Background:** The utility of the trabecular bone score (TBS) is controversial.

**Objectives:** To analyse the clinical usefulness of FRAX-TBS in patients with fragility fracture seen in a Fracture Liaison Service (FLS) compared to FRAX without TBS.

**Methods:** Consecutive outpatients >50 y seen in our FLS were included, excluding patients admitted with hip fracture. The variables included were: age, sex, type of fracture, risk factors for FRAX, FRAX for major and hip fractures with and without TBS, bone densitometry (DXA) and indication of treatment to prevent new fractures.

**Results:** We included 251 patients, mean age 69 y, 86% women. The most frequent type of fracture was the forearm (n=122) followed by the humerus (n=64). The DXA scan results (taking the lowest value of column/hip) was osteoporosis in 41%. The average TBS was 1.307 (SD 0.103, range 0.961–1.550): forearm fracture 1.313 (SD 0.102), vertebra 1.281 (SD 0.131) and hip 1.291 (SD 0.103). 32% presented normal TBS result 53% partially degraded and 15% degraded (table 1). The results of FRAX with and without TBS were similar, with an average for major/hip fracture of 10.7/4.2 with DXA and 10.6/4.0 with TBS respectively (p>0.05). A high risk of hip fracture (FRAX ≥3) was observed in 43% of patients using FRAX-DXA and 41% using FRAX-TBS. A high risk of major fracture (FRAX ≥10) in 40% of patients using FRAX-DXA and 41% using FRAX-TBS. In 241 cases (96%) there was concordance in level of risk for FRAX-DXA and FRAX-TBS, while the 10 discordant cases for high risk of fracture were distributed as follows: in 6 cases FRAX-DXA was high and FRAX-TBS was normal, and in 4 cases FRAX-DXA was normal and FRAX-TBS was elevated. In our FLS, a bisphosphonate was prescribed to 169 patients (67%). Regarding patients with a low FRAX risk (n=82), in one patient FRAX-TBS was in favour of treatment. Thus, in 1/251 fractures FRAX-TBS could have influenced the treatment indication compared to FRAX-DXA.

	TBS≥1.350 Normal	TBS<1.350 y≥1.200 partially degraded	TBS<1.200 Degraded
Number of patients	80	134	37
Age, mean (SD)	67 (11)	70 (10)	71 (10)
Sex, women, n (%)	65 (81)	124 (92)	33 (92)
<b>Risk factors, n (%)</b>			
BMI, mean	27	29	31
Previous fracture	8 (10)	34 (25)	7 (19)
Parent's hip fracture	8 (10)	21 (16)	2 (5)
Glucocorticoids	6 (8)	5 (4)	5 (13)
Smoking	9 (11)	20 (15)	6 (16)
Alcohol	2 (3)	4 (3)	1 (3)
Rheumatoid arthritis	3 (4)	2 (1)	0
Secondary osteoporosis	13 (16)	22 (18)	10 (28)
<b>Bone Densitometry, n (%)</b>			
Normal	24 (30)	7 (5)	3 (8)
Osteopenia	37 (46)	65 (49)	12 (32)
Osteoporosis	19 (24)	62 (46)	22 (60)

**Conclusions:** In our FLS unit, TBS does not help to classify patients' risk. The values of FRAX-TBS are similar to those of FRAX-DXA, not offering advantages when classifying patients with high risk who are candidates for treatment.

**Disclosure of Interest:** None declared

#### THU0502 ASSESSMENT OF SEVERITY OF ATHEROSCLEROTIC LESIONS OF CAROTID ARTERIES IN MEN WITH CORONARY HEART DISEASE DEPENDING ON BONE MINERAL DENSITY AND RISK OF OSTEOPOROTIC FRACTURES

T. Raskina<sup>1</sup>, A. Voronkina<sup>2</sup>, M. Letaeva<sup>1</sup>, A. Kokov<sup>3</sup>, O. Barbarash<sup>3</sup>, E. Maluta<sup>2</sup>. <sup>1</sup>Federal State Educational Institution of Higher Education "Kemerovo State Medical University"; <sup>2</sup>State Autonomous Healthcare Institution Kemerovo region "Regional Clinical Hospital of Emergency Medical Care named M. Podgorbunsky"; <sup>3</sup>Federal State Budgetary Scientific Institution "Scientific-Research Institute of Complex Issues of Cardiovascular Disease", Kemerovo, Russian Federation

**Objectives:** To assess severity of atherosclerotic lesions of carotid arteries (CA) in men with coronary heart disease (CHD) depending on bone mineral density (BMD) and risk of osteoporotic fractures according to FRAX scale.

**Methods:** The study involved 102 men aged 51–75 years (median age of 61<sup>55</sup>; 65 with CHD, verified by coronary angiography method. All patients underwent dual energy X-ray absorptiometry of lumbar vertebral bodies L1-LIV and femoral neck and colour duplex scanning of extracranial arteries. Assessment of severity of carotid atherosclerosis was carried out by presence of atherosclerotic plaques (ASP) and stenosis of CA, thickness of intima-media (TIM) CA. Threshold TIM for men over age of 50 was considered 0.9 mm (recommendations of American Society of Echocardiography, 2008 Based on results of densitometry value of T-criterion (recommendations ISCD, 2007 men were divided into three groups: 33 patients with osteoporosis (OP, T-criterion ≤2.5), 48 patients with osteopenia (OPE, T-criterion of –1 to –2.5) and 21 men with normal BMD (NBMD, T-criterion ≥–1). On the basis of information on the presence of clinical risk factors of osteoporotic fractures and densitometry data at all included in the study patients FRAX calculator was used to quantify probability of major osteoporotic fractures and hip fracture in next 10 years.

**Results:** It was found that 86.3% of patients value TIM exceeds threshold value (0.9 mm). Thickening of intima-media complex was in men with OP in 88.0% of cases, with OPE – in 87.5%, with NBMD – in 81.0% without statistically significant differences (p>0.05). In a comparative analysis of atherosclerotic lesions CA found that men with OP significantly were more likely to have ASP in CA (75.8%) compared to patients with OPE (43.7%, p=0.010) and NBMD (38.1%, p=0.016). Stenosis of CA in all investigated men was discovered in 54 cases (53%). Comparative analysis showed that in patients with OP percentage of patients with stenosis of CA was 2 times more than men with NBMD (75.8% vs 38.1%, p=0.006) and was significantly higher than proportion of such patients in the group with OPE (44.0%, p=0.004). In all included the study patients 10 year absolute risk of major osteoporotic fracture by FRAX was equal to 9.88±7.22, risk of hip fracture – 3.97 ±6.27. There was inverse correlation of TIM with T-criterion (r=–0.21, p=0.035) and with BMD (r=–0.20, p=0.045) at level of hip and reliable direct correlation between TIM and risk of hip fracture by FRAX (r=0.21, p=0.035).

**Conclusions:** In men with CHD aged over 50 years low BMD (T-criterion is less than 2.5) is associated with more severe carotid atherosclerosis, and thickening of intima-media CA – with an increased risk of hip fracture.

**Disclosure of Interest:** None declared

#### THU0503 COST ANALYSIS OF ANTI-OSTEOPOROTIC DRUGS IN REAL-WORLD CLINICAL PRACTICE

V. Orlando<sup>1</sup>, V.M. Monetti<sup>1</sup>, F. Guerriero<sup>1</sup>, V. Russo<sup>1</sup>, R. Piscitelli<sup>1</sup>, M. Ruggeri<sup>2</sup>, E. menditto<sup>1</sup>. <sup>1</sup>CIRFF Center of Pharmacoeconomics, University of Naples Federico II, Naples; <sup>2</sup>School of Economics, Catholic University of Sacred Heart, Rome, Italy

**Background:** Nonadherence can reduce treatment effectiveness and can negatively affect healthcare costs and thus the treatments' cost-effectiveness. Adherence in the setting of osteoporosis has been shown to be just as problematic, if not worse, than that in other chronic diseases. Economic evaluations based on modelling are commonly used to compare alternative treatment strategies in osteoporosis, to support decision-makers and to inform treatment guidelines.

**Objectives:** The aim of this study is to analyse healthcare costs of osteoporosis and to build a economic model cost-effectiveness of pharmacological interventions based on real world data.

**Methods:** The data of the analysed subjects were drawn from the administrative databases of four Local Health Authorities in the Abruzzo Region. Patients 60 years of age or older were included if at least one prescription for any

antiosteoporosis drugs had been filled in between January 1, 2006 and December 31, 2006. The patients were classified as exposed or not exposed to osteoporotic fracture. For each group, compliance with antiosteoporosis drugs was calculated. Patients were considered compliant if their Medication Possession Ratio (MPR) was  $\geq 80\%$ . The cost analysis was conducted taking each healthcare service into account, i.e. drug therapy, diagnostic tests and hospitalisation admissions, during the study period. A hypothetical scenario based on the real-life available evidence was constructed. The mean level of adherence to populate the hypothetical scenario of "full adherence" was set at  $MPR > 80\%$ . The model built by adding a step value, constrained by a normal random variable, to the real-world adherence of each subject so that the subject shifted to the hypothetical scenario of full adherence, in order to quantify the clinical outcome (number of fractures) achievable in the hypothetical scenario. Cost-effectiveness of full adherence compared to real world adherence was expressed in terms of Incremental Cost Effectiveness Ratio (ICER) and the number of fractures avoided was set as an effectiveness unit of measure.

**Results:** The mean annual healthcare cost per fracture avoided was € 247.44, of which medical treatments and diagnostic tests accounted for € 103.60 (41.9%) and € 143.84 (58.1%), respectively. The mean annual healthcare cost per fractured patient was € 1,044.85, of which medical treatments, diagnostic tests and hospitalizations for osteoporotic fracture accounted for € 88.73 (8.5%), € 169.48 (16.2%) and € 786.65 (75.3%), respectively.

**Conclusions:** Costs per fractured patients resulted to be about four times greater than those of not fractured patients. Therefore, only enhancing adherence to medication may lead to reductions in the number of patients requiring hospitalisation.

#### THU0504 UTILISATION OF ANTI-OSTEOPOROTIC DRUGS IN REAL-WORLD DATA: A STUDY OF GENDER-RELATED DIFFERENCES

V. Orlando<sup>1</sup>, V.M. Monetti<sup>1</sup>, F. Guerriero<sup>1</sup>, V. Russo<sup>1</sup>, A. Moretti<sup>2</sup>, A. Piscitelli<sup>1</sup>, R. Piscitelli<sup>1</sup>, G. Iolascon<sup>2</sup>, E. Menditto<sup>1</sup>. <sup>1</sup>CIRFF Center of Pharmaco-economics, University of Naples Federico II; <sup>2</sup>Department of Medical and Surgical Specialties and dentistry, University of Campania Luigi Vanvitelli, Naples, Italy

**Background:** Osteoporosis is mostly defined as the disease of women, because the prevalence and fracture rates are much higher in postmenopausal women than in older men. However, there has been increasing recognition that male osteoporosis also represents an important burden as a common cause of morbidity, mortality and health care expenditure. Also, men are more likely than women to have osteoporosis that is undiagnosed and undertreated.

Moreover, bone fracture are important factors of high mortality and morbidity rates in osteoporotic patients. Lack of persistence is common among subjects using oral anti-osteoporotic drugs, and leads to increased risk of fragility fracture.

**Objectives:** The aim of this study is to perform gender specific analysis regarding the persistence to antiosteoporosis drugs.

**Methods:** We conducted a retrospective cohort study using administrative data from four local health authorities in the Abruzzo Region (Central Italy), which comprise about 9 00 000 inhabitants (68% of the overall regional population). Patients 60 years of age or older were included if at least one prescription for any antiosteoporosis drugs had been filled in between January 1, 2006 and December 31, 2006. Persistence estimates over time (discontinuation rates were assessed at 365 days) were derived using Kaplan–Meier survival analysis, stratifying for gender, considering treatment discontinuation as failure event and comparing differences using Log-rank test (1 degree of freedom).

**Results:** The final cohort consisted of a total of 7867 patients (87.2% women). The mean patient age for both genders at the index date was 74.5 years. The crude analysis of long-term gender persistence showed a significant difference between women and men: the relative number of persistence patients after 1 year was 66.4% in men and 44.7% in women. The Kaplan Meier plots of time to persistence start to differ for men vs women approximately 60 days after treatment start (figure 1).

**Conclusions:** The results showed that gender influences adherence to therapy and this is an issue that could be taken in strong consideration in tailor intervention to improve adherence.

#### THU0505 INFLUENCE OF ORAL PREDNISOLONE ON EFFECT OF DENOSUMAB ON OSTEOPOROSIS IN PATIENTS WITH JAPANESE RHEUMATOID ARTHRITIS; 36 MONTHS OF FOLLOW-UP –A MULTICENTER REGISTRY STUDY–

Y. Kanayama<sup>1</sup>, Y. Hirano<sup>2</sup>, N. Takahashi<sup>3</sup>, S. Asai<sup>3</sup>, N. Ishiguro<sup>3</sup>, T. Kojima<sup>3</sup>, on behalf of TBCR-BONE study group. <sup>1</sup>Orthopedic Surgery And Rheumatology, Toyota Kosei Hospital, Toyota; <sup>2</sup>Rheumatology, Toyohashi Municipal Hospital, Toyohashi; <sup>3</sup>Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya, Japan

**Background:** Denosumab (DMB) is a fully human monoclonal antibody to the receptor activator of nuclear factor-kappaB ligand (RANKL) that blocks its binding RANK, inhibiting the development and activity of osteoclasts, decreasing bone resorption, increasing bone density and reducing fracture risk. Osteoporosis(OP) is more frequent in patients with rheumatoid arthritis(RA) than in the general population due to active systemic inflammation as well as the use of glucocorticoid and immobility. We investigated the influence of oral prednisolone on effect of DMB in patients with Japanese RA from initiation to 36 months at this time.

**Objectives:** This prospective study investigated the efficacy of DMB for 36 months on glucocorticoid-induced OP in RA patients.

**Methods:** Patients with a diagnosis of RA according to the 2010 ACR/EULAR criteria who had been prescribed DMB from Tsurumi Biologics Communication Registry (TBCR)-BONE between October 2013 and October 2014 were enrolled. The final study cohort of 56 patients received continuous DMB therapy more than 36 months. The DMB dose was 60 mg at once every 6 months. In all cases native or activated vitamin D has been used. We reviewed the results for 36 months about the increase and decrease of bone mineral density(BMD) of lumbar spine (LS) and total hip (TH) by DEXA and bone turnover markers, intact n-terminal propeptide type I procollagen(PINP) and tartrate-resistant acid phosphatase form 5b (TRACP-5b).

**Results:** In the patients receiving oral prednisolone group(n=20, GC+) and not receiving group(n=36, GC-), the number of female was each 18 (90%) and 35 (98%) cases(p=0.288). The mean age was 69.5±7.0 and 70.5±6.6 years old (p=0.700); disease duration was 15.9±9.5 and 16.3±13.7 years (p=0.688); the body mass index was 20.6±3.5 and 19.5±3.0 (p=0.225) and the FRAX was 33.8

±19.1 and 23.5±13.7 (p=0.024). Clinical findings related to RA and OP at baseline were as follows; CRP 1.2±1.4 and 0.4±1.0 mg/dl(p=0.012); DAS-CRP 3.14 ±1.24 and 2.40±1.24(p=0.019); m-HAQ 1.27±0.81 and 0.70±0.73(p=0.018); P1NP 59.7±41.3 and 53.0±26.2 µg/L(p=0.694); TRACP-5b 528±269 and 493 ±192 mU/dL (p=0.986); LS-BMD 0.86±0.20 and 0.81±0.16 g/cm<sup>2</sup>(p=0.285) and TH-BMD 0.60±0.12 and 0.60±0.08 g/cm<sup>2</sup> (p=0.899). The rate of decreased P1NP from baseline to 6, 12, 24 and 36 months were each -20.6% vs -40.0% (p=0.110) at 6 month, -3.5% vs -42.0% (p=0.046) at 12 month, -8.7% vs -32.4% (p=0.113) at 24 month and -16.8% vs -33.7% (p=0.215) at 36 month and TRAC-5b were -25.9% vs -39.6% (p=0.847) at 6 month, -17.5% vs -36.4% (p=0.111) at 12 month, -19.5% vs -30.3% (p=0.521) at 24 month and -20.2% vs -29.5% (p=0.513) at 36 month in the GS +vs GS- group. The rate of increased LS-BMD from baseline to 6, 12, 24 and 36 months were each 4.1% (p=0.753) at 6 month, 5.5% vs 6.7% (p=0.587) at 12 month, 10.4% vs 7.3% (p=0.043) at 24 month and 12.3% vs 12.6% (p=0.738) at 36 month and TH-BMD were 3.3% vs 3.2% (p=0.892) at 6 month, 1.3% vs 4.3% (p=0.751) at 12 month, 6.2% vs 5.0% (p=0.838) at 24 month and 8.4% vs 6.0% (p=0.889) at 36 month in the GS +vs GS- group (figure1 and 2).

Figure 1. The rate of increased LS-BMD from baseline to 36 month

Figure 2. The rate of increased TH-BMD from baseline to 36 month

**Conclusions:** DMB was effective in OP of RA patients. Oral prednisolone use did not influence the efficacy of DMB for 36 months.

### THU0506 CROSS-SECTIONAL ANALYSIS OF THE ASSOCIATIONS BETWEEN FIBROMYALGIA AND CANCER

A. Lichtenstein<sup>1,2,3</sup>, S. Tiosano<sup>2,3</sup>, D. Comaneshter<sup>4</sup>, A.D. Cohen<sup>4,5</sup>, H. Amital<sup>2,3</sup>.  
<sup>1</sup>Tel-Aviv Sourasky Medical Center; <sup>2</sup>Sackler School of Medicine, Tel-Aviv University, Tel-Aviv; <sup>3</sup>Department of Medicine 'B', Zabudowicz Center for Autoimmune Diseases, Sheba Medical Center, Ramat-Gan; <sup>4</sup>Chief Physician's Office, Clalit Health Services, Tel-Aviv; <sup>5</sup>Faculty of Health Sciences, Sial Research Center for Family Medicine and Primary Care, Ben Gurion University of the Negev, Beer-Sheva, Israel

**Background:** Fibromyalgia syndrome (FMS) is defined as chronic widespread musculoskeletal pain and tenderness with concomitant mood and cognitive dysfunction. Several comorbidities have been reported to be associated with FMS. However, these studies are mostly based on small populations and lack solid evidence.

**Objectives:** To evaluate the association of FMS with Cancer diagnoses.

**Methods:** This cross-sectional study used the database of the largest Health Maintenance Organisation in Israel, Clalit Health Services, serving more than 4 million members. FMS patients were compared to age- and sex-matched controls regarding comorbid Cancer diagnoses. Chi-square and t-tests were used for univariate analysis.

**Results:** Our study utilised data from 14,296 FMS patients and 71 324 age- and sex-matched controls. FMS patients compared to controls had a higher proportion of the following types of cancer: Cervix and Uteri, Connective Tissue Sarcoma, Thyroid, Non Hodgkin Lymphoma (NHL) and Benign brain tumours (OR=1.39, 1.60, 1.68, 1.26, 1.87 respectively, P value<0.005) – See table 1.

Characteristics	Fibromyalgia N=14,296	No Fibromyalgia N=71,324	Odds ratio	P-value
Age	55.2±13.9	56.0±13.7	1.00 [0.99,1.00]	<0.001
Females	13210 (92.4%)	65910 (92.4%)	1.00 [0.93,1.07]	0.978
BMI	29.1±6.20	28.0±6.01	1.03 [1.03,1.03]	<0.001
Smoking	4679 (32.7%)	19987 (28.0%)	1.25 [1.20,1.30]	0.000
SES				
Low	6669 (46.8%)	27747 (39.2%)	Ref.	Ref.
Medium	5397 (37.9%)	27499 (38.8%)	0.82 [0.78,0.85]	0.000
High	2192 (15.3%)	15554 (22.0%)	0.58 [0.55,0.61]	0.000
Malignancy diagnosis				
Cervix / Uteri	50 (0.35%)	180 (0.25%)	1.39 [1.01,1.89]	0.046
Connective Tissue Sarcoma	32 (0.22%)	100 (0.14%)	1.60 [1.06,2.36]	0.026
Thyroid	150 (1.05%)	448 (0.63%)	1.68 [1.39,2.02]	<0.001
Non Hodgkin Lymphoma (NHL)	99 (0.69%)	394 (0.55%)	1.26 [1.00,1.56]	0.048
Benign Brain Tumor	182 (1.27%)	490 (0.69%)	1.87 [1.57,2.21]	<0.001

Adjusted for age, sex, SES, smoking and BMI  
 BMI: Body mass index, kg/m<sup>2</sup>; SES: Socioeconomic status

Figure 1. BMI: Body mass index, kg/m<sup>2</sup>; SES: Socioeconomic status

**Conclusions:** Study results show a higher proportion of malignancy diagnoses amongst FMS patients compared to matched controls. Accordingly, in treating FMS patients, physicians should bear in mind the likelihood of concomitant tumour as it might explain various FMS symptoms, and more importantly, shorten a patients' time for diagnosis and treatment of the oncological condition.

**Disclosure of Interest:** None declared

THU0507

### HETEROGENITY OF FIBROMYALGIA: PSYCHOPATHOLOGICAL CHARACTERISTICS OF DIFFERENT SUBTYPES AND EFFICACY OF THERAPY

A. Sarapulova, O. Teplyakova. URALS STATE MEDICAL UNIVERSITY, Ekaterinburg, Russian Federation

**Background:** fibromyalgia (FM) is one of the most complicated diseases in the rheumatology and therapeutic practice. Despite the relative success in diagnosing pathology and developing new diagnostic criteria, the treatment of FM remains uncertain. This, in particular, may be due to the presence of various subtypes of disease, which differ in their pathogenesis and, therefore, require differentiated therapy.

**Objectives:** to identify the subtypes of FM, to determine their basic psychopathological characteristics and adherence to therapy.

**Methods:** the study included 104 patients with FM according to 2010/2011 diagnostic criteria. All patients were questioned about their attitudes towards employment and sports, and determined the level of anxiety and depression by the HADS scale, as well as therapy compliance 2 months later.

**Results:** the results obtained support the presence of five subtypes of FM. Patients with a high level of anxiety (10.57±2.87) and minimal widespread pain index (WPI) (6.30±6.04) were included in Group 1. This group consisted of 40.35% of the total number of patients with the minimum average age (45 years) and the highest ratio of men/women (8/38). Group 1 was also characterised by the greatest employment (34 of 46 patients) and a relatively rare abandonment of physical exercises (14 of 46 patients). The second group of patients was conditionally called anxious-depressive because of the frequent detection of both anxiety and depression (11.33±4.64 and 11.67±3.64, respectively) with a moderate number of WPI (10.78±4.09). They differed from the Group 1 by mainly female sex and more frequent avoidance of physical exercises (8 of 18 patients). Group 3 (the proposed name is hysteroid) consisted of women with the maximum number of WPI (14.33±4.22) and low levels of anxiety and depression. Despite the average working age, they were mostly unemployed with the lowest level of adherence to physical activity (4 of 24 patients). The fourth subtype of FM consisted of patients with concomitant chronic diseases. They were expected to be the oldest (68 years on average) with a high number of painful areas (13.44±5.0), low levels of anxiety and depression. All of them refused to perform physical exercises and were unemployed. Finally, Group 5 included patients without concomitant affective and somatic disorders. This group has taken the middle position for all indicators, except the lowest level of anxiety and depression among all groups.

The lowest rates of therapy compliance were demonstrated in Group 3. At the same time, the time of communication with these patients was the maximum.

**Conclusions:** patients with FM are a heterogeneous group, differing in their psychopathological characteristics. Younger patients are more likely to exhibit an elevated level of anxiety and depression and are prone to catastrophize their sensations, while older patients usually have a severe somatic pathology. They are often found in therapeutic practice, which makes it necessary to conduct educational programs on FM diagnostic and management for general practitioners. We consider it very important to identify the hysteroid subtype of FM, since these patients are not inclined to seek recovery and represent a huge difficulty for the treating doctors. We proposed that they use their disease to attract the attention of others.

THU0508

### EVALUATION OF TISSUE SPECIFIC AUTOANTIBODIES IN FIBROMYALGIA PATIENTS WITH SICCA AND/OR XEROSTOMIA

E. Applbaum, A. Lichtbroun. Rutgers- Robert Wood Johnson Medical School, New Brunswick, USA

**Background:** A significant proportion of patients with fibromyalgia complain of dry eyes and mouth. The 2010 preliminary criteria for fibromyalgia even includes dry eyes and mouth as part of the somatic symptoms severity complex used to diagnose this condition. A significant proportion of Sjögren's syndrome patients also complain of fibromyalgia symptoms, and there is literature that suggests that there is interplay between these two disorders. Recently, the presence of novel tissue specific autoantibodies (TSAs), SP-1, CA6, and PSP, has been observed in the early stages of Sjögren's syndrome (SS). These early markers present themselves before the classic autoantibodies, such as SSA/Ro, SSB/La, ANA, and RF.

**Objectives:** This study aims to examine the relationship between SS and fibromyalgia by testing patients with fibromyalgia, that also complain of xerostomia and sicca symptoms, for Sjögren's related biomarkers SSA/Ro, SSB/La, SP-1, CA6, and PSP.

**Methods:** Over the past 5 years, we identified a cohort of 310 patients that presented with symptoms of fibromyalgia and fulfilled both the 1990 and 2010

preliminary diagnostic criteria. These patients were further questioned about xerostomia and sicca symptoms. Patients that admitted to using artificial tears at least biweekly, drinking water excessively to relieve dry mouth, or have previously experienced a blocked tear duct, but did not meet the strict diagnostic criteria for SS and did not have elevated inflammatory markers ESR or CRP, were selected for this study. Serum from study patients was sent to a tertiary lab, Immco Diagnostics, for testing of the classic autoantibodies (SSA/Ro, SSB/La, ANA and RF) and Tissue Specific Autoantibodies (SP-1, CA6, PSP). Patients testing positive for the TSA markers were provided with literature on the disease and offered appropriate treatment options, such as hydroxychloroquine.

**Results:** As of November, 2017 310 patients were selected for this study and tested for the SS markers. 91.0% of the patients were female and 8.6% of the patients were male. The average patient age was 56.5 years. 271 of the study patients were tested for both the TSAs and classic autoantibodies, while 39 were tested for only TSAs. Of the patients that were evaluated for both the TSAs and classic Sjögren's autoantibodies, 29.8% (81) tested positive for SS. 22.8% (71) of the patients were positive for TSAs, 9.4%<sup>29</sup> were positive for the classic Sjögren's markers, and 2.3%<sup>7</sup> were positive for both the TSA and classic Sjögren's autoantibodies. Further analysis of all the patients that tested positive for the TSAs (n=71), found 74.5% (53) were positive for SP-1, 8.5%<sup>6</sup> were positive for CA6% and 44.7%<sup>32</sup> were positive for PSP. 68.1%<sup>48</sup> of these patients were positive for only one of the TSA and 23 (31.9%) were positive for more than one TSA.

**Conclusions:** In this cohort of 310 fibromyalgia patients, about 1/3 of patients that were tested for both the TSAs and classic Sjögren's markers tested positive for SS, with the majority of those patients being positive for one or more of the TSAs. This suggests that autoimmunity, specifically early-stage Sjögren's syndrome, may be a confounding variable in the pathophysiology of fibromyalgia.

THU0509

### THE ROLE OF THIOL-DISULFIDE HOMEOSTASIS IN THE ETIOPATHOGENESIS OF FIBROMYALGIA

E. Sahingoz<sup>1</sup>, B. Nacir<sup>1</sup>, M. Alisik<sup>2</sup>, E. Oğus<sup>3</sup>, O. Erel<sup>2</sup>, H. Genc<sup>1</sup>. <sup>1</sup>Physical therapy and rehabilitation, Ankara Training and Research Hospital, <sup>2</sup>Clinical Biochemistry, Faculty of Medicine, Yildirim Beyazit University, <sup>3</sup>Clinical Biochemistry, Ankara Training and Research Hospital, Ankara, Turkey

**Background:** Fibromyalgia syndrome (FMS) is a chronic disease with unknown etiology, characterised by widespread pain, fatigue, sleep disturbance, cognitive dysfunction and anxiety. Oxidative stress has also been implicated in etiopathogenesis in recent years.

**Objectives:** In this study we aimed to investigate the role of thiol-disulfide balance in the etiopathogenesis of fibromyalgia, as an indicator of oxidative stress.

**Methods:** 98 female patients with fibromyalgia, 61 of whom were newly diagnosed and 37 were presently ongoing treatment and 82 healthy female controls were included in the study. Fibromyalgia impact questionnaire, pain visual analogue scale, Pittsburgh sleep quality index, fatigue severity scale, short form-36, tender point count, Beck depression inventory and Beck anxiety inventory were evaluated in both groups. To determine the oxidative balance, the thiol/disulfide balance was investigated by the new automatic measurement method developed by Erel and Neselioglu.

**Results:** Serum native thiol levels were 394.43±52.43 μmol/L and 418.12±49.95 μmol/L (p=0.002), total thiol levels were 429.55<sup>53.5</sup> μmol/L and 440.95<sup>58.7</sup> μmol/L (p=0.052) and serum disulphide levels were 17.5 (9.8) μmol/L and 14.8 (10.3) μmol/L in the FMS and control groups, respectively (p=0.002). In the FMS group, disulphide/native thiol percent ratios (p<0.001) and disulphide/total thiol percent ratios (p<0.001) were statistically significantly higher while native/total thiol percent ratios (p<0.001) were statistically significantly lower than those of the control group. Serum native thiol levels (p=0.008) were 384.2 (76.7) μmol/L, 387.6 (65.05) μmol/L and 416.55<sup>53.4</sup> μmol/L; disulfide levels were measured as 17.2 (7.5) μmol/L, 18.3 (14.55) μmol/L and 14.8 (10.3) μmol/L newly diagnosed patients, treated patients and control groups, respectively. Serum native thiol values at the thiol-disulfide balance did not improve disulfide in spite of being slightly approaching the control group in the treated patients. When the ratio of disulfide/native thiol was examined, it was seen that both newly diagnosed and treated patients remained in a balanced disulfide state. There were statistically significantly correlations between tender points (respectively p=0.02, r=-0.241; p=0.039, r=-0.213; p=0.039, r=-0.213; p=0.039, r=0.213), SF-36 pain subscale (respectively p=0.032, r=0.216, p=0.041, r=0.206, p=0.042, r=0.206, p=0.041, r=0.207) and Beck anxiety inventory scores (respectively p=0.009, r=-0.216, p=0.027, r=-0.225, p=0.026, r=-0.225, p=0.026, r=0.225) with disulphide levels, disulphide/native thiol, disulphide total thiol and native thiol/total thiol ratio.

**Conclusions:** The disulfide shift of the thiol-disulfide balance and the correlation between the clinical parameters and the thiol-disulfide balance components suggesting the presence of oxidative stress in FMS patients suggests that the role of thiol-disulfide balance in the etiopathogenesis of FMS.

#### THU0510 HYPERSENSITIVITY, ALEXITHYMIA AND DISEASE CHARACTERISTICS OF PATIENTS PRESENTING WITH SYMPTOMS OF FIBROMYALGIA

H. Jacobs<sup>1</sup>, B.A. Grillet<sup>2</sup>, D. De Bacquer<sup>3</sup>. <sup>1</sup>Physical Medecine and Rehabilitation, AZ Maria Middelaers Ziekenhuis, Ghent, Belgium; <sup>2</sup>Rheumatology, Reumazorg Zuid West Nederland, Terneuzen, Netherlands; <sup>3</sup>Departement of Public Health, Ghent University, Ghent, Belgium

**Background:** Fibromyalgia (FM) is characterised by chronic widespread pain and other symptoms such as fatigue, sleep disturbances and cognitive problems. Psychosocial factors and personality traits may be present in a variable degree and may play a role in the perception, coping and treatment of FM.

**Objectives:** We looked for symptoms of hyperventilation, depression, anxiety and burn-out as well as for personality traits such as hypersensitivity and alexithymia in a large sample of patients. We looked at differences in prevalence of these symptoms in the population when selected by the 1990 FM classification criteria and by the 2010 diagnostic FM criteria.

**Methods:** A large group of patients presenting on the Unit of Physical Medicine between 2014 and 2017 with chronic widespread pain was analysed and grouped depending on the 1990 ACR classification criteria for FM on one hand and the 2010 ACR diagnostic criteria for FM on the other hand. Self-administered tools used were the Nijmegen questionnaire (hyperventilation), the Aron questionnaire (hypersensitivity), the HADS questionnaire (anxiety and depression), the BMS-10 questionnaire (burn-out) and the TAS alexithymia questionnaire.

**Results:** Out of 1085 patients, 828 (76%) fulfilled the 1990 ACR classification criteria for FM. Hyperventilation (score  $\geq 12$ ) was found in 97% and hypersensitivity (score  $\geq 12$ ) in 75%. Symptoms of anxiety and depression (scores  $\geq 11$ ) were observed in 59% and 36% respectively. Burn-out (score  $\geq 4.5$ ) was seen in 40% of patients while a high TAS score ( $\geq 8$ ) was found in 70% of patients. Overall, 906 patients fulfilled the 2010 ACR diagnostic criteria for FM. The distributions of disease characteristics and personality traits in this population were very similar. Only 38 out of these 906 patients had a wide spread pain index (WPI) of 3 to 6.

**Conclusions:** A significant number of patients demonstrated high levels of anxiety, more than depression. Hypersensitivity and alexithymia were also found to be highly prevalent. There was a substantial level of hyperventilation. It may be useful to consider all these characteristics in the development of treatment programs for FM patients. Results were similar when groups were selected by 1990 ACR classification criteria for FM or by the 2010 ACR diagnostic criteria for FM. Only a minority of patients had a WPI of 3 to 6.

#### THU0511 EFFECTS OF ADD-ON TRANSCRANIAL DIRECT CURRENT STIMULATION ON PAIN IN KOREAN PATIENTS WITH FIBROMYALGIA

J.-H. Kang, K.-E. Lee, D.-J. Park, S.-S. Lee. CHONNAM NATIONAL UNIVERSITY MEDICAL SCHOOL AND HOSPITAL, Gwangju, Korea, Republic of Ireland

**Objectives:** Despite promising preliminary results of transcranial direct current stimulation (tDCS) treatment in patients with fibromyalgia (FM), several issues need to be addressed, including its limited efficacy, low response rate, and poor tolerability. We investigated the efficacy and safety of tDCS as an add-on treatment for chronic widespread pain in Korean patients with FM.

**Methods:** This study enrolled 38 patients, who were refractory to pain medications, seen at Chonnam National University Hospital from May 2016 to December 2016. A conventional tDCS device was used to supply 2 mA of current for 20 min on 5 consecutive days. The anode was placed over the primary motor cortex (M1)

and the cathode was located contralateral supraorbital area. The primary end point was a change in visual analogue scale (VAS) pain score at the end of treatment and secondary end points included changes in Fibromyalgia Impact Questionnaire (FIQ), Brief Pain Inventory (BPI), Brief Fatigue Inventory (BFI), Beck Depression Inventory (BDI), State-Trait Anxiety Inventory (STAI), and Medical Outcomes Study Sleep Scale scores.

**Results:** After tDCS, 38 patients showed clinical improvements in the VAS pain score on days 6, 13 and 36 compared with day 0 ( $p < 0.001$ ). However, improvement of FIQ scores was only seen at day 36. The BPI and BDI were significantly decreased on days 6 and 13, while BFI and STAI-I were significantly improved only at day 6. The most of improved indices were not maintained until day 36. There were no significant improvements in Sleep Scale scores after tDCS at days 6, 13, and 36. No serious adverse event was observed.

**Conclusions:** Our results suggest that tDCS has the potential to produce significant pain relief in FM patients, and may constitute an effective add-on treatment for these patients.

#### THU0512 HYPERBARIC OXYGEN THERAPY (HBOT) TREATMENT IN FIBROMYALGIA

M. Muratore<sup>1</sup>, L. Quarta<sup>2</sup>, P. Sarzi Puttini<sup>3</sup>, C. Cosentino<sup>4</sup>, A. Grimaldi<sup>1</sup>, E. Quarta<sup>2</sup>. <sup>1</sup>O.U. of Rheumatology, Galateo Hospital, ASL-LE, San Cesario di Lecce; <sup>2</sup>O.U. of Rheumatology, Galateo Hospital, ASL-LE, San Cesario di Lecce; <sup>3</sup>U.O. Reumatologia- Ospedale "Luigi Sacco", Milano; <sup>4</sup>Dipartimento di Medicina e Chirurgia, Università di Parma, Parma, Italy

**Background:** Chronic pain conditions, such as fibromyalgia (FM), are among the most common health problems managed by general practitioners, rheumatologists, clinical psychologists. FM is characterised by multifocal pain, fatigue, non-restorative sleep, cognitive complaints high levels of distress, associated with greater affect intensity. There's evidence from randomised controlled trials that some treatments like pharmacotherapy, patient education, behavioural therapy and physiotherapy are effective in reducing symptoms; however the majority of the patients aren't satisfied with the current treatments. HBOT showed some clinical effects that may induce a significant improvement of the FM symptoms.

**Objectives:** The goal of this work was to evaluate the effect of HBOT on FM symptoms.

**Methods:** 33 female patients aged 29–63 y, with FM were included in this work. Patients initially pharmacologically treated (Pregabalin 150 mg/die, Duloxetine 60 mg/die) with unsatisfactory clinical improvement, were enrolled at the Rheumatology Unit San Cesario-Italy. The HBOT protocol comprised 20 sessions, 3d/w, 90 min, 100% oxygen at 2.5ATA. Patients were randomly assigned to treated and control groups and evaluated every month for the next 4 months: patients in group A were treated with 20 sessions of HBOT in the first 2 months and evaluated for the following 2 months; patients in group B used the pharmacological treatment for the first 2 months and then were treated with 20 sessions of HBOT in the last 2 months. During HBOT no pharmacological treatment was allowed. The treated group patients were evaluated at baseline and after 10 and 20 HBOT sessions. Evaluations consisted of physical examination, including tender point count, and socio-demographic and clinimetric questionnaires: Fibromyalgia Impact Questionnaire (FIQ), Functional Assessment of Chronic Illness Therapy, Pittsburgh Sleep Quality Index, Quality of life, Beck Depression Inventory, State Trait Anxiety Inventory, Pain Catastrophizing Scale.

**Results:** 5 patients withdrew from the HBOT treatment for claustrophobia. HBOT led to significant amelioration of all FM symptoms, with significant improvement in life quality. HBOT leads to a reduction in the number of tender points in the 2 groups. This reduction occurs in the group A without changing during the following 2 months of observation. In the group B the improvement is more related to the HBOT than to the therapy. The FIQ score improves in group A. No improvement was observed in the control group.

**Conclusions:** The analgesic effects of HBOT have been studied in nociceptive, in inflammatory and neuropathic pain models, and may be useful for the treatment of various chronic pain syndromes. Excessive pain in FM may be due to hyperexcitability of the pain processing pathways and under-activity of the pain inhibiting pathways in the brain. It has been shown that HBOT increases cell metabolism, reduces apoptosis, alleviates oxidative stress, increases neurotrophin and nitric oxide levels by enhancing mitochondrial function in neurons and glial cells, it may even promote the neurogenesis of endogenous neural stem cells. HBOT-induced neuroplasticity also leads to the repair of chronically impaired brain functions. Our data confirm the efficacy of HBOT in treating FM. Further studies are required to evaluate the protocol and to understand the duration of the clinical effect.

### THU0513 IS THERE A ROLE OF SERUM NESFATIN-1 LEVEL IN FIBROMYALGIA?

B. Bilgici<sup>1</sup>, Y. Akyol<sup>2</sup>, Y. Ulus<sup>2</sup>, S.S. Urkmez<sup>1</sup>, O. Kuru<sup>2</sup>. <sup>1</sup>Biochemistry; <sup>2</sup>Physical Therapy and Rehabilitation, Ondokuzmayis university, Samsun, Turkey

**Background:** Fibromyalgia (FM) is characterised by chronic widespread pain, sleep disturbances, affective disorders, fatigue, cognitive dysfunction, anxiety and depressive episodes and its pathogenesis is still unclear.<sup>1</sup> Nesfatin-1 is a recently identified anorexigenic hypothalamic polypeptide which plays role on mood, stress, sleep, anxiety, eating behaviour, and metabolic regulation.<sup>2, 3</sup> Serum level of nesfatin-1 may be associated with the physiopathology and clinical symptoms of FM.

**Objectives:** The aim of the present study was to compare serum nesfatin-1 level in patients with FM with healthy controls, and to investigate its relationship with demographic features and clinical parameters such as pain severity, disease activity, fatigue, emotional status, and sleep quality in FM patients.

**Methods:** Forty-six female patients with FM and 46 healthy female controls were included in the study. Demographic characteristics of participants were recorded. Severity of Pain by Visual Analogue Scale (VAS), disease activity by Fibromyalgia Impact Questionnaire (FIQ) were evaluated in patients with FM. Fatigue by Multidimensional Assessment of Fatigue (MAF), sleep quality by Pittsburgh Sleep Quality Index (PSQI), emotional status by Beck Depression Inventory (BDI) and Beck Anxiety Inventory (BAI) were performed in both groups. Serum nesfatin-1 concentrations were measured in all participants.

**Results:** Serum nesfatin-1 concentrations were significantly low in patients with FM compared to the healthy subjects ( $p<0.05$ ). When compared to the FM patients without anxiety, serum nesfatin-1 concentrations were significantly increased in FM patients with anxiety ( $p<0.05$ ). Serum nesfatin-1 concentrations were positive correlated with BAI scores in patients with FM ( $p<0.05$ ) whereas no statistically significant correlations were found between serum nesfatin-1 concentrations and age, BMI, and other clinical parameters in the patient and control group ( $p>0.05$ ).

**Conclusions:** According to the results of this study, it can be suggested that decreased nesfatin-1 plays a role in the FM pathogenesis and nesfatin-1 may mediate anxiety-related responses in FM patients.

### THU0514 FAT BUT FIT. THE COMBINED ASSOCIATION OF BODY MASS INDEX AND CARDIORESPIRATORY FITNESS WITH THE FIBROMYALGIA SEVERITY AND TENDERNESS: THE AL-ÁNDALUS PROJECT

P. Acosta-Manzano<sup>1</sup>, B. Gavilán-Carrera<sup>1</sup>, V. Segura-Jiménez<sup>2</sup>, M. Borges-Cosic<sup>1</sup>, I.C. García-Rodríguez<sup>1</sup>, V.A. Aparicio<sup>3</sup>. <sup>1</sup>Department of Physical Education and Sports, University of Granada, Granada; <sup>2</sup>Department of Physical Education, University of Cádiz, Cádiz; <sup>3</sup>Department of Physiology, University of Granada, Granada, Spain

**Background:** Since fibromyalgia is a complex widespread pain condition with large impact on physical and psychological health,<sup>1</sup> it is imperative to focus on modifiable factors that might decrease the impact of the disease on patients' lives. Accordingly, obesity and cardiorespiratory fitness (CRF) have been proposed as possible targets related to lower fibromyalgia severity and tenderness.<sup>2, 3</sup> However, based on the Fat but Fit Paradigm,<sup>4</sup> no previous studies have examined if women with adverse body mass index (BMI) but high CRF, might present lower fibromyalgia severity and tenderness than those with non-adverse BMI and low CRF.

**Objectives:** To examine the combined association of BMI and CRF with fibromyalgia severity and tenderness in women with fibromyalgia.

**Methods:** A total of 433 women with fibromyalgia (51.8±7.5 years old) were included in this cross-sectional study. BMI was calculated and CRF was assessed with the 6 min walk test (6-MWT). The fibromyalgia severity and its components (function, overall impact and symptom severity) along with tenderness were assessed with the Revised Fibromyalgia Impact Questionnaire (FIQR) and algometry, respectively. BMI groups were stratified according to international criteria.

Fit and unfit cut-offs were established according to the median value (fit  $\geq 489$  m, unfit  $<489$  m in the 6-MWT). Analyses of covariance and Bonferroni post-hoc analyses were used to assess the combined association of BMI and CRF with FIQR variables and tenderness, and the differences of these outcomes variables between the groups created from the combination of the different levels of BMI and CRF, respectively. The potential confounders were age, occupational status, medication for relaxing or sleeping, and antidepressants.

**Results:** Normal-weight and fit women showed better function, and lower overall impact and fibromyalgia severity than obese and unfit women (all,  $p\leq 0.05$ ). Overweight but fit women showed better function, and lower overall impact and fibromyalgia severity than normal-weight and unfit women (all,  $p<0.01$ ) or obese and unfit women (all,  $p<0.001$ ). Additionally, overweight but fit women showed lower symptom severity than obese and unfit women ( $p<0.001$ ). Obese but fit women experienced lower tenderness than normal-weight and unfit women ( $p=0.038$ ). For the remaining analyses, differences of outcomes variables between groups were not statistically significant ( $p>0.05$ ).

**Conclusions:** The combination of BMI and CRF was significantly associated with the fibromyalgia severity and tenderness. Since overweight and obese fit women showed lower fibromyalgia severity and tenderness, it seems that the "Fat but Fit" paradigm might play an important role on fibromyalgia. These findings suggest that fitness might be able to counteract the adverse influence of obesity on fibromyalgia severity and tenderness. However, future physical exercise and dietary interventions are warranted to ascertain these findings.

### THU0515 SOMATOSENSORY TEMPORAL DISCRIMINATION IS IMPAIRED IN FIBROMYALGIA

Z. Gunend<sup>1</sup>, M. Polat<sup>2</sup>, D. Vural<sup>3</sup>, B. Cengiz<sup>3</sup>. <sup>1</sup>Physical Medicine and Rehabilitation, Division of Rheumatology; <sup>2</sup>Physical Medicine and Rehabilitation; <sup>3</sup>Gazi University Faculty of Medicine, Ankara, Turkey

**Background:** Fibromyalgia is the prototypical central sensitivity syndrome which is associated with increased sensitivity to pain and other stimuli. Somatosensory temporal discrimination (STD) is the perception of two discrete stimuli applied at short intervals as separate. The evaluation of STD ability essentially provides information about central processing of sensory stimuli.<sup>1</sup>

**Objectives:** In this study, we aimed to evaluate whether STD ability, which requires an intact central sensory processing, is altered in patients with fibromyalgia.

**Methods:** Fifteen patients with fibromyalgia and 15 healthy subjects participated in the study. Demographic characteristics of participants and severity for fatigue, sleep quality, cognitive symptoms, somatic symptoms and health-related quality of life in fibromyalgia patients were recorded. STD thresholds were measured from the dorsum of the dominant hands of the participants by using a constant current stimulator.<sup>2</sup>

**Results:** Patients with fibromyalgia had higher STD thresholds than healthy subjects (table 1). There were significant correlations between STD thresholds and pain intensity, fibromyalgia impact questionnaire scores and symptom severity scale scores in fibromyalgia group ( $p=0.006$ ,  $r=0.68$ ;  $p=0.037$ ,  $r=0.54$ ;  $p=0.017$ ,  $r=0.61$  respectively).

**Table 1 STD measures and clinical characteristics of study participants**

	Fibromyalgia group (n:15) mean±SD	Control group (n:15) mean±SD	Mean difference (95% CI)	p
Pain (VAS), cm	7.3±1.1			
FIQ score	58.8±5.5			
SSSS	7.7±1.4			
STDT, ms	69.1±8.6	33.4±4.6	35.7 (30.6– 40.8)	<0.001

VAS: Visual analogue scale, FIQ: Fibromyalgia impact questionnaire, SSSS: Symptom severity scale score, STDT: Somatosensory temporal discrimination threshold, SD: Standard deviation, CI: Confidence interval

**Conclusions:** Somatosensory temporal discrimination ability is impaired in fibromyalgia patients compared to healthy subjects. Disrupted somatosensory temporal discrimination ability correlates with increased widespread pain and severity of

other symptoms including fatigue, sleep quality, cognitive symptoms, somatic symptoms and decreased functional status. The impaired somatosensory temporal discrimination ability indicates an alteration in higher cognitive sensory processing in fibromyalgia.

THU0516

#### EFFICACY AND SAFETY OF VITAMIN D3 IN PATIENTS WITH FIBROMYALGIA. RANDOMISED, DOUBLE BLIND, PLACEBO-CONTROLLED TRIAL

L.J. Lozano Plata<sup>1</sup>, M.A. Garza Elizondo<sup>1</sup>, D. Vega Morales<sup>1</sup>, J.A. Esquivel Valero<sup>1</sup>, D.A. Galarza Delgado<sup>1</sup>, K. Silva Luna<sup>1</sup>, R. Díaz Niño de Rivera<sup>2</sup>, A. Garza Guerra<sup>2</sup>, G. Serna Peña<sup>1</sup>, I. Hernández Galarza<sup>1</sup>, L.E. Ramírez Monterrubio<sup>1</sup>, J.P. Carrizales Luna<sup>1</sup>. <sup>1</sup>Rheumatology Service; <sup>2</sup>Psychiatry Service, Universidad Autónoma de Nuevo León, Monterrey, Mexico

**Background:** fibromyalgia (FM) is a disease characterised by widespread pain, sometimes fatigue, memory problems and sleep disturbances. It has been suggested that low blood levels of vitamin D correlate with increased pain scores in patients with FM. A recent meta-analysis indicated that vitamin D may decrease pain scores in patients with FM, but with a low quality trials.

**Objectives:** to assess the efficacy and safety of vitamin D3 in Fibromyalgia patients.

**Methods:** a 12 week randomised, double blind, placebo-controlled trial in eighty FM patients according to the criteria of the American College of Rheumatology (ACR) 2010 who were randomised into two groups, the treatment group (n=40) received 50,000 IU of oral vitamin D3 weekly, the second group (n=40) received placebo for 12 weeks. The primary outcome was to assess the change in the Spanish version of Fibromyalgia Impact Questionnaire (S-FIQ) and Visual Analogue Scale (VAS 0–10) from baseline to week 12. Baseline serum calcium levels were measured in all subjects. Vitamin D levels were measured by chemiluminescence considering normal ranges between 30 and 100 ng/ml, insufficiency between 10 and 30 ng/ml and deficiency less than 10 ng/ml, baseline and after 12 weeks.

**Results:** of the total, 61/80 (76%) had vitamin D insufficiency, 8/80 (10%) deficiency and 11/80 (14%) normal levels, the mean overall level of vitamin D was 21.2±9.0. There was no statistically significant reduction in S-FIQ scores in patients in the treatment group compared with placebo (47.0±23.3 vs 43.9±25.0, p=0.56) after 12 weeks; there was also no statistically significant decrease in VAS scores (6±5 vs 4±4.5, p=0.57). There was no improvement in the perception of pain when normalising vitamin D levels. No serious adverse events were reported in both groups.

**Table 1 Baseline characteristics:**

	Treatment (n=40)	Placebo (n=40)	p
Age, mean (SD), years	50.3 (11.9)	51.4 (9.5)	0.6
BMI median (IQR)	26.8 (7.3)	27.2 (5.29)	0.7
Primary FM n (%)	18 (48.6)	19 (51.4)	0.8
Secondary FM n (%)	22 (51.2)	21 (48.8)	0.8
Tender Points median (IQR)	12.5 (4.4)	14 (7)	0.2
Basal Vitamin D median (IQR)	20.1 (14.5)	12.6 (13.4)	0.2
Vitamin D (%)			0.24
Normal	7 (17.5)	4 (10)	
Insufficiency	31 (77.5)	30 (75)	
Deficiency	2 (5)	6 (15)	
Baseline FIQ mean (SD)	64.51 (15.25)	61.88 (18.21)	0.48
Baseline VAS median (IQR)	6 (3)	6 (3.5)	0.36
<b>Primary outcomes</b>			
Final FIQ mean (SD)	47.09 (23.37)	43.9 (25.02)	0.56
Final VAS median (IQR)	6 (5)	4 (4.5)	0.57
Delta FIQ median (IQR)	-16.39 (35.28)	-18.94 (105.13)	0.59
Control Vitamin D median (IQR)	50.8 (24.9)	20.7 (5.84)	0.0001

**Conclusions:** at 12 weeks of treatment with vitamin D3 50,000 IU versus placebo in patients with fibromyalgia had no statistically significant differences in the FIQ and VAS. It may be possible to find greater benefit from vitamin D if this period is extended.

#### IDENTIFICATION OF CANDIDATE GENES ASSOCIATED WITH FIBROMYALGIA SUSCEPTIBILITY IN SOUTHERN SPANISH WOMEN: THE AL-ÁNDALUS PROJECT

F. Estevez-Lopez<sup>1,2</sup>, D. Camiletti-Moirón<sup>3</sup>, V.A. Aparicio<sup>1</sup>, V. Segura-Jiménez<sup>3</sup>, I. C. Álvarez-Gallardo<sup>3</sup>, A. Soriano-Maldonado<sup>4</sup>, M. Borges-Cosic<sup>1</sup>, P. Acosta-Manzano<sup>1</sup>, R. Geenen<sup>2</sup>, M. Delgado-Fernández<sup>1</sup>, L.J. Martínez-González<sup>5</sup>, J. R. Ruiz<sup>1</sup>, M.J. Álvarez-Cubero<sup>5</sup>. <sup>1</sup>University of Granada, Granada, Spain; <sup>2</sup>Utrecht University, Utrecht, Netherlands; <sup>3</sup>University of Cádiz, Cádiz; <sup>4</sup>University of Almería, Almería; <sup>5</sup>GENyo, University of Granada, Granada, Spain

**Background:** Family aggregation suggests genetic susceptibility to fibromyalgia. Candidate-gene studies on fibromyalgia susceptibility often include a small number of SNPs,<sup>2,3</sup> which is a limitation.<sup>4</sup> Additionally, there is a paucity of evidence in Europe.

**Objectives:** To compare genotype frequencies of candidate single nucleotide polymorphisms (SNPs) in a well-characterised sample of Spanish women with fibromyalgia and healthy non-fibromyalgia women.

**Methods:** Three hundred and fourteen women with a diagnosis of fibromyalgia (cases) and 112 non-fibromyalgia healthy (controls) women participated in the present candidate-gene study. Buccal swabs were collected for DNA extraction. Using TaqMan OpenArray, we analysed 63 single nucleotide polymorphisms (SNPs) of 33 genes related to fibromyalgia susceptibility, symptoms, or potential mechanisms.

**Results:** The rs841 and rs1799971 GG genotype was more frequently observed in fibromyalgia than in controls (p=0.04 and p=0.02, respectively). The rs2097903 AT/TT genotypes were also more often present in the fibromyalgia participants than in their control peers (p=0.04).

**Conclusions:** We identified, for the first time, associations of the rs841 (guanosine triphosphate cyclohydrolase 1 gene) and rs2097903 (catechol-O-methyltransferase gene) SNPs with higher risk of fibromyalgia susceptibility. We also confirmed that the rs1799971 SNP (opioid receptor μ1 gene) might confer genetic risk of fibromyalgia. Further studies are needed to confirm or refute the present findings.

THU0518

#### THE DIAGNOSTIC VALUE OF SELECTED MICRORNAS IN PATIENTS WITH FIBROMYALGIA ASSOCIATED WITH RHEUMATOID ARTHRITIS: A PILOT STUDY

L.J. Ghib<sup>1</sup>, R. Cojocneanu-Petric<sup>2</sup>, L. Budisan<sup>2</sup>, L. Muntean<sup>1</sup>, I. Filipescu<sup>1</sup>, I. Berindan-Neagoe<sup>2</sup>, S. Rednic<sup>1</sup>. <sup>1</sup>Rheumatology Department, <sup>2</sup>Research Center for Functional Genomics and Translational Medicine, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj Napoca, Romania

**Background:** Fibromyalgia (FM) is present in a significant proportion of patients with rheumatoid arthritis (RA).<sup>1</sup> Diagnosis and management of patients with rheumatoid arthritis and associated fibromyalgia (FRA) is challenging.<sup>1</sup> MicroRNAs (miRNA) are small noncoding RNAs that target mRNA and repress protein production. Recent studies have identified specific patterns of microRNA (miRNA) expression in FM patients.<sup>3</sup>

**Objectives:** Our objectives were to determine if there are differences in expression levels of miR let-7a, miR-21–5 p, miR –143 and miR-103a-3p in the blood of

FRA, RA and FM patients and to determine if any of the aforementioned miR could differentiate between FRA and RA.

**Methods:** We performed a case control study on 10 FRA patients compared to 10 FM, 10 RA patients with pain of at least 50 mm on VAS, and 10 healthy controls. All patients underwent clinical and laboratory examinations. Cell lysate from peripheral blood was used for the extraction of total RNA with TriReagent; miRNA reverse transcription was performed with the miScriptII Reverse Transcription kit (Qiagen) according to manufacturer's instructions. cDNAs obtained were further amplified by quantitative PCR (qPCR) with the miScript SYBR Green PCR kit. miRNA relative expression was quantified using the  $2^{-\Delta\Delta Ct}$  method. Relative miRNA levels are expressed as fold change (Fc). Data are expressed as median (interquartile range).

**Results:** There were no significant differences in terms of baseline characteristics between the groups. Clinical characteristics of included patients are listed in table 1. Patients with RA had higher SJC values and higher ESR and CRP levels as compared to FRA and FM patients. However, the mean DAS28 scores of RA and FRA patients were not significantly different, due to higher TJC values and higher pain levels in the FRA group.

Expression levels for miR let-7a, miR-21-5 p3 and miR-103a-3p were similar between the groups. miR-143 was downregulated in FRA, with a median Fc of 0.6 (IQR 0.3) and FM patients with a median Fc=0.5 (IQR 1.6) and upregulated in RA patients with a median Fc of 1.4 (IQR 0.5). miR-143 expression levels correlated negatively with TJC ( $r=-0.7$ ;  $p<0.05$ ) and with the Fibromyalgia Impact Questionnaire score ( $-0.8$ ,  $p<0.01$ ) in patients with FRA. ROC analysis showed that the AUC to identify FRA from RA patients was 0.89 (95%CI 0.7–1),  $p=0.03$  (Fig 1). A cut-off value for miR-143 Fc of  $>1.04$  had a sensitivity of 90% and specificity of 70% in differentiating FRA from RA.

Abstract THU0518 – Table 1. Demographic and clinical data of patients

Variable	FRA n=10	RA n=10	FM n=10	Controls n=10	p
Age (years)	54 <sup>(14)</sup>	55.5 (11)	55 <sup>(14)</sup>	46.5 (9)	0.1
TJC	17 <sup>(12)</sup>	9 (7)	7 (11)	0	0.006
SJC	4 (10)	7 (3;9)	0	0	<0.001
Pain on VAS(mm)	75 <sup>(32)</sup>	70 <sup>(30)</sup>	70 <sup>(25)</sup>	0	0.01
ESR(mm/h)	25 <sup>(33)</sup>	54 <sup>(46)</sup>	9 (7)	5 (9)	0.002
CRP(g/dl)	6 (21.4)	24.6 (41.1)	1.3 (1.2)	1.3 (4.3)	0.001
DAS28ESR	5.9 (1.9)	5.5 (2)	3.8 (1.4)	-	0.001
DAS28CRP	5.5 (2)	5.5 (2)	3.8 (0.8)	-	<0.001
HAQ	1.8 (0.9)	1.8 (0.7)	1.1 (1.4)	0	0.001
Tender point count	16 <sup>(6)</sup>	6 (7)	15 <sup>(5)</sup>	0 (1)	<0.001

**Conclusions:** miR-143 is downregulated in patients with FRA and may discriminate between patients with FRA and RA. Further studies are needed in order to validate these results.

## Epidemiology, risk factors for disease or disease progression

### THU0519 PREDICTION OF PERSISTENT KNEE PAIN BY PRESSURE PAIN DETECTION THRESHOLDS: RESULTS FROM THE KNEE PAIN IN THE COMMUNITY COHORT (KPIC)

D.F. McWilliams<sup>1</sup>, N. Frowd<sup>1</sup>, L. Marshall<sup>1</sup>, J. Stocks<sup>1</sup>, A. Sarmanova<sup>2</sup>, G. S. Fernandes<sup>2</sup>, M. Hall<sup>3</sup>, W. Zhang<sup>1</sup>, M. Doherty<sup>1</sup>, A.M. Valdes<sup>1</sup>, D.A. Walsh<sup>1</sup>.  
<sup>1</sup>Arthritis Research UK Pain Centre and Academic Rheumatology; <sup>2</sup>Academic Rheumatology; <sup>3</sup>Physiotherapy, University of Nottingham, Nottingham, UK

**Background:** Knee pain results from a combination of nociceptive input from the joint, and processing of that input by the central nervous system. Pressure pain detection thresholds (PPTs) are lower and pain is more severe in people with greater central sensitisation.

**Objectives:** We hypothesised that lower PPTs predicted worse pain prognosis in people with knee pain.

**Methods:** KPIC participants were people aged  $>40$  years recruited from Nottingham, UK. Participants were mailed questionnaires at baseline and 1 year. This study reports the sample of responders who attended baseline and 1 year clinical assessment, had self-reported knee pain (within the last 4 weeks) and underwent PPT. PPT was measured at the knee, anterior tibia and the sternum. Radiographic knee OA was classified using an atlas. Questionnaires measured ICOAP (constant and intermittent knee pain), painDETECT (neuropathic-like) and average knee pain severity over 4 weeks (0–10).

The presence of pain at baseline and 1 year (persistent pain), or pain severity were predicted from baseline anterior tibia PPT. Additional analyses adjusted for baseline pain score, age, sex, BMI, or for radiographic knee OA. Pain persistence (Yes/No) was analysed using t tests, odds ratios (OR) and logistic regression. Pain severity was analysed using linear regression.

**Results:** The sample for this study contained  $n=419$  people at baseline, of whom  $n=182$  people reported knee pain persistent over both time points. The mean (SD) values for those with persistent knee pain at 1 year, were age 61<sup>9</sup> years, BMI 30.1 (5.8)  $\text{kg m}^{-2}$ , 59% female, and 36% fulfilled radiographic OA criteria at the index knee.

In univariate analysis, persistent knee pain was associated with a lower PPT at baseline (461 vs 424 kPa; OR (95% CI) 0.58 (0.34–0.97)  $p=0.020$ ). Adjustments for age, sex and BMI removed the significance from the association (adjusted OR (95% CI) 0.64 (0.36–1.13)  $p=0.120$ ).

In those with persistent pain, worse 1 year ICOAP-constant, ICOAP-intermittent, painDETECT and knee pain severity were correlated with lower baseline anterior tibia PPT ( $r=-0.28$  to  $-0.24$ ;  $p<0.004$ ). After adjustment for baseline pain, 1 year ICOAP-constant pain scale was significantly predicted by baseline PPT (B (95% CI),  $-1.05$  ( $-1.91$  to  $-0.20$ )  $p=0.016$ ). Linear regression with adjustments for age, sex and BMI also indicated that baseline PPT predicted worse ICOAP-constant pain (B (95% CI)  $-0.99$  ( $-1.94$  to  $-0.04$ )  $p=0.041$ ).

The presence of radiographic OA at baseline predicted pain at 1 year, but was not significantly associated with PPT at baseline. Adjustment for baseline radiographic OA did not remove the association between baseline PPT and ICOAP-constant at 1 year (anterior tibia PPT  $-1.04$  ( $-1.89$  to  $-0.18$ )  $p=0.018$ ). PPT at joint lines or sternum displayed similar patterns of association with 1 year pain as did PPT at the anterior tibia.

**Conclusions:** Pressure pain detection thresholds suggestive of central sensitisation at baseline were associated with knee pain prognosis at 1 year, in particular with constant knee pain. The presence of radiographic OA also predicts 1 year pain prognosis, but does not explain its prediction by PPT.

## Fibromyalgia

THU0520

## ASSESSMENT OF CARDIOVASCULAR RISK IN PATIENTS WITH FIBROMYALGIA BY CAROTID-FEMORAL PULSE WAVE VELOCITY – RESULTS OF A PROSPECTIVE STUDY

K. Triantafyllias<sup>1</sup>, M. Stortz<sup>2</sup>, M. de Blasi<sup>1</sup>, C. Leistner<sup>1</sup>, J. Weinmann-Menke<sup>2</sup>, A. Schwarting<sup>1</sup>. <sup>1</sup>Rheumatology, Acura Clinics Rhineland-Palatinate, Bad Kreuznach; <sup>2</sup>Rheumatology, University Medical Center of the Johannes Gutenberg University Mainz, Germany, Mainz, Germany

**Background:** Autonomic dysfunction, a basic element of fibromyalgia (FM), has been in some cases related to increased risk of cardiovascular (CV) disease. CV risk associates with aortic stiffness, which can be reliably assessed by carotid-femoral pulse wave velocity (cfPWV).

**Objectives:** Aims of this study were to test the hypothesis of increased cfPWV in a group of patients with FM and to examine its association with FM associated parameters and selected traditional CV risk factors.

**Methods:** We performed measurements of cfPWV in 99 FM patients and 102 healthy controls. The difference between cfPWV values in the two groups after controlling for possible confounding factors was evaluated through multiple regression analysis. The associations of cfPWV with FM related parameters such as pain severity on the EuroQol visual analogue scale (EQ-VAS) and FM tender points were also analysed. Finally, we explored the relationship of cfPWV with various laboratory parameters (patients' group) and traditional CV risk factors (both groups).

**Results:** Adjusted statistical analyses for confounding factors showed significantly higher cfPWV values in FM patients in comparison to controls ( $p_{adj}=0.044$ ). cfPWV associated significantly with age in both the patients and the control group ( $\rho=0.614$ ,  $p<0.001$  and  $\rho=0.678$ ,  $p<0.001$  accordingly). Moreover, cfPWV correlated in the control group with systolic, diastolic and mean arterial pressure ( $p<0.001$ ,  $p=0.013$  and  $p<0.001$  accordingly) as well as with Body Mass Index ( $p=0.003$ ).

Abstract THU0520 – Table 1. Descriptive characteristics by group.

	Controls (n=102)	Patients (n=99)	Significance (p)
cfPWV (m/s)	7.50 (6.78–8.40)	8.00 (7.20–9.30)	0.004*
Age (years)	50 (38.25–56.25)	53 (46.00–59.00)	0.025*
Gender (female)	92 (90.2%)	93 (93.9%)	0.436
Nicotin (smokers)	21 (20.6%)	28 (28.6%)	0.250
Antihypertensive drugs	16 (15.2%)	35 (36.1%)	0.001*

\*p&lt;0.05

**Conclusions:** Our data reveal that patients with FM have higher aortic stiffness than healthy controls, even after adjusting for confounding factors of cfPWV. Therefore, FM may be associated with an increased CV risk. To our knowledge, this is the largest study to examine the gold standard assessment method of aortic stiffness in patients with FM and the first one to find increased cfPWV-values in comparison to healthy subjects.

THU0521

## A SIMPLE INDEX BASED ON SCORES ON A MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE (MDHAQ) PROVIDES INFORMATION QUITE SIMILAR TO ACR CRITERIA FOR FIBROMYALGIA IN ROUTINE CARE

J. Schmukler, I. Castrejon, T. Pincus. Rheumatology, Rush University Medical Center, Chicago, USA

**Background:** Fibromyalgia (FM) is common in the general population, easily identified in many patients, but subtle in some, particularly when patients meet criteria for rheumatic diseases such as rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), osteoarthritis (OA), and others. American College of Rheumatology (ACR) FM criteria were reported in 1990 (Arth Rheum 33:160, 1990) and 2010 (Arth Care Res 62:600, 2010) as "preliminary diagnostic criteria," modified for patient self-report in 2011 (Ann Med 43:495, 2011), and in 2016 as the "2016 revisions to the 2010/2011 fibromyalgia diagnostic criteria" (Sem Arth Rheum 46:319, 2016). These FM criteria are not used in most routine care settings. A multidimensional health assessment questionnaire (MDHAQ) is more widely used in the USA (Arth Care Res 64:640, 2012), and is informative in RA, OA, SLE, and most rheumatic diseases (J Clin Rheumatol 19:169, 2013). MDHAQ may provide clues to primary and secondary FM in routine care, EULAR 2016, 2017

**Objectives:** To compare 2 indices of MDHAQ scales to the 2011 and 2016 FM criteria to identify patients with possible primary or secondary FM in routine care.

**Methods:** All patients with all diagnoses seen at an academic rheumatology clinic complete an MDHAQ at each visit. The modified FM criteria questionnaire was added from April-July 2017. Two MDHAQ scales were studied: MDHAQ-FM3 includes a 0–10 pain visual analogue scale (VAS), 0–48 self-report rheumatoid arthritis disease activity index (RADAI) painful joint count, and 0–60 symptom checklist; one point each is scored for pain  $\geq 6/10$ , RADAI  $\geq 16/48$ , symptom checklist  $\geq 16/60$  – total=0–3. MDHAQ-FM4 adds a MDHAQ fatigue VAS; 6/10 is scored 1 (Total 0–4). Both MDHAQ indices were compared to both modified 2011 and 2016 FM criteria using kappa statistics and the proportion correctly classified ("Correct").

**Results:** We studied 502 patients; primary diagnoses (ICD10 in the medical record) included FM in 49, OA in 74, RA in 78, SLE in 88, others in 213. Overall, 131 patients (26.1%) met 2011 modified FM criteria and 112 (22.3%) 2010 modified FM criteria. Agreement between physician diagnosis of FM and 2016 modified criteria was 80.9% (kappa 0.44,  $p<0.001$ ), and with 2011 modified criteria was 80.3% (kappa 0.45,  $p<0.001$ ). Agreement of MDHAQ-FM3 score  $\geq 2$  with 2011 modified FM criteria was 84.3% (kappa 0.63,  $p\leq 0.001$ ), and with 2016 FM criteria 81.7% (kappa 0.56,  $p\leq 0.0001$ ). MDHAQ-FM4 increased the level of agreement only slightly (table 1).

Abstract THU0521 – Table 1. Prevalence and agreement of criteria and FAST3 and FAST4 versions in 502 university rheumatology clinic attendees

FM criteria status	FM2011		FM2016	
	Criteria Positive	Criteria Negative	Criteria Positive	Criteria Negative
<b>MDHAQ-FM3</b> (n=502)				
Screening positive	112 (85.5%)	60 (16.2%)	96 (55.8%)	16 (4.8%)
Screening negative	19 (14.5%)	311 (83.8%)	76 (44.2%)	314 (95.1%)
	Correct 84.3% Kappa 0.63 (0.56–0.70)*		Correct 81.7% Kappa 0.56 (0.48–0.63)*	
<b>MDHAQ-FM4</b> (n=464)				
Screening positive	93 (73.8%)	32 (9.5%)	81 (64.3%)	27 (7.9%)
Screening negative	33 (26.2%)	306 (90.5%)	45 (35.7%)	311 (92.0%)
	Correct 85.9% Kappa 0.64 (0.57–0.72)*		Correct 84.5% Kappa 0.59 (0.50–0.67)*	

**Conclusions:** Two indices derived from MDHAQ variables for pain, painful joints, somatic symptoms, and fatigue, provide a useful clue to FM in routine rheumatology care.

**Disclosure of Interest:** J. Schmekler: None declared, I. Castrejon: None declared, T. Pincus Shareholder of: Dr. Pincus holds a copyright and trademark for MDHAQ and RAPID3 for which he receives royalties and license fees. ## Back pain, mechanical musculoskeletal problems, local soft tissue disorders

### THU0522 EXPERIMENTAL TENDINOPATHY TREATMENT WITH SM04755, A TOPICAL SMALL MOLECULE INHIBITOR OF THE WNT PATHWAY

V. Deshmukh<sup>1</sup>, T. Seo<sup>1</sup>, Y. Yazici<sup>1</sup>. <sup>1</sup>Samumed, LLC, San Diego, United States

**Background:** Tendinopathy is an inflammatory and degenerative disorder caused by injuries and overuse. Affected tendons become fibrotic, with micro tears that can lead to pain and rupture. Current therapeutic options treat symptoms and not underlying causes. The Wnt pathway is upregulated in chronic tendinopathy and involved in inflammation, tenocyte differentiation and fibrosis.

**Objectives:** SM04755, a novel, topical, small molecule Wnt pathway inhibitor, has previously been shown to inhibit inflammation, reduce fibrosis and increase tenocyte differentiation in nonclinical models<sup>1</sup>. Two further experiments are presented: 1. SM04755 treatment in an acute dose response tendinopathy model and 2. SM04755 treatment in a repeat injury/delayed treatment (RIDT) tendinopathy model. These models simulate acute and acute-on-chronic clinical tendinopathy, respectively.

**Methods:** SM04755 was assessed in rodent Achilles tendinopathy models, induced by intra-tendon collagenase injection (500 µg). In the acute dose response model, a single injection of collagenase or sham per animal on Day -4 was followed on Day 0 by daily topical vehicle, or 0.3 mg/cm<sup>2</sup> or 0.9 mg/cm<sup>2</sup> SM04755. Achilles tendons were harvested on Days 7, 14, and 21. In the RIDT model, collagenase injections were given at Days -28 and -14, followed on Day 0 with daily topical vehicle or 0.3 mg/cm<sup>2</sup> SM04755. Achilles tendons were harvested on Days 7, 14, 21 and 28. Blinded histology analyses scored tendon health based on linearity, tendon cell shape, tendon cell density, inflammation, and haemorrhage (range 5–20). Statistical analyses used one-way ANOVA for multiple group comparisons and t-tests for comparison between two groups.

**Results:** In the acute dose response model, SM04755 improved tendon health from baseline compared to vehicle as assessed by tendon histology scores. Vehicle scores were 10.77 [±1.46] at Day 7, 10.44 [±0.66] at Day 14, and 10.31 [±1.02] at Day 21. SM04755 0.3 mg/cm<sup>2</sup> dose group scores were 12.30 [±0.62] at Day 7 (NS), 10.45 [±1.29] at Day 14 (NS), and 14.37 [±0.82] at Day 21 (p<0.05). SM04755 0.9 mg/cm<sup>2</sup> dose group scores were 12.22 [±1.02] at Day 7 (NS), 14.57 [±0.41] at Day 14 (p<0.05), and 14.67 [±0.76] at Day 21 (p<0.05) (figure 1). In the RIDT model, vehicle scores were 12.35 [±0.30] at Day 7, 10.09 [±0.76] at Day 14, 11.92 [±0.77] at Day 21 and 13.72 [±0.35] at Day 28. SM04755 0.3 mg/cm<sup>2</sup> dose group scores were 11.86 [±2.13] at Day 7 (NS), 9.44 [±0.48] at Day 14 (NS), 14.61 [±0.77] at Day 21 (p<0.05), and 14.93 [±0.46] at Day 28 (NS) (figure 2).

**Abstract THU0522 – Figure 1.** Progression of tendon health scores after SM04755 treatment in the acute treatment collagenase model.

**Abstract THU0522 – Figure 2** Treatment with SM04755 in the delayed treatment collagenase model

**Conclusions:** In the acute dose response model, SM04755 0.3 mg/cm<sup>2</sup> dose showed statistically significant improvements in tendon scores compared to vehicle at Day 21. The 0.9 mg/cm<sup>2</sup> dose achieved significance at Days 14 and 21, indicating faster response at higher SM04755 dose. In the RIDT model of repeat collagenase injections and delayed intervention, SM04755 0.3 mg/cm<sup>2</sup> dose promoted accelerated tendon healing compared to vehicle. Therefore, SM04755 demonstrated accelerated improvement of tendon histology in acute and RIDT models compared to vehicle and has potential as a tendinopathy therapy. Clinical studies are planned.

### THU0523 DO WE NEED STEROID INJECTION AFTER ULTRASOUND GUIDED PERCUTANEOUS LAVAGE OF A ROTATOR CUFF CALCIFICATION ? RESULTS AT 3 MONTHS OF A DOUBLE BLINDED RANDOMISED CONTROLLED STUDY

C. Darrieurtot-Lafitte<sup>1</sup>, S. Varin<sup>2</sup>, G. Coiffier<sup>3</sup>, J.-D. Albert<sup>3</sup>, G. Cormier<sup>2</sup>, B. Le Goff<sup>1</sup>.

<sup>1</sup>Rheumatology department, Hopital Hotel Dieu/Hme, Nantes Cedex 1;

<sup>2</sup>Rheumatology Department, CHD, La Roche-Sur-Yor; <sup>3</sup>Rheumatology Department, Hopital Sud, Rennes, France

**Background:** Rotator cuff calcific tendinopathy is a common condition causing up to 20% of the painful shoulder. Ultrasound guided percutaneous lavage (UGPL) is indicated after failure of conservative treatments. Steroids injections in the subacromial bursa (SAB) are usually performed after the lavage to prevent the pain induced by the procedure. However, some suggested that this injection could prevent the inflammatory reaction leading to the disappearance of the calcific deposit. Moreover, its efficacy to prevent post-procedure pain has never been demonstrated.

**Objectives:** The goal of this study was to evaluate the effect of a steroid injection in the SAB after UGPL on the pain and the radiographic evolution of the calcification.

**Methods:** This was a multicentric prospective double blinded randomised controlled study. We included patients with shoulder pain for more than 3 months and a type A or B calcification >5 mm on X-Ray. Patients were treated with UGPL using a single needle technic. At the end of the procedure, they received a blind injection of either 2 mL of methylprednisolone acetate or 2 mL of serum saline. The primary outcome was the maximal VAS pain (0–100) the first week following UGPL. Secondary outcomes were the evolution of VAS pain at 7 days, 6 weeks and 3 months and the radiographic changes of the calcification at 3 months.

**Results:** We included 134 patients, mean age 49.8 (±9.7) years, 89 females (67.4%). Calcifications involved the supraspinatus, infraspinatus and subscapularis in 114 (85%), 14 (10%) and 6 patients (5%) respectively. Calcifications were type A and type B in 42,5% and 57,5% of the cases respectively and mean size of the calcification was 1,5 cm (±0,5). Backflow of calcific material was obtained in 107 patients (81.1%). Maximum pain during the first week following UGPL was 71.5 [CI95%:63.9–79.20] in the serum saline group versus 59.8 [CI95%:52.2–67.41] in the steroid group with a mean difference of 11.7 [CI95%:3.7–19.7]. More patients in the placebo group needed to take NSAID (12.1% versus 6.1%) and paracetamol (16.7% versus 9.1%) during the first week. VAS pain at rest and during activities decreased significantly more in the steroid group compared to the placebo: VAS pain during activity was 72.02 [62.98–81.06], 26.63 [17.60–35.67], 32.30 [23.11–41.49] and 43.27 [34.18–52.37] in the steroid group versus 72.46 [63.41–81.51], 48.22 [39.14–57.31], 51.44 [42.26–60.62] and 51.09 [41.95–60.24] in the placebo group at day 0, 7, 6 weeks and 3 months respectively (figure

1). At 3 months no difference was found in the radiographic evolution: 62.1% of the patients treated with steroid and 64.8% treated with serum saline had more than 50% of resorption of their calcification.

**Conclusions:** Our study shows that steroid injection in the SAB leads to a significant decrease of maximal pain the following week. This treatment also decreases significantly the pain during the 3 first months after UGPL. Importantly, we found no difference between the 2 groups in the radiographic evolution of the calcification at 3 months. Overall, steroids injections in the SAB can be recommended after UGPL.

#### THU0524 IS THERE ANY EFFECT OF KINESIOTAPING ON RADIAL NERVE IN PATIENTS WITH UNILATERAL LATERAL EPICONDYLITIS? A RANDOMIZED-SINGLE BLIND STUDY

B. Mansiz-Kaplan, S. Vural, O.F. Celik, H. Genc. *Department of Physical Medicine and Rehabilitation, University of Health Sciences, Ankara Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Ankara, Turkey, Ankara, Turkey*

**Objectives:** Lateral epicondylitis is characterised by pain in the lateral epicondyle of the humerus and common extensor tendon (CET). It was reported that radial nerve cross-sectional area were increased in refractory lateral epicondylitis measuring with ultrasonography, although nerve conduction studies were normal. In literature, it is indicated that kinesiotaping is effective at the treatment of lateral epicondylitis. In this study, we aimed to evaluate the effect of kinesiotaping with the larger sample size and using ultrasonography in addition to clinical parameters with patients lateral epicondylitis.

**Methods:** Eighty-five patients with unilateral lateral epicondylitis who completed the inclusion criteria were randomised into two groups. The non-steroidal anti-inflammatory drug (NSAID) was administered to the control group (CON) twice daily for 10 days, while kinesiotaping (KT) was performed 3 times a week for 2 weeks, in addition to the same NSAIDs. Clinical and ultrasonographic evaluation was performed before treatment, at 2 weeks (at the end of treatment) and at 6 weeks. Visual analogue scale (VAS), Nirschl grading, and PRTEE (Patient Based Tennis Elbow Evaluation Test) were used for clinical evaluation. The radial nerve cross-sectional area (RNCSA) were measured at two level: spiral groove, just before bifurcation and CET thickness was calculated by ultrasonography. Clinical evaluation, ultrasonographic evaluation and management of treatment were performed by blind investigators.

**Results:** The study was completed with 80 patients and there were 40 patients in both groups. There were no significant difference age, gender, education, occupation, symptom duration and body mass index in both groups. The improvement of VAS was significant in CON at 2nd week ( $p < 0.05$ ), but not at 6th weeks. In KT group, improvement of VAS was significant both at the 2nd and at 6th weeks ( $p = 0.00$ ). Significant improvement was observed in spiral groove RNCSA and CET thickness in both groups. In the KT group, RNCSA at the level of pre-bifurcation was decreased significantly at the 2nd and 6th weeks ( $p = 0.00$ ), but there was no descreation in the CON. When the groups were compared, significant differences were observed in clinical parameters, CET thickness, and bifurcation RNCSA values at 2 and 6 weeks in the KT group ( $p < 0.01$ ).

**Conclusions:** Kinesiotaping improves clinical parameters and decreases ultrasonographic parameters such as CET thickness and radial nerve cross-sectional area. Therefore, kinesiotaping may be an alternative method that can be used in the treatment of lateral epicondylitis.

#### THU0525 EFFECT OF LOCAL INSULIN INJECTION IN THE TREATMENT OF MILD TO MODERATE CARPAL TUNNEL SYNDROME IN PATIENTS WITH TYPE 2 DIABETES MELLITUS

A.H. Ismail, S.R. Kamel, H.A. Sadek, O.A. Sayed. *rheumatology and rehabilitation department, faculty of medicine- Minia University-Egypt, Minia, Egypt*

**Background:** Carpal tunnel syndrome (CTS) is the most common focal nerve entrapment and is a significant cause of morbidity; this syndrome has a higher incidence in diabetic patients. It has been suggested that insulin influences nerve regeneration in a similar way to that of nerve growth factor.

**Objectives:** Aim: The aim of the study was to compare the effectiveness of local insulin injection, with that of local steroid injection and of local steroid followed by insulin injections in treating mild to moderate carpal tunnel syndrome in patients with type 2 diabetes mellitus.

**Methods:** Patients and methods: The study included 60 type 2 diabetic patients with electrophysiologic evidence of mild to moderate CTS. They were randomly assigned to three groups: group I received insulin injection of 10 IU Neutral Protamine Hagedorn insulin (NPH insulin) locally into the affected carpal tunnel at the first visit and a similar dose of insulin after 2 weeks; group II received a single injection of 40 mg methylprednisolone acetate injection into the carpal tunnel. And group III received a steroid injection into the carpal tunnel then followed by insulin injection twice after 2 and 4 weeks from the steroid injection. Clinical, electrophysiologic and ultrasonographic evaluations were carried out at the start of the study and at 10 weeks after treatment.

**Results:** Results: In all groups, there was significant improvement in symptoms, signs and assessment questionnaires (SS score, FD score, and VAS) after receiving the injection. Also, there was a statistically highly significant improvement in DML, SNCV, PSL, and a statistically significant improvement in Samp in the insulin group. While in steroid group there was a statistically highly significant improvement in PSL, and a statistically significant improvement in SNCV. In the third group (steroid followed by insulin), there was a statistically highly significant improvement in DML, SNCV and PSL. As for ultrasonographic assessment, there was a statistically significant improvement in CSA and PD in all groups. The third group (steroid followed by insulin) showed the best improvement as regard the CSA.

**Conclusions:** Conclusion: Local insulin injection was found to be as effective as steroid in reducing the symptoms of CTS and improving electrophysiological and ultrasonographic findings, being a safer alternative for diabetic patients. Our findings suggest that local insulin injection after local steroid injection may be of additional benefit in improving median nerve ultrasonographic parameters in mild to moderate diabetic CTS. **Keywords:** Type 2 diabetes mellitus, carpal tunnel syndrome, local insulin injection.

**THU0526 ACUTE PARASPINAL MUSCLE NECROSIS WITH CRACK COCAINE AND HEROIN; A CASE REPORT**

A. Masood<sup>1</sup>, L. Attipoe<sup>1</sup>, D. D'Cruz<sup>1</sup>, S. Al-Saraj<sup>2</sup>, S. Williams<sup>1</sup>, K. Sabzevari<sup>1</sup>.  
<sup>1</sup>Rheumatology, Guys and St Thomas Hospital Trust; <sup>2</sup>Clinical Neuropathology, Kings College Hospital, London, UK

**Background:** Cocaine can cause serious muscle injury ranging from asymptomatic creatine phosphokinase (CK) elevation to massive rhabdomyolysis with acute renal failure. Muscle injury is more common after intravenous use or after smoking the alkaloid freebase (crack cocaine) because of the more rapid effect and higher blood levels of the drug achieved via those routes. The onset of symptoms is acute and can even happen with one time drug use.

**Objectives:** to broaden the knowledge about severe focal myositis as a consequence of crack cocaine abuse

**Methods:** We report a case of Acute Paraspinal myositis and Rhabdomyolysis in a previously healthy African gentleman after smoking crack cocaine and heroin.

**Results:** 35 years old gentleman, previously well, presented to the emergency with 12 hour history of severe lower back pain and stiffness in the absence of any trauma or systemic symptoms. On admission he was conscious and alert with tenderness and stiffness of paraspinal muscles, urinary retention requiring catheterization but no muscle weakness. Serum Creatinine was elevated at 597 µmol/L and Creatine Kinase was 66000 U/L. Urinalysis showed haematoproteinuria (3 +blood, 4+protein). Patient reported smoking crack cocaine and snorting heroin, as well as drinking alcohol 12 hours before the onset of symptoms. Drug screen was positive for cocaine and benzodiazepines while autoimmune serology was negative for ANA, muscle specific antibodies anti-GBM and ANCA-antibody. Infection screen was negative and Urine and blood cultures were sterile. STIR images on MR scan revealed ill-defined areas in the paraspinal muscles consistent with Myositis. The muscle biopsy showed necrosis and focal intense infiltration by sheets of macrophages associated with proliferation of myoblast forming multinucleated giant cells but no evidence of granuloma formation the overall appearances being consistent with focal myositis. Serum Creatinine and CK improved progressively. He was treated with a tapering dose of steroids for 8 weeks while clinical and biochemical markers continued to improve.

**Conclusions:** Drug induced Rhabdomyolysis can occur with cocaine, heroin and alcohol but it is the first reported case of focal myopathy affecting Paraspinal Muscles alone. There is one case report in the literature suggesting isolated myopathy with cocaine in the absence of central nervous system manifestations. One of the main differentials in such a scenario is Pyomyositis which requires early identification and prompt treatment to prevent systemic complications.

**THU0527 EFFECTS OF MANUAL THERAPY, SACROILIAC AND LUMBAR EXERCISES IN PATIENTS WITH SACROILIAC JOINT DYSFUNCTION SYNDROME**

A. Javadov, A. Ketenci. *Dept. of Physical Medicine and Rehabilitation, Istanbul Medical Faculty, Istanbul, Turkey*

**Objectives:** The aim of this study was to determine the effects of sacroiliac joint (SIJ) manipulation, sacroiliac and lumbar home exercises on pain, sacroiliac mobilisation levels and functional status in patients with sacroiliac joint dysfunction syndrome (SIJDS).

**Methods:** In a prospective, randomised interventional trial 69 eligible women were assigned to SIJ manual therapy +sacroiliac home exercise group (Group 1, n=23), SIJ manual therapy +lumbar home exercise group (Group 2, n=23) (n=19), or lumbar home exercise group (Group 3, n=23). All the patients who were included in the study were evaluated on the 0 th, 28 th day and 90 th day of the treatment. Specific tests (motion palpation and pain provocation tests) for SIJ were performed. Activity and rest pain was assessed by using the Visual Analogue Scale (VAS). Functional status and quality of life were assessed using the Modified Oswestry Disability Index (MODI) and Short Form-36 (SF-36), respectively.

**Results:** The VAS scores significantly decreased in all three groups (p<0,05). Gillet test, Vorlauf test, Posterior Shear Test (POSH), Irritation point test and Compression test showed significant decrease after treatment in both training groups (p<0.05). A significant improvement was determined in functional disability score (MODI), quality of life scores, Short Form-36 (SF-36) and neuropathic pain in all three groups (p<0.05). However, a more significant improvement was detected with manual therapy and sacroiliac home exercise program compared to patients in group 2 and group 3.

**Conclusions:** Our data suggest that manual therapy, sacroiliac and lumbar exercises programs can be effective in patients with sacroiliac joint dysfunction syndrome. In SIJDS, a pathology that should be considered in patients with low back pain, it is necessary to know that special SIE exercises and SIE manipulation therapy can be applied in combination with lumbar exercises and SIE manipulation therapy, or that exercises alone can be given but the benefit expected from exercise alone is less than combined treatment revealed.

**THU0528 THE RELIEF OF CHRONIC LOW BACK PAIN (CLBP) IMMEDIATELY AFTER ONE SESSION OF LOW LEVEL LASER ACUPUNCTURE THERAPY (LLLAT)**

D. Houssien<sup>1</sup>, A. Houssien<sup>2</sup>. <sup>1</sup>Dr Dhiya Center for Rheumatism, Dr Dhiya Center for Rheumatism, Jeddah, Saudi Arabia; <sup>2</sup>Immunology, King's college, London, UK

**Background:** Low-level Laser acupuncture therapy (LLLAT) is defined as the stimulation of acupuncture points with low-intensity, laser irradiation and is widely used in treating musculoskeletal pain.

**Objectives:** To determine whether the use of a single session of LLLAT for Chronic Low Back Pain (CLBP) will result in better outcome than using acupuncture alone.

**Methods:** 40 patients with CLBP were randomly assigned to two treatment groups: G1 (Acupuncture; 20 patients) and G2 (laser acupuncture; 20 patients). All patients received a single session only. The Acupuncturists inserted a stainless steel needle in local low back (Du3,4, UB23,5,6), distal (UB36, 40,54,7,8,60, GB30,1,4, Li4) and auricular points. laser-acupuncture treatment with a 20 Hz 200 mW 820 nm Gallium Aluminium Arsenide diode laser was used the same previous points. Pain intensity was assessed on a 100 mm visual analogue scale (VAS). The lumbar range of motion was measured by fingertip-to-floor method. A

physiotherapist, who was blinded to treatment assignment, evaluated the patients immediately before and after treatment as well as 4, 12 and 24 weeks later.

**Results:** Immediately after the completion of treatment, the mean VAS dropped from 78 to 66 mm in the acupuncture group (G1) but increased at the follow up visits to 76 mm after 24 weeks. In contrast, VAS scores decreased from 80 to 48 mm in the laser acupuncture group. Although it increased in the follow up visits 60 mm after 24 weeks, it remained significantly better (24 mm  $P < 0.0001$ ) than at the initial assessment. The mean of fingertips and floor distance decreased significantly in G2 from 41 cm to 15 cm immediately after the completion of the first session (the difference from baseline was 26 cm) compared to a decrease from 44 to 35 after the first session in G1. Forward flexion of the lumbar spine improvement remained stable between the first assessment and the other four assessments in patients exposed to prayers with the difference between the baseline and 24 week assessments highly significant ( $p < 0.0001$ ) compared to G1 ( $p > 0.05$ ).

**Conclusions:** Both measures were decreased in both groups but laser acupuncture resulted in a significant improvement in functional and symptomatic outcomes in this group of patients with CLBP even after 24 weeks follow up.

**Disclosure of Interest:** None declared

#### THU0529 THE COMPARISON OF PHYSICAL ACTIVITY LEVEL IN PREGNANT WOMEN WITH AND WITHOUT LOW BACK PAIN

E. Üzelpasacı<sup>1</sup>, S. Topuz<sup>1</sup>, C. Orhan<sup>1</sup>, E. Baran<sup>1</sup>, G. Nakip<sup>1</sup>, S. Özgül<sup>1</sup>, S. Beksac<sup>2</sup>, T. Akbayrak<sup>1</sup>. <sup>1</sup>Physical Therapy and Rehabilitation, Hacettepe University Faculty of Health Sciences; <sup>2</sup>Department of Obstetrics and Gynecology, Hacettepe University Faculty of Medicine, Ankara, Turkey

**Background:** Low back pain (LBP) is one of the most common musculoskeletal problems during pregnancy that occurs due to a combination of mechanical, hormonal, circulatory and psychological factors. The changes in the load, body mechanics and centre of gravity, increased levels of relaxin, and decreased venous circulation in the pelvic and lumbar region may contribute to LBP in pregnant women.<sup>1,2</sup> It has been reported that the prevalence of LBP ranges between 50% and 80%. Pregnant women suffer from LBP may experience significant physical, psychological and social problems which adversely affect their quality of life.<sup>3</sup>

**Objectives:** The aim of the study was to compare the physical activity level of pregnant women with and without LBP.

**Methods:** A total of 151 pregnant women without obstetric and medical complications were included in this study. Sociodemographic and obstetric characteristics of the participants were assessed with a standart questionnaire. The presence of LBP was recorded as "yes" and "no". The level of physical activity was assessed with the Pregnancy Physical Activity Questionnaire (PPAQ). The PPAQ is self-administered and asks respondents to report the time spent participating in 32 activities including household/caregiving, occupational, sports/exercise, transportation and inactivity. Independent samples t test was used to determine whether there was a difference in physical activity level between two independent groups (Group 1: Pregnant women with LBP, Group 2: Pregnant women without LBP).

**Results:** 77 pregnant women (mean age: 29.28±5.14 years, mean body mass index (BMI): 25.95±3.86 kg/m<sup>2</sup>) had no LBP. However, 74 pregnant women (mean age: 29.22±4.90 years, BMI: 26.85±2.78 kg/m<sup>2</sup>) have experienced LBP. There was no statistically significant difference in gestational week between two groups ( $p > 0.05$ ). Exercise-sports activity (mean: 5.69±7.29 MET-h.week<sup>-1</sup>) and vigorous activity (mean: 2.39±3.80 MET-h.week<sup>-1</sup>) scores of PPAQ were significantly lower in the pregnant with LBP than in those without LBP. Other activity scores were similar between groups ( $p > 0.05$ ).

**Conclusions:** The presence of LBP during pregnancy causes decreased levels of sports and exercise activities in the pregnant women while household/caregiving and occupational activities are being carried out. LBP can be a barrier to perform physical activities and exercises for pregnant women. Therefore, it should be treated with appropriate methods and pregnant women should be encouraged to regularly participate to exercise programs.

#### THU0530 CHRONIC LOW BACK PAIN AND DEPRESSION: SIGNIFICANT DECREASE WITH GLUCOSAMINE-CHONDROITIN SULFATE TREATMENT IN A LARGE, COMMUNITY-BASED, PILOT, OPEN PROSPECTIVE INTERVENTIONAL STUDY

G. Singh<sup>1</sup>, L. Alexeeva<sup>2</sup>, D. Goryachev<sup>2</sup>, A. Barinov<sup>3</sup>, A. Mithal<sup>4</sup>. <sup>1</sup>Gastroenterology And Hepatology, Stanford University, Woodside, USA; <sup>2</sup>State NII of Rheumatology of Russian Academy of Sciences; <sup>3</sup>I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation; <sup>4</sup>ICORE, Woodside, USA

**Background:** Low back pain (LBP) is the leading cause of Years Lived with Disability worldwide.<sup>1</sup> The number of people suffering from LBP grew more than 50% from 1990 to 2013, to 651 million.<sup>1</sup> Chronic low back pain can often lead to depression. Data on 1 90 593 community-dwelling adults aged ≥18 years from the World Health Survey (WHS) 2002–2004 in 43 Low and middle-income countries show a strong correlation between chronic back pain and depression.<sup>2</sup> Glucosamine-chondroitin sulfate (GCS) combination is widely used in the treatment of OA; however, there are few prospective scientific investigations of its therapeutic merits in severe LBP.

**Objectives:** To study the efficacy of GCS in the decreasing depression in patients with chronic low back pain in a large open pilot prospective observational study.

**Methods:** We enrolled patients between 40 and 65 years of age who had LBP for at least 12 weeks with a pain intensity >3 on a 0–10-point visual analogue scale (VAS) in a single-arm, open-label prospective interventional study. Major exclusion criteria were the presence of fibromyalgia, degenerative spondylolisthesis, and alcohol and/or drug abuse. All patients were treated with a combination of glucosamine hydrochloride 500 mg and chondroitin sulfate 500 mg in tablet form (Unipharm Inc.) at a dose of 1 tablet bid for the first month and then 1 tablet daily for the next two months. The primary endpoint was pain intensity (at rest and movement) as measured on a 0–10 point VAS. Depression was measured by the 13-questionnaire Beck's Depression Inventory (BDI). There are 13 questions in this score with highest possible score of 39 (5–7 is mild depression; 8–15 moderate depression, 16 and over severe depression).<sup>3</sup>

**Results:** A total of 8598 subjects (mean age 52.1 years, 67.3% women, mean BMI 27.4) were enrolled in the study, and formed the intent-to-treat (ITT) population. All but 95 subjects (1.1%) completed the study. Previously-reported ITT analysis with worst observation carried forward (WOCF) showed an improvement in pain at rest from mean (±SD) of 5.2±1.9 at study entry to 1.4±1.6 at 3 months ( $p < 0.0001$ ). Pain at movement decreased from 6.8±1.6 to 2.2±1.8 ( $p < 0.0001$ ). Baseline BDI scores showed a highly significant correlation with baseline pain scores at rest and movement ( $p < 0.0001$  for both). After 12 weeks of GCS treatment, the mean BDI score dropped from 8.7 (95% CI 8.6 to 8.9) to 2.9 (95% CI 2.8–3.0) (paired-test  $p < 0.0001$ ). An adverse event (AE) was reported by 604 (7.0%) patients (mostly gastrointestinal in origin, such as nausea, abdominal pain and dry mouth) but only 85 (1.0%) patients deemed it severe enough to discontinue therapy.

**Conclusions:** Although open and uncontrolled, this large pilot community-based study shows dramatic reductions in pain and depression in patients with LBP treated with GCS. With its benign safety profile, GCS therapy deserves serious evaluation in the management of LBP in a prospective randomised double-blinded clinical trial.

#### THU0531 COMPARISON OF THREE DIFFERENT TRIGGER POINT TREATMENT IN THE MANAGEMENT OF LOW BACK PAIN: A PILOT STUDY

L.O. Dayanir<sup>1</sup>, E. Kaya Mutlu<sup>2</sup>, M.A. Akçetin<sup>3</sup>, A.O. Akdemir<sup>3</sup>. <sup>1</sup>Institute of Health Science, Istanbul University, Bakırköy; <sup>2</sup>Faculty of Health Science, Istanbul University, Bakırköy; <sup>3</sup>Haseki Eğitim ve Araştırma Hastanesi, Haseki, Turkey

**Background:** Low-back pain is a common health problem worldwide. In the majority of cases, the pathoanatomical source of an individual's pain cannot be identified and are therefore defined as non-specific in nature. Although there are many potential contributing factors to low back pain, one area that has received

scientific emphasis is the trigger point (TrP). TrP is defined as hyperirritable areas within taut bands of skeletal muscle and classified as either active or latent. Although many methods have been proposed for use in the treatment of TrP, there has been no study investigating which method is more effective.

**Objectives:** The aim of our study is to compare the different trigger point techniques used in the treatment of low back pain.

**Methods:** 28 cases with low back pain with trigger point origin were included in the study. The subjects were randomly divided into 3 groups. Strain-Counter Strain (SCS) technique was applied to Group 1 (n=16), Integrated Neuromuscular Inhibition Technique (INIT) for Group 2 (n=16), and Ischaemic Compression Technique (ICT) for Group 3 (n=16). The duration of treatment was a maximum of 6 weeks (12 sessions) in both three groups. Visual Analogue Scale (VAS) was used for pain severity, algometer examination was used to measure pain threshold, and Oswestry Disability Index was used to assess disability score. In addition, the Beck Depression Scale was used to assess the psychosocial status of the cases, and the STAI (State Trait Anxiety Inventory)- I and STAI-II scales were used to assess emotion-state and continuity. The evaluations were made before the treatment, after the 1st session of the treatment and at the end of the treatment (after 6 weeks). The data were analysed by using Kruskal-Wallis Test.

**Results:** Mean age and body mass index (BMI) of our study group were, respectively, 38.6±12.3 years and 26.6±6.2 kg/m<sup>2</sup> in the SCS group, 34.2±10.1 years and 26.3±5.9 kg/m<sup>2</sup> in the INIT group and 34.8±14.2 years and 24.5±5.2 kg/m<sup>2</sup> in the ICT group. There was no significant difference among groups in respect of age, BMI, depression and anxiety score (p>0.05) before the treatment. Three groups had significant decreases in pain according to the VAS and algometer (p<0.05). The ROM values and function level significantly improved within three groups after treatment (p<0.05). There was no statistically significant difference in pain (p=0.13), lumbar flexion (p=0.77), lumbar extension ROM (p=0.43) and disability score (p=0.65) among the three groups before and after the treatment.

**Conclusions:** The results indicate that patients with low back pain gain clinically benefit from trigger point treatment on pain, ROM and function. Therefore, we suggest that physiotherapist either can apply SCS, INIT or ICT based on their clinical experience in the management of low back pain. #### THU0532 TO ASSESS WHETHER THERE IS AN ASSOCIATION BETWEEN HYPERMOBILITY AND SPORTS INJURY

J.A. Nathan, K. Davies. *Rheumatology, Brighton and Sussex University Hospitals, Brighton, UK*

**Background:** Joint Hypermobility (JH) is an extremely heritable condition in which joints have a range of motion beyond normal limits. This is frequently seen in healthy individuals.<sup>1</sup> It is important to differentiate this from Joint Hypermobility Syndrome (JHS).<sup>2</sup> (JH is diagnosed as a Beighton score of four or more).<sup>3</sup>

**Objectives:** The objective of this project was to determine whether there is an association between hypermobility and sports injury.

**Methods:** A quantitative observational approach using a cross sectional survey was adopted. A pilot study and initial focus group was arranged, involving 10 university students. Individuals were identified as hypermobile or not using the Beighton score. All participants were asked to complete two questionnaires; the first asking demographic information; the second questionnaire was injury specific. Fisher's exact test was used for statistical analysis.

**Results:** A total of 114 individuals participated in the study. 62 were women and 52 men. 26% of participants were found to be hypermobile. There was no significant association between hypermobility and sports injury (p=0.6596). There was a significant increase in joint and ligament sprain amongst the non-hypermobile (NH) group covering all sports studied (p=0.0269). Results showed that joint dislocation was found exclusively amongst hypermobile individuals. Duration of injury in hypermobile individuals was higher than NH. The use of oral painkillers or anti-inflammatories in the semi professional group was greater than the general population.

Table 1 Prevalence of hypermobility in each sport

Sport	Total Participants	H	NH	H (%)
Running	26	8	18	30.8
Football	24	6	18	25
Cycling	5	2	3	40
Squash	2	0	2	0
Swimming	1	1	0	100
Rugby	16	2	14	12.5
Hockey	19	6	13	31.6
Tennis	4	1	3	25
Netball	17	4	13	23.5
Total	114	30	84	26.3

**Conclusions:** Hypermobility is relatively common amongst individuals and there is a lot of anecdotal evidence associating it with increased rates of injuries. This

project finds that NH individuals are more likely to sustain a ligament or joint sprain in sports. This is thought to be due to increased joint laxity and flexibility preventing injury.

#### THU0533 PREVALENCE OF LOW BACK PAIN AND KINESIOPHOBIA IN ELDERLY RESIDENTS OF SAO PAULO CITY: A CROSS-SECTIONAL PRELIMINARY DATA

K.E. Chang<sup>1</sup>, J.W.C. Silva<sup>2</sup>, I.M.B. Souza<sup>1</sup>, P.A. Moura<sup>1</sup>, F.J.R. França<sup>2</sup>, J. E. Pompeu<sup>1</sup>, A.P. Marques<sup>1</sup>. <sup>1</sup>Department of Fonoaudiology, Physical Therapy and Occupational Therapy, Medical School at University of Sao Paulo; <sup>2</sup>Departamento de Gerontologia Social, 2Pontifical Catholic University of Sao Paulo, Sao Paulo, Brazil

**Background:** Low back pain (LBP) is an important health problem around the world associated with disability, high costs for the health system and work absenteeism. A recent systematic review estimated that in Brazil, the point prevalence of LBP in the elderly is 25%, superior to knee osteoarthritis and rheumatoid arthritis, being considered one of the most relevant health conditions in the elderly.

**Objectives:** To measure the prevalence of LBP and kinesiophobia in the elderly, following the existing guidelines on conducting specific prevalence studies about LBP and to investigate the factors associated.

**Methods:** This is a cross-sectional study and the total sample to be recruited is 513 individuals of both genders, over 60 years old. Pain was investigated at two different times: current and last year, and pain intensity was measured by Numerical Pain Rating Scale (NPRS). Disability was measured using the Roland Morris Disability Questionnaire - Brazil version (RMDQ - BRA) and kinesiophobia was measured by the Tampa Scale for Kinesiophobia (TSK).

**Results:** Until now, 387 elderly were interviewed, of which 77% were women and the mean age was 71.98 (±7.70). The prevalence of LBP was 76.23%, with a punctual prevalence of 72.54% and a 12 months prevalence of 93.22%. The mean NPRS score was 7.52 (±2.16), the mean RMDQ - BRA score was 11.32 (±5.35), and the mean of the TSK score was 43.78 (±7.50).

**Conclusions:** Preliminary data indicate that the prevalence of LBP and kinesiophobia are high in this population. However, the level of functional disability due is moderate. There are few studies that approach these symptoms in the elderly population, and will serve as the basis for the creation of health policies.

#### THU0534 THE EFFECT OF LUMBER STABILISATION EXERCISE ON THE BALANCE AND CLINICAL HEALTH

K. Barut<sup>1</sup>, E. Taştaban<sup>2</sup>, F. Sendur<sup>2</sup>. <sup>1</sup>PMR, Aydın Devlet Hastanesi; <sup>2</sup>PMR, Adu Tip, Aydın, Turkey

**Objectives:** The aim of this study is to investigate the effects of lumbar stabilisation exercises on chronic low back pain in term of pain, functioning, quality of life, balance and trophic improvement of lumbar multifidus muscles.

**Methods:** 66 patients with chronic low back pain were enrolled in this study. The patients were randomised and divided into two groups. Lomber stabilisation exercises, TENS and Hotpack treatments were given to the first group (n: 28) while the second group (n: 37) were treated with only TENS and Hotpack. Patients' evaluations have been carried out before and after 8 weeks following the exercises. Visual Analogue Scale (VAS) were used to determine the pain as a numeric scale during the rest and physical activity. Modified Oswestry Questionnaire Survey and Roland Morris Scale were used to evaluate of functional disability. The Short Form-36 (SF36) applied to measure of quality of life. Tetrax device has been used to evaluation the body balance. 7–15 MHZ Ultrasound has been used to evaluate the change of trophic changes of multifidus muscle's cross-sectional areas.

**Results:** Except falling risk, in all parameters we have observed significant improvement in group 1. Cross-sectional area of the multifidus muscles, physical role of SF-36, mental health and energy/vitality sub parameters were found significantly better in group 1 when compared to the other group. There was no significant difference between the groups when the fall index, VAS scores, Roland Morris Questionnaire and Oswestry Disability Index were considered.

**Conclusions:** As a result, lomber stabilisation exercises have positive effect on pain relief, improve the functional capacity and quality of life. Additionally the exercises also had benefit and increased cross-sectional areas of multifidus muscles.

**Disclosure of Interest:** None declared

**THU0535 TITLE: SAFETY AND EFFICACY OF PLATELET-RICH PLASMA IN TREATMENT OF CARPAL TUNNEL SYNDROME; A RANDOMISED CONTROLLED TRIAL**

L. Bagherzadeh, S.A. Raeissadat, A. Karimzadeh, M. Hashemi. *Physical medicine and rehabilitation, shahid beheshti university of medical sciences, ehran, Iran, Islamic Republic of Ireland*

**Background:** Carpal tunnel syndrome is the most common peripheral entrapment neuropathy, for which conservative treatments are the first measures taken but they are not usually sufficient.

**Objectives:** Recently major attention has been drawn to platelet-rich plasma, for its possible effects on axon regeneration and neurological recovery. Although few studies have evaluated the effects of this treatment in carpal tunnel syndrome, further investigations are required to reach concrete conclusion.

**Methods:** In this randomised controlled trial, women referring to the physical medicine and rehabilitation clinic at Shahid Modarres Hospital during 2016 with a diagnosis of mild and moderate idiopathic carpal tunnel syndrome were included and randomly assigned to two groups of control, only using a wrist splint, and platelet-rich plasma that received wrist splints along with a single local injection of platelet-rich plasma. The outcome measures were assessed via Visual Analogue Scale, the Boston Carpal Tunnel Syndrome Questionnaire and electrophysiological findings including the peak latency of sensory nerve action potential and the onset latency of the compound muscle action potential.

**Results:** A total of 41 women were included and randomly assigned to two groups of control (20 wrists) and platelet-rich plasma (21 wrists). Before treatment there were no significant differences between the two groups except for the median peak latency of sensory nerve action potential which was significantly higher among the patients in the platelet-rich plasma group ( $p=0.03$ ). All the measured variables significantly decreased in both groups after 10 weeks of treatment except for the median onset latency of the compound muscle action potential ( $p=0.472$ ). Finally, the changes in neither of the outcome measures evaluated were found to significantly differ between the two groups, even when the analyses were adjusted for age of the patients.

**Conclusions:** The findings of this study showed that in a relatively short period of time after treatment, a single injection of platelet-rich plasma in the wrist does not add significantly to the effects of conservative treatment with wrist splints, in regards to the women pain and symptom severity, functional status and electrophysiological parameters.

**THU0536 KNOWLEDGE OF AND EXPECTATIONS ABOUT FUNCTIONAL RESTORATION PROGRAM FOR CHRONIC LOW BACK PAIN ARE OFTEN FALSE: A MIRROR SURVEY OF 40 PATIENTS AND 59 PHYSICIANS IN 2017**

L. Pierre<sup>1</sup>, F. Bailly<sup>1</sup>, M. Assadourian<sup>1</sup>, V. Foltz<sup>1</sup>, A. Potel<sup>1</sup>, L. Morardet<sup>1</sup>, S. Ascione<sup>1</sup>, M. Le Ralle<sup>1</sup>, A. Dupeyron<sup>2</sup>, N. Ibrahim<sup>3</sup>, I. Griffoul-Espitalier<sup>4</sup>, B. Duplan<sup>5</sup>, J. Beaudreuil<sup>6</sup>, B. Fautrel<sup>1</sup>, L. Gossec<sup>1</sup>. <sup>1</sup>Sorbonne university; <sup>2</sup>Nîmes hospital; <sup>3</sup>Orleans hospital; <sup>4</sup>Tours hospital; <sup>5</sup>Metropole Savoie hospital; <sup>6</sup>Lariboisiere hospital, Paris, France

**Background:** Functional restoration programs (FRP) are multi-disciplinary programs that have demonstrated their effectiveness in chronic low back pain (CLBP) but they appear to be little known by patients and/or physicians.

**Objectives:** To assess the knowledge and expectations of CLBP patients and physicians about FRP.

**Methods:** Multicenter cross-sectional study in 2017 in 6 tertiary-care hospitals in France. Consecutive patients with CLBP (more than 6 weeks) who were seen for their CLBP were included. Physicians (rheumatologists or general practitioners, GPs) who had referred at least 5 patients to the tertiary-care centres were sent a survey. Patients and physicians were asked about their knowledge and expectations of a FRP. Results were scored as 'correct' regarding health professionals involved in the FRP, if both doctors and (physiotherapists or physical activity coach) were ticked; and 'correct' for duration if 3 to 6 weeks. Expectations regarding the FRP were rated on a list of potential expectations on a scale of 0–10. Expectations were scored 'correct' if return to work was scored  $\geq 7/10$ , and 'fully correct' if physical activity and pain management, but not 'healing' were also expected. Responses were then compared between patients and physicians by Chi 2 test.

**Results:** Of 172 patients, median age 48 years (IQR 38–58), median CLBP duration 5 years (IQR 2–10), 60.0% women: 110 (64.0%) had no knowledge of FRP; 22 had already participated in an FRP. The remaining 40 patients were compared to physicians (figure 1). Of 80 physicians, 42.5% GPs and 53.7% rheumatologists, 57.5% women: 21 (26.2%) had no knowledge of FRP ( $p$  value $<0.0001$  vs patients). The remaining 59 were compared to the 40 patients.

Knowledge of FRP health professionals was 'correct' for 13/40 (32.5%) patients vs 41/59 (69.5%) physicians ( $p=0.0003$ ); and knowledge of duration was 'correct' for 26/40 (65.0%) vs 46/59 (78.0%) physicians ( $p=0.15$ ).

Expectations were 'correct' for 21/40 (52.5%) patients vs 44/59 (74.6%) for physicians ( $p=0.02$ ), and 'fully correct' for 9/40 (22.5%) patients vs 16/59 (27.1%) for physicians ( $p=0.6$ ).

**Conclusions:** FRP was largely unknown to patients with CLBP. Even those who were aware of the FRP did not know what to expect. While physicians' knowledge and perception of the FRP was better, there was still a lack of knowledge and therefore a likely underutilization or misuse of the FRP. Information campaigns are needed.

THU0537

### ASSOCIATION BETWEEN BIG FIVE PERSONALITY TRAITS AND RESPONSE TO MULTIDISCIPLINARY PROGRAM IN PATIENTS WITH CHRONIC LOW BACK PAIN: A PROSPECTIVE STUDY

M.E. Ibrahim<sup>1,2</sup>, K. Weber<sup>3</sup>, S. Genevay<sup>1</sup>. <sup>1</sup>Rheumatology, University Hospitals of Geneva, Geneva, Switzerland; <sup>2</sup>Rheumatology, Suez Canal University, Ismailia, Egypt; <sup>3</sup>Medical Direction, University Hospitals of Geneva, Geneva, Switzerland

**Background:** Chronic back pain is a multifactorial condition, which cannot be thoroughly addressed without understanding the psychological factors that influence its onset, maintenance and the response to its management. Patient attitudes and personality traits often determine how they experience pain, how they adjust to it, and their response to the different management strategies.

**Objectives:** This study aimed to identify whether patients with specific Big Five personality traits are more likely to seek medical care, and to uncover whether there is an association between personality and the patient's response to multidisciplinary functional rehabilitation program.

**Methods:** 97 patients (57% male) aged 41.1 (10.1) with chronic low back pain, enrolling in an intensive 4 week multidisciplinary functional rehabilitation program, completed the NEO Personality Inventory-Revised (NEO PI-R) at baseline. Outcome was assessed at treatment admission and discharge, and at 6 months follow up, including Core Outcome Measure Index (COMI), Tampa Scale for Kinesiophobia (TSK), Oswestry Disability Index (ODI) and Hospital Anxiety and Depression Scale (HADS).

**Results:** Both men and women had significantly lower scores in the Openness to Experience domain and significantly higher scores in the Conscientiousness domain than the average general population. At baseline, Neuroticism was found to correlate positively with TSK and HADS. Low Openness to Experience, and low Extraversion correlated with high HADS at baseline as well. Analysis of the follow up data showed a significant reduction in the COMI, ODI, HADS and TSK at the end of the program, and at 6 months follow up. There was no correlation between the improvement in COMI, ODI or TSK scores after 6 months and any of the 5 domains of the NEO PI-R

**Conclusions:** Low Openness to Experience and high Conscientiousness seem to be key factors of chronicity in patients with low back pain. Significant decrease in pain, disability as well as depressive and anxious moods showed that these patients were effectively treated by the multidisciplinary functional rehabilitation program regardless of their personality traits.

**Disclosure of Interest:** None declared

THU0538

### PATIENTS WITH CHRONIC LOW BACK PAIN ORIENTED TO FUNCTIONAL RESTORATION PROGRAM ARE YOUNGER, WITH HIGHER SMOKING AND LONGER SICK LEAVE: A CROSS-SECTIONAL STUDY OF 166 PATIENTS

M. Assadourian<sup>1</sup>, F. Bailly<sup>1</sup>, P. Letellier<sup>1</sup>, S. Ascione<sup>1</sup>, M. Le Ralle<sup>1</sup>, A. Potel<sup>1</sup>, L. Morardet<sup>1</sup>, V. Foltz<sup>1</sup>, A. Dupeyron<sup>2</sup>, N. Ibrahim<sup>3</sup>, I. Griffoul-Espitalier<sup>4</sup>, B. Duplan<sup>5</sup>, J. Beaudreuil<sup>6</sup>, B. Fautrel<sup>1</sup>, L. Gossec<sup>1</sup>. <sup>1</sup>Pitié Salpêtrière Hospital, Paris; <sup>2</sup>Nîmes Hospital, Nîmes; <sup>3</sup>La Source Hospital, Orléans; <sup>4</sup>Tours Hospital, Tours; <sup>5</sup>Reine Hortense Hospital, Aix les Bains; <sup>6</sup>Lariboisière Hospital, Paris, France

**Background:** Functional Restoration Programs (FRP) are multi-disciplinary programs that have demonstrated effectiveness to promote functional status and return to work in patients with chronic low back pain (cLBP)<sup>1, 2, 3</sup> and moderate or high disability.

**Objectives:** To explore the characteristics of cLBP patients oriented or not towards a FRP.

**Methods:** This was an observational cross-sectional, multi-centric study in France in 2017. Consecutive patients with cLBP (>6 weeks) with or without radiculalgia, aged 18–66 years and visiting the rheumatologist for cLBP were included. Patient and disease characteristics were collected. Patients oriented or not towards a FRP were compared in particular for demographic characteristics, duration of sick leave over the past 12 months, smoking, ongoing aerobic physical activity (patient-reported as <or at least 30 min sessions twice a week), anxiety or

depression (Hospital Anxiety and Depression Scale $\geq$ 11), disability (Oswestry >40%) and kinesiophobia (Tampa Kinesiophobia Scale $\geq$ 40).

**Results:** In all, 166 patients were analysed: median age 48 years, median cLBP duration 5 years, and 100 (60%) were females. Overall, 62 (37%) were proposed for a FRP. Patients oriented towards a FRP, versus not, were more frequently male (50% vs 44%,  $p=0.04$ ), younger (median 46 vs 52 years,  $p=0.02$ ), and had lower pain levels (median 6 vs 7 of 0–10 numeric scale,  $p=0.006$ ). They had longer sick leave (mean 18 vs 10 weeks/year,  $p=0.006$ ), were more frequently smokers (33% vs 23%,  $p=0.02$ ), had similar pain duration (60 month vs 72,  $p=0.32$ ), functional disabilities (39% vs 49%,  $p=0.22$ ), kinesiophobia (62% vs 55%,  $p=0.65$ ), anxiety (52% vs 55%,  $p=0.60$ ) and depression score (40% vs 35%,  $p=0.54$ ), but less physical activity practice (38% vs 54%,  $p=0.04$ ).

**Conclusions:** Patients oriented towards a FRP were younger and more often males, with higher smoking and longer sick leave. It appears that kinesiophobia, functional status and duration of low back pain didn't influence the orientation toward a FRP. More comprehensive assessments of patients with cLBP are needed; multifactorial questionnaires such as StartBack or BP2 may be useful to orient patients towards FRPs.

### MECHANICAL TRACTION FOR LUMBAR RADICULAR PAIN: SUPINE OR PRONE? A RANDOMISED CONTROLLED TRIAL

M. Bilgilişoy Filiz<sup>1</sup>, Z. Kılıç<sup>2</sup>, A. Uçkun<sup>3</sup>, T. Çakır<sup>4</sup>, S. Koldaş Doğan<sup>1</sup>, N. F. Toraman<sup>1</sup>. <sup>1</sup>Physical Medicine and Rehabilitation, Antalya Training and Research Hospital, Antalya, Turkey, Antalya; <sup>2</sup>Physical Medicine and Rehabilitation, Ankara Atatürk Training and Research Hospital, Antalya, Turkey, Ankara; <sup>3</sup>Physical Medicine and Rehabilitation, Mut State Hospital, Mersin; <sup>4</sup>Physical Medicine and Rehabilitation, Private Likya Hospital, Antalya, Turkey

**Background:** Mechanical lumbar traction has been used to treat spinal disorders and low back pain for centuries, since Hippocrates.<sup>2,3</sup> Although the supine position is generally preferred, the patient may also be positioned prone during traction treatment.<sup>4,5</sup> However, to the best of our knowledge, no studies have compared the effects of lumbar traction in these two different positions for patients with chronic LBP.

**Objectives:** To compare the effects of mechanical lumbar traction either in the supine or prone position with conventional physical therapy (PT) in patients with chronic low back pain (LBP) and lumbosacral nerve root involvement in terms of disability, pain, and mobility.

**Methods:** Participants ( $n=125$ ) were randomly assigned to receive 15 sessions of PT with additional mechanical lumbar traction either in the supine position (supine traction group), or in the prone position (prone traction group), or only PT without traction (PT only group). Patients were assessed at baseline and at the end of the PT sessions in terms of disability, pain, and mobility. Disability was assessed using the modified Oswestry Disability Index (ODI); pain was assessed using a visual analogue scale (VAS); and lumbar mobility was assessed using the modified lumbar Schober test (mLST).

**Results:** 118 patients completed the trial. All groups improved significantly in the ODI, VAS, and mLST ( $p<0.05$ ) (table 1). In the between-group analysis, improvements of ODI and VAS were found significantly better in the prone traction group compared with the PT only group (adjusted  $p=0.031$  and  $0.006$ , respectively).

**Conclusions:** Addition of traction in prone position to other modalities resulted in larger immediate improvements in terms of pain and disability, and the results suggest that when using traction, prone traction might be first-choice. Further research is needed to confirm the benefits of lumbar traction in the prone position.

THU0540

#### INCREASED WORK CAPACITY IN CHRONIC LOW BACK PAIN PATIENTS AFTER A MULTIDIMENSIONAL PROGRAM ASSOCIATED WITH DECREASE IN FEAR AND APPREHENSION

M. Norberg<sup>1,2</sup>, L. Belgrand<sup>2</sup>. <sup>1</sup>Rehabilitation, Centre medical et therapeutique La Lignière, Gland; <sup>2</sup>Rehabilitation, Lavey Medical SA, Lavey Les Bains, Switzerland

**Background:** Chronic low back pain has a high burden in our society. Almost 85% of the population would be affected from low back pain. Less than 10% would be chronic but they have an important economic impact since they have the highest costs. According to Vlayen, the kinesiophobia (avoidance of movement) is the most important prognostic factor when evaluating the return to work

**Objectives:** To study the importance of kinesiophobia, fear and anxiety in the chronic low back (CLB) pain patient and their relationship to workability after a multidimensional intensive treatment program.

**Methods:** We included 850 patients who had followed an outpatient program of functional restoration during 3 weeks. The program was composed of physical exercises, occupational therapy and psychological group discussions. They were followed over 1 year. Using different questionnaires (TSK -Tampa scale of Kinesiophobia, FABQ, Pact -subjective work capacity-, Phoda, SF 36), physical performances tests (muscular endurance: Shirado, Biering-Sörensen, Bruce; lumbar mobility, Pile lifting test) we analysed the important factors for their work capacity.

**Results:** There were a clear relationship between a decrease in kinesiophobia and an increase of work capacity. Globally, the work capacity increased from 41.2% to 79%. There were no long standing increases in muscular performances, but the important change appeared in the decrease in the physical part of FABQ (14 to 9/24) and the SF36 limitations physical health/emotional problems (19.4% to 51.8%/36 to 65.7%).

**Conclusions:** A multidimensional intensive program including approaches on fear and apprehension has an important impact on work capacity. This observation is important to take into account in creating functional restoration programs

**Disclosure of Interest:** None declared

THU0541

#### THE EFFECT OF PHYSICAL THERAPY ON CLINICAL AND QUALITY OF LIFE IN CHRONIC NECK PAIN PATIENTS: A RANDOMISED CONTROLLED TRIAL

N. Şahin<sup>1</sup>, M. Şahin<sup>2</sup>. <sup>1</sup>Physical Medicine and Rehabilitation, Balikesir University, Balikesir; <sup>2</sup>Physical Medicine and Rehabilitation, Magnet Hospital, Kayseri, Turkey

**Background:** In the treatment of chronic neck pain (CNP), education, medical treatment, exercise and physical therapy (PT) modalities are in place. However, there are not enough studies on the efficacy of PT modalities in CNP

**Objectives:** To evaluate the effectiveness of the addition of PT modalities to exercise and medical treatment in relieving pain and improving the functional status of patient with CNP

**Methods:** 80 patients with CNP were included in a randomised, controlled trial. Patients were assigned in two groups randomly. Treatment group (TG) received conventional PT (hot pack (HP), ultrasound (US), Transcutaneous Electrical Nerve Stimulation (TENS)) treatment in addition. PT was applied ten sessions. HP treatment was applied in 20 min. US treatment was applied with 1,5watt/cm<sup>2</sup> dose and continuous type in 10 min. TENS treatment was applied with conventional type in 30 min. All patients were informed about correct posture and daily life activities. Both groups received home-based exercises program and analgesic medical treatment if it is necessary. Patients were evaluated before and after therapy and 3th month later by Visual Analogue Scale (VAS), cervical range of motion (ROM), Beck Depression Scale (BDS) and short form-36 (SF-36)

**Results:** In both groups there is significant improvement in VAS, cervical ROM, SF 36 and BDS after treatment (p<0.01). In TG significant improvement was seen on 3th month follow up. But the significant improvement was not seen on 3th month in control group (CG).

There is no significant difference between groups for VAS, SF-36 parameters and BDS before and after treatment (p>0.05). There was a significant improvement in VAS, SF-36 parameters and BDS in the TG compared with the CG at the end of therapy and 3 months post-treatment (p < 0.01)

**Conclusions:** Medical treatment and exercise with HP, US and TENS therapy was effective on both pain and disability during the treatment. This improvement kept on 3th month follow up. Also same improvement was seen on mood and life quality. Exercise has better effects on after treatment, but these good effects decrease on 3th month follow up. So we think physical medicine modalities should be used in CNP with disability

#### EVALUATION OF THE EFFECTIVENESS OF ULTRASOUND GUIDED EPIDURAL CORTICOSTEROID INJECTION AND PULSED ELECTROMAGNETIC FIELD STIMULATION IN CHRONIC LOW BACK PAIN

S.A. Tabra<sup>1</sup>, M. ElSergany<sup>2</sup>, M.E. Mowafy<sup>1</sup>, H. Khallaf<sup>1</sup>, G. Elsharnoby<sup>3</sup>.

<sup>1</sup>Rheumatology and Rehabilitation, Faculty of Medicine, Tanta University;

<sup>2</sup>Rheumatology and Rehabilitation, Faculty of medicine Tanta university; <sup>3</sup>clinical pathology, Faculty of Medicine, Tanta University, Tanta, Egypt

**Background:** Epidural injections are one of the most common nonsurgical interventions for managing chronic low back pain. They have been used to treat radicular pain from herniated discs, spinal stenosis, and axial spinal pain. Pulsed electromagnetic field stimulation therapy (PEMFs) provides a noninvasive and safe method to treat the site of injury, the source of pain, inflammation by modulating factors involved in pain signalling and the inflammatory response.

**Objectives:** To assess the improvement in patients with chronic low back pain treated with epidural steroid injection or Pulsed electromagnetic field stimulation. To compare the efficacy of epidural steroid injection and pulsed electromagnetic field stimulation in treatment of patients with chronic low back pain.

**Methods:** In this study; sixty patients with chronic discogenic low back pain (diagnosed clinically and by magnetic resonant imaging of lumbosacral region) with or without radicular pain of at least 6 months duration were selected. We excluded patients with other causes of back pain as spondylololthesis, inflammatory, infective, neoplastic, traumatic causes. Patients were randomly divided into two equal groups (30 patients each); after informed consent; group I treated by ultrasound guided caudal epidural injection of 40 mg methylprednisolone and 2 ml 2% lidocaine and 20 ml of 9% NaCl twice one week in between and group II received PEMFs daily for 4 weeks. And all patients will be instructed to follow an exercise program. All patients were assessed clinically, functionally by Oswestry Disability Index (ODI) and by measuring serum level of beta-endorphin by ELIZA before, at the end treatment and six months after the end of treatment.

**Results:** In both groups; there was highly significant improvement in pain after treatment (P1 <0.0001) the mean value of the (VAS) was 8.13+0.63, 7.70 +1.34 respectively before treatment and 3.33+2.63, 2.30+2.32 respectively after treatment. Still further significant improvement at the end follow up (P1 <0.0001) in group I. There was highly significant improvement (p<0.0001) of functional status in both groups after treatment and at follow up period as compared to before treatment but there was significant decrease of functional status at follow up period as compared to after treatment in group II. There was significant improvement of serum level of beta endorphin (p>0.05) in both groups after treatment and follow up period as compared to before treatment but there was insignificant difference at follow up period as compared to after treatment. Our result showed insignificant difference between two groups in clinical, functional or laboratory parameters.

**Figure 1.** Comparison regarding low back pain as measured by VAS before, after treatment and at 6 months follow up

**Figure 2.** Comparison regarding serum beta endorphin before, after treatment and at 6 months follow up

**Conclusions:** Epidural corticosteroid injection and Pulsed electromagnetic field stimulation are effective tools in management of chronic low back pain

THU0543

#### COMPARISON OF THE EFFECTIVENESS OF LOW LEVEL LASER THERAPY AND STEROID INJECTION IN MODERATE CARPAL TUNNEL SYNDROME: A RANDOMISED CONTROLLED TRIAL

S. Badil Güloğlu<sup>1</sup>, M. Bilgiliyoz Filiz<sup>1</sup>, K.K. Kılıç<sup>2</sup>, S. Koldaş Doğan<sup>1</sup>, I. Erdem Toslak<sup>2</sup>, N.F. Toraman<sup>1</sup>. <sup>1</sup>Physical Medicine and Rehabilitation; <sup>2</sup>Radiology, Health Sciences University, Antalya Training and Research Hospital, Antalya, Turkey, Antalya, Turkey

**Background:** Recent studies have reported that low-level laser therapy (LLLT) reduces pain and improves function in carpal tunnel syndrome (CTS). However, to the best of our knowledge, there exist no studies that compares the effectiveness of LLLT and steroid injections in moderate CTS.

**Objectives:** Is to evaluate the effectiveness of LLLT and steroid injection in moderate CTS, by comparing the symptoms, the electrophysiologic and the Magnetic Resonance Imaging (MRI) findings of the patients.

**Methods:** 87 patients with moderate CTS were included in the study. 87 patients were randomised to the steroid or LLLT groups. LLLT was applied to the carpal tunnel area (6 joules/5 min) five times per week, for a total of 10 sessions. Steroid injections were performed once after randomization. Numbness and pain of the patients were assessed using a Visual Analogue Scale (VAS), disability was assessed using the Quick arm-shoulder-hand (Quick DASH) disability questionnaire. Rough and fine grasping strength tests, Tinel and Phalen tests and

electrophysiological test were performed. All the patients were evaluated by MRI in terms of median nerve cross-sectional area, median nerve intensity and intensity rate, and median nerve palmary spring rate. All tests were performed before the treatment, and 1. month and 6. months after the treatment, except the MRI evaluations, which were done before and after 6. months of the treatment.

**Results:** The study was completed with 80 patients, 133 wrists at the end of six months. There were no significant differences between the groups in terms of demographic and baseline clinic characteristics, electrophysiologic and MRI findings of the patients ( $p>0,05$ ). While the VAS scores of numbness and pain and Quick Dash symptom scores were better in the steroid group in the first month, there were no significant differences between the groups in the sixth month. In both groups, there were similar significant improvements in the Phalen and Tinel tests, rough and fine grasping forces, median nerve motor distal latency value in the first and sixth months after the treatment in comparison to pretreatment values ( $p<0,05$ ). Median nerve sensory distal latency and median sensory NCV showed significant improvements in the 1st and the 6th months after treatment in comparison to pretreatment only in the steroid group ( $p<0,05$ ). In both groups, there were similar significant improvements in the median nerve intensity rate in the radioulnar plane and median nerve palmary spring rate on the MRI after the treatment. Median nerve intensity rate was improved in both groups also at the pisiform plane but this improvement was significant only in the steroid group.

**Conclusions:** It is possible to conclude that LLLT reduces the signs and symptoms of the patients who has moderate CTS as well as the steroid treatment. Our study offers a data regarding LLLT's efficiency in short-intermediate terms. Further studies are needed to make comments about long-term efficiency of LLLT. LLLT is a noninvasive treatment option in moderate CTS and with a similar efficacy as steroid treatment.

#### STUDY OF THE EFFECTS OF OZONE VERSUS STEROID INJECTION ON PATIENTS WITH RECALCITRANT TENNIS ELBOW; A CLINICAL TRIAL

S.A. Raeissadat<sup>1</sup>, M.H. Abdollahzadeh<sup>2</sup>. <sup>1</sup>Physical Medicine and Rehabilitation Department of Shahid Beheshti University of Medical Sciences, Research Development Center of Shahid Modarres Hospital; <sup>2</sup>Physical Medicine and Rehabilitation Department of Shahid Beheshti University of Medical Sciences, Physical Medicine and Rehabilitation Research Center, Tehran, Iran, Islamic Republic of Ireland

**Background:** Tennis elbow is a prevalent musculoskeletal disorder. In recent years ozone injection has been proposed as a treatment for many musculoskeletal disorders. This study aims to compare the effect of ozone injection with steroid in patients with recalcitrant tennis elbow.

**Objectives:** The aim of this study is to compare the effect of ozone with the standard treatment of steroid injection in patients with tennis elbow, resistant to conservative treatments. This comparison is made according to VAS score, Pressure pain threshold (PPT) and modified Mayo clinic performance index for elbow.

**Methods:** In this study 64 patients with tennis elbow, which have had the symptoms for more than 3 months and were resistant to conservative treatments, were randomised to two groups. In steroid injection group 40 mg of methylprednisolone acetate and in ozone injection group 4 ml of ozone with concentration of 15mcg/ml was injected. 32 patients in steroid and 29 patients in ozone injection group finished this study. Data were gathered before injection and 2 and 6 months after that by VAS score, modified Mayo clinic performance index for elbow and PPT (measured by the means of an algometer). Variables were compared between the two groups and also the changes in each group have been measured in reference to baseline data.

**Results:** In both groups VAS score, Mayo clinic performance index and PPT improved significantly in 2 and 6 month follow up. Steroid injection was significantly better than ozone injection in improving 2 and 6 months pressure pain threshold and 6 months Mayo clinic performance index. Other data didn't show significant difference between the two groups.

**Conclusions:** Both steroid and ozone injection improved pain and function in patients with recalcitrant tennis elbow for at least 6 months. Steroid injection was superior to ozone injection in improving PPT during the 2 and 6 month follow up and function improvement in steroid group was significantly more than ozone group after 6 month.

### CHARACTERISING A MOUSE MODEL OF TEMPOROMANDIBULAR JOINT (TMJ) ARTHRITIS TO STUDY OROFACIAL PAIN AND INFLAMMATION

X. Kodji<sup>1</sup>, J.D.S. Valente<sup>1</sup>, F. Lundy<sup>2</sup>, I. El Karim<sup>2</sup>, S.D. Brain<sup>1</sup>. <sup>1</sup>BHF Centre of Excellence, Vascular Biology and Inflammation, King's College London, London; <sup>2</sup>The Wellcome-Wolfson Institute for Experimental Medicine, School of Medicine, Dentistry and Biomedical Sciences, Queen's University Belfast, Belfast, UK

**Background:** The temporomandibular joints (TMJ) encompass the jawbones (mandibular condyle) and the skull region (temporal bone)<sup>1</sup>. Dysfunctions in these joints and surrounding muscles result in a condition known as TMJ disorder (TMD), which include mastication-related pain. 16%–59% of patients reported painful symptoms while 33%–86% of these patients showed clinical signs<sup>1</sup>. Currently, the etiology of TMD is unknown, although lavage samples from patients showed signs of synovitis, which may lead to the development of degenerative disorders, such as TMJ arthritis<sup>2</sup>. There are only a few murine models available, as the most commonly used animal model is TMJ arthritis in rats.

**Objectives:** We aimed to characterise a mouse model of TMJ arthritis by mimicking the formation of synovitis using zymosan. We sought to characterise the development of orofacial pain by performing various behavioural measurements and measure joint inflammation.

**Methods:** All *in vivo* procedures were carried out according to the UK Home Office Animals (Scientific Procedure) Act 1986. Male CD1 mice (6–8 weeks) were anaesthetised transiently using 2% isoflurane. Zymosan (10, 30, or 100 µg; 10 µl), or saline was administered unilaterally into the TMJ as previously described<sup>3</sup>. Spontaneous pain behaviours were observed by counting the number of unilateral cheek wipes. All studies were terminated by cervical dislocation and the tissue was collected for *ex vivo* analyses. Mean ±SEM was calculated and data were analysed by unpaired Student's T-test or 2-way repeated measures ANOVA with Bonferroni's *post hoc* test.  $p < 0.05$  was accepted as statistically significant.

**Results:** A dose response study showed that 30 µg, but not 10 µg and 100 µg of zymosan, resulted in a maximal wiping response at 2 hours, which was maintained at 4 hours (table 1; \*\*\* $p < 0.001$  zymosan ipsi vs saline ipsi; ##  $p < 0.01$  zymosan ipsi vs contra). Hind paw scratching was negligible. Hence, 30 µg was used for subsequent experiments. Increased neutrophils (measured by MPO assay) was observed in zymosan-treated joints (table 1 \*\* $p < 0.01$  saline ipsi vs zymosan ipsi), while a similar trend was also observed in 3-nitrotyrosine protein expression, a marker of protein nitrosylation ( $p = 0.053$ ). Preliminary studies are being undertaken to characterise other inflammatory markers in addition to the development of *in vivo* orofacial mechanical hyperalgesia using the Von Frey filaments.

Table 1 A summary of zymosan-mediated spontaneous orofacial pain behaviours and inflammation.

	Saline (n=4)		Zymosan					
			10 µg (n=6)		30 µg (n=5)		100 µg (n=6)	
	Ipsi	Contra	Ipsi	Contra	Ipsi	Contra	Ipsi	Contra
Unilateral cheek wipe (no. of events)	5.0 ±1.0	5.5 ±1.9	5.7 ±2.6	6.0 ±1.2	22.0 ±4.4	8.2 ±2.6	5.3 ±3.3	3.1 ±1.2
					*** ##			
Unilateral hind paw scratching (no. of events)	0.5 ±0.5	0.0 ±0.0	1.0 ±0.7	4.5 ±2.6	3.4 ±0.8	2.1 ±1.0	0.4 ±0.2	0.4 ±0.2
MPO (U/mg of protein)		0.01±0.003		N/A	0.08±0.01	**		N/A
3-nitrotyrosine/GAPDH		2.3±0.4			3.8±0.5			

**Conclusions:** We have established a mouse model of TMJ arthritis, which showed significant orofacial pain responses *in vivo*. Our data highlights an inflammatory profile typical of zymosan and shows a potential use for this model to investigate novel TMD treatments.

THU0546

### CHILDREN WITH PSORIASIS ALSO SHOW ENTHESOPATHY SIGNS RELATED TO SKIN DISEASE ACTIVITY

T.C. Meneghetti, T.M. Padilha, V.F. Azevedo, V.O. Carvalho. *Federal University of Paraná, Curitiba, Brazil*

**Background:** Many recent evidences shows the role of enthesopathy in psoriatic disease and the high prevalence of musculoskeletal widespread pain in patients with psoriasis and psoriatic arthritis. It may be very difficult to distinguish between inflammatory disease activity and fibromyalgia. Limited data are available about the prevalence of rheumatological findings in children with psoriasis.

**Objectives:** To determine the prevalence of musculoskeletal pain complaints, enthesitis and tender points in a population of children and adolescents with psoriasis and correlate it to the skin disease activity and quality of life.

**Methods:** 26 children and adolescents with psoriasis were included in this cross sectional study and assigned a written informed consent. Patients and parents were interviewed about musculoskeletal complaints, personal and familiar history of rheumatic diseases. A paediatric rheumatologist performed the physical examination, which included evaluation of active joint count, palpation of entheses and tender points of fibromyalgia. A paediatric dermatologist performed PASI score and BSA to assess skin disease activity. Nails involvement were assessed by NAPS. The functional capacity was assessed by CHAQ. The quality of life was assessed by CDLQI.

**Results:** Participants were 69% female, with a mean age of 10.1±3.0 years at observation. The median of age at the beginning of skin disease was 3 (0.5–12) years. PASI median was 4 (0.6–30.2), BSA 6 (2–39) and NAPS 12.<sup>3–36</sup> A severe PASI above 5 were present in 38.5%. Complaints of any kind of musculoskeletal recurrent pain were seen in 46.1% of the patients and lumbar pain in 15.4%. Pain, limit on motion or joint oedema were seen in 26.9% whereas tenderness on palpation of any site of entheses was found in 30.7% and tenderness on palpation of sacroiliac joint was found in 19.2% of the patients. The median of fibromyalgia tender points was 5 (0–16). The presence of enthesitis was associated to the skin disease activity scores of PASI ( $p < 0.006$ ), BSA ( $p < 0.016$ ) and nail index NAPS ( $p < 0.05$ ) (figure 1). As expected, the presence of enthesitis was associated to the number of tender points ( $p < 0.001$ ). For those with a severe PASI>5, we found a higher number of tender points (Med 0 versus 10;  $p < 0.03$ ), a worst functional capacity by CHAQ (Med 0 versus 0.12;  $p < 0.03$ ) and worst quality of life by CDLQI (Med 1 versus 9;  $p < 0.05$ ).

**Conclusions:** High prevalence of musculoskeletal pain symptoms, enthesitis and fibromyalgia tender points was observed in this sample of children and adolescents with psoriasis. Differently from adults, we do not expect to have age-related degenerative changes in entheses in this population, what reinforce the inflammatory origin of these rheumatologic findings. Otherwise, the association with the severity of psoriasis increases the need for vigilance against the appearance of psoriatic spondyloarthropathy in this group.

## Rheumatoid arthritis – biological DMARDs

THU0547

### REAL-WORLD EFFECTIVENESS OF EARLY AGGRESSIVE TREATMENT WITH BIOLOGICAL DISEASE-MODIFYING ANTIRHEUMATIC DRUGS FOR THE TREATMENT OF NEWLY DIAGNOSED POLYARTICULAR FORM OF JUVENILE IDIOPATHIC ARTHRITIS

B. Huang<sup>1</sup>, E.M. Morgan<sup>2</sup>, C. Chen<sup>3</sup>, J. Guo<sup>4</sup>, D.J. Lovell<sup>5</sup>, H.I. Brunner<sup>6</sup>, on behalf of PCATS. <sup>1</sup>Div. of Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center, Cincinnati, OH; <sup>2</sup>Div. of Rheumatology; <sup>3</sup>Div. of Biostatistics and Epidemiology, Cincinnati Children's Hospital Medical Center; <sup>4</sup>University of Cincinnati School of Pharmacy; <sup>5</sup>Div. of Rheumatology, Cincinnati Children's Hospital Medical Center; <sup>6</sup>Cincinnati Children's Hospital Medical Center, Cincinnati, USA

**Background:** Limited evidence from randomised clinical trial suggested early aggressive treatment with biological disease modifying antirheumatic drugs (DMARDs) maybe a better treatment strategy in children with polyarticular form of Juvenile idiopathic arthritis (pJIA).<sup>1</sup> Three consensus treatment plans (CTP) were recommended for treating children with newly onset of pJIA.<sup>2</sup> The real-world effectiveness is unknown.

**Objectives:** Evaluate the comparative effectiveness of early combination CTP vs. the step-up CTP, in treating children with newly diagnosed pJIA, utilising electronic health records (EHR) data collected from routine clinical care.

**Methods:** This inception cohort is derived from data captured in a single institute EHR from January 2009 to July 2017. Eligible patients are 2–16 years of age, newly (<6 m) diagnosed with pJIA and treated on DMARD. The first clinical encounter initiate DMARDs is identified as the baseline. The primary end point is clinical Juvenile Arthritis Disease Activity Score (cJADAS) 6 months after the treatment.

**Results:** Out of 1834 pJIA patients captured in EHR, 432 are eligible for the study. Most patients (362, 84%) initiated DMARD within 6 month of diagnosis: 105 (29%) on early combination and 257 (71%) on step-up plan. Three months following the initial DMARD assignment, 98 (93%) and 244 (95%) remained on the initial early combination and step-up plan respectively, thus are used in this study. Patients on early combination had significantly higher cJADAS score at the baseline (15.5±6.6 vs. 12.5±5.9; Student P value<0.01), and higher rate of RF (18% vs. 7%, Chisq p<0.01). After 6 months of treatment, their cJADAS scores are more comparable (mean ±SD of 6.9±5.4 in early combination, and 7.1±6.1 in step-up; Student T p=0.7). After statistically adjusting for treatment selection bias, causal inference methods suggest lower cJADAS is expected had the patient been treated on early combination than on the step-up plan, mean and 95% confidence interval of averaged treatment effect is 2.90 (0.89, 4.91).

**Conclusions:** The early combination approach improves clinical outcomes at 6 months more effectively than the step-up strategy in children with newly onset pJIA.

**Background:** Musculoskeletal ultrasound (MSUS) is dependent on sensitivity of the machine used and the skills of the operator. Additional specificities are unique features of the growing skeleton, which include age-related variation of the thickness of the articular cartilage (due to incomplete ossification) and the presence of physiologically detected vascularisation even in healthy children.

**Objectives:** EULAR/PRES task force objective was to develop EULAR/PRES Standardised Procedures for Ultrasound Imaging in Paediatric Rheumatology through a consensus process among rheumatologists, paediatric rheumatologists, and radiologists highly experienced in the performance, teaching and research in paediatric MSUS in rheumatic diseases.

**Methods:** In the first phase we performed a systematic literature review (SLR) on guidelines for MSUS for children endorsed by international societies and articles on how to perform MSUS scanning in children. Based on the SLR results, project conveners formulated a Delphi survey by selecting the items to be included (i.e. musculoskeletal anatomic structures evaluable by US, scanning technique, and their lesions/abnormalities detectable by US at the principal joint areas). The Delphi survey was distributed among a broad panel of experts in MSUS, selected for their high experience in the performance, teaching and research in MSUS in children. Based on the Delphi results the main anatomical structures (for definitions, photo and video recordings) were selected to be analysed in the final phase organised as an exercise on live healthy children models. The meeting involved: 16 project participants (13 paediatric US experts, fellow, as well as, AHP and PARE representatives), 16 healthy children models (representing four different age groups) accompanied by their parents (who had signed informed consent to participate), 4 photo/imaging technicians, 2 expert technicians in US machines.

**Results:** Structures from 8 musculoskeletal areas (i.e. shoulder, elbow, wrist and hand, hip, knee, ankle and foot) in 4 age groups of children were selected. Detailed scanning procedures (i.e. patient position, probe placement, scanning method and bony/other landmarks) were defined. We recorded the reference photo (live and US image) and video (procedure video clip and US video record) of the scanning procedures. As a result, we obtained photo and video image library with a detailed description of the standardised US procedures in children which can be used as EULAR/PRES web-based educational application.

**Conclusions:** This task force has produced a consensus-based comprehensive and practical framework on standardised procedures for MSUS imaging in paediatric rheumatology.

### ABSENCE OF ASSOCIATION BETWEEN DRUG EXPOSURE AND INFECTION IN PATIENTS WITH POLYARTICULAR-COURSE JUVENILE IDIOPATHIC ARTHRITIS AND INADEQUATE RESPONSE TO BIOLOGIC OR NON-BIOLOGIC DMARDs TREATED WITH SC AND IV ABACEPT

N. Ruperto<sup>1</sup>, H. Brunner<sup>2</sup>, N. Tzaribachev<sup>1</sup>, I. Louw<sup>1</sup>, I. Calvo<sup>1</sup>, G. Horneff<sup>1</sup>, M. Henrickson<sup>2</sup>, M.E. Rama<sup>1</sup>, M. Fischbach<sup>1</sup>, T. Miraval<sup>1</sup>, M.M. Ally<sup>1</sup>, X. Li<sup>3</sup>, R. Wong<sup>3</sup>, M. Nys<sup>4</sup>, B. Murthy<sup>3</sup>, K. Lin<sup>5</sup>, J.A. Passarell<sup>6</sup>, A. Martini<sup>1</sup>, D.J. Lovell<sup>2</sup>, on behalf of the PRINTO and PRCSG working groups. <sup>1</sup>PRINTO, Istituto Gaslini, Genoa, Italy; <sup>2</sup>PRCSG, CHMC Cincinnati, Cincinnati; <sup>3</sup>Bristol-Myers Squibb, Princeton, USA; <sup>4</sup>Bristol-Myers Squibb, Braine-L'Alleud, Belgium; <sup>5</sup>Cognigen Corporation, a SimulationsPlus Company, Buffalo, USA

**Background:** Infections are the most common expected AEs linked to biologic (b) DMARDs in paediatric patients (pts) with juvenile idiopathic arthritis (JIA). Blood concentrations achieved with bDMARDs vary greatly between individual pts. It is not known if higher abatacept (ABA) exposure is linked to higher infection risk in paediatric populations.

**Objectives:** To assess the relationship between the incidence of infection and SC (50–125 mg weekly) and IV (10 mg/kg monthly) ABA exposure in pts with polyarticular-course JIA (pJIA).

**Methods:** Data from the 4 month open-label periods of a Phase III SC ABA study (NCT01844518; weight-tiered ABA: 10–<25 kg [50 mg], 25–<50 kg [87.5 mg], ≥50 kg [125 mg]; 219 pts aged 2–17 years) and an IV ABA study (NCT0095173; ABA 10 mg/kg monthly; 184 pts aged 6–17 years) in pts with pJIA were analysed. The association between serum ABA exposure measures (steady-state trough [ $C_{\min ss}$ ], maximum [ $C_{\max ss}$ ] and time-averaged [ $C_{\text{avgss}}$ ] concentrations) estimated by population pharmacokinetic analysis and time to first infection (regardless of seriousness) was assessed. Kaplan–Meier (KM) plots of infection probability versus time to first infection by ABA exposure quartiles were created and log-rank test was performed to test the differences in distribution of time to first infection across exposure quartiles. Box plots of ABA exposure measures over time to Month 4 were generated, stratified by first infection occurrence (yes/no). Data for SC and IV ABA were assessed separately and pooled.

**Results:** Baseline demographic and clinical characteristics were comparable in the SC and IV studies.<sup>1,2</sup> Overall, 135/403 pts (33.5%) had ≥1 infection over 4 months: 77/219 (35.2%) with SC ABA and 58/184 (31.5%) with IV ABA. KM plots for pooled SC and IV ABA showed no statistically significant difference in infection probability across four quartiles of ABA  $C_{\min ss}$  (Fig A;  $p=0.2317$ ; log-rank test),  $C_{\max ss}$  ( $p=0.5501$ ) or  $C_{\text{avgss}}$  ( $p=0.3808$ ). Consistent results were seen for individually studied SC and IV ABA  $C_{\min ss}$  (Fig B, C),  $C_{\max ss}$  and  $C_{\text{avgss}}$  (not shown). In addition, there was no difference in median ABA exposure measures by infection occurrence (yes/no) in pooled and separate SC and IV analyses.

**Abstract THU0549 – Figure 1.** Kaplan–Meier Plots of Probability of First Infection, Regardless of Seriousness, Versus Days From First Dose to Infection by Abatacept  $C_{\min ss}$  Quartiles and Route of Administration: Pooled SC and IV (A); SC (B); IV (C)

**Conclusions:** In pts with pJIA who received SC or IV abatacept, higher relative abatacept exposure was not associated with a higher risk of infections for 4 months.

THU0550

### NEW IL10 RECEPTOR GENE MUTATION ASSOCIATED TO A SPECTRUM OF INFLAMMATORY APHTHOSIS AND CROHN'S DISEASE

R. Dagher<sup>1</sup>, V. Modica<sup>1</sup>, N. El Rifai<sup>2</sup>, E. Chouery<sup>3</sup>, M.C. Fadous Khalife<sup>1</sup>. <sup>1</sup>pediatrics, Notre Dame De Secours University Hospital, Byblos; <sup>2</sup>pediatrics, Makassed General Hospital; <sup>3</sup>medical genetics, Saint Joseph University, Beirut, Lebanon

**Background:** IL-10 is defined as an anti-inflammatory cytokine. Its activity is mediated by interaction with a cell surface receptor composed of 2 subunits: alpha (IL-10RA) and beta (IL-10RB). Homozygous mutations of IL-10RA gene have been linked to Very Early Onset Inflammatory Bowel Disease (VEO-IBD) in children with a total of 28 mutations identified till present.

**Objectives:** We report a Lebanese family presenting with a new exonic mutation in the IL-10RA gene variably associated to inflammatory aphthosis and adult onset IBD.

**Methods:** The proband is a boy born to consanguineous parents who presented to our attention at the age of 9. He suffered from persistent severe oral aphthosis, recurrent fever and intermittent diarrhoea since the age of 2 months, and anal aphthosis since the age of 7.

His Familial history is notable for moderate oral aphthosis in the father and adult onset Crohn's disease in a paternal uncle.

He was diagnosed with Behçet disease and received colchicine since the age of 8 with no efficiency.

His physical exam was normal except for severe oral and anal ulcers. No history of genital ulcers.

Laboratory tests revealed normal inflammatory markers. ANA titers, anti-DNA and anti-ENA were negative with normal complement level. Pathergy test and HLA B51 were negative as well as pANCA and cANCA. Iron, Zinc, vitamin and immune deficiencies were ruled out.

Yearly ophthalmologic screening revealed no signs of inflammation.

Repeated gastroscopy and colonoscopy and enteric MRI showed no pathologic findings.

**Results:** A genomic sequencing study for recurrent fever was performed. A novel heterozygous exonic mutation of the IL-10RA gene (c.G172A G>A, p.E58K) was identified. The child's father and his uncle were found to have the same mutation at homozygous state, however with different phenotypic presentations.

The child was started on Infliximab with favourable outcome after 3 months.

**Conclusions:** In this Lebanese family, the previously unreported IL-10RA gene mutation (c.G172A G>A, p.E58K) is associated to a variable spectrum from

benign oral aphthosis to IBD, both in homozygous and heterozygous forms. Our finding suggests that the presence of this mutation is a risk factor for inflammatory aphthosis. Whether this mutation will eventually lead to IBD is uncertain. Other unknown environmental and genetic factors might have a role in the final phenotype of the disease.

As bipolar aphthosis and recurrent fever can be misdiagnosed as Behçet disease, pro-inflammatory genetic mutations such as IL-10RA mutations should be considered in the setting of incomplete Behçet disease.

**Background:** In rheumatoid arthritis treatment, targeted treatment has shown to improve disease outcomes including the option of drug tapering and discontinuation. In non-systemic juvenile idiopathic arthritis (nsJIA) this has not been tried in a trial.

**Objectives:** To investigate which of three treatment strategies, targeting at drug-free inactive disease, is most effective and safe in recent onset DMARD-naive nsJIA.

**Methods:** We conducted a randomised, multicenter, treatment strategy study with 24 months of follow up. Patients, 2–16 years old with symptom duration <18 months were randomised to 1) Sequential DMARD-mono therapy (sulfasalazine (SSZ) or methotrexate (MTX), 2) Combination therapy MTX +6 weeks prednisolone, 3) Combination therapy MTX +etanercept. Treatment to target entailed three-monthly treatment intensifications in case of persistent disease activity. DMARDs were tapered to nil in case of inactive disease for at least 3 (in oligoarticular) or 6 (in polyarticular) months. After 24 months, primary outcomes were time-to-inactive-disease and time-to-flare after DMARD discontinuation. Secondary outcomes were adapted ACRPedi30/50/70/90 scores, functional ability and toxicity. Missing data were imputed.

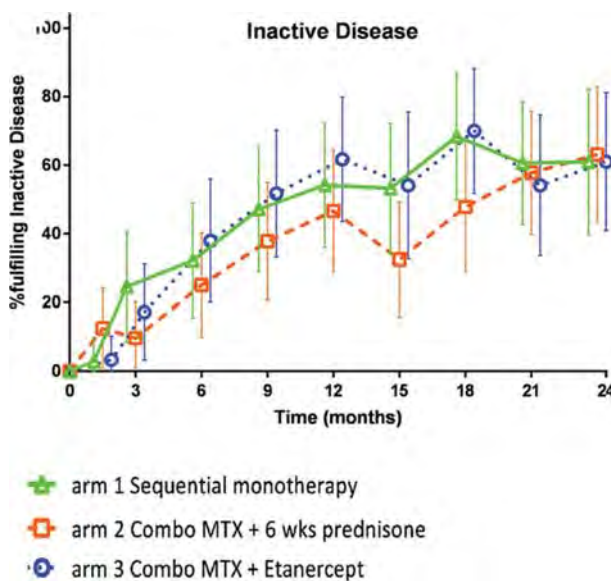

**Results:** 94 children (67% girls) with a median (InterQuartile Range) age of 9.1 (4.6–12.9) years were enrolled: 32 in arms 1 and 2, 30 in arm 3. Eleven had oligoarticular JIA, n=73 polyarticular JIA and n=8 juvenile psoriatic arthritis, 37% were ANA positive. At baseline VAS physician was median (IQR) 50<sup>39–58</sup> mm, VAS patient 54<sup>37–70</sup> mm, ESR 6 (2–14) mm/hr, active joints 8, <sup>5–12</sup> limited joints 2.5 (1–5), and CHAQ score 0.9 (0.6–1.5).

After 24 months 61% (arm 1), 63% (arm 2) and 61% (arm 3) of patients had inactive disease and 45% (arm 1) 31% (arm 2) and 38% (arm 3) had stopped all DMARD(s). Time to inactive disease (median 9.0 (6.0–12.0) months) was not significantly different between arms, nor was time to flare (18.0 (15.0–21.0) months). Adapted ACRPedi-scores were comparably high between arms. Functional ability

improved and remained almost normal. Toxicity reports showed mild events in similar rates across all arms.

	Arm 1 n=31	Arm 2 n=32	Arm 3 n=29
ACRPedi50 (%) (CI)	85.5 (72.4–98.6)	83.8 (70.1–97.4)	93.1 (83.7–102.4)
ACRPedi70 (%) (CI)	69.0 (52.1–85.9)	68.8 (51.6–85.9)	82.8 (68.8–96.8)
ACRPedi90 (%) (CI)	58.4 (40.6–76.1)	55.3 (37.3–73.3)	69.0 (51.8–86.1)
Inactive disease (%)	61.0 (39.7–82.3)	63.1 (43.6–82.7)	61.0 (40.9–81.2)

Results after 24 months by GEE.

**Conclusions:** Treatment to target drug free inactive disease is feasible in recent onset non-systemic JIA, resulting, regardless of initial treatment, in over 60% of patients in inactive disease and 38% drug free.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.2623

#### THU0552 ARTICULAR AND EXTRA-ARTICULAR DAMAGE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS – RESULTS FROM THE INCEPTION COHORT OF NEWLY DIAGNOSED PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (ICON)

J. Kloetsche<sup>1</sup>, C. Sengler<sup>1</sup>, M. Niewerth<sup>1</sup>, J. Kuemmerle-Deschner<sup>2</sup>, F. Weller<sup>3</sup>, T. Hospach<sup>4</sup>, G. Ganser<sup>5</sup>, I. Foeldvar<sup>6</sup>, K. Minden<sup>1</sup>. <sup>1</sup>Epidemiology, German Rheumatism Research Center, Berlin; <sup>2</sup>Rheumatologisches Zentrum/Ambulanz für Autoimmunerkrankungen, Universitätsklinikum Tübingen, Tübingen; <sup>3</sup>Prof. Hess Kinderklinik für Kinderheilkunde und Jugendmedizin am Klinikum Bremen-Mitte, Bremen; <sup>4</sup>Olgahospital, Clinical Center Stuttgart, Stuttgart; <sup>5</sup>St. Josef-Stift Sendenhorst Hospital, Sendenhorst; <sup>6</sup>Hamburg Center for Pediatric and Adolescent Rheumatology, Schön Klinik Hamburg Eibek, Hamburg, Germany

**Background:** Juvenile idiopathic arthritis (JIA) may lead to disability and damage, preventing both is an important therapeutic goal. The frequency of damage in children and adolescents with JIA and the question of whether the damage increases with the duration of the disease also in the biologic treatment era have hardly been investigated.

**Objectives:** To assess the prevalence and accrual of damage in patients with JIA over six years and to analyse damage association with disease activity, quality of life and functional limitations.

**Methods:** We analysed data of patients with JIA who were enrolled in ICON. Clinical characteristics such as disease activity (e.g. JIA core set criteria) and details on current treatment as well as patient's quality of life (PedsQL) and functional limitations (CHAQ) were assessed quarterly during the first 12 months in ICON and half-yearly thereafter. The Juvenile Arthritis Damage Index (JADI, range 0–89, best=0) was reported by the physician at the 3 year, 4 year and 6-year-FU, respectively. The JADI is composed of two sub-scores, the JADI-A scores joint

damage (in 36 joints or joint groups) and the JADI-E extraarticular damage (in 5 different organs/systems: ocular, musculoskeletal excluding joints, cutaneous, endocrine, any organ/system).

**Results:** A total of 953 patients (67.2% female, mean age 7.9 years (SD 4.8)) with JIA were included in ICON after a median disease duration of 6 months (IQR: 3.0–11.1). About half of the patients (46%) had oligoarthritis, followed by rheumatoid factor-negative polyarthritis (RF-PA) (26%) and enthesitis-related arthritis (11%). The mean disease activity score cJADAS10 was 9.8 (6.2) and the mean CHAQ was 0.57 (0.69) at enrolment. Any damage was reported for 58 patients (8.6%) at the 3-year-Follow-up (FU) (mean JADI-A 0.17, mean JADI-E 0.06, JADI-A >0: 6.1%, JADI-E >0: 3.1%). At the 4 year (mean JADI-A 0.17, mean JADI-E 0.07) and 6-year-FU (mean JADI-A 0.13, mean JADI-E 0.12), 8.6% and 10.7% of patients had any damage. The number of patients with articular damage did not change during FU (6-year-FU: 6.5%), whereas the proportion of patients with extra-articular damage slightly increased (6-year-FU: 5.0%). At the 6-year-FU, the most frequently scored joints were the knee joints, followed by the wrist. JADI-E was dominated by eye damage. Among the JIA categories, patients with RF-PA showed most frequently damage (16.7%), followed by patients with enthesitis-related arthritis (15.4%) and extended oligoarthritis (14.3%) at the 6 year FU. The JADI-A score significantly correlated ( $r=0.27$ ,  $p<0.001$ ) with the number of active joints and JADI-E with the cJADAS10 ( $r=0.14$ ,  $p=0.041$ ) However, there was no significant association between the JADI scores and quality of life (PedsQL), and functional limitations (CHAQ, all  $r<0.05$ ).

**Conclusions:** About one in ten patients with JIA has developed any damage three, four and six years after disease onset. Thus, a relevant increase in damage over time does not occur under current therapeutic conditions. Articular and extra-articular damage is similarly frequent.

**Acknowledgements:** ICON is funded by the Federal Ministry of Research (FKZ: 01ER0812)

#### TNF-INHIBITOR AND LEFLUNOMIDE COMBINATION THERAPY IN POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS IN CLINICAL PRACTICE – LESSONS FROM THE GERMAN BIOLOGICS JIA REGISTRY (BIKER)

M. Napp<sup>1</sup>, G. Horneff<sup>1,2</sup>, on behalf of BIKER registry working group. <sup>1</sup>ASKLEPIOS, Sankt Augustin; <sup>2</sup>University of Cologne, Cologne, Germany

**Background:** Leflunomide has been shown to be a safe and effective therapy for adult rheumatoid arthritis.

**Objectives:** Safety and efficacy of combination of TNF inhibitors with leflunomide versus methotrexate for treatment of polyarticular-course juvenile idiopathic arthritis (pcJIA) were assessed in the prospective BIKER registry 2000–2016.

**Methods:** 3 cohorts of pcJIA patients ageing 3–17 years were analysed: Patients receiving leflunomide starting a TNF inhibitor,<sup>1</sup> a TNF inhibitor starting leflunomide,<sup>2</sup> methotrexate starting a TNF inhibitor.<sup>3</sup> Efficacy was determined using the JADAS response criteria, JADAS-10 minimal disease activity (MDA) and remission. Safety assessments were based on adverse events reports from the responsible physician.

**Results:** We identified 94 patients treated with Leflunomid-TNF-inhibitor in combination. 44 started a TNF-inhibitor on background Leflunomide, 50 started Leflunomide on background TNF inhibitor. 1361 patients starting a TNF-inhibitor on background Methotrexate served as control group. Differences in patients' characteristics at baseline limit direct comparison. Patients of cohort 3 had higher CRP, patients of cohort 2, already treated with a biologic, had lower disease activity parameters such as mean active joint count, physician and patient global disease activity judgement and JADAS10. At month 6, upon MTX +TNFi 54.6%/41.7%/19.6% and upon LEF +TNFi 35.0%/36.2%/13.8% reached JADAS improvement/JADAs minimal disease activity/JADAs remission. Thus significantly more patients with MTX +TNFi reached JADAS improvement (OR 2.22 [1.44–3.44];  $p<0.001$ ) while there comparable rates of patients reached JADAS-MDA and JADAS-remission. In the LEF cohorts, there were 95 adverse events in 54 patients (58%) compared to 1845 events in 626 (46%) on MTX (OR 1.6 [1.0–12.4]  $p=0.031$ ). No differences were noted for the number of infections, nausea or elevated transaminases.

**Abstract THU0553 – Table 1.** Baseline patients' and disease characteristics

	Cohort 1 (n=44) LEF+TNFi	Cohort 2 (n=50) TNFi+LEF	Cohort 3 (n=1361) MTX+TNFi
Female	28 (64%)	40 (80%)	937 (68.8%)
Age at disease onset, median (IQR)	6.9 (2.1;11.3)	6.2 (1.8;9.6)	7.4 (2.9;11.5)
Disease duration, median (IQR)	6.3 (3.0;8.5)	5.1 (2.0;7.2)	4.1 (1.3;6.0)
ANA positive, n (%)	19 (43%)	28 (56%)	647 (47.5%)
CRP, median (IQR)	14.8 (3;22)	9.5 (0.6;4;.5)	20.8 (1.4;23)

Active joint count, median (IQR)	6.2 (2;7.8)	3.5 (0;5.3)	7.3 (2;9)
Physician global, median (IQR)	5.3 (3.6;7.0)	2.6 (4.3;3.2)	5.4 (3.2;7.6)
Patient global, median (IQR)	4.4 (1.7;6.7)	2.9 (0.6;5.0)	4.4 (2.0;6.5)
CHAQ-DI, median (IQR)	0.59 (0;1)	0.5 (0;0.8)	0.7 (0.1;1.1)
JADAS10, median (IQR)	17 (13.1;19.2)	9.7 (12.5;3.5)	15.2 (11.5;22.5)

**Abstract THU0553 – Table 2.** Improvement at month 6 and tolerability

	Cohort 1 +2 LEF+TNFi	Cohort 3 MTX +TNFi	OR (Cohort 3 vs. 1+2)	P
JADAS improvement	35.1%	54.6%	2.2 [1.4–3.4]	<0.001
JADAS MDA ( $\leq 3.8$ )/ remission ( $\leq 1$ )	36.2%/13.8%	41.7%/19.6%		n.s.
AE (rate)	160 (57.4%)	1845 (46%)	0.63 [0.41–0.96]	0.031
Infections (rate)	37 (23.4%)	410 (22.2%)		n.s.
Nausea (rate)	9 (5.3%)	156 (8.5%)		n.s.
Elevated transaminases (rate)	8 (5.3%)	112 (6.1%)		n.s.

**Conclusions:** Combination with both leflunomide and methotrexate to treatment with TNF-inhibitors resulted in clinically meaningful improvements with a comparable rate of patients reaching JADAS-MDA and JADAS-remission at month 6 of treatment. Leflunomide turned out to be a well-tolerated alternative to methotrexate for polyarticular JIA.

THU0554

#### RITUXIMAB (RTX) IN PAEDIATRIC DISEASES: DESCRIBING ITS PHARMACODYNAMICS WITH A FOCUS ON B-CELL DEPLETION AND REPOPULATION, INFECTIONS AND ANTI-DRUG ANTIBODIES

A. Nassar-Sheikh Rashid<sup>1</sup>, R. Kampinga<sup>1</sup>, M. Peters<sup>1</sup>, M. Oosterveld<sup>2</sup>, T. W. Kuijpers<sup>1</sup>, J.M. van den Berg<sup>1</sup>, D. Schonenberg-Meinema<sup>1</sup>. <sup>1</sup>Department of Pediatric Hematology, Immunology, Rheumatology and Infectious Diseases; <sup>2</sup>Department of Pediatric Nephrology, Emma Children's Hospital, Academic Medical Center, Amsterdam, Netherlands

**Background:** Rituximab (RTX) is increasingly used in rheumatologic,<sup>1,2</sup> hematologic<sup>3</sup> and renal diseases.<sup>4</sup> The induced B cell depletion can lead to hypogammaglobulinemia and thus an increased risk of infection.<sup>5</sup> B cell depletion is not always achieved, and this has a negative effect on therapeutic response.<sup>6</sup> Anaphylaxis is a frequent side effect of RTX and has been associated with the occurrence of anti-drug antibodies (ADA) against RTX.<sup>7</sup>

**Objectives:** To describe in different paediatric patient groups the pharmacodynamics of RTX in children by outcome variables, i.e. success of B-cell depletion and time of B cell repopulation, as well as the risk factors for severe infections and anaphylaxis.

**Methods:** Patient data of children who received RTX between 2008 and 2017 at our centre were retrospectively collected. Three patient subgroups were defined: autoimmune diseases (AID), immune dysregulation (ID) and renal diseases (RD). B cell repopulation was defined as a number above the cut-off value of B cell depletion ( $=0.050 \times 10^6/l$  or  $<2\%$  of the total amount of lymphocytes).

**Results:** B cell measurements were performed in 53/55 patients. B cell depletion was not achieved in 9 patients. In the 35 patients with B cell repopulation, median time until repopulation was 155 days (IQR 105–222): in the AID group (n=12) 129 days (IQR 77.5–243,  $p=0.363$ ), in the ID group (n=5) 172 days (IQR 154–181,  $p=0.574$ ) and in the RD group (n=18) 163 days (IQR 121–229,  $p=0.847$ ). After RTX treatment, in 36 patients IgG levels were measured of which 14 (39%) had low IgG levels on at least one occasion (median 7 g/L [range 0.6–38.1 g/L]). Severe infections leading to hospitalisation occurred in 15 (27%) cases. An allergic reaction during or directly after RTX infusion was observed in 27 patients (49%). Anaphylaxis, defined as a systemic allergic reaction, characterised by impairment of airway, breathing, circulation or consciousness, occurred in 10 of these patients (18% of total cohort). Seven patients were tested for anti-RTX antibodies of whom 6 tested positive: 5 patients in the AID-group and one patient with renal disease. Allergic reactions occurred in all 6 while RTX failed to induce B cell depletion in 4 of these.

**Conclusions:** Time-to-B-cell-repopulation after RTX did not significantly differ between different paediatric patients groups. Severe infections were common (27%) in the cohorts studied. It is unclear from our data whether this is merely related to RTX treatment. Presence of ADA against RTX seems to predict failure of B-cell depletion and/or anaphylaxis after RTX treatment.

**THU0555** **GUIDELINES FOR JUVENILE IDIOPATHIC ARTHRITIS MANAGEMENT: IS THERE A ROOM FOR COMBINED METHOTREXATE AND LEFLUNOMIDE THERAPY IN THE TREATMENT RECOMMENDATIONS**

Y. Atef<sup>1</sup>, H. Lotfy<sup>2</sup>, N. El Arousy<sup>3</sup>, D. Mekawy<sup>3</sup>, W. Hassan<sup>4</sup>, S.I. Nasef<sup>5</sup>, G. El Deriny<sup>6</sup>, M. Eissa<sup>7</sup>, Y. Farag<sup>2</sup>, M. El Gaafary<sup>8</sup>, Y. El Miedany<sup>3,9</sup>, on behalf of PRINTO Egypt. <sup>1</sup>Rheumatology and Rehabilitation, School of Medicine Assiut University, Assiut; <sup>2</sup>Pediatrics, School of Medicine Cairo University; <sup>3</sup>Rheumatology and Rehabilitation, School of Medicine Ain Shams University, Cairo; <sup>4</sup>Rheumatology and Rehabilitation, School of Medicine Banha University, Banha; <sup>5</sup>Rheumatology and Rehabilitation, School of Medicine Suez Canal University, Ismailia; <sup>6</sup>Pediatrics, School of Medicine Alexandria University, Alexandria; <sup>7</sup>Rheumatology and Rehabilitation, School of Medicine Cairo University; <sup>8</sup>Community and Public Health, School of Medicine Ain Shams University, Cairo, Egypt; <sup>9</sup>Rheumatology, Darent Valley Hospital, Dartford, UK

**Objectives:** To set recommendations for the management of children and adolescents living with JIA and assess whether there is a room for combined methotrexate and leflunomide therapy, adopting treat to target approach.

**Methods:** the treatment guidelines were developed based on systematic review, local studies, formal consensus and feedback. Initiation of methotrexate or leflunomide was recommended for polyarticular JIA children who, after 3 month of treatment, did not respond to methotrexate or leflunomide monotherapy, or those whose DMARD dose could not be optimised; a new management step was introduced where a combination of both medications was administered. This was a multicentre study including 76 JIA patients who had been treated with the combination of methotrexate plus leflunomide. All patients were classified according to the International League of Associations for Rheumatology (ILAR) criteria. Recorded data included: demographics, JIA subtype, reason for starting combined treatment, treatment duration, withdrawals, causes of discontinuation, efficacy and safety. Patients were classified as “responders” or “non-responders”. Responders were those patients with articular improvement  $\geq$ ACR-Paediatric 30 and/or ocular improvement according to the Standardisation of Uveitis Nomenclature Working Group (SUN) definitions. Efficacy was assessed at 3, 6- and 12 month and outcomes were compared to methotrexate monotherapy.

**Results:** Out of the 76 children there were, oligoarthritis (34%), polyarthritis (31%), systemic JIA with synovitis (>4 joints) (20%), and psoriatic arthritis (15%). Mean age at initiation of combined therapy 10.2 $\pm$ 3.4 years, mean disease duration is 9.4 $\pm$ 4.8 months. The combined therapy was superior to methotrexate alone and did not significantly increase the rate of adverse events. ACR-Ped 30 was achieved in 64% at 3 months, 75% at 6 months. This was superior to methotrexate alone (37.3% and 53.8%;  $p < 0.01$  at 3- and 6 months respectively). At 1 year, 81% reached Ped 30, 74.5% reached ACR-Ped 50, 64% achieved ACR-Ped 70 whereas 51% met ACR-Ped 90 criteria. There were no serious adverse events. One of the two DMARDs was stopped in 51% of the children; of them: 25% were due to adverse events, clinical remission in 25% whereas 21% were switched to anti-TNF therapy according to guidelines due to inefficacy or loss of efficacy. All patients who had had uveitis responded well and achieved clinical remission.

**Conclusions:** For the children with polyarticular JIA who did not respond to monotherapy with methotrexate, combination of methotrexate and leflunomide treatment appeared to be efficacious and maintain a durable response. The current recommendation would be to use combined methotrexate and leflunomide in children with polyarticular JIA who are either intolerant to higher methotrexate doses or who did not have a satisfactory response to methotrexate. The combination should be considered prior to the use of a biologic agent.

**THU0556** **IMPACT OF METHOTREXATE ON GROWTH IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS**

A. Faza<sup>a</sup>, M. Sellami, K. Ouenniche, S. Miladi, S. Kassab, S. Chekil, K. Ben Abdelghani, A. Laatar. *Rheumatology, Mongi Slim Hospital – La Marsa, Tunis, Tunisia*

**Background:** Juvenile idiopathic arthritis (JIA) is a heterogeneous group of chronic inflammatory disease which could be responsible for functional impairment and severe growth disturbance. Conventional disease-modifying antirheumatic drugs, such as methotrexate (MTX), may improve growth velocity especially by regulating systemic inflammation.

**Objectives:** The objective of this study was to evaluate the effect of MTX on growth parameters in pre-pubertal children with JIA and to determine the factors affecting the growth velocity.

**Methods:** We assessed height and changes in the height standard deviation score (SDS) at disease onset, at the onset of MTX and at the last follow-up visit in a cross-sectional study of JIA children. All patients were pre-pubertal when MTX began and were followed for at least 6 months afterward. We compared growth parameters (height, growth rate, weight and body mass index (BMI)) in responders and non-responders to MTX. The growth rate was defined as the number of millimetres of height acquired during 1 year. Associations between changes in the height SDS and discrete variables were evaluated using chi-square or Fisher's exact tests. The significance level was set at 0.05.

**Results:** We enrolled 36 pre-pubertal children with JIA (24 boys and 12 girls) who had been treated with MTX orally. Median patient age was 6.2 years<sup>4–13</sup> at the onset of MTX and 8.4 years [6.1–14.9] at the latest follow-up. The median disease duration was 2.7 years [2.5–5.3]. Twenty-one patients (58.3%) had oligoarticular JIA, 2 patients (5.5%) had systemic JIA, 10 (27.7%) had polyarticular JIA and 3 (8.3%) had enthesitis-related arthritis. Nineteen children (52.7%) had received corticosteroids during an average period of 1.7 years [0.6–3] with a mean of 10 mg/day of prednisone or equivalent. The median duration of MTX at the latest follow-up was 3.1 years [0.62–5.5] with a mean MTX dose of 10 mg/m<sup>2</sup>/week.<sup>10–15</sup> Twenty-eight patients responded to MTX treatment and 8 did not. There were no significant differences between the responders and non-responders for age at treatment initiation, disease duration and mean MTX dose. At MTX onset, no significant differences between the two groups in terms of height ( $p = 0.52$ ), growth rate ( $p = 0.08$ ), weight ( $p = 0.74$ ) and BMI ( $p = 0.9$ ) were found. One year after MTX therapy, mean height (0.2 versus  $-1.1$ ;  $p = 0.03$ ), mean growth rate (0.5 versus  $-2.9$  SDS;  $p = 0.01$ ), mean weight (0.4 versus  $-2.3$  SDS;  $p = 0.01$ ) and mean BMI (0.6 versus  $-1.9$ ;  $p = 0.04$ ) were significantly higher in the responder group than in non responders, respectively. At the latest follow-up, this increase was significantly maintained for growth rate ( $p = 0.001$ ) and height ( $p = 0.002$ ) in the responder group. In the multivariate analysis, patients who required more than 10mg/m<sup>2</sup>/week of MTX, systemic JIA and patients with reliance on steroids had a significantly lower growth velocity after the onset of MTX ( $p < 0.01$ ,  $p = 0.02$ ,  $p = 0.02$  respectively).

**Conclusions:** In our study, the increase in growth parameters in pre-pubertal children with JIA was associated with a better control of the disease activity under MTX therapy.

**THU0557** **THERAPEUTIC DRUG MONITORING OF BIOLOGICALS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA): AN OVERVIEW OF CURRENT PRACTICE IN ANTI-TNF THERAPY**

A. Nassar-Sheikh Rashid<sup>1</sup>, D. Schonenberg-Meinema<sup>1</sup>, A. de Vries<sup>2</sup>, T. Rispen<sup>2</sup>, T.W. Kuijpers<sup>1</sup>, G. Wolbink<sup>2</sup>, J.M. van den Berg<sup>1</sup>. <sup>1</sup>Department of Pediatric Hematology, Immunology, Rheumatology and Infectious Diseases, Emma Children's Hospital, Academic Medical Center; <sup>2</sup>Department of Immunopathology, Sanquin Diagnostic Services Amsterdam, Sanquin, Amsterdam, Netherlands

**Background:** Juvenile idiopathic arthritis (JIA) is the most prevalent paediatric rheumatic disease.<sup>1</sup> Long term complications include physical disability and a decreased quality of life.<sup>2,3</sup> Since the introduction of anti-TNF drugs for JIA, its prognosis has improved significantly.<sup>1</sup> Personalised medicine is the next step to improve treatment in JIA. Anti-TNF trough levels and demonstration of the presence of anti-drug antibodies (ADA) could help individualise treatment decisions in JIA patients, but evidence supporting this is missing.

**Objectives:** To describe cross-sectional data of anti-TNF trough levels and ADA, combined with decision effects, in children with JIA.

**Methods:** Patients' records in children with JIA using etanercept, adalimumab or infliximab were retrospectively checked for measurements of anti-TNF trough levels and ADA. Anti-TNF trough concentrations and ADA were measured using an enzyme-linked immunosorbent assay (ELISA) and antigen-binding test. Data on age, sex, JIA subtype, reason for testing and the decision effect of trough level or presence of ADA on the current therapy were collected.

**Results:** Eighty-one anti-TNF trough levels were measured in 45 children with JIA. A wide variety of anti-TNF trough levels was found. Therapeutic drug concentrations, according to adult ranges in RA and IBD<sup>4,5,6</sup> were found in 11 (58%) patients on etanercept (n=19), 2 (14%) on adalimumab (n=14) and 8 (17%) on infliximab (n=48). Four patients on adalimumab and one patient on infliximab showed ADA. All of these five patients had non-detectable drug trough levels. Reasons for testing trough level and/or presence of ADA were loss of response (20%), partial or no response (40%), measurement after dosage increase (2%), remission (17%), uveitis flare (9%) and allergic reaction (11%). Treatment decisions were influenced by trough levels in 70/81 (86.4%) of measurements and in 5/5 (100%) of patients with ADA.

Abstract THU0557 – Figure 1. Dose vs Concentration (etanercept, adalimumab, infliximab)

**Conclusions:** Measuring anti-TNF trough levels and ADA was a valuable tool in making personalised treatment decisions in JIA. Treatment changes included dose/frequency increase, or stopping and switching treatment in the presence of ADA combined with undetectable drug levels. More data are needed to access optimal therapeutic drug levels in anti-TNF treatment in JIA and to implement this strategy more widely.

THU0558

#### INCREASED FREQUENCY OF FEBRILE SEIZURES IN TWO PERIODIC FEVER SYNDROMES: FAMILIAL MEDITERRANEAN FEVER AND PFAPA SYNDROME

H. Kilic<sup>1</sup>, A. Gurup<sup>1</sup>, K. Barut<sup>2</sup>, E. Pehlivan<sup>2</sup>, S. Sahin<sup>2</sup>, A. Adrovic<sup>2</sup>, O. Kasapcopur<sup>2</sup>, S. Saltik<sup>1</sup>. <sup>1</sup>*Pediatric Neurology*, <sup>2</sup>*Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey*

**Background:** Fever and the fear of febrile seizure risk in parents are a common reason that lead parents to seek care in childhood emergency departments. The most frequently seen periodic fever syndromes in Turkey are periodic fever, aphthous stomatitis, pharyngitis, cervical adenitis (PFAPA) syndrome and familial Mediterranean fever (FMF). There is lack of data regarding the frequency of febrile seizures in periodic fever syndromes.

**Objectives:** To document the frequency of febrile seizure in patients with Familial Mediterranean Fever and PFAPA syndrome.

**Methods:** Patients with FMF and PFAPA, who were diagnosed according to Turkish paediatric FMF diagnostic criteria and Marshall criteria, were enrolled to the study. Past medical history of all subjects from postnatal six months to 6 years of age were assessed in terms of febrile seizure. Clinical, demographic and laboratory data of both patient groups were obtained from patient files. The frequency of febrile seizure in both disease groups was compared with the prevalence in healthy children of a previous Turkish study.

**Results:** A total of 417 FMF and 157 PFAPA subjects were recruited to the study with a female frequency of 49.9% and 42.8%, respectively. The mean age of the FMF and PFAPA patients at study time was 12.4±4.5 years and 5.3±2.1 years, respectively. The mean age at disease onset was 5.1±3.8 (IQR: 2–7) years in FMF group, whereas it was 21±16.5 months (IQR: 10–30) in PFAPA group. The frequency of febrile seizure in FMF and PFAPA syndrome was similar (8.4% versus 8.6%, p>0.05). Among the subjects with febrile seizure, 42.9% (n=15) in FMF group and 30.8% (n=4) in PFAPA group underwent electroencephalography. The EEG result of all subjects were reported to be normal. While 8 subjects with febrile seizure (22.9%) in FMF group required anticonvulsant therapy, 2 patients (15.4%) in PFAPA group used anticonvulsant treatment. Among the PFAPA subjects with febrile seizure (n=13), 53.9% (n=7) underwent tonsillectomy. Thereafter, 85.7% (n=6) of the patients with tonsillectomy never experienced a febrile seizure.

Both the FMF and PFAPA syndrome group were found to have a higher frequency of febrile seizure compared with the healthy subjects of the previous Turkish study (FMF versus healthy children: 8.4% versus 3.2%) (PFAPA syndrome versus healthy children: 8.6% versus 3.2%); and this was statistically significant (p<0.001). However, the frequency of febrile seizure in FMF did not differ from the patients with PFAPA syndrome (8.4% versus 8.6%, p>0.05).

**Conclusions:** Compared to the healthy children, the frequency of febrile seizure in FMF and PFAPA syndrome was significantly increased. The recurrent fever, which is the main shared manifestation of these two diseases, is possibly a trigger for febrile seizure. This increased frequency of febrile seizure in both periodic syndrome seems to be a result of recurrent fever, other than a neurologic involvement of the FMF itself.

THU0559

#### THE PERFORMANCE OF THE NEWLY PROPOSED EULAR/ACR CLASSIFICATION CRITERIA IN JUVENILE-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS-A PRELIMINARY STUDY

S. Sahin<sup>1</sup>, S. Bektas<sup>1</sup>, A. Adrovic<sup>1</sup>, O. Koker<sup>2</sup>, K. Barut<sup>1</sup>, O. Kasapcopur<sup>1</sup>. <sup>1</sup>*Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School*; <sup>2</sup>*Pediatric Rheumatology, Istanbul University, Istanbul Medical School, Istanbul, Turkey*

**Background:** The sensitivity and specificity of the ACR-1997 and SLICC-2012 classification criteria in juvenile-onset systemic lupus erythematosus (SLE) are already studied. In previous reports, the main limitations of the ACR-1997 and

SLICC-2012 were low sensitivity and low specificity, respectively. To avoid misclassifications, a new set of classification criteria have been developed by the collaboration of the European League Against Rheumatism (EULAR) and the American College of Rheumatology (ACR) and the draft was presented at the 2017 ACR/ARHP Annual Meeting in San Diego, California. After application on 500 SLE patients and 500 controls, the sensitivity and specificity were found as 98% and 97%, respectively.

**Objectives:** To compare the sensitivity of the new EULAR/ACR criteria with those of the 1997 American College of Rheumatology (ACR) criteria and 2012 Systemic Lupus International Collaborating Clinics criteria in juvenile-onset SLE patients.

**Methods:** Patients initially were evaluated by ACR-1997, SLICC-2012 and EULAR/ACR classification criteria at baseline, when the diagnosis for the first time had been established by an expert paediatric rheumatologist (OK). All data were obtained from patient records. The diagnostic sensitivity of the three sets of classification criteria were further tested within 1 year of diagnosis and at last patient visit, longitudinally.

**Results:** A total of 104 juvenile-onset SLE patients were enrolled for the sensitivity performance of classification criteria at diagnosis. Since the follow-up period was less than 1 year, 12 subjects excluded after baseline evaluation. Finally, 92 subjects were eligible for sensitivity evaluation within 1 year of diagnosis and at last visit. The median age at diagnosis of clinician was 13.0 years (range 3.1–17.9 years, interquartile range (IQR) 11.1–16.5 years) with a median disease duration of 5.0 years (IQR 3.0–8.0 years). The female-to-male ratio was 4.7:1. The newly developed EULAR/ACR classification criteria were more sensitive than SLICC-2012 and ACR-1997 at diagnosis (93.3% versus 91.3% and 85.6%, respectively), and at first year (95.7% versus 94.6% and 90.2%, respectively ( $p>0.05$ )). At last visit the sensitivity of the new set of criteria and SLICC-2012 were same (97.8%), but higher compared to ACR-1997 criteria (95.7%).

**Conclusions:** Juvenile-onset systemic lupus erythematosus was classified by the newly proposed EULAR/ACR criteria with higher sensitivity compared with SLICC-2012 and ACR-1997 at disease onset and within one year of diagnosis. However, last visit assessment demonstrated equal sensitivity between new EULAR/ACR criteria and SLICC-2012. Although the difference was not significant, the new set of criteria seem to be capable of recruiting more children with juvenile SLE to clinical trials.

#### THU0560 CHRONIC RECURRENT MULTIFOCAL OSTEOMYELITIS: FOUR TERTIARY SPANISH HOSPITALS EXPERIENCE. A MULTICENTRIC STUDY

A. García Fernández<sup>1</sup>, J. Arroyo Palomo<sup>1</sup>, D. Clemente Garrulo<sup>2</sup>, B. Serrano Benavente<sup>3</sup>, J. Novoa Medina<sup>4</sup>, J.C. Nieto González<sup>3</sup>, S. Machín García<sup>4</sup>, A. M. Brandy García<sup>5</sup>, J.C. López Robledillo<sup>2</sup>, I. Monteagudo Sáez<sup>3</sup>, A.L. Boteanu<sup>1</sup>.  
<sup>1</sup>Paediatric Rheumatology, Ramón y Cajal University Hospital; <sup>2</sup>Paediatric Rheumatology, Niño Jesús University Child Hospital; <sup>3</sup>Paediatric Rheumatology, Gregorio Marañón General University Hospital, Madrid; <sup>4</sup>Paediatric Rheumatology, Insular Maternity Child University Hospital of Gran Canaria, Las Palmas de Gran Canaria; <sup>5</sup>Rheumatology, Central University Clinic Hospital of Asturias, Oviedo, Spain

**Background:** Chronic recurrent multifocal osteomyelitis (CRMO) is a rare autoinflammatory polygenic bone disease characterised by aseptic bone inflammation in paediatric population. Its management, clinical, radiological findings and treatment have not yet been standardised.

**Objectives:** Retrospective, descriptive multicentric study of patients diagnosed of CRMO in four tertiary level hospitals' paediatric rheumatology section. There were 16 patients included. The clinical, radiological characteristics were analysed as well as response to treatment options.

**Results:** The median age at diagnosis was 10.5 years, female:male ratio 62.5:37.5%. The delay in the diagnosis had a median of 4.5 months, being less than one year in 11 patients. Bone pain was the first symptom in 100% of the patients accompanied by fever in 25% of them. A single patient presented perilesional arthritis. A slight-moderate increase on acute phase reactants was observed at the debut of the disease: median ESR 47.5 mm/h.

The median number of locations at debut was 2.5 (range 1–14), with multifocal involvement in 75%. The most frequent location was tibia (56%), followed by pelvis (44%) and vertebrae (31.25%). Other locations less frequent were: carpus (12.5%), femur (12.5%) mandible (6%) and sternum (6%).

Biopsy was performed in 14/16 patients and bone scintigraphy with Tc99 in 12/16 patients, with pathological uptake observed in 91.6% of cases. MRI was the radiological test of suspected diagnosis in 15/16 patients.

NSAIDs were the initial treatment. 5 patients received different antibiotic therapy regimens, without clinical or radiological improvement. 56.25% of patients required other treatments. Systemic corticosteroids were used in 12.5% of patients and bisphosphonates in 43.75% (100% of patients with axial involvement). After 6 months of treatment with bisphosphonates, 57.14% had complete remission, 28.57% partial remission and 14.28% worsening. 12.5% of the patients had a torpid evolution, receiving sequential therapies with multiple synthetic or biological DMARDs (Anakinra, Canakinumab, Etanercept), and another 12.5% required surgery.

**Conclusions:** The diagnosis of CRMO is a challenge in the absence of pathognomonic features which leads to delay in diagnosis and the initiation of treatment. In our centres the bisphosphonates were the treatment strategy used in patients with spinal involvement with 85.67% response at 6 months.

#### THU0561 ANAKINRA FIRST- OR SECOND-LINE IN SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS PATIENTS

A. Klein<sup>1,2</sup>, A. Hospach<sup>3</sup>, I. Foeldvari<sup>4</sup>, G. Horneff<sup>1,2</sup>. <sup>1</sup>ASKLEPIOS, Sankt Augustin; <sup>2</sup>University Cologne, Cologne; <sup>3</sup>Olga Hospital, Stuttgart; <sup>4</sup>Hamburg Centre Paediatric Rheumatology, Hamburg, Germany

**Background:** Treatment of systemic juvenile idiopathic arthritis (sJIA) still remains a challenge.

**Objectives:** Patients newly starting treatment with Anakinra (ANA) as first-line biologic were compared to ANA second-line users regarding efficacy and safety.

**Methods:** ANA treatment courses are documented by the German Biologics registry (BiKeR). Demographics, clinical characteristics, disease activity parameters as well as efficacy and safety parameters were compared in pts using ANA as first biologic with those previously treated with other biologics. For efficacy analyses ACR inactive disease, JADAS minimal disease activity (MDA), JADAS remission (REM) and active joint count as well as functional ability assessment (CHAQ) were used. "Intention to treat" (ITT) and "as observed" (AO) analyses was performed. Safety assessments were based on adverse events (AE) reports.

**Results:** 47 pts started treatment with ANA, 33 pts were pretreated with other biologics (Etanercept n=29, Tocilizumab n=4, Infliximab and Canakinumab n=1). ANA first line pts had significantly shorter disease duration and had received DMARDs and i.a. steroids significantly less frequent than second line users. At baseline, ANA first-line users had higher disease systemic activity indicators (fever, rash, ESR), functional disability (CHAQ) and impaired parent/patient global assessment of overall well-being significantly more often, while there were no significant differences in Physician global assessment of disease activity, active joint count and JADAS 10. At last follow-up 43%>66% of pts in both groups reached ACR inactive disease, 43%>63% JADAS MDA, 29%–50% JADAS REM and 43%>69% reached status of no functional disability. Rates did not differ between the 2 cohorts (table 1). 13 pts experienced adverse events (AE) with a rate of 53/100PY, 5 pts experienced serious AE (9/100PY) and in 11pts infections were reported (33/100PY). Macrophage activation syndrome was reported once in each group. One case of AML was reported in a patient one year after last exposure to ANA. No deaths were reported.

**Conclusions:** Anakinra is a feasible first-line biologic for treatment of sJIA. In the BiKeR cohort ANA treated pts showed a marked treatment response, as first or consecutive biologic. Rates of AE, SAE and infectious AE seem acceptable.

**Disclosure of Interest:** None declared

#### THU0562 EVOLUTION OF SERUM CALPROTECTIN IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS IN CLINICAL PRACTICE

B. Magallares López<sup>1</sup>, L. Martínez-Martínez<sup>2</sup>, M.C. Hernandez-Lafuente<sup>2</sup>, E. Moltó<sup>2</sup>, Y. Alvaro<sup>2</sup>, H. Park<sup>1</sup>, I. Castellví<sup>1</sup>, M. Millán<sup>1</sup>, C. Díaz-Torné<sup>1</sup>, P. Moya<sup>1</sup>, A. Laiz<sup>1</sup>, H. Corominas<sup>1</sup>, J. Casademont<sup>3</sup>, E. Carreras<sup>4</sup>, C. Juarez<sup>2</sup>.  
<sup>1</sup>Rheumatology; <sup>2</sup>Immunology; <sup>3</sup>Internal Medicine; <sup>4</sup>Pediatrics, Santa Creu i Sant Pau Hospital, Barcelona, Spain

**Background:** Serum Calprotectin (MPR8/MPR14) is a promising biomarker in the management of juvenile idiopathic arthritis (JIA), mainly as a predictor of flare, especially in treatment de-escalation

**Objectives:** To describe the evolution of serum Calprotectin in patients with JIA, their clinical evolution and its impact on therapeutic decisions

Abstract THU0562 – Table 1 ND=Not Done

Subtype	Sex	Age (years)	Calpro1 (µg/mL)	RCP(mg/dl)	ESR (mmHg)	Disease Activity	Decision	Outcome	Calpro2 (µg/mL)	Decision	Outcome
Oligo JIA	Fem	3	2.25	0.7	9	No	Same treatment	Flare	3.6	Escalate	Remission
	Fem	11	2.2	0.7	20	Yes	Start MTX	Gets better	5.28	Escalate	Remission
	Mas	11	5.01	1.5	3	Yes	Start MTX	Remission	2.01	Same treat.	Equal (remission)
	Fem	7	2.17	ND	34	No	Same treatment	Equal (remission)	1.37	Same treat.	Equal (remission)
	Mas	6	1.56	0.8	15	No	De-escalate	Equal (remission)	3.14	No de-escalate	Equal (remission)
	Fem	18	2.27	0.7	12	No	De-escalate	Equal (remission)	2.09	Same treat.	Equal (remission)
	Fem	22	1.16	0.9	6	No	Same treatment	Equal (remission)	ND		
Sis JIA	Fem	12	1.73	0.7	3	No	De-escalate	Equal (remission)	2.74	No de-escalate	Equal (remission)
Poli JIA	Fem	8	3.78	ND	8	No	No De-escalate	Equal (remission)	4.47	No de-escalate	Equal (remission)
	Fem	9	2.75	0.7	6	Yes	Same treatment	Flare	ND		
ERA JIA	Mas	15	3.61	5.7	8	Yes	Escalate	Gets better	3.02	Escalate	Gets better
	Mas	13	3.39	9.2	51	Yes	Start MTX	Gets better	3.08	Same treat.	Remission
	Mas	11	0.78	4.6	8	No	Same treatment	Equal (remission)	ND		
	Fem	12	3.3	1.9	8	No	Same treatment	Equal (remission)	1.81	Same treat.	Equal (remission)
Psor JIA	Fem	11	1.95	2.2	6	No	Same treatment	Equal (remission)	ND		

**Methods:** Demographic, clinical and inflammatory activity data (RCP and ESR) were retrospectively collected in patients with JIA of any subtype in whom serum Calprotectin had been determined at least once

**Results:** We present the data of 15 children, 7 with Oligoarticular subtype JIA, 1 Systemic, 3 Polyarticular, 1 Psoriatic and 3 Entesitis Related Arthritis (ERA)

The average age was 11 years, 66% female. The characteristics of each patient can be seen in table 1, together with the first determination of serum Calprotectin, CRP and ESR. It also shows the physician's decision, and the outcome, obtained from the assessment in the next visit

Considering the cutoff point of serum Calprotectin in our sample of: 2.2 µg/mL (80% sensitivity and 69% specificity), 9 of 15 patients presented high values, 2 of them presented a flare (1 Oligo and 1 Poly), both had maintained the same treatment, because they were considered inactive. There were no flares in patients with negative Calprotectin

The evolution of serum Calprotectin, together with the clinical decisions (based on clinical and analytical assessment) are described in table 1

In most of stable patients in whom serum calprotectin was high, it was decided not to lower treatment, and only in one case it was de-escalated. There were no flares in any of them

**Conclusions:** Serum Calprotectin is a useful biomarker in routine clinical practice, together with other markers such as CRP and ESR, and our clinical judgment, it helps us to make therapeutic decisions

**Disclosure of Interest:** None declared

#### THU0563 ULTRASOUND CHANGES IN JOINTS INDUCED BY INTRA-ARTICULAR CORTICOSTEROID INJECTION IN JUVENILE IDIOPATHIC ARTHRITIS

B. Sozeri, L.G. Bolac, M. Kariminikoo. *Pediatric Rheumatology, University of Health Sciences, Istanbul, Umraniye Training and Research Hospital, Istanbul, Turkey*

**Background:** Ultrasonography (US) studies carried out on joints of juvenile idiopathic arthritis (JIA) patients in clinical remission demonstrate the presence of subclinical synovitis. The significance of subclinical synovitis and the positive power Doppler (PD) signal on US in JIA.

**Objectives:** The objectives of this study were to assess whether the changes detected by US induced by intra-articular corticosteroid injection in JIA patients.

**Methods:** We evaluated 49 joints (47 knees, 1 tibiotalar and 1 elbow) of 32 patients who diagnosed JIA. We used grey-scale US by high frequency transducer (7.5–10) MHz at study entry and after a therapeutic intervention. Each joint was scored for grey-scale (GS) and power Doppler (PD) abnormalities according to a 4-point semiquantitative scale. Pre- and post-treatment US scores were compared and the sensitivity to change of GSUS and PDUS was estimated. US assessment was performed separately, immediately after the clinical evaluation, by an experienced paediatric rheumatologist (BS) with certificated by EULAR. Medical records were reviewed for JIA subtype and state of disease. Clinical examination, including routine joint examination was carried. Clinical response was assessed using the ACR paediatric (pedi ACR) response criteria

**Results:** Five patients had polyarthritis, 5 had entesitis-related arthritis, 22 had oligoarthritis. Nine patients (28%) underwent intra-articular corticosteroid injection (IACI) only, 23 (71.9%) were given IACI and systemic medications. The medication used were methotrexate (22 patients), Sulfasalazine (2 patients), and methotrexate and biologic (5 patient). Synovial hyperplasia, joint effusion, PD signal and tenosynovitis in at least one joint were detected in 77.4%, 100%, 33.3% and 15% of patients, respectively. Both GSUS and PDUS scores improved significantly ( $p < 0.0001$ ) from baseline to follow-up. At the follow-up visit, 18/49 (36.7%) joints complete resolution among these patients 2 had minimal synovial hyperplasia. Although, 31/49 (63.3%) joints residual US abnormalities were judged in remission on clinical grounds.

**Conclusions:** US is a sensitive tool to assess therapeutic response in patients with JIA. Subclinical disease on US is common in joints with clinically-defined

THU0564

#### EFFICIENCY AND SAFETY EVALUATION OF BIOSIMILAR INFILIXIMAB FOR TREATMENT OF PAEDIATRIC NON-INFECTIOUS UVEITIS IN SINGLE CENTRE

B. Sozeri<sup>1</sup>, E. Kardes<sup>2</sup>, L.G. Bolac<sup>1</sup>, B.I. Sezgin Akçay<sup>2</sup>. <sup>1</sup>*Pediatric Rheumatology; <sup>2</sup>Ophthalmology Clinic, University of Health Sciences, Istanbul, Umraniye Training and Research Hospital,, Istanbul, Turkey*

**Background:** Biosimilar infliximab (Remsima) has been introduced in our country, together with other European countries in 2014. Information regarding the use in child age group is limited but it is reported that its therapeutic efficiency and safety is similar to the reference molecule regarding the paediatric Chron disease

**Objectives:** In this study, our aim was to report the efficiency and safety of BI used for children with non-infectious uveitis

**Methods:** In this study, there were 13 subjects (9 boys, and 4 girls) diagnosed with non-infectious uveitis.

BI (Remsima) treatment had been given in 5 mg/kg in 0.,2.,4 th week and then every 8th week. Ophthalmic assessment of disease activity and ocular complications were measured throughout the trial with the use of slit-lamp biomicroscopy for uveitis activity, according to the SUN criteria. The Drug exposure has been evaluated by calculated of patient year (HY), adverse event (AE) was assessed using the CTCAE criteria. The median values due to the small number of patients are considered

**Results:** The patients who were include the study, 5 had diagnosed extended oligo JIA, 2 with enthesitis-related arthritis (ERA), 2 with persistent oligo JIA, 2 with pars planitis and one of them Behcet's disease. At the time of evaluation, the median age was 10 years,<sup>3-13</sup> age at diagnosis of their disease 8 years,<sup>1-13</sup> respectively. The median age of uveitis diagnosis was 8 years. The median disease duration before BI was 10 months. All of the patients had methotrexate therapy with BI and BI before.

Only one patient used a different biological agent prior to BI, and revealed they were determined that considered unresponsive.

Other patients (n=12) had biosimilar infliximab as first biologic drug due to the activation of disease after using the drug methotrexate.

After therapy of BI, in all of the patients, joint and eye symptoms were improvement.

The systemic steroid therapy was cut down in the first month in all patients, 2 of them continue prophylactic topical steroids.

The median duration of BI therapy was 10 months. There was one case of anaphylaxis in all the patients, whereas five of them frequent upper respiratory tract infection have been observed as side effect

**Conclusions:** In this preliminary report, This biosimilar infliximab treatment appears to be safe and effective in paediatric age group on the paediatric patients with non-infectious uveitis. These results must be supported by multicenter studies and registries.

**Disclosure of Interest:** None declared

THU0565

#### NEEDS ASSESSMENT OF TRAINING IN PAEDIATRIC RHEUMATOLOGY AMONG SPANISH PAEDIATRICIANS. MULTICENTER DESCRIPTIVE STUDY

C. Udaondo, S. Murias, R. Alcobendas, A. Remesal. *Paediatric Rheumatology, University Hospital La Paz, Madrid, Spain*

**Background:** There is a perception that care for paediatric patients with pathology

Rheumatic is heterogeneous, as several previous publications have shown. Likewise, in Spain we do not have the recognition of a specialisation in Rheumatology Paediatric, for which it is possible that the training in this field is not sufficiently specific. This could be detrimental to the best care received on the part of the patients.

Paediatric rheumatology has some specific characteristics that make it unique, but there is yet no recognised specialisation in some countries.

**Objectives:** To examine the needs assessment for specific training in paediatric rheumatology among paediatricians and paediatricians in training from different countries using a specific questionnaire.

**Methods:** An online anonymous questionnaire was sent to paediatricians and paediatricians in training from different centres in Spain, London and Mexico. Data on working place, city, and perception of the state of training in paediatric rheumatology in their workplace were collected.

**Results:** A total of 447 questionnaires were answered: 287 by senior paediatricians (64.5%) and 125 by paediatric trainees (28.1%); 96.4% in different Spanish cities and 3.6%<sup>16</sup> a in other countries.

For 54.7% (254) of the respondents there is no specialisation in paediatric rheumatology in their workplace. The main responsible of children with rheumatic pathology is a paediatric rheumatologist in 59.7% (257) cases, with or without recognised specialisation, a general paediatrician in 21.2% (91) cases and an adult rheumatologist in 19.1% (82) cases.

96.8% of the respondents believe that there should be an accredited training in paediatric rheumatology. The formative aspects that were believed to be more important were the knowledge in paediatric rheumatology, general paediatrics and immunology, and the most valued capacities were the physical exploration, arthrocentesis and infiltration and the performance of musculoskeletal ultrasound.

**Conclusions:** The majority of paediatricians reached believe there is a lack of recognised specialisation in paediatric rheumatology in Spain, and a need for accredited training. The attention to children with rheumatic diseases in Spain is heterogeneous. This survey reinforces the perception that training in paediatric rheumatology in our country should be improved.

#### ASSESSMENT OF BEHAVIOURAL DISORDERS IN CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

D. Dop, C.E. Niculescu. *Departement of Pediatrics, University of Medicine and Pharmacy of Craiova, Craiova, Romania*

**Background:** Juvenile Idiopathic Arthritis(JIA) is the most frequent paediatric rheumatologic disease which, because of its chronic, winding evolution, long-term treatment and dreadful complications, has a powerful impact on the somatic and psycho-social development of the children affected by it.

**Methods:** A number of 49 children with Juvenile Idiopathic Arthritis followed-up in the District Emergency University Hospital in Craiova and aged between 6 and 18, and a control group consisting in 49 healthy children of similar age and sex, were examined using the Child Behaviour Checklist (CBCL).

**Results:** Our results showed that 57.1% of the patients with JIA were classified as borderline and 6.12% as clinical behaviour, compared to the control group in which just 16.3% presented Internalising and Externalising problems. Thus, the majority of children with progressing forms of JIA presented social adjustment disorders, anxiety/depression, attention deficit, and 3 of them, males, presented verbal/physical aggressiveness and Rule-Breaking Behaviour. While among the patients with JIA it was mostly the feminine gender that presented behavioural disorders, in the control group all children with Internalising and Externalising problems were males.

**Conclusions:** Children with JIA must be carefully kept under observation for an early detection and treatment of behavioural deviations. Further studies are necessary, on large groups of patients, in order to identify the manner in which Juvenile Arthritis affects the patient and his or her family.

**THU0567 TESTING PERFORMANCE MEASURES IDENTIFIES GAPS IN JUVENILE IDIOPATHIC ARTHRITIS (JIA) CARE**

C. Barber<sup>1</sup>, D. Lacaille<sup>2</sup>, L. Lix<sup>3</sup>, K. Kroeker<sup>3</sup>, D.A. Marshall<sup>1</sup>, N. Shiff<sup>4</sup>. <sup>1</sup>University of Calgary, Calgary; <sup>2</sup>University of British Columbia, Vancouver; <sup>3</sup>University of Manitoba, Winnipeg, Canada; <sup>4</sup>University of Florida, Gainesville, USA

**Background:** JIA is the most prevalent type of childhood inflammatory arthritis. Timely diagnosis, treatment and ongoing care by a paediatric rheumatologist are associated with improved outcomes.

**Objectives:** To test the Arthritis Alliance of Canada's JIA Performance Measures: i) The percentage of patients with new onset JIA with at least one visit to a paediatric rheumatologist in the first year of diagnosis; ii) The percentage of patients with JIA under rheumatology care seen in follow-up by a paediatric rheumatologist at least once per year.

**Methods:** Validated JIA case ascertainment algorithms were used to identify cases from provincial health administrative databases in Manitoba, Canada in patients <16 years of age with ≥6 months of health insurance coverage in the population registry between 01/04/2005 and 31/03/2015. Cases were identified by either 1 hospitalisation separation with an International Classification of Disease (ICD)-10 code for JIA (M05.X, M06.X, M08.X, M45.X) or ≥2 physician billing claims (ICD-9 codes: 714.x or 720.x) for JIA ≥8 weeks apart within 2 years. A 3 year washout period prior to the first code was used to determine the percentage of incident JIA patients with ≥1 visit to a paediatric rheumatologist in the first year. For reporting the percentage of JIA patients seen in yearly follow-up, once a patient is seen at least twice by a paediatric rheumatologist they are considered under rheumatology care. The measure was computed by comparing yearly observed and expected follow-ups. The proportion of patients with gaps in care of >12 and >14 months between consecutive rheumatologist visits was also calculated. As there is no paediatric rheumatologist identifier in Manitoba administrative datasets, a physician was identified as a paediatric rheumatologist if they had ≥40 visits for individuals ≤16 years in a year and at least 50% of those visits in a year were JIA. This identified 5 physicians.

**Results:** 194 incident cases of JIA were diagnosed between 01/04/2008 and 03/31/2015. The median age at diagnosis was 9.1 years (Q1 5.5, Q3 12.8) and 71% were female. Table 1 describes the number of JIA cases who saw a paediatric rheumatologist within a year of diagnosis (between 51% and 81%). Table 2 describes the percentage of patients seen on a yearly basis with no significant changes seen over time (p=0.47). A single gap of >12 months was seen in 52% (n=144) and ≥2 gaps of >12 months were seen in 11% (n=28). One gap of >14 months was seen in 34% of cases, and only 5% had ≥2 gaps >14 months.

**Abstract THU0567 – Table 1.** Number of incident JIA cases that have seen a paediatric rheumatologist within the first year

Fiscal Years (Some year combined due to small sample sizes, n<5)	Number of incident JIA cases	Percentage seen by a paediatric rheumatologist within a year
2008/2010	50	80%
2010/2012	54	81%
2012/2014	55	78%
2014/2015	35	51%

**Abstract THU0567 – Table 2.** Proportion of JIA follow-up visits by a paediatric rheumatologist using fixed 12-month intervals

	2008/ 09	2009/ 10	2010/ 11	2011/ 12	2012/ 13	2013/ 14	2014/ 15
Observed	74	94	82	72	70	66	68
Expected	101	120	114	116	123	116	118
Percent	73	78	72	62	57	57	58

**Conclusions:** Many JIA patients are not seen by a paediatric rheumatologist within a year of diagnosis, and up to half of those followed have at least 1 gap in care of >12 months. Such gaps may lead to a delay in diagnosis, timely treatment and ongoing care that could impact outcomes.

**THU0568 BIOSIMILAR USE IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS IN A REAL-WORLD SETTING IN THE UNITED KINGDOM**

D. De Cock<sup>1</sup>, L. Kearsley-Fleet<sup>1</sup>, R. Davies<sup>1</sup>, E. Baildam<sup>2</sup>, M. Beresford<sup>2</sup>, H. Foster<sup>3</sup>, T. Southwood<sup>4</sup>, W. Thomson<sup>5</sup>, K. Hyrich<sup>1,6</sup>, on behalf of the BCRD investigator group. <sup>1</sup>Arthritis Research UK Centre for Epidemiology, Manchester University, Manchester; <sup>2</sup>Clinical Academic Department of Paediatric Rheumatology, Alder Hey Children's NHS Foundation Trust, Liverpool; <sup>3</sup>Newcastle University, Newcastle; <sup>4</sup>School of Immunity and Infection, Birmingham University, Birmingham; <sup>5</sup>Arthritis Research UK Centre for Genetics and Genomics, Manchester University; <sup>6</sup>Manchester Academic Health Science Centre, Central Manchester NHS Foundation Trust, Manchester, UK

**Background:** Although biosimilars are routinely used in adults with musculoskeletal diseases, there are limited data regarding the use of biosimilars in patients with juvenile idiopathic arthritis (JIA).

**Objectives:** To describe the characteristics of patients with JIA starting biosimilars in the United Kingdom (UK) following their approval in the UK with musculoskeletal diseases.

**Methods:** Patients were selected from the Biologics for Children with Rheumatic Diseases (BCRD) study, launched in 2010, an ongoing prospective UK study of biologic therapies other than the etanercept originator (followed in a separate parallel study) in JIA. Baseline information is collected via questionnaires completed by the treating physician or affiliated clinical research nurse. Follow-up data including disease activity measures and changes in drug therapy are collected at 6 months, 1 year and annually thereafter. From 30-Sept-2015, data has been captured on 3 biosimilars available in the UK: 2 infliximab and 1 etanercept biosimilar.

**Results:** To 12-Dec-2017, 58 patients were identified in the BCRD study starting a biosimilar; 48 (84%) infliximab and 10 (17%) etanercept biosimilars (table 1). Of these, 36 (62%) started a biosimilar as their first biologic therapy. Seventeen (29%) switched to a biosimilar from a non-originator biologic. Five patients switched from their originator. Follow-up data ranging from 6 months to 2 years were available in 14 patients. Four patients switched to another biologic in this period, 3 switching from an infliximab biosimilar to tocilizumab, and 1 etanercept biosimilar patient to adalimumab. Two serious adverse events in a 90 day exposure window were reported, both cases of recurrent uveitis in patients on an infliximab biosimilar switching from a non-originator biologic.

**Abstract THU0568 – Table 1**

Patients who are	Biological naive	Switched from a non-originator	Switched from originator
<b>Number</b>	36	17	5
<b>Biosimilar</b>			
Infliximab biosimilars	28 (77%)	17 (100%)	3 (60%)
etanercept biosimilar	8 (22%)	0 (0%)	2 (40%)
<b>ILAR class</b>			
Persistent Oligoarthritis	4 (11%)	4 (24%)	0 (0%)
Extended Oligoarthritis	8 (22%)	5 (29%)	1 (20%)
RF Negative Polyarthritis	13 (36%)	4 (24%)	1 (20%)
RF Positive Polyarthritis	0 (0%)	0 (0%)	0 (0%)
Psoriatic Arthritis	2 (6%)	3 (18%)	3 (60%)
Enthesitis Related Arthritis	8 (22%)	1 (6%)	0 (0%)
Unknown	1 (3%)	0 (0%)	0 (0%)
<b>Active uveitis at start of therapy</b>	4 (11%)	7 (41%)	2 (40%)
<b>Female</b>	22 (61%)	12 (71%)	2 (40%)
<b>Age (years)</b>	13 (9-15)	14 (11-15)	13 (12-16)
<b>Disease duration (years)</b>	2 (1-5)	6 (3-10)	7 (6-13)
<b>Active Joints (71 joints)</b>	2 (1-4)	0 (0-2)	0 (0-0)
<b>Limited Joints (71 joints)</b>	2 (1-4)	2 (0-4)	0 (0-1)
<b>Physician Global (0-10cm)</b>	2 (2-4)	1 (0-2)	0 (0-0)
<b>Patient Global (0-10cm)</b>	5 (1-7)	2 (0-4)	2 (0-4)
<b>Pain VAS (0-10cm)</b>	4 (1-7)	4 (2-5)	1 (0-1)
<b>CHAQ (0-3)</b>	1 (0-1)	0 (0-2)	0 (0-1)

All data presented are number (percentages) or median (interquartile range). International League of Associations for Rheumatology (ILAR), Rheumatoid Factor (RF), Visual Analog Scale (VAS), Childhood Health Assessment Questionnaire (CHAQ).

**Conclusions:** Biosimilars in children and young people are used as both first-line and subsequent-line biologic therapy, although currently few UK children have been switched directly from an originator product. Whether a move towards switching all children receiving originator products to biosimilar products, as has been seen in rheumatoid arthritis, will occur is currently unknown but it is imperative that the safety of these treatment decisions are captured in patient registers.

**Disclosure of Interest:** None declared

### A RANDOMISED, DOUBLE-BLIND, PARALLEL STUDY TO COMPARE RATES OF REMISSION (INACTIVE DISEASE) IN PATIENTS WITH JIA ON MTX TREATMENT ALONE VERSUS A COMBINATION OF MTX AND ETANERCEPT

E. Alexeeva<sup>1,2</sup>, T. Dvoryakovskaya<sup>1,2</sup>, R. Denisova<sup>1</sup>, I. Nikishina<sup>3</sup>, E. Zholobova<sup>2</sup>, V. Malievskiy<sup>4</sup>, G. Santalova<sup>5</sup>, E. Stadler<sup>5</sup>, L. Balykova<sup>6</sup>, Y. Spivakovskiy<sup>7</sup>, I. Becker<sup>8</sup>, G. Homeff<sup>9</sup>. <sup>1</sup>National Medical Research Center of Children's Health; <sup>2</sup>Federal State Autonomous Educational Institution of Higher Education I.M. Sechenov First Moscow State Medical University; <sup>3</sup>V.A. Nasonova Research Institute of Rheumatology, Moscow; <sup>4</sup>Federal State Educational Institution of Higher Education Bashkir, Ufa; <sup>5</sup>State Samara Medical University, Samara; <sup>6</sup>Medical Institute of National Research Ogarev Mordovia State University, Saransk; <sup>7</sup>Saratov State Medical University n.a. V. I. Razumovsky, Saratov, Russian Federation; <sup>8</sup>University of Cologne, Cologne; <sup>9</sup>Asklepios Clinic, Sankt Augustin, Germany

**Background:** Remission is the major goal of treatment of juvenile idiopathic arthritis (JIA). Advances in treatment options allowed achievement of remission to come into reach. Timing for initiating intensive treatment in a treat to target approach to early reach remission is still a debate.

**Objectives:** Multi-centre, double-blind, randomised study in polyarticular JIA patients (pts) receiving either Etanercept+Methotrexate (cohort 1) or Placebo +Methotrexate (cohort 2) for 24 weeks followed by 24 week open label phase. Escape to open-label ETN and MTX for pts not achieving paedACR30 at week 12 or not achieving inactive disease at week 24.

**Results:** 35 pts were randomised to cohort 1 and 33 to cohort 2. Baseline demographic and clinical characteristics were comparable between the groups except mean tender joint count, physician assessment of global disease activity and JADAS10 which all were higher in cohort 1. At week 12, 12 pts randomised to cohort 2 did not reach paedACR30. At week 24, further 10 pts of cohort 2 not reaching inactive disease escaped to ETA and MTX. 5 pts of cohort 1 and 4 pts of cohort 2 dropped out. At week 12, significantly more pts on ETA and MTX (33 (94%)/27 (79%)) than on PLC and MTX (17 (52%)/15 (47%)) reached paedACR30/50 (p<0.001/0.01). At week 24, inactive disease was reached by 10 pts on ETA and MTX vs. 6 on PLC and MTX. Inactive disease at week 48 was achieved by 5 pts of cohort 2 on MTX alone while 22 patients (67%) escaped to open label ETA and MTX. 15 (43%) pts of cohort 1 and 16 (49%) of cohort 2 reached inactive disease at week 48. At week 48, paedACR30/50/70/90 was reached by 100%/97%/97%/77% in cohort 1 compared to (97%/93%/93%/73%) in cohort 2. The number of visits with inactive disease in cohort 1 (87 (24%)) was comparable to that of cohort 2 (79 (21%)) while the number of visits with no active joint was significantly higher in cohort 1 (178(48%) vs. 146 (39%); OR 1.45 (1.08–1.94); p=0.012). 44 (74/100 y) adverse events (AE) were noted leading to discontinuation in 6 patients. 3 serious AE occurred, two first uveitis events and one diagnosis of dermatomyositis, all in the placebo group. No new safety signal arose from our observation.

**Conclusions:** Early combination of ETA and MTX proved to be highly effective with a high rate of patients reaching high paediatric ACR response and 50% reaching inactive disease. Pre-defined targets to treat to, paediatric ACR30 at week 12, defining minimal response or inactive disease at week 24/48 were more often reached upon ETA and MTX than with MTX alone. Compared to immediate intense anti-rheumatic combination treatment with ETA and MTX, a comparable rate of patients on targeted therapy reached the final endpoint of inactive disease at week 48 but numbers of visits with active arthritis were higher in patients receiving delayed combination therapy.

### LONG-TERM EFFICACY AND SAFETY OF CANAKINUMAB IN PATIENTS WITH COLCHICINE-RESISTANT FMF (CRFMF), TRAPS AND HIDS/MKD: RESULTS FROM THE PIVOTAL PHASE 3 CLUSTER TRIAL

F. De Benedetti<sup>1</sup>, J. Frenkel<sup>2</sup>, A. Simon<sup>3</sup>, J. Anton<sup>4</sup>, H. Lachmann<sup>5</sup>, M. Gattorno<sup>6</sup>, S. Ozen<sup>7</sup>, I. Kone-Paut<sup>8</sup>, E. Ben-Chetrit<sup>9</sup>, M.B. Wozniak<sup>10</sup>, J.G. Wang<sup>11</sup>, E. Vritzali<sup>11</sup>. <sup>1</sup>IRCCS Ospedale Bambino Gesù, Rome, Italy; <sup>2</sup>University Medical Center Utrecht, Utrecht; <sup>3</sup>Radboud University Medical Centre, Nijmegen, Netherlands; <sup>4</sup>Hospital Sant Joan de Déu, Barcelona, Spain; <sup>5</sup>UK National Amyloidosis Centre, University College London Medical School, London, UK; <sup>6</sup>Pediatric Rheumatology, G. Gaslini Institute, Genoa, Italy; <sup>7</sup>Hacettepe University Children's Hospital, Ankara, Turkey; <sup>8</sup>Hôpital Kremlin Bicêtre, University of Paris SUD, Paris, France; <sup>9</sup>Hadassah—Hebrew University Medical Center, Jerusalem, Israel; <sup>10</sup>Novartis Ireland Ltd, Dublin, Ireland; <sup>11</sup>Novartis Pharma AG, Basel, Switzerland

**Background:** Canakinumab (CAN), a selective, human anti-interleukin (IL)–1 $\beta$  mAb, has demonstrated efficacy and safety in patients (pts) with colchicine-resistant familial Mediterranean fever (crFMF), TNF receptor-associated periodic syndrome (TRAPS), and hyper-IgD syndrome (HIDS)/mevalonate kinase deficiency (MKD) in the epoch 2 and 3 (E2 and E3) of the CLUSTER study (NCT02059291).<sup>1</sup>

**Objectives:** To evaluate the long-term maintenance of optimal control of disease activity (median of no or 1 flare, and no up-titration) and safety on every 4 weeks (q4w) and every 8 weeks (q8w) dosing regimens of CAN in pts with crFMF, TRAPS or HIDS/MKD from the epoch 4 (E4; 112 weeks) of the CLUSTER study.

**Methods:** The study comprised 4 epochs (E1–E4). Study design for E2 and E3 have been reported earlier.<sup>1</sup> After lead-in E1, in E2, a 16 wk randomised, double-blind, placebo (PBO)-controlled epoch, efficacy of CAN 150/300 mg q4w to induce complete response (absence of flares) was assessed. E3 (24 wks) evaluated whether responders to CAN 150/300 mg q4w in E2 could maintain clinical efficacy on 150/300 mg q8w or PBO. In E4, a 72 wk, open-label epoch, the long-term maintenance of efficacy and safety of CAN 150/300 mg q4w or q8w in pts with crFMF, TRAPS or HIDS/MKD was evaluated. Pts who did not maintain clinical response on q8w could be up-titrated to 150/300 mg q4w. Safety assessments included adverse events (AEs) and serious AEs.

**Results:** At the end of E4 (Wk 112), a substantial proportion of pts maintained optimal control of disease activity following treatment with 150/300 mg q4w or q8w in all 3 cohorts (figure 1). HIDS/MKD pts more often required up-titration to 300 mg q4w. Majority of pts in all 3 cohorts had 1 or no new flare (crFMF: 96.6%, TRAPS: 94.3%, HIDS/MKD: 83.3%) and physician global assessment <2 (no or minimal disease activity). In all 3 cohorts, the median SAA levels decreased rapidly from baseline and remained suppressed through E4 (crFMF: 618 to 21 mg/L, TRAPS: 243 to 12 mg/L and HIDS/MKD: 2061 to 16 mg/L). No new safety findings were reported in CAN-treated pts through E4.

**Abstract THU0570 – Figure 1** Proportion of responders who maintained optimal control of disease activity\* at the end of epoch 4 (Week 112); following treatment with canakinumab 150/300 mg q4w or q8w)

**Conclusions:** Epoch 4 of the CLUSTER study demonstrated that optimal control of disease activity in the crFMF, TRAPS and HIDS/MKD patients can be maintained following long-term treatment with canakinumab 150/300 mg q4w. For all 3 cohorts, patients requiring 150/300 mg q8w in epoch 3 to maintain disease control were less likely to control disease during epoch 4 and therefore a substantial number of these patients were uptitrated to q4w regimen by the end of epoch 4. No new or unexpected safety issues were reported over 112 weeks of canakinumab treatment.

#### THU0571 PROTEOMIC IDENTIFICATION OF SYSTEMIC-ONSET JUVENILE IDIOPATHIC ARTHRITIS PHENOTYPIC BIOMARKERS

F. Gohar<sup>1,2</sup>, A. McArdle<sup>3</sup>, M. Jones<sup>3</sup>, N. Callan<sup>3</sup>, B. Hernandez<sup>3,4</sup>, M. Miranda-Garcia<sup>1,5</sup>, M. Lavric<sup>1,6</sup>, C. Kessel<sup>1</sup>, D. Holzinger<sup>1,7</sup>, O. FitzGerald<sup>3,8</sup>, S. R. Pennington<sup>3</sup>, D. Foell<sup>1</sup>. <sup>1</sup>Department of Paediatric Rheumatology and Immunology, University of Muenster; <sup>2</sup>Department of Paediatrics and Adolescent Medicine, Clemenshospital, Muenster, Germany; <sup>3</sup>UCD Conway Institute of Biomolecular and Biomedical Research, School of Medicine, University College Dublin; <sup>4</sup>UCD School of Mathematical Sciences, University College Dublin, Dublin, Ireland; <sup>5</sup>Paul Ehrlich Institute, Langen, Germany; <sup>6</sup>Department Industrial Engineering and Business Information Systems, University of Twente, Enschede, Netherlands; <sup>7</sup>Klinik für Kinderheilkunde III, Zentrum für Kinder- und Jugendmedizin, Universitätsklinikum Essen, Essen, Germany; <sup>8</sup>Department of Rheumatology, St Vincent's University Hospital, Dublin, Ireland

**Background:** Systemic juvenile idiopathic arthritis (SJIA) is a childhood rheumatic auto-inflammatory disorder of largely unknown pathogenesis. The presence of fever, rash and arthritis support a diagnosis of SJIA, though early in disease arthritis may be minimal, complicating the exclusion of alternative diagnoses such as infection. Furthermore, two clinical phenotypes of SJIA can be identified, a chronic articular-dominant (ART\_SJIA) and a classical auto-inflammatory phenotype (AID\_SJIA).

**Objectives:** To identify novel serum protein biomarkers that may discriminate ART\_SJIA from AID\_SJIA and distinguish AID\_SJIA from infection.

**Methods:** Patients with active SJIA (joint activity plus or minus fever and elevated laboratory inflammation markers) were sub-grouped into the two clinical phenotypes (ART\_SJIA and AID\_SJIA). Serum from patients with SJIA or confirmed infection was analysed for the standard laboratory markers: C-reactive protein (CRP), white cell count (WCC) and erythrocyte sedimentation rate (ESR). A "discovery cohort" (n=10 per group) of patient serum samples was subjected to unbiased label-free proteomics using liquid chromatography mass spectrometry (LC-MS/MS) and in a separate "verification cohort" (AID\_SJIA, n=48; ART\_SJIA, n=29; infection, n=32) candidate biomarkers were measured by multiple reaction monitoring MS (MRM-MS; Agilent 6490 and 6495) and microsphere bead-based immunoassay (Luminex). Serum concentrations of S100A12 and MRP8/14 were also measured in all samples using enzyme linked immunoabsorbant assays (ELISAs).

**Results:** The routine laboratory markers CRP, WCC, ESR, as well as ELISA-measured S100A12 and MRP8/14 serum concentrations were highest in AID\_SJIA, followed by infection and were lowest in patients with ART\_SJIA. Proteins identified and quantified by LC-MS/MS could differentiate patients with ART\_SJIA from those with AID\_SJIA (area under the curve, AUC: 0.97). The discrimination between AID\_SJIA and infection performed less well, AUC: 0.58. Targeted MRM measurement of novel protein candidate biomarkers verified the discovery cohort data. A combined biomarker panel consisting of MRM, ELISA and Luminex analysis which was evaluated using a Random forest model, indicated the correct

overall identification of the clinical groups to be as follows: ART\_SJIA: 24/29 (83%), AID\_SJIA: 37/45 (82%) and infection: 20/32 (63%).

**Conclusions:** Significant differences in the serum protein signature between two phenotypes of SJIA suggest that different immunological processes may underlie these phenotypes. Serum protein profiles also distinguished patients with SJIA and infection. Distinguishing these two groups remains an important goal of research and therefore this study could help inform future prospective studies.

#### THU0572 ORGANISED SPORTS IN CHILDREN AND ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS (JIA): A COMPARISON OF PATIENT AND GENERAL POPULATION PARTICIPATION

F. Milatz<sup>1</sup>, M. Niewerth<sup>1</sup>, N. Geisemeyer<sup>1</sup>, R. Berendes<sup>2</sup>, M. Hufnagel<sup>3</sup>, N. Onken<sup>4</sup>, A. Thon<sup>5</sup>, F. Weller-Heinemann<sup>6</sup>, K. Minden<sup>1,7</sup>. <sup>1</sup>Epidemiology Unit, German Rheumatism Research Centre, Berlin; <sup>2</sup>Paediatric Rheumatology, Children's Hospital St Marien, Landshut; <sup>3</sup>Department of Paediatrics and Adolescent Medicine, University Medical Center, Freiburg; <sup>4</sup>Paediatric Practice, Lüneburg; <sup>5</sup>Children's Hospital, Medical School Hannover, Hannover; <sup>6</sup>Department of Paediatrics, Prof. Hess Children's Hospital, Bremen; <sup>7</sup>Children's University Hospital, Charité University Hospital, Berlin, Germany

**Background:** Despite the well-established physical, social and mental health benefits of physical activity (PA) in childhood, a substantial proportion of children and adolescents with JIA seem to be not active enough to achieve their age-appropriate fitness level.<sup>1</sup> Previous research revealed that organised sports (OS)<sup>1</sup> is associated with greater health benefits compared to non-organised sporting activities, as intensity and net exercise duration are usually higher,<sup>2</sup> has a strong predictive value in improving leisure time PA, and<sup>3</sup> has a positive influence on mental well-being and life satisfaction.<sup>2</sup>

**Objectives:** This study was aimed at comparing OS prevalence in JIA with the general population and at determining correlates associated with OS participation.

**Methods:** Data from the German National Paediatric Rheumatologic Database (NPRD) were considered for the analyses. The outcome variable 'OS participation' was analysed in patients aged 3 to 17 and compared to a population-based nationwide sample (German Health Interview and Examination Survey for Children and Adolescents; KiGGS). Correlates of OS participation were analysed using data of the year 2014.

**Results:** 5,056 children and adolescents with JIA (mean disease duration 4.5 ±3.6 years) provided information about their exercise habits, of which 36% stated to be involved in OS (34% of girls, 41% of boys). The prevalence was higher in the age groups 7 to 10 and 11 to 13 years with almost 50% than in the age groups 3 to 6 and 14 to 17 years with 35% and 42%, respectively. In KiGGS participants, almost 60% reported to be physically active in OS (54% aged 3 to 6, 65% aged 7 to 10, 60% aged 11 to 13% and 49% aged 14 to 17). Non-participation in OS was associated with active disease status (cJADAS), functional disability (C-HAQ), low parental education, higher body mass index (BMI) and worse patient-reported pain, fatigue and overall well-being.

**Conclusions:** The prevalence of OS participation in JIA was considerably lower compared to the general population and varied with increasing age, parental education and functional ability. Considering that low levels of PA might even be more dangerous for young patients with JIA, as they also have signs of inflammation, it is all the more important to create opportunities and incentives in the future to improve young rheumatic's exercise habits.

THU0573

### 15-YEAR TRENDS AND CORRELATES OF SCHOOL SPORTS ATTENDANCE AMONG CHILDREN AND ADOLESCENTS WITH JIA ENROLLED IN THE GERMAN NATIONAL PAEDIATRIC RHEUMATOLOGIC DATABASE

F. Milatz<sup>1</sup>, J. Klotsche<sup>1</sup>, M. Niewerth<sup>1</sup>, N. Geisemeyer<sup>1</sup>, S. Hansmann<sup>2</sup>, M. Hartmann<sup>3</sup>, T. Kallinich<sup>4</sup>, J. Peitz<sup>5</sup>, R. Trauzeddel<sup>6</sup>, K. Minden<sup>1,4</sup>. <sup>1</sup>Epidemiology Unit, German Rheumatism Research Centre, Berlin; <sup>2</sup>Department of Paediatrics, University Hospital Tuebingen, Tuebingen; <sup>3</sup>German Centre for Paediatric and Adolescent Rheumatology, Garmisch-Partenkirchen; <sup>4</sup>Children's University Hospital, Charité University Hospital, Berlin; <sup>5</sup>Department of Paediatrics and Neonatology, Asklepios Clinics, Sankt Augustin; <sup>6</sup>Department of Paediatric Rheumatology, Helios Hospital Berlin-Buch, Berlin, Germany

**Background:** Besides leisure-based physical activities (PA), the school-setting is described as one of the most effective areas for providing opportunities for PA, collectively reaching school-aged children vulnerable to sedentary behaviours.<sup>1</sup> In this context, regular participation in school sports can help children and adolescents achieve a part of the recommended amount of daily physical activity and help gain the knowledge and attitudes they need to engage in lifelong active lifestyle.

**Objectives:** Since adolescents with juvenile idiopathic arthritis (JIA) are less involved in physical and social activities compared to their healthy peers, the objectives were as follows:<sup>1</sup> to describe the extent to which school sports attendance among patients with JIA changed over time, and<sup>2</sup> to determine correlates associated with exemption from school sports.

**Methods:** Data of school-aged children and adolescents with JIA recorded in the National Paediatric Rheumatologic Database (NPRD) in the years 2000 to 2015 were considered for the analyses. Whether school sports participation had changed between 2000 and 2015 was determined using linear mixed models. Data from 2015 were inspected to analyse correlates of school sports absenteeism.

**Results:** During the observation period, participation rates in school sports were determined in 23,016 patients. The proportion of patients who participated always steadily increased from 31% in 2000 to 64% in 2015 ( $\beta=0.017$ , 95% confidence interval (CI) 0.015, 0.020), whereas the exemption rate simultaneously decreased from 44% in 2000 to 16% in 2015 [ $\beta=-0.009$ , 95% CI  $-0.011$ ,  $-0.007$ ]. In 2015, data from 5879 patients (mean age 13.1 $\pm$ 3.3 years, disease duration 5.9 $\pm$ 4.0 years, persistent oligoarthritis 37%) were available for evaluation. Fully exemption was associated with functional limitations, disease activity and any use of DMARDs, intra-articular glucocorticoid injection or physiotherapy.

**Conclusions:** School sports attendance among children and adolescents with JIA has increased significantly over the last 15 years. Possible explanations may

include improved functional ability, probably due to earlier and more frequent use of DMARDs. Considering the impact of JIA on daily life, the sedentary habits that come with it, and the potentially favourable effect of PA, it is important to promote an active lifestyle in children with JIA. In order to encourage patients to attend more frequently, it will be necessary to provide comprehensive information among teachers, parents and physicians regarding opportunities and risks of school sports.

**Results:** A total of 3975 courses of biologics with a total exposure of 7592 PY were identified with Etanercept (5376PY) followed by Adalimumab (1334PY), Tocilizumab (435PY), Abatacept (109PY), Infliximab (99PY), Anakinra (96 PY), Canakinumab (71PY) and Golimumab (67PY). Differences in JIA category distribution and concomitant treatment were noted. A total of 3586 AE (47.2/100PY), 461 (6.1) SAE and 629 (8.3) AESI were reported. The most common AESI were uveitis (194 (2.6)) followed by medically important infections (155 (2.0)), cytopenias (62 (0.8)), hepatic events 39 (0.5), anaphylaxis (28 (0.4)), other autoimmune-pathies (25 (0.3)), chronic inflammatory bowel disease (23 (0.3)), depression (17 (0.2)), macrophage activation syndrome (12 (0.2)), malignancies (8 (0.1)) and pregnancies (8 (0.1)). There were marked differences in the rate of AESI with different biologics. Uveitis was most common in TNF-antibody treated cohorts, infections upon GOL, TOC, ANA, cytopenias upon TOC, CAN, hepatic events upon TOC, anaphylaxis upon INF, TOC, CED upon ETA, INF (table 1). One case of latent TB but no further opportunistic infections were reported. There was a single death due to sepsis.

[KM1]Vorn 2481

[KM2]Vorn 67?

**Conclusions:** Surveillance of pharmacotherapy as provided by BIKER is an important approach especially for long term treatment of children. Overall, tolerance is acceptable. Differences between several biologics were noted and should be considered in daily patient care

**Disclosure of Interest:** None declared

#### THU0575 ANAKINRA FOR FIRST LINE STEROID FREE TREATMENT IN SYSTEMIC ONSET JUVENILE IDIOPATHIC ARTHRITIS

G. Homeff<sup>1,2</sup>, A.C. Schulz<sup>1</sup>, A. Klein<sup>1,2</sup>, K. Eising<sup>1</sup>. <sup>1</sup>ASKLEPIOS, Sankt Augustin; <sup>2</sup>Cologne University, Cologne, Germany

**Background:** Systemic juvenile idiopathic arthritis (sJIA) is characterised by arthritis accompanied or preceded by systemic autoinflammation. High-dose steroids has been the mainstay of therapy with proven effectiveness but also with side-effects. In many patients a chronic course with destructive arthritis long-term cannot be prevented.

**Objectives:** In patients naïve for steroids, a steroid-free treatment may allow reconstitution of an impaired NK-cell function and probably remission of sJIA.

**Methods:** First experience with first line Anakinra without steroids in 9 consecutive patients is reported.

**Results:** All patients presented with ongoing spiking fever and rash and further features of sJIA, high CRP, S100 and IL18 (table 1). Daily sq. injections of Anakinra 2 mg/kg for 3 months resulted in complete remission in 4 and partial response in two children presenting with an oligoarticular involvement. One patient with typical sJIA and very high S100 (MRP8/9) levels did not respond to Anakinra nor to Canakinumab. Two patients presented with polyarthritis. One had no response, the other showed a minor response but improved on steroids and was later treated with tocilizumab. One of the oligoarticular patients with an initial partial response had a flare upon anakinra captured by increased dosing (4 mg/kg) but finally developed macrophage activation syndrome. Anakinra was discontinued after 3 months in 3 of the 4 responders. Two remained in drug free remission while the remainder flared several months later and retreatment was instituted. The patients with polyarticular involvement first received corticosteroids and were later both treated successfully with the IL-6 inhibitor.

**Conclusions:** Experience with first line steroid free treatment with Anakinra for sJIA is presented. A complete remission was reached in 4 cases with oligoarticular

involvement. In 3 further cases improvement was observed and 2 had no response including one who also failed Canakinumab. A toddler with a particular response to Anakinra later on developed MAS. One patient did not respond to both IL-1 inhibitors. Thus, steroid free treatment regimen with Anakinra is feasible and resulted into remission in most but not all patients. Aside, unwarranted effects of long lasting steroid application were avoided.

#### THU0576 CARDIOVASCULAR RISK IN LONG-TERM JUVENILE IDIOPATHIC ARTHRITIS

I. Aranda-Valera, I. Arias de la Rosa, R. Roldan Molina, C. Ábalos-Aguilera, C. Pérez-Sánchez, A. Escudero, R. López-Pedreira, E. Collantes-Estévez, N. Barbarroja. *Rheumatology, Rheumatology service, IMIBIC/Reina Sofía Hospital/ University of Cordoba., Córdoba, Spain*

**Background:** Juvenile Idiopathic Arthritis (JIA) is one of the more common chronic diseases of childhood that often persists into adulthood and can result in significant long-term morbidity, including physical disability. The long-term risk of cardiovascular disease for individuals with Juvenile Idiopathic Arthritis (JIA) remains uncertain.

**Objectives:** This study aims to determine whether adults with JIA in remission and medium-long duration of the disease have an increased risk of cardiovascular disease.

**Methods:** This is a cross-sectional study including 25 patients (14 females and 11 males) diagnosed with JIA according to the International League of Associations for Rheumatology criteria ILAR 2001 were compared to 20 age- and sex-matched controls. Remission was determined by JADAS27 <1 and according to Wallace criteria. An extensive clinical analysis including body index mass, lipid profile, HOMA-IR and intra-arterial blood pressure was performed. Intima media thickness of the common carotid artery (CIMT) was measured as a marker of sub-clinical atherosclerosis. Different proinflammatory cytokines (TNF $\alpha$ , IL1b and IL6), molecules involved in the endothelium dysfunction (VEGF and E-Selectin) and adipokines (resistin and visfatin) were analysed on serum by ELISA.

**Results:** Mean duration of the disease was 13.31 $\pm$ 1.14 years. Mean age was 27.21 $\pm$ 0.68. Time in remission was 3.52 $\pm$ 0.84 years. Metabolic comorbidities such as obesity and metabolic syndrome were more prevalent in our cohort of JIA patients compared to controls. Levels of cholesterol were significantly elevated in patients. However, HOMA-IR values and intra-arterial pressure were not significantly increased in JIA patients. CIMT was higher in JIA patients compared to controls (0.44 $\pm$ 0.009 vs 0.41 $\pm$ 0.017, p=0.078), although it did not reach the statistical significance. Serum levels of cytokines (including TNF $\alpha$ , IL6 and IL1b), adipokines (such as resistin and visfatin), and VEGF were significantly augmented in the cases vs healthy donors. In addition, IMT values significantly correlated with the disease duration (r=0.439, p=0.046) and serum VEGF levels (r=0.498, p=0.030).

**Conclusions:** In our cohort of JIA patients the increased CIMT was not associated with inflammatory markers, but disease duration. Although patients were in clinical remission, the serum levels of inflammatory cytokines, adipokines and VEGF were elevated, molecules with a relevant role in the onset and progression of endothelial dysfunction and atherosclerosis. These results might suggest that long-term JIA patients could have higher cardiovascular risk, although they are in sustained remission.

**Background:** Juvenile systemic sclerosis (jSSc) is an orphan disease, with an estimated prevalence of 3 per 1000 000 children. Most jSSc patients primarily present with Raynaud phenomenon (RP). We investigated in our patient of the juvenile scleroderma inception cohort, how fare patients with (RP+) and without (RP-) RP differed in their clinical presentation at enrolment.

**Methods:** The jSSc is a prospective cohort of jSSc patients. Patients were enrolled who were diagnosed with jSSc, had a jSSc onset age under 16 years and were younger as age of 18 years at the time of inclusion. The patients are prospectively assessed every 6 months according to a standardised protocol. We reviewed the organ involvement pattern of our patients currently followed in the cohort.

**Results:** 100 patients are currently followed in the cohort and 89 (89%) of them had RP. The female/male ratio was lower in the RP +group, 3.7:1 compared to 4.5:1 (p=0.808). Diffuse subtype was more common in the RP +group, 72% compared to 63%. Mean age of onset of first non-Raynaud symptomatic was 10.4 years in both groups. Mean disease duration was slightly higher in the RP +group, 3.4 compared to 2.2 years. ANA positivity was higher in the RP +group, 88% compared to 70% (p=0.48). Anti-Sc170 was 34% in the RP +and 20% in the RP-group (p=0.34). Interestingly 7% of RP +but none of the RP +were anti-centromere positive. The mean modified skin score was lower in RP +group (mean of 14.8 compared to 17.0). There were significantly more nailfold capillary changes (70% compared to 18%, p=0.001) and a higher rate of history of ulceration in the RP +group (49% compared to 20%, p=0.083). Decreased DLCO and FVC <80% was higher in the RP-negative group with 45%/50% compared to 37.5%/31% respectively. Pulmonary hypertension occurred in 7% in the RP +group and there was no case in the RP- group (p=0.335). RP- group had a higher rate of urinary sediment changes 18% compared to 4.5% in the RP +group (p=0.07). No renal crisis or hypertension was reported in neither groups. Gastrointestinal involvement was similar between the two groups with around 35%. Occurrence of swollen joints was similar in both groups as the frequency of muscle weakness with around 20%. The tendon friction rub occurred around 10% in both groups. In the patient related outcomes, there was only a difference in rating of Raynauds activity.

**Conclusions:** The RP- group differed from RP +group in the clinical presentation at enrolment. The absence of Raynaud phenomenon was associated with a decreased rate of history of ulceration, no occurrence of pulmonary hypertension. Interestingly higher rate of urinary sedimentary changes and no anticentromere positivity was observed in RP- patients.

### PATIENTS AND PHYSICIAN RELATED OUTCOMES IMPROVE SIGNIFICANTLY OVER 12 MONTHS FOLLOW UP IN PATIENTS WITH JUVENILE SYSTEMIC SCLEROSIS. RESULTS FROM THE JUVENILE SCLERODERMA INCEPTION COHORT. WWW.JUVENILE-SCLERODERMA.COM

I. Foeldvari<sup>1</sup>, J. Klotsche<sup>2</sup>, M.T. Terreni<sup>3</sup>, M. Katsikas<sup>3</sup>, V. Stanevicha<sup>3</sup>, T. Avcin<sup>3</sup>, R. Cimaz<sup>3</sup>, M. Kostic<sup>3</sup>, W.-A. Sifuentes-Giraldo<sup>3</sup>, F. Sztajnbock<sup>3</sup>, J. Anton<sup>3</sup>, D. Nemcova<sup>3</sup>, M.J. Santos<sup>3</sup>, C. Battagliotti<sup>3</sup>, L. Berntson<sup>3</sup>, J. Brunner<sup>3</sup>, D. Eleftheriou<sup>3</sup>, L. Harel<sup>3</sup>, M. Janarthanan<sup>3</sup>, T. Kallinich<sup>3</sup>, M. Moll<sup>3</sup>, S. Nielsen<sup>3</sup>, V. Smith<sup>3</sup>, K. Torok<sup>3</sup>, A. Stevens<sup>3</sup>, C. Pilkington<sup>3</sup>, N. Helmus<sup>1</sup>. <sup>1</sup>Hamburg Center for Pediatric and Adolescent Rheumatology, Am Schoen Klinik Eilbek, Hamburg; <sup>2</sup>German Rheumatism Research Center, Berlin; <sup>3</sup>JSSc Collaborative Group, Hamburg, Germany

**Background:** Juvenile systemic sclerosis (jSSc) is an orphan disease with an estimated prevalence of around 3 per 1 000 000 children. There are no studies which evaluated prospectively the patient related outcomes in these patients. We report the data from juvenile scleroderma inception cohort (jSSc) regarding organ involvement and patient related outcomes.

**Methods:** The jSSc is a prospective cohort of jSSc patients. Patients were enrolled who were diagnosed with jSSc, had a jSSc onset age under 16 years and were younger as age of 18 years at the time of inclusion. The patients are prospectively assessed every 6 months according to a standardised protocol. Patients with available 12 months follow up data were included in the analyses.

**Results:** Currently 100 patients are followed in the jSSc cohort. 51 of them had available 12 months follow up data. Among those patients 37 (72.5%) had diffuse and 14 (27.5%) limited subtype. Mean age of onset of disease was 9.5 (±4.1) years and the mean disease duration at time of inclusion was 3.1 years (±3.2). The proportion of patients treated with DMARD increased from 74.5% to 88% at 12 months follow up. 86% were ANA positive at both assessments. Anti-scl70 positivity increased from 38% to 42%. Anticentromere antibody positivity was 2.4% at both assessments. Mean modified skin score decreased from 17.7 to 14.3 (p=0.151) Raynaud phenomenon occurred in 86% at enrolment and increased up to 88% at 12 months follow up. Nailfold capillary changes occurred around 70% at both assessments, but number of patients with active ulceration decreased from 28% to 16% (p=0.148). The number of patients with decreased FVC (FVC under 80%) decreased from 40.5% to 32% (p=0.497). The number of patients with pulmonary hypertension remained around 10%. No renal crisis or hypertension were reported. The gastrointestinal involvement was around 40% at both assessments. The number of patients with swollen joints decreased from 24% to 10% (p=0.06). The number of patients with muscle weakness decreased significantly from 33% to 9% (p=0.016), parallel to the number of patients with elevated CK values which decreased from 27% to 12% (p=0.074). All patient related outcomes, like global disease activity (p=0.048), global disease damage (p=0.05), Raynaud activity (p=0.003) and ulceration activity (p=0.001) improved significantly over 12 months. Physician assessed global disease activity (p=0.003) and ulceration activity (p=0.001) also improved significantly.

**Conclusions:** Our data show, that jSSc patients over a 12 months disease course stayed quite stable or improved regarding organ involvement. But patient and physician related outcomes regarding activity assessment improved significantly.

### VALIDATION OF CONTRAST-ENHANCED MRI SCORES ON (TENOSYNOVITIS OF THE WRIST IN JUVENILE IDIOPATHIC ARTHRITIS) PATIENTS BY COMPARISON WITH CHILDREN UNAFFECTED BY CLINICAL ARTHRITIS

J.M. Van Der Krogt<sup>1</sup>, E.C. van Gulik<sup>1</sup>, R. Hemke<sup>1</sup>, J.M. van den Berg<sup>2</sup>, D. Schonenberg<sup>2</sup>, A. Kindermann<sup>3</sup>, K.M. Dolman<sup>4</sup>, M.A. Benninga<sup>3</sup>, T.W. Kuijpers<sup>2</sup>, M. Maas<sup>1</sup>, C.M. Nusman<sup>2</sup>. <sup>1</sup>Radiology and Nuclear Medicine, Academic Medical Center; <sup>2</sup>Pediatric Hematology, Immunology, Rheumatology and Infectious Disease; <sup>3</sup>Pediatric Gastroenterology and Nutrition, Emma Children's Hospital AMC; <sup>4</sup>Pediatrics, OLVG Hospital, location West, Amsterdam, Netherlands

**Background:** Delayed and/or inappropriate treatment of juvenile idiopathic arthritis (JIA) may lead to permanent loss of joint functionality.<sup>1</sup> Contrast-enhanced MRI is increasingly being accepted as a sensitive tool for detecting JIA disease activity in an early stage.<sup>2</sup>

**Objectives:** The aim of this study was to assess the validity of two reliable contrast-enhanced MRI scores for the assessment of synovitis and tenosynovitis in the wrist of clinically active JIA patients by a comparison with children unaffected by clinical arthritis.

**Methods:** An axial T1-weighted MRI sequence with contrast-enhancement and fat-saturation was performed on the wrist of 25 children who had no signs of joint inflammation at clinical examination and who were already subjected to contrast-enhanced MR enterography. Wrist MRI scans of 25 clinically active JIA patients were matched based on time-interval between contrast injection and start of the MRI sequence. After being blinded for clinical status, two radiologists scored synovitis and tenosynovitis in consensus. Synovitis was scored at 5 locations by degrees of synovial enhancement (0–2 scale) and synovial inflammation (0–3 scale). Tenosynovitis was scored at the extensor tendons (compartments II, IV and VI) and flexor tendons by degree of inflammation based on a 0–3 scale.<sup>3,4</sup>

**Results:** Children unaffected by clinical arthritis had significantly lower total synovial enhancement (median=1 vs 4, p<0.001) and total synovial inflammation (median=1 vs 4, p<0.001) scores compared to clinically active JIA patients (graph). No significant difference in total tenosynovitis score was found between both groups (median=0 vs 0, p=0.220). Fifteen out of 25 (60%) clinically active JIA patients were given a total tenosynovitis score of 0.

**Conclusions:** The contrast-enhanced MRI scores for the assessment of synovial enhancement and synovial inflammation in the wrist of clinically active JIA patients appear valid. Due to a low incidence of wrist tenosynovitis in this cohort, the validity of the tenosynovitis score could not be assessed. These findings further establish contrast-enhanced MRI as a diagnostic tool with synovitis as the primary target of disease in the wrist of JIA patients.

#### THU0580 THE ACR RECOMMENDATIONS FOR JIA IN DAILY CLINICAL PRACTICE: ARE THEY FOLLOWED OR WOULD TREAT-TO-TARGET THERAPY LEAD TO BETTER RESULTS?

J.F. Swart, S. de Roock, P. van Dijkhuizen, N. Wulffraat. *Pediatric Rheumatology, UMC Utrecht, Utrecht, Netherlands*

**Background:** What factors drive the physician decision to escalate to anti-TNF therapy 3 and 6 months after start of methotrexate (MTX) in both persisting oligoarthritis (OJIA) and polyarticular course (PJIA) juvenile idiopathic arthritis.

**Objectives:** Are the escalation-decisions in accordance with the ACR JIA treatment recommendations (ACR-CPG)<sup>1</sup> and if not, what factors drive these decisions. How does it perform as a "prognostic" test to predict failure when not escalated. Could the clinical Juvenile Arthritis Disease Activity Score (cJADAS) be used instead. What is the value of the patient-VAS in the ACR-CPG, the physician decision and in the cJADAS.

**Methods:** Monocentric retrospective cohort study analysing all OJIA and PJIA patients starting MTX for the first time between 2011 and 2016.

**Results:** The ACR-CPG is mostly not followed and implementation would increase the anti-TNF-use from 12.0% to 65.1%. However, the physician decision not to escalate was now correct in 70%–75%, therefore implementation results in an overuse of anti-TNF. Some items of the ACR-CPG were non-discriminatory. The use of cJADAS in predicting failure if not escalated outperformed the ACR-CPG with a much higher sensitivity and specificity for the OJIA and PJIA group respectively. The omission of the patient-VAS-scores resulted in a substantial decrease of the identification of patients failing to respond without escalation.

**Conclusions:** The ACR-CPG not only is too complicated to be applicable in clinical practice, it also fails to identify those patients really in need of escalation to

anti-TNF. The cJADAS can be used instead since this is user-friendly, does not require waiting for ESR results and performs better than the ACR-CPG. The patient-VAS is a critical item for the decision to escalate.

**Background:** Juvenile idiopathic arthritis (JIA) is the most frequent chronic rheumatic disease in childhood. The early disease recognition and treatment is critical to prevent long-term complications and disability in childhood. During the last decade the arrivals of biologics has dramatically changed the prognosis of these patients. A number of well-designed clinical trials, as well as cohort studies have demonstrated that biologics are an effective option for JIA patients who do not respond or cannot tolerate treatment with synthetic disease modifying drugs (DMARDs).

JIA is not confined to childhood, and a 41% had active disease are on medication after 30 years and 28% had a high symptom state.

**Objectives:** The aim of this work was to study the pattern of use, drug survival and adverse events of biologic therapy in JIA patients during the transition period from the diagnostic to the adulthood.

**Methods:** Information was obtained from BIOBADASER, a safety multicenter prospective registry. All patients included in the registry diagnosed of JIA between 2000 and 2015 were analysed. Proportions, means and standard deviations (SD) were used to describe population. Incidence rates and 95% confidence intervals were calculated to assess adverse events. Kaplan-Meier analysis was used to compare the drug survival.

**Results:** 469 patients, 46.1% women were included in this study. Age at diagnosis was 9.4 (SD=5.3) and years of disease evolution 24.1 (SD=14.1). The age at biological treatment initiation was 23.9 years (SD=13.9). The pattern of use of biologics in JIA patients in the paediatric age shows a linear increase from 24% in 2000 to 65% in 2014. Interestingly, the biologic suspension for disease remission was higher in patients who initiated its use under 16 years (25.7%) than in those who began at 16 years or later (7.9%,  $p < 0.0001$ ). Serious adverse events showed a total incidence rate of 41.4 (35.2–48.7) (1000 patients/year) without differences between patients younger or older than 16 years old. However, patients younger than 16 years old showed a significant increment in infection and infection ( $p < 0.001$ ).

**Conclusions:** The biologic survival and suspension by remission was higher when the biologic therapy started before 16 years old in JIA patients. The incidence rate severe adverse events in the childhood and adulthood in JIA patients treated with biologics was similar, however, a significant increment of infection was observed in patients under 16 years old.

**THU0582 A SYSTEMATIC REVIEW OF EMPLOYMENT OUTCOMES OF ADULTS WITH CHILDHOOD-ONSET SYSTEMIC AUTOIMMUNE RHEUMATIC DISEASES**

K. Gu, T. Gottschalk, L.S.H. Lim. *University of Manitoba, Winnipeg, Canada*

**Background:** Childhood-onset systemic autoimmune rheumatic diseases (ChildCRD) include: systemic lupus erythematosus (SLE), Sjogren's syndrome, systemic sclerosis, inflammatory myositis, and chronic systemic vasculitides (Takayasu arteritis, polyarteritis nodosa, anti-neutrophil cytoplasmic antibodies (ANCA) associated systemic vasculitides). These conditions had mortality rates of up to 50%, but most patients now live into adulthood. Employment is an important milestone in adulthood: it has direct effects on one's socioeconomic status and access to health insurance, which could in turn affect disease outcomes.

**Objectives:** To perform a systematic review of the employment outcomes of ChildCRD individuals. To identify gaps of knowledge and methodological issues in this field so as to inform future studies.

**Methods:** ChildCRD patients have disease-onset <18 years old and adulthood outcomes reported at ≥18 years old. We developed a search strategy for employment outcomes of ChildCRD with an academic librarian; this was iteratively refined and finalised after peer-review by other librarians. We included English language articles published from Jan 1990 Oct 2017 in MEDLINE, EMBASE, and Scopus. Case reports, case series, editorials, letters, or short reports were excluded. We supplemented our search by hand-searching references in review articles. Information on outcomes, prognostic factors, and study designs was recorded. Studies were graded independently by 2 reviewers (after prior training for agreement) using the Quality in Prognosis Studies (QUIPS) risk-of-bias tool which examines quality in 6 study domains. Authors were contacted as necessary for further information or clarification.

**Results:** Of 2109 studies, we identified 3 publications (G1) studying SLE patients. None studied other ChildCRD. Two papers were from a single study and studied both SLE and juvenile arthritis; we only used SLE patients' information. Three additional manuscripts (G2) studied childhood- and adult-onset patients but did not report outcomes separately. All G1 publications were from North America (2 Canada, 1 USA). 193 patients in 2 studies were examined; 1 study had longitudinal (non-inception) design. Only G1 studies have data for report. Patients' disease durations were a mean of 7.6–15 years and the mean ages at study were 23–29 years. Half of the patients were employed. Lower disease activity, better physical function, and higher education were associated with longitudinal employment in 1 study; greater independence and social support were associated with employment in another. One study showed psychosocial and work context factors to be associated with absenteeism, disease activity with job disruptions, and fatigue and work context factors with lost productivity. Of QUIPS-graded G1 publications, study populations and confounding were at moderate-high risk-of-bias. Study outcomes, prognostic factors, and statistical analyses were at low-moderate risks-of-bias. Attrition was low in the longitudinal study.

**Conclusions:** Currently, there is minimal information on employment outcomes in ChildCRD adults except for few studies on SLE; information about other ChildCRD is needed. Study populations and confounding are at moderate-high risks-of-bias, limiting the generalizability. More information on employment outcomes, the specific aspects of employment, disease and non-disease related prognostic factors affecting employment are needed.

**THU0583 PAIN INTERFERENCE ASSOCIATED FACTORS IN A COHORT OF FINNISH YOUNG ADULTS WITH JUVENILE IDIOPATHIC ARTHRITIS**

K. Rebane<sup>1</sup>, T. Orenius<sup>2</sup>, L. Ristolainen<sup>2</sup>, H. Relas<sup>3</sup>, H. Kautiainen<sup>4</sup>, R. Luosujärvi<sup>3</sup>, H. Säilä<sup>2</sup>, K. Aalto<sup>1</sup>. <sup>1</sup>Children's Hospital, University of Helsinki and Helsinki University Central Hospital; <sup>2</sup>Orton Ortopaedic Hospital, Orton; <sup>3</sup>Rheumatology, Helsinki University Central Hospital; <sup>4</sup>Department of General Practice and Primary Health Care, University of Helsinki and Helsinki University Central Hospital, Helsinki, Finland

**Background:** Pain is one of the most distressing and persisting features of JIA and frequently interferes with everyday life.

**Objectives:** This study was conducted to find out the factors associated with pain interference in young adults (aged 18 to 30 years) with JIA.

**Methods:** 195 adult patients with JIA were eligible for the study. Associations between patients reported outcome data and pain interference were examined. Sociodemographic and clinical data were analysed. Pain interference was measured by a single item from the RAND 36 questionnaire. Five response categories were coded into different groups: patients reporting "extremely" and "quite a bit" or "moderate" were classified having significant pain interference; "a little bit" as having minor pain interference; and "not at all" as having no pain interference. Functional disability was measured by HAQ, depressive symptoms were measured by Beck Depression Inventory-II, self-esteem was assessed by Rosenberg Self-

Esteem Scale, and anxiety was assessed by PASS-20. Leisure time physical activity (LTPA) metabolic equivalent (MET) score was calculated.

**Results:** Pain intensity scores were higher in patients expressing significant pain interference (mean 5.3, SD 2.1) and minor pain interference (mean 2.8, SD 2.09);  $p$  for linearity <0.001, thus the mean pain intensity for the whole study group was quite low (mean 2.3, SD 2.3). Of the 195 patients 98 (50.3%) reported no pain interference, 59 (30.3%) reported minor pain interference, and 39 (20%) reported significant pain interference. We found that pain interference was associated with older age ( $p=0.029$ ), female gender ( $p=0.028$ ) and receiving antirheumatic treatment ( $p=0.032$ ), analgesics ( $p<0.001$ ), antidepressants ( $p=0.008$ ), and opioids ( $p<0.001$ ). Also cohabiting ( $p=0.003$ ), LTPA MET ( $p=0.032$ ), smoking (0.006), being more disabled ( $p<0.001$ ), having fewer leisure time activities ( $p<0.001$ ) or having co-morbidities ( $p=0.006$ ), and headache ( $p<0.001$ ) were associated with having pain interference. Higher anxiety scores were associated with more pain interference ( $p<0.001$ ). When controlling for gender, age, depression, LTPA MET, disability, life situation, disease remission, analgesics, antidepressants, and pain intensity, all subscales in PASS-20 were significantly associated with higher pain interference levels: cognitive anxiety ( $p=0.004$ ), escape/avoidance ( $p<0.001$ ), fear ( $p=0.001$ ), psychological anxiety ( $p=0.016$ ).

**Conclusions:** Half of the JIA patients reported pain interference, and they also expressed higher pain scores. Age, gender, using antirheumatic drugs, antidepressants, analgesics or opioids, cohabiting, lower LTPA MET score, disability, smoking, co-morbidities, lack of activities, and suffering anxiety were most significantly related to pain interference. Our study highlights the need to develop better strategies for pain-relieving interventions and for supporting patients' health-behaviour in order to achieve better pain outcome in young adults with JIA.

**THU0584 VITAMIN D STATUS IN PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS AND ITS ASSOCIATION WITH DISEASE ACTIVITY AND PROGRESSION – RESULTS FROM THE INCEPTION COHORT ICON**

C. Sengler<sup>1</sup>, J. Zink<sup>1</sup>, J. Klotsche<sup>1</sup>, D. Foell<sup>2</sup>, M. Niewerth<sup>1</sup>, I. Liedmann<sup>1</sup>, G. Homeff<sup>3</sup>, J.-P. Haas<sup>4</sup>, K. Moenkemoeller<sup>5</sup>, A. Thon<sup>6</sup>, K. Minden<sup>1</sup>. <sup>1</sup>Epidemiology unit, GERMAN RHEUMATISM RESEARCH CENTRE, Berlin; <sup>2</sup>Department of Paediatric Rheumatology and Immunology, University of Muenster, Muenster; <sup>3</sup>Asklepios Clinic Sankt Augustin, Sankt Augustin; <sup>4</sup>German Centre for Paediatric and Adolescent Rheumatology, Garmisch-Partenkirchen; <sup>5</sup>Clinics of the City of Cologne, Cologne; <sup>6</sup>Hannover Medical School, Hannover, Germany

**Background:** Vitamin D has been shown to have immunomodulatory properties in addition to its well-established role in the maintenance of mineral homeostasis and bone health. Conflicting data have been available regarding vitamin D status in children and adolescents with juvenile idiopathic arthritis (JIA) and its influence on the disease.

**Objectives:** To determine 25–0 hour-vitamin D3 (25-OHD) levels in patients with JIA, and to evaluate whether 25-OHD levels are associated with disease activity and disease course.

**Methods:** Serum 25-OHD levels were determined in a pair of serum samples from patients with JIA who were enrolled in the JIA inception cohort study ICON and prospectively followed for three years. The frequencies of 25-OHD deficiency (defined as <20 ng/ml) and 25-OHD sufficiency (≥30 ng/ml) were determined and compared with those of the age-, sex- and ethnicity-matched general population (KIGGS study). The association of 25-OHD levels and the likelihood for uveitis were analysed by a Cox-proportional hazard model. Logistic regression analysis was used to investigate the predictive value of 25-OHD in terms of disease progression into extended oligoarthritis (OA).

**Results:** In 360 patients with early JIA (48% OA, 27% rheumatoid-factor negative polyarthritis), 25-OHD levels were determined twice: after a median disease duration of 6.6 and of 13.0 months. The mean 25-OHD level of all JIA samples was insufficient (22.1 ng/ml, SD 7.8), but significantly higher than that of the control population (18.4 ng/ml, SD 10,  $p<0.001$ ). Vitamin D levels decreased with age in patients and controls, but did not differ between males and females.

An insufficient mean 25-OHD level was found in 40% of JIA patients and in 25% in both samples each, sufficient levels in 13% and 7%, respectively. There were no significant differences in 25-OHD levels among the JIA categories. Disease activity, measured by the cJADAS-10, was inversely correlated with the first 25-OHD level ( $\beta=-0.20$ , 95% CI  $-0.37,-0.03$ ,  $p=0.018$ ), especially in 141 DMARD-naïve patients ( $\beta=-0.26$ , 95% CI  $-0.44,-0.01$ ,  $p=0.041$ ). Up to the 3-year-follow-up, 17% (61/360) developed uveitis, and 30% (52/173) of OA patients an extended OA. While 20% (17/87) of those with 25-OHD deficiency at both measurements were affected by uveitis, this applied to only 9% (2/23) in those with sufficient levels. Multivariable regression analysis revealed that the 25-OHD level was significantly associated with the risk to develop uveitis (Hazard ratio 0.95, 95% CI 0.91,0.99,  $p=0.008$ ). Twelve out of 29 (41%) patients with OA and two deficient

vitamin D levels, but only 2 of 14 (14%) with two sufficient 25-OHD levels developed extended OA during the first 3 years ( $p=0.034$ ).

**Conclusions:** Overall, vitamin D levels were higher in JIA patients than in matched controls. JIA patients with higher disease activity had lower 25-OHD levels. In particular, complicated courses with uveitis or the development of polyarthritis seem to be associated with lower 25-OHD levels. Further studies are needed to substantiate these results.

#### THU0585 PERSONALISED TREATMENT IN JUVENILE IDIOPATHIC ARTHRITIS – FUTURE OR FICTION? PRELIMINARY RESULTS OF USING S100A8A9, S100A12 AND VASCULAR ENDOTHELIAL CADHERIN AS DIAGNOSTIC AND PROGNOSTIC BIOMARKERS

K. Orczyk, E. Smolewska. Department of Pediatric Rheumatology, Medical University of Lodz, Lodz, Poland

**Background:** Serological biomarkers with ability to predict outcome and therapeutic response of patients might be helpful in introducing the concept of treat-to-target into management of juvenile idiopathic arthritis (JIA). Among others, calprotectin (S100A8A9) and calgranulin C (S100A12) are considered to be valuable markers of disease activity and risk factors for flare after withdrawal of treatment. Vascular endothelial cadherin (VE-cadherin) is a marker of endothelial permeability which has been postulated to predict response to methotrexate therapy in rheumatoid arthritis (RA) patients.

**Objectives:** The aim of the study was to assess the clinical significance of measuring serum concentrations of S100A8A9, S100A12 and VE-cadherin in patients with freshly diagnosed JIA and those with exacerbated course of the disease.

**Methods:** Serum levels of the listed biomarkers were determined in 30 patients diagnosed with JIA and 21 age- and sex-matched healthy controls. In the study group blood samples were obtained in two time points in order to evaluate dynamics of concentrations of markers.

**Results:** S100A8A9 and S100A12 serum concentrations at baseline were positively correlated with ESR at second time point ( $r=0.378$  and  $0.425$ ,  $p=0.0397$  and  $0.0193$ , respectively). S100A12 had equal correlation with CRP at second time point ( $r=0.391$ ,  $p=0.0329$ ). Patients freshly diagnosed with JIA had higher levels of S100A12 ( $8.49\pm 4.92$  ng/ml vs.  $5.49\pm 2.21$  ng/ml,  $p=0.007$ ) and VE-cadherin ( $5.31\pm 1.13$  ng/ml vs.  $3.50\pm 0.58$  ng/ml,  $p<0.001$ ) when compared to healthy controls. VE-cadherin level was elevated in JIA patients at second time point as well ( $4.10\pm 0.93$  ng/ml,  $p=0.0194$ ). Patients who underwent arthrocentesis at baseline had higher concentrations of S100A12 at second time point ( $6.69\pm 3.56$  ng/ml vs.  $3.84\pm 2.58$  ng/ml,  $p=0.0168$ ). Levels of markers were independent of sex and age.

**Abstract THU0585 – Table 1.** General characteristics of the study group

No. of patients (%)	30 (100.0%)
Age at diagnosis of JIA $\pm$ standard deviation	9.6 $\pm$ 4.8 years
Female (%)	23 (76.7%)
Oligoarticular JIA (%)	24 (80.0%)
Enthesitis-related JIA (%)	2 (6.7%)
Polyarticular RF-negative JIA (%)	3 (10.0%)
Polyarticular RF-positive JIA (%)	1 (3.3%)
Freshly-diagnosed JIA at 1st time point (%)	10 (33.3%)
Exacerbated course of the disease at 1st time point (%)	15 (50.0%)
Minimal disease activity at 1st time point (%)	5 (16.7%)
Arthrocentesis performed at 1st time point (%)	16 (53.3%)
Duration of period between time points $\pm$ standard deviation	99.1 $\pm$ 27.7 days
Exacerbated course of the disease at 2nd time point (%)	9 (30.0%)

**Abstract THU0585 – Table 2.** Serum concentrations of assessed biomarkers (values presented as mean $\pm$ standard deviation)

Marker	Study group – 1st time point (n=30)	Study group – 2nd time point (n=30)	Control group (n=21)
S100A8A9 [ug/ml]	2.56 $\pm$ 2.15	1.69 $\pm$ 1.42	1.47 $\pm$ 0.68
S100A12 [ng/ml]	9.08 $\pm$ 5.25	5.36 $\pm$ 3.41	5.49 $\pm$ 2.21
VE-Cadherin [ng/ml]	4.85 $\pm$ 0.93	4.10 $\pm$ 0.93	3.50 $\pm$ 0.58

**Conclusions:** Presented study group needs to be expanded with more patients, especially with minimal disease activity, in order to validate demonstrated preliminary results. VE-cadherin may be considered as a future diagnostic biomarker, however its specificity requires detailed assessment. S100A8A9 and S100A12 merit further evaluation as potential prognostic biomarkers for more aggressive course of the disease.

Foster<sup>5</sup>, T.R. Southwood<sup>6</sup>, W. Thomson<sup>7,8</sup>, K. L. Hyrich<sup>1,8</sup>, on behalf of the Biologics for Children with Rheumatic Diseases (BCRD) investigator group, and the British Society for Paediatric and Adolescent Rheumatology Etanercept Cohort Study (BSPAR-ETN).

<sup>1</sup>Arthritis Research UK Centre for Epidemiology, Manchester Academic Health Science Centre, <sup>2</sup>Division of Pharmacy and Optometry, School of Health Sciences, The University of Manchester, Manchester, <sup>3</sup>Clinical Academic Department of Paediatric Rheumatology, Alder Hey Children's NHS Foundation Trust, <sup>4</sup>Institute of Translational Medicine (Child Health), University of Liverpool, Liverpool, <sup>5</sup>Newcastle University and Great North Children's Hospital, Newcastle, <sup>6</sup>Institute of Child Health, University of Birmingham and Birmingham Children's Hospital, Birmingham, <sup>7</sup>Arthritis Research UK Centre for Genetics and Genomics, Manchester Academic Health Science Centre, The University of Manchester, <sup>8</sup>National Institute of Health Research Manchester Musculoskeletal Biomedical Research Centre, Manchester Academic Health Science Centre, Manchester University NHS Foundation Trust, Manchester, UK

**Background:** Methotrexate is usually the first-line disease modifying anti-rheumatic drug (DMARD) for patients with juvenile idiopathic arthritis (JIA), due to its efficacy, the low-cost and favourable safety profile in patients. However, one of the most reported adverse effects of interest (AEIs) of methotrexate is nausea.

**Objectives:** The objectives of this analysis were to (i) calculate methotrexate monotherapy drug survival, (ii) describe AEIs over the first two years of treatment, and (iii) investigate factors associated with occurrence of AEIs among children with JIA.

**Methods:** Patients with all forms of JIA starting methotrexate monotherapy from both the UK BSPAR Etanercept Cohort Study (BSPAR-ETN) and Biologics for Children with Rheumatic Diseases study (BCRD) were included. Patient characteristics and anti-rheumatic therapy details were collected at treatment start. Follow-up data were collected at six months, one year, and annually thereafter, on changes to anti-rheumatic therapy and any adverse events. AEIs were grouped into gastrointestinal-related (nausea, vomiting, abdominal pain), raised liver enzymes, leukopenia, drug hypersensitivity (injection site reaction), rash, needle phobia, and any other event leading to permanent discontinuation of methotrexate. All person time was included from methotrexate start date until first methotrexate stop date, start of biologic therapy, last patient follow-up date, or 30-June-2017 (study cut-off date), whichever came first. Survival analysis was used to assess time on methotrexate monotherapy and time to first AEI on methotrexate monotherapy. Multivariable logistic regression was used to assess baseline characteristics associated with experiencing an AEI, and a gastrointestinal-related AEI only.

**Results:** Of 505 patients starting methotrexate between 01-January-2010 and 30-June-2015 (to allow at least two years of follow-up for all children), median time on monotherapy was 1.5 years (IQR 0.7, 2.3). At two years, 274 (54%) patients were no longer on methotrexate monotherapy. Reasons included: inefficacy ( $n=174$ ; 64%) mostly due to start of biologic therapy ( $n=161$ ), adverse events ( $n=54$ ; 20%), remission ( $n=24$ ; 9%), and patient/family decision ( $n=9$ ; 3%). Within the first two years of methotrexate monotherapy, 181 (36%) patients experienced at least one AEI; the most common were gastrointestinal problems ( $n=116$ ; 53%) and liver enzyme abnormalities ( $n=42$ ; 19%). No clinical factors were associated with occurrence of any AEI, nor a gastrointestinal-related AEI.

**Conclusions:** After two years, over half of the patients were no longer on methotrexate monotherapy, whilst one-third experienced at least one AEI, most commonly gastrointestinal-related problems. Further research focussing on identifying which children will respond and/or experience an AEI with methotrexate is crucial, such that AEIs can be minimised or prevented and treatment benefit maximised.

THU0587

### CLINICAL AND THERAPEUTIC ASPECTS OF A SOUTH ASIAN POPULATION OF SYSTEMIC ONSET JUVENILE IDIOPATHIC ARTHRITIS IN A TERTIARY CARE PEDIATRIC RHEUMATOLOGY CENTRE IN SRI LANKA

M. Adikari<sup>1</sup>, A. Subasinghe<sup>1</sup>, M. de Silva<sup>2</sup>. <sup>1</sup>Department of Rheumatology, National Hospital of Sri Lanka; <sup>2</sup>Department of Rheumatology, Lady Ridgway Hospital for Children, Colombo, Sri Lanka

**Background:** Systemic onset juvenile idiopathic arthritis is a rare multisystem inflammatory disease of childhood associated with significant morbidity and mortality. Sri Lanka is a country situated in south Asia. Disease characteristics of systemic onset juvenile idiopathic arthritis is not well studied in this geographical region. Sri Lanka offers public funded free universal healthcare for all citizens including biological disease modifying drugs. Lady Ridgway hospital for children is the national centre for tertiary paediatric care and draws patients from wider geographical territory of Sri Lanka.

**Objectives:** To describe the demographic parameters, clinical features, disease activity and therapeutic aspects of systemic onset juvenile idiopathic arthritis among a population of Sri Lankan patients.

**Methods:** A descriptive cross sectional study was conducted at the department of rheumatology at Lady Ridgway hospital for children. Systemic onset juvenile idiopathic arthritis patients of 1–16 years of age, with minimum 6 months follow up in the study centre were recruited. Patients' demographic, clinical and laboratory data were collected.

**Results:** Data of 32 patients were analysed. Eleven (34.4%) were males and 21 (65.6%) were females. Mean age was 9.3 years (SD=4.19) while mean age at diagnosis was 5.95 years (SD=3.35). Majority n=17 (55%) had polyarthritis at the onset while n=12 and n=2 showed oligo-arthritis and mono-arthritis respectively. Mean inflammatory joint count at presentation was 5.4 (SD=3.7). Fifteen (46.9%) patients had persistent disease while 11 (34.4%) showed monocyclic and 6 (18.7%) had polycyclic disease pattern. Mean erythrocyte sedimentation rate of the study population at diagnosis was 104.02 mm/1st hour, dramatically reduced to 43.9 mm/1st hour after 6 months of treatment. All patients received corticosteroids for variable durations and doses during the disease course. Methotrexate was given to majority of patients (n=25, 78.1%). Thirteen patients (40.6%) received Tocilizumab. Disease remission was achieved by majority of 18 (56.2%) patients. All eligible patients received biological disease modifying drugs when indicated. Mean JDAS 10 score of the population was 4.4.

**Conclusions:** The above study revealed important demographic data, clinical features and therapeutic aspects of a population of systemic onset juvenile idiopathic arthritis in a tertiary care paediatric rheumatology centre in a south Asian population in Sri Lanka. Majority of patients were able to achieve remission or low disease activity with treatments.

### REDUCTION IN THE UTILISATION OF PREDNISON AND/OR METHOTREXATE FOLLOWING THE INITIATION OF ETANERCEPT IN PAEDIATRIC PATIENTS

M. Khraishi<sup>1</sup>, B. Millson<sup>2</sup>, J. Woolcott<sup>3</sup>, H. Jones<sup>4</sup>, L. Marshall<sup>4</sup>. <sup>1</sup>Memorial University of Newfoundland, St Johns; <sup>2</sup>IQVIA, Kanata, Canada; <sup>3</sup>Global Outcomes and Evidence, Pfizer; <sup>4</sup>Global Medical Affairs, Pfizer, Collegeville, USA

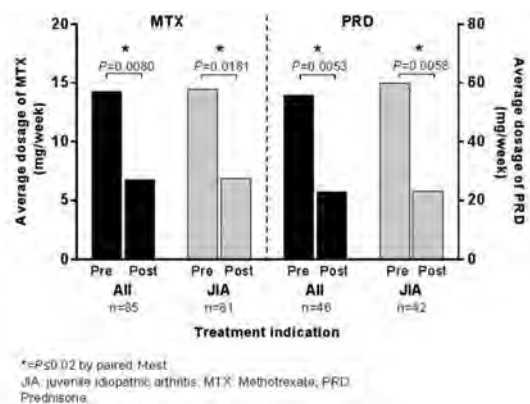

**Background:** In Canada, the paediatric indications of the soluble TNF $\alpha$  receptor etanercept (ETN) are active ankylosing spondylitis (AS) and moderate to severely active juvenile idiopathic arthritis (JIA); in those who have had an inadequate response to  $\geq 1$  disease-modifying anti-rheumatic drugs and are  $\geq 4$  years of

age). A previous analysis of Canadian claims data for children demonstrated a 78% yearly retention rate over Year 1 for ETN, which remained high over Years 2–6 (80%–90% per year). However, at this time, the changes in co-medication during ETN treatment in paediatric patients have rarely been evaluated in the real-world setting.

**Objectives:** To evaluate co-treatment utilisation and ETN costs in Canadian paediatric patients initiating ETN therapy.

**Methods:** A retrospective cohort study was conducted using longitudinal prescription drug claims data from the IQVIA Private Drug Plan (PDP), Ontario Public Drug Plan (OPDP), and Quebec Public Drug Plan database (RAMQ). Biologic-naïve paediatric patients (<18 years, with no biologic treatment in the preceding 12 months) were included if they initiated ETN during the selection period Jan 2008–Jan 2016). Disease indications were inferred through patient drug history. Analyses of ETN doses and co-treatments were conducted in patients <17 years at index and with no missing data or drug histories indicative of conditions other than JIA, AS, or psoriatic arthritis (PSA). Weekly ETN dose was estimated for patients who completed 12 month continuous ETN therapy (7 x [mg dispensed/days between claims]). Co-treatments were captured for the 6 months preceding and 12 months following index. Drug costs of ETN (manufacturing plus wholesale and pharmacy mark-up) were estimated for all those <18 years who initiated ETN therapy.

**Results:** The study identified 391 patients <18 years old who initiated ETN and who had not received treatment with a biologic in the preceding 12 months. From this group 330 patients provided data for the evaluation of ETN doses and co-treatments (67% female, 39% aged 10–14 years). The majority were from Quebec (36%) or Ontario (33%), insured on PDP (87%). Drug history was consistent with JIA (96%), PSA (3%), and AS (1%). Among the 316 patients who completed 12 months of continuous ETN therapy, the average weekly ETN dose was 31 mg (range 29–35 mg), but varied with age. Overall, 103 of 330 patients (31%) used methotrexate (MTX) before initiating ETN, with 85/103 (83%) continuing this through the first 12 months of treatment; 28% of patients (n=92) used prednisone (PRD) before initiating ETN, with 46/92 (50%) continuing PRD during the first 12 months of ETN treatment. In patients continuing co-treatment, weekly dosages were significantly reduced ( $p \leq 0.008$  by paired *t*-test; figure 1). The average yearly cost of ETN among the 330 paediatric patients indexed was \$13 671 (Canadian \$ per year).

**Abstract THU0588 – Figure 1** Average. dose of methotrexate or prednisone pre- and post-initiation of etanercept in paediatric patients with continuing co-treatment

**Conclusions:** This evaluation of Canadian claims data demonstrated that less than a third of paediatric patients initiating ETN were co-treated with MTX or PRD. Many patients discontinued their co-therapies, and among those who continued therapy with these agents, weekly dosages of MTX or PRD were significantly lower within the first year of initiating treatment with ETN.

**THU0589 PHYSICAL ACTIVITY IN CHILDREN AND ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS**

M. Sellami, A. Fazaa, S. Miladi, K. Ouenniche, S. Kassab, S. Chekili, K. Ben Abdelghani, A. Laatar. *Rheumatology, Mongi Slim Hospital – La Marsa, Tunis, Tunisia*

**Background:** Juvenile Idiopathic Arthritis (JIA) is the most common rheumatic disease of childhood which may cause physical dysfunction and inactive sedentary lifestyle. Physical activity (PA), known to maintain optimal metabolic function and normal development could be impaired during JIA.

**Objectives:** The aim of this study was to assess PA in children and adolescents with JIA compared with a healthy population and to analyse associations between PA, functional ability and disease activity.

**Methods:** This is a cross-sectional study including patients with JIA (ILAR criteria) and age and gender-matched healthy Tunisian schoolchildren. Disease activity was evaluated by Juvenile Arthritis Disease Activity Score (JADAS) and functional ability by the Childhood Health Assessment Questionnaire (CHAQ). PA was assessed by children's physical activity questionnaire (CPAQ) for children and for adolescents (APAQ) and expressed as physical activity level (PAL). Moderate to vigorous PA (MVPA) (hours/day) and sedentary time (hours/day) were determined.

**Results:** A total of 55 patients (38 boys and 17 girls) with JIA and 60 healthy schoolchildren were included. No significant differences for age, height, weight, and body mass index between JIA patients and controls were observed. A quarter of children lived in poor socio-economic conditions. Subtypes of JIA were: oligoarticular (52.7%), rheumatoid factor-negative (16.3%) or positive (10.9%) polyarthritis, systemic JIA (9%), and enthesitis-related arthritis (7.2%). The mean disease duration was 3.2 years.<sup>2-6</sup> Twelve patients had active disease (21.8%), 25 patients had inactive disease (45.4%) and 18 patients were in remission (32.7%). The mean average of CHAQ was 0.98. Seventy six percent of the JIA group spent most of the time (average of 15 hours/week) on the two lowest categories: sleeping and sitting compared with the control group (average of 8 hours/week). Only 11 children with JIA (20%) played sport regularly with an average of 40 minutes/week which was significantly lower compared with controls (120 minutes/week;  $p=0.01$ ). Children with JIA spent less time in MVPA compared with the control group ( $0.5\pm 0.6$  versus  $1.9\pm 0.9$  hours/day;  $p<0.01$ ). Only 34.5% of JIA patients met public health recommendations to perform  $\geq 1$  hour daily MVPA compared with 66.6% in the control group ( $p<0.01$ ). No associations were found between PA level, disease duration and disease activity. However, lower PAL in children with JIA was significantly associated with young age ( $p=0.03$ ), worse well-being ( $p=0.01$ ) and CHAQ  $>1$  ( $p<0.001$ ). A higher CHAQ score was associated with less time spend in MVPA ( $p<0.001$ ) and poor willingness to practice PA ( $p=0.001$ ). Sedentary time was associated with higher body mass index ( $p=0.02$ ).

**Conclusions:** In our study, children and adolescents with JIA were less physically active than the healthy peers and less active than recommended for general health. This population needs more attention in achieving normal PA.

**THU0590 THE ROLE OF STAT4 RS7574865 G/T AND IFR5 RS2004640 G/T GENE POLYMORPHISM IN JUVENILE IDIOPATHIC ARTHRITIS SUSCEPTIBILITY AMONG RUSSIAN PAEDIATRIC POPULATION**

M. Krylov<sup>1</sup>, E. Fedorov<sup>1</sup>, S. Salugina<sup>1</sup>, N. Konovalova<sup>2</sup>, D. Varlamov<sup>2</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology, <sup>2</sup>All-Russian Research Institute of Agricultural Biotechnology, Moscow, Russian Federation

**Background:** Juvenile idiopathic arthritis (JIA) is the common chronic condition in paediatric population aged under 16 y.o. JIA is an autoimmune disorder with the potential contribution from genetic factors and environmental exposures. Signal transduction and activation of transcription 4 (STAT4) gene and interferon regulatory factor 5 (IRF5) are the common set of susceptibility genes in many autoimmune disorders.

**Objectives:** To study STAT4 rs7574865 G/T and IFR5 rs2004640G/T gene polymorphisms impact on JIA susceptibility among Russian children.

**Methods:** The study included 177 subjects, 66 JIA cases and 111 healthy volunteers (the control group). Mean age of JIA patients was  $11.7\pm 4.2$  y (3–17 y), mean disease duration was  $4.8\pm 3.8$  y. All JIA patients were on the record at V. A. Nasonova Research Institute of Rheumatology, meeting ILAR-2001 criteria for JIA diagnosis. JIA group was comprised of 30 (45%) patients with oligoarthritis (oligo-JIA), 20 (30%) patients with polyarthritis (poly-JIA) and 16 (24%) patients with systemic onset arthritis (SoJIA). Oligo-JIA subgroup included 20 (67%) HLA-B27-seropositive patients (JIA-B27), and 10 (34%) patients with anterior uveitis (JIA-uveitis). The variables used for patients classification were: sex (44 girls and 22 boys); disease duration:  $\leq 4$  years - 34 (51%) patients and  $>4$  years - 32 (49%) patients; the number of joints involved:  $\leq 4$  - 29 (44.0%) and  $>4$  - 37 (56.0%);

positive antibody titers to nuclear antigens (ANA) - 26 (39%) patients. STAT4 and IFR5 genes polymorphism was studied using real time PCR.

**Results:** There was no significant difference between JIA and healthy volunteers in the incidence of various genotypes and alleles in the studied range of polymorphisms. The only significant difference was found between the rates of T STAT4 allele in oligo-JIA group and T allele in the control group (38% and 20.4%, respectively,  $p=0.006$ ). Similar differences with the controls in T allele rates were observed in JIA-B27 and JIA-uveitis subgroups (35% and 45% vs 20.4%  $p=0.044$  and  $p=0.021$ , respectively). Therefore, carriers of T STAT4 allele demonstrate high JIA susceptibility as compared to healthy subjects (OR 2.43 95% CI (1.23–4.70),  $p=0.007$ ). The risk in JIA-B27 and JIA-uveitis was (OR 2.10 95% CI (0.38–4.60),  $p=0.070$  and OR 3.19 95% CI (1.09–9.06),  $p=0.021$ , respectively). There was no specific association between studied gene polymorphisms and increased JIA susceptibility depending on sex, disease duration, number of joints involved and ANA status.

**Conclusions:** Obtained data confirm the specific role of STAT4 rs7574865 G/T polymorphism as the susceptibility factor to oligo-JIA associated with uveitis, HLA-B27 in Russian paediatric population.

**THU0591 SERUM 25 OH VITAMIN D IN PAEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS: IN RELATION TO DISEASE ACTIVITY, DURATION AND BONE MINERAL DENSITY**

M.H. Abu-Zaid<sup>1</sup>, H.H. Abdelnabi<sup>2</sup>, A.M. El-Barbary<sup>1</sup>. <sup>1</sup>Rheumatology and Rehabilitation; <sup>2</sup>Pediatric, Faculty of Medicine, Tanta University, Egypt, Tanta, Egypt

**Background:** Vitamin D has immunomodulatory effects and is commonly deficient in Paediatric SLE (pSLE) so associated with the disease activity and low bone density<sup>1,2</sup>

**Objectives:** To assess serum level of 25(OH)vitamin D in paediatric lupus patients and correlate it with disease activity, duration and bone density

**Methods:** A retrospective cohort study conducted on 90 patients with pSLE classified into three groups (30 patients in each) according to disease activity and duration. Group I (Initial active patients), group II (relapsing active patients) and group III (inactive patients), compared with 60 healthy children as controls (group IV). Disease and drugs duration, present steroid dose, medications' history and SLEADI for disease activity were evaluated. CBC, serum C3, C4, 24 hour urinary proteins, anti-dsDNA, Ca, P, PTH, 25(OH) D levels and lumbar spine BMD Z score were measured. Vitamin D levels were correlated with clinical, laboratory and radiological parameters.

**Results:** There were significant differences in mean 25(OH) D concentration between the patients' groups (I= $15.37\pm 5.72$ , II= $17.70\pm 4.88$ , III= $26.98\pm 6.59$  ng/ml) and controls= $35.90\pm 9.66$  ng/ml ( $p<0.05$ ), with significant difference between active groups (I, II) and inactive group III ( $p<0.05$ ). Lumbar spine Z-score was significantly different between groups (I:  $-0.39\pm 0.81$ , II:  $-1.58\pm 1.12$ , III:  $-0.99\pm 0.89$ , IV:  $0.58\pm 0.71$ ). There were significant negative correlations between serum 25(OH) D and SLEADI ( $r = -0.545$ ,  $p = 0.001$ ), steroid dose ( $r = -0.561$ ,  $p = 0.001$ ), anti-dsDNA ( $r = -0.685$ ,  $p = 0.006$ ), 24 hr-proteinuria ( $r = -0.738$ ,  $p = 0.001$ ) and PTH ( $r = -0.335$ ,  $p = 0.001$ ), significant positive correlations between 25(OH) D and C3 ( $r = 0.617$ ,  $p = 0.001$ ), C4 ( $r = 0.544$ ,  $p = 0.001$ ) and serum Ca ( $r = 0.424$ ,  $p = 0.001$ ) with non-significant correlations between 25(OH) D and disease duration, steroids' duration, serum P and Z scores ( $p>0.05$ ).

**Abstract THU0591 – Table 1.** different correlations in this study

Pearson Correlation	25(OH) Vit D	
	(r)	(P value)
SLEADI	-0.545	0.001*
Steroid dose	-0.561	0.001*
Anti-dsDNA	-0.685	0.006*
24 hr-proteinuria	-0.738	0.001*
PTH	-0.335	0.001*
C3	0.617	0.001*
C4	0.544	0.001*
Ca	0.424	0.001*
Disease duration	-0.215	0.080
Steroid duration	-0.089	0.363
Z-score	0.084	0.431
P	0.154	0.092

**Conclusions:** Vitamin D deficiency is common in pSLE and is considered a risk factor for the disease occurrence as it is correlated significantly with the disease activity not duration.

**THU0592** PUBERTAL DELAY DESPITE INTENSIVE TREATMENT OF JUVENILE IDIOPATHIC ARTHRITIS: RESULTS OF A LONGITUDINAL STUDY

P. Van Pelt<sup>1,2</sup>, A. Hokken-Koelega<sup>3</sup>, R. Dolhain<sup>4</sup>, A. Kruijze<sup>5</sup>, H. Bijlsma<sup>5</sup>, N. Wulffraat<sup>2</sup>. <sup>1</sup>Rheumatology and paediatric rheumatology, Erasmus Medical Centre Rotterdam, Rotterdam; <sup>2</sup>Paediatric immunology and rheumatology, University Medical Centre Utrecht, Utrecht; <sup>3</sup>Paediatric endocrinology; <sup>4</sup>Rheumatology, Erasmus Medical Centre Rotterdam, Rotterdam; <sup>5</sup>Rheumatology, University Medical Centre Utrecht, Utrecht, Netherlands

**Background:** Delayed puberty and reduced adult height have been reported in JIA before the era of biologicals. Long-term consequences of delayed puberty are among others growth disturbances, low bone mineral mass and decreased fertility. Treatment with anti-TNF restores growth, but data on puberty are unknown

**Objectives:** We evaluated onset and course of puberty and growth, in JIA-patients who are treated intensively, including the possibility of biologicals, and identified variables related with puberty and growth

**Methods:** In a longitudinal JIA-cohort, all consecutive patients (10–21 years) were followed for three years. Annual examinations were performed regarding demographic and disease-related items as well as Tanner pubertal stages and anthropometric measurements. Median ages at reaching each stage were estimated by Kaplan-Meier curves. Parametric tests were used to determine differences between patients and healthy controls, non-parametric tests between patient-groups. Univariate analyses and mixed models were used to identify associated variables

**Results:** 138 patients were included (66% girls). Median disease-duration was 7,8 years (IQR 3.7–10.5), median JADAS-27 3,7 (IQR 1,3–8,0), DAS-28 2,16.<sup>1,5–2,8</sup> Puberty onset was 1,2 years delayed in girls (p<0,01), in boys 0,6 years (ns). The progression was also delayed: end-stage (Tanner-5) in girls was 3,3 years delayed (p<0,01), in boys 1,7 years (p<0,01). A positive association was found for longer disease-duration and a lower BMI. Biological-use was not associated. Both for girls and boys, standardised height was not different at the onset and at the end of puberty

**Abstract THU0592 – Figure 1** Vertical. lines indicate median age of healthy population of Tanner stages

**Conclusions:** In contrast to normalised longitudinal growth, we found in JIA-patients in disease remission or with low disease activity a delayed onset and progression of puberty despite intensive treatment including biologicals. Eventually, puberty was completed and normal adult height was reached. The effects on bone mass and fertility will have to be evaluated in cohort studies

**THU0593** MULTICENTRIC OSTEOLYSIS WITH NODULOSIS AND ARTHROPATHY (MONA): REPORT OF THE FIRST LEBANESE FAMILY

R. Dagher<sup>1</sup>, E. Saliba<sup>2</sup>, M. Rizkallah<sup>2</sup>, M.C. Fadous Khalife<sup>1</sup>, A. Megarbane<sup>3</sup>. <sup>1</sup>pediatrics, Notre Dame de Secours University Hospital, Byblos; <sup>2</sup>orthopedics, Hotel Dieu de France University Hospital, Beirut, Lebanon; <sup>3</sup>medical genetics, Institut Jérôme Lejeune, Paris, France

**Background:** “Multicentric Osteolysis with Nodulosis and Arthropathy” (MONA) also known as Winchester-Torg syndrome is a rare chronic skeleton disorder caused by matrix metalloproteinase 2 (MMP2) deficiency. It is characterised by facial dysmorphism, subcutaneous fibrocollagenous nodules, carpal and tarsal osteolysis and interphalangeal joint erosions. Short stature and Osteopenia are frequent and heart defects have been described. As children first present with joint pain, swelling and stiffness, MONA is often misdiagnosed as Juvenile Idiopathic Arthritis (JIA).

**Objectives:** We report the first Lebanese family with 3 siblings presenting MONA, two of which were diagnosed at first as JIA.

**Methods:** The proband is the eldest boy born of consanguineous parents. At birth, a ventricular septal defect (VSD) was noted. At the age of 5 bone erosions and nodules in his hands and feet, and cuneiform vertebrae of unknown cause appeared. He was diagnosed with JIA. His pain partially improved with methotrexate and TNF agonist treatment; steroid injections were performed in wrists and permitted a gain in range of motion. Secondly, Osteopenia was detected.

The middle boy was examined at the age of 7; he had wrist arthritis and metacarpal tenosynovitis. He was known to have psoriasis. He was treated first with steroid injections then with NSAID and methotrexate with a good response but his condition slowly progressed to deviated fingers.

The youngest boy suffered from foot pain and Kohler disease was diagnosed at the age of 4. Soon after he developed global stiffness of the foot with erosions and nodules. He had failure to thrive and a VSD was detected.

**Results:** This family history along with the progressive coarsening of face features in the 3 siblings raised the possibility of a genetic disorder. Exome sequencing for skeletal dysplasia in the eldest boy detected a mutation in the MMP2 gene (NM\_001127891:exon2:c.8A>G:p.Y3C). The same mutation was found in the 2 other siblings.

**Conclusions:** These cases are to add to the 44 individuals coming from 27 different families, with molecularly proven MONA reported in the medical literature. This diagnosis should be raised in front of patients having resistant articular erosions with hand and feet nodules, despite anti-rheumatic drugs. Till date, no specific therapy is available and management is only supportive. In this described family, steroid injections were efficient when children presented with swelling and stiffness of joints and seemed to slow progression to erosion.

**THU0594 SHIARI-JAVADI CRITERIA FOR THE DIAGNOSIS OF GENERALISED JOINT HYPERMOBILITY IN CHILDREN**

R. Shiri, V.J. Parvaneh. *Pediatric Rheumatology, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of Iran*

**Background:** Benign joint hypermobility syndrome (BJHS) is the occurrence of musculoskeletal symptoms in hypermobile individuals in the absence of systemic rheumatologic disease.<sup>1–3</sup> One of the most common criteria for the evaluation of generalised joint hypermobility is Beighton's criteria. However, Beighton criteria were designed for all ages not specifically for children group (according to the children physiological and growth characteristics). Inability to identify limited hypermobility, failure to differentiate generalised joint hypermobility from joint hypermobility syndrome and BJHS and the restrictions on the use of epidemiological studies are further limitations.<sup>4, 5</sup>

**Objectives:** Because of the disadvantages of the existing criteria and the high prevalence of generalised joint hypermobility in children, we decided to propose further modifications to Beighton criteria for the diagnosis of joint hypermobility.

**Methods:** A case-control study was designed with 200 participants from 3 to 16 years of age with 100 children with BJH (according to Beighton criteria) in case group and 100 age-sex matched children as control group. Cases were selected from outpatients Clinic of Rheumatology and the control group was selected from the emergency department of hospital. The case group consisted of children who had musculoskeletal pain complaints or were suspected to be hypermobile. The Beighton criteria were used as the gold standard, and all of cases fulfilled the Beighton criteria. In addition, the participants in the control group should be free of chronic disease or musculoskeletal complaints. For the determination of new criteria we performed literature review on the range of motion in different age and gender paediatric groups, studied the various existing criteria and their differences, and utilised our own clinical observations. Eight manoeuvres were set for examination (Fig 1). All were bilateral, except the neck hyperextension.

**Results:** There were 42 (42%) male children in each group. The mean age was 6.8 years. Table 2 compares the results of the new and Beighton criteria in both cases and controls. All cases were hypermobile, and two of the 100 controls were hypermobile with the new criteria. Based on these results, new proposed criteria had the sensitivity, specificity, positive predictive value and negative predictive value of 100%, 98%, 100% and 98% respectively.

**Conclusions:** Shiri-Javadi criteria appears to be useful for detecting hypermobility. In addition, they have also overcome many of the disadvantages of the Beighton criteria, and are easier, more practical and more comprehensive to be used in children. However, further studies are required to validate this criteria.

**THU0595 CLINICAL AND THERAPEUTICAL DIFFERENCES BETWEEN ADULTS AND CHILDREN IN A COLOMBIAN COHORT WITH INFLAMMATORY IDIOPATHIC MYOPATHY**

R. Fuentes<sup>1</sup>, M. Cañola<sup>1</sup>, J.C. Diaz-Coronado<sup>2</sup>, A. Rojas-Villarraga<sup>2</sup>, D. Hernandez-Parra<sup>2</sup>, P. Perez-Estrada<sup>2</sup>, J.C. Salazar-Uribe<sup>3</sup>, R. Pineda-Tamayo<sup>2</sup>. <sup>1</sup>Rheumatology Department, <sup>2</sup>Clinical Research, Artmedica, <sup>3</sup>National University of Colombia, Medellin, Colombia

**Background:** Age-related autoimmunity is a key differentiating factor with diverse presentations in different age groups possibly depending on immune regulatory mechanisms. Even patients with the same diagnostic category may have different presentations according to age and other factors. Inflammatory Idiopathic Myopathies (IIM) are not the exception with important clinical and prognostic differences between adults and children.

**Objectives:** To describe the clinical and therapeutical differences between adults and children (younger than 18 m years old) in a cohort with IIM

**Methods:** A cross-section retrospective research was done with data collected between 2014 and 2017 from a population diagnosed with IIM according to Peter and Bohan criteria and followed up for at least six months. Statistical association was evaluated by means of Chi-square and Fisher's tests.

**Results:** Out a total of 149 patients, 112 were adults and 37 were children. There was significant difference between the clinical presentation of symmetrical muscle weakness 98% in adults vs 73% in children (p: 0,0001), Gottron's papules 32% vs 89% (p: 0,0001), Heliotrope rash 31% vs 62% (p: 0,0016), Calcinosis cutis 1% vs 37% (p: 0,0001), Dermatological involvement 47% vs 94% (p: 0,0001), Myopathic changes in the electromyogram 41% vs 25% (p: 0,0001), and Myopathy proven biopsy 41% vs 25% (p: 0,0001). Therapeutical options showed a significant difference in the use of steroid therapy 93% vs. 84% (p: 0,045), Methotrexate (58% vs 91% p: 0,0001), Azatioprine (62% vs 27% p: 0,0002) and Cloroquine (31% vs 73% p: 0,0001). Other therapies like Cyclophosphamide (19% vs 5% p: 0,04) and Inmunoglobulins (23% vs 5% p: 0,01) were significantly different between adults and children.

**Abstract THU0595 – Table 1.** Clinical characteristics of Colombian Patients with Inflammatory Idiopathic Myopath (Adults and Children)

	Juvenile n=37		Adults n=112		p-value
	N	%	N	%

Myopathic changes (EMG)	9/23	39,1	68/81	84,0	<,0001
Biopsy-proven myopathy (Positive)	4/16	25	46/54	41,1	<,0001
ANA(+)	14/27	51,9	65/89	73,0	0,0580

EMG, electromyogram

**Conclusions:** Several differences in the clinical and therapeutical characteristics were found between adults and children with IIM. Adults had more frequently symmetrical weakness, myopathic changes in EMG and biopsy proven myopathy. In contrast children had higher skin involvement. Calcinosis constituted an important manifestation of IIM in children. These results suggest that paediatric IIM is a distinct sub-phenotype related to the early age at onset and possibly mediated by different immune interplay key factors.

### MEASUREMENT OF SERUM CALPROTECTIN MRP8/14 IN PAEDIATRIC PATIENTS DIAGNOSED WITH JUVENILE IDIOPATHIC ARTHRITIS AND AUTOINFLAMMATORY DISEASES

S. Murias<sup>1</sup>, C. Udaondo<sup>1</sup>, R.M. Alcobendas<sup>1</sup>, A. Remesa<sup>1</sup>, D. Pascual-Salcedo<sup>2</sup>.  
<sup>1</sup>Pediatric Rheumatology; <sup>2</sup>Immunology Department, University Hospital La Paz, Madrid, Spain

**Background:** There is evidence of the correlation between serum levels of calprotectin MRP8/14 and disease activity in Juvenile Idiopathic Arthritis (JIA), but the same correlation with other rheumatic diseases in children such as autoinflammatory diseases has not been studied as much.

**Objectives:** To analyse calprotectin MRP8/14 in serum of patients with juvenile idiopathic arthritis (JIA) and various autoinflammatory diseases with different degrees of activity. To check if there is a correlation between serum MRP8/14 and disease activity.

**Methods:** Study in two phases: **1)** Initial, transversal, in JIA and/or autoinflammatory disease patients, determining serum MRP8/14 (by ELISA test) and collecting clinical data: number of active joints, Visual Analogue Scale parents/patients (VASp), VAS physician (VASph); and analytical: C-Reactive Protein (CRP) and white cells blood count (WBC) (among others). **2)** Second prospective phase, repeating the same analysis 3–6 months later. Disease activity was assessed by Juvenile Arthritis Disease Activity Score (JADAS) in AIJ; and by VASp, VASph and CRP in autoinflammatory diseases.

**Results:** The sample included 90 patients (25 males) between the ages of 1 and 21 years (median 11.1); 61 diagnosed with JIA (excluding systemic category), and 29 with different autoinflammatory diseases (including systemic JIA). 69 patients (20 males, with median age 11.2, 48 AIJ, 21 autoinflammatory) participated in the prospective phase. The main results are shown in table 1.

MRP=myeloid related proteins. JADAS=Juvenile arthritis disease activity score. ACJ=active joints count. VASm=visual analogue scale–physician. VASp=visual analogue scale–parents/patient. CRP=C reactive Protein.

**Conclusions:** In patients with non-systemic JIA, a positive correlation was found between serum MRP8/14 and JADAS, VASph, VASp, CRP, WBC, neutrophilia and (inversely) haemoglobin.

In autoinflammatory diseases positive correlation has been found with VASm, CRP, leukocytosis, neutrophilia, thrombocytosis and (inversely) haemoglobin. MRP8/14 seems to behave as a marker of activity in both JIA and autoinflammatory diseases, although with a stronger association in the latter.

### PULMONARY MANIFESTATIONS IN MIXED CONNECTIVE TISSUE DISEASE WITH JUVENILE AND ADULT ONSET – ARE THERE ANY DIFFERENCES?

S.O. Hetlevik<sup>1,2</sup>, S. Reiseter<sup>1</sup>, Ø. Molberg<sup>1,2</sup>, B. Flatø<sup>1,2</sup>, R. Gunnarsson<sup>1</sup>, T. M. Aaløkken<sup>3</sup>, M.B. Lund<sup>4</sup>, V. Lilleby<sup>1</sup>. <sup>1</sup>Rheumatology, Oslo University Hospital; <sup>2</sup>Faculty of medicine, University of Oslo; <sup>3</sup>Department of radiology and nuclear medicine; <sup>4</sup>Department of respiratory medicine, Oslo University Hospital, Oslo, Norway

**Background:** Mixed connective tissue disease (MCTD) presents in childhood in 7%–23% of cases, but there is limited knowledge about the comparability of juvenile and adult onset of the disease. A common and serious manifestation is interstitial lung disease (ILD), possibly more common in adult MCTD according to a retrospective report<sup>1</sup>.

**Objectives:** To compare disease variables in juvenile and adult onset MCTD, particularly regarding pulmonary manifestations, after long-term follow-up.

**Methods:** Two cohorts consisting of, respectively, 52 patients with juvenile onset MCTD and 90 patients with adult onset MCTD from all regions of Norway were compared. Inclusion criteria were fulfilment of the Kasukawa- or the Alarcon-Segovia criteria. Patients with onset of symptoms before the age of 18 years were considered to have juvenile onset. All patients were clinically examined, including high resolution CT and pulmonary function tests.

**Results:** Mean age at examination was 28.0 (SD 10.3) in juvenile onset, and 54.3 (SD 13.0) in adult onset MCTD (p<0.001). Age at disease onset was 14.4 (SD4.4) and 37.9 (SD 15.1) years, respectively. Patient and disease characteristics are shown in table 1.

	Juvenile onset	Adult onset	p-value
Male gender, n (%)	8 (15)	28 (24)	0.192
Disease duration from symptom onset, mean (SD)	16.2 (10.3)	17.0 (8.9)	0.766
Anti-RNP levels, median (IQR)	180 (36.0–240.0)	44.0 (7.0–237.0)	0.002
ESR, median (IQR)	8.0 (5.0 to 16.0)	11.0 (7.0–18.5)	0.048
CRP, median (IQR)	0.7 (0.5–2.5)	2.0 (0.7–4.9)	<0.001
ILD, n (%)	14 (27)	39 (43)	0.051
ILD% of TLV, median (IQR)	4.0 (1.0–8.3)	5.0 (1.8–20.0)	0.258
ILD in >20% of TLV, n (%)	1 (2)	10 (11)	0.048
DLCO% pred, mean (SD)	73.0 (12.5)	72.0 (19.4)	0.598
FVC% pred, mean (SD)	89.2 (14.7)	89.2 (20.8)	0.711
FEV1% pred, mean (SD)	89.4 (13.7)	81.2 (20.0)	0.016

Juvenile patients had higher levels of anti-RNP, but lower ESR and CRP compared to adult onset patients. ILD was found in 27% of juvenile and 43% of adult patients (p=0.051), and more adult onset patients had ILD in >20% of total lung volume (TLV). Adult onset patients had lower forced expiratory volume in 1 s (FEV1), but similar diffusing capacity (DLCO) and forced vital capacity (FVC) as the juvenile patients.

**Conclusions:** ILD tended to be more frequent in patients with adult onset MCTD than in those with juvenile onset, although not statistically significant. More patients with adult onset had affection of >20% of TLV. Juvenile and adult patients

	JIA (n=61)		Autoinflammatory diseases (n=29)

#### SAFETY OF TOCILIZUMAB IN PATIENTS AGED <2 YEARS WITH ACTIVE SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS TREATED FOR ONE YEAR

S. Wimalasundera<sup>1</sup>, I. Calvo Penades<sup>2</sup>, R. Cuttica<sup>3</sup>, H.-I. Huppertz<sup>4</sup>, R. Joos<sup>5</sup>, D. Milojevic<sup>6</sup>, M. Rosenkranz<sup>7</sup>, K. Schikler<sup>8</sup>, T. Constantin<sup>9</sup>, W. Douglass<sup>1</sup>, C. Wells<sup>1</sup>, Y. Kimura<sup>10</sup>, C. Wouters<sup>11</sup>. <sup>1</sup>Roche Products Ltd, Welwyn Garden City, UK; <sup>2</sup>Hosp Universitario y Politécnico La Fe, Valencia, Spain; <sup>3</sup>Hosp General de Niños Pedro de Elizalde, Buenos Aires, Argentina; <sup>4</sup>Professor Hess Children's Hosp, Bremen, Germany; <sup>5</sup>ZNA, Antwerp, and UZ, Gent, Belgium; <sup>6</sup>Tufts Med Ctr, Boston; <sup>7</sup>Children's Hosp Pittsburgh UPMC, Pittsburgh; <sup>8</sup>U Louisville Med School, Louisville, USA; <sup>9</sup>Semmelweis University, Budapest, Hungary; <sup>10</sup>Hackensack U Med Ctr, Hackensack, USA; <sup>11</sup>University Hosp Gasthuisberg, Leuven, Belgium

**Background:** Intravenous (IV) tocilizumab (TCZ) was approved in the, US (2011), EU (2013) and other countries for the treatment of systemic juvenile idiopathic arthritis (sJIA) patients (pts) ≥2 years of age, based on a phase 3 study WA18221.<sup>1</sup> US Food and Drug Administration approval resulted in postmarketing requirement to investigate TCZ in pts with sJIA <2 years of age (study NP25737; ClinicalTrials.gov, NCT01455701). Results from the 12 week main evaluation period (MEP) have been reported.<sup>2</sup>

**Objectives:** Report safety results after completion of the optional extension period (OEP) of NP25737 (until 52 weeks from baseline or 2 years of age, whichever was longer).

**Methods:** NP25737 was a multicenter, open-label, single-arm study to evaluate the pharmacokinetics and safety of IV TCZ, 12 mg/kg every 2 weeks, for 12 weeks in pts aged <2 years with active sJIA for ≥1 month who failed corticosteroid and nonsteroidal anti-inflammatory drug treatment and received stable background therapy during the MEP. After the 12 week MEP, pts could participate in the OEP and continue TCZ treatment (without requirement for stable background therapy). Cumulative adverse events (AEs) over the entire study period are reported.

**Results:** Seven of 11 pts enrolled in the MEP continued to the OEP and received ≥1 dose of TCZ. Over the entire study period (n=11), the median number of TCZ doses was 11 (range, 2–26) and the median duration of TCZ exposure was 22 weeks (range, 4–58). Most pts (10/11; 91%) had ≥1 AE; most were mild or moderate in intensity and unrelated to study drug. The most common AEs were upper respiratory tract infection (6/11 pts, 55%), hypersensitivity, neutropenia, rash, viral upper respiratory tract infection, and vomiting (each in 3/11 pts; 27%). Seven serious AEs occurred in 5 of 11 pts (46%): 2 in the OEP (transaminases increased and histiocytosis hematophagic), 3 in the MEP (3 hypersensitivity events), and 2 in the safety follow-up of the MEP (sJIA flare and hand-foot-and-mouth disease). AEs leading to dose modification occurred in 5 of 11 pts (1 in the MEP, 4 in the OEP) mostly because of infections, neutropenia, and elevated liver enzymes, all mild or moderate in intensity. AEs leading to withdrawal occurred in 5 of 11 pts (46%): 1 in the OEP because of serious increased transaminases, 3 in the MEP because of serious hypersensitivity reactions to TCZ, and 1 in the MEP because of thrombocytopenia. No deaths were reported during the study. AE rates per 100 pt-years of exposure are reported in the table 1.

Abstract THU0598 – Table 1. Rates of AEs

Table: Rates of AEs	TCZ 12 mg/kg IV Every 2 Weeks		
	Main Evaluation Period n = 11	Optional Extension Period n = 7	Entire Study Period n = 11
Total patient-years at risk	2.3	8.1	7.4
Number of events (AE rate per 100 patient-years at risk)			
Ave. AE	32 (1396.5)	47 (579.3)	79 (1072.7)
Serious AE	5 (216.3)	3 (370.4)	7 (945.1)
AE with fatal outcome	0	0	0
AE leading to withdrawal	4 (174.0)	1 (119.7)	5 (67.9)
AE leading to dose interruption	1 (43.6)	12 (146.5)	13 (176.5)

**Conclusions:** During the OEP of the study, long-term treatment with TCZ was well tolerated in sJIA pts aged <2 years, and no additional safety signals were reported in the OEP beyond those reported in the MEP or observed previously for pts with sJIA aged ≥2 years.

THU0599

#### EVALUATION OF EFFICACY AND SAFETY OF CANAKINUMAB IN JAPANESE PATIENTS WITH SYSTEMIC JUVENILE IDIOPATHIC ARTHRITIS IN PHASE III CLINICAL TRIAL, COMPOSED PREDOMINANTLY OF PATIENTS WITH PRIOR USE OF TOCILIZUMAB

S. Takei<sup>1</sup>, R. Hara<sup>2</sup>, H. Umebayashi<sup>3</sup>, N. Iwata<sup>4</sup>, T. Imagawa<sup>5</sup>, M. Shimizu<sup>6</sup>, M. Tomiita<sup>7</sup>, N. Seko<sup>8</sup>, T. Kitawaki<sup>9</sup>, G. Wang<sup>9</sup>, S. Yokota<sup>10</sup>. <sup>1</sup>Pediatrics, Kagoshima University Graduate School of Medical and Dental Sciences, Kagoshima; <sup>2</sup>Department of Pediatrics, Yokohama City University Hospital, Yokohama; <sup>3</sup>Department of Rheumatology and Infectious disease, Miyagi Children's Hospital, Sendai; <sup>4</sup>Department of Infection and Immunology, Aichi Children's Health and Medical Center, Obu; <sup>5</sup>Department of Infection and Immunology, Kanagawa Children's Medical Center, Yokohama; <sup>6</sup>Department of Pediatrics, Kanazawa University Hospital, Kanazawa; <sup>7</sup>Department of Allergy and Collagen disease, Chiba Children's Hospital, Chiba; <sup>8</sup>Novartis Pharma KK, Tokyo, Japan; <sup>9</sup>Novartis Pharma AG, New Jersey, USA; <sup>10</sup>Children's intractable disease rheumatism center, Fuji Toranomon Orthopedic Hospital, Gotemba, Japan

**Background:** Systemic juvenile idiopathic arthritis (SJIA) is a distinct form of juvenile idiopathic arthritis (JIA), accounting for approximately 4% to 17% of JIA<sup>1</sup>. In Japan, a higher frequency of SJIA, 41.7% of JIA<sup>2</sup> has been reported compared to Europe and United States. Tocilizumab (TCZ) is the only approved biologic for SJIA treatment in Japan. However, some patients (pts) demonstrate persistently high disease activity and/or drug intolerance. Therefore, new treatment options are required. Here, we evaluated the efficacy and safety of canakinumab (CAN), a human anti-interleukin-1β monoclonal antibody, in Japanese SJIA pts.

**Objectives:** To report the results of a 28 week (Wk) interim whole analysis of Phase III data (NCT02396212) of CAN, and the subgroup analysis of pts with or without prior use of TCZ.

**Methods:** Patients (age ≥2-<20 years) received open-labelled CAN 4 mg/kg (max 300 mg) every 4Wks (q4w) subcutaneously (s.c.). The primary objective was to evaluate the proportion of pts who achieved 30% improvement from baseline of adapted ACR Paediatric criteria (aACR 30) at Wk8 and who achieved corticosteroid tapering at Wk28. Steroid reduction was allowed from Wk8. We also analysed the data with or without prior use of TCZ.

**Results:** The trial enrolled 19 pts who had insufficient response to prior treatment; the majority (15/19, 78.9%) had received TCZ (table 1). Of the 19 pts, 3 discontinued CAN due to lack of efficacy or adverse events (AE) by Wk28 and 16 completed the assessment of Wk28. All pts (19/19) achieved aACR 30/50/70 at Wk8 (figure 1). Overall, 73.7% (14/19) pts achieved corticosteroid tapering at Wk28 and 2 pts (10.5%) achieved "steroid free". Of 15 pts with prior use of TCZ, 12 pts (80.0%) achieved aACR 100 at Wk8 and 11 pts (73.7%) achieved corticosteroid tapering (26.3%, 5/19). Serious AE (SAE) was seen in 41.1% (8/19) pts, and the most frequent SAE was JIA (flare or worsening of SJIA, 21.1%, 4/19). One macrophage activation syndrome (MAS) but no death was reported.

Abstract THU0599 – Table 1. Patient Characteristics

Characteristic	G1301 trial n=19
Male (%)	6 (31.6)
Age (mean)	9.9
BMI (kg/m <sup>2</sup> ) (mean)	19.59
Time from SJIA diagnosis to study entry (years) (mean)	6.1
CRP at baseline (standardised in mg/L) (mean)	357.79
Oral prednisone equivalent dose (mg/kg/day) (mean)	0.309
Oral steroid use at baseline - n(%)	19 (100)
Number of active joints (mean)	6.3
Number of joints with limitation of motion (mean)	4.4
Prior use of tocilizumab (%)	15 (78.9)

**Abstract THU0599** – Figure 1 Efficacy of canakinumab with adapted ACR Paediatric criteria in SJA patients with/without prior use of tocilizumab (TCZ)

**Conclusions:** CAN 4 mg/kg q4w s.c. provided improvement in disease activity and a reduction of oral steroid dose in Japanese SJA pts, including those who were not well-controlled with TCZ. No new safety concerns were reported.

#### HIGH VACCINE COVERAGE RATES ARE NOT ENOUGH: VACCINATION DELAY AND RISK FOR VACCINE-PREVENTABLE DISEASES IN PAEDIATRIC PATIENTS WITH RHEUMATIC DISEASES WITH AND WITHOUT IMMUNOSUPPRESSIVE THERAPY

T. Welzel<sup>1</sup>, T. Zumbunn<sup>2</sup>, J. Bonhoeffer<sup>3</sup>, E. Cannizzaro Schneider<sup>4</sup>, M. Hofer<sup>5</sup>, D. Kaiser<sup>6</sup>, V. Hentgen<sup>7</sup>, A. Woerner<sup>1</sup>, on behalf of Juvenile Inflammatory Rheumatism (JIR) Cohort. <sup>1</sup>*Pediatric Rheumatology, University of Basel Children's Hospital*; <sup>2</sup>*Clinical Trial Unit, University of Basel Hospital*; <sup>3</sup>*Pediatrics Infectious Diseases and Vaccines, University of Basel Children's Hospital, Basel*; <sup>4</sup>*Pediatric Rheumatology, Children's Hospital Zurich, Zurich*; <sup>5</sup>*Unité romande de rhumatologie pédiatrique, CHUV, University of Lausanne and Hôpitaux Universitaires de Genève, Lausanne*; <sup>6</sup>*Pediatric Rheumatology, Children's Hospital Lucerne, Lucerne, Switzerland*; <sup>7</sup>*Centre de référence des maladies autoinflammatoires CeRéMAI, Versailles Hospital, Versailles, France*

**Background:** Paediatric patients with rheumatic diseases (PedRD) are more susceptible to invasive infectious diseases, due to their underlying disease, high disease activity and immunosuppressive therapy (IT).<sup>1,2</sup> In Switzerland, specially indicated (SI) vaccinations for PedRD patients against pneumococcus, varicella zoster, hepatitis B, influenza and human papilloma virus should be administered as early as possible. On-time and complete coverage reduces the risk of vaccine-preventable infections<sup>3</sup> and its associated morbidity. Information about on-time vaccination is scarce, especially in PedRD patients.

**Objectives:** To assess the relationship of vaccine coverage and on-time vaccination in PedRD patients in Switzerland with and without IT.

**Methods:** Multicenter retrospective prevalence study based on the Juvenile Inflammatory Rheumatism (JIR) cohort, an international registry for rheumatic diseases. Patients treated in Swiss paediatric rheumatology centres (Basel, Geneva, Lausanne, Lucerne, Zurich) were included. Vaccine coverage and timeliness of administered vaccines were assessed for routine and for SI vaccinations according to the Swiss Federal Office of Public Health.

**Results:** 239 patients were included. 93 (39%) received IT during a median observation period of 2.7 years (IQR 1.1–5.4). Median age was 6.7 years (IQR 2.9–10.3) at diagnosis, 10.9 years (IQR 7–14.3) at reference date (12th April 2016). At diagnosis, 185 patients (77%) had complete routine vaccine coverage; 76 (32%) fulfilled Swiss on-time immunisation criteria. At reference date, the routine vaccine coverage rate decreased to 74% with on-time vaccination achieved in 29% of PedRD patients without IT and in 23% with IT, respectively. Completeness of SI vaccinations was documented in 19 PedRD patients (13%) without IT and 6 patients (6.5%) with IT. On-time vaccination for SI vaccination was fulfilled in 7 patients without IT; no patient with IT was vaccinated on-time. Only 23 (9.6%)

patients showed complete and thereof 4 (1.6%) on-time vaccination status for routine and SI vaccinations.

**Conclusions:** Despite moderate to high routine vaccination coverage in Switzerland, vaccinations particularly recommended for PedRD patients to prevent from complications, are incompletely administered. Moreover, the high frequency of delayed vaccination implicates a potential increase of vaccine-preventable disease. Close surveillance of vaccination status improves standard of care for this susceptible population.

#### CARRIER RATE OF FAMILIAL MEDITERRANEAN GENE (MEFV) MUTATION IN PARENTS OF CHILDREN WITH FAMILIAL MEDITERRANEAN FEVER

V. Ziaee<sup>1,2</sup>, Y. Aghighi<sup>3</sup>, L. Shahbaznejad<sup>4</sup>, S.-R. Raeeskarami<sup>5</sup>, F. Tahghighi<sup>3</sup>, A. Shakoori<sup>6</sup>, H.R. Ajeedeh<sup>7</sup>. <sup>1</sup>*Pediatric Rheumatology Research Group, Rheumatology Research Center*; <sup>2</sup>*Pediatrics*; <sup>3</sup>*Pediatrics, Tehran University of Medical Sciences, Tehran*; <sup>4</sup>*Department of Pediatrics, Mazandaran University of Medical Sciences, Sari*; <sup>5</sup>*Pediatric*; <sup>6</sup>*Genetic, Tehran University of Medical Sciences*; <sup>7</sup>*Imam Khomeini Hospital, Tehran University of Medical Sciences, Tehran, Iran, Islamic Republic of Iran*

**Background:** Familial Mediterranean Fever (FMF) is one of the most prevalent periodic fever syndromes, MEFV, the responsible gene for the disease is in the short arm of chromosome 16. In the considerable count of the FMF patients, only one mutation is found in the MEFV, and parents who was the obligatory carriers for that mutation, were asymptomatic.

**Objectives:** The aim of this study was to evaluate these asymptomatic parents in regard to mutation in MEFV gene and similarity between parents and offspring patients.

**Methods:** In this cross sectional study, asymptomatic parents of FMF patients enrolled the study, which were referred to periodic fever clinic or paediatric rheumatology clinic of Tehran University of medical sciences. The patients should have at least one mutation in MEFV gene and none of them had any family history of auto inflammatory disease. Twelve mutations in MEFV gene was assessed in the parents by Vienna Lab FMF Strip Assay kit by MAS PCR/Reverses hybridization.

**Results:** Forty three patients and their parents participated in the study. Sixty three percent<sup>27</sup> of patients were male. Onset of disease symptoms in 31 patients (72%) were before 4 years of old. Nine (21%) of the patients were homozygote, 16 (37%) compound heterozygote and 17 (40%) heterozygote for MEFV mutation, there was a case of complex alleles mutations (2%). M694V/M694V in 4 patients (9%) was the most homozygote genotype, M694V/R761H in 4 (9%) and E148Q in 7 (16%) were the most compound heterozygote and heterozygote genotype, respectively. M694V, M680I and E148Q were the most mutation in the parents. Overall, 41 patients, had mutations similar to their parents' mutation, except in 2, which parents had not mutation, but patient did.

**Conclusions:** It seems that occurrence of new mutations in offspring is not prevalent among FMF patients, and there are other reasons for different clinical presentation in similar mutation carriers. On the other hand, in ethnicities with high prevalence of FMF, new mutation in descendant may occurs, infrequently.

**Acknowledgements:** This research was part of a Fellowship thesis (of Dr. L. Shahbaznejad) and it was approved and financially supported by a grant from Tehran University of Medical Sciences (No: 93–11–46–5001). The authors would like to thank parents who participated in the study.

### TARGETING GENERATION Z: DEVELOPMENT AND VALIDATION OF AN ILLUSTRATED TRANSITION READINESS QUESTIONNAIRE FOR ADOLESCENTS WITH JUVENILE IDIOPATHIC ARTHRITIS

H. Lotfy<sup>1</sup>, M. El Gaafary<sup>2</sup>, N. El Aroussy<sup>3</sup>, D. Mekkwaw<sup>3</sup>, Y. Farag<sup>1</sup>, Y. El Miedany<sup>3,4</sup>, on behalf of PRINTO Egypt. <sup>1</sup>*Pediatrics, School of Medicine Cairo University*; <sup>2</sup>*Community and Public Health*; <sup>3</sup>*Rheumatology and Rehabilitation, School of Medicine Ain Shams University, Cairo, Egypt*; <sup>4</sup>*Rheumatology, Darent Valley Hospital, Dartford, UK*

**Objectives:** To develop, validate and implement a transition readiness assessment tool to be completed by adolescents living with juvenile idiopathic arthritis.

**Methods:** Cross sectional, quantitative multicenter study. Patients with juvenile idiopathic arthritis aged 14 years or older were included. The assessment tool, designed to be self-administered, is divided into 4 domains: medical, psychosocial, emotional/cognitive, and academic. The medical domain assesses managing medications, booking appointments, disease literacy, self-management, and organ screening. The psychosocial domain assesses the adolescents' understanding of information related to adult rights, talking to providers as well as child motivation. Emotional concerns related to transition, self-advocacy skills, and completion of a personal health record. The academic domain assesses whether the adolescent is meeting school graduation requirements, able to verbalise an educational/job training plan and on track with future planning (eg, completed required testing). Items within each domain have equal value (ie, each question on the checklist is worth 1 point) and the sum of points yields the quantifiable assessment of how well patients are performing in each area of their health. Assessment meetings occur monthly when eligible patients are discussed. The questions are supported with illustrations explaining every answer. The tool was available in both paper and electronic formats. The children were also asked to rate the comprehensibility of the questionnaire on 0–10 numeric VAS. Sociodemographic, clinical as well as motivation scores were recorded.

**Results:** A total of 104 patients participated. The majority of patients (95.8%) understood the questionnaire and completed it correctly, in self-administered modality. Mean comprehensibility score was 9.3±0.2. Mean completion time was 6.2 min, with little or no help (78%). Children from low income families or those who had lower education level for their age needed more help. Internal consistency (Cronbach's alpha) for each domain score were 0.872, 0.861, 0.892, and 0.884 respectively. Construct validity was demonstrated by testing different hypotheses ( $p < 0.01$ ).

**Conclusions:** The developed illustrated questionnaire was a valid, patient-centred questionnaire which can be used by the paediatricians/rheumatologists to assess the level of preparedness of adolescents with JIA during planning for adult transition. The questionnaire gives information regarding the adolescents' ability to make appointments, attend their consultations, understand their treatment and to develop other skills required for transition to adult care. The questionnaire can be used to identify aspects in which the adolescent need education or training to achieve independence in transition-relevant skills. The questionnaire can be used also to set goals for the achievement of skills that will help adolescents manage their health and health care into adulthood. Implementing the questionnaire in the standard practice has the potential to improve transition assessment and support as well as improve health outcomes during healthcare transition for adolescents with inflammatory arthritic conditions.

### DISEASE MODIFYING ANTI-RHEUMATIC DRUGS IN JUVENILE IDIOPATHIC ARTHRITIS: MOVING TOWARDS TARGETED INDIVIDUALISED TREATMENT STRATEGY

S.I. Nasef<sup>1</sup>, G. El Deriny<sup>2</sup>, M. Eissa<sup>3</sup>, M.A. Mortada<sup>4</sup>, W. Hassan<sup>5</sup>, D. Mekkwaw<sup>6</sup>, Y. El Miedany<sup>6,7</sup>. <sup>1</sup>*Rheumatology and Rehabilitation, School of Medicine, Suez Canal University, Ismailia*; <sup>2</sup>*Pediatrics, School of Medicine Alexandria University, Alexandria*; <sup>3</sup>*Rheumatology and Rehabilitation, School of Medicine Cairo University, Cairo*; <sup>4</sup>*Rheumatology and Rehabilitation, School of Medicine Zagazig University, Zagazig*; <sup>5</sup>*Rheumatology and Rehabilitation, School of Medicine Banha University, Banha*; <sup>6</sup>*Rheumatology and Rehabilitation, School of Medicine Ain Shams University, Cairo, Egypt*; <sup>7</sup>*Rheumatology, Darent Valley Hospital, Dartford, UK*

**Background:** Despite the expansion in the number of medications available in the treatment of juvenile idiopathic arthritis (JIA), inter-individual variation in therapeutic response and drug-associated toxicities continue to be a major concern and has driven efforts towards individualised therapy. Recent advances in paediatric treatment strategies and guidelines, as well as innovative approaches to identify a priori predictors of drug response, hold the promise for an individualised approach to therapy that will yield the highest efficacy and safety potential for each JIA patient.

**Objectives:** To determine whether baseline demographic, clinical, articular, laboratory variables and adherence to therapy may act as predictors of good response to DMARDs therapy in JIA.

**Methods:** Patients with JIA treated with DMARDs (methotrexate (MTX), leflunomide (LEF) or combination of MTX and LEF) were recruited for this study. Juvenile arthritis disease activity score (JADAS-27) was calculated at 3, 6 and 12 months. Multivariate logistic regression analysis was used to identify predictors of good response according to JADAS-27 score, development of deformities and extra-articular manifestations (uveitis).

**Results:** A total of 114 children were included in this study. The majority of patients were females 91 (79.8%). Mean age was 11.97±3.26 years; mean age at disease onset was 8.19±3.46 years whereas mean disease duration was 3.68±2.89 years. The most common ILAR subtype was polyarthritis RF negative (50.9%), Polyarticular RF positive (21%), oligoarticular extended (14.9%), oligoarticular persistent (7.9%) and systemic type (5.3%). Over half of the patients were on MTX (55.3%), and (34.2%) were using combined MTX and LEF while (10.5%) of patients were on LEF monotherapy. Mean MTX dose was 12.9±3.4 mg/week, and mean LEF dose was 16.67±4.78 mg/day. Prevalence of positive RF was 24/114 (21.05%). Anti-nuclear antibody (ANA) was detected in 20/114 (17.5%) of patients. 10.5% of patients had chronic anterior uveitis. At baseline, joint deformities were present in (13.1%) of patients. After one-year follow up (45.6%) of patients achieved remission while (27.1%) reached a state of low disease activity. Multivariate logistic regression analysis revealed that the most important predictors of JADAS-27 remission/low disease activity status were: Short disease duration <6.1±0.4 months (OR 1.93), polyarticular disease subtype, Childhood Health Assessment Questionnaire (CHAQ) disability index <2.125 (OR 1.75), absence of joint damage/deformities (OR 1.92). A short duration of NSAIDs therapy (<3 months) before moving to MTX therapy as well as from MTX to combination of MTX and LEF therapy (<4 months) were associated with the targeted disease activity status (OR 1.76 and 1.95 respectively). Adherence to therapy was also a predictor of good response (OR 1.86). 15.4% of patients did not achieve the disease activity target and received biologic therapy.

**Conclusions:** The subgroup of JIA patients with polyarticular disease onset, shorter disease duration, rapid optimisation/escalation of DMARDs therapy as well as those who were adherent to therapy were significantly associated with a good response to DMARDs therapy.

**Disclosure of Interest:** None declared

### JUVENILE INFLAMMATORY ARTHRITIS: THE DEVELOPMENT AND VALIDATION OF AN ILLUSTRATED QUESTIONNAIRE TO MEASURE CHILDREN'S MOTIVATION

Y. El Miedany<sup>1,2</sup>, H. Lotfy<sup>3</sup>, N. El Aroussy<sup>2</sup>, D. Mekkwaw<sup>2</sup>, S.I. Nasef<sup>4</sup>, W. Hassan<sup>5</sup>, M. Eissa<sup>6</sup>, G. El Deriny<sup>7</sup>, S. Almedany<sup>8</sup>, Y. Farag<sup>3</sup>, M. El Gaafary<sup>9</sup>, on behalf of PRINTO Egypt. <sup>1</sup>*Rheumatology, Darent Valley Hospital, Dartford, UK*; <sup>2</sup>*Rheumatology and Rehabilitation, School of Medicine Ain Shams University*; <sup>3</sup>*Pediatrics, School of Medicine Cairo University, Cairo*; <sup>4</sup>*Rheumatology and Rehabilitation, School of Medicine Suez Canal University, Ismailia*; <sup>5</sup>*Rheumatology and Rehabilitation, School of Medicine Banha University, Banha*; <sup>6</sup>*Rheumatology and Rehabilitation, School of Medicine Cairo University, Cairo*; <sup>7</sup>*Pediatrics, School of Medicine Alexandria University, Alexandria*; <sup>8</sup>*Rheumatology and Rehabilitation, School of Medicine Tanta University, Tanta*; <sup>9</sup>*Community and Public Health, School of Medicine Ain Shams University, Cairo, Egypt*

**Background:** Self-determination theory (SDT) is a macro theory of human motivation and personality that concerns people's inherent growth tendencies and innate psychological needs. SDT is concerned with the motivation behind choices people make without external influence and interference. JIA disrupts a child's sense of normality and impairs his or her motivation capacity. Children with JIA have a sense of being misunderstood and stigmatised, and they feel perpetually caught between having hope and control over their bodies and overwhelming pain and despair. To increase their confidence and the ability to manage pain, children need ongoing information about treatments, lifestyle management, and active involvement in their own health decision making.

**Objectives:** To develop a questionnaire for evaluating the "motivation" amongst children living with inflammatory arthritic conditions and assess the psychometric properties of that measure.

**Methods:** Based on content analysis and semi structured group discussion as well as Rasch analysis, ten domains were identified and used as a frame for an expert consensus and patient focus groups. The questionnaire was developed including: 10-items scale (0–10 on VAS scale). A mean score is calculated across all items. The total score ranged from 0–10. Each item was supported by illustrations explaining both ends of the measure. The questionnaire was formatted, one copy for adolescents and another copy was directed for the parents of younger children. Construct validity was assessed by correlating the score of the questionnaire to disease activity scores (JADAS-27, SLEDAI-2K, ASDAS-CRP);

measures of functional disability, quality of life, patient self-helplessness measure as well as the patients' adherence to therapy. Reliability and comprehensibility and sensitivity to change were also assessed.

**Results:** The questionnaire was assessed in 71 children with JIA, 32 with enthesitis related arthritis and 34 with cSLE. Results revealed that the developed illustrated questionnaire mean score correlated significantly with disease activity measures: JADAS-27:  $r=-0.87$ ; ASDAS-CRP:  $r=-0.85$ , SLEDAI-2K:  $r=-0.86$  reflecting its validity. It also correlated significantly with the scores of functional disability:  $r=-0.89$ , QoL:  $r=-0.88$  as well as patient self-helplessness  $r=-0.91$ . The questionnaire was reliable (Cronbach's alpha 0.926 and had no misfitting items. The illustrations were well received and this was reflected on the questionnaire comprehensibility (9.5) and sensitivity to change ( $p<0.01$ ). The patient motivation score showed significant ( $p<0.01$ ) correlation with adherence to therapy.

**Conclusions:** The illustrated children motivation measure, is a patient-centred unidimensional scale that is valid, reliable and comprehensible. The measure has good psychometric properties indicating that it can be used at the individual child's level to tailor management and monitor changes in response to therapy. The illustrations enhanced the questionnaire perception by the children as well as the parents.

#### THU0605 FACILITATING PATIENT CENTRED CARE: THE DEVELOPMENT OF ILLUSTRATED MULTIDIMENSIONAL PATIENT REPORTED OUTCOME MEASURE FOR CHILDREN WITH JUVENILE IDIOPATHIC ARTHRITIS

Y. El Miedany<sup>1,2</sup>, H. Lofly<sup>3</sup>, N. El Aroussy<sup>2</sup>, D. Mekkawy<sup>2</sup>, S.I. Nasef<sup>4</sup>, W. Hassan<sup>5</sup>, G. El Deriny<sup>6</sup>, Y. Farag<sup>3</sup>, M. Eissa<sup>7</sup>, S. Almedany<sup>8</sup>, M. El Gaafary<sup>9</sup>, on behalf of PRINTO Egypt. <sup>1</sup>Rheumatology, Darent Valley Hospital, Dartford, UK;

<sup>2</sup>Rheumatology and Rehabilitation, School of Medicine Ain Shams University; <sup>3</sup>Pediatrics, School of Medicine Cairo University, Cairo; <sup>4</sup>Rheumatology and Rehabilitation, School of Medicine Suez Canal University, Ismailia; <sup>5</sup>Rheumatology and Rehabilitation, School of Medicine Banha University, Banha; <sup>6</sup>Pediatrics, School of Medicine Alexandria University, Alexandria; <sup>7</sup>Rheumatology and Rehabilitation, School of Medicine Cairo University, Cairo; <sup>8</sup>Rheumatology and Rehabilitation, School of Medicine Tanta University, Tanta; <sup>9</sup>Community and Public Health, School of Medicine Ain Shams University, Cairo, Egypt

**Background:** The advances in paediatric rheumatology management have mandated a drastic change in the way children with juvenile arthritis are assessed and monitored. As a consequence, there has been a call for new outcome measures that reflect a more holistic approach to day to day standard management. Such an emphasis reflects contemporary views about the relation between mind and body, and acknowledges the critical link between physical and psychological health as well as adherence to therapy amongst the children living with inflammatory arthritis.

**Objectives:** To assess validity; reliability and responsiveness to change of an illustrated child/parent Multidimensional Patient Reported Outcome Measures questionnaire which can assess construct outcome measures of children with juvenile inflammatory arthritis.

**Methods:** 106 children with juvenile inflammatory arthritis were included in this work in a multicentre study. The questionnaire was developed by integrating information obtained from children living with JIA as well as their parents. The questionnaire included 5 main categories which are patient-centred: 1. Health related quality of life: functional ability (children health assessment questionnaire) and quality of life (10-items reflecting psychological, social, school and behavioural issues as well as the patient's own perception). 2. Disease activity measure: pain intensity, the child's overall well-being, measure of fatigue and morning stiffness using (0–10 numerical visual analogue scale), 3. self-reported joint tenderness and swelling. 4. Current medication, side effects as well as adherence to therapy (2 questions using 0–10 numerical visual analogue scale); 4. Comorbidities as well as 5. Patient motivation. All the items were supported by illustrations to explain the question and make it easier to understand. The questionnaire has parent and patient versions. The disease activity status was assessed using JADAS-27.

**Results:** The questionnaire was reliable as demonstrated by a high-standardised alpha (0.890–0.978). The questionnaire items correlated significantly ( $p<0.01$ ) with clinical parameters of disease activity. The patient reported tender joints correlated significantly with the physician's scores (0.842). Changes in functional disability, quality of life as well as the motivation score showed significant variation ( $p<0.01$ ) with diseases activity status in response to therapy. The illustrated PROMs questionnaire showed also a high degree of comprehensibility (9.6).

**Conclusions:** Integrating patient reported outcome measures into standard clinical practice is feasible and applicable. This version of illustrated multidimensional questionnaire was found to be valid and reliable. It provides informative quantitative measure for the disease activity core set data, and in the meantime, facilitates

assessing the children's health related quality of life measure, adherence to therapy, comorbidities as well as motivation on individual basis.

#### THU0606 EFFECT OF INTERLEUKIN-1 ANTAGONISTS ON THE QUALITY OF LIFE IN FAMILIAL MEDITERRANEAN FEVER PATIENTS

Ö. Varan<sup>1</sup>, H. Küçük<sup>2</sup>, H. Babaoğlu<sup>1</sup>, N. Atas<sup>1</sup>, H. Sats<sup>1</sup>, R. Bilici Salman<sup>1</sup>, A. Tufan<sup>1</sup>, B. Göker<sup>1</sup>, S. Haznedaroğlu<sup>1</sup>, M.A. Öztürk<sup>1</sup>. <sup>1</sup>Rheumatology, Gazi University, Ankara; <sup>2</sup>Rheumatology, Education and Training Hospital, erzurum, Turkey

**Background:** Familial Mediterranean Fever (FMF) is characterised by febrile inflammatory painful attacks of peritonitis, pleuritis, arthritis and erythema. Colchicine is the mainstay of treatment in FMF but about 10% of patients do not respond well to colchicine. IL-1 antagonists have been shown to be effective in the prevention of attacks in colchicine resistant FMF (crFMF) patients. Herein we investigated effect of these agents on quality of life of crFMF patients.

**Objectives:** to investigate effect of IL-1 antagonists on quality of life of crFMF patients.

**Methods:** Data is derived from Gazi FMF cohort which was established in year 2010. Since then data of patients with FMF who were diagnosed according to the Tel Hashomer criteria were registered. Co-morbidities, detailed attack characteristics, treatments, laboratory parameters and impact of FMF on their life in terms of quality of life were recorded. A retrospective cohort analysis was made from records of patients who were treated with IL-1 inhibitors. SF-36 form was filled before and 3 months after the IL-1 antagonist treatment. Wilcoxon test was used for the analyses and a p value equal or less than 0.05 is considered as statistically significant.

**Results:** there were 41 patients (24 women and 17 men). Anakinra was used in 33 patients and 8 patients received canakinumab. There was a statistically significant reduction in the frequency, severity and the duration of attacks after treatment with IL-1 antagonists ( $p<0.001$ , for each). A statistically significant improvement was observed in all domains of SF-36 (figure 1).

Figure. The change of SF-36 parameters before and after treatment

**Conclusions:** IL-1 inhibitor therapy reduces frequency, severity and duration of attacks and significantly improves the quality of life of crFMF patients.

#### THU0607 AUTOINFLAMMATORY SYNDROMES: CLINICAL AND GENETIC CHARACTERISATION OF A COHORT OF ADULT PATIENTS IN A SINGLE REFERENCE CENTRE

A. Ruiz Roman<sup>1</sup>, S. Garcia Morillo<sup>2</sup>, M.A. Montes Cano<sup>3</sup>, M. Lisbona Muñoz<sup>1</sup>, C. Aguilera Cros<sup>1</sup>, A. Muñoz Jimenez<sup>1</sup>, E. Rubio Romero<sup>1</sup>. <sup>1</sup>Reumatología; <sup>2</sup>Medicina Interna; <sup>3</sup>Inmunología, Hospital Universitario Virgen del Rocío, Sevilla, Spain

**Background:** Autoinflammatory syndromes are diseases that are characterised by increased inflammation mediated by cells and molecules of the innate immune system. Currently, new techniques have been developed that allow earlier diagnosis and treatment of these pathologies.

**Objectives:** Describe the clinical characteristics, genetic variants of different autoinflammatory diseases of a cohort of adult patients with follow-up in a 3rd level hospital

**Methods:** We carried out a descriptive cross-sectional study of adult patients with follow-up in reference hospital consultations with suspicion and/or diagnosis of autoinflammatory disease. Clinical, demographic, and treatment variables were characterised. A descriptive analysis was carried out by subgroup of pathology. The qualitative variables were expressed in frequency and percentages and the quantitative variables in median and interquartile range (IQR). The statistical software IBM SPSS v.18 was used for the analysis

**Results:** A total of 51 patients were included, 31 women (60.8%). Overall, the median age at diagnosis was 28 years (RI 15–40). The most used treatment was colchicine (60.8%), steroids (43.1%), FAMES (21.6%), anti IL-1 (17.6%). By subgroup of pathologies the most prevalent with 31 cases (60.78%), 16 women (51.6%) was familial Mediterranean fever (FMF) presenting 15 patients (48.4%) pathogenic mutations, 8 patients (25, 8%) low penetrance mutations and the rest (25.8%) genetic polymorphisms. The median age at diagnosis was 30.6 years (IQR16–44). The most common symptoms were fatigue (80.6%), acute phase reactants (APR) elevation (71%), fever and myalgias (67.7%), arthralgias (64%), abdominal pain (48.4%), rash (31%), arthritis (29%), lymphadenopathy (29%), serositis (12.9%)

With regard to TRAPS, 10 patients were diagnosed (19.6%), 7 women (70%), with a median age at diagnosis of 26.5 years (IQR 15–31.5). The most common symptoms were arthralgias, fatigue and myalgias (90%) with elevated APR, fever (80%), abdominal pain (70%), rash (60%) and arthritis (50%). There were 2 cases of women (4%) with Schnitzler syndrome, with arthritis symptoms, elevated APR and chest pain (in 1 case). There were 6 cases (11.8%) of disease associated with NOD 2 gene with a median age at diagnosis of 30 years (IQR 12.5–40), 4 were women (66.7%). The most common symptoms were arthralgias, fever and myalgias (83.3%) with increased APR, arthritis (66.7%), abdominal pain, oral thrush and rash (66.7%).

In the disease associated with NLRP12 gene there were 2 cases (3.9%), both cases were women. The most common symptoms were arthralgias, arthritis, fever, fatigue, increased APR and serositis (in one case). There was a case of sickness associated with the NLRP3 gene (cryopyrinopathy) (2%) in a woman with fever and refractory pyoderma gangrenosum and another woman with a diagnosis of Muckle-Wells (2%) with clinical signs of deafness since childhood, conjunctivitis, fever and arthritis. There was a case of PFAPA (2%) in a woman with fever, pharyngitis, rash and lymphadenopathy.

**Conclusions:** In our series, the most frequent pathology was FMF followed by TRAPS. The most prevalent symptoms were systemic manifestations (fever, fatigue, APR elevation) and musculoskeletal manifestations.

THU0608

#### THE RELATIONSHIP BETWEEN SERUM SOLUBLE KLOTHO, FGF-23 LEVELS AND FLOW-MEDIATED DILATATION (FMD) IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER (FMF)

M. Çelik<sup>1</sup>, F. Candan<sup>2</sup>, M.E. Derin<sup>3</sup>, I. Karadağ<sup>3</sup>, M. Timuçin<sup>2</sup>, H.O. Doğan<sup>4</sup>, A. C. Urhan<sup>3</sup>, M. Şahin<sup>4</sup>, A. Şahin<sup>3</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Internal Medicine – Nephrology; <sup>3</sup>Rheumatology – Internal Medicine; <sup>4</sup>Biochemistry, Cumhuriyet University Medical Faculty, Sivas, Turkey

**Background:** Familial Mediterranean fever (FMF) is a disease having inflammatory attacks.<sup>1</sup> Systemic inflammation has an important role in the etiology of endothelial dysfunction. Fibroblast Growth Factor 23 (FGF-23) is expressed by osteoblasts and needs serum soluble klotho. FGF-23 provides phosphate regulation. Increased FGF-23 is associated endothelial dysfunction.<sup>2</sup> An invasive way of measuring endothelial dysfunction is Flow-Mediated dilatation (FMD).<sup>3</sup>

**Objectives:** To investigate the possible relationship between FGF23, serum soluble klotho levels and FMD in patients with FMF and healthy subjects.

**Methods:** Between March 2017 - September 2017, sixty -FMF patients that following-up at Cumhuriyet University Medical Faculty Rheumatology-Internal Medicine Department and thirty healthy volunteers were included into the study. Blood samples were taken from all participants and serum soluble klotho, FGF23 values were measured. Clinical findings of all patients were recorded. Blood tests were examined by Elisa method in Cumhuriyet University Department of Biochemistry. FMD assessed by Doppler ultrasound in all participants.

**Results:** Mean serum FGF 23 level was measured as 221.01 pg/ml pg in FMF group and 99.4 pg/ml in healthy control (HC) group. There was statistically significant difference between two groups (p<0.05). The mean serum levels of serum soluble Klotho was measured as 3.0 pg/ml FMF group and 8.25 pg/ml in the HC group. There was statistically significant difference between the two groups (p<0.05) (figure 1). The mean percentage of FMD was measured as 10.1 in FMF group and 13.6 in the HC group. There was statistically significant difference between the two groups (p<0.05).

**Abstract THU0608 – Figure 1** Serum. Levels of FGF-23 and Serum Soluble klotho in FMF patients and control group

**Conclusions:** We found that high FGF 23 levels in FMF patients caused a significant decrease in FMD. In addition, FGF23 may be a parameter for the early diagnosis and prognosis of possible cardiovascular events showing significant change in FMD which demonstrates endothelial dysfunction indirectly.

THU0609

#### CLINICAL CHARACTERISTICS AND OUTCOME OF SPANISH PATIENTS WITH ACUTE MYELITIS ASSOCIATED WITH AUTOIMMUNE DISEASES

A. González García<sup>1</sup>, W.A. Sifuentes Giraldo<sup>2</sup>, S. Sainz de la Maza<sup>3</sup>, I. Barbolla Díaz<sup>1</sup>, J. L<sup>1</sup>, L. Manzano Espinosa<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Rheumatology; <sup>3</sup>Neurology, Hospital Ramón y Cajal, Madrid, Spain

**Background:** Acute myelitis (AM) is a focal inflammatory disorder of the spinal cord characterised by motor, sensory, and autonomic dysfunctions that usually develop during a short period (several hours to days) and may resolve over several weeks to months. Acute has been reported as an unusual complication of autoimmune diseases (AD), mainly in systemic lupus erythematosus (SLE) and Sjögren's syndrome (SS).

**Objectives:** To analyse the frequency of concomitant AD in patients with patients with AM seen in a Spanish tertiary centre and to compare their clinical characteristics and outcome with those of AM patients without other AD.

**Methods:** We performed a retrospective study including all the patients diagnosed with AM in our centre between January 1989 and December 2017. Patients with previous history of spinal disease (multiple sclerosis [MS], compression, trauma, arteriovenous malformation, radiotherapy) and children were excluded. Demographics, clinical, laboratory, imaging, therapeutic and outcome data were obtained from their medical records.

**Results:** During the study period 144 cases of AM were identified, 76 of them had complete data and were analysed. Most of the patient were women (47, 62%), with a mean age at diagnosis 42±17 years. The main causes of AM in our series were MS (35%), AD (18%), postviral myelitis (9%) and idiopathic (34%). The AD diagnosed in these patients were: SLE,<sup>4</sup> SS,<sup>3</sup> undifferentiated connective tissue disease,<sup>2</sup> Graves' disease,<sup>1</sup> ulcerative colitis,<sup>1</sup> polymyalgia rheumatica,<sup>1</sup> cryoglobulinemic vasculitis<sup>1</sup> and sarcoidosis.<sup>1</sup> A patient with MS had concomitantly another AD (inflammatory myopathy). Most of the patients with AD (12, 80%) were diagnosed of these disorders before the AM episode (median 48 months, range: 24–120). No differences regarding to sex, age and anatomical extension of AM were detected between AD and non-AD patients. The recurrence of AM was more frequent in non-AD patients (7% vs 54%, p<0.001) and a tendency to less severe clinical course was found in AD patients (67% vs 41%, p=0.08).

**Conclusions:** AD were an important cause of AM in our series and this usually occurred after diagnose of AD, so it is important to consider AM when these patients develop neurological dysfunctions that suggest spinal cord damage. The outcome of AM seem to be better in patients with concomitant AD.

**Disclosure of Interest:** None declared

**THU0610** **SERUM CALPROTECTIN LEVELS IN BEHÇET'S DISEASE: RELATIONSHIPS BETWEEN DISEASE ACTIVITY AND CLINICAL PARAMETERS**

M. Torgutalp<sup>1</sup>, A.B. Kelesoglu Dincer<sup>1</sup>, E.M. Yayla<sup>1</sup>, E. Uslu Yurter<sup>1</sup>, E.I. Okatan<sup>1</sup>, G.E. Aydemir Guloksuz<sup>1</sup>, S. Sezer<sup>1</sup>, E. Us<sup>2</sup>, G. Kinikli<sup>1</sup>, M.T. Turgay<sup>1</sup>, A. Ates<sup>1</sup>.

<sup>1</sup>Rheumatology, <sup>2</sup>Microbiology, Ankara University Faculty of Medicine, Ankara, Turkey

**Background:** Behçet's disease (BD) is an inflammatory disease with chronic systemic vasculitis. The disease is characterised by attacks of oral and genital ulcers, skin lesions, arthritis, uveitis and deep vein thrombosis. The main histopathologic feature is known to be vascular inflammatory changes. Calprotectin is expressed by granulocytes, monocytes and endothelial cells, and produce an inflammatory response in human microvascular endothelial cells.

**Objectives:** The aim of this study was to evaluate serum calprotectin levels and their relationships with disease-related variables in patients with BD.

**Methods:** Forty-eight patients diagnosed with BD according to International Study Group of BD classification criteria and 22 demographically matched healthy control subjects participated in this study. Calprotectin levels were measured in blood samples from patients and controls. The disease durations of the patients were between 1 and 28 years. The Behçet's Disease Current Activity Form (BDCAF), that scores the history of clinical features presenting during four weeks prior to the day of assessment, and *Behçet's Syndrome Activity Scale (BSAS)* were used for the evaluation of disease activity.

**Results:** Mean serum calprotectin levels were significantly higher in patients with BD compared to the control group (60.6±43.8, 37.6±37.5, respectively; p=0.037) (Figure 1). Distribution of age (years; 40.6±12.9, 46.6±11.4, respectively; p=0.075) and sex (male; 62.5%, 45.5%, respectively, p=0.191) between these groups were similar. In the comparison of the calprotectin levels of the patients with or without the components of BD, we found significantly higher levels of calprotectin in patients with oral and genital ulceration versus without these involvements (table 1). Since there were only 2 uveitis patients in this patient group, no calculations were made on uveitis. Serum calprotectin was significantly associated with BDCAF, BSAS, patient's impression of disease activity, clinician's impression of disease activity, ESR (Erythrocyte sedimentation rate) and CRP (C-reactive protein) (table 2).

**Abstract THU0610 – Table 1.** Comparison of calprotectin levels of patients with or without the components of disease activity

	(n)	Calprotectin (ng/ml)	P value
Oral ulceration	yes <sup>29</sup> no <sup>19</sup>	73.2±46.2	0.007
		41.4±32.3	
Genital ulceration	yes <sup>9</sup> no <sup>39</sup>	94.5±45.6	0.009
		52.8±40.0

Vascular activation	yes <sup>9</sup> no <sup>39</sup>	59.5±52.3	0.93
		60.9±42.4	

**Abstract THU0610 – Table 2.** Correlation between calprotectin level and disease characteristics in patients with BD

	Calprotectin	p
BSAS	0.409	0.004
BDCAF	0.375	0.009
Patient's impression of disease activity	0.401	0.005
Clinician's impression of disease activity	0.385	0.007
ESR	0.440	0.002
CRP	0.312	0.031

**Abstract THU0610 – Figure 1** Serum calprotectin levels in BD and control groups

**Conclusions:** Our study demonstrated that serum calprotectin levels were significantly higher in patients with BD relative to the control group, and were significantly correlated with disease activity scores. The presence of a newly-developed genital and oral ulceration may be associated with higher levels of calprotectin. It can be concluded that serum calprotectin level seems to be useful marker to monitor disease activity in BD.

**THU0611** **ANAKINRA TREATMENT IN PATIENTS WITH FAMILIAL MEDITERRANEAN FEVER: A SINGLE-CENTRE EXPERIENCE**

B. Ergezen, S. Ugurlu, H. Ozdogan. *Division of Rheumatology, Department of Internal Medicine, Cerrahpasa Medical Faculty, University of Istanbul, Istanbul, Turkey*

**Background:** Approximately 5 to 10% of FMF patients do not respond to colchicine treatment and/or intolerant to colchicine due to side effects. Several case reports and case series have pointed out the efficacy of IL-1 blockade in colchicine resistant FMF subgroup.

**Objectives:** To review the patients followed in our centre with FMF who received anakinra, an anti-IL-1 receptor antagonist, because of insufficient colchicine response.

**Methods:** FMF patients who were treated with anakinra were retrospectively reviewed with regard to indication, effect on disease activity and acute phase response, adverse events. Patient global assessment was recorded before and after anakinra treatment.

**Results:** There were 48 FMF patients with FMF who were treated with anakinra for various indications (colchicine resistant recurrent febrile attacks in 42, colchicine related side effects in 6). The mean age of the group was 31.8±9.2 years. The mean duration of the disease was 12.3±7.9 years. There were various co-existing pathologies among this study group like multiple sclerosis,<sup>1</sup> ankylosing spondylitis,<sup>1</sup> SLE,<sup>1</sup> Behçet's disease,<sup>1</sup> low grade lymphoma,<sup>1</sup> psoriasis,<sup>2</sup> vasculitis<sup>2</sup> and PAN.<sup>2</sup> The mean colchicine dose was 2,13±0,51 mg/d. The mean duration of anakinra treatment was 14.47±10.8 months. Twenty seven patients reported no attacks after anakinra treatment whereas 10 patients reported at least 50% decrease in the attack frequency. There are 4 patients who were primarily irresponsive to the therapy, whereas in 5 patients response to therapy ameliorated during the course of the treatment. Mean patient global assessment decreased from 8.58±1.2 to 2.72±3.16 under anakinra treatment (p=0.001). Four patients had severe allergic reactions (severe disseminated rash in 1 patient and severe injection site reaction in 3 patients) and therefore the drug was stopped. Two patients had infections (one had genital warts and urinary tract infection, the other had sinusitis and folliculitis) and the treatment was terminated.

One of our patients reported that her psoriatic lesions got worse on anakinra. Forty one patients reported no adverse events during the treatment.

**Conclusions:** Anakinra was effective in controlling the symptoms in colchicine-resistant FMF cases. It was also effective in FMF related amyloidosis. The major cause of treatment termination was injection site reactions. Anakinra seems to be an effective alternative in patients who have insufficient response to colchicine.

#### THU0612 BONE SARCOIDOSIS: A RETROSPECTIVE MULTICENTER STUDY OF 27 CASES

C. Glanowski<sup>1</sup>, R. Mestiri<sup>2</sup>, L. Bialé<sup>1</sup>, T. Carmoi<sup>2</sup>, D. Lechevalier<sup>1</sup>, G. Leroux<sup>3</sup>, D. Saadoun<sup>3</sup>, C. Chapelon-Abriç<sup>3</sup>, P. Cacoub<sup>3</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Internal Medicine, Hôpital Bégin, Saint Mandé; <sup>3</sup>Internal Medicine, Hôpital de la Pitié Salpêtrière, Paris, France

**Background:** Studies on bone involvement of sarcoidosis (BS) are scarce.

**Objectives:** To analyse in depth main features, treatments and follow up of patients presenting a BS.

**Methods:** Among 926 patients with a proved sarcoidosis from four tertiary hospitals in Paris (France) seen between 2000 and 2015, all cases of BS were retrospectively analysed for demography, clinical features, biological tests and imaging results. Inclusion criteria were a) a bone biopsy with epithelioid granuloma and no casein necrosis, or b) radiological evidence of BS, after exclusion of other diagnoses.

**Results:** 27 out 926 (2.9%) sarcoidosis patients fulfilled inclusion criteria for BS. Most patients were caucasian (56%), M/F sex ratio 1.5, 30% were active smokers, mean age at sarcoidosis diagnosis was 39±12 years and at BS diagnosis 43 ±11 years. Extra-osseous involvement of sarcoidosis was found in lymph nodes (93%), lungs (78%), skin (52%), CNS (33%), ENT (33%), and heart (19%). BS was symptomatic in 15/27 (56%) patients i.e. bone pain (15/15), local inflammation (5/15), bone deformation (3/15), arthritis (4/15), and myalgia (5/15). BS was never the revealing symptom of sarcoidosis. BS was more frequently symptomatic when it was a Perthes-Jüngling osteitis and an appendicular skeleton involvement.

On imaging exams, BS lesions were found at the spine skeleton alone (14/27, 52%), appendicular skeleton alone (10/27, 37%) or both (3/27, 11%). BS lesions had an aspect of pseudo-metastasis (59%), micro-cysts (Perthes-Jungling, 37%) or Paget disease (4%). Bone lesion was unique in 22% and 26% of patients had more than 10 lesions. When a bone biopsy was done it always confirmed the diagnosis (n=9); in all other cases extra-osseous biopsies confirmed the diagnosis of sarcoidosis.

Nine patients received a treatment for BS, i.e. prednisone (n=8, 0.25–1 mg/kg/day), hydroxychloroquine (n=8), and methotrexate (n=5). Response to treatment was complete (n=3), partial (n=4) or nul (n=2). Of note, 21 out of 27 patients received an immunosuppressant for a severe form of systemic sarcoidosis (n=11) or for a steroid-sparing effect (n=10). A relapse of BS was noted in 13 patients, with a mean number of relapse of 2.1–24. After a mean follow up of 49 months, BS was in complete remission (8/27, 30%), partial remission (16/27, 59%) or remained active (3/27, 11%).

**Conclusions:** Bone involvement remains a rare manifestation of sarcoidosis. It was symptomatic in 56% of patients, mainly when Perthes-Jüngling osteitis and appendicular skeleton involvement were present. Extra-osseous involvement of sarcoidosis were always present at the time of BS diagnosis. Treatment remains difficult with frequent relapses.

#### THU0613 THE FREQUENCY AND CHARACTERISTICS OF HEADACHE IN BEHCET'S DISEASE AND ITS EVALUATION BY TRANSCRANIAL DOPPLER ULTRASONOGRAPHY

F. Salgür<sup>1</sup>, D. Üsküdar Cansu<sup>2</sup>, N. Uzuner<sup>3</sup>, C. Korkmaz<sup>2</sup>. <sup>1</sup>Internal Medicine, Endocrinology, Kent Hospital, izmir; <sup>2</sup>Internal Medicine, Rheumatology; <sup>3</sup>Neurology, Eskişehir Osmangazi University, Eskişehir, Turkey

**Background:** Behcet's disease (BD) is a multisystem vasculitic disease and the most often neurologic manifestation of BD is headache. Transcranial Doppler ultrasonography (TCD) is a test which used for evaluating the changes in blood flow velocity developed against visual stimulation. It is not well known TCD findings in BD patients who suffered from headache.

**Objectives:** To evaluate the frequency and the types of headache and to investigate cerebral reactivity by TCD in BD patients.

**Methods:** 113 patients with BD diagnosed based on diagnostic criteria of BD by ISG and 40 healthy individuals were included in the study. The patients with BD

who had neurological involvement were not included to the study. Headache type was specified by a specialist neurologist according to International classification of headache disorders society criteria. TCD was applied to 62 patients with BD and 40 healthy individuals. TCD results were evaluated by a specialist neurologist.

**Results:** Headache was determined in 89 (78.8%) patients with BD. It was statistically significant compared to HC group (60%, p<0.03). 48 of 89 BD patients had tension type of headache and 33 of them had migrainous type. No significant difference was found between BD patients and HC group in terms of cerebral reactivity by TCD. Low pulsatility index for both the right side and the left side were noted in BD patients suffering from headache compared to BD patients not having headache (p<0.006, p<0.003). No significant differences were found between tension type and migrainous type of headache in terms of TCD parameters.

**Conclusions:** Headache is common in BD patients, but cerebral reactivity is maintained.

#### THU0614 INTERSTITIAL LUNG DISEASE IN PATIENTS WITH ANTISYNTHEASE SYNDROME AND ANTI-RO52 ANTIBODIES POSITIVE

C. Aguilera Cros<sup>1</sup>, A. Ruiz Román<sup>1</sup>, L. Méndez Díaz<sup>1</sup>, G. Morote Ibarrola<sup>2</sup>, N. Garrido Puñal<sup>1</sup>, M. Arcila Durán<sup>1</sup>, M.A. Montes Cano<sup>3</sup>, J.A. Rodríguez Portal<sup>4</sup>. <sup>1</sup>Rheumatology, University Hospital Virgen del Rocío; <sup>2</sup>Rheumatology, Quirón Sacred Heart Hospital; <sup>3</sup>Immunology; <sup>4</sup>Pneumology, University Hospital Virgen del Rocío, Seville, Spain

**Background:** Antisynthetase syndrome (ASS) is characterised by the presence of myositis, arthritis, interstitial lung disease (ILD), fever, Raynaud's phenomenon and mechanical's hand, in the presence of antisynthetase autoantibodies (AA), the most frequent being anti-Jo1, anti-PL7 and anti-PL12. An association between ASS and anti-Ro52 with increased ILD has been described and it is believed that the presence of both antibodies is accompanied by a more severe ILD.

**Objectives:** To describe the clinical and analytical characteristics of a cohort of patients with ASS. To analyse the lung involvement in this type of patient and to determine the possible relationship between the different subtypes of ILD and the presence of anti-Ro52.

**Methods:** Retrospective descriptive study of patients treated in our Hospital (2006–2017), with AA and at least 2 clinical characteristics. The data was obtained through the review of medical records.

Variables analysed: age, sex, age, smoking, clinical presentation, diagnosis of ASS, associated neoplasia and paraneoplastic syndrome (PS) (neoplasia 3 years before or after the diagnosis of ASS), muscle enzymes (CK and aldolase), autoimmunity, glucocorticoids (GC), immunosuppressants (IS), diagnosis of ILD, HRCT pattern (High Resolution Computed Tomography) and respiratory function tests (RFT) at the beginning of ILD.

**Results:** We included 27 patients (20 women), mean age 61±13 years. 7.4% smokers and 18.5% ex-smokers. 88.8% were anti-Jo1, 7.4% anti-PL12% and 3.7% anti-PL7. Anti-Ro52 present in 18 patients. The most common clinical presentation: ILD 88% (59% had Ro52), followed by myositis 85% (40% are dermatomyositis), arthritis 81%, mechanic's hand 51%, fever 37% and Raynaud's phenomenon 25%. The classic triad (arthritis, myositis, ILD) was present in 16 patients. Three patients presented neoplasia in the course of the disease, being identified as PS. Elevation of CK in 70% and aldolase in 74%. 96% of patients have been treated with GC and IS.

The HRCT patterns were: non-specific interstitial pneumonia (NSIP) (66%), usual interstitial pneumonia (UIP) (29%), organised cryptogenic pneumonia (OP) (4%), baseline RFT were performed in 19 patients. Diagnosis of ASS and ILD, both entities appear at the same time in 6 patients, in 3 patients the ILD appears before and in 14 after. In these, the median duration (range) of the ASS until the diagnosis of ILD was 1 year (0–1).

There is no relationship between the HRCT and anti-Ro52 patterns (chi-square considering the exact distribution p=0.892), nor between the ILD and anti-Ro52 (Fisher exact test p=0.999).

**Conclusions:** Our results, in general, agree with what is published in the literature. Three patients have an uncommon presentation of ASS, with a diagnosis of ILD prior to myopathy (in most of the published cases, myositis precedes or coincides with the onset of ILD), and it is important to include ASS in the differential diagnosis of ILD. In our cohort, the association between ILD and anti-Ro52 has not been demonstrated, nor among the different subtypes of ILD to Ro52. Therefore, prospective studies with a greater number of patients are necessary to define Ro52's role in the development of ILD in ASS.

**THU0615 IMMUNE RELATED ADVERSE EVENTS (IRAES) ASSOCIATED WITH CHECKPOINT INHIBITORS: 12 CASES FROM A SINGLE CENTRE**

D. Ennis, F. To, S. Jamal. *Rheumatology, University of British Columbia, Vancouver, Canada*

**Background:** Immune checkpoint inhibitors (ICI) have made a significant impact on the treatment of many advanced malignancies. There is little data on the rheumatologic complications of these treatments.

**Objectives:** We describe 12 cases of rheumatologic IRAEs following ICI treatment to further characterise the spectrum of disease and treatment responses.

**Methods:** We report patients evaluated in a general Rheumatology outpatient clinic from 2014 to 2017. Cases were defined as those with new rheumatologic symptoms following treatment with an ICI. Alternative explanations for the presenting syndrome were excluded clinically. Clinical data was extracted by retrospective chart review.

**Results:** This case series includes 12 patients (6 female, 6 male) with a mean age at IRAE onset of 63.9 years (range 33–79). Multiple cancers were represented including melanoma (n=9), Hodgkin's lymphoma (n=1), squamous cell lung cancer (n=1), and adenocarcinoma of the lung (n=1). 5/12 patients received Nivolumab, 8/12 received Pembrolizumab, and 2/9 received Ipilimumab. ICI exposure was associated with various rheumatologic IRAEs including PMR-like syndrome (n=4), symmetric polyarthritis (n=6), psoriatic arthritis (n=1), oligoarthritis (n=1), and erythema nodosum (n=1). Other IRAEs were also noted including vitiligo (n=1), pulmonary capillaritis (n=1), ulcerative colitis flare (n=1), inflammatory seborrheic keratosis and psoriasis (n=1). The mean time of onset of the IRAE from the first exposure to an ICI was 6.8 months (range 0–21 months). In 7 cases, rheumatologic symptoms worsened with each ICI dose. Laboratory investigations demonstrated elevated CRP in 7 cases (mean 75.6; range 3.7–290.1), RF positivity in 2 cases, weak positive ANAs in 4 cases (1:80), SSA positivity in 2 cases, and a single case where a pre-existing anti-CCP antibody was identified. Steroids were used in 11 cases at a mean starting dose of 36 mg (range 10–50 mg) by mouth daily for an average duration of 6.1 months (range 1–12 months). Other DMARDs were necessary in some cases (Hydroxychloroquine n=1; Methotrexate n=5). While 6 patients experienced rapid improvement, 4 experienced gradual improvement. Most patients achieved partial resolution of symptoms (n=6) while only 4 achieved complete resolution. Tumour response was observed in all 12 patients.

**Conclusions:** This case series of IRAEs associated with ICI treatment suggest that symmetric polyarthritis and PMR-like syndromes are the most common rheumatologic IRAEs, although the spectrum is broad. IRAEs seem to develop around 6 months after first exposure, worsen with ongoing doses of ICI administration, and respond to treatment with corticosteroids. Treatment doses and duration were higher than expected for phenotype, with few patients achieving significant improvement with short courses. Those with IRAEs tend to have good tumour response, despite concurrent use of immunosuppressants. MTX and HCQ appear to be safe and effective, but more experience with these and other DMARDs/biologics is required in these patients.

**THU0616 ELEVATED THYROID STIMULATING HORMONE AS A POTENTIAL BIOMARKER FOR RHEUMATIC IMMUNE-RELATED ADVERSE EVENTS FOLLOWING PD-1 INHIBITOR THERAPY**

D.F.L. Liew<sup>1,2,3</sup>, J.L.Y. Leung<sup>1,3</sup>, C. McMaster<sup>2</sup>, F. Djukiadmodjo<sup>2</sup>, B. Liu<sup>1</sup>, J. Cebon<sup>4</sup>, A.G. Frauman<sup>2,3</sup>, R.R.C. Buchanan<sup>1,3</sup>. <sup>1</sup>*Rheumatology*; <sup>2</sup>*Clinical Pharmacology and Therapeutics, Austin Health, Heidelberg*; <sup>3</sup>*Medicine, University of Melbourne, Parkville*; <sup>4</sup>*Olivia Newton-John Cancer Wellness and Research Centre, Heidelberg, Australia*

**Background:** Programmed cell death protein (PD-1) inhibitor immunotherapy is being increasingly used in oncology, but may cause immune-related adverse events (irAEs) resembling classical rheumatic and non-rheumatic autoimmune diseases. While oncological response to therapy has been associated with the development of rheumatic irAEs, no biomarker to predict the development of rheumatic irAEs has yet been identified. Thyroid stimulating hormone (TSH) is readily available in clinical practice and is frequently tested prior to the administration of PD-1 inhibitors to screen for existing thyroid disease.

**Objectives:** To investigate whether thyroid stimulating hormone, or changes to it, are associated with the development of immune-related adverse events (irAEs) following PD-1 inhibitor therapy for cancer.

**Methods:** This was a retrospective chart review of all patients at a single centre who had a TSH level performed in the institutional laboratory prior to the patient being dispensed nivolumab or pembrolizumab before January 1, 2017, with follow-up until July 1, 2017. TSH levels before and during PD-1 inhibitor therapy were recorded. Patients with any diagnosis of a rheumatic irAE or any non-

cutaneous irAE were identified. Linear regression was performed to determine the relationship between TSH and the development of irAEs. Youden's index was used to derive the optimal cut-off point. Recursive partitioning methods with imbalanced prior probabilities were used to create a decision tree model.

**Results:** There were 213 episodes of therapy which met criteria, of which a non-cutaneous irAE occurred in 62 episodes (29.1%), thyroid irAEs occurred in 22 episodes (10.3%) and rheumatic irAEs were diagnosed in 16 episodes (7.5%). Even when corrected for duration of exposure to PD-1 inhibitor therapy, elevated TSH levels (>4.2 mU/L) were statistically significantly associated with the development of rheumatic irAEs (adjusted OR 6.08, 1.53–24.22), and this was not weakened by excluding patients who went on to develop thyroid irAEs. There was no significant association between elevated TSH levels and the development of any non-cutaneous irAE. Change in TSH levels with PD-1 inhibitor therapy was also not associated with the development of non-cutaneous irAEs or rheumatic irAEs specifically. Using a TSH level >2.4 to predict rheumatic irAEs led to a positive predictive value of 25% and a negative predictive value of 93% in our cohort. A decision tree model to predict rheumatic irAEs combining a pre-PD-1 inhibitor TSH level >2.4 and an oncological response to therapy led to a positive predictive value of 50% and a negative predictive value of 94% in our cohort.

**Conclusions:** Elevated TSH levels may be a potential biomarker for the development of rheumatic irAEs. In particular, a pre-PD-1 inhibitor TSH level of >2.4 mU/L, in combination with oncological response to therapy, may identify patients at risk of rheumatic irAEs. Associations observed in this cohort should be examined in larger cohorts to determine the clinical utility of TSH in predicting rheumatic irAEs.

**Disclosure of Interest:** None declared

**THU0617 IS THE NUMBER OF IGG4+ PLASMA CELLS SEEN BY IMMUNOSTAINING USEFUL BEYOND ITS DIAGNOSTIC UTILITY IN IGG4-RELATED DISEASE?**

E. Martín Nares<sup>1</sup>, J. Guerrero Castillo<sup>2</sup>, A. Angeles Angeles<sup>2</sup>, G. Hernández Molina<sup>1</sup>. <sup>1</sup>*Immunology and Rheumatology Department*; <sup>2</sup>*Pathology Department, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

**Background:** The histopathological findings in IgG4-related disease (IgG4-RD) includes the presence of marked IgG4 +plasma cell infiltration seen by immunostaining and it has been used in clinical practice only as a diagnostic tool. Whether the number of IgG4 +plasma cells in tissue is associated with any clinical or serological feature of the disease has not been previously evaluated.

**Objectives:** To evaluate if the number of IgG4 +plasma cell infiltration is associated with any clinical or serological outcome.

**Methods:** We included 30 patients with biopsy proven IgG4-RD according to the Comprehensive Diagnostic Criteria for IgG4-RD who regularly attended a tertiary referral centre in Mexico City (2000–2017). We collected demographics, clinical (organ involvement, relapses and the disease activity assessed by the IgG4-RD Responder Index [IgG4-RD RI] at baseline) as well as baseline laboratory data (C3, C4, total eosinophil count, IgG4 levels). Patients were divided in three groups according to the number of IgG4 +plasma cells seen by immunostaining as follows: <50 IgG4 +plasma cells/HPF, 50–100 IgG4 +plasma cells/HPF, and >100 IgG4 +plasma cells/HPF.

**Results:** We included 30 patients, 17 (56.6%) women, mean age 53±13.9 years and median disease duration 13 months. The biopsies were from the following tissues: lacrimal gland (n=6), pancreas (n=5), orbit (n=4), kidney (n=4), lymph node (n=3), mediastinum (n=2), salivary gland (n=2) and other tissues (n=4). Eleven patients (36.6%) had <50 IgG4 +plasma cells/HPF, 9 patients (30%) 50–100 IgG4 +plasma cells/HPF and 10 (33.3%) patients >100 IgG4 +plasma cells/HPF. We did not find any difference regarding age, gender, time of follow up, number of involved organs and relapses. The median basal IgG4-RD RI was 9, 6 and 15, for the <50 IgG4 +plasma cells/HPF, 50–100 IgG4 +plasma cells/HPF, and >100 IgG4 +plasma cells/HPF groups respectively, however, they did not reach statistical significance. The group with >100 IgG4 +plasma cells/HPF had more frequently lymphadenopathy when compared with the other groups (36.4%, 66.7% and 80%, p=0.02; respectively) while the proportion of involvement of the other anatomic sites were similar. We found a statistical difference in serum C3 levels (99.5 mg/dl, 159 mg/dl, 78.5 mg/dl, p=0.04) and a tendency for serum C4 levels (20 mg/dl, 27 mg/dl, and 6 mg/dl, p=0.08) among the groups, whereas the levels of serum IgG4 (60.8 mg/dl, 196 mg/dl, 245 mg/dl, p=0.35) and the eosinophil count (284/mm<sup>3</sup>, 189/mm<sup>3</sup>, 283/mm<sup>3</sup>, p=0.46) were similar. The C3 and C4 serum levels negatively correlated with the basal IgG4-RD RI ( $\tau=-0.48$ , p=0.005 and  $\tau=-0.58$ , p=0.001).

**Conclusions:** Our results show that the number of IgG4 +plasma cells seen by immunostaining in IgG4-RD may be of value in identifying a subset of patients with hypocomplementemia, lymphadenopathy and probably higher basal disease activity. The finding of an association between hypocomplementemia and higher tissue infiltration by IgG4 +plasma cells expands the evidence that complement activation may contribute to the pathogenesis of IgG4-RD.

### THU0618 HYPHOPHOSPHATASIA IN FRENCH TERTIARY CARE HOSPITALS

E. Ebstein<sup>1</sup>, T. Thomas<sup>2</sup>, B. Cortet<sup>3</sup>, K. Briot<sup>1</sup>, C. Roux<sup>1</sup>. <sup>1</sup>Rheumatology, Hôpital Cochin, Paris; <sup>2</sup>Rheumatology, CHU Saint Etienne, Saint Etienne; <sup>3</sup>Rheumatology, CHRU Lille, hôpital Roger Salengro, Lille, France

**Background:** Hypophosphatasia is a rare heritable metabolic disorder. Its prevalence is estimated at 1: 1 00 000. Its diagnosis can only be established after genetic confirmation. A low serum total alkaline phosphatase (ALP) level is the hallmark for the diagnosis of hypophosphatasia. Its prevalence is 0.05% in the general population and may be associated with symptoms similar to those of adult forms of hypophosphatasia: excess of joint pathology (chondrocalcinosis, osteoarthritis), periarticular disorders (calcifications, tendinopathies enthesopathies), and disorders of bone mineralization (risk of fracture).

**Objectives:** The aim of this study was to assess the recognition of persistent low ALP in 3 tertiary care hospitals in France.

**Methods:** All of the ALP assays of 3 tertiary care hospitals measured in 2013 were reviewed. Persistent hypophosphatasemia was defined by at least one assay <30 IU/L without any assay >40 IU/L. Selected records were analysed to eliminate secondary causes of hypophosphatasemia. A telephone questionnaire was conducted with included patients from the rheumatology and internal medicine departments.

**Results:** In 2013, 288,851 PAL assays were performed in 1 24 044 patients. Excluding emergency and intensive care unit services, 216,817 PAL assays were performed in 83 657 patients. 716 patients had a value ≤30 IU/L. Of these, 174 had 1 single dosage, 542 multiple dosages, of which 186 never had value >40. 31 patients were excluded due to secondary hypophosphatasemia: severe caloric restriction (n=10), massive surgery (n=6), cancer/hemopathy (n=8), acute pathology -sepsis/voluntary drug intoxication (n=4), high-dose corticosteroid therapy (n=3). 155 patients were selected; the prevalence of hypophosphatasemia in hospitals is therefore 0.124%. Hypophosphatasemia was noticed in the summary discharge in 1,3%. 4 patients received bisphosphonates despite low PAL (before treatment) and 2 patients had a fracture under treatment. Of the 155, 38 were followed in the rheumatology and internal medicine departments and 33 answered a standardised telephone questionnaire (78% women, average age 43.8 years). 11 patients reported a history of fracture, 2 patients had a history of rickets in childhood, and 1 had known hypophosphatasia in the family. 9 patients had tooth enamel disorders, 7 had gingival recession, 3 had spontaneous tooth loss, and 1 had lost their deciduous teeth by the age of 3 years.

**Conclusions:** The prevalence of hypophosphatasemia is higher in hospitals than in the general population. This biological anomaly is almost never recorded in the files. However, the existence of hypophosphatasemia should be systematically reported as it is a contraindication to anti-resorptive therapy because of the risk of atypical femoral fracture.

**Disclosure of Interest:** None declared

### THU0619 THE FREQUENCY OF EXON-10 MUTATIONS IN MEFV GENE IN "PROBABLE" DIAGNOSED FMF PATIENTS ACCORDING TO TEL HASHOMER CRITERIA

F. Cosan<sup>1</sup>, S. Arda<sup>1</sup>, O.M. Gedar Totuk<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology; <sup>2</sup>Department of Ophthalmology, Bahcesehir University, Faculty of Medicine, Istanbul, Turkey

**Background:** Familial Mediterranean Fever (FMF) is characterised with recurrent inflammatory attacks with serosal inflammation. The clinical findings of FMF is seen in a large spectrum. Tel Hashomer criteria are widely used for classifying FMF. According to this criteria set FMF is classified as 'definite' and 'probable' disease.

**Objectives:** We aimed in this study to investigate the frequency of exon-10 MEFV mutations in 'probable' FMF patients according to Tel Hashomer criteria.

**Methods:** The study group consisted of 117 patients (79 male, 38 female, median age:31±11, <sup>12-69</sup> which is classified as 'probable' FMF according to Tel-Hashomer criteria. The 12 frequently seen mutations in Turkey analysed in all blood samples and compared with the previous reported 'definite' FMF data from Turkey.

**Results:** We found in probable FMF group single mutation in 36 patients (%30,8), two mutations in 56 patients (%47,9), 3 mutations in 5 patients (%4,3) and no

mutations in 20 patients (%17,1). The distribution of exon 10 mutations showed single exon-10 mutation in 46 patients (%39,3) and two exon-10 mutations only in 23 patients (%19,7). The detailed distribution of MEFV mutations in 'probable' FMF group is shown in table 1.

**Abstract THU0619 – Table 1.** The Distribution of MEFV gene mutations in 'probable' FMF group

	Homozygout	Heterozygout	Negative
M694V	5 (4,3%)	42 (35,9%)	70 (59,8%)
M680I	2 (1,7%)	18 (15,5%)	82,8 (96%)
V726A	1 (0,9%)	12 (10,3%)	104 (88,9%)
M694I	-	3 (2,6%)	114 (97,4%)
R202Q	2 (1,7%)	35 (29,9%)	80 (68,4%)
E148Q	1 (0,9%)	15 (12,8%)	101 (86,3%)
P369S	-	3 (2,6%)	114 (97,4%)
R761H	1 (0,9%)	6 (5,1%)	110 (94%)
K695R	-	2 (1,7%)	115 (98,3%)
A744S	-	2 (1,7%)	115 (98,3%)

**Conclusions:** We found decreased frequency of exon 10 mutations in the MEFV gene in "probable FMF" group according to Tel-Hashomer criteria in comparison previous reported MEFV mutations data. The distribution of non-exon 10 mutations were similar in the definite FMF group. It is needed more clinical studies with large patient group for the clinical significance of non-exon 10 mutations in "probable" FMF patients.

### THU0620 ON DEMAND USE OF ANAKINRA FOR THE ATTACKS OF FAMILIAL MEDITERRANEAN FEVER (FMF)

H. Babaoglu<sup>1</sup>, O. Varan<sup>1</sup>, H. Kucuk<sup>2</sup>, N. Atas<sup>1</sup>, H. Satis<sup>1</sup>, R.B. Salman<sup>1</sup>, M. A. Ozturk<sup>1</sup>, B. Goker<sup>1</sup>, S. Haznedaroglu<sup>1</sup>, A. Tufan<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Gazi University Hospital, Ankara; <sup>2</sup>Department of Internal Medicine, Division of Rheumatology, Erzurum Research and Training Hospital, Erzurum, Turkey

**Background:** IL-1 blocking agents have been shown to be effective in the prevention of attacks in colchicine-resistant FMF (crFMF) patients by their regular use. However, their high cost, side effects and treatment noncompliance limit their use which might be overwhelmed by on-demand use of them which has not been reported in FMF patients. Herein, we evaluated the efficacy of on demand use of anakinra in crFMF patients.

**Methods:** Data were derived from Gazi FMF cohort which was established in the year 2010. From that date patients with FMF who were diagnosed according to the Tel Hashomer criteria were registered. Co-morbidities, detailed attack characteristics, type, duration, severity, treatments, laboratory parameters and impact of FMF on their life in terms of quality of life and work productivity were recorded either by FMF diary or a mobile phone application (FMF AIDD free to download from AppStore and Android market). A retrospective cohort analysis was made from records of patients who have ever been treated with IL-1 inhibitors.

**Results:** A total of 60 patients were treated with anakinra in our cohort and 15 patients were identified who were received on demand anakinra protocol. Rationale for on demand use of anakinra was prominent prodrome or trigger for attacks and patients' personal claim. Six patients were switched from regular use and 9 were directly started as on demand use. All were using background colchicine in maximum tolerated doses. None of patients had evidence of persistently elevated acute phase reactants or proteinuria. The median duration of on demand anakinra use was 6 (min 3- max 36) months. Pre- and post- on demand anakinra periods were compared (table 1). Patient reported attack severity (p=0.002), duration (p=0.001), absenteeism (p=0.001) and presenteeism (p=0.002) were significantly

improved but C-reactive protein (CRP) remained in the same levels. On demand anakinra prevented progression of prodromes to full-blown attacks which was demonstrated by decrease in the rate of attack/prodrome ratio ( $p=0.002$ ). On demand anakinra can be continued in 10 subjects on long-term but continuous treatment was required in 5 subjects.

**Abstract THU0620 – Table 1.** Comparison of attack characteristics before and after on demand anakinra protocol

	Colchicine period	Colchicine plus On-Demand Anakinra period	p
Attack severity, VAS	10 (2)	6 (3)	0.002
Duration, days	3 (2)	1.5 (1)	0.001
Frequency*, number	4 (1.5)	1.5 (1.75)	0.001
CRP (mg/L)	5.1 (6.1)	4.1 (5.9)	0.58
AIDAI	18 (22.5)	4 (5)	0.001
Attack/prodrom ratio, (n=10)	1	0.6 (0.4)	0.002
Absenteeism, days	7 (8)	2 (2.5)	0.001
Presenteeism, days	9 (7.5)	2.5 (3)	0.002

Attack frequency and work productivity parameters are adjusted for 3 months intervals. VAS: visual analogue scale, CRP: C-reactive protein, AIDAI: autoinflammatory disease activity index

**Conclusions:** On demand anakinra significantly improved FMF attacks which suggest this approach would be of benefit in daily practice in selected patients.

**THU0621** **PERSISTENT PRURITIC SKIN LESIONS WITH DYSKERATOTIC CELLS IN UPPER LAYER OF EPIDERMIS ARE SPECIFIC AND ASSOCIATED WITH HIGH LEVELS OF SERUM IL-18 IN ADULT-ONSET STILL'S DISEASE**

H. Nishikawa<sup>1</sup>, Y. Taniguchi<sup>1</sup>, N. Maeda-Aoyama<sup>1</sup>, K. Nakajima<sup>2</sup>, S. Inotani<sup>1</sup>, Y. Shimamura<sup>1</sup>, K. Inoue<sup>1</sup>, K. Arai<sup>3</sup>, S. Sano<sup>2</sup>, Y. Terada<sup>1</sup>. <sup>1</sup>Nephrology and Rheumatology; <sup>2</sup>Dermatology, Kochi Medical School Hospital, Nankoku; <sup>3</sup>Internal Medicine, Kochi Red Cross Hospital, Kochi, Japan

**Background:** Adult-onset Still's disease (AOSD) is an acute and systemic inflammatory disorder that is characterised by high spiking fever, evanescent rash, arthralgia/arthritis and hyperferritinemia. However, recent reports showed that not only typical evanescent salmon-coloured rash but also atypical skin lesions, persistent pruritic papules and plaques, could be associated with AOSD.

**Objectives:** To assess the clinical significance of dyskeratotic cells (DCs) in skin lesions of AOSD.

**Methods:** We assessed histology of skin lesions including persistent pruritic skin lesions in Japanese patients with AOSD (n=15). Moreover, we compared histology of AOSD with dermatomyositis (DM) (n=6), drug eruptions (DE) (n=7), and graft versus host disease (GVHD) (n=6).

**Results:** AOSD with persistent pruritic skin lesions (n=10) histologically showed DCs only in upper layer of epidermis and horny layer without inflammatory cells infiltrations, indicating dyskeratosis. AOSD with evanescent rash (n=5) histologically showed no DCs. DCs were positive by ssDNA staining, suggesting apoptotic cells. Serum IL-18 showed significantly higher in AOSD patients with dyskeratosis (n=10) than without dyskeratosis (n=5). In contrast to AOSD with DCs, the histology of DM, DE and GVHD demonstrated that DCs existed in all layers of epidermis with inflammatory cells infiltrations.

**Conclusions:** Persistent pruritic skin lesions in AOSD are specific by prominent epidermal apoptosis involving the upper layers of epidermis. Moreover, hyper IL-18 might be related with dyskeratosis.

**Disclosure of Interest:** None declared

**THU0622** **HISTOPATHOLOGY AND EXPRESSIONS OF CHEMOKINES, CXCL10, CXCL13, AND CXCR3, AND AN ENDOGENOUS LIGAND S100A8/A9 IN LYMPH NODES OF PATIENTS WITH ADULT-ONSET STILL'S DISEASE**

H.-A. Kim<sup>1</sup>, J.H. Han<sup>2</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Pathology, Ajou University School of Medicine, Suwon, Korea, Republic of Ireland

**Background:** Adult-onset still's disease (AOSD) is a rare systemic inflammatory disease with several symptoms, such as a persistent high spiking fever, typical rash, and lymphadenopathy. Endogenous factors related to interleukin (IL)-1,

such as S100A8/A9 and several chemokines including CXCL10, CXCL13 and CXCR3, could play a potential role in the pathogenesis of AOSD.

**Objectives:** We aimed to find out typical histopathologic features, expressed pattern of chemokines in lymph nodes (LN) of AOSD patients.

**Methods:** Formalin-fixed paraffin-embedded excisional LN tissues from 48 AOSD patients and 6 nonspecific reactive hyperplasia were histologically reviewed. The immunohistochemical stain for CXCL10, CXCL13, CXCR3 and S100A8/A9 were done. The clinical and laboratory data of the patients who underwent LN biopsies were reviewed.

**Results:** The LN specimens were categorised according to four distinctive patterns: follicular (n=2, 4.2%), paracortical (n=19, 39.6%), diffuse (n=9, 18.8%) hyperplasia, or mixed pattern (n=18, 37.5%). The other examined histologic features were presence of necrosis, karyorrhexis, immunoblastic, histiocytic and vascular proliferation. Most of the cases were required to take into differential diagnosis such as dermatopathic lymphadenitis (n=16, 33.3%), lymphoma (n=11, 22.9%) and histiocytic necrotizing lymphadenitis (n=9, 18.8%). The expression of chemokines and S100A8/A9 were higher than that of nonspecific reactive hyperplasia. The expression of chemokines and S100A8/A9 were higher than that of nonspecific reactive hyperplasia.

**Conclusions:** Histopathologic findings of LN in AOSD patients are diverse enough to be included various differential diagnosis. Because the several chemokines and S100A8/A9 were more expressed in AOSD patients than those of reactive hyperplasia, they may serve as a pathogenesis of AOSD.

**THU0623** **SERUM IGG4 LEVELS AT DIAGNOSIS CAN PREDICT THE OUTCOMES OF UNTREATED PATIENTS WITH IGG4-RELATED DISEASE: A RETROSPECTIVE STUDY**

I. Mizushima, N. Suzuki, M. Yoshida, A. Takeji, T. Matsunaga, T. Zoshima, S. Hara, K. Ito, H. Fujii, K. Yamada, M. Kawano. *Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Kanazawa, Japan*

**Background:** IgG4-related disease (IgG4-RD) is a recently recognised systemic fibro-inflammatory disorder that can affect many organs.<sup>1</sup> In IgG4-RD, spontaneous, or at least temporary, remissions without treatment have been reported, and watchful waiting may be appropriate in certain patients with asymptomatic and inactive disease.<sup>2</sup> However, the outcomes of patients with IgG4-RD who do not undergo treatment are still unclear.

**Objectives:** This study aimed to clarify the outcomes of untreated patients with IgG4-RD and the factors related to the outcomes.

**Methods:** We retrospectively reviewed the medical records of 107 patients with IgG4-RD, who were followed up for more than 6 months, at a single centre in Japan. Among them, 27 patients were followed up without treatment after the initial diagnosis. We compared the clinical features of these 27 patients with those of the 80 patients who underwent treatment. The outcomes of untreated patients were investigated, and logistic regression analysis was performed to assess factors related to the outcomes. Deterioration of IgG4-RD was defined as symptomatic, radiological, or functional exacerbation of the organ involved or new organ involvement.

**Results:** The patients comprised 73 men and 34 women (mean age 65.7 years). The follow-up periods were 7–252 (mean, 64.1) months, and the serum IgG4 levels at diagnosis were 10.7–3610 (mean, 706) mg/dL. The 27 untreated patients had significantly fewer affected organs ( $1.9 \pm 1.2$  vs  $3.0 \pm 1.6$ ,  $p=0.001$ ), lower IgG4-RD responder index ( $10.8 \pm 5.1$  vs  $13.8 \pm 6.8$ ,  $p=0.048$ ), and lower frequency of ophthalmic and renal parenchymal lesions ( $25.9\%$  vs  $53.8\%$ ,  $p=0.015$ , and  $3.7\%$  vs  $26.3\%$ ,  $p=0.012$ , respectively) than did the 80 patients who underwent treatment. Of these 27 patients, 8 experienced deterioration of IgG4-RD 3–232 months (mean, 62.8) after the diagnosis. New organ involvement was observed in all 8 patients, 2 of whom concurrently suffered exacerbation of the organs involved. In age- and sex-adjusted logistic regression analysis, serum IgG4 elevation (per 100 mg/dL, odds ratio 1.194, 95% confidence interval 1.017–1.402,  $p=0.030$ ) was the only significant factor related to deterioration of disease in untreated patients with IgG4-RD.

**Conclusions:** The present study suggests that serum IgG4 levels may be useful to predict the outcomes of untreated patients with IgG4-RD, who tend to have fewer affected organs and lower IgG4-RD responder index.

### THU0624 COLCHICINE: AN EFFECTIVE TREATMENT OPTION FOR UNCLASSIFIED AUTOINFLAMMATORY DISEASES IN CHILDREN

J.B. Kuemmerle-Deschner<sup>1</sup>, A.-L. Schock<sup>1</sup>, S. Hansmann<sup>1</sup>, S.M. Bensele<sup>2</sup>.<sup>1</sup>Department of Pediatrics, Division of Rheumatology, University Hospital Tuebingen, Tuebingen, Germany; <sup>2</sup>Rheumatology, Department of Paediatrics, Alberta Children's Hospital, University of Calgary, Calgary, Alberta, Canada

**Background:** Children and adults with clinically and genetically defined autoinflammatory diseases (AID) including CAPS, TRAPS and HIDS can receive expensive Interleukin-1 (IL-1) inhibitors in many countries around the world. However, patients suffering from unclassified autoinflammatory conditions characterised by recurrent fevers and organ dysfunction and the absence of a known pathogenic mutation commonly have no access to these treatment options.

**Objectives:** The aim of this study was to explore the efficacy and safety of colchicine treatment in children and adults with autoinflammatory diseases without pathogenic mutations.

**Methods:** Consecutive children and adults with autoinflammatory diseases without pathogenic mutations treated with colchicine were included in this single centre study and observed for a median of 12.94 months (range 1.25–66.73). Clinical features, autoinflammatory disease activity indices (AIDAI), inflammatory markers ESR, CRP, SAA and S100, frequency and duration of flares and physician global assessment of disease activity (VAS) were recorded serially and compared at baseline and while receiving Colchicine therapy.

**Results:** A total of 39 patients were included in the study. These were 16 girls and 23 boys, median age at start of colchicine therapy was 4 years (range 1–54). The diagnoses included PFAPA in 15, mutation-negative FMF in 11, autoinflammation with low-penetrance variants in nine (all *NLRP3*) and other unclassified AID in four patients. Recurrent fever was the leading symptom, mostly associated with arthralgia and myalgia. The mean disease activity decreased from 4.4 at baseline to 2.2 on colchicine. Mean SAA-levels decreased from 159 to 63.3 mg/L, CRP levels from 6.4 to 2.3 mg/dl. Flare frequency was reduced in 72% and remained unchanged in 28% of patients. Flare duration was reduced in 82%, unchanged in 14% and increased in only 4% of patients. Most common adverse events were abdominal pain and nausea in 50% of patients and appeared to be dose dependent.

**Conclusions:** Children and adults with unclassified autoinflammatory diseases may benefit significantly for colchicine therapy. Control of clinical disease activity and improved inflammatory markers were documented in 59% of patients. Colchicine should be considered in patients with active inflammatory disease with no access to IL-1 inhibitors. Controlled trials are needed to further explore this approach.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2018-eular.7473

### THU0625 IGG4-RELATED DISEASE MANIFESTATIONS DIFFER BETWEEN ASIAN AND NON-ASIAN SUBJECTS

Z.S. Wallace<sup>1</sup>, K. Okazaki<sup>2</sup>, C. Perugini<sup>1</sup>, H. Umehara<sup>3</sup>, T. Saeki<sup>4</sup>, M. Kawano<sup>5</sup>, Y. Zen<sup>6</sup>, R. Naden<sup>7</sup>, J.H. Stone<sup>1</sup>, on behalf of For the EULAR/ACR IgG4-Related Disease Classification Criteria Development Group. <sup>1</sup>Massachusetts Gen Hosp Rheumatol Unit, Harvard Med School, Boston, USA; <sup>2</sup>Kansai Medical University, Osaka; <sup>3</sup>Shiritsu Nagahama Byoin, Nagahama; <sup>4</sup>Nagaoka Red Cross Hospital, Nagaoka; <sup>5</sup>Kanazawa University, Kanazawa; <sup>6</sup>University of Kobe, Kobe, Japan; <sup>7</sup>University of Hamilton, Hamilton, Canada

**Background:** IgG4-related disease (IgG4-RD) is a multi-system immune-mediated condition that can affect nearly any organ. No study has evaluated differences in disease manifestations according to race. We evaluated this in a large cohort of IgG4-RD subjects submitted by an international group of investigators.

**Objectives:** To evaluate racial differences in manifestations of IgG4-RD.

**Methods:** To validate the ACR/EULAR IgG4-RD Classification Criteria, 76 investigators from North America, South America, Europe, and Asia submitted cases they considered to be IgG4-RD in either the preliminary phase or the validation phase. For each case, investigators included details related to diagnostic certainty, age at disease onset and diagnosis, race, organ involvement, biopsy findings, and laboratory results. Based on reported race, we dichotomized subjects into either Asian or non-Asian categories; subjects of South Asian (n=14) descent (e.g., India, Pakistan), all of whom resided in North America or Europe were grouped with non-Asian subjects. We compared the distribution of disease features according to race using t-tests, Wilcoxon tests, and Chi square tests, where appropriate, as well as in multivariable-adjusted models.

**Results:** In the validation phase, there were 493 cases of IgG4-RD submitted by 23 investigators who practice in Asia and 29 investigators who practice in North America or Europe. There was no significant difference in the distribution of specialists (e.g., rheumatology, gastroenterology) between Asian and non-Asian investigators (p=0.3). The majority of IgG4-RD subjects, both Asian (n=208) and non-Asian (n=285), were male (61% and 69%, respectively). Asian subjects were significantly older both at symptom onset and diagnosis (61.2±13.2 years and 62.6±12.8 years, respectively) compared to non-Asian subjects (55.1±14.9 years and 57.2±14.4 years, respectively, p<0.0001 for both comparisons). There was a significantly shorter diagnostic delay among Asian subjects compared to non-Asian subjects (1.4±2.7 years vs 2.2±3.7 years, p=0.01). Head/neck involvement was more common in Asians (52% vs 27%, p<0.0001) whereas hepatobiliary involvement was more common in non-Asians (52% vs. 42%, p=0.04). Asian subjects had a significantly higher median serum IgG4 concentration (666 mg/dL, IQR 320.5–1230 vs 240.5, IQR 100–505, p<0.0001) and were more likely to have a serum IgG4 concentration greater than five times the upper limit of normal (48% vs 20%, p<0.0001). In multivariable-adjusted models, differences in age and serum IgG4 concentration according to race remained strongly significant (p<0.001 for both comparisons).

**Conclusions:** Asian and non-Asian subjects differed regarding the age of disease onset and diagnosis, the distribution of organ involvement, and baseline serum IgG4 concentrations. There was a significantly shorter diagnostic delay among Asian subjects compared to non-Asian subjects. The etiology(ies) of these observed differences in the respective presentation of IgG4-RD in Asian and non-Asian subjects requires further investigation, but could include differences in diagnostic approach, environmental factors, and genetic predisposition.

### THU0626 CORRELATION AMONG SERUM AMYLOID A LEVELS, CLINICAL MANIFESTATIONS, TREATMENT AND DISEASE ACTIVITY IN PATIENTS WITH BEHÇET'S DISEASE

J. Sota<sup>1</sup>, A. Vitale<sup>1</sup>, O.M. Lucherini<sup>1</sup>, R. Franceschini<sup>1</sup>, B. Frediani<sup>1</sup>, I. Orlando<sup>1</sup>, M. Galeazzi<sup>1</sup>, C. Fabiani<sup>2</sup>, G.M. Tosi<sup>1</sup>, L. Cantarini<sup>1</sup>. <sup>1</sup>University of Siena, Siena; <sup>2</sup>Humanitas Clinical and Research Center, Milan, Italy

**Background:** Behçet's disease (BD) is an inflammatory disorder potentially leading to life- and sight-threatening complications: no laboratory marker correlating with disease activity or predicting the occurrence of disease manifestations is currently available in the clinical practice.

**Objectives:** To search for a correlation between serum amyloid-A (SAA) levels and disease activity evaluated via BD current activity form (BDCAF), to assess disease activity in relationship with different SAA thresholds, to examine the association between single organ involvements and the overall major organ involvement with different SAA thresholds, and to assess the influence of biologic therapy on SAA levels.

**Methods:** Ninety-five serum samples were collected from 64 BD patients, and their related demographic, clinical and therapeutic data were retrospectively collected.

**Results:** No correlation was identified between SAA levels and BD disease activity (Spearman  $\rho=0.085$ ; p=0.411), while a significant difference was found in the mean BDCAF score between patients presenting SAA levels<200 mg/L and those with SAA levels>200 mg/L (p=0.027). SAA levels higher than 200 mg/L were significantly associated with major organ involvement (p=0.008). A significant association was found between SAA levels>150 mg/dl and ocular (p=0.008), skin (p=0.002) and mucosal manifestations (p=0.012). Patients undergoing biologic therapies were significantly associated with SAA levels<200 mg/L compared with patients who were not treated with biologics (p=0.012).

**Conclusions:** SAA level does not represent *per se* a biomarker of disease activity, but might be useful as a predictor of major organ involvement and ocular disease relapse at certain thresholds in patients with BD.

**Disclosure of Interest:** None declared

### THU0627 DEMOGRAPHICS AND PRESENTING ORGAN INVOLVEMENT IN A COHORT OF PATIENTS WITH SARCOIDOSIS

K. Sheth<sup>1</sup>, G. Jeyashanmugaraja<sup>2</sup>, J. Simard<sup>1</sup>, S. Shoor<sup>1</sup>. <sup>1</sup>Stanford University, Palo Alto, USA; <sup>2</sup>Stanley Medical College, Chennai, India

**Background:** Sarcoidosis is a multisystem disorder of unknown etiology characterised pathologically by non-caseating granulomas in involved organs. Although mortality is reported in only 1%–5% of patients, there is data suggesting it might

be increasing and there is little information about the clinical and epidemiological characteristics of this group of patients.

**Objectives:** To compare basic demographics of a cohort of deceased sarcoid patients with a non-deceased sarcoid population, and to describe the presenting organ involvement among the deceased sarcoid population.

**Methods:** Patients seen at the Stanford University Hospital and Clinics from 2009–2017 who were >18 years of age with at least one ICD-9 or 10 diagnosis of sarcoidosis and at least one clinical note with the term "sarcoidosis" were identified by EMR. After determining the demographics of this cohort, deceased patients were identified and an extensive chart review of these subset of patients was conducted. The project was approved by Stanford's Institutional Review Board.

**Results:** 1190 adult patients with an ICD code for sarcoidosis were identified. Demographic comparison between the non-deceased and deceased population is summarised in the table 1 below.

	Non-deceased sarcoid patients	Deceased sarcoid patients
Total patients	1086	104
Gender:	660 (60.8%)	59 (56.7%)
Females	426 (39.2%)	45 (43.3%)
Males		
Race:		1 (0.9%)
Asian	67 (6.2%)	26 (25%)
Black	197 (18.1%)	45 (43.2%)
White	596 (54.9%)	0 (0%)
Native American	6 (0.6%)	18 (17.4%)
Others	128 (11.8%)	14 (13.5%)
Unknown	91 (8.4%)	
Ethnicity	918 (84.5%)	80 (76.9%)
Non-Hispanic	67 (6.2%)	11 (0.5%)
Hispanic/Latino	101 (9.3%)	13 (12.6%)
Unknown		

In comparison with non-deceased patients with sarcoidosis, the proportion of African American population was higher in the deceased population, whereas the proportion of Asians and whites was lower in the deceased population. The percentage of male patients in the deceased subset was slightly higher than the non-deceased population. 65 (62.5%) of the 104 deceased patients were symptomatic at diagnosis, 6 (5.8%) were asymptomatic and information was not available for 33 (31.7%) patients. Of the 65 symptomatic patients, presenting organ involvement was either pulmonary (34, 52.3%), cardiac (11, 16.9%), cutaneous (8, 12.3%), neurological (4, 6.2%), ocular (3, 4.6%), constitutional (5, 7.7%), unknown (1, 1.5%), musculoskeletal (1, 1.5%), renal–calcium related (1, 1.5%), hepatic (2, 3%), laryngeal (1, 1.5%), nasal and sinus (2, 3%), parotid gland (1, 1.5%), gastrointestinal (1, 1.5%), or others (5, 7.6%).

**Conclusions:** This study compares the demographics of subset of deceased sarcoid patients with a population of non-deceased sarcoid patients, and describes the presenting organ involvement among the deceased sarcoid population. African American males had a higher mortality rate compared to Asians and Caucasians. Pulmonary and cardiac disease represented 69.2% of organ involvement in the deceased. Our study showed a mortality rate of 8.7% in the sarcoid population which is in keeping with the newer studies that mortality in patients with sarcoid might be on the rise. With further study of this population, we aim to compare the characteristics of non-deceased sarcoid patients with the deceased patients, including presenting organ involvement, diagnostic workup and treatment regimen and hope to gain a better understanding of the possible reasons for increasing mortality in patients with sarcoidosis.

#### THU0628 DIFFERENCES IN CLINICAL MANIFESTATIONS OF BEHCET'S SYNDROME BY GENDER: CROSS-SECTIONAL ANALYSIS IN A UK COHORT

L. Chadwick<sup>1</sup>, T. Blake<sup>2</sup>, N.J. Goodson<sup>1</sup>, D. Situnayake<sup>2</sup>, R.J. Moots<sup>1</sup>. <sup>1</sup>Behçet's Syndrome Centre of Excellence, Aintree University Hospital NHS Foundation Trust, Liverpool; <sup>2</sup>Behçet's Syndrome Centre of Excellence, Sandwell and West Birmingham NHS Foundation Trust, Birmingham, UK

**Background:** Geographical variations in genotype and phenotype of Behçet's syndrome (BS) are reported.<sup>1,2</sup> Previous meta-analysis of international cohorts has highlighted differences in clinical manifestations of BS by gender.<sup>3</sup> A comparison of BS clinical manifestations by gender has not been analysed previously in a large UK BS cohort.

**Objectives:** 1) To compare the clinical manifestations of BS in a UK cohort by gender and 2) to compare this to published international data.

**Methods:** A retrospective cross sectional analysis was performed using clinical databases at the Liverpool and Birmingham BS Centres of Excellence. Patients with a multi-disciplinary diagnosis of BS or International Study Group (ISG) diagnostic criteria were included. Clinical manifestations and HLA-B51 positivity were compared by gender. T-tests and chi-squared tests were used for continuous and categorical data respectively and a p value of 0.05 or less was considered statistically significant.

**Results:** 433 patients met inclusion criteria (140 males, 32.3%). Male patients were younger and had significantly higher rates of ocular and vascular involvement, papulopustular skin rash and HLA-B51 positivity. Female patients had significantly higher rates of genital aphthosis and arthralgia.

	Male (n=140)	Female (n=293)	p value
Age (years), mean (s.d.)*	41.2 (12.5)	44.1 (11.9)	0.02
Recurrent oral aphthosis, n (%)	139 (99.3)	291 (99.3)	0.97
Genital aphthosis, n (%)*	111 (79.3)	278 (94.9)	<0.01
Papulopustular skin rash, n (%)*	69 (49.3)	107 (36.5)	0.01
Erythema nodosum, n (%)	29 (20.7)	56 (19.1)	0.70
Skin aphthosis (n,%)	7 (5.0)	8 (2.7)	0.23
Uveitis, n (%)*	81 (57.9)	99 (33.8)	<0.01
Retinal vasculitis, n (%)*	39 (27.9)	36 (12.3)	<0.01
Central nervous system involvement, n (%)	16 (11.4)	20 (6.8)	0.11
Large vein thrombosis, n (%)*	22 (15.7)	19 (6.5)	<0.01
Arterial thrombosis or aneurysm, n (%)	4 (2.9)	7 (2.4)	0.77
Thrombophlebitis, n (%)*	10 (7.1)	5 (1.7)	<0.01
Gastro-intestinal involvement, n (%)	8 (5.7)	25 (8.5)	0.30
Arthralgia, n (%)*	68 (48.6)	180 (61.4)	0.01
Ethnicity (British or White), n (%)*	90 (64.3)	238 (85.9)	<0.01
	(n=126)	(n=277)	
HLA-B51 positive, n (%)*	14 (58.3)	9 (20.0)	<0.01
	(n=27)	(n=45)	

\*statistically significant

**Conclusions:** Similar to published international cohorts, male patients with BS in the UK have higher rates of ocular and venous involvement, papulopustular skin rash and HLA-B51 positivity and lower rates of genital aphthosis and arthralgia in comparison to female patients. However, the extent to which these differences are attributable to ethnicity is unclear.

#### THU0629 A STUDY OF WBMRI IN ESTIMATING DISEASE ACTIVITY OF PM/DM AND THE FOLLOWING DISEASES DIAGNOSIS

Y. Li, D. Jiang, X. Zheng, L. Lu, Z. Li, Y. Guo, J. Tang, X. He, D. Xu, G. Gao. *the First Affiliated Hospital of Zhengzhou University, Zhengzhou, China*

**Background:** IM is a group of disease characterised by chronic symmetrical myasthenia, muscle fatigue and monocyte infiltrating skeletal muscle. This disease usually associates with the muscle of trunk and proximal limbs, skin lesions accompanied or not. Dermatomyositis (DM) and polymyositis (PM) account for the major part of IM clinically. The diagnose of these diseases mainly rely on clinical manifestation, biopsy, ECG and serum creatase. Whole-body magnetic resonance imaging (WBMRI) has been reported succeeding in diagnosing PM/DM through short tau inversion recovery (STIR) sequence, but the ability to estimate disease activity hasn't been reported.

**Objectives:** To evaluate the value in WBMRI through STIR sequence in evaluating the disease activity of polymyositis (PM) and dermatomyositis (DM) and screening interstitial lung disease (ILD) and osteonecrosis.

**Methods:** PM/DM patients meeting the Bohan and Peter diagnostic criteria from the First Affiliated Hospital of Zhengzhou University were admitted between 2015 August to 2017 December. A retrospective analysis of the WBMRI imaging data, serum creatine kinase, electromyography and muscle biopsy were performed. The WBMRI images were estimated by semiquantitative score and the disease activity was estimated by MDAAT. SPSS 20.0 was utilised to analyse the statistical significance.

**Results:** This study includes 61 patients, including 41 DM cases and 20 PM cases, all of these shows typical pathological feature and inflammatory muscle in WBMRI. Significant statistical correlation was found between the grade of muscle oedema estimated by WBMRI and the clinical assessment through MDAAT for muscle disease activity (DM  $r=0.57$ ,  $p=0.006$ ; PM  $r=0.84$ ,  $p=0.001$ ). The positive rate of serum creatine kinase test was 63% (39/61). Besides muscular changes, we also detected 35 cases in interstitial lung disease, 2 cases in osteonecrosis, 1 case in bone marrow oedema.

**Conclusions:** WBMRI is a sensitive, noninvasive method to evaluate the disease activity, which is better than serum creatine kinase. And it is of great value to screen the complication or concomitant diseases such as ILD and osteonecrosis.

#### THU0630 IMMUNE-RELATED ADVERSE EVENTS ASSOCIATED WITH IMMUNE CHECKPOINT INHIBITORS IN SPANISH PATIENTS

L. Villalobos, W.A. Giraldo-sifuentes, P. Moran-alvarez, J. Arroyo palomo, A. Briones-figueroa, C. Rita, J.L. Morell-hita. *Hospital Ramon Y Cajal, Madrid, Spain*

**Background:** Immune checkpoint inhibitors (ICI), a type of immunotherapy which block negative co-stimulation of T-cells, have surfaced as an important alternative of treatment for advanced malignancies. Unfortunately, these agents have been associated with immune-related adverse events (irAE).

**Objectives:** To analyse the frequency, type and outcome of irAE in Spanish patients treated with ICI.

**Methods:** We carried out a retrospective, observational and longitudinal study, including adult patients diagnosed with cancer and treated with ICI followed in our centre (Spanish university hospital) from October 2012 to December 2017. Demographics, clinical, therapeutic and outcome data were collected from their medical records.

**Results:** We included 125 patients, 66.4% males, all them Caucasians, with a mean age at diagnosis 63 years (range:42-81). The most common types of cancers were lung carcinoma (61.6%) and melanoma (12.8%). The ICI most frequently used was nivolumab (29.6%), followed by pembrolizumab (8.8%) and atezolizumab (8.8%), as monotherapy. It was also common, combinations, or the use of consecutive way with different drugs. Occurrence of irAE was reported in 51 patients (table 1) and the systems more frequently involved were gastrointestinal tract, endocrine glands and skin. Most of these cases were treated steroids at high doses but a case of colitis required infliximab. Withdrawal of immunotherapy was required in almost half of the adverse events (45%). During the follow-up period there were 5 deaths associated with irAE.

**Conclusions:** The frequency and type of irAE associated ICI in our series were similar to those reported in previous studies, except for rheumatological events, being arthritis and sicca syndrome the most frequently reported in other series. These adverse events are not rare and may be a potential cause of morbidity in these patients, so it is important to recognise them early and treat properly, with the rheumatologist being one of the specialists involved.

#### THU0631 REFRACTORY AND SEVERE UVEITIC CYSTOID MACULAR OEDEMA IMPROVES WITH TOCILIZUMAB IN DIFFERENT IMMUNE-MEDIATED INFLAMMATORY DISEASES

N. Vegas-Revenga<sup>1</sup>, V. Calvo-Río<sup>1</sup>, M. Mesquida<sup>2</sup>, A. Adán<sup>3</sup>, M. Hernandez<sup>3</sup>, E. Beltrán<sup>4</sup>, E. Valls Pascual<sup>5</sup>, D. Díaz-Valle<sup>6</sup>, G. Díaz-Soriano<sup>6</sup>, M. Hernandez-Grafella<sup>7</sup>, L. Martínez-Costa<sup>7</sup>, I. Calvo<sup>8</sup>, A. Atanes<sup>9</sup>, L. Linares<sup>10</sup>, C. Modesto<sup>11</sup>, E. Aurrecochea<sup>12</sup>, M. Cordero<sup>13</sup>, R. Demetrio-Pablo<sup>1</sup>, L. Domínguez-Casas<sup>1</sup>, J. Hernández<sup>1</sup>, M. González-Gay<sup>1</sup>, R. Blanco<sup>1</sup>. <sup>1</sup>HUMV, Santander; <sup>2</sup>H. Clinic; <sup>3</sup>H. Clinic, Barcelona; <sup>4</sup>H. General Universitario de Valencia, Valencia; <sup>5</sup>H. Clínico San Carlos, Madrid; <sup>6</sup>H. Regional Universitario, Málaga; <sup>7</sup>H. Peset; <sup>8</sup>H. la Fe, Valencia; <sup>9</sup>HUAC, A Coruña; <sup>10</sup>H. Arrixaca, Murcia; <sup>11</sup>H. Vall d'Hebron, Barcelona; <sup>12</sup>H. de Sierrallana, Torrelavega; <sup>13</sup>H. de León, León, Spain

**Background:** Cystoid macular oedema (CME) represents the leading cause of blindness in uveitis of different immune-mediated inflammatory diseases (IMIDs).

**Objectives:** Our aim was to evaluate the efficacy of Tocilizumab (TCZ) in different IMIDs with refractory CME.

**Methods:** Multicentre study of 24 patients with CME due to uveitis of different IMIDs refractory to traditional treatment with systemic corticosteroids and at least one conventional immunosuppressive drug including in most cases biological therapy (n=21). CME was defined by (OCT >300 µm). We studied CME with TCZ in 4 different IMID: juvenile idiopathic arthritis (JiA), Behçet's disease (BD), Birdshot retinochoroidopathy (BR) and idiopathic.

The main outcome was the improvement of macular thickness. Other variables assessed were inflammation of the anterior chamber and vitreous and best corrected visual acuity (BCVA)

**Results:** We studied 16 ♀/8 ♂, mean age 35.2±19.3 years. The associated diseases were: JiA (n=9), BD, BR<sup>4</sup> and idiopathic.<sup>4</sup> The ocular patterns were: panuveitis,<sup>9</sup> anterior uveitis,<sup>6</sup> posterior uveitis<sup>5</sup> and intermediate uveitis.<sup>4</sup> Most patients had bilateral involvement.<sup>22</sup> The biological therapy used before the administration of TCZ were infliximab,<sup>8</sup> adalimumab,<sup>18</sup> etanercept,<sup>2</sup> golimumab,<sup>2</sup> rituximab,<sup>2</sup> abatacept,<sup>3</sup> anakinra<sup>1</sup> and daclizumab.<sup>1</sup>

TCZ administration schedule was 8 mg/kg/4 weeks iv.<sup>23</sup> or every 2 weeks.<sup>1</sup> TCZ was used in monotherapy<sup>12</sup> or combined with conventional immunosuppressive drugs.<sup>12</sup> OCT values improved considerably in 12 months: in JiA from 340.6±134.1 µm to 252.5±30 µm, in BD from 375.1±117 µm to 235±7.1 µm, in BR from 550.7±214.4 µm to 295.5±43.2 µm and in idiopathic from 515±219.6 µm to 208.3±46.7 µm (figure 1). Inflammation in anterior chamber and vitritis and BCVA also improved in the 4 subtypes. No minor side effects were observed, so no patient had to stop treatment.

**Conclusions:** TCZ seems a rapid effective treatment in severe and refractory uveitic CME, regardless of the underlying IMIDs.

#### IDENTIFICATION OF ABERRANT T-CELL PHENOTYPE IN EPISODIC ANGIOEDEMA WITH HYPEREOSINOPHILIA (GLEICH SYNDROME) IN 30 PATIENTS: FREQUENCY, CLINICAL IMPLICATION AND PROGNOSIS

N. Abisror<sup>1</sup>, A. Mekinian<sup>1</sup>, A. Dechartres<sup>2</sup>, O. Fain<sup>1</sup>, J.E. Kahn<sup>3</sup>, on behalf of Guillaume Lefevre, Alice Berezne, Nicolas Noel, Chafika Morati, Julien Haroche, Mathilde Hunault-Berger, Christian Agard, Matthieu Groh, Loïk Geffray, Pierre Yves Jeandel, Sébastien Trouillier, Thomas Quemeneur, Jean François Dufour, Isa. <sup>1</sup>Internal Medicine, Sorbonne Université, APHP Hôpital Saint Antoine; <sup>2</sup>Center for Clinical Epidemiology, Hôtel Dieu, AP-HP, Paris; <sup>3</sup>Service de Médecine Interne, Université Versailles Saint-Quentin-en-Yvelines, Centre de Référence des Syndromes Hyperéosinophiliques (CEREO), Hôpital Foch., Suresnes, France

**Background:** Gleich's syndrome or "Episodic Angioedema with eosinophilia" (EAE) is a rare disorder characterised by recurrent episodes of angioedema, concomitant hyper eosinophilia and frequent elevated serum Immunoglobulin M (IgM) levels. So far, no series were reported in literature.

**Objectives:** In this retrospective French study we report the clinical spectrum and therapeutic management of patients with EAE in a large French nationwide retrospective multicenter cohort study, with a particular focus on lymphoid variant of hyper eosinophilic syndromes-related EAE.

**Results:** Thirty patients were included with a median age at diagnosis of 41 years<sup>5-84</sup> and a median follow up duration of 53 months.<sup>31-99</sup> The median time between two angioedema crises was 30 days<sup>7-192</sup> and the median duration of each crisis was 5.5 days<sup>1-90</sup> with swelling affected the face, the neck, the upper limbs, and the lower limbs. Twelve patients (40%) had an abdominal. The median blood eosinophil count at diagnosis was 6.9 G/L [1.44-53.5] and total serum IgM levels were increased in 20 patients (67%). Abnormal T-cell immunophenotypes were detected in 12 patients (40%): CD3-CD4+ in 8 patients, CD3 +CD4+CD7 in 2, CD3-CD3ic+CD4 CD8-CD5+CD7 in 1 patient and CD3 +4-8-2+5+7+TCR γδ in 1 patients with presence of clonal TCR γ gene rearrangement in 5 cases (17%). Fourteen patients (47%) had bone marrow cytology and/or histology revealing high eosinophil counts and/or infiltration by non-dystrophic eosinophils in all cases. Eosinophilic perivascular infiltration (without vasculitis) was reported in 2 patients (7%) in which a skin biopsy was performed. An eosinophilic infiltrate was also found in various organs (stomach, gallbladder, liver, ileon, and colon) that were biopsied and/or surgically removed.

All 30 patients were initially treated with glucocorticoid with a median initial dose of 40 mg of daily prednisone.<sup>5-80</sup> After first line treatment and a median time of 15.2 months (95% CI: 9.4-50.1), disease was considered as uncontrolled in 24 patients (80%) with relapses in 15 patients (50%) or glucocorticoid's dependence in 9 (30%).

Glucocorticoid-sparing agents were used in 14 cases (47%) for relapses (n=8) or glucocorticoid- dependence (n=6). Associated treatments consisted of interferon-α (n=8, 27%), mepolizumab (n=2, 7%), ciclosporin A (n=5, 17%), methotrexate (n=4, 13%), hydroxycarbamide (n=2, 7%).

The presence of an abnormal T-cell population was the sole factor associated with a shorter time to relapse (hazard ratio 4.15 [CI 95% 1.18-14.66; p=0.02]).

Two deaths occurred during follow-up (7%) due to lymphoma evolution for one and unexplained sudden death for the other.

**Conclusions:** EAE could be classified as a lymphoid variant of hyper eosinophilic syndrome but that it is an heterogeneous condition. Although patients usually respond well to glucocorticoids, those with a circulating T-cell clonal population are at higher risk of both relapse and lymphoma suggesting necessity to long-term treatment and close monitoring.

THU0633

#### ACUTE FORM OF SARCOIDOSIS (LÖFGREN SYNDROME) IN RHEUMATOLOGY PRACTICE

O.N. Egorova<sup>1</sup>, B.S. Belov<sup>1</sup>, S.G. Radenska-Lopovok<sup>2</sup>, <sup>1</sup>FSBI V. A. Nasonova Research Institute of Rheumatology; <sup>2</sup>1 FSBEIHE I.M. Sechenov Moscow State Medical University, Moscow, Russian Federation

**Background :** Löfgren syndrome (LS) is the acute form of sarcoidosis, characterised by erythema nodosum (EN), joints involvement, fever and intrathoracic lymphadenopathy. LS clinical polymorphism leads to diagnostic errors.

**Objectives:** To study the clinical, laboratory and radiological features of early stages of sarcoidosis in a cohort of patients referred to rheumatology centre.

**Methods:** The study included 125 patients (104 females and 21 males, mean age 42±12 y) with clinical and radiological features of LS. All patients were referred to rheumatology centre with EN diagnosis. The median duration of disease was 1 (0,5-2,0) months. All patients were subjected to comprehensive clinical and laboratory-instrumental examination, including biochemical panel and immunological parameters, chest X-ray or CT, as well as (15 cases) histopathology examination of nodular biopsy specimens of the skin and subcutaneous fat.

**Results:** In 97% pts EN involved the lower legs, mostly the anterior surface, in 35% - the hips, in 25% - the upper limbs and in 3% - the trunk. Symmetric lesions were documented in 50% of patients. Confluence of nodules forming conglomerates was registered in 48% pts. The involvement of more than 50% of lower leg surface (68%) was directly associated with the number of nodules (p<0.001; r=0.60) and C-reactive protein level (p=0.006; r=0.38). There was a direct correlation between the number of nodules and EN duration (p=0.04; r=0.20), and also the tendency to nodules confluence (p<0.001; r=0.39). Joint involvement was documented in 106 (85%) patients, with predominantly ankle (66,4%) and knee (40%) joints affected. Asymmetry of joint involvement was documented in 8% pts. Articular manifestations preceded the emergence of EN in 35 (28%) patients by mean 12±9 days. There was a significant direct correlation between the duration of articular syndrome and appearance of nodules and their number (p=0.02; r=0.45). Joint involvement after EN manifestation - in an average 12±7 days - was documented in 10% of cases. Male gender (odds ratio (OR) 6.5; confidence

interval (CI) 1.2–35;  $p=0.026$ ) and presence of nodular conglomerates (OR 4.8; CI 1.4–16.1;  $p=0.01$ ) were the key predictors of ground glass opacity (GGO) CT phenomenon. In 90% of patients EN did not relapse, and articular syndrome almost completely regressed during 1 year follow-up.

**Conclusions:** Patients with an acute form of sarcoidosis require coordinated action of different medical specialties, including rheumatologists, to determine the scope of further examination and adequate therapeutic regimen.

**Disclosure of Interest:** None declared

**THU0634 RISK OF SUDDEN CARDIAC DEATH IN PATIENTS WITH SARCOIDOSIS: A POPULATION-BASED RETROSPECTIVE COHORT STUDY**

A.A. Chahal<sup>1</sup>, P.A. Brady<sup>1</sup>, C.S. Crowson<sup>2</sup>, V.K. Somers<sup>1</sup>, E.L. Matteson<sup>2</sup>, P. Ungprasert<sup>3</sup>. <sup>1</sup>Cardiovascular Diseases, <sup>2</sup>Rheumatology, Mayo Clinic, Rochester, USA; <sup>3</sup>Research and development, Faculty of Medicine Siriraj Hospital, Mahidol University, Bangkok, Thailand

**Background:** Sarcoidosis is an inflammatory, non-caseating, granulomatous disorder of unknown etiology which can affect any body system including the heart and can be associated with increased risk of cardiovascular disease including sudden cardiac death (SCD). However, the risk and incidence of SCD are unknown.

**Objectives:** We sought to determine whether the risk of SCD in patients with sarcoidosis is higher than in the general population.

**Methods:** A population-based cohort of 345 incident cases of sarcoidosis (50% female; 90% Caucasian, 5% African-American; mean age 45.6 years) among Olmsted County, Minnesota residents in 1976–2013 was identified from a comprehensive medical record-linkage system. Medical records of those cases were individually reviewed to confirm the diagnosis of sarcoidosis which required physician diagnosis supported by histopathology, compatible clinical presentation and exclusion of other granulomatous diseases. A total of 345 sex and age-matched comparators (50% female; 95% Caucasian, 1% African-American; mean age 45.4 years) were also identified from the same underlying population. Mortality, including time, place and cause of death of cases and comparators were individually reviewed for SCD events. SCD incidence rates are reported per 1 00 000 person-years and Cox proportional hazards models were used for comparisons between groups.

**Results:** The median length of follow-up was 12.9 (6.0–23.4) years and 15.8 (6.8–25.5) for cases and comparators, respectively. Of the 58 deaths in patients with sarcoidosis, 10 were due to definite/probable SCD, versus 57 all-cause and 9 definite/probable SCDs in comparators. Incidence rate of SCD in sarcoidosis was 192 per 1 00 000 person-years (PY) (95% confidence interval (CI), 92–352) versus 155 per 100,000 PY (95% CI, 71–294) in comparators, corresponding to the hazard ratio of 1.28 (95% CI, 0.52–3.17,  $p=0.59$ ). Analysis by time of SCD, sex, age, calendar year of incidence/index date also did not reveal a significantly different rate of SCD between the 2 groups as demonstrated in table 1.

Category	Number of deaths in sarcoidosis/non-sarcoidosis	Rate per 100,000 PY in sarcoidosis (95% CI)	Rate per 100,000 PY in non-sarcoidosis (95% CI)	Hazard Ratio (95% CI)	p-value
SCD at night (22:00–06:00)	3/1	57 (12–168)	17 (0.4–95)	3.76 (0.39–36.47)	0.25

**Conclusions:** In this first ever population-based evaluation of SCD in sarcoidosis, patients are not at increased risk for SCD (all sub-types). These findings may reflect actual risk, but estimates may be affected by low statistical power. Future studies may further elucidate the risk and nature of cardiac death among patients with sarcoidosis.

**THU0635 PREGNANCY OUTCOMES IN MIXED CONNECTIVE TISSUE DISEASE: RESULTS FROM A MULTICENTRE COHORT STUDY**

M. Radin<sup>1</sup>, K. Schreiber<sup>2</sup>, M. Cuadrado<sup>2</sup>, I. Cecchi<sup>1</sup>, A. Laura<sup>3</sup>, F. Franceschini<sup>3</sup>, T. Caleiro<sup>4</sup>, E. Gibbone<sup>5</sup>, M. Khamashta<sup>6</sup>, J. Buyon<sup>7</sup>, P. Izmirly<sup>7</sup>, M. Aguirre Zamorano<sup>8</sup>, D. Roccatello<sup>1</sup>, L. Marozio<sup>5</sup>, S. Sciascia<sup>1</sup>. <sup>1</sup>Università di Torino, Turin, Italy; <sup>2</sup>Guy's and St Thomas' Hospital, London, UK; <sup>3</sup>Università di Brescia, Brescia, Italy; <sup>4</sup>Universidade de Sao Paulo, Sao Paulo, Brazil; <sup>5</sup>Sant'Anna University Hospital, Turin, Italy; <sup>6</sup>Dubai Hospital, Dubai, United Arab Emirates; <sup>7</sup>New York University School of Medicine, New York, USA; <sup>8</sup>University Hospital Reina Sofia, Cordoba, Spain

**Background:** Mixed connective tissue disease (MCTD) is characterised by signs and symptoms of a combination of disorders, primarily systemic lupus erythematosus (SLE), scleroderma and polymyositis and is characterised by the presence of high titre antibodies to U1-ribonucleoprotein (RNP).

When planning a pregnancy in patients with connective tissue diseases, ENA profiling is suggested but generally refers to testing for maternal antibodies specifically to components of the SSA/Ro-SSB/La ribonucleoprotein complex since these have been associated with foetal cardiac conduction abnormalities and neonatal skin rashes. Nevertheless, little is known about the maternal and foetal pregnancy outcomes in women with the presence of anti-U1RNP antibodies absent reactivity to SSA/Ro-SSB/La.

**Objectives:** We aimed to investigate foetal and maternal pregnancy outcomes from a large multicentre cohort of MCTD women.

**Methods:** Data was retrospectively collected from S. Giovanni Bosco Hospital and Sant' Anna University Hospital, Turin, Italy, the Lupus Unit, Department of Rheumatology at St Thomas' Hospital, London, UK, Hospital das Clínicas da Faculdade de Medicina da Universidade de Sao Paulo, Sao Paulo, Brazil, Hospital Reina Sofia de Córdoba, Spain, ASST Spedali Civili di Brescia, Brescia, Italy.

**Inclusion criteria included:** Women ever pregnant who fulfilled the established criteria of MCTD with confirmed anti-U1RNP positivity.

**Results:** This multicentre retrospective cohort study describes the foetal and maternal outcomes of 203 pregnancies in 94 consecutive women ever pregnant (mean age at data collection 45.1 years old, S.D. 10.9; mean disease duration at data collection 12.9 years, S.D. 8.5). Demographic, clinical and laboratory characteristics are summarised in table 1. Of the 203 pregnancies analysed the foetal outcomes were as follows: 146 (71.9%) resulted in live births, 38 (18.7%) in miscarriages, 18 (8.9%) in stillbirths (after 20 weeks gestation) and eleven (5.4%) cases showed intrauterine growth restriction (IUGR). Maternal pregnancy outcomes were as follows: eight (3.9%) cases developed pre-eclampsia, two (0.9%) cases developed eclampsia, 31 (15.3%) women developed gestational hypertension and three (1.5%) cases were diagnosed with gestational diabetes. Moreover, we report a case of complete congenital heart block (0.45%) and a case of skin rash in consecutive offspring born to a mother with anti U1RNP antibodies in the absence of anti-Ro/SSA-SSB/La antibodies.

Patients Characteristics	# (n)	%
Age at data collection, mean (S.D.), years	45.1 (10.9)	
Ethnicity		
Caucasian, n	148	72.9
Black, n	8	3.9
Asian, n	4	2.0
Other, n	13	6.4
Diagnosis

Laboratory testing		
Hypocomplementemia (C3), n	28	13.8
Hypocomplementemia (C4), n	25	12.3
anti-dsDNA positive, n	12	5.9
Hypogammaglobulinemia, n	47	23.2

**Conclusions:** The observed live-birth-rate was as high as 72%, with poorer foetal outcomes observed in MCTD women with antiphospholipid antibodies and

pulmonary or muscular involvement. While the true frequency of heart block associated with anti-U1RNP remains to be determined, this study raises the consideration of echocardiographic surveillance in this setting. Women with MCTD should receive a specific counselling when planning a pregnancy, as it is currently done in women with SLE.

**THU0636 CANAKINUMAB TREATMENT IN ADULT-ONSET STILL'S DISEASE: CASE SERIES**

S. Ugurlu<sup>1</sup>, G. Guzelant<sup>1</sup>, B. Yurttas<sup>1</sup>, B. Ergezen<sup>1</sup>, E. Dalkilic<sup>2</sup>, T. Kasifoglu<sup>3</sup>, B. Yagiz<sup>2</sup>, H. Ozdogan<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Istanbul University, Cerrahpasa Medical Faculty, Istanbul; <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Uludag University, Medical Faculty, Bursa; <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, Osmangazi University, Medical Faculty, Eskisehir, Turkey

**Background:** In Adult-onset Still's disease (AOSD), cases refractory to typical DMARDs. Canakinumab (an anti-IL-1 $\beta$  monoclonal antibody) has been reported to be effective in a limited number of refractory cases.<sup>1</sup>

**Objectives:** The aim of this retrospective study was to represent AOSD patients treated with Canakinumab in 3 centres.

**Methods:** The follow up data of 10 AOSD patients (8 female, 2 male), who were followed up in outpatient clinics of 3 tertiary centres were reviewed retrospectively. The initial characteristics and follow up findings were reported.

**Results:** The mean timespan between the initial diagnosis and Canakinumab treatment 45.2 $\pm$ 29 months (mean  $\pm$ SD). Before the onset of Canakinumab therapy, all patients were exposed to methotrexate, 1 to leflunomide, 8 to Tocilizumab and 8 to Anakinra. As for the biologic agents, 3 patients were also treated beforehand with Infliximab, 2 with Adalimumab, 2 with Etanercept and 2 with Rituximab. Canakinumab therapy was initiated in all patients with the indication of refractory disease under other medications, except for the one in whom neutropenia became evident under anakinra. The mean number of Canakinumab injections was 9.3 $\pm$ 8. The mean follow-up period of patients treated with Canakinumab was 43.1 $\pm$ 33 months. Seven out of 10 patients are still being treated with Canakinumab of 150 mg/month and one of 150 mg/every 2 months. One patient had a single injection and was fully controlled. The mean ferritin measure of 9 patients was reduced from 1292.3 $\pm$ 1530 ng/ml to 354 $\pm$ 530.2 ng/ml following the Canakinumab therapy (p=0.035). The mean of patient-reported global visual analogue scale (PG-VAS) scores was reduced from 7.4 $\pm$ 2.4 to 2.3 $\pm$ 2.2 with Canakinumab (p<0.001). Mean Erythrocyte sedimentation rate (ESR) was reduced from 44.2  $\pm$ 35.1 to 22.7 $\pm$ 26.5 with the help of Canakinumab therapy (p=0.005). Six patients are still on prednisolone at a maximum dose of 10 mg/day. The indication of therapy termination in the remaining 1 patient was the diagnosis of tuberculosis at 9th month of the treatment despite isoniazid prophylaxis. The patient was also treated with multiple biological agents beforehand, therefore it is not easy to conclude that treatment with Canakinumab induces tuberculosis flares.

**Conclusions:** Canakinumab treatment seems to be effective in refractory AOSD patients who were previously treated with various agents. We state that an IL-1 blocking agent, Canakinumab is a relatively safe and effective alternative in managing refractory AOSD cases. On the other hand, randomised controlled trials are needed to further investigate the role of Canakinumab in these cases as well as its use as the first choice of biologic agents.

**THU0637 EVALUATIONS OF COMPLEMENT PATHWAYS IN IGG4 RELATED DISEASE**

S. Fukui, Y. Fujita, T. Origuchi, A. Kawakami. *Immunology and Rheumatology, NAGASAKI UNIVERSITY GRADUATE SCHOOL OF BIOMEDICAL SCIENCES, Nagasaki, Japan*

**Background:** In IgG4 related disease (IgG4-RD), hypocomplementemia is known to be seen. Complement pathways consist of three pathways, classical,

alternative, and lectin pathways. Although IgG1 and IgG3 have ability to activate complement, IgG4 is known to be ineffective at activating complement.

**Objectives:** We attempted to elucidate which complement pathway is mainly associated with IgG4-RD.

**Methods:** Levels of complement elements and complement-associated elements, C1q, C2, C3, C3b/iC3b, C4, C4b, C5, C5a, C9, Factor D, Factor I, mannose-binding lectin (MBL), Factor B, Factor H, and properdin in preserved sera of patients with IgG4-RD at diagnosis and at remission were measured using multiplex bead-based assay. We compared complement levels at diagnosis of IgG4-RD patients with those of sex-matched healthy donors.

**Results:** This study included 28 IgG4-RD patients and sex-matched 28 healthy donors. The median age at diagnosis and healthy donors' age were 65 [interquartile range (IQR): 55–70] and 64 (IQR:56–73), respectively. Patients with IgG4-RD at diagnosis had significantly higher levels of C5 and C5a [33347 ng/mL vs. 30375 ng/mL (median), p=0.0293, 16417 pg/mL vs. 7083 pg/mL, p<0.0001, respectively] and significantly lower levels of C4, C4b, and Factor D (219671 ng/mL vs. 325596 ng/mL, p=0.0140, 8784 ng/mL vs. 16285 ng/mL, p=0.0101, 4569 ng/mL vs. 5482 ng/mL, p=0.0299, respectively) compared to healthy donors. Levels of C5, C5a, C4, C4b, and Factor D were not different in two groups which were divided by clinical manifestations at diagnosis except for lower C4b levels in patients with lymphadenopathy compared with patients without lymphadenopathy. There were no differences in MBL, which was associated with the lectin pathway. In remission after the administrations of prednisolone, levels of C5a significantly decreased compared to levels of C5a at diagnosis (16305 pg/mL to 10029 pg/mL, p=0.0043). Other complement factors did not change significantly.

**Conclusions:** The classical complement pathway may be associated with IgG4-RD rather than the alternative pathway and the lectin pathway based on results except for Factor D.

**THU0638 CLINICAL CHARACTERISTIC OF A GROUP OF PATIENTS WITH PSTPIP1-ASSOCIATED MYELOID-RELATED PROTEINEMIA INFLAMMATORY SYNDROME (PAMI)**

V.I. Burlakov<sup>1</sup>, A. Kozlova<sup>1</sup>, I. Mersiyanova<sup>2</sup>, A. Laberko<sup>1</sup>, E. Viktorova<sup>1</sup>, O. Shvets<sup>1</sup>, D. Yukhacheva<sup>1</sup>, G. Gordeeva<sup>1</sup>, E. Raykina<sup>2</sup>, V. Zakharova<sup>2</sup>, J. Rodina<sup>1</sup>, A. Shcherbina<sup>1</sup>. <sup>1</sup>Immunology, National Medical Research Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russia; <sup>2</sup>Laboratory of Molecular Biology, National Medical Research Center of Pediatric Hematology, Oncology and Immunology named after Dmitry Rogachev, Moscow, Russian Federation

**Background:** PSTPIP1-gene associated autoinflammatory diseases is a group of clinically diverse syndromes predominantly manifested by various skin conditions (pyoderma gangrenosum, acne, hidradenitis suppurativa, necrotizing fasciitis). Yet one of them – PAMI – manifests mainly with haematologic abnormalities and autoinflammation with or without purulent features, presenting diagnostic difficulties for treating physicians – mainly haematologists. PAMI treatment is also challenging as IL-1 inhibitors alleviate inflammatory symptoms but cytopenias usually require additional therapeutic agents.

**Methods:** We describe five PAMI patients from 3 families: (2 girls, 2 boys, and affected mother of two patients). c.748G>A(p.E250K) heterozygous mutation in PSTPIP1 was detected in all patients via targeted panel next generation sequencing and confirmed by Sanger sequencing.

**Results:** The median age of disease onset was 2 years (varied from at-birth onset to 7 years), the adult patient manifested at the age of 3. As described all patients manifested with cytopenias: thrombocytopenia in three, severe anaemia in five, neutropenia in three. All patients had elevated CRP and zinc levels, as previously described. Splenomegaly was noted in five, lymphadenopathy in one, colitis in one, severe arthritis in one (adult patient) and arthropathy in two patients. Mild pyoderma was noted only in one patient, two patients had skin vasculitis. One patient developed myelodysplastic syndrome and underwent successful hematopoietic stem cell transplantation (HSCT).

All patients received various immunosuppression prior to diagnosis with partial effect. After PAMI diagnosis rituximab was effective in two out of three, tocilizumab in one out of two, high dose anakinra in one patient. The girl who underwent HSCT is currently well, with full donor chimerism.

**Conclusions:** Haematologists need to be aware of the PAMI phenotype and include it in the diagnostic algorithm. Treatment still remains challenging and requires further investigation in larger groups of patients.

**THU0639 CHINESE EXPERIENCE WITH METHOTREXATE AS MAINTENANCE THERAPY IN IGG4-RELATED DISEASE**

F. Lian, J. Zhou, Y. Wang, H. Xu, L. Liang, X. Yang. *Dept. Of Rheumatology, 1st Affiliated Hospital Of Sun Yat-Sen University, Guangzhou, China*

**Background:** So far, for IgG4-related disease, no randomised clinical trials concerning therapy are published. Corticosteroids are considered the first-line treatment and most patients respond promptly to steroids. However, recurrent or refractory cases are common. Various immunosuppressive agents such as azathioprine (AZA), methotrexate or mycophenolate mofetil (MMF) have been introduced as corticosteroid-sparing treatment on small case series.<sup>1</sup> High cost of MMF and occasional severe bone marrow toxicity of Aza have limited their use in Chinese patients. Efficacious therapies with less toxicity and more cost-effectiveness were required to be identified and thus modify the immunotherapeutic strategies. Methotrexate (MTX) was commonly used in many other autoimmune disease. In the present study, we retrospectively reviewed 84 IgG4-RD patients who received MMF, Aza or MTX as maintenance regimens, compared the efficacy among these three groups and observed side effects of the medication.

**Objectives:** To assess the efficacy, safety and tolerability of methotrexate as maintenance therapy in the treatment of IgG4-related disease.

**Methods:** We retrospectively reviewed 84 IgG4-RD patients refractory or recurrent to steroids in south China from January 2012 to December 2015 who received MMF, Aza or MTX as maintenance regimen. MMF was administered daily to a maximum of 3 g/day. Aza was given at a dose maximum of 200 mg/day. MTX was given at a dose of 10–20 mg/week. Steroids were continued at the lowest effective dose. Details of the clinical presentation, serological, immunological variables and side effects were collected.

**Results:** Of the 84 patients, no significance of demographic variables was found among MMF group (22 cases), Aza group (29 cases), and MTX group (33 cases). The 2 year overall, the three groups had similar rates of remaining remission, which was 87.9% (29/33) in MTX group, 86.2% (25/29) in Aza group and 86.3 (19/22) in MMF group. Of the 11 recurrent cases despite immunosuppressive therapies, 2 cases were related to thyroid gland, 4 cases were related to pancreas, 3 cases were related to nose, and 2 cases were related to brain. All cases but the 2 patients with brain lesions achieved remission again after we changed the immunosuppressives. One case on Aza had severe bone marrow toxicity and 2 cases on MMF had severe infection. None of the cases on MTX had side effects affecting the treatment course. It's only associated with reversible liver dysfunction in our study.

**Conclusions:** MTX was as efficacious as MMF and Aza in maintaining remission in IgG4-related diseases, but with lower price and less severe side effects. IgG4-related brain lesions may be refractory and probably need to be treated with more aggressive agents.

**THU0640 PHARMACOLOGICAL TREATMENT AMONG NEWLY DIAGNOSED PATIENTS WITH JUVENILE IDIOPATHIC ARTHRITIS IN THE UNITED STATES**

A. Marshall<sup>1</sup>, K. Gupta<sup>1</sup>, M. Pazirandeh<sup>1</sup>, M. Bonafede<sup>2</sup>, D. McMorrow<sup>2</sup>. <sup>1</sup>Bristol-Myers Squibb, Princeton; <sup>2</sup>IBM Watson Health, Cambridge, USA

**Background:** Juvenile idiopathic arthritis (JIA) is a chronic condition affecting approximately 3 000 000 children and adolescents in the United States, yet little is documented about its real-world burden or treatment patterns.<sup>1</sup>

**Objectives:** To describe treatment patterns among JIA patients (pts) who initiated biological and non-biologic DMARDs.

**Methods:** Truven Health Analytics MarketScan<sup>®</sup> Commercial Database was used to identify pts aged 2–17 years with a new JIA diagnosis (index date; 2008–2016) and 12 months of continuous enrolment pre- and post-diagnosis. Pts with other rheumatic or autoimmune conditions were excluded. Receipt of a biologic and/or non-biologic was evaluated on or after the new JIA diagnosis. JIA-related

healthcare resource utilisation was defined as the presence of JIA diagnosis on a medical claim.

**Results:** A total of 3815 pts newly diagnosed with JIA met study selection criteria (mean [SD] age 10.0 [4.5] years, 69.0% female). Pts with 12 months of continuous enrolment post-treatment initiation (n=2014) were classified as non-biologic only (n=734), biologic only (n=873), and both biologic and non-biologic (n=407) users. Among all three cohorts, baseline corticosteroid use was 48.8%–60.4%, prescription NSAID use 69.6%–85.3% and opioid use 24.5%–29.0%. Mean (SD) number of JIA-related outpatient office visits was 4.9 (3.2) in non-biologic-only users, 6.0 (3.8) in biologic and non-biologic users, and 5.0 (4.4) in biologic-only users. The most commonly used non-biologic was MTX and biologic was etanercept (table 1). In the year following diagnosis, total JIA-related costs were highest among pts who used only biologics (mean \$27,292; SD \$32,833; median \$20,782) vs biologic and non-biologic agents (mean \$15,808; SD \$16,086; median \$11,925) and vs only non-biologics (mean \$4094; SD \$9292; median \$1918) (all p<0.001). Mean prescription costs in the year following biologic initiation were \$17 985 (SD \$11,188) for etanercept, \$26 217 (SD \$15,039) for adalimumab and \$38 260 (SD \$42,260) for infliximab. Of pts treated with a biologic only, TNF inhibitors (TNFi) comprised 87.1% of their treatment costs.

**Abstract THU0640 – Table 1.** JIA Treatment Frequency

	First agent used	Biologic-only users (n=873)	Biologic and non-biologic users (n=407)	Non-biologic-only users (n=734)	All treated patients (n=2014)	
<b>Biologics</b>	Abatacept	15 (1.7)	6 (1.5)		21 (1.0)	
	Adalimumab	188 (21.0)	106 (25.7)		294 (14.4)	
	Anakinra	43 (4.8)	9 (2.2)		52 (2.5)	
	Etanercept	523 (58.4)	259 (62.7)		782 (38.3)	
	Infliximab	71 (7.9)	20 (4.8)		91 (4.5)	
	Intravenous immunoglobulin	17 (1.9)	1 (0.2)		18 (0.9)	
	Tocilizumab	16 (1.8)	6 (1.5)		22 (1.1)	
	<b>Non-biologics</b>	Hydroxychloroquine		31 (7.5)	149 (20.2)	180 (8.8)
		MTX		341 (82.6)	506 (68.8)	847 (41.4)
		Sulfasalazine		42 (10.2)	75 (10.2)	117 (5.7)
Other (azathioprine, leflunomide)			5 (1.2)	15 (2.0)	20 (1.0)	

Data are n (%)

**Conclusions:** Initial JIA treatment is driven by etanercept, MTX and adalimumab, with the majority of biologic costs coming from TNFi. Receipt of other supportive medications (corticosteroids and NSAIDs) was common and JIA-related costs varied substantially by treatment cohort.

**THU0641 MUSCULOSKELETAL DISEASE CLINIC MANAGED BY A RHEUMATOLOGY DEPARTMENT**

A.J. Aznar Esquivel<sup>1</sup>, H. Sánchez-Pérez<sup>1</sup>, A. López-Hijazo<sup>2</sup>, S. Bustabad-Reyes<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Unidad De Gestión, Hospital Universitario De Canarias, San Cristobal De La Laguna, Spain

**Background:** Medical pathology of the Locomotor Apparatus (LA) is highly prevalent in the general population, tends to chronicity, generates an important temporary or definitive disability with great impact on the quality of life and functionality of the patient and entails high indirect and direct costs for the System National Health Classically, the medical pathology of LA has been managed by Traumatology departments.

**Objectives:** To analyse the characteristics of an LA clinic managed by the Rheumatology department and compare the data with the Traumatology department in the health area of the north of Tenerife (Reference population: 4 30 021 inhabitants).

**Methods:** We present the data collected from the Rheumatology clinic aimed to treat the medical pathology of the LA during the first 3 months, October to December 2017 and we compared the results with the same period of 2016, when this consultation was in charge of Traumatology department. Patients are referred from Primary Care (PC). We recorded the epidemiological characteristics of the patients, reason for consultation and final diagnosis, ability to resolve the consultation, need to request additional tests, treatment prescribed at discharge and referrals to other specialties.

**Results:** We treated 744 patients, with an average age of 55.26 years ( $\pm 15.02$ ), mainly women (62.6%). The most frequent referral consultation were: gonalgia (30.6%), polyarthralgia (14.5%) and low back pain (13.7%). Peripheral Osteoarthritis (26.6%) and soft tissue diseases (24.2%) were the most frequent processes. In 11.6% of the cases, no organic cause was found that justified the referred clinic ("nonspecific mechanical pathology") and 4.3% were asymptomatic when assessed. They provided complementary tests in the first consultation 85.2% of patients: 92.43% simple radiographs and 10.72% magnetic resonances. We requested: 7.2% MRI (54), 7.8% X-Ray (58), 7.1% Ultrasound (53), 5% Analysis,<sup>37</sup> 4.2% neurophysiological study,<sup>31</sup> 1.2% scintigraphy.<sup>9</sup> Discharged at the first consultation 72.4% and at the second visit 5%, leaving 22.6% of patients still in follow-up. 23.1% of the patients were referred to another specialty, mainly to Traumatology (15.3%). During the same period of time, October-December 2016, Traumatology treated 3730 patients and requested 506 MRI (13.5%).

**Conclusions:** The management of a locomotor apparatus clinic carried out by rheumatologists is more efficient: high resolution capacity in the first consultation, less number of complementary tests requested, mainly MRI (7.2% vs. 13.5%), and little referral to other specialties. It is necessary to create referral protocols from Primary Care to Rheumatology and to enhance the Rheumatology as the medical specialty of reference of the locomotor apparatus musculoskeletal diseases.

Goodman<sup>1,2</sup>. <sup>1</sup>Rheumatology, HOSPITAL FOR SPECIAL SURGERY; <sup>2</sup>Rheumatology, Weill Cornell Medicine; <sup>3</sup>Columbia Mailman School of Public Health; <sup>4</sup>Biostatistics; <sup>5</sup>Orthopaedics, HOSPITAL FOR SPECIAL SURGERY; <sup>6</sup>Orthopaedics, Weill Cornell Medicine, New York, USA

**Background:** Social factors affect TKA outcomes in osteoarthritis, both at the individual and neighbourhood level.<sup>1</sup> However, prior studies have not evaluated the influence of the proportion of immigrants within a neighbourhood, as reported for other high-volume and high-cost procedures.<sup>2</sup>

**Objectives:** Our objective was to determine the association of neighbourhood immigrant proportion (IP) on Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) pain and function scores at baseline and 2 years after elective TKA, and to examine if this is different between sexes.

**Methods:** Individual patient-level variables were obtained from a single institution TKA registry between May 2007 and February 2011, including demographics, baseline and 2 year WOMAC pain and function (0–100; 100 best), and geocodable US addresses. We only included patients living in the tri-state area - i.e. New York, Connecticut and New Jersey which is the catchment area for the hospital. Individual patient level variables were then linked to US Census Bureau data at the census tract level. Data was analysed using univariate and multivariable linear mixed effects models, with census tracts variables treated as random effects. A separate linear mixed-effects model was used to assess the interaction between neighbourhood IP and gender.

**Results:** Table 1 describes the 3,898 TKA cases analysed. In multivariable analyses, patients from neighbourhoods with low IP (<10%) had slightly higher baseline and 2 year WOMAC pain and function scores than those with high IP ( $\geq 40\%$ ), but these differences were not statistically significant (table 2). While women had

worse baseline and 2 year WOMAC pain and function scores (all  $p \leq 0.04$ ), this difference was not significantly influenced by neighbourhood IP (all  $p_{\text{interaction}} \text{ NS}$ ).

2-year		0.80		0.87
IP* $\geq 10\%$	45.08 $\pm$ 3.02		45.93 $\pm$ 3.11	
IP* $\geq 40\%$	44.81 $\pm$ 3.09		45.90 $\pm$ 3.18	

Table 2 Impact of neighbourhood immigrant proportion (IP) on WOMAC pain and function.

**Conclusions:** Patients coming from high (>40%) IP neighbourhoods present with worse baseline pain and function. Two years later, worse pain and function persist; however, the difference is not significant. Although sex differences favouring males are notable, these differences are not associated with IP. Social factor contributions to healthcare disparities are multidimensional, and future studies examining immigration-related neighbourhood characteristics may be warranted.

**THU0643 IMPACT OF SHOULDER ULTRASOUND IN QUALITY OF CARE INDICATORS IN PATIENTS WITH RECENT ONSET OF PAIN**

C.A. Guillen-Astete<sup>1</sup>, R. Penedo Alonso<sup>2</sup>, C. De La Casa Resino<sup>2</sup>. <sup>1</sup>Rheumatology Department; <sup>2</sup>Ramon y Cajal University Hospital, Madrid, Spain

**Background:** Ultrasound is a technique that has demonstrated diagnostic accuracy in the periarticular pathology of the shoulder. Although its value is not questioned, any diagnostic or therapeutic instrument must also demonstrate a beneficial impact for the patient in terms of quality of care. The quality of care can be measured by direct indicators (satisfaction surveys, waiting times) or indirect ones (referral rate, need for new consultations). We do not have studies that measure the impact of ultrasound in the assessment of hyperacute shoulder pain or of recent onset (less than a week) pain.

**Objectives:** Our purpose is to determine to what extent its use modifies three indicators of quality of care in relation to hyperacute omalgia of non-traumatic origin.

**Methods:** We conducted an analysis of three indirect indicators of quality of care: Need for reassessment due to pain (NRD), specialised referral rate (TDE) and length of stay in the emergency room (TDU). Records of patients treated for acute omalgia between 2014 and 2016 were reviewed and classified according to whether or not ultrasound was used as a diagnostic tool. For the statistical analysis we used the Student's T test, Fisher's exact test and survival curve (for TDU, TDE and NRD, respectively). The design used was that of a retrospective descriptive study. The information on waiting times was obtained from the CAJAL registry, information on new consults and specialised referral registration were obtained from the HORUS program and CAJAL registry. A comparative retrospective study was carried out based on the usual clinical practice. We examined the records of patients treated between 2015–2016 in the rheumatological emergency unit, who were known diabetics and who underwent an ultrasound-guided infiltration. Using the HORUS program we reviewed the patient's files of the immediate outcome after infiltration and the follow up consults.

**Results:** We included 1433 records of patient. Of these, 547 (38.1%) were examined with ultrasound assistance (Group-ECO) from which 2 were performed by a radiologist and the rest by a trained physician (Rheumatologist or Family Physician). The rest of the assessments, 886 (61.8%) were made without using the ultrasound (Control group), although in 540 cases a different imaging test was used. At 30 days after the first assessment, 90 patients (10.1%) in the control group had consulted again (56 due to emergencies and 34 per AP), while in the ECO-Group 14 (2.5%) consulted again at least once (12 for emergencies and 2 for AP) ( $p<0.001$ ). The referral rate to the specialist in the Control-Group was 36.5%, while in the ECO-Group was 6.21% ( $p<0.0001$ ). The average stay time was 94.5 DE 34.3 min in the Control Group and 105.4 DE 40.1 min in the ECO-Group ( $p<0.0001$ ).

**Conclusions:** The use of ultrasound as a diagnostic tool reduces the need for re-evaluations of patients and the rate of referrals to the specialist in a significant way. On the contrary, it increases the patient's stay time in the emergency room, probably due to delays in the availability of the equipment to perform the diagnostic procedure. Globally, our results show that most quality health care indexes improve in patients assessed by using ultrasonography.

#### THU0644 PERCEPTIONS OF BIOSIMILARS AMONG PRACTICING RHEUMATOLOGISTS: RESULTS FROM A MULTICOUNTRY STUDY IN EUROPE

C. Karki<sup>1</sup>, S. Shah<sup>1</sup>, L. Archer<sup>2</sup>, A. Baskett<sup>2</sup>, E. Baynton<sup>2</sup>, L. Ha<sup>1</sup>, B. Shah-Manek<sup>3</sup>.  
<sup>1</sup>Ipsos Healthcare, New York, USA; <sup>2</sup>Ipsos Healthcare, London, UK; <sup>3</sup>Ipsos Healthcare, San Francisco, USA

**Background:** In recent years, a substantial number of biosimilar (BioSm) products have come into the market for the treatment of rheumatic disorders, that might potentially improve patient access to treatment, resulting in cost savings and improved outcomes. However, given the limited regulatory evidence, clinical decision making continues to be a challenge.

**Objectives:** The objective of the study was to assess perceptions of prescribing biosimilars among rheumatologists and gain insights on barriers to access in the EU5 countries (United Kingdom (UK), France (FR), Italy (IT), Spain (SP) and Germany (DE)).

**Methods:** A cross-sectional survey was conducted in Q4 2016 in the EU5 among national, regional and hospital physicians who had been practicing between 3–30 years. Respondents completed a Physician Biosimilar Perceptual Questionnaire, which assessed the overall perception of anti-TNF biosimilars, specific barriers to prescribing them and cost factors influencing the current use and adoption of biosimilars. Data was analysed using descriptive statistics.

**Results:** A total of 256 rheumatologists in the EU5 were recruited as part of the study (with almost equal number of rheumatologists representing each EU5 country). Treating rheumatologists were practicing for an average of 16 years, mainly practicing in teaching hospitals (52%), and urban hospitals (21.9%). Overall, 83% of rheumatologists had awareness of biosimilars (range: 70% in DE and IT to 92% in UK). Among the different domains queried, only one in four rheumatologists trusted BioSm as much as branded biologics (range: 17.3% in IT to 39.2% in UK) and about 30% were comfortable with the safety profiles, and reported that long term efficacy and safety was of great importance for prescribing BioSm. Comparing perceptions of BioSm across countries, only 25% of rheumatologists in IT felt that BioSm offered equivalent efficacy to branded biologics, whereas 60.8% in the UK agreed with the same statement (figure 1). There was a consensus among respondents in all five countries regarding the lower cost of BioSm (range: 56.9% in SP to 72.5% in UK). Over 35% of the rheumatologists anticipated that clinical guidelines would require them to prescribe biosimilars. Data also showed that 63% chose BioSm for cost and 49% for formulary placement in clinical practice.

**Abstract THU0644 – Figure 1** Perceptions of Physicians in EU5: Equivalent efficacy as branded biologics

**Conclusions:** Overall, rheumatologists expressed the greatest level of awareness of biosimilars, even though differences were seen among the countries. Long term safety and efficacy data was of key importance; however, cost and formulary coverage did impact the prescribing pattern.

#### THU0645 IMPACT OF SECOND-LINE THERAPY WITH ABATACEPT VERSUS OTHER TARGETED DMARDS ON THE RISK FOR INFECTION-RELATED HOSPITALIZATIONS AND ASSOCIATED COSTS AMONG RA PATIENTS IN THE UNITED STATES

D. Paul<sup>1</sup>, L. McDonald<sup>1</sup>, A. Marshall<sup>1</sup>, T. Curtice<sup>1</sup>, M. Lingohr-Smith<sup>2</sup>, B. Menges<sup>2</sup>, J. Lin<sup>2</sup>.  
<sup>1</sup>Bristol-Myers Squibb, Princeton; <sup>2</sup>Novosys Health, Green Brook, USA

**Background:** Abatacept is a targeted DMARD (tDMARD) with a unique mechanism of action that has demonstrated a lower risk of infection-related hospitalizations as a second-line (2L) therapy compared with other tDMARDs among patients (pts) with RA. The cost savings in the United States associated with this reduced risk of infection-related hospitalizations is not well understood.

**Objectives:** To compare infection-related hospitalisation risk and associated healthcare costs of RA pts who were treated at 2L with abatacept versus other tDMARDs, including TNF- $\alpha$  inhibitors (TNFis) and non-TNFis.

**Methods:** Pts prescribed a 2L tDMARD (index date) who had  $\geq 1$  inpatient diagnosis or  $\geq 2$  outpatient diagnoses of RA in the 12 months prior to the index date were identified from the MarketScan<sup>®</sup> Commercial and Medicare claims databases between 1 January 2010 and 30 September 2015. Pts were required to have 12 months of continuous insurance coverage prior to the index date (baseline period) and throughout the follow-up period ( $\geq 12$  and up to 36 months). All pts were treated with a TNFi in first line. Infection-related hospitalizations and associated costs (on a per-pt per-month [PPPM] basis) were evaluated during baseline and follow-up periods. Multivariable regression analyses were used to evaluate the impact of index drugs on the risk of infection-related hospitalisation, as well as infection-related medical cost change from baseline to follow-up periods, while controlling for differences in baseline pt characteristics.

##### Unadjusted Comparison of Medical Cost, PPPM

	Abatacept	TNFis	Non-TNFis	p-value
Baseline medical costs	\$121	\$48	\$39	0.02
Follow-up medical costs	\$30	\$69	\$102	0.16
Medical cost difference (follow-up – baseline)	–\$91	\$21	\$63	0.005

##### Regression Adjusted Comparison of Difference of Medical Cost, PPPM

	Cost difference, PPPM	p-value
TNFi vs abatacept	\$51	0.09
Non-TNFi vs abatacept	\$76	0.04

**Results:** Among the study population, 285 pts (mean age 55 years; 85% female) were treated with abatacept, 954 with TNFis (mean age 52 years; 82% female) and 288 with non-TNFis (mean age 55 years; 76% female). After controlling for differences in pts' characteristics, Cox regression showed that the risk for an infection-related hospitalisation was significantly greater among those treated with TNFis (hazard ratio [HR] 2.8; 95% CI 1.2, 6.7;  $p=0.02$ ) and higher, although not

significant, among those treated with other non-TNFis (HR 2.4; 95% CI 0.9, 6.3;  $p=0.08$ ) compared with those treated with abatacept. Infection-related medical costs were lower for abatacept compared with other non-TNFis as shown in the table 1.

**Conclusions:** In the real-world setting in the United States, pts treated with abatacept versus other tDMARDs tended to have a lower risk for infection-related hospitalisation and lower infection-related medical costs.

#### THU0646 EVALUATING THE QUALITY OF CARE FOR RHEUMATOID ARTHRITIS

C. Barber<sup>1</sup>, D. Marshall<sup>1</sup>, E. Szefer<sup>2</sup>, D. Thompson<sup>2</sup>, D. Lacaille<sup>3</sup>. <sup>1</sup>University of Calgary, Calgary; <sup>2</sup>Emmes Canada; <sup>3</sup>University of British Columbia, Vancouver, Canada

**Background:** The Arthritis Alliance of Canada (AAC) has developed performance measures (PMs) to evaluate RA care quality.

**Objectives:** To operationalize and report on 4 PMs using administrative data for British Columbia (BC), Canada: PM1) percentage of patients with new onset RA with at least one visit to a rheumatologist in the first year after diagnosis, PM2) percentage of RA patients under the care of a rheumatologist seen in follow-up at least once per year, PM3) percentage of RA patients dispensed a disease modifying anti-rheumatic drug (DMARD) during the measurement year, PM4) time to DMARD therapy in new onset RA.

**Methods:** All patients with RA visits between 01/01/1997 and 31/12/2009 in BC were identified using health administrative data and followed until December 2014. Cases were identified by  $\geq 2$  physician billing codes for RA  $\geq 8$  weeks but  $\leq 5$  years apart. For this study, only cases age  $>18$  who were seen by a rheumatologist at some point over follow-up were included. PM1: The percentage of incident RA cases with at least one visit to a rheumatologist within one year of their first RA visit was evaluated. PM2: The proportion of prevalent RA cases having at least one visit per year was calculated for those under rheumatology care. PM3: The percentage of prevalent RA patients dispensed a DMARD (including biologic agents and small molecule inhibitors) was calculated. PM4: time from RA onset (defined as first RA visit) to DMARD therapy was reported (in the calendar year of RA incidence), using median and 90th percentile wait time, as well as the proportion meeting the benchmark of 14 days.

**Results:** The cohort included 18 976 incident and 29 639 prevalent RA cases. The percentage of patients seen by a rheumatologist within 1 year from RA diagnosis increased over time, while the percentage of RA patients under the care of a rheumatologist seen in yearly follow-up declined steadily overtime. Further analysis (data not shown) suggests this is due to having more people with longer follow-up in the latter years, and lost to follow-up increasing over time, rather than a true

calendar year effect. The percentage of RA patients dispensed a DMARD was suboptimal (56% $>$ 65%). Of note, patients were not necessarily seen by a rheumatologist during the measurement year. The median time to DMARD improved over time to 23 days in 2009, with roughly one third receiving a DMARD within the benchmark of 14 days.

**Conclusions:** The present study represents the first time the AAC's PMs have been tested in administrative data and highlights where the measures are being met and potential gaps in care which require further examination.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2018-eular.5023

#### THU0647 LONGITUDINAL STUDY OF LONG-TERM POVERTY AND PERSISTENT DEPRESSIVE SYMPTOMS IN SLE

E. Yelin<sup>1</sup>, J. Yazdany<sup>1</sup>, L. Trupin<sup>1</sup>, N. McCormick<sup>2</sup>, P. Katz<sup>1</sup>. <sup>1</sup>Medicine/Rheumatology, University of California, San Francisco, San Francisco, USA; <sup>2</sup>Arthritis Research Centre of Canada, University of British Columbia, Vancouver, Canada

**Background:** A prior study found that persons with SLE in long-term poverty have greater accumulation of disease damage over 6 years than those exiting poverty or never in poverty<sup>1</sup>. The present study evaluates the effect of long-term poverty status on depressive symptoms over the same duration of time.

**Objectives:** Analyse the impact of long-term poverty on prevalent and incident persistent depression after accounting for other risk factors for depression among persons with SLE.

**Methods:** Data are from the UCSF Lupus Outcomes Study in which persons with SLE were recruited in 2003 throughout the U.S. and interviewed annually through 2015. In each year we characterised respondents' poverty status based on household income and family size and administered the CESD measure of depressive symptoms, defining a high level of depressive symptoms using a validated SLE-specific cutpoint ( $\geq 24$ ) associated with a formal diagnosis of depression<sup>2</sup>. Prevalent persistent depression was defined as having high levels of depressive symptoms for  $\geq 3$  years between 2009 and 2015. Incident persistent depression used the same criteria, measured only among those who had low levels of depressive symptoms between 2006 and 2009. Logistic regression was used to estimate the impact of being poor in every year from 2003–2009, permanently leaving poverty by 2009, or never being poor on prevalent and incident persistent depression, with and without adjustment for gender, age, marital status, race/ethnicity, education, disease duration, extent of accumulated damage by 2009 using the Brief Index of Lupus Damage<sup>3</sup>, smoking status, and BMI.

**Results:** 535 persons with SLE were interviewed in each year from 2003 to 2015 (94% female, 65% non-Hispanic whites, mean age in 2003 50 years, range 20–83, mean disease duration 17 years, range 1–51). Between 2003 and 2009, 81% were never poor, 8% exited poverty, and 11% were poor in every year. 89 of the 535 (16.6%) met the study definition of prevalent persistent depression; 23 (7.4%) of the 312 free of high levels of depressive symptoms from 2006–2009 had incident persistent depression as of 2015. Table 1, below, indicates that those who were poor in every year had significantly higher rates of prevalent and incident persistent depression than those exiting poverty or never poor.

Abstract THU0646 – Table 1. Results of Four Performance Measures for RA.

Measurement Year <sup>1</sup>	Prevalent RA cases	Incident RA cases	PM1: Patients seeing rheumatologist within 1 year of RA onset	PM2:% of Patients under rheum care with yearly rheumatology visits	PM3: % Patients dispensed a DMARD	PM4: Median (90th percentile) days to DMARD	PM4: % with DMARD within 14 days of onset
2004	17 472	1647	80%	57%	59%	31 (825)	27%
2005	19 097	1614	82%	56%	60%	26 (579)	30%
2006	20 612	1704	85%	54%	60%	23 (411)	31%
2007	21 764	1430	83%	53%	60%	29 (399)	28%
2008	22 721	1305	86%	50%	60%	26 (339)	29%
2009	23 386	921	92%	49%	61%	23 (188)	34%
2010	23 122	-	-	46%	60%	-	-
2011	22 781	-	-	44%	56%	-	-
2012	22 370	-	-	42%	56%	-	-
2013	21 966	-	-	41%	57%	-	-
2014	21 412	-	-	41%	57%	-	-

<sup>1</sup>PMs reported on a prevalent cohort until 2014, and on an incident cohort reported until 2009

**Abstract THU0647 – Table 1.** Odds Ratios (95% CI) for Effect of Poverty Status between 2003 and 2009 on Prevalent and Incident Persistent Depression. CESD Score  $\geq 24$  in 3 or More Years), between 2009 and 2015, with and without Adjustment

Outcome	Poor Every Year	Exited Poverty	Never Poor
<b>Prevalent Persistent Depression (n=535)</b>			
Unadjusted	3.9 (2.1, 7.2) *	1.0 (0.4, 2.2)	Ref.
Adjusted†	2.9 (1.4, 6.1) *	0.8 (0.3, 1.8)	Ref.
<b>Incident Persistent Depression (n=312)‡</b>			
Unadjusted	4.5 (1.3, 15.4) *	0.9 (0.2, 3.9)	Ref.
Adjusted†	4.1 (0.9, 19.1)	0.7 (0.1, 3.7)	Ref.

\*  $p < .01$

† Adjusted for gender, age, marital status, race/ethnicity, education, disease duration, extent of accumulated damage in 2009, smoking status, and BMI

‡ Excludes persons with high levels of depressive symptoms 2006–2009

**Conclusions:** Public policy to help persons with SLE stay out of poverty or to exit poverty may lower their rates of prevalent and incident persistent depression. Attention to the economic status of persons with SLE should be part of an overall treatment strategy including treatment for depression since such attention may help reduce accumulation of damage as well as reduce the prevalence and incidence of persistent depression.

#### THU0648 “AS A PRACTITIONER I FEEL ENRICHED”: RHEUMATOLOGY TUTORS' EXPERIENCES OF DELIVERING A MANUALISED GROUP COGNITIVE-BEHAVIOURAL FATIGUE PROGRAMME TO PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

E. Dures<sup>1</sup>, A. Hammond<sup>2</sup>, S. Hewlett<sup>1</sup>, on behalf of The RAFT Group. <sup>1</sup>School of Health Sciences, University of the West of England, Bristol, Bristol; <sup>2</sup>School of Health Sciences, University of Salford, Salford, UK

**Background:** Reducing Arthritis Fatigue by clinical Teams using cognitive-behavioural approaches (RAFT) is a 7-centre RCT of a manualised group cognitive-behavioural (CB) programme to reduce fatigue impact.<sup>1</sup> After four days training plus a delivery observed by clinical supervisors, tutor pairs (rheumatology nurses and occupational therapists (OTs)) delivered the programme four times to patients with RA. Quality assurance observations confirmed tutors used CB approaches and RAFT results show the programme reduced patients' fatigue impact at 26 weeks.<sup>2</sup>

**Objectives:** The aim of the current study was to understand tutors' experiences of RAFT training and delivery to inform future programme roll out.

**Methods:** 14 RAFT tutors (9 nurses; 5 OTs) participated in one-to-one interviews, which were audio-recorded and transcribed. Data were analysed by ED, SH, and AH using inductive thematic analysis.

**Results:** Four main themes were identified.

Theme 1: “It's quite daunting” - Delivering a complex programme that was “quite different to what any of us had done before” required time and effort (“I couldn't really make sense of it without actually doing a lot of work around it”). Initially, training with clinical supervisors (“experts”) who are “so good at what they do” challenged tutors' confidence (“the anxiety is are we going to deliver it the way they did?”).

Theme 2: “Most useful was actually getting to practice the sessions” - Tutors valued watching clinical supervisors demonstrate programme sessions during training (“professionals who have shown us how to do it”) plus the opportunity to practice themselves (“role playing the sessions was really helpful”).

Theme 3: “Putting it in a way that was still true to the message” - The RAFT manual was “very valuable” and “it had to be adhered to”; however, tutors wrote individual crib notes (“our own manual in our own words”) to consolidate information, deepen understanding, and gain confidence. The process was supported by “positive and constructive criticism” in the observed delivery (“the supervisor kept putting us back on track”).

Theme 4: “As a practitioner I feel enriched” - CB skills acquired during RAFT impacted tutors' wider work (“making a massive difference to my clinical practice”), and enhanced the self-management support they offered patients, including

“the particular ability to draw things out from people” and “learning when to listen and stand back and try and get the patients to find the answers”.

**Conclusions:** Initially, RAFT training and delivery were a challenge for tutors because the CB approach was a new way of working. Individually adapting RAFT manual wording plus feedback from supervisors increased tutors' confidence. Tutors believed the CB skills acquired during RAFT enhanced their wider clinical practice and the self-management support they offered patients. Future training should include RAFT session demonstrations and skills practice for tutors, with feedback from clinical supervisors.

#### THU0649 UNDERSTANDING ETHNIC DIFFERENCES IN THE UTILISATION OF EXERCISE FOR OSTEOARTHRITIS

E.R. Vina<sup>1</sup>, D. Ran<sup>2</sup>, M.J. Hannon<sup>3</sup>, C.K. Kwok<sup>1</sup>. <sup>1</sup>Division Rheumatology, Medicine; <sup>2</sup>Arthritis Center, University of Arizona, Tucson; <sup>3</sup>Medicine, University of Pittsburgh, Pittsburgh, USA

**Background:** According to a US survey, the prevalence of arthritis-attributable activity limitation, work limitation and severe pain are all significantly higher among Hispanics than among non-Hispanics (NHs). Ethnic differences in osteoarthritis (OA) patients' experience of pain may be related to marked disparities in the use of OA treatments. According to EULAR OA guidelines, exercise should be an integral part of the management of knee and hip OA. Whether or not exercise is underutilised and why it may be underutilised by Hispanics to treat OA is unclear.

**Objectives:** The objective of this study was to determine if there are ethnic differences in the history and current use of exercise as therapy for patients with knee or hip OA. The secondary objective was to compare Hispanic and NH patients with lower extremity OA with respect to their familiarity and perceptions of the efficacy and risk of exercise as treatment for OA.

**Methods:** Research participants  $\geq 50$  years of age with chronic and frequent pain due to knee or hip OA were recruited from a university medical centre. Structured interviews were conducted to determine patient sociodemographic characteristics, clinical information, self-reported actual use/prescription receipt of exercise for OA treatment (currently, last 5 years), and familiarity with exercise (3 items, yes/no response). Perceptions of the benefits (4 items) and risks (3 items) of exercise, and willingness to exercise to treat OA were also evaluated; each question in these measures has a five-category ordinal response scale. Fisher's exact or Wilcoxon-Mann-Whitney tests were conducted to determine if knowledge and perceptions about exercise were associated with ethnicity (Hispanic vs NH).

**Results:** In our cohort of patients with knee or hip OA, Hispanics (n=119), in comparison to NHs (n=201), were younger (mean age 61.5 vs. 65.3) and less likely to have an annual income of  $\geq \$50,000$  (13.5% vs. 39.1%). A lower proportion of Hispanics than NHs reported using exercise to treat OA at present (51% vs. 66%,  $p=0.0165$ ) and in the last five years (68% vs. 84%,  $p=0.0010$ ) or receiving a prescription for exercise in the last five years (45% vs. 67%,  $p<0.0001$ ) (figure 1).

Hispanics, compared to NHs, were also less likely to report ever hearing about exercise to treat OA (71.43% vs. 91.83%,  $p<0.0001$ ), having family/friends that received it for treatment (33.33% vs. 51.20%,  $p=0.0023$ ), or having a good understanding of it as a treatment for OA (66.96% vs. 79.33%,  $p=0.0161$ ). A lower proportion of Hispanics than NHs believe that exercise is beneficial (or very beneficial) for arthritis (49.12% vs. 69.09%,  $p<0.0001$ ) and that exercise is helpful (or very helpful) for them (60.52% vs. 75.61%,  $p=0.0056$ ). No ethnic differences in the perceptions of risk of exercise were observed. Hispanics were also less willing to exercise to treat OA than NHs (67.83% vs. 82.61%,  $p=0.0018$ ).

**Abstract THU0649 – Figure 1** Proportion who reported use of or prescription receipt for exercise to treat OA by ethnicity **Conclusions:** Among patients with knee or hip OA, Hispanics were less likely than NHs to utilise exercise as treatment for arthritis.

They were also less familiar with its use for OA treatment, less likely to believe in its efficacy, and less willing to use it as treatment for OA. Improving patient knowledge and attitudes about exercise may increase utilisation of this OA treatment and help reduce ethnic differences in OA outcomes.

#### THU0650 EARLY HELP SEEKING OR SELF-MANAGEMENT: A QUANTITATIVE ASSESSMENT IN THE CONTEXT OF RHEUMATOID ARTHRITIS

G. Simons<sup>1</sup>, J. Belcher<sup>2</sup>, K. Kumar<sup>1</sup>, M. Falahee<sup>1</sup>, C.D. Mallen<sup>2</sup>, R.J. Stack<sup>1,3</sup>, K. Raza<sup>1</sup>, <sup>1</sup>University of Birmingham, Birmingham; <sup>2</sup>Keele University, Keele; <sup>3</sup>Nottingham Trent University, Nottingham, UK

**Background:** Rheumatoid arthritis (RA) should be treated with DMARDs in its earliest stages to reduce the likelihood of permanent joint damage and disability<sup>1</sup>. This therapeutic window is often missed. One important cause is delayed help seeking by patients themselves<sup>2</sup>. Qualitative work with members of the public has previously identified a number of potential causes for this delay<sup>3</sup>.

**Objectives:** To quantify and extend the findings of existing qualitative research investigating factors which impact on speedy help seeking for symptoms of RA.

**Methods:** A survey of members of the public without a diagnosis of inflammatory arthritis assessed the speed with which they would seek medical attention if they were to experience symptoms of RA (stiffness, pain and joint swelling). It explored factors which might impact on the speed with which help would be sought, including: self-management of symptoms; barriers to and drivers of help seeking and information seeking.

**Results:** 1088 people (788 females; 9 undisclosed) aged between 18 and 96 years completed the survey. 48% indicated that they would seek help quickly for RA symptoms, however 63% would delay seeing their GP in order to try to self-manage the symptoms. Most intended to self-manage with over the counter medication (e.g. ibuprofen), massaging the joint or exercising. Barriers endorsed included difficulty getting a GP appointment (39%); fear of wasting the GP's time (34%) and being busy with family/work (37%). Drivers (>90%) included worsening of symptoms, inability to work, struggling to do usual activities, symptoms spreading to other parts of the body or inability to self-manage symptoms. Most participants would seek out information prior to seeking medical attention for the symptoms. Sources of information frequently endorsed were: Internet (74%); relatives/friends (49%); someone with a joint problem (41%) and pharmacists (37%).

**Conclusions:** Less than half of the current sample would seek help quickly for the symptoms of RA. Several barriers and drivers identified in qualitative research<sup>3</sup> were endorsed by the survey sample making them valid targets for interventions. Most participants would further seek out information about the symptoms prior to seeking medical attention and their preferred sources of information such as the internet or the pharmacist should be used in these targeted interventions.

#### THU0651 THE INFLUENCE OF AGE, GENDER, EMPLOYMENT STATUS, OR EDUCATION ON THE CHOICE OF BIO-SIMILAR VS. BIO-ORIGINAL VARIANT OF THE SAME BDMARD IN PATIENTS WITH RA OR AS STARTING BIOLOGICAL THERAPY – REAL LIFE DATA FROM THE CZECH BIOLOGICS REGISTRY ATTRA

J. Zavada<sup>1</sup>, L. Nekvindova<sup>2</sup>, K. Pavelka<sup>1</sup>, J. Vencovsky<sup>1</sup>, on behalf of collaborators of the ATTRA registry. <sup>1</sup>INSTITUTE OF RHEUMATOLOGY, Prague; <sup>2</sup>Institute of Biostatistics and Analyses spin-off, Faculty of Medicine, Masaryk University, Brno, Czech Republic

**Background:** Perceptions on bio-originator (bo) and bio-similar (bs) biologics among HCPs and pts, as well administrative regulations or economic incentives may influence their utilisation in clinical practice. The ATTRA registry captures more than 95% of pts with RA and AS treated with biologics in the Czech Republic (CZ). Access to biological therapy in CZ is limited to about 30 authorised centres. Bs infliximab (INF) has been prescribed in CZ since 11/2013, and bs etanercept (ETA) since 1/2016 concurrently with bo INF and ETA. There has been no administrative regulation concerning the use of bs or bo in CZ.

**Objectives:** To explore whether age, gender, employment status, or level of education influence the choice of bs vs. bo variant of the same bDMARD in pts with RA or AS starting bDMARD in CZ.

**Methods:** Data from the ATTRA registry on pts with RA or AS starting their first bDMARD between 11/2013 and 10/2017 were used. The start of bo vs. bs ETA, or bo vs. bs INF as the first bDMARD was the main outcome of interest. Multivariate logistic regression analysis was used to explore the impact of education, employment status, age and gender on the start of a first bDMARD after adjustment for disease characteristics, and the bDMARD molecule.

**Results:** 560 pts started ETA (22.6% bo, 14.2% bs) or INF (9.7% bo, 53.5% bs) in the study time frame. In the multivariate model (table 1) pts starting ETA (ref. INF) had lower odds to receive a bs (OR 0.11, CI95% 0.07–0.17), and pts with primary education (vs. secondary or tertiary) had higher odds to receive any bs (OR 1.84, CI95% 1.08–3.13). When we performed separate analyses for pts treated in academic/public hospitals (n=314), the adjusted OR for pts with primary education was 0.78 (CI95% 0.37–1.64), while in private centres (n=246) the OR was 5.32 (CI 95% 2.32–12.16). When we introduced an interaction term for type of practice x level of education, the adjusted OR for pts with primary education in private centres was 2.26 (CI95%, 1.14–4.46, p=0.019).

Abstract THU0651 – Table 1.

Parameters	OR (95% CI)	p-value
HDA vs. REM+LDA+ MDA (acc to DAS28/ASDAS)	0.94 (0.50; 1.77)	0.859
CRP [mg/l]	1.00 (0.99; 1.01)	0.770
HAQ	1.16 (0.75; 1.78)	0.513
AS (vs. RA)	1.40 (0.81; 2.40)	0.229
ETA (vs. INF)	0.11 (0.07; 0.17)	<0.001
Age at start of 1st bDMARD	1.01 (0.99; 1.04)	0.271
Disease duration	1.01 (0.98; 1.04)	0.693
Female	0.78 (0.48; 1.26)	0.316
Primary education (vs. Secondary or Tertiary)	1.84 (1.08; 3.13)	0.024
Sick leave (vs. employed)	1.61 (0.68; 3.82)	0.283
Disability pension (vs. employed)	0.74 (0.36; 1.54)	0.421
Old age pension (vs. employed)	0.61 (0.28; 1.31)	0.205
Unemployed (vs. employed)	1.08 (0.48; 2.42)	0.845
Maternity leave/student (vs. employed)	1.48 (0.43; 5.08)	0.529

**Conclusions:** We found that in private centres providing biological therapy in CZ, pts with primary education had higher adjusted odds to obtain bs as the first bDMARD. We cannot exclude that different pt characteristics and residual confounding may have been involved. The interpretation is complex and related not only to perception of bs by HCPs and pts, but also to unmeasured economic incentives and other factors.

THU0652

### COMPARATIVE COST PER RESPONSE FOR FOUR CLINICAL OUTCOMES OF TOCILIZUMAB MONOTHERAPY VERSUS ADALIMUMAB MONOTHERAPY IN A HEAD-TO-HEAD RANDOMISED DOUBLE-BLIND SUPERIORITY TRIAL (ADACTA) IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Best, J. Pei. Genentech, Inc., South San Francisco, USA

**Background:** The cost-effectiveness of different biologic therapies is an important component in guiding treatment decisions for patients with rheumatoid arthritis (RA).

**Objectives:** To compare drug and adverse event costs and cost per successful clinical response with tocilizumab (TCZ) monotherapy vs adalimumab (ADA) monotherapy in patients with RA.

**Methods:** Patients in the ADACTA trial<sup>1</sup> were randomised to either TCZ 8 mg/kg intravenously every 4 weeks or ADA 40 mg subcutaneously every 2 weeks as monotherapy for 24 weeks. Drug costs of \$397.71/80 mg vial for TCZ (plus \$136 administration cost per infusion) and \$2220.62/40 mg for ADA were based on Wholesale Acquisition Costs (WAC) drug prices (July 2017). Outcomes included patient-level drug costs and cost of hospitalisation due to adverse events, and cost per response. Cost per response was calculated by dividing the mean drug plus administration cost by the proportion of patients achieving Disease Activity Score-28 joints (DAS28) <2.6 (remission) or American College of Rheumatology response criteria 20%/50%/70% (ACR20/ACR50/ACR70). The proportions of patients achieving DAS28 <2.6, ACR 20, ACR50 and ACR70 were 39.9%, 65.0%, 47.2% and 32.5% for TCZ, respectively, and 10.5%, 49.4%, 27.8% and 17.9% for ADA, respectively; p<0.0001, p=0.0038, p=0.0002, p=0.0023 for TCZ vs ADA, respectively. Hospitalisation costs were calculated using the daily hospital cost of \$2433 (2017) and number of hospital days.

**Results:** Among the 163 patients treated with TCZ and 162 with ADA, mean total drug and administration costs per patient over 24 weeks were \$16,674.74 and \$23,357.63, respectively. Mean drug and administration costs were lower per each clinical response achieved with TCZ compared with ADA (DAS28 <2.6: \$41 791 vs \$222,454; ACR20: \$25 653 vs \$47,283; ACR50: \$35 328 vs \$84,020; ACR70: \$51 307 vs \$130,490). The total hospital days/costs were 32/\$77 856 for TCZ and 43/\$1 04 619 for ADA.

**Conclusions:** In this comprehensive comparative assessment, the cost to achieve all four clinical responses was lower for patients receiving TCZ than for ADA.

THU0653

### CHANGES IN RHEUMATOLOGY PROVISION AND PRACTICE IN A PUBLICLY-FUNDED SINGLE PAYER HEALTHCARE SYSTEM

J. Widdifield<sup>1</sup>, S. Bernatsky<sup>2</sup>, V. Ahluwalia<sup>3</sup>, C. Barber<sup>4</sup>, L. Eder<sup>5</sup>, C. Hofstetter<sup>6</sup>, B. Kuriya<sup>5</sup>, V. Ling<sup>7</sup>, A. Lyddiatt<sup>6</sup>, M. Paterson<sup>7</sup>, J. Pope<sup>8</sup>, C. Thorne<sup>9</sup>. <sup>1</sup>Sunnybrook Research Institute, Toronto; <sup>2</sup>McGill University, Montreal; <sup>3</sup>William Osler Health System, Brampton; <sup>4</sup>University of Calgary, Calgary; <sup>5</sup>University of Toronto; <sup>6</sup>Ontario Rheumatology Association; <sup>7</sup>Institute for Clinical Evaluative Sciences, Toronto; <sup>8</sup>Western University, London; <sup>9</sup>Southlake Regional Health Centre, Newmarket, Canada

**Background:** The global shortage of rheumatologists is an increasing concern. Statistics from physician surveys have projected changes in the workforce composition (ageing, feminization, and generational trends), which have implications for the workforce clinical activity. In order to adequately document the issues and potential solutions, more detailed information is needed regarding clinical activity, demographic changes and the implications of these, in a population-based sample.

**Objectives:** To describe changes in the number, demographics and clinical activity of Ontario rheumatologists over the past decade.

**Methods:** We analysed administrative health data from 2000 to 2013 in Ontario, Canada, where all 13 million residents are covered by a publicly funded health-care system. Rheumatologists, and their characteristics, were identified using a validated physician registry. We used fee-for-service billing claims to quantify clinical activity levels expressed as full-time equivalents (FTE). Physicians below the 40th percentile of total billings were classified as providing less clinical activity

(<1 FTE i.e. professor/scientist); 40–60th percentile were classified as 1 FTE; and >60 th percentile as >1 FTE (i.e. high volume community practice).

**Results:** In 2000, there were 146 rheumatologists in Ontario (88 of whom worked  $\geq 1$  FTEs); this increased to 187 rheumatologists (114  $\geq 1$  FTEs) in 2013. Despite the increase, due to an increase in the Ontario population over this time, the proportion of Ontarians seen by a rheumatologist annually remained constant (2.7%) as was the overall provincial per capita supply (1.2 rheumatologists per 75 000 population, 0.7 FTEs/75,000). In 2000, 34% of rheumatologists were female compared to 48% in 2013. During this time, the proportion of rheumatologists aged >60 + years increased (16% to 26%). The annual median (IQR) number of days of clinical service decreased from 220<sup>178–243</sup> days in 2000 to 176<sup>138–213</sup> days in 2013. The percentage of rheumatologists with patient encounters on at least 209 days/year (an alternative FTE benchmark) showed a downward trend from 46% in 2000 to 22% in 2013. Male rheumatologists had more patient encounters each year, and a higher proportion of male rheumatologists worked as  $\geq 1$  FTE. Average practice sizes declined over time (figure 1A), as did the median number of patient encounters per rheumatologist per year (figure 1B).

**Abstract THU0653 – Figure 1.** A) Average Rheumatology Practice/Panel Size (Number of Unique Patients per Rheumatologist) According to FTE Classification; B) Average Number of Patient Encounters per Rheumatologist According to FTE Classification

**Conclusions:** Although there has been an increase in the number of rheumatologists, the per capita supply and access to rheumatologists have remained unchanged. We observed changing workforce demographics and declining clinical activity over time. Factors affecting clinical activity (including an ageing and greater feminization of the workforce, clinic saturation, increasing care complexity, models of care, greater demands for continuing medical education and research activity) warrants further study.

### ABSTRACT WITHDRAWN

THU0655

### PATIENTS' EVALUATION OF DUTCH HEALTH CARE IN SYSTEMIC SCLEROSIS: UNMET NEEDS AND PREFERENCES

J. Spierings<sup>1</sup>, C.H. van den Ende<sup>2,3</sup>, M.R. Schriemer<sup>4</sup>, J.K. de Vries-Bouwstra<sup>5</sup>, M. C. Vonk<sup>3</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, University Medical Centre Utrecht, Utrecht; <sup>2</sup>Department of Rheumatology, st Maartenskliniek; <sup>3</sup>Department of Rheumatology, Radboud University Medical Centre, Nijmegen; <sup>4</sup>Schriemer Peil, Rotterdam; <sup>5</sup>Department of Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

**Background:** Systemic sclerosis (SSc) is a chronic, heterogeneous autoimmune disease with a large impact on quality of life. To optimise health care, more insight is needed in patients' experiences of the currently provided care.

**Objectives:** To identify unmet needs and preferences from a patient point of view regarding health care in the Netherlands

**Methods:** 2093 patients with SSc, from both regional (n=7) and university hospitals (n=6) in the Netherlands, were invited through their rheumatologist for an online, anonymous questionnaire comprising multiple choice, multiple response

and open questions about health care needs, quality of care (CQ index), and additional sociodemographic characteristics. Questions were based on results from a literature study and three semi-structured multicenter focusgroup interviews with 23 patients. Eight themes were identified (table 1).

**Results:** 493 patients, median age was 60 years and 73% were women, completed the questionnaire at the 10th of January 2018. Inclusion is still ongoing. Patients had been diagnosed for a median period of four years, 38% and 23% reported having been diagnosed with limited or diffuse cutaneous SSc, respectively. Interestingly, 39% did not know the subtype. 50% received care in a centre of expertise and 32% in  $\geq$ two centres. 32% had to travel >one hour for each visit. Themes containing the most important unmet needs were:<sup>1</sup> multidisciplinary collaboration;<sup>2</sup> education of caregivers;<sup>3</sup> patient information;<sup>4</sup> the role of the patient and;<sup>5</sup> non-pharmacological care. Multidisciplinary collaboration was rated 68 out of 100 and information exchange among physicians 66 out of 100. The lack of knowledge about the disease among health professionals (40%) and difficulty finding experts in SSc (25%) were most reported hurdles. 10% of patients did not receive any information from the rheumatologist at time of diagnosis, but when provided 97% thought this information was clear. Although most of the patients were involved in treatment decisions (83%), 12% did not receive the care they needed in their opinion. 60% was referred to a specialised nurse for non-pharmacological support. During hospital visits, more focus was preferred on fatigue (45%, n=227), Raynaud's phenomenon (31%, n=155), physical disabilities (29%, n=147), impaired hand function (26%, n=129) and coping with the unpredictable course of the disease (25%, n=124). Highest priority was given to improved knowledge among general practitioners (67%), multidisciplinary collaboration (43%) and information exchange among health care providers (25%) (figure 1)

Abstract THU0655 – Table 1. Identified health care themes from focusgroup interviews

Themes
Multidisciplinary collaboration
Education of caregivers
Patient information
Role of the patient
Shared care; regional and university hospitals
Information exchange among caregivers
Organization of health care services
Non-pharmacological support

Abstract THU0655 – Figure 1 Top. five prioritised points for improvement

**Conclusions:** SSc patients mainly prefer more attention to symptoms during doctor's visits and wish for improved collaboration and information exchange among health care providers. This knowledge will guide the nation-wide initiative to optimise health care for patients with SSc in The Netherlands.

**Disclosure of Interest:** None declared

## THU0656 SYSTEMIC LUPUS ERYTHEMATOSUS IN COLOMBIA: A BIBLIOMETRIC ANALYSIS

J.E. Barahona-Correa. Pontificia Universidad Javeriana, Bogota, Colombia

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with a high burden of disease on individuals and healthcare systems.<sup>1</sup>

Bibliometric analyses assess scientific literature on a given topic, and allow the identification of novel research trends, based on statistical data of scientific literature and their indicators.<sup>2,3</sup> In Colombia, few efforts have addressed at Rheumatology or Autoimmunity.

**Objectives:** To perform a bibliometric study on the scientific production on SLE in Colombia that describes its distribution, development trends, national and international collaboration trends, and its impact on the scientific community.

**Methods:** A descriptive bibliometric study was performed using three databases (Web of Science, SCOPUS and Scielo). Annual national research output, number of articles, city and institution of origin, national and international collaboration, scientific journals, publication language, and citations number were assessed. VOS-viewer was used to illustrate collaboration networks.

**Results:** SCOPUS disclosed 307 articles, Web of Science 270, and Scielo 90. The highest number of citations per item (19.8) and the maximum national H index<sup>41</sup> were found in SCOPUS. More than 80% of articles, regardless of the database, were published during the last 10 years. 'Universidad del Rosario' and 'Universidad de Antioquia' showed the highest research output. Bogotá and Antioquia, followed by Valle del Cauca, presented the highest number of articles. An important number of national and international collaborations were observed, which differed in each database.

Production per institution in WoS, Scielo and SCOPUS

Item	WoS	SCOPUS	Scielo
Number of articles	270	307	90
Number of registries <sup>a</sup>	376	469	150
Articles in the last 10 years (%)	86	87	91
Mean historic number of publications (SD)	5.9 (9.7)	6.7 (11)	1.9 (3.4)
Annual mean number of publications in the last 10 years (SD)	21.2 (7.5)	24.2 (9.6)	7.4 (2.5)
Original articles (%)	62	73	74
National H index for the last 10 years	32	41	3
Total number of cites	5260	6093	39
Total number of cites adjusted by auto-citation	4953	4987	24
Mean cites per element	19.5	19.8	0.43
Most frequent journals (% of grand total)	'Annals of the rheumatic diseases'(10) and 'Arthritis and rheumatism' (8)	'Revista Colombiana de Reumatología' <sup>18</sup> (7)	'Revista Colombiana de Reumatología' (68) and 'Acta Médica Colombiana' (7)

<sup>a</sup> Defined as the number of positive results in each database, which may differ due to co-authors as both sum up for both institutions.

Abbreviations: WoS Web of Science, SD Standard deviation

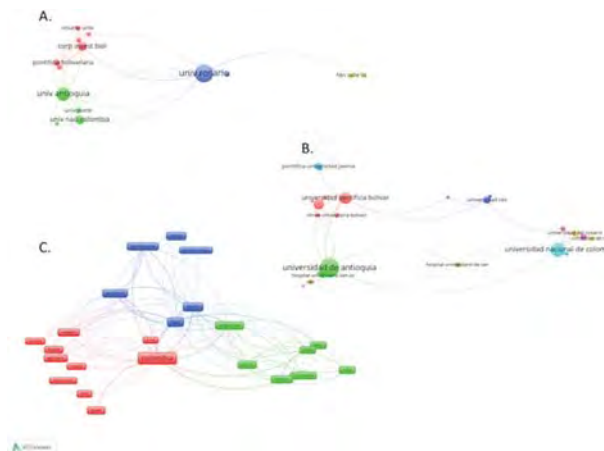

Figure. National and international collaboration networks on SLE research in Colombia. A. National (WoS) B. National (Scielo) C. International (WoS)

**Conclusions:** A significant growth of the research on SLE in Colombia was observed, however, its impact is far from being meaningful. Strategies aimed at strengthening the interest in Rheumatology and research in undergraduate

students must be encouraged, particularly supporting research seedbeds and young researchers.

#### THU0657 EFFECTS OF ADALIMUMAB INITIATION ON CORTICOSTEROID UTILISATION AND MEDICAL COSTS AMONG PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Qiao<sup>1</sup>, K.L. Winthrop<sup>2</sup>, J. Griffith<sup>3</sup>, C.M. Kaplan<sup>1</sup>, C.A. Spivey<sup>1</sup>, A. Postlethwaite<sup>1</sup>, J. Wang<sup>1</sup>. <sup>1</sup>University Of Tennessee Health Science Center, Memphis; <sup>2</sup>Oregon Health Sciences University, Portland; <sup>3</sup>AbbVie, North Chicago, USA

**Background:** Treatment guidelines recommend low dose corticosteroids (steroids) as a short-term (<3 months) therapy among rheumatoid arthritis (RA) patients to 'bridge' patients until benefits of disease modifying anti-rheumatic drugs (DMARDs) are observed.<sup>1</sup> However, for many patients it may be difficult to wean/eliminate steroids once they are initiated. Initiation of more effective therapies such as biologics may help promote reduction in steroid use.

**Objectives:** This study examined the impact of initiating adalimumab (ADA) on steroid utilisation and medical costs among patients with RA.

**Methods:** A retrospective analysis was conducted among adult RA patients initiating ADA as the initial biologic in the MarketScan Database (2012–2016). Study outcomes included whether oral/injectable steroids were used, daily dose, dosage categories (<5 and ≥5 mg/day), number of steroid injections, and medical costs. Outcomes were compared 6 months pre- and post ADA initiation using Chi-square tests for categorical variables and paired t-tests and Wilcoxon rank sum tests for continuous variables. Because various types of variables were used for study outcomes, mixed effects logistic, classical linear, multinomial logistic models, and linear model with a log link and gamma distribution were used to adjust for patient demographic and health characteristics such as age, gender, health plan type, census region, and Charlson Comorbidity Index.

**Results:** The study sample included 6,214 ADA initiators. As compared to the 6 months prior to ADA initiation, there was a reduction in proportions of patients using oral steroids (from 72% to 59.5%) and injectable steroids (from 34.9% to 26.9%), average daily dose of oral steroids (from 3.3 mg/day to 2.5 mg/day), patients with dose ≥5 mg/day (from 22.3% to 15.1%), number of steroid injections (from 0.63 to 0.47), and medical costs (from \$5,233.5 to \$4,807.9) ( $p < 0.01$  for all comparisons). Multivariate analysis produced similar patterns. In the 6 months post-ADA initiation, patients were less likely to use oral steroids (Odds Ratio (OR): 0.40; 95% Confidence Interval (CI): 0.36–0.45) or steroid injections (OR: 0.59; 95% CI: 0.54–0.65). Coefficient estimate for daily dose reduction was  $-0.87$  (95% CI:  $-1.00$ – $-0.74$ ). Post-ADA relative risk ratios for dosage categories <5 mg/day and ≥5 mg/day compared to zero were 0.48 (95% CI: 0.43–0.53) and 0.36 (95% CI: 0.32–0.41), respectively. Post-ADA incidence rate ratio for number of steroid injections was 0.72 (95% CI: 0.69–0.76). Ratio estimate for medical costs was 0.84 (95% CI: 0.79–0.89). All multivariate results reported were significant ( $p < 0.01$ ).

**Conclusions:** Among patients with RA, following ADA initiation, there is a reduction in steroid utilisation and its dose, and patients' medical costs. Prospective studies should be conducted to confirm this relationship in the future.

#### THU0658 RECOMMENDATIONS FOR THE ASSESSMENT AND OPTIMISATION OF ADHERENCE TO DISEASE-MODIFYING DRUGS IN CHRONIC INFLAMMATORY RHEUMATIC DISEASES: A PROCESS BASED ON LITERATURE REVIEWS AND CONSENSUS

L. Gossec<sup>1</sup>, A. Molto<sup>1</sup>, X. Romand<sup>1</sup>, D. Puyraimond-Zemmour<sup>1</sup>, M. Lavielle<sup>2</sup>, C. Beauvais<sup>2</sup>, E. Senbel<sup>2</sup>, R.-M. Flipo<sup>2</sup>, S. Pouplin<sup>2</sup>, C. Richez<sup>2</sup>, A. Saraux<sup>2</sup>, L. Gutermann<sup>2</sup>, P. Gaudin<sup>2</sup>, D. Wendling<sup>2</sup>, M. Dougados<sup>2</sup>. <sup>1</sup>Rencontres d'Experts 2017 Working Group, Paris; <sup>2</sup>Rencontres d'Experts 2017 Working Group, Paris, France

**Background:** In chronic inflammatory rheumatic diseases including rheumatoid arthritis (RA), spondyloarthritis (SpA), psoriatic arthritis (PsA) and connective tissue diseases (CTD), adherence to disease-modifying drugs is only moderate over the long term and non-adherence may lead to complications, unnecessary treatment switches and heightened costs.

**Objectives:** To develop recommendations to facilitate in daily practice, the measurement of non-adherence, the individualised assessment of risk of non-adherence and the management of non-adherence with the objective to optimise adherence to treatments in patients with chronic inflammatory rheumatic diseases.

**Methods:** The project scope was limited to chronic inflammatory rheumatic diseases (i.e., RA, SpA, PsA, CTD, crystal-induced arthritis, vasculitis and auto-inflammatory diseases), and to disease-modifying drugs (i.e., mainly conventional DMARDs, biologics and targeted synthetic DMARDs). The process comprised (a) systematic literature reviews of data from 3 key databases and several websites, of methods (including questionnaires) to measure non-adherence, risk factors for non-adherence and management options for non-adherence with their reported efficacy. (b) a consensus of 104 rheumatologist and nurse experts during a 2 day face-to-face meeting. (c) Final recommendations were anonymously evaluated by the participants for agreement and ease of applicability (1–5 were 5 is highest).

**Results:** (a) After screening 1131 publications and 194 other documents, 231 relevant papers were analysed. (b) The consensus process led to 5 overarching principles and 10 recommendations regarding adherence. In summary, adherence is important, imperfect, and multi-factorial. Patient-physician interactions play an important role, as do patient beliefs. Adherence should be assessed at each outpatient visit, at least using an open question. Questionnaires and hydroxychloroquine blood level assessments may also be useful. People who are younger, worried of side effects, do not see the necessity of the treatment, and are in psychological distress are more prone to non-adherence. Patient information and education, and patient/physician shared decision, are key to optimise adherence. Other techniques such as formalised education sessions, motivational interviewing and cognitive behavioural therapy may be useful. All health professionals can get involved and e-health may be a support. (c) The agreement with the recommendations was high (range of means, 3.88–4.47) but ease of applicability was lower (2.69–4.38).

**Conclusions:** Using an evidence-based approach followed by expert consensus, this initiative should improve the assessment and optimisation of adherence in chronic inflammatory rheumatic disorders. Next steps include dissemination and implementation.

**Acknowledgements:** AbbVie France funded this initiative but played no role in the recommendations.

#### THU0659 EUORRHEUMAVISION: ARE THE LARGEST EUROPEAN RHEUMATOLOGY SOCIETIES THE ONES WITH THE MOST ORAL COMMUNICATIONS?

M. Paulino Huertas. *Rheumatology, Hospital General De Ciudad Real, Ciudad Real, Spain*

**Background:** Between June 14 and 17, 2017, coinciding with the 70th anniversary of its foundation, the annual EULAR congress took place in Madrid. With 14,000 participants from 130 countries, 4845 accepted abstracts, 2300 posters and more than 800 oral communications, it became a record congress in the history of European rheumatology.

Now, EULAR is formed, among others, by 45 national rheumatology societies. Are the various countries proportionally represented at a scientific level? Those with the greatest number of rheumatologists have a greater weight in communications to the congress?

**Objectives:** To assess the scientific weight of the different European rheumatological societies in the EULAR congress

**Secondary objective:** To analyse the characteristics of these societies in terms of the number of rheumatologists, specialists for 100,000 inhabitants and percentage with the total number of doctors

**Methods:** The scientific communications of the 2017 EULAR congress (Madrid) are analysed, according to the country of origin of the speakers.

The number of rheumatologists in each country is assessed, their specific weight with respect to the total of European rheumatologists and in relation to the total number of doctors in their respective countries.

**Results:** Results: The countries with the highest number of rheumatologists in Western Europe are France 2,600, Italy (1800), Spain (1155), UK (950), Germany (800) and Netherlands (775). However, in number of communications The order changes, so the UK is the most productive (121), followed by the Netherlands (101), Germany (91), France (74), Italy (51), Sweden<sup>37</sup> and Spain.<sup>36</sup>

In proportion, the Dutch presented 1 communication for every 7.6 rheumatologists, 1 German for every 8.7, 1 for every 7.8 British. The Mediterranean countries are far away, with 1 communication for every 32 Spanish rheumatologists and 1 for every 35 in the case of France and Italy

#### Oral Communications EULAR Madrid 2017

UNITED KINGDOM	121
GERMANY	91
FRANCE	74
ITALY	51
SPAIN	36
NETHERLANDS	101
REST OF EU	250 (37 Swe, 17 Port., Swith, Denma, Norw, Bel, Irel.)
REST OF THE WORLD	156

Country	N° of rheumatologist (N° of communications x rheumatologist)
UK	950 (1 com x 7,82reum)
GER	800 (1 com x 8,79 reum)
FRA	2600 (1 com x 35,1 reum)
ITA	1800 (1 com x 35,29 reum)
SPA	1155 (1 com x 32 reum)
NETHE	775 (1 com x 7,6 reum)

#### REPRESENTATION AT A SCALE OF COUNTRIES BY EULAR ACADEMIC POWER

**Conclusions:** There is a marked disparity between the number of rheumatologists by country and number of oral communications. While the Netherlands, United Kingdom and Germany are protagonists of more than a third of the oral communications, nations such as Spain, France or Italy only contribute, together, to the 18% although nearly 5600 rheumatologists work in their countries. Therefore, with twice as many specialists, they present half of communications.

THU0660

#### GOLIMUMAB IMPROVES SOCIO- AND HEALTH ECONOMIC PARAMETERS IN PATIENTS WITH RA, PSA AND AS: REAL WORLD-DATA FROM A NON-INTERVENTIONAL CLINICAL STUDY IN GERMANY

K. Krüger<sup>1</sup>, G.R. Burmester<sup>2</sup>, M.H. Thomas<sup>3</sup>, S. Wassenberg<sup>4</sup>.

<sup>1</sup>Rheumatologisches Praxiszentrum, München; <sup>2</sup>Department of Rheumatology and Clinical Immunology, Charité- Universitätsmedizin, Berlin; <sup>3</sup>Medical Affairs, MSD Sharp and Dohme GmbH, Haar; <sup>4</sup>Rheumazentrum Ratingen, Ratingen, Germany

**Background:** Golimumab (GLM) has shown its efficacy and safety in various clinical trials. Data from socio- and health economic parameters in daily clinical practice in Germany are rare.

**Objectives:** Our objective was to describe effects on socio- and health economic parameters and on health care resource use in patients in Germany with rheumatoid arthritis (RA), psoriatic arthritis (PsA), and ankylosing spondylitis (AS) who were initiated on subcutaneous GLM.

**Methods:** Descriptive post-hoc analysis of socio- and health-economic parameters of the non-interventional, multicenter, prospective GO-NICE study (n=1458) at baseline (BL) compared to the situation at 24 months (M24) (n=664, 45.5%) to explore the impact of GLM on days of sick leave/absenteeism, and days of impaired capability/presentism, as well as the work productivity, quality of work and normal course of life (in the past 30 days and 6 months) using. Further gather the number of consultations, ambulatory treatments, alternative treatments days of hospitalizations and rehabilitation measures in the past 6 months.

**Results:** The mean number of sick leave days in the previous 30 days decreased from baseline (BL) 4.0 to 0.9, and in the past 6 months from BL 13.7 to 3.3 at M24. The improvement was greatest in patients with RA. The mean number of days with impaired capability in the previous 30 days decreased from BL 14.9 to 4.5, in the previous 6 months from BL 65.8 to 19.8 at M24. The improvement was greatest in patients with AS. On a numeric rating scale (range: 1=no limitation to 10=very strong limitation), the patients' mean ratings on the impact of disease during the previous 6 months of work productivity decreased from BL 5.5 to 2.5 points, on quality of work from 4.8 to 2.2 points, and on the normal course of life from 5.3 to 2.4 points at M24, respectively. The decrease in the mean scores BL to M24 was comparable in patients with RA, PsA and AS. Intersubject variability was high. On retrospective evaluation for the past 6 months, the percentage of patients with physician consultations declined from BL to M24: with general practitioners in patients with PsA -19.7%, AS by -17.8%, RA -6.8% in patients with RA. A marked decline was also observed in the percentage of patients with PsA having dermatologist consultations (-15.0%). The percentage of patients receiving physiotherapy, massages, occupational therapy and packs declined from BL to M24, primarily the application of physiotherapy (-16.9%, -10.9% and -9.1%) in patients with AS, PsA and RA. The frequency of hospitalizations decreased from 10.4/7.6/14.0% at BL to 1.7/2.2/0.8%, and the frequency of rehabilitation decreased from 3.3/3.7/7.5% at BL to 0.6/1.8/2.1% at M24 in patients with RA, PsA, and AS

**Conclusions:** This evaluation showed remarkable improvements in socio- and health-economic parameters. On GLM treatment, there was a reduction in the days of absenteeism from work, impaired capability/presentism and the days with limited productivity, while the quality of work increased, in a very similar manner across the three indications.

The proportion of patients requiring physician consultations, days of hospitalisation and furthermore the need for rehabilitation measures decreased on GLM 50 mg treatment.

THU0661

#### OSTEOPOROSIS SCREENING, PRIMARY PREVENTION, AND TREATMENT IN GLUCOCORTICOID TREATED INDIVIDUALS WITH RHEUMATOLOGIC DISEASE

P. Onkka, S. Khandelwal, N. Shakoar, J. Block, L. Fogg. Rush University Medical Center, Chicago, USA

**Background:** Glucocorticoids are commonly used in a wide variety of inflammatory conditions treated by rheumatologists. Bone loss from glucocorticoids is known to occur early and with relatively small doses. The American College of Rheumatology outlines that Glucocorticoid-Induced Osteoporosis (GIOF) is under screened and undertreated. The ACR guidelines suggest standard clinical care to

obtain a baseline DEXA in any individual with anticipated long-term steroid use, primary prevention with calcium, and vitamin D initiation and medical therapy when appropriate based on fracture risk assessments.

**Objectives:** The objective of this study was to determine how successfully the ACR GIOP guidelines are implemented in daily rheumatologic practice. The study investigates the prevalence of osteoporosis screening, prevention, and treatment in patients with rheumatologic diseases over a 2 year period at a large medical centre.

**Methods:** A retrospective cohort study of patients who received rheumatology care between 2014 and 2015 at a large medical centre was performed. Patients were included if they were older than 18 years of age, had a diagnosis of rheumatoid arthritis, systemic lupus, vasculitis, polymyalgia rheumatica, or gout and were receiving  $\geq 5$  mg prednisone daily for  $\geq 90$  days. Electronic medical records were reviewed and medication history was evaluated. Screening was defined as bone mineral density testing with DEXA within one year of glucocorticoid initiation. Primary prevention and treatment were derived from ACR GIOP criteria and included the initiation of appropriate doses of calcium and vitamin D and initiation of medical therapy to prevent bone loss. The prevalence of screening and treatment was assessed and the relationships with age, gender, and ethnicity were evaluated using Chi Squared analyses and independent samples t-tests.

**Results:** Of the 600 patients reviewed, 61 met criteria of new long-term glucocorticoid initiations. Overall 61% received BMD testing and 48% received osteoporosis primary prevention. Of those who qualified for treatment by ACR GIOP criteria, only 19% received treatment. Patients who received a baseline DEXA were older than those who did not ( $65 \pm 15$  vs  $57 \pm 16$  years,  $p=0.046$ ). Age did not influence treatment. More women compared to men received screening DEXA (68% F vs 41% M,  $p=0.053$ ) and primary prevention (55% F vs 29% M,  $p=0.078$ ). Patients who received a longer duration of steroid treatment were more likely to receive primary prevention ( $16 \pm 10$  months vs  $10 \pm 8$  months,  $p=0.015$ ). There was no association between ethnicity or disease status on screening, prevention, or treatment.

**Conclusions:** Glucocorticoid-induced osteoporosis in the setting of a rheumatology practice is a common and manageable condition that should be screened, prevented, and treated. These results from one large academic medical centre in the United States suggest that rheumatologists may not be following ACR guidelines for the assessment and management of patients on chronic steroids. Quality improvement initiatives may be necessary in order provide optimal care for patients.

THU0662

#### IMPACT OF THE INTERVENTION OF A MULTIDISCIPLINARY ADHERENCE TEAM IN CLINICAL OUTCOMES OF PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHROPATHIES IN COLOMBIA

R. Pineda-Tamayo, K. Sanchez, M.-A. Alzate, D. Hernandez-Parra, D. Echeverry, P. Ortiz-Salazar, A. Rojas-Villarraga. *Rheumatology division, Artmedica IPS, Medellin, Colombia*

**Background:** The multidisciplinary adherence team (MAT) is a interprofessional health care group conformed by a general practitioner, a pharmaceutical chemist and a psychologist, which evaluate the patient to provide a simultaneous multidisciplinary approach focused on promoting strategies to improve adherence to treatment in patients with high disease activity of autoimmune or autoinflammatory pathologies

**Objectives:** To determine the impact of the MAT group intervention on the disease activity and therapeutic adherence of Colombian patients with rheumatoid arthritis (RA) and seronegative spondyloarthropathies (SpA).

**Methods:** A quasi-experimental analytical study was performed where 4.921 RA and 756 SpA patients were analysed, of which 395 and 90 respectively presented high persistent disease activity (from moderate to severe persistent), despite of conventional strategies implemented; therefore they underwent intervention by the MAT group between January and December of 2016. Clinical disease activity according to each disease (DAS28 and BASDAI measurements respectively) and adherence level (categories through the Morisky-Green test: no adherence, partial adherence, total adherence) were measured before and after the MAT intervention. The impact on disease activity and adherence level was determined through the McNemar test for independent samples

**Results:** A significant increase in the proportion of patients in total adherence level was found for both diseases when comparing the initial and final measurements after the intervention by the MAT (table 1). Furthermore, statistical significant differences in the disease activity level were found, identifying a reduction in the proportion of patients with moderate to severe disease activity (Graph 1, A and B) after the MAT intervention

**Abstract THU0662 – Table 1.** Impact in adherence in patients with RA and SpA underwent by the MAT group intervention

Treatment adherence (Morisky-Green test)	AR n=395			SpA n=90		
	Initial (%)	Final (%)	P-value	Initial (%)	Final (%)	P-value
No adherence	9,1	8,1	<0001	7,8	2,2	0002
Partial Adherence	40,8	32,9		37,8	40	
Total Adherence	50,1	59		54,4	57,8	

**Figure 1** A) Disease Activity in patients with RA (DAS28); B) Disease Activity in patients with SpA (BASDAI)

**Conclusions:** The intervention by the MAT interprofessional group is an efficient strategy impacting the disease activity and therapeutic adherence of RA and SpA patients, improving their clinical outcomes and the natural history of the disease. These findings are relevant and may highlight the potential benefits for the implementation of this approach in patients with devastating autoimmune diseases.

**Disclosure of Interest:** None declared

THU0663

#### RHEUMATOLOGY ADOLESCENT AND YOUNG ADULT CARE: REAL WORLD CHALLENGES AND OPPORTUNITIES

R. Malaiva<sup>1</sup>, S. Steer<sup>2</sup>, S. Das<sup>2</sup>, C. Mathews<sup>3</sup>, U. Davies<sup>4</sup>, E. Godbold<sup>5</sup>, S. Lamb<sup>6</sup>, S. Vale<sup>5</sup>, V. Goncalves<sup>1</sup>, M. Sumbwanyambe, M. Sumbwanyambe<sup>7</sup>, S. Thurlbeck<sup>7</sup>, N. Wilkinson<sup>5</sup>, on behalf of Rheumatology Adolescent & Young Adult (RAYA) collaboration. <sup>1</sup>Guy's Hospital; <sup>2</sup>King's College Hospital, London; <sup>3</sup>Lewisham Hospital, London; <sup>4</sup>East Surrey Hospital, Redhill; <sup>5</sup>Evelina Children's Hospital; <sup>6</sup>Herne Hill GP Practice; <sup>7</sup>St George's Hospital, London, UK

**Background:** Adolescents and young adults (AYA) form one sixth of the world's population and account for 6% of the world's global burden of disease. Those with chronic illness are particularly vulnerable. Globally, significant improvements in healthcare related morbidity and mortality have been seen, but not within the 10–24 year old group. Adolescence is a rapidly changing, formative phase of human development; opportunities exist to impact this through restructuring care pathways and patient empowerment.

**Objectives:** Establish awareness of current national guidance and identify unmet needs in existing rheumatology AYA systems.

**Methods:** Interested parties from South East England (South London, Kent, Surrey and Sussex) formed a multi-disciplinary, patient based, co-design initiative (RAYA collaborative) which included representatives from primary/secondary/tertiary care, allied health professionals and a youth worker/patient from the charity sector. Our discussions and an anonymous survey to hospitals in the region, formed the basis of a qualitative and quantitative analysis, which helped gain a holistic insight into the challenges and opportunities in delivering AYA care in our region.

**Results:** 15/20 centres, covering an 8 million population, responded; 4 tertiary care hospitals, 11 district general hospitals with 32 responses (19 consultants, 13 senior registrars).

31 (97%) of responders felt that AYA cohort (16–25 years old) required an approach different to that of older adults. 25 (78%) felt there was a need for dedicated AYA services. 23 (72%) and 17 (53%) were aware of UK national guidelines<sup>CCC 2014</sup>/NICE NG43 2016 respectively) for transitional/integrated and coordinated care.

Barriers to developing dedicated AYA services (% of responders): Not a priority for NHS managers,<sup>31</sup> other clinical priorities,<sup>31</sup> insufficient patient numbers,<sup>22</sup> not cost effective,<sup>19</sup> unlikely to be commissioned,<sup>19</sup> more research required,<sup>13</sup> cohort by diagnosis,<sup>13</sup> other ways to deliver care,<sup>13</sup> only focus on transitioning patients from paediatrics<sup>13</sup>

Responders would like assistance in future care delivery through: Clinical toolkit: 63% n=20, Service commissioning toolkit: 43% n=14, Training: 43% n=14, Workshops: 47% n=15.

Potential low cost/neutral approaches to systems change, cultural change, education and sharing of resource were discussed (see image).

Questions	Comments/Objections	Potential Solutions	Potential Outcomes/Actions
1. How to fund additional activity or support staff required for AYA services?	<ul style="list-style-type: none"> <li>These patients are already being seen in the service so no additional activity needs to be accounted for</li> <li>Restructuring the service allows for a more streamlined and efficient use of services</li> </ul>	<ul style="list-style-type: none"> <li>Restructuring the clinics into specialist matched subjects</li> <li>Slightly longer time slots (45mins for, 30mins follow up)</li> <li>Support services - physiotherapy/ psychology run in parallel for "One stop shop clinics"</li> <li>A key worker (nurse/young worker) has demonstrated significant improvements through helping to sign base to relevant support services</li> </ul>	<ul style="list-style-type: none"> <li>Improve patient engagement, self management and self advocacy</li> <li>Should reduce follow up/acute admissions/disease flares / non-attendance rates</li> <li>Encourage this to be cost neutral over current need and increasing population base to address</li> </ul>
2. How do we structure our departments and managers there is a need for age appropriate care?	<ul style="list-style-type: none"> <li>District General Hospital - Not enough patients to colour a whole clinic</li> <li>Problems with out patient capacity</li> <li>Treat need incentive from commissioners</li> <li>Continative appointments do not allow flexibility (patients have care or last minute appointments/ exams/work / social commitments)</li> </ul>	<ul style="list-style-type: none"> <li>Dedicate the first hour (2-3 patients) of a clinic to AYA cohort</li> <li>Bring or work out clinics to accommodate additional priority</li> <li>Follow up coordinator. One center has reduced non-attendance rates by 19% as this allows flexibility/urgent appointments to be re-scheduled without excessively overbooking clinics</li> </ul>	<ul style="list-style-type: none"> <li>Engage in dialogue with commissioners/ community agencies early on (Lambeth &amp; Southwark commissioners are moving towards population based commissioning model)</li> <li>Business case for a patient pathway coordinator</li> </ul>
3. What resources are available to support clinicians / direct patients?	<ul style="list-style-type: none"> <li>General lack of recognition within organisations about importance of supporting young adults through the process of a chronic health condition</li> <li>Importance of sharing resource throughout the RAYA network</li> </ul>	<ul style="list-style-type: none"> <li>Improve training and understanding of age appropriate care</li> <li>Modification of registrar training curriculum to encompass age appropriate care</li> <li>Regional website to share resource</li> <li>Collaboration with existing AYA networks</li> </ul>	<ul style="list-style-type: none"> <li>Summary of resources and training modules</li> <li>Website / app would require a web master to manage and update regularly (Could this be patient led)</li> <li>Shape of training: Curriculum wording has been modified to encompass age appropriate care and admitted to training body</li> </ul>
4. What is the benchmark standard of good practice for AYA patients we should be aspiring to?	<ul style="list-style-type: none"> <li>Models of care will need to be flexible and based on local needs</li> </ul>	<ul style="list-style-type: none"> <li>Complex patients may need referral to a tertiary center or a Hub and Spoke model may work better for more district general hospitals.</li> </ul>	<ul style="list-style-type: none"> <li>NICE, QIC and JRCAR guidance are useful resources</li> <li>Future RAYA meetings could be a platform for peer review and complex case discussion</li> </ul>

**Conclusions:** Improving outcomes for AYA patients through delivering age appropriate care and self advocacy has driven global strategy and guidelines. Our survey identifies that the majority of rheumatologists agree with this, however there is room for improvement regarding awareness and implementation of current guidance.

Financial constraints and whole population healthcare delivery has limited change. A systematic, unified approach within regions may help to effect change. There is a demand for the development of clinical and commissioning toolkits and training/workshops to help facilitate this.

#### TREATMENT ADHERENCE TO CONVENTIONAL AND BIOLOGIC DISEASE MODIFYING ANTIRHEUMATIC DRUGS IN PATIENTS WITH RHEUMATOID ARTHRITIS

C.H. Feldman, J. Lii, C. Gopalakrishnan, J.M. Franklin, S.C. Kim. *Brigham and Women's Hospital, Boston, USA*

**Background:** While treatment with conventional or biologic disease-modifying antirheumatic drugs (DMARDs) is highly effective in preventing radiographic progression and improving long-term functional outcome among patients with rheumatoid arthritis (RA), patient adherence to DMARD treatment is required for these positive effects. Suboptimal medication adherence has been repeatedly noted in patients with chronic medical conditions including RA.

**Objectives:** To examine patient adherence to different DMARDs for RA in a real-world setting.

**Methods:** We conducted a population-based cohort study using claims data from a US commercial health plan (Optum Clinformatics™ Datamart 2004–2015) and Medicaid (2000–2010). Eligible patients were those aged between 18 and 65 years and had at least two visits, 7–365 days apart, coded for RA (ICD-9: 714.xx). We then identified patients who newly started a conventional or biologic DMARD. The index date was the first dispensing date of conventional or biologic DMARDs after a 12 month continuous enrollment period. We examined patient demographics, clinical characteristics and health care utilisation factors specific to DMARDs types and their adherence to conventional or biologic DMARDs. All patients were required to be continuously enrolled for at least 1 year after the index date. Patients' adherence to each DMARD was measured using the proportion of days covered (PDC) calculated as the number of days supplied divided by 365 days post-index.

**Results:** We identified a total of 77,999 RA patients (37 018 in Optum and 40 981 in Medicaid) who started a conventional or biologic DMARD. Of those, 28 332 initiated methotrexate, 27 157 hydroxychloroquine, 6505 sulfasalazine, 2773 leflunomide and 19 381 biologic DMARDs. Table 1 shows patients' adherence specific to DMARD types. Overall, adherence was better in patients enrolled in Optum (i.

e., a commercial health plan) than Medicaid. Except for infliximab given only intravenously, the PDC for the 1 year after initiating a conventional or biologic DMARD ranged from 30.99% (sulfasalazine in Medicaid) to 60.84% (abatacept in Optum).

**Abstract THU0664 – Table 1.** Adherence to DMARDs in patients with RA: Proportion of days covered for 1 year

	Optum	Medicaid
Mean (SD) in percentage		
<b>Conventional DMARDs</b>		
Methotrexate	58.13 (31.39)	44.00 (29.58)
Hydroxychloroquine	50.87 (31.72)	39.79 (28.71)
Sulfasalazine	36.59 (29.46)	30.99 (25.65)
Leflunomide	48.54 (32.09)	41.72 (30.62)
<b>Biologic DMARDs</b>		
Abatacept	60.84 (30.36)	49.70 (31.51)
Adalimumab	53.02 (29.60)	49.09 (29.01)
Certolizumab	49.53 (29.10)	39.54 (27.91)
Etanercept	52.71 (29.37)	50.00 (29.25)
Golimumab	51.10 (28.92)	48.36 (26.82)
Infliximab *	74.39 (28.65)	60.69 (30.63)
Tocilizumab	57.95 (27.77)	-

\*assumed infliximab was given every 8 weeks.

**Conclusions:** In this large population-based cohort of RA patients enrolled in a commercial health plan or Medicaid, the 1 year medication adherence is generally low regardless of type of DMARDs. While adherence is better in the commercial health plan cohort than Medicaid, other factors predicting medication adherence need to be determined further. There is a strong need for future research examining the impact of medication adherence on long-term RA-related clinical outcomes.

#### PHARMACOVIGILANCE SURVEILLANCE OF AUTOIMMUNE DISEASES INDUCED BY BIOLOGICAL AGENTS: A REVIEW OF 16123 CASES (AEBIOGEAS-SEMI REGISTRY)

M. Ramos-Casals<sup>1</sup>, S. Retamozo<sup>1,2,3</sup>, A. Flores-Chavez<sup>1,4,5</sup>, B. Kostov<sup>6</sup>, A. Sisó-Almirall<sup>6,7</sup>, M. Pérez-de-Lis<sup>8</sup>, R. Pérez-Alvarez<sup>9</sup>, P. Brito-Zerón<sup>1,10</sup>, on behalf of BIOGEAS-SEMI Study Group. <sup>1</sup>Autoimmune Diseases, ICMiD, IDIBAPS, Hospital Clínic, Barcelona, Spain; <sup>2</sup>Hospital Privado Universitario de Córdoba (IUCBC); <sup>3</sup>INICSA, UNC-CONICET, Córdoba, Argentina; <sup>4</sup>Unidad de Investigación Biomédica 02, Unidad de Investigación en Epidemiología Clínica, Centro Médico Nacional de Occidente (CMNO), Instituto Mexicano del Seguro Social (IMSS), Hospital de Especialidades, Guadalajara; <sup>5</sup>Programa de Doctorado en Ciencias Médicas, Centro Universitario de Investigaciones Biomédicas (CUIB), Universidad de Colima, Colima, Mexico; <sup>6</sup>Primary Healthcare Transversal Research Group, IDIBAPS; <sup>7</sup>CAP Les Corts, CASPBE, Barcelona; <sup>8</sup>Department of Anesthesia, Complejo Hospitalario Universitario A Coruña (CHUAC), A Coruña; <sup>9</sup>Department of Internal Medicine, Hospital Alvaro Cunqueiro, Vigo; <sup>10</sup>Autoimmune Diseases Unit, Department of Internal Medicine, Hospital CIMA-Sanitas, Barcelona, Spain

**Objectives:** The increasing use of biological agents has been linked with the paradoxical development of autoimmune processes. The scenario has dramatically change in recent years due to the increased number of biologics used in daily practice and the emerging use of biologics in patients with solid cancers.

**Methods:** In 2006, the Study Group on Autoimmune Diseases (GEAS) of the Spanish Society of Internal Medicine created the BIOGEAS project, a multicenter study devoted to collecting data on the use and safety of biological agents in adult patients. The aeBIOGEAS Registry (autoimmune events) was designed to collect data on autoimmune diseases secondary to the use of biologic agents, with the aim of formulating a standardised, consensual protocol for these patients, through a systematic and yearly MEDLINE search. We present the updated results of the aeBIOGEAS Registry (cases collected until Dec 31, 2017).

**Results:** The aeBIOGEAS Registry currently includes 16 123 cases of more than 50 different systemic and organ-specific triggered autoimmune diseases related to the administration of 46 different biological molecules in patients with inflammatory diseases (9907 cases, overwhelmingly rheumatic diseases in 8639) and cancer (6216 cases, overwhelmingly solid neoplasia in 5955). The main biological agents identified consisted of anti-TNF agents in 9514 cases (mainly adalimumab in 4147, infliximab in 3028 and etanercept in 1648), checkpoint inhibitors in 5264 (overwhelmingly the CTL4 inhibitor ipilimumab in 4980 cases), tyrosine kinase inhibitors in 952 (mainly imatinib in 377 cases) and B-cell targeted therapies in

298 cases. Organ-specific classification of triggered autoimmune diseases included cutaneous (n=7140), digestive (n=2323), endocrine (n=1701), pulmonary (n=1683), systemic/rheumatic (n=1230), neurological (n=1172), ocular (n=349), cardiac (n=322), haematological (n=106) and renal (n=96) diseases. The most frequently reported induced individual autoimmune diseases were psoriasis (n=6401), enterocolitis (n=1947), interstitial lung diseases (n=1680), thyroiditis (n=1076), hypophysitis (n=492), demyelinating CNS diseases (n=452), peripheral neuropathies (n=431), lupus (n=371), vasculitis (n=339), uveitis (n=298), vitiligo (n=256) and sarcoidosis (n=185).

**Conclusions:** The number and diversity of induced autoimmune disorders is increasing exponentially in parallel with the increased use of biological therapies in neoplastic diseases, which are currently representing 40% of reported cases. Management of these biologic-induced autoimmune diseases will be an increasing multidisciplinary clinical challenge in the daily practice in the next years.

#### THU0666 COSTS ASSOCIATED WITH SWITCHING SUBCUTANEOUS TUMOUR NECROSIS FACTOR- $\alpha$ INHIBITOR IN THE TREATMENT OF IMMUNE-MEDIATED RHEUMATIC DISEASE

J. Dalén<sup>1</sup>, A. Svedbom<sup>1</sup>, K. Luttropp<sup>1</sup>, S. Kachroo<sup>2</sup>. <sup>1</sup>Mapi, Stockholm, Sweden; <sup>2</sup>Center for Observational and Real-World Evidence (CORE), Merck and Co., Inc., Kenilworth, NJ, USA

**Background:** Few studies have investigated the costs associated with switching subcutaneous tumour necrosis factor- $\alpha$  inhibitor (SC-TNFi) in the treatment of immune-mediated rheumatic disease (IMRD; rheumatoid arthritis, ankylosing spondylitis, and psoriatic arthritis),<sup>1-2</sup> and to our knowledge no studies have been performed in a European setting.

**Objectives:** The objective of this retrospective observational study was to explore costs of health care resource utilisation (HCRU) associated with switching SC-TNFi in patients with IMRD in Sweden.

**Methods:** Using data from Swedish Health Data Registers, adult, treatment naïve IMRD patients filling prescriptions between May 1st 2010 and December 31st 2015 for any of the currently available SC-TNFi (adalimumab, etanercept, certolizumab, and golimumab) were included. Prescriber specialty and department were used to exclude patients with SC-TNFi treatment unrelated to IMRD. A switch was defined as a filled prescription for a subsequent SC-TNFi within 60 days of first line discontinuation. HCRU, including non-DMARD medication, inpatient and specialised outpatient care, was captured 12 months pre- and post-treatment initiation. Eligible patients had at least 12 months follow-up, and were either persistent throughout or switched treatment during the follow-up period. The analysis was performed on a propensity score matched (PSM) cohort.

Figure 1. Total Cost of Health Care Resource Utilization

Abstract THU0666 – Figure 1 Total. cost of health care resource utilisation

**Results:** In total, 6213 eligible patients were identified, of which 5092 were persistent with their index therapy throughout the follow-up period while 1120 patients switched SC-TNFi. The PSM cohort was derived as “Persistent” vs. “Switched” with a total of 1120 matched pairs. Patients switching therapy had higher total

HCRU costs during the baseline period and maintained their average cost during the follow-up period (figure 1), whereas persistent patients decreased their average costs from the baseline period to the follow-up period. The average yearly cost during baseline and follow-up was USD 4,512 vs USD 4,690 for patients switching SC-TNFi, and USD 3,630 vs USD 2,662 for persistent patients. This corresponds to a difference in difference of USD 1,146 (p<0.001).

**Conclusions:** Similar to previous findings,<sup>3-4</sup> patients switching maintained their higher costs, while persistent patients decreased their costs from baseline to the follow-up period. This further highlights the notion that persistence may not only serve as a marker for drug effectiveness, safety, and treatment satisfaction, but also for reduced HCRU and costs.

#### THU0667 DISEASE, WORK AND PERSONAL RELATED FACTORS ASSOCIATED WITH PRESENTEEISM IN PATIENTS WITH RHEUMATOID ARTHRITIS: RESULTS FROM THE NATIONAL RHEUMATOID ARTHRITIS SOCIETY SURVEY (NRAS)

S. Verstaappen<sup>1</sup>, M. Gignac<sup>2</sup>, L. Lunt<sup>1</sup>, D. Beaton<sup>3</sup>, A. Bosworth<sup>4</sup>, M. Bezzant<sup>4</sup>, K. Walker-Bone<sup>5</sup>. <sup>1</sup>CIMR, Manchester, UK; <sup>2</sup>University of Toronto; <sup>3</sup>IWH, Toronto, Canada; <sup>4</sup>NRAS, Maidenhead; <sup>5</sup>ARUK/MRC CIMHW, Southampton, UK

**Background:** At-work productivity loss (i.e. presenteeism) is a major problem for patients with rheumatoid arthritis (RA) and employers and could be a marker of long-term absenteeism. To develop interventions to prevent presenteeism, a better understanding of which factors are associated with presenteeism is needed.

**Objectives:** To assess the association between disease and work related factors with presenteeism.

**Methods:** A large survey about employment amongst patients with RA was conducted in the UK using an online platform and inviting NRAS members and non-members to participate. Patients completed the multi-item Workplace Activity Limitation Scale (WALS; range 0–36 worst score), a measure of presenteeism. Other job related questions included: occupation (NS-SEC coding), job demand questions, help from colleagues (categorised into: always/often, sometimes, rarely/never) and a patient acceptable state questionnaire about work (PASS). Patients also completed the disease specific RAID questionnaire (score 0–10=worst score). Univariable and multivariable linear regression analyses were performed to assess the association between the disease and job related factors and presenteeism, adjusting for age and gender.

**Results:** 891 respondents were in paid work at the time of the survey (51.5% working for others, 33.1% self-employed and 15.4% on temporary sick leave). The majority of participants were women (91.5%) and 4.9% were aged 16–30, 69.2% 31–54 and 25.8% aged 55–74 years. Over half (51.5%) had a higher managerial, administrative or professional occupations, 33.1% an intermediate occupation, and 15.4% a routine/manual occupation. Mean (SD) RAID score was 5.2 (2.2). 58.2% rated their current job performance somewhat/much worse than before the onset of their arthritis. In univariable regression analyses greater disease activity, less control, lower support from colleagues and being in a unacceptable disease state (PASS) were associated with higher levels of presenteeism. In multivariable analysis, disease activity, ability to influence work and a unacceptable disease state remained statistically significantly associated with presenteeism.

Abstract THU0667 – Table 1

	N (%) or mean (SD)	Univariable analysis R (95%CI)*	Multivariable analysis R (95%CI)*
<b>RAID users</b>	5.3 (2.2)	<b>1.96 (1.80, 2.12)</b>	<b>1.59 (1.43, 1.78)</b>
RAID requires using a lot of force, e.g. lifting, pulling or use of tools and machines using a lot of force:			
• Never/Rarely	328/865 (62%)	1	
• Sometimes	366/865 (19%)	0.81 (-0.3, 1.03)	
• Often/Always	359/865 (19%)	<b>2.48 (1.26, 3.70)</b>	
RAID requires a lot of standing:			
• Never/Rarely	385/865 (45%)	1	
• Sometimes	142/865 (17%)	0.44 (-0.88, 1.73)	
• Often/Always	337/865 (39%)	<b>1.90 (0.90, 2.91)</b>	
RAID requires use of computer for more than 4 hours:			
• Never/Rarely	225/865 (26%)	1	
• Sometimes	93/86 (11%)	0.67 (0.98, 2.33)	
• Often/Always	535/865 (63%)	<b>-0.20 (-1.26, 0.86)</b>	
Able to influence work:			
• Never/Rarely	218/865 (25%)	1	
• Sometimes	244/865 (29%)	<b>-2.13 (-3.33, -0.94)</b>	<b>-1.02 (-2.02, -0.03)</b>
• Often/Always	398/865 (46%)	<b>-4.33 (-5.42, -3.24)</b>	<b>-1.87 (-2.95, -0.80)</b>
Able to take time off, small breaks, when needed:			
• Never/Rarely	268/865 (31%)	1	
• Sometimes	213/865 (25%)	<b>-1.78 (-2.92, -0.54)</b>	
• Often/Always	372/865 (44%)	<b>-3.22 (-4.27, -2.17)</b>	
How often do you get help and support from colleagues:			
• Never (reference)	67/773 (9%)	1	
• Sometimes	305/773 (42%)	<b>-1.94 (-3.65, -0.19)</b>	
• Often/Always	341/773 (45%)	<b>-2.94 (-4.71, -1.17)</b>	
<b>PASS</b>			
• Acceptable	187/786 (24%)	1	
• Not acceptable	399/786 (51%)	<b>7.10 (6.84, 7.46)</b>	<b>2.65 (1.78, 3.52)</b>

**Conclusions:** In this large national survey in patients with RA we found that not only disease activity, but also having control, especially the flexibility to influence work and take breaks when needed, were associated with levels of presenteeism. Preventing presenteeism should therefore be aimed at managing the disease, but also toward adapting work circumstances and finding the right balance between work requirements and personal needs.

THU0668

**CHOICE OF INITIAL BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUG IMPACTS HEALTHCARE RESOURCE USE AMONG PATIENTS WITH RAPIDLY PROGRESSING RHEUMATOID ARTHRITIS**

A.J. Klink<sup>1</sup>, K. Tuell<sup>2</sup>, R. Szymialis<sup>2</sup>, T. Curtice<sup>2</sup>, K. Gupta<sup>2</sup>, D. Nero<sup>1</sup>, B. A. Feinberg<sup>1</sup>. <sup>1</sup>Cardinal Health Specialty Solutions, Dublin; <sup>2</sup>Bristol-Myers Squibb, Princeton, USA

**Background:** Current management of rheumatoid arthritis (RA) in the United States is often directed by payer medical policy, typically requiring a tumour necrosis factor- $\alpha$  inhibitor (TNFi) as a first-line (1L) biologic disease-modifying antirheumatic drug (bDMARD). Recent studies<sup>1</sup> suggest clinical subsets of patients with RA may benefit from early intervention with a non-TNFi bDMARD.

**Objectives:** To characterise 6 month healthcare resource utilisation (HRU) for patients with RA in the United States when treated with different 1L bDMARDs (1L TNFi or 1L abatacept) and assess the impact of initial bDMARD selection on 6 month HRU.

**Methods:** Early, rapidly progressive RA (eRRA) is a recognised clinical entity comprising a constellation of clinical and biomarker features: anti-cyclic citrullinated peptide-2 positivity (ACCP+), DAS28 (CRP)  $\geq 3.2$ , symptomatic synovitis in  $\geq 2$  joints for  $\geq 8$  weeks and onset of symptoms  $\leq 2$  years. Physicians with adult RA patients meeting these criteria for eRRA used patient medical records to provide patient data via an electronic case report form. Patients received either abatacept or TNFi in 1L. Patient characteristics and HRU in the first 6 months of bDMARD treatment were summarised and compared across treatment groups. Odds ratios (OR) of HRU were estimated using multivariable logistic regression to adjust for baseline indicators of disease severity and patient mix (age, sex, race, ethnicity, region, payer type, time from RA diagnosis to bDMARD start, baseline concomitant medication use, baseline swollen joint count [SJC], tender joint count [TJC], Clinical Disease Activity Index [CDAI], extra-articular manifestations).

**Results:** There were 60 abatacept and 192 TNFi patients in 1L. Mean ages at bDMARD start were 49.1 and 49.9 years, and mean times from RA diagnosis to bDMARD initiation were 1.5 and 6.4 months for abatacept and TNFi users, respectively (all  $p > 0.05$ ). At bDMARD start, patients with eRRA treated with abatacept or TNFi, respectively, had mean SJC of 6.8 and 7.3, TJC of 10.4 and 10.2, ESR of 39.8 and 44.0 mm/h, CRP of 8.1 and 8.2 mg/L and numbers of bony erosions of 1.2 and 1.7 (all  $p > 0.05$ ). 45% and 47% ( $p > 0.05$ ) of abatacept and TNFi users, respectively, had concomitant oral corticosteroids at bDMARD start. A lower proportion of patients treated with abatacept had hospitalizations (72 vs 88%), emergency department (ED) visits (75 vs 90%) and MRI (65 vs 82%) (all  $p < 0.05$ ), while use of ultrasound (82 vs 88%) and radiography (88 vs 93%) during the first 6 months of bDMARD treatment was similar. After adjusting for patient

characteristics, those treated with 1L abatacept had significantly lower odds of hospitalisation (OR 0.42; 95% CI 0.18, 0.95), ED visits (OR 0.39; 95% CI 0.16, 0.93) and MRI (OR 0.45; 95% CI 0.21, 0.97) compared with 1L TNFi (all  $p < 0.05$ ). Adjusted odds of achieving CDAI low disease activity within 100 days of bDMARD favoured 1L abatacept vs 1L TNFi (OR 3.26; 95% CI 1.32, 8.07;  $p < 0.05$ ).

**Conclusions:** After adjusting for baseline disease severity, patients treated with 1L abatacept were less likely to have hospitalizations, ED visits and MRIs during the first 6 months of bDMARD treatment compared with those who received a 1L TNFi.

THU0669

**A SELF-REPORT SYMPTOM CHECKLIST ON A MULTIDIMENSIONAL HEALTH ASSESSMENT QUESTIONNAIRE (MDHAQ) TO CAPTURE A “POSITIVE REVIEW OF SYSTEMS” AS A STANDARD, QUANTITATIVE, AND INFORMATIVE “SCIENTIFIC” CLUE TO FIBROMYALGIA SIMILAR TO MODIFIED CRITERIA FOR FIBROMYALGIA**

T. Pincus, S. Jamal, I. Castrejon. Rheumatology, Rush University Medical Center, Chicago, USA

**Background:** The scientific method is based on recording information as quantitative standard data rather than as narrative descriptions, to test possible value in diagnosis, management, and outcomes. This approach generally is applied to laboratory tests and other data from high technology sources. However, information from a patient history and physical examination can be analysed for scientific validity if collected in as standard, quantitative and reproducible data. A symptom checklist of 60 items was initially designed as a review of systems to screen for symptoms and possible adverse events of medications, for which it has been helpful. It has also been observed that patients who report a large number of symptoms may provide a clue to the presence of fibromyalgia (FM); Clin Exp Rheumatol. 2004. 22:453–61).

**Objectives:** To compare results of a 60-item symptom checklist on a multidimensional health assessment questionnaire (MDHAQ) vs the modified 2016 revised preliminary diagnostic criteria for fibromyalgia (Sem Arth Rheum 46:319–329, 2016).

**Methods:** All patients seen at an academic rheumatology clinic complete an MDHAQ; J Rheumatol 2005 32:1432–9) at each visit, which includes a 60-item symptom checklist. In April-July 2017, patients also completed a questionnaire to identify the 2016 revised preliminary diagnostic criteria for FM. The likelihood of reporting each symptom by a patient with RA who did not have FM was compared to patients who met 2016 criteria for FM using a chi-square test. Receiver operator characteristic (ROC) curves were performed of the 60 symptom checklist as well as the 10 most discriminatory symptoms vs the FM criteria.

**Abstract THU0669 – Table 1.** Proportion of patients with rheumatoid arthritis (RA) who did not meet fibromyalgia criteria versus patients with primary or secondary fibromyalgia to meet fibromyalgia criteria who responded positively regarding the 10 most discriminatory symptoms on a symptom checklist

Symptom	RA (84)	FM (110)	Chi2*
Muscle pain, aches, or cramps	30 (35)	100 (31)	65.6367
Muscle weakness	16 (19)	82 (75)	58.6852
Dizziness	11 (13)	65 (59)	42.2875
Headaches	25 (30)	84 (76)	42.0177
Problems with thinking	7 (8)	57 (52)	40.7405
Problems with memory	12 (14)	65 (59)	39.9442
Neck pain	29 (35)	87 (79)	39.3505
Problems with sleeping	30 (36)	88 (80)	39.2017
Numbness or tingling of arms or legs	16 (19)	70 (64)	38.3709
Unusual fatigue	23 (27)	79 (72)	37.7207

\*all  $p < 0.001$

**Results:** We studied 84 patients with RA who did not meet FM criteria vs 110 patients who met FM criteria – no differences were seen between patients with primary or secondary FM who met criteria. Patients who met FM criteria were more likely to report each of the 60 symptoms. The 10 symptoms that were most discriminatory of RA vs FM are illustrated in the table 1. A ROC curve for the 60 symptoms vs the FM Criteria had an area of 0.896 (Confidence interval 0.872–0.925), and for the 10 most discriminatory symptoms of 0.8975 (Confidence interval 0.8667–0.928).

**Conclusions:** A simple MDHAQ symptom checklist may be informative in routine rheumatology care to identify possible primary and secondary FM in agreement with FM criteria. The MDHAQ may provide a useful and feasible alternative to FM Criteria for busy clinical settings.

**Disclosure of Interest:** T. Pincus Shareholder of: Dr. Pincus holds a copyright and trademark on MDHAQ and RAPID3 for which he receives royalties and license fees. All revenue is used to support further development of quantitative questionnaire measures for patients and doctors in clinical rheumatology care., S. Jamal: None declared, I. #### THU0670 A REUMATOLOGIST'S EVALUATION OF HOW EFFICIENCIES IN THE MANAGEMENT OF PAINFUL LUMBAR SYNDROME IN WORK DISABILITY CREATES BENEFITS & SAVINGS

V.M. Flores Rodríguez<sup>1</sup>, F. Díaz Gonzalez<sup>1</sup>, S. Bustabad Reyes<sup>2</sup>, M. Carballo Correa<sup>3</sup>. <sup>1</sup>Departament of Rheumatology; <sup>2</sup>Departamento de Rheumatology, University Hospital of the Canary Islands; <sup>3</sup>PhD student of the Pharmacy Faculty, University of La Laguna, San Cristóbal de La Laguna, Spain

**Background:** Musculoskeletal disorders are the most important cause of sick leave in the world.<sup>1</sup> Lumbar pain is the main cause of temporary incapacity which significant socio-economic impact.

**Objectives:** Test efficiency of Healthcare approach by rheumatologist as savings in indirect costs e.g days off work and in direct costs derived from medical assistance in controlled patient group on sick leave diagnosed with lumbar pain.

**Methods:** 2 year quasi-experimental bi-directional analytical design trial. Retrospective cohort in Control Group- CG and prospective cohort for intervention group -IG. Two groups, IG and CG respectively contain 150 (56% women aged 47.5 years±10) and 172 (48.8% women aged 44.2 years±10) working age patients with lumbar pain. Study made by Program for the Management of Temporary Disability implemented by Rheumatology Service of University Hospital of the Canary Islands. Study included early intervention, protocol in diagnostic tests and treatment. This study was evaluated by the Ethics Committee of the research of the University Hospital of Canary Islands fulfilling the requirements of suitability.

**Results:** 24% of patients of IG fit to return to work after first appointment. Maximum efficiency of study between 30th and 45th day of sick leave. At 45 days 8% IG and 18,6% CG remained on sick leave. Average reduction 26 days of sick leave respect to CG, a total saving of 6.182 days of sick leave over 1 year, with efficiency of 62,2%. Saving in direct costs in IG over CG: medicaments, complementary tests, inter-consultations, follow up 48%. Absolute saving of 38.891€, or equivalent 256.680€ for 1.000 patients. National Institute of Social Security Indirect sick leave costs 67,1%. Absolute saving of 129.883€, or equivalent of 857.227€ for 1.000 patients. Indirect costs savings for Employers for intervention 50%. Absolute saving 108.649€, or equivalent to 717.083€ for 1.000 patients. Workers in program saved 50% in salary loss. Average saving 605€/worker. Total saved by implementation of program to State, to worker, to Employer-360.142€. Program Cost effective, producing average annual saving per patient of 259€ and average reduction of sick leave days of 41,2. Program cost efficiencies produced. Every day of disability saved equivalent to implementation cost of 5,06€. Cost-benefit program produced for State saving of 6,44€ for every € invested in implementation 137.248€. Program had 93,8% patient acceptance expressing maximum satisfaction.

**Conclusions:** Management of disability by rheumatologist highly profitable given low program implementation cost compared to savings generated for State and Employer.

## Epidemiology, risk factors for disease or disease progression

#### THU0671 STANDARDISED MORTALITY RATES FOR SYSTEMIC LUPUS ERYTHEMATOSUS IN WESTERN AUSTRALIA FROM 1980 TO 2015

W.D. Raymond<sup>1</sup>, D. Preen<sup>2</sup>, H. Keen<sup>1</sup>, C. Inderjeeth<sup>1</sup>, J. Nossent<sup>1</sup>. <sup>1</sup>School of Medicine and Pharmacology; <sup>2</sup>School of Population and Global Health, The University of Western Australia, Perth, Australia

**Background:** Patients with Systemic Lupus Erythematosus (SLE) are at increased risk of premature mortality. However, population-level mortality rates for SLE have not yet been reported in Australia.

**Objectives:** Calculate the standardised mortality rates (SMR) for SLE patients in Western Australia (WA) from 1980 to 2015, overall and by age and gender.

**Methods:** Utilising whole-population linked hospital admission, cancer registration and death data for WA from 1980 to 2015, we compared characteristics and calculated SMRs (95% CI) for patients with SLE (ICD-9-CM 695.4, 710.0, ICD-10-AM L93.0, M32.0) against controls (5:1) free of rheumatic disease after matching for age, gender, Aboriginality and year of first SLE event.

**Results:** SLE patients (n=2,868) and controls (n=12,785) recorded 1335 and 4400 deaths with crude mortality rates of 56.3/1,000 vs 37.1/1,000 person-years, respectively. SLE patients were approximately 10 years younger (71 vs 81 years) and 2.2-times more likely hospitalised at death (p<0.001). The age-adjusted SMR (per 1,000) for SLE patients was 4.4 (95%CI 3.0, 5.8), and higher in females 5.4 (95%CI 3.5, 7.4) than in males 3.4 (95%CI 1.5, 5.4). Five-year period SMRs were 8.6 (95%CI 5.0, 12.2) between 1990–1994, 9.3 (95%CI 4.4, 14.2) between 1995–1999, 7.6 (95%CI 3.1, 12.1) between 2000–2004, 4.5 (95%CI 0.2, 8.7) between 2005–2009, and 4.9 (95%CI 1.32, 8.5) between 2010–2015.

**Conclusions:** SLE patients in WA experienced a decline in SMRs over time, but remain at increased risk of premature mortality. Within the limitations of administrative linked data, SLE in WA associates with an average reduction in life span of 10 years.

#### THU0672 IMPACT OF PREGNANCY ON PHYSICAL FUNCTION AND HEALTH-RELATED QUALITY OF LIFE IN WOMEN WITH AXIAL SPONDYLOARTHRITIS

K. Ursin<sup>1</sup>, S. Lydersen<sup>2</sup>, J. Skomsvoll<sup>1</sup>, M. Wallenius<sup>1</sup>. <sup>1</sup>National advisory unit on pregnancy and rheumatic diseases, Department of rheumatology, St. Olavs hospital; <sup>2</sup>Regional center for child and youth mental health and child welfare, Faculty of Medicine and health sciences, Norwegian University of science and technology, Trondheim, Norway

**Background:** The only previous study exploring the impact of pregnancy on health-related quality of life in women with axial spondyloarthritis (axSpA), included only ten women.<sup>1</sup>

**Objectives:** To prospectively study physical function and health-related quality of life in a large cohort of women with axSpA during and after pregnancy, using Bath Ankylosing Spondylitis Functional Index (BASFI) and three of the dimensions of RAND 36-Item Health Survey (RAND-36): Physical functioning, bodily pain and mental health.

**Methods:** RevNatus is a Norwegian nationwide register designed for the follow-up of pregnant women with rheumatic diseases. Our study comprised 179 pregnancies in 166 women with axSpA included in RevNatus between 2006 - 2016. The women had seven visits at a rheumatology unit; before pregnancy, in each trimester, and six weeks, six months and twelve months postpartum. BASFI-scores and scores of RAND-36 physical functioning, bodily pain and mental health from each visit were analysed in a linear mixed model. BASFI has an overall index score between 0 ("no functional impairment") and 10 ("maximal functional

impairment").<sup>2</sup> The dimensions of RAND-36 have scores between 0–100 (where 100="best possible health").<sup>3</sup>

**Results:** BASFI-scores were highest in third trimester, significantly higher than six weeks postpartum (mean BASFI 3.6 vs. 2.6,  $p<0.001$ ). In line with this result, scores of RAND-36 physical functioning was significantly lower in third trimester compared to six weeks postpartum (mean physical function 54.5 vs. 71.0,  $p<0.001$ ). The women reported considerable pain throughout the study period, with worst reported pain in second trimester, when scores of RAND-36 bodily pain were significantly lower than six weeks after postpartum (mean bodily pain 44.3 vs. 49.6,  $p=0.01$ ). Scores of RAND-36 mental health were high and stable throughout the study period, with best reported mental health six weeks after delivery, when mental health was significantly better than in all time points in pregnancy.

**Abstract THU0672 – figure 1.** shows changes in functionality and mental health from preconception to one year after delivery, and disease activity and CRP in the same time period.

**Conclusions:** Even though women with axSpA reported considerable pain and gradually worsening of physical function in pregnancy, they experienced good and stable mental health from preconception to one year after delivery.

#### THU0673 DISEASE ACTIVITY DURING AND AFTER PREGNANCY IN WOMEN WITH PSORIATIC ARTHRITIS

K. Ursin<sup>1</sup>, S. Lydersen<sup>2</sup>, J. Skomsvoll<sup>1</sup>, M. Wallenius<sup>1</sup>. <sup>1</sup>National advisory unit on pregnancy and rheumatic diseases, Department of rheumatology, St. Olavs hospital, <sup>2</sup>Regional center for child and youth mental health and child welfare, Faculty of Medicine and health sciences, Norwegian university of science and technology, Trondheim, Norway

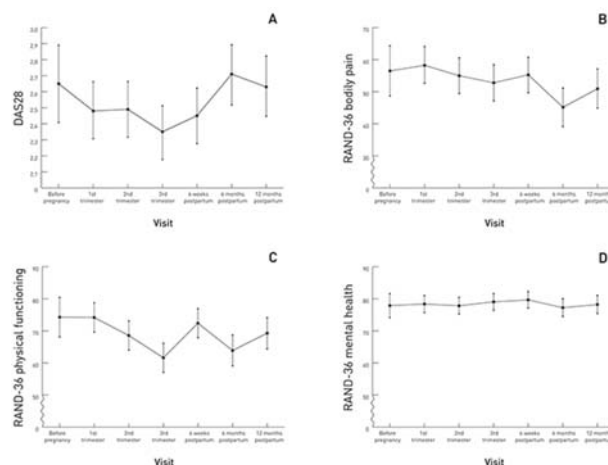

**Background:** The few previous studies on disease activity of psoriatic arthritis in pregnancy have shown diverging results.<sup>1–3</sup> None of the studies used validated disease activity measures and the only prospective study was conducted before the widespread use of biological DMARDs.

**Objectives:** The aim of this project was to prospectively study disease activity in women with psoriatic arthritis before, during and after pregnancy with DAS28-CRP-3 as disease activity measure.

**Methods:** RevNatus is a Norwegian nationwide register designed for the follow-up of pregnant women with rheumatic diseases. Our study comprised 108 pregnancies in 103 women with psoriatic arthritis with mainly peripheral involvement, included in RevNatus between 2006 - 2017. The women had seven visits at a rheumatology unit; before pregnancy, in each trimester, and six weeks, six months and twelve months postpartum. DAS28-CRP-3-scores from each visit

were analysed in a linear mixed model. We did additional analyses with "tumour necrosis factor inhibitor (TNFi) in pregnancy (yes/no)" as covariate.

**Results:** Altogether, our study demonstrated stable, low disease activity during and after pregnancy in women with psoriatic arthritis. However, as shown in figure 1, disease activity decreased in pregnancy and increased within six months postpartum, with disease activity six months postpartum significantly higher than six weeks postpartum (estimated mean DAS28 2.71 vs. 2.45,  $p=0.016$ ). Women using TNFi in pregnancy had significantly lower disease activity than women not using TNFi (estimated mean DAS28 six weeks postpartum 1.97 vs. 2.48,  $p=0.039$ ).

**Abstract THU0673 – Figure 1.** also shows self-reported pain, physical functioning and mental health throughout the study period.

**Conclusions:** Studying women with psoriatic arthritis, we found that disease activity was highest six months postpartum, but altogether stable in the period from planning pregnancy to one year after delivery. Women using TNFi in pregnancy had significantly lower disease activity.

#### THU0674 RHEUMATIC DISEASES AND PREGNANCY: A SINGLE CENTRE DEDICATED CLINIC EXPERIENCE

E. Motta<sup>1,2</sup>, V. Ramoni<sup>1</sup>, B. Vitolo<sup>1</sup>, A. Milanese<sup>1</sup>, F. Beneventi<sup>3</sup>, S. Quagliani<sup>4</sup>, R. Caporali<sup>1,2</sup>, C. Montecucco<sup>1,2</sup>. <sup>1</sup>Unit of Rheumatology, IRCCS Foundation Policlinico San Matteo; <sup>2</sup>University of Pavia; <sup>3</sup>Department of Obstetrics and Gynecology, IRCCS Foundation Policlinico San Matteo and University of Pavia; <sup>4</sup>Department of Electrical, Computer and Biomedical Engineering, University of Pavia, Pavia, Italy

**Background:** Pregnancy causes immune and endocrine systems alterations, therefore it can change the course of the rheumatic diseases. On the other hand, rheumatic diseases can negatively influence pregnancy outcome. Therefore, in the past pregnancy has been discouraged in patients with rheumatic diseases, for high maternal-fetal risks. Nowadays we are aware that counselling, planning of pregnancy, multidisciplinary management and follow up in a dedicated clinic are mandatory for a good maternal-fetal outcome.

**Objectives:** To assess the impact of close multidisciplinary rheumatological-obstetrical management on high risk pregnancies.

**Methods:** We considered patients diagnosed with a rheumatic disease before pregnancy who had at least one pregnancy prospectively followed at our dedicated clinic. Each patient underwent a monthly rheumatological and obstetrical evaluation during the all pregnancy. All obstetrical complications were recorded and a final pregnancy outcome was assessed: favourable outcome (delivery) or

unfavourable outcome (spontaneous abortion/stillbirth/induced abortion). We then compared prospective versus anamnestic pregnancy outcomes.  
**Results:** Between 2005 and 2016, 862 women were evaluated. We included in the study 201 patients followed prospectively during 261 pregnancies. The patients were affected by 19 different rheumatic diseases, alone or in association. The most represented diagnoses were undifferentiated connective tissue disease (UCTD) (72 patients, 33.03%), rheumatoid arthritis (33, 15.14%), systemic lupus erythematosus (LES) (22, 10.09%), ankylosing spondylitis (14, 6.42%), psoriatic arthropathy (12, 5.5%), antiphospholipid antibody syndrome (APS) (10, 4.59%). Maternal age at conception was 34 years (range 18.3–45.7); 19 patients underwent medically assisted reproductive techniques. The most frequent obstetric complications were fluximetric changes, premature rupture of membranes, hypertension and related disorders, gestational diabetes, hypothyroidism and intrauterine growth retardation. The average gestational age at delivery was 38.24 weeks (range 26.71–41.29) with higher frequency of prematurity in patients with APS (55%), LES (39%) and UCTD (19%), as well as in the two pregnancies of patients with mixed connective tissue disease and systemic sclerosis. The comparison between favourable outcomes of prospective versus anamnestic pregnancies showed a significant difference ( $p < 0.001$ ) for prospectively followed pregnancies, regardless of maternal diagnosis.

Figure 1: Outcome of anamnestic vs prospective pregnancies in patients followed in our dedicated clinic.

**Abstract THU0674 – Figure 1** Outcome of anamnestic vs prospective pregnancies in patients followed in our dedicated clinic.

**Conclusions:** Pre-conception counselling and close multidisciplinary follow-up during pregnancy are essential for a better maternal-fetal outcome in patients with rheumatic diseases.

**THU0675 THE IMPACT OF AUTOIMMUNE RHEUMATIC DISEASES ON BIRTH OUTCOMES IN AN ETHNICALLY DIVERSE COHORT OF WOMEN IN THE UNITED STATES**

J.L. Strouse<sup>1</sup>, B.M. Donovan<sup>2</sup>, M. Fatima<sup>1</sup>, R. Fernandez-Ruiz<sup>1</sup>, L. Jelliffe-Pawlowski<sup>3</sup>, R.J. Baer<sup>4</sup>, C. Smith<sup>5</sup>, G. Bandoli<sup>4</sup>, R. Paynter<sup>6</sup>, N. Parikh<sup>3</sup>, K. Ryckman<sup>2</sup>, N. Singh<sup>1</sup>. <sup>1</sup>Internal medicine, University of Iowa Hospitals and Clinics; <sup>2</sup>Epidemiology, University of Iowa, Iowa City; <sup>3</sup>UCSF School of Medicine, San Francisco; <sup>4</sup>Pediatrics, University of California, San Diego; <sup>5</sup>Internal medicine, UCSD, San Diego; <sup>6</sup>Bioinformatics, UCSF, San Francisco, USA

**Background:** Autoimmune rheumatic diseases (ARDs) often affect women of childbearing age and have been associated with adverse pregnancy outcomes. Most of the literature on the impact of ARDs on birth outcomes to date has focused on the burden of common ARDs (e.g., rheumatoid arthritis (RA) and systemic lupus erythematosus (SLE)) within Caucasian populations. The effect of race/

ethnicity on birth outcomes among women with ARDs is not well understood. Identification of groups who are at highest risk of adverse birth outcomes may aid in increased prenatal surveillance and prevention of maternal and fetal morbidity.

**Objectives:** To evaluate the impact of ARD on adverse birth outcomes, specifically preterm birth (PTB), congenital anomalies, and low birth weight (LBW), in a large, ethnically diverse cohort.

**Methods:** We conducted a matched cohort analysis of retrospective data from all singleton live births in California occurring between 2007 and 2012. Data on ARD diagnosis, including RA, SLE, antiphospholipid syndrome (APS), psoriatic arthritis (PsA), ankylosing spondylitis (AS), or juvenile idiopathic arthritis (JIA), and birth outcomes were derived from birth certificate records linked to hospital/discharge ICD9 codes present anytime at or one year prior to delivery. Women without any of the previously mentioned rheumatic diseases were age- and ethnicity-matched in 2:1 ratio to women with ARD; their characteristics were compared using conditional logistic regression. We also examined the association between specific ARD diagnoses and birth outcomes stratified by race/ethnicity.

**Results:** We identified 10 975 women with a recorded ARD diagnosis (RA: 3129 (26%), SLE: 3863 (33%), APS: 4180 (35%), PsA: 173 (2%), AS: 144 (1%), and JIA: 354 (3%). The odds of PTB were increased for women with any ARD (aOR 1.90 (95% CI 1.76–2.05)) and among those with RA (aOR 1.65 (95% CI 1.47–1.85)), SLE (aOR 2.25 (95% CI 2.05–2.47)), APS (aOR 1.82 (95% CI 1.64–2.01)), and JIA (aOR 1.76 (95% CI 1.32–2.35)) compared to women without ARD. After stratifying by race/ethnicity, the odds of PTB and congenital anomalies were highest among Asian women and the odds of LBW were highest among Hispanic women compared to other race/ethnicity-matched controls (table 1). Further sub-analyses revealed that it was predominantly women with SLE who were contributing to the adverse outcomes seen in the combined ARD group.

**Abstract THU0675 – Table 1.** Odd of adverse birth outcomes among women with autoimmune rheumatic disease (ARD) compared with women without a recorded ARD by race/ethnicity.

Outcome	Total Population		White		Black		Hispanic		Asian	
	No. ARD	OR (95% CI)	No. ARD	OR (95% CI)	No. ARD	OR (95% CI)	No. ARD	OR (95% CI)	No. ARD	OR (95% CI)
Preterm birth	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)
Low birth weight	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)
Stillbirth	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)	1,989 (18.0)	1.90 (1.76-2.05)

OR, Odds Ratio; CI, Confidence Interval; ARD, autoimmune rheumatic disease; PTB, preterm birth; LBW, low birth weight.

**Conclusions:** Consistent with prior literature, we found that women with ARDs tend to be more likely to have PTB and infants of LBW. To our knowledge, this is the largest study to date to analyse these associations in Asian women. Our results suggest that Asian and Hispanic women with ARDs may disproportionately benefit from additional monitoring throughout pregnancy. Our study raises the need for public health initiatives that can help improve pregnancy outcomes in women with autoimmune rheumatic diseases across all races and ethnicities.

THU0676

### A SYSTEMATIC REVIEW AND META-ANALYSIS OF VIRAL EXPOSURES AS A RISK FACTOR FOR RHEUMATOID ARTHRITIS

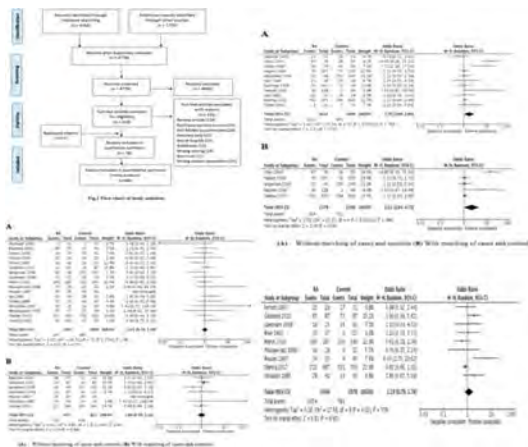

F. Kudaeva<sup>1</sup>, M.R. Speechley<sup>2</sup>, J.E. Pope<sup>3</sup>. <sup>1</sup>Epidemiology and Biostatistics; <sup>2</sup>Epidemiology and Biostatistics, Schulich School of Medicine and Dentistry, Western University; <sup>3</sup>Division of Rheumatology, St. Joseph's Health Care, Schulich School of Medicine and Dentistry, London, Canada

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease with a complex and poorly understood etiology. Development of autoimmune disease stems from a combination of immune, genetic, hormonal and environmental factors. Infections are viewed as triggers of some autoimmune disorders, including RA.

**Objectives:** Different viral exposures have been implicated in the etiology of RA via several mechanisms of immune activation, such as molecular mimicry. The purpose of this systematic review was to summarise the evidence relating to the association between putative viral exposures and the development of RA

**Methods:** A systematic literature search was conducted using MEDLINE-OVID, EMBASE-OVID, PUBMED and Cochrane library databases. Articles were included if they were case-controls, cross-sectional or cohort studies and were published in English. Case-series were included if there was a lack of other study designs.

**Results:** Of 6724 citations, 78 studies were selected for review, and 48 were included in meta-analysis. Studies had poor quality. Based on the IgG antibodies (n=12 studies) and viral DNA detection (n=3 studies), the odds of parvovirus B19 (PBV19) infection were increased in RA patients than in controls (odds ratio (OR) (95% CI)=1.77 (1.11; 2.80), p=0.02, OR (95% CI)=3.53 (1.00; 12.53), p=0.05 for PVB19 IgG and DNA, respectively). For Epstein-Barr virus (EBV), patients with RA had not significant OR of anti-Epstein-Barr nuclear antigen (EBNA) (n=17 studies, OR (95% CI)=1.05 (0.79; 1.39), p=0.75), but significant OR of anti-viral capsid antigen (VCA) (n=18 studies, OR (95% CI)=1.5 (1.07; 2.10), p=0.02) and anti-early antigen (EA) (n=11 studies, OR (95% CI)=2.74 (1.27; 5.94), p=0.01). Cytomegalovirus (CMV) was not associated with RA (n=13 studies, OR (95% CI)=1.24 (0.78; 1.95), p=0.36). Chronic hepatitis B (HBV) was not associated with RA in 5 case-control (OR (95% CI)=1.37 (0.83; 2.25), p=0.22) and 1 cohort studies (HR 1.09 (0.74, 1.63), p>0.05). Chronic hepatitis C (HCV) was associated with increased risk of RA in 7 case-control (OR (95% CI)=2.82 (1.35; 5.90), p=0.006) and 1 cohort studies (HR 2.03 (1.27, 3.22), p<0.01). There seem to be a risk of persistent arthritis after Chikungunya fever (CHIKV) (n=2 studies, OR (95% CI)=90 (15.2; 134.3).

**Abstract THU0676 – Figure 1.** Flow chart of study selection. Abstract THU0676 – Figure 2. Forest plots for cumulative odds ratio (95%CI) of serum IgG anti-PVB19 antibodies in RA cases and controls. (A) Without matching of cases and controls (B) With matching of cases and controls. Abstract THU0676 – Figure 3. Forest plot for cumulative odds ratio (95% CI) of serum anti-EBNA IgG in RA cases and controls. (A) Without matching of cases and controls (B) With matching of cases and controls. Abstract THU0676 – Figure 4. Forest plot for cumulative odds ratio (95% CI) of serum anti-CMV IgG in RA patients and controls.

**Conclusions:** Studies about the risk of RA after viral exposures suffer from inconsistent methodological quality. There is a risk of RA after Parvo B19 infection and possibly HCV but not EBV or HBV. There seems not to be a risk of RA after EBV infection. CHIKV is associated with the persistent inflammatory arthritis. There is not enough evidence to support an association between some viruses and RA development, but they probably lead to RA in genetically susceptible individuals.

**Disclosure of Interest:** None declared

THU0677

### PNEUMOCOCCAL ANTIBODY PROTECTION IN RHEUMATOLOGICAL PATIENTS RECEIVING BDMARD THERAPY – A CROSS-SECTIONAL STUDY

S. Rasmussen<sup>1</sup>, K. Fuursted<sup>2</sup>, K. Nielsen<sup>1</sup>, N. Parks<sup>1</sup>, M. Sørensen<sup>3</sup>, P. Leutscher<sup>3</sup>, C. Rasmussen<sup>4</sup>. <sup>1</sup>Regional Hospital North Jutland, Hjørring; <sup>2</sup>Statens Serum Institut, Copenhagen; <sup>3</sup>Center for Clinical Research; <sup>4</sup>Department of Rheumatology, Regional Hospital North Jutland, Hjørring, Denmark

**Background:** Severe pneumococcal infections contribute to increased mortality in patients with rheumatic diseases, and is preventable by vaccination against *Streptococcus pneumoniae*. EULAR recommends that pneumococcal vaccination should be strongly considered in patients with rheumatic diseases, however, need and timing of revaccination for this patient group remains unknown<sup>1</sup>. Since 2009, rheumatological patients from our department have been vaccinated against *S. pneumoniae* prior to initiation of bDMARD therapy, by use of the 23-valent pneumococcal polysaccharide vaccine (PPV23). To our knowledge, we are the only centre in Denmark to vaccinate these patients routinely.

**Objectives:** The aim of the study was to determine the prevalence of rheumatological patients receiving bDMARD therapy with a protective level of antibodies against *S. pneumoniae*, and to identify possible factors of relevance affecting antibody production.

**Methods:** Antibodies against 12 pneumococcal serotypes were measured in the period of June to December 2017 in patients receiving bDMARD therapy initiated before March 1st 2017. A geometric mean level of all serotypes above 1 µg/ml was considered a protective antibody level. The patients had been diagnosed with rheumatoid arthritis, spondyloarthritis, psoriatic arthritis or juvenile idiopathic arthritis. The study group consisted of both vaccinated and unvaccinated individuals, where unvaccinated individuals initiated bDMARD therapy before vaccination occurred routinely.

Differences in protection between vaccinated and unvaccinated patients were evaluated using the  $\chi^2$  test. We included the following variables in a logistic regression model, to analyse factors of possible significance to the protective level of antibodies: age, sex, diagnosis, methotrexate (MTX) and/or prednisolone treatment at time of vaccination, and years since vaccination.

**Results:** A total of 319 patients were included in the study: 186 (58%) vaccinated and 133 (42%) unvaccinated patients. Among the vaccinated patients, 30% had a protective antibody level versus 0% of the unvaccinated patients (p<0.0001).

Logistic regression analysis showed that a significantly smaller proportion of patients treated with MTX at time of vaccination had a protective antibody level compared with patients not treated with MTX (p=0.03; odds ratio: 2.3; 95% CI [1.1;4.7]). The same applied for advanced age at time of vaccination (p=0.04), whereas years since vaccination did not decrease antibody protection significantly (p=0.12).

**Conclusions:** Only one third of PPV23 vaccinated rheumatological patients treated with bDMARD were observed with a GML of pneumococcal antibodies above 1 µg/ml. This suggests that a majority of these patients are not protected adequately against pneumococcal disease in spite of vaccination. MTX treatment at time of vaccination and advanced age were both independently associated with lack of protective antibody level.

THU0678

### TREND OF VENOUS THROMBOEMBOLISM AMONG SELECT RHEUMATOLOGIC DISEASES: AN AUDIT OF LARGE NATIONAL US DATABASE

D.R. Poudel<sup>1</sup>, R. Dhital<sup>1</sup>, P. Paudel<sup>2</sup>, S. Basnet<sup>1</sup>, P. Sharma<sup>1</sup>, P. Shrestha<sup>1</sup>, P. Karmacharya<sup>1,3</sup>. <sup>1</sup>Internal Medicine, Tower Health System, Reading Hospital, West Reading; <sup>2</sup>Internal Medicine, Berkshire Medical Center, Pittsfield; <sup>3</sup>Division of Rheumatology, Mayo Clinic, Rochester, USA

**Background:** Venous thromboembolism (VTE) is 3rd commonest cause of cardiovascular deaths and encompasses deep-venous thrombosis (DVT) and pulmonary embolism (PE). Rheumatologic diseases have been found to be associated with an increased risk of VTE among hospitalised patients.

**Objectives:** To describe the trend of VTE among select rheumatologic diseases over 15 years.

**Methods:** We used National Inpatient Sample (NIS) database for years 2000–2014 to identify adults ≥18 years with select rheumatologic diseases and VTE based on ICD-9 codes. Prevalence was age-sex adjusted against US census population data. STATA was used for querying database and Joinpoint regression

<b>Adjusted odds of VTE association (p-value, 95% CI)</b>										
Overall	-	1	1.24 (<0.0001, 1.22–1.3)	2.2 (<0.0002, 2.17–2.3)	1.3 (<0.0003, 1.28–1.4)	1.4 (<0.0004, 1.3–1.45)	1.3 (<0.0005, 1.2–1.33)	2 (<0.0006, 1.9–2.2)	1.8 (<0.0007, 1.76–1.9)	-

was used to analyse annual trends of prevalence in terms of annual percentage change (APC). Logistic regression with survey command was used to derive adjusted odds of VTE association for all years combined.

**Results:** We included a total of 461,089,203 hospitalizations among which 8,822,456 (1.91%) had VTE (table 1). An upward trend in the prevalence of VTE (APCs 2.45–4.16) (and PE subset) was noted in most of the rheumatologic disease groups (figure 1). DVT, however, had a decreasing or non-significant increasing trend among most disease groups (data for DVT and PE not shown). The adjusted odds of VTE association was highest among SLE group (aOR=2.2, CI=2.17–2.3) followed by DM/PM (aOR=2.0, CI=1.9–2.2) (table 1).

Table 1 Frequency counts of rheumatologic diseases and controls; prevalence of VTE and adjusted regression analysis of VTE association

**Abstract THU0678 – Figure 1** Trend of proportion of VTE by disease groups and controls (APCs with \* are statistically significant trends)

**Conclusions:** Inflammatory rheumatologic diseases seem to be associated with higher prevalence and odds of having VTE among hospitalised patients and the overall trend is rising. This might indicate some lag in following of guidelines for VTE prophylaxis. Closer look into the implications of stricter prophylaxis among rheumatologic patients is a matter of further studies.

**THU0679 INCREASED HOSPITALISATION RATES FOLLOWING HEART FAILURE DIAGNOSIS IN RHEUMATOID ARTHRITIS**

E. Myasoedova<sup>1,1</sup>, J.M. Davis, III<sup>1</sup>, S.J. Achenbach<sup>2</sup>, E.L. Matteson<sup>1</sup>, S. Setoguchi<sup>3</sup>, S.E. Gabriel<sup>4</sup>, C.S. Crowson<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Health Sciences Research, Mayo Clinic College of Medicine, Rochester, MN; <sup>3</sup>Rutgers School of Public Health; <sup>4</sup>Rutgers Robert Wood Johnson Medical School, New Brunswick, NJ, USA

**Background:** There is a 2-fold increased risk of heart failure (HF) in rheumatoid arthritis (RA) compared to the general population. Little is known about hospitalisation rates in patients with RA and HF.

**Objectives:** We aimed to compare the frequency of and trends in hospitalizations after HF diagnosis in patients with and without RA during 1987–2015 and to assess risk factors for hospitalizations following HF in RA.

**Methods:** The study included a retrospectively identified population-based cohort of patients with incident HF and prior RA (age ≥18 years, 1987 ACR criteria) and a cohort of incident HF patients without RA matched 3:1 on age, sex, and year of HF diagnosis. Hospitalizations at the time of HF diagnosis were excluded. All subjects were followed until death, migration, or 12/31/2015. Person-years methods and rate ratios (RR) from Poisson regression models were used to compare hospitalisation rates (number of hospitalizations divided by person-years of follow-up) between the groups. Conditional frailty models were used to examine risk factors for hospitalisation.

**Results:** The study included 212 patients with RA (mean age at HF diagnosis 78.3 years; 68% female) and 636 non-RA patients (mean age at HF diagnosis 78.6 years; 68% female). The hospitalisation rate after HF diagnosis was higher in RA vs non-RA (RR 1.16; 95% CI 1.08–1.25). This difference may be decreasing after 2010 (figure 1). The magnitude of the increase was similar in both sexes and across all ages. In a subset with available echocardiography (n=68 RA and 449 non-RA), HF with preserved ejection fraction (HFpEF) was similarly prevalent in RA (57%) vs non-RA (51%; p=0.3). Among those with HF with reduced ejection fraction (HFrEF) RA patients had more hospitalizations than non-RA subjects (RR

1.65; 95% CI 1.29–2.09); this was not observed in HFpEF (RR 0.80; 95% CI 0.63–1.01). Following HF diagnosis, RA patients were more likely to be hospitalised for non-cardiovascular causes (RR 1.26; 95% CI 1.14–1.39), but not for HF (RR 0.96; 95% CI 0.76–1.21) or other cardiovascular causes (RR 0.99; 95% CI 0.81–1.20) compared to the non-RA patients. Readmission rates within 30 days of prior discharge were similar in RA and non-RA ( $p=0.14$ ). Smoking (current or former), prior myocardial infarction (MI) and higher score on Charlson comorbidity index were associated with increased risk for hospitalisation: hazard ratio (HR) 1.33, 95% CI 1.06–1.68; HR 1.37, 95% CI 1.03–1.82; and HR 1.10, 95% CI 1.06–1.14, respectively.

**Conclusions:** Hospitalisation rate following HF diagnosis was 16% higher in RA than in non-RA patients regardless of sex and age. This difference was particularly apparent between 1990 and 2010. Increased hospitalisation risk was mostly among patients with RA who had HFpEF rather than HF, and was predominantly due to non-cardiovascular causes. Smoking, prior MI and Charlson comorbidity index were associated with increased risk of hospitalisation suggesting that increased complexity of management of patients with comorbid RA may play a role in more frequent hospitalizations in the RA cohort.

## Epidemiology, risk factors for disease or disease progression

THU0680

### SURVIVAL ANALYSIS OF PATIENTS WITH CONNECTIVE TISSUE DISEASE ASSOCIATED INTERSTITIAL LUNG DISEASE

*T. Xu, X. ZHANG. Rheumatoid Immunologic Department, Guangdong Academy of Medical Sciences, Guangdong General Hospital, Guangzhou, China*

**Background:** Interstitial lung disease (ILD) is common in connective tissue diseases (CTDs) and can lead to significant shortened survival. Although the various CTDs associated with ILD are often considered as a whole because of their sharing the same autoimmune nature, there are substantial differences in the natural course in each specific CTD. Still, there is little research comparing the mortalities in different underlying CTDs and investigated the risk factors.

**Objectives:** We aimed to examine mortality in patients with ILD secondary to dermatomyositis and polymyositis (DM/PM), systemic sclerosis (SSc), rheumatoid arthritis (RA), primary Sjögren syndrome (pSS), and systemic lupus erythematosus (SLE), to test whether the survival was associated with ILD imaging subtypes, as well as to identify independent risk factors for CTD-ILDs.

**Methods:** We retrospectively reviewed the medical records of patients with newly diagnosed CTD-ILD. The high-resolution computed tomography of lung images was reviewed by two expert pulmonary radiologists. According to imaging manifestations, ILD was categorised into three subtypes, i.e., usual interstitial pneumonia (UIP), nonspecific interstitial pneumonia (NSIP) and indeterminate, respectively. The extensity of ILD lesions was also evaluated as grade 1, 2, 3. The primary outcome assessed was all-cause mortality. We examined survival after stratifying on each specific CTD, or lung-CT imaging subtypes, respectively. We used Cox proportional hazards model to identify independent predictors of survival.

**Results:** Three hundred and twenty-five patients were included with a median follow-up time of 54 months. Eighty-four (25.8%) had DM/PM, 73 (22.5%) had SSc,

63 (19.4%) had RA, 58 (17.8%) had pSS, 47 (14.5%) had SLE. Overall, 98 (30.2%) patients died. The survival rate of pSS-ILD (85.1%) and SLE-ILD (79.3%) were significantly higher than other CTD-ILDs [SSc-ILD (68.5%), RA-ILD (66.7%), DM/PM-ILD (58.6%),  $p=0.009$ ]. However, after categorised into three different ILD imaging subtypes, it showed no statistical differences in survival rates (64.5%, 73.6%, 69.5% of the UIP group, NSIP group, indeterminate group, respectively,  $p=0.558$ ). Multivariable analysis revealed that compared with DM/PM-ILD, the mortality rate was significantly lower in pSS-ILD (RR=0.321,  $p=0.001$ ), RA-ILD (RR=0.466,  $p=0.016$ ), SSc-ILD (RR=0.566,  $p=0.045$ ), and SLE-ILD patients (RR=0.363,  $p=0.018$ ), and old age (RR=1.028,  $p=0.002$ ), long course of disease (RR=1.004,  $p=0.005$ ), extended ILD lesions (RR=1.854,  $p=0.025$ ) were independent predictors of mortality in all types of CTD-ILD. The present study shows DM/PM-ILD patients had the worst prognosis then pSS-ILD, RA-ILD, SSc-ILD, and SLE-ILD patients. Age, disease course, intensity of ILD lesions at baseline is also critical for the survival of CTD-ILD patients.

**Conclusions:** The present study shows DM/PM-ILD patients had the worst prognosis then pSS-ILD, RA-ILD, SSc-ILD, and SLE-ILD patients. Age, disease course, intensity of ILD lesions at baseline is also critical for the survival of CTD-ILD patients.

**Background:** Ankylosing spondylitis (AS) is a chronic spinal inflammatory disorder which leads to progressive fusion and deformity. The loss of spinal mobility is recognised as an important clinical sign. The BASMI, a composite index of spinal mobility is used internationally in clinical practice and research. However, the interpretation of BASMI has been impeded by the absence of normative values.

**Objectives:** We aimed to attain the normative values for BASMI in Malaysian healthy individuals.

**Methods:** BASMI data of 142 healthy individuals and 187 AS patients were analysed. Each BASMI component was assessed, using the 10-point scoring system, where zero is no mobility and 10 is very severe limitation. Measurements were performed by the rheumatologists and trained researchers following a designated protocol. Data were summarised and analysed according to sex and age groups.

**Results:** The total BASMI scores ranged from 0.2 to 4.2 and 0.6 to 9.6 in the healthy individuals and the AS cases, respectively. There was no significant difference for the BASMI median score between healthy men and women (men=1.2, women=1.6,  $p>0.05$ ). The estimated median score for healthy individuals aged 15–19 years was 1.2, increasing with age to 2.7 for healthy individuals aged  $\geq 60$

years. In AS cases, the estimated median score was 5.4 and 5.8 for men and women, respectively ( $p > 0.05$ ). We observed significant increase of estimated median score between AS patients aged 15–19 years (BASMI score=2.0) and AS patients aged  $\geq 60$  years (BASMI score=6.4) ( $p < 0.05$ ).

**Conclusions:** Our data suggest that it is uncommon for healthy individuals to score zero on the BASMI. The magnitude of increase in BASMI score is apparent with increasing age, but not sex in the healthy individuals. Establishment of normative values may aid baseline measurement and monitor change of spinal mobility in AS patients over time, as well as help assess the impact of clinical interventions.

#### THU0682 HUMAN HISTOCOMPATIBILITY ANTIGENS (HLA) CLASS I IN ANTERIOR UVEITIS PATIENTS WITH AND WITHOUT SPONDYLOARTHRITIS

A. Godzenko<sup>1</sup>, I. Guseva<sup>2</sup>, I. Razumova<sup>3</sup>. <sup>1</sup>Russian Medical Academy of Postgraduate Education; <sup>2</sup>Scientific research institute of rheumatology named after V. A. Nasonova; <sup>3</sup>Scientific research institute of ophthalmology, Moscow, Russian Federation

**Background:** Anterior uveitis (AU) and spondyloarthritis (SpA) are associated with HLA-B27. Previous genetic studies in different populations demonstrated other associations, in particular, HLA, both common and different for AU and SpA

**Objectives:** To assess the relationship of HLA class I antigens with AU depending on the presence or absence of SpA

**Methods:** 148 pts with AU were typed. All pts were divided into 2 groups: 1–52 pts with confirmed diagnosis of SpA (AU +SpA), 96 pts – with other forms of AU (52 – idiopathic AU, 29 – viral AU, 2- multiple sclerosis, 2 - toxoplasmosis, 1- sarcoidosis, 1- tuberculosis, 3- chlamydial AU, 2 - Behcet's disease, 3 - juvenile chronic arthritis, 1 - Fuchs's heterochromic iridocyclitis). 150 healthy donors formed control group. Analysis of the distribution of HLA- class I antigens (loci A, B, Cw) was performed comparing 2 groups of patients with AU and each group with control.

**Results:** HLA-27 in the group of pts AU +SpA identified in 96.1% (50/52), in the group AU – in 40.6% (39/96), in control – in 7.3% (11/150). If HLA-27 was present in the genotype, the risk of developing of common pathology (AU +SpA) was OR=315.9 [95% CI 61.9–2176.7],  $p < 0.0000001$ , the risk of AU - OR=8.7 [95% CI 3.9–19.4],  $p < 0.000001$ . Among locus C antigens high frequency of Cw2 was identified in the groups AU +SpA and AU compared with control (64.0%, 36.3% and 10.0%, respectively): AU +SpA vs control -  $p < 0.000001$ , AU vs control, -  $p < 0.0001$ . The occurrence of Cw7 was significantly lower in the group AU +SpA in comparison with control: 12.8% and 38.7%,  $p = 0.002$ . In the group AU the occurrence of this antigen was not significantly different from the control group and the group AU +SpA.

**Conclusions:** The analysis of the distribution of HLA class I antigens confirmed association of HLA- B27 with AU in Russian population. Other associations, except Cw2, were not identified. Such significant increase of Cw2 in two groups of pts with high frequency of B27 is natural due to the phenomenon of linkage disequilibrium for HLA-B27 and Cw2 antigens. Cw7 antigen can play a "protective" role in relation to SpA, because the frequency of this gene in the group AU was not reduced compared to control.

#### THU0683 PREDICTORS FOR PRETERM DELIVERY AMONG PREGNANT WOMEN WITH RHEUMATOID ARTHRITIS AND JUVENILE IDIOPATHIC ARTHRITIS

C.J.F. Smith<sup>1</sup>, F. Förger<sup>2</sup>, C. Chambers<sup>3</sup>. <sup>1</sup>Rheumatology, Allergy, Immunology, University of California San Diego, La Jolla, USA; <sup>2</sup>University Hospital and University of Bern, Bern, Switzerland; <sup>3</sup>Pediatrics, University of California San Diego, La Jolla, USA

**Background:** It has previously been shown that pregnant women with inflammatory arthritis are at an increased risk for preterm delivery (PTD), yet it remains unclear what underlying maternal factors may drive this excess risk.

**Objectives:** The aim of our study is to identify overall predictors for PTD among women with rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA) and to

analyse the contribution of maternal disease activity, medication use, and comorbid pregnancy conditions on the risk for PTD in this population.

**Methods:** Data were obtained from the Organisation of Teratology Information Specialists (OTIS) Autoimmune Disease in Pregnancy Project, a prospective cohort study among pregnant women in the U.S. and Canada. Women who enrolled between 2004 and 2017 prior to 19 weeks' gestation, had not enrolled with a previous pregnancy, and delivered at least one live born infant were considered eligible for analysis. All data were obtained by maternal report via telephone interviews and confirmed in the medical record when available. For our statistical analysis, Poisson regression with robust standard errors was used to estimate multivariable adjusted risk ratios.

**Results:** Mothers with RA and JIA had a higher risk of PTD, preterm labour, early term delivery, and caesarian section versus comparison women. Women with RA additionally had a higher risk of gestational diabetes mellitus (GDM), and women with JIA had a higher risk of preeclampsia versus the comparison group. Active disease (defined as patient activity scale (PAS) score  $> 3.70$ ) was associated with PTD among women with RA both at intake and anytime during pregnancy, and this association remained after adjustment for corticosteroid (CS) use (aRR 1.60, 95% CI 1.12–2.30; aRR 1.54, 95% CI 1.08–2.20, respectively). CS use in all three trimesters was associated with PTD among women with both RA and JIA, an association that remained after multivariable adjustment for maternal factors including disease activity. Use of non-steroidal anti-inflammatory drugs (NSAIDs) in the first trimester was associated with PTD in women with JIA (aRR 2.31, 95% CI 1.04–5.14). Additional analysis showed that preeclampsia was associated with a higher risk of PTD among both RA and JIA women (aRR 1.92, 95% CI 1.12–3.31; aRR 3.01, 95% CI 1.10–8.23, respectively) but not in the comparison group. GDM and caesarian section were associated with a higher risk of PTD exclusively among RA women (aRR 1.84, 95% CI 1.07–3.15 and aRR 1.58, 95% CI 1.09–2.28, respectively) and fever during pregnancy increased the risk for PTD exclusively among women with JIA (aRR 3.45, 95% CI 1.47–8.08).

**Conclusions:** Women with RA and JIA are at risk for preterm delivery. Maternal disease activity and medication use, particularly corticosteroid use, may explain much of this excess risk.

DOI: 10.1136/annrheumdis-2018-eular.4967

#### THU0684 PREVALENCE OF RHEUMATIC DISEASES IN ADULT POPULATION IN SPAIN. EPISER 2016 STUDY

D. Seoane-Mato<sup>1</sup>, C. Sánchez-Piedra<sup>1</sup>, F. Díaz-González<sup>2</sup>, S. Bustabad<sup>2</sup>, on behalf of EPISER 2016 working group. <sup>1</sup>Research Unit, Spanish Society of Rheumatology, Madrid; <sup>2</sup>Rheumatology, H. U. de Canarias, Santa Cruz de Tenerife, Spain

**Background:** Prevalence of rheumatic diseases was first studied in Spain in 2000 (EPISER 2000 study<sup>1</sup>). Sociodemographic and lifestyle changes during the last 16 years and their possible influence in prevalence figures justify a new study.

**Objectives:** To estimate the prevalence of rheumatoid arthritis (RA), psoriatic arthritis (PsA), ankylosing spondylitis (AS), systemic lupus erythematosus (SLE), Sjögren syndrome, symptomatic osteoarthritis (knee, hip, hands, cervical and lumbar spine), fibromyalgia, gout and symptomatic osteoporotic fracture in adult population in Spain.

Disease	Prevalence	95% CI
Cervical osteoarthritis	10.1%	9.1–11.2
Lumbar osteoarthritis	15.5%	14.3–16.8
Hand osteoarthritis	7.9%	7.0–8.9
Hip osteoarthritis	5.2%	4.4–6.0
Knee osteoarthritis	13.9%	12.7–15.1
RA	0.9%	0.7–1.3
PsA	0.6%	0.4–0.8
AS	0.4%	0.3–0.7
Gout	2.5%	2.0–3.1
SLE	0.2%	0.1–0.4
Sjögren syndrome	0.3%	0.2–0.5
Fibromyalgia	2.4%	2.1–2.9
Symptomatic osteoporotic fracture	1.8%	1.4–2.4

**Methods:** Population-based multicenter cross-sectional study, with the participation of 78 municipalities in the 17 Spanish autonomous communities. The reference population are adults aged 20 and above residing in Spain. All participants gave their informed consent. CATI system (Computer Assisted Telephone Interview) was used for initial data collection and screening questionnaire. Diagnostic suspicions and diagnosis referred by the participants were studied by rheumatologists in the referral hospital for the selected municipalities. Statistical analysis: the prevalence of the rheumatic diseases were calculated using estimators and their

95% confidence intervals. Weights were calculated in each of the sampling stages in accordance with the probability of selection. The distribution of population in Spain obtained from the National Statistics Institute was taken into account.

**Results:** 4916 subjects were included in the study. 4753 completed their participation. Prevalence of rheumatic diseases were the following: The negative predictive value (NPV) of the initial screening questionnaire was 93.8%. The lower NPV corresponded to knee osteoarthritis (95.1%).

**Conclusions:** Prevalence of RA, PsA, AS, gout and SLE seems to be higher than previously published in other European countries.

#### THU0685 CARDIOVASCULAR RISK ESTIMATION IN SLE PATIENTS: A COMPARISON OF THREE ALGORITHMS

D. Chimera, C. Tani, C. Stagnaro, E. Elefante, R. Vagelli, L. Carli, M. Mosca. *University of Pisa, Pisa, Italy*

**Background:** Cardiovascular (CV) disease is a major cause of mortality and morbidity in SLE patients; several instruments have been developed to estimate the 10 years risk of major CV events in the general population according to the presence of traditional CV risk factors. However, it is well known that traditional CV risk factors cannot fully explain the increased CV disease in SLE. Recently, a new version of the Qrisk algorithm was released (QRISK3) incorporating new variables associated with increased risk of CV disease, including SLE diagnosis and the GC use.

**Objectives:** To assess the 10 years CV risk in a cohort of SLE patients by comparing three different algorithms.

**Methods:** Consecutive patients with a diagnosis of SLE according to the ACR criteria were recruited from the inpatients and outpatients clinics of our Unit. Previous major CV events (myocardial infarction and stroke) were considered exclusion criteria. Traditional CV risk factors, disease activity and damage as well as therapies and comorbidities were evaluated. Disease activity was assessed with the SLEDAI score, organ damage with the SLICC/DI. Three algorithms to estimate the 10 years risk of major events were applied: the Framingham score, the ACC/AHA score and the QRISK3. This latter incorporates new variables associated with increased risk of cardiovascular disease, including SLE and GC use.

Abstract THU0685 – Table 1

Cumulative organ involvement (%)	
Renal	45%
Articular	75%
Hematological	52%
Cutaneous	52%
Neuropsychiatric	10%
Serositis	20%
Ongoing therapies (%)	
Antimalarials	80%
Glucocorticoids	60%
Immunosuppressants	45%
Traditional CV risk factors (%)	
BMI > 30	5.8%
BMI > 25	12.5%
Sedentary life style	46%
Hypertension	33%
Diabetes	4%
Family history of CV events	15%
Actual smoking	20%
Dyslipidemia	35%
Metabolic syndrome	12%

**Results:** 115 SLE patients (90.5%) without previous major CV events were included in this analysis. They were predominantly females (93%), Caucasian (96.5%) with a mean age at enrollment of 42.8±12.5 and a mean disease duration

of 13.4±9.2 years. The prevalence of organ involvement and traditional risk factors are reported in table 1. Disease activity at enrollment was low (median SLE-DAI 2, IQR 0–4) while 39.1% was presenting at least one organ damage.

The median Framingham risk score resulted 4.5% (IQR 2.4–8.6), the ACC/AHA resulted 1.2% (0.5–3.2), the QRISK3 resulted 5.4% (2.4–9.6). According to the three methods, there was a significant difference in the risk stratification: 10% of patients at medium-high CV risk according to the Framingham score, 5% with the ACC/AHA score and 21% with the QRISK3. The median “healthy heart age” of our cohort (the age at which a healthy subject has the same CV risk) provided by the QRISK3 resulted 62 years.<sup>52–68</sup>

**Conclusions:** These data show that by applying the QRISK3 algorithm a significant percentage of patients would be reclassified at high risk of CV events with respect to the traditional CV risk scores. Longitudinal data are necessary to validate the QRISK3 accuracy against the traditional scores in the identification of SLE patients at higher risk of CV events.

Assistance Publique – Hôpitaux de Paris; INSERM (U1153): Clinical epidemiology and biostatistics, PRES Sorbonne Paris-Cité, Paris; <sup>5</sup>Nîmes University Hospital, EA 2415, Montpellier I University, Nîmes; <sup>6</sup>Inserm CIC, 1433 Epidémiologie clinique, CHRU de Brabois, Nancy; <sup>7</sup>CHU de Toulouse, Hôpital Pierre-Paul Riquet, Toulouse, France

**Background:** Health-related quality of life (HRQoL) is a priority for patients.

**Objectives:** The objectives were to describe the changes in HRQoL over 5–8 years in patients with early arthritis (EA) or early inflammatory back pain (IBP), and to explore factors associated with HRQoL.

**Methods:** In 2 prospective observational French cohorts (ESPOIR for EA patients and DESIR for early IBP patients), HRQoL was assessed every 6 months during the first 24 months and then every year over 5–8 years, using the SF36 physical composite score (PCS) and mental composite score (MCS) (range 0–100, US population norm: 50). Disease activity was assessed by DAS28-ESR and ASDAS-CRP. Univariate and multivariate linear mixed-effect models, and trajectory-based mapping (k-means) were applied.

Figure: Evolution of SF36-MCS and PCS over follow-up in EA and early IBP

Figure 1 Evolution of SF36-MCS and PCS over follow-up in EA and early IBP

**Results:** In all, 1 347 patients (701 EA and 646 early IBP) were analysed: mean age 48.4±12.2 and 33.9±8.7 years respectively; mean disease duration 3.4±1.7 and 18.2±10.8 months, 76.3% and 55.0% females. At baseline, in EA, mean PCS and MCS were respectively 40.2±9.1 and 40.4±11.2, and in early IBP respectively 38.5±8.5 and 39.8±10.9. Over follow-up, HRQoL mean levels and trajectories improved mostly over the first 6 months (p<0.001). Overall, 54%–61% of patients reached levels of HRQoL close to population norms. DAS28-ESR and ASDAS-CRP over time were related to PCS (range of explained variance: 9% >43%, p<0.001 in the mixed models) but not to MCS.

Lines represent changes of mean SF36-MCS and mean SF36-PCS for EA and IBP; 95% confidence intervals were not represented because they were very small; The number of available data is between 696 and 508 according to the timepoint for SF-36 in EA and 646 to 422 according to the timepoint for SF-36 in IBP.

**Conclusions:** HRQoL was altered similarly for both physical and mental aspects in EA and early IBP. More than half the patients reached levels of HRQoL close to the general population. Disease activity only partly explained HRQoL: the drivers of HRQoL should be further explored.

#### THU0687 THE IMPACT OF URATE-LOWERING THERAPY ON KIDNEY FUNCTION (IMPULSKF): PRELIMINARY RESULTS

D.D. Ivanov<sup>1</sup>, O.V. Sinjchenko<sup>2</sup>, I.Y. Golovach<sup>3</sup>, T.B. Bevzenko<sup>1</sup>, M.D. Ivanova<sup>4</sup>.  
<sup>1</sup>Nephrology and RRT, Shupyk National Medical Academy of Postgraduate Education Kiev, Ukraine, Kiev, <sup>2</sup>Donetsk National Medical University, Lyman;  
<sup>3</sup>Hospital "Feofaniya" of Agency of State Affairs,, Kiev, Ukraine, <sup>4</sup>Milano-Bicocca, Milano, Italy

**Background:** The extended 2016 EULAR updated report states that for patients on ULT, SUA level should be monitored and maintained to <6 mg/dL (360 μmol/L). SUA level <3 mg/dL (180 μmol/L) is not recommended in the long term. And among EULAR proposals for future research is mentioned the optimal duration for prophylaxis of acute attacks when starting ULT, long-term impact of very low urate levels on the central nervous system, impact of ULT on kidney function.

**Objectives:** This project aims to investigate the impact of two target levels urate-lowering therapy (ULT) caused by hyperuricemia (HU) on kidney function and CKD progression measured by eGFR and albuminuria (A).

This trial had been formulated by 2016 updated EULAR evidence-based recommendations for the management of gout as a perspective proposal task for future research.

The key points are: 1) an unknown target HU level and 2) the time duration of ULT resulting in preserved kidney function in two subject groups a) with gout and b) without gout but highly elevated uricemia and CKD.

**Methods:** The trial has a POEM design with 36 months duration. IMPULSKF is a Clinical Randomised Prospective Controlled Open Multicenter trial that randomly (by chance) assigns 180 participants in parallel groups. These patients with high SUA level (>8 mg/dL; 480 μmol/L) were divided into 2 arms (90+90) 1) with gout (EULAR's criteria) and 2) without gout but with presence of CKD 1–4) and 2 target SUA levels in each group as 5 mg/dL (300 μmol/L) and ultralow SUA <3 mg/dL (180 μmol/L) achieved either with allopurinol or febuxostat. The data obtained will be compared with control group (45 with gout without CKD and 45 with CKD).

**Results:** Retrospective analysis and 6 mothes in trial results has been shown that treatment with febuxostat improves GFR and BP control in patients with asymptomatic HU in non-diabetic CKD 2–3.<sup>2</sup>

Febuxostat treatment led to the most beneficial decrease in the level of uric acid (–223±16 μmol/l, p<0,01 with control and p<0,05 with allopurinol group), increased GFR (+10±2 ml/min, p<0,01 with control and p<0,05 with allopurinol group), blood pressure decrease (- 7±2/–3±1 mm hg, p<0,05 with control and p=0,93 with allopurinol group), albuminuria (–131±19 mg, p<0,01 with control and p<0,05 with allopurinol group. Potential benefits of febuxostat were better tolerability compared with allopurinol group with target levels of uricemia less 180 μmol/l in 32% of people.

**Conclusions:** Treatment with febuxostat (better than allopurinol) improves GFR and BP in patients with asymptomatic hyperuricemia in non-diabetic CKD 2–3. Ultralow SUA levels seems to be safe in majority of patients but its effect on CKD function is not yet clear.

#### THU0688 DO CERTAIN DMARDS INCREASE RISK OF NEW-ONSET TYPE 2 DIABETES? EVALUATION OF PATIENTS' BASELINE CHARACTERISTICS

E. Alemao, Z. Guo, L. Ferri, L. Burns. *Bristol-Myers Squibb, Princeton, USA*

**Background:** The risk of cardiovascular morbidities is higher in patients (pts) with RA and is exacerbated with type 2 diabetes (T2D).<sup>1</sup> Recent analysis showed that abatacept (ABA), a biologic (b)DMARD, has a lower incidence of T2D in pts with RA in clinical practice.<sup>2</sup>

**Objectives:** To compare baseline characteristics of pts with RA on DMARDs and evaluate incidence of T2D among these pts based on DMARD exposure.

**Methods:** Administrative claims data (2006–2016) from Optum Clinformatics (database A), QuintilesIMS PharMetrics Plus (database B) and Truven Market-Scan® (database C). Inclusion criteria were: 2 RA diagnosis codes+1 DMARD prescription; age ≥18 years; ≥3 months baseline (pre-index date); and 3 months of follow-up (post-index date). Mutually exclusive treatment groups (grp) were created based on the first prescription (index date) using a hierarchy of ABA, non-ABA bDMARDs (TNF inhibitors [TNFi] and non-TNFi [excluding ABA]) and conventional DMARDs (cDMARD; MTX or hydroxychloroquine [HCQ]). Also, an RA grp without DMARD use (NoDMARD) was identified. The index date for NoDMARD was first diagnosis date. Incident T2D was identified as those without T2D prior to index using one International Classification of Disease (ICD)–9 or ICD-10 diagnosis code for T2D. Assessment of T2D risk between treatment grps was based on regression and disease risk score (DRS) models. Adjusted incidence rate for T2D was based on a Cox model (stratified by DRS grps and categorised into 4 equal grps using quartile scores) with treatment as the independent variable.

**Results:** In databases A, B and C, 84,875, 2 07 811 and 1 94 819 pts with RA were identified, respectively (table 1). The combined proportions of pts in each treatment grp were: 3%–4% ABA; 12%–16% non-ABA bDMARD; and 41%–45% cDMARDs. Pts treated with ABA were older compared with those on non-ABA bDMARDs and a greater proportion had T2D risk factors of obesity, hypertension, dyslipidaemia and heart failure (table 1). The adjusted hazard ratios for T2D were significantly higher for non-bDMARD grps of TNFi and other bDMARDs vs ABA (figure 1).

**Abstract THU0688 – Table 1.** Baseline Risk Factors for T2D in Pts With RA by DMARD Grps

#### THU0689 VARIABILITY OF PAIN LEVELS IS EXPLAINED BY SELF-REPORTED DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS AND AXIAL SPONDYLOARTHRITIS: A 3-MONTHS PROSPECTIVE STUDY OF 165 PATIENTS

E. Bailly<sup>1</sup>, C. Jacquemin<sup>2</sup>, H. Servy<sup>3</sup>, B. Fautrel<sup>4</sup>, L. Gossec<sup>4</sup>. <sup>1</sup>Pain Department; <sup>2</sup>Assistance Publique – Hôpitaux de Paris, Paris; <sup>3</sup>Sanoia, Gardanne; <sup>4</sup>Rheumatology Department, Assistance Publique – Hôpitaux de Paris, Paris, France

**Background:** Pain is a central characteristic of rheumatoid arthritis (RA) and axial spondyloarthritis (axSpA), but it is multifactorial. Some patients describe high fluctuation of pain intensity, but fluctuation of pain and its association with disease activity has been little investigated.

**Objectives:** To compare the variability of pain and of self-reported disease activity in patients with RA or axSpA through repeated assessments, and to describe clinical characteristics of patients with high variability of pain.

**Methods:** Data were extracted from a prospective cohort study (ActConnect) including patients with clinician-confirmed RA or axSpA owning a smartphone.<sup>1</sup> Baseline characteristics were collected. Over 3 months, weekly self-assessments of pain and patient global assessment of disease activity on 0–10 points numerical rating scales (NRS) were obtained. For each patient, the mean of the inter-assessment differences of NRS (average of absolute change – AAC) of pain and disease activity were calculated. RA and AxSpA patients were compared by t-test. High variability was defined as the upper tercile of AAC. Pearson's correlation was used to evaluate the correlation between variability of pain and of self-reported disease activity. Univariate and multivariate logistic regression compared patients with high vs low variability of pain, without imputation of missing data, on R, including weekly self-reported flare over follow-up.

**Results:** Eighty-six patients with RA and 79 with axSpA were included, mean age was respectively 48.7 (SD 12.7) and 41.7 (SD 10.2) years, mean disease duration was 8 (SD 8.8) and 8.6 (SD 8.6) respectively years, 81% and 44% respectively were female. Mean DAS28 and BASDAI were respectively 2.27 (SD 1.18) and 3.21 (SD 2.06) at baseline; 44% and 62% respectively of patients were receiving a biologic.

Mean levels of pain and patient global assessment of disease activity were non-significantly higher in AxSpA than RA patients (table 1) and variability of pain and disease activity were also higher in AxSpA (table 1). Correlation between AAC of pain and activity was 72% in RA, and 84% in AxSpA. In multivariate analyses, self-reported flares were the only determinant of pain AAC (Odds ratio 2.25 [1.27–4.38] p=0.01 and 3.26 [1.67–6.35] p<0.001 respectively for RA and axSpA).

#### Abstract THU0689 – Table 1

	RA	AxSpA	p value
Baseline pain	2.90 (SD 2.36)	3.40 (SD 2.30)	0.16
AAC of pain	1.02 (SD 0.74)	1.20 (SD 0.70)	0.10
Baseline PGA of disease activity	3.09 (SD 2.27)	3.73 (SD 2.48)	0.08
AAC of PGA of disease activity	0.98 (SD 0.67)	1.22 (SD 0.70)	0.02

**Conclusions:** In this population of overall well-controlled patients, close repeated assessments of pain showed relatively low fluctuations of pain in RA and axSpA (around 1 point on a 0–10 scale). Patients with axSpA reported slightly more pain, self-reported disease activity and fluctuations of these outcomes, than patients with RA. Fluctuations in pain were highly correlated to fluctuations in patient global assessment of disease activity, indicating significant overall between these 2 patient-reported outcomes. Self-reported flares were the main element explaining fluctuations in pain, confirming the validity of self-reported flares.

#### THU0690 RETROSPECTIVE ANALYSIS OF TEMPORAL ARTERY BIOPSY AND ITS IMPACT IN THE MANAGEMENT OF GIANT CELL ARTERITIS

G. Kasavkar, A. sinha. *Rheumatology, HEART OF ENGLAND NHS TRUST, Birmingham, UK*

**Background:** Prevalence of Giant cell arteritis (GCA) as per primary care data is 17/10000 for patients >55 years of age<sup>1</sup>. British society of rheumatology (BSR) guidelines recommend that suspected cases of GCA should be started on treatment with high dose corticosteroids immediately and then referred for temporal artery biopsy<sup>2</sup>. Temporal artery biopsy has diagnostic yield around 13%<sup>3</sup>. We have done a retrospective analysis of patients who had temporal artery biopsy in order to assess the compliance with BSR guidelines and assess the diagnostic yield.

**Objectives:** To assess the yield of temporal artery biopsy and its impact in the management of Giant cell arteritis

**Methods:** The medical records of patients who had temporal artery biopsy from September 2015 to August 2017 were retrospectively reviewed. We documented demographics, management pre and post biopsy, and timeframes between referral, treatment and biopsy. Data was searched through the clinic letters, referral letters and pathology results.

**Results:** Total number of patients identified was 45. Among them 23 (51%) patients had typical clinical features of GCA and 21 (49%) had atypical features as per the referral letter. Age distribution found was as following: 50 years and below-3; 51 to 60 years-7; 61 to 70 years-15; 71 to 80 years-12; 81 to 90 years-7 and above 90 years-1. Timeframe between biopsy referral and biopsy was as following: within 1 week-27; between 1–2 weeks-10; between 2–3 weeks-6 and more than 3 weeks-1. Ophthalmologists performed biopsy for 37 patient and vascular surgeons for 8 patients. Referral was made by primary care for 7 patients, acute medicine for 12 patients, neurology for 3 patients and by rheumatologist for 23 patients. Treatment was initiated in 37 (82%) patients prior to biopsy. Biopsy was positive in 11 (25%) patients, negative in 30 (66%) patients and 4 (8%) showed healed inflammatory changes (HIC). Age distribution of biopsy positive patients was as following - age 61 to 70 years - 4; age 71 to 80 years - 4; age 81 to 90 years - 3. Out of the 11 biopsy positive patients 7 were started on treatment prior to the biopsy and remaining 4 were initiated on treatment after the results. The distribution of duration of treatment before biopsy was as following - within 1 week - 2; between 1 to 2 weeks - 3; between 2 to 3 weeks - 2.

**Conclusions:** - Majority of the patients (80%) had temporal artery biopsy done within 2 weeks of referral

- Diagnostic yield of temporal artery biopsy was found nearly twice the existing data

- Biopsy was positive in the age group between 61 to 90 years
- Positive biopsy was seen up to 3 weeks of treatment with high dose corticosteroids
- Duration of treatment pre biopsy and age group appear to impact the diagnostic yield of temporal artery biopsy.

THU0691

### ASSOCIATION BETWEEN PERIODONTITIS AND CLINICAL RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS UNDER BIOLOGICAL TREATMENT

H.-H. Chen<sup>1,1,1</sup>, D.-Y. Chen<sup>2</sup>, L.-G. Huang<sup>3</sup>. <sup>1</sup>Department of Medical Research; <sup>2</sup>Department of Internal Medicine; <sup>3</sup>Department of Stomatology, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

**Background:** Previous studies showed that periodontitis (PD) was a propagation factor for the severity of rheumatoid arthritis (RA) and our previous epidemiological study revealed that PD was associated with discontinuation risk of etanercept.

**Objectives:** To investigate the association between PD and the risk of 3 month clinical non-response using the Disease Activity Score (DAS)-based European League Against Rheumatism (EULAR) response criteria in RA patients under biological therapy.

**Methods:** We enrolled 111 RA patients treated with biologics, including etanercept (n=16), adalimumab (n=44), golimumab (n=7), tocilizumab (n=23), abatacept (n=14), and rituximab (n=7). A qualified periodontist performed the periodontal assessment, and the 3 month clinical response was determined DAS-based EULAR response criteria. We quantified the association between PD and the risk of non-response by calculating odds ratios (ORs) with 95% confidence intervals (CIs) using the logistic regression analysis, after adjusting for confounders including age, sex, tobacco use, RA disease duration, biologic treatment duration, rheumatoid factor and anti-citrullinated peptide antibody, erythrocyte sedimentation rate and C-reactive protein, concurrent medication, and diabetes.

**Results:** Of 111 RA patients, 83 (74.8%) had PD. 37 (44.6%) of PD patients received periodontal treatment within three months. After adjusting for potential confounders, PD patients had a higher risk of non-response to treatment than non-PD patients (OR, 4.20; 95% CI, 1.06–16.68; p=0.041). Compared with non-PD patients, the risk of non-response was significantly greater in PD patients who did not receive periodontal therapy (OR, 5.12; 95% CI, 1.16–22.56; p=0.031), but not in PD patients who received periodontal therapy (OR, 3.28; 95% CI, 0.72–15.06; p=0.126). Among those who were under tumour necrosis factor inhibitor therapy (n=67), the risk of clinical non-response was markedly higher in those with PD (OR, 9.65; 95% CI, 1.33–70.04; p=0.025), particularly in those who did not receive periodontal therapy (OR, 14.39; 95% CI, 1.59–130.38; p=0.018).

Significant predictor of 3 month non-response	Univariable analysis OR (95% CI)	Multivariable	
		Model A OR (95% CI)	Model B OR (95% CI)
Periodontitis			
No	Reference:	Reference:	Reference:
Yes	1.39 (0.56–3.45)	4.20 (1.06–16.68)	
Not treated	1.77 (0.66–4.74)		5.12 (1.16–22.56)
Treated	1.01 (0.36–2.90)		3.28 (0.72–15.06)
RA duration, incremental year	1.03 (1.00–1.06)	1.13 (1.04–1.24)	1.13 (1.03–1.23)
Baseline DAS28	1.00 (0.86–1.15)	1.64 (0.99–2.73)	1.69 (1.01–2.82)
Baseline ESR	1.06 (1.02–1.09)	1.06 (1.004–1.11)	1.06 (1.003–1.11)

**Conclusions:** In RA patients under biological therapy, an increased risk of clinical non-response to treatment was observed in patients with PD, especially among those who did not receive periodontal treatment.

THU0692

### RISK OF END-STAGE RENAL DISEASE REQUIRING DIALYSIS IN ANKYLOSING SPONDYLITIS PATIENTS STARTING MEDICAL THERAPY: A NATIONWIDE, POPULATION-BASED, COHORT STUDY

H.-H. Chen<sup>1,1,1</sup>, D.-Y. Chen<sup>2</sup>, T.-Y. Hsieh<sup>3</sup>, K.-L. Lai<sup>3</sup>, Y.-M. Chen<sup>1</sup>, C.-W. Tseng<sup>3</sup>, C.-T. Lin<sup>3</sup>. <sup>1</sup>Department of Medical Research; <sup>2</sup>Department of Internal Medicine; <sup>3</sup>Division of Allergy, Immunology and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

**Background:** From the year 2000 Taiwan has had the highest incidence and prevalence of end-stage renal disease (ESRD) among the regions investigated by the US Renal Data System. Also, previous studies had suggested a possible association between IgA nephropathy and ankylosing spondylitis (AS) because an increased prevalence of microscopic hematuria and a higher proportion of elevated serum IgA levels were found in AS patients. However, whether the risk of ESRD was increased in treated AS patients or not is still unknown.

**Objectives:** To examine the risk of ESRD requiring dialysis in patients with AS who started medical therapy.

**Methods:** Using 2003–2012 claims data from the Taiwanese National Health Insurance Research Database, we identified 38,259 AS patients who received at least 3 courses of AS-related medical therapy (i.e., non-steroidal anti-inflammatory drugs, methotrexate, salazopyrine or corticosteroid) and started therapy from 2005 to 2012. The first date of medical therapy was defined as the index date. After excluding those who had a history of chronic renal disease (ICD9-CM 585, 586) or receiving dialysis before the index date, we identified 37 070 newly-treated AS cases. We randomly selected 3 70 700 non-AS individuals matching (1:10) AS cases for age, sex and the year of the index date without a history of chronic renal failure or dialysis before the index date. After adjusting for age, sex, moderate to severe renal disease, diabetes mellitus, hypertension, and annual cumulative defined daily dose (cDDDs) of traditional non-steroidal anti-inflammatory drugs (NSAIDs), selective cyclooxygenase-2 inhibitors (COX2i), and preferential COX2i, we calculated the adjusted hazard ratios (aHRs) with 95% confidence intervals (CIs) using the Cox proportional hazard model to quantify the risk of ESRD in AS patients compared with non-AS controls. We re-selected 6,621 AS patients and 6621 non-AS subjects by further matching (1:1) for cDDDs of three groups of NSAIDs to re-estimate the aHRs for ESRD.

**Results:** 51 (0.14%) of 37,070 AS patients and 1,17 (0.38%) of non-AS individuals developed ESRD after a follow-up of 1 58 846 and 1,707,757 person-years respectively. The aHR for ESRD was 0.4 (0.30–0.54) in AS patients compared with non-AS individuals. However, after further matching for cDDDs of NSAIDs, the aHR of ESRD was 0.80 (0.34–1.86). Significant risk factors included diabetes mellitus, hypertension, renal disease, and use of COX2i.

**Conclusions:** The risk of ESRD was not significantly different between treated AS patients and age, sex, index date, and NSAIDs use matched non-AS individuals.

**THU0693 GOUT AND THE RISK OF PARKINSON'S DISEASE IN THE ELDERLY**

J.A. Singh, J.D. Cleveland. *University of Alabama at Birmingham, Birmingham, USA*

**Background:** A recent systematic review and meta-analysis, based on two cohort studies and three case-control studies, reported a pooled risk ratio of subsequent Parkinson's disease (PD) in patients with gout was 0.93 (95% CI, 0.79 to 1.09), a non-significant result. However, statistical heterogeneity was high at 87%–96%, indicating that studies differed from each other. Thus, it is not clear that gout is associated with PD and if so, what is the direction and magnitude of the risk of PD with gout.

**Objectives:** To assess the association of gout with the risk of incident Parkinson's disease.

**Methods:** We used the 5% Medicare sample from 2006–2012 to assess whether a diagnosis of gout was associated with the risk of incident Parkinson's disease in the elderly. Multivariable Cox regression model adjusted for demographics, Charlson-Romano comorbidity index, common medications, allopurinol and febuxostat use, was used to obtain hazard ratios (HR) and 95% confidence interval (CI).

**Results:** The mean cohort age was 73 years (standard deviation [SD], 6.5), mean Charlson-Romano comorbidity index score was 1.2 (SD, 1.9), 58% were female, 86% were White and 30% had Charlson-Romano comorbidity index score of  $\geq 2$  (n=15,675). The crude incidence rates of incident PD of 3.3 vs. 1.7 per 1000 person-years in those with gout vs. without gout. Gout was associated with a higher risk of PD in the main analysis, 1.18 (95% CI, 1.10, 1.27). Older age, male gender, White race, higher Charlson-Romano comorbidity index score were associated with higher risk of PD. Sensitivity analyses confirmed main findings. No gender or race differences were noted, but the risk differed by the age: ages 65–<75, 75–<85 and  $\geq 85$  years were associated with hazard ratios of incident PD with gout of 1.27, 1.12 and 0.98, respectively.

**Conclusions:** Gout was associated with a higher risk of incident PD in the elderly. The risk of PD with gout was highest in the age group 65–75 years. Mechanisms of this increased risk need to be evaluated in future studies.

**THU0694 THE EXCESS RISK OF DISABILITY IN PEOPLE WITH NEUROPATHIC PAIN WHEN COMPARED TO THOSE WITH NOCICEPTIVE PAIN IS EXPLAINED BY PAIN CATASTROPHISING AND PHYSICAL INACTIVITY**

J. Mcbeth<sup>1</sup>, M. Mulvey<sup>2</sup>, J. Anderson<sup>1</sup>, A. Rashid<sup>1</sup>, K. Druce<sup>1</sup>. <sup>1</sup>*Arthritis Research UK Centre for Epidemiology, The University of Manchester, Manchester*, <sup>2</sup>*Leeds University, Leeds, UK*

**Background:** Neuropathic pain (NP) is associated with worse patient outcomes including poorer quality of life and increased disability and mortality when compared to persons with pain that is predominantly nociceptive (NCP). It is not known if the higher rate of co-morbid psychosocial factors (e.g. depression, fatigue) in persons with NP explains the increased risk of poor outcomes.

**Objectives:** To test the hypotheses that pain predominantly of NP origin would be associated with higher levels of disability when compared to NCP, and the excess risk would be independent of putative confounders.

**Methods:** 1587 participants in a population based prospective study completed a baseline and follow up questionnaire 12 months later. Participants were asked about the presence, location and duration of musculoskeletal pain and they completed the Douleur Neuropathique 4 (scores  $\geq 3$  indicating NP). Participants were classified according to their pain reports as having no pain (NP), some pain with (SPn) and without (SP) NP, and chronic widespread pain American College of Rheumatology 1990 criteria) with (CWPn) and without (CWP) NP. The primary outcome was the Stanford Health Assessment Questionnaire (HAQ) from which

the Standard Disability Index (HAQ-DI) was calculated. Participants also completed the Hospital Anxiety and Depression Scale (HADS), Chalder Fatigue scale (CF); the Pain Catastrophising Scale (PCS); Rapid Assessment of Physical Activity (RAPA); Social Support scale (SS); Joint Hypermobility scale (JH); Jenkins Sleep Scale (JSS). Ordered logistic regression tested the relationship between pain status at baseline and HAQ-DI at follow up with results expressed as odds ratios (OR) with 95% confidence intervals (CI).

**Results:** 1235 (77%) participants provided complete data and formed the cohort for this analysis. At 12 month follow up the mean (standard deviation) HAQ-DI score was 0.31 (0.62), with higher scores in women and older participants. After adjusting for age and sex, when compared to those with NP at baseline participants with SP were 3 times (OR=2.9, 95% CI (2.2, 3.9)) and those with SPn almost 9 times (8.7 (5.4, 14.0)) more likely to have higher HAQ-DI scores at follow up. Those with CWP were 8 (7.8 (5.7, 10.8)) and those with CWPn 38 (38.1 (23.3, 62.5)) times more likely to have higher HAQ-DI scores. When these associations were adjusted for putative confounders and baseline HAQ-DI scores having pain remained associated with increased HAQ-DI scores at follow up although the relationships were significantly attenuated, and the 95% CIs were similar across pain groups: SP 1.8 (1.3, 2.5); SPn 2.6 (1.4, 4.8); CWP 2.3 (1.6, 3.4); 3.3 (1.9, 6.0). The PCS helplessness scale (1.07 (1.01, 1.13)) and RAPA (0.93 (0.87, 0.99)) were significantly associated with 12 month HAQ-DI scores.

**Conclusions:** The increased risk of disability in persons with NP was not independent of common pain co-morbidities. Screening and targeting treatment for pain-related helplessness and physical inactivity has the potential to significantly improve disability outcomes for persons with NP.

**Disclosure of Interest:** None declared

**THU0695 DOES HORMONE REPLACEMENT THERAPY PREVENT UNDIFFERENTIATED ARTHRITIS PROGRESSING TO RHEUMATOID ARTHRITIS**

K. Miyachi<sup>1,2</sup>, A. Ihara<sup>3</sup>, B. Sasse<sup>4</sup>. <sup>1</sup>*Rheumatology and Women's Health, Keigu Clinic*; <sup>2</sup>*The Technological Development, Health Sciences Research Institute*; <sup>3</sup>*Rheumatology, Keigu Clinic, Yokohama, Japan*; <sup>4</sup>*Rheumatology, Monash Health, Victoria, Australia*

**Background:** Oral contraceptive (OC) and hormone replacement therapy (HRT) have been reported to have a protective and preventive effect on the progression of rheumatoid arthritis (RA). Although these observations are controversial, progression of undifferentiated arthritis (UA) to RA in pre- and post-menopausal women is largely unreported.

**Objectives:** Over a 10 year period, we followed patients with undifferentiated arthritis (UA) who were referred to rheumatologists and did not fulfil classification or diagnostic criteria for RA or other connective tissue disease. We studied the efficacy of hormone replacement therapy (HRT) in this setting. In this study, the primary objective was to determine whether HRT reduces joint pain and/or decreased the progression of UA to RA.

**Methods:** From 2007 to 2016, 1076 patients (male:60, female:1016) classified as UA were referred to one of two clinics because of complaints of joint pains and were enrolled in this study. Beginning in 2012, premenstrual, perimenstrual and postmenstrual women with UA were prescribed ultra-low dose tocopherol (600 mg/day) and HRT. A reduction of over 70% joint pain on a p-visual analogue scale (p-VAS) was set as the criterion of a favourable outcome. Each patient was assigned into one primary disease category. For example, primary SjS was regarded as a disease category but if a patient had secondary SjS, they were assigned to the primary (RA, SLE, SSc) disease category.

**Results:** During the 5 year observation period, 213/343 (62.1%) had postmenopausal arthralgia (PoMA), 46/112 (41.1%) with perimenopausal arthralgia (PeMA), 17/25 (68%) with premenopausal arthralgia (PrMA). In the RA patients, 10.2% had RF alone, 73.1% (250/342) had ACPA and/RF or ACPA alone and 16.7% had neither ACPA or RF. The specificity of ACPA was 93.2%. Regarding efficacy of HRT, the incidence of RA in RF positive individuals was 9.1% (5/55) in patients undergoing HRT (current and past user), which was significantly lower ( $p < 0.01$ ) than the 48.4% (30/62) in those never treated with HRT. Likely due to low numbers in the cohort, the incidence of RA in ACPA positive females was 22.2% (2/9) in those receiving HRT was not statistically significantly lower than the 70% (7/10) in those with without HRT.

Figure 1 Postmenopausal women responded to conventional HRT in 2013–2015

**Conclusions:** The progression of UA to RA is apparently ameliorated in RF positive females who received conventional HRT and oral E3 treatment. Although the numbers were smaller, a significant protective effect was not observed in ACPA positive UA females, because they developed RA before menopause. Our observations suggest that HRT in peri- and post-menopausal and oestrogen (E3) in pre-menopausal females with RF and ACPA positive UA may be important in ameliorating the progression of UA to RA.

#### THU0696 IS AUTOIMMUNITY RELATED TO NAILFOLD VIDEOCAPILLAROSCOPY PATTERNS PROGRESSION? DATA FROM A TERTIARY CENTRE

L. Torrens, C. Soletto, J.C. Nieto-González, on behalf of Dra. Alicia Silva, Dra Ana López-Cerón; Dr. Juan G. Ovalles-Bonilla, Dra. Iustina Janta, Dra. Claudia Sáenz, Dr. Carlos M. González, Dr. Indalecio Monteagudo. *Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain*

**Background:** Nailfold videocapillaroscopy (NVC) is a non-invasive technique that allows to evaluate the structure and distribution of capillaries in the nail microcirculation.

**Objectives:** Our objective was to investigate the relation between the autoantibodies (Ab) detected in the patients who undergo follow-up NVCs and the progression from lower to higher severity of the NVCs patterns.

**Methods:** Longitudinal, observational and descriptive study that includes patients with at least two NVCs, between June 2012 and December 2016 in the Rheumatology service of a tertiary centre. We collected demographics data, number of NVCs performed, Ab positivity, as well as the NVCs patterns. The relationship between the basal autoimmunity and the progression of the NVCs patterns during the follow-up period, defining progression from non-specific patterns to patterns of scleroderma to late scleroderma.

**Results:** 473 patients were included, 115 had two or more NVCs performed, 104 women (90.51%). Of these, 40 (34.78%) had a third NVC, 9 (7.82%) a fourth and only two patients a fifth. Regarding the Ab registered in patients before the first NVC, 27 patients did not present positivity to any Ab (23.47%), 28 had isolated ANA + (24.34%), 33 Anticentromere+with or without ANA (28.69%), 7 patients Anti-scl70 +with or without ANA (6.08%), 10 patients Anti-Ro or Anti-La with or without ANA (8.69) and 10 patients presented other types of antibodies than those mentioned (11.3%). The most frequent pattern in the first NVC was non-specific mild alterations (49 cases) in 42.6%, followed by normal pattern<sup>20</sup> in 17.39%, early scleroderma<sup>19</sup> in 16.52%, non-specific moderate lesions<sup>17</sup> and pattern of late scleroderma<sup>10</sup>. There was a progression from lower to higher severity in 25 NVCs,

88 maintained a similar pattern and 2 NVCs presented significant regression (table 2).

**Abstract THU0696 – Table 1.** Baseline diagnosis before first NVC.

Baseline diagnosis	n:	%
	<b>115</b>	
Primary Raynaud Phenomenom	56	48.27
Systemic scleroderma	27	23.27
Systemic Lupus Erythematosus	8	6.89
Undifferentiated connective tissue	8	6.89
Mixed Connective Tissue	4	4.31
Diseasee		
Dermatomyositis	2	1.72
Others	10	8.62

**Abstract THU0696 – Table 2.** Patients whose NVC progresses, patterns and related autoantibodies.

n:25 (%)	Autoantibodies	Progression
2 (8%)	Ninguno	1/2: NMI to ES, 1/2: NML to LS
4 (16%)	ANA+	2/4: NMI to AS, 1/4: NML to AS, 1/4: NMI to ES
10 (40%)	ANA ±Anticentrómero	3/10: AS to LS, 3/10: ES to LS, 2/10: NML to ES, 1/10: NMI to ES, 1/10: NMI to AS
3 (12%)	ANA±AntiScl70 +	1/3: NML to AS, 1/3: AS to LS, 1/3: ES to AS
3 (12%)	ANA±Anti-Ro/ Anti-La+	2/3: NML to ES, 1/3: ES to LS
3 (12%)	Otros	2/3: ES to LS, 1/3: NMI to LS

**NVC patterns:** Normal (N), non-specific mild alterations (NMI), non-specific moderate lesions (NML), Early scleroderma (ES), Active scleroderma (AS) y Late scleroderma (LS)

**Conclusions:** Autoimmunity does not seem to influence on the degree of progression of NVCs patterns. The association between positive ANA with anticentrome + or not, it is the most frequently combination related to the progression of such patterns.

#### THU0697 RISK OF MAJOR CONGENITAL MALFORMATIONS ASSOCIATED WITH EXPOSURE TO CONVENTIONAL SYNTHETIC DISEASE MODIFYING ANTIRHEUMATIC DRUGS IN WOMEN WITH INFLAMMATORY ARTHRITIS: A POPULATION-BASED COHORT STUDY

M.A. De Vera<sup>1,2</sup>, E.C. Sayre<sup>2</sup>, N.W. Tsao<sup>1,2</sup>, A. Howren<sup>1</sup>. <sup>1</sup>Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver; <sup>2</sup>Arthritis Research Canada, Richmond, Canada

**Background:** Prior studies of perinatal exposure to conventional synthetic disease modifying antirheumatic drugs (csDMARDs) and risk of major congenital malformations (MCM) have often lacked comparator groups and specific timing of medication exposure.

**Objectives:** To evaluate the association between csDMARD use before and during pregnancy and risk of MCM.

**Methods:** We conducted a population-based, retrospective cohort study using British Columbia administrative data from 01/01/2002 and 12/31/2012 on all physician visits, hospital admissions, and dispensed medications, linked to a perinatal registry with valid information on date of conception. We created a pregnancy cohort of women with inflammatory arthritis (IA) using a case definition of 2 ICD9 codes  $\geq 2$  months and  $\leq 2$  years apart for rheumatoid arthritis, systemic autoimmune rheumatic diseases, ankylosing spondylitis, juvenile idiopathic arthritis, and psoriatic arthritis. We categorised csDMARDs according to accepted safety profiles: Group 1 - antimalarials, cyclosporine-A, gold, and sulfasalazine; and Group 2 - methotrexate, leflunomide, cyclophosphamide, azathioprine, chlorambucil, penicillamine, mycophenolate mofetil, and minocycline. We defined exposure over two periods: binary use (yes/no) during the 90 days preconception and first trimester of pregnancy. The outcome was occurrence of  $\geq 1$  MCM identified

at birth. We used logistic regression models fitted with generalised estimating equations.

**Results:** There were 598 pregnancies in 503 women (32±5 years), and 5651 pregnancies in 4086 women (31±5 years) in the csDMARDs exposed and unexposed groups, respectively. The adjusted odds ratio (OR) for exposure to csDMARDs preconception and during pregnancy and risk of MCM was 1.60 (95% CI, 1.19, 2.14) (table 1). In subgroup analyses, risk of MCM births was highest in those exposed to Group 2 csDMARDs during pregnancy (OR 3.63, 95% CI, 1.21, 10.92). For methotrexate specifically, we observed an OR of 1.62 (95% CI, 0.53, 4.91).

**Abstract THU0697 – Table 1.** Association of csDMARD exposure preconception and/or during pregnancy and risk of MCM

Models*	Exposure period	OR	95% Confidence Interval
Model 1	Preconception only vs. unexposed	1.37	0.84–2.24
All csDMARDs	During pregnancy only vs. unexposed	2.39	1.20–4.77
	Preconception AND during pregnancy vs. unexposed	1.60	1.19–2.14
Model 2	Preconception only vs. unexposed	1.04	0.55–1.99
Group 1 csDMARDs	During pregnancy only vs. unexposed	2.16	1.02–4.61
	Preconception AND during pregnancy vs. unexposed	1.49	1.09–2.05
Model 3	Preconception only vs. unexposed	1.43	0.73–2.77
Group 2 csDMARDs	During pregnancy only vs. unexposed	3.63	1.21–10.92
	Preconception AND during pregnancy vs. unexposed	1.71	1.06–2.76
Model 4	Preconception only vs. unexposed	1.19	0.49–2.87
Methotrexate only	During pregnancy only vs. unexposed	3.06	0.55–16.90
	Preconception AND during pregnancy vs. unexposed	1.62	0.53–4.91

\*All models were adjusted for baseline covariates including maternal characteristics, obstetrical history, comorbidities, and medication use before/during pregnancy.

**Conclusions:** We found associations with exposure to csDMARDs before and during pregnancy, namely the first trimester, with MCMs. These have implications for informing women with IA who are pregnant or planning to become pregnant.

**Disclosure of Interest:** None declared

#### THU0698 CLINICAL OUTCOME OF ULTRASONOGRAPHIC DETECTED UNDIFFERENTIATED SYNOVITIS IN PATIENTS WITH POLYARTHRALGIA

M. Mortada, F.I. Abdelrahman, S. Alyan. *Rheumatology, Faculty Of Medicine Zagazig University, Zagazig, Egypt*

**Background:** Ultrasonography (US) has better sensitivity than clinical evaluation for the detection of synovitis in early inflammatory arthritis. The clinical importance and fate of undifferentiated synovitis in patients with polyarthralgia are still unknown.<sup>1</sup>

**Objectives:** To identify clinical outcome of undifferentiated synovitis detected by ultrasound in patients with polyarthralgia and to identify variables that can predict differentiation into specific type of arthritis.

**Methods:** New patients with polyarthralgia and undifferentiated synovitis were followed by clinical and ultrasound examination in the period between June 2015 to June 2017. Undifferentiated synovitis was defined as ultrasound detected synovial hypertrophy in cases in which no definitive diagnosis can be made.

Baseline assessments included: clinical examinations of complaining joints, laboratory investigations (CBC, ESR, CRP, RF, ACPA, ANA) and ultrasonographic evaluation of fifty joints (DIPs, PIPs, MCPs, wrists, elbows, shoulders, hips, knees, ankles and MTPs)

Follow ups were every 6–8 weeks until remission of synovitis or a definite clinical diagnosis was reached. Remission was defined as absence of a previously US detected synovitis in two consecutive follow-ups eight weeks apart.

Patients were received treatment according to the opinion of the treated rheumatologist who had a full data about clinical, laboratory and ultrasonographic data. Multivariate logistic regression analysis was used to identify predictors of remission, RA, PsA and continuation as undifferentiated synovitis.

**Results:** 174 patients (88.6% women, mean age 43.2±14.2 years (range 17–75)) were included.

Duration of follow up period ranged from 3 to 38 months (mean 11.4 months)

Final diagnoses were as follow; complete remission in 73 (41.7%) cases, rheumatoid arthritis (RA) in 20 cases (11.4%), psoriatic arthritis (PsA) in 10 cases (5.7%), spondyloarthropathy (SPA) in 11 cases (6.1%), sarcoidosis in 4 cases (2.3%), osteoarthritis (OA) in 10 cases (5.7%) and 46 cases (26.4%) continued as undifferentiated synovitis up to the end of the follow up period.

Remission of undifferentiated synovitis was associated with significantly older mean age, acute onset and absence of PD activity (OR 1.92, 1.95 and 1.86 respectively).

Development of RA was associated with chronic onset, positive rheumatoid factor, positive ACPA and US detected synovitis in more than three joints (OR 1.91, 1.75, 1.92 and 1.79 respectively). All patients with final diagnosis of RA had US detected synovitis in wrist joint with increased PD activity. PsA was associated with chronic onset, PD activity, bilateral knee synovitis, negative RF and ACPA (OR 1.84, 1.83, 1.94, 1.88 and 1.79 respectively). Cases with significantly younger mean age and shorter disease duration completed with undifferentiated synovitis (OR 1.92 and 1.87).

**Conclusions:** In our study, more than half of cases of ultrasound detected undifferentiated synovitis in patients with polyarthralgia differentiated into specific type of arthritis during the follow up period. older age and acute onset of symptoms are associated with remission while positive rheumatoid factor, positive ACPA, US detected synovitis in more than 3 joints including wrist joints are associated with development of RA. Bilateral knee synovitis are in favour of PsA and OA.

#### THU0699 PREDICTORS OF FRACTURE AND LOW BONE MINERAL DENSITY IN PATIENTS WITH HISTORY OF PARENTAL FRACTURE

M. Dey, M. Bukhari. *Rheumatology, University Hospitals of Morecambe Bay NHS Foundation Trust, Lancaster, UK*

**Background:** Predictors of fragility fracture (FF) risk and low bone mineral density (BMD) in the general population are well-documented. Previous studies have shown strong familial association between parental and offspring BMD and hip fracture, varying according to factors including body mass index and corticosteroids. Little data exists on predictors of FF and BMD in patients with a family history of fracture, despite this increasing fracture risk.

**Objectives:** We aimed to evaluate predictors of FF and low BMD in patients attending for dual energy X-ray absorptiometry scanning.

**Methods:** Patients referred for BMD estimation, between 2004 and 2016, with a history of parental fracture, were included. Parameters recorded: femoral and vertebral BMD, height, weight, fat mass, age, smoking, alcohol, corticosteroids, aromatase inhibitors, Depo-Provera, hormone replacement therapy (HRT), rheumatoid arthritis (RA), polymyalgia rheumatica (PMR), breast or prostate cancer, and coeliac disease.

Logistic regression was used to model fracture risk, and linear regression was used to model the impact of each factor on vertebral and femoral BMD.

**Results:** 6053 patients (5513 female) were included. 2094 patients (34.6%) had sustained at least one fracture. Smoking, alcoholism, corticosteroid, increased age, height, and fat mass significantly increased fracture risk. Coeliac disease, HRT, and aromatase inhibitors were protective. Cancer, aromatase inhibitor use, and female gender significantly decreased vertebral BMD. Corticosteroids, RA, and PMR significantly decreased L1–2 BMD. Increased age and height, and decreased weight, fat mass, and tissue thickness decreased vertebral and right femoral BMD; this significantly increased FF risk. Corticosteroids, RA, PMR, Depo-Provera, female gender, and aromatase inhibitors decreased BMD; in the left femur, alcohol, corticosteroid use, increased age, height, and decreased weight decreased BMD.

**Conclusions:** Similar to studies in the general population, smoking, alcohol, and corticosteroid therapy increase fracture risk, while HRT decreases it. Chronic aromatase inhibitor use increases fracture risk, suggesting a dose-dependent effect. Coeliac disease was found to be protective; previous studies have shown coeliac disease to decrease BMD, with a variable impact on fracture. Concurrent with previous studies, a differential effect of BMD in the dominant and non-dominant hip was found, with decreased right femoral BMD significant for fracture risk. Limitations of this study include lack of dose and duration of medications and lack of comparative data before and after fracture in a single patient.

Our study confirms the effect of the above factors on spinal BMD, but suggests a differential effect of smoking and alcohol on L1–2, with corticosteroids, RA and PMR affecting the lower lumbar spine. Our results also suggests a differential effect of the studied factors on the right femur compared to the left, suggesting the dominant femur is more susceptible to factors decreasing BMD. Limitations of this study include the large proportion of female subjects and lack of data on dose and duration of medications studied.

THU0700

### PERINATAL EXPOSURE TO DISEASE MODIFYING ANTIRHEUMATIC DRUGS IN WOMEN WITH INFLAMMATORY ARTHRITIS AND THE RISK OF SMALL-FOR-GESTATIONAL-AGE NEWBORNS: A POPULATION-BASED COHORT STUDY

N.W. Tsao<sup>1,2</sup>, E.C. Sayre<sup>2</sup>, A. Howren<sup>1</sup>, M.A. De Vera<sup>1,2</sup>. <sup>1</sup>Faculty of Pharmaceutical Sciences, University of British Columbia, Vancouver, <sup>2</sup>Arthritis Research Canada, Richmond, Canada

**Background:** Currently there exists limited data on pregnancy outcomes among women with inflammatory arthritis (IA) using conventional synthetic DMARDs (csDMARDs), and the risk of small-for-gestational-age (SGA) births.

**Objectives:** To investigate the association between csDMARD use before and during pregnancy and SGA births.

**Methods:** We linked population-based health data in British Columbia, Canada over a 10 year study period (01/01/2002 – 12/31/2012) on all physician visits, hospital admissions, and dispensed medications with a perinatal registry containing valid information on date of conception. We created a pregnancy cohort of women with IA using a case definition of 2 outpatient physician ICD9 codes  $\geq 2$  months and  $\leq 2$  years apart for rheumatoid arthritis, systemic autoimmune rheumatic diseases, ankylosing spondylitis, juvenile idiopathic arthritis, and psoriatic arthritis. We categorised csDMARDs according to accepted safety profiles - antimalarials, cyclosporine-A, gold, and sulfasalazine (Group 1); and methotrexate, leflunomide, azathioprine, cyclophosphamide, chlorambucil, penicillamine, mycophenolate mofetil, and minocycline (Group 2). We determined exposure as binary use (yes/no) during the 90 days preconception; and during pregnancy from date of conception until date of delivery. The SGA outcome was defined as  $< 10$  th percentile of sex- and gestational-age specific weights for singleton births or with ICD9/10 codes. We used logistic regression models fitted with generalised estimating equations and adjusted for baseline covariates.

**Results:** There were 611 pregnancies in 513 women ( $32 \pm 5$  years), and 5638 pregnancies in 4077 women ( $31 \pm 5$  years) in the csDMARDs exposed and unexposed groups, respectively. We identified 13%, 18%, and 42% of newborns as SGA in unexposed pregnancies and exposed to Group 1 and 2 csDMARDs, respectively. The adjusted odds ratio (OR) for exposure to Group 1 csDMARDs preconception and during pregnancy and risk of SGA births was 1.49 (95%CI 1.12, 1.97) (table 1). The risk of SGA births was higher in those exposed to Group 2 csDMARDs (OR 1.78, 95% CI 1.14, 2.78). With respect to specific csDMARDs, we observed an OR of 1.25 (95% CI, 0.41, 3.82) for methotrexate.

**Abstract THU0700 – Table 1.** Association of csDMARD exposure preconception and/or during pregnancy and risk of SGA births

Models*	Exposure period	OR	95% Confidence Interval
Model 1	Preconception only vs. unexposed	0.79	0.42–1.50
Group 1	During pregnancy only vs. unexposed	1.57	0.83–2.99
csDMARDs	Preconception AND during pregnancy vs. unexposed	1.49	1.12–1.97
Model 2	Preconception only vs. unexposed	0.85	0.42–1.72
Group 2	During pregnancy only vs. unexposed	2.65	0.95–7.37
csDMARDs	Preconception AND during pregnancy vs. unexposed	1.78	1.14–2.78
Model 3	Preconception only vs. unexposed	0.77	0.31–1.88
Methotrexate	During pregnancy only vs. unexposed	2.24	0.48–10.48
	Preconception AND during pregnancy vs. unexposed	1.25	0.41–3.82

\*All models were adjusted for baseline covariates including maternal characteristics, obstetrical history, comorbidities, and medication use before/during pregnancy.

**Conclusions:** Our findings suggesting a risk of SGA births with exposure to csDMARDs preconception and during pregnancy have implications for informing women with inflammatory arthritis who are pregnant or planning to become pregnant.

THU0701

### UPDATED INCIDENCE AND COSTS OF HIP FRACTURES IN ELDERLY ITALIAN POPULATION

P. Piscitelli<sup>1</sup>, M. Feola<sup>2</sup>, C. Neglia<sup>1</sup>, C. Rao<sup>1</sup>, E. Rizzo<sup>1</sup>, U. Tarantino<sup>2</sup>. <sup>1</sup>Euro Mediterranean Scientific Biomedical Institute – ISBEM Research Centre, Mesagne; <sup>2</sup>Division of Orthopaedics and Traumatology, University of Tor Vergata, Rome, Italy

**Background:** It had already been evaluated the hospitalisation rate of femoral neck fractures in the elderly Italian population over ten years, showing that incidence of hip fractures in Italy are continuously increasing, although women aged 65–74 years old started showing a decreasing trend.

**Objectives:** To update our previous researches about the burden of hip fractures in elderly Italian population.

**Methods:** We analysed national hospitalizations records from 2007 to 2014 to compute age- and sex-specific standardised rates.

**Results:** 7 41 633 hospitalizations were observed in people  $\geq 65$  (women: 568,203; men: 173,430), with an overall increase of 5.50% over the 8 year period (females:+3.36; males:+12.9%). About 43.75% of total hip fractures were suffered by patients aged  $\geq 85$  years old. Women aged  $\geq 85$  accounted for 34.49% ( $n=255,763$ ) of total fractures. The incidence rate per 10 000 inhabitants in people aged 65–74 decreased from 28.65 to 25.31 in women ( $-13.02\%$ ) and from 13.41 to 11.65 in men ( $-13.12\%$ ). Incidence per 10 000 in people 75–84 decreased from 121.6 to 105.2 in women ( $-13.49\%$ ) and from 55.8 to 47.5 in men ( $-14.87\%$ ). Paradoxically, also in people aged  $\geq 85$ , the incidence per 10 000 declined from 300.99 to 268.72 in women ( $-10.72\%$ ) and from 174.59 to 171.17 in men ( $-1.96\%$ ) because the number of subjects aged  $\geq 85$  is growing faster than the number of fractures occurring in this latter age group. Direct hospitalisation costs and rehabilitation costs increased from 433 to 457 million Euros and from 478 to 504 million Euros over the 8 year period, respectively. Overall costs of hip fractures in people aged  $\geq 65$  years old raised from 911 to 961 million Euros from 2007 to 2014.

**Abstract THU0701 – Table 1**

Year	2007	2008	2009	2010	2011	2012	2013	2014
Hospitalizations due to hip fractures (female) (n/1000)	88,801	92,532	93,169	92,549	91,733	92,408	94,116	94,525
Overall hospitalizations due to hip fractures (€)	433,210,977	447,402,694	450,482,661	447,484,891	443,339,438	451,038,253	450,061,513	457,039,074
Overall rehabilitation costs (€)	478,324,281	493,971,382	497,371,926	494,662,138	489,706,016	488,647,810	502,427,386	504,610,782
Overall direct costs estimation (€)	911,535,258	941,374,076	947,854,587	942,147,028	933,045,454	939,686,063	952,488,909	961,649,856

**Conclusions:** The number of hip fractures and related hospitalizations costs in Italian elderly population is still increasing due to the fractures occurring in people  $\geq 85$  years old, although incidence rates are decreasing in all the age groups.

### SECULAR TRENDS OF HIP FRACTURES IN FRANCE BETWEEN 2002 AND 2013: IMPACT OF THE REFERENCE VALUES

R. Garofoli, M. Cohen-Solal, A. Ostertag. *75, Lariboisiere Hospital, Paris, France*

**Background:** Hip fractures are a societal burden because of their high related morbidity and mortality, and the cost they generate. With the ageing of the population, worries grow about an increase of the incidence and incidence rate of hip fracture in the next years. Numerous studies have shown an increase in the incidence whilst a decrease in the incidence rates of hip fracture in the majority of Europe countries and North America. These data come from heterogeneous studies regarding the reference population used, and thus their interpretations remain controversial.

**Objectives:** The aim of our study was to assess the impact of the choice of the reference population in the interpretation of incidence rates data, using country-based data of French population.

**Methods:** We used data related to the hospitalizations for hip fracture in France between 2002 and 2013 in patients over 59 years, extracted from the French National Hospital Database. Data were based on the whole French population and were classified by sex and age (60–74, 75–84, over 84 years, over 59 years). We first calculated the crude incidence rates of hip fracture by dividing the number of hospitalizations for hip fracture by the corresponding populations. To assess the impact of the choice of the reference population, we then calculated the crude and adjusted incidence rates using direct standardisation on age with three different reference populations (2002, 2013, mean population of 2002–2013).

**Results:** Between 2002 and 2013 in France, the incidence of hip fracture raised of 4.8% in women (from 49 287 to 51,661) and 21.8% in men (from 12 716 to 15,482), aged 59 years and over. In the meantime, French population over 59 years increased more with a rise of 21.3% in women and 28.7% in men, which explained a decrease in the crude incidence rates of 13.6% in women and 5.4% in men. However, this decrease was even more obvious after direct standardisation

whatever population of reference was used in women: 24.9%, 25.6% and 26.1% and men 18.2%, 19.2%, 19.8% with respectively 2002, 20013, and 2002–2013 as population of reference.

**Conclusions:** The incidence rates of hip fracture decreased in France between 2002 and 2013 in men and women aged 60 years and over. The decrease is more important after direct standardisation whatever population used as a reference as a results of a difference in age-structure of the population that can be erased by the process of direct standardisation. In conclusion, the incidence of hip fractures continues to grow despite a reduced incidence rate throughout a 12 year-period.

### THU0703 IDENTIFYING CLINICAL, PSYCHOLOGICAL AND WORK RELATED FACTORS ASSOCIATED WITH PRESENTEEISM: THE INTERNATIONAL EULAR-PRO AT-WORK PRODUCTIVITY STUDY

S. Verstappen<sup>1</sup>, D. Laccaille<sup>2</sup>, C. Hoffstetter<sup>3</sup>, S. Talli<sup>4</sup>, G. Saellariou<sup>5</sup>, S. Dadoun<sup>6</sup>, C. Mihai<sup>7</sup>, S. Hagel<sup>8</sup>, A. Bosworth<sup>9</sup>, S. Ramiro<sup>10</sup>, J. Canas da Silva<sup>11</sup>, G. Crepaldei<sup>5</sup>, J. Wallman<sup>9</sup>, S. Leggett<sup>1</sup>, A. Boonen<sup>12</sup>, on behalf of EULAR-PRO Worker productivity group. <sup>1</sup>CMR, University of Manchester, Manchester, UK; <sup>2</sup>ARC, Vancouver; <sup>3</sup>OMERACT, Toronto, Canada; <sup>4</sup>Central Hospital, Tallinn, Estonia; <sup>5</sup>IRCCS, Pavia, Italy; <sup>6</sup>APHP Hospital, Paris, France; <sup>7</sup>IC Hospital, Bucharest, Romania; <sup>8</sup>Lund University, Lund, Sweden; <sup>9</sup>NRAS, Maidenhead, UK; <sup>10</sup>LUMC, Leiden, Netherlands; <sup>11</sup>Garcia Hospital, Almada, Portugal; <sup>12</sup>MUMC, Maastricht, Netherlands

**Background:** Worker productivity loss, including presenteeism, is an important outcome for patients with inflammatory (IA) diseases and osteoarthritis (OA) and is frequently seen as a health outcome in clinical studies. It is important to understand which factors are related with this patient reported outcome in order to inform future work related interventions.

**Objectives:** To assess the association between disease related, psychological and work related factors with presenteeism.

**Methods:** In a large international study evaluating measures of presenteeism we recruited patients with IA and OA from UK, Fr, NL, Es, Se, Ro, It, Pt, and Ca. Absence rates and presenteeism levels (range 0–10=worst score) were measured using the Work Productivity and Activity Impairment (WPAI) questionnaire. Other job related questions were about demands and satisfaction, help from colleagues and opportunities to postpone or organise ones work. Disease related variables included HAQ, EQ-5D, VAS health status. The Hospital Anxiety and Depression Scale (HADS) was also completed. Cross-sectional univariable and multivariable Zinb regression models were applied to assess the association between these disease related, psychological, and work related factors and presenteeism, adjusting for age, gender and country. Due to high co-linearity only HAQ and HAD-anxiety were included in the multivariable model.

**Results:** A total of 544 patients (AS=138, OA=43, PsA=97, RA=266) were recruited with a mean (SD) age of 47<sup>10</sup> yrs and a median symptom duration [IQR] of 10<sup>5–18</sup> yrs; 62% were women. 17% had a manual occupation. 111/544 (20.4%) reported being absent during the previous 7 days. Mean (SD) presenteeism score was 2.9 (2.7). In univariable analyses, worse self-reported disease activity and high levels of depression and anxiety were significantly associated with presenteeism in both the count and inflate part of the model (table 1). Less consistent results were observed for work related factors. In the multivariable model (β, 95% CI), worse functional disability was associated with presenteeism in both the count and excess zero part of the model (0.63; 0.49, 0.78: -2.70, -3.73, -1.66, resp). In addition, higher HAD-anxiety score (-0.09; -0.18; -0.00) was associated with a decreased likelihood of excessive zeros whilst not receiving help from colleagues (1.47; 0.64, 2.30) was associated with an increased likelihood of

excessive zeros. There was a trend towards an association between very demanding jobs (-0.79; -1.63, 0.05) and presenteeism.

**Abstract THU0703 – Table 1**

	Value: N (%) / Mean (SD)	Univariable analyses	
		Count part Zinb model β (95%CI)	Inflate part Zinb model β (95%CI)
Age	47.7 (10.1)		
Gender	337/544 (62%)		
VAS health status	39.1 (25.8)	0.013 (0.01, 0.16)	-0.13 (-0.20, -0.06)
HAD-score	0.50 (0.50)	0.66 (0.52, 0.80)	-4.61 (-7.11, -2.11)
EQ-5D score	0.63 (0.65)	-0.82 (-1.04, -0.60)	7.53 (5.81, 9.76)
HAD Anxiety	6.2 (5.9)	0.02 (0.01, 0.03)	-0.21 (-0.32, -0.11)
HAD Depression	4.7 (3.7)	0.05 (0.03, 0.07)	-0.29 (-0.46, -0.12)

- (very)unsatisfied	70/542 (13%)	0.14 (-0.08, 0.35)	-0.36 (-1.17, 0.45)
Help colleagues:			
- often/always	159/541 (29%)	ref	ref
- sometimes	278/541 (52%)	0.05 (-0.13, 0.23)	-0.09 (-0.87, 0.69)
- never	103/541 (19%)	0.09 (-0.16, 0.34)	1.65 (0.83, 0.46)
Ability to postpone tasks:			
- often/always	92/542 (17%)	ref	ref
- sometimes	319/542 (59%)	0.06 (-0.15, 0.27)	-0.08 (-0.86, 0.69)
- never	131/542 (24%)	0.33 (0.09, 0.57)	0.49 (-0.34, 1.33)
Ability to organise own work:			
- often/always	353/542 (65%)	ref	ref
- sometimes	147/542 (27%)	0.11 (-0.06, 0.29)	-0.12 (-0.72, 0.48)
- never	42/542 (8%)	0.30 (0.04, 0.55)	-0.37 (-1.34, 0.60)

VAS=visual analogue scale (0–100 worst score); EQ-5D=EuroQol-5D (-0.11–1=perfect health); HAD=Hospital Anxiety Scale (0–21=abnormal); PASS=do you feel your current condition is satisfactory, when you take your general functioning and your current pain into account (satisfactory/unsatisfactory). Count part=score in those with a score >0; inflate part=estimate of excess zero scores.

**Conclusions:** In this large international study of patients with IA and OA having a median symptom duration of 10 years, worse functional ability was the main factor associated with presenteeism.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6581

### THU0704 A NEW ASSESSMENT TOOL FOR ULNAR DRIFT IN PATIENTS WITH RHEUMATOID ARTHRITIS USING PATHOPHYSIOLOGICAL PARAMETERS OF THE METACARPOPHALANGEAL JOINT

S. Toyama<sup>1</sup>, R. Oda<sup>1</sup>, D. Tokunaga<sup>1</sup>, M. Asada<sup>1</sup>, Y. Kawahito<sup>2</sup>, H. Fujiwara<sup>1</sup>, T. Kubo<sup>1</sup>. <sup>1</sup>Department Of Orthopaedics; <sup>2</sup>Department of Inflammation and Immunology, Graduate School Of Medical Science, Kyoto Prefectural University Of Medicine, Kyoto, Japan

**Background:** Ulnar drift (UD) in rheumatoid arthritis (RA) is the most common and difficult to manage deformity in the rheumatoid hand; it is reported that 44% of patients develop UD within the first 10 years. Nevertheless, the assessment of UD is challenging; the Fearnley classification method, first reported in 1951, is still used for evaluation. However, it is sometimes difficult to determine the best surgical procedure simply based on the Fearnley classification, which only evaluates reducibility. Therefore, we have been using both the Fearnley classification as a 'gold standard' and an original scoring method that enables us to easily treat the deteriorated condition contributing to UD.

**Objectives:** To establish and verify a new assessment tool for UD in rheumatoid hand.

**Methods:** We established an observational cohort of 67 patients (134 rheumatoid hands) beginning in 2004, among the RA outpatients who had any apparent finger deformity in either hand. Fifty-two patients (100 hands) had follow-up in 2009, and thirty-seven patients (63 hands) completed follow-up in 2015. For evaluation of UD, we used both the Fearnley classification as a 'gold standard' and an original scoring method which assesses four parameters of the metacarpophalangeal joint. Cluster analysis using UD parameters divided hands into groups. For functional assessment, we used the modified Kapandji index (MKI). The MKI enables us to assess unilateral hand functional mobility within a few minutes. Changes in UD over time, correlation of the Fearnley stage and cluster with MKI, and reliability of the parameters with clustering were analysed.

**Results:** The 10 year follow-up rate was 55.2%, and UD increased and worsened over time (p<0.001). A dendrogram indicated five clusters would be appropriate. Twenty-six hands in total changed to a higher cluster number during the follow-up period. Both the Fearnley classification and cluster were associated with MKI

significantly. Though the Fearnley classification showed a floor effect, our method related to function more linearly (R-squared: 0.42). Each parameter of our method showed statistical significance for the clusters by regression analysis. And the ratio of the partial regression coefficient of each parameter was around 1:1:3:2, so we calculated a 'cluster score' using a weighted score for each parameter. A regression analysis has shown a strong correlation ( $r=0.95$ ,  $p<0.001$ ); however, its scatter plot also suggested that it is difficult to classify the cluster using CS only. We found one type of hand in which bone destruction precedes the joint dislocation and one type in which joint dislocation progresses with little deviation during UD progression. It is considered that two patterns of pathological findings and included some suggested indications for operative therapy to recover disability due to UD.

**Conclusions:** Our UD evaluation method is quite simple but is closely related to function. Additionally, it enables dividing UD hands into five stages. Thus, our assessment should be beneficial compared to the Fearnley classification in considering treatments of UD.

#### THU0705 OCCURRENCE OF ANKYLOSING SPONDYLITIS (AS) AMONG RELATIVES OF PROBANDS WITH RADIOGRAPHIC AS AND NON-RADIOGRAPHIC AS/ AXIAL SPONDYLOARTHRITIS (SPA)

S. Van Der Linden<sup>1</sup>, P. Villiger<sup>2</sup>, H. Baumberger<sup>3</sup>, M. Brown<sup>4</sup>, A. Boonen<sup>1</sup>, M. A. Khan<sup>5</sup>. <sup>1</sup>Rheumatology, University Medical Center, Maastricht, Netherlands; <sup>2</sup>Rheumatology, Inselspital, University of Bern, Bern; <sup>3</sup>NA, Flims, Switzerland; <sup>4</sup>Health and Biomedical Innovation, Queensland University of Technology, Brisbane, Australia; <sup>5</sup>Rheumatology, Case Western Reserve University, Cleveland, OH, USA

**Background:** The occurrence of AS in families as it relates to the presence or absence of HLA-B27 and radiographic sacroiliitis is not well-known.

**Objectives:** To assess among relatives the occurrence of AS and its association with HLA-B27 and presence of sacroiliitis among AS probands. AS is broader than just radiographic (classical) AS by modified New York criteria (mNY). We asked whether the likelihood of having a relative with classical AS is comparable for probands with radiographic AS by mNY criteria, and probands with non-radiographic AS/axSpA.

**Methods:** Re-analysis of the 1985–86 Swiss AS Family Study: 1178 subjects (363 clinically defined AS probands, 806 first-degree relatives, and 9 spouses) had participated. The AS patients were members of the Swiss AS patient society. The invited and consenting participants underwent physical exam of the spine and joints, completed questionnaires dealing with musculoskeletal problems, had pelvic radiographs taken, and provided blood samples for HLA-A,B,C typing. Radiographs were blindly read twice by each of up to 4 experienced readers. They scored sacroiliac joints according to NY criteria for sacroiliitis (bilateral grade  $\geq 2$  or unilateral grade  $\geq 3$ ). The study had been approved by the ethical committee of the University of Bern, Switzerland.

**Results:** Among 358 AS probands, 308 (86%) were HLA-B27(+) and 50 (14%) lacked this gene. The radiographic NY criteria were met by 81% of the 308 HLA-B27(+) probands versus only 44% of the 50 HLA-B27(-) probands. AS, as defined by NY criteria, was observed only among relatives of HLA-B27(+) probands; and all 14 of these relatives were also HLA-B27(+). Note: The probands in 12 of these 14 cases met the NY criteria, while 2 did not. Two of 59 HLA-B27(+) relatives from AS probands not-fulfilling the mNY criteria met the NY criteria, compared with 12 of 245 HLA-B27(+) relatives from AS probands fulfilling the mNY criteria ( $p=0.62$ ). Interestingly, inflammatory back pain (by Calin criteria) occurred among 46 of 286 (16.1%) HLA-B27(+) relatives of HLA-B27(+) probands, but in only 27 of 272 (9.9%) HLA-B27(-) relatives of HLA-B27(+) probands ( $p=0.031$ ).

**Conclusions:** AS among relatives was only observed in families of HLA-B27(+) AS/axSpA probands. The risk for HLA-B27(+) relatives to develop AS by NY criteria seems not to be influenced by the presence of sacroiliitis in the HLA-B27(+) AS/axSpA probands. HLA-B27(+) relatives who do not show radiographic

sacroiliitis are at higher risk to demonstrate symptoms of non-radiological AS/axSpA as they seem more prone to have inflammatory back pain.

#### THU0706 PRESENCE OF EXTRACTABLE NUCLEAR ANTIGENS (ENA) ANTIBODIES IN A LARGE POPULATION-BASED COHORT FROM THE NETHERLANDS

S. Arends<sup>1</sup>, L. Brouwer<sup>1</sup>, C. Roozendaal<sup>2</sup>, B. Doestzada<sup>1</sup>, H. Bootsma<sup>1</sup>, K. de Leeuw<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Laboratory Medicine, UMCG, Groningen, Netherlands

**Background:** Previous studies have demonstrated that years before the clinical onset of auto-immune diseases, auto-antibodies can already be present in the blood of these patients. However, it is also known that some individuals can have these auto-antibodies and will never develop an auto-immune disease. So far, little information is available on the presence of Extractable Nuclear Antigens antibodies (anti-ENA) in the general population in relation to the risk of developing an auto-immune disease.

**Objectives:** To estimate the prevalence of anti-ENA and their association with the presence of known risk factors of Systemic Lupus Erythematosus (SLE) and Sjögren Syndrome (SS) in the general Dutch population.

**Methods:** Lifelines is a prospective population-based cohort study in the Netherlands. Cross-sectional data from 40 135 participants were analysed. The detection of anti-ENA was performed using the ENA-CTD (connective tissue disease) screen on the Phadia-250 analyser with a ratio  $>1.0$  are considered positive. An extensive questionnaire was taken on demographic and clinical information (e.g. early musculoskeletal symptoms). Furthermore, some general blood parameters were available. SLE and SS were defined by a combination of self-reported SLE or SS, specific medication use and visiting a medical specialist within the last year. Characteristics were compared between 3 groups: SLE/SS patients, anti-ENA positive, and anti-ENA negative participants (without defined SLE/SS).

**Results:** Of the total 40 135 consecutive individuals, 41 were detected as having defined SLE or SS of whom 48% were anti-ENA positive SLE/SS patients were older and more often female. Of the remaining individuals, <sup>40,094</sup> 1089 (2.7%) were anti-ENA positive and anti-ENA positivity was also significantly associated with older age and female gender in this population. No significant associations were found for smoking and alcohol intake. As might be expected, SLE/SS patients reported more often complaints concerning fatigue, joint pain and joint stiffness. But also anti-ENA-positive participants reported significantly more often joint stiffness compared to anti-ENA-negative participants. Interestingly, levels of haemoglobin, leucocytes and lymphocytes were significantly decreased in anti-ENA-positive participants compared to anti-ENA-negative participants.

**Conclusions:** In this large population-based study, the prevalence of anti-ENA-positivity was 2.8% for the total group and 2.7% when excluding patients with SLE or SS. Older age, female gender, joint complaints and lower levels of haemoglobin, leucocytes and lymphocytes were more frequently present in anti-ENA-positive participants. Longitudinal studies are performed up to 15 years to investigate which individuals might develop SLE or SS to be able to develop prediction models.

#### THU0707 ANALYSIS OF ANTINUCLEAR ANTIBODIES IN BREAST CANCER PATIENTS

A. Neppel, M.C.C. Machoski, T. A. F. G. Santos, R. Nishihara, T.L. Skare. Departamento de Reumatologia, Hospital Universitário Evangélico de Curitiba, Curitiba, Brazil

**Background:** Analysis of antinuclear antibodies (ANA) may be found in malignant diseases

**Objectives:** To study the prevalence of ANA in breast cancer patients and its association with tumour characteristics.

**Methods:** Ninety one patients with breast mass detected by image studies and assigned to do diagnostic biopsy and eventual surgical treatment were studied for demographical, tumour data and presence of ANA. Serum of positive ANA patients was submitted to examination of ENA (extractable nuclear antigens)

profile. As comparison 91 healthy individuals paired for age and from same geographical area had ANA determination.

**Results:** In this sample 72/91 (79.1%) had malignant lesions (83% ductal infiltrative carcinoma). Ana was positive in 44.4% of malignant tumour patients, in 15.7% of benign lesions ( $p=0.03$ ) and in 5.4% of controls ( $p<0.0001$ ). The most common immunofluorescence pattern was fine dense speckled pattern. In the ANA positive patients with malignant lesions, 7 had positivity for ENA profile (3 for anti-RNP and anti-Sm, 1 for just anti-RNP, 2 for anti-Ro and anti-LA e 2 for just anti-La). It was not possible to associate ANA positivity with tumour histological characteristics or staging, neither with patient's age. A negative association of ANA with hormonal receptor status was found ( $p=0.01$ ).

**Abstract THU0707 – Table 1.** Comparison of malignant breast lesions characteristics according to positivity of antinuclear antibody (ANA)

	Positive ANA n=32	Negative ANA n=40	P
Ethnic background	Caucasians=32/32–100%	Caucasians –38/40–95% Afro descendentes - 2/40%–5%	0.49

#### DISPARITY IN OSTEOARTHRITIS KNEE PREVALENCE- A TALE OF TWO CITIES IN IRAN (TEHRAN) AND INDIA (PUNE): FINDINGS FROM WHO ILAR COPCORD POPULATION SURVEY (STAGE I)

A. Jamshidi<sup>1</sup>, T. Kianifard<sup>2</sup>, R. Ghorpade<sup>3</sup>, M. Shayan<sup>4</sup>, M. Mahmoudi<sup>4</sup>, A. Chopra<sup>3</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Rheumatology Research, Tehran Univ of Medical Sciences, Tehran, Iran, Islamic Republic of Iran; <sup>3</sup>Rheumatology, CENTER FOR RHEUMATIC DISEASES, Pune, India; <sup>4</sup>Rheumatology Research, Tehran Univ Medical Sciences, Tehran, Iran, Islamic Republic of Iran

**Background:** Radiographs are a major deterrent in population surveys. COPCORD (community oriented program for control of rheumatic diseases), a low infrastructure low cost model. advocates clinical approach ([www.copcord.org](http://www.copcord.org)). Iran and India completed COPCORD surveys during 2000–2010. Tehran (dominantly Muslim Shia ethnic) is 35° N, 51° E, altitude 3907' and Pune (dominantly Hindu Maratha ethnic) is 18° N, 73° E altitude 1817'. Tehran and Pune represent distinct culture and ethnicity but people in both communities sit and squat (ground). Early reports showed an adjusted prevalence of OA knee was 15.3 in Tehran and 3.4 in Pune.

**Objectives:** To determine and compare the age gender specific prevalence of knee OA in an urban survey in Iran and India

**Methods:** 8145 population (51% women) in Pune and 10 107 population (53% women) in Tehran were screened (convenience sampling). House to house survey (Phase 1) identified respondents with past(last 3 months) and/or current musculoskeletal (MSK) pain (last 7 days). Trained community volunteers interviewed respondents to map MSK pain and disability (Phase 2). Concurrently, rheumatologists examined cases to make a clinical diagnosis (phase 3). 8.1% in Iran and 16.6% in Pune population were aged 65+years. The age-gender structure in both surveys (phase 1) was similar to the respective national census. Current data pertains to clinically diagnosed symptomatic OA knees (No X-Rays). Crude prevalence (95% confidence intervals) rate is shown.

**Results:** The prevalence was 15.1 (14.5, 15.9) in Tehran and 5.6 (5.1, 6.1) in Pune (OR=3.15, 95% confidence interval 2.83, 3.52,  $p<0.001$ , ANOVA); knee was the commonest affliction amongst OA sites- 93% in Tehran and 87% in Pune (data not shown). The age gender specific prevalence (percent) is shown in the figure 1. The prevalence was exceptionally high in Iran, both men and women, compared to Pune (Men: OR=2.84,  $P$ -value<0.001; Women: OR=2.56,  $P$ -value<0.001). The odds ratio remained more or less unchanged for each of the age group by gender. Presentation will include probable risk factors (culture) and global comparisons.

**Conclusions:** Based on a unique community model, urban surveys in Iran and India showed an enormous burden of OA knee. Women suffered more. The burden was strikingly high and unprecedented in Iran. Further research of life styles and risk factors is required to improve understanding of OA in the community.

**THU0709 REUMAHEART – A PORTUGUESE POPULATION BASED STUDY ON CARDIOVASCULAR RISK FACTORS**

V. M. Da Silva Domingues<sup>1</sup>, A. Rodrigues<sup>2</sup>, S. Dias<sup>2</sup>, J. Branco<sup>2</sup>, H. Canhão<sup>3</sup>, on behalf of EpiReuma. <sup>1</sup>Inflammation and Lymphocyte Physiology labs, Internal Medicine Department, Instituto Gulbenkian de Ciência, Centro Hospitalar do Porto; <sup>2</sup>EpiReuma, CEDOC, Lisbon; <sup>3</sup>EpiReuma, CEDOC, Lisboa, Portugal

**Background:** Individuals diagnosed with rheumatic diseases have shown an increased risk of developing several comorbid conditions, of which cardiovascular (CV) comorbidities are the most common and have the greatest effect on mortality.

**Objectives:** Our global aim is to assess the impact of Inflammatory Rheumatic Diseases (IRD) in the development of cardiovascular diseases controlling for traditional CV risk factors in a Portuguese national-wide population-based cohort.

**Methods:** This study used data from a population-based longitudinal cohort study – the EpiDOC cohort. IRD participants were selected according to Rheumatoid Arthritis (RA), Systemic Lupus Erythematosus (SLE), Ankylosing Spondylitis (SpA) and polymyalgia rheumatic (PMR) diagnosis criteria fulfilment. Outcome was defined as a composite of myocardial infarction or angor pectoris (ischaemic heart disease), arrhythmias, valvular disease, stroke or transient ischaemic attack and peripheral artery disease. Multivariate logistic regression models were used to assess predictors of CV events in IRD participants. Calibration and discrimination of

a predictive model were assessed by goodness-of-fit and area under receiver operating characteristic curve.

**Results:** In a national cohort of 10 661 people, patients with RA (n=61), SLE (n=13), SpA (n=92), PMR (n=8) were identified. Patients with IRD had similar age as non-IRD (mean age 55 vs 53 years-old; 72,1% female), with a predominance of dyslipidaemia diagnosis (40.7% vs 31.4%; p=0,033) and sedentary lifestyle (exercise practise 22.7% vs 33%; p=0,016). IRD participants were followed by a median follow-up of 2.6 years compared with 2.4 years in the non-IRD group (p<0,01). Cardiovascular events were proportional in both populations, leading ischaemic heart disease on IRD group (34.6%) and arrhythmias in controls (29.4%). After adjustment for risk factors, the odd of cardiovascular event is high (OR 1.64, 95% CI: 1.04–2.58; p=0.03). A stepwise approach to find the best predictive model attained that gender, age, history of hypertension, body mass index, IRD and follow-up time are the most important predictive variables of CV event, with an area under ROC of 0,80.

**Conclusions:** We report an increase odd of major CV events in inflammatory rheumatic disease in Portugal adjusting for potential modifiers. This study brings forward a contemporary awareness of physicians and patients with IRD for a premature identification and control of higher risk patients among this population.

**EXTENDED OLIGOARTICULAR AND POLYARTICULAR JUVENILE IDIOPATHIC ARTHRITIS PATIENTS HAVE A SIMILAR B CELL PHENOTYPE WHEN COMPARED TO ESTABLISHED RHEUMATOID ARTHRITIS**

R.A. Moura<sup>1</sup>, A. Brito<sup>1</sup>, S. Oliveira<sup>1</sup>, R.L. Teixeira<sup>1,2</sup>, V.C. Romão<sup>1,2</sup>, V. Teixeira<sup>1,2</sup>, R. Campanilho-Marques<sup>1,2</sup>, F. Oliveira-Ramos<sup>1,2</sup>, J.E. Fonseca<sup>1,2</sup>. <sup>1</sup>Instituto de Medicina Molecular João Lobo Antunes; <sup>2</sup>Rheumatology Department, Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, Lisbon, Portugal

**Background:** Our group has recently described that the majority of polyarticular juvenile idiopathic arthritis (pJIA) and a large fraction of extended oligoarticular JIA (oJIA) patients fulfil classification criteria for rheumatoid arthritis (RA) in adulthood. B cells play several important roles in RA pathogenesis, but it is still unclear if the pattern of B cell involvement in pJIA and extended oJIA follows what has been described for adults with RA.

**Objectives:** The main goal of this study was to characterise peripheral blood B cell phenotype and cellular activation in pJIA and extended oJIA patients when compared to established RA.

**Methods:** Blood samples were collected from JIA patients (n=10; mean age 10±4 years), established RA patients treated with synthetic DMARDs (n=10; mean age 72±7 years) and two corresponding groups of age- and sex-matched healthy donors. B cell phenotype was characterised by flow cytometry and B cell apoptosis was assessed after 48 hour of *in vitro* cell culture.

**Results:** JIA patients recruited in this study were either classified as extended oJIA (n=6) or pJIA (n=4). Seven JIA patients (4 extended oJIA and 3 pJIA) were treated with methotrexate and three patients (2 extended oJIA and 1 pJIA) were untreated. We found that JIA patients had similar CD19 +B cell levels in circulation when compared to controls, but significantly higher CD19 +B cell frequencies in comparison to established RA. In addition, increased frequencies of transitional (IgD +CD38++) and naïve (IgD +CD27+) B cell subpopulations were observed in JIA patients when compared to RA. However, established RA patients had significantly higher levels of CD21<sup>low</sup>CD38<sup>low</sup>, post-switch (IgD-CD27+) and IgD-CD27-memory B cell subsets when compared not only to controls, but also to JIA patients. No significant differences were detected in pre-switch (IgD +CD27+) memory and plasmablasts (IgD-CD38++) levels in JIA patients when compared to both controls and RA. Furthermore, the frequency of CD5 +B cells, CD5 median fluorescence intensity (MFI), CD40 MFI and CXCR5 MFI B cell expression levels were significantly increased in JIA patients when compared to established RA, but not to controls. No significant differences were observed between JIA and established RA patients in BAFF-R, FcγRIIB, CD21, CD23, CD38, CD86, CD95, HLA-DR, TLR9 and RANKL expression on B cells. After 48 hour of *in vitro* cell culture a significantly higher B cell death was found in JIA in comparison to RA patients.

**Conclusions:** The increased frequencies of transitional, naïve and CD5 +B cells in circulation and reduced levels of memory B cell subpopulations in JIA patients when compared to established RA are probably related to an immature immune system present in children when compared to adults. Nevertheless, the similarity in B cell phenotype found between extended oJIA, pJIA and established RA patients suggests an early B cell involvement in the pathogenesis of these two categories of JIA.

**ANALYSIS OF B CELLS AND T CELLS SUBPOPULATIONS AND COLLAGEN SPECIFIC T CELL REPERTOIRE IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS**

G. Di Sante<sup>1,2</sup>, M.C. Caparelli<sup>3</sup>, B. Tolusso<sup>2</sup>, C. Di Mario<sup>2</sup>, M. Valentini<sup>1</sup>, F. Ria<sup>1</sup>, G. Ferraccioli<sup>2</sup>, R. Cimaz<sup>3</sup>, E. Gremese<sup>2</sup>. <sup>1</sup>Institute of General Pathology, Università Cattolica del Sacro Cuore – Fondazione Policlinico Universitario A. Gemelli; <sup>2</sup>U.O. C. of Rheumatology, Fondazione Policlinico Universitario A. Gemelli – Università Cattolica del Sacro Cuore, Rome; <sup>3</sup>Institute of Pediatric Rheumatology, Azienda Ospedaliera A. Meyer, Florence, Italy

**Background:** The cause of the breach in immune tolerance in the arthritic joint is not fully understood; many associations between subsets of JIA and HLA and non-HLA molecules have been described.<sup>1</sup> An important role is played by T cell population, that is driven also by its specific T cell receptor (TCR) repertoire; it has been previously observed that synovial T cells exhibit oligoclonal TCR repertoires.<sup>2</sup>

**Objectives:** To examine frequency and distribution of human Collagen<sub>261–273</sub>-specific T cells and the phenotypes of B and T cells subpopulations and the role of DR alleles in JIA, in order to find new biomarker for management of JIA.

**Methods:** HLA genotyping and CDR3 TRBV-TRBJ spectratyping (TCR repertoire Immunoscope analysis)<sup>3</sup> were performed on Peripheral blood mononuclear cells (PBMCs) on a total of 40 Juvenile Idiopathic arthritis (JIA) patients (and in 2 cases also in samples of Synovial fluids) and 6 Healthy Controls. The enrolled patients were mainly affected by polyarticular arthritis (26 out 40) and were free of CS (38 out 40) and cDMARDs (24 out 40) treatments. The mean disease duration was 37 months. All the patients were ACPA and RF negative and the mean ESR and PCR values were respectively 39.5±32.4 mm/h and 17.5±37.4 mg/L. B cells and T cells subpopulations were analysed by flow cytometry assays.

**Results:** In our cohort 4 patients were DR4+ (10%) and 8 were DR1+ (20%). In the entire cohort no differences were found in terms of B cells subpopulations, but dividing the cohort on the basis of the age of disease onset it was possible to identify a upregulation of Switched B cells compartment in younger patients more than the JIA with an exordium after 12 years, confirming the data recently published.<sup>4</sup> We checked for the presence of collagen specific TRBV25-TRBJ2.2 T cells, whom the expansion were significantly associated with disease activity and modulated by therapy in RA patients, as described in our previous work.<sup>3</sup> Our preliminary results in a so small cohort of patients indicate that the same expansion in JIA patients seems to associate with JADAS and DR4/DR1 positivity, independently from any conventional and biological treatment. Moreover our T cells subpopulation analysis allowed to find interesting correlation between Tregs and switched memory, Tregs and double negative (IgD<sup>neg</sup>/CD27<sup>neg</sup>) B cells (r=0.476, p=0.04) and Tregs and DR4/1 positivity (0.432 p=0,03) and between CD27<sup>high</sup>/CD38<sup>high</sup> cells and Il17a producing cells (r=0.414, p=0.04); these correlations are more significant in JIA patients with a disease onset at a young age (age <6 years).

**Conclusions:** These preliminary results suggest that the analysis of collagen specific T cells repertoire, T and B cells subpopulations and HLA-DR haplotype can provide useful information to characterise peculiar details of each JIA patient

**EPIGENETIC ALTERATIONS LEADING TO SPECIFIC EXPRESSION PATTERNS OF IMMUNE RESPONSE REGULATING GENE MIGHT BE RESPONSIBLE FOR DISTINCTIVE MICROBIOTA COMPOSITION AND DISEASE DEVELOPMENT IN JUVENILE SPONDYLOARTHRITIS PATIENTS**

L. Lamot<sup>1,2</sup>, K. Gotovac Jercic<sup>3</sup>, A. Blazekovic<sup>3</sup>, T. Catela Ivkovic<sup>4</sup>, M. Vidovic<sup>1</sup>, M. Lamot<sup>1</sup>, S. Kapitanovic<sup>4</sup>, F. Borovecki<sup>3</sup>, M. Harjacek<sup>1,2</sup>. <sup>1</sup>Department of Pediatrics, Clinical Hospital Center Sestre Milosrdnice; <sup>2</sup>Department of Pediatrics; <sup>3</sup>Department of Functional Genomics, University of Zagreb School of Medicine; <sup>4</sup>Laboratory for Personalized Medicine, Rudjer Boskovic Institute, Zagreb, Croatia

**Background:** Juvenile spondyloarthritis (jSpA) is a diverse group of related syndromes with shared symptoms and pathogenic mechanisms in which both extrinsic environmental factors and intrinsic genetic background perpetuate inflammatory response through immune system alterations. Recently obtained gene signatures in jSpA patients revealed TLR4 and CXCR4 gene had increased, while NLRP3 and PTPN12 had decreased expression.<sup>1</sup> Although gene expression is regulated by various mechanisms, the increasing numbers of studies is showing the importance of epigenetic mechanisms in this fundamental biological process.

**Objectives:** To investigate the possible mechanistic role of DNA promoter region methylation and several non-coding micro RNA (miR-150, miR-146a, miR-181a, miR-223) in jSpA patients regarding the expression of genes with previously observed alterations.

**Methods:** The expression of specific microRNAs was analysed in 8 jSpA patients and 5 matched controls using RT-PCR with predeveloped microRNA assays. Methylated DNA Immunoprecipitation (MeDIP) was performed in 19 patients and 7 controls. Enrichment in MeDIP fraction was determined by qRT-PCR using the AriaMx.

**Results:** The difference in fold enrichment of immunoprecipitated DNA was significant only for NLRP3 promoter site (p=0.0220). Expression analysis of selected

miRNAs showed no significant difference in fold change between jSpA patients and healthy controls.

**Table 1.** Results of DNA promoter methylation and previously performed gene expression analysis in juvenile spondyloarthritis patients<sup>1</sup>

GENES	Fold Enrichment of Immunoprecipitated DNA		Fold Change of Expression <sup>1</sup>		
	Controls (n=19)	p	Fold Change	p	
TLR4	0213	0153	0,5759	+3,91	<0,01
NLRP3	11,24	5412	0,0220	-5,00	<0,01
CXCR4	0303	0170	0,2658	+1,87	<0,01
PTPN12	0338	0202	0,3768	-2,63	<0,01

**Conclusions:** Our study indicated epigenetic modifications are probably responsible for some of the expression alterations in jSpA patients in the initial phase of the disease. Since NLRP3 has a crucial role in inflammasome assembly and inflammasomes have been shown to shape microbiota, it is reasonable to assume dysbiosis in jSpA patients can at least partially be explained by reduced NLRP3 expression due to hypermethylation, stressing for the first time the epigenetic contribution to jSpA pathophysiology. While it is still not clear if these epigenetic alterations are caused by genetic mutations in epigenetic factors or exposure to certain environmental factors that mediate the occurrence of aberrant epigenetic profiles, the discovery of DNA methylation-based signature of the NLRP3 gene could have important implications in addressing extrinsic and intrinsic contribution to jSpA pathophysiology, whereas the possibility of reverting epigenetic modifications opens whole new prospects for therapeutic treatment of this complex disease.

#### GRANULOCYTE MACROPHAGE COLONY STIMULATING FACTOR IS SECRETED AT HIGHER LEVELS FROM STIMULATED MONOCYTE-DERIVED MACROPHAGES FROM PATIENTS WITH ENTHESITIS RELATED ARTHRITIS AND IS SIGNIFICANTLY ENHANCED BY THE UNFOLDED PROTEIN RESPONSE

C. Fisher<sup>1,2</sup>, D. Eleftheriou<sup>1</sup>, D. Sen<sup>1,2</sup>, Y. Ioannou<sup>1</sup>. <sup>1</sup>Arthritis Research UK Centre for Adolescent Rheumatology, University College London; <sup>2</sup>National Institute for Health Research University College London Hospitals Biomedical Research Centre, University College London and University College London Hospital, London, UK

**Background:** Enthesitis related arthritis (ERA) is a subtype of juvenile idiopathic arthritis exhibiting many similarities to the adult spondyloarthropathies (SpA). The innate immune system and intracellular stress responses, including the unfolded protein response (UPR), have been implicated in the pathogenesis of SpA. Granulocyte macrophage colony stimulating factor (GMCSF), as well as being a haemopoietic growth factor, plays a central role in regulating innate immunity and has recently been implicated in the pathogenesis of SpA<sup>1</sup> but has not been studied in ERA.

**Objectives:** To compare levels of GMCSF produced by monocyte-derived macrophages (MDMs) from patients with ERA and healthy controls and to observe the effect of inducing the UPR on those levels.

**Methods:** Peripheral blood monocytes were isolated from 39 patients with ERA (68% HLA B27 positive, 84% male, median age 16 years 4 months, median disease duration 3 years 10 months) and 21 age and gender-matched healthy controls and differentiated *in vitro* with macrophage-colony stimulating factor. Cells were treated with interferon gamma for 24 hours to upregulate HLA B, washed and then stimulated with lipopolysaccharide (LPS) alone (50 ng/mL) or LPS and tunicamycin (TM) (5 µg/mL), an inducer of the unfolded protein response. GMCSF was measured from the cell culture supernatants after 24 hours culture by luminex assay.

**Results:** Levels of GMCSF at baseline were similar in patients and healthy controls [median 121.3 pg/mL (IQR 96.6–194.0 pg/mL) vs 157.1 pg/mL (124.2–203.3 pg/mL), p=0.1]. However, with LPS stimulation, MDMs from patients secreted significantly higher levels of GMCSF [median 1853 pg/mL (IQR 1206–3061 pg/mL) vs 1342 pg/mL (IQR 713.3–1797 pg/mL), p=0.0057]. On stimulation with TM in addition to LPS, GMCSF production was further enhanced in both patients and healthy controls [median 9027 pg/mL (IQR 4746–13961 pg/mL) vs

3834 pg/mL (IQR 1603–9158 pg/mL)] and remained significantly higher in patients (p=0.0096). To investigate the effect of the UPR, fold change in GMCSF was calculated for each sample between MDMs stimulated with LPS alone and MDMs stimulated with both LPS and TM. Median fold change in patients was 3.95 (IQR 1.54–5.47) and 2.36 (IQR 0.49–4.69) in healthy controls. Interestingly, MDMs from patients who were HLA B27 positive exhibited significantly higher median fold change in GMCSF with UPR induction compared to HLA B27 negative patients [4.14 (IQR 2.22–6.10) vs 1.33 (IQR 0.36–3.91), p=0.0098]. No associations were seen with different treatment regimes in the patient group.

**Conclusions:** MDMs from patients with ERA produce significantly higher levels of GMCSF after stimulation compared to healthy controls and this is further enhanced by the UPR, especially in HLA B27 positive patients. These results potentially implicate GMCSF in the pathogenesis of ERA and thus further support the concept of GMCSF as a novel target for treatment in certain subgroups of patients.

#### THE RELATIONSHIP BETWEEN JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS AND THE TRANSCRIPTION FACTORS NF-KAPPAB AND PPAR-GAMMA

S. Sahin<sup>1</sup>, S. Dumus<sup>2</sup>, A. Adrovic<sup>1</sup>, K. Barut<sup>1</sup>, R. Gelisgen<sup>2</sup>, H. Uzun<sup>2</sup>, O. Kasapcopur<sup>1</sup>. <sup>1</sup>Pediatric Rheumatology; <sup>2</sup>Department of Biochemistry, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterised by high-levels of autoantibodies mainly targeting nuclear antigens and loss of self-tolerance. Peroxisome-proliferator activated receptor gamma (PPAR $\gamma$ ) and nuclear factor-kappa beta (NF- $\kappa$ B) are transcription factors, which, within normal levels, have shown to be crucial in immunomodulation namely, activation and development of normal lymphocytes, negative and positive selection of T and B cells. High-levels of NF- $\kappa$ B has inflammatory properties such as release of autoreactive T cells. On the contrary, PPAR $\gamma$  has anti-inflammatory effects, which has been demonstrated to be effective when used early in prevention of disease in murine models of systemic lupus erythematosus.

**Objectives:** Herein, we investigated whether NF- $\kappa$ B and PPAR $\gamma$  could exert opposite effects in the immune response and the possible implications in immunomodulation of juvenile systemic lupus erythematosus.

**Methods:** Serum NF- $\kappa$ B and PPAR $\gamma$  levels were measured in 42 juvenile systemic lupus erythematosus. In addition, 19 juvenile systemic sclerosis and 25 age-matched healthy children were selected for patient control and healthy control, respectively. We have also assessed the relation of these transcription factors with disease activity and anti-ds DNA.

**Results:** The control group did not differ from the juvenile SLE and juvenile systemic sclerosis patients for age (p>0.05). According to our study, serum NF- $\kappa$ B levels of juvenile SLE and juvenile systemic sclerosis patients were significantly higher (1.87±1.0 and 2.17±1.0 versus 1.25±0.7), while serum PPAR $\gamma$  levels were significantly lower than that of healthy controls (1.58±0.6 and 1.52±0.5 versus 2.03±0.9). The difference was not significant between juvenile systemic lupus erythematosus and juvenile systemic sclerosis. In patients with juvenile systemic sclerosis serum NF- $\kappa$ B levels negatively correlated with serum PPAR $\gamma$  levels (R=-0.49; p=0.032); however, this relationship was not observed in juvenile SLE patients and healthy controls.

**Conclusions:** Increased serum NF- $\kappa$ B levels represent upregulated signalling cascades, so it is associated with increased levels of pro-inflammatory cytokines. Since juvenile systemic sclerosis and juvenile systemic lupus erythematosus are autoimmune diseases, patients had high levels of NF- $\kappa$ B and low levels of PPAR than controls, as expected. Previous studies revealed that PPAR $\gamma$  activation inhibits NF- $\kappa$ B transcriptional activity. Correlation results in juvenile systemic sclerosis cohort are compatible with this finding, however not in juvenile systemic lupus erythematosus patients. This could be due to the limited number of patients. Further studies with large number of patients are needed to better elucidate the implication of these transcription factors in therapeutic pathways.

**FRI0006** **ASSOCIATION BETWEEN INTERLEUKIN-10 POLYMORPHISMS AND JUVENILE IDIOPATHIC ARTHRITIS: A META-ANALYSIS**

J.H. Jung, J.-H. Kim, G.G. Song, S.J. Choi. *Internal Medicine, Korea University Medical Center, Seoul, Korea, Republic Of*

**Background:** Juvenile idiopathic arthritis (JIA) is the most common chronic arthritis in children. JIA is a heterogeneous group of complex diseases and the result of a combination of genetic and environmental factors. Multiple genes contribute to the risk of developing JIA. Interleukin-10 (IL-10) is an anti-inflammatory cytokine that is associated with inflammatory diseases. IL-10 is considered a candidate gene for JIA based on its chromosomal location and functional relevance.

**Objectives:** IL-10 genetic polymorphisms associated with JIA were previously identified, especially in haplotypes studies. However, results from different studies have been inconsistent. Thus, we investigated whether IL-10 polymorphisms were associated with susceptibility to JIA.

**Methods:** A meta-analysis was conducted of the associations between the IL-10-1082G/A, -819 C/T, and -592 C/A polymorphisms and JIA. A total of eight studies involving 1495 patients and 1670 controls were considered in the meta-analysis. This meta-analysis was conducted based on the Preferred Reporting Items for Systemic Reviews and Meta-Analyses (PRISMA) guidelines.

**Results:** There was no association between the IL-10-1082G/A, -819 C/T, and -592 C/A polymorphisms and JIA in allele contrast and any of the genetic models (allele contrast: OR=0.90, 95% CI=0.79–1.02, p=0.09; OR=0.97, 95% CI=0.83–1.13, p=0.68; OR=0.92, 95% CI=0.81–1.06, p=0.24, respectively). Subgroup analyses revealed a significant association between the IL-10-1082 G allele and systemic JIA (OR=0.80, 95% CI=0.67–0.96, p=0.02). Meta-analysis of the IL-10 haplotype revealed no association between GCC, ACC, and ATA haplotypes and JIA.

**Abstract FRI0006 – Figure 1.** ORs and 95% CIs of the individual studies and pooled data for the associations between the IL-10 -1082 G allele and systemic JIA

**Conclusions:** This meta-analysis indicated lack of associations between IL-10 polymorphisms and susceptibility to JIA. However, there was a significant association between IL-10-1082 G allele and systemic JIA.

**Rheumatoid arthritis – prognosis, predictors and outcome**

**FRI0007** **PERFORMANCE OF MUSCULOSKELETAL ULTRASONOGRAPHY (MSUS) AND OPTIMAL CUTOFF CRITERIA FOR PATIENTS AT RISK FOR RHEUMATOID ARTHRITIS: A META-ANALYSIS**

A. Castro<sup>1</sup>, J. Diaz<sup>2</sup>, S. Kumar<sup>3</sup>. <sup>1</sup>University of Miami/JFK Medical Center Palm Beach Regional GME Consortium, West Palm Beach, USA; <sup>2</sup>Universidad de los Andes, Bogota, Colombia; <sup>3</sup>Rheumatology, VA Medical Center, West Palm Beach, USA

**Background:** The identification of patients with rheumatoid arthritis (RA) in the early stages of the disease leads to early treatment and improved outcomes. MSUS is a relatively easy, accessible and low cost method, which has been proven more sensitive in detecting findings suggestive of inflammatory arthritis than clinical or radiographic exams. Evidence shows that MSUS seems to bring additional knowledge when assessing the joints on patients with suspected RA, however, there is still controversy whether it can improve substantial discriminatory value for early arthritis.

**Objectives:** To assess the diagnostic value of MSUS and optimal cutoff criteria for the diagnosis of RA in patients with arthralgia and non-classified arthritis.

**Methods:** We conducted a meta-analysis for original studies evaluating ultrasound on patients with arthralgias and non-classified arthritis, published in Pubmed, EMBASE and Cochrane databases until December 2017. Statistical analysis included i) the calculation of sensitivity and specificity for ultrasound ii) summary receiver operating characteristic (SROC) curves for a linear regression model iii) I squared test for heterogeneity.

**Results:** Sixteen studies were included in the review. The overall sensitivity and specificity were 0.75 (95% CI 0.62, 0.88) and 0.72 (95% CI 0.60, 0.83) respectively. The overall diagnostic odds ratio (DOR) was 11.45 (95% CI 6.52, 20.11). The relative DOR for studies performed in Asia (10.43, p=0.002), published before 2013 (15.71, p=0.001) and involving MCP (11.27, p=0.003) and MTP (2.78,

**Abstract FRI0007 – Table 1**

PD <sub>≥</sub> 3	6	0.38	0.84	4.5	(5.2–9.4)	<0.001	2.0	(0.29–14.4)	0.462
Tenosynovitis	3	0.27	0.65	0.73	(0.01–82.8)	<0.001	1.0		
Erosions	6	0.40	0.84	3.3	(1.7–6.2)	0.242	1.0		

p=0.021) exhibited higher diagnostic performance. Meta-regression after adjusting for country, year, and type of joint involved, showed that Grey Scale (GS)  $\geq 1$  RDOR 6.0 (95% CI 1.6, 22.5; p=0.009) and Power Doppler (PD)  $\geq 1$  RDOR 3.9 (95% CI 1.3, 11.7, p=0.018) had greater diagnostic accuracy when compared to higher cutoff values.

**Conclusions:** MSUS is a valuable diagnostic tool when used in patients with arthralgia and at risk for RA. GS  $\geq 1$  and PD  $\geq 1$  combined have better discriminative ability for diagnosing RA due that the overall specificity is greater than for either alone.

**FRI0008 TISSUES ARE DIFFERENTLY MODULATED BY TOCILIZUMAB AND METHOTREXATE; ASSESSMENT OF CONNECTIVE TISSUE METABOLITES IN THE AMBITION STUDY**

A.C. Bay-Jensen, A.S. Siebuhr, C.S. Thudium, M.A. Karsdal. *Rheumatology, Nordic Bioscience Biomarkers and Research, Herlev, Denmark*

**Background:** Response to any treatment in rheumatoid arthritis (RA) is assessed by symptomatic changes, such as swollen joint count. Such assessments does not provide information regarding the effect of the treatment at tissue level. Chronic inflammation has a detrimental effect resulting in elevated levels of tissue remodelling and the release of extracellular matrix (ECM) metabolites into the circulation. The tissues consist mainly of interstitial matrix, basement membrane and cells, which are all affected by auto-immune disorders. Tissue metabolites can be measured in serum as biomarkers of tissue remodelling.

**Objectives:** The purpose was to investigate if tissue remodelling is differently modulated by tocilizumab (TCZ) and methotrexate (MTX).

**Methods:** The AMBITION study, a phase III RCT with tocilizumab vs. Methotrexate in which TCZ monotherapy (8 mg/kg every 4 weeks) was compared to methotrexate monotherapy over 24 weeks in patients with moderate-severe RA (AMBITION, NCT00109408). TCZ is a compound that inhibits the IL-6 receptor. Tissue metabolites were measured in baseline and 8 weeks sera (n=319) by ECM specific ELISAs: Connective tissue remodelling was measured by C3M (type III collagen degradation), basement membrane remodelling by C4M (type IV collagen), inflammation by C-reactive protein (CRP) and its metabolite CRPM. Comparison between groups were done by ANCOVA adjusting for age, gender, BMI and disease duration.

**Results:** Tissue remodelling was increased by 10% in the placebo group and significantly (p<0.001) inhibited by both MTX and TCZ compared to placebo. Inhibition with TCZ was 14% greater than that of MTX (p=0.0005). Basement membrane remodelling was likewise inhibited by both MTX and TCZ; the effect of TCZ was 20% greater than MTX (p<0.0001). MTX had limited effect on CRP and its metabolite CRPM compared to placebo or baseline. TCZ reduced the level to 27% and 73% of baseline, respectively. Although the effect of TCZ was much greater when assessing CRP, this was the least significant response marker, due to the huge placebo modulation, as well as the general high variation in response. Only changes in CRP was correlated to 8 week changes in DAS (rho=0.27, p=0.001) in the TCZ group. In the MTX group all changes in markers were correlated to change in DAS (rho=0.28 to 0.41, p<0.001). Only changes in C4M and CRP in the TCZ treatment arms were significantly correlated with DAS changes (rho=0.31, p<0.05).

**Abstract FRI0008 – Table 1**

Table	Mean change baseline (%)	8-week from	Lower 95%-CI	Upper 95%-CI	8 week change difference	P value
<b>Connective tissue metabolite (C3M)</b>						
PLACEBO	111		101	120	TCZ vs PLACEBO	<0.0001
MTX	88		83	94	MTX vs PLACEBO	0.0001
TCZ	74		69	79	TCZ vs MTX	0.0005
<b>Basement membrane remodeling metabolite (C4M)</b>						
PLACEBO	107		98	116	TCZ vs PLACEBO	<0.0001
MTX	87		82	93	MTX vs PLACEBO	0.0007
TCZ	67		62	72	TCZ vs MTX	<0.0001
<b>C-reactive protein metabolite (CRPM)</b>						
PLACEBO	112		91	133	TCZ vs PLACEBO	0.005
MTX	99		87	111	MTX vs PLACEBO	ns
TCZ	73		61	85	TCZ vs MTX	0.0091
<b>C-reactive protein (CRP)</b>						
PLACEBO	450		214	686	TCZ vs PLACEBO	0.007
MTX	102		-36	240	MTX vs PLACEBO	0.034
TCZ	27		-110	164	TCZ vs MTX	ns

**Conclusions:** Chronic inflammation results in an increased amount of tissue remodelling. There was a significant difference in the magnitude of effect MTX and TCZ on tissue remodelling. In addition there was a disconnect between tissue remodelling and change in disease activity, which was treatment dependent.

**FRI0009 A COMPARISON OF THE JOINT SYNOVITIS AND TENOSYNOVITIS USING ULTRASONOGRAPHY AND HISTOPATHOLOGICAL FINDINGS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

A. Abe<sup>1</sup>, H. Ishikawa<sup>1</sup>, A. Murasawa<sup>1</sup>, K. Wakaki<sup>2</sup>. <sup>1</sup>*Rheumatology, Niigata Rheumatic Center,* <sup>2</sup>*Pathology, Niigata Prefectural Shibata Hospital, Shibata, Japan*

**Background:** In the treatment of rheumatoid arthritis (RA), the early diagnosis and early medical treatment via tight control have become increasingly important with the advent of biological therapy. In addition, the existence of inflammation without bone destruction on magnetic resonance imaging has been found to be significantly associated with symptoms in the patient standpoint type inspection of early RA patients.

**Objectives:** This study was conducted to clarify the differences between the joint synovium and tendon sheath synovium, local disease activity using ultrasonography (US) and the findings on a synovial histopathological evaluation.

**Methods:** Between March 2011 and November 2017, 663 synovectomies were surgically treated, and synovial biopsies were performed at the time of surgery. Among them, 75 tendon sheath synovia and 588 joint synovia were investigated. A total of 81 men and 582 women were examined, with an average age of 64 years old. We examined the finger in 312 cases (39 tendons, 273 joints), wrist in 323 cases (33 tendons, 290 joints) and ankle in 28 cases (3 tendons, 25 joints). There were no cases with both tendon sheath synovium and joint synovium. Just before surgery, the US probe was placed on the dorsal and palmar/plantar aspect of the joint or the tendon sheath to evaluate the activity of local synovitis. The maximum grade of power Doppler (PD) signal was determined, ranging from 0 to 3. The serum C reactive protein (CRP), matrix metalloproteinase-3 (MMP-3) and DAS28 values were also examined just before surgery. A histopathological examination of the gathered synovium at the surgical site was performed using the Rooney score (RS).

**Results:** For the tendon sheath synovium, PD0, 14 cases; PD1, 32 cases; PD2, 19 cases and PD3, 10 cases were observed, with an average score of 1.33. For the joint synovium, PD0, 114 cases; PD1, 179 cases; PD2, 209 cases and PD3, 86 cases were observed, with an average score of 1.45. Regarding the DAS28, for the tendon sheath synovium, the average score was 3.59, and for the joint synovium, the average score was 3.61. Regarding the CRP, for the tendon sheath synovium, the average score was 0.64, and for the joint synovium, the average score was 0.66. Regarding the MMP-3, for the tendon sheath synovium, the average score was 113, and for the joint synovium, the average score was 123. There were no marked differences in the grade of PD, DAS28, CRP or MMP-3 between the synovia. The rate of synoviocytes hyperplasia did not differ between the synovia, but the rates of fibrosis and proliferating blood vessels were significantly high in the tendon sheath synovium, perivascular infiltrates of lymphocytes, focal aggregates of lymphocytes, diffuse infiltrates of lymphocytes was significantly high in joint synovium.

**Conclusions:** There was no marked difference in the US findings and the disease activity between the tendon sheath synovium and the joint synovium. However, there were differences in the local disease activities between the synovia. These results show that the tendon sheath synovium lacked acute inflammation.

Arima<sup>3</sup>, H. Nakamura<sup>1</sup>, T. Origuchi<sup>1</sup>, S. Sato<sup>4</sup>, M. Uetani<sup>2</sup>, A. Kawakami<sup>1</sup>. <sup>1</sup>Department of Immunology and Rheumatology; <sup>2</sup>Department of Radiological Sciences; <sup>3</sup>Department of Public Health, Nagasaki University Graduate School of Biomedical Sciences; <sup>4</sup>Clinical Research Center, Nagasaki University Hospital, Nagasaki, Japan

**Background:** Magnetic resonance imaging (MRI) and ultrasound (US) are both useful modality to monitor disease status of RA whereas combination analysis of disease course by both modalities are quite few.

**Objectives:** To clarify the predictors of radiographic progression in patients with RA examined by both MRI and US.

**Methods:** Thirty-three patients with active RA, managed with a treat-to-target strategy and checked disease activity score every three months along with examination of both MRI and US, were enrolled from June 2010 to June 2016 and observed for 12 months. US of wrist and finger joints was examined every three months, MRI and radiograph were done every six months. US were evaluated by synovitis score of semi-quantitative manner by gray-scale (GS) and power Doppler (PD) proposed from EULAR. In MRI, synovitis, bone oedema and bone erosion were assessed by the Rheumatoid Arthritis Magnetic Resonance Imaging Scoring system (RAMRIS). Radiographic bone erosion and joint space narrowing (JSN) were scored by Genant-modified Sharp Score (GSS). Radiographic progression was defined as delta radiographic score >0.5. Multivariate analysis was employed to clarify independent predictors for radiographic progression at 12 month.

**Results:** Thirteen patients were treated with methotrexate monotherapy and eighteen were received combination of methotrexate and biologics. Three were given biologic monotherapy. Median of age was 57.0 years and that of disease duration was 9 months. Female was 84.8%, positive rate of RF was 87.1% and that of ACPA was 79.3%. DAS28-CRP was 4.20, total GS score 6.0, total PD score 4.0, MRI synovitis score 6.0, MRI bone oedema score 3.0, MRI bone erosion score 3.0, and GSS score 1.0 at baseline. Radiographic progression was found in 12 patients. Multivariate analysis revealed that high MRI bone oedema score at baseline, high MRI bone oedema score and PD ≥ grade 2 articular synovitis at any joints at 6 month were associated with radiographic progression at 12 months. Clinical indices of DAS28-CRP at any point did not predict radiographic progression compared with MRI or US.

	odds ratio	95% CI	p-value
MRI bone edema score at 0m	1.52	1.06-2.17	0.02
CRP at 0m	4.75	0.29-77.74	0.28
GSS JSN at 0m	1.05	0.80-1.38	0.72

MRI bone edema score at 6m	1.37	1.04-1.81	0.03
CRP at 6m	7.00	0.96-51.15	0.06

PD ≥ grade 2 at 6m	13.84	1.84-104.03	0.01
CRP at 6m	8.24	0.59-115.45	0.12

**Conclusions:** During treat-to-target strategy, the presence of MRI bone oedema as well as PD ≥ grade 2 articular synovitis are found to be important to predict radiographic outcome in active RA patients. These imaging indices may be more sensitive to monitor radiographic progression as compared with clinical indices.

#### FRI0011 ULTRASONOGRAPHIC CRITERIA FOR THE DIAGNOSIS OF EROSIIVE RHEUMATOID ARTHRITIS DISEASE USING OSTEOARTHRITIC PATIENTS AS CONTROLS COMPARED TO VALIDATED RADIOGRAPHIC CRITERIA

C. Roux<sup>1</sup>, F. Gandjbakhch<sup>2</sup>, A. Pierreisnard<sup>2</sup>, M. Couderc<sup>3</sup>, C. Lukas<sup>4</sup>, R. Masri<sup>5</sup>, J.-P. Sommier<sup>1</sup>, I. Clerc-Urmes<sup>6</sup>, C. Baumann<sup>6</sup>, I. Chary-Valckenaere<sup>1</sup>, D. Loeuille<sup>1</sup>. <sup>1</sup>Rheumatology, University Hospital of Nancy, Vandoeuvre-lès-Nancy; <sup>2</sup>Rheumatology, Academic Hospital Pitie Salpêtrière, Paris; <sup>3</sup>Rheumatology, University Hospital of Clermont- Ferrand, Clermont- Ferrand; <sup>4</sup>Rheumatology, University Hospital of Lapeyronie, Montpellier; <sup>5</sup>Rheumatology, University Hospital of Nancy, Vandoeuvre-lès-Nancy; <sup>6</sup>Platform of Clinical Research Support PARC, University Hospital of Nancy, Vandoeuvre-lès-Nancy, France

**Background:** Rheumatoid arthritis (RA) is the most prevalent chronic inflammatory joint disease<sup>1,2</sup> responsible for structural damage. Radiography (RX) is considered as the gold standard for visualising and quantifying bone lesions in RA.<sup>3</sup> Musculoskeletal ultrasound (US) is booming in clinical practice for the diagnosis of RA. US can detect more erosions than RX at the joint level, especially at an early stage of the disease.<sup>4</sup>

**Objectives:** To determine thresholds for the diagnosis of erosive RA by US in RA and osteoarthritic (OA) patients and to compare these US thresholds with RX ACR/EULAR 2013 criteria for erosive RA.

**Methods:** Patients fulfilling ACR 1987 and/or ACR/EULAR 2010 criteria for RA or hand OA criteria were prospectively included. A modified Sharp erosion score was assessed by two blinded readers and one adjudicator for discordant cases (number of eroded joints ≤ three). Erosions in US were scored on six bilateral joints (MCP2-3, 5; MTP2-3, 5) with a four-grade scale to calculate total US score for erosions (USSE).

**Results:** A total of 168 patients were included: 122 RA (32 early RA <2 years; 90 late RA ≥2 years); 46 OA patients. On RX: 42 RA patients (6 early; 36 late) and 5 OA patients were eroded according to ACR/EULAR 2013 criteria with sensitivity at 34.4% and specificity at 89.1%. On US, 95 RA patients (21 early; 78 late) and 12 OA patients were eroded. Considering at least two joint facets eroded or at least one joint facet eroded at grade 2 on US, sensitivities were good (68%–72.1%) and specificities excellent (89.1%–100%). Agreement between RX and US was excellent (90%–92%). US diagnosed two times more patients than RX as erosive disease in both early and late RA patients.

**Conclusions:** USSE can differentiate RA from OA in erosive disease and detect two times more patients with erosive RA than RX with excellent specificity and agreement, according to two different criteria (number of facets eroded and severity of erosion at the joint facet level).

#### FRI0012 SHARING THE BURDEN OF RHEUMATOID ARTHRITIS THROUGH REMOTE MONITORING OF RHEUMATOID ARTHRITIS (REMORA): IMPLICATIONS FOR PATIENTS AND CLINICIANS

C.A. Sharp<sup>1</sup>, L. Austin<sup>2</sup>, M. Machin<sup>3</sup>, J. Humphreys<sup>4</sup>, P. Mellor<sup>4</sup>, J. McCarthy<sup>5</sup>, S. van der Veer<sup>1</sup>, L. Davies<sup>2</sup>, J. Ainsworth<sup>6</sup>, C. Sanders<sup>2</sup>, W. Dixon<sup>1</sup>. <sup>1</sup>Arthritis Research UK Centre for Epidemiology; <sup>2</sup>NIHR School for Primary Care Research; <sup>3</sup>The Farr Institute of Health Informatics Research; <sup>4</sup>NIHR CLAHRC GM; <sup>5</sup>Alliance Manchester Business School; <sup>6</sup>Centre for Health Informatics, The University of Manchester, Manchester, UK

**Background:** People living with rheumatoid arthritis (RA) experience continuous, daily symptoms that fluctuate over time. Clinical decisions made by healthcare

professionals at intermittent consultations rely upon history taking, which is subject to pitfalls including recall bias, variable help-seeking behaviours and difficulty in summarising fluctuating symptoms.

**Objectives:** REMote MONitoring in Rheumatoid Arthritis (REMORA) was a pilot study to design, implement and evaluate a system of remote data collection for RA patients, for health and research purposes. A unique feature was its aim to integrate patient-generated data from a smartphone app into the electronic health record (EHR).

**Methods:** Semi-structured interviews with key stakeholders informed project design and evaluation, comprising three stages: 1) co-design of smartphone app prototype and integration into the electronic patient record (EHR); 2) end-to-end prototype testing (1 month); 3) evaluation of feasibility and acceptability (3 months).

Qualitative data from audio-recorded interviews and 'routine' consultations, following app use, were coded using *a priori* and emergent themes, and triangulated.

**Results:** Daily, weekly and monthly question sets were developed. Patients tracked daily symptoms for one month (n=8) and three months (n=20). Patients submitted daily scores on most days (median 91% of days; IQR 78%-95%) with 4/20 patients submitting on <60% days. Further detail on feasibility has been reported elsewhere.<sup>1</sup> REMORA data were successfully integrated into the EHR (figure 1).

Data from interviews with 16 patients, 2 clinician-researchers (WD and CAS) and 17 clinical consultations were analysed. Patients and clinicians found remote monitoring acceptable and easy to use.

Three themes emerged with REMORA data providing the 'bigger picture' by highlighting episodes that might otherwise have been missed, for example short-lived flares and gradual changes in disease; **empowering patients** through increased self-awareness and improved understanding of RA; and **changing the nature of consultations** with graphs integrated into the EHR facilitating shared conversations and leading to more personalised care.

**Conclusions:** This study demonstrates the acceptability and feasibility of the REMORA system. Novel integration of patient-generated data into the EHR positively impacted consultations and was felt to empower patients. The system generated a unique, temporally-rich research dataset. The next challenge is to scale-up and spread the adoption of this innovation across a range of clinical contexts.

FRI0013

**CONVERTING PATIENT-REPORTED PHYSICAL FUNCTION OUTCOMES SCORES TO PROMIS METRIC SCORES IN PHASE 3 TRIALS OF BARICITINIB IN RHEUMATOID ARTHRITIS**

C.O. Bingham III<sup>1</sup>, C. Gaich<sup>2</sup>, A.M. DeLozier<sup>2</sup>, A. Quebe<sup>2</sup>, L. Sun<sup>2</sup>, S. Otawa<sup>2</sup>, J. Pope<sup>3</sup>. <sup>1</sup>Johns Hopkins University, Baltimore; <sup>2</sup>Eli Lilly and Company, Indianapolis, USA; <sup>3</sup>Joseph's Health Care, London, Alberta, Canada

**Background:** In patients (pts) with RA, physical function (PF) can be measured with the Health Assessment Questionnaire-Disability Index (HAQ-DI). Patient-Reported Outcomes Measurement Information System (PROMIS) was developed by the National Institutes of Health using a population-calibrated T-score metric (Mean 50, SD 10). Crosswalk tables that link legacy instruments to PROMIS instruments, including PF, have been developed. Comparisons to the general population can also be made from PROMIS scores.<sup>1-2</sup>

**Objectives:** To convert HAQ-DI scores to PROMIS PF scores to determine how the PROMIS metric performs in 2 phase 3 baricitinib (bari) clinical trials in pts with RA.

**Methods:** In RA-BEAM, pts with inadequate response (IR) to methotrexate were randomised 3:3:2 to placebo (PBO) once daily (QD), bari 4 mg QD, or adalimumab (ADA) 40 mg biweekly.<sup>3</sup> In RA-BEACON, pts with IR to bDMARDs were randomised 1:1:1 to receive PBO or bari 2 mg or 4 mg QD.<sup>4</sup> In both studies, PF was assessed using HAQ-DI. Patient-level HAQ-DI scores were converted to PROMIS PF scores using a validated crosswalk table.<sup>1</sup> Analysis of covariance was conducted on the PROMIS PF score conversions to compare bari to all treatment arms in both studies. Missing data were imputed using modified last observation carried forward.

**Results:** Pts had considerable PF impairment at baseline; mean scores exceeded 2 SD (20 points on the T-score metric) from population means (table 1). Treatment with bari was associated with clinically relevant improvements approaching or exceeding 0.5 SD (5 points on the T-score metric) by week 24 (minimally important difference for PROMIS PF: 0.2 SD or 2 points<sup>5</sup>) vs PBO in HAQ-DI converted to PROMIS PF scores (table 1). Using the converted PROMIS scores, bari remained associated with significant improvements in PF vs PBO through 24 weeks in both studies and vs ADA through 52 weeks in RA-BEAM (figure 1).

**Abstract FRI0013 – Table 1.** PROMIS Physical Function scores<sup>a</sup> converted from HAQ-DI in RA-BEAM and RA-BEACON

	RA-BEAM			RA-BEACON <sup>b</sup>		
	PBO (n=488)	Bari-4 mg (n=487)	ADA (n=330)	PBO (n=176)	Bari-2 mg (n=174)	Bari-4 mg (n=177)
Baseline	31.9 (6.8)	31.9 (6.6)	31.7 (7.5)	30.0 (5.3)	30.7 (5.7)	30.3 (6.1)
Week 1	33.8 (7.0)	35.0 (7.5)	35.0 (8.0)	30.7 (5.6)	32.8 (6.3)	32.4 (7.6)
Week 4	34.5 (7.7)	37.6 (8.8)	36.7 (8.3)	31.6 (6.2)	33.5 (6.9)	33.7 (8.8)
Week 12	35.9 (8.6)	39.4 (9.5)	37.8 (9.0)	32.1 (6.8)	34.9 (8.5)	35.1 (8.5)
Week 24	36.0 (8.7)	40.8 (10.3)	39.1 (9.7)	31.6 (6.4)	35.2 (9.0)	35.7 (10.2)
Week 52		41.2 (10.2)	39.6 (10.1)			

Data are mean (SD)

<sup>a</sup>Higher PROMIS Physical Function score means better physical function.

<sup>b</sup>RA-BEACON was a 24 week study

ADA=adalimumab; bari=baricitinib; PBO=placebo

**Abstract FRI0013 – Figure 1.** Change from baseline for PROMS Physical Function converted from HAQ-DI in RA-BEAM and RA-BEACON

**Conclusions:** While RA-BEAM and RA-BEACON did not use the PROMIS instrument directly, these results indicate PROMIS PF has the potential to show responsiveness and differentiate between active treatments in clinical trials.

#### LOW-DOSE ASPIRIN MAY HAVE A ROLE AS PRIMARY PROPHYLAXIS OF CARDIOVASCULAR EVENTS IN RHEUMATOID ARTHRITIS: EVIDENCE FROM AN ITALIAN MULTICENTRIC RETROSPECTIVE STUDY

D. Iacono<sup>1</sup>, S. Fasano<sup>1</sup>, I. Pantano<sup>1</sup>, V. D'Arosca<sup>1</sup>, P. Ruscitti<sup>2</sup>, D.P.E. Margiotta<sup>3</sup>, L. Navarini<sup>3</sup>, N. Maruotti<sup>4</sup>, F.P. Cantatore<sup>4</sup>, A. Afeltra<sup>3</sup>, R. Giacomelli<sup>2</sup>, G. Valentini<sup>1</sup>.

<sup>1</sup>Rheumatology, University of Campania Luigi Vanvitelli, Naples; <sup>2</sup>Rheumatology, University of L'Aquila, L'Aquila; <sup>3</sup>Rheumatology, Campus Bio-Medico, Rome; <sup>4</sup>Rheumatology, University of Foggia, Foggia, Italy

**Background:** Cardiovascular (CV) morbidity and mortality are significantly greater in Rheumatoid Arthritis (RA) patients than in the general population. Acetylsalicylic acid (ASA) is known to be associated with a significant decrease in the incidence of CV events in patients at high CV risk, as we have recently demonstrated in patients with Systemic Lupus Erythematosus, but its effectiveness as primary prophylaxis in RA patients has not yet been addressed.

**Objectives:** To investigate the role of ASA in reducing the incidence of CV events in an Italian multicentre RA cohort from the GIRRCS (*Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale*).

**Methods:** The clinical charts of RA patients consecutively admitted to 4 GIRRCS centres for their 1<sup>st</sup> visit from November 1<sup>st</sup> 2000 to December 31<sup>st</sup> 2015, who, at admission, satisfied 2010 ACR/EULAR criteria for RA and had not experienced any CV event, were analysed. The incidence of CV events during follow-up was recorded at December 2016. Kaplan Meier curve and log-rank test were used to investigate differences in event-free survival. Cox regression analysis served to identify factors associated with CV event occurrence.

**Results:** Seven hundred and forty-six consecutive RA patients were enrolled and followed up for a median of 5.6 years (range 2.9–8.9 years). The incidence rate (IR) of CV events was 7.8/1000 person-years (pys) in the overall cohort. Patients were subdivided into two groups, namely ASA- (242 patients) and non-ASA-treated (504 patients). The IR of CV events was significantly lower in the ASA-treated with respect to the non-ASA-treated group (IR 1.7 vs 11.5/1000 pys;  $p=0.0002$ ). Furthermore, the CV event-free rate was longer in ASA-treated than in non-ASA-treated patients (log-rank test 12.3;  $p=0.0004$ ). Figure 1.

At multivariate analysis hypertension and metabolic syndrome (HR 5.6, 95% CI:1.2–26.3;  $p=0.03$  and HR 3.7, 95% CI:1.3–9.8;  $p=0.009$ ) resulted to be the only positive predictors; ASA treatment (HR 0.04, 95% CI:0.06–0.33;  $p=0.02$ ) the only negative one.

**Conclusions:** The incidence rate of CV events in our Italian multicentric cohort was lower than that reported in other European and non-European cohorts. Low-dose ASA may have a role in the primary prophylaxis of CV events in RA patients.

#### TREATING RHEUMATOID ARTHRITIS TO TARGET: IS LOW DISEASE ACTIVITY GOOD ENOUGH?

E. Nikiphorou<sup>1</sup>, S. Norton<sup>1</sup>, A. Young<sup>2</sup>, L. Carpenter<sup>1</sup>, J. Dixey<sup>3</sup>, D. Walsh<sup>4</sup>, P. Kiely<sup>5</sup>, on behalf of ERAS-ERAN working group. <sup>1</sup>Academic Rheumatology, King's College London, London; <sup>2</sup>Life Sciences, University of Hertfordshire, Hertfordshire; <sup>3</sup>Rheumatology, The Royal Wolverhampton, Wolverhampton; <sup>4</sup>Rheumatology, The University of Nottingham, Nottingham; <sup>5</sup>Rheumatology, St George's Hospital, London, UK

**Background:** Treat-to-target (T2T) principles in rheumatoid arthritis (RA) are now widely recognised as effective in achieving optimal disease outcomes.

**Objectives:** To examine for differences in outcomes between low (LDAS) and remission (RDAS) disease activity score (DAS) categories, addressing the question: is LDAS a 'good enough' treatment target in RA?

**Methods:** Data from two consecutive UK multi-centre RA inception cohorts with similar design were used: the Early RA Study (ERAS) and Early RA Network (ERAN). Recruitment figures/median follow up for ERAS and ERAN were 1465/10 years (maximum 25 years), and 1236/6 years (maximum 10 years) respectively. Standard demographic and clinical variables were recorded at baseline and then annually until the end of study follow up. Disease activity was categorised by mean DAS28 score between years 1–5 as remission [mRDAS <2.6] or low [mLDAS 2.6–3.2]; as sustained low/remission DAS (sLDAS/sRDAS) based on DAS persisting in each of the two categories at years 1–2 and as Boolean remission (years 1–2). Change in HAQ and SF36 (physical [PCS] and mental [MCS] components) for each disease activity category were modelled using linear mixed models with time incorporated as a linear spline with change-point at 12 months. Year of onset, age, gender and use of steroids or conventional DMARDs at first visit were included as covariates.

**Results:** Out of 2701 patients, 468 (17%) were in mRDAS, 284 (11%) in mLDAS in the first five years of disease. Lower proportions had achieved sRDAS (8%), sLDAS (6%) and Boolean (2%) remission. Mean age was similar across categories; more women were in low vs remission DAS. Compared to mLDAS or sLDAS, inflammatory markers, DAS, functional (HAQ, PCS) and mental (MCS) scores tended to be better in the mRDAS, sRDAS or Boolean remission categories (figure 1). Significant differences ( $p<0.05$ ) were noted between the mRDAS and mLDAS between years 1–5 for all outcomes; for sRDAS compared to sLDAS, the difference was significant at one year but not by five years.

**Conclusions:** The results demonstrate striking differences between remission and low DAS categories, suggesting worse functional and SF36 outcomes over

time in the low DAS categories. This supports that remission should be the primary T2T goal in RA.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3890

#### FRI0016 NO RELATIONSHIPS BETWEEN ACPA AND PERIODONTITIS IN EARLY RHEUMATOID ARTHRITIS

F. Mechid<sup>1</sup>, C. Zehraoui<sup>1</sup>, M. Meddad<sup>2</sup>, S. Salah<sup>3</sup>, M. Benidir<sup>3</sup>, S. Merad<sup>4</sup>, N. Saidi<sup>1</sup>, O. Cheikh<sup>1</sup>, N. bliidi<sup>1</sup>, C. Dahou<sup>1</sup>. <sup>1</sup>Rheumatology, Mohamed Lamine Debaghine hospital; <sup>2</sup>Periodontology, Mustapha Bacha Hospital; <sup>3</sup>Immunology; <sup>4</sup>Bacteriology, Dely brahim, institut Pasteur, Algiers, Algeria

**Background:** Proteins citrullination contributes to generate anticitrullinated peptide antibodies (ACPA) in rheumatoid arthritis (RA). Porphyromonas gingivalis (Pg) is one of main germs incriminated in the development of periodontitis (PD), it has an enzyme called peptidyl arginine deiminase which is able to citrullinate the host proteins

**Objectives:** The aim of this study was to seek for a possible association between ACPA and periodontitis

**Methods:** We conducted a case-control study of 69 patients with early rheumatoid arthritis ( $\leq 2$  years), naive of biotherapy and 138 age- and sex matched healthy controls. Smokers, diabetics, and subjects who received dental care and those who used antibiotics in the previous 6 months were not included. Demographic data and ACPA were determined. A periodontal examination was performed to all participants. Subgingival plaque samples were analysed to seek for Porphyromonas gingivalis (Pg) in both population in the case of periodontitis.

**Results:** The mean age of our patients was  $40.75 \pm 12.04$ , the mean duration of the illness was  $14.30 \pm 6.76$  months (extremes: 1–24 months). ACPA was detected in 88% of patients and the mean titre was  $255.57 \pm 409.78$ . PD frequency was higher in patient with PR compared with healthy controls (43% versus 29%) and a significant association was found between PR and PD ( $p < 10^{-3}$ ). Patients with RA had 2.46 (CI 1.12 to 5.39) higher odds of having PD compared with healthy controls. In early RA, ACPA titre and rate was not associated with PD ( $p = 0.06, p = 0.44$  respectively). Regarding the frequency of Porphyromonas gingivalis, there was no significant difference between the PR group and the control group ( $p = 0.45$ ). In addition, there was no significant difference between RA group and controls ( $p = 0.68$ ) concerning Porphyromonas gingivalis and ACPA

**Conclusions:** Periodontitis is a risk factor for the occurrence of rheumatoid arthritis. The ACPA does not seem to be related to periodontitis. In addition there was no association between ACPA and the presence of porphyromonas gingivalis.

Rossini<sup>1</sup>, on behalf of Study Group on Osteoporosis and Metabolic Skeletal Diseases of the Italian Society of Rheumatology (SIR). <sup>1</sup>Rheumatology Unit, University of Verona, Verona; <sup>2</sup>Rheumatology Unit, Policlinico San Matteo Foundation/University of Pavia, Pavia; <sup>3</sup>Rheumatology Unit, University of Foggia, Foggia; <sup>4</sup>Rheumatology Unit, Gaetano Pini Institute, Milano; <sup>5</sup>Rheumatology Unit, University of Bologna Sant'Orsola-Malpighi Hospital, Bologna; <sup>6</sup>Rheumatology Unit, University Federico II of Naples, Napoli; <sup>7</sup>Rheumatology Unit, Galateo San Cesario Hospital, Lecce, Italy

**Background:** Lower serum vitamin D levels have been associated with various autoimmune disorders. Especially in patients affected by Rheumatoid Arthritis

(RA), has been observed an inverse correlation between serum levels of 25-hydroxyvitamin D (25OHD), pain and disease activity, but the cause-effect relationship is not clear.

**Objectives:** The aim of this exploratory study is to investigate the effects of supplementation with cholecalciferol (vitD3) in improving pain and disease activity in RA patients with or without vitamin D deficiency ( $25\text{OHD} < 20$  ng/ml).

**Methods:** In this prospective open-label intervention study, patients fulfilling the EULAR/ACR 2010 criteria for diagnosis of RA, in non-remission ( $\text{DAS28-CRP} > 2.6$ ), on stable disease-modifying antirheumatic drugs, and whose treatment was not expected to be changed over a 3 month period following inclusion, were recruited. DAS28-CRP, VAS pain and serum levels of 25OHD, were evaluated at the baseline and after 3 months of supplementation with oral 100,000 IU/monthly of vitD3.

**Results:** A sample composed by 61 patients (47 females), with an average age (SD) of 58.12 years within 26–86 years range were included. At baseline the mean (SD) 25OHD levels were 22.10 ng/mL. 57% of the patients were found to have vitamin D deficiency ( $< 20$  ng/mL). Mean serum 25OHD levels improved from  $13 \pm 5$  to  $32 \pm 12$  and from  $29 \pm 7$  to  $41 \pm 10$  ng/mL in patients with or without vitamin D deficiency, respectively. At baseline, mean VAS pain was significantly higher in patients with vitamin D deficiency. In the figure are shown DAS28-CRP and VAS pain at baseline and after 3 months of vitD3 supplementation both in patients with or without vitamin D deficiency. After large doses of VitD3, VAS pain significantly decreased in patients with vitamin D deficiency, while DAS28-CRP significantly improved only in patients without vitamin D deficiency at baseline.

**Conclusions:** VitD3 supplementation appears to be associated with significant and different effects on pain and disease activity in RA patients dependent on 25OHD serum levels. Vitamin D deficiency ( $< 20$  ng/mL) seems to be mainly correlated with pain, while higher levels of 25OHD might have immunomodulatory effects. A randomised, double-blind, low versus high vitD3 dose, placebo-controlled trial is recommended.

#### FRI0018 THE ABILITY OF DISEASE ACTIVITY MEASURES TO PREDICT MAJOR THERAPEUTIC CHANGE IN US VETERANS WITH RHEUMATOID ARTHRITIS

G. Cannon<sup>1</sup>, C.-C. Teng<sup>1</sup>, N.A. Accortt<sup>2</sup>, D.H. Collier<sup>2</sup>, T.-C. Lin<sup>2</sup>, B.C. Sauer<sup>1</sup>. <sup>1</sup>Salt Lake City VA Medical Center and University of Utah, Salt Lake City; <sup>2</sup>Amgen, Thousand Oaks, USA

**Background:** Current rheumatoid arthritis (RA) treatment guidelines recommend the use of disease activity measures (DAMs) to guide RA therapy. These guidelines recommend considering escalation of therapy in RA patients with high or moderate disease activity. Recent work by our group has demonstrated that many RA patients with high/moderate RA by Disease Activity Score with 28 joints (DAS28) did not have therapy escalated despite active disease ( $\text{DAS28} \geq 3.2$ ).

**Objectives:** 1) To determine if the rate of major therapeutic change (MTC) for RA patients with high/moderate disease activity based on DAS28 was similar when measured using two other common DAMs; 2) to compare the ability of different DAMs to predict MTC across the full spectrum of RA disease activity.

**Methods:** US Veterans enrolled in the VA Rheumatoid Arthritis (VARA) registry with 1) a complete set of DAMs (DAS28, Clinical Disease Activity Index [CDAI], Routine Assessment of Patient Index Data 3 [RAPID3]) recorded (index date), 2) two other visits during the preceding 18 months separated by at least 60 days, and 3) clinical data available for 18 months prior to through 30 days following index date were eligible. Each patient was assessed for MTC within 1 week before and 30 days after index date. MTC was defined as any of the following: 1) initiation of new biologic or nonbiologic DMARD, 2) escalation of DMARD dose by  $\geq 25\%$ , 3) initiation of prednisone (as new agent or after 90 day gap during baseline), or 4) increase in monthly average prednisone dose by 25% and/or 5) injection of 2 or more joints with corticosteroids. MTC was analysed by DAM severity thresholds of 1) high, moderate, low, and remission, and 2) high, high/moderate, and high/moderate/low levels. Analyses of the latter thresholds included sensitivity, specificity, predictive values, and accuracy estimations for MTC at each DAM level.

**Results:** Of 1776 eligible patients, 89% were male, mean age was 63.4 years, mean disease duration was 13.4 years, 79% tested positive for rheumatoid factor,

and 63% positive for anti-cyclic citrullinated peptide antibodies. Overall, 33.1% (591/1776) of patients had an MTC. A markedly larger percentage of patients with high disease activity had MTC (range 55.1%–43.5%) compared to patients with moderate disease (range 38.7%–27.8%) (table 1). Sensitivity, specificity, predictive values, and accuracy at each DAM threshold level varied markedly by DAM, with RAPID3 having a higher sensitivity, lower specificity, and less accuracy than DAS28 or CDAI (table 2).

**Abstract FRI0018 – Table 1.** Rates of MTC Stratified by DAM

	Patients with MTC, n/N (%)		
	DAS28	CDAI	RAPID3
High	165/313 (52.7%)	231/419 (55.1%)	346/795 (43.5%)
Moderate	285/737 (38.7%)	219/601 (36.4%)	155/568 (27.8%)
Low	72/283 (25.4%)	105/547 (19.2%)	47/217 (21.7%)
Remission	69/443 (15.6%)	36/209 (17.2%)	43/206 (20.9%)

n, number of patients with MTC; N, number of patients with level of disease severity

**Abstract FRI0018 – Table 2.** Performance of DAMs for Prediction of MTC

		Positive Threshold		
		High	High/Moderate	High/Moderate/Low
Sensitivity	DAS28	27.9%	76.1%	88.3%
	CDAI	39.1%	76.1%	94.9%
	RAPID3	58.5%	84.8%	92.7%
Specificity	DAS28	87.5%	49.4%	31.6%
	CDAI	84.1%	51.9%	14.6%
	RAPID3	62.1%	28.1%	13.8%
Positive Predictive Value	DAS28	52.7%	42.9%	39.2%
	CDAI	55.1%	44.1%	35.4%
	RAPID3	43.5%	37.0%	34.9%
Negative Predictive Value	DAS28	70.9%	80.6%	84.4%
	CDAI	73.5%	81.3%	82.8%
	RAPID3	75.0%	78.7%	79.1%
Accuracy	DAS28	67.7%	58.3%	50.5%
	CDAI	69.1%	60.0%	41.0%
	RAPID3	60.9%	47.0%	40.0%

**Conclusions:** Most patients with high/moderate disease activity did not have a MTC. This observation was consistent regardless of which DAM was utilised. MTC increased with disease activity with all DAMs; however, DAS28 and CDAI appeared to have greater accuracy than RAPID3 at predicting MTC at all disease severity thresholds. There is need for continued evaluation of DAM thresholds for defining disease activity for MTC decisions, better DAMs, and/or better application of DAMs in clinical practice to improve the treatment of patients with active RA.

**FRI0019** **ARE DISEASE ACTIVITY, DISABILITY OR PSYCHOLOGICAL FACTORS MOST ASSOCIATED WITH PATIENTS WITH RHEUMATOID ARTHRITIS BEING SATISFIED WITH THEIR CONDITION AFTER 12 MONTHS FOLLOWING TREATMENT ONSET?**

J. Gwinnett<sup>1</sup>, K. Hyrich<sup>1,2</sup>, M. Lunt<sup>1</sup>, A. Barton<sup>2,3</sup>, S. Verstappen<sup>1,2</sup>, on behalf of RAMS coinvestigators. <sup>1</sup>Arthritis Research UK Centre for Epidemiology, The University of Manchester, <sup>2</sup>NHR Manchester Biomedical Research Centre, Manchester University Hospitals NHS Foundation Trust, <sup>3</sup>Arthritis Research UK Centre for Genetics and Genomics, The University of Manchester, Manchester, UK

**Background:** An important treatment goal in the management of patients with rheumatoid arthritis (RA) is patients being satisfied with their condition, the patient acceptable symptom state (PASS). It is unclear whether reduction in disease activity, the main therapeutic aim of RA treatment, is associated with reaching PASS, or whether reductions in other factors are also important.

**Objectives:** To analyse change over one year of disease activity, patient reported outcomes (PROs) and psychological factors and their association with PASS at one year.

**Methods:** The Rheumatoid Arthritis Medication Study (RAMS) is a prospective cohort of patients with RA starting MTX for the first time in the United Kingdom. At baseline and one year, patients reported demographics and completed pain and fatigue visual analogue scales (VAS-pain/VAS-fatigue), the Hospital Anxiety and Depression Scale (HADS-A, HADS-D) and the Health Assessment Questionnaire (HAQ). A research nurse performed a 28 swollen and tender joint count (SJC28/TJC28) and the disease activity score (DAS28) was calculated. Patients answered the question "Is your current condition satisfactory, when you take your general functioning and your current pain into consideration?" at baseline and at one year. Only patients not in PASS at baseline are included in this analysis. Change in disease related factors (SJC28, TJC28, DAS28), PROs (HAQ, VAS-pain, VAS-fatigue), and psychological factors (HADS-A, HADS-D) from baseline to one year were calculated (see table 1). Predictors of PASS at one year were assessed using multivariable logistic regression, adjusting for age and gender. The discriminative power of disease activity, PROs and psychological factors were assessed by comparing the area under the curve (AUC) of the receiver operating characteristic curve.

**Results:** Of 358 not in PASS at baseline (mean (SD) age: 58.1 (13.0) years; 244 (68.2%) women), 241 (67.3%) were in PASS after one year. The only independent predictors of PASS were change in HAQ, VAS-pain and HADS-D (OR (95% CI) per unit change from baseline: HAQ 0.38 (0.16, 0.91); VAS-pain 0.96 (0.95, 0.98); HADS-D 0.86 (0.75, 0.99)). The model containing PROs had significantly greater AUC compared to a disease activity model (0.91 vs. 0.84, p=0.004) and a psychological factors model (0.91 vs. 0.81, p<0.0001).

**Abstract FRI0019 – Table 1.** Baseline, one year and change scores stratified by whether patients were in PASS at one year

Variable	Median (IQR) baseline score		Median (IQR) one year score		Median (IQR) Change		
	PASS at one year	Not-PASS at one year	PASS at one year	Not-PASS at one year	PASS at one year	Not-PASS at one year	
Disease activity	SJC28	6.5 (2.5, 11.0)	6.0 (3.0, 12.0)	0.0 (0.0, 2.0)	3.0 (0.0, 7.0)†	-5 (-9, -2)†	-2 (-6, 1)†
	TJC28	6.0 (3.0, 12.0)	9.0 (5.0, 17.0)†	1.0 (0.0, 4.0)	6.0 (2.0, 14.0)†	-4 (-9, -1)†	-2 (-6, 3)†

**FRI0020** **ANTI-CEP-1 ANTIBODIES AND OTHER AUTOANTIBODIES IN EARLY ARTHRITIS**

M. Ponikowska<sup>1</sup>, J. Świerko<sup>2</sup>, B. Nowak<sup>3</sup>, L. Korman<sup>2</sup>, P. Wiland<sup>2</sup>. <sup>1</sup>Department of Rheumatology and Internal Medicine, Wrocław University Hospital; <sup>2</sup>Department of Rheumatology and Internal Medicine; <sup>3</sup>Department of Pharmacology, Wrocław Medical University, Wrocław, Poland

**Background:** As it is very important to identify patients with a high risk of developing rheumatoid arthritis (RA), new, diagnostic methods, evaluating the possibility of progression from undifferentiated arthritis (UA) to RA are needed.

**Objectives:** The aim of this work was the evaluation of the frequency of rheumatoid factor, anti-cyclic citrullinated peptide (anti-CCP) antibodies, mutated citrullinated vimentin antibodies (a-Sa), anti-CEP-1 antibodies, anti-filaggrin antibodies (AFA), heterogeneous nuclear ribonucleoprotein compies/anti-RA33-antibody (HnRNPI/RA33), anti-CarP antibodies (a-Carp) in patients with early arthritis.

**Methods:** 74 patients with early arthritis and 20 healthy volunteers were enrolled to the study. 51 patients were diagnosed with RA, 23 with UA. Exclusion criteria were the application of disease-modifying antirheumatic drugs or glucocorticosteroids. In all patients the following laboratory tests were performed: inflammatory markers, rheumatoid factor (RF) and antibodies mentioned above, together with necessary diagnostic that enables diagnosis.

**Results:** In patients with early arthritis the sensitivity and specificity of the presence of RF was 69% and 95%, respectively, and of anti-CCP was 67% and 97%. In patients with early arthritis we observed significantly higher concentration of CEP-1 (65.8±111.6) than in the healthy group (2.0±0.0). In RF(+) RA patients we

observed higher concentration of antibodies a-Sa and CEP-1 than in other groups.

Antibodies a-Sa were positive in 69% of RF(+) RA patients, in 37% of RF(-) RA patients, in 26% of UA patients and in 10% of healthy people. In 8 aCCP (-) and RF(-) patients we observed the presence of a-Sa; 3 of them were diagnosed with RF(-) RA with and 5 with UA. Anti-CEP-1 antibodies were positive in 77% of RF(+) RA patients, in 56% of RF(-) RA patients, in 4,5% of UA patients, but their presence were not observed in the healthy people. In 8 aCAPP (-) and RF (-) patients we observed positive anti-CEP-1 antibodies; 6 of them were diagnosed with RA, 2 of them with UA. Anti-CEP-1 antibodies were positive in 50% of RF(-) RA patients, in whom there was no aCCP nor RF, and only in 4,5% of UA patients.

In case of marking a-Car-P, positive values were present in: the group of RF(+) RA in 40% of patients, in patients diagnosed with RF(-) RA in 6%, in case of UA in 22% of patients. In patients with RF(+) RA, positive anti-CarP antibodies are present statistically significantly more often than in the group of RF (-) RA patients ( $p < 0,05$ ).

In case of marking hnRNP/RA33 and AFA no statistically significant differences between RF(+) RA, RF(-) RA and UA in their occurrence were observed. In patients with arthritis no correlation between smoking and analysed autoantibodies was observed. In smokers higher CRP concentration and ESR values was observed.

**Conclusions:** Our results suggest that a-Sa and CEP-1 parameters allow to differentiate RF(+) RA, RF(-) RA and UA, but do not differentiate UA from RF(-) RA. Marking CEP-1 in patients with early arthritis may help in differentiation between RF(-) RA and UA. Marking CEP-1 and a-Sa may be useful in diagnosing early arthritis patients. The presence of Anti-CarP antibodies in UA patients is probably considerable risk factor in RA development. Smoking cessation may contribute to decrease RA activity.

FRI0021

#### PREDICTORS OF RHEUMATOID ARTHRITIS DEVELOPMENT IN PATIENTS WITH EARLY UNDIFFERENTIATED ARTHRITIS: A 2-YEARS FOLLOW-UP STUDY

J. Molina Collada, M.G.G. Álvarez, V. Navarro-Compán, L. Nuño Nuño, A. Villalba, D. Peiteado, P. Bogas, A. Balsa. *Rheumatology, Hospital Universitario La Paz, Madrid, Spain*

**Background:** Early treatment of rheumatoid arthritis (RA) improves longterm outcomes<sup>(1)</sup>. However, at the beginning of the disease, some patients with RA fall within undifferentiated arthritis (UA) patients. Several studies have shown that almost half of patients with UA may experience spontaneous remission<sup>(2)</sup>. So, in order to prevent overtreatment and poor outcomes, the identification of predictors of RA development is desirable.

**Objectives:** To determine the frequency of patients with UA evolving into RA after 2 years of follow-up and the factors contributing to predict this outcome.

**Methods:** A prospective analysis of an early arthritis cohort of 1377 patients from 1993 to 2017 was undertaken. For this study, 2 years follow-up data of patients who presented with UA were analysed. A detailed baseline assessment was completed including clinical features, physical examination and laboratory tests. Patients were stratified in two groups based on progression to RA (according to physician's diagnosis) or to another disease (non-RA). First, differences between groups were tested using chi-squared and Student-t tests in the univariate analysis. Second, multivariate logistic regression models were employed to investigate the association between possible predictive factors and RA development.

**Results:** A total of 471 UA patients were included for analysis. Mean age was 48.7±17.5 years, 352 (74.9%) were females, and mean symptoms duration was 13.9±13.9 weeks. After 2 years of follow-up, 93 (19.7%) of UA patients evolved into RA. Meanwhile, 175 (37.2%) remained undifferentiated and 203 (43.1%) developed into other musculoskeletal diseases. In the univariate analysis, the presence of rheumatoid factor (RF) and anti-citrullinated peptides antibodies (ACPA), tender and swollen joint count, duration of morning stiffness, smoking, symmetry and ESR values were significantly associated with RA development. In the multivariate analysis, RF (OR=5,899; 95% CI 1,795–19,382), ACPA (OR=123,238; 95% CI 29,353–517,410) and swollen joint count (OR=1,233; 95% CI 1,048–1,450), remained significantly associated with RA development (table 1).

**Abstract FRI0021 – Table 1.** Independent predictors of RA development based on logistic regression model

	Odds ratio	95% C.I.	
		Lower	Upper
Physician Global Assessment (0–100)	1016	,983	1051
28 Tender Joint Count	,949	,852	1057
28 Swollen Joint Count	1233	1048	1450
ESR(mm/h)	1018	,992	1044
Race	,633	,021	19 250
Smoking	,851	,223	3245
Symmetry	,568	,145	2225
RF(IU/mL)	5899	1795	19 382
ACPA(IU/mL)	1 23 238	29 353	5 17 410

**Conclusions:** Approximately, 1 out of 5 patients with UA evolves into RA after 2 years of follow-up. Swollen joint count, and the presence of rheumatoid factor (RF) and anti-citrullinated peptides antibodies (ACPA) are independent predictors for the development of RA, supporting the early DMARDs initiation in such patients.

#### RAPID AND SUSTAINED REMISSION CONTRIBUTES TO IMPROVED PSYCHOSOCIAL OUTCOMES AFTER 1 YEAR OF TREATMENT IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: DATA FROM THE CARERA TRIAL

K. Van der Elst<sup>1,2</sup>, P. Verschuere<sup>1,2</sup>, V. Stouten<sup>2</sup>, S. Pazmino<sup>2</sup>, D. De Cock<sup>2,3</sup>, J. Joly<sup>1</sup>, P. Moons<sup>4,5</sup>, R. Westhovens<sup>1,2</sup>. <sup>1</sup>Rheumatology, University Hospitals Leuven; <sup>2</sup>Skeletal Biology and Engineering Research Centre, KU Leuven, Leuven, Belgium; <sup>3</sup>Manchester Academic Health Science Centre, University of Manchester, Manchester, UK; <sup>4</sup>Centre for Health Services and Nursing Research, KU Leuven, Leuven, Belgium; <sup>5</sup>Institute of Health and Care Sciences, University of Gothenburg, Gothenburg, Sweden

**Background:** The goal of early rheumatoid arthritis (RA) treatment is to reach remission as soon as possible, as this initial treatment response is a strong predictor of long-term clinical outcomes. Rapidly reaching remission is not only clinically meaningful, it also matters from the patient's perspective.<sup>1</sup> Yet, the influence of an initial response on patients' future psychosocial functioning remains understudied in early RA.

**Objectives:** To explore the association between the initial clinical response of patients with early RA and their psychosocial functioning after 1 year of treatment.

**Methods:** We included patients with early RA (disease duration  $\leq 1$  year) who started first-time treatment within the Care in early RA (CareRA) trial.<sup>2</sup> Based on the speed of response defined as the response at week 16, and the stability of response evaluated from week 16 onwards until week 52 of treatment, we created 4 profiles of initial clinical response relevant to patients: persistent responders, secondary failures, delayed responders and non-responders (table 1). Having a response was defined as a disease activity score (DAS28CRP) < 2.6 indicating remission. Psychosocial functioning was operationalized using relevant subscales of the Short-form 36 (SF-36) and the Revised Illness Perception Questionnaire (IPQ-R) (table 2). We built multiple linear regression models for each psychosocial outcome separately adjusted for confounding variables. Imputation using the Expectation-Maximisation method was performed for missing SF-36 and IPQ-R scores (range 22.2% > 23.1%) only at week 52.

**Results:** The 333 included patients shared typical characteristics of an early RA population (69.5% being woman, mean(SD) age of 52.3 (13.0) years), with no differences in demographics between patients for the different response profiles. In almost all regression models, the initial clinical response profiles were identified as significant predictors for each psychosocial outcome at week 52 (table 2). A rapid and sustained response, when compared to having a relapse after initial response or a delayed response or no response at all, resulted in higher vitality, less interference with normal social activities, less problems with work or other daily activities because of emotional problems, an improved mental health, more positive beliefs about disease consequences, a higher belief in the effect of treatment, and a more coherent illness understanding.

**Abstract FRI0022 – Table 1.** Definitions of the self-created profiles of initial clinical response throughout the first year of treatment in patients with early rheumatoid arthritis.

Clinical response* profiles	Group size	Definition of the profiles
Persistent responders	n=140	Early response at week 16 and stability of this response over year 1
Secondary failures	n=92	Early response, but relapse between week 16 and week 52 of treatment
Delayed responders	n=71	Late response, between week 16 and week 52 of treatment
Non-responders	n=30	No response to treatment throughout year 1

\* Having a response was defined as a disease activity score (DAS28CRP) <2.6 indicating remission.

**Abstract FRI0022 – Table 2.** The contribution of the initial clinical response to psychological outcomes (patient-reported) after 1 year of early RA treatment.

## FIVE-YEAR PROGRESSION OF RHEUMATOID ARTHRITIS DISEASE ACTIVITY AND QUALITY OF LIFE IN 2002 AND 2011. HAVE REDUCTIONS IN DISEASE ACTIVITY IN RECENT YEARS RESULTED IN IMPROVEMENTS IN QUALITY OF LIFE?

L. Carpenter<sup>1</sup>, S. Norton<sup>1</sup>, E. Nikiphorou<sup>2</sup>, P. Kiely<sup>3</sup>, J. Dixey<sup>4</sup>, P. Creamer<sup>5</sup>, D. Walsh<sup>6</sup>, A. Young<sup>7</sup>, on behalf of ERAS-ERAN. <sup>1</sup>Health Psychology; <sup>2</sup>Academic Rheumatology, King's College London; <sup>3</sup>Rheumatology, St George's Hospital, London; <sup>4</sup>Rheumatology, The Royal Wolverhampton, Wolverhampton; <sup>5</sup>Rheumatology, North Bristol NHS Trust, Bristol; <sup>6</sup>Rheumatology, The University of Nottingham, Nottingham; <sup>7</sup>Post Graduate Medical School, University of Hertfordshire, Hatfield, UK

**Background:** The treat-to-target (T2T) approach, with earlier, aggressive treatment has resulted in improvements in rheumatoid arthritis (RA) outcomes<sup>1,2</sup>. Whether these improvements have translated into improvements in patient reported outcomes is less clear. Studies have indicated declines in pain and function as well as depression and anxiety. However, these studies are limited to short

follow-up periods or were restricted to cross-sectional, rather than longitudinal analyses.

**Objectives:** To assess changes in 5 year progression rates for disease activity and patient reported outcomes in a prospective cohort of early RA patients between 2002 and 2011.

**Methods:** The Early RA Network (ERAN) is a longitudinal prospective cohort study that recruited 1236 early RA patients from 2002 to 2011. DAS-28 and SF-36 were measured at baseline, 6 months, 12 months and then yearly. Multi-level linear regression were used to model 5 year progression rates of both DAS-28 and SF-36 in patients recruited between 2002–2011. Models controlled for sex and age and seropositivity at baseline. DMARD use at baseline was controlled for using propensity score weighting. Year of diagnosis was entered as a continuous variable, allowing for the mean of the outcome variables to be estimated for 2002 and 2011. Restricted cubic splines were used to account for non-linear progression over time.

**Results:** Disease activity for patients diagnosed in 2011 demonstrated a statistically significant decrease at year 5 compared to patients diagnosed in 2002 (5 year estimated mean difference –0.35; 95% CI 0.22–0.49, p<0.001). Using the SF-36 measure, Physical Function, Bodily Pain, Vitality (indicating fatigue) and Mental Health indicated similar levels at year-5 between those patients diagnosed in 2011 to those diagnosed in 2002 (p>0.05). Mental health was similar to the normalised population mean of 50, irrespective of year diagnosed. However, levels of vitality/fatigue, function and pain remain less favourable for all early RA patients over the first 5 years.

**Conclusions:** Although disease activity has shown a marked decline at 5 years between 2002 and 2011, there is little evidence that this has led to improvements of an equivalent magnitude in function, pain, fatigue and mental health. Treatment should also focus on improved function, pain management, fatigue and mental health as part of the T2T protocol.

## DO AGE AND EDUCATION INFLUENCE THE DISEASE ACTIVITY SCORE? AN EXPLORATIVE ANALYSIS IN THE NORWEGIAN COHORT STUDY NOR-DMARD

M. Van Onna<sup>1,2</sup>, P. Putrik<sup>1,2</sup>, E. Lie<sup>3</sup>, T. Kvien<sup>3</sup>, A. Boonen<sup>1,2</sup>, T. Uhlig<sup>3</sup>. <sup>1</sup>Rheumatology, Maastricht University Medical Center; <sup>2</sup>CAPHRI Research Institute, Maastricht University, Maastricht, Netherlands; <sup>3</sup>Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

**Background:** While ageing influences auto-immune inflammation and the structure of the joints, knowledge about its influence on appraisal of disease outcomes is more limited.

**Objectives:** To examine the effect of age and education on the components of the 28-joint Disease Activity Score (DAS28-ESR) in patients with rheumatoid arthritis (RA).

**Methods:** Baseline data of Disease Modifying Anti-Rheumatic Drug (DMARD)-naive patients with RA from the Norwegian Register of DMARDs (NOR-DMARD) were used. Linear regression models, adjusted for gender and education (low, intermediate and high level), were used to investigate the strength of the association between age (<45, 45–65 and >65 years) and each DAS28-component (Erythrocyte Sedimentation Rate (ESR), 28-tender joint count (28-TJC), 28-swollen joint count (28-SJC), and patient global assessment of disease activity (PGA)). Adjusted scores for components of DAS28 and total DAS28-ESR were computed and relative change across age categories was explored. Interactions between age and gender and age and education were also tested.

**Results:** Baseline data from 2037 patients (mean (SD) age 55.2 (14.0) years, 68% female) were available. Regression models were stratified for gender ( $p$  – interaction <0.05); education was a significant covariate in all regression analyses. Older males (>65 years) with an intermediate level of education would have a 21% higher ESR and 14% higher 28-SJC, as compared to their younger counterparts (<45 years). For females in the intermediate education category, the corresponding differences were 16% and 15%, respectively. Conversely, differences in 28-TJC and the PGA between the highest and lowest age group were negligible in both males and females (table 1). In absolute effects on DAS28, this means that in male patients the adjusted DAS28 for those >65 years was 4.8 compared to 4.3 in patients <45 years (females 5.0 compared to 4.6). For low and high levels of education, the results were comparable in terms of relative contribution to each DAS28-component.

**Abstract FRI0024 – Table 1.** Effect of age on DAS28 (ESR) for patients with an intermediate educational level.

Component	< 45 years (reference) n = 181 (25%)	45 – 65 years n = 419 (58%)	> 65 years n = 123 (17%)	Difference between highest and lowest age group (%)
<b>Males</b>				
28-TJC	1.32	1.33	1.34	2%
28-SJC	0.62	0.66	0.71	14%*
PGA	0.57	0.59	0.58	2%
ESR	1.83	2.00	2.22	21%*
DAS28-ESR	4.34	4.58	4.83	11%
<b>Females</b>				
28-TJC	1.32	1.39	1.33	1%
28-SJC	0.59	0.63	0.68	15%*
PGA	0.67	0.68	0.68	1%
ESR	1.99	2.14	2.31	16%*
DAS28-ESR	4.57	4.84	5.00	9%

Abbreviations: TJC, tender joint count; SJC, swollen joint count; PGA, patient global assessment; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; DAS28, 28-joint Disease Activity Score.

\*Difference in scores is significant ( $p < 0.05$ ).

**Conclusions:** As expected, DAS28 increases with age. However, the components of DAS28 increase at different rates. The age-related increase in ESR and 28-SJC without a simultaneous increase in 28-TJC and PGA might imply that age-related processes (e.g. osteoarthritis and physiological increase in ESR) drive the DAS28 in older patients. The observed patterns were largely comparable between males and females. The age effect on DAS28 is relevant in a treat-to-target strategy and may be considered when identifying a defined target in individual patients.

### FRI0025 SERUM MEDIATED PEPTIDYLARGININE DEIMINASE (PAD) ACTIVATION IN EARLY RHEUMATOID ARTHRITIS

M.K. Jonsson<sup>1,2</sup>, K. Falkowski<sup>3</sup>, A. Aliko<sup>4</sup>, A.-B. Aga<sup>2</sup>, S. Lillegraven<sup>2</sup>, J. Sexton<sup>2</sup>, B.-T. S. Fevang<sup>1,4</sup>, P. Mydel<sup>4</sup>, E.A. Haavardsholm<sup>2,5</sup>. <sup>1</sup>Department of Rheumatology, Haukeland University Hospital, Bergen; <sup>2</sup>Department of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; <sup>3</sup>Department of Microbiology, Jagiellonian University, Kraków, Poland; <sup>4</sup>Department of Clinical Science, Broegelmann Research Laboratory, Bergen; <sup>5</sup>University of Oslo, Oslo, Norway

**Background:** Peptidylarginine deiminases (PADs) are a family of enzymes catalysing the conversion of arginine residues to citrulline, a post translational modification which has been recognised in the generation of neo-epitopes due to anti-citrullinated protein antibodies (ACPAs) in rheumatoid arthritis (RA). ACPAs are

included in the classification criteria for RA, and may be present before disease onset and predictive of disease progression.

**Objectives:** To investigate whether serum of patients with early RA have the capacity to significantly increase the citrullination performed by PAD enzymes, and the possible role of increased enzyme activation as a mechanism preceding the production of ACPAs.

**Methods:** Serum from DMARD-naive, early RA patients from the ARCTIC trial<sup>1</sup> classified according to the 2010 ACR/EULAR criteria were analysed for PAD4 activating capacities using HPLC fluorometric method. A sample was defined as positive if above mean +2 SD of the healthy controls. Patient characteristics and subgroups with PAD activity were assessed using Mann-Whitney U-test and chi-square test as appropriate.

**Results:** A total of 225 patients and 63 controls were included in the study. Patient characteristics and measures of disease activity and radiographic damage are presented in the table 1. Median PAD activity levels were higher in patients than in healthy controls (8768 [7491,11393] vs. 7046 [6347,7905],  $p < 0.0001$ ; figure 1). ACPA and rheumatoid factor (RF) positive patients had higher PAD activity than ACPA and RF negative patients (9104 [7739,13213] vs. 7281 [6764,9010],  $p < 0.0001$ , and 8871 [7715,12259] vs. 8407 [6867,10062],  $p = 0.048$ , respectively). PAD positivity occurred in 42% (n=95) of the patients and was more prevalent in ACPA positive compared to ACPA negative patients (47 vs. 20%,  $p = 0.002$ ), but not in RF positive vs. RF negative patients (44 vs. 38%,  $p = 0.49$ ). Disease Activity Score was numerically higher in patients positive for PAD than patients who were PAD negative (3.6 (1.1) vs. 3.3 (1.2),  $p = 0.08$ ).

**Abstract FRI0025 – Table 1.** Baseline characteristics in subgroups of RA patients and healthy controls

### U-ACT-EARLY TRIAL 3 YEARS FOLLOW-UP. THE LONGER EFFECTIVENESS OF TREAT-TO-TARGET STRATEGIES IN EARLY RA WITH TOCILIZUMAB, METHOTREXATE, OR THEIR COMBINATION

M. Verhoeven<sup>1</sup>, M. de Hair<sup>1</sup>, P. Welsing<sup>1</sup>, A. Pethö-Schramm<sup>2</sup>, M. Borm<sup>3</sup>, X. Teitsma<sup>1</sup>, J. van Laar<sup>1</sup>, F. Lafeber<sup>1</sup>, J. Bijlsma<sup>1</sup>, J. Jacobs<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands; <sup>2</sup>Global Medical Affairs – Immunology, F. Hoffmann-La Roche AG, Basel, Switzerland; <sup>3</sup>Gastrolimmunology, Roche Nederland BV, Woerden, Netherlands

**Background:** The U-Act-Early trial was a 2 year placebo controlled, double-blind randomised controlled trial in early (DMARD-naïve) RA patients treated to the target of sustained remission (SR), starting with tocilizumab (TCZ), methotrexate (MTX) or their combination (TCZ +MTX)<sup>1</sup>. When the treatment target was achieved, medication was tapered and stopped, if patients remained in remission. During the trial period, the strategies starting with TCZ were more effective than the strategy initiating MTX only. Subsequently, patients were followed for 3 years, during which treatment was open and according to usual care.

**Objectives:** To establish the effectiveness of step-up strategies starting with MTX, TCZ or their combination in early RA over a 5 year period.

**Methods:** 226 of the 317 patients starting in the U-Act-Early trial (initial strategy: 75 TCZ +MTX, 79 TCZ, 72 MTX) participated in the 3 year follow-up phase.

DAS28 was collected every 3 months during the first year and every 6 months thereafter.

The primary endpoint, was SR, defined as DAS28 <2.6 AND 28 joint count ≤4 for >24 weeks. Secondary endpoints were sustained drug free remission (sDFR), defined as remission for ≥3 months after tapering and stopping all medication during SR, and DAS28 over 5 years.

Differences between the randomised strategies in proportions of patients achieving SR and sDFR and durations of SR and sDFR were tested with Cochran-Mantel-Haenszel and Kruskal-Wallis tests, respectively.

A mixed model analysis was used to compare DAS28 over time, with a random intercept and fixed effects for: treatment, visit-week, the interaction visit-week\* treatment, and it was corrected for gender, age, and for DAS28, RA-duration, CRP and RF-positivity at baseline.

**Results:** Baseline characteristics at the start of U-Act-Early of the patients included in this 3 year follow-up study were not significantly different from those of all patients included in U-Act-Early trial. Over 5 years, SR was achieved in 224/226 (99%) patients without significant differences (p=0.15) between the initial treatment strategies in proportions of patients achieving it, nor in durations (p=0.96) of these endpoints (table 1). Neither between-group significant differences were found for sDFR (proportion; p=0.10, duration; p=0.27), only a tendency for longer duration in TCZ +MTX. The mean DAS28 over 5 years was not significantly different between initial strategy groups (figure 1), but it was on average 0.15 (95% CI -0.12 to 0.42) units higher in the TCZ+(MTX) groups, compared to MTX initiation group.

**Abstract FRI0026 – Table 1.** Outcome for sustained (drug free) remission over 5 years

	Initial treatment strategy group			p-value
	TCZ+MTX	TCZ+placebo	MTX+placebo	
<b>Sustained remission</b>				
Proportion achieving, n/N (%)	75/75 (100)	77/79 (97.5)	72/72 (100)	0.15 <sup>1</sup>
Duration weeks, Median (IQR)	49 (37 - 81)	52 (40 - 71)	46 (36 - 114)	0.96 <sup>2</sup>
<b>Sustained drug free remission</b>				
Proportion achieving, n/N (%)	26/75 (34.7)	19/79 (24.1)	14/72 (19.4)	0.10 <sup>1</sup>
Duration weeks, Median (IQR)	106 (72 - 157)	83 (31 - 156)	71 (30 - 147)	0.27 <sup>2</sup>

<sup>1</sup>= Cochran-Mantel-Haenszel test. <sup>2</sup>=Kruskal-Wallis test

**Abstract FRI0026 – Figure 1.** DAS28 over time stratified for initial treatment strategy

**Conclusions:** On the short term, initiation of TCZ-based strategies yields the most benefit, but on longer term, no difference in important clinical outcomes was found anymore between initial strategy groups, probably due to continuation of the treat-to-target principle<sup>2</sup>. Almost all patients achieved SR over 5 years, with a tendency for longer duration of sDFR in the TCZ+MTX strategy.

### PATIENT-BASED DISEASE ACTIVITY SCORE PREDICTS FLARE BETTER THAN IMPROVEMENT – BLOOD TEST PROVIDES INSIGNIFICANT CONTRIBUTION

M.-H. A. Leung<sup>1</sup>, C.-S. Lau<sup>2</sup>, E. Choy<sup>3</sup>. <sup>1</sup>Department of Medicine, Queen Elizabeth Hospital, Kowloon; <sup>2</sup>Department of Medicine, LKS Faculty of Medicine, University of Hong Kong, HK, Hong Kong; <sup>3</sup>Rheumatology and Translational Research, Cardiff University School of Medicine, Cardiff, UK

**Background:** Patient-derived Disease Activity Score (PDAS) was developed to allow rheumatoid arthritis (RA) patients to self-assess without the need of evaluator. Two versions, PDAS1 with ESR (erythrocyte sedimentation rate) and PDAS2 without, had been validated and shown to correlate well with DAS28 and display responsiveness to change in patients put on disease-modifying drugs. PDAS has the potential to inform disease activity change between evaluator's assessments and/or blood tests. This would be a useful monitoring tool to deliver treat-to-target tight RA control.

**PDAS1**=0.019×(PGA out of 100)+0.842×ln(ESR +2)+0.432×ln(patient 50 TJC +2)+0.271×HAQ

$PDAS2=2.667+0.021 \times (PGA \text{ out of } 100)+0.483 \times HAQ +0.033 \times (\text{patient } 28 \text{ SJC}) +0.002 \times (EMS \text{ in minutes})$  whereas PGA=patient global assessment, TJC=tender joint count; SJC=swollen joint count; HAQ=Health Assessment Questionnaire; EMS=early morning stiffness

**Objectives:** To assess whether PDAS is sensitive to change for an evaluator-based flare and improvement and whether PDAS1 (with ESR) is better than PDAS2.

**Methods:** A prospective cohort of 92 RA patients completed PDAS1 and 2 scores at the first and second clinic visits in a tertiary referral rheumatology centre. **Flare** was taken as increased RA activity from Simplified Disease Activity Index (SDAI) (remission or low activity) at the 1st visit → (moderate or high activity) at the 2nd visit, while **improvement** was the reverse change. Overall changes ( $\Delta$ ) of SDAI and PDAS1 and 2, in both directions, between these two visits were correlated using Spearman correlation coefficients. Further subgroup analysis (flare and improvement) was done by comparing the magnitude of changes between SDAI and PDAS1 and 2 using Mann-Whitney U test.

**Results:** Mean age of the cohort was 60 years, mean RA duration 14 years, 90% female, 71% sero-positive, 64% in remission/low disease activity at the 1st visit and follow-up interval was 17.5 weeks (standard deviation 9.4 weeks). At the 2nd visit, 11 out of 59 patients had a flare while 10 out of 33 patients improved. The Spearman correlation coefficients of  $\Delta SDAI$  with  $\Delta PDAS1$  and  $\Delta PDAS2$  were 0.55 and 0.54 respectively (both  $p \leq 0.001$ ). Data distributions were depicted in the scatterplot.

For the subgroup of flare, both  $\Delta PDAS1$  and 2 were significantly associated with the corresponding  $\Delta SDAI$  (all  $p < 0.02$ ). However, this association was not significant in the subgroup of improvement (See table 1). PDAS1 did not appear to perform better than PDAS2 in both groups of flare and improvement.

Abstract FRI0027 – Table 1

Flare (n=59)			
	Flare (11/59)	No flare (48/59)	P-value
$\Delta SDAI$	+6.90 (8.20)	0.12 (0.16)	<0.001
$\Delta PDAS1$	+0.75 (1.40)	0.01 (0.59)	0.016
$\Delta PDAS2$	+0.52 (0.74)	0.00 (0.32)	<0.001
Improvement (n=33)			
	Improved (10/33)	Not improved (23/33)	P-value
$\Delta SDAI$	-6.80 (7.20)	0.40 (6.90)	<0.001
$\Delta PDAS1$	-1.40 (0.96)	0.06 (0.49)	0.20
$\Delta PDAS2$	-0.16 (0.35)	0.00 (0.54)	0.25

Values are median (interquartile range). P-values are results of Mann-Whitney U test.

**Conclusions:** Overall PDAS1 and 2 are sensitive to change, but both predicted flare better than improvement. Clinically signalling flare has a far greater utility than documenting improvement. PDAS2 was as sensitive as PDAS1 in predicting flare yet without the need of a blood test for ESR. Hence, PDAS2 is suitable to serve as a purely patient-based home monitoring tool to detect a flare.

**Background:** Using a treatment target in rheumatoid arthritis (RA), such as DAS-28 and involving patients in their disease management can improve prognosis.

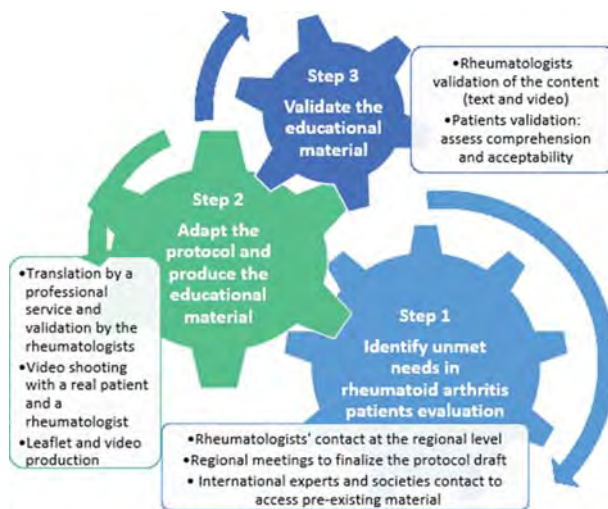

**Objectives:** To develop and implement an educational video that instructs patients with RA for self-assessment of disease activity using DAS-28.

**Methods :** *Step 1:Initiation.* Rheumatologists from some Middle Eastern Arab countries were invited to participate in this study. International experts and societies were contacted to access pre-existing educational material.

*Step 2: Development.* Different material sources were synthesized and translated into Arabic and validated by the rheumatologists. The educational video was shot by a professional team with a real patient and a rheumatologist on set.

*Step 3. Validation.* The final products (leaflets and video) were validated by the rheumatologists and tested with patients (figure 1). Obstacles were noted at the various study levels.

**Results:** 23 rheumatologists from 7 Middle Eastern Arab countries participated in the study. A one-page educational leaflet was developed in Arabic and English languages. An educational video presenting the treat-to-target concept and the basics of DAS performance was produced in Arabic language with English subtitles. Obstacles at the rheumatologist, patient, cultural and logistic levels were identified and the potential solutions were addressed by the study team.

Abstract FRI0028 – Table 1

Rheumatologist	Patient	Cultural	Logistics
DAS as target	Patient empowerment	Uniform text	Multiple IRB
Patient empowerment	Video understanding	Acceptable video	Funding
Patient adherence	Confidence in performance	Cultural mix	Computerised data

**Conclusions:** Collaboration between several countries sharing the same language and similar cultural backgrounds was possible and able to produce an

educational video aiming at the empowerment of RA patients for the self-assessment of their disease activity. The video will serve for future studies in the Arabic-speaking countries and will be available later for clinical use according to the rheumatologist's clinical judgment.

**Background:** 14–3–3 $\eta$  is a protein that is overexpressed in serum and joint fluid of patients with rheumatoid arthritis (RA) and may represent a diagnostic biomarker for RA.

**Objectives:** We assessed the prevalence and serum levels of 14–3–3 $\eta$  in patients with RA and with other rheumatic diseases.

**Methods:** Serum levels of 14–3–3 $\eta$  were measured in 96 patients with RA, in 101 patients with other rheumatic diseases and in 66 healthy subjects. The RA group consisted of 51 patients with well-established RA who were treated with different DMARDs, and 45 patients with early untreated disease (onset of less than 1 year). The disease control group included 33 patients with systemic lupus erythematosus (SLE), 44 patients with ankylosing spondylitis (AS) and 24 psoriatic arthritis (PsA) patients. All of the sera samples were evaluated by JOINT stat 14–3–3 $\eta$  ELISA test kits (Augurex Life Sciences Corp.). The cut-off was defined as 0.19 ng/ml.

**Results:** Median (IQR) 14–3–3 $\eta$  levels were significantly higher in the early RA group [0.25 ng/ml (0.075–3.11)] and in established RA patients [0.15 ng/ml (0.08–1.26)] in comparison with healthy subjects [0 ng/ml (0–0)] and disease controls: SLE [0.01 ng/ml (0–0.055)], AS [0.05 ng/ml (0–0.255)] and PsA [0.01 ng/ml (0–0.065)].

The prevalence of 14–3–3 $\eta$  positivity in early RA patients was 58%, significantly higher than in the disease control group (SLE: 9%,  $p < 0.001$ ; AS: 27%,  $p < 0.002$ , PsA: 12.5%,  $p < 0.001$ ) and in the healthy subjects group (5%,  $p < 0.001$ ). In established-RA patients, this prevalence was 43%, and it was significantly higher than in disease control and healthy subjects groups ( $p < 0.05$ ), excluding the AS group ( $p = 0.054$ ).

**Conclusions:** The concentration of 14–3–3 $\eta$  protein may be used to distinguish between patients with early RA and patients with other rheumatic diseases and serve as an additional biomarker in the diagnosis of RA.

#### FRI0030 COMPARISON OF CLINICAL AND ULTRASOUND MEASURES OF DISEASE ACTIVITY IN A LARGE NATIONAL 'REAL LIFE' COHORT OF RA PATIENTS

P. Zufferey<sup>1</sup>, D. Courvoisier<sup>2</sup>, M. Nissen<sup>3</sup>, B. Moeller<sup>4</sup>, H.R. Ziswiler<sup>5</sup>, L. Brulhart<sup>6</sup>, G. Tamborini<sup>7</sup>, A. Ciurea<sup>8</sup>, M.A. D'agostino<sup>9</sup>, A. Finckh<sup>3</sup>. <sup>1</sup>DAL, CHUV, Lausanne; <sup>2</sup>Rheumatology; <sup>3</sup>Huge, Geneva; <sup>4</sup>Rheumatology, Inselspital; <sup>5</sup>Osteorheuma, Bern; <sup>6</sup>Medecine, Hôpital Neuchatelois, la chaud de fond; <sup>7</sup>Unispital, Basel; <sup>8</sup>Unispital, Zurich, Switzerland; <sup>9</sup>Chu Ambroise Paré, Paris, France

**Background:** Several studies have demonstrated that the clinical measures of disease activity, such as the DAS-score and ultrasound (US) scores can sometimes yield discordant results. Little research has attempted to understand the reasons for the discordances and how frequently these discordances occur in real life. **Objectives:** The objectives of this study were to determine the percentage of patients presenting discordances between DAS and US assessments in a real-life cohort, to describe associated factors and to evaluate the evolution of both measures of disease activity over time.

**Methods:** All patients with at least one concomitant US assessment and DAS score, performed since the introduction of validated US scoring in the Swiss registry for inflammatory arthritis SCQM registry between 2009 and 2017 were included. Disease activity was categorised as remission, low, moderate and high activity based on previously established cut-offs (for clinical: DAS categories and for US: on cutoffs of SONAR score established in previous testing among RA patients and asymptomatic subjects<sup>1,2</sup>). A search for potential clinical and US predictors of discordance was performed. Finally a longitudinal analysis was done in all patients with at least 2 subsequent visits. Discordances were analysed using successively DAS and US categories as references (see table 1)

**Results:** 1196 out of 2367 assessments were found discordant (50.4%). The proportion discordant assessments did not significantly differ by clinical disease status or when US categories were considered as the reference. Disease activity was equally frequently over-estimated by DAS compared to US-score (26.9%) and by US-score compared to DAS (23.5%). Factors associated with the presence of discordant results were all the components of the DAS when US categories were the reference. The presence of tenosynovitis was a significant factor when DAS was the reference. For 1181 patients with several DAS and US assessments, the proportion of discordances during follow up remained similar to the initial evaluation. Initial discordance/concordances could however change status without obvious reason in up to 30% of cases.

Abstract FRI0030 – Table 1

DAS	Remission (<2.6)	Low/moderate activity (DAS $\geq$ 2.6 and $\leq$ 5.2)	High activity (>5.1)	Total
Discordance: n (%)	449/893 (50.3%)	547/1138 (48.1%)	200/341 (58.7%)	1196/2372 (50.4%)
US > DAS n (%)	449/893 (50.3%)	189/1138 (16.6%)	0	638/2369 (26.9%)
US $\leq$ DAS n (%)	0	358/1138 (31.5%)	200/341 (58.7%)	558/2369 (23.5%)
US	Remission	Low or moderate disease	Very active disease	Total
Discordance:	393/837 (47.0%)	559/1149 (48.7%)	245/386 (63.5%)	1196/2372 (50.4%)
US > DAS n (%)	0	393/1149 (34.2%)	245/386 (63.5%)	638/2372 (26.9%)
US $\leq$ DAS n (%)	393/837 (47.0%)	165/1149 (14.4%)	0	558/2372 (23.5%)

**Conclusions:** Discordances between DAS and US assessments appear to be higher than expected in real life. Both outcome measures could lead to over- or under-estimations of the disease activity.

FRI0031

**CHANGE IN FUNCTIONAL DISABILITY IN ACPA-POSITIVE ARTHRALGIA PATIENTS PRIOR TO PROGRESSION TO INFLAMMATORY ARTHRITIS**

P. Pentony<sup>1,2</sup>, S. Twigg<sup>1,2,3</sup>, J.L. Nam<sup>1,2</sup>, K. Mankia<sup>1,2</sup>, L. Hunt<sup>1,2</sup>, E.M. Hensor<sup>1,2</sup>, P. Emery<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>Leeds Biomedical Research Centre, National Institute of Health Research, Leeds; <sup>3</sup>Rheumatology, Bradford Teaching Hospital, Bradford, UK

**Background:** Only one study<sup>1</sup> has assessed functional limitation in the pre-clinical phase of rheumatoid arthritis. Finding that functional limitations already exist during the symptomatic pre-arthritis phase. It is unclear if patient reported outcomes (PROs) are associated with progression to inflammatory arthritis (IA).

**Objectives:** To assess baseline and change in PROs in the lead up to progression to IA and its association with progression to IA.

**Methods:** From June 2008 to August 2016, 205 CCP positive patients without clinical synovitis were observed 3 monthly for 12 months and then as clinically indicated. The end point was development of IA within 12 months. PROs including HAQ, fatigue VAS, disease activity (DA) VAS and pain VAS were recorded at each visit. Cox regression was used to assess the association of each PRO at baseline with progression, then latent growth curves (LGC) were constructed to model change in PRO over time. The LGC were added as covariates in the cox regression models to determine whether changes in PROs over 12 months were associated with progression.

**Results:** 204 anti-CCP positive cases were included (one case excluded as had only baseline data). Of these, 50 developed IA within 12 months. Estimated mean baseline HAQ was 0.53 (Standard Error, SE 0.04) and mean increase in HAQ 0.06 per 12 months (SE 0.04). Mean baseline fatigue and pain VAS were 32 mm and 28 mm, respectively (SE 1.8 and 1.6, respectively). Mean increases in fatigue and pain per 12 months were 3.9 mm (SE 2.6) and 3.5 mm (SE 2.1), respectively. Table 1 shows how hazard ratios for progression IA relate to baseline and change in HAQ and VAS. Hazards for progression to IA were increased with greater baseline fatigue VAS, and greater rate of increase in reported functional impairment, fatigue and pain.

**Abstract FRI0031 – Table 1.** Hazards for progression to inflammatory arthritis in relation to reported baseline and changes in function, fatigue and pain

	HR for progression to IA	95% CI	p
<b>Covariate at baseline</b>			
HAQ	1.38	(0.95–3.38)	0.070
Fatigue	1.01	(1.01–1.04)	0.003
Pain	1.01	(0.99–1.03)	0.434
<b>Rate of change in covariate over 12 months</b>			
HAQ	2.07	(1.81–31.34)	0.005
Fatigue	1.01	(1.01–1.07)	0.002
Pain	1.03	(1.02–1.08)	<0.001

CI, confidence interval; IA, inflammatory arthritis; HAQ, Health Assessment Questionnaire; HR, hazard ratio; p, (statistical) probability. Each covariate was included in a separate model; all were controlled for age and gender.

**Conclusions:** Greater rates of increase in HAQ, fatigue and pain VAS were associated with small, but statistically significant increases in hazards of progression. Therefore, patient reported measures may be helpful for risk stratification in patients with positive anti-CCP.

**ROLE OF ULTRASOUND IN ASSESSING DISEASE ACTIVITY IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS TREATED BY TWO TREAT-TO-TARGET STRATEGIES**

P. Wong, D. Wu, Q.W. Mak, I.T. Cheng, T.K. Li, E.K. Li, L.S. Tam. *Department of Medicine and Therapeutics, Prince of Wales Hospital, The Chinese University of Hong Kong, New Territories, Hong Kong*

**Background:** Ultrasound (US) is a sensitive tool for detecting joints and tendon inflammation in patients with rheumatoid arthritis (RA). Subclinical inflammation is often found in patients with RA in composite score remission. We hypothesise that achieving the ACR/EULAR remission, which reflects a more rigorous control of disease inflammation than the DAS28-based definition, may be associated with less subclinical inflammation detected by US.

**Objectives:** To determine the effect of two treat-to-target (T2T) strategies aiming at the Simplified Disease Activity Index (SDAI) remission (SDAI  $\leq$ 3.3) and DAS28 remission (DAS28-CRP <2.6) on US outcomes in patients with early RA.

**Methods:** This is a sub-study of the Hong Kong Early RA Vascular Study.<sup>1</sup> Fifty-five patients were randomised to receive 1 year of tight-control treatment with an aim to achieve either SDAI  $\leq$ 3.3 (group 1, n=21) or DAS28 <2.6 (group 2, n=34). Both wrists, 1 st to 5th metacarpophalangeal joints, 2nd to 5th proximal interphalangeal joints and the thumb inter-phalangeal joints were evaluated for synovial hypertrophy (SH) by greyscale and power Doppler (PD), scored 0–3. Global indexes for SH and PD (SH- and PD- index) and the Global OMERACT-EULAR Synovitis Score (GLOESS) were calculated. A post-hoc analysis was performed to ascertain whether achieving sustained DAS28 remission (SDR) from month 6 to 12 could improve the US outcomes which included the change in SH- and PD-index, and GLOESS between baseline and 1 year.

**Results:** At baseline, SH and PD signal were found at both wrists and the MCP joints (SH: 79.9%; PD: 82.6%) with moderate grade (SH: 58.3%; PD: 65.8%). Both groups demonstrated significant improvements in clinical and laboratory markers of inflammation. The SH-index, PD-index and GLOESS (median [IQR]: change: group 1: –8 [–22,–4], –6 [–15,–4], –8 [–22,–4]; group 2: –7 [–11,–3], –5 [–8,–2], –7 [–11,–3]) also improved in both groups to a similar extent (p=0.224, 0.297, 0.306 respectively). In view of the lack of differences in all outcomes in both groups, the results of all 55 patients were combined for a post-hoc analysis. Twenty-four patients achieved SDR from month 6 to month 12. After 12 months, the SDR group had a significantly greater improvement in swollen joint count, erythrocyte sedimentation rate, pain, patient global assessment, physician global assessment and Health Assessment Questionnaire. Significant improvements in SH-index, PD-index and GLOESS (–8 [–16,–5], –6.5 [–14,–5], –8 [–16,–6]) were observed in the SDR group and the non-SDR group (–6 [–11,–2], –4 [–10, 0], –6 [–11,–3]). Nonetheless, the SDR group had a significantly greater improvement in the PD-index (p=0.017) compared to that in the non-SDR group; while the SH-index (p=0.179) and GLOESS (p=0.094) were similar between the two groups.

**Conclusions:** In early RA, a SDAI remission-driven T2T strategy led to more intensive treatment but was not associated with significantly better clinical or US outcomes than a DAS28-driven strategy. However, patients who achieved SDR had a significantly greater clinical improvement and reduction in PD index compared to those who could not achieve SDR.

Barbadillo<sup>4</sup>, H. Godoy<sup>4</sup>, M. Galindo<sup>10</sup>, O. Guzón Illescas<sup>1</sup>, A. Herranz<sup>11</sup>. <sup>1</sup>H. U. Fundación Alcorcón; <sup>2</sup>C.S. La Rivota; <sup>3</sup>H. U. Severo Ochoa; <sup>4</sup>H. U. Puerta de Hierro; <sup>5</sup>H. U. Móstoles; <sup>6</sup>H. U. Ramón y Cajal; <sup>7</sup>H. Clínico San Carlos; <sup>8</sup>H. La Princesa, Madrid; <sup>9</sup>H. U. Guadalajara, Guadalajara; <sup>10</sup>H. U. 12 de Octubre; <sup>11</sup>H. U. del Henares, Madrid, Spain

**Background:** The need of orthopaedic surgery (OS) is a marker of disease severity in RA. During the last 20 years, the treatment in RA has changed, incorporating strategies based on "treat-to-target" and biological therapies. But, have these new strategies modified the incidence of OS in RA?

**Objectives:** To analyse the incidence and trend of hospital admissions for OS in patients with RA, in Spain, during the period between 1999 and 2015.

**Methods:** This is a national retrospective population based study. We analysed a national administrative database that includes a Minimum Basic Data Set (MBDS) of all hospital admissions of patients with RA. Period: 1999 to 2015. The OS were identified by the presence of ICD9 codes for arthrodesis, Total Hip Arthroplasty -THA-, Total Knee Arthroplasty -TKA-, Total Superior Limb Arthroplasty -TSLA. The population at risk was estimated through the population census of the National Institute of Statistics. The adjusted rates of hip fracture were calculated, by sex and age. The trend was analysed by Generalised Linear Models (GLM).

**Results:** Of a total of 338.343 hospital admissions, 21.088 (6,62%) were for OS. The main clinical-demographic characteristics are shown in the next table 1.

Table

	OS	THA	TKA	Arthrodesis	TSLA
N (% of total admissions)	21.088 (6.2)	8.709 (2.6)	9.006 (2.7)	1.372 (0.4)	2.230 (0.7)
Females (% of OS)	16.432 (100)	6.545 (39.83)	7.117 (43.31)	1.118 (6.8)	1.846 (11.23)
Age (SD)	65.02 (13.26)	66.57 (14.78)	65.97 (10.9)	55.90 (13.12)	59.93 (12.5)
Stay (SD)	10.97 (12.55)	13.48 (13.5)	10.73 (11.2)	6.69 (18.6)	4.54 (4.69)
In-hospital exitus	125 (0.6)	104 (1.2)	20 (0.2)	1 (0)	1 (0)

The mean age of OS increased 6 years during the study period ( $p < 0.001$ ). The OS age-adjusted rate during the study period was 752,9/10<sup>5</sup> inhab-year. The global fracture age-adjusted remained stable during the study period (IRR 1,002; IC95% 0,9–1,01). In RA patients >60 the rate increase while in RA <60 years the rate decrease (figure 1).

**Conclusions:** In Spain, during the period from 1999 to 2015, the global incidence rate of orthopaedic surgery in patients with RA has remained stable. In RA patients >60 years the rate increase while in RA <60 years the rate decrease. The mean age of OS increased 6 years.

FRI0034

### EFFICACY OF ETANERCEPT BY BODY MASS INDEX IN WOMEN AND MEN WITH RHEUMATOID ARTHRITIS: A POST HOC ANALYSIS OF THREE RANDOMISED TRIALS

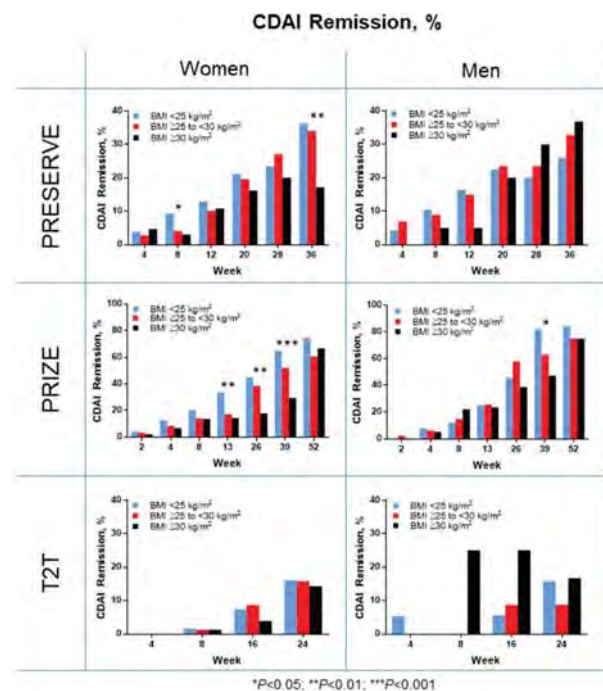

R. Alten<sup>1</sup>, E. Mysler<sup>2</sup>, A. Wajdula<sup>3</sup>, H.E. Jones<sup>4</sup>, R. Pedersen<sup>4</sup>, L. Marshall<sup>4</sup>. <sup>1</sup>Schlosspark-Klinik University Medicine, Berlin, Germany; <sup>2</sup>Organización Médica de Investigación, Buenos Aires, Argentina; <sup>3</sup>Lehigh University, Bethlehem, PA; <sup>4</sup>Inflammation and Immunology, Pfizer, Collegeville, PA, USA

**Background:** In patients with rheumatoid arthritis (RA) treated with tumour necrosis factor  $\alpha$  (TNF $\alpha$ ) inhibitors, a higher body mass index (BMI) has been associated with lower odds of achieving disease remission.

**Objectives:** To evaluate the effect of BMI on response to etanercept (ETN) therapy in women and men with RA, (a) during open-label treatment and (b) following dose reduction or dosing off in patients who achieved low disease activity (LDA) or remission.

**Methods:** In this post hoc analysis, data were collected from three randomised trials (PRESERVE, n=834; PRIZE, n=306; T2T, n=489) in which patients with RA were assigned to an open-label treatment with ETN (50 mg) and MTX for 24–52 weeks, followed by randomised double-blind treatment with ETN (25 mg or 50 mg)+MTX, placebo +MTX, or placebo for 28–52 weeks in those who achieved LDA or remission. Data (observed cases) were analysed by BMI (<25 kg/m<sup>2</sup>,  $\geq 25$  and <30 kg/m<sup>2</sup>, or  $\geq 30$  kg/m<sup>2</sup>) for women and men separately, using a one-way ANCOVA model with baseline value and BMI category for continuous variables and a logistic regression model with BMI as factor for categorical variables. The parameters analysed included changes from baseline in Clinical Disease Activity Index (CDAI), 28-joint Disease Activity Score with C-reactive protein level (DAS28 CRP) or erythrocyte sedimentation rate (DAS28 ESR), and Health Assessment Questionnaire – Disability Index (HAQ-DI), as well as the percentages of patients who achieved CDAI remission (CDAI  $\leq 2.8$ ) or LDA (CDAI >2.8 and  $\leq 10$ ).

**Results:** In the open label periods of all three studies, there was no significant BMI effect on treatment response to ETN in male patients, except for CDAI remission at a single visit in PRIZE (figure 1). In open-label periods of the PRIZE and T2T trials, a significantly smaller decrease in DAS28 CRP and DAS28 ESR in women with BMI  $\geq 30$  kg/m<sup>2</sup>, compared with the other two BMI categories, was observed at most visits. In addition, in PRIZE trial (but not in PRESERVE or T2T), women, but not men, with BMI  $\geq 30$  kg/m<sup>2</sup> had a significantly smaller decrease in CDAI and HAQ-DI scores and lower rates of CDAI LDA at most visits, compared with their counterparts with BMI <30 kg/m<sup>2</sup>. For CDAI remission, there was evidence of the effect of BMI  $\geq 30$  kg/m<sup>2</sup> in women in both PRIZE and PRESERVE (figure 1). Overall, these nominally significant differences between women with BMI  $\geq 30$  kg/m<sup>2</sup> and <30 kg/m<sup>2</sup> were transient: most of them diminished or were no longer significant toward the end of the open-label periods. In randomised, double-blind periods, there were no discernible trends attributable to BMI category in either women or men.

Abstract FRI0034 – Figure 1

**Conclusions:** Results of this post hoc analysis suggest that, in men with RA, there was no impact of BMI on ETN efficacy. In women, there was evidence of a transient negative impact of BMI  $\geq 30$  kg/m<sup>2</sup> on ETN efficacy in open-label periods, but it diminished by the end of the induction period and was not consistent across trials. There was no evidence of BMI effect in men or women during the double-blind periods.

### FRI0035 DISEASE REMISSION IS MORE COMMON BUT LESS STRINGENT IN ANTI-CITRULLINATED PROTEIN ANTIBODY-POSITIVE PATIENTS WITH EARLY RHEUMATOID ARTHRITIS TREATED WITH CONVENTIONAL SYNTHETIC DISEASE MODIFYING DRUGS

A. Manzo, S. Bugatti, G. Zanframundo, F. Benaglio, G. Sakellariou, C. Montecucco, R. Caporali. *Early Arthritis Clinic, Division of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy*

**Background:** Early diagnosis and goal-steered treatment strategies allow the achievement of disease remission in a significant proportion of patients with early rheumatoid arthritis (RA). Autoantibodies such as anti-citrullinated protein autoantibodies (ACPA) identify a subset of patients with a common pathogenetic background and more severe course of the disease. However, whether autoantibodies also impact the response to conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) remains object of debate.

**Objectives:** To investigate the frequency and the characteristics of disease remission in relation to the autoantibody status in patients with early RA treated with csDMARDs.

**Methods:** The study population consisted of 578 early RA patients (<12 months of symptoms) consecutively recruited at our Early Arthritis Clinic, treatment-naïve at inclusion and prospectively followed-up at regular intervals upon initiation of therapy with methotrexate (MTX) aimed at the achievement of low disease activity (28-joints disease activity score [DAS28]  $\leq 3.2$ ). ACPA and rheumatoid factor (RF) were centrally determined on baseline sera. The frequency of remission according to the DAS28 (<2.6) and to the simplified disease activity index (SDAI  $\leq 3.3$ ) over the first 12 months stratified by the autoantibody status was assessed by Cox regression. The following characteristics were further analysed: time to remission, swollen and tender joint count, and acute phase reactants at remission.

**Results:** 533/578 (92.2%) patients completed a follow-up of at least 12 months. Patients fulfilled the 2010 classification criteria for RA (81% also fulfilled the 1987 criteria) and had short disease duration at inclusion (median [IQR] 15.6 [9.4–27.8] weeks). Collectively, 53.9% and 44% of the patients achieved DAS28 and SDAI remission, respectively, at least once over the first 12 months of treatment. After adjusting for age, gender, symptoms' duration, baseline disease activity, MTX starting dose and prednisone co-medication, ACPA positivity was associated with slightly increased hazards of achieving both DAS28 (HR [95% CI] 1.24 [1.01–1.63]) and SDAI remission (HR [95% CI] 1.36 [1.01–1.85]) (figure 1A, B). However, irrespective of the remission criterion, ACPA-positive patients had higher numbers of residual swollen joints while being in remission, particularly in association with high levels of RF (>3 ULN) (figure 1C, D). Furthermore, remission was delayed in RF-high ACPA-positive patients compared to RF-low (figure 1E, F). Other features such as joint tenderness and acute phase reactants did not show significant differences among different serological subgroups.

Abstract FRI0035 – Figure 1

**Conclusions:** Early diagnosis and initial treatment with MTX result in high remission percentages in RA patients regardless of autoantibody positivity. However, remission appears less stringent in ACPA-positive patients, particularly when RF is also high. These findings indicate that current treatment approaches may be insufficient at effectively suppressing joint inflammation in autoantibody-positive patients.

### FRI0036 SUSTAINED REMISSION RELATED FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS: IS IT POSSIBLE TO PREDICT SUSTAINED REMISSION?

S. Yilmaz-Oner, U. Gazel, M. Can, P. Atagunduz, H. Direskeneli, N. Inanc. *Rheumatology, Marmara University, School of Medicine, Istanbul, Turkey*

**Background:** The management of RA have been changed during past decades and sustained remission (SR) is the ultimate goal to halt joint damage and prevent the accrual of disability. Factors predicting SR are essential to individualise treatment and recognise patients that have an opportunity to taper medications in daily practice.

**Objectives:** To determine baseline predictors of sustained remission and comparison of its predictability by different remission criteria.

**Methods:** A total of 428 consecutive patients with RA visiting our outpatient clinic routinely between September 2012–2013 were evaluated. Seventy seven of these patients satisfying the DAS28 remission (<2.6) within the time frame were enrolled and followed-up prospectively for 62.2±9.9 months. Of these fulfilling the DAS28 remission  $\geq 6$  months (sustained remission) and shorter (non-sustained remission:N-SR) were compared in terms of baseline demographic and clinical data and the presence of anxiety, depression, fibromyalgia and fatigue to determine possible predictors of SR. At enrollment, first and fifth years, the DAS28, SDAI and Boolean remission rates of patients were determined and compared with regard to DAS28 remission visit counts throughout the follow-up. We also assessed the difference between the SDAI and Boolean remission rates at initial, first and fifth years' visits.

**Results:** Of these 77 patients, 63 were in SR and 14 were in N-SR. Lower baseline DAS28 and HAQ scores ( $p=0.045$ ;  $p=0.026$ , respectively) and anti-CCP positivity ( $p=0.035$ ) were positive predictors of SR. Although the presence of anxiety, depression, fibromyalgia and fatigue were lower in SR group, there was no statistical significance.

DAS28 remission visit counts of patients in Boolean ( $n=32$ ) and DAS28 ( $n=77$ ) remission at enrollment ( $5.7\pm 3.2$  vs  $5.4\pm 3.1$ ;  $p=0.995$ ) were not different. Similarly, no difference was found between patients in SDAI ( $n=38$ ) and DAS28 remission ( $5.6\pm 3.3$  vs  $5.4\pm 3.1$ ;  $p=0.769$ ). Patients meeting the DAS28 criteria ( $n=77$ , 100%) reduced 64% ( $n=50$ ) at first and 42.6% ( $n=29$ ) at fifth years. Patients satisfying SDAI and Boolean criteria were 49%, 44% vs 32.4% ( $n=22$ ) and 41%, 28% vs 20.6% ( $n=14$ ), respectively.

If the duration of SR is considered as 6 months, the remission rates of SDAI were not different between patients at inclusion and fifth years but Boolean remission rates differed significantly and if it is accepted as  $\geq 12$  months, the SDAI and Boolean remission rates were not different than at fifth year visit.

**Conclusions:** Low DAS28 and HAQ score at baseline and anti-CCP positivity were positive predictors of SR. Although the presence of anxiety, depression, fibromyalgia and fatigue were lower in SR group, there was no statistical significance. Compared to the DAS28, remission determined by the Boolean and especially SDAI criteria continued consistently in long term.

**FRI0037 CHARACTERISTICS OF RECENT ELDERLY-ONSET RHEUMATOID ARTHRITIS PATIENTS**

T. Oshige, Y. Kaneko, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University, Tokyo, Japan*

**Background:** Elderly-onset rheumatoid arthritis (EORA) has been increasing along with the ageing society. EORA is believed to be different from young-onset RA (YORA) in clinical characteristics, however, it is unknown whether the characteristics of recent EORA are similar with those in the past.

**Objectives:** To elucidate recent characteristics of recent EORA patients.

**Methods:** Consecutive patients who were newly diagnosed with RA in our institution from November 2015 until May 2017 (group 1), and those from February 2011 until December 2012 (group 2) were enrolled. Each group was divided into EORA and YORA according to the onset age of 65 years old. Clinical data were collected from their medical records and compared.

**Results:** In group 1, 176 patients with newly diagnosed RA were identified; EORA 37% and YORA 63%. The mean age was 74.0±1.5 and 46.3±2.4 years old, and female was 73.9% and 84.7%, respectively. The duration from onset to first visit was significantly shorter in the EORA compared to the YORA (4.7±3.0 to 13.9±5.9 months;  $p=0.038$ ). Disease activity was significantly higher in EORA than the YORA (DAS28-CRP; 4.47±0.35 vs 3.49±0.27,  $p<0.001$ ; CDAI, 20.5±3.6 vs 15.1±2.2,  $p=0.009$ ). Inflammatory biomarkers at the first visit were also significantly higher in the EORA than the YORA; CRP (2.6±0.7 vs 1.2±0.5 mg/dl,  $p<0.001$ ), ESR (68±9 vs 38±6 mm/hr,  $p<0.001$ ), and serum ferritin (173.3±36.7 vs 102.3±18.8 ng/ml,  $p<0.001$ ). RF and anti-CCP antibody were less positive in EORA than in YORA (RF 55.4 vs 72.1%,  $p=0.024$ ; anti-CCP 40.0 vs 63.1%,  $p=0.003$ ). Large joints were more involved in EORA, but small joint involvement was not different between EORA and YORA. In group 2, 255 patients with newly diagnosed RA were enrolled, EORA 44% and YORA 56%, and female was 85.3% and 84.6%, respectively. The mean age at onset of RA was not different between group 1 and group 2 (58.3±2.4 vs 58.9±2.0,  $p=0.512$ ).

**Conclusions:** EORA developed more rapidly and showed severer inflammatory signs with more large joints involved. Conflicting with previous reports, the age at onset of RA did not increase between the patients in 2015–2017 and in 2011–2012.

**FRI0038 CORRELATION BETWEEN CLINICAL AND ULTRASONOGRAPHIC REMISSION? THE EFFECT OF NON-INFLAMMATORY PATIENT-BASED FACTORS ON DIFFERENT REMISSION DEFINITIONS**

Ü. Gazel<sup>1</sup>, S. Yılmaz-Öner<sup>2</sup>, G. Özen<sup>1</sup>, Y. Yalçınkaya<sup>1</sup>, Z. Ertürk<sup>1</sup>, M. P. Atagündüz<sup>1</sup>, H. Direskeneli<sup>1</sup>, N. İnanç<sup>1</sup>. <sup>1</sup>Rheumatology, Marmara University, School of Medicine; <sup>2</sup>Rheumatology, Bakırköy Sadi Konuk Research and Training Hospital, Istanbul, Turkey

**Objectives:** In this study, we aimed to investigate the concordance of ultrasonographic remission with other remission criteria and to show the influence of non-inflammatory patient-induced factors such as depression, anxiety, fibromyalgia and fatigue on both clinical and ultrasonographic remission.

**Methods:** Fifty consecutive patients with clinical remission (DAS-28-ESR<2.6) who were diagnosed according to the 2010 ACR/EULAR criteria were recruited to this study.

Patients were also assessed whether they met the Boolean and SDAI remission criteria. 28 joint grey scale (GS) and power Doppler (PD) ultrasonography were performed. Patients' depression and anxiety were assessed by The Hospital Anxiety and Depression Scale (HADS), and their fatigue was assessed by multidimensional Assessment of Fatigue (MAF) scores and patients' fibromyalgia was assessed by widespread pain index (WPI) and symptom severity score (SS).

**Results:** Patients were divided into 4 groups according to different remission definitions by ultrasonography. (Group1: PD=0 and GS=0, Group2: PD=0 and GS≥0, Group3: PD=1 or 0 and GS=1 or 0, Group4: PD=1 or 0 and GS≥0).

Although it is not statistically significant, the highest agreement with all the clinical remission criteria was found in the USG remission group 4 (table 1).

Patients with ultrasonographic remissions at their first visit in 2011 were reevaluated with clinical remission criteria at the end of 5 years. The highest remission rates were found in patients with USG remission group 3 (DAS28 58%, Boolean 29%, SDAI 47%). There was no significant difference between fatigue, fibromyalgia, depression and anxiety measures between remission and non-remission in all USG remission groups. In contrast, depression ( $p<0.05$ ) and anxiety ( $p<0.03$ ) were significantly higher in patients without SDAI remission. Depression ( $p<0.008$ ) and anxiety ( $p<0.014$ ) were also significantly higher in patients without Boolean remission.

**Abstract FRI0038 – Table 1.** The concordance between Ultrasound remission and other remission criteria

		Das28 (n=50)	SDAI (n=23)	Boolean (n=22)
Group 1: PD=0 GS=0	n (%)	13 (% 26)	8(%34,7)	5 (%22,7)
Group 2: PD=0 GS≥0	n (%)	22 (% 44)	10 (%43,4)	8(%36,3)
Group 3: PD=1 or 0 and GS=1 or 0	n (%)	17 (%34)	8 (%34,7)	7 (%31,8)
Group 4: PD=1 or 0 and GS≥0	n (%)	28 (%56)	13(%56,5)	11 (%50)

**Conclusions:** Clinical and ultrasonographic remission was found to be compatible in half of the patients.

The compliance of the USG remission in Group 4 with the clinical remission definitions was good, and clinical remission continuity was higher in the group meeting the definition of group 3. In contrast the ultrasound remission, the high levels of depression and anxiety in patients without SDAI and Boolean remission suggest that non-inflammatory patient-derived measures have less influence on the ultrasound remission.

**FRI0039 MEASURING HEALTH RELATED QUALITY OF LIFE (EQ-5D) IN PATIENTS WITH RHEUMATOID ARTHRITIS AFTER ONE YEAR TREATMENT WITH csDMARDS AND BIOLOGIC DMARDS**

V.V. Boyadzhieva<sup>1</sup>, N. Stoilov<sup>1</sup>, G. Petrova<sup>2</sup>, R. Stoilov<sup>1</sup>. <sup>1</sup>Rheumatology, University hospital Sv. Iv. Rilski; <sup>2</sup>Social Pharmacy and Pharmacoeconomics, Medical University, Sofia, Bulgaria

**Background:** Health-related quality of life (HRQoL) is a multi-dimensional concept that includes domains related to physical, mental, emotional, and social functioning. It goes beyond direct measures of patients' health, and focuses on the impact health status has on quality of life.

**Objectives:** To measure the QoL (EuroQoL – 5D) of patients with RA and analyse their change after one year treatment with csDMARDS and biologic DMARDS (bDMARDS).

**Methods:** For the purpose of the study were selected 220 patients: 29 males (13%) and 86 women (87%) meet the classification criteria for RA by ACR 1987 Patient's age is between 18–85 years (mean age for DMARDS – 54.8, biologic DMARDS – 55.3 years). The duration of the disease is between 0.5–44 years. In our study 96 patients are treated with DMARDS and 124 with bDMARDS. Patients with significant comorbidity, infectious diseases, congestive heart failure (NYHA class III or IV), malignant hypertension, psychiatric illness, a history of lymphoproliferative disease or neoplasia were excluded from the study. All of the patients completed the questionnaire EuroQoL-5D on baseline, 6th and 12th month of treatment. The results were calculated via licensed calculator

**Results:** On Baseline, first part of EQ-5D mean values in patients with biologic therapy were significantly lower than those in the csDMARDS group ( $p=0.001$ ). During the follow-up period patients on biologic DMARDS experienced significant improvement in this indicator in both time intervals (6th month – 63.24±16.52 SD, 12th month – 76.38±14.85). After 6 months of treatment the group on bDMARDS have higher mean values for EQ-5D than the patients on csDMARDS (57.64±20.2 SD), which shows significantly higher Quality of life ( $p=0.0025$ ). During the following period from 6th to 12th month the patients on csDMARDS didn't have significant improvement in QoL (58.65±22.41 SD) ( $p=0.214$ ). On the 12th month of the treatment the patients on bDMARDS have significantly higher QoL than the group on csDMARDS ( $p=0.000$ ). Analysing the data from the second part of the questionnaire, we found similar results with the data obtained from the first. Patients on biological therapy experienced a significant improvement in quality of life during the entire follow-up period. In contrast, patients on csDMARDS had significant improvement in the mean values of the EQ-5D – 0.51±0.2 3SD to 6th month, after which there was a non-significant reduction of EQ-5D=0.49±0.23 SD to 12th month ( $p=0.266$ ).

**Conclusions:** The patients on biologic DMARDS have significantly higher QoL than the patients on csDMARDS on the 6th and 12th month of treatment period.

**Disclosure of Interest:** None declared

FRI0040

### DEVELOPMENT AND VALIDATION OF CLINICAL PREDICTORS FOR INADEQUATE RESPONSE TO TREAT-TO-TARGET METHOTREXATE THERAPY IN NEWLY DIAGNOSED RA PATIENTS

X.M. Teitsma<sup>1</sup>, J.W. Jacobs<sup>1</sup>, P.M. Welsing<sup>1</sup>, P.H. de Jong<sup>2,3</sup>, J.M. Hazes<sup>2</sup>, A. E. Weef<sup>2,3</sup>, A. Pethö-Schramm<sup>4</sup>, M.E. Borm<sup>5</sup>, J.M. van Laar<sup>1</sup>, F.P. Lafeber<sup>1</sup>, J. W. Bijlsma<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, UMC UTRECHT, Utrecht; <sup>2</sup>Rheumatology, Erasmus Medical Center Rotterdam; <sup>3</sup>Rheumatology, Maasstad Hospital, Rotterdam, Netherlands; <sup>4</sup>F Hoffmann-La Roche, Basel, Switzerland; <sup>5</sup>Roche Nederland BV, Woerden, Netherlands

**Background:** In new-onset rheumatoid arthritis (RA), therapy should be aimed at achieving sustained remission according to current guidelines, in which methotrexate (MTX) is recommended to be included in the initial treatment strategy. However, a large proportion (~30%) eventually need additional treatment to control inflammation making it necessary to find predictors which helps clinicians in choosing the optimal initial therapy to further improve the long-term outcome of early RA patients.

**Objectives:** To identify and validate clinical baseline predictors associated with inadequate response (IR) to MTX therapy in disease modifying anti-rheumatic drug (DMARD)-naïve early RA patients.

**Methods:** For identifying clinical predictors, data was used from the U-Act-Early trial of newly diagnosed RA patients treated-to-target with a MTX strategy (n=108, development sample). MTX (oral) was started at 10 mg/week and increased in monthly steps up to 30 mg/week or maximum tolerable dose until remission. If no remission, hydroxychloroquine (HCQ) was added and, if the target, remission, thereafter still was not achieved, HCQ was replaced by tocilizumab. Patients in the tREACH trial who initiated MTX (25 mg/week) in combination with a prednisone tapering scheme were used as validation sample (n=83). In tREACH, if disease activity score (DAS) was  $\geq 2.4$  after three months, etanercept was added. When three months thereafter the target still was not achieved, patients switched to another tumour necrosis factor alpha inhibitor. In both studies, the definition of IR to MTX, (designated here "MTX+" therapy), was met if patients needed a biological DMARD within the first year. Clinical predictors were identified using logistic regression with backward selection ( $p \leq 0.10$ ).

**Results:** In the development sample, the following predictors for IR to "MTX+" therapy were identified: DAS assessing 28 joints (DAS28), adjusted odds ratio (OR<sub>adj</sub>) 2.1, 95% CI 1.4–3.1;  $p < 0.001$ ; current smoking, OR<sub>adj</sub> 3.0, 95% CI 1.1–8.0;  $p = 0.027$ ; and alcohol consumption, OR<sub>adj</sub> 0.3, 95% CI 0.1–0.9;  $p = 0.021$ . A risk matrix, categorised by these predictors, shows nearly a twelve and a half fold risk difference in predicted probabilities (figure 1). The area under the receiver operating characteristic curve (AUROC) of the model is 0.75 (95% CI 0.66–0.84); no statistically significant difference ( $p = 0.96$ ) was found between the observed and predicted probabilities (i.e. calibration). When using a negative predictive value (NPV), i.e. predicted chance of not failing "MTX+" therapy, of  $> 80\%$  as cut off in the development sample, the positive predictive value (PPV) was 65% (sensitivity: 0.89, specificity: 0.52). The AUROC of the model in the validation sample was 0.67 (95% CI 0.55–0.79) with no significant difference ( $p = 0.28$ ) between observed and predicted probabilities, indicating good calibration. In the validation sample, a cut-off of NPV  $> 80\%$ , the PPV was 54% (sensitivity: 0.88, specificity: 0.38).

Alcohol consumption, yes:  $\geq 1$  unit per week. DAS28 = disease activity assessing 28 joints; LDA = low disease activity (DAS28  $2.6 < 3.2$ ); MDA = moderate disease activity (DAS28  $3.2 < 5.1$ ); HDA = high disease activity (DAS28  $\geq 5.1$ ); NS = not specified, insufficient data to calculate predicted probability; IR = inadequate response.

**Abstract FRI0040 – Figure 1.** Risk matrix of predicted probability (%) of IR to "MTX+" therapy.

**Conclusions:** Higher DAS28, current smoking and no alcohol consumption were associated with an increased risk of IR to "MTX+" therapy in newly diagnosed RA patients.

FRI0041

### ASSOCIATIONS BETWEEN TYMS POLYMORPHISMS AND RESPONSIVENESS TO OR TOXICITY OF METHOTREXATE IN RHEUMATOID ARTHRITIS

Y.H. Lee, Y.H. Seo. Rheumatology, Korea University, Seoul, Korea, Republic Of

**Background:** Thymidylate synthase (TYMS) is a key protein in the *de novo* synthesis of pyrimidines, and is essential for DNA replication and cell proliferation. MTX is polyglutamylated to form MTX polyglutamates after entering cells, and directly inhibits TYMS. TYMS is an important target for MTX, and over-expression of the TYMS gene is associated with resistance to TYMS-targeted drugs.

**Objectives:** The aim of this study was to investigate whether the thymidylate synthase (TYMS) 2R/3R and 6 bp I/D polymorphisms can predict the response to or toxicity of methotrexate (MTX) in patients with rheumatoid arthritis (RA).

**Methods:** We conducted a meta-analysis of studies on the association between the TYMS 2R/3R and 6 bp I/D polymorphisms and non-responsiveness to or toxicity of MTX in RA patients.

**Results:** A total of 11 studies involving 1613 patients were considered. Meta-analysis showed no association between the TYMS 2R/3R 3R allele and non-responsiveness to MTX therapy (OR=1.087 CI=0.682–1.731,  $p=0.726$ ). The meta-analysis indicated that there was no association between the TYMS 6 bp I/D D allele and non-responsiveness to MTX therapy (OR=0.688, 95% CI=0.281–1.683,  $p=0.413$ ). Meta-analysis revealed no association between the overall toxicity of MTX treatment in RA and the TYMS 2R/3R 3R allele. However, meta-analysis revealed that MTX toxicity was associated with the TYMS 2R/3R polymorphism in RA patients when a co-dominant model (3 R2R vs. 3 R3R +2R2R) was used, indicating that heterozygotes (3 R2R) for the polymorphism had a higher risk of developing MTX toxicity than homozygotes (3 R3R+2R2R). Stratification by ethnicity indicated an association between the TYMS 2R/3R 3R allele and non-responsiveness to MTX in Caucasians, but not in non-Caucasians. In contrast, meta-analysis revealed no association between the overall toxicity of MTX and the TYMS 6 bp I/D D allele.

**Conclusions:** This meta-analysis demonstrates that the TYMS 2R/3R and 6 bp I/D polymorphisms may not be associated with non-responsiveness to MTX therapy, but that the TYMS 2R/3R polymorphism may be associated with MTX toxicity in RA, particularly in Caucasians.

### TENDER JOINTS HAVE LOW AGREEMENT WITH PATIENT'S EVALUATION OF SPONTANEOUS JOINT PAIN, JOINT SWELLING AND ULTRASOUND VERIFIED SYNOVITIS IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS

H.B. Hammer, J. Sexton, B. Michelsen, S. Provan, T. Uhlig, T.K. Kvien. Dept Of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway

**Background:** Tender joint count is included in the clinical composite scores (CDAI, SDAI, DAS28) which serves as a proxy for inflammatory activity. However, there may be several causes of joint tenderness, including both nociception and central sensitisation. Ultrasonography (US) is sensitive for evaluation of joint inflammation (synovitis (grey scale, GS) and vascularisation (power Doppler, PD)).

**Objectives:** In patients with rheumatoid arthritis (RA) to explore the agreement at a joint level between tenderness, spontaneous patient reported joint pain, swelling and US synovitis.

**Methods:** 174 patients with established RA (mean (SD) age 52<sup>13</sup> years, disease duration 10<sup>9</sup> years, 82% women, 79% anti-CCP positive were assessed when they initiated bDMARD treatment and after 1, 2, 3, 6 and 12 months. An experienced study nurse assessed presence/absence of joint tenderness and swelling (wrist, MCP1–5, PIP2–3, elbow, knee, ankle and MTP1–5 bilaterally). The same 32 joints were assessed by use of a manikin for Patient Reported Spontaneous Joint Pain (PRSJP) the last day as well as US (GS and PD, both scored 0–3) by an experienced sonographer (HBH). Agreement at joint level was explored between categorical variables using Cohens kappa (US scores transformed to presence (PD score 1–3/GS score 2–3) versus absence (PD score 0/GS score 0–1), and in addition agreement between presence of tenderness/swelling and the different US scores were explored.

**Results:** A total of 4091 (baseline) and 22 885 (all visits) joints were assessed. Tender joints had moderate agreement with PRSJP and swollen joints, and lower with US synovitis. Swollen joints had high agreement with US synovitis (table 1), and US synovitis was found in 75% of swollen joints. There were no differences in agreement between results at baseline and all visits, or if subgroup analyses were performed of only finger joints. A clear relationship was found between increasing GS/PD scores and percentages of joints being swollen, but this association was not found for tender joints (table 2).

**Abstract FRI0042 – Table 1. Kappa values for agreement between categorical variables at baseline (4091 joints)/all visits (22885 joints)**

	PRSJP	Swollen joint	GS US	PD US
Tender joint	0.34/0.40	0.32/0.32	0.21/0.21	0.20/0.20
PRSJP		0.25/0.26	0.23/0.24	0.25/0.23
Swollen joint			0.57/0.56	0.56/0.54

**Abstract FRI0042 – Table 2. At joint level; percentages of agreement between joints being tender and/or swollen and US synovitis (all visits, number of joints in parenthesis)**

	GS=0 (n=13874)/PD=0 (n=18656)	GS=1 (n=4077)/ PD=1 (n=1888)	GS=2 (n=3079)/ PD=2 (n=1791)	GS=3 (n=1855)/ PD=3 (n=550)
Swollen joints	3.8%/7.9%	16.3%/45.7%	47.1%/70.1%	77.7%/86.7%
Swollen, but not tender joints	2.1%/4.4%	8.8%/28.2%	26.7%/42.0%	49.4%/51.8%
Tender joints	9.7%/12.7%	20.4%/27.5%	29.7%/33.1%	32.7%/39.3%
Tender, but not swollen joints	8.0%/9.1%	12.8%/10.0%	9.3%/4.8%	4.4%/3.8%

**Conclusions:** Tender joints had weak agreement with presence of US synovitis, while swollen joints had strong agreement. PRSJP had moderate/weak agreement with all the other assessments. Presence of swelling was highly associated with the degree of US synovitis, while this association was not found for tenderness. Our results raise questions regarding the prominent role of tender joint count in RA clinical composite scores for disease activity.

**FRI0043 TRENDS IN ALL-CAUSE AND CARDIOVASCULAR MORTALITY IN PATIENTS WITH RHEUMATOID ARTHRITIS. A 10- TO 20-YEAR FOLLOW-UP STUDY IN 3 CONSECUTIVE INCIDENCE COHORTS**

S.A. Provan, S. Lillegraven, E.A. Haavardsholm, T.K. Kvien, J. Sexton, T. Uhlig. *Department of Rheumatology, Diakonhjemmet Hospital, Oslo Norway, Oslo, Norway*

**Background:** The mortality rate in patients with rheumatoid arthritis (RA) has been estimated to be 1.5–1.6 compared to the general public. Moreover, RA patients are still not benefitting fully from the declining mortality rate that the general population has enjoyed and cardiovascular disease (CVD) continues to be a major concern.

**Objectives:** To examine the all-cause and CVD mortality in 3 consecutive cohorts of patients with incident RA, compared to population controls

**Methods: The Oslo RA register (ORAR)** was established in 1994. The inclusion criteria were a diagnosis of RA according to the 1987 ACR criteria and residency in Oslo. The register was updated annually until 2009, and validated for completeness.<sup>1</sup> In January 2012, 3328 patients were registered in ORAR. We grouped patients into 3 successive incidence cohorts; 1996(1994–1998), 2001 (1999–

2003) and 2006(2004–2008). For each patient we identified 5 historical population controls matched according to age at disease incidence, gender and postal code of residence. Patients and controls were linked to the Norwegian Cause of Death Registry. Counts were compared using chi<sup>2</sup> tests. The hazard ratio (HR) for survival was calculated using stratified cox-regression models adjusted for highest achieved level of education.

**Results:** 422, 477 and 459 patients in the 1996, 2001 and 2006 cohorts were matched to 2110, 2385 and 2295 controls respectively. 20, 15 and 10 years follow-up for 1996, 2001 and 2006 cohorts were available in 201, 292 and 311 patients respectively. Results are presented in the table 1.

	1996		2001		2006	
	ORAR	Controls	ORAR	Controls	ORAR	Controls

HR 20 year CVD mortality (95% CI)	2.27 (1.56–3.31)**		-		-	

\*p<0.05.

**Conclusions:** RA patients with disease incidence in the period 1994–2003 had increased all-cause and CVD related mortality after 10–15 years of disease duration, compared to the population of Oslo. The increased mortality was not observed in the 2004–2008 cohort. Improved survival in recent years may be related to more effective therapies and earlier diagnosis, but further analyses are warranted.

**FRI0044 EXCEEDING PREDEFINED THRESHOLDS FOR MRI BONE OEDEMA AND EROSION AND HAQ-DI CAN PREDICT RELAPSE AFTER WITHDRAWAL OF ALL TREATMENT IN MTX-NAÏVE PATIENTS WITH RA IN REMISSION AFTER 12 MONTHS OF ABATACEPT THERAPY IN THE AVERT TRIAL**

H.A. Ahmad<sup>1</sup>, J.F. Baker<sup>2</sup>, M. Østergaard<sup>3</sup>, P. Emery<sup>4</sup>, T. Huizinga<sup>5</sup>, Y. Elbez<sup>6</sup>, S. Banerjee<sup>1</sup>, P.G. Conaghan<sup>4</sup>. <sup>1</sup>Bristol-Myers Squibb, Princeton; <sup>2</sup>Philadelphia VA Medical Center and the University of Pennsylvania, Philadelphia, USA; <sup>3</sup>Rigshospitalet and University of Copenhagen, Copenhagen, Denmark; <sup>4</sup>University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds, UK; <sup>5</sup>Leiden University Medical Center, Leiden, Netherlands; <sup>6</sup>Excelya, Boulogne-Billancourt, France

**Background:** To assist in clinical decision making it is important to understand the factors, and their thresholds, that might predict relapse following treatment

withdrawal in patients with RA in remission. In a previous *post hoc* analysis of the AVERT trial (NCT01142726), in which several potential factors were assessed, erosions, synovitis and bone oedema scores on MRI and HAQ-DI scores in patients with DAS28 (CRP) <2.6 were associated with clinical relapse 6 and 12 months after complete drug withdrawal following 12 months of blinded treatment with abatacept +MTX or abatacept or MTX alone.<sup>1,2</sup> Knowledge of the thresholds for these measures, above which relapse is more likely to occur, may aid clinical decisions about when to withdraw treatment in patients who have achieved remission.

**Objectives:** To evaluate *post hoc* the association between different thresholds of MRI and HAQ-DI scores at Month 12 and the risk of relapse at Months 18 and 24 in AVERT.

**Methods:** This analysis compared relapse event rates at Months 18 and 24 in patients with DAS28 (CRP) <2.6 but with differing severities of synovitis, bone oedema and erosion (assessed by MRI individual and combined scores) and HAQ-DI scores at Month 12. A relapse event was defined by the doubling of TJC28 and SJC28 and an increase in DAS28 (CRP)  $\geq 1.2$  relative to the Month 12 visit. Synovitis, bone oedema and erosion in the dominant hand and wrist MRI were scored using the OMERACT RAMRIS. Severity of each score was defined by cut-offs of >3 for synovitis, >2 for bone oedema, >7 for (weighted) combined synovitis and bone oedema, >5 for erosion and >0.5 for HAQ-DI. Univariate logistic models were conducted for comparisons and odds ratios (OR) with 95% CI and associated p values.

**Results:** All randomised and treated patients with DAS28 (CRP) <2.6 at Month 12 and relapse status available at Months 18 and 24 (n=155) were included. Among the overall study cohort at Month 12, 70 (45.2%) patients with DAS28 (CRP) <2.6 had a higher synovitis score (>3), 28 (18.1%) had a higher bone oedema score (>2), 39 (25.2%) had a higher combined score (>7), 73 (47.1%) had a higher erosion score (>5) and 42 (27.1%) had a higher HAQ-DI score (>0.5). Relapse events at Months 18 and 24 were significantly associated with supra-threshold MRI bone oedema, erosion and combined scores and with supra-threshold HAQ-DI score at Month 12 (figure 1). There was a trend toward association of relapse at Months 18 and 24 with high synovitis score (figure 1).

**Abstract FRI0044 – Figure 1.** Association Between Month 12 MRI and HAQ-DI Scores and Relapse Status at Months 18 and 24

**Conclusions:** It was possible to define MRI and HAQ-DI scores in patients with DAS28 (CRP) remission that were predictive of relapse 6 and 12 months after complete drug withdrawal in AVERT. Assessment of imaging and physical function, using predefined thresholds, in patients achieving remission may aid clinical decisions on when to withdraw therapy in MTX-naïve patients with RA.

#### FRI0045 EVALUATION OF SERUM PROTEIN LEVELS AT BASELINE AS PREDICTORS OF RESPONSE TO METHOTREXATE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS: RESULTS FROM SWEFOT TRIAL POPULATION

K. Hambarzumyan<sup>1</sup>, C. Hamsten<sup>2</sup>, H. Idborg<sup>1</sup>, L. Lourido<sup>3,4</sup>, S. Saevarsdottir<sup>1</sup>, P. Nilsson<sup>3</sup>, R.F. van Vollenhoven<sup>1,5</sup>, P.-J. Jakobsson<sup>1</sup>. <sup>1</sup>Rheumatology Unit, Department of Medicine; <sup>2</sup>Unit of Immunology and Allergy, Department of Medicine, Karolinska Institutet; <sup>3</sup>Affinity Proteomics, SciLifeLab, School of Biotechnology, KTH – Royal Institute of Technology, Stockholm, Sweden; <sup>4</sup>Rheumatology Division, ProteoRed/ISCIII Proteomics Group, INIBIC – Hospital Universitario de A Coruña, A Coruña, Spain; <sup>5</sup>Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands

**Background:** Methotrexate (MTX) is a standard first-line therapy option for patients with early rheumatoid arthritis (eRA). However, a substantial proportion of patients still do not respond to MTX.

**Objectives:** To identify biomarkers for prediction of response to MTX.

**Methods:** We analysed a group of patients (n=135) with eRA from the Swedish Pharmacotherapy (SWEFOT) trial population. Baseline serum levels of 177 proteins were profiled using 380 antibodies in a suspension bead array format. Median fluorescent intensity (MFI) levels of the proteins were subsequently analysed for association with achievement of low 28-joint disease activity score (DAS28  $\leq 3.2$ ) after 3 months of MTX therapy (primary outcome). Proteins that remained significant in multivariate model were analysed using receiver operating characteristic (ROC) curve analysis for cut-off definition of MFI and categorisation into high and low categories. Proportion of patients with primary outcome between the generated categories were compared using Chi-squared test.

**Results:** In multivariate analysis, serum levels of two of the 177 proteins at baseline, matrix metalloproteinase 7 (MMP-7) and alpha-chain of fibrinogen (FGA) were significantly different among patients who achieved or not achieved low DAS28 at 3 months. ROC curve analysis revealed AUC of 0.692 for MMP-7 and 0.699 for FGA (p<0.001; figure 1A). ROC curve-based dichotomisation indicated that of patients with low versus high levels of either MMP-7 or FGA, 60% versus 24% and 58% versus 22%, respectively, achieved low DAS28 (p<0.001; figure 1B and C). Among patients with low categories of both proteins, 79% achieved low DAS28 at 3 months, while only 18% of those in high categories for both proteins (p<0.001; figure 1D).

Validation in the COMBINE cohort with available MMP-7 data (whose concentration was measured by different method) did not confirm results from the SWEFOT trial.

**Abstract FRI0045 – Figure 1.** Assessment of baseline levels of MMP-7 and FGA as predictors of LDA at 3 months. Receiver operating characteristic curve analysis and area under the curve of MMP-7 and FGA (A), proportion of patients achieving low DAS28 among groups dichotomised by MMP-7 (B), FGA (C) or using combination of MMP-7 and FGA (D).

**Conclusions:** Low levels of MMP-7 and FGA at baseline were associated with better clinical outcome in eRA patients. Following further characterisation, such biomarkers would be of high clinical relevance for the optimisation of treatment of RA.

**FRI0046 PATIENTS PRESENTING WITH NEW MUSCULOSKELETAL SYMPTOMS IN THE WRISTS, HANDS AND FEET ENRICHES DETECTION OF ANTI-CCP ANTIBODIES IN PRIMARY CARE – A NATIONAL COHORT STUDY**

P. Pentony<sup>1,2</sup>, K. Karkalemis<sup>1</sup>, J.L. Nam<sup>1,2</sup>, K. Mankia<sup>2,3</sup>, L. Hunt<sup>1,2</sup>, E. M. Hensor<sup>1,2</sup>, P. Emery<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>Leeds Biomedical Research Centre, National Institute of Health Research; <sup>3</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds University, Leeds, UK

**Background:** Selecting patients with new non-specific musculoskeletal complaints can enrich the prevalence of anti-cyclic citrullinated peptide (anti-CCP) antibodies compared with the general population.<sup>1</sup> Patients with rheumatoid arthritis (RA) frequently present with involvement of the wrist, hands and feet. Patients with elderly onset RA have a higher frequency of polymyalgic onset. However, it is unknown if elderly patients with shoulder complaints are more likely to be CCP positive.

**Objectives:** To confirm the proportion of individuals with new-onset, non-specific MSK symptoms who were anti-CCP positive (CCP+) across a national cohort and investigate the initial presenting complaint of all individuals, as this may help determine whether there is a symptom complex that would prompt antibody testing. In addition to determine if the risk of being CCP + is increased in older patients presenting with shoulder symptoms.

**Methods:** Individuals aged  $\geq 18$  years with new musculoskeletal complaints without synovitis from primary care were recruited prospectively. Participants completed a questionnaire on baseline musculoskeletal symptoms and provided a blood sample for anti-CCP antibody (Phadia CCP-2) testing. CCP+ individuals were invited to attend follow-up in the rheumatology department, Leeds. The association between CCP status, smoking and shared epitope status was also assessed.

**Results:** 4257 individuals were recruited, 2.9% (125/4257) were CCP+, a significantly higher proportion compared with the general population (1% (95% CI 2.4% >3.5%  $p < 0.001$ )). Patients who presented with pain in the wrists, hands (RR 2.2 (1.5–2.9),  $p < 0.001$ ) or feet (RR 1.72 (1.2–2.4),  $p < 0.001$ ) had an increased relative risk of being CCP+. Patients who were older than 60 years who presented with shoulder symptoms (4.8% (7/146)) were no more likely to be CCP + than those who did not have shoulder symptoms (3.2% (31/1007), chi square  $p = 0.313$ ) and had the same prevalence of CCP + as those <60 years (3.5% (13/370), chi square  $p = 0.461$ ). A significantly higher proportion of ever smokers were CCP+ (14.2% (48/337)) compared with never smokers (3.3% (64/1926); chi square  $p < 0.001$ ). Ever smokers were also more likely than never smokers to be shared epitope positive in CCP + individuals (62.2% (23/37) cf 37.8% (14/37);  $p < 0.007$ ).

**Conclusions:** Selecting individuals with new non-specific MSK symptoms without synovitis enriched the prevalence of anti-CCP positivity to 2.9%. Patients presenting with symptoms localising to the wrists, hands and feet were more likely to be CCP + which could prompt anti-CCP testing in these patients in primary care. Patients with shoulder complaints were no more likely to be CCP + than those without shoulder symptoms and had the same prevalence of CCP + as those <60 years.

**FRI0047 MRI INTEROSSEOUS TENDON INFLAMMATION OCCURS IN ANTI-CCP POSITIVE AT-RISK INDIVIDUALS AND MAY PRECEDE THE DEVELOPMENT OF SYNOVITIS**

K. Mankia<sup>1</sup>, M.A. D'Agostino<sup>1</sup>, E. Hensor<sup>2</sup>, E. Rowbotham<sup>3</sup>, L. Hunt<sup>1</sup>, I. Moller<sup>4</sup>, M. Miguel<sup>5</sup>, J.L. Nam<sup>1</sup>, A.L. Tan<sup>1</sup>, J. Freeston<sup>6</sup>, L. Garcia-Montoya<sup>1</sup>, A. Grainger<sup>3</sup>, P. Emery<sup>1</sup>. <sup>1</sup>Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine and NIHR Leeds Biomedical Research Centre; <sup>2</sup>Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine; <sup>3</sup>Radiology, Leeds Teaching Hospitals Trust and NIHR Leeds Biomedical Research Centre, Leeds, UK; <sup>4</sup>Rheumatology; <sup>5</sup>Anatomy, University of Barcelona, Barcelona, Spain; <sup>6</sup>Rheumatology, Leeds Teaching Hospitals Trust and NIHR Leeds Biomedical Research Centre, Leeds, UK

**Background:** Tenosynovitis (TSV) occurs in individuals at-risk of developing RA and could explain pain and stiffness in the absence of synovitis. TSV of the wrist and finger flexor tendons has been described in at-risk individuals but involvement of other hand tendons has not been well investigated. The hand interossei are crucial to hand function and can become inflamed in RA.<sup>1</sup> Whether the interosseous tendons (IT) are sites of inflammation in at-risk individuals, and how this relates to joint inflammation and clinical features is unknown.

**Objectives:** To describe the anatomy, prevalence, pattern and clinical associations of IT inflammation in anti-CCP positive at-risk individuals.

**Methods:** Anti-CCP positive individuals with no synovitis (CCP+), healthy controls (HC), DMARD-naïve early RA patients (ERA) and treated 'late' RA patients (LRA) were recruited. All subjects underwent clinical and MRI assessment. 1.5T or 3T unilateral hand MRI scans were consensus scored for RAMRIS, TSV and IT inflammation by two radiologists. IT inflammation was defined as enhancing tissue around the tendon evident in two planes. For RAMRIS and tenosynovitis, scores were adjusted for 193 age-matched controls.<sup>2</sup> To understand the anatomical basis for MRI IT inflammation, a cadaveric study was performed on 20 fresh hand specimens; coloured dyes were injected along the first dorsal IT and into the adjacent second MCP joint and specimens were frozen and sectioned.

**Results:** 93 CCP+, 20 HC, 47 ERA and 28 LRA were recruited. Frequency of swollen and tender joints, MRI inflammation (synovitis, BME, erosions, TSV) and CRP level increased along the RA continuum with increasing disease duration. The proportion of patients with IT inflammation increased along the RA continuum. No HC, 18/93 (19%) CCP+, 23/47 (49%) ERA and 16/28 (57%) LRA patients had inflammation of  $\geq 1$  IT ( $p < 0.001$ ). The number of affected ITs increased along the RA continuum ( $p < 0.001$ ) and tendons associated with MCPJs 2 and 5 were most commonly affected. IT inflammation and MRI synovitis were associated with MCPJ swelling [OR 2.7 (0.9, 8.1) and OR 3.1 (1.0, 9.8) respectively] but IT inflammation was the only feature independently associated with MCPJ tenderness [OR 3.1 (1.4, 6.8)  $p = 0.004$ ]. In CCP+, 99/372 (27%) MCPJs had only one MRI abnormality; in 68% of these the abnormality was extra-capsular (57% TSV and 11% IT inflammation). No IT sheath was identified in the cadaveric specimens suggesting the MRI findings represent peri-tendonitis rather than TSV. Dye studies indicated no clear communication between the IT and the adjacent joint (figure 1).

Axial MRI showing inflammation of the 3<sup>rd</sup> palmar interosseous tendon and frozen section showing green dye around the interosseous tendon and blue dye within the MCP joint

**Abstract FRI0047 – Figure 1.** Axial MRI showing inflammation of the 3<sup>rd</sup> palmar interosseous tendon and frozen section showing green dye around the interosseous tendon and blue dye within the MCP joint

**Conclusions:** IT inflammation represents a peri-tendonitis and is present in anti-CCP +at risk individuals and RA patients where it is associated with MCPJ swelling and tenderness. IT inflammation can occur as the lone MRI abnormality in CCP +at risk individuals suggesting the interossei may be an early extra-capsular target in the development of RA.

#### MORTALITY AND MORBIDITY OF RHEUMATOID ARTHRITIS-ASSOCIATED LUNG DISEASE DURING A 10-YEAR PERIOD: A LONGITUDINAL COHORT STUDY OF 103 JAPANESE PATIENTS

S. Shimoyama, Y. Fujieda, M. Kato, K. Oku, T. Bohgaki, O. Amengual, S. Yasuda, T. Atsumi. *Department of Rheumatology, Endocrinology and Nephrology, Faculty of Medicine and Graduate School of Medicine, Hokkaido University, Sapporo-shi, Japan*

**Background:** Subclinical and overt lung diseases associated with rheumatoid arthritis (RA-LD) are present in 30%–50% of the patients. Early and effective intervention improved joint prognosis in RA. By contrast, lung complications are still the primary contributors to premature deaths in patients with RA. Lung complication in RA can be due to a variety of conditions. However, the individual mortality and progression of pulmonary manifestations have not been established.

**Objectives:** To clarify the prognostic factors of patients with RA-LD.

**Methods:** This cohort study comprised RA patients examined with lung high resolution CT (HRCT) scan regardless of respiratory symptoms from 2005 to 2009. Respiratory diagnoses were certified by pulmonologists. The patients were reassessed by one follow-up CT scan after 10 years. All patients were evaluated for the events defined as death, serious infections and others (admission due to bone fracture, and ischaemic heart disease) from 2005 to 2017. Mortality risks were assessed using Kaplan-Meier method.

**Results:** Clinical features of 103 (82 females) patients are shown in table 1. Thirty-one (30%) had RA-LD including 18 interstitial pneumonia and 13 bronchiolitis at the start of observation. Mean observation period was 110 months. During observation, patients without RA-LD (non RA-LD) never developed new lung complications. The 10 year survival rate (SR) was 92% (mortality rate was 1.3 per 100 patient-years) and the 10 year event free survival rate (EFS) 69% (event rate was 4.8 per 100 patient-years). SR in RA-LD was significantly low compared with non RA-LD ( $p=0.008$ ) (figure 1). EFS in RA-LD was significantly lower than in non RA-LD ( $p=0.03$ ). Types of lung complication didn't correlate with high mortality. The causes of death comprised infection (55%), malignant tumour (27%), interstitial pneumonia (9%), and the others (9%). The adverse events included infection (41%), malignant tumour (21%), bone fracture (15%), cardiac disease (10%), and severe drug eruption including Steven-Johnson syndrome (13%). Univariate analysis showed that infection ( $p<0.001$ , HR 26.7) and acute exacerbation of RA-LD ( $p<0.001$ , HR 57.3, 95% CI 13–287) were strong risk factors for deaths.

**Abstract FRI0048 – Table 1.** Characteristics of RA patients with and without LD at the start of observation

	RA-LD(n=31)	non RA-LD(n=72)
Female (%)	80	80
age(y)	74±10	68±13
age at RA diagnosis(y)	54±14	48±13
RF positive (n,%)	20(65)	48(67)
ACPA positive (n,%)	19(61)	45(63)
DAS28	4.3±1.4	4.4±1.5
Stage (n,%)	6 (20)	15(21)
Stage (n,%)	10(32)	21(29)
Stage (n,%)	5 (16)	16(22)
Stage (n,%)	10(32)	20(28)

**Conclusions:** RA-LD is a serious complication in RA, and related with a high mortality.

<sup>18</sup>Department of Rheumatology and Immunology, Peking Union Medical College hospital, Beijing, China

**Background:** Treat-to-Target (T2T) strategy are critical for the treatment of RA, but the Chinese rheumatologists can hardly provide patients with a complete assessment in the clinic due to limited time. The SSDM includes interfaces of both physicians' and patients' application. After inputting lab test records, treatment regimens, and executing DAS28 assessment by patients themselves, all data can be synchronised automatically to the authorised physicians' mobile tool. The rheumatologists can adjust treatment regimens base on patients' profile. Our previous study showed that patients in China can master the application of SSDM for accurately evaluating DAS28 and health assessment questionnaire (HAQ) after training.

**Objectives:** The objective of this study is to explore the effectiveness of applying SSDM in improvement of disease activity after repeated self-assessment in Chinese RA patients.

**Methods:** Patients were trained to do DAS28 evaluation with SSDM and asked to repeat the self-assessment once a month. Descriptive statistics were performed

for patient and disease characteristics. According to DAS28 scores, disease activity, the cohort was divided into four groups: remission (Rem), low disease activity (LDA), moderate disease activity (MDA) and high disease activity (HDA). T2T, achieving a DAS28 score lower than 2.6 (Rem) or below 3.2 (LDA), is the main management strategy recommended by ACR and EULAR.

**Results:** From Jun 2014 to Jan 2018, a total of 24,731 RA patients from 486 centres in China participated in the study. The mean age was  $49.28 \pm 16.08$  (18 to 99) years and the median disease duration was 18.30 months. All patients performed self-assessment of DAS28, HAQ and morning stiffness time totally for 30 358 times. Proportion of patients in Rem, LDA, MDA and HDA was 18%, 13%, 45% and 24% respectively at baseline. Of which, 3492 patients performed repeated assessment for 11 251 times. Proportion of patients in Rem, LDA, MDA and HDA changed into 44%, 18%, 31% and 7% at the last assessment. The proportion of T2T at the last assessment was significantly higher than that of baseline significantly ( $p < 0.001$ ). According to the assessments, the rate of T2T from baseline to 3 months, 6 months, 9 months, 12 months and over 12 months were 31%, 47%, 56%, 58%, 61% and 62% (see figure 1). With the increase of the times of self-assessment, the T2T rate was significantly improved ( $p < 0.001$ ).

**Abstract FRI0049 – Figure 1.** The times of repeated self-assessment and the proportion of DAS28 stratification

**Conclusions:** Under repeated self-assessment of DAS28 using SSDM, RA patients can achieve better T2T result. Though empowering patients, SSDM can assist rheumatologist to rationally adjust treatment for RA patients.

### FRI0050 TOCILIZUMAB ACHIEVES BETTER REPAIR OF FOCAL BONE EROSIONS THAN TUMOUR NECROSIS FACTOR INHIBITION IN RA PATIENTS – DATA FROM THE PROSPECTIVE REBONE STUDY ON EROSION REPAIR

G. Schett<sup>1</sup>, S. Finzel<sup>2</sup>, S. Kraus<sup>1</sup>, A. Regensburger<sup>1</sup>, R. Kocijan<sup>3</sup>, J. Rech<sup>1</sup>. <sup>1</sup>FAU Erlangen-Nuremberg, Erlangen; <sup>2</sup>University of Freiburg, Freiburg, Germany; <sup>3</sup>Medical University of Vienna, Vienna, Austria

**Background:** Focal bone erosions are considered as markers for irreversible structural damage in patients with rheumatoid arthritis (RA). Several studies have suggested that limited repair of focal bone erosion can occur but no study has so far compared the effect of different biological disease modifying anti-rheumatic drugs (bDMARDs) on erosion repair.

**Objectives:** To compare focal bone erosion repair in RA patients treated with interleukin-6 receptor inhibitor (tocilizumab, TOC) with patients receiving tumour necrosis factor inhibitors (TNFi)

**Methods:** Prospective non-randomised observational study in 66 erosive RA patients with active disease (DAS28-ESR > 3.2) and inadequate response to methotrexate receiving treatment with TOC monotherapy (n=33) or TNFi in combination with methotrexate (n=33) for 52 weeks. Patients received high-resolution peripheral quantitative computed tomography (HR-pQCT) of the MCP and wrist joints of the dominant hand at baseline and after 52 weeks. Volume (in mm<sup>3</sup>) of the largest (“sentinel”) erosion in the MCP joints and in the wrist was assessed by two readers blinded for treatments and for the sequence of the images. Demographic (sex, age, body mass index, smoking, Charlson comorbidity index) and disease specific parameters (disease duration, ACPA and RF status) were assessed at baseline and activity scores (DAS28, SDAI, CDAI, HAQ) at baseline and every three months thereafter.

**Results:** Groups were balanced for age, sex, BMI and comorbidities as well as disease duration, disease activity, functional state, autoantibody status and bone damage at baseline. TOC (DAS28-ESR: baseline:  $6.2 \pm 0.5$ ; 52wk:  $2.3 \pm 1.0$ ) and TNFi (DAS28-ESR: baseline:  $6.3 \pm 0.6$ ; 52wk:  $2.8 \pm 1.2$ ) significantly reduced

disease activity to a similar extent, achieving DAS28 remission in 22/33 and 19/33 patients, respectively, after 52 weeks. Volumes of the sentinel erosions significantly decreased in the MCP joints of TOC patients ( $-1.0 \pm 1.1$  mm<sup>3</sup>), while remaining stable in TNFi treated patients ( $-0.05 \pm 0.9$  mm<sup>3</sup>) (TOC vs. TNFi:  $p < 0.001$ ). Similar effects were observed in the wrist (TOC:  $-2.9 \pm 5.6$  mm<sup>3</sup>;  $-0.08 \pm 4.1$  mm<sup>3</sup>) with significant differences between the two groups ( $p = 0.0017$ ). Erosion repair was particularly frequent in RA patients reaching fast remission within the first 3 months of treatment.

### Erosion repair in the metacarpophalangeal joints of tocilizumab treated RA patients after 52 weeks

Y axis shows the volume of the sentinel erosion at baseline (black circles) and 52-weeks follow-up (red squares), x-axis the patient numbers (N=33)

**Abstract FRI0050 – Figure 1.** Erosion repair in the metacarpophalangeal joints of tocilizumab treated RA patients after 52 weeks

Y axis shows the volume of the sentinel erosion at baseline (black circles) and 52 weeks follow-up (red squares), x-axis the patient numbers (n=33)

**Conclusions:** The REBONE study shows that TOC has higher efficacy than TNFi to repair existing bone erosions in patients with RA. In contrast, the effects of TOC and TNFi on the inflammatory symptoms of RA are comparable. These data suggest that IL-6 is the central factor for the disturbed homeostasis between bone resorption and bone formation in the joints of RA patients.

### FRI0051 THE RISK OF ASEPTIC ARTHROPLASTY LOOSENING IN PATIENTS WITH RHEUMATOID ARTHRITIS

C. Böhler<sup>1</sup>, P. Weimann<sup>1</sup>, F. Alasti<sup>2</sup>, J.S. Smolen<sup>2</sup>, R. Windhager<sup>1</sup>, D. Aletaha<sup>2</sup>. <sup>1</sup>Orthopaedics and Traumatology, <sup>2</sup>Rheumatology, Medical University Of Vienna, Vienna, Austria

**Background:** Total joint arthroplasty (TJA) of the hip (THA) and knee (TKA) are well-established operations for end stage degenerative or inflammatory joint disease, and has excellent outcomes. In rheumatoid arthritis (RA), it is performed in about 25% of the patients.<sup>1</sup> According to registry data septic complications after TJA are more frequent in RA than in osteoarthritis (OA), which is likely linked to the immunomodulatory therapy that RA patients receive.<sup>2</sup> However, aseptic prosthesis loosening (APL) is the most common complication and it remains unclear whether RA *per se* is also a risk factor for non-infectious complications, e.g. by the presence of higher levels of systemic inflammation.

**Objectives:** To compare the rates of APL between OA and RA patients, and to investigate the influence of disease activity levels on the risk for APL in RA patients.

**Methods:** We identified all patients who underwent THA and TKA between 2002 and 2015 at our academic centre, and linked them with an existing prospective RA database to identify documented RA patients. Age and sex-matched OA patients were used as controls. Our primary endpoint were radiographic signs of APL as previously established.<sup>3,4</sup> Radiographs were evaluated by two independent observers blinded to the clinical diagnosis.

To explore the effects of systemic inflammation, we compared the time integrated level of disease activity by the Simplified Disease Activity Index (SDAI) during the year before an x-ray indicated loosening (for those with loosening) with the respective levels over one year before the last available x-ray (for those without loosening).

We used nonparametric tests and the chi-square test to compare rates of loosening between RA and OA patients and to compare AUC SDAI between patients with and without APL. Additionally, we calculated a Cox proportional hazard

regression to estimate the risk of loosening with increasing SDAI, stratified for TKA and THA.

**Results:** Data of 49 RA patients and 88 OA patients were available for analysis. The rate of APL was 36.7% in the RA and 13.6% in the OA group ( $p=0.002$ ). This was explained by a much higher rate of APL in the TKA group (RA: 34.4%; OA: 6.5%;  $p=0.001$ ), while the rates in the THA group were only numerically different (RA: 41.2%; OA: 30.8%;  $p=0.528$ ).

In the RA group one year time integrated SDAI was significantly higher prior to loosening than in controls without loosening ( $p=0.043$ ). In the Cox model, SDAI was also significantly related to time to APL with a Hazard ratio of 1.125 (95% CI 1.021–1.241) ( $p=0.018$ ). Figure 1 depicts cox regression adjusted for AUC SDAI 3, 13 and 26 separately for TKA and THA.

**Conclusions:** RA is not only a risk factor for infectious complications after TJA, but also for APL after THA or TKA. This effect might—at least partly—be explained by systemic and local inflammation in RA patients as depicted by higher levels of disease activity in RA patients with APL. In the context of treatment-to-target of RA, the presence of an arthroplasty should be considered as an indication for even more stringent control of disease activity.

## Rheumatoid arthritis – comorbidity and clinical aspects

### FRI0052 HIGHER URIC ACID IS ASSOCIATED WITH A LOWER DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS

A. Al-Herz<sup>1</sup>, A. Aldei<sup>2</sup>, K. Saleh<sup>3</sup>, A. Al-Awadi<sup>2</sup>, W. Al-Kandari<sup>3</sup>, E. Hasan<sup>2</sup>, A. Ghanem<sup>4</sup>, M. Hussain<sup>2</sup>, E. Nahar<sup>4</sup>, F. Abutiban<sup>5</sup>, A. Alenizi<sup>5</sup>, Y. Ali<sup>4</sup>, H. Alhajer<sup>6</sup>, S. Hayat<sup>4</sup>, A. Khadrawy<sup>7</sup>, A. Fazal<sup>3</sup>, K. Mokaddem<sup>2</sup>, A. Zaman<sup>4</sup>, G. Mazloum<sup>6</sup>, Y. Bartella<sup>2</sup>, S. Hamed<sup>2</sup>, R. Alsouk<sup>5</sup>, A. Al-Saber<sup>8</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Amiri Hospital, Kuwait; <sup>3</sup>Farwania Hospital, Farwania; <sup>4</sup>Mubarak Al-Kabeer Hospital, Hawalli; <sup>5</sup>Jahra Hospital, Jahra; <sup>6</sup>Mubarak Al-Kabeer Hospital, Kuwait; <sup>7</sup>Rheumatology, Farwania Hospital, Farwania; <sup>8</sup>Department of Mathematics, Kuwait Technical College, Kuwait

**Background:** An association between serum uric acid (UA) and disease activity in rheumatoid arthritis (RA) patients has not been well studied.

**Objectives:** We describe RA patients with high and normal UA and study its association with RA activity.

**Methods:** Adult RA patients from The Kuwait Registry for Rheumatic Diseases (KRRD) who satisfied the ACR classification criteria for RA from four major hospitals were studied from February 2013 through April 2017. Patients with recorded

UA were identified. Visits with documented UA levels were included. UA of  $\geq 357$   $\mu\text{mol/L}$  (6 mg/dL) was considered high. Statistical correlations were made.

**Results:** A total of 564 RA patients with 2710 hospital visits and available UA were identified, 353 (62.6%) females. Mean age  $50.8 \pm 11.5$  years and disease duration  $10.5 \pm 2.9$  years. Mean DAS28 was  $2.9 \pm 1.2$  and mean HAQ-DI  $0.77 \pm 0.67$ . Rheumatoid factor (RF) was positive in 431/564 (76.4%) and anti-cyclic citrullinated peptide antibodies (ACPA) in 374/564 (66.3%).

Mean UA was  $271 \pm 78$   $\mu\text{mol/L}$  with 12.7% readings being high. There were more males among patients with high UA than with normal UA (56% vs 36%,  $p < 0.01$ ) with no difference in age.

UA was negatively correlated with DAS28 ( $p < 0.001$ ), CDAI ( $p < 0.001$ ), SDAI ( $p = 0.038$ ), ESR ( $p = 0.034$ ), VAS pain ( $p = 0.049$ ), morning stiffness ( $p = 0.033$ ), patient's global assessment ( $p = 0.006$ ), physician's global assessment ( $p = 0.033$ ), number of tender joints ( $p < 0.001$ ) and number of swollen joints ( $p < 0.001$ ). There was no significant correlation with RF, ACPA or HAQ. The use of steroid, synthetic and biologic antirheumatic drugs, either individually or as a class, was similar among patients with high and normal UA.

**Conclusions:** RA patients with a higher UA had a lower disease activity despite using similar antirheumatic drugs. Reasons behind such association need to be further studied.

**Disclosure of Interest:** None declared

### FRI0053 THE CHANGING FACE OF RHEUMATOID ARTHRITIS AT THE END OF THE 20TH CENTURY – A COMPARATIVE POSTMORTEM CLINICOPATHOLOGIC STUDY OF 237 RHEUMATOID ARTHRITIS PATIENTS WITH AA AMYLOIDOSIS AND SYSTEMIC VASCULITIS

M. Bély<sup>1</sup>, Á. Apáthy<sup>2</sup>. <sup>1</sup>Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest; <sup>2</sup>Department of Rheumatology, St. Margaret Clinic, Budapest, Hungary

**Objectives:** Most clinicians accept that the course of rheumatoid arthritis (RA) has changed in the last decades. The aim of this study was to verify this clinical impression characterised by systemic vasculitis (SV) and AA amyloidosis (AAa).

**Methods:** At the National Institute of Rheumatology 12 138 patients died between 1969 and 2000; among them 237 with RA, who were autopsied.

RA was complicated in 53 (22.36%) by SV, and in 49 (20.68%) of 237 patients by AAa. RA was confirmed clinically according to the criteria of the American College of Rheumatology.<sup>1</sup> The presence of SV and of AAa was determined histologically. The "severity" of vasculitis and the extent of amyloid A deposition/patient was evaluated by semi-quantitative visual estimation on a 0 to 3 plus scale.<sup>2</sup> The average prevalence of SV and AAa was calculated in percentage of the number of RA patients, who died during four periods of time (8–8–8–8 years) covering 32 years (between 1969 and 2000).

**Results:** During these four periods of time (from 1969 to 2000) the average age of RA patients with SV continuously increased from 57.00 to 68.00 years, and with AAa from 56.71 to 64.08 years. The prevalence of SV and AAa and the proportion of severe cases in % of RA patients are demonstrated on figure 1.

**Conclusions:** According to our data RA became more aggressive with higher prevalence of SV and AAa at the end of the last century.

The longer life spans (longer duration of the immune processes) with repeated exacerbations of vasculitis may have contributed to the increased prevalence of SV at death. The increased prevalence of SV (including fourfold mild and double severe cases) in 32 years supports the changing face of RA.

The increased prevalence of AAa may be related to the longer duration of the inflammation as well. The changing trend (inverse proportion) of severe and mild amyloid deposition, i.e. the increase of mild and decrease of severe cases could likely have been related to the introduction of more effective immunosuppressive therapy.

The longer disease duration and later death of RA patients with SV or AAa point to more effective therapy.

#### FRI0054 RISK FACTORS FOR POSTPARTUM FLARE IN RHEUMATOID ARTHRITIS – A ROMANIAN COHORT

A. Bobirca<sup>1</sup>, F. Bobirca<sup>2</sup>, I. Ancuta<sup>1</sup>, M. Micu<sup>3</sup>, C. Ancuta<sup>4</sup>, M. Bojinca<sup>1</sup>, C. Mihai<sup>1</sup>, V. Stoica<sup>1</sup>. <sup>1</sup>Internal Medicine and Rheumatology; <sup>2</sup>Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania, Bucharest; <sup>3</sup>Department of Rehabilitation II, Clinical Rehabilitation Hospital, Cluj-Napoca; <sup>4</sup>Clinical Hospital of Rehabilitation, Grigore T. Popa University of Medicine and Pharmacy, Iasi, Romania

**Background:** Patients diagnosed with rheumatoid arthritis (RA) before pregnancy may experience a postpartum flare. This event may occur independently of the patient treatment, according to recent guidelines.<sup>1</sup>

**Objectives:** The aim of this study was to identify possible risk factors of postpartum RA flares.

**Methods:** We analysed pregnant RA patients treated with b DMARDs pre-conception/during pregnancy which delivered children. Data analysis was performed in a combined manner: prospectively and retrospectively. Data collection was focused on 5 distinct periods of time: pre-conception, 1 st, 2nd, 3rd pregnancy trimesters, postpartum period before 12 weeks and after 12 weeks. Following parameters were analysed: demographic data (type of pregnancy- planned/unplanned), immunology (RF and ACPA positivity), disease activity score DAS-CRP,<sup>2</sup> type of medication and duration. Subfertility status and postpartum flares were registered. The retrospective analysis was represented by interview collected data. Flare was defined as early (<12 weeks postpartum) or late >12 weeks)

**Results:** Among 96 pregnant patients, 54 (56%) patients delivered 57 children. Out of 54 patients, 17 (31.5%) were analysed prospectively and 37, 68.5% retrospectively. The patients were exposed to 3 types of b DMARDs: TNF blockers,<sup>9</sup> Rituximab<sup>5</sup> and Tocilizumab.<sup>1</sup> Rituximab was stopped before pregnancy in 4 out of 5 patients (1 continued therapy during the 1 st trimester- unplanned pregnancy) and all presented a postpartum flare. Out of 9 patients with TNF blocker therapy, 2 of them stopped the drug before pregnancy and the other 7 used the medication until pregnancy test positivity or until the end of the 2nd trimester. In this group, 6 of 9 patients presented a postpartum flare. One patient was treated with Tocilizumab before pregnancy and experienced an early flare. table 1 presents the analysis of a set of collected parameters. Overall, the majority of the patients (77.8%) experienced a postpartum flare. An early postpartum flare was identified in 53.7% and late one in 24.1%, with a mean value of 11.59±9.45 weeks. The prospective group experienced more frequently an early flare in comparison to group 2 (0.244 (95% CI 0.62–0.965) but without statistic significance. A positive correlation was found between active disease during the 2<sup>nd</sup> and 3<sup>rd</sup> trimester and postpartum early flare occurrence (p=0.044). No correlation was found between postpartum flare, fertility status or therapy type and duration.

**Table 1.** Risk factors for early postpartum RA flare

Variable	Early flare	p
Prospective	87%	0.044
Planned pregnancy	55%	0.534
Active disease during third trimester	100%	0.044
Active disease during second trimester	87.5%	0.044
Active disease during first trimester	77.8%	0.117
Active disease during preconception	73.8%	0.629
Subfertility	44.4%	0.371
Seropositivity	87%	0.593

**Conclusions:** RA pregnant patients treated with b DMARDs experience a postpartum flare in the majority of the cases. Persistent active disease during the second and third trimester was identified as a risk factor for postpartum disease flare. Larger prospective studies are needed in order to make a better analysis of all evaluated parameters.

#### FRI0055 SAFETY OF ETANERCEPT IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS: A POOLED ANALYSIS

C.J. Edwards<sup>1</sup>, K. Roshak<sup>2</sup>, J. Bukowski<sup>2</sup>, R. Pedersen<sup>2</sup>, M. Thakur<sup>3</sup>, L. Marshall<sup>2</sup>, H. Jones<sup>2</sup>. <sup>1</sup>University Hospital Southampton, Southampton, UK; <sup>2</sup>Pfizer, Collegeville, USA; <sup>3</sup>Pfizer, Sandwich, UK

**Background:** Both ageing and rheumatoid arthritis (RA) are associated with a higher risk of comorbidities, some of which may be increased by current therapies. However, failure to control RA can lead to a particularly rapid loss of function and independence in the elderly population.

**Objectives:** To assess the safety of etanercept (ETN) in older (aged >65 years) vs younger (aged ≤65 years) patients with RA.

**Methods:** Patient-level data were pooled from the double-blind, placebo (PBO)-controlled phases of all completed, randomised, Pfizer- or Amgen-sponsored ETN studies in patients with RA. The occurrence of adverse events (AEs,%) in PBO- and ETN-treated patients was analysed by age (≤65 years vs >65 years), using the exact Poisson method to calculate 95% confidence intervals (CI). Fisher's Exact tests and Breslow Day tests for interaction were used to assess statistical differences.

**Results:** Data on 6418 patients were collected from 19 studies (≤65 years: PBO, n=1910; ETN, n=3497;>65 years: PBO, n=364; ETN, n=647). In PBO-treated patients, the occurrence of congestive heart failure (CHF), interstitial lung disease (ILD), and angioedema was significantly higher in older than younger patients (CHF and ILD: figure 1; angioedema: 0.82%, 95% CI 0.17–2.41% and 0%, 95% CI 0–0.19, respectively, p<0.0001). In patients treated with ETN, the occurrence of CHF, serious infections (SI), and non-melanoma skin cancers (NMSC) was significantly higher in older than younger patients (all p<0.0001, figure 1), as was the occurrence of anaphylactic reactions (p=0.02), central nervous system and peripheral demyelinating events (both p=0.001), and seizures (p=0.02). In contrast, the occurrence of non-serious infections and injection site reactions (ISRs) was significantly lower in older than younger ETN-treated patients (infections: 43.12%, 95% CI 38.21–48.49% and 48.27%, 95% CI 45.99–50.63,

respectively,  $p=0.016$ ; ISRs: 17.31%, 95% CI 14.25–20.83% and 22.36%, 95% CI 20.82–23.99, respectively,  $p=0.004$ ). The difference between PBO- and ETN-treated patients was statistically significant in the 2 age groups combined (Breslow Day interaction) for angioedema ( $p=0.003$ ), ISRs ( $p=0.042$ ), and NMSC ( $p=0.042$ ). Older, but not younger, patients had greater (but not statistically significant) occurrence of CHF, SI, and NMSC when taking ETN vs PBO. There was an interesting, non-significant, reduction of ILD occurrence in older, but not younger ETN-treated vs PBO-treated patients (figure 1). There were no significant age-related increases in the occurrence of other AEs of interest such as uveitis, opportunistic infections (invasive fungal, protozoal, bacterial, and atypical mycobacterial infections and Legionella), tuberculosis, lymphoma, melanoma, or leukaemia. The smaller number of patients in the older cohort was a study limitation, and further stratification of the data in the higher age brackets may provide key information on the age at which the risk of particular AEs increases.

SI included pneumonia, cellulitis, septic arthritis, sepsis, and parasitic infection.

**Abstract FRI0055 – Figure 1.** Occurrence of AEs with notable age-related differences in patients with RA

SI included pneumonia, cellulitis, septic arthritis, sepsis, and parasitic infection.

**Conclusions:** The occurrence of CHF, SI, and NMSC was higher in older vs younger patients taking ETN. While the analysis suggests an overall acceptable safety profile of ETN, the relative risks and benefits need to be considered when treating older patients.

#### FRI0056 CLINICAL FEATURES AT THE ONSET OF LYMPHOPROLIFERATIVE DISORDER IN PATIENTS WITH RHEUMATOID ARTHRITIS

D. Kobayashi<sup>1,2</sup>, S. Ito<sup>2</sup>, Y. Wada<sup>1</sup>, I. Narita<sup>1</sup>, K. Nakazono<sup>2</sup>. <sup>1</sup>Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata; <sup>2</sup>Rheumatology, Niigata Rheumatic Center, Shibata, Japan

**Background:** Rheumatoid arthritis (RA) is intrinsically associated with an increased incidence of lymphoproliferative disorders (LPDs). Furthermore, treatment with immunosuppressing agents, such as methotrexate (MTX) sometimes

leads to the development of immunosuppressing agents related LPDs. Thus the development of LPDs is an increasingly important issue. However, previous studies focused on the pathological features and regression of LPDs after ceasing MTX administration, and evidence that could allow for the early diagnosis of LPDs in patients with RA is lacking.

**Objectives:** We surveyed the clinical course of patients with RA who developed LPDs at our hospital, with a focus on the clinical course and laboratory findings leading to their development.

**Methods:** Patients with RA who were treated at Niigata Rheumatic Centre between April 2011 and December 2017 were analysed. Patient data were obtained retrospectively from medical records. Twenty-nine patients (14 men, 15 women) developed a LPD (LPD group). We compared them with 87 patients without LPD (non-LPD group), who were matched for age, sex, and RA duration among 2628 patients with RA who attended our outpatient department in 2017. Data indicated are median (IQR<sub>1/4–3/4</sub>) values.

**Results:** The median patient age was 71.0 (64.0–74.0) years, and the duration of RA was 16.0 (10.0–22.0) years in both groups. Twelve patients were diagnosed with diffuse large B cell lymphoma, 5 with Hodgkin lymphoma, and 4 with T cell lymphoma; 8 patients had other diagnosis.

Of 29 patients, 23 were treated with MTX, 10 with tacrolimus, 8 with biological disease-modifying antirheumatic drugs (bDMARD). Twenty-two patients had Steinbrocker stage-IV RA. Multivariate analysis showed that Steinbrocker stage IV and MTX treatment were risk factors for the development of LPDs, with hazard ratios of 4.65 and 3.32, respectively.

In the LPDs group, although the C-reactive protein level (CRP) level and lactate dehydrogenase (LDH) level significantly rose (CRP, 0.10 [0.090–0.20] mg/dL 6 months before LPD diagnosis to 1.9 [1.1–3.8] mg/dL at LPD diagnosis, LDH, 198.0 [184.0–230] to 310 [210–489] IU/L), neither the tender joint count (TJC) and swollen joint count (SJC), nor matrix metalloproteinase-3 (MMP-3) level showed any significant change. On the contrary, CRP and LDH levels, as well as TJC, SJC, and MMP-3 level did not change significantly at the 6 month follow-up in non-LPDs group. LDH, MMP, and CRP ratios were calculated as the ratio of them at LPD diagnosis to those at 6 months before diagnosis. CRP and LDH ratios were significantly higher in the LPD group (CRP, 1.00 [0.65–1.75] in the non-LPD group vs 9.50 [2.40–23.0] in the LPD group; LDH, 1.00 [0.93–1.09] in the non-LPD group vs 1.46 [1.17–2.04] in the LPD group). However, the MMP-3 ratio was not different significantly between the non-LPD and LPD groups (1.00 [0.88–1.12] vs 0.98 [0.85–1.21]). MMP-3 ratio/CRP ratio was significantly lower in the LPD group than in the non-LPD group (0.0979 [0.036–0.384] vs 1.00 [0.54–1.67]). The receiver operating characteristic curve suggested that MMP-3 ratio/CRP ratio <0.476 was the best cut-off point for the prediction of LPD development, with a sensitivity of 90.9%, specificity of 79.0%, and an area under the curve of 0.894.

**Conclusions:** LDH elevation, and CRP elevation that is disproportionate to TJC, SJC, and MMP-3 level might indicate underlying LPD.

#### FRI0057 EFFECTS OF ANTI-TNF THERAPY ON VASCULAR BIOMARKER LEVELS IN RHEUMATOID ARTHRITIS

E. Végő<sup>1</sup>, A. Hamar<sup>1</sup>, Á. Horváth<sup>1</sup>, S. Szántó<sup>1</sup>, G. Szűcs<sup>1</sup>, A. Pusztai<sup>1</sup>, A. Domján<sup>1</sup>, K. Hodosi<sup>1</sup>, G. Kerekes<sup>2</sup>, R. Gesztelyi<sup>3</sup>, J. Zsuga<sup>4</sup>, Z. Prohászka<sup>5</sup>, Z. Szekanez<sup>1</sup>.

<sup>1</sup>Department of Rheumatology; <sup>2</sup>Intensive Care Unit, Department of Internal Medicine; <sup>3</sup>Department of Pharmacology and Pharmacotherapy, University of Debrecen, Faculty of Medicine; <sup>4</sup>Department of Healthy Systems Management, University of Debrecen, Faculty of Public Health, Debrecen; <sup>5</sup>Third Department of Internal Medicine, Semmelweis University, Faculty of Medicine, Budapest, Hungary

**Background:** Previous studies have shown an increased risk of cardiovascular disease in rheumatoid arthritis (RA), due to RA-associated inflammation. Different vascular biomarkers, such as anti-hsp65 antibodies, asymmetric dimethylarginine (ADMA) and B-type natriuretic peptide (BNP) have been associated with atherosclerosis and RA. Anti-hsp65 antibodies are also linked also to autoimmunity, inflammation and atherosclerosis. ADMA is an endogenous competitive inhibitor of NOS and consequential can lead to increased nitrosative and oxidative stress. ADMA has been implicated with atherosclerosis, and in RA. BNP is also involved in cardiovascular diseases.

**Objectives:** The aim of this study was to assess the effects of anti-TNF therapy on different vascular biomarkers, such as anti-hsp65, ADMA and BNP in patients with RA and their correlation with different laboratory and clinical markers.

**Methods:** Altogether 36 RA patients were recruited and treated with either etanercept (ETN) or certolizumab pegol (CZP) in this 12 months follow-up study. Assessments were performed at baseline, at month 6 and 12. Amounts of IgG antibodies reacting with recombinant M. bovis hsp65 (Lionex, Braunschweig, Germany) were measured by ELISA. Asymmetric dimethylarginine (ADMA) was assessed by HPLC with fluorescent detection. BNP fragments were assessed by commercially available ELISA kit (Biomedica, Vienna). In addition, disease activity

(DAS28), age, disease duration, CRP, IgM rheumatoid factor, anti-CCP and plasma lipid levels were also measured. Arterial flow-mediated vasodilation (FMD), carotid intima-media thickness (cIMT) and arterial pulse-wave velocity (PWV) were assessed by ultrasound.

**Results:** There were no significant changes in the levels of anti-hsp60, ADMA and BNP due to anti-TNF therapy. However, baseline level of BNP is strongly correlated with the levels of rheumatoid factor (RF) ( $R=0.479$ ,  $p=0.004$ ) and cyclic citrullinated peptid (CCP) ( $R=0.591$ ,  $p<0.001$ ). Serum BNP levels at baseline and at month 6 were significantly increased in RF positive compared to RF negative patients ( $680.60\pm 381.64$  versus  $292.94\pm 198.27$  pmol/L;  $p=0.007$  and  $668.95\pm 346.51$  versus  $312.20\pm 207.01$  pmol/L;  $p=0.001$ ) and also in CCP positive compared to CCP negative patients ( $670.61\pm 323.04$  versus  $137.98\pm 436.41$  pmol/L;  $p=0.030$  and  $652.93\pm 283.21$  versus  $456.48\pm 423.11$  pmol/L;  $p=0.021$ ). Furthermore we found the following correlations between baseline values: anti-hsp60 level correlated with ADMA ( $R=0.900$ ,  $p=0.037$ ), triglyceride (TG) ( $R=0.462$ ,  $p=0.040$ ) and PWV ( $R=0.564$ ,  $p=0.040$ ). Baseline level of ADMA positively correlated with body mass index (BMI) score ( $R=0.720$ ,  $p=0.040$ ) and also with HDL levels (high density lipoprotein) of patients ( $R=0.473$ ,  $p=0.047$ ). Baseline level of BNP also correlated with triglyceride (TG) level ( $R=0.377$ ,  $p=0.036$ ).

**Conclusions:** BNP levels were significantly higher in RF +compared to RF- patients, which imply that BNP may associate with RF positivity. Specific biomarkers, such as ADMA, anti-hsp60 and BNP may play important role cardiovascular disease in RA.

### FRI0058 SERUM AND SYNOVIAL SURVIVIN ARE ASSOCIATED WITH EROSIIVE NOT ACTIVE RHEUMATOID ARTHRITIS

E. Baraka, M. Serag El Din, A. El Shambky, M. Aboul Gheir. *Rheumatology, Rehabilitation and Physical medicine, Benha Faculty of Medicine, Benha University., Cairo, Egypt*

**Background:** Rheumatoid arthritis (RA) is a progressive debilitating autoimmune disease leading to cartilage and bone destruction caused by insufficient apoptosis in the inflamed RA synovium. Survivin is a proto-oncogene biomarker known for its anti-apoptotic and cell cycle regulating properties and has been linked linked to inflammation, presumably contributing to the decreased apoptosis in the T cells in non cancerous processes.

**Objectives:** The aim of this study is to measure the serum and synovial levels of survivin and clarify their relations to disease activity, functional capacity and radiographic damage in RA patients.

**Methods:** This study was carried out on 50 RA patients (F:M=39:11) had a mean age of ( $46.4\pm 10.94$ ) years and 30 subjects of matched age and sex with a mean age of ( $46.03\pm 10.53$ ) years and F:M (23/7) as a control group. All patients were subjected to full history taking, thorough clinical examination, assessment of disease activity by DAS-28 score and functional capacity and using Health assessment Questionnaire (HAQ). Plain x- ray radiographs of both hands and feet were done, scored and graded by Larsen score. Survivin levels in all studied subjects' sera and the synovial fluid aspirated from 18 RA patients presented with knee effusion at the time of examination were measured by enzyme- linked immunosorbent assay (ELISA).

**Results:** The mean serum survivin level was highly significantly elevated ( $p<0.001$ ) in the RA patients sera than in the controls' being  $479.61\pm 52.68$  (pg/ml) and  $239.1\pm 115.15$  (pg/ml) respectively. Synovial survivin levels ranged between  $420-575$  (pg/ml) with a mean of  $479.61\pm 52.68$  (pg/ml) and was significantly higher than in the RA patients' sera ( $p<0.001$ ). RA patients were divided into survivin -ve group included 21/50 (42%) and survivin +ve group included 29/50 (58%), the serum survivin cut off point ( $167.63$  pg/ml) was selected at the mean plus 3 SD for the control group. Survivin+ve RA patients group have significantly longer mean disease duration and higher HAQ and larsen scores ( $p<0.001$ ) than survivin -ve RA patients group. 9/13 (69%) of the RA patients with Sjogren's syndrome, 8/10 (80%) of the patients with pleural effusion, 3/6 (50%) patients with Raynaud's phenomenon, all patients with sc nodules (5, 100%), episcleritis (2, 100%) and vasculitis (1, 100%) were survivin +ve. RA patients who had Larsen score grading  $\geq 2$  (27/50, 52%) were considered to have an erosive RA disease. There were no statistically significant differences between RA patients according to the presence of erosion regarding age, sex, VAS, DAS score, the presence of RF abs, Anti- CCP abs, mean HB%, WBCs count, PLTs count, ESR 1 st hr value or CRP level.

All RA patients with erosive disease were survivin +ve and had statistically significantly elevated mean serum and synovial survivin levels than the RA patients with non erosive disease ( $337.37\pm 55.19$  pg/ml vs  $126.78\pm 24.33$  pg/ml and  $422.5\pm 3.53$  pg/ml vs  $486.75\pm 51.52$  pg/ml respectively)

**Conclusions:** High levels of survivin are detected in the blood and synovial fluid of RA patients and are associated with erosive joint damage and poor functional outcomes but not related to disease activity.

### FRI0059 INTERSTITIAL LUNG DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS OF A COHORT TREATED WITH METHOTREXATE MONOTHERAPY

E. Chamizo-Carmona<sup>1</sup>, C. Carrasco Cubero<sup>2</sup>, S.M. Rojas Herrera<sup>1</sup>, J. Malave Calzada<sup>1</sup>, R. Veroz Gonzalez<sup>1</sup>, L.M. Chaves Chaparro<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Ciudad de Merida, Merida; <sup>2</sup>Rheumatology, CHU de Badajoz, Badajoz, Spain

**Background:** Diffuse interstitial lung disease (ILD) is a common extra-articular manifestation of rheumatoid arthritis (RA) and an important cause of morbidity and mortality in this patient population. The predisposing and prognostic factors of this complication are a matter of debate.

**Objectives:** To determine the characteristics associated with the development of ILD in a cohort of patients with RA who received Methotrexate (MTX) monotherapy.

**Methods:** Case-control study in a cohort of patients with RA who had received MTX monotherapy, being cases those who developed ILD and controls, those who did not develop it.

**Results:** The cohort consisted of 301 patients (67% women), with a mean age of 49.6 ( $\pm 13.2$ ) years and a follow-up of 135.8 ( $\pm 93.5$ ) months. There were 15 (5%) cases of ILD, classified by high resolution chest CT as usual interstitial pneumonitis 7, nonspecific interstitial pneumonitis 7 and interstitial bronchiolitis 1. The distribution by sex was 8 ILD among 202 women (3.9%) and 7 ILD among the 99 men (7.1%). They all had RF and/or ACPA positive. ILD was associated with longer duration of the disease ( $p<0.05$ ), exposure to DMARDs prior to MTX ( $OR=3.3$ ,  $p<0.05$ ), history of chronic lung disease ( $OR=6.5$ ;  $p<0.01$ ) and coexistence with secondary Sjögren syndrome ( $OR=3.2$ ,  $p<0.05$ ). We did not find significant differences in mean values of age, RF, ACPA, baseline CRP and DAS28, dose, route and time of exposure to MTX, smoking, functional capacity, presence of erosions, MTX response and toxicity. The predictive factors in the logistic regression were the history of chronic pneumopathy, extra-articular involvement, time of evolution and basal biological activity (CRP) of the disease. Of the 15 patients with ILD, 5 (33.3%) had good response (DAS28-CRP  $< 3.2$ ) with MTX and remained on monotherapy, another 3 continued with MTX combined with another DMARD and 7 (46.7%) discontinued MTX. In addition, 8 of these 10 patients received a biological therapy. Eleven patients died during follow-up, 3 (20%) cases (ILD) and 8 (2.8%) controls ( $p<0.01$ ).

Clinical characteristics of the cohort

	Total (301)	ILD(15)	No ILD (286)	p
Age, years, mean(SD)	49,6 (13,2)	53,5 (13,9)	49,3 (13,2)	0,23
Women, n(%)	202 (67,1)	8 (53,3)	194 (67,8)	0,24
RA Duration, months, mean(SD)	135,8 (93,5)	105,0 (27,1)	92,4 (5,5)	0,04
Smoker, n(%)	183 (60,8)	8 (53,3)	175 (61,2)	0,54
Previous chronic lung disease, n (%)	51(16,9)	8 (53,3)	43 (15,0)	0001
Sjogren síndrome, n(%)	33 (11,0)	4 (26,7)	29 (10,1)	0,04
Previous FAME, n(%)	81(26,9)	8 (53,3)	73 (25,5)	0,02
CRP, mg/l, mean(SD)	17,8 (21,3)	32,3 (31,9)	17,0 (20,4)	0,09
DAS28-CRP, mean(SD)	4,5 (0,8)	4,6 (0,8)	4,5 (0,8)	0,54
RF, mean (SD)	141,7 (212,3)	226,0 (314,1)	137,2 (205,4)	0,30
ACPA, mean (SD)	156,4 (156,7)	198,3 (161,5)	154,2 (156,5)	0,31
MTX, mg/week, mean (SD)	16,5 (3,7)	16,2 (3,9)	16,5 (3,7)	0,74
MTX Response, n(%)	149 (49,5)	5 (33,3)	144 (50,3)	0,20
Withdrawal of MTX, n(%)	71 (23,6)	7 (46,7)	64 (22,4)	0,03
Deaths, n(%)	11 (3,6)	3 (20,0)	8 (2,8)	0001

**Conclusions:** ILD is a frequent and serious complication in RA. It appears more frequently in patients with previous pneumopathy and long-term disease and with extra-articular involvement of RA.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5495

**FRI0060 ARE OLDER RA PATIENTS FRAIL, OR LONELY AND DEPRESSED?**

F. Cleutjens<sup>1</sup>, A. Boonen<sup>2</sup>, M. van Onna<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Maastricht University; <sup>2</sup>Department of Internal Medicine, Division of Rheumatology, Maastricht University Medical Center, Maastricht, Netherlands

**Background:** The average rheumatoid arthritis (RA) patient has approximately 2 comorbidities, and this number increases with age. Both comorbidity and ageing are considered risk factors for frailty, a physiological syndrome characterised by reduced functional reserves and resistance to 'stressors' due to a cumulative decline of physiological and psychosocial systems. Frailty results in adverse health outcomes including hospitalisation and increased risk of mortality. The extent to which frailty is a relevant problem in elderly RA patients remains unknown.

**Objectives:** (1) To assess the prevalence of frailty and (2) to identify which factors are associated with frailty in elderly patients with RA.

**Methods:** Consecutive patients of the outpatient clinic were invited to participate in a study on ageing while ensuring equal representation of patients in three pre-defined age groups: 55–64, 65–74, and ≥75 years. Rheumatologists recorded the number of comorbidities. Patients rated their overall health on a visual analogue scale (0–100; 100 very bad health) and completed the validated Groningen Frailty Indicator (GFI), which contains 15 questions on the loss of functions and resources across 4 domains: physical (mobility functions, multiple health problems, physical fatigue, vision, hearing), cognitive (cognitive dysfunction), social (emotional isolation), and psychological (depressed mood and feelings of anxiety). Scores on items are dichotomized, "1"; indicating a problem or dependency. Prevalence of problems/dependency was compared among the 3 age-groups using a Kruskal-Wallis test. Characteristics of patients classified as frail (GFI score ≥4) or non-frail (GFI score <4) were compared using a chi-square test for categorical data or the independent samples t-test for continuous data.

**Results:** The prevalence of frailty across age groups was respectively 43.3%, 40.0% and 43.4%. Frail RA patients were more often female, had a lower subjective health status. Remarkable, patients classified as frail identified problems in the social and psychosocial domains. Of interest, there were no differences regarding age, polypharmacy, number of comorbidities, and cognitive domain (figure 1).

**Table 1** Comparison of demographics, clinical characteristics, and number of patients with problems/dependency per frailty domain between frail and non-frail elderly rheumatoid arthritis patients.

	Frail (n=38)	Non-frail (n=52)	p-value
<b>DEMOGRAPHICAL CHARACTERISTICS</b>			
Male	8 (21)	23 (42)	0.035
Age, mean (SD)	69.9 (9)	69.6 (7)	0.878
<b>CLINICAL CHARACTERISTICS</b>			
Patient global health (0–100), mean (SD)	45.7 (20)	34.5 (16)	0.004
Comorbidities, mean number (SD)	0.6 (1)	0.5 (1)	0.862
<b>FRAILTY DOMAIN SCORES</b>			
<b>Physical domain GFI; problem or dependency: n (%)</b>			
Grocery shopping	5 (13)	2 (4)	0.103
Walk outside the house	3 (8)	0 (0)	0.039
Getting (un)dressed	3 (5)	0 (0)	0.094
Visiting restroom	1 (3)	0 (0)	0.239
Vision	5 (13)	2 (4)	0.103
Hearing	6 (16)	6 (12)	0.558
Nutrition	6 (16)	1 (2)	0.015
Use of 4+ medication types	30 (79)	38 (73)	0.522
Subjective physical fitness	23 (61)	13 (25)	0.001
<b>Cognitive domain GFI; problem or dependency: n (%)</b>			
Memory complaints	10 (26)	6 (12)	0.070
<b>Social domain GFI; problem or dependency: n (%)</b>			
Emptiness	24 (63)	2 (4)	<0.001
Missing the presence of people around	25 (66)	4 (8)	<0.001
Feelings of loneliness	23 (55)	0 (0)	<0.001
<b>Psychosocial domain GFI; problem or dependency: n (%)</b>			
Feelings of depression	28 (74)	4 (12)	<0.001
Nervous or anxious feelings	22 (58)	8 (15)	<0.001

Data are presented as number (percentage) of patients unless stated otherwise.

**Conclusions:** Using validated questionnaires, frailty is highly prevalent in all RA patients older than 55 years and seems to be a distinctive health construct which is not necessarily related to increasing age, polypharmacy and comorbidity in patients with RA. An alternative explanation of our findings is that rheumatologists seem to miss symptoms of depression and loneliness among RA patients.

**FRI0061 CARDIOVASCULAR RISK FACTOR AND DISEASE BURDEN IN BELGIAN PATIENTS WITH RHEUMATOID AND MUSCULOSKELETAL DISEASES OF NORTH AFRICAN COMPARED TO EUROPEAN DESCENT**

F. Fleurinck<sup>1</sup>, L. Tsang<sup>1</sup>, M. Walschot<sup>1</sup>, M. Reyskens<sup>1</sup>, A.O. Solomon<sup>2</sup>, A. Millen<sup>2</sup>, P. Dessen<sup>1</sup>. <sup>1</sup>Free University Brussels, Brussels, Belgium; <sup>2</sup>Witwatersrand University, Johannesburg, South Africa

**Background:** Patients with rheumatic and musculoskeletal diseases (RMDs) from developed populations often experience increased atherosclerotic cardiovascular disease (ACVD) risk. In European countries, increasing proportions of inhabitants originate in developing countries and are therefore reportedly at an earlier epidemiological transition stage, which is associated with reduced ACVD.<sup>1</sup>

**Objectives:** This study aimed to determine whether population origin specific cardiovascular risk management is indicated in Belgian patients with RMDs.

**Methods:** We recorded major conventional cardiovascular risk factors included in the Systematic Coronary Risk Evaluation (SCORE) or/and Framingham score equation, other conventional and non-conventional cardiovascular risk factor profiles and the prevalence of subclinical ACVD comprising arterial stiffness (pulse pressure >60 mmHg) and established ACVD (coronary artery disease, ischaemic cerebrovascular disease or/and peripheral artery disease) in 673 consecutive patients with RMDs; 126 and 547 were of North-African and European ancestry, respectively. Cardiovascular risk factors and disease were compared between patients of North African and European descent in multivariable logistic and linear regression models.

**Results:** Patients of North African descent tended to have less frequently inflammatory RMDs (OR (95% CI)=0.69 (0.45–1.04)) including rheumatoid arthritis (RA) (OR (95% CI)=0.46 (0.19–1.09)), and had more often fibromyalgia (OR (95% CI)=2.93 (1.84–4.65)). Patients of North African descent were younger than their European descent counterparts (mean (SD)=47.5 (14.7) vs 55.7 (16.5) years, p<0.0001). In age, sex and inflammatory RMD adjusted analysis, North African descent patients had less prevalent hypertension (OR (95% CI)=0.54 (0.33–0.87)) and more frequent diabetes (OR (95% CI)=3.69 (2.00–6.80)); North African descent patients exercised ((OR (95% CI)=0.34 (0.20–0.57)) and used alcohol (OR (95% CI)=0.05 (0.02–0.12)) less often, and had a less frequent family history of ACVD (OR (95% CI)=0.64 (0.41–0.99)), smaller body height (mean (SD)=1.64 (0.09) vs 1.66 (0.11) m, p<0.0001) and larger the Arthritis Impact Measurement Scales Depression score (mean (SD)=4.4 (1.9) vs 3.7 (2.0), p=0.009). These findings translated into a frequencies of having ≥1 major cardiovascular risk factor, overall 10 year high risk for any (Framingham score ≥20) and fatal (SCORE ≥5) ACVD, and prevalence of subclinical and established ACVD that were as large in RMD patients from North African compared to European descent. European League Against Rheumatism multiplier<sup>2</sup> application in patients with RA did not alter these findings.

**Conclusions:** Consistent disparities exist in ACVD risk factor profiles between RMD patients of North-African and European descent. However, the overall cardiovascular risk factor and disease burden is currently as large in RMD patients of North African compared to European ancestry. Adequate ACVD risk management in RMD patients should be performed irrespective of population origin.

**FRI0062 CORTICOSTEROID INJECTION FOR PLANTAR HEEL PAIN: A SYSTEMATIC REVIEW AND META-ANALYSIS**

G. Whittaker, S.E. Munteanu, H.B. Menz, D.R. Bonanno, J.M. Gerrard, K. B. Landorf. *La Trobe University, Melbourne, Australia*

**Background:** Plantar heel pain is one of the most common conditions affecting the foot in adults, with prevalence estimates between 4% and 7%.<sup>1,2</sup> Corticosteroid injection is a common intervention used to treat plantar heel pain,<sup>3</sup> however there is limited high quality evidence to support this practise. Because corticosteroid injection is frequently used for plantar heel pain, it is important that health professionals understand whether the evidence-base supports the use of this intervention.

**Objectives:** To conduct a systematic review and meta-analysis of the effectiveness of corticosteroid injection for pain and function in people with plantar heel pain.

**Methods:** Databases searched include Medline, CINAHL, SPORTDiscus, Embase and the Cochrane Library. Included studies had to be randomised trials that evaluated the effectiveness of corticosteroid injection on pain or function for plantar heel pain. The primary outcomes were pain (including 'first step' pain) and function, categorised as short (0 to 6 weeks), medium (7 to 12 weeks) or longer term (13 to 52 weeks). A secondary outcome was plantar fascia thickness. Mean differences or standardised mean differences and 95% confidence intervals were calculated. The Cochrane Collaboration tool for assessing risk of bias was used to assess trial quality, and the GRADE approach was used to assess the strength of evidence.

**Results:** A total of 37 trials (2200 participants) were included. In the short term, corticosteroid injection was more effective for reducing pain than autologous blood injection (SMD  $-0.56$  [ $-0.86, -0.26$ ]) and orthotic devices (SMD  $-1.20$  [ $-2.30, -0.11$ ]). There were no significant findings in the medium term. In the longer term, corticosteroid injection was less effective than platelet-rich plasma injection (SMD  $0.87$  [ $0.30, 1.45$ ]). For function, corticosteroid injection was more effective than physical therapy in the short term only (SMD  $-0.69$  [ $-1.31, -0.07$ ]). Notably, corticosteroid injection was not more effective than placebo injection for reducing pain in the short (SMD  $-0.98$  [ $-2.06, 0.11$ ]) and medium (SMD  $-0.86$  [ $-1.90, 0.19$ ]) terms. When trials considered to have high risk of bias were excluded, there were no significant findings.

**Conclusions:** Our review found that corticosteroid injection is more effective for reducing pain than some comparators, and more effective for improving function than physical therapy in the short term. Corticosteroid injection is more effective than platelet-rich plasma injection in the longer term. Corticosteroid injection is *not* more effective than placebo injection for reducing pain or improving function.

#### FRI0063 RAPAMYCIN INDUCES REMISSION IN PATIENTS WITH REFRACTORY RHEUMATOID ARTHRITIS

H. Yao<sup>1</sup>, H. Niu<sup>1</sup>, N. Yan<sup>1</sup>, X. Sun<sup>1</sup>, Z. Li<sup>1</sup>, M. Chen<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>, C. Wang<sup>1</sup>.  
<sup>1</sup>Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China; <sup>2</sup>Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, USA

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease that results in destruction of joint cartilage and bone. However, many patients do not achieve satisfactory disease control by current therapy with high risk of adverse reactions. We have reported that absolute number of peripheral regulatory T (Treg) cells reduced in RA patients (EULAR Abstract). Moreover, rapamycin has been reported to inhibit differentiation of Th17 and promote growth of FoxP3 +Treg cells by inhibiting mTOR pathway<sup>[1]</sup>.

**Objectives:** To observe the therapeutic efficacy of rapamycin on the reduction of disease activity, increase in Tregs and decrease in Th17 to restore balance of Th17/Treg cells in RA patients with high disease activity (DAS28  $\geq 2.6$ ).

**Methods:** Fifty RA patients who treated with two kinds of DMARDs for more than half a year did not achieve remission (DAS28  $\geq 2.6$ ) were enrolled and were treated with rapamycin at a dose of 0.5 mg every 2 days for 24 weeks. The absolute number of CD4 +T cell subsets in peripheral blood from these patients were assessed by flow cytometry combined with internal standard beads before the treatment as baseline and at week 24 after treatment. Meantime, the DAS28, the dosage of corticosteroids and immunosuppressant were also recorded.

**Results:** Rapamycin treatment reduced the disease activity and induced remission (DAS28 < 2.6) in 44.9% of active RA patients. Their DAS28 was reduced from a median 2.9 (at week 0) to 1.9 (at week 24) ( $P < 0.001$ ) and the absolute number of peripheral Treg cells was increased from  $27.14 \pm 15.11$  cells/ $\mu$ l (at week 0) to  $36.59 \pm 17.23$  cells/ $\mu$ l (at week 24) ( $p = 0.002$ ). The ratios of Th17/Treg cells also had a significant decrease from  $0.36 \pm 0.29$  at baseline to  $0.27 \pm 0.20$  at week 24 ( $P < 0.041$ ). In contrast, the decrease in the absolute number of Th17 cells was not

statistically significant ( $p = 0.846$ ). After the treatment, the proportion of patients taking glucocorticoids decreased from 66.0% to 64.0% and the mean dosage of prednisone decreased from 9.89 mg/d to 7.70 mg/d. And the usages of DMARDs were also reduced ( $P < 0.001$ ).

**Conclusions:** Rapamycin combined with low level of conventional therapy effectively reduced disease activity and induced remission among RA patients who received long-term conventional treatment without remission (DAS28  $\geq 2.6$ ) by increasing the absolute number of Treg cells and restoring the balance of Th17 cells and Treg cells. As the research progresses, rapamycin is likely to become a promising therapeutic candidate.

#### FRI0064 RIGHT VENTRICLE DIASTOLIC DYSFUNCTION IN EARLY RHEUMATOID ARTHRITIS PATIENTS: RISK FACTORS AND THE EFFECT OF ANTIRHEUMATIC THERAPY

I.G. Kirillova, D. Novikova, T. Popkova, H. Udachkina, E. Markelova, A. Volkov, Y. Gorbunova. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Objectives:** To determine the frequency of diastolic dysfunction of the right ventricle (RVDD) in patients (pts) with early rheumatoid arthritis (RA) prior to therapy with basic anti-inflammatory drugs (DMARDs), examine its relationship with traditional risk factors of cardiovascular disease and markers of inflammation, to study the effect of antirheumatic therapy administered in accordance with "treat to target" (T2T) principles on RVDD in early RA pts during 18 month follow-up.

**Methods:** A total of 66 pts with early RA (ACR/EULAR criteria, 2010) were included: 71% of women, age  $56^{46;61}$  years, disease duration  $6^{4;8}$  months; DAS28  $5.3$  [ $5.0;6.2$ ], positive for ACCP (100%)/RF (87%), without prior administration of DMARDs and glucocorticoides. All pts underwent blood pressure monitoring (BP), echocardiography, tissue Doppler imaging. Methotrexate (MT) therapy was started in all pts with an escalation of the dose up to 30 mg/week subcutaneously. In case of no remission 3 months later, MT was added with biologic therapy (BT): Adalimumab, Certolizumab pegol, Abatacept, Rituximab. After 18 months 29 (44%) pts achieved remission. Antihypertensive therapy was administered in 51 (77%) pts: ACE inhibitors, ARBs, beta-blockers, calcium antagonists, diuretics.

**Results:** At baseline RVDD was detected in 16 (24%) pts. RVDD related factors that remained associated on a multivariable forward stepwise linear regression analysis were body mass index (BMI) ( $\beta$ -coefficient (95% CI)  $0.3$  ( $-0.003; -0.008$ ), SDAI  $0.2$  ( $-0.009; -0.001$ ), carotid atherosclerosis (CA)  $0.2$  ( $-0.3; 0.01$ ), disease duration  $0.2$  ( $-0.02; 0.001$ ). Multiple coefficient of determination ( $R^2$ ) was 38% ( $p = 0.03$ ). After 18 months the incidence rate of RVDD decreased from 24% to 18%,  $p > 0.05$ . The dynamics of diastolic function was multidirectional. RVDD was normalised in 10 (63%) of 16 RA pts with RVDD ( $p = 0.02$ ). All of them had effective control of BP and achieved remission. 67% of pts with normalised RVDD received MT+BT. 5 (31%) pts with new cases of RVDD and 6 pts with preserved RVDD did not reach the target values of BP and RA remission.

**Conclusions:** Presence of CA, higher BMI, SDAI and disease duration strongly associated with the incidence rate of RVDD. A significant decrease of RVDD in case of achieved targeted BP values and RA remission was observed during 18 month therapy of early RA pts in accordance with "T2T" principles

**Disclosure of Interest:** None declared

FRI0065

### DHCR7 AND GENETIC POLYMORPHISMS IN THE ASSOCIATION BETWEEN VITAMIN D AND LIPID PROFILE IN RA: NEW PLAYERS IN CARDIOVASCULAR DISEASE?

J. Rodríguez-Carrio<sup>1,2,3</sup>, M. Alperi-López<sup>2,4</sup>, M. Naves-Díaz<sup>1,2</sup>, A. Dusso<sup>1,2</sup>, P. López<sup>2,3</sup>, F.J. Ballina-García<sup>2,4</sup>, J.B. Cannata-Andía<sup>1,2</sup>, A. Suárez<sup>2,3</sup>. <sup>1</sup>Bone Mineral and Research Unit, Instituto Reina Sofía de Investigación Nefrológica, Redinren Isciii, Hospital Universitario Central de Asturias; <sup>2</sup>Instituto de Investigación Sanitaria del Principado de Asturias (ISPA); <sup>3</sup>Area of Immunology, University of Oviedo; <sup>4</sup>Department of Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain

**Background:** rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) risk. Although vitamin D deficiency has been linked to CV disease in other conditions, studies in RA have yielded contradictory results and pointed to the involvement of additional factors. On the one hand, several genetic polymorphisms have been linked to vitamin D levels. Moreover, emerging evidence suggests a role for the enzyme DHCR7 in the crosstalk between cholesterol and vitamin D synthesis.

**Objectives:** to evaluate the effect of genetic polymorphisms and DHCR7 levels in the interaction between vitamin D and lipid profile in RA.

**Methods:** serum levels of vitamin D and DHCR7 were measured in 212 RA patients (2010 EULAR/ACR criteria) and 104 matched healthy controls (HC) by chemiluminescence and immunoassays, respectively. VDR rs2228750 and DHCR7 rs12785878 SNPs were studied by TaqMan Assays. The effect of vitamin D deficiency on clinical features was assessed by linear regression analyses adjusting for age, gender, seasonality, vitamin D supplementation and DMARD usage.

**Results:** decreased vitamin D was found in RA compared to HC ( $p < 0.001$ ), vitamin D deficiency ( $< 20$  ng/ml) being more prevalent in winter/spring (58/151, 38.4%) than in summer/autumn (12/61, 19.6%;  $p = 0.010$ ). Vitamin D levels were positively correlated to those of HDL ( $r = 0.217$ ,  $p < 0.001$ ), this association being restricted to patients with the rs2228750 AG/AA genotype ( $r = 0.287$ ,  $p = 0.003$ ) but not in those with the GG one ( $r = 0.082$ ,  $p = 0.531$ ). Equivalent results were obtained for total/HDL-cholesterol ratio. Vitamin D deficiency was associated with lower HDL ( $p = 0.040$ ), higher tender joint count ( $p = 0.003$ ), swollen joint count ( $p = 0.005$ ), DAS28 ( $p = 0.028$ ) and HAQ ( $p = 0.030$ ) in AG/AA-patients but not in those with the GG status (all  $p > 0.050$ ). Decreased DHCR7 levels were found between RA and HC in winter/spring ( $p = 0.008$ ) but not in summer/autumn ( $p = 0.116$ ). RA patients with CV disease exhibited lower DHCR7 levels ( $p = 0.012$ ) than their CV-free counterparts. Moreover, the associations among DHCR7, vitamin D and HDL levels followed a seasonal pattern: DHCR7 was correlated to vitamin D levels in summer/autumn ( $r = 0.441$ ,  $p = 0.004$ ), where vitamin D was associated with both HDL levels ( $r = 0.354$ ,  $p = 0.009$ ) and total/HDL ratio ( $r = -0.393$ ,  $p = 0.003$ ). A DHCR7 rs12785878-driven effect was observed for these associations. On the contrary, a weak correlation between HDL and vitamin D was found in winter/spring ( $r = 0.215$ ,  $p = 0.014$ ), where decreased DHCR7 was associated with age at onset ( $r = -0.285$ ,  $p = 0.006$ ) and RF titre ( $r = -0.326$ ,  $p = 0.013$ ).

**Conclusions:** the effect of vitamin D on the lipid profile is dependent on genetic polymorphisms. DHCR7 has a pivotal role in the interaction between vitamin D and lipid profile in RA. Seasonality and DHCR7-HDL axis may be novel mediators in the CV disease in RA.

### IMPACT OF SERUM ADIPOKINES IN EARLY STAGES OF RHEUMATOID ARTHRITIS

J.A. Chaparro<sup>1,2</sup>, J.M. Bello-Gualtero<sup>1,2</sup>, W. Bautista-Molano<sup>2,3</sup>, L. Chila<sup>3</sup>, M. A. Cano<sup>3</sup>, R. Valle-Oñate<sup>1</sup>, P. Chalem<sup>4</sup>, C. Romero-Sánchez<sup>1,2,3</sup>. <sup>1</sup>Rheumatology and Immunology, Hospital Militar Central; <sup>2</sup>Clinical Immunology Group, Universidad Militar Nueva Granada; <sup>3</sup>Unit of Oral Basic Investigation, Universidad El Bosque; <sup>4</sup>Fundación Instituto de Reumatología Fernando Chalem, Bogotá D.C., Colombia

**Background:** Rheumatoid arthritis (RA) is a systemic chronic inflammatory disease. Adipose tissue is regarded as an active endocrine organ producing adipokines such as leptin and adiponectin, and some proinflammatory cytokines which have proinflammatory properties that account for chronic low-grade systemic inflammation

**Objectives:** To investigate the levels of adipokines in eRA and establish their association with the state of rheumatic condition

**Methods:** Cross sectional study was conducted. 51 patients with eRA according to the ACR/EULAR 2010 criteria and 51 healthy controls matched by age and gender, were included. A complete medical history was obtained. Adiponectin levels measured by Luminex technology, IL6 by chemiluminescence and Iptin by Enzyme-linked immunosorbent assay. Serum markers of RA such as rheumatoid factor, erythrocyte sedimentation rate(ESR), C reactive protein(CRP), and anticitrullinated protein antibodies-APCA IgG/IgA. Disease activity was evaluated by

DAS28CRP, DAS28ESR, CDAI, SDAI and RAPID3, the functional status using Multidimensional health assessment questionnaire(MDHAQ) and radiological status by Simple Erosion Narrowing Score(SENS). An association analysis was made to evaluate the relationship between adipokines levels and rheumatologic conditions using X2 test, Mann Whitney and logistic regression model was performed to confirm this associations. All the results were performed with a level of significance of 95%

**Results:** In the eRA group, 80.39% were women, the mean age was 48.54  $\pm$  10.93 years. 37.25% had overweight and 13.72% had obesity Among the controls, 80.39% were women, with the mean age of 48.55  $\pm$  11.07 years. 27.45% had overweight and 5.88% had obesity. 45.09% moderate activity and 17.64% high activity by DAS28ESR. High leptin levels were found in 64.7% vs 23.5% in healthy controls ( $p = 0.001$ ). High adiponectin levels was found associated to BMI  $< 25$  ( $p = 0.017$ ) and high leptin level to BMI  $> 25$  ( $p = 0.038$ ) and disease activity by RAPID3 ( $p = 0.039$ ). The presence of joint space narrowing in hands was associated with low adiponectin levels ( $p = 0.044$ ). The association of leptin levels  $> 1.67$  ng/mL with the diagnosis of RA was maintained in the model adjusted for the presence of *P. gingivalis*, DAS28-ESR, CRP  $> 3$  mg/L, economic status and BMI  $> 30$ , OR = 2.79 95% CI (1.54–5.07). The presence of high leptin and IL6 levels and low level adiponectin at the same time were more frequently found in the female gender ( $p = 0.047$ ), primary schooling ( $p = 0.050$ ), BMI  $> 30$  ( $p = 0.023$ ), patients with radiological damage SENS  $> 3$  ( $p = 0.047$ ) and were found associated at the same time to MDHAQ  $> 3$ , BMI  $> 25$  and RAPID3  $> 12$  (OR 5.03 95% CI 1.05–24) adjusted to clinical variables

**Conclusions:** The role of adipokines as the leptin could be considered to be the bridge between immune tolerance, metabolic function and autoimmunity and suggests the possibility to use circulating levels of adipokines as potential biomarkers of disease activity and functional status in early stage of rheumatoid arthritis

Herranz<sup>12</sup>, C. Martinez Prada<sup>13</sup>, C. Morado Quiñoa<sup>13</sup>, V. Villaverde<sup>14</sup>, on behalf of TREND-AR. <sup>1</sup>Rheumatology, Hospital Universitario Ramón y Cajal; <sup>2</sup>Rheumatology, Hospital Universitario Fundación Alcorcón; <sup>3</sup>Rheumatology, Hospital Universitario Fundación Alcorcón; <sup>4</sup>Rheumatology, Hospital Universitario Fundación Alcorcón; <sup>5</sup>Rheumatology, Hospital Universitario Severo Ochoa; <sup>6</sup>C.S La Rivota; <sup>7</sup>Rheumatology, Hospital Universitario Fundación Alcorcón; <sup>8</sup>Rheumatology, Hospital Universitario Puerta de Hierro, Madrid; <sup>9</sup>Rheumatology, Hospital Universitario de Guadalajara, Guadalajara; <sup>10</sup>Rheumatology, Hospital Universitario doce de octubre; <sup>11</sup>Rheumatology, Hospital Universitario La Princesa; <sup>12</sup>Rheumatology, Hospital del Henares; <sup>13</sup>Rheumatology, Hospital Clínico San Carlos; <sup>14</sup>Rheumatology, Hospital Universitario de Mostoles, Madrid, Spain

**Background:** Felty's syndrome (FS) is an infrequent entity related to Rheumatoid Arthritis (RA) but it's unknown the trend of FS in Spain.

**Objectives:** To analyse the incidence and trend of hospital admissions for FS in RA patients in Spain from 1999 to 2015.

**Methods:** We performed an observational retrospective population study analysing the spanish administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of RA patients from 1999 to 2015. We selected the MBDSs for FS. Cases were identified by the presence in primary and secondary diagnosis of its ICD9 code. The population at risk was estimated with an estimated prevalence of RA of 0,5% (0,8% women and 0,2% men). Crude and adjusted rates were calculated, and the trend was analysed using the Generalised Linear Model (GLM) with the year as the analysis variable. SPSS version 20 (SPSS Inc, Chicago, IL) was used.

**Results:** 338.343 RA hospital admissions were detected, being 802 (0,2%) due to FS, 455 (56,7%) women and 347 (43,3%) men. Mean age was 67,94(SD 13,76). There were 61 (7,6%) deaths. Age-adjusted rate during the period was 42,19/10<sup>5</sup> inhab. per year (19,76 women and 64,61 men). FS age-adjusted rate decreased from 25,90/10<sup>5</sup> inhab. per year in 1999 to 17,20 in 2015, both women (12,85 in 1999 to 11,75 in 2015) and men (80,15 in 1999 to 38,75 in 2015). An annual decrease in the FS rate of 0,5% is estimated (RRI 0,995; CI 95% 0,976–1,014).

**Conclusions:** In Spain FS hospital admissions in patients with RA decreased between 1999–2015 with an estimation of 0,5% annual reduction not statistically significant.

**Disclosure of Interest:** None declared

### FRI0068 ULTRASONOGRAPHIC SUBCLINICAL CARDIOVASCULAR FINDINGS IN HISPANIC RA PATIENTS: A CASE-CONTROL STUDY

J.R. Azpiri-López<sup>1</sup>, D.A. Galarza-Delgado<sup>2</sup>, I.J. Colunga-Pedraza<sup>2</sup>, A.H. Guillén-Lozoya<sup>2</sup>, J.A. Dávila-Jiménez<sup>2</sup>, E.E. Abundis-Márquez<sup>2</sup>. <sup>1</sup>Cardiology; <sup>2</sup>Rheumatology, Hospital Universitario "Dr José E. Gonzalez", UANL, Monterrey, Mexico

**Background:** Patients with RA have a 1.5–2.0 fold increased risk of developing coronary artery disease (CAD) compared with the general population. Patients with RA are typically managed by several physicians, and coordination of care may be suboptimal.<sup>1</sup> The leading cause of death in RA-patients is atherosclerotic cardiovascular disease (ASCVD).<sup>2</sup> Carotid artery and heart evaluation by ultrasound is a useful tool for detection of cardiovascular conditions.

**Objectives:** To compare the presence of subclinical cardiovascular conditions among Mexican-mestizo RA patients and matched controls.

**Methods:** Design: Observational, cross-sectional, case-control study. Patients of 40 to 75 years old who fulfilled the 2010 ACR/EULAR and/or the 1987 ACR classification criteria for RA were consecutively enrolled. Patients with previous ASCVD or any other rheumatic disease were excluded. Two board-certified radiologist performed and assessed all carotid ultrasounds (cUS) and two board-certified cardiologist performed and assessed transthoracic echocardiography (TTE) according to guidelines of the American Society of Echocardiography. ASE, 2016

**Results:** The RA patients showed higher prevalence of cardiovascular risk conditions with respect to control population, such as concentric remodelling/hypertrophy, diastolic dysfunction, valve regurgitation and Carotid intima media thickness (CIMT) (See table 1).

**Abstract FRI0068 – Table 1.** Ecographic cardiovascular pathological conditions among RA patients.

Ecographic findings	RA n=50 (%)	Controls n=50 (%)	P	O.R. (C.I. 95%)
Valve regurgitation, n (%)	42 (84)	32 (64)	0.023	2.93 (1.14-7.64)

### FRI0069 DIFFERENCE OF CLINICAL IMPLICATION REGARDING THE NUMBERS OF AUTOANTIBODIES AT PRESENTATION IN KOREAN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

J.Y. Pyo<sup>1</sup>, C.-H. Mun<sup>2</sup>, S.M. Jung<sup>2</sup>, S.W. Lee<sup>2</sup>, J. Song<sup>2</sup>, S.K. Lee<sup>2</sup>, Y.B. Park<sup>2</sup>.

<sup>1</sup>Department of Internal Medicine, Yonsei University Wonju College of Medicine, Wonju; <sup>2</sup>Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

**Background:** Epitope spreading occurs prior to the clinical diagnosis of rheumatoid arthritis (RA), the number of peptide recognised and its titer increases remarkably as becoming close to the clinical diagnosis. However, the effect of multiple autoantibodies on the clinical outcome is not well known.

**Objectives:** This study is to investigate the association between the number of autoantibodies at presentation and the clinical aspects in Korean patients with early RA.

**Methods:** The number of baseline autoantibody (rheumatoid factor, anticitrullinated peptide antibodies (ACPA), and anti-carbamylated protein antibodies (anti-CarP)) was analysed in the Korean Intensive Management of Early Rheumatoid Arthritis (KIMERA) cohort. All patients were disease-modifying antirheumatic drug (DMARD)-naïve RA patients with symptom duration less than 1 year. They were intensively treated by adjusting medications every 4 weeks, and treated to target as DAS28 of <2.6. Patients were classified regarding the number of autoantibodies and clinical characteristics were compared between the groups.

**Results:** A total of 128 patients were included, seronegative patients showed higher baseline physician global VAS (7.3 vs 4.7 vs 4.6 vs 4.4, p=0.005) and DAS28-ESR (7.1 vs 4.5 vs 5.0 vs 4.7, p=0.003) than patients with 1, 2, and 3 autoantibodies. Also seronegative patients showed a trend to have higher baseline HAQ score and pain VAS. After intensive treatment, there were no differences in remission rate and DAS28-ESR at 12, 24, and 36 months.

**Abstract FRI0069 – Table 1.** Disease characteristics regarding number of autoantibodies

Variables	0 (n=5)	1 (n=13)	2 (n=58)	3 (n=52)	p-value
Age, years	58.2±16.2	46.4±12.4	52.8±12.9	48.2±13.5	0.104
Female sex, N (%)	5 (100%)	7 (53.8%)	44 (75.9%)	44 (84.6%)	0.062
Symptom duration, days	7.0±4.8	10.2±12.1	10.5±16.0	8.1±7.5	0.736
BMI (kg/m <sup>2</sup> )	24.1±4.2	21.7±1.9	23.0±2.9	23.0±3.1	0.508
ESR (mm/hour)	59.0±15.8	44.4±17.6	56.8±32.0	57.9±32.2	0.543
CRP (mg/L)	20.9±17.3	13.6±26.9	19.0±29.4	12.9±15.7	0.559
HAQ score	1.4±0.5	0.6±0.6	0.7±0.6	0.7±0.6	0.092
Pain VAS	7.6±0.9	4.0±2.0	4.5±2.7	4.4±2.9	0.073
Patient global VAS	7.3±1.7	4.7±2.2	4.6±2.5	4.4±2.7	0.127
Physician global VAS	7.0±0.9	4.9±1.1	5.5±1.2	4.5±1.6	0.005
DAS28-ESR	7.1±0.6	4.5±1.2	5.0±1.4	4.7±1.4	0.003

Values are expressed as means±standard deviation or N (%). BMI, body mass index; ESR, erythrocyte sedimentation rate; CRP, C-reactive protein; HAQ: health assessment questionnaire; VAS, visual analogue scale; DAS, disease activity score

### Changes in DAS28 according to number of autoantibodies

**Conclusions:** Seronegative patients showed higher levels of baseline inflammation than seropositive patients. However, they had favourable treatment response with rapid improvement which resulted in excellent clinical outcome.

### COST-EFFECTIVENESS OF BIOLOGIC AGENTS FOR RHEUMATOID ARTHRITIS WAS SUPERIOR TO TRADITIONAL/CONVENTIONAL DMARDs WHEN ANALYSED WITH NUMBER NEEDED TO TREAT(NNT) METHOD

K. Harigane<sup>1</sup>, Y. Mochida<sup>1</sup>, K. Sahara<sup>1</sup>, N. Mitsugi<sup>2</sup>. <sup>1</sup>Center For Rheumatic Diseases; <sup>2</sup>Orthopaedic Surgery, Yokohama City University Medical Center, Yokohama, Japan

**Background:** Recently biologic agents are widely used for patients with rheumatoid arthritis (RA). Biologic agents are reported to have higher effectiveness than other disease-modifying anti-rheumatic drugs (DMARDs) including methotrexate (MTX), however, those new agents are more expensive.

**Objectives:** This study evaluated the cost-effectiveness of biologic agents for RA using number needed to treat (NNT) method. NNT is an index for determining the number of patients who need to be treated in order to reach a patient toward to clinical goal when a new treatment is introduced.

**Methods:** Fifty-three patients with RA was included in this study. These patients were introduced biologic agents between September 2012 to <sup>March 2017</sup> and continued same agent up to 24 weeks. NNT was calculated based on disease activity score (DAS28-ESR) and clinical disease activity index (CDAI) at 24 weeks. Ninety-four patients were investigated as a control group who treated with DMARDs. In addition, actual healthcare cost including doctor's fee, laboratory examination, prescription fee, and cost of biologic agents in each patient were calculated based on hospital's medical receipt, then averaged and compared between two groups.

**Results:** In biologic group, tocilizumab (TCZ) were used for 20 patients, golimumab (GLM) for 14 patients, etanercept (ETN) for 13 patients, and other biologics for six patients. In control group, 66 patients administered MTX and/or conventional DMARDs (csDMARDs), and 28 patients administered only csDMARDs. In biologic group, 53 patients (79.2%) achieved remission in DAS28-ESR, and 24 patients (45.2%) achieved remission in CDAI. On the other hand, the rate of remission was 61.7% and 23.4% respectively in control group. NNT was 1.26 (DAS28) and 2.21 (CDAI) in biologic group, and 1.62 and 4.27 respectively in control group. In biologic group, NNT based on DAS28-ESR of each agent was 1.11 of TCZ, 1.30 of ETN, 1.40 of GLM, and 1.50 of others (table 1). The total actual healthcare cost in the study period was 7,812.5 Euro (1044066 JPY; 1 Euro=133.6 JPY, in December 2017) in biologic group and 583.8 Euro (78020 JPY) in control group.

	Number	Ave. DAS28-ESR	Remission	ARR	NNT
Biologic group	53	1.92	42	0.79	1.26
TCZ	20	1.58	18	0.90	1.11
GLM	14	2.10	10	0.71	1.40
ETN	13	2.05	10	0.77	1.30
others	6	2.56	4	0.67	1.50
Control group	97	2.39	58	0.62	1.62
MTX	66	2.30	41	0.61	1.61
csDMARDs	28	2.63	17	0.61	1.65

	Number	Ave. CDAI	Remission	ARR	NNT
Biologic group	53	4.31	24	0.45	2.21
TCZ	20	2.94	11	0.55	1.82
GLM	14	5.10	5	0.36	2.80
ETN	13	4.52	7	0.54	1.86
others	6	6.58	1	0.17	6.00
Control group	94	5.43	22	0.23	4.27
MTX	66	5.19	16	0.24	4.13
csDMARDs	28	6.00	6	0.21	4.67

**Conclusions:** The total actual health care cost of biologic group was much higher than DMARDs group, however, the cost-effectiveness of biologics was superior to DMARDs from the stand point of NNT.

### OUTCOMES FROM RHEUMATOLOGY AND REPRODUCTIVE HEALTH CLINIC 2013–2016

K. Murray<sup>1</sup>, L. Moore<sup>2</sup>, C. O'Brien<sup>3</sup>, A. Clohessy<sup>3</sup>, C. Brophy<sup>3</sup>, P. Minnock<sup>2</sup>, A. B. Mongey<sup>1,2</sup>, E. Molloy<sup>1,2</sup>, O. FitzGerald<sup>1,2</sup>, S. Higgins<sup>3</sup>, M. Higgins<sup>3</sup>, F. McAuliffe<sup>3,4</sup>, D.J. Veale<sup>1,2</sup>. <sup>1</sup>Saint Vincent's University Hospital, Dublin 4; <sup>2</sup>Our Lady's Hospice, Dublin 6; <sup>3</sup>National Maternity Hospital, Dublin 2; <sup>4</sup>UCD Perinatal Research Centre, School of Medicine, University College Dublin, Dublin, Ireland

**Background:** A multidisciplinary approach to pregnancy in women with rheumatic diseases will ensure best outcomes for mother and baby.<sup>1</sup>

**Objectives:** In 2013, we developed a dedicated nurse-led multidisciplinary Rheumatology Reproductive Health Clinic (RRHC) in order to provide a multidisciplinary service.

**Methods:** 98 women attended the RRHC from January 2013–16. They were prospectively assessed for age, diagnosis, medications, use of assisted reproductive technology (ART) and pregnancy outcomes.

**Results:** The mean (range) age was 35 years.<sup>19–48</sup> The majority of patients had rheumatoid or psoriatic arthritis. The characteristics of the patients is summarised in table 1 and their outcomes in table 2. 24 women were on a biologic DMARD therapy at the time of conception. 10 discontinued in the first semester and 5 in the second trimester. 9 continued throughout their pregnancies. 90% of women surveyed were "very satisfied" with the physical and emotional support received in the clinic.

Abstract FRI0071 – Table 1. Patient Characteristics

Diagnosis	Number of Patients
Rheumatoid Arthritis	41
Psoriatic Arthritis	16
Ankylosing Spondylitis	3
Systemic Lupus Erythematosus	2
Juvenile Idiopathic Arthritis	2
Chronic Regional Pain Syndrome	2
Giant Cell Arteritis	1
Reactive Arthritis	2
Behcet's Disease	2
Sicca Syndrome	2
Takayasu's Arteritis	2
Raynaud's Syndrome	2
Fibromyalgia Syndrome	2
Sarcoidosis	1
Mixed Connective Tissue Disease	1
Systemic Sclerosis	1
Total	98

Abstract FRI0071 – Table 2. Outcomes

Outcome	Number of Patients
Information gathering only	10
Pregnancy achieved	62
Using Assisted Reproductive Technology	3
Actively trying to conceive	26
Total number of pregnancies	68
Births	76
Mothers who had one birth only	49
Mothers who had two births (including one set of twins)	27
1st trimester pregnancy loss	11
2nd trimester pregnancy loss	1
Neonatal death (fetal aplasia diagnosed in utero)	1
Breastfeeding continued to 6 week postpartum review	21
Total number of women	98

**Conclusions:** This is the first report of results from a multidisciplinary RRHC. These data show high levels of successful pregnancy outcomes and patient satisfaction.

The majority of patients had an inflammatory arthritis. Successful pregnancy outcomes were achieved in 70% of women actively trying to conceive. 38% of

patients on biologic DMARDs continued these throughout pregnancy. There were comparable miscarriage rates observed when compared with the general population (14% versus 20%).<sup>2</sup> Breastfeeding rates were low at 28% compared to the figure of 55% for the general population in Ireland.<sup>3</sup> Most patients were "very satisfied" with the service.

**FRI0072 THE IMPACT OF ANTI-TNF-THERAPY ON ENDOTHELIAL FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS OR ANKYLOSING SPONDYLITIS**

K. Heinz<sup>1</sup>, P. Oelzner<sup>1</sup>, T. Eidner<sup>1</sup>, K. Goetze<sup>1</sup>, A. Saemann<sup>1</sup>, G. Wolf<sup>1</sup>, T. Neumann<sup>1,2</sup>. <sup>1</sup>Internal Medicine III, Jena University Hospital, Jena, Germany; <sup>2</sup>Rheumatology, Kantonsspital St. Gallen, St. Gallen, Switzerland

**Background:** Increased mortality in chronic rheumatic diseases is mostly attributed to cardiovascular events (CVE). Assessment of endothelial dysfunction can help to identify patients at risk for major CVE. Studies have shown that the underlying endothelial dysfunction in rheumatoid arthritis is closely associated with inflammation. Only limited information is available whether the blockade of TNF $\alpha$  can restore endothelial function.

**Objectives:** To investigate parameters of endothelial function before and after initiation of immunosuppressive therapy (anti-TNF-therapy or methotrexate) in patients with rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis in an open-label, prospective study.

**Methods:** Patients with active RA, PsA or SpA were eligible for inclusion with active disease and when new treatment with sDMARD (methotrexate) or bDMARD (anti-TNF-therapy) was started. Study visits were performed at baseline, at 3 and at 12 months. Clinical disease activity and inflammation marker were obtained. Systemic Coronary Risk Evaluation (SCORE) and measurement of intima media thickness (IMT) were performed to assess baseline cardiovascular (CV) risk. Endothelial function was measured as arterial dilatation (artFD), arterial constriction (artFIC) and venous dilatation (venFD) in response to flicker light by dynamic vessel analysis (DVA; IMEDOS) and by peripheral arterial tonometry (EndoPAT) as reactive hyperemia index (RHI). For the primary endpoint, we analysed the endothelial function before and during treatment (month 12). Secondary endpoints were ACR20/50 response for RA and PsA and ASAS20 response for SpA. A comparison was made for changes in endothelial function in responder and non-responder to immunosuppressive treatment.

**Results:** 62 patients (37 RA, 13 PsA, 14 SpA) were included (mean age 51.3  $\pm$  14.9 years, 46.8% females). The mean ten-year risk of fatal cardiovascular disease (SCORE) was estimated with 2.2% (95%CI: 1.5–3.0). Mean IMT was 0.59  $\pm$  0.13 mm. Treatment was initiated with etanercept (n=21), certolizumab (n=10), infliximab (n=2), adalimumab (n=13), golimumab (n=4) or methotrexate (n=12). Response to treatment after 3 (n=57) and 12 months (n=32) measured by ACR20/50 (RA and PsA) and ASAS20 (SpA) was found in 33.3/16.7% and 57.2% (month 3) and 29.2/20.8% and 50.0% (month 12). ArtFD increased (3.1% $\pm$ 2.8% to 4.0  $\pm$ 3.2%; p<0.05), while artFIC and venFD remained unchanged (-0.3 $\pm$ 1.6% to -0.2 $\pm$ 2.1%; p=0.613, 3.7 $\pm$ 3.0% to 3.9% $\pm$ 2.2%; p=0.383). RHI did not change (1.9% $\pm$ 0.5% to 1.8 $\pm$ 0.5%; p=0.166). There were no differences in changes of endothelial function between responder and non-responder to immunosuppressive therapy or between anti-TNF-therapy and methotrexate.

**Conclusions:** Our data indicate, that patients with active RA, PsA or SpA are at risk for cardiovascular events. Immunosuppressive treatment can improve endothelial function at retinal arteries but has no effect on reactive hyperemia index at peripheral arteries. The effect of immunosuppressive treatment on parameters of endothelial function was not different in responders or non-responders and did not depend on whether the patients were treated with anti-TNF-therapy or methotrexate.

**FRI0073 CHANGES OF BONE MINERAL DENSITY OVER 10 YEARS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

L. Theander<sup>1</sup>, M. Willim<sup>2,3</sup>, J. Å. Nilsson<sup>1,3</sup>, M. Karlsson<sup>4</sup>, K. Åkesson<sup>4</sup>, C. Turesson<sup>1,3</sup>. <sup>1</sup>Rheumatology, Department of Clinical Sciences, Malmö, Lund University, Malmö; <sup>2</sup>Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund; <sup>3</sup>Department of Rheumatology, Skåne University Hospital, Malmö and Lund; <sup>4</sup>Clinical and Molecular Osteoporosis Research Unit, Department of Clinical Sciences, Malmö, Lund University, Malmö, Sweden

**Background:** Patients with Rheumatoid Arthritis (RA) have been shown to have an increased risk of osteoporosis and fractures. Most studies on RA and osteoporosis are cross-sectional. There are very few studies on changes in bone mineral density (BMD) over time.

**Objectives:** To study changes in BMD in men and women with early RA over a period of ten years.

**Methods:** An inception cohort of consecutive patients with early RA (n=233, symptom duration <12 months), recruited 1995–2005, was investigated. Patients were followed according to a structured program, including dual-energy X-ray absorptiometry (DXA) of the left femoral neck and the lumbar spine (L2-L4) at inclusion and after 2, 5 and 10 years. Z-scores (standard deviations above or below the mean BMD for the given age and sex) were calculated using a cohort of healthy individuals from the same area as a reference population. The mean Z-score over the study period was estimated using mixed linear effect models. Changes in Z-scores between follow-up visits were analysed using the paired T-test. Data are presented as mean (95% confidence interval (CI)).

**Results:** At inclusion, 219 patients were examined with DXA. The corresponding numbers at 2, 5 and 10 years were 196, 172 and 121. Among those with baseline DXA data, mean age was 60 years, mean symptom duration 7.4 months and 70% were women. Men were older (mean age 63 vs 59 years) and more often treated with corticosteroids (49% vs 35%) than women at inclusion. The majority of men and women were on disease modifying anti-rheumatic drugs (86% vs 81%). More women were treated for osteoporosis (bisphosphonates and/or calcium and vitamin D) and of the women, 16% were on oestrogen at inclusion.

At the femoral neck, the mean Z-score over 10 years of time was -0.07 (-0.22; 0.08) in women and -0.33 (-0.57; -0.08) in men. Men had significantly lower BMD at the femoral neck than expected by age at inclusion (estimated by the intercept Z-score value -0.35; 95% CI -0.61; -0.09), whereas there was no significant overall change in Z-score over time in men or women. At the lumbar spine, the mean Z-score for women was 0.06 (-0.10; 0.21) and for men -0.05 (-0.29; 0.19). There was a significant increase in Z-scores at the lumbar spine over time in both groups (change/year 0.04 (0.03; 0.05) in women and 0.02 (0.00; 0.05) in men).

The paired comparisons of BMD at different follow-up visits are shown in table 1. In the femoral neck, Z-scores for men decreased significantly from inclusion to the 5 year follow-up visit. After 5 years, no further reduction was seen. Lumbar spine BMD Z-scores increased in both men and women over the study period.

**Abstract FRI0073 – Table 1.** Bone mineral density (femoral neck and lumbar spine – L2-L4) in the early RA cohort, by sex. Pairwise comparisons of different follow-up visits.

**Conclusions:** In this study of patients with early RA, men had low femoral neck BMD at study start and kept losing bone mass during the first 5 years of follow up. Lumbar spine BMD Z-scores in both women and men increased significantly over the study period. Potential explanations for the low femoral neck BMD in men include exposures that may predispose to both RA and low BMD, such as smoking and low androgen levels. The increasing lumbar spine BMD could be due to more extensive anti-osteoporotic treatment compared to the reference population, and possibly more artefacts, such as extensive aortic calcification or degenerative spinal changes, in patients with RA.

### FACTORS ASSOCIATED WITH THE DEVELOPEMENT OF SEVERE RESPIRATORY INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS INCLUDED IN A VACCINATION PROGRAM

L.C. Domínguez Casas<sup>1</sup>, P. Rodríguez-Cundin<sup>2</sup>, V. Calvo-Río<sup>1</sup>, N. Vegas-Revinga<sup>1</sup>, V. Portilla<sup>1</sup>, F. Antolin<sup>2</sup>, M. Rebollo-Rodrigo<sup>2</sup>, A. Corrales<sup>1</sup>, N. Palmou-Fontana<sup>1</sup>, D. Prieto-Peña<sup>1</sup>, M. Calderón Goercke<sup>1</sup>, R. Blanco<sup>1</sup>, M. Gonzalez-Gay<sup>1</sup>.  
<sup>1</sup>Rheumatology; <sup>2</sup>Preventive Medicine, HUMV, Santander, Spain

**Background:** Rheumatoid arthritis (RA) patients are at increased risk of severe infections. Besides the disease itself, the immunosuppressive treatment appears to play an important role in the risk of infections. Vaccination programs are designed to decrease the risk of infections in these patients.

**Objectives:** Our aim was to assess the incidence of severe respiratory infections in patients with RA and to determine the underlying risk factors for the development of these complications.

**Methods:** Retrospective study of 401 patients diagnosed with RA who were invited to participate in a vaccination program from October 2011 to October 2016. The follow-up was made until June 2017 with a minimum follow-up period of 8 months and maximum of 5.5 years.

Information on severe respiratory infection episodes was retrieved from the hospital medical records. Serious infections were defined as those that required hospitalisation or at least one dose of intravenous antibiotic treatment at the emergency room.

Only 7 patients refused vaccination (2%). Information was not obtained in 4 of the remaining 394 patients. Therefore, these 4 patients were not included in the assessment.

**Results:** 390 patients (307♀/83 ♂) average age 61.28±12.9 years were vaccinated a followed-up. The main features at the time of vaccination were: median disease duration (4 years), positive rheumatoid factor (56.7%), subcutaneous nodules (4.9%), erosive arthritis (36.9%), pulmonary fibrosis (3.8%), Sjögren syndrome (5.1%) other extraarticular manifestations (14.6%) and rheumatoid vasculitis (5.6%). Most patients had received immunosuppressive drugs before the vaccination program. The most frequently used were systemic corticosteroids (n=228), methotrexate (n=362) and biologic agents (40.3%).

During the follow-up, 42 patients (10.7%) had required hospital admissions due to infections, 17 of them were severe respiratory infections (4.35%) The remaining 25 admissions were in the setting of urinary tract infections (n=12), intraabdominal infections (n=7), skin and soft tissues (n=12) and articular (n=1). Also 12 of these patients had a zoster herpes.

The presence of anti-citrullinated protein antibodies (ACPA) was associated with an increased frequency of admissions due to these infections. It was also the case for the presence of a history of biologic therapy prior to vaccination. No association of severe respiratory infection with rheumatoid factor, erosions or pulmonary fibrosis was found. (table 1).

Abstract FRI0074 – Table 1

Admission for severe respiratory infections (CI 95%)	Crude OR (CI 95%)	p	Adjusted OR* (CI 95%)	p
RF positivity	2.13 (0.67-6.83)	0.2011	2.26 (0.69-7.84)	0.1799
ACPA positivity	3.73 (1.04-13.43)	0.0441	4.49 (1.2-16.83)	0.0259
Erosions	2 (0.71-5.64)	0.1896	2.16 (0.75-6.25)	0.1573
Rheumatoid vasculitis	1.48 (0.40-5.42)	0.5527	1.38 (0.37-5.22)	0.6336
Pulmonary fibrosis	4.27 (0.87-20.91)	0.2932	2.45 (0.46-13.05)	0.2932
Biologic treatment before vaccination	3.02 (1.01-9.02)	0.0476	2.61 (0.85-8.07)	0.0947

\*adjusted by age and sex

**Conclusions:** Vaccinated patients with RA present a low incidence of severe respiratory infections. Positivity for ACPA and the use of biologics prior to vaccination are associated with increased risk of severe respiratory infections in these patients. Therefore, vaccination should be performed prior to the onset of biologic treatment.

### RISK OF HEPATITIS B INFECTION REACTIVATION IN RHEUMATIC DISEASES PATIENTS TREATED WITH ANTI-CD20 THERAPY

M. Fornaro<sup>1</sup>, G. Lopalco<sup>1</sup>, V. Venerito<sup>1</sup>, M. Barone<sup>2</sup>, L. Cantarini<sup>3</sup>, C. Fabiani<sup>4</sup>, G. Emmi<sup>5</sup>, E. Silvestri<sup>5</sup>, G. Lapadula<sup>1</sup>, F. Iannone<sup>1</sup>.  
<sup>1</sup>Rheumatology Unit; <sup>2</sup>Department of Emergency and Organs Transplantation (DETO), University of Bari; <sup>3</sup>Section of Gastroenterology, Department of Emergency and Organ Transplantation, University "Aldo Moro", Piazza Giulio Cesare, Bari 70124, Bari; <sup>4</sup>Rheumatology Unit Policlinico "Le Scotte", University of Siena, Siena; <sup>5</sup>Department of Ophthalmology, Humanitas Clinical and Research Center, Rozzano (Milan); <sup>5</sup>Department of Experimental and Clinical Medicine, University of Florence, Firenze, Italy

**Background:** It has been widely established that the risk of hepatitis B reactivation is high in haematological patients receiving ANTI-CD20 therapy. For these patients the use of prophylaxis with antiretroviral drugs is recommended, and the same approach is also advocated in patients affected with rheumatic diseases, although the real risk seems to be lower.

**Objectives:** To evaluate the risk of HBV infection reactivation in patients with rheumatic diseases undergoing treatment with ANTI-CD20 therapy.

**Methods:** Retrieved data including demographical, therapeutic and clinical features as well as serological data were collected in 92 patients with different rheumatic diseases who underwent treatment with ANTI-CD20 from January 2009 to December 2016. Occult HBV infection at baseline (HBsAg negative, anti-HBcAg positive with or without anti-HBsAg and undetectable HBV-DNA) was observed in 25 patients (18 rheumatoid arthritis, 4 vasculitis, 2 systemic sclerosis and 1 dermatomyositis), none of them was treated with antiretroviral prophylaxis. HBV-DNA value was recorded at least every year, whereas HBsAg together with anti-HBsAg every six months and ALT every three months.

**Results:** During the whole observation period (mean time 39.28±26.6 months) none of the 25 patients (mean age 58.64±8.58 years; 68% women) had hepatitis B reactivation or HBsAg seroreversion. During the evaluated period 2 patients dropped out therapy, 1 stopped treatment for adverse event and 1 for ineffectiveness. After 70 months of therapy 1 patient presented low fluctuation of HBV-DNA title (13 IU/ml), that spontaneously returned negative after 3 months without therapeutic changes. In addition 1 patients shown an ALT increase unrelated to HBV reactivation.

**Conclusions:** In line with previous data, our experience suggests that the risk of hepatitis B reactivation in rheumatic patients undergoing treatment with ANTI-CD20 combined with sDMARD is very low. The regular monitoring of transaminases and hepatitis markers (HBsAg, antiHBsAg and HBV-DNA) during treatment has to be preferred to universal prophylaxis.

### CHRONIC WIDESPREAD PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SEVEN YEAR FOLLOW-UP OF PAIN DISTRIBUTION AND FACTORS FOR IMPROVEMENT

M.L. Andersson<sup>1</sup>, B. Svensson<sup>1</sup>, S. Bergman<sup>2</sup>, on behalf of the BARFOT study group. <sup>1</sup>Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund; <sup>2</sup>Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, the Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

**Background:** The knowledge of chronic widespread pain and factors associated to improvement of pain in patients with RA is sparse, in particular regarding longitudinal studies.

**Objectives:** To describe the change of pain distribution reports over time and to identify factors that predict improvement from chronic widespread pain in patients with RA.

**Methods:** Two postal questionnaires were sent out to patients included in the BARFOT (Better anti-rheumatic pharmacotherapy) study, the first in 2010 and the second in 2017. The questionnaire included a pain mannequin, NRS scales of pain, patient global assessment (PatGA) and fatigue, health assessment questionnaire (HAQ), health related quality of life measured by EQ-5D and patient reported BMI and 28-joint count of tender (TJC) and swollen joints (SJC). The responders to both questionnaires were divided into 3 groups according to the reported pain duration and distribution at each time point— patients having no chronic pain (NCP), chronic widespread pain (CWP), and chronic regional pain (CRP).

**Results:** 1525 (73%) patients answered the pain questions in 2010 and 1046 (68%) in 2017. In all 950 of the patients answered the questions at both time points and were included in the study. One third (324) of the patients had reported <sup>CWP</sup> in 2010 and 140 (43%) of the patients with CWP in 2010 had improved in 2017. The patients, who improved, had lower BMI,  $p=0.045$ , less tender joint counts,  $p=0.007$ , less pain,  $p=0.005$ , less fatigue,  $p<0.001$  and less painful regions,  $p<0.001$ , better PatGA,  $p=0.002$ , better HAQ,  $p<0.001$  and better EQ-5D,  $p=0.003$ . Fifty-five percent of the patients who improved were treated with DMARD, compared to 52% of those not improving, the rate treated with biologics were 32% vs. 26%. There were, however, no statistical significant difference in medical treatment between the groups,  $p=0.088$ .

Age and sex adjusted logistic regression models showed an increased chance for improvement from CWP in patients with normal BMI, less TJC, pain, fatigue and tender regions and better PatGA, HAQ and EQ-5D, table 1. Biologic treatment also increased the chances to improve from CWP. The most common biologic treatment was anti-TNF treatment. Of the patients, who were treated with biologics, 86% in the group, who improved from CWP and 74% in the group, who did not improve, were treated with anti-TNF treatment. Age, gender, smoking habits, SJC and glucocorticoid treatment were not associated with improvement in the model.

**Abstract FRI0076 – Table 1.** A crude logistic regression model were the data were age and sex adjusted, except age, which was adjusted for sex and sex, adjusted for age.

	OR	95% CI	
Age 2010	1.011	0.992-1.031	
Gender			
women	0.960	0.542-1.702

Pain 2010	<5	1.836	1.164-2.898
Fatigue 2010	<6	3.249	2.013-5.246
EQSD 2010	≥0.725	2.092	1.318-3.3821
HAQ 2010	<0.75	1.988	1.246-3.173
Total pain regions 2010	<8	2.987	1.888-4.727
Medical treatment 2010			
DMARD	1.779	0.940-3.366	
Biologics	2.202	1.099-4.413	
Prednisolone treatment 2010			
Pred	0.753	0.448-1.265	

**Conclusions:** Lower scores in pain related variables and fatigue, normal BMI, better physical function and health-related quality of life, and biologic treatment were associated to improvement from CWP in patients with RA. Knowledge of factors associated to improvement from CWP could be helpful when treating RA patients with CWP. More studies with focus on improvement from chronic pain in patients with RA are needed.

#### HEPATITIS B VIRUS REACTIVATION IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BARICITINIB: POST-HOC ANALYSIS FROM CLINICAL TRIALS

M. Harigai<sup>1</sup>, K. Winthrop<sup>2</sup>, T. Takeuchi<sup>3</sup>, T.-Y. Hsieh<sup>4</sup>, Y.-M. Chen<sup>4</sup>, J.S. Smolen<sup>5</sup>, G.R. Burmester<sup>6</sup>, C. Walls<sup>7</sup>, W.-S. Wu<sup>7</sup>, C. Dickson<sup>7</sup>, R. Liao<sup>7</sup>, M.C. Genovese<sup>8</sup>.  
<sup>1</sup>Tokyo Women's Medical Univ, Tokyo, Japan; <sup>2</sup>Oregon Health Sciences Univ, Portland, USA; <sup>3</sup>Keio University, Tokyo, Japan; <sup>4</sup>Taichung Veterans General Hospital, Taichung, Taiwan, Province of China; <sup>5</sup>Medical Univ of Vienna, Vienna, Austria; <sup>6</sup>Charite Universitätsmedizin Berlin, Berlin, Germany; <sup>7</sup>Eli Lilly and Company, Indianapolis; <sup>8</sup>Stanford Univ, Palo Alto, USA

**Background:** Baricitinib (BARI) is an oral selective Janus kinase (JAK)1 and JAK2 inhibitor approved in the EU, Japan, and other countries for treatment of moderately to severely active rheumatoid arthritis (RA) in adults. RA therapies may increase risk of hepatitis B virus (HBV) infection<sup>1</sup>. HBV reactivation is a concern in previously infected patients (pts), including those with serologic evidence of resolution. HBV exposure is common in many Asian countries.<sup>2</sup> Limited data exist on HBV reactivation among pts with RA treated with JAK inhibitors.

**Objectives:** To assess HBV reactivation in pts with RA treated with BARI during Phase (Ph) 3 trials.

**Methods:** At screening, all pts were tested for HBV surface antigen (HBsAg), core antibody (HBcAb) and surface antibody (HBsAb). In Japan and elsewhere if required, pts had screening HBV DNA tests. Pts were excluded if they had 1) HBsAg+, 2) HBcAb+/HBsAb- (in Japan, could enrol if HBV DNA-), or 3) HBsAb +and HBV DNA+. Routine HBV DNA monitoring was performed in Japan for pts with HBcAb +and/or HBsAb +at screening, and was later instituted globally for HBcAb +pts. Pts with post-baseline HBV DNA+ (≥29 IU/mL) were discontinued from the study and referred to a hepatologist. In select cases, investigators continued study drug following a HBV DNA +test in consultation with the sponsor and in accordance with HBV management guidelines. Data were integrated from 4 completed Ph 3 trials and 1 ongoing long-term extension (LTE) (data to April 2017).

**Results:** Of 2890 pts with ≥1 dose of BARI (6993 pt-years exposure), 2679 pts had baseline serology suggestive of prior infection (HBcAb+/HBsAb+, n=255; HBcAb+/HBsAb-, n=14) (figure 1). Post-baseline HBV DNA tests were performed for 290 pts (including some pts without a baseline HBV DNA result). After BARI initiation, 7 of 201 pts (3%) with HBcAb+/HBsAb+ at baseline had quantifiable HBV DNA +levels (≥29 IU/mL; median 256, range 31–1547 IU/mL). An additional 23 (11%) had qualitative HBV DNA +results below the lower limit of detection (LLD) (<29 IU/mL). Of these 30 HBcAb+/HBsAb+ pts with HBV DNA +tests post-baseline, 22 had HBV DNA- tests at baseline. Among 14 pts with HBcAb+/HBsAb-, all had HBV DNA- tests at baseline; repeat HBV DNA test results post-baseline were quantifiable (1 at 36 IU/mL), below the LLD,<sup>1</sup> and undetectable.<sup>1,2</sup> Of pts with quantifiable HBV DNA, adverse events (AE) of detectable HBV DNA resulted in discontinuation of 4 of 8 pts of whom 3 received antivirals. 4 of 8 pts continued BARI in the LTE and have not received antivirals. All pts with quantifiable HBV DNA had alanine transaminase (ALT) or aspartate transaminase (AST) within normal limits, and none had an investigator-reported AE of hepatitis.

#### HBV serology and DNA detectability in patients treated with baricitinib in Phase 3 trials

\*Total number of patients with baseline serology is n=2881 due to missing data for 9 patients (8 missing surface antibody and 1 missing core antibody data).  
<sup>1</sup>Patients with detectable post-baseline HBV DNA were from China (11), Japan (9), Taiwan (6), Israel (2), Greece (2), Russia (2), United States (2), Argentina (1), and South Korea (1).  
<sup>2</sup>Nine patients had quantifiable HBV DNA levels of 31, 36, 60, 76, 92, 256, 257, 859, and 1547 IU/mL.  
<sup>3</sup>Patient with ALT/AST ≥3xULN was discontinued from study due to abnormal liver function test. Patient had a single detectable HBV DNA test result <29 IU/mL. At last available observation, ALT and AST were <5xULN and <2xULN, respectively.  
<sup>4</sup>Baseline HBV DNA not detected (5), not tested (5).  
<sup>5</sup>Baseline HBV DNA not detected (5), not tested (2).  
<sup>6</sup>Baseline HBV DNA not detected.  
 Abbreviations: AE=adverse event, ALT=alanine transaminase, AST=aspartate transaminase, BARI=baricitinib, HBcAb=hepatitis B virus core antibody, HBsAb=hepatitis B virus surface antibody, HBV=hepatitis B virus, DNA=deoxyribonucleic acid, Ph=phase, RA=rheumatoid arthritis, ULN=upper limit of normal.

**Abstract FRI0077 – Figure 1.** HBV serology and DNA detectability in patients treated with baricitinib in Phase 3 trials

**Conclusions:** Approximately 12% of BARI-treated pts with prior HBV infection later tested HBV DNA+ (3% were above the LLD), although no pts developed clinical evidence of hepatitis and in most cases antiviral therapy was not used.

Fernández-Nebro<sup>7</sup>. <sup>1</sup>UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA) Hospital Regional Universitario de Málaga, Universidad de Málaga., Málaga; <sup>2</sup>Department of Rheumatology, Hospital Virgen de Valme, Sevilla; <sup>3</sup>Department of Rheumatology Hospital Virgen de las Nieves., Granada; <sup>4</sup>UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Clínico Virgen de la Victoria, Universidad de Málaga; <sup>5</sup>Department of Radiology Hospital Regional de Málaga; <sup>6</sup>Department of Rheumatology at the University Regional Hospital of Malaga (HRUM). Institute for Biomedical Research in Malaga (IBIMA). Malaga University; <sup>7</sup>UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA) Hospital Regional Universitario de Málaga, Departamento de Medicina y Dermatología, Universidad de Málaga., Málaga, Spain

**Objectives:** To describe prospectively the evolution of interstitial lung disease (ILD) in RA treated with modifying antirheumatic drugs (DMARDs) in clinical practice.

**Methods:** **Design:** Multicenter prospective observational cohort. **Patients:** Patients with RA (ACR<sup>EULAR</sup> 2010 criteria) and ILD (American Thoracic Society) from different centres of Málaga, Valme Hospital of Sevilla and Virgen Nieves of Granada were included. **Protocol:** All patients with RA and ILD who visited clinic from 2015 to 2017 were recruited. They were reviewed according to a predetermined protocol for data collection. Resolution Computed Tomography (HRCT), Pulmonary function test (PFT) and echocardiogram were requested for all patients who did not have it in the last year. This visit was marked as v0 (index date). At 12 months (v12) the joint assessment (DAS28), echocardiogram, PTF and HRCT were again evaluated. HRCT's were assessed by the same radiologist. **Outcomes:** At v12: (1) improvement (ie improvement in FVC  $\geq$ 10% or DLCO  $\geq$ 15% and no radiological progression), (2) non-progression (stabilisation or improvement in FVC  $\leq$ 10% or DLCO  $<$ 15% and no radiological progression), (3) progression (worsening of FVC  $>$ 10% or DLCO  $>$ 15% and radiological progression), or (4) death due to ILD. **Variables:** Description of ILD type and lung function by PTF, HRCT. Presence of PTH by echocardiogram and dyspnoea. Disease activity by DAS28-ESR; Adverse events during the follow-up period. **Statistical analysis:** Descriptive analysis and Wilcoxon or T test between the v0 and v12. One factor ANOVA between sDMARD, bDMARD and combination therapy groups.

**Results:** The main characteristics at V0 of the patients (n=41) are shown in the table 1. Nine patients (21.9%) received a sDMARDs with a bDMARDs; 25 patients (60.9%) monotherapy with sDMARD and 7 (17.0%) monotherapy with bDMARDs (table 1). Nine patients (21.9%) had improvement (2 with MTX, 1 with MTX +HCQ, 2 with RTX, 2 HCQ +RTX, 1 MMF +RTX and 1 with ABA); 24 patients (58.5%) remained stable (6 with MTX, 6 with LFN, 3 with HCQ, 1 AZA, 1 SSZ, 1 MMF, 1 TCZ, 2 ABA, 1 MTX +ETN, 1 HCQ +RTX, 1 HCQ +ADA, 1 RTX +MMF); and 7 (17.0%) got worse of ILD (2 with MTX developed lung nodules not known, 2 with LFN, 1 with LFN +IFX, 1 with ETN +MTX and 1 with SSZ). One patient died due to respiratory infection (with RTX). Two patients developed PPH. We did not find significant differences between Vo DAS28 and v12 (2.61 [0.74] vs 2.54 [1.12]; p=0.684) or in HAQ (1.12 [0.89] vs 1.23 [0.73], p=0.368). There were no significant differences in PTF, HRCT or DAS28 between sDMARD, bDMARD and combination therapy groups. During the follow-up period 27 patients had infections, the majority (53.7%) respiratory infection.

VARIABLES	Patients
Sex (male), n (%)	21 (51.2)
Age (years), mean (DE)	67.9 (7.8)
Smoker, n (%)	8 (19.5)
Ex-smoker, n (%)	32 (78)
Body mass index (BMI), mean (SD)	28.7 (5.3)
Disease duration (months), median (p25-p75)	138.1 (77.7-285.3)
ILD duration (months), median (p25-p75)	41.4 (10.1-79.2)
Rheumatoid factor, n (%)	39 (95.1)
Anti-cyclic citrullinated peptide, n (%)	35 (85.4)
Erosions, n (%)	27 (66)
DAS28, mean (DE)	2.8 (0.8)
HAQ, mean (DE)	1.2 (0.8)
Treatment	
sDMARD, n (%)	34 (82.9)
Methotrexate, n (%)	13 (31.7)
Leflunomide, n (%)	9 (22.0)
Sulfasalazine, n (%)	2 (4.9)
Hydroxychloroquine, n (%)	6 (14.6)
Azathioprine	1 (2.4)
Mycophenolato	3 (7.3)
MTX+HCQ	2 (4.9)
bDMARDs, n (%)	16 (39.0)
Rituximab, n (%)	7 (17.1)
Abatacept, n (%)	3 (7.3)
Etanercept, n (%)	3 (7.3)
Infliximab, n (%)	1 (2.4)
Adalimumab, n (%)	1 (2.4)
Tocilizumab, n (%)	1 (2.4)

**Conclusions:** Most patients with RA and ILD who are receiving treatment with DMARD (80.5%) remained stable or improved after at least one year of both synthetic and biological DMARD treatment. More prospective studies are necessary to identify the influence of DMARDs in this evolution.

**Disclosure of Interest:** None declared

### ADIPONECTIN LEVEL, INSULIN RESISTANCE, ENDOTHELIAL DYSFUNCTION IN FEMALES WITH RHEUMATOID ARTHRITIS AND COMORBID HYPERTENSION

O. Sirenko, O. Kuryata, T. Lysunets. State Establishment «Dnipropetrovsk medical academy of Health Ministry of Ukraine», Dnipropetrovsk, Ukraine

**Background :** Rheumatoid arthritis (RA) associates with accelerated atherosclerosis and high cardiovascular mortality. Cardiovascular risk assessment in RA pts with comorbid hypertension (HT) is do not fully reflected by traditional risk scales, thus additional factors searching is required.

**Objectives:** We aimed to estimate the adiponectin level, insulin resistance, endothelial function in RA females with comorbid HT and its relationship with subclinical manifestations of atherosclerosis.

**Methods:** The study included 82 RA females with low disease activity and comorbid HT (mean age of 54.6 [49.7; 62.5] years) and 40 HT females without RA (control group). All pts received stable therapy of RA more than 6 months. Pts with coronary artery disease were excluded. The risk of fatal cardiovascular disease was calculated using mSCORE. RA disease activity was measured using DAS28 scale. Carotid ultrasound detection and endothelial-dependent flow mediated vasodilatation (EDVD) by Celermajer method were performed. The levels of adiponectin, insulin were measured using ELISA kit test, insulin resistance was estimated using HOMA2 index.

**Results:** Endothelial dysfunction was established in the majority of main group patients – 61 (74.4%), insulin resistance – in 70 (85.4%), elevated levels of adiponectin – in 35 (42.7%). Hypertensive females with RA had significantly higher adiponectin, insulin, insulin resistance levels compare to control (p<0.05). Subclinical manifestations of atherosclerosis were established in 64 (78.0%) HT females with RA and 10 (50%) control group pts. While the median cardiovascular risk level was 4.2 [2.7; 6.5] matched by mSCORE. The presence of atherosclerotic plaques in HT females with RA was associated with age (OR=1.242, p=0.004, 95% CI 1.007–1.78), glucocorticosteroid therapy >3 months (OR=1.56, p=0.001, 95% CI 1.22–2.45), endothelial dysfunction (OR=3.584, p=0.001, 95% CI 1.71–4.723), insulin resistance (OR=1.684, p=0.011, 95% CI 1.22–2.74), abnormal adiponectin level (OR=1.71, p=0.028, 95% CI 1.17–2.43). AUROC index for prognostic role of adiponectin and HOMA2 in subclinical atherosclerosis develop were 0.79 (95% CI 0.64–0.95; p<0.05) and 0.76 (95% CI 0.61–0.92; p<0.05) respectively, that indicate a good quality of diagnostic models.

**Conclusions:** Hypertensive females with rheumatoid arthritis are characterised by higher frequency of insulin resistance, endothelial dysfunction, adiponectin level changes which associates with subclinical atherosclerosis manifestations.

**FRI0080 THE ROLE OF PAIN IN RHEUMATOID ARTHRITIS (RA) PATIENTS' ASSESSMENTS OF THEIR HEALTH**

P. Katz<sup>1</sup>, Y.C. Lee<sup>2</sup>, A. Quebe<sup>3</sup>, L. Sun<sup>3</sup>, H. Patel<sup>3</sup>, C. Gaich<sup>3</sup>, N. Boytsov<sup>3</sup>, K. Michaud<sup>4,5</sup>. <sup>1</sup>Medicine, University of California, San Francisco, San Francisco; <sup>2</sup>Northwestern University, Chicago; <sup>3</sup>Eli Lilly and Co, Indianapolis; <sup>4</sup>Forward/NDB, Wichita; <sup>5</sup>University of Nebraska Medical Center, Omaha, USA

**Background:** Patients often describe pain as the most important symptom of RA. Despite advances in RA therapy to improve disease control, some patients continue to have significant pain<sup>1,2</sup>. The relative impact of pain on RA patients' evaluations of overall health and RA-specific global assessments is unknown.

**Objectives:** Determine the relative role of pain in RA patients' health assessments.

**Methods:** Data derived from the Forward (The National Databank for Rheumatic Diseases) longitudinal cohort, collected January-May 2017. Respondents (n=5471) have rheumatologist-confirmed RA. Two health assessments were examined:<sup>1</sup> overall satisfaction with health (SAT) measured by the item: "How satisfied are you with your health now?" with responses of very unsatisfied to very satisfied; and<sup>2</sup> patient global assessments of RA impact (GBL) measured using a numeric rating scale (NRS): "Considering all the ways that your RA affects you, rate how you are doing on a scale of 0-10, where 0=very well and 10=very poor." For regression analyses, SAT was dichotomized as "very satisfied" or "somewhat satisfied" vs. other responses. Current pain severity was rated on an NRS from 0 (no pain) to 10 (extreme pain). Spearman correlations examined the association of pain with SAT and GBL. Initial multiple regression analyses (table 1, Model 1) examined the following as predictors of SAT and GBL: age, sex, education, disease duration, obesity (BMI >30), conventional and biologic DMARD use, Rheumatic Disease Comorbidity Index<sup>3</sup> (RDCI), self-report of depression, fatigue, and functional limitations (Health Assessment Questionnaire [HAQ] score). Follow-up models (Model 2) added pain to determine its relative independent role in health assessments.

**Results:** The sample was 84% female, mean age 65 years, mean RA duration 22 years. 53% were satisfied with their health, and mean GBL was 3.6±2.5. Mean pain severity rating was 3.8±2.8. Correlations of pain with SAT and GBL were 0.58 and 0.71, respectively (each p<0.0001). Regression models predicting both SAT and GBL improved with the addition of pain (table 1). Pain was significantly and independently associated with both health assessments.

	Model 1 (excluding pain)	Model 2 (adding pain)
Satisfied with health		0.81 (0.79, 0.84)*
Pain		0.40
Model R <sup>2</sup>	0.37	0.40
Global assessment of RA		0.33 (<0.0001)†
Pain		0.57
Model R <sup>2</sup>	0.51	0.57

\*Odds ratio (95% CI)

† b (p-value)

Regression models included age, sex\*, education, disease duration, obesity, medications, RDCI, depression, fatigue\*, and HAQ\*. Variables noted with asterisk were also statistically significant (p<0.05) in both final models.

**Conclusions:** Pain plays a critical role in RA patients' assessments of general and RA-specific health. Analyses suggest that pain may be more important to RA global assessments than to overall health satisfaction, though the clinical relevance of this difference is not known. RA global assessments are included in some indices of disease activity. Future research should focus on distinguishing between non-inflammatory and inflammatory causes, which may lead to more accurate assessment of RA disease activity.

**FRI0081 THE IMPORTANCE OF TRANSFERRIN SATURATION, SERUM FERRITIN, LOG FERRITIN AND TRANSFERRIN/LOG FERRITIN IN DIFFERENTIATING IRON DEFICIENCY ANAEMIA FROM ANAEMIA OF CHRONIC DISEASE IN RHEUMATOID ARTHRITIS PATIENTS**

R.A. Abdel Noor<sup>1</sup>, M.H. Abu-Zaid<sup>2</sup>, S.A. Elshweikh<sup>3</sup>, E.S. Rabee<sup>4</sup>, G.E. Khed<sup>5</sup>. <sup>1</sup>Internal Medicine and Rheumatology; <sup>2</sup>Physical medicine, Rheumatology and Rehabilitation; <sup>3</sup>Internal Medicine and Hematology; <sup>4</sup>Clinical pathology, Faculty of Medicine, Tanta University; <sup>5</sup>Clinical pathology, Tanta Cancer Center, Tanta, Egypt

**Background:** The most common types of anaemia in rheumatoid arthritis (RA) are iron deficiency anaemia (IDA) and anaemia of chronic disease (ACD). The differentiation between both is very important and challenging.

**Objectives:** is to select the most simple, cheap, accurate method differentiate IDA from ACD in RA patients.

**Methods:** This case control study was carried out on 80 RA patients. Group I 40 RA patients with anaemia Group II 40 RA patients without anaemia, complete blood count, assessment of disease activity using DAS 28 score, serum iron, total iron binding capacity (TIBC) "transferrin level", transferrin saturation (TSAT), serum ferritin, log ferritin and transferrin/log ferritin were tested, then we divided the patients in group 1 into 2 subgroups according to TSAT : group Ia (RA patients with anaemia and low TSAT) and group Ib (RA patients with anaemia and normal TSAT) and we compared the parameters.

**Results:** There was a statistically significant difference between anaemic and non anaemic RA patients as regard serum iron level and transferrin saturation and there was no significant difference as regard serum ferritin, log ferritin, transferrin and transferrin/log ferritin. Among the anaemic group (67.5%) had low TSAT (IDA) and only (32.5%) had normal TSAT (ACD). In these 2 subgroups there was no significant differences as regard DAS28 score, blood indices, serum ferritin and transferrin/log ferritin) except Log ferritin and there was positive correlation between TSAT and (ferritin and log ferritin) and significant negative correlation between TSAT and transferrin/log ferritin.

**Abstract FRI0081 – Table 1.** Clinical and laboratory parameters in both groups

Characteristic	Group I <sup>40</sup> RA +anaemia	Group II <sup>40</sup> RA without anaemia	P
DAS-28	2.99±1.07	2.35±0.77	0.002*
Hb (g/dl)	9.62±0.96	12.95±0.64	<0.0001*
MCV (fl)	79.71±7.29	83.0±9.34	0.083
MCH (pg/cell)	26.06±4.05	28.05±2.66	0.006*
MCHC (g/dl)	31.1±2.21	31.23±2.38	0.8
Serum iron (µg/ml)	0.66±0.37	0.89±0.38	0.0076*
Serum ferritin (ng/ml)	83.02±93.08	84.87±86.82	0.927
TIBC (µg/ml)	3.94±1.06	3.71±0.59	0.23
TSAT (%)	17.7±10.6	24.73±11.36	0.0054*
Log ferritin	1.61±0.75	1.7±0.46	0.52
Transferrin/Log ferritin	3.23±3.8	2.41±0.9	0.18

Figure 1 Correlation between TSAT and (serum ferritin, log ferritin and Transferrin/Log ferritin)

**Conclusions:** Iron deficiency anaemia is prevalent in RA patients. A combination use of serum ferritin and TSAT is the most simple, accurate parameter now to differentiate both. log ferritin, transferrin/log ferritin may be promising new parameters in diagnosis of IDA in general population but their use in inflammatory diseases like RA still has a limitation so we suggest further large studies to be done in order to assess their accuracy.

#### FRI0082 PREDICTORS OF FATIGUE AND PERSISTENT FATIGUE IN EARLY RHEUMATOID ARTHRITIS: A LONGITUDINAL OBSERVATIONAL STUDY

S. Rodríguez-Muguruza<sup>1</sup>, B. Combe<sup>2</sup>, F. Guillemain<sup>3,4</sup>, B. Fautrel<sup>5</sup>, A. Olive<sup>6</sup>, S. Marsal<sup>7</sup>, O. Valero<sup>8</sup>, N. Rincheval<sup>9</sup>, C. Lukas<sup>2</sup>. <sup>1</sup>Rheumatology, Verge de la Cinta Hospital, Tarragona, Spain; <sup>2</sup>Rheumatology, CHU Montpellier, Montpellier University, Montpellier; <sup>3</sup>Université de Lorraine, EA 4360 APEMAC, École de Santé Publique, Faculté de Médecine de Nancy; <sup>4</sup>INSERM CIC 1433 clinical epidemiology, Nancy Hospital, Nancy; <sup>5</sup>Rheumatology, Pitié-Salpêtrière hospital, AP-HP, 75013, Paris, France; <sup>6</sup>Rheumatology, Germans Trias i Pujol University Hospital; <sup>7</sup>Rheumatology, Vall d'Hebrón Hospital; <sup>8</sup>Servei d'estadística aplicada, Universitat Autònoma de Barcelona, Barcelona, Spain; <sup>9</sup>UFR de Médecine, Institut Universitaire de Recherche Clinique, Université Montpellier 1, Montpellier, France

**Background:** Fatigue is a multifactorial and persistent symptom reported by patients with rheumatoid arthritis (RA). It is considered as frequent as pain. It would be of value to identify potential predictive factors of fatigue that can influence on its evolution.

**Objectives:** To identify predictive factors of fatigue and of persistent fatigue in a large prospective cohort of early RA patients.

**Methods:** *The Etude de Suivi des polyarthrites Indifférenciées Récentes (ESPOIR)* is a multicenter French cohort of patients with early arthritis. We selected patients fulfilling the 2010 ACR/EULAR criteria for RA during the first year of follow-up. We recorded sociodemographic and clinical characteristics, the SF-36 vitality score, Health Assessment Questionnaire (HAQ) score and 28-joint Disease Activity Score (DAS28) at baseline and every 6 months up to 5 years. The association of fatigue (SF vitality score  $\leq 40$ ) or persistent fatigue (SF vitality score  $\leq 40$  at the end of the study and at least in 50% of visits in the 5 years follow up) with other characteristics were evaluated by bivariate logistic regression models/tests (chi-squared test for qualitative variables and t-test/Mann-Whitney test for quantitative variables). A multivariate logistic regression model was used to determine independent predictors of persistent fatigue.

**Results:** We included 677 patients (73.4% women, mean  $\pm$ SD age 48.6 $\pm$ 12 years); 46.5%, 28% and 22% of RA patients presented fatigue at baseline, 6 months and 5 years of follow up respectively. At baseline, fatigue was independently and significantly associated with single patients (OR=2.5 95% CI [0.30–0.70]  $p < 0.001$ ), higher BMI (OR=1.1 95% CI [1.01–1.10]  $p = 0.007$ ), higher DAS28 (OR=1.3 95% CI [1.08–1.60]  $p = 0.006$ ), higher severity of morning stiffness (scored 0–10) (OR=1.0 95% CI [1.00–1.01]  $p = 0.012$ ), higher HAQ (OR=2.4 95% CI [1.70–3.44]  $p < 0.001$ ), negativity of FR (OR=1.5 95% CI [1.09–2.29]  $p = 0.016$ ) and history of depression or anxiety (OR=6.1 95% CI [3.90–9.83]  $p < 0.001$ ). A 14.9% of patients presented persistent fatigue. Independent predictors of persistent fatigue at 5 years of follow-up were HAQ (OR=2.5 95% CI [1.63–3.67]  $p < 0.001$ ), history of depression/anxiety (OR=3.7 95% CI [1.53–9.15]  $p = 0.004$ ),  $> 3$  comorbidity (OR=2.1 95% CI [1.23–3.73]  $p = 0.007$ ), dry syndrome (OR=2.4 95% CI [1.39–4.17]  $p = 0.002$ ), and negativity in RF (OR=1.85 95% CI [1.07–3.21]  $p = 0.027$ ).

**Conclusions:** Fatigue was frequent in this cohort of early RA patient, its presence decreased at 6 months and remained stable over time. Baseline fatigue and persistent fatigue were both predicted by functional impairment, negativity of RF and history of depression or anxiety. Disease activity measured by DAS28 was strongly associated to fatigue at baseline but it was not a predictor of persistent fatigue.

**Disclosure of Interest:** None declared

#### FRI0083 ADJUSTMENT OF THE THRESHOLD MAY IMPROVE CARDIOVASCULAR RISK STRATIFICATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Velmakin, E. Troitskaya, S. Villevalde, Z. Kobalava. *Internal diseases, Peoples' Friendship University of Russia (RUDN University), Moscow, Russian Federation*

**Background:** Rheumatoid arthritis (RA) is associated with increased cardiovascular (CV) risk. Besides monitoring of the disease activity, identification of high CV risk patients is of great importance<sup>1,2</sup>.

**Objectives:** The aim of the study was to assess the abilities of 3 risk models (SCORE, QRisk2 and 10 year ASCVD) in detecting high CV risk RA patients.

**Methods:** 56 patients with RA (ACR/EULAR<sup>2010</sup> without known CV disease were examined (84% females, age 58.4 $\pm$ 14.1 (M $\pm$ SD) years, BMI 26.1 $\pm$ 5.4 kg/m<sup>2</sup>, smokers 9%, arterial hypertension (AH) 64%, dyslipidemia 57%, diabetes 7%). Median duration of RA was 7 years (IQR 2–14). Seropositive RA was diagnosed in 73% of patients. Median hsCRP was 7.8 mg/dl (IQR 2;21.4), rheumatoid factor (RF) – 61.2 IU/ml (IQR 18.5;179.2), mean DAS-28(CRP) – 3,7 $\pm$ 1,2. All patients received disease-modifying antirheumatic drugs. SCORE, QRisk2 and 2013 ACC/AHA 10 year ASCVD risk and EULAR recommended modified versions were calculated. Patients with SCORE  $\geq 5\%$ , QRisk2  $\geq 20\%$  and ASCVD risk  $\geq 7.5\%$  were classified as having high CV risk. Carotid intima-media thickness (CIMT)  $\geq 0,9$  mm and/or carotid plaques detected by ultrasonography were used as the gold standard test for high CV risk.  $p < 0.05$  was considered significant.

**Results:** The median SCORE, QRisk2 and ASCVD were 2.2% (IQR 0.6;4.9), 10.2% (3.4;19.2) and 4.9% (1.5;12.8) respectively. The proportion of high-risk patients was as follows: 14 (25%), 13 (23%), 24 (43%) for SCORE, QRisk2 and ASCVD. Mean CIMT was 0.76 $\pm$ 0.24 mm. US criteria for subclinical atherosclerosis (US+) were found in 27 (48%) pts. Discriminating capacities for the indexes were as follows: AUC 0.723 (CI 95% 0.626–0.821) for SCORE, AUC 0.705 (CI 95% 0.606–0.804) for QRisk2 and AUC 0.837 (CI 95% 0.757–0.917) for ASCVD. The percentages of high-risk patients in US+group were as follows: 13 (48%), 12 (44%) and 21 (78%), respectively, ( $p < 0.05$  compared to ASCVD). After multiplying by 1.5 EULAR 2016 mASCVD reclassified 2 (7.4%) and mSCORE – 4 (14.8%) pts from moderate to high risk. Use of lower cut-off values for risk indices (SCORE  $\geq 1\%$ , QRisk2  $\geq 10\%$  and ASCVD  $\geq 5\%$ ) resulted in better detection of US+pts (100%, 85% and 85% respectively).

**Conclusions:** The 2013 ACC/AHA 10 year ASCVD risk estimator is better than the SCORE and QRisk2 indices for the detection of high CV risk RA patients. Adjustment of the threshold may be a better modification of risk scales than use of the EULAR multiplier factor.

#### FRI0084 INTENSE AEROBIC AND RESISTANCE EXERCISE REDUCES THE FREQUENCY OF PERIPHERAL BLOOD REGULATORY CELL POPULATIONS IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

S. Andersson<sup>1</sup>, E. Lange<sup>2</sup>, D. Kucherski<sup>1</sup>, S. Svedlund<sup>3</sup>, K. Önnheim<sup>1</sup>, J. Lord<sup>4</sup>, I.-L. Mårtensson<sup>1</sup>, K. Mannerkorpi<sup>2</sup>, I. Gjørtsson<sup>1</sup>. <sup>1</sup>Dept of Rheumatology and Inflammation Research; <sup>2</sup>Department of Health and Rehabilitation; <sup>3</sup>Department of Molecular and Clinical Medicine, University of Gothenburg, Göteborg, Sweden; <sup>4</sup>Institute of Inflammation and Ageing, University of Birmingham, Birmingham, UK

**Background:** RA is an autoimmune joint disease driven by complex immune dysregulation. Exercise can improve immune health and is beneficial for physical function in elderly patients with RA, but the immunological mechanisms are largely unknown.

**Objectives:** We evaluated the effect of a person-centred randomised controlled exercise programme on regulatory immune cell populations in aged persons with RA.

**Methods:** Aged persons with RA were randomised to either a 20 week of aerobic and resistance exercise intervention of moderate-to high intensity (n=24) or to an active control group performing low-intensity home exercise (n=25). Blood samples were collected at baseline and after 20 weeks. The frequency of the adaptive regulatory populations Foxp3 +CD25+CD127<sup>+</sup>CD4<sup>+</sup>T cells and CD24hiCD38hi B

cells and the CD33 +CD11b+myeloid derived suppressor cells were assessed using flow cytometry.

**Results:** After 20 weeks of exercise intervention there was a decrease in the frequency of Foxp3 +CD25+CD127 regulatory T cells and CD24hiCD38hi B cells but no change was observed in the active control group. The reduction in Tregs by exercise was most pronounced in the female participants. Despite lower levels of adaptive immune cell populations the disease activity did not increase.

**Conclusions:** Aerobic and resistance exercise in elderly patients with rheumatoid arthritis lead to a decreased number of regulatory Foxp3 +CD25+CD127 regulatory T cells and CD24hiCD38hi B cells. This decrease was not associated with an increased disease activity score or increased inflammation.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrhumdis-2018-eular.4668

#### FRI0085 A STUDY OF THE RELATIONSHIP BETWEEN SERUM VITAMIN D LEVEL AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS PATIENTS

S. Datta<sup>1</sup>, A. Kar<sup>2</sup>, T.K. Bhaumik<sup>3</sup>, T. Santra<sup>4</sup>. <sup>1</sup>Anti Retroviral Therapy Center, <sup>2</sup>Department of General Medicine, Malda Medical College and Hospital, Malda; <sup>3</sup>Department of General Medicine, Calcutta Medical Research Institute, Kolkata; <sup>4</sup>Department of General Medicine, Midnapore Medical College and Hospital, Midnapore, India

**Background:** Vitamin D is an essential component of our body. Approximately 3% of the human genome is directly or indirectly regulated by the Vitamin D endocrine system, which supports the idea that Vitamin D insufficiency has widespread adverse consequences for human health.<sup>[1]</sup>Till date several studies have been done regarding the relation of Vitamin D and Rheumatoid Arthritis but there are limited studies in Eastern India. Hence this study is being done to examine the relation of serum 25 hydroxy Vitamin D level and Disease Activity in Rheumatoid Arthritis patients.

#### Objectives:

- To examine the relationship between Serum 25 Hydroxy Vitamin D level and SDAI (Simplified Disease Activity Index) in Rheumatoid Arthritis patients.
- To examine the relationship between Serum 25 Hydroxy Vitamin D level and Tender Joint Count(TJC), Swollen Joint count(SJC) and CRP in Rheumatoid Arthritis patients.
- To evaluate the relation of serum vitamin D level with various socio demographic factors like Gender, Diet, Occupation, Season, Height, Weight, BMI in Rheumatoid Arthritis Patients.

**Methods:** Ninety six RA patients attending The Rheumatology clinic of Out Patient Department of An Urban Tertiary care hospital (Latitude of KOLKATA is 22°32'N) from October 2013 to September 2014, fulfilling the ACR –EULAR 2010 criteria for classification of RA, were included in the study. 25(OH)vitamin D levels were measured. Disease activity of RA was assessed by SDAI score.

**Results:** More than Ninety Percent of the RA patients were found to have either Vitamin D deficiency or insufficiency. The mean serum vitamin D level of these RA patients was 20.02 (±8.92) ng/ml. The RA patients with High Disease Activity (SDAI between 26.1 and 86) had significantly low ( $p < 0.0001$ ) mean serum vitamin D level [11.11 (±6.08) ng/ml] than those with Moderate (SDAI between 11.1 and 26) or Low Disease Activity (SDAI between 3.4 and 11.0) whose serum vitamin D level was 21.15 (±7.47) ng/ml and 25.58 (±7.30) ng/ml respectively. There is a significant negative correlation between the Serum Vitamin D level and SDAI score ( $r = -0.669$ ,  $p < 0.0001$ ) in the whole group of the study population. However On analysing the data separately in RA patients with Vitamin D deficiency, insufficiency and sufficiency, this significant relation is separately evident only in the RA patients with Vitamin D deficiency (serum vitamin D level  $< 20$  ng/ml) but not in those who were in the insufficient or sufficient groups. There is an independent negative impact of Simplified Disease Activity Index (SDAI) on Serum Vitamin D level (Adjusted  $R^2 = 0.464$ ,  $p < 0.0001$ ).

**Conclusions:** RA patients having high disease activity in terms of SDAI Score had significantly low vitamin D level compared to patients of RA having low or moderate disease activity. Lower levels of serum vitamin D was associated with increased disease activity in RA patients. On subgroup analysis, there is significant negative correlation separately evident only in the RA patients with Vitamin D deficiency (serum vitamin D level  $< 20$  ng/ml) but not in those who were in the insufficient or sufficient groups.

#### FRI0086 IS THE DISCORDANCE BETWEEN THE DOCTOR AND THE PATIENT A DETERMINANT OF ADHERENCE?

T. Oton<sup>1</sup>, J. Calvo-Alén<sup>2</sup>, L. Cea-Calvo<sup>3</sup>, L. Carmona<sup>1</sup>. <sup>1</sup>INMUSC, Madrid; <sup>2</sup>Hospital Universitario Araba, Vitoria; <sup>3</sup>Medical Affairs, Merck Sharp and Dohme S.A, Madrid, Spain

**Background:** Adherence is a critical factor in the therapeutic response in rheumatoid arthritis (RA), which may be influenced by the doctor-patient relationship. In the ARCO study, we previously reported a percentage of lack of adherence to the subcutaneous biologic of 14.3% during the first 14 months of treatment, and that the adherence was better in patients without induction and with a monthly administration schedule.<sup>1</sup> In this *post hoc* analysis, we explored whether doctor-patient disagreements may be related to lower adherence rates.

**Objectives:** To analyse the percentage of patients with discrepancies in the evaluation of the activity of the disease between doctors and patients and a possible association between the existence of disagreement and adherence to subcutaneous biological drugs.

**Methods:** The ARCO study was a multicenter, cross-sectional study in which patients with RA were included according to EULAR-ACR 2010 criteria, who had been prescribed a subcutaneous biological drug in the previous 12–18 months. As part of the evaluation of the disease, patients and doctors were asked to rate the disease on a visual analogue scale (VAS), with values ranging from 0 to 10; with higher values indicating worst symptoms. Disagreement was defined as a difference of  $\geq 3$  points between the absolute values. Adherence was assessed retrospectively by means of the Medication Possession Ratio (MPR), considering adherence those patients with MPR  $> 80\%$ . The association between adherence and disagreement was studied using bi and multivariate logistic regression models with covariates-adjustments.

**Results:** We included 360 patients (77.5% women, mean age:  $55 \pm 0.6$  years). Disagreement was detected in 56 (15.5%). In patients with disagreement, the mean VAS score of the patient was  $5.75 \pm 1.8$  versus  $2.7 \pm 2.2$  in the group without disagreement ( $p < 0.001$ ), and there were no differences in terms of the doctors VAS (group with disagreement =  $2.7 \pm 1.8$  versus  $2.2 \pm 2.0$  in the group without disagreement,  $p = 0.110$ ). The two groups of patients presented differences in terms of age (5 years more than average in the group with disagreement,  $p = 0.010$ ), presence of comorbidity (14% more frequent in the group with disagreement,  $p = 0.030$ ) and the value of the mean DAS28 (0.6 points higher in the group with disagreement,  $p < 0.001$ ). Among the patients who presented a VAS disagreement, the percentage of non-adherence was 10.7%, and of 14.5% among those who had a VAS similar to the doctor ( $p = 0.45$ ). The regression analysis showed no difference in the association between adherence and disagreement; by introducing into the models covariates associated with adherence (induction, frequency of administration and age) or with disagreement (age, comorbidity and DAS28).

**Conclusions:** We observed a disagreement between patients and doctor VAS scores in 15.5% of cases, with higher values coming from patients. We did not observe an association between this disagreement and adherence to subcutaneous biological drugs.

#### FRI0087 REGIONAL AGE- AND SEX-SPECIFIC INTIMA-MEDIA THICKNESS CRITERIA IN YOUNG PATIENTS WITH RHEUMATOID ARTHRITIS

V. Omelchenko<sup>1,2</sup>, E. Letyagina<sup>1</sup>, M. Korolev<sup>1</sup>, R. Khapaev<sup>1</sup>, T. Pospelova<sup>2</sup>, V. Konenkov<sup>1</sup>. <sup>1</sup>FSBSI «Scientific Institute of clinical and experimental lymphology» – a branch of the FSBSI «Federal Research Center of the Institute of Cytology and Genetics of the Siberian Branch of the Russian Academy of Sciences»; <sup>2</sup>Novosibirsk State Medical University, Novosibirsk, Russian Federation

**Background:** Rheumatoid arthritis (RA) is associated with early progression of cardiovascular (CV) diseases. The CV risk calculators had been verified on a specific population<sup>1</sup> and should be applied predominantly for them. Systematic Coronary Risk Evaluation (SCORE) was recommended by EULAR for use in RA patients with multiplying coefficient 1.5.<sup>2</sup> Nevertheless, SCORE don't consider RA-specific factors and couldn't be used in young patient. For timely prevention

additional criteria is needed to evaluate CV risk in RA-patients. A presence of atherosclerotic plaque (API) or intima-media thickening, assessed by carotid ultrasonography, may be used as a high CV risk marker after adjustment by age and sex factors.

**Objectives:** To investigate the prevalence of carotid intima-media thickening, using regional age- and sex-specific criteria.

**Methods:** One hundred forty eight Caucasian patients with RA (age – 53 years;<sup>40;</sup> <sup>60</sup> DAS28 5.01 [3.91; 5.90]) without (API) were included in our study. Patients had ACR-defined RA (1987 classification criteria). All patients gave written informed consent before enrollment. SCORE with multiplying coefficient 1.5 was used for the CV risk determining. Range of atherosclerotic progression was assessed by ultrasonography with measurement of carotid intima-media thickness (IMT). IMT measured had been compared with ranges followed: <35/35–44/45–54/55–64/65–74/>75 age – 0,55/0,72/0,72/0,80/0,86/1,0 mm for the right artery and 0,53/0,65/0,73/0,85/0,89/1,0 mm for the left one (men); 0,47/0,51/0,71/0,78/0,87/0,87/0,87 mm for the right artery and 0,50/0,55/0,71/0,80/0,91/0,98 for the left one (women), respectively.<sup>3</sup> Descriptive statistics, Chi-squared test, Spearman rank correlation coefficient were used for data analysis. Results are presented as median and 25th/75th percentiles (Me [25th percentile; 75th percentile]).

**Results:** IMT significantly correlated with age ( $p=0,63$ ;  $p<0,001$ ), systolic blood pressure ( $p=0,22$ ;  $p=0,017$ ), but not with other parameters (sex, smoking, cholesterol, etc). Risk was evaluated by SCORE for 109 RA patients elder than 40 years (age – 57 years<sup>50;</sup> <sup>63</sup>) and was 0%>15% (1.95%–3%) [0.75; 3.15]. An intima-media thickening had been revealed in 86 from 109 (78,9%) patients and correlated with SCORE value ( $p=0,42$ ;  $p<0,001$ ). 34 patients (23,0%) were younger than 40 years (age – 30.5 years<sup>28,0;</sup> <sup>36,0</sup>), therefore the relative CV risk scale had been used for ones. Risk evaluated was medium (1.5%–3%) for all young patient. An intima-media thickening had been revealed in 31 from 34 (91,2%) patients and didn't correlate with SCORE value ( $p=0,37$ ;  $p=0,104$ ). Number of patients with carotid thickening between two groups didn't significantly difference ( $p=0,13$ ).

**Conclusions:** Using age- and sex-specific criteria for the IMT evaluation may be useful in young patients with RA.

#### FRI0088 PSYCHOLOGICAL IMPACT IN RHEUMATOID ARTHRITIS: ROLE OF SPECIFIC TREATMENT AND ASSOCIATED MEASURES

X. Grapton<sup>1</sup>, on behalf of CREER, P. Lemesle<sup>2</sup>, L. Arabian<sup>3</sup>, on behalf of CREER, V. Strotz<sup>4</sup>, on behalf of CREER. <sup>1</sup>Private Rheumatology Practice, Colombes; <sup>2</sup>Private Rheumatology Practice, Bois-Colombes; <sup>3</sup>Private Rheumatology Practice, Clamart; <sup>4</sup>Private Rheumatology Practice, Antony, France

**Background:** Psychological issues in rheumatoid arthritis (RA) are often spontaneously mentioned by patients or identified by rheumatologists. Besides classic follow up parameters like DAS28, we have to consider those issues to improve our patients psychological well-being.

**Objectives:** Explore reasons of psychological impact in RA. Analyse in a quantitative way symptoms of discontent and their repercussions. Evaluate consequences of disease treatment on those symptoms and propose recommendations for rheumatologists.

**Methods:** RA cases were collected by a group of 20 private practice rheumatologists in the Paris area. Basic informations about the patient and his disease were provided by his rheumatologist. Questionnaire including 14 items about psychological and life quality involvement was filled in by the patient.

**Results:** 167 cases collected : 82% women, mean age 57 years, 56% moderate and 14% severe disease, 76% ACPA positive, 73% structural damage. Initial DAS28 4.7. Post treatment DAS28 2.7. Drugs: classic DMARDs 95%, corticosteroids 73%, biological DMARDs 22%, combination therapy 76%.

In 82% of the cases, the rheumatologist recommends more than only specific RA drug treatment: rest (47%), physiotherapy, ergotherapy, balneotherapy (42%), adapting professional activity and environment, help for housework (33%), psychological support or psychoactive drugs (19%), yoga or other relaxation exercises (11%), balneology...

Psychological repercussions are spontaneously mentioned by 71% of the patients.

Psychological state is altered by : disease announcement, pain (85%), physical fatigue (71%), handicap (58%), other people's attitude.

Are limited : housework (51%), getting about (44%), do-it-yourself (55%), sports (61%), artistic activities (41%), professional activity (29%).

Social life is affected by : lack of being listened to (72%), lack of being understood (68%), lack of empathy (49%).

RA treatment reduces all those factors by at least one third, except impact on family relations.

Before treatment, RA patients report: sleeping trouble (70%), anxiety (57%), lack of motivation (55%), dependency (49%), frustration (42%), lack of self-esteem (37%), concentration problems (35%), disillusion (31%), depression (30%), family tension (29%), isolation (27%) and libido decrease (23%).

After treatment, all those factors are 41%–55% less frequent, except libido decrease (–28%).

55% sleep better, 49% aren't depressed anymore, concentration problems diminish by 48% and social life is improved by 50%.

**Conclusions:** There is a major psychological impact in RA patients, with repercussions on their well-being and life quality. This can be improved by specific anti RA treatment, but we must also consider other measures and, if necessary, psychological support and/or psychoactive drugs. All chosen items are improved, except impact on family relations.

**Disclosure of Interest:** None declared

#### FRI0089 ASSESSMENT OF COGNITIVE FUNCTION IN RHEUMATOID ARTHRITIS

Z. Kardos<sup>1</sup>, C. Oláh<sup>2</sup>, M. Andrejkovics<sup>3</sup>, E. Bodnár<sup>2</sup>, K. Hodosi<sup>4</sup>, K. Fazekas<sup>1</sup>, Á. Flórián<sup>1</sup>, K. Lukács<sup>1</sup>, Á. Miksi<sup>1</sup>, Z. Baráth<sup>1</sup>, L. Tamási<sup>1</sup>, Z. Szekanez<sup>4</sup>.

<sup>1</sup>Department of Rheumatology, Semmelweis Teaching Hospital; <sup>2</sup>Department of Neurosurgery, Borsod County Teaching Hospital, Miskolc; <sup>3</sup>Institute of Behavioural Sciences, University of Debrecen, Faculty of Public Health; <sup>4</sup>Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

**Background:** For long, rheumatoid arthritis (RA) was thought not to associate with central nervous system (CNS) involvement. In recent years some studies suggest that cognitive function is impaired in RA patients. Accelerated atherosclerosis and reduced function of intracranial vessels in RA can be associated with vascular dementia.

**Objectives:** We assessed RA patients and healthy controls by neuropsychological tests, cognitive function such as attention, intelligence, memory tests and also by anxiety and depression tests. We wished to explore the prevalence of neuropsychiatric manifestations and cognitive impairment in patients with RA. Intracerebral vascular lesions were investigated by brain MRI.

**Methods:** Sixty RA female patients were included. Among them, 20 were MTX-treated, biologic-free, 40 patients received biologics. The controls included 39 non-RA healthy women. The following standardised tests were used: the Montreal Cognitive Assessment (MoCa) Test, the Victoria Stroop Test (VST), the Spielberger State-Trait Anxiety Inventory (STAI), the Benton Visual Retention Test (BVRT), the Beck Depression Inventory (BDI), the Brigg's and Nebe's Test, the Trail Making Test (TMT) A and B, the Word fluency with the letter (WF-L) and with category naming tests (WF-C), the Rey-Osterreich Auditory Verbal Learning Test (RAVLT), the Weschler Adult Intelligence Scale (WAIS). We also performed brain MRI in all patients in order to associate cognitive function with MRI changes.

**Results:** The MoCa total score was significantly lower in RA patients (23.3±3.8) especially in biologic-treated group (22.6±4.3) compared to controls (25.6±2.4) ( $p=0,002$ ;  $0,001$ ). The attention MoCa test score was significantly lower in biologic- (4.5±1.6) compared to MTX-treated patients (5.7±0.6)( $p=0,001$ ). The STAI scores were significantly higher in RA (STAI-S: 45.5±8.5; STAI-T: 48.0±11.0) compared to controls (STAI-S: 36.9±9.1; STAI-T: 41.1±9.0)( $p<0,001$ ;  $0,002$ ). The BDI score was significantly higher in RA (13.2±8.8) and in biologic-treated patients (13.7±8.7) than in controls (8.9±6.5)( $p<0,05$ ). The TMT scores were significantly higher in RA (TMT-A: 69.0±26.3; TMT-B:100.2±48.5) compared to controls (TMT-A: 53.1±14.3; TMT-B: 53.1±22.7)( $p<0,05$ ). The VST scores were also significantly higher in RA vs controls. The WAIS and Benton scores were significantly lower in

RA and in biologic-treated patients than in controls ( $p=0.005$ ). On brain MRI scans, there were significantly more vascular lesions both in the left and the right side in RA patients (55,1%>53,1%) than in controls (23,5%>20,1%) ( $p<0,05$ ), the cerebral atrophy is much more common in RA (0,26 vs. 0,03; $p=0,005$ ).

**Conclusions:** These findings suggest that the presence of neuropsychiatric manifestations and cognitive impairment in RA patients is significant. Biologic-treated patients may represent a more severe RA subset thus having cognitive dysfunction more commonly. Brain atrophy, emollition and vascular lesions are more often in RA patients than controls.

#### FRI0090 ASSOCIATION OF BODY COMPOSITION WITH DISEASE ACTIVITY AND DISABILITY IN RHEUMATOID ARTHRITIS

K.M. Son<sup>1</sup>, S.Y. Lee<sup>2</sup>, S.H. Kang<sup>2</sup>, Y.I. Seo<sup>2</sup>, H.A. Kim<sup>2</sup>. <sup>1</sup>Hallym University Dongtan Sacred Heart Hospital; <sup>2</sup>Hallym University Sacred Heart Hospital, Gyeonggi-Do, Korea, Republic Of

**Background:** Rheumatoid arthritis (RA) is a chronic form of inflammatory arthritis characterised by multiple joint involvement and significant disability. Previous studies showed that RA is associated with considerable changes in body composition, lipid profile, adipokines and insulin sensitivity

**Objectives:** To explore the association of body composition with pain, disease activity and disability in rheumatoid arthritis (RA)

**Methods:** Three hundred thirty five patients with RA visiting the Hallym University Sacred Hospital underwent body composition measurement with inbody analyzer and examined the disease activity score (DAS28). The association of body mass index (BMI), body fat mass and skeletal muscle mass with DAS28, DAS28-P (an index derived to measure subjective component of DAS28), pain VAS and disability measured with the health assessment questionnaire (HAQ) was explored. Obesity was defined as BMI  $\geq 25$  kg/m<sup>2</sup>. Pain VAS was dichotomized as  $\leq 40$  and  $>40$ . Low HAQ score was defined as  $\leq 0.5$ . Logistic regression was divided in female versus male.

**Results:** Mean age of patients was  $56 \pm 11.9$  years and 84.8% were female. The median(IQR) disease durations was 6 (3.5–9) years and mean DAS28 score was  $3.55 \pm 1.14$ . Mean BMI was  $23.6 \pm 3.7$  kg/m<sup>2</sup> and 109 patients (32.5%) were obese. Obese patients had higher CRP level (1.68 ml/dL vs 0 ml/dL,  $p=0.013$ ), ESR level (25 mm/hr vs 18 mm/hr,  $p=0.032$ ), pain VAS score (40 vs 35,  $p=0.045$ ), and higher DAS28-ESR score ( $3.75 \pm 1.18$  vs  $3.46 \pm 1.11$ ,  $p=0.031$ ), than non obese patients. In multivariable regression analysis, DAS28 score in female was positively associated with current steroid dose, HAQ and body fat mass. In univariable logistic regression, higher pain VAS category in female was associated with older age, higher BMI and higher body fat mass. In multivariable logistic regression analysis, higher HAQ score in female was associated with older age, higher DAS28, higher body fat/skeletal muscle ration and lower skeletal muscle mass. In multivariable regression analysis, DAS28-P score in female was positively associated with higher body fat/skeletal muscle ratio and negatively associated with positivity of anti-CCP.

**Conclusions:** Body compositions such as body fat mass and skeletal muscle mass are significantly associated with pain and disability in RA patients

**Disclosure of Interest:** None declared

#### FRI0091 SOMATOSENSORY DYSFUNCTION IN RHEUMATOID ARTHRITIS – A QUANTITATIVE SENSORY TESTING ASSESSMENT

T.M. Rocha<sup>1</sup>, M. Barbosa<sup>2</sup>, S. Pimenta<sup>1</sup>, M. Bernardes<sup>1</sup>, A. Bernardo<sup>1</sup>, R. Lucas<sup>3</sup>, L. Costa<sup>1</sup>, J. Vollert<sup>4</sup>, C. Maier<sup>4</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pain Unit, Centro Hospitalar de São João; <sup>3</sup>Clinical Epidemiology, Faculty of Medicine University of Porto, Porto, Portugal; <sup>4</sup>Pain Management, BG-University Hospital Bergmannsheil GmbH, Bochum, Germany

**Background:** Significant pain persists in a substantial proportion of Rheumatoid Arthritis (RA) patients and features suggestive of neuropathic pain (NP) were described. Few studies applied quantitative sensory testing (QST) to evaluate the somatosensory phenotype of RA pain.

**Objectives:** To explore the sensory abnormalities in RA and study its association with clinical and disease activity parameters.

**Methods:** Cross-sectional study was performed with RA patients followed at our rheumatology department. QST was performed in patients classified with NP (according to LANSS and/or pain DETECT scores) in both the most painful and non-painful contralateral joint areas. The evaluation followed the protocol of the German Research Network on Neuropathic Pain. Patients with diagnosed neuropathy or non-RA risk factors for NP were excluded. Proportions of abnormal detection/pain thresholds were calculated after z-transformation of QST data

based on gender, age and site reference values. Correlations were studied (Spearman correlation coefficient) and comparison between groups was performed (Mann-Whitney and  $\chi^2$  tests).

**Results:** From 112 evaluated RA patients, 47% were classified with NP and 39 performed QST. Thirty four (87%) were women, with a mean age of  $53.5 \pm 11.8$  years and median disease duration of 11 years; <sup>2-31</sup> 74% were seropositive for Rheumatoid Factor and/or ACPA; 90% were treated with conventional synthetic Disease-Modifying Antirheumatic Drugs (DMARDs) and 39% with biological DMARDs (bDMARDs). Mean DAS28 CRP was  $3.44 \pm 0.7$ . For non-nociceptive parameters, 23 (59%) patients exhibited sensory loss (Lo), 6 to thermal stimuli (L1), 10 to mechanical stimuli (L2) and the reminder for both (L3). Concerning nociceptive parameters, hyperalgesia (Ga) was noted in almost all the patients (97%), 1 to thermal (G1), 20 to mechanical (G2) and 17 for both stimuli (G3). Twenty two (60%) patients presented both Lo and Ga findings. Higher proportion of Lo was noted in bDMARDs group (86% vs 46%,  $p=0.02$ ). Lo patients had significant lower median CRP and ESR levels, but no differences were observed concerning disease activity scores. Thermal Lo (L1 and L3) was also more frequent in the bDMARDs group (57% vs 21%,  $p=0.04$ ) and cold Lo in hydroxychloroquine (HCQ) treated patients (90% vs 21%  $p=0.02$ ). Cold Ga was more frequent in patients under methotrexate (MTX) (48% vs 6%,  $p=0.04$ ) and less frequent in the bDMARDs group (7% vs 46%,  $p<0.05$ ). A weak correlation of Z cold detection and Z warm detection values with CRP and ESR levels was noted ( $r=0.34$  and  $r=0.35$ ,  $p=0.04$ ). Time exposure to HCQ, MTX and bDMARDs was negatively correlated with Z cold detection ( $r=-0.34$ ,  $p=0.03$ ), Z pressure pain ( $r=-0.33$ ,  $p=0.04$ ) and Z vibration detection ( $r=-0.32$ ,  $p=0.04$ ), respectively.

**Conclusions:** Almost all patients presented hyperalgesia, but a sizable proportion also had sensory loss, frequently involving A $\beta$  fibres. CRP and ESR levels possibly influence small fibre function, but no association with disease activity scores was found. Possible association of bDMARDs and HCQ treatment with sensory detection loss and of MTX with lower pain thresholds was pointed.

#### FRI0092 THE ASSOCIATION OF PSYCHOLOGICAL STRESS WITH INFLAMMATION IN PATIENTS WITH CLINICALLY SUSPECT ARTHRALGIA – A STUDY DURING RHEUMATOID ARTHRITIS DEVELOPMENT

A.C. Boer<sup>1</sup>, R.M. ten Brinck<sup>1</sup>, A.W.M. Evers<sup>2</sup>, A.H.M. van Der Helm – van Mil<sup>1,3</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Centre; <sup>2</sup>Medical and Neuropsychology, Faculty of Social and Behavioural Science, Leiden University and Department of Psychiatry, Leiden University Medical Centre, Leiden; <sup>3</sup>Rheumatology, Erasmus Medical Centre, Rotterdam, Netherlands

**Background:** Within established Rheumatoid Arthritis (RA), stress can have pro-inflammatory effects by activating the immune system via the hypothalamic-pituitary-adrenal axis and the autonomic nervous system. It is unknown if stress-levels promote also inflammation during RA-development.

**Objectives:** We studied whether the psychological stress response was increased in Clinically Suspect Arthralgia (CSA) and if this associated with inflammation at presentation with arthralgia and with progression to clinical arthritis.

**Methods:** In 241 CSA-patients, psychological stress was measured by the Mental Health Inventory (MHI-5) and the Perceived Stress Scale (PSS-10) at first presentation and during follow-up. Systemic inflammation was measured by C-reactive protein (CRP) and joint inflammation by 1.5T-MRI of wrist-, MCP- and MTP-joints.

**Results:** At baseline, 10% of CSA-patients had a high psychological stress-response according to the MHI-5. This was not different for patients presenting with or without an elevated CRP, with or without subclinical MRI-detected inflammation and for patients who did or did not develop arthritis. Similar findings were obtained with the PSS-10. When developing clinical arthritis, the percentage of patients with 'high psychological stress' increased to 31% ( $p=0.025$ ); during the first year of treatment this decreased to 8% ( $p=0.020$ ). 'High psychological stress' in non-progressors remained infrequent over time (range 7%–13%). Stress was associated with fatigue ( $p=0.003$ ) and wellbeing ( $p<0.001$ ).

**Conclusions:** Psychological stress was not increased in the phase of arthralgia, raised at the time of diagnoses and decreased thereafter. This temporal-relationship, and the lack of association with inflammation in arthralgia, argue against psychological stress having a significant contribution to inflammatory arthritis development.

**Disclosure of Interest:** None declared

**FRI0093** **DON'T MISS THE DEPRESSION! COMORBIDITIES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND THEIR IMPACT ON PATIENT-REPORTED OUTCOMES: RESULTS OF CLAIMS DATA LINKED TO A QUESTIONNAIRE SURVEY**

K. Albrecht<sup>1</sup>, A. Luque Ramos<sup>2</sup>, J. Callhoff<sup>1</sup>, I. Redeker<sup>1</sup>, F. Hoffmann<sup>2</sup>, A. Zink<sup>1</sup>.  
<sup>1</sup>Epidemiology, German Rheumatism Research Center, Berlin; <sup>2</sup>Health Services Research, Carl von Ossietzky University, Oldenburg, Germany

**Background:** Comorbidities are increasingly acknowledged as important clinical manifestation in patients with rheumatoid arthritis (RA).

**Objectives:** To investigate the prevalence of comorbidities in RA and their association with patient-reported outcomes.

**Methods:** Data of 96 921 persons with RA and 4 84 605 age- and sex-matched controls of a German statutory health fund were studied on the presence of selected comorbidities in 2015. Diagnoses and therapies were assigned to the provider (general practitioner, rheumatologist or another specialist). A self-reported questionnaire, comprising joint counts (TJC, SJC), functional status (FFbH), impact of the disease (RAID) and well-being (WHO-5) was sent to a random sample of 6195 persons with RA of whom 3184 responded. For respondents who confirmed their RA (n=2,535), the association between comorbidities and patient-reported outcomes were analysed by multivariable linear regression analyses.

**Results:** Compared to controls, persons with RA (mean age 63 years, 80% female) had higher prevalences of all comorbidities, the most common were depression and osteoporosis besides cardiovascular risk factors (table 1). The diagnosis of depression was provided in 50% of cases by general practitioners, in 13% by rheumatologists and in 48% by other specialists while the diagnosis of osteoporosis was made in 76% by general practitioners, in 48% by rheumatologists and in 46% by other specialists. Among the survey respondents, increasing numbers of comorbidities were associated with worse TJC, SJC, function and WHO-5 values. Depression, obesity and osteoporosis had the highest impact on functional status and TJCs. The percentage of patients in rheumatologic care decreased from 73% with 0–1 comorbidity to 62% with ≥8 comorbidities (age-adjusted).

**Abstract FRI0093 – Table 1.** Prevalence of selected comorbidities in cases and controls

	RA patients n=96 921 % (95% CI)	Controls n=4 84 605 % (95% CI)
<b>Cardiovascular risk factors</b>		
Hypertension	61.8 (61.5–62.1)	48.0 (47.8–48.1)
Hyperlipidemia	39.4 (39.1–39.7)	32.4 (32.2–32.5)
Obesity	17.7 (17.5–18.0)	12.3 (12.2–12.3)
<b>Comorbid disorders</b>		
Depression	31.4 (31.1–31.7)	20.4 (20.3–20.5)
Osteoporosis	25.7 (25.4–26.0)	9.7 (9.6–9.8)
Diabetes	21.5 (21.2–21.7)	15.3 (15.2–15.4)
Cardiac arrhythmia	18.8 (18.5–19.0)	13.2 (13.1–13.3)
Hypothyroidism	17.9 (17.6–18.1)	12.8 (12.7–12.9)
Coronary heart disease	15.2 (15.0–15.4)	9.6 (9.5–9.7)
Liver disease	13.8 (13.6–14.0)	9.1 (9.0–9.1)
Vascular diseases	12.9 (12.7–13.1)	8.5 (8.4–8.6)
Asthma	12.3 (12.1–12.5)	7.4 (7.3–7.4)
COPD	11.3 (11.0–11.4)	6.6 (6.5–6.6)

**Conclusions:** Osteoporosis and depression are amongst the most common disorders in persons with RA. While osteoporosis is usually taken into account by the rheumatologist, more attention should be paid to depression as both disorders strongly affect patient-reported outcomes.

**Acknowledgements:** This study was funded by the German Federal Ministry of Education and Research (01EC1405).

**FRI0094** **DOES SUBCLINICAL INFLAMMATION EXPLAIN JOINT PAIN IN PATIENTS WITH ARTHRALGIA SUSPICIOUS FOR PROGRESSION TO RHEUMATOID ARTHRITIS? – RESULTS OF A CROSS-SECTIONAL MRI-STUDY**

L.E. Burgers, R.M. ten Brinck, D.M. Boeters, A.H.M. van der Helm-van Mil.  
Rheumatology, Leiden University Medical Centre, Leiden, Netherlands

**Background:** The development of Rheumatoid Arthritis (RA) is often preceded by a symptomatic phase of arthralgia. The etiology of symptoms in this phase is unclear.

**Objectives:** Since subclinical joint inflammation is expected to be causally related to pain, we aimed to determine associations between subclinical MRI-detected inflammation and pain in patients with arthralgia suspicious for progression to RA.

**Methods:** Unilateral MRIs of the wrist, MCP(2–5)- and MTP(1–5)-joints of 325 patients who fulfilled the EULAR definition of arthralgia suspicious for progression to RA were made and scored by two readers on subclinical inflammation (synovitis, bone marrow oedema (BME) and tenosynovitis). Associations between MRI-detected inflammation and overall pain severity at patient level (measured using the visual analogue scale (VAS)), and local tenderness at joint palpation, were studied in all patients, in ACPA-positive and ACPA-negative patients separately, and in the subgroup of patients that progressed to inflammatory arthritis.

**Results:** At patient level, synovitis ( $\beta=0.10$ ,  $p=0.048$ ) and tenosynovitis ( $\beta=0.11$ ,  $p=0.026$ ) associated with the VAS-pain. Of the 1620 imaged joints, 447 (28%) were tender. Subclinical inflammation was present in 32% of tender joints and in 25% of non-tender joints. MRI-detected synovitis associated independently with joint tenderness (OR 1.74,  $p<0.001$ ). In ACPA-negative patients synovitis associated independently with joint tenderness (OR 1.96,  $p<0.001$ ), while BME was independently associated with joint tenderness in ACPA-positive patients (OR 2.39,  $p=0.005$ ). Sensitivity analyses in patients who developed arthritis during follow-up (n=61) revealed similar associations.

**Conclusions:** In patients with arthralgia suspicious for progression to RA, joint tenderness and pain are associated with MRI-detected subclinical inflammation. The association is incomplete, indicating that subclinical inflammation is not the sole explanation of the arthralgia.

**Background:** This study shows that treatment with biologic drugs, including anti-TNF drugs, in NION associated to IMIDs, refractory to conventional treatment, seems to be effective. These results must be confirmed in prospective and randomised trials.

**Objectives:** Our aim was to compare anti-TNF $\alpha$  vs Rituximab (RTX) in refractory PUK.

**Methods:** Multicenter study of 24 patients with PUK. All of them presented inadequate response to corticosteroids and at least 1 systemic traditional immunosuppressive drug.

Anti-TNF $\alpha$  were used in 17 patients: Adalimumab (n=9) 40 mg/sc every 1–2 weeks, infliximab (IFX) (n=7) 3–5 mg/kg iv/4–6 weeks, etanercept (n=1) 50 mg/week. RTX was used in 7 patients 1–2 g i.v. every 6 or 12 months.

The main outcomes were Best Corrected Visual Acuity (BCVA), signs of inflammation (scleritis and episcleritis), progression to corneal thinning, central keratolysis and ocular perforation.

Abstract FRI0095 – Table 1

	anti-TNF $\alpha$ n=17	RTX n= 7	P
<b>General features</b>			
Sex ( $\bar{x}/\bar{z}$ )	4/2	13/5	0.79
Mean age (years)	59.1 $\pm$ 18.3	54.28 $\pm$ 10.7	0.49
Ocular bilateral involvement #	23.53	57.14	0.13
Duration of underlying diseases (days)	183.06 $\pm$ 18.3	138.85 $\pm$ 77.68	0.59
<b>Basal</b>			
BCVA*	0.58 $\pm$ 0.38	0.56 $\pm$ 0.34	0.68

Scleritis #	-	-	-
Episcleritis #	-	+	-
Uveitis #	1	0	0.38
<b>1st year</b>			
BCVA*	0.75 $\pm$ 0.22	0.70 $\pm$ 0.24	0.77
Peripheral thinning #	7	3	0.25
Central keratolysis #*	1	1	0.89
Ocular perforation #	0	1	0.30
Scleritis #	-	-	-
Episcleritis #	-	-	-
Uveitis #	1	0	0.35

Comparisons were made between baseline and 1<sup>st</sup> month, 6<sup>th</sup> month and 1<sup>st</sup> year (STATISTICA, StatSoft Inc. Tulsa, Oklahoma, USA). Quantitative variables were expressed as mean  $\pm$ SD or median [IQR], accordingly to its distribution. They were compared with the Student t or the Mann-Whitney U test respectively. Dichotomous variables were expressed as percentages and compared by the chi-square test.

**Results:** We studied 24 patients/32 affected eyes. The underlying diseases in the anti-TNF $\alpha$  group were Rheumatoid Arthritis (RA) (n=14), Psoriatic Arthritis (n=2) and Behçet Disease (n=1); and in the RTX group: RA (n=5), granulomatous polyangiitis (n=1) and microscopic polyangiitis (n=1).

At baseline there were no significant differences between both groups in general features or in ocular involvement (table 1). Before biologic therapy they had received the following systemic drugs (anti-TNF $\alpha$  vs RTX) i.v. methylprednisolone (2 vs 4), doxycycline (7 vs 1), ascorbic acid (2 vs 0), MTX (11 vs 4), AZA (1 vs 2) and others (7 vs 3). In addition, 10 patients, in both groups, had required surgery: amniotic membrane (n=5), penetrating keratoplasty (n=2), conjunctival resection (n=2), tissue adhesives (n=2), conjunctival flap (n=1) and lamellar keratoplasty (n=1).

Once the treatment was initiated the ocular outcome was similar (table 1). After a mean follow-up of 22.53 $\pm$ 22.60 (anti-TNF $\alpha$ ) and 22.28 $\pm$ 8.28 months with RTX the following severe side effects were observed: supraventricular tachycardia (n=1) with RTX and pulmonary tuberculosis (n=1) with IFX.

**Conclusions:** In this study, anti-TNF $\alpha$  therapy and RTX were equally effective for the treatment of peripheral ulcerative keratitis associated to rheumatic diseases refractory to conventional treatment.

**Disclosure of Interest:** None declared

#### FRI0096 IS SIDE EFFECTS AND TREATMENT RESPONSE TO METHOTREXATE ASSOCIATED TO COMORBIDITY IN EARLY RHEUMATOID ARTHRITIS

K.L. Pedersen<sup>1</sup>, J. Hallas<sup>2</sup>, I.M.J. Hansen<sup>3</sup>, P. Ahlquist<sup>4</sup>, T. Ellingsen<sup>5</sup>. <sup>1</sup>Hospital Pharmacy of Funen, Odense University Hospital; <sup>2</sup>Clinical Pharmacology and Pharmacy, Department of Public Health; <sup>3</sup>Dept of Rheumatology, Odense University Hospital; <sup>4</sup>Reumaclinic Funen, Reumaclinic Funen; <sup>5</sup>Rheumatology, Odense University Hospital, Odense, Denmark

**Background:** In Denmark approximately 0.7% (35.000) of the population is diagnosed with rheumatoid arthritis (RA). RA is a risk factor in development of comorbidity, and comorbidities are not well managed in RA patients. In addition of being first line treatment of early RA, methotrexate (MTX) gives a 70% reduction in cardiovascular disease caused mortalities, and if treatment exceeds a year, the general mortality risks are lowered by 60%. Discontinuation of MTX is therefore a bad outcome for RA. It remains unclear whether side effects and treatment response to MTX is associated to comorbidity in early RA.

**Objectives:** To evaluate the association between comorbidity and persistence to MTX treatment and side effects for RA patients.

**Methods:** Patient files from three centres were evaluated retrospectively. Inclusion criteria were: diagnosis obtained according to ACR/EULAR 2010 criteria for RA in the period 01/01/2010 to present, and MTX as first line of treatment. Medical records were reviewed for side effects, dose changes of MTX, formulation changes and persistence. Comorbidities and comedication was evaluated by usage of the Danish National Patient Registry (DNPR), and the Odense Pharmacoepidemiological Database (OPED). Comorbidities were scored according to the Charlson Comorbidity Index (CCI), and analysed by the cox proportional hazards model for discontinuation of MTX treatment and dose reduction.

**Results:** 501 patients were screened, 177 were eligible and analysed at baseline for disease characteristics, medication besides MTX and comorbidities in a 5 year window before RA diagnosis baseline. The highest risk of MTX discontinuation was a CCI of 3–4, they had crude 4.18 (95% CI 1.67–10.45) increased risk compared to the reference group (RA with no comorbidities). Risk of dosage reduction was highest at CCI 1–2: 1.38 (95% CI 0.72–2.62). A CCI of 5 or higher gave a –4.83 mg (95% CI –10.24– –0.59) adjusted difference in maximum weekly tolerable MTX dosage. Side effects occurred for 23.7%. Most likely dosage causing side effect was 20 mg (IQR 15–20 mg). Nausea occurred in 29% and hepatic events 21%.

**Conclusions:** Patients with CCI in the range of 3–4 had an increased risk for discontinuing MTX treatment.

**Disclosure of Interest:** None declared

#### FRI0097 EXPRESSION OF UNCOUPLING PROTEIN-1 IN SUBCUTANEOUS FAT REDUCES THE TOTAL CHOLESTEROL LEVEL AND CARDIOVASCULAR RISK IN FEMALE RA PATIENTS

L.I. Lyngfelt, M.C. Erlandsson, M. Nadali, K.M. Andersson, S.T. Silfverward, R. Pullerits, M.I. Bokarewa. Department of Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg, Sweden

**Objectives:** To improve understanding of fat-related molecular mechanisms behind the increased cardiovascular (CV) morbidity in patients with rheumatoid arthritis (RA).

**Methods:** Transcription of uncoupling protein 1 (UCP1) was measured in the subcutaneous fat tissue and serum levels of lipoproteins, adipokines, and inflammation markers in 185 middle-aged female patients (mean age 51 years) with RA and compared between the groups stratified by the total cholesterol (TC) levels and the body mass index (BMI). The risk of dying of CV disease within 5 years was calculated electronically using the strategy proposed by Pocock et al.<sup>1</sup>

**Results:** CVR was highest (risk score 27.76, 5 year CVR 0.67%) in the patients combining high TC (>5.1 mmol/L) and high BMI (>25 kg/m<sup>2</sup>), while those with low levels of TC and BMI had lowest CVR (risk score 10.82, CVR 0.11%). CVR was significantly decreased if either TC (TC<sup>0</sup>BMI<sup>hi</sup>) or BMI (TC<sup>hi</sup>BMI<sup>lo</sup>) was low (p=0.017 and p=0.014, respectively). With the exception of TC<sup>lo</sup>BMI<sup>lo</sup> group, these groups had no difference with respect to age, disease duration, inflammation defined by serum IL6 and IL1, and disease activity measured by DAS28. TC<sup>lo</sup>BMI<sup>hi</sup> patients had an overall increase in fat expression of UCP1 (p=0.047) that has the cholesterol lowering capacity and may explain low TC levels in this

group. In contrast, TC<sup>hi</sup>BMI<sup>lo</sup> patients had high prevalence of cases with unmeasurable UCP1 expression and higher levels of serum adiponectin (p=0.053) and HDL (p<10<sup>-5</sup>).

Measurable expression of UCP1 was found in 79%. In total cohort, the patients with measurable UCP1 had higher inflammation and RA activity presented by IL-6 (p=0.0001), IL1b (p=0.037) and DAS28 (p=0.0086), compared to those with no UCP1 expression. TC<sup>lo</sup>BMI<sup>hi</sup> patients had an overall increase in fat expression of UCP1 (p=0.047) and lowest prevalence of cases with no UCP1 expression (6.2%).

**Conclusions:** The study shows that UCP-1 expression in subcutaneous fat may be a CV protective mechanism in RA patients. The inflammation seems to be the driving force of UCP1 expression in RA.

#### HEPATIC SAFETY IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO RECEIVED ISONIAZID FOR LATENT TUBERCULOSIS: POST-HOC ANALYSIS FROM PHASE 3 BARICITINIB STUDIES

T.-Y. Hsieh<sup>1</sup>, W.-N. Huang<sup>1</sup>, H.-P. Tony<sup>2</sup>, A. Balsa<sup>3</sup>, K. Winthrop<sup>4</sup>, M. Harigai<sup>5</sup>, C. Dickson<sup>6</sup>, W.-S. Wu<sup>7</sup>, I. de la Torre<sup>8</sup>, R. Liao<sup>6</sup>, L. Chen<sup>6</sup>, S. Kumar<sup>6</sup>, B. Combe<sup>9</sup>.

<sup>1</sup>Department of Internal Medicine, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China; <sup>2</sup>Rheumatologie, Klinische Immunologie, Klinikum der Universität Würzburg, Würzburg, Germany; <sup>3</sup>Department of Rheumatology, Hospital Universitario La Paz, Madrid, Spain; <sup>4</sup>Center for Infectious Disease Studies, OHSU-PSU School of Public Health, Portland, USA; <sup>5</sup>Institute of Rheumatology, Tokyo Women's Medical University, Tokyo, Japan; <sup>6</sup>Eli Lilly and Company, Indianapolis, USA; <sup>7</sup>Eli Lilly and Company, Taipei, Taiwan, Province of China; <sup>8</sup>Eli Lilly and Company, Madrid, Spain; <sup>9</sup>Département of Rheumatology, Montpellier University Hospital, University of Montpellier, Montpellier, France

**Background:** Baricitinib (BARI) is an oral selective Janus kinase (JAK 1/2)<sup>1</sup> inhibitor approved in the EU, Japan, and other countries for treatment (tx) of moderately to severely active rheumatoid arthritis (RA) in adults. RA therapies may increase risk of tuberculosis (TB).<sup>2</sup> The use of isoniazid (INH) plays a vital role to control TB. However, INH may result in hepatic adverse events (AEs)<sup>3</sup>. Limited data exist on hepatic safety in TB patients (pts) with RA treated with JAK inhibitors and INH.

**Objectives:** To evaluate the hepatic safety in pts with RA, who were receiving INH for latent TB (LTBI) in BARI phase 3 trials.

**Methods:** This is a descriptive post-hoc analysis of three phase 3 studies: RA-BEAM, RA-BUILD, and RA-BEACON. All pts were screened for LTBI prior to randomisation. Pts with untreated LTBI and without documentation of prior completed tx, received INH at least for 4 weeks (wk) prior to randomisation and during the clinical trial period. Changes in ALT levels ( $\geq 1X$ ,  $\geq 3X$ ,  $\geq 5X$ , and  $\geq 10X$  of ULN) from baseline up to 24 wk were analysed by tx groups (BARI 4 mg, BARI 2 mg, adalimumab [ADA], and placebo [PBO]).

**Results:** In total, 2516 pts were included in this analysis. Of these, 891 pts were treated with BARI 4 mg, 403 with BARI 2 mg, 330 with ADA, and 892 with PBO. Background csDMARDs, mainly methotrexate (MTX) were continued. Overall, 246 pts reported LTBI at screening across all tx groups. Of these, 169 with confirmed lab data received INH as LTBI tx. At wk 24, ALT $\geq 1X$  was reported in 24 (41.4%) pts receiving BARI 4-mg+INH. None of the pts in BARI 4-mg+INH reported ALT level of  $\geq 3X$ ,  $\geq 5X$ , and  $\geq 10X$  ULN. For BARI 2-mg+INH, ALT $\geq 1X$  reported in 9 (33.3%) pts, ALT $\geq 3X$  in 2 (7.4%), ALT $\geq 5X$  in 1 (3.7%), and ALT $\geq 10X$  in 1 (3.7%) of the pts. Among pts treated with ADA +INH, ALT $\geq 1X$  was reported in 12 (44.4%), ALT $\geq 3X$  in 2 (7.4%), ALT $\geq 5X$  in 1 (3.7%), and ALT $\geq 10X$  in none of pts. Among pts treated with PBO+INH, ALT $\geq 1X$  was reported in 21 (36.8%), ALT $\geq 3X$  and ALT $\geq 5X$  levels were reported in 2 (3.5%, for both) of the pts. None of the pts reported ALT $\geq 10X$ . One pt receiving INH in RA-BEAM PBO arm had temporary interruption of tx due to abnormal hepatic lab results. No study tx interruption or discontinuation was reported in INH users in BARI or ADA groups due to abnormal hepatic lab results.

**Abstract FRI0098 – Table 1.** Changes in ALT level from baseline to week 24 in patients receiving BARI, ADA, and PBO

	BARI 4-mg (RA-BEAM, RA-BUILD, RA-BEACON) N=891		BARI 2-mg (RA-BUILD, RA- BEACON) N=403		ADA (RA-BEAM) N=330		PBO (RA-BEAM, RA-BUILD, RA-BEACON) N=892	
	INH (n=58)	No INH (n=833)	INH (n=27)	No INH (n=376)	INH (n=27)	No INH (n=303)	INH (n=57)	No INH (n=835)
ALT $\geq 1X$ ULN	24 (41.4%)	260 (31.2%)	9 (33.3%)	82 (21.8%)	12 (44.4%)	91 (30.0%)	21 (36.8%)	183 (21.9%)
ALT $\geq 3X$ ULN	0	13 (1.6%)	2 (7.4%)	6 (1.6%)	2 (7.4%)	9 (3.0%)	2 (3.5%)	13 (1.6%)
ALT $\geq 5X$ ULN	0	5 (0.6%)	1 (3.7%)	1 (0.3%)	1 (3.7%)	3 (1.0%)	2 (3.5%)	3 (0.4%)
ALT $\geq 10X$ ULN	0	2 (0.2%)	1 (3.7%)	0	0	1 (0.3%)	0	0

ALT=alanine transaminase; ULN=upper limit of normal; INH=isoniazid.

All pts were on concomitant use of csDMARDs, mainly MTX.

**Conclusions:** The percentage of pts with  $\geq 1X$  ULN ALT was numerically higher in INH group vs no INH and was consistent across PBO, BARI and ADA tx groups. The data do not suggest an increased hepatic safety risk in pts treated with BARI who were receiving concomitant INH.

#### LIVER ENZYME ABNORMALITIES AFTER TOFACITINIB TREATMENT IN PATIENTS WITH HEPATIC STEATOSIS FROM THE RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND PSORIASIS CLINICAL PROGRAMMES

E.R. Soriano<sup>1</sup>, H. Madariaga<sup>2</sup>, O. Castañeda<sup>3</sup>, G. Citera<sup>4</sup>, E.E. Schneeberger<sup>4</sup>, M. H. Cardiel<sup>5</sup>, T. Hendrikx<sup>6</sup>, D. Graham<sup>7</sup>, H. Shi<sup>8</sup>, D. Ponce de Leon<sup>9</sup>. <sup>1</sup>Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; <sup>2</sup>Clinica del Sur, Arequipa; <sup>3</sup>Clinica Anglo Americana, Lima, Peru; <sup>4</sup>Instituto de Rehabilitación Psicosfísica, Buenos Aires, Argentina; <sup>5</sup>Centro de Investigación Clínica de Morelia, Morelia, Mexico; <sup>6</sup>Pfizer Inc, Collegeville, PA; <sup>7</sup>Pfizer Inc, Groton, CT, USA; <sup>8</sup>Pfizer Inc, Lima, Peru

**Background:** Non-alcoholic fatty liver disease, characterised by hepatic steatosis (HS), is a major cause of chronic liver disease in many countries. Limited data are available on liver enzyme elevation in patients (pts) with HS who are receiving medications for inflammatory conditions, such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) and psoriasis (PsO). Tofacitinib is an oral Janus kinase inhibitor for the treatment of RA and PsA, and has also been studied in PsO.

**Objectives:** To describe baseline characteristics and liver enzyme abnormalities in pts from the tofacitinib RA, PsA and PsO clinical programmes with/without HS at baseline.

**Methods:** Pts randomised to the tofacitinib (5 or 10 mg twice daily; doses pooled) and placebo arms of 25 studies in the RA, PsA and PsO programmes were

included in this pooled post hoc analysis. Most studies allowed or mandated concomitant treatment with disease-modifying antirheumatic drugs. HS was determined by the investigator and captured per the Medical Dictionary for Regulatory Activities term at baseline. Baseline characteristics, incidence of elevated total bilirubin, aspartate aminotransferase (AST) and alanine aminotransferase (ALT) >1 x and >3 x the upper limit of normal (ULN) up to Month (M) 3, and change from baseline in C-reactive protein (CRP) at M3 – all by HS at baseline – are reported.

**Results:** A total of 10 212 pts were in the analysis. The prevalence of HS was 1.6% across indications (RA: 87/6729 [1.3%]; PsA: 277/10 [3.8%]; PsO: 45/2773 [1.6%]). Baseline characteristics were generally similar in pts with or without HS (table 1). However, baseline obesity, diabetes, triglycerides and liver enzymes were numerically higher, and CRP was numerically lower, in pts with HS than in those without HS (table 1). In both tofacitinib- and placebo-treated pts, incidence of elevated total bilirubin, AST and ALT >1 x ULN up to M3 was higher in pts with HS than in those without HS, across indications (table 1). Incidence of elevated total bilirubin, AST and ALT >3 x ULN up to M3 was low across indications, irrespective of HS (table 1). Among tofacitinib-treated pts, CRP was reduced at M3 in pts with or without HS, but to a lesser extent in those with HS, across indications. Among placebo-treated pts, changes in CRP were small, irrespective of HS (table 1).

**Abstract FRI0099 – Table 1.** Baseline characteristics and liver function up to Month 3, by HS at baseline

**Conclusions:** In this exploratory analysis, prevalence of HS at baseline was 1.6% across the tofacitinib RA, PsA and PsO programmes. After up to 3 months of tofacitinib treatment, incidence of mildly elevated liver enzymes was higher in pts with HS than in those without HS. Incidence of severely elevated liver enzymes was low overall, and similar in pts with or without HS. Further studies are needed to evaluate the effects of tofacitinib on CRP and liver enzymes, and the potential impact on clinical response, in pts with RA, PsA or PsO who have comorbid HS.

**Background:** Tumour Necrosis Factor (TNF) inhibitors have improved the management of many patients with rheumatoid arthritis (RA). However, ~30% of anti-TNF treated patients do not show a significant clinical improvement. To date, little is known on the biological mechanisms underlying the differential response to anti-TNF agents.

**Objectives:** We sought to identify genetic variation associated with the anti-TNF response in RA using a sequential multi-omics approach.

**Methods:** First, we aimed to identify gene coexpression modules (GCMs) associated with anti-TNF response. For this objective, we extracted the RNA from synovial biopsies of 13 RA patients starting anti-TNF therapy and determined the expression profiles using Illumina microarrays. GCMs were identified using the WGCNA approach. The association between GCMs and anti-TNF response was performed using the eigengene of each GCM. Clinical response was defined using the EULAR criteria at week 14. To analyse the association of GCMs with anti-TNF response at the genetic level, we used 348 anti-TNF treated RA patients from Spain. The statistical analysis was performed using GWAS data and the set-based test in PLINK. The GCMs that were significantly associated with anti-TNF response were subsequently tested for validation in an independent cohort of 2706 anti-TNF treated RA patients. The functional implication of the validated GCMs was studied via pathway and cell type epigenetic enrichment analyses.

**Results:** We identified 148 GCMs in the RA synovium. From these, 15 GCMs were found to be associated with anti-TNF response (p<0.05). At the genetic level, we found two of the 15 GCMs to be associated with the adalimumab (ADL) and infliximab response (p<0.05) in the Spain cohort. In the independent cohort, we replicated the association of the GCM associated with ADL response (p=0.01). The validated GCM was found to be enriched in genes that participate in the nucleotides metabolism (p=2.41e-5). The epigenetic analysis revealed that ADL-associated variants are enriched in epigenetic marks from immune cell types like Tregs (p=0.04).

**Conclusions:** Our study shows the existence of a drug-specific genetic basis for the anti-TNF response. Therefore, this molecular diversity should be considered for biomarker research in RA.

**FRI0101 UNMET NEEDS IN THE TREATMENT OF RHEUMATOID ARTHRITIS. AN OBSERVATIONAL STUDY AND A REAL-LIFE EXPERIENCE FROM A SINGLE UNIVERSITY CENTRE**

E. Kaltsonoudis, E. Pelechas, P.V. Voulgari, A.A. Drosos. *Rheumatology Clinic, Department Of Internal Medicine, Medical School, University of Ioannina, Ioannina, Greece*

**Background:** Despite the progress in the treatment of rheumatoid arthritis (RA), a significant number of patients does not achieve low disease activity (LDA).

**Objectives:** The purpose of this study was to estimate the size of unmet needs in the treatment of RA, using all the conventional synthetic disease modifying antirheumatic drugs (csDMARDs) and/or biological DMARDs (bDMARDs) in a long-term observational study.

**Methods:** Between January 2006 and December 2017, 538 patients with early RA were followed up in the outpatient rheumatology clinic. All patients fulfilled the 2010 ACR/EULAR classification criteria, had disease duration less than 1 year and were csDMARDs and bDMARDs naive. The patients were treated according to EULAR and ACR recommendations and strategies for RA. The following

csDMARDs were introduced: methotrexate (MTX), leflunomide (LFN), sulfasalazine (SSZ) and hydroxychloroquine (HCQ). In addition, the following bDMARDs were used: abatacept, adalimumab (ADA), certolizumab, etanercept (ETN), golimumab, infliximab (INF), rituximab and tocilizumab. Finally, small doses of steroids were used. During follow-up the clinical, laboratory findings as well as the treatment decisions and strategies were all recorded. In addition, the adverse drug reactions, the reason of termination or changing strategies, disease complications and comorbidities were all recorded. Finally, disease activity was measured with the 28 joint count, Disease Activity score-28 (DAS-28) using the erythrocyte sedimentation rate.

**Results:** All patients have received one csDMARD, at least for 6 months. The csDMARD of first choice was MTX (58%), followed by LFN (32%), HCQ (8%), and SSZ (2%) with or without small doses of steroids. The bDMARD of first choice was INF (37%) followed by ETN (32%) and ADA (31%). During the follow up period, 14 patients were lost. In addition, 7 patients never received bDMARDs due to various comorbidities. Thus, the final results are referred to 517 patients. Among those patients, 324 (66%) were treated with csDMARDs as monotherapy or in combination therapy with or without the use of steroids with significant clinical improvement and sustained LDA. However, eleven patients (3,2%) from this group neither achieved LDA, nor received bDMARDs, due to comorbidities. On the other hand, 175 patients (34%) were treated with bDMARDs with or without csDMARDs or/and steroids. The majority of them demonstrated sustained LDA for a long period of time. From this group 31 patients (17,7%) never achieved LDA, despite that they switched and received all bDMARDs. Thus a total of 20,9% of our patients never achieved LDA.

**Conclusions:** Using the EULAR and ACR recommendations for RA therapy we successfully treated the majority of our patients. However, we found that the size of gap and the unmet needs for RA treatment is about twenty per cent. This is the first study aiming to estimate the gap and the size of unmet needs for RA treatment in a large patient population followed-up in a tertiary university centre.

FRI0102

#### REDUCTION OF ANTIDRUG ANTIBODY LEVELS AFTER SWITCHING TO RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH PREVIOUS FAILURE TO INFILIXIMAB OR ADALIMUMAB

A. Martínez-Feito<sup>1</sup>, C. Plasencia<sup>1</sup>, V. Navarro-Compan<sup>1</sup>, B. Hernández-Breijo<sup>1</sup>, D. Pascual-Salcedo<sup>1</sup>, P. Nozal<sup>2</sup>, C. Diego<sup>2</sup>, I. Monjo<sup>1</sup>, L. Nuño<sup>1</sup>, A. Balsa<sup>1</sup>.

<sup>1</sup>Immuno-Rheumatology research group; <sup>2</sup>Immunology, University Hospital La Paz, Madrid, Spain

**Background:** Rituximab (Rtx), a monoclonal antibody against CD20+, induces transient depletion of B cells and was approved for the treatment of patients with active rheumatoid arthritis (RA). Previous data<sup>1</sup> showed that Rtx is particularly effective on autoimmune diseases in which auto-antibodies (auto-Ab) are produced. Based on this, it is hypothesised that auto-Ab produced by short-lived plasma cells expressing CD20 are targets of Rtx. Given this scenario, the immunogenicity related to the use of Infliximab (Ifx) or Adalimumab (Ada) could be cleared by Rtx.

**Objectives:** First, to analyse the persistence of anti-drug antibodies (ADA) after switching to either a 2nd biological therapy (TNFi or Rtx) after 12 months of follow-up. Second, to evaluate whether the reduction of ADA levels are influenced by the mechanism of action of the second biological therapy (BT).

**Methods:** Dataset from a prospective cohort including all patients with RA starting BT at the Unit of Complex Therapy in a tertiary hospital was used. For this study, data from 21 patients who had experienced previous failure to Ifx (57%) or Ada (43%) related to ADA detection and then switched to a 2nd TNFi (Ifx, Ada, Etanercept or Certolizumab) or to Rtx was analysed. Additionally, patients should have both determinations of ADA levels: at the end of the first BT and 12 months after switching. ADA were determined by a bridging ELISA. The proportion of patients with ADA positive levels at 12 months was determined. Also, the relative reduction (in median) of ADA levels between patients switching to a 2nd TNFi vs Rtx in both visits was compared.

**Results:** Out of 21 ADA positive patients with RA, 15 (71%) switched to a 2nd TNFi and 6 (29%) to Rtx. Demographic characteristics of patients are shown in table 1.

ADA remained positive in 80% of patients at 12 months after switching BT. The percentage of patients with undetectable ADA levels at 12 months was higher in

the group of patients treated with Rtx compared with patients receiving a 2nd TNFi (33% vs 13%, respectively). The median ADA levels (AU/ml) values at baseline and at 12 months were 536 and 123 for Rtx and 3625 and 1842 for TNFi. The relative reduction of median ADA levels between baseline and 12 months visits was higher in patients with Rtx than in patients treated with TNFi (-78% vs -50%, respectively).

**Abstract FRI0102 – Table 1.** Demographics characteristics of the 21 patients according to the second biological.

Switch to:	TNFI(n=15)	RTX(n=6)
Women, n(%)	13 (87%)	6 (100%)
Age, years, median(IQR)	47 <sup>(37–56)</sup>	50.5 (42.5–65.5)
Smoking status, n(%)	2 (13%)	1 (17%)
IMC, Kg/m <sup>2</sup> , median(IQR)	23.6 (19.3–28.6)	34.1 (25.2–32.5)

**Conclusions:** Despite discontinuing TNFi, ADA titers remain positive in a high proportion of patients with RA after one year. Over time, ADA levels decrease in patients who switch to a second BT, being this effect more pronounced in patients receiving Rtx than a 2nd TNFi. This effect could be explained by the intrinsic action mechanism of Rtx on plasmatic CD20+ cells.

FRI0103

#### ONE-YEAR FOLLOW-UP OF A NATIONWIDE COHORT OF PATIENTS WITH INFLAMMATORY ARTHRITIS, WHO SWITCHED FROM ORIGINATOR TO BIOSIMILAR ETANERCEPT, FOCUSING ON PATIENTS WHO SWITCHED BACK TO ORIGINATOR. AN OBSERVATIONAL DANBIO STUDY

B. Glinborg, I.J. Sørensen, E. Omerovic, F. Mehnert, N. Manilo, K. Danebod, D. V. Jensen, H. Nordin, A.G. Loft, O. Hendricks, S. Chrysidis, B.L. Andersen, J. L. Raun, H. Lindegaard, J. Espesen, S.H. Jakobsen, I.M.J. Hansen, E. B. Dalsgaard, D.D. Pedersen, S. Kristensen, A. Linauskas, L.S. Andersen, J. Grydehøj, N.S. Krogh, M.L. Hetland. *The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark*

**Background:** In Denmark, patients (pts) treated with originator etanercept (ETA) 50 mg SC conducted a mandatory non-medical switch to biosimilar SB4 in April 2016 (*switchers*). Pts treated with 25 mg ETA or 50 mg powder-solution were not mandated to switch (*non-switchers*). Some switchers resumed ETA during follow-up (*back-switchers*).

**Objectives:** To investigate the frequency of *back-switching* after the non-medical switch from ETA to SB4, and in *back-switchers* to study, 1) baseline characteristics at the time of initial switch (ETA->SB4), 2) reasons for SB4 withdrawal, 3) changes in disease activity during treatment with SB4 and after *back-switching*.

**Methods:** Patient data were retrieved from the DANBIO registry (censored August 2017). For *back-switchers*, disease activity at the start of SB4 (=baseline) and at the time of *back-switching* to ETA were compared, and changes in disease activity between the two time points were calculated (=delta values), stratified by indication (RA/PsA/AxSpA). Baseline characteristics of *back-switchers* were compared to the rest of the switch population (Chi-sq, Mann-Whitney U-test). Abbreviations are shown in table 1.

**Results:** 1641 pts switched from ETA to SB4. Of these, 299 (18%) withdrew SB4 therapy during 1 year follow-up and either switched back to ETA (n=120, 7%), started another bDMARD (n=104), died (n=9), were lost to follow-up (n=1) or did not re-start bDMARDs (n=65).

Among the 120 *back-switchers*, SB4 was withdrawn due to LOE (52%), AE (39%), or other/unknown reasons (9%). The reasons for withdrawal of SB4 in *back-switchers* are listed in table 1. No major safety events occurred. The median time on SB4 before *back-switching* was 120 (IQR 73–193) days, and the time

between stop of SB4 and re-start of ETA was  $1^{1-1}$  days. Baseline characteristics of back-switchers vs the rest of the switch population were similar (all  $p>0.05$ ). Among back-switchers who stopped SB4 due to LOE, PGA increased during SB4 treatment, whereas CRP and SJC were largely unchanged (table 1). At the date of censoring, 104/120 back-switchers (87%) were still treated with originator ETA (median treatment duration 236 (155–302) days).

**Abstract FRI0103 – Table 1.** Description of ETA-SB4-ETA back-switchers (n=120)

	RA, n=80	PsA, n=20	AxSpA, n=20
<b>Characteristics upon start of SB4, n=120</b>			
Female, %	73	55	35
Age, years	59 (52-70)	45 (36-56)	43 (38-56)
SJC, n	0 (0-1)	0 (0-0)	-

PGA, mm	27 (12-54)	25 (13-63)	23 (13-44)
<b>Characteristics upon re-start of ETA in pts who back-switched due to LOE, n=62</b>			
Pt number, n	38	11	13
SJC, n	2 (0-5)	0 (0-2)	-
CRP, mg/L	3 (2-11)	3 (2-7)	4 (1-6)
PGA, mm	64 (50-76)	78 (18-90)	42 (35-63)
<b>Delta-values among pts who stopped due to LOE and back-switched, n=62**</b>			
Delta-SJC, n	1 (0-4)	0 (0-0)	-
Delta-CRP, mg/L	0 (-1-5)	1 (0-2)	0 (0-4)
Delta-PGA, mm	30 (12-52)	15 (7-77)	25 (19-35)
Pts stopped due to AE, n=47: Arthralgia 1 pt, bladder dysfunction 1, blurred vision 1, diarrhea 4, dizziness 2, dyspnea 2, erectile dysfunction 1, hair loss 1, headache/migraine 4, hyperhidrosis 2, hypertension 1, hypotension 1, infections 2, leg cramps 1, local injection problems 3, myalgia 1, nausea 2, neuropathies 1, psoriasis/pustulosis 1, rash/itching 9, not stated 21 (total =62 events)			
Numbers are medians (IQR) unless otherwise stated, *DAS28<2.6 (RA, PsA), ASDAS<1.3 (AxSpA)			
** Disease activity at time of re-start ETA minus SB4 start			
<b>Abbreviations:</b> AE: adverse event, CRP: C-reactive protein, ETA: originator etanercept, LOE: lack of effect, PGA: patient global score, SB4: biosimilar etanercept, SJC: swollen joint count			

**Conclusions:** In a nationwide cohort of 1621 arthritis patients that were switched from ETA to SB4, 7% switched back to ETA. Back-switchers had no distinct clinical or disease characteristics upon start of SB4. AEs prior to back-switching were largely unspecific. In pts who withdrew SB4 due to LOE, PGA had increased. Reasons for back-switching appeared to be predominantly subjective rather than objective (nocebo effect). Originator drug was still available (25 mg or 50 mg powder-solution), which may have encouraged back-switching.

#### PREDICTORS FOR THE RESPONSE TO ANTI-TNF THERAPY AND THE IMPACT OF SMOKING IN RHEUMATOID ARTHRITIS- RESULTS ON A GROUP OF PATIENTS IN ROMANIA

B.I. Gavrilă<sup>1</sup>, C.S. Ciofu<sup>1</sup>, L. Macovei<sup>2</sup>, A.M. Gheorghiu<sup>1</sup>, M. Sasu<sup>2</sup>, C. Mihai<sup>1</sup>, V. Stoica<sup>1</sup>, I. Ancuta<sup>1</sup>, M. Bojinca<sup>1</sup>. <sup>1</sup>Internal Medicine and Rheumatology Cantacuzino Hospital, University of Medicine and Pharmacy Carol Davila, Bucharest, Romania; <sup>2</sup>Internal Medicine and Rheumatology, Cantacuzino Hospital, Bucharest, Romania

**Background:** 20%–40% of the patients are declared nonresponders to at least one of the biologic agents.

**Objectives:** to test the possible predictive role of RF type IgM and IgA, anti-CCP, anti-MCV, 14–3–3eta protein and COMP on a group of patients treated with anti-TNF $\alpha$  agents. We also followed the evolution of serum titres of these biomarkers under biologic therapy and the impact of smoking regarding response to treatment.

**Methods:** prospective and observational study including 64 patients followed 12 months with active RA, uncontrolled by csDMARDs. Clinical assessment was performed at 0,6 and 12 months according to ACR criteria and evaluation of treatment response according to EULAR criteria (good/moderate/nonresponder).

**Results:** Following baseline immunological parameters titres and the response at 6 months, tests for identifying differences between the groups showed that lower titres of both RF isotypes, anti-CCP, 14–3–3eta protein and COMP had predictive value on achieving a good EULAR response at 6 months. Grouping patients in 2 categories (responders/nonresponders), just 14–3–3eta protein and anti-CCP maintained their predictive value for the response at 6 months.

For the visit at 12 months, lower baseline titres for RF type IgM (92.93 $\pm$ 120.22 U/ml,  $p=0.010$ ) and IgA (49.96 $\pm$ 98.08 U/ml,  $p=0.002$ ) had predictive value for achieving a good response at 12 months. We didn't obtain other informations grouping patients in 2 categories.

The status pretreatment influenced the good response for COMP at 6 months ( $p=0.001$ ) and RF IgA at 12 months ( $p=0.004$ ).

Using multivariate logistic regression methods we obtained a statistical model for predicting the response at 6 months including normal values for 14–3–3eta protein, anti-CCP and COMP (Hosmer and Lemeshow according test  $\lambda^2=5.795$ ,  $p=0.670 \geq 0.05$  with a predictive response accuracy of 89.1%).

Smoking had a negative impact on the EULAR response as well as on 2 groups response at 6 months of treatment ( $p=0.017$ ).

	6 Months response nonresponders	6 Months response moderate	6 Months response good
<b>Smoking</b>	2/7 (28.6%)	29/38 (76.3%)	17/19 (89.5%)
No	0/6 (0.0%)	3/38 (7.9%)	1/19 (5.3%)
Past	5/7 (71.4%)	6/38 (15.8%)	1/19 (5.3%)
Yes			

0.046 (Likelihood Ratio corrected Bonferroni)

Following the evolution of serum levels, we noticed a reduction for all biomarkers tested, statistically significant at 6 and/or 12 months from baseline.

**Abstract FRI0104 – Table 1.** Description of ETA-SB4-ETA back-switchers (n=120)

	Nonresponder	Moderate response	Good response	p value	Nonresponder	Responder	p value
No.	7	38	19		7	57

İnanc<sup>6</sup>, A. Çefle<sup>5</sup>, Z. Ertürk<sup>6</sup>, S. Akar<sup>7</sup>, B. Yağız<sup>2</sup>, B. Göker<sup>8</sup>, A. M. Birlik<sup>3</sup>, F. Önen<sup>3</sup>. <sup>1</sup>Rheumatology Department, Firat University, Elazığ; <sup>2</sup>Rheumatology Department, Uludağ University, Bursa; <sup>3</sup>Rheumatology Department, Dokuz Eylül University, İzmir; <sup>4</sup>Rheumatology Department, Erciyes University, Kayseri; <sup>5</sup>Rheumatology Department, Kocaeli University, Kocaeli; <sup>6</sup>Rheumatology Department, Marmara University, İstanbul; <sup>7</sup>Rheumatology Department, Katip Çelebi University, İzmir; <sup>8</sup>Rheumatology Department, Gazi University, Ankara, Turkey

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease leading to deformities and disabilities. In the treatment of RA glucocorticoids are selected sometimes to relieve symptoms and to increase compliance for treatment.

**Objectives:** The purpose of our study is to investigate whether concomitant glucocorticoid treatment at the baseline affects drug survival for abatacept treatment in RA.

**Methods:** Data on patient characteristics, diagnosis, previous treatment and outcomes have been collected since 2011 in Turkish Biologic (TURKBIO) Registry. By the end of December 2017, 338 RA patients, received abatacept from the TURKBIO registry, were included in the analysis. Patients were divided into groups according to the use of glucocorticoid when abatacept therapy was started. Demographic and clinical data including age, sex, disease type, disease duration, and previous or current treatment with DMARDs and biological drug durations are recorded in the database. Kaplan-Meier survival analysis was performed to estimate the drug survival. Subgroups were compared by log-rank.

**Results:** There were no significant differences in age, gender, seropositivity, tender and swollen joint counts at baseline in the study groups. The disease duration was higher in the glucocorticoid users ( $p=0.001$ ). Abatacept was the first choice bDMARDs in the 44.5% of glucocorticoid users while it was 68.6% in the glucocorticoid non-users ( $p<0.001$ ). In addition to abatacept, use of sDMARDs were 96.7% and 53.8% in the glucocorticoid users and non-users, respectively. Baseline VAS-pain and ESR were higher in the glucocorticoid non-users ( $p=0.047$ ,  $p=0.009$ , respectively), but other baseline parameters were similar in glucocorticoid users and non-users. There was no difference between groups in terms of drug survival rates for abatacept (figure 1).

**Abstract FRI0105 – Table 1.** Clinical and laboratory characteristics

	Glucocorticoid non-users (n=156)	Glucocorticoid users (n=182)	p
Age, year	56 (47–64)	57 (47–63)	0.827
Gender (Females), n (%)	135 (86.5)	151 (82.9)	0.390
Disease duration, years	10 (5–15)	13 (8–18)	0.001
1 st choice bDMARDs is abatacept,%	68.6%	44.5%	<0.001
Concomitant sDMARD usage,%	53.8%	96.7%	<0.001
RF positivity, n (%)	68.1	65.8	0.735
CCP positivity, n (%)	61.8	66.7	0.485
Baseline ESR, mm/h	38 (24–55)	28 (18–44)	0.009
12th month ESR, mm/h	33 (20–50)	27 (16–39)	0.155
Baseline CRP, mg/dl	12 (5–21)	12 (4.89–30.9)	0.870
12th month CRP, mg/dl	4 (3–8)	9 (3–19)	0.020
Baseline DAS28-CRP	4.95 (4.2–5.4)	4.8 (3.9–5.35)	0.123
12th month DAS28-CRP	2.05 (1.7–2.9)	2.6 (2.1–3.9)	0.002
Baseline CDAI	22 (13.8–28.3)	19.8 (13.2–27)	0.278
12th month CDAI	3.2 (2–7.95)	6.3 (3–10.7)	0.061

**Abstract FRI0105 – Figure 1.** Drug survival curve in glucocorticoid user and non-user patients

**Conclusions:** When abatacept treatment started, concomitant use of glucocorticoid at the baseline could not significantly alter drug survival for abatacept in the RA.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5819

#### FRI0106

#### IMPACT OF BIOLOGICAL AND TARGETED SYNTHETIC DMARDs ON WORK IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHRITIS : A META ANALYSIS OF RANDOMISED CONTROLLED TRIALS AND CONTROLLED COHORTS

C. Traverson<sup>1</sup>, A. tubery<sup>1</sup>, C. Hua<sup>1</sup>, F. Barchechath-Flaisler<sup>1</sup>, C. Lukas<sup>2,3</sup>, B. Combe<sup>2</sup>, J. Morel<sup>2</sup>, C. Gaujoux-Viala<sup>1,4</sup>. <sup>1</sup>Rheumatology, Nîmes University Hospital, Nîmes; <sup>2</sup>Rheumatology, Montpellier University Hospital; <sup>3</sup>Rheumatology, CHU Lapeyronie and EA2415, Montpellier University, Montpellier; <sup>4</sup>Rheumatology, Hospital and EA2415 Montpellier University, Nîmes, France

**Background:** The addition of biological (b) and new targeted synthetic (ts) DMARDs agents in chronic inflammatory arthritis (CIAs) therapeutic strategies

has improved the possibility of controlling disease activity and slowing the progression of joint damage. However their impact on work participation is unclear.

**Objectives:** To assess the effect of biological and tsDMARDs versus conventional treatments in patients with CIAs on work outcomes: employment, presenteeism and absenteeism.

**Methods:** A systematic review of the literature using Pubmed-Medline and the Cochrane library was performed until January 2017. All randomised controlled trials (RCT) and controlled cohorts (CC) comparing work outcomes in patients with rheumatic diseases such as rheumatic arthritis (RA), ankylosing spondylarthritis (AS) and psoriatic arthritis (PsA) treated with biological or tsDMARDs versus conventional therapies were selected. Statistical analysis determined in each study effect size (ES) or odds-ratios (OR) as appropriate to assess the magnitude of treatment effect. Pooled ES and OR were computed by meta-analysis. A random effect model was used in case of heterogeneity.

**Results:** Thirty six RCTs and eight CCs were analysed ie 12 769 patients with conventional treatment and 19 875 patients with bDMARD or tsDMARD (4619 Infliximab, 4629 Etanercept, 3872 Adalimumab, 670 Golimumab, 2101 Certolizumab, 691 Abatacept, 444 Sirukumab, 1668 Baricitinib, 672 Tofacitinib, 365 Sarilumab, 444 Sirukumab etc); 34 studies included 30 423 patients with RA, 7 studies included 1496 patients with AS and 3 studies included 725 patients with PsA.

This meta-analysis showed in patients treated by bDMARD vs conventional treatment:

- a significant decrease of accumulated missed workdays at week 24: ES  $-0.34$  IC95% $[-0.6; -0.08]$  and at week 52: ES  $-0.04$  IC95% $[-0.29; 0.2]$ ,

- a significant decrease of patients losing hours due to CIAs: RR 0.63 IC95% $[0.48; 0.83]$ ,

- a significant improvement in VAS productivity: ES  $-1.81$  IC95% $[-2.61; -1.01]$ ,

- For the employment loss, the positive effect of bDMARDs was nearly significant: OR 0.60 IC95% $[0.33; 1.09]$ .

**Conclusions:** Despite the heterogeneity of the data, this meta-analysis showed the beneficial effect of bDMARDs on both absenteeism and presenteeism in CIAs. Thus the high cost of biologic agents could be partly balanced with savings in indirect costs.

#### FRI0107 FIVE SUCCESSFUL PREGNANCIES WITH ANTENATAL ANAKINRA EXPOSURE

C.J.F. Smith<sup>1</sup>, C. Chambers<sup>2</sup>. <sup>1</sup>Rheumatology, Allergy, Immunology, <sup>2</sup>Pediatrics, University of California San Diego, La Jolla, USA

**Background:** Current recommendations are to discontinue the interleukin-1 (IL-1) inhibitor anakinra prior to pregnancy given lack of safety evidence.<sup>1</sup> A total of 39 previous exposed pregnancies have been documented in the literature, and two resulting cases of fetal renal agenesis have been described.<sup>2,3</sup>

**Objectives:** Our aim is to add to the limited existing data on IL-1 inhibitor use in pregnancy.

**Methods:** Data were obtained from the Organisation of Teratology Information Specialists (OTIS) Autoimmune Disease in Pregnancy Project, a prospective cohort study of pregnancy outcomes in the U.S. and Canada. Eligible women enrolled prior to 19 weeks' gestation between 2004 and 2017. Women who consented to participate were interviewed two to three times during pregnancy with a standard questionnaire regarding medical history, exposures during pregnancy, and demographic characteristics. Outcomes were obtained by maternal interview and medical record abstraction.

**Results:** Five pregnancies with anakinra exposure were identified, all resulting in full-term singleton live births, mean gestational age at delivery of 38.9 weeks, with no major or long-term infant complications. Three maternal subjects used anakinra for adult-onset Still's disease (AOSD) and two for juvenile idiopathic arthritis (JIA). One mother was diagnosed with AOSD during pregnancy, and anakinra was started at 20 weeks' gestation. All other subjects had a known diagnosis prior to pregnancy, and four subjects used the medication into the third trimester. All maternal subjects used 100 mg dosing of anakinra, four with daily use, one with weekly use. For all subjects who discontinued anakinra, some amount of steroid medication was necessary for treatment of disease flare. Two subjects developed oligohydramnios, one also with pregnancy-induced hypertension. Two women

had caesarian sections, one medically-indicated and one scheduled. One infant had low birth weight, but follow-up records indicated normal adjusted weight at one year. Three women successfully breastfed their infants, at least two of whom continued anakinra while breastfeeding.

**Conclusions:** Anakinra was used successfully in five full term pregnancies. Two subjects developed oligohydramnios, however. With the two previous reported cases of fetal renal agenesis, a process leading to low fluid levels, and the fact that maternal hyperthermia has been previously linked to fetal renal anomalies,<sup>4</sup> it is worth further exploring the potential link between anakinra use, uncontrolled maternal febrile disease, and fetal outcomes. These data add to the limited knowledge regarding antenatal anakinra use and support its use in pregnant women without access to effective alternative therapies that have a larger volume of reassuring safety data.

Univ. Doz. Dr. Peter Peichl, Vienna; <sup>12</sup>Private Office Dr. Angelika Kraus, Melk; <sup>13</sup>Merck Sharp and Dohme GmbH, Ares Tower, Donau-City-Straße 11, 1220 Vienna, AUSTRIA, Vienna, Austria

**Background:** Golimumab has shown clinical efficacy and tolerability within its clinical trial program. No systemic outcome data regarding patient-reported outcomes and health economic parameters reflecting the real world use of golimumab in Austria are currently available.

**Methods:** Go Active is a prospective, non-interventional, multi-centre study in Austria. The impact of golimumab therapy on work productivity and activity (WPAI) and quality of life (RAQoL for RA patients, AsQoL for axSpA patients, PsAQoL for PsA patients) is assessed by using patient reported outcomes. Patients (target recruitment: n=320) are followed up to 2 years. For the current interim analysis (data cut-off: 18DEC2017) changes in the primary endpoint from baseline to month 3 were analysed in 167 patients.

**Results:** 167 patients are included in the current analysis (74 patients with RA, 49 patients with axSpA, and 44 patients with PsA). At study entry, most patients were biological-naïve and employed.

Median age at registration was 52 years (patients with RA: 57 years, patients with axSpA: 41 years, and patients with PsA: 44 years). Almost 2/3 of patients were female (84% of patients with RA, 37% patients with axSpA, and 55% of patients with PsA). Most patients were biological-naïve at study entry (77% of all patients, 73% of patients with RA, 80% of patients with axSpA, and 82% of patients with PsA). 42% of patients were not employed (58% of patients with RA, 29% of patients with axSpA, and 30% of patients with SpA); 14% due to incapacity for work (12% of patients with RA, 21% of patients with axSpA, and 16% of patients with SpA) and 54% due to age-related pension (60% of patients with RA, 21% of patients with axSpA, and 69% of patients with SpA). Most of the patients, who worked for pay, worked full time. 159 of all patients and 66 of employed patients completed the WPAI questionnaire at baseline and after 3 months. Overall work productivity improved by  $-33$  ( $-40$  for patients with RA, and  $-31$  for patients with axSpA and PsA) and activity impairment by  $-30$  ( $-40$  for patients with RA and

axSpA, and  $-20$  for patients with PsA; figure 1). Quality of life improved by  $-5$  for patients with axSpA and PsA, and by  $-7$  for patients with RA.

Abstract FRI0108 – Figure 1. WPAI questionnaire – Changes from baseline after 3 months of golimumab treatment

**Conclusions:** This interim analysis shows that golimumab treatment is effective in improving work productivity, daily activities as well as quality of life already within the first 3 months of treatment in RA, axSpA and PsA patients.

#### FRI0109 DRUG IMMUNOGENICITY AND THE DEVELOPMENT OF PARADOXICAL ADVERSE EVENTS WITH BIOLOGIC THERAPIES

C. Ancuta<sup>1,2</sup>, C. Pomirleanu<sup>1</sup>, R. Paiu<sup>1</sup>, G. Strugariu<sup>1</sup>, L. Petriariu<sup>1</sup>, E. Ancuta<sup>3</sup>, A. Chiriac<sup>4</sup>, R. Chiriace<sup>5</sup>. <sup>1</sup>Clinical Rehabilitation Hospital; <sup>2</sup>University of Medicine and Pharmacy Grigore T Popa Iasi; <sup>3</sup>Elena Doamna Clinical Hospital; <sup>4</sup>CMI Dermatology Nicolina Center; <sup>5</sup>Sanocare Medical and REsearch Center, Iasi, Romania

**Background:** Defined as *de novo* or exacerbation of pathologies that usually responds to biologic agents, paradoxical reactions encompass for a wide spectrum of manifestations (cutaneous, intestinal, ocular) reported during biological therapy (TNF and non-TNF medications) regardless of the underlying rheumatic or non-rheumatic disorder.

**Objectives:** To assess drug levels (DL) and anti-drug antibodies (ADA) in patients with paradoxical reactions (*de novo* or exacerbation of psoriasis, uveitis, Crohn's disease) induced by biological drugs (bDMARS) in Rheumatoid Arthritis (RA), Ankylosing Spondylitis (AS) and Psoriatic Arthritis (PsA).

**Methods:** We performed a retrospective observational study in cohorts of consecutive RA (267), PSA (65) and AS (145) undergoing TNF (i-TNF) or non-TNF biologics according to the local recommendations for initiation and monitoring, attending a single academic rheumatology department.

All patients were assessed at every 24 weeks months for disease activity and outcomes; supplementary, drug immunogenicity (ADA and DL) was systematically evaluated in patients developing paradoxical adverse events.

DL and ADA were measured with an ELISA assay and antibody binding test, respectively. Serum drug levels were considered positive for infliximab if  $>0.035$   $\mu\text{g/mL}$ , for adalimumab  $>0.024$   $\mu\text{g/mL}$ , for etanercept  $>0.035$   $\mu\text{g/mL}$ , rituximab  $>0.75$   $\mu\text{g/mL}$ , while the cut-offs for ADA positivity to infliximab was established at 5AU/ml, for adalimumab at 10AU/ml, etanercept at 142 AU/ml, rituximab 140 AU/mL (ELISA, Progenika)

**Results:** 42 patients with paradoxical psoriasis (30 with *de novo* lesions, 18 with palmo-plantar pustulosis, 12 with exacerbation of pre-existent lesions), 12 with paradoxical uveitis (5 with a new onset uveitis) and 3 with paradoxical Crohn's were included in the final analysis. Paradoxical events related to abatacept, certolizumab (one *de novo* psoriasis per agent) or golimumab (2 new onset uveitis, one flare of Chron's disease) were excluded from the final analysis as no immunogenicity lab tests were provided.

Drug induced paradoxical events were described not only with all TNF inhibitors but also with rituximab. DL was in normal range in all these patients; in addition,

ADA were either negative, or, if present, had no impact on drug concentration. Furthermore, we found no significant differences in drug levels of TNF inhibitors for RA, PsA and AS.

Moreover, no statistical significant differences were observed in the detection of ADA between the three groups.

**Conclusions:** Patients who develop either true or borderline paradoxical AE have adequate drug levels, with normal ADA concentrations.

**Disclosure of Interest:** None declared

Santos<sup>8</sup>, V. Hernandez<sup>9</sup>, F. Iannone<sup>10</sup>, J.-E. Gotteberg<sup>11</sup>, X. Mariette<sup>12</sup>, S. Kubo<sup>13</sup>, Y. Tanaka<sup>13</sup>, D. Choquette<sup>14</sup>, R. Ionescu<sup>15</sup>, A. Finckh<sup>1</sup>. <sup>1</sup>University Hospitals of Geneva, Geneva, Switzerland, <sup>2</sup>DANBIO, Rigshospitalet, Denmark, <sup>3</sup>Institute of Rheumatology, <sup>4</sup>Rheumatology, First Faculty of Medicine, Charles U, Prague, Czech Republic, <sup>5</sup>Lund University, Malmö, Sweden, <sup>6</sup>LUMC, Leiden, Netherlands, <sup>7</sup>Diakonhjemmet Hospital, Oslo, Norway, <sup>8</sup>Reuma.pt, Lisbon, Portugal, <sup>9</sup>Hospital Clinic, Barcelona, Spain, <sup>10</sup>University of Bari, Bari, Italy, <sup>11</sup>Chu, Strassbourg, <sup>12</sup>Paris-Sud University, Le Kremlin-Bicêtre, France, <sup>13</sup>University of Occupational and Environmental Health, Fukuoka, Japan, <sup>14</sup>Institut de rhumatologie de Montreal, Chum, U de M, Montreal, Canada, <sup>15</sup>Department of Internal Medicine and Rheumatology, Sf Maria Hospital, U Medicine and Pharmacy, Bucharest, Romania

**Background:** Rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) are used as diagnostic tools, but may also be used as prognostic factors, as these biomarkers have been associated with better clinical responses to some biologic agents in rheumatoid arthritis (RA).

**Objectives:** To compare the impact of seropositivity on drug discontinuation and effectiveness for abatacept (ABA) and TNF inhibitors (TNFi) in patients (pts) with RA.

**Methods:** Pooled analysis of 13 observational RA registries from countries (FR, IT, CZ, DK, NO, PT, RO, ES, SE, CH, NL, JP, CA) where both ABA and TNFi were available concomitantly. Inclusion criteria were RA diagnosis, treatment with ABA or TNFi, and available RF or ACPA status. Main exposure was seropositivity: positive if RF or ACPA were positive, negative if both were negative, and missing if one was missing and the other was negative. Primary endpoint was drug discontinuation, analysed using Cox models, including treatment, seropositivity, and their interaction, adjusting for patient-, treatment-, and disease-characteristics, using strata terms for country and calendar year. We first tested for effect modification by country by additionally including an interaction term between treatment, seropositivity and country. Since we found no effect modification, we took out the interaction term. Effectiveness was analysed using DAS28 remission and low disease activity (LDA) at 1 year, corrected for attrition using Lundex<sup>1</sup>.

**Results:** Using data from 39 266 treatment-courses, in crude analyses, seronegativity was associated with higher drug discontinuation for pts on ABA but not on TNFi ( $p$  interaction  $<0.001$ ), with a hazard ratio (HR) for seropositive vs seronegative of 0.74 (95%CI: 0.66–0.82) for pts on ABA and 0.96 (95%CI: 0.92–1.01) for

pts on TNFi. On average, pts on ABA were older and had more prior bDMARDs. Adjusting for potential confounding factors did not modify the results qualitatively (figure 1), with significantly longer time before discontinuation in seropositive vs seronegative pts on ABA (adj. HR: 0.74 (95% CI: 0.67–0.84) but not on TNFi (adj. HR: 0.99 (95% CI: 0.94–1.04)).

The proportion of pts reaching DAS28 remission or LDA at 1 year was significantly higher for seropositive vs seronegative pts on ABA (difference in proportion: remission: 5.0%; LDA: 9.7%), but similar for seropositive vs seronegative pts on TNFi (difference in proportion: remission: –2.7%; LDA: –2.3%).

**Conclusions:** Data from this large pooled registry suggests that seropositivity in RA pts is associated with increased drug retention and effectiveness for ABA but not for TNFi.

#### FRI0111 ANALYSIS OF REAL-LIFE INFLIXIMAB AND ADALIMUMAB DATA: DRUG SWITCHING AND FATE OF ANTIDRUG ANTIBODIES AND TROUGH LEVELS OVER TIME

D. Ho<sup>1</sup>, S. Valtanen<sup>2</sup>, M. Havana<sup>2</sup>, L. Kröger<sup>3</sup>, K. Eklund<sup>4</sup>, T.S. Jokiranta<sup>1,2</sup>.

<sup>1</sup>Research Programs Unit, Immunobiology, University of Helsinki; <sup>2</sup>United Medix Laboratories, Helsinki; <sup>3</sup>Kuopio University Hospital, Pediatric Rheumatology, Kuopio; <sup>4</sup>Helsinki University and Helsinki University Hospital, Rheumatology, Helsinki, Finland

**Background:** Infliximab (IFX) and adalimumab (ADL) are biological drugs used in the treatment of rheumatoid arthritis (RA), spondyloarthritis (SpA), and juvenile idiopathic arthritis (JIA). Development of antidrug antibodies (ADAb) may lead to increased drug clearance and loss of therapeutic drug trough levels (TL). Switching to another drug may be necessary after ADAb development.

**Objectives:** To use real-life data from a large Finnish rheumatology patient cohort to determine the association between drug switching and ADAbs and the fate of ADAbs and TLs after ADAb development.

**Methods:** Serum samples for IFX or ADL ADAb and TL measurements from 1345 (567 RA, 479 SpA, and 299 JIA) rheumatology patients were taken on a clinical basis in daily practice in 20 Finnish referral hospitals. ADAb analyses were performed at Sanquin laboratories (Amsterdam, The Netherlands) using radioimmunoassays; TL analyses were performed at United Medix Laboratories (Helsinki, Finland) using commercial methods (Promonitor ELISA, Progenika Biopharma). Samples were collected and analysed from January 2012 until September 2017. ADAb values  $\geq 12$  AU/ml were considered positive; ADAb values were classified as low (12–30 AU/ml), intermediate (30–100 AU/ml) and high ( $\geq 100$  AU/ml).

**Results:** On the basis of TL data, we identified 67 patients (5%) who switched drugs. Of these patients, 47 (70.2%) provided ADAb measurements for the first drug; 33 (49.3%) patients were ADAb positive. Most (22 patients, 63.6%) had high ADAbs. Forty-nine (73.1%) patients provided ADAb measurements for the second drug. Of these patients, 11 (16.4%) were ADAb positive against the second drug; seven (63.6%) had high ADAbs. We identified 48 (3.6%) ADAb-positive patients who provided at least one follow-up ADAb measurement. Of these patients, 32 (66.7%) experienced ADAb loss; most (24 patients, 50%) experienced complete ADAb loss (most recent ADAb value  $\leq 12$  AU/ml). Twenty-five

patients that experienced ADAb loss had available TL measurements both before and after ADAb loss; 23 (92%) had increased TL after ADAb loss. Of the 16 patients that experienced ADAb gain, only 3/11 (27.3%) patients that had available TL measurements both before and after ADAb gain had increased TL after ADAb gain.

**Conclusions:** ADAb positivity is associated with drug switching; ADAb development against a second biologic drug is common. A significant proportion of ADAb-positive patients lose ADAbs over time. ADAb loss is associated with TL increase.

#### FRI0112 PERSISTENCE ON TUMOUR NECROSIS FACTOR INHIBITOR (TNFI) MONOTHERAPY AFTER ACHIEVING REMISSION OR LOW DISEASE ACTIVITY (LDA) ON COMBINATION THERAPY AMONG PATIENTS WITH RHEUMATOID ARTHRITIS (RA)

D.A. Pappas<sup>1,2</sup>, H.J. Litman<sup>2</sup>, T. Lesperance<sup>3</sup>, S. Rebello<sup>2</sup>, E. Karis<sup>4</sup>, G. Kricorian<sup>4</sup>, W. Hua<sup>2</sup>, N. Accortt<sup>4</sup>. <sup>1</sup>Columbia University College of Physicians and Surgeons, New York, NY; <sup>2</sup>Corrona, LLC, Waltham, MA; <sup>3</sup>DOCS Global, Inc., North Wales, PA; <sup>4</sup>Amgen Inc., Thousand Oaks, CA, USA

**Background:** Combination therapy with TNFis and conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) is standard for moderate to severe RA.

**Objectives:** To estimate persistence with etanercept (ETN) or other TNFi monotherapy among RA patients who achieved remission/LDA on combination TNFi +csDMARD therapy and then discontinued the csDMARD.

**Methods:** Data from RA patients in the Corrona registry during 10/1/2001–8/31/2017 were analysed. All patients had to be treated with TNFi +csDMARD combination therapy and to have reached Clinical Disease Activity Index remission/LDA and then discontinued the csDMARD (index date). ETN (fusion protein comprising TNF receptor and human IgG1 Fc) and other TNFi therapies (monoclonal antibodies: adalimumab, certolizumab pegol, golimumab, and infliximab) were analysed separately. Outcomes were percentages of patients persistent on index TNFi monotherapy, discontinued index TNFi, switched (to another biologic or to csDMARD monotherapy), or added csDMARD therapy (to receive combination therapy) at 6 months (primary analysis) and 12 months post-index.

**Results:** Data from 617 patients were analysed (182 ETN, 435 other TNFi); mean age (standard deviation [SD]) was 57.4 (13.3) years, 73% were female. Mean time (SD) in remission/LDA before csDMARD discontinuation was 17.0 (24.3) months. Rates of monotherapy persistence at 6 months were 56% for ETN and 45% for other TNFi (table 1). Patients with  $\geq 6$  month persistence on monotherapy had mean duration (SD) of 28.2 (22.1) months on ETN monotherapy or 27.8 (23.3) months on other TNFi monotherapy. Rates of persistence for all patients at 12 months were 46% for ETN and 33% for other TNFi. Patients with  $\geq 12$  month persistence had mean duration (SD) of 35.9 (22.6) months on ETN monotherapy or 39.3 (24.4) months on other TNFi monotherapy. For a subset of patients with  $< 6$  months in remission/LDA before index date (44% of patients), rates of monotherapy persistence at 6 months were 60% for ETN and 42% for other TNFi.

	Treatment pattern, n (%)			
	Persistent on index TNFi monotherapy	Not persistent on index TNFi monotherapy		
		Discontinued index TNFi	Switched to new biologic or csDMARD	
<b>6 months</b>				
ETN (n=182)	102 (56)	6 (3)	10 (6)	64
Other TNFi (n=435)	195 (45)	21 (5)	23 (5)	(35) 196 (45)
<b>12 months</b>				
ETN (n=120)	55 (46)	1 (1)	8 (7)	56
Other TNFi (n=307)	102 (33)	22 (7)	19 (7)	(47) 164 (53)

**Conclusions:** Monotherapy with ETN or other TNFi is an option for patients in remission/LDA;  $> 50\%$  of patients on ETN remained on monotherapy 6 months after discontinuing their csDMARD.

#### FRI0113 SWITCHING TO ANTI-IL-6 BIOLOGICS AFTER ANTI-TNF THERAPY IN CHILDREN WITH JIA

E. Alexeeva<sup>1,2</sup>, T. Dvoryakovskaya<sup>1,2</sup>, M. Soloshenko<sup>1</sup>, R. Denisova<sup>1</sup>, K. Isaeva<sup>1</sup>, A. Mamutova<sup>1</sup>, V. Gladkikh<sup>3,4</sup>, A. Moskalev<sup>3,4</sup>. <sup>1</sup>National Medical Research Center for Children's Health; <sup>2</sup>Sechenov First Moscow State Medical University (Sechenov University), Moscow; <sup>3</sup>EOL Labs Ltd, Department of Biostatistics; <sup>4</sup>Institute of Computational Mathematics and Mathematical Geophysics SB RAS, Novosibirsk, Russian Federation

**Background:** Development of biologics gives rise to novel classes of drugs, offering more options for treating children with primary or secondary failure of anti-TNF therapy. However, the question of whether or not previous exposure to biologic therapy and the number of previously administered biologics influence the efficacy of current treatment still needs to be solved.

**Objectives:** To compare tocilizumab efficacy in biologics-naïve and biologics-switched patients with JIA.

**Methods:** Comparative analysis involved patients who had initiated TOC treatment at the National Medical Research Centre of Children's Health (Moscow) depending on previous history of biologics therapy. Treatment efficacy was evaluated according to the dynamics of clinical and laboratory signs using the ACR-Pedi criteria. The Wallace criteria were used to evaluate whether or not remission had been achieved.

**Results:** Thirty-two patients were biologics-naïve and 43 patients switched to TOC were previously treated with ETA (n=10), ADA (n=34), certolizumab (n=2), and infliximab (n=1). Children in the biologics-naïve group differed from the switchers in a number of important baseline parameters: shorter disease duration (2.13 [1.25:5.34] and 7.42 [3:10.75] years, respectively; p<0.001) and lower arthritis severity indices (the number of joints affected, the CHAQ and JADAS scores). Therapy with TOC in children was found very effective. The CHAQ and JADAS disease activity scores, the CRP and ESR laboratory values, morning stiffness duration, and the VAS score (assessed by both patient and physician), and the number of affected joints (swollen or painful joints, joints with the limited range of motion and with active arthritis) significantly decreased after 4 week therapy in all patients (p<0.01). The percentages of biologics-naïve patients and switchers who achieved ACR90 after the first 12 months of therapy were 31.25% and 25.6%, respectively (p=0.613). A smaller percentage of children achieved stable remission: 4.65% of switchers and 6.25% of biologics-naïve patients (p>0.999).

**Conclusions:** Tocilizumab therapy is highly efficient both as the first and subsequent biologic agent. Children with history of therapy with at least one biologic agent have lower chances for achieving remission during the first 12 months of therapy. However, this difference is most likely caused by the longer and more severe arthritis course in children allocated to the group of biologics-switched patients compared to biologics-naïve ones. Further matched large-cohort study is needed to identify predictors of response to therapy.

#### FRI0114 EFFICACY AND RETENTION RATE OF CERTOLIZUMAB PEGOL IN RHEUMATOID ARTHRITIS: DATA FROM A LARGE REAL-LIFE MULTICENTRE RETROSPECTIVE COHORT

E.G. Favalli<sup>1</sup>, A. Becciolini<sup>1</sup>, P. Sarzi Puttini<sup>2</sup>, F. Atzeni<sup>3</sup>, R. Bortolotti<sup>4</sup>, S. Monti<sup>5</sup>, C. Lomater<sup>6</sup>, R. Gorla<sup>7</sup>, C. Bazzani<sup>7</sup>, R. Caporalì<sup>5</sup>, on behalf of on behalf of LORHEN group. <sup>1</sup>Department of Rheumatology, Gaetano Pini Institute; <sup>2</sup>Rheumatology Unit, University Hospital L. Sacco, Milano; <sup>3</sup>Rheumatology, University of Messina, Messina; <sup>4</sup>Rheumatology Unit, Santa Chiara Hospital, Trento; <sup>5</sup>Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; <sup>6</sup>Rheumatology, Ospedale Mauriziano, Torino; <sup>7</sup>Rheumatology Unit, Spedali Civili, Brescia, Italy

**Background:** Even though certolizumab pegol (CZP) has been licensed for the treatment of rheumatoid arthritis (RA) since longtime, observational data in a real-life setting are still lacking.

**Objectives:** To retrospectively evaluate the use of CZP in a multicentric observational cohort of Northern Italy (the LORHEN registry), calculating both clinical response and retention rate. To explore the effectiveness of CZP in childbearing age female.

**Methods:** Data were retrospectively extracted from the LORHEN registry which includes all RA patients treated with CZP as first or second-line biologic agent between December 2010 and April 2017. The 2 year clinical response was evaluated as EULAR response and proportion of patients achieving Disease Activity Score 28 (DAS28-ESR) remission. The 5 year retention rate was calculated by Kaplan-Meier method. Cox proportional hazard models were developed to examine potential predictors of CZP persistence, including sex, line of CZP treatment (naïve vs switchers), childbearing age, and concomitant MTX as categorical variables, whereas age, disease duration, and baseline DAS28-ESR as continuous variables.

**Results:** The overall study population included 242 RA patients (78.9% female; mean [±standard deviation, SD] age 54.2±13.8 years; mean disease duration 10 ±13.1 years; baseline DAS28-ESR 4.58±1.39), who received CZP as first- (64%) or second-line (36%) biologic agent, as monotherapy (40.9%) or in combination with methotrexate (MTX, 59.1%). Two-year EULAR good +moderate response and remission rates were similar in first- and second-line patients (66% vs 60.7% [p=0.65] and 39.6% vs 32.1% [p=0.52], respectively). The overall 5 year retention rate was 42.5%, with no difference between first- and second-line therapy (43.5% vs 40.5%, respectively; p=0.98), but with a clear trend in favour of childbearing subpopulation versus older women (62.8% vs 32.3%, respectively; p=0.07). Concomitant MTX was a predictor of CZP persistence (Hazard Ratio [HR] 1.79, 95% confidence interval [95% CI] 1.08–2.95; p=0.02), whereas sex (HR 1.35, 95% CI 0.71–2.54, p=0.35), age (HR 1.01, 95% CI 0.99–1.03; p=0.14), mean disease duration (HR 0.99, 95% CI 0.97–1.02; p=0.87), and baseline DAS28-ESR (HR 1.15, 95% CI 0.96–1.38; p=0.12) were not associated with CZP retention rate. The most frequent reason for discontinuation was inefficacy (60%), whereas only 21% of patients stopped the drug because of adverse events.

**Conclusions:** In our real-life experience, CZP showed a very good clinical response, with more than one third of patients achieving 2 year clinical remission and more than 40% persisting on treatment after 5 years. Unexpectedly, no significant difference was found between first and second line of treatment. The use of CZP in childbearing women seems to be associated with a higher retention rate.

**Disclosure of Interest:** None declared

#### FRI0115 INDIRECT STANDARDISED ASSESSMENT OF INJECTION SITE PAIN FOLLOWING SUBCUTANEOUS ADMINISTRATION OF CITRATE-FREE FORMULATION OF ADALIMUMAB AND ITS BIOSIMILAR ABP 501

E. Krishnan, N. Zhang, H. Wang, R. Kaushik. Biosimilars Development, Amgen Inc., Thousand Oaks, USA

**Background:** In randomised double-blind studies in patients with rheumatoid arthritis (RA) and psoriasis (PsO), ABP 501, an approved adalimumab biosimilar, had significantly lower injection site pain (ISP) perception compared with the citrate-containing formulation (CCF) of adalimumab reference product (RP) (40 mg/0.8 mL); however, there have been no direct or indirect comparisons of ISP perception between ABP 501 and the CFF of the RP (40 mg/0.4 mL).

**Objectives:** To demonstrate that pain perception after injection of both the ABP 501 formulation and the CFF-RP formulation was lower than after CCF-RP.

**Methods:** We analysed ISP perception data after injection from two ABP 501 phase 3 studies, one in patients with RA (NCT01970475) and another in patients with PsO (NCT01970488) and 2 citrate-free RP formulation studies (NCT01561313, NCT01502423) where the "control" group received the CCF-RP. In all studies, patients were equally randomised between the 2 treatment arms. Patients were asked to rate the ISP perception on a visual analogue scale (VAS) on which the current pain level was marked from 0 cm (no pain) to 10 cm (worst possible pain). We calculated Cohen's d-statistic for difference in ISP perception with ABP 501 compared with CCF-RP for the 2 ABP 501 studies. Similar comparisons were performed between the ISP perception associated with CFF-RF and CCF-RF. These measures were subsequently compared in a descriptive manner.

**Results:** Both ABP 501 and CFF-RF were associated with lower ISP perception after injection with maximum reduction observed immediately post-injection. The 95% confidence intervals of relative reduction in ISP perception for ABP 501 formulation and the CFF-RP (table 1) were provided descriptively.

**Abstract FRI0115 – Table 1.** Cross-sectional indirect comparison of ISP after injection between adalimumab CFF and ABP 501.

Time point of pain assessment	Within 2 minutes		Within 5 minutes		15 minutes after injection	
Investigational products	CFF-RP vs. CCF-RP		ABP 501 vs. CCF-RP		CFF-RP vs. CCF-RP	
Study	Study 1	Study 2	RA study baseline visit	PsO study baseline visit	Study 1	Study 2
Overall number of subjects	62	60	576	343	62	60
Mean (SD) [n] ISP VAS score for CCF-RP (cm)	3.3 (2.2) [62]	4.2 (2.8) [60]	2.1 (2.3) [262]	1.9 (2.0) [173]	1.0 (1.52) [62]	1.0 (1.61) [60]
Mean (SD) [n] ISP VAS score for ABP 501/CCF-RP (cm)	1.6 (2.1) [62]	0.9 (1.1) [60]	1.0 (1.6) [264]	0.5 (0.8) [170]	0.9 (1.66) [62]	0.4 (1.08) [60]
Difference in mean VAS score (cm)	1.7	3.3	1.1	1.4	0.1	0.6
Cohen's d statistic (95% confidence interval)	0.80 (0.42, 1.17)	1.56 (1.19, 1.94)	0.56 (0.39, 0.73)	0.92 (0.76, 1.08)	0.06 (-0.22, 0.34)	0.44 (0.20, 0.69)

**Conclusions:** Compared with CCF-RP, both ABP 501 and CFF-RP were associated with lower injection site pain perception.

#### IMPACT OF PRIOR BIOLOGIC USE ON TREATMENT RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING ADALIMUMAB IN ROUTINE CLINICAL CARE: RESULTS FROM THE PASSION STUDY

F. Van den Bosch<sup>1</sup>, S. Wassenberg<sup>2</sup>, P. Zueger<sup>3</sup>, J. Kalabic<sup>4</sup>, M. Wu<sup>3</sup>, K. Monastiriakos<sup>3</sup>, A. Ostor<sup>5</sup>. <sup>1</sup>Ghent University Hospital, Ghent, Belgium; <sup>2</sup>Rheumazentrum Ratingen, Ratingen, Germany; <sup>3</sup>AbbVie, N Chicago, USA; <sup>4</sup>AbbVie Deutschland Co. GmbH, Ludwigshafen, Germany; <sup>5</sup>Cabrini Medical Centre, Melbourne, Australia

**Background:** It is recognised that early diagnosis and treatment are important in maximising long-term quality of life in patients (pts) with rheumatoid arthritis (RA). Prior biologic disease modifying antirheumatic drug (bDMARD) use has been shown to affect treatment response to further biologic therapy including adalimumab (ADA).

**Objectives:** To evaluate the impact of prior bDMARD use on clinical and pt-reported outcomes in pts enrolled in the PASSION study.

**Methods:** PASSION was a 78-wk postmarketing, multinational, observational study that assessed the effectiveness of ADA in pts with moderate to severe RA receiving ADA in routine clinical care in the context of participation in the voluntary AbbVie pt support program. Pts with an insufficient response to  $\geq 1$  DMARD (1 prior bDMARD was allowed) and newly initiating ADA were enrolled and categorised as bDMARD-naïve or bDMARD-experienced. For the present analysis, ADA treatment response was determined by evaluating least squares (LS) mean change from baseline for multiple clinical and pt-reported outcomes (table 1). Missing data for each efficacy endpoint were imputed using last observation carried forward, and differences between groups for efficacy endpoints at wks 24, 52, and 78 were based on ANCOVA models adjusting for baseline and demographic variables (table 1). Additionally, the percentages of pts at each time point (observed population) who achieved HAQ-DI minimal clinically important difference (MCID; improvement from baseline of  $\geq 0.22$ ) were assessed.

**Results:** Of 1025 pts included in the intent-to-treat population, 182 were bDMARD-experienced and 843 were bDMARD-naïve at baseline. There were no significant differences between groups in sex, race, ethnicity, weight, height, body mass index, TJC28, SJC28, and pain at baseline. However, bDMARD-

experienced pts were significantly older, had longer RA duration, and had lower values for HAQ-DI, DAS28(CRP), CDAI, SDAI, PtGA, and PhGA than bDMARD-naïve pts at baseline ( $p < 0.05$  for all). ADA treatment response was significantly higher for bDMARD-naïve vs bDMARD-experienced pts at all timepoints for HAQ-DI, DAS28(CRP), CDAI, PtGA, and pain, at wks 24 and 52 for SDAI, and at wk 24 for TJC28 and SJC28 (table 1). In the observed population, a large percentage of bDMARD-naïve and bDMARD-experienced pts achieved HAQ-DI MCID at wk 24 (67% and 60%), wk 52 (71% and 65%), and wk 78 (74% and 59%).

**Abstract FRI0116 – Table 1.** Least Squares Mean Change from Baseline in Efficacy Measures by Prior bDMARD Use at Each Study Visit (Intent-to-Treat Population, LOCF)

Amberger<sup>12</sup>. <sup>1</sup>CIRI am Klinikum der Johann Wolfgang Goethe-Universität, Rheumatologie, Fraunhofer Institute for Molecular Biology and Applied Ecology IME, Project Group Translational Medicine and Pharmacology TMP, Frankfurt/Main; <sup>2</sup>Rheumatologische Schwerpunktpraxis Saarbrücken, Saarbrücken; <sup>3</sup>Charité – Universitätsmedizin Berlin, Medizinische Klinik mit Schwerpunkt Rheumatologie und klinische Immunologie, Berlin; <sup>4</sup>Rheumatologie/Klinische Immunologie, Kreiskliniken Altötting-Burghausen, Burghausen; <sup>5</sup>Roche Pharma AG, Grenzachwyhlen; <sup>6</sup>Chugai Pharma AG, Frankfurt/Main; <sup>7</sup>MVZ Ambulantes Rheumazentrum Erfurt, Erfurt; <sup>8</sup>Schwerpunktpraxis für Rheumatologie und Gastroenterologie, München; <sup>9</sup>Rheumatologische Praxis, Neubrandenburg; <sup>10</sup>Praxis, Haldensleben; <sup>11</sup>Universitätsklinikum Würzburg, Medizinische Klinik und Poliklinik II, Schwerpunkt Rheumatologie und klinische Immunologie, Würzburg; <sup>12</sup>Rheumatologische Gemeinschaftspraxis Dr. Pick/Dr. Amberger, Bad Neuenahr, Germany

**Background:** The non-interventional study (NIS) ARATA (NCT02251860) observes the clinical effectiveness and safety of subcutaneous Tocilizumab (TCZ) s.c. treatment under routine conditions over a 2 year period.

**Objectives:** In this interim analysis, the patients were subgrouped according to their pretreatment: (I) pretreated exclusively with sDMARD or (II) also pretreated with bDMARD.

**Methods:** TCZ-naïve patients (Pts) ( $\geq 18$  years) with RA, who receive TCZ s.c. treatment, could be included in the study since 2014. Demographic and disease-specific characteristics, the progression of the disease (rheumatoid activity scores), concomitant medications, adverse events (AE) and patient questionnaires were documented.

**Results:** In this interim analysis (reporting date 01-FEB-2017), the data of 912 Pts were evaluated. 319 Pts (35%) were pretreated exclusively with sDMARD and 585 Pts (64.8%) were also pretreated with bDMARD. The main reason for a switch to TCZ s.c. was lacking effectiveness of the pretreatment.

In comparison, patients exclusively pretreated with sDMARD demonstrated a shorter median disease duration (6 vs. 9 years), TCZ s.c. was applied at BL more rarely in combination with MTX (23.5% vs. 35.6%) and more rarely with glucocorticoids (59.2% vs. 69.5%). The comorbidity rates were comparable in both groups. However, patients exclusively pretreated with sDMARD suffered half as often from osteoporosis (9.1% vs. 21.2%). Patients Exclusively pretreated with sDMARD had a longer median treatment duration (380.5 vs. 341.0 days) and a higher retention rate to week 52 (78.9% vs. 70.5%). The effectiveness of the TCZ s.c. treatment was examined with 831 patients. More patients with exclusively sDMARD pretreatment achieved a DAS28 remission and remained in remission (figure 1). The change from BL for the CDAI and Dcrt response was higher in the sDMARD subgroup. No new safety signals and no differences between the subgroups for all safety parameters were observed.

**Abstract FRI0117 – Figure 1.** Clinical remission (DAS28-ESR <2.6) after pretreatment (N=831). DAS28-ESR, Disease activity score 28-erythrocyte sedimentation rate.

**Conclusions:** The results of the third interim analysis of the NIS ARATA confirm the efficacy of TCZ s.c. observed in the approval trials in clinical practice. A fast and effective reduction of disease activity in the treated RA patients as well as a lasting improvement in all RA progression parameters collected was observed. In case of the earlier application of TCZ s.c., directly after sDMARD failure, higher response rates and a longer retention of the treatment were observed.

### DEKAVIL (F8IL10) – UPDATE ON THE RESULTS OF CLINICAL TRIALS INVESTIGATING THE IMMUNOCYTOKINE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Galeazzi<sup>1</sup>, G. Sebastiani<sup>2</sup>, R. Velli<sup>3</sup>, O. Viapiana<sup>4</sup>, J. Dudler<sup>5</sup>, P. Zufferey<sup>6</sup>, E. Selvi<sup>1</sup>, S. Finzel<sup>7</sup>, F.S. Bootz<sup>7</sup>, D. Neri<sup>8</sup>, on behalf of Dekavil Study Group. <sup>1</sup>University Hospital Siena, Siena; <sup>2</sup>Rheumatology, San Camillo-Forlanini Hospital, Rome, Italy; <sup>3</sup>University Medical Center Freiburg, Freiburg, Germany; <sup>4</sup>University Hospital Verona, Verona, Italy; <sup>5</sup>Cantonal Hospital Fribourg, Fribourg; <sup>6</sup>CHUV, Lausanne; <sup>7</sup>Philochem Ag, Philogen Group, Otelfingen, Switzerland; <sup>8</sup>Philogen SpA, Siena, Italy

**Background:** The targeted pharmacodelivery of cytokines by means of antibody-fusion proteins aims at selective accumulation of the active compound at the site of disease while sparing healthy tissues. Dekavil (F8IL10) is a fully human fusion protein composed of the vascular targeting antibody F8 fused to the cytokine interleukin-10. A phase 1 dose escalation study in patients with rheumatoid arthritis (RA) has recently been completed. Dekavil is currently under investigation in a phase 2 clinical study for the treatment of RA.

**Objectives:** The phase 1 study investigated safety, tolerability and the maximum tolerated dose of Dekavil when administered in combination with methotrexate (MTX). The currently ongoing phase 2 (in patients with active RA despite MTX therapy who had failed anti-TNF treatment) measures the mean change from baseline in DAS28-CRP between F8IL10 and placebo arms as primary endpoint.

**Methods:** The target population of both RA studies comprises patients with active RA despite MTX therapy who had failed anti-TNF treatment. Dekavil is administered once weekly for 8 consecutive weeks by s.c. injection in combination with a fixed dose of MTX (10–25 mg). The recently completed phase 1 study investigated escalating doses of Dekavil (6–600 µg/kg +MTX). The ongoing randomised multicenter, double-blind, placebo-controlled phase 2 trial assesses therapeutic activity in two treatment groups (Dekavil 30 or 160 µg/kg plus MTX) and one placebo group (placebo plus MTX).

**Results:** Dekavil was well tolerated up to the highest investigated dose (600 µg/kg) and an MTD was not reached. In 34 out of 35 patients treated in the phase 1 study no SAEs and no SUSARs were reported. One subject (cohort 9, 450 µg/kg) experienced a DLT (G2 purpura), which was accompanied by an SAE (G2 dyspnea, not drug related). The patient fully recovered within one week following corticosteroid administration. The most frequently observed adverse event was mild (G1) injection site reaction and occurred in 60% of the patients. Furthermore, two cases of drug related anaemia (G3 and G2; 160 µg/kg and 450 µg/kg, respectively) were reported in this study. All adverse reactions resolved completely. After 4 cycles of treatment, 36.4% of patients (12/33) exhibited ACR responses. The fraction of responses increased to 45.8% (11/24) after 8 cycles. Two patients achieved an ACR70 for more than 12 months after the last drug administration. As of January 2018, 25 patients have been treated in the phase 2 clinical study and neither SUSARs nor treatment-related deaths were recorded. Immunogenicity assessment is completed for the first 20 study subjects did not reveal an antibody response specific to F8IL10. An interim read-out after 45 patients will provide a more thorough understanding of the therapeutic activity of F8IL10.

**Abstract FRI0118 – Figure 1.** ACR responses after 4 and after 8 weeks of Dekavil treatment in the phase 1 study population including all dose levels (6 – 600µg/kg)

**Conclusions:** The data obtained in the population studied to date suggest that Dekavil may be a safe and well tolerated novel therapeutic for the potential treatment of RA.

#### FRI0119 EFFECT OF DISCONTINUING TNF INHIBITORS DURING PREGNANCY ON THE COURSE OF RHEUMATOID ARTHRITIS AND JUVENILE IDIOPATHIC ARTHRITIS

E. Förger<sup>1</sup>, G. Bandol<sup>2</sup>, Y. Luo<sup>2</sup>, L. Robinson<sup>2</sup>, D.L. Johnson<sup>2</sup>, C.D. Chambers<sup>2</sup>.  
<sup>1</sup>Rheumatology, Immunology, Allergology, Inselspital Universitätsspital Bern, Bern, Switzerland; <sup>2</sup>Department of Pediatrics, Medicine, and Family and Preventive Medicine, University of California San Diego, San Diego, USA

**Background:** Treatment changes at early pregnancy can be followed by a disease worsening.<sup>1</sup>

**Objectives:** To investigate whether the discontinuation of tumour necrosis factor inhibitors (TNFi) use during pregnancy is associated with any changes of disease activity at the third trimester in women with rheumatoid arthritis (RA) and juvenile idiopathic arthritis (JIA).

**Methods:** A prospective cohort study was conducted using the Organisation of Teratology Information Specialists (OTIS) Autoimmune Diseases in Pregnancy Project in the U.S. and Canada. Pregnant women with RA and JIA were enrolled between 2005 and 2017. Information about medication and disease activity were collected by telephone-based interviews prior to gestational week 20 and at gestational week 32. Disease activity was assessed by the Health Assessment Questionnaire Disability Index (HAQ-DI), the patient's pain scale and the patient's global scale. The composite tool Patient Activity Scale (PAS) was calculated in retrospect.

**Results:** In the OTIS cohort, data were available for 490 women of whom 397 had RA and 93 had JIA. Of all patients, 323 (65.9%) used TNFi during pregnancy of whom 122 (24.9%) patients discontinued TNFi before gestational week 20 (the mean time of discontinuation was gestational week 6 (SD ±5.03)) and 201 (41.0%) used TNFi beyond week 20. There were 167 (34.1%) patients not taking TNFi during pregnancy. At the time of enrollment, disease activity was low to minimal in 357 (72.9%) patients as defined by PAS scores below 3.7.

From the first to the third trimester, women using TNFi beyond week 20 showed a decrease of the PAS scores ( $p=0.02$ , figure 1) whereas women not using TNFi and those discontinuing TNFi before gestational week remained stable.

The univariate regression analysis, but not the adjusted model, revealed that TNFi use beyond week 20 was associated with improved HAQ scores at the third trimester (coefficient B  $-0.142$ , 95% CI  $-0.258$  to  $-0.026$ ) and with improved PAS scores (coefficient B  $-0.423$ , 95% CI  $-0.843$  to  $-0.002$ ). However, the various TNFi treatment modes during pregnancy were not associated with any minimum clinically important difference at the third trimester.

When selecting for 58 patients with active disease (PAS score  $\geq 3.71$ ) at the first trimester, the discontinuation of TNFi before gestational week 20 was not associated with any clinically important worsening of the disease at the third trimester.

**Conclusions:** In patients with RA and JIA who enter pregnancy with well controlled disease, the discontinuation of TNFi before gestational week 20 is possible without a risk of disease flares at the third trimester.

**Background:** Rhupus, a combination of Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus, is a rare entity. Existing epidemiological and therapeutic data are limited.

**Objectives:** The aim of this study was to describe the therapeutic impact and safety of three biologic therapies: Rituximab, Tocilizumab and Abatacept in a french Rhupus cohort.

**Methods:** We have set up a transverse observational retrospective and multicentric study. To be included in the cohort, patients had to present an overlap syndrome fulfilling criterias for rheumatoid arthritis and lupus, and to be treated at least by one of these three therapies. Enrollment has been made with a file available on the CRI website and the analysis of the French RA registers (AIR, REGATE and ORA). Primary endpoint was the median time in therapeutic maintenance for each biological agent.

**Results:** Forty patients from fifteen rheumatologic centres were included. The main demographic data for these patients are given in table 1. Thirty of them received a treatment with Rituximab, twelve with Tocilizumab and seven with Abatacept. Nine patients received 2 biologics at two different times of the disease. The medians of therapeutic maintenance were 82 months with Rituximab, 48 with Tocilizumab and 55 with Abatacept. The detailed analysis of clinical and biologic parameters revealed differences in effectiveness between therapies: corticosteroid doses decreased more in Rituximab group, VAS activity decreased more in Abatacept group, CRP decreased more in Tocilizumab group. Safety of biologics was similar to the data in literature for RA patients.

	RITUXIMAB (n=30)	TOCILIZUMAB (n=12)	ABATACEPT (n=7)
Disease duration (years)	4.8	8.3	11.9
Median of therapeutic maintenance (month)	82	48	55
Average duration of treatment (month)	44.8 [5.8;83.8]	27.0 [4.3;49.7]	26.0 [-0.79;52.93]
DAS 28 CRP evolution	-1.03 [-2.73;0.67]	-1.88 [-3.36;-0.38]	-1.97 [-3.55;-0.41]
Prednisone evolution (mg/d)	-8.45 [-23.15;9.25]	-5.15 [-10.95;0.65]	-2.71 [-5.00;-0.43]
VAS evolution (/100)	-5.40 [-32.70;21.90]	-18.50 [-35.3;35.04]	-30.43 [-65.27;4.41]
CRP evolution (mg/L)	-14.46 [-46.46;17.54]	-21.75 [-53.41;9.91]	-12.86 [-25.95;0.26]

**Conclusions:** This study provides original data on the effectiveness and safety of non-TNF biologics, mostly rituximab, in a large cohort of patients with rhupus. We have not enough patients treated with Tocilizumab and Abatacept to conclude but the therapeutic maintenance of Rituximab in Rhupus is similar to the one usually observed in RA.

**Disclosure of Interest:** None declared

### CHARACTERISTICS OF PATIENTS WITH EARLY RHEUMATOID ARTHRITIS WHO HAVE A DELAYED RESPONSE TO TREATMENT WITH METHOTREXATE IN MONOTHERAPY OR IN COMBINATION WITH ADALIMUMAB

J. Smolen<sup>1</sup>, X. Bu<sup>2</sup>, X. Wang<sup>2</sup>, J. Suboticki<sup>2</sup>, A. Kavanaugh<sup>3</sup>. <sup>1</sup>Medical University of Vienna, Vienna, Austria; <sup>2</sup>AbbVie Inc., North Chicago; <sup>3</sup>University of California, San Diego, USA

**Background:** In patients (pts) with rheumatoid arthritis (RA), treat-to-target recommendations call for adjustment of treatment if a target is not met within 3–6 months of initiation. While some pts continue therapy beyond 3–6 months despite not achieving the target, it's unclear if they still can achieve the target, and how the timing of target attainment impacts long-term outcomes.

**Objectives:** To evaluate clinical, functional, and radiographic outcomes on the basis of initial time to low disease activity (LDA) attainment among early RA pts who are naïve to MTX, or are MTX-insufficient responders (MTX-IR).

**Methods:** This post hoc analysis included pts receiving MTX in monotherapy or in combination with adalimumab (ADA) in 2 randomised, controlled trials (RCTs) of MTX-naïve pts with early RA: PREMIER included a 104 week (wk) RCT<sup>1</sup>; OPTIMA included a 26 wk RCT followed by treatment adjustments based on a target of LDA at wks 22 and 26<sup>2</sup>. Pts not achieving stable LDA received open-label (OL) ADA +MTX for an additional 52 wks (MTX-inadequate responders, IR). Pts were subgrouped by treatment and time to first LDA event [SDAI ≤11: 0-3 months (mths), 3-6 mths, >6-12 mths]. The following were summarised for each subgroup: mean values and change from baseline in SDAI, HAQ-DI and modified total Sharp score (mTSS). The proportions of pts achieving SDAI remission (REM) at 1 year (yr) were assessed.

**Results:** Roughly equal proportions of pts on MTX alone experienced their first LDA response between 0-3 mths (21%), 3-6 mths (21%), and >6-12 mths (17%). More pts on ADA+MTX experienced LDA within 3 mths (0-3: 45% and 56% for MTX-naïve and MTX-IR backgrounds, respectively), with smaller proportions in the 3-6 mths (19% for both MTX-naïve and -IR backgrounds), and >6-12 mths groups (14% and 4% for MTX-naïve and MTX-IR backgrounds). Approximately 50% of the 0-3 mth group across treatments achieved SDAI REM at 1 year. Interestingly, 10%, 14%, and 8% of the MTX, ADA+MTX (MTX-naïve), and ADA+MTX (MTX-IR) pts who first experienced LDA after 6 mths were in SDAI REM at 1 year.

Among MTX-naïve pts, pts on ADA+MTX had greater ΔHAQ and smaller ΔmTSS than pts on MTX alone at Wks 26 and 52 (table 1). Regardless of their time to first SDAI LDA response, pts on MTX monotherapy or ADA+MTX experienced comparable improvements in SDAI, HAQ-DI and comparable ΔmTSS at Wks 26 and 52.

Table 1 Mean Values at Baseline and Change From Baseline in Clinical, Functional, and Structural Parameters in Patients with Early RA Receiving MTX or ADA+MTX, on the Basis of First Achievement of Low Disease Activity by SDAI.

<sup>1</sup> Timing of LDA outcome from time of ADA addition.

BL, baseline; Wk, week; SDAI, simplified disease activity index; HAQ-DI, health assessment questionnaire-disability index; mTSS, modified total Sharp score

**Conclusions:** Pts on ADA+MTX achieved a first SDAI LDA response earlier than pts on MTX monotherapy, regardless of whether they were MTX-naïve or MTX-IR. More pts with a very early response went on to achieve SDAI REM at 1 year. However, pts with a longer time (>6 mths) to their first SDAI LDA response had comparable clinical, functional and radiographic outcomes compared to pts who responded earlier (within 3 or 6 mths). Therefore, achieving a clinical response in the direction of the treatment target, even if not yet achieving it, may be sufficient to continue therapy in appropriate pts.

FRI0122

### DRUG SURVIVAL OF ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS, ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS OVER 10 YEARS IN REAL-WORLD SETTING OF CZECH REGISTRY ATTRA

K. Pavelka<sup>1</sup>, J. Zavadá<sup>1</sup>, Z. Kristkova<sup>2</sup>, L. Szczukova<sup>3</sup>. <sup>1</sup>Institute of Rheumatology, Praha 2; <sup>2</sup>Institute of Biostatistics and Analyses, Ltd., Spin-off company of the Masaryk University; <sup>3</sup>Institute of Biostatistics and Analyses, Ltd., Masaryk University, Brno, Czech Republic

**Background:** Drug survival in real clinical practice is reflecting both efficacy and safety of the drug. It is valuable outcome measure complementary to data from RCT.

**Objectives:** To evaluate 10 years efficacy and survival of adalimumab (ADA) in Czech registry ATTRA. To analyse reasons for drug discontinuation and analyse baseline demographic and clinical characteristics predictive for drug discontinuation. We also aimed to compare survival of ADA between 3 different diagnosis (RA, AS, SpA). Finally we aimed to compare survival between different anti TNF drugs.

**Methods:** All patients fulfilled criteria of Czech Rheum. Soc. for indication of anti TNF therapy and were included in registry. They were followed each 3 month first

year and than each 6 month. The main outcome measures in RA were DAS 28, HAQ, EuroQuol, SF36, CRP, in AS BASDAI, HAQ and ASDAS. Reasons for drug discontinuation were reported as primary failure, secondary failure, adverse event, remission and others. Statistics – survival on therapy was estimated by Kaplan-Meier analysis. The search for outcome predictors was performed by log-rank test (continuous predictors were appropriately categorized).

**Results:** Altogether 3159 patients with RA, 1785 with AS and 723 with PsA were included.

1598 patients with RA were treated with adalimumab and retention was 75,8 % in one year, 43,8 % in 5 years and 27,7 % in 10 years. The reasons for drug discontinuation were: primary failure 24,9 %, secondary failure 30,5 %, and adverse events (19,8 %)

Predictive factors for adalimumab retention in rheumatoid arthritis were: younger age < 50 years, failure of  $\leq 1$  csDMARDs in past, combination therapy with csDMARDs at baseline. Sex, RF and anti CCP were not predictive. Drug retention was longest in AS (median 99,6 m), than PsA (median 62,5 m) and shortest in RA (median 43,9 m) (graph 1). Drug survival in rheumatoid arthritis was longer on etanercept than on infliximab ( $p < 0,001$ ), longer on adalimumab than infliximab ( $p < 0,001$ ) and equal between adalimumab and etanercept ( $p = 0,85$ ).

**Conclusions:** Adalimumab retention in registry ATTRA was comparable to other European registries. Predictors of drug retention in RA were: younger age (< 50 years),  $\leq 1$  csDMARDs in past and in combination with csDMARDs. Survival on adalimumab was longer in AS, than PsA and RA and the same was true for all three anti TNF drugs. Survival on drug in rheumatoid arthritis was longer in adalimumab and etanercept compared to infliximab.

### FRI0123 COMPARATIVE EFFECTIVENESS OF SUBCUTANEOUS VERSUS INTRAVENOUS TOCILIZUMAB IN A PAN-EUROPEAN COLLABORATION OF REGISTRIES

K. Lauper<sup>1,2</sup>, M.J. Santos<sup>3</sup>, on behalf of Rheuma.pt, F. Ianonne<sup>4</sup>, Z. Rotar<sup>5</sup>, D. C. Nordström<sup>6</sup>, C. Codreanu<sup>7</sup>, T.K. Kvien<sup>8</sup>, E.K. Kristianslund<sup>9</sup>, K. Pavelka<sup>9</sup>, G. Lukina<sup>10</sup>, M.V. Hernández<sup>11</sup>, S.L. Gale<sup>12</sup>, K. Sarsour<sup>12</sup>, Y. Luder<sup>13</sup>, D. S. Courvoisier<sup>1</sup>, C. Gabay<sup>1,2</sup>. <sup>1</sup>Rheumatology, University Hospitals of Geneva, Geneva; <sup>2</sup>SCQM, Zürich, Switzerland; <sup>3</sup>Rheumatology Department, Hospital Garcia de Orta, Almada, Portugal; <sup>4</sup>GISEA, University Hospital of Bari, Bari, Italy; <sup>5</sup>BioRx.si, University Medical Centre Ljubljana, Ljubljana, Slovenia; <sup>6</sup>ROB-FIN Helsinki University Hospital and Helsinki University, Helsinki, Finland; <sup>7</sup>Center of Rheumatic Diseases, University of Medicine and Pharmacy, Bucharest, Romania; <sup>8</sup>Diakonhjemmet Hospital, Oslo, Norway; <sup>9</sup>Charles University, Prague, Czech Republic; <sup>10</sup>ARBITER, Institute of Rheumatology, Moscow, Russian Federation; <sup>11</sup>Rheumatology, Hospital Clinic Barcelona, Barcelona, Spain; <sup>12</sup>Genentech, South San Francisco, CA, USA; <sup>13</sup>F. Hoffmann-La Roche, Basel, Switzerland

**Background:** In randomised controlled trials, subcutaneous tocilizumab (TCZ sc) has been found non-inferior to intravenous TCZ (TCZ iv) for the treatment of rheumatoid arthritis (RA) patients. However, to our knowledge, there are no observational studies comparing these two different routes of administration in routine care.

**Objectives:** To compare the real-world effectiveness of TCZ sc and TCZ iv in RA patients.

**Methods:** We included RA patients treated with TCZ from 8 European registries. We compared drug retention using Kaplan-Meier and Cox models. The proportions of patients achieving CDAI remission and low disease activity (LDA) at

1 year were compared using LUNDEX correction with computation of confidence intervals by bootstrapping.<sup>1</sup>

**Results:** 2896 patients were retrieved from the collaborative registries before January 2017, including 2469 TCZ iv and 427 TCZ sc. Baseline demographics were similar between both groups, but patients in the TCZ iv group had a more severe disease activity, with higher DAS28, CDAI, tender joint count (TJC), swollen joint count (SJC), ESR and physician global assessment values (table 1). Crude median retention was 2.14 years (95% CI 2.03–2.33) for TCZ iv and 1.00 year for TCZ sc (95% CI 0.83–1.10),  $p < 0.001$ . However, in a covariate-adjusted analysis, stratified by country- and year of treatment initiation, we found that hazards of discontinuation were similar among patients on TCZ iv compared to patients on TCZ sc (hazard ratio: 0.92, CI 95% 0.77–1.09). The average adjusted CDAI change at 1 year was  $-1.15$  for TCZ iv, and  $-1.06$  for TCZ sc patients ( $p$ -value of interaction between treatment group and time: 0.68). The average adjusted DAS28 change at 1 year was also similar between groups ( $-0.28$  for TCZ iv and  $-0.09$  for TCZ sc,  $p$  value of interaction: 0.21). CDAI remission and LDA at 1 year (LUNDEX corrected) were similar between TCZ sc and TCZ iv patients (CDAI remission: 9.5% in TCZ iv vs. 9.4% in TCZ sc (difference:  $-0.1\%$ , bootstrap 95% CI:  $-3.8\%$ – $3.8\%$ ); CDAI LDA: 37.3% in TCZ iv vs. 33.7% in TCZ sc (difference:  $-3.6\%$ ; bootstrap 95% CI:  $-9.4\%$ ; 2.5%)). Likewise, DAS28 remission and LDA at 1 year (LUNDEX corrected) were comparable between TCZ sc and TCZ iv (difference in DAS28 remission:  $-2.7\%$ ; bootstrap 95% CI:  $-8.8\%$ ; 3.5%; difference in DAS28 LDA:  $-5.8\%$ ; bootstrap 95% CI:  $-11.9\%$ ; 0.4%).

Abstract FRI0123 – Table 1. Baseline characteristics

N = 2896	TCZ i.v. (n=2469)	TCZ s.c. (n=427)	p
Number of visits (median [IQR])	2 [1-5]	2 [1-3]	
Total patient-years	5099.16	379.11	
Age, yr (median [IQR])	56.2 [48.0, 64.0]	55.6 [47.1, 63.6]	0.30
Female gender, n (%)	2004 (81.2)	345 (80.8)	0.91
Ever smoker, n (%)	319 (21.7)	68 (22.1)	0.94
BMI (median [IQR])	25.3 [22.4, 28.6]	25.2 [22.7, 28.5]	0.73
Disease duration, yr (median [IQR])	7.8 [3.4, 14.7]	8.0 [3.4, 15.7]	0.52
Seropositivity (RF and/or ACPA), n (%)	1799 (83.1)	291 (81.5)	0.52

**FRI0124 PREVENTION OF EXTENSIVE BONE MARROW OEDEMA AND CONSEQUENT RAPID RADIOGRAPHIC PROGRESSION BY SHORT TERM USAGE OF BIOLOGICS IN DRARDS RESISTANT PATIENTS WITH EARLY DESTRUCTIVE RHEUMATOID ARTHRITIS**

K. Katayama<sup>1</sup>, T. Okubo<sup>2</sup>, T. Sato<sup>1</sup>, R. Fukai<sup>3</sup>, Y. Kon<sup>4</sup>, Y. Makino<sup>5</sup>, S. Kodama<sup>5</sup>, H. Ito<sup>6</sup>. <sup>1</sup>Orthopedic Surgery, <sup>2</sup>Radiology, Katayama Orthopedic Rheumatology Clinic; <sup>3</sup>Pharmacology, Seien Pharmacy, Asahikawa; <sup>4</sup>Rheumatology, Sapporo Rheumatology and Immunology Clinic, Sapporo; <sup>5</sup>Medicine; <sup>6</sup>Orthopedic Surgery, Asahikawa Medical University, Asahikawa, Japan

**Objectives:** To investigate possible preventive effect of radiographic joint damage, especially RRP by short term treatment with biologics in non-biological disease-modifying ant-rheumatic drugs(non-bio DMARDs) resistant early RA (Clinical registration number; UMIN-CTR 000013614).

**Methods:** Fifty early RA patients with extensive BE by hand MRI test despite treatment with non-bio DMARDs were recruited. Among these, 44 patients were diagnosed as RRP. Twenty three patients (male 5, female 18) were treated with combination of non-bio DMARD and biologic DMARDs (Bio group) and 26 patients were treated with enhanced DMARDs therapy using MTX with or without other DMARDs (enhanced DMARDs group). Baseline demographics of both groups were not significantly different (Data not shown). In the Bio group, the following biologics were added: Adalimumab (13 cases), Tocilizumab (3 cases), Abatacept (3 cases), Infliximab (2 cases), Certolizumab (1 case), Golimumab (1 case). In enhanced DMARDs group, mean MTX dose was increased from 7.3 mg/w to 11.3 mg/w or other DMARDs were added. Bone destruction was determined before and 3 or 6 months after treatment by modified total Sharp scoring (mTSS) using by conventional radiography, and expressed as yearly progression of mTSS ( $\Delta$ mTSS/y). BE score was measured by RAMRIS method using T1 or STIR image of hand MRI (HITACHI, Elis, 0.5T).

**Results:** Significant reduction in DAS28-ESR values after 3 or 6 months treatment were observed: from 4.2 to 3.3(p=0.0004) in the enhanced DMARDs group, and 4.37 to 3.0(p<0.0001) in the Bio groups. Similarly, improvement of BE: 7 out of 26 (26.9%) and 14 out of 23 patients (60.9%), mean  $\Delta$ mTSS/y: 5.8 and 2.4, incidence of RRP: 9 (34.6%) and 9 (34.6%), and structural remission: 5 (21.7%) and 16 patients (69.6%), in the enhanced DMARDs and the Bio group, respectively. Accordingly, improvement of BE and incidence of structural remission was higher, whereas mean  $\Delta$ mTSS/y value was significantly lower (p<0.05) in the Bio group compared to in the enhanced DMARDs group (table 1, figure 1).

**Abstract FRI0124 – Table 1.** Comparison between the Enhanced DMARDs group and the Bio group

	Enhanced DMARDs group (n=23)	Bio group (n=26)	P
$\Delta$ mTSS/y	5.8	2.4	0.0142*
% RRP	34.6% (9/26)	21.7% (5/23)	n.s
% Structural remission (%)	34.6% (9/26)	69.6% (16/23)	0.0146*

**Abstract FRI0124 – Figure 1.** Radiographic data

**Conclusions:** Results of this study indicated that short term (3 or 6 months) treatment with biologics is effective in the reducing BE, and consequently prevent further progression of the disease into RRP status in 80% of early destructive RA despite extensive DMARDs therapy. The effect of withdrawal of biologics in RA improving BE are currently under investigation (figure 1). We consider that a short-term treatment with biologics for early RA patients, who are resistant to

DMARDs and at high risk to transit to RRP, will be an effective and economical treatment strategy.

**FRI0125 QUANTIFICATION OF TUMOUR NECROSIS FACTOR IN ANKYLOSING SPONDYLITIS PATIENTS DURING ADALIMUMAB TREATMENT**

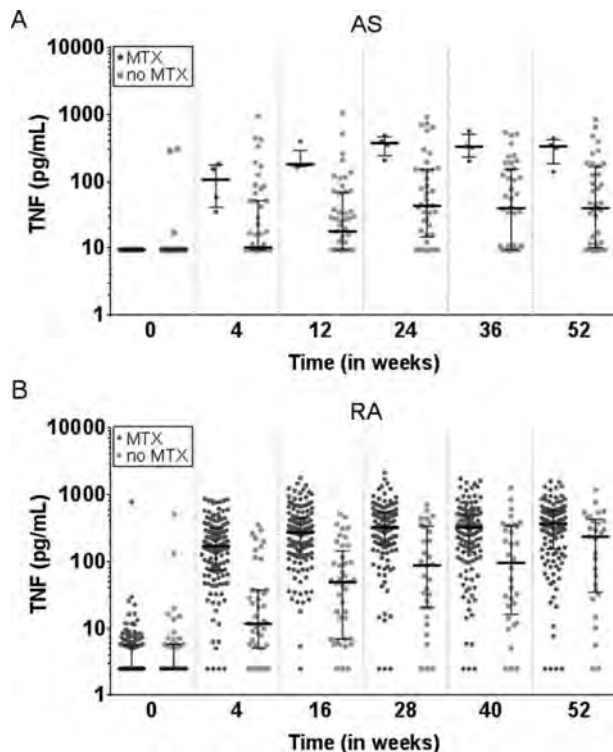

L. Berkhout<sup>1</sup>, J. Ruwaard<sup>2</sup>, M.J. l'Ami<sup>2</sup>, G. Wolbink<sup>1,2</sup>, T. Rispen<sup>1</sup>. <sup>1</sup>Department of Immunopathology, Sanquin Research; <sup>2</sup>Amsterdam Rheumatology and Immunology Center, Reade, Amsterdam, Netherlands

**Background:** Tumour necrosis factor- (TNF) inhibitors, including adalimumab, are widely used in the treatment of inflammatory autoimmune diseases. Longitudinal (drug-bound) TNF levels in rheumatoid arthritis (RA) patients increased upon adalimumab treatment, and remained stable over two years follow-up. Low TNF levels at week four were associated with a significantly higher frequency of anti-drug antibodies (ADAs) at subsequent time points, significantly less methotrexate (MTX) use at baseline and a significantly reduced clinical response after 52 weeks (unpublished data).

**Objectives:** To investigate TNF levels during adalimumab treatment in ankylosing spondylitis (AS) patients and to compare this with TNF levels measured in RA patients.

**Methods:** Longitudinal TNF levels were quantified in 76 consecutive AS patients during adalimumab treatment, using a competition enzyme-linked immunosorbent assay (ELISA). This ELISA is drug-tolerant, which enables the quantification of TNF in the presence of large amounts of TNF-inhibitor. The relationship between TNF levels, drug levels and ADA detection was evaluated.

**Results:** At baseline, TNF levels were close to the detection limit, but levels increased during adalimumab treatment (figure 1A; stratified to concomitant MTX use; black lines represent median TNF (IQR)). The increase in TNF was more gradual in patients treated with adalimumab monotherapy, compared to the increase in TNF levels in patients concomitantly treated with MTX (only 9% of the patients). Similar results were found for adalimumab-treated RA patients, stratified to concomitant MTX use (figure 1B; Black lines show median (IQR)). Furthermore, at week four, low TNF levels in AS patients tended to associate with a higher frequency of ADAs after 24 weeks.

**Conclusions:** This is the first study describing an increase in TNF levels in AS patients during one year of adalimumab treatment. The dynamics in TNF levels is different for patients concomitantly treated with MTX, compared to patients treated with adalimumab monotherapy. Low TNF levels at week four tended to associate with a higher frequency of ADAs, which is potentially associated with the low frequency of MTX use at baseline.

**FRI0126 PATIENTS' CONCERNS ABOUT AND PERCEPTION OF BIOSIMILARS IN RHEUMATOLOGY : A FRENCH SURVEY**

L. Frantzen<sup>1</sup>, J.-D. Cohen<sup>2</sup>, S. Tropé<sup>3</sup>, M. Beck<sup>4</sup>, R. Diebold<sup>5</sup>, M. Sittler<sup>6</sup>, A. Munos<sup>7</sup>, L. Arnaud<sup>8</sup>, J.-E. Gottenberg<sup>8</sup>, J. Sibilia<sup>8</sup>, N. Afif<sup>1</sup>, C. Sordet<sup>8</sup> on behalf of CERBER : Comité d'Etudes et de Réflexion sur les Biosimilaires en Rhumatologie. <sup>1</sup>Service de Rhumatologie, GHR Mulhouse Sud Alsace, Mulhouse; <sup>2</sup>Service de rhumatologie, Centre Hospitalier Universitaire de Montpellier; <sup>3</sup>ANDAR, Montpellier; <sup>4</sup>Agence Régionale de Santé; <sup>5</sup>Service de Rhumatologie, Association France Spondylarthrite; <sup>6</sup>Hôpitaux Universitaires de Strasbourg, Strasbourg; <sup>7</sup>Université de Tours, Tours; <sup>8</sup>Service de Rhumatologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

**Background:** Patient adherence to biosimilars DMARDs have become a big medico-economic issue. Indeed, savings will depend on penetration rate of biosimilars on the biologics market. Like generics, biosimilars are unknown by the general population and patients reluctance appears to be an obstacle to the diffusion of these therapeutics.

**Objectives:** To assess patients' knowledge, information and concerns about biosimilars and to identify levers and obstacles to adherence to biosimilars prescription.

**Methods:** National cross-sectional study assessing information, knowledge and concerns about biosimilars of french patients treated for a rheumatism (whether they were treated by a bDMARDs or not). The data were collected from march to july 2017 by an online assessment.

**Results:** 629 patients answered the assessment. 43% knew the definition of biosimilars. 65% felt insufficiently informed about biosimilars. The principal sources of information were the rheumatologist and the patient associations. 44% of patients treated with a biosimilar were not informed before they received a biosimilar. Patients concerns focused on molecular structure (46%), efficacy (60%) and tolerance (57%) comparatively to originator bDMARDs.

Receiving information about biosimilars and understanding the definition of biosimilarity were two characteristics associated with better adherence to biosimilars. The rheumatologist was considered the most influent source of information about biosimilar. Patients trust him concerning the decision to switch from the originator biologic to its biosimilar. Patient were reluctant to substitution by the pharmacist (2%).

**Conclusions:** Biosimilars are largely unknown by french patients at present. Information seems to be instrumental in patient adherence to biosimilars and in the preservation of the therapeutic relationship.

**FRI0127 OPEN-LABEL NON-MANDATORY TRANSITIONING FROM ORIGINATOR ETANERCEPT TO BIOSIMILAR SB4: 6-MONTH RESULTS FROM A CONTROLLED COHORT STUDY**

L. Tweehuysen<sup>1</sup>, V.J.B. Huiskes<sup>2</sup>, B.J.F. van den Bemt<sup>2,3</sup>, J.E. Vriezekolk<sup>1</sup>, S. Teerenstra<sup>4</sup>, F.H.J. van den Hoogen<sup>1,5</sup>, C.H. van den Ende<sup>1,5</sup>, A.A. den Broeder<sup>1,5</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pharmacy, Sint Maartenskliniek; <sup>3</sup>Pharmacy; <sup>4</sup>Radboud Institute for Health Sciences, department for Health Evidence; <sup>5</sup>Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands

**Background:** Open-label mandatory transitioning to a biosimilar has no impact on disease activity in inflammatory rheumatic diseases.<sup>1</sup> In light of shared treatment decision-making between patients and physicians, non-mandatory transitioning might be preferable above mandatory transitioning. First attempts with non-mandatory transitioning unfortunately showed suboptimal acceptance and persistence rates to a biosimilar.<sup>2</sup>

**Objectives:** To evaluate the effects of non-mandatory transitioning from originator etanercept (ENB) to biosimilar etanercept (SB4) on drug survival and effectiveness in a controlled cohort study of patients with an inflammatory rheumatic disease.

**Methods:** In 2016, 642 ENB treated patients were asked to transition to SB4 by a structured communication strategy with opt-out option. Consenting patients were eligible for the current study [BIO-SPAN]. ENB treated patients in 2014 were recruited as historical cohort. Drug survival was compared by Cox regression analyses adjusting for age, gender, diagnosis, ENB treatment duration, ENB dose interval, csDMARD and CRP, using a robust variance estimator to account for repeated subjects. Adjusted differences in CRP, DAS28-CRP and BASDAI change over 6 months were assessed.

**Results:** 635 (99%) patients agreed to transition to SB4 of whom 625 patients (433 RA, 128 PsA, 64 axSpA) were included in the transition cohort. Additionally, 600 patients were included in the historical cohort. Crude 6 months retention rates of SB4 in the transition cohort and ENB in the historical cohort were: 90% (95%CI 88%-93%) vs 92% (95%CI 90%-94%). The transition cohort had a significantly higher relative risk of discontinuation (adjusted HR 1.57, 95% CI 1.05-2.36). Reasons for discontinuing SB4 (n=60) and ENB (n=46) were: lack of effect (43% vs 61%), adverse events (47% vs 28%), malignancy (3% vs 4%), pregnancy (4% vs 4%), other (3% vs 3%). In the transition cohort, 17 patients restarted ENB, 32 patients switched to another biologic and 11 patients maintained biologic-free. DAS28-CRP, BASDAI and CRP were similar between baseline and month 6. Compared with the historical cohort, the transition cohort had a smaller decrease in CRP (adjusted diff 1.8 (95%CI 0.3-3.2)) and DAS28-CRP (adjusted diff 0.15 (95%CI 0.05-0.25)) over 6 months.

**Conclusions:** Open-label non-mandatory transitioning from ENB to SB4 using a structured communication strategy showed a slightly lower persistence rate and smaller decreases in disease activity compared with a historical cohort, but these differences were considered as not being clinically relevant. The acceptance and persistence rates of SB4 in our transition cohort were similar to those of mandatory transitioning. Since mandatory transitioning is not acceptable in many countries, the use of a communication strategy which might optimise acceptance and persistence rates of non-mandatory transitioning seems attractive.

**Background:** Intravenous golimumab (IV GLM) is approved for treatment of adults w/rheumatoid arthritis (RA), psoriatic arthritis (PsA) and ankylosing spondylitis (AS).

**Objectives:** To present the integrated safety data from three Phase 3 studies of IV GLM in patients (pts) w/RA, PsA and AS up to 24 weeks (wks). Safety outcomes in pts receiving concomitant methotrexate (MTX) and low-dose oral corticosteroids (CS) were assessed when used in treatment of the indicated disease.

**Methods:** Integrated safety data from Phase 3 double-blind placebo-controlled trials (RA [GO-FURTHER], PsA [GO-VIBRANT] and AS [GO-ALIVE]) were analysed up to wk24. In general, pts received either IV PBO or IV GLM (2 mg/kg) at 0, 4, 12, and 20 wks. PBO pts crossed over to GLM at wk24 except RA pts randomised to PBO who met early escape criteria crossed over at wk16 and AS pts randomised to PBO, who crossed-over at wk16. Data before crossover are presented. Infusion reactions, infections, serious infections, serious adverse events (SAEs), death, and antidrug antibodies (ADAs) were evaluated.

**Results:** Overall, 740 and 539 pts were randomised to IV GLM and PBO groups, respectively. The % of IV GLM vs PBO pts reported the following across studies: infusion reactions (2.8 vs 0.2); SAEs (3.8 vs 2.4); infections (23.8 vs 17.3); serious infections (0.8 vs 0.4) and malignancies (0.1 vs 0.4). No deaths occurred in IV GLM group through wk24. Pts on IV GLM (n=574) vs PBO (n=391) w/concomitant MTX had similar proportions of serious infections (0.9 vs. 0.6). In IV GLM (n=349) vs PBO (n=224) pts who received CS, serious infections were 1.1% vs 0.9%; in pts who did not receive CS, serious infections were 0.5% vs 0%. In IV GLM pts w/ normal ALT at baseline, 30% had postbaseline ALT elevation w/concomitant MTX vs 28% w/o. CS use had inconsistent effect on ALT elevations. Overall incidence of ADAs via drug tolerant assay was 20% (19% w/ MTX and 25% w/o MTX) through wk20 across RA, PSA and AS studies.

\*w/drug tolerant assay

**Conclusions:** IV GLM demonstrates the expected safety profile across RA, PSA and AS clinical trials in the PBO-controlled period. Differences between studies may be related to age, use of concomitant medications and disease indication.

### FRI0129 SWITCH BETWEEN REFERENCE ETANERCEPT (ETN) AND GP2015, AN ETANERCEPT BIOSIMILAR, DID NOT IMPACT EFFICACY AND SAFETY IN PATIENTS WITH MODERATE-TO-SEVERE RHEUMATOID ARTHRITIS: 48-WEEK RESULTS FROM THE PHASE 3 EQUIRA STUDY

M. Matucci-Cerinic<sup>1</sup>, H. Schulze-Koops<sup>2</sup>, M. Buch<sup>3</sup>, A. Kavanaugh<sup>4</sup>, Y. Allanore<sup>5</sup>, E.J. Kucharz<sup>6</sup>, G. Babic<sup>7</sup>. <sup>1</sup>University of Florence, Florence, Italy; <sup>2</sup>Ludwig-Maximilians-University, Munich, Germany; <sup>3</sup>University of Leeds, Leeds, UK; <sup>4</sup>UC San Diego School of Medicine, La Jolla, California, USA; <sup>5</sup>Cochin Hospital, Paris Descartes University, Paris, France; <sup>6</sup>Medical University of Silesia, Katowice, Poland; <sup>7</sup>Hexal AG, a Sandoz company, Holzkirchen, Germany

**Background:** GP2015 is an etanercept biosimilar. It has shown an equivalent efficacy, and comparable safety and immunogenicity to ETN in patients with chronic plaque-type psoriasis.<sup>1</sup>

**Objectives:** To compare the efficacy and safety of GP2015 versus ETN in patients with moderate-to-severe rheumatoid arthritis (RA) and evaluate the effects of switching from ETN to GP2015.

**Methods:** EQUIRA was a 48 week, randomised, double-blind, Phase 3 study. The primary endpoint was equivalent change from baseline (BL) in DAS28-CRP at Week 24. Patients ≥18 years with active RA ACR 1987 or ACR<sup>EULAR 2010</sup> criteria for ≥6 months before BL and active disease defined as DAS28-CRP ≥3.2 and CRP >5 mg/L or ESR ≥28 mm/h and inadequate response to methotrexate (MTX) were randomised 1:1 to 50 mg GP2015 or ETN subcutaneously once weekly for 24 weeks (Treatment period 1). Patients with at least moderate EULAR response at Week 24 either continued GP2015 treatment or, in the ETN group, were switched to receive 50 mg GP2015 up to 48 weeks (Treatment period 2 [TP2]). All patients continued to receive concomitant MTX (10–25 mg/week) at a stable dose and folic acid. Efficacy outcome measures included change in DAS28-CRP, EULAR and ACR20/50/70 responses.

**Results:** Baseline characteristics were comparable between the GP2015 (n=186) and ETN (n=190) groups. The primary endpoint for equivalence was met.<sup>2</sup> The mean change in DAS28-CRP from BL to Week 48 was comparable between the continued and switched to GP2015 groups (TP2 per-protocol set; figure 1). At Week 48, the EULAR and ACR 20/50/70 response rates were comparable between the two groups (table 1). In TP2, treatment-emergent adverse events (AEs) occurred in 42.9% vs 38.0% patients in the continued GP2015 (n=175) vs the switched (n=166) groups; serious AEs occurred in 2.3% vs 2.4% patients (TP2 safety set). Injection site reactions occurred in 6 (3.6%) patients in the switched group but none in the continued GP2015 group. In TP2, 4 (2.4%) patients in the continued GP2015 group had single-event, very low titer, non-neutralising antidrug antibodies detected.

**Abstract FRI0129 – Table 1.** Efficacy response over 48 weeks, TP2 per-protocol set (W=week)

Variables	Time	Continued GP2015 n=148	Switched to GP2015 n=131
EULAR good response, n (%)	W48	80 (54.4)	67 (51.9)
EULAR moderate response, n (%)	W48	61 (41.5)	57 (44.2)
ACR20 response, n (%)	W4	70 (47.9)	70 (53.8)
	W12	114 (78.1)	100 (76.9)
	W24	132 (89.8)	122 (93.1)
	W36	128 (87.7)	114 (87.0)
	W48	131 (89.1)	108 (82.4)
ACR50 response, n (%)	W4	19 (13.0)	26 (20.0)
	W12	48 (32.9)	61 (46.9)
	W24	93 (63.3)	96 (73.3)
	W36	90 (61.6)	83 (63.4)
	W48	93 (63.3)	86 (65.6)
ACR70 response, n (%)	W4	6 (4.1)	6 (4.6)
	W12	18 (12.3)	24 (18.5)
	W24	50 (34.0)	60 (45.8)
	W36	47 (32.2)	50 (38.2)
	W48	54 (36.7)	55 (42.0)

**Abstract FRI0129 – Figure 1.** Change from Baseline in DAS28-CRP up to Week 48 (TP2 per-protocol set)

**Conclusions:** The efficacy of GP2015 was comparable to that of ETN. Moreover, the switch from ETN to GP2015 did not impact on efficacy and safety of etanercept in patients with moderate-to-severe RA.

**FRI0130** **CERTOLIZUMAB PEGOL EXPOSURE DURING PREGNANCY IN WOMEN WITH RHEUMATOID ARTHRITIS: EVALUATION OF THE LONG-TERM NEWBORN OUTCOMES**

M. Meroni<sup>1</sup>, M. De Santis<sup>1</sup>, M. Caprioli<sup>1</sup>, A. Ceribelli<sup>1</sup>, N. Isailovic<sup>1</sup>, P. Rossi<sup>2</sup>, M. Cutolo<sup>3</sup>, C. Selmi<sup>1,4</sup>. <sup>1</sup>Internal Medicine Dept., *Rheumatology and Clinical Immunology, Humanitas Research Hospital, Rozzano (MI)*; <sup>2</sup>Internal Medicine Dept., *Rheumatology Unit, A.O. S.S. Antonio e Biagio e Cesare Arrigo, Alessandria*; <sup>3</sup>Internal Medicine Dept., *Research Laboratory and Academic Division of Rheumatology, University of Genoa, Genoa*; <sup>4</sup>Biometra Department, *University of Milan, Milan, Italy*

**Background:** Increased TNF alpha (TNF $\alpha$ ) levels have been associated to pregnancy complications such as intra-uterine growth retardation and fetal loss. Even if pregnancy has classically been considered as having a positive impact on RA, disease flares potentially leading to poor obstetrical outcomes are not uncommon, raising the challenge of RA management in the early stages of pregnancy. Among TNF $\alpha$  inhibitors indicated for rheumatoid arthritis (RA), the use of certolizumab pegol (CTZ) has been reported as safe during pregnancy. As such, CTZ is allowed during pregnancy as provided by the factory-issued product's sheet.

**Objectives:** To assess the CTZ use safety during RA pregnancies, including maternal-fetal outcomes.

**Methods:** We retrospectively evaluated twelve women with RA, fulfilling the 2010 ACR/EULAR criteria, who had been exposed to CTZ throughout pregnancy. All women had signed an informed consent prior to treatment initiation.

**Results:** All cases were free from any potentially teratogenic drug, stopped at least 6 months before conceiving. Due to the underlying disease activity, and thanks to the approval for CTZ to be continued throughout the whole pregnancy, we carried on the treatment. Mean maternal age at conception was 31.6 $\pm$ 4.0 months; mean disease duration dated of 51 $\pm$ 26 months. All patients were on low-dose daily oral prednisone ranging from 2.5 to 5 mg; four subjects were on sulfasalazine 500 mg TID and four others on hydroxychloroquine 200 mg TID. We observed 12 singleton pregnancies; 8/12 mothers were primiparous. Mean gestational duration was 37 $\pm$ 3 weeks and mean birth weight 3.037 $\pm$ 0.58 grams. No stillbirths or fetal deaths were recorded. Five patients experienced elective caesarean section, while the others had vaginal delivery (four labour were induced by intravenous oxytocin; no dystocic births were reported). Mean APGAR scores after 1, 5 and 10 min from delivery were, respectively, 8 $\pm$ 2; 8 $\pm$ 1 and 9 $\pm$ 1. No obstetric, perinatal or neonatal complications were observed. Eight/12 newborns were breastfed. After a 12 months observational gap, all babies were healthy and the development index above the 75th percentile. All children underwent the Italian scheduled vaccine program, without complications. Their antibody vaccine response is nowadays being investigated by our Research team.

**Conclusions:** The data from our case series confirm the safety of CTZ administration during pregnancy in women with RA, regarding both the mothers and the offspring. No infection rate increase, neither major maternal-fetal issue were reported. The higher caesarean section rate in our patients, in comparison to the average of northern Italy (20%), could have a iatrogenic explanation, as suggested by the fact that all had been scheduled ahead of time. Similarly, the relative low rate of breastfeeding could be justified by the lack of information given to mothers. Further large data collection and perspective, controlled studies are needed to confirm this statement.

**FRI0131** **POTENTIAL FACTORS ASSOCIATED WITH LONG-TERM CONTINUATION OF ETANERCEPT**

M. Kamiya<sup>1</sup>, N. Okada<sup>2</sup>, H. Kikuchi<sup>3</sup>, S. Soen<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery and Rheumatology, *Kindai University Nara Hospital, Ikoma-City*; <sup>2</sup>Department of Orthopaedic Surgery, *Sumoto Itsuki Hospital, Sumoto-City*; <sup>3</sup>Department of Orthopaedic Surgery, *Kindai University Sakai Hospital, Sakai-city, Japan*

**Background:** With the advent of biologic agents, it has become possible to prevent progression of symptoms and joint destruction in rheumatoid arthritis (RA). However, less than half of patients achieve remission. The patient subgroup that benefits from a specific biologic agent remains unclear. Etanercept has been repeatedly reported to have a high long-term continuation rate, and can also be tapered once the therapeutic goal has been achieved. Identification of a patient

subgroup that benefits from long-term use of etanercept would not only benefit the patients but would also reduce healthcare costs.

**Objectives:** The purpose of this study was to evaluate the characteristics of patients who benefited from long-term use of etanercept and patients who discontinued the drug due to loss of efficacy using our hospital records, and evaluated factors that may predict the difference in efficacy.

**Methods:** We compared RA patients who continued etanercept treatment for at least 3 years, without interruption for 3 months or longer for reasons other than remission, including patients who switched from other biologics (continuation group), and patients who discontinued treatment within 3 years of treatment initiation due to loss of efficacy (discontinuation group). All patients were treated at our hospital before October 31, 2017. Multiple regression analysis was used to determine factors that may predict long-term etanercept efficacy, using 10 patient background characteristics, including age at initiation of etanercept and DAS28ESR, as explanatory variables.

**Results:** At the time of evaluation, the 3 year continuation rate of etanercept by the Kaplan-Meier method was 49.7%. Reasons for discontinuation included adverse events (33.3%), loss of efficacy (50%), and patient preference (17.3%). The continuation group comprised 87 cases, including 5 cases where etanercept was discontinued due to remission. Initial dose was 50 mg, and relative dose intensity was 0.78 (95% confidence interval 0.66–0.89). The discontinuation group included 51 cases. Regarding patient characteristics at the time of etanercept initiation, age (continuation group 60.1 vs. discontinuation group 66.7, p=0.019), number of previously used biologics (continuation group 1.24 vs. discontinuation group 1.45, p=0.016), and disease duration (continuation group 110.2 months vs. discontinuation group 74.2 months, p=0.035) were statistically significant with  $\alpha=0.05$ , suggesting potential utility in predicting long-term response. In contrast, combination therapy with methotrexate (p=0.259), rheumatoid factor, or anti-cyclic citrullinated peptide antibody positivity (p=0.086), and DAS28ESR (p=0.056) were not statistically significant.

**Conclusions:** Although this was a retrospective study, the results showed that young RA patients who have previously used few biologics, with long disease duration, may be more likely to benefit long-term from etanercept without loss of efficacy.

**Disclosure of Interest:** None declared

**Background:** Biologics are effective for improving disease activity in patients with rheumatoid arthritis (RA). However, improved disease activity of RA alone does not always lead to high patient satisfaction.

**Objectives:** We evaluate which factors among items of disease activity and health status are correlated with improvement of patient satisfaction in patients with RA treated with biological agent.

**Methods:** Patients with RA who were planning to be treated with tocilizumab (TCZ) were enrolled in this study. Satisfaction, disease activity, and health status were assessed at week 0 and week 24 of TCZ therapy. Disease activity was evaluated using SJC, TJC, PGA, EGA and CDAl. Pain was also assessed using Visual Analogue Scale (VAS). Satisfaction and health status were assessed using the patient satisfaction score and the 5 components of the Arthritis Impact Measurement Scale 2 (AIMS-2).

Multiple linear regression analysis was used to assess the correlation between changes in satisfaction, disease activity and health status adjusted for CDAl at week 0. Also, Wilcoxon signed rank test was used to evaluate effect of TCZ on satisfaction, disease activity, and health status.

**Results:** Nineteen patients (male/female: 4/15) were evaluated. Patients' data at baseline were as follows: mean of age (51.3), disease duration (7.6 years), SJC (12.2), TJC (9.6), PGA (47.9 mm), EGA (51.4 mm), CRP (2.9 mg/dl) and CDAl (10.2), respectively. SJC, TJC, PGA, CDAl and RA-pain showed a statistically significant decrease at week 24 compared to the baseline (p<0.001, for each of all items). Out of the 5 components of AIMS-2, "physical", "symptom", "role" and "affect" improved statistically significantly at week 24 compared to the baseline (p<0.0001, p=0.0179, p<0.0005, p=0.0056, respectively), while there was no statistically significant improvement for "social interaction". Patient satisfaction was also statistically significantly higher compared to the baseline (p=0.00038).

After adjusting for CDAl at week 0, the change in satisfaction from week 0 to week 24 showed statistically significant correlation with changes in PGA and pain-VAS (all p-values<0.05), but not with changes in TJC, SJC EGA. Regarding

health status, the change in patient satisfaction adjusted for CDAI at week 0 was statistically significantly correlated with changes in "symptom" and "affect" (all  $p$ -values  $< 0.05$ ). However, there were no statistically significant correlations between change in patient satisfaction and change in "physical", "role", and "social interaction".

**Conclusions:** Satisfaction was correlated with pain, PGA and psychological state in patients with RA treated with tocilizumab. On the other hand, satisfaction was not correlated with TJC, SJC and EGA. In other words, it appears that patient satisfaction is more closely linked with how symptoms are experienced physically and mentally. Further research into specific factors influencing the patients' experience could shed more light on conditions for improving patients' satisfaction and QOL.

**Disclosure of Interest:** None declared

### FRI0133 CENTRAL ROLE OF TOCILIZUMAB IN FIBROBLAST DOMINATED MODELS OF INFLAMMATORY AUTOIMMUNE ARTHRITIS

M.A. Nielsen, B. Deleuran, T.W. Kragstrup. *Biomedicine, Aarhus University (AU), Aarhus, Denmark*

**Background:** Immune mediated inflammatory arthritis including rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA) all characterised by joint synovitis. Disease-modifying antirheumatic drugs (bDMARDs) targeting specific components of the pathogenesis have radically improved the treatment of the diseases. However, a fair proportion of patients are non-responders.

Today, the first choice of DMARD is dependent on market pricing, regardless of the immunological target. This is due to the rather similar efficacy profile of the different DMARDs. Therefore, there is a need for stratification of patients suffering from Immune mediated inflammatory arthritis in order to reduce the fraction of DMARD non-responders.

**Objectives:** The objective of this study was to study the effects of various DMARDs on different synovial cell subsets using several human *ex vivo* models of immune mediated inflammatory arthritis. This could potentially guide future studies of personalising DMARDs in these diseases.

**Methods:** Synovial fluid was obtained from a study population of patients with active rheumatoid arthritis (RA) or peripheral spondyloarthritis (SpA). Synovial fluid mononuclear cells (SFMCs) containing primarily synovial monocytes and lymphocytes cultured for 48 hours ("Macrophage and Lymphocyte model") were used to study the effect of different biological agents on secretion of monocyte chemoattractant protein-1 (MCP-1) ( $n=14$ ). Further, fibroblast-like synovial cells (FLSs) were co-cultured with autologous PBMCs ("FLS model") to study the effects of the same biological agents ( $n=6$ ) in cultures dominated by synovial FLSs. Finally, SFMCs cultured for 21 days ("Osteoclast model") were studied to assess the effects on inflammatory osteoclastogenesis ( $n=10$ ) measured by tartrate-resistant acid phosphatase (TRAP). The DMARDs investigated are shown in table 1.

**Results:** "Macrophage and Lymphocyte model"; In SFMCs cultured for 48 hours, all DMARDs included, except anakinra, had the ability to decrease the production of MCP-1. The two TNF inhibitors (adalimumab and etanercept) ( $p < 0.05$  and  $p < 0.01$ ) and baricitinib ( $p < 0.05$ ) had the most pronounced effects and reduced the production of MCP-1 by approximately 25%. Tocilizumab had in this culture a non-significant reduction of MCP-1 production.

"FLS model"; In the FLS+PBMCs cultured for 48 hours, tocilizumab ( $p < 0.001$ ) and the two JAK inhibitors (tofacitinib and baricitinib,  $p < 0.05$  and  $p < 0.05$ ) were exclusive in decreasing the cytokine production of MCP-1 by around 50%.

"Osteoclast model"; In SFMCs cultured for 21 days, only the two TNF inhibitors, adalimumab and etanercept were able to significantly reduce the secretion of TRAP from adherent macrophage like synovial cells by roughly 25% ( $p < 0.01$ ,  $p < 0.001$ ).

#### Abstract FRI0133 – Table 1

##### Generic name:

Adalimumab  
Etanercept  
Tocilizumab  
Anakinra  
Ustekinumab  
Secukinumab  
Tofacitinib  
Baricitinib

**Conclusions:** This study reveals that most DMARDs have effects in the "Macrophage and Lymphocyte model" whereas tocilizumab, tofacitinib and baricitinib were superior in the "FLS model" and only the two TNF inhibitors were effective in

the "Osteoclast model". The findings in the "FLS model" reveals a possible beneficial effect of tocilizumab and JAK inhibitors to patients with fibroblast dominated arthritis. This study could potentially guide future studies of personalising DMARDs to treat immune mediated inflammatory arthritis.

**Background:** TURKIBIO registry is the Turkish version of Danish DANBIO rheumatologic database which has been established in 2011. Demographics and previous or current treatment with conventional (csDMARD) and targeted synthetic (tsDMARD), and biological DMARDs (bDMARDs) were collected.

**Objectives:** We aimed to investigate the efficacy and safety status of methotrexate (MTX) vs. leflunomide (LEF) use as a concomitant treatment with bDMARDs and tsDMARD in this registry.

**Methods:** Frequencies of achievement of remission or remission +low disease activity (LDA) at the 6th month of bDMARD or tsDMARD treatment were compared between patients who were on these medications with MTX vs. LEF as a concomitant treatment. Drug survival and switch rates of bDMARDs and tsDMARD treatments either with MTX or LEF were compared. The adverse effects with MTX and LEF concomitant use were evaluated as well.

**Results:** The study included 725 bDMARD or tsDMARD receiving RA patients from 8 participating centres of the TURKIBIO registry. Of these patients, 462 (63.7%) were receiving concomitant MTX and 263 (36.3%) LEF. Demographic findings are given in the table 1. Achievement of remission and remission +LDA at the 6th month of bDMARD or tsDMARD initiation was similar in concomitant MTX vs LEF groups (51.4% vs. 53%,  $p=0.683$ ). When each bDMARD and tsDMARD was evaluated separately, achievement of remission were again similar in MTX and LEF concomitant users (TNFi: 53% vs. 54%; ABA: 50% vs. 59%; RTX: 53% vs. 61%; TCZ: 42% vs. 35%;  $p > 0.05$  for all). For TOFA, although remission +LDA rate was numerically higher in MTX concomitant group than LEF group (42% vs. 21%), the difference was not statistically significant due to the smaller sample size of TOFA ( $n=33$ ). The results were similar for all DMARD groups when remission was evaluated alone. Drug survival ( $17 \pm 12$  vs.  $16 \pm 11$  months,  $p > 0.05$ ) and drug discontinuation (42,2 vs 38,  $p > 0.05$ ) rates of bDMARDs or tsDMARD were also not different in MTX vs. LEF concomitant users. Adverse effects rate (19.5% vs 20.5%,  $p > 0.05$ ) were similar between MTX vs. LEF concomitant users as well.

#### Abstract FRI0134 – Table 1. Demographic findings of patients.

Sex, n (%)	Female	596 (82,2)
	Male	129 (17,8)
Age, Median (Q1-Q3)		55 (45-62)
Age, Mean±SD		54±13
Disease duration, Orttan (Q1-Q3)		12 (8-17)
Disease duration, Ortt±SD		13±8
Biological and targeted synthetic drugs, n (%)	TNFi*	354 (48,8)
	RITUXIMAB	144 (19,9)
	ABATACEPT	127 (17,5)
	TOCILIZUMAB	61 (8,4)
	TOFACITINIB	36 (5,0)
	ANAKINRA	3 (0,4)
Biological+MTX, n (%)		462 (63,7)
Biological+LEF, n (%)		263 (36,3)

\*TNFi: ETANERCEPT, ADALIMUMAB, CERTOLIZUMAB, GOLIMUMAB, INFILIXIMAB, REMSIMA.

**Conclusions:** Achievement of remission or remission +LDA was not different with the concomitant use of MTX vs. LEF with any bDMARD or tsDMARD treatment in RA patients with a similar safety profile. LEF might be an alternative as a concomitant DMARD in MTX-intolerant RA patients initiating bDMARDs or tsDMARD.

### FRI0135 HAVE PREVALENCE OF JOINT SURGERY DECREASED WITH THE USE OF BIOTHERAPY IN RHEUMATOID ARTHRITIS?

O. Saidane, M. Sellami, R. Barhoumi, A. Ben Tekaya, H. Ajlani, R. Tekaya, I. Mahmoud, L. Abdelmoula. *Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia*

**Background:** Biological response modifiers have greatly expanded therapeutic arsenal of rheumatoid arthritis (RA) leading to a better control of inflammation, a reduced long-term complications and a prevention of joint damage.

**Objectives:** Our objective was to assess the impact of use of biologics on joint surgery during RA.

**Methods:** This is a retrospective study including patients with RA according to American College of Rheumatology (1987) followed- over 15 years period [2000–2014]. We excluded patients who underwent joint surgery without direct relevance to RA. The significance level was set at 0.05.

**Results:** A total of 500 RA patients (422 women and 78 men) were enrolled in this period. The mean age was 53.3 years (21–83) and the mean disease duration was 12 years (2–40). Rheumatoid factor was positive in 71.4% cases. A high disease activity was noted at diagnosis with a mean disease activity score of 5.90 ± 1.38. The mean Health Assessment Questionnaire index was 1.62 [0.2 à 3]. All patients received at least 2 conventional disease-modifying antirheumatic drugs, one of which was methotrexate. Twenty seven per cent of RA patients (135 patients) received biologics: 35 patients received Rituximab (7%) and 100 patients (20%) received anti TNF  $\alpha$  (infliximab, etanercept and adalimumab in 10%, 6.8% and 3.2% respectively). The trend curve of biologics use showed a linear increase with spikes of use in 2008, 2011 and 2014. A surgical act was considered necessary in 59 cases (11.8%) mainly total knee arthroplasty (56%). The mean duration between the onset of RA and surgery was 7.02 (1–33). Patients who received biologics had less joint surgery without significant association ( $p=0.350$ ). The joint surgery showed a decrease in the number of procedures from 2004, concomitantly with promoting biologics.

**Conclusions:** Our study concluded that joint surgery was less frequent in RA patients who received biologics without a significant association.

### FRI0136 PERSISTENCE OF MONOTHERAPY OR COMBINATION THERAPY WITH DISEASE-MODIFYING AGENTS IN PATIENTS WITH PSORIATIC ARTHRITIS IN A REAL-WORLD SETTING

P.J. Mease<sup>1</sup>, N.A. Accortt<sup>2</sup>, S. Rebello<sup>3</sup>, C. Etzel<sup>3</sup>, R.W. Harrison<sup>3</sup>, G.A. Aras<sup>2</sup>, M. M.F. Gharaibeh<sup>2</sup>, J.D. Greenberg<sup>3</sup>, D.H. Collier<sup>2</sup>. <sup>1</sup>Swedish Medical Center and University of Washington, Seattle; <sup>2</sup>Amgen Inc., Thousand Oaks; <sup>3</sup>Corrona LLC, Waltham, USA

**Background:** Until recently, treatment for moderate to severe psoriatic arthritis (PsA) mainly focused on conventional synthetic disease-modifying antirheumatic drugs (csDMARDs) and tumour necrosis factor inhibitors (TNFi). However, the persistence of TNFi alone or in combination with csDMARDs is not well understood.

**Objectives:** To assess real-world treatment patterns among patients with PsA receiving TNFi monotherapy, csDMARD monotherapy, or TNFi and csDMARD combination therapy.

**Methods:** This retrospective study utilised data from patients with PsA aged  $\geq 18$  years, enrolled in the Corrona PsA registry between March 21, 2013, and July 31, 2017, treated with a TNFi and/or csDMARD (index therapy), and with  $\geq 6$  months of follow-up time. Patients were stratified by prevalent (initiation before enrollment) or incident (initiation after enrollment) therapy use; cohorts were based on index therapy: TNFi monotherapy, csDMARD monotherapy, or combination therapy. Outcomes of interest were the percentage of patients who were persistent on their index therapy or had a therapy change (discontinued, switched, or restarted) 12 months after the index visit.

**Results:** There were 1266 patients in this study: 1144 prevalent and 122 incident (table 1). Patient characteristics at the index date were similar among patients; however, csDMARD monotherapy patients had higher disease activity than either TNFi group. Among prevalent patients, TNFi monotherapy patients were likely to be female (59%) and younger (51.9 years), nearly all patients had psoriasis, and BSA was similar and  $\leq 5$ . At month 12, among patients with a follow-up visit within the 9–15-month window, the vast majority of prevalent patients and half of incident patients were persistent on their index therapy, and one quarter to one third of incident patients discontinued or switched therapy (table 1).

Characteristic at index date	Prevalent TNFi mono N=421	Prevalent csDMARD mono N=347	Prevalent combi N=375	Incident TNFi mono N=43	Incident csDMARD mono N=56	Incident combi N=23
Sex (female), n (%)	244 (58)	158 (46)	165 (50)	15 (44)	24 (43)	11 (48)
Age, mean (SD)	51.9 (12.3)	57.7 (13.3)	53.9 (11.3)	50.7 (14.0)	55.8 (14.1)	53.3 (13.5)
BMI (obese), n (%)	202 (51)	182 (54)	204 (66)	18 (46)	37 (70)	8 (47)
Current psoriasis, n (%)	366 (93)	300 (90)	312 (90)	35 (93)	48 (94)	15 (88)
HASQ, mean (SD)	0.2 (0.4)	0.3 (0.4)	0.3 (0.4)	0.3 (0.4)	0.3 (0.3)	0.4 (0.5)

DAS28 CRP, mean (SD)	2.4 (0.9)	2.7 (1.0)	2.8 (1.0)	3.0 (0.7)	3.4 (0.8)	2.8 (1.4)
Enthesitis, n (%)	74 (18)	52 (15)	75 (20)	14 (32)	8 (14)	3 (13)
Dactylitis, n (%)	27 (6)	25 (7)	12 (3)	7 (16)	14 (25)	4 (17)
BSA (%), mean (SD)	4.9 (8.7)	4.8 (9.3)	5.0 (11.1)	6.2 (8.8)	5.4 (8.9)	1.3 (2.1)
Psoriasis VAS, mean (SD)	5.6 (12.4)	8.1 (22.6)	7.2 (14.3)	11.9 (18.8)	5.9 (15.2)	10.3 (23.3)
History of biologic, n (%)	421 (100)	0	375 (100)	2 (5)	0	0
History of csDMARD, n (%)	132 (46)	347 (100)	369 (98)	13 (30)	0	13 (57)
Treatment pattern, n (%)						
Persistent						
patients with a follow-up visit within 9-15 month window	733/251 (92.8)	196/225 (87.1)	186/214 (86.9)	13/26 (50.0)	15/25 (42.9)	8/15 (53.3)
Time on drug (mo), mean (SD)	88.8 (46.4)	82.5 (78.1)	49.8 (37.7)	15.9 (5.4)	16.9 (8.7)	16.0 (5.0)
Discontinuation	3 (1.2)	8 (3.6)	17 (7.9)	5 (19.2)	9 (25.7)	4 (28.7)
Switch (to another biologic)	2 (0.8)	2 (0.9)	4 (1.9)	1 (3.8)	4 (11.4)	2 (13.3)
Restart	0	3 (1.3)	1 (0.5)	0	0	0

**Conclusions:** Most patients who were prevalent on therapy at the time of enrollment in Corrona remained persistent on their therapy for 12 months in this study, while roughly half of patients initiating therapy after enrollment remained persistent over the same period. Young, female patients were more likely to receive TNFi monotherapy; the TNFi monotherapy cohort was associated with the least disease activity. The incident group was not different from the prevalent group. Although the prevalent group is more likely to have patients who responded to treatment, the data suggest that most therapy changes occur within the first year of PsA treatment.

### FRI0137 EFFICACY, SAFETY AND IMMUNOGENICITY FROM WEEK 30 TO WEEK 54 IN A RANDOMISED, DOUBLE-BLIND PHASE III STUDY COMPARING A PROPOSED INFLIXIMAB BIOSIMILAR (PF-06438179/GP1111) WITH REFERENCE INFLIXIMAB

B. Alten<sup>1</sup>, V. Tseluyko<sup>2</sup>, T. Hala<sup>3</sup>, S. Mehmedagic<sup>4</sup>, M. Pileckyte<sup>5</sup>, E. Dokoupilová<sup>6</sup>, D. Jovic<sup>7</sup>, M. Rehman<sup>8</sup>, M. Zhang<sup>9</sup>, L. Sewell<sup>10</sup>, S. Hackley<sup>11</sup>, S. Salts<sup>9</sup>, C. Cronenberger<sup>12</sup>, K. Schumacher<sup>13</sup>, O. von Richter<sup>13</sup>, B. Batko<sup>14</sup>. <sup>1</sup>Schlosspark Klinik, Berlin, Germany; <sup>2</sup>Kharkiv Medical Academy of Postgraduate Education, Kharkiv, Ukraine; <sup>3</sup>Center for Clinical and Basic Research, Pardubice, Czech Republic; <sup>4</sup>Clinical Center University of Sarajevo, Sarajevo, Bosnia and Herzegovina; <sup>5</sup>Hospital of Lithuanian University of Health Sciences, Kaunas, Lithuania; <sup>6</sup>Medical Plus s.r.o., Uherske Hradiste, University of Veterinary and Pharmaceutical Sciences, Brno, Czech Republic; <sup>7</sup>University Clinical Centre of the Republic of Srpska, Banja Luka, Bosnia and Herzegovina; <sup>8</sup>Pfizer Inc., Andover, MA; <sup>9</sup>Pfizer Inc., La Jolla, CA; <sup>10</sup>Pfizer Inc., Cambridge, MA, USA; <sup>11</sup>Pfizer Ltd, Sandwich, UK; <sup>12</sup>Pfizer Inc., Collegeville, PA, USA; <sup>13</sup>Kandov Biopharmaceuticals, Holzkirchen, Germany; <sup>14</sup>J. Dietl Specialist Hospital, Krakow, Poland

**Background:** PF-06438179/GP1111 (GP1111) is an infliximab (IFX) biosimilar in development for the treatment of immune-mediated inflammatory diseases, including rheumatoid arthritis (RA). The efficacy, safety and immunogenicity of GP1111 and European reference IFX (IFX-EU) have been reported to be similar over 30 weeks (Wks).

**Objectives:** To evaluate the efficacy, safety and immunogenicity of GP1111 and IFX-EU with longer-term treatment, and after treatment transition from IFX-EU to GP1111.

**Methods:** A randomised, double-blind, parallel-group study compared GP1111 with IFX-EU in biologic-naïve, adult patients with moderate-to-severe active RA on a stable dose of methotrexate (MTX). Patients were randomised (1:1) to GP1111 or IFX-EU (3 mg/kg IV at Wks 0, 2, 6, and then every 8 wks, with one dose escalation to 5 mg/kg allowed at or after Wk 14 for inadequate responders)

for 30 weeks (treatment period 1). The primary endpoint was a  $\geq 20\%$  improvement in ACR response (ACR20) at Wk 14. At Wk 30 (treatment period 2 [TP2]), patients receiving IFX-EU were blindly re-randomised (1:1) to remain on IFX-EU or transition to GP1111 for 24 wks. Here we report longer-term efficacy, safety and immunogenicity data from Wks 30–54.

**Results:** 650 patients were randomised initially (GP1111, n=324; IFX-EU, n=326). At Wk 30, 566 patients entered TP2 (continued GP1111, n=280; continued IFX-EU, n=143; switched from IFX-EU to GP1111, n=143). ACR20 rates and DAS28-CRP scores were comparable between groups at all TP2 visits after re-randomisation in the TP2 population (figure 1). Incidences of TP2 treatment-emergent adverse events (AEs) (36.8%, 33.6%, and 37.8%), serious AEs (4.6%, 7.7% and 2.8%) and infusion-related reactions (3.2%, 8.4% and 4.2%) were comparable between the GP1111/GP1111, IFX-EU/IFX-EU, and IFX-EU/GP1111 groups, respectively. Pre-dose ADA rates at Wk 30 (TP2) were 47.1%, 53.8% and 45.5% for the GP1111/GP1111, IFX-EU/IFX-EU, and IFX-EU/GP1111 groups, respectively. Overall, post-dose ADA rates in TP2 were comparable between groups (52.1%, 60.1%, and 58.0% respectively).

**Abstract FRI0137 – Figure 1.** ACR20 response rate and change in DAS28-CRP score at Wk 30 and 54 for the overall population during TP2

**Conclusions:** Results from TP2 (Wks 30–54) continued to show the absence of clinically meaningful differences in efficacy, safety and immunogenicity between patients with RA remaining on GP1111 or IFX-EU, or when blindly switched from IFX-EU to GP1111.

**FRI0138 TREAT TO TARGET STRATEGY PLUS CERTOLIZUMAB IN COMPARISON TO CONTINUED, FIXED CSDMARD PLUS CORTICOSTEROIDS IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO CSDMARDS (REMISSION BY INTRA-ARTICULAR INJECTION PLUS CERTOLIZUMAB, THE RICE STUDY): A MULTI-CENTRE RANDOMISED CONTROLLED TRIAL**

R. Mueller<sup>1</sup>, M. Spaeth<sup>2</sup>, C. von Restorff<sup>3</sup>, C. Ackermann<sup>4</sup>, J. von Kempis<sup>1</sup>.

<sup>1</sup>Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen; <sup>2</sup>Division of Rheumatology, Spital Linth, Uznach; <sup>3</sup>Medical practice, Männedorf, Switzerland;

<sup>4</sup>Medical practice, Triesen, Liechtenstein

**Background:** Treatment of rheumatoid arthritis (RA) includes the use of conventional (cs) or targeted synthetic (ts) and biologic disease-modifying anti-rheumatic drugs (DMARDs) and oral or subcutaneous (SC) glucocorticoids (GC).

**Objectives:** We aimed to test the hypothesis that an improved outcome can be achieved by employing a treat to target (T2T) strategy optimising csDMARD, oral, and SC-GC treatment in parallel to a new onset certolizumab pegol (CZP) in RA patients with an incomplete response to csDMARD as compared to a conventional step up strategy with CZP.

**Methods:** We designed a randomised controlled trial in four specialised rheumatological units. 43 patients with active RA ( $\geq 6$  tender,  $\geq 6$  swollen joints, and ESR  $\geq 20$  mm/h or CRP  $\geq 7$  mg/L) despite csDMARD treatment for  $\geq 3$  months and

naïve to biologic DMARDs were randomly allocated either to CZP plus a treat to target strategy (T2T group, n=21) or add on of CZP to a fixed dose of the already established csDMARD with or without established GCs (fixed dose group, n=22). Patients of both groups received 400 mg CZP at week 0, 2, and 4 (loading dose), followed by 200 mg every 2 weeks. The T2T strategy consisted in a step up in, or to, SC-methotrexate (dose:  $15 \geq 20 \geq 25$  mg/week), followed by leflunomide (20 mg/d) and then by sulfasalazine ( $2 \times 1000$  mg/d). In parallel, oral GCs were initiated in the T2T group at 20 mg/d and tapered every 5 days (15–12.5–10–7.5–5–2.5–0 mg/d). The decision to take the next step in the DMARD modification and addition of oral GCs was taken depending on the achievement of LDA (low disease activity: DAS28  $< 3.2$ ) at the 4-weekly visits. Injections of up to five tender and/or swollen joints with triamcinolone (small joints 10 mg, intermediate 20 mg, and big joints 40 mg; max. 100 mg/visit) was allowed in the T2T group. The primary outcome measure was ACR 50 response after 24 weeks. The analysis was intention-to-treat.

**Results:** Three patients dropped out during the study (n=2 T2T, n=1 fixed dose). ACR 50 was achieved in 16 out of 21 T2T patients (76.2%) as compared to 8 out of 22 fixed dose patients (36.4%;  $\text{Chi}^2: 5.355, p=0.020$ ). ACR 20 and 70 responses were achieved in 90.5% and 71.4% of the T2T patients and 59.1% and 27.3% of the fixed dose patients, respectively ( $p=0.045$  and  $p=0.010$ , resp.). Mean reduction in DAS28 were significantly and HAQ-DI markedly greater in the T2T group than in the fixed dose group (DAS28:  $-3.9$  [SD 1.2] vs.  $-2.2$  [SD 1.5],  $p<0.0006$ ; HAQ-DI:  $-0.63$  [SD 0.58] vs.  $0.20$  [SD 0.67],  $p<0.14$ ). All but five of the T2T patients required only one modification of csDMARD and one additional course of oral GC. 10.2 joints (mean) were infiltrated with triamcinolone in the T2T group (av. dose 14.1 mg/injection). The adverse event rate was similar for both groups (T2T n=51; fixed dose n=55).

**Conclusions:** Treat to target management with optimisation of csDMARDs, oral and intra-articular glucocorticoids of RA patients in parallel to additional CZP treatment was safe and substantially improves disease activity and the patient related outcome HAQ-DI in comparison to additional CZP to a fixed dose of csDMARDs.

**Disclosure of Interest:** R. Mueller Grant/research support from: Unlimited grant by UCB pharmaceuticals, M. Spaeth: None declared, C. von Restorff: None declared, C. Ackermann: None declared, J. von Kempis: None declared

**FRI0139 COMPARATIVE SAFETY OF ABATACEPT IN RHEUMATOID ARTHRITIS WITH COPD: A REAL-WORLD POPULATION-BASED OBSERVATIONAL STUDY**

S. Suissa<sup>1</sup>, P. Ernst<sup>1</sup>, S. Dell'Aniello<sup>1</sup>, S. Shen<sup>2</sup>, T.A. Simon<sup>2</sup>. <sup>1</sup>McGill University, Montreal, Canada; <sup>2</sup>Bristol-Myers Squibb, Princeton, USA

**Background:** In the ASSURE trial (NCT00048932) comparing abatacept with placebo for the treatment of RA, there was an increased incidence of respiratory serious adverse events (SAEs; COPD exacerbation/worsening, bronchitis and pneumonia) in those receiving abatacept among the subgroup of 54 patients with a history of chronic obstructive pulmonary disease (COPD).<sup>1</sup>

**Objectives:** To assess whether patients with RA and a history of co-morbid COPD treated with abatacept in a real-world, observational setting, have an increased risk of respiratory SAEs compared with similar patients treated with other biologic (b)DMARDs or the targeted synthetic DMARD tofacitinib (tofa).

**Methods:** The Truven MarketScan<sup>®</sup> Commercial and Supplemental Medicare databases were used to identify adult patients diagnosed with RA and COPD who were treated with abatacept, another bDMARD or tofa between January 2007 and December 2015. Other bDMARDs included adalimumab, anakinra, certolizumab, etanercept, golimumab, infliximab, rituximab and tocilizumab. A prevalent new-user study cohort design<sup>2</sup> was used in which each new user of abatacept was time- and propensity score-matched to two new users of other bDMARDs or tofa. Patients were required to have  $\geq 6$  months of continuous health plan enrolment before cohort entry and were followed up until the end of enrolment in the database or 31 December 2015. Propensity scores of abatacept treatment were estimated from the baseline covariates using a conditional logistic regression model separately in incident new users and prevalent new users. Patients with score ranges common to both abatacept and the comparator cohorts were included. An as-treated analysis based on the Cox proportional hazard regression model was used to estimate the hazard ratios (HRs) of respiratory SAEs associated with abatacept compared with other bDMARDs or tofa, further adjusted for confounders found to be unbalanced despite matching on propensity scores.

**Results:** A total of 9746 patients with RA and COPD initiated bDMARD or tofa therapy and included 1807 new users of abatacept matched to 3547 new users of another bDMARD or tofa. The matched cohort was followed for up to 9 years (mean 2.0 years); 53% were incident users. For users of abatacept relative to other bDMARDs or tofa, the adjusted HRs (95% CI) of respiratory SAEs were: hospitalisation for COPD exacerbation: 0.57 (0.30, 1.05); hospitalisation for pneumonia/influenza: 1.39 (0.91, 2.12); outpatient pneumonia/influenza: 1.04 (0.85,

1.28) and outpatient bronchitis: 0.80 (0.57, 1.14). Results remained unchanged with sensitivity analyses.

**Conclusions:** In this real-world study of patients with RA and COPD, the incidence of pre-specified respiratory SAEs was not significantly increased in patients using abatacept compared with those using other bDMARDs or tofa. The safety signal based on the subgroup of 54 patients from the ASSURE trial could not be confirmed in this large and long-term cohort study of over 5000 patients.

### FRI0140 INDIVIDUALISED INFLIXIMAB TREATMENT: A TREATMENT STRATEGY BASED ON THERAPEUTIC DRUG MONITORING

S.W. Syversen<sup>1</sup>, G.L. Goll<sup>1</sup>, K.K. Jørgensen<sup>2</sup>, Ø. Sandanger<sup>3</sup>, J. Gehin<sup>4</sup>, C. Mørk<sup>5</sup>, T.K. Kvien<sup>1</sup>, J. Jahnsen<sup>2</sup>, N. Bolstad<sup>4</sup>, E.A. Haavardsholm<sup>1</sup>. <sup>1</sup>Rheumatology, Diakonhjemmet; <sup>2</sup>Gastroenterology, Akershus University Hospital; <sup>3</sup>Dermatology; <sup>4</sup>Laboratory Medicine, Oslo University Hospital, Oslo; <sup>5</sup>Dermatology, None, Lørenskog, Norway

**Background:** Infliximab (INX) and other targeted therapies have greatly improved the treatment of patients with RA, SpA and PsA, but a significant proportion of patients either do not respond sufficiently to therapy or loose efficacy over time. Recent advances in assay development have revealed an extensive individual variation in serum drug concentrations suggesting both under- and overtreatment of a substantial proportion of patients. Many patients develop anti-drug antibodies (ADAb) during therapy, contributing to reduced drug levels, inefficacy and adverse events. Therapeutic drug monitoring (TDM), i.e. individual dose adjustments according to serum drug levels, can probably increase effectiveness of treatment with INX and other biological drugs.

**Objectives:** To develop an individualised treatment strategy based on TDM in order to optimise efficacy of INX treatment.

**Methods:** The treatment strategy has been developed by the steering committee of the Norwegian DRUG Monitoring study (NOR-DRUM), based on a systematic literature review (SLR), unpublished data and expert opinion. A SLR was performed in May 2016 to identify the therapeutic range. In Norway neutralising ADAb are measured with an "in house" assay. For this assay, ADAb levels >50 µg/L are defined as "high" leading to a recommendation to switch therapy. This cut-off is based on own s-INX and ADAb data (Diakonhjemmet Hospital during 2015–2016) and clinical experience. The proposed strategy has been developed through a series of meetings in the project group consisting of national leading experts in this field (both clinicians experienced with TDM and laboratory physicians) and with additional input from international key experts in the scientific advisory board of the NOR-DRUM study.

Serum INX level (µg/ml)	(3.0) and high ADAb (>50 µg/L)	<3.0	3.0–3.5	3.6–8.0	8.1–38.0	>60.0
Action	Switch therapy, possibly to another TNFi	Increase dose by 2-2.5 mg/kg or by decreasing the dose interval by 2 weeks to a min of 4 weeks	Consider increasing dose	No action	Consider decreasing dose	Decrease dose
Guideline for action		Increase the dose by increasing the dose by 2-2.5 mg/kg to a max dose of 10 mg/kg or by decreasing the dose interval by 2 weeks to a min of 4 weeks	Consider increasing the dose based on clinical judgement and the patients factors given below*	Within target range. Continue with the same dose and dosing interval	Consider to decrease the dose based on clinical judgement and the patients factors given below*	Decrease the dose by increasing the dose interval by 2 weeks to a max of 30 weeks or by decreasing the given dose by 2-2.5 mg/kg

\*Patient factors to be considered when making the treatment decisions in the yellow zones: Disease activity and trend in disease activity, the trend of the trough level over time, previous drug interval changes, availability of alternative drug, diagnosis (RA patients are expected to have lower trough levels due to lower recommended dosing)

**Results:** The treatment strategy from infusion number 4 onwards is depicted in the figure 1. The therapeutic range for serum INX (through levels) is defined as 3–8 µg/ml (figure 1, green zone). During the induction phase (infusion 1–3) the recommendation is to keep the level >20 µg/ml at infusion 2 and >15 µg/ml at infusion 3. A guideline for action according to levels outside the therapeutic range is given in the figure 1. Dose modifications may be performed either as changes in doses or intervals as stated in the figure 1. If the patients develop high levels of ADAb the recommendation is to switch therapy.

**Conclusions:** An individualised treatment strategy based on TDM has the potential to optimise therapy with infliximab and other biological drugs by; 1) prevention of treatment failure by identification of patients with drug levels below the therapeutic range, 2) reduction of overtreatment, which predispose to side effects and increase costs, and 3) early identification of ADAb development, with the possibility to detect treatment failures prior to a clinical flare and to prevent hypersensitivity reactions. This approach has high face validity, and the effectiveness compared to regular care is being investigated in an ongoing randomised clinical trial, NOR-DRUM (NCT03074656).

### FRI0141 VACCINATION DECISIONS AND INCIDENCE OF NEONATAL INFECTIONS IN MOTHERS EXPOSED TO BIOLOGICALS DURING PREGNANCY

S.J. Bond<sup>1,2</sup>, L. Young<sup>1,2</sup>, K. Poulsen<sup>2</sup>, H.L. Barrett<sup>3</sup>, A.L. Taylor<sup>4,5</sup>, C. Barrett<sup>1,2</sup>. <sup>1</sup>University of Queensland; <sup>2</sup>Metro North, Queensland Health; <sup>3</sup>Mater Health, Brisbane; <sup>4</sup>Royal Perth Hospital; <sup>5</sup>University of Western Australia, Perth, Australia

**Background:** Rheumatologic diseases commonly affect women of childbearing age.<sup>1,2</sup> There is currently limited data available regarding the safety of vaccinations in infants after in utero exposure to biologics.

**Objectives:** To determine the vaccination decisions of mothers with rheumatologic diseases exposed to biologics during pregnancy and the incidence of serious neonatal infections after third trimester exposure.

**Methods:** All Australian women with inflammatory arthritis, exposed to biologics during the preconception, antenatal and/or postpartum periods, were invited to participate in the Pregnancy Exposed to Biological (PEB) study from May 2009 – Jan 2018. Recruitment was via direct invitation from patients treating rheumatologists, community groups, and via social media. Following self-referral to the study, retrospective data was collected, including biological exposure, vaccination history and the incidence of serious neonatal infections, defined as infection requiring hospitalisation.

**Results:** Preliminary data is available regarding 35 offspring from 28 mothers. 34 of 35 offspring were vaccinated. 29 received vaccinations in accordance with the Australian National Immunisation Program Schedule. 1 mother declined to immunise her infant due to personal preference.

13 infants were exposed to a tumour necrosis factor inhibitor (TNFi) during the third trimester. Of these, 4 had Rotavirus vaccine delayed from 2 to 4 months and 1 infant until 6 months. 1 infant did not receive the Rotavirus vaccine at 2 months due to exposure to a TNFi while breastfeeding. There were no incidences of serious neonatal infections.

**Conclusions:** Current guidelines recommend deferring live vaccines, such as rotavirus, until after 6 months if exposed to a biologic in the third trimester.<sup>3-5</sup> Compliance with these recommendations was only observed in one infant in our study. One infant received delayed Rotavirus vaccination due to concern about TNFi exposure during breastfeeding; this is not in keeping with current guidelines. Of the 12 infants exposed to a biologic during the third trimester who did not delay live vaccination until after 6 months, there were no incidents of serious neonatal infections, in keeping with the findings of current published case series.

**FRI0142 THE COMPARISON OF THE ULTRASONOGRAPHIC SYNOVIAL FINDINGS BETWEEN INTRAVENOUS ADMINISTRATION AND SUBCUTANEOUS INJECTION OF TOCILIZUMAB**

T. Okano<sup>1</sup>, K. Inui<sup>1</sup>, Y. Yamada<sup>1</sup>, K. Mandai<sup>1</sup>, K. Mamoto<sup>1</sup>, Y. Sugioka<sup>2</sup>, M. Tada<sup>3</sup>, T. Koike<sup>2,4</sup>, H. Nakamura<sup>1</sup>. <sup>1</sup>Department of Orthopedic surgery; <sup>2</sup>Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine; <sup>3</sup>Department of Orthopedic surgery, Osaka City General Hospital, Osaka; <sup>4</sup>Search Institute for Bone and Arthritis Disease (SINBAD), Shirohama Foundation for Health and Welfare, Wakayama, Japan

**Background:** Biologic disease-modifying anti-rheumatic drugs (bDMARDs) that target cytokines and cytokine receptors such as tumour necrosis factor (TNF) alpha and interleukin (IL) 6 have been established as a standard therapy in patients with rheumatoid arthritis (RA). Tocilizumab (TCZ) that targets IL-6 receptors has two administration routes such as intravenous administration (IV) or subcutaneous injection (SC). The effect of TCZ-SC therapy demonstrated comparable efficacy and safety to TCZ-IV therapy in clinical study.<sup>1, 2</sup> However, there have been no reports that evaluate the effect of TCZ-IV and SC for synovitis by imaging modality.

**Objectives:** The aim of this study was to compare the ultrasound findings between patients with rheumatoid arthritis (RA) treated by TCZ-IV and SC.

**Methods:** All patients with RA who treated with TCZ in Osaka City University RA registry (1140 patients with RA and 390 patients using bDMARDs) were included in this cross-sectional study. US examination was performed in MCP, PIP, wrist and MTP joints and finger flexor tendon and wrist extensor tendon, by using HI VISION Ascendus (Hitachi Medical Corporation, Japan) with a multifrequency linear transducer (18–6 MHz). The grey scale (GS) and power Doppler (PD) findings were assessed by the semi-quantitative method (0–3). GS score and PD score (both 0–156 points) were defined as the sum total of each score.

**Results:** We analysed total 76 patients who treated TCZ, 27 patients in IV group and 49 patients in SC group (mean age: 62.9±14.0 vs 66.0±13.2 years, p=0.343, mean duration of RA: 17.1±11.1 vs 13.7±12.3 years, p=0.218). The duration of TCZ use was significantly longer in IV (4.6±2.2 vs 3.0±2.4 years, p=0.004). Clinically, DAS28-ESR improved from 5.3±1.5 at baseline to 2.4±1.1 at US examination in IV group, and it improved from 5.2±1.4 to 2.8±1.5 in SC group. US findings were not significantly differenced in both groups, GS score: 11.7±12.5 vs 10.9±9.6 (p=0.751), PD score: 5.3±8.1 vs 5.7±6.8 (p=0.832), max PD grade: 1.3±0.9 vs 1.4±0.9 (p=0.571) in IV and SC respectively.

**Abstract FRI0142 – Table 1.** The comparison of demographic and ultrasonographic findings between TCZ-IV and SC patients with rheumatoid arthritis.

	TCZ-IV group (n=27)	TCZ-SC group (n=49)	P value
Age (years old)	62.9±14.0	66.0±13.2	0.343
Disease duration (years)	17.1±11.1	13.7±12.3	0.218
Duration of TCZ use (years)	4.6±2.2	3.0±2.4	0.004
DAS28-ESR at baseline	5.3±1.5	5.2±1.4	0.780
DAS28-ESR at ultrasound examination	2.4±1.1	2.8±1.5	0.175
CDAI at baseline	21.8±14.5	22.8±14.4	0.787
CDAI at ultrasound examination	7.3±5.9	10.6±10.4	0.082
Total GSUS score	11.7±12.5	10.9±9.6	0.751
Total PDUS score	5.3±8.1	5.7±6.8	0.832
Maximum PDUS grade	1.3±0.9	1.4±0.9	0.571

**Conclusions:** We compared the ultrasound findings between patients with RA treated by TCZ-IV and SC. Ultrasound findings between IV and SC were not significantly differenced. Both administration routes of TCZ are effective for the treatment in patients with RA.

**Background:** The use of glucocorticoid (GC) in Rheumatoid arthritis (RA) is recognised by the current treatment approach as a valid adjunct to DMARDs therapy. Despite its efficacy, safety of GC is still an issue and the best strategy of use is still debated, including patients under bDMARDs therapy

**Objectives:** To analyse in RA the differences of GC users versus non-users of baseline features, response to therapy and persistence in bDMARDs from the Italian biologics registry GISEA (Italian Group for the Study of Early Arthritis)

**Methods:** Consenting patients satisfying 1987 or 2010 ACR criteria for RA included in the Italian GISEA registry were enrolled. Data recorded comprehend demographic and clinimetric variables. Data are collected at baseline and 6 monthly during follow-up. To be included in the study patients needed a minimum follow-up time of 12 months and if data were not updated after 2012 patients were considered lost to follow-up. EULAR and HAQ responses were calculated. Statistical analysis included descriptive measures, parametric and nonparametric comparisons between groups and univariate analysis of survival on therapy

**Results:** A total of 8545 patients were enrolled, of them 4193 (49%) using a variable dose of GC. In 3035 (72%) the dose was ≤5 mg. Baseline demographic and disease-specific features at the start of bDMARD therapy were not different between GC users and non-users, both in 1st and 2nd line bDMARDs RA patients. EULAR response rates were generally better in GC users at 6 and 12 months, but without statistical significance: good/moderate EULAR responses at 6 months were attained in 76.5% of GC users versus 67% in non users, while at 12 months in 81.5% vs 73% respectively (both Ps not significant). Similarly, HAQ responses (<0.5) were slightly better in users vs non users at 6 (42.5% vs 37.4%) and 12 months (46.5% vs 42%) but again without statistical significance. Finally, mean survival on bDMARDs therapy after 2 years was significantly influenced by GC with better survival curves in steroid-treated patients (55.8% vs 47%, p<0.001). This difference was also maintained subanalysing patients in 1st or 2nd bDMARD lines of therapy (56.2% in users vs 48% in non users in 1st line and 55.3% vs 45.9% in 2nd line, both Ps <0.001).

**Conclusions:** Our data show that GC are used in a high percentage of RA patients on bDMARD therapy. GC significantly improve the persistence on bDMARDs therapy in 1st and 2nd line. No obvious other differences are evident in baseline, EULAR and HAQ response rates. This fact should be kept in mind when evaluating the persistence on bDMARD treatment reported in different registries. Safety evaluations in individual patients should be further analysed to guide the use of GC in this setting

**Disclosure of Interest:** None declared

**FRI0144 PATIENT-REPORTED OUTCOMES WITH SARILUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS ARE SIMILAR REGARDLESS OF PRIMARY OR SECONDARY FAILURE WITH TUMOUR NECROSIS FACTOR INHIBITORS**

V. Strand<sup>1</sup>, S. Boklage<sup>2</sup>, E. Mangan<sup>2</sup>, M. Reaney<sup>3</sup>, M. Iglesias-Rodriguez<sup>4</sup>, T. Kimura<sup>2</sup>. <sup>1</sup>Stanford University, Palo Alto; <sup>2</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, USA; <sup>3</sup>Sanofi, Guildford, UK; <sup>4</sup>Sanofi, Bridgewater, USA

**Background:** Sarilumab is a human monoclonal antibody that binds membrane and soluble IL-6 and was recently approved for the treatment of moderate-to-severe rheumatoid arthritis. Among inadequate responders to a TNF inhibitor (TNFi), patients may respond differently to sarilumab depending on whether they had a primary (1<sup>o</sup>) failure or initially responded but then subsequently lost response (secondary [2<sup>o</sup>] failure).

**Objectives:** To understand if changes in patient reported outcomes (PROs) differ among patients with 1° or 2° TNFi failure.

**Methods:** In TARGET (NCT10709758), patients with intolerance or an inadequate response to TNFi were randomised to placebo or sarilumab 150 mg or 200 mg plus csDMARD. For patients with an inadequate response to TNFi (92% of the sample), 1° or 2° failure was investigator-determined at enrollment. The following PROs were assessed at Week 0 (treatment initiation) and Week 24: HAQ-DI, patient global assessment of disease visual analogue scale (VAS), pain VAS, SF-36, morning stiffness VAS, EQ-5D, and Rheumatoid Arthritis Impact of Disease (RAID) scale. All scales produce global (total) scores, except the SF-36 which has eight domains and two summary scores (physical and mental component scores [PCS and MCS]) and the EQ-5D which has a single index utility score and a global health VAS. The PRO change from baseline was analysed through mixed model repeated measures with treatment, region, number of prior TNFis, baseline of the PRO analysed, visit, treatment-by-visit interaction, 1° and 2° subgroup, treatment-by-subgroup interaction, and treatment-by-visit-by-subgroup interaction. *Post-hoc* analysis of the sarilumab 200 mg data are reported here as this is the recommended dose of sarilumab.

**Results:** In this *post-hoc* analysis, 174 of 181 patients in the placebo group and 167 of 184 in the sarilumab 200 mg group were classified as TNFi 1° or 2° failures (the remaining patients were classed as intolerant or other and not included in this analysis); 75 and 64 were 1° and 99 and 103 were 2° treatment failures in the placebo and the sarilumab 200 mg groups, respectively. At Week 24, changes in all PROs were numerically similar in the 1° or 2° TNFi failures for both the sarilumab 200 mg and placebo groups (table 1). Furthermore, treatment-by-subgroup interaction testing did not show a statistically significant interaction of TNFi failure status and PRO outcome (all interaction *P*-values>0.05). Treatment emergent adverse events occurred in 65.6% of sarilumab 200 mg patients in the 1° failure group and 63.1% in the 2° failure group and were consistent with safety data reported previously.

**Abstract FRI0144 – Table 1.** Least square mean (SE) change from baseline to Week 24 in patient-reported outcomes with sarilumab 200 mg and placebo following primary and secondary TNFi failure

PRO	1° failure		2° failure		Interaction <i>P</i> -value

**FRI0145 A BAYESIAN NETWORK META-ANALYSIS ON EFFICACY OF BIOLOGICS AND SMALL MOLECULES IN EARLY RHEUMATOID ARTHRITIS**

V. Venerito, F. Cacciapaglia, G. Lapadula, F. Iannone. *Department of Emergency and Organ Transplantations, Rheumatology Unit, University of Bari "Aldo Moro", Bari, Italy*

**Background:** The use of several biologic drugs as well as small molecules, in combination or not with methotrexate (MTX), is licensed for the treatment of Rheumatoid Arthritis (RA). Treating patients within the 'therapeutic window of opportunity' may reset the disease's long-term trajectory. Which agent would fit better the need of promptly achieving remission of patients affected with early RA is

currently a matter of debate. Ideally head to head comparison are required to estimate which treatment is the most effective. Alternatively, indirect comparisons based on a common comparator may be useful. Previous indirect comparisons did not take into account all the biologics and small molecules approved for the treatment of RA, being also biased, identifying early RA in patients with high variance of disease duration, ranging from to 6 months to 2 years.

**Objectives:** To provide an estimate through a Bayesian Network Meta-Analysis of which biologic or small molecule in association with MTX is more likely to determine a good clinical response in patients affected with early RA (i.e. mean disease duration <1 year).

**Methods:** A literature search was performed in accordance with the Preferred Reporting Items for Systematic Reviews and Meta-analyses (PRISMA) statement to identify results of Randomised Controlled Trials (RCTs) of biologic agents and small molecules at licensed doses to treat patients affected by early RA. MEDLINE, EMBASE, Cochrane Library, and Clinicaltrials.gov were searched for all published RCTs ranging from 1990 to September 2017. Patients had to fulfil the ACR 1988 revised criteria and/or the 2010 ACR/EULAR criteria for classified RA. We included all completed RCTs of biologics or small molecules in combination with MTX, compared with MTX plus placebo or in combination with other biologics or small molecules, in patients whose RA had mean duration of less than 1 year. American College of Rheumatology (ACR) 50% response and ACR 70% response had to be evaluated after one year of continuous treatment both in examined drug branch and in placebo branch. WinBUGS 1.4 software (MRC Biostatistics Unit, Cambridge, UK) was used to perform the analyses, using a fixed-effect model.

**Results:** Thirteen studies were included in the analysis. All the biologics as well as Tofacitinib proved to be more effective than MTX plus placebo in inducing an ACR50 response. In this regard, Tofacitinib was the most effective overall (probability of being the best treatment: 75.04%) followed by Etanercept (21.52%). The agent with the highest probability of inducing ACR70 response was Etanercept (52.00%) followed by Abatacept (20.22%). All compared biologics in combination with MTX were superior to MTX alone in inducing ACR70 response.

**Conclusions:** After one year of continuous treatment, Tofacitinib and Etanercept are the agents with the highest probability of inducing ACR50 response in patients

affected by early RA, while Etanercept and Abatacept are the biologics with the highest probability of inducing ACR70.

#### CORRELATION BETWEEN THE RHEUMATOID FACTOR POSITIVITY AND THE HIGHER DISCONTINUATION RATE OF BIOLOGICAL THERAPY IN RHEUMATOID ARTHRITIS: A FINE-GREY PROPORTIONAL HAZARD REGRESSION ANALYSIS

Y. Ogawa<sup>1</sup>, N. Takahashi<sup>2</sup>, T. Kojima<sup>2</sup>, N. Ishiguro<sup>2</sup>. <sup>1</sup>Nakatsugawa Municipal General Hospital, Nakatsugawa; <sup>2</sup>Nagoya University Graduate School of Medicine, Nagoya, Japan

**Background:** As quantifying the occurrence of outcome over time holds vital importance in clinical medicine, the presence of competing risks must be considered when assessing the impact of prognostic factors on the incidence of an outcome over time. A competing risk is defined as an event that precludes the occurrence of an event of interest. For example, event arising from adverse effect causes is a competing risk when evaluating the effect of risk factors on the incidence of discontinuation of biological therapy because of inadequate response. The presence of biased estimates of the effect of covariates on the incidence in the presence of competing risks is attributed to the naïve use of the conventional Cox proportional hazards model that censors the competing event. Fine and Grey developed the subdistribution hazard model that facilitates modelling the effects of covariates on the cumulative incidence function in the presence of competing risks.

**Objectives:** The discontinuation of biological therapy in rheumatoid arthritis (RA) is attributed to several reasons, including inadequate response, adverse effect, remission, and changing hospital. In particular, inadequate response constitutes a principal and compelling reason. This study aims to investigate the correlation between covariates, including the rheumatoid factor (RF) positivity and the discontinuation of biological therapy due to inadequate response in bio-naïve patients with RA using the Fine–Grey proportional hazard regression for competing events.

**Methods:** In this study, we enrolled patients in the Tsurumi Biologic Communication Registry that comprises Nagoya University and 15 affiliated institutions in Japan. We assessed the correlation between individual characteristic components and patient outcomes using the Fine–Grey proportional hazard regression for competing events. Apparently, time-based models estimate the effects of various characteristics (e.g., RF positivity, sex, and age) on time to develop events of interest, including the discontinuation owing to inadequate response. The Fine–Grey proportional hazard regression considered competing events, implying that this model generated separate hazard ratios for each competing event. All analyses were conducted in EZR version 1.36.

**Results:** A higher crude discontinuation rate was observed due to inadequate response in RF-positive patients than that in RF-negative patients using the cumulative incidence function of competing events and Grey test (figure 1). After adjusting for the baseline characteristics, including age, sex, stage, disease at the baseline, methotrexate use, prednisolone use, and tumour necrosis factor inhibitor (TNFi) or non-TNFi (HR, 1.57; 95% CI: 1.01–2.43;  $p < 0.05$ ; table 1), the difference was significant in the Fine–Grey proportional hazard regression analysis.

	Hazard ratio	Lower 95% CI	Upper 95% CI	p.value
RF positivity	1.57	1.01	2.43	<0.05
Sex	0.91	0.61	1.36	0.67
Age	0.99	0.98	1.01	0.12
Das28esr at baseline	1.31	1.15	1.48	<0.05
non-TNFi	0.53	0.31	0.91	<0.05
MTX use	1.64	1.01	2.67	<0.05
PSL use	1.16	0.82	1.64	0.38
Stage	0.99	0.98	1.01	0.57

**Conclusions:** Using the Fine–Grey proportional hazard regression for competing events, this study demonstrated a correlation between the RF positivity and inadequate response to biological therapy on bio-naïve patients with RA.

#### ANALYSIS OF RADIOGRAPHIC JOINT DESTRUCTION IN THE PATIENTS WITH RHEUMATOID ARTHRITIS WHO HAVE WITHDRAWN, SPACED AND CONTINUED BIOLOGICS AFTER ACHIEVING SUSTAINED REMISSION FROM LOCAL BIOLOGICS REGISTRY

Y. Takakubo, J. Nagai, H. Oki, Y. Naganuma, S. Yang, J. Ito, Y. Suzuki, K. Sasaki, M. Takagi. Department of Orthopaedic Surgery, Yamagata University Faculty of Medicine, Yamagata, Japan

**Background:** Increasing of remission reached by biologics agents in early and established RA patients<sup>1, 2</sup>. Data on withdrawn, spacing or reducing of biologics (BIO) medication after sustained remission are limited<sup>3, 4</sup>. After withdrawn, spacing or reducing, it is less known to be influenced the radiographic destruction of the joints.

**Objectives:** To retrospectively analyse the joint destruction using modified Total Sharp Score (mTSS) in RA patients in sustained remission, either withdrawing, spacing and continuing BIO.

**Methods:** Local prefectural (ZAO) registry which is open-labelled BIO cohort study has registered 356 RA patients. RA Patients were enrolled into this study if they maintained in DAS remission (DAS28-ESR<2.6) more than one year after starting BIO.  $\Delta$ mTSS1 was estimated between starting BIO and withdrawn or spacing or reaching remission in each group,  $\Delta$ mTSS2 between the beginning of withdrawn or spacing, or reaching remission in continuing group and latest follow-up or flare-up.

**Results:** 40 RA patients (32 female) using BIO was fulfilled in the criteria of this study in ZAO registry. Of 40 RA Patients, 10 has withdrawn BIO, 15 has spaced and 15 has continued it after maintain DAS remission more than one year. Mean age was 43, 55, 54 year-old, mean RA affiliation 4.6, 15.3, 9.1 years before BIO and mean duration of remission 6.2, 7.6, 7 years, mean dosage of MTX and PSL was 7.7, 6, 5 mg/week and 1.1, 3, 4 mg/day, respectively.  $\Delta$ mTSS1 and  $\Delta$ mTSS2 was +2.4 and +4.5 in withdrawn group, +3.6 and +0.9 in spacing group, +0.2 and -1.4 in continuing group, respectively (figure 1,  $p < 0.05$ ). Five cases in withdrawing group had resumed BIO because of flare-up of their disease activity.

**Abstract FRI0147 – Figure 1.** Radiographic destruction of joint in each withdrawn, spacing, continuing groups

lumbar spine specimens from mCIA mice. (G) A schematic diagram illustrating the theory in the current study.

**FRI0150** **MTOR BLOCKADE BY RAPAMYCIN DECREASES ARTHRITIS AND SPONDYLITIS DEVELOPMENT AND SEVERITY IN HLA-B27 TRANSGENIC RATS**

S. Chen<sup>1</sup>, M. van Tok<sup>1</sup>, D. Pots<sup>1</sup>, J. Taurog<sup>2</sup>, M. van de Sande<sup>1</sup>, D. Baeten<sup>1</sup>, L. van Duivenvoorde<sup>1</sup>. <sup>1</sup>Clinical Immunology and Rheumatology, Amsterdam Medical Center, Amsterdam, Netherlands; <sup>2</sup>Internal Medicine, Rheumatic Diseases Division, UT Southwestern Medical Center, Dallas, USA

**Background:** HLA-B27 misfolding is thought to play an important role in the pathogenesis of spondyloarthritis (SpA), possibly through triggering of ER stress and the unfolded protein response. One of the mechanisms that regulates the unfolded protein response is autophagy. Autophagy is a process that degrades proteins, cytoplasmic particles and organelles in lysosomes and is regulated by protein kinases, mechanistic target of rapamycin (mTOR) and AMP activated protein kinase.

**Objectives:** To study whether blockade of mTOR will affect spondyloarthritis development and/or severity in the *Mycobacterium tuberculosis* (*M. tub*) induced disease HLA-B27 tg rat model.

**Methods:** 6 weeks old, female or orchietomized male HLA-B27/Huβ2m transgenic rats were immunised with 60–90 µg heat-inactivated *M. tub* in IFA. Rats were prophylactically or therapeutically treated three times a week intra-peritoneally with 1.5 mg/kg rapamycin or vehicle. Clinical measurements included weight, clinical scores for spondylitis and arthritis, and hind paw swelling measured by plethysmometry. After 5 weeks of treatment rats were sacrificed; axial and peripheral joints were isolated for histology and metacarpophalangeal joints, spleen and lymph nodes were isolated for RNA isolation.

**Results:** In the prophylactic experiment 72.7% (8/11) and 18.2% (2/11) rapamycin treated rats developed arthritis and spondylitis compared to respectively 100% (13/13; p=0.0225) and 92.3% (12/13; p<0.0001) control animals. Also severity of arthritis and spondylitis was significantly decreased in rapamycin treated animals compared to control treated animals; mean arthritis severity of diseased rats was respectively 0.45 versus 7.15 on a scale from 0–12 (p<0.0001) and mean spondylitis severity was respectively 0.18 versus 2.07 on a scale from 0–3 (p<0.0001). Clinical findings were confirmed by histology with a significant decrease of inflammation (p<0.0001), bone- and cartilage destruction (p=0.0021) and new bone formation (p=0.0010) in peripheral joints of rapamycin treated rats compared to vehicle treated rats and a similar trend was observed in spinal joints. Also in a therapeutic setting rapamycin treatment decreased arthritis severity (mean score of 6 compared to 8.8 in controls; p=0.0317) and spondylitis severity (mean score of 1.23 compared to 2.8 in controls; p=0.0159). Histology for the therapeutic experiment is currently being performed as well as RNA analyses for autophagy genes and pro-inflammatory cytokines, like IL-17A and TNF.

**Conclusions:** mTOR blockade significantly suppressed arthritis and spondylitis in the *M. tub* induced disease HLA-B27 transgenic rat model of SpA.

**FRI0151** **PROTEIN INHIBITOR OF ACTIVATED STAT3 PREVENTS PERIPHERAL ARTHRITIS AND GUT INFLAMMATION BY REGULATING TH17/TREG CELL IMBALANCE VIA STAT3 SIGNALLING IN MICE MODEL OF SPONDYLOARTHRITIS**

E. Kwon<sup>1</sup>, H.K. Min<sup>1</sup>, M.Y. Kim<sup>1</sup>, J. Choi<sup>2</sup>, S.-Y. Lee<sup>2</sup>, H.-B. Seo<sup>2</sup>, K. Jung<sup>3</sup>, H. S. Na<sup>2</sup>, J.-G. Ryu<sup>2</sup>, S.-K. Kwok<sup>1</sup>, M.-L. Cho<sup>2</sup>, S.-H. Park<sup>1</sup>. <sup>1</sup>College of Medicine, The Catholic University of Korea; <sup>2</sup>Catholic Research Institute of Medical Science, The Catholic University of Korea; <sup>3</sup>Impact Biotech, Seoul, Korea, Republic Of

**Background:** Spondyloarthritis (SpA) is inflammatory arthritis, and interleukin (IL) –17 is crucial on pathogenesis of SpA. Type 17 helper T cell (Th17) is one of major IL-17 secreting cells. Signal transducer and activator of transcription (STAT)–3 signalling induces Th17 cell differentiation. Present study investigated the effect of protein inhibitor of activated STAT3 (PIAS3) on SpA pathogenesis.

**Methods:** Curdlan was injected to SKG ZAP-70<sup>W163C</sup> mice for SpA induction. Then PIAS3 or Mock vector was inserted to mice for 10 weeks. Clinical score and histologic scores of paw, spine, and gut were evaluated. Expressions of IL-17, tumour necrosis factor-α (TNF-α), STAT3, bone morphogenic protein (BMP) were

measured. Confocal stain and flow cytometry were used to assess helper T cell differentiation.

**Results:** PIAS3 significantly diminished the histological scores of paw and gut. PIAS3 group displayed lesser expression of IL-17, TNF-α, and STAT3 in the paw, spine, and gut. BMP-2/4 expressions were lower in spine of PIAS3 group. Helper T cell differentiation was polarised toward upregulation of regulatory T cell (Treg) and downregulation of Th17 in the PIAS3 mice.

**Conclusions:** PIAS3 showed preventive effects in mice with SpA by suppressing peripheral arthritis and gut inflammation. Proinflammatory cytokines and Th17/Treg differentiation were controlled by PIAS3. Additionally BMPs were decreased in spine of PIAS3 mice. These findings suggest that PIAS3 could be a potential therapeutic choice of SpA treatment.

**FRI0152** **INFLAMMASOMES ACTIVATION OCCURS IN THE INFLAMED TISSUES OF AS PATIENTS AND DRIVES IL-23 EXPRESSION**

F. Ciccia<sup>1</sup>, A. Rizzo<sup>2</sup>, G. Guggino<sup>1</sup>, R. Alessandro<sup>1</sup>, S. Raimondo<sup>1</sup>, F. Macaluso<sup>1</sup>, S. Peralta<sup>1</sup>, S. Milling<sup>3</sup>, D. Elewaut<sup>4</sup>. <sup>1</sup>University of Palermo; <sup>2</sup>Azienda Ospedaliera Ospedali Riuniti Villa Sofia Cervello, Palermo; <sup>3</sup>University of Glasgow, Glasgow, Italy; <sup>4</sup>University of Ghent, Ghent, Belgium

**Background:** A growing body of evidences indicate that the aberrant activation of innate immune systems, occurring in genetically predisposed patients, drives inflammatory processes in Ankylosing Spondylitis (AS).<sup>1</sup>

**Objectives:** Aim of this study was to evaluate the activation and the functional relevance of inflammasome pathways in patients with AS.

**Methods:** Intestinal, synovial and bone marrow expression of inflammasome pathways, pyroptosis and IL-1b and IL-18 was evaluated in AS patients. Organic acid extraction was performed on ileal samples as previously described on. The expression of the metabolite-sensing receptors GPR43 and GPR109A involved in the regulation of the intestinal inflammasome was also assessed. The role of intestinal dysbiosis in modulating inflammasome activation was also studied in AS patients and HLA-B27 transgenic rats. Inflammasome activation was evaluated in isolated peripheral AS monocytes. The role of LPS, PGE2 and nicotine in inducing monocyte inflammasome activation and the role of inflammasome in modulating IL-23 production was also evaluated.

**Results:** Activation of inflammasomes was observed in the inflamed gut, synovial and bone marrow samples of AS patients and associated with an increased expression of caspase-1, IL-1b and IL-18. In AS, AIM2 expression was observed in the context of tuft cells and of adherent ileal bacteria. Inflammasome activation in AS gut, was associated with the occurrence of dysbiosis and increased pyroptosis as demonstrated by the membrane localization of Gasdermin D. Isolated intestinal bacteria from AS ileal samples, significantly modulated inflammasome activation in isolated monocytes. Reduced Short-chain fatty acids concentrations and increased expression of GPR43 and GPR109 were demonstrated in the AS ileal samples. Inflammasome activation was also observed in the inflamed gut of HLA-B27 TG rats and suppressed by antibiotics treatment. Increased expression of NLRP3, NLRC4 and AIM2 was confirmed in AS isolated peripheral monocytes. Serum levels of IL-1b and IL-18 were increased in AS patients, especially in smoker patients, and directly correlated with the ASDAS-CRP. In *in vitro* studies, LPS and nicotine strongly activated NLRP3, NLRC4 and AIM2 pathways in AS monocytes. The CC genotype of PTGER4 SNP rs6896969 was associated with a significantly increased activation of inflammasome in AS. Finally, inflammasome activation in AS monocytes was required for the induction of IL-23p19 expression in an IL-1b-dependent way.

**Conclusions:** Inflammasome activation occurs in AS patients being modulated by a plethora of different stimuli. Inflammasome drives IL-23 production in an IL-

1b-dependent mechanism in AS patients supporting the auto-inflammatory nature of the disease and possibly representing a future therapeutic target in AS.

#### FRI0153 ROLE OF ROR GAMMA T INHIBITION IN THE IL-23 MINICIRCLE MODEL AND SPA PATIENT TISSUE CULTURES

K. Hoyt<sup>1</sup>, J. Galdamez<sup>2</sup>, M. Panzenbeck<sup>1</sup>, D. Souza<sup>1</sup>, E. Glynn<sup>1</sup>, J. Pelletier<sup>1</sup>, M. Lewis<sup>1</sup>, G. Nabozny<sup>1</sup>, E. Purdue<sup>2</sup>, L.A. Mandl<sup>2</sup>, J. Wahle<sup>1</sup>. <sup>1</sup>*Immunology and Respiratory Disease Research, Boehringer Ingelheim Pharmaceutical Inc, Ridgefield;* <sup>2</sup>*Hospital for Special Surgery, New York, USA*

**Background:** Retinoic acid receptor related Orphan Receptor gamma t (ROR $\gamma$ t) is a nuclear hormone receptor expressed in a subset of pathogenic T cells and innate lymphoid cells. ROR $\gamma$ t regulates the transcription of key pro inflammatory cytokines such as IL-17 and IL-22 in response to multiple activation signals including cytokines and T cell receptor engagement. Antagonism of ROR $\gamma$ t is hypothesised to block transcription of these pathogenic cytokines resulting in reduced tissue inflammation and aberrant joint remodelling.

Spondyloarthropathy (SpA) is characterised by a peripheral oligoarthritis and enthesitis. A key feature of SpA is the imbalance between bone resorption and formation leading to aberrant bone formation and ankylosis. The contribution of the IL-23/IL-17 axis to the pathogenesis of SpA is supported by several lines of evidence. However, the specific role of ROR $\gamma$ t in regulating the cellular and molecular pathways contributing to enthesal and synovial inflammation remains incompletely understood.

**Objectives:** The goal of this study was to determine the role of ROR $\gamma$ t antagonism in both an IL-23 minicircle *in vivo* model and *ex vivo* tissue culture model.

**Methods:** Model 1: Mice were administered an IL-23 minicircle via hydrodynamic injection to induce systemic IL-23 expression on day 1. Starting on day 2, mice were dosed p.o. for 28 days. Mice were monitored daily for signs of arthritis. Upon sacrifice tissue was collected for mRNA biomarker analysis and histologic assessment.

Model 2: Patients undergoing total hip replacement were recruited into 2 groups: SpA (either psoriatic arthritis or ankylosing spondylitis) or OA (osteoarthritis). Enthesal and synovial tissues were collected and cultured  $\pm$ ROR $\gamma$ t inhibitor and cytokine stimulation (hTNF $\alpha$ /hIL23) for 24 and 48 hours and then analysed for gene expression.

**Results:** Model 1: Overexpression of IL-23 induced SpA like phenotype including enthesitis, synovitis and aberrant bone formation. ROR $\gamma$ t inhibition resulted in significant reduction of inflammation and arthritic score, histologic parameters of bone remodelling, and tissue biomarkers associated with the IL-23 axis (IL17A, IL17F, IL22).

Model 2: Both enthesal and synovial cultures from SpA patients expressed increased Th17 axis genes relative to OA after cultures. ROR $\gamma$ t inhibition reduced the expression of these Th17 axis genes (IL17A, IL17F, IL22) as well as reducing tissue remodelling related genes (FN1, MMP1/3, BMP5), in alignment with the results seen in model 1.

**Conclusions:** IL-23 induced Th17 axis gene expression induced a SpA-like phenotype in mice, including arthritis and aberrant bone formation, that was reversed upon ROR $\gamma$ t inhibition. Similarly, SpA patient explants showed increased expression of Th17 axis cytokines and tissue remodelling related genes that were decreased with ROR $\gamma$ t inhibition. Together, these complementary approaches support the hypothesis that ROR $\gamma$ t treatment could block inflammation as well the underlying pathologies associated with SpA.

#### FRI0154 ADDED VALUE OF BIOMARKERS COMPARED TO ROUTINE CLINICAL PARAMETERS FOR THE PREDICTION OF RADIOGRAPHIC SPINAL PROGRESSION IN AXIAL SPONDYLOARTHRITIS

J. Rademacher<sup>1,2</sup>, L. Tietz<sup>1</sup>, L. Le<sup>3</sup>, A. Hartl<sup>1</sup>, M. Rudwaleit<sup>4</sup>, J. Sieper<sup>1</sup>, U. Mansmann<sup>3</sup>, D. Poddubnyy<sup>1</sup>. <sup>1</sup>*Rheumatology, Charité Campus Benjamin Franklin, University Hospital Charité, Berlin, Germany;* <sup>2</sup>*Berlin Institute of Health, Berlin;* <sup>3</sup>*Institut für Medizinische Informationsverarbeitung Biometrie und Epidemiologie (IBE), Ludwig-Maximilian University, Munich;* <sup>4</sup>*Rheumatology, Klinikum Bielefeld Rosenhöhe, Bielefeld, Germany*

**Background:** Structural damage in the spine determines the functional status and spinal mobility in axial spondyloarthritis (axSpA). Already present syndesmophytes, elevated C-reactive protein, cigarette smoking, and to a lesser extent male sex are routine clinical parameters predicting radiographic spinal progression. In the last years, several biomarkers with a predictive value for radiographic spinal progression were identified. It is, however, not known, if biomarkers have a meaningful added value over clinical parameters in prediction of radiographic spinal progression in axSpA.

**Objectives:** The objective of the study was to examine whether adding biomarkers to the routine clinical parameters would improve prediction of radiographic spinal progression in axSpA.

**Methods:** Altogether 117 patients with ankylosing spondylitis who completed a 2 year clinical and radiographic follow-up in the ENRADAS trial were included. Radiographic spinal progression was defined as a worsening of the modified Stoke Ankylosing Spondylitis Spine Score (mSASSS) by  $\geq 2$  points after 2 years. A clinical prediction model for radiographic spinal progression was constructed out of already present syndesmophytes, elevated CRP, cigarette smoking, and male sex. Serum biomarkers measured at baseline included: matrix metalloproteinase-3, vascular endothelial growth factor (VEGF), calprotectin, leptin, high molecular weight adiponectin (HWM-APN), osteoprotegerin, sclerostin, N-terminal telopeptide, procollagen type II N-terminal propeptide, and serum amyloid A.

**Results:** Repeated cross-validation analyses revealed the following biomarker combination with added predictive value for radiographic progression compared to the clinical model (syndesmophytes, smoking, elevated CRP, and sex): Leptin +HWM-APN+VEGF. A combination of these biomarkers resulted in an Area Under the Curve (AUC) of  $AUC_{\text{Biomarkers}}=0.731$  (95%CI 0.614–0.848), thus numerically superior to the clinical model ( $AUC_{\text{Clinical}}=0.665$  (95%CI 0.553–0.776)). A combination of both models resulted in improvement of the predictive value reflected by the  $AUC_{\text{Clinical+Biomarkers}}=0.768$  (95%CI 0.666–0.871); though this improvement was not statistically significant compared to the clinical model in the permutation test ( $p=0.051$ ). However, when only considering the part of receiver operating characteristic (ROC) curves with a specificity of  $\geq 75\%$ , the improvement becomes statistically significant (partial  $AUC_{\text{Clinical+Biomarkers}}=0.119$  versus partial  $AUC_{\text{Clinical}}=0.053$ ;  $p=0.010$ ).

**Abstract FRI0154 – Figure 1.** ROC curve analyses of biomarker and clinical model alone versus the combined model for the prediction of radiographic spinal progression (mSASSS worsening  $\geq 2$  after 2 years) in ankylosing spondylitis. Area under the curves (AUC) and respective 95% confidence intervals (CI) shown. \*Leptin + HWM-APN + VEGF.

**Conclusions:** Biomarkers are able to improve prediction of radiographic spinal progression in axSpA, especially if used in addition to the clinical parameters, but the added value seems to be rather small.

**Disclosure of Interest:** None declared

FRI0155

#### GENES REGULATING BONE HOMEOSTASIS ARE DIFFERENTIALLY EXPRESSED AT PERIPHERAL VERSUS AXIAL ENTHELIAL SITES IN AN ANIMAL MODEL OF SPONDYLOARTHRITIS

Z. Stavre, Y. Maeda, T. Huang, E. Gravallesse. *Department of Medicine-Rheumatology, University of Massachusetts Medical School, Worcester, USA*

**Background:** In spondyloarthritis (SpA), mechanisms of enthesial bone formation are not well understood. Currently, no treatment can reverse this process, although TNF inhibitors may modify bone formation if initiated early. SKG mice exhibit features of SpA with both peripheral joint and axial inflammation after induction by curdlan via the Dectin-1 pathway residing upstream of TNF $\alpha$ , IL-23 and IL-17.

**Objectives:** The goal of this study was to identify genes and pathways that regulate enthesial bone formation. SKG mice were previously reported to develop axial bone formation within 12 weeks of curdlan injection, as well as enthesial bone formation around peripheral joints<sup>1</sup>.

**Methods:** 9 week-old SKG or control BALB/c mice were injected IP with curdlan. Histology and microCT scanning were performed at serial time points. Laser capture microscopy was performed on formalin-fixed paraffin-embedded (FFPE) tissue sections from enthesial sites around the ankle and tail vertebrae 3 weeks after curdlan injection. RNA was extracted using the Qiagen RNeasy FFPE kit and whole transcriptome analysis was performed using Affymetrix gene array MTA 1.0.

**Results:** Inflammation at axial entheses developed earliest at the tail base. Contrary to previous reports, we did not observe axial bone formation, but rather saw significant erosion of vertebral bodies, throughout the spine. The absence of axial bone formation was noted as late as 24 weeks post curdlan. In contrast, exuberant enthesial bone formation occurred around ankles at predictable sites of tendon/ligament insertions into bone. We identified distinct expression of genes involved in bone resorption and formation at ankle when compared to spine enthesial sites. IPA upstream regulator analysis identified significant gene expression of upstream regulators of TGF- $\beta$ , known to recruit early osteoblast precursors to bone (z-value 2.83), and WNT3A, a WNT signalling pathway agonist that promotes osteoblast differentiation and function (z-value 2.54), in the ankle, but not the spine. These findings support the histologic observation of bone formation at ankle, but not spine, enthesial sites. In addition, significant increased gene expression of upstream regulators of the aryl hydrocarbon receptor (AhR) (z-value 2.14) was found at spine, but not ankle, enthesial sites (z-value -1.78). AhR is a ligand-activated transcription factor that is a positive regulator of osteoclastogenesis via c-fos-mediated RANKL signalling.

**Conclusions:** Whole transcriptome analysis revealed increased expression of upstream regulators of genes in anabolic pathways, including WNT3A and TGF- $\beta$ , at ankle enthesial sites where bone formation occurs, but not at spine enthesial sites where bone erosions persist without bone formation. These pathways may thus contribute to peripheral enthesial bone formation. Significantly increased gene expression of upstream regulators of AhR, a positive regulator of osteoclastogenesis, was found at spine enthesial sites. AhR is thus a candidate regulator of continued bone resorption at spine enthesial sites in this murine model of SpA.

#### AN ANTIMICROBIAL MECHANISM, NETOSIS, IS POTENTIALLY INVOLVED IN ANKYLOSING SPONDYLITIS PATHOGENESIS

P. Ruiz-Limon<sup>1</sup>, M.C. Castro<sup>1</sup>, C. Lopez-Pedrer<sup>1</sup>, M.C. Abalos-Aguilera<sup>1</sup>, N. Barbarroja<sup>1</sup>, C. Perez-Sanchez<sup>1</sup>, I. Arias-de la Rosa<sup>1</sup>, R. Ortega<sup>1</sup>, P. Font<sup>1</sup>, J. A. Gonzalez-Reyes<sup>2</sup>, J.M. Villalba<sup>2</sup>, C. Lopez-Medina<sup>1</sup>, A. Escudero<sup>1</sup>, E. Collantes<sup>1</sup>, Y. Jimenez-Gomez<sup>1</sup>. <sup>1</sup>Rheumatology Service, IMIBIC/Reina Sofia University Hospital/Cordoba University; <sup>2</sup>Dept. Cell Biology, Physiology and Immunology, Cordoba University; ceiA3, Cordoba, Spain

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory disease, of unknown etiology, that mainly affects the axial skeleton and the sacroiliac joints in the pelvis. Neutrophils are critical actors in innate immunity and their activation has been involved in the progression of AS symptoms. Recently, NETosis has been suggested to play a central role in several pathologic states, including rheumatology diseases. Nevertheless, this process has not been described yet in AS patients

**Objectives:** 1) To evaluate and characterise the presence of NETosis in AS patients. 2) To explore the relationship among NETosis markers and clinical characteristics of this disease

**Methods:** Thirty patients with AS and 32 healthy donors (HD) were included in the study. Disease activity was determined by BASDAI index and CRP and ESR levels; in parallel, inflammatory markers were determined in plasma by ELISA kits. Spinal mobility of AS patients was measured by the BASMI index, and structural damage was calculated by the mSASSS index. *Ex vivo*, spontaneous NETosis generation in purified neutrophils from AS patients and HDs were measured by fluorescence (n=6) and scanning electron (n=3) microscopy after 6 hour of incubation. PMA, known to promote NETosis, was used as positive control. DNA extrusion was analysed by fluorescence microscopy and fluorimetry after SYTOX staining, whereas elastase percentage (NE) was analysed by fluorescence microscopy after staining of neutrophils with NE antibody. *In vivo*, mieloperoxidase (MPO) and NE protein expression were measured by flow cytometry (FACSCalibur), whereas extracellular DNA was examined in plasma using fluorimetry after SYTOX staining

**Results:** Compared to HDs, AS neutrophils showed spontaneous extracellular release of a meshwork of DNA nuclear and granule proteins (NETs), as demonstrated by fluorescence microscopy, fluorimetry, and scanning electron microscopy. Indeed, analysis of DNA fibres staining by SYTOX revealed that NETosis rate was above baseline levels after 6 hour of *ex vivo* AS neutrophil incubation as compared to those from HDs (p<0.05). Furthermore, higher cell free-DNA levels were observed between AS patients and HDs at 6 hour (p<0.05). Increased spontaneous NETs production in this pathology was additionally corroborated by the observation of an enhanced percentage of NE-staining cells after 6 hour of incubation (p<0.05). *In vivo*, higher intracellular NE levels (p=0.036), and plasma DNA concentrations (p=0.021) were also found in AS patients as compared to HDs. Correlation studies showed that plasma DNA levels positively correlated with inflammatory markers (i.e. CRP, ESR and TNF $\alpha$ ), and with the spinal mobility index BASMI. In addition, a positive correlation was found between intracellular NE levels and plasma IL-1 $\beta$  concentration

**Conclusions:** 1) NETosis is increased in AS patients. 2) Raised NETosis in AS is associated with several markers of inflammation and mobility. Thus, NETosis might act as a key mediator in the etiopathogenesis of AS. Funded by JA PI-0314-2012, SER, ISCIII (RIER RD16/0012/0015)

#### ALTERED EXPRESSION OF THE SPLICEOSOME COMPONENTS IN LEUKOCYTES SUBSETS FROM PATIENTS WITH ANKYLOSING SPONDYLITIS: ASSOCIATION TO DISEASE PATHOGENESIS AND THERAPEUTIC RESPONSE

L. Ladehesa<sup>1</sup>, M.C. Castro<sup>1</sup>, C. Lopez-Pedrer<sup>1</sup>, R. Ortega<sup>1</sup>, S. Pedraza<sup>2</sup>, M. del Río<sup>2</sup>, M.C. Abalos-Aguilera<sup>1</sup>, P. Ruiz-Limon<sup>1</sup>, C. Perez-Sanchez<sup>1</sup>, A. Ibañez-Costa<sup>1</sup>, Y. Parra-Manso<sup>1</sup>, N. Barbarroja<sup>1</sup>, I. Arias-de la Rosa<sup>1</sup>, P. Font<sup>1</sup>, A. Escudero<sup>1</sup>, J.P. Castaño<sup>2</sup>, R.M. Luque<sup>2</sup>, E. Collantes<sup>1</sup>, Y. Jimenez-Gomez<sup>1</sup>. <sup>1</sup>Rheumatology Service, IMIBIC/Reina Sofia University Hospital/Cordoba University; <sup>2</sup>Dept. Biología Celular, Fisiología e Inmunología, IMIBIC/Universidad de Córdoba/Hospital Reina Sofia; CIBERObn y ceiA3, Cordoba, Spain

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory disease for which the etiopathogenesis has not yet been fully clarified. Splicing is a post-

transcriptional process involved in the RNA maturation. Recent studies have revealed that a pathological deregulation of the spliceosome is associated to several human diseases. Yet, the spliceosome alterations and their modulation in therapeutic response have not been described in AS

**Objectives:** 1) To evaluate the potential deregulation of the spliceosome in AS leukocytes and their involvement in the disease pathophysiology. 2) To analyse the *in vivo* effects of anti-TNF drugs on the spliceosome components of AS leukocytes

**Methods:** Thirty two AS patients and 29 healthy donors (HDs) were included in a cross-sectional study. Eight AS patients were selected for a three-month longitudinal study of response to anti-TNF $\alpha$  therapy. Disease activity was determined by BASDAI index and, CRP and ESR levels. Physical function was measured by the BASFI index, spinal mobility by the BASMI index, and structural damage by the mSASSS. The expression of selected components of the major-(n=12) and minor-spliceosome (n=4), and splicing factors (n=28) was evaluated in purified leukocyte by Fluidigm methodology; in parallel, inflammatory marker expression was determined by RT-PCR

**Results:** Compared to HDs, a significant deregulation in the expression of splicing factors and spliceosome components was found in lymphocytes, monocytes and neutrophils from AS patients, being neutrophils which displayed the highest number of altered molecules. Interestingly, a specific altered profile of spliceosome members was observed when compared lymphocytes (U1, U4, U5, SRSF6), monocytes (CELF4, ESRP2, RBM3, SRSF3, TIA1) and neutrophils (FBP11, SF3BTV1, U6, U12, PTB, RBM17, MAGOH, SRSF5, SRSF10). Correlation studies revealed that inflammatory profile, disease activity (CRP, ESR, BASDAI) and structural damage (BASMI, mSASSS) were associated to the alteration of a vast number of spliceosome components in all the leukocyte subsets evaluated. In addition, the BASFI index correlated with the expression of SKIP and U6atac in neutrophils.

Anti-TNF $\alpha$  treatment of selected AS patients reversed the altered expression of several spliceosome components and splicing factors in PBMCs (UA2F2, nSR100) and neutrophils (ESRP1, NOVA1, SND1, SRM160, SRSF1, CUGBP). Association studies demonstrated that disease remission was associated with reversing the altered expression of a high number of the spliceosome molecules

#### FRI0158 PROSTAGLANDIN E2 AND ITS RECEPTOR SUBTYPE EP4 ARE INVOLVED IN ANKYLOSING SPONDYLITIS DISEASE PROGRESSION

A. Srinath<sup>1</sup>, N. Haroon<sup>1</sup>, G. Guggino<sup>2</sup>, I. Sari<sup>1</sup>, F. Zeng<sup>1</sup>, R. Alessandro<sup>2</sup>, A. Rizzo<sup>3</sup>, F. Ciccia<sup>2</sup>. <sup>1</sup>University of Toronto, Toronto, Canada; <sup>2</sup>University of Palermo; <sup>3</sup>Azienda Ospedaliera Ospedali riuniti Villa Sofia Cervello, Palermo, Italy

**Background:** Single Nucleotide Polymorphisms (SNPs) in PTGER4 were found to be associated with Ankylosing spondylitis (AS) in GWAS. PTGER4 codes for the prostaglandin-E2 receptor EP4. PGE2/EP4 interaction can affect bone formation and inflammation.

**Objectives:** We studied serum PGE2 levels and SNPs in PTGER4 in relation to spinal fusion in AS patients. We also evaluated the interaction of smoking, PGE2 and EP4 in driving IL23 production and ILC3 functions.

**Methods:** Patients diagnosed with AS using the modified New York criteria and followed prospectively using a standardised protocol, were included in this study. Biological samples including serum, gut, synovial and bone marrow (BM) samples, DNA and RNA were stored and radiographs of the spine obtained every two years to assess progression. ELISA for Serum PGE2 and immunohistochemistry tissue expression of PTGS1, EP4 and pCREB were performed. Radiographs were scored by mSASSS. Patients with an increase of  $\geq 1$  mSASSS unit/year on follow up were deemed progressors. Five PTGER4 SNPs, associated with AS or related diseases, call rate above 90%, MAF >0.1 and not in LD above 0.8, were studied. Immune cell subsets from PBMCs were analysed for surface expression of the EP4 receptor. Additionally, PBMCs were incubated with nicotine, PGE2, or EP4 agonist to evaluate changes in ILC3 percentages and to determine cytokine expression by flow cytometry and RT-PCR.

**Results:** Serum PGE2 levels were significantly higher in AS progressors (n=88) than in non-progressors (n=101) (p<0.001). In multivariable regression analysis, there was significantly more progression in patients with higher baseline mSASSS

(B=0.02; p=0.01) and serum PGE2 (B=0.001; p=0.002), but lower progression with longer TNF inhibitor use (B=-0.01; p=0.03). There was a trend towards higher progression with higher baseline ESR (B=0.012; p=0.08). 3). A total of 172 AS patients had DNA and X-ray data for analysis. Patients with CC genotype of PTGER4 SNP rs6896969 were significantly more likely to progress compared to AA/AC (OR: 2.45, 95% CI: 1.3 to 4.6; p=0.006). Progressors tended to more likely be homozygous for the major allele G of the rs4957341 SNP (OR 2.1; 25% CI: 0.98–4.35; p=0.058). Increased expression of EP4, PTGS1 and pCREB were observed in the gut, BM and synovial samples of AS patients. EP4 expression was upregulated in circulating AS monocytes and ILC3, especially smokers, and the percentage of EP4<sup>+</sup> monocytes and ILC3 correlated with the BASDAI. Sorted EP4<sup>+</sup>CD14<sup>+</sup> cells showed a higher expression of CREB and IL-23 and *in vitro* stimulation of monocytes with PGE2 increased IL-23 expression, demonstrating the functional relevance of EP4 expression on monocytes. The expression of EP4 is dependent on the transcription factor AP-2a (TFAP-2a). *In vitro* stimulation of monocytes with nicotine induced a significant monocyte over-expression of EP4 and TFAP-2a. Finally, PGE2 stimulation of isolated PBMC from AS patients significantly expanded IL-23-producing ILC3.

**Conclusions:** PGE2 and its receptor EP4 are significant players in AS driving both inflammation and spinal fusion. The complex interaction of smoking, prostaglandin pathway upregulation and IL-23 dependent innate immune activation can contribute to the pathogenesis of AS

#### FRI0159 ANTIBODIES TO POST-TRANSLATIONALLY MODIFIED COLLAGEN II IN SPONDYLOARTHRITIS

C. Vinci<sup>1,2</sup>. <sup>1</sup>Biochemical Pharmacology, Queen Mary University of London, London, UK; <sup>2</sup>Campus Biomedico of Rome, Rome, Italy

**Background:** Spondyloarthritis (SpA) are a group of rheumatic diseases with either predominantly axial inflammatory symptoms of the spine and sacroiliac joints, or predominantly peripheral arthritis. The most common axial SpA (axSpA) are non-radiographic axSpA and in particular ankylosing spondylitis. The current gold standard diagnostic criteria for axSpA are clinical symptoms, radiology, MRI or ultrasound according to Assessment of SpondyloArthritis international Society (ASAS) criteria.<sup>1</sup> We have previously showed that antibodies to oxidative post-translationally modified collagen type II (oxPTM-CII) are present and specific in RA patients whether ACPA positive or negative.<sup>2</sup>

**Objectives:** The aim of the current study was to test the presence of antibody to oxidised collagen type II (CII) in axSpA, based on the hypothesis that spinal inflammation in axial SpA results in oxidative posttranslational modification (oxPTM) of axial joints cartilage matrix proteins such as CII with the consequently formation of neoepitopes and a secondary humoral autoimmune response.

**Methods:** CII was oxidised by exposing CII to ribose and hypochlorous acid. Levels of antibodies specific to native CII and CII post-translationally modified by oxidants (oxPTM-CII) was assessed by enzyme-linked immunosorbent assays (ELISA) in serum samples obtained from patients with axSpA (n=67) in remission and axSpA patients (n=14) non in remission. Reactivity in axSpA was compared to reactivity in samples from patients with predominantly peripheral arthritis such as psoriatic arthritis (PsA, n=54), undifferentiated arthritis (UA, n=49) and early rheumatoid arthritis (ERA, n=60). As a control we used fibromyalgia (FM, n=19) and healthy subjects (HC, n=70). The specificity of the binding was further assessed by competitive ELISA and western blot.

**Results:** Stronger binding to oxPTM-CII was observed in serum samples from axSpA patients, the positivity was 72% for patients in remission and 86% for patients not in remission (86%) compare to positivity in PsA group (33%), UA group (35%) and FM group (16%), (p<0.0001). Interestingly, binding of axSpA samples was similar to binding of serum samples from ERA (95%). Binding to ROS-CII was directed to a range of ROS-CII fragments between 25 and 150 kDa.

**Conclusions:** Formation of oxPTM-CII neoantigens in the inflamed axial joints results in an immune response that elicits antibodies specific to oxPTM-CII. Once established in future studies, antibodies to oxPTM-CII may be developed as potential biomarker for axSpA.

### FRI0160 INTERLEUKIN-17A INDUCES INFLAMMATORY RESPONSE VIA NLRP3 INFLAMMASOME IN ANKYLOSING SPONDYLITIS

*D. Kim, S.-W. Lee, J.J. Song, Y.-B. Park, M.-C. Park. Division of Rheumatology, Yonsei University College of Medicine, Seoul, Korea, Republic Of*

**Background:** Inflammasomes are cytoplasmic multiprotein complexes that recognise various exogenous and endogenous danger signals in myeloid cells, particularly macrophages. Inflammasome activation eventually induces inflammatory responses in macrophages by activating gasdermin-d-mediated pyroptosis and the secretion of pro-inflammatory cytokines including interleukin (IL)-1 $\beta$  and IL-18 in a caspase-1-dependent manner. The production of IL-1 has been found to be highly induced in AS<sup>1</sup> and caspase-1 level was significantly elevated in spondyloarthritis patients than in those with other arthritic diseases,<sup>2</sup> suggesting the possibility that inflammasomes might be involved in pathogenesis of ankylosing spondylitis (AS). However, few studies have addressed the roles of inflammasomes in AS.

**Objectives:** This study was performed to investigate the role of NOD-like receptor family, pyrin domain containing 3 (NLRP3) inflammasome in the peripheral blood mononuclear cells (PBMCs) from AS patients.

**Methods:** PBMCs from 11 patients and 9 healthy controls were isolated and mRNA expression levels of NLRP3 inflammasome, pro-IL-1 $\beta$ , IL-1 $\beta$ , pro-caspase-1, and caspase-1 were determined using quantitative real-time PCR. IL-17A (100 ng/mL) was added to the cell cultures, then, cytokine expression, signalling pathways, and inflammasome machinery are determined using real-time RT-PCR and Western blot. After transfection of siNLRP3 to AS PBMCs, mRNA and proteins levels of IL-1 $\beta$  and caspase-1 were determined using real time PCR and western blot.

**Results:** Expressions of NLRP3, IL-1 $\beta$ , and caspase-1 mRNAs, but not IL-18, were increased in PBMCs from AS patients compared to controls. Incubation of AS PBMCs with IL-17A significantly increased NLRP3, IL-1 $\beta$ , IL-18, and caspase-1 expressions in AS PBMCs. Western blot showed IL-17A treatment induced the phosphorylation of Akt, p38 MAPK, and NF- $\kappa$ B p65 in AS PBMCs. Down-regulation of NLRP3 by transfection of siRNA decreased mRNA expressions and productions of IL-1 $\beta$  and caspase-1 in AS PBMCs.

**Conclusions:** Activity of NLRP3 inflammasome was increased in AS patients and IL-17A potentiated the activation of NLRP3 inflammasome. Our data suggest the possible role of NLRP3 inflammasome in inflammatory response in AS.

### FRI0161 ROLE OF GITR/GITRL IN MODULATING TH9 RESPONSE IN PSORIATIC ARTHRITIS

*G. Guggino<sup>1</sup>, D. di Iorio<sup>1</sup>, A. Rizzo<sup>2</sup>, M. La Manna<sup>1</sup>, A. Ferrante<sup>1</sup>, L. Saieva<sup>1</sup>, R. Alessandro<sup>1</sup>, G. Sireci<sup>1</sup>, F. Ciccio<sup>1</sup>. <sup>1</sup>Università Degli Studi Palermo; <sup>2</sup>Ospedali riuniti Villa Sofia-Cervello, Palermo, Italy*

**Background:** GITR/GITRL interaction is pivotal in regulating the activity of Treg and Th9 effector cells.<sup>1</sup> Psoriatic arthritis (PsA) is a chronic inflammatory disease characterised by a strong expression of IL-9 and Th9 polarisation in the inflamed gut, synovial tissues and peripheral blood.<sup>2</sup> Factors involved in the regulation of Th9 responses in PsA have been not yet investigated.

**Objectives:** Aim of the study: to investigate the role of GITR/GITRL in PsA.

**Methods:** GITR, GITRL expression were assessed by rt-PCR and immunohistochemistry in synovial biopsies, gut specimens and bone marrow of PsA patients and healthy controls (HC). The co-localization of CD4 and GITR was analysed by immunofluorescence. The expression of GITR was also assessed by flow cytometry analysis in isolated PBMC of patients and controls (Tregs, CD4 and CD8).

Peripheral and intestinal IL-9 producing cell (Th9) percentages and cytotoxic activity of T lymphocytes were also studied by flow cytometry analysis *ex vivo* and after *in vitro* stimulation with GITRL. A mouse model of induced arthritis (collagen induced arthritis, CIA) was used to study GITR/GITRL axis and the effect of anti-GITRL blocking agent.

**Results:** Increased GITR and GITRL expression was observed in the inflamed gut and synovial samples of PsA patients. Analysis of GITR expression among PBMC and LPMC from PsA patients demonstrated its down-regulation among Tregs and upregulation on effector CD4<sup>+</sup> and CD8<sup>+</sup>T cells. In *in vitro* studies, GITR co-stimulation potently induced Th9 activation and IL-9 production. In particular, GITR ligation subverted the induction of Foxp3(+) Tregs, directing the activated CD4(+) T cells to a Th9 phenotype and enhancing the function of DCs and cytotoxic T lymphocytes. Moreover, in a murine model of CIA massive expression of IL-9 and GITR was observed in the synovial tissues and anti-GITR therapy significantly ameliorated arthritis score.

**Conclusions:** We demonstrated that GITR/GITRL axis modulates IL-9/Th9 responses in PsA, representing GITR activation a relevant upstream pathway involved in Th9 polarisation. A novel mechanism by which GITR agonist exert an inflammatory response was also demonstrated in PsA indicating GITR blocking agents as possible therapy in PsA.

### FRI0162 THE LINK BETWEEN ANGIOGENESIS AND OSTEOGENESIS IN SPONDYLOARTHRITIS

*M.H. Kaajij<sup>1,2</sup>, J.P. van Hamburg<sup>1,2</sup>, G. Kollias<sup>3,4</sup>, D.L.P. Baeten<sup>1,2</sup>, L.M. van Duivenvoorde<sup>1,2</sup>, S.W. Tas<sup>1,2</sup>. <sup>1</sup>Amsterdam Rheumatology and immunology Center; <sup>2</sup>Department of Experimental Immunology, AMC/University of Amsterdam, Amsterdam, Netherlands; <sup>3</sup>Division of Immunology, Biomedical Sciences Research Center Alexander Fleming, Vari; <sup>4</sup>Department of Physiology, Medical School, National and Kapodistrian University of Athens, Athens, Greece*

**Background:** Spondyloarthritis is characterised by inflammation, extensive angiogenesis and pathological osteogenesis. Transmembrane (tm)TNF transgenic (tg) mice<sup>1</sup> that overexpress tmTNF exhibit features of SpA, including chronic inflammation and pathological osteogenesis. tmTNF ligation to TNF receptor 2 in endothelial cells (ECs) can induce signal transduction pathways, that may promote these processes. Of note, angiogenesis and osteogenesis are coupled by EC differentiation towards a type H (CD31<sup>hi</sup>endomucin<sup>hi</sup>) phenotype.<sup>2</sup>

**Objectives:** To investigate the link between pathological angiogenesis and osteogenesis in tmTNF tg mice.

**Methods:** Vertebrae and ankles from 6 and 12 weeks and 8 months old tmTNF tg mice or sex-matched non-tg littermates (n=18) were prepared by cutting 60  $\mu$ m thick cryosections for confocal imaging.

**Results:** tmTNF tg mice exhibited ectopic osteogenesis which was not observed in non-tg littermates. The provided image demonstrates an ectopic lesion at the white arrow. Immunostainings showed that type H vessels are in the vicinity of the ectopic osteogenesis and osterix<sup>+</sup> osteoprogenitors. At six weeks of age, osterix<sup>+</sup> cells are located throughout the ectopic lesion, while at eight months, osterix<sup>+</sup> cells are only present at the border of the lesion. Furthermore, there is increased osteogenesis and a different vessel architecture within the vertebrae of tmTNF tg mice compared to non-tg littermates that progresses with age. Non-tg littermate vertebrae only have physiological osteogenesis, which is in the metaphysis and periosteum. In addition, tmTNF tg mice also exhibit altered bone marrow (BM) architecture containing extensive lymphoid aggregates, which predominantly consisted of B220<sup>+</sup> B cells.

**Abstract FRI0162 – Figure 1.** Type H vessel association with ectopic bone formation in 6-week-old murine vertebra. Left panel: Confocal tile scan of tmTNF tg vertebrae showing endomucin\* (red), which labels all vessels except arteries, and CD31\* (green) endothelial cells. Osterix (white) labels osteoprogenitors and nuclei are labelled by Hoechst (blue). Right panel: Higher magnification of osterix\* osteoprogenitors at ectopic location. Osterix\* cells are found around type H (CD31<sup>hi</sup>endomucin<sup>hi</sup>) vessels.

**Conclusions:** tmTNF overexpression in mice leads to development of type H vessels associated with ectopic osteogenesis. In addition, extensive lymphoid aggregates develop in the BM. Current studies are aimed at identification of signalling pathways in ECs that contribute to these processes.

#### FRI0163 DEVELOPMENT OF A PRECLINICAL TESTING PIPELINE FOR A NOVEL TRANSMEMBRANE TNF-DRIVEN SPONDYLOARTHRITIS MODEL

K. Kranidioti<sup>1</sup>, L. Ntari<sup>1</sup>, E. Argyropoulou<sup>1</sup>, C. Geka<sup>1</sup>, N. Karagianni<sup>1</sup>, M.C. Denis<sup>1</sup>, G. Kollias<sup>2,3</sup>. <sup>1</sup>Biomedcode Hellas SA; <sup>2</sup>Institute of Immunology, Biomedical Sciences Research Center (BSRC) Alexander Fleming, Vari; <sup>3</sup>Department of Physiology, School of Medicine, National and Kapodistrian University of Athens, Athens, Greece

**Background:** Spondyloarthritis (SpA) is a complex disease characterised by chronic inflammation, bone erosion and pathological new bone formation. The TgA86 transmembrane TNF (tmTNF) transgenic mouse is a unique model of SpA, developing spontaneously and with 100% incidence early progressive SpA characterised by peripheral inflammatory arthritis and axial ankylosing spondylitis with cardiovascular involvement. This closely recapitulates the pathological findings and comorbid conditions described in human patients.

**Objectives:** To characterise in greater detail the development and progression of the TgA86 pathology and its similarities to human disease and to standardise reliable preclinical protocols and specific readouts for the assessment of the efficacy of human therapeutics.

**Methods:** TgA86 peripheral and axial pathology was assessed at different time points from 2.5 to 28 weeks of age. Disease severity was evaluated using clinical parameters and histopathological analysis of ankle and sacroiliac joints, lumbar and caudal vertebrae, as well as whole mount skeletal staining. Clinical and histopathological readouts were used to assess the therapeutic effect of Etanercept that was administered thrice weekly at 30 mg/Kg starting either from 2.5–5 weeks of age (prophylactic protocol) or from 9 weeks of age (therapeutic protocol).

**Results:** Clinical pathology in TgA86 mice appears already from 2.5 weeks of age, with signs of paw swelling, digit deformation and tail crinkling, while by 9 weeks of age pathology is fully established, with severe peripheral arthritis and tail and spine ankylosis. Pathology progression was also evident histopathologically, characterised by the originally described features of progressive inflammation, cartilage destruction and bone erosion observed in sacroiliac and ankle joints as well as in lumbar and caudal vertebra. Additionally, new pathology features were detected by identifying signs of enthesitis, new bone formation appearing as

cartilaginous structures at the edges of vertebrae endplates, presence of red bone marrow during all stages of disease progression as well as signs of intervertebral disc (IVD) degeneration. Prophylactic treatment with Etanercept ameliorated effectively all clinical and histopathological features of the peripheral and axial pathology. Therapeutic treatment while affecting only minimally the clinical signs of both peripheral and axial pathology, it was found to reduce the peripheral arthritis histopathological score by at least 50%. Finally, treatment with Etanercept was also efficient in ameliorating the comorbid heart valve pathology observed in these animals.

**Conclusions:** We have shown that TgA86 pathology includes features of sacroiliitis, enthesitis, new bone formation, persisting red bone marrow and intervertebral disk degeneration, further strengthening the similarities of this model to human pathology. Based on the assessment of all pathology features during prophylactic anti-TNF treatment we suggest that early on in disease there may be a therapeutic window during which optimal treatment of the pathology can be achieved.

#### FRI0164 ANTI-PFDN5 ANTIBODY AS A BIOMARKER FOR UVEITIS IN ANKYLOSING SPONDYLITIS

O.C. Kwon<sup>1</sup>, E.-J. Lee<sup>1</sup>, E.-J. Chang<sup>2</sup>, W.J. Seo<sup>3</sup>, J.S. Oh<sup>4</sup>, S. Hong<sup>1</sup>, C.-K. Lee<sup>1</sup>, B. Yoo<sup>1</sup>, Y.-G. Kim<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Medicine, University of Ulsan, College of Medicine, Asan Medical Center; <sup>2</sup>Department of Biomedical Sciences, University of Ulsan College of Medicine, Asan Medical Center; <sup>3</sup>Division of Rheumatology, Department of Medicine, Seoul Veterans Hospital; <sup>4</sup>Clinical Research Center, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic Of

**Background:** Noninfectious uveitis is the most common extra-articular manifestation of ankylosing spondylitis (AS). However, molecules related to the disease pathogenesis have yet to be identified, and no biomarkers are available for uveitis in AS.

**Objectives:** We aimed to identify the biomarkers for uveitis in AS, and elucidate the possible pathogenesis of uveitis in AS associated with the identified biomarkers.

**Methods:** Protein microarray using ProtoArray was performed to profile autoantibodies present in sera from patients with various autoimmune diseases, including eight AS patients with uveitis. The autoantibodies with higher reactivity in AS patients with uveitis compared with other patients were selected, and the levels of autoantibodies were measured using ELISA in the sera from AS patients with (n=32) or without uveitis history (n=32), patients with rheumatoid arthritis (n=20) and from healthy individuals (n=12). To evaluate the involvement of target antigen in pathogenesis of spondyloarthritis-related uveitis, we conducted an *in vivo* study using curdlan-induced SKG mice, which spontaneously develops arthritis as well as uveitis, and an *in vitro* study using retinal pigment epithelium cell-line (RPE19).

**Results:** 4 antibodies (Abs) were selected as a candidate for biomarker (anti-PFDN5, area under curve [AUC]=1.00; anti-serine threonine protein kinase 24 Ab, AUC=0.906; anti-odontogenic ameloblast associated protein Ab, AUC=0.859; anti-protocadherin alpha C2 Ab, AUC=0.859). In ELISA, anti-PFDN5 Abs was significantly elevated in AS patients with uveitis compared to AS patients without uveitis. Ocular histology showed that compared to PBS-treated SKG mice, SKG mice with uveitis had strong expression of PFDN5 in iris, ciliary body, and retina. PERK and pelf2 $\alpha$ , which are ER stress related proteins, were downregulated in PFDN5 siRNA-treated RPE19 cells in tunicamycin-induced condition, suggesting that PFDN5 enhances ER stress via PERK and pelf2 $\alpha$  pathway.

**Conclusions:** We identified anti-PFDN5 antibody as a putative biomarker for uveitis in AS. PFDN5 was increased in ocular lesion, which may be associated with disease pathogenesis.

### MICRORNAS DYSREGULATION IN MONOCYTES AND CD4 LYMPHOCYTES FROM PATIENTS WITH AXIAL SPONDYLOARTHRITIS

O. Fogel<sup>1</sup>, A. Bugge Tinggaard<sup>2</sup>, M. Fagny<sup>1</sup>, N. Sigrist<sup>1</sup>, E. Roché<sup>1</sup>, L. Leclère<sup>1</sup>, J.-F. Deleuze<sup>1</sup>, M. Dougados<sup>3</sup>, C. Miceli-Richard<sup>3,4</sup>, J. Tost<sup>1</sup>. <sup>1</sup>Laboratory for Epigenetics and Environment, Centre National de Recherche en Génomique Humaine, Institut François Jacob, CEA, Evry, France; <sup>2</sup>Biomedicine, Aarhus University, Aarhus, Denmark; <sup>3</sup>Rheumatology, Cochin Hospital; <sup>4</sup>Immunoregulation unit, Department of Immunology, Pasteur Institute, Paris, France

**Background:** MicroRNAs have been shown to play a crucial role during innate or adaptive immune response. Dysregulation of miRNAs has been described in several autoimmune or rheumatic diseases including rheumatoid arthritis, inflammatory bowel disease or psoriasis. In spondyloarthritis (SpA), only few studies on miR expression have been reported with highly diverse methodologies and involving small samples of patients.

**Objectives:** Because T CD4 lymphocytes and monocytes are important cells in SpA pathophysiology, we wanted to assess the miR expression profile in these two cell types sorted from axial SpA (AxSpA) patients.

**Methods:** Eighty one AxSpA patients were included in this study. Among these patients, 74 fulfilled the ASAS classification criteria (imaging arm) with sacro-iliitis on X-rays (n=56) or objective signs of inflammation on MRI (n=18). Two independent cohorts of 22 and 59 SpA patients were compared to 17 and 38 age and sex-matched controls. Both SpA patients and controls were recruited from October 2014 to July 2017 in the department of rheumatology at Cochin Hospital in Paris, France. All SpA patients had an active disease despite NSAIDs intake (mean BASDAI score of 49±19 and mean ASDAS score of 3±0.9), were free of any biological treatment and were eligible for a TNF-blocker treatment. Seventy-seven percent were HLA-B27 positive. T lymphocytes and monocytes were isolated from PBMC by direct isolation with magnetic microbeads (CD4 +and CD14+). Three-hundred seventy two miRs were screened by q-RT-PCR on the exploratory cohort and only MiRs showing a significant differential expression in the first cohort were analysed in the validation cohort. An unpaired T-test was used for comparison of miR expression level.

**Results:** In the exploratory cohort, 51 (CD14+) and 70 miRs (CD4+) were found to be differentially expressed between patients and controls. Among these, 15 miRs (in CD14+), and 12 miRs (in CD4+) were also found dysregulated in the validation cohort. These validated miRNAs were found to play a key role in physiological pathways such as NFkB or TGFb, Wnt signalling and monocyte differentiation that have been involved in the pathophysiology of the disease. Neither clinical subphenotypes nor biological parameters were associated with different profiles of miR expression after adjusting for multiple tests. We found a negative correlation between miR-146a-5p level and BASDAI (r=-0.28, p=0.011) and ASDAS (r=-0.38, p=5.9 10<sup>-4</sup>) in monocytes.

**Conclusions:** We found a dysregulation of miR expression in monocytes and T CD4 lymphocytes from patients with axial spondyloarthritis, whose consequences could contribute to the pathophysiology of the disease and be of interest for therapeutic perspective. Moreover, identifying biomarkers with the potential of diagnostic signature should help the clinician in daily practice.

FRI0168

### PHENOTYPIC, FUNCTIONAL AND MOLECULAR CHARACTERISATION OF IL-17+CD8+ T CELLS IN HUMAN HEALTH AND PSORIATIC ARTHRITIS

U. Srenathan<sup>1</sup>, K.J. Steel<sup>1</sup>, M.L. Ridley<sup>1</sup>, B.W. Kirkham<sup>2</sup>, L.S. Taams<sup>1</sup>. <sup>1</sup>Centre for Inflammation Biology and Cancer Immunology, Dept Inflammation Biology, King's College London; <sup>2</sup>Department Rheumatology, Guy's and St Thomas' Hospital, London, UK

**Background:** Psoriatic arthritis (PsA) is a spondyloarthritis affecting the joint and skin. The genetic association with HLA Class I and the clinical efficacy of IL-17A inhibitors in the treatment of PsA suggest a potential role for IL-17 +CD8+T cells in PsA pathogenesis. This concept is supported by our previous data showing that IL-17 +CD8+T cell frequencies are increased in the synovial fluid (SF) vs the peripheral blood (PB) of patients with PsA<sup>1</sup>. We hypothesise that IL-17 +CD8+T cells are pro-inflammatory contributors to PsA pathogenesis.

**Objectives:** To perform molecular, phenotypic and functional characterisation of IL-17 +CD8+T cells.

**Methods:** Healthy donor PB CD8 +T cells were cultured for 3 days with anti-CD3/CD28 mAb, IL-1β and IL-23 to induce IL-17 +CD8+T cells *in vitro*, whilst PB and SF mononuclear cells were isolated from patients with PsA and stimulated *ex vivo* with PMA/ionomycin. Cytokine secretion assays were used to sort IL-17 +CD8+T cells, from which RNA was extracted for RNA-sequencing of PsA PB and SF cytokine-secreting T cells. 24 hour supernatants were generated from cultured sorted cells for cytokine analysis (Luminex) or culture with fibroblasts (IL-6 and IL-8 secretion measured by ELISA).

**Results :** *In vitro*-generated IL-17 +CD8+T cells produced significant levels of IL-17A, IL-17F, IFN-γ, TNF-α, IL-22 and GM-CSF (10–9000 pg/ml range), but little IL-10. Flow cytometry showed that *in vitro*-generated IL-17 +CD8+T cells co-expressed IFN-γ (median 80%), TNF-α (40%) and GM-CSF (35%) at comparable frequencies to *ex vivo* PsA synovial IL-17 +CD8+T cells (70%, 50%, 55% respectively). Whilst only 5% of PsA SF IL-17 +CD8+T cells co-expressed the MAIT cell marker Vα7.2, 50% of *in vitro*-generated IL-17 +CD8+T cells co-expressed Vα7.2. The cytokine profile of *in vitro*-generated Vα7.2+and Vα7.2- IL-17 +CD8+T cell supernatants was however comparable, sharing the cytokine profile of total IL-17 +CD8+T cells. Functionally, *in vitro*-generated sorted IL-17 +CD8+T cell culture supernatants enhanced IL-6 and IL-8 production by synovial tissue fibroblasts from patients with PsA compared to IL-17- counterparts, thus exhibiting pro-inflammatory capacity; we will also determine if this response is IL-17 and/or TNF-mediated. Additionally, the majority of synovial IL-17 +CD8+T cells co-expressed cytotoxic molecule Granzyme B, which may contribute to PsA pathogenesis. Finally, RNA-sequencing revealed that IL-17 +CD8+T cells from PsA synovial fluid displayed a distinct transcriptomic signature compared to PB IL-17 +CD8+T cells as well as to synovial Th17 or Tc1 cells.

**Conclusions :** *In vitro*-generated and *ex vivo*-derived synovial IL-17 +CD8+T cells display a type 17 profile, as evidenced by flow cytometry and Luminex. In contrast to *ex vivo* PsA synovial IL-17 +CD8+T cells, 50% of *in vitro* IL-17 +CD8 +T cells co-express Vα7.2; however, both Vα7.2+and Vα7.2- subsets share a similar cytokine profile. Functionally, IL-17 +CD8+T cells exhibit pro-inflammatory potential, upregulating IL-6 and IL-8 production via fibroblasts. Analysis of our RNA-sequencing data will further reveal the molecular profile of human IL-17 +CD8+T cells, and how they may contribute to joint inflammation in PsA.

### FIRST VALIDATION OF CONSENSUS DEFINITIONS FOR MRI LESIONS IN THE SACROILIAC JOINT BY THE ASSESSMENTS IN SPONDYLOARTHRITIS INTERNATIONAL SOCIETY (ASAS) MRI GROUP

W.P. Maksymowych<sup>1</sup>, U. Weber<sup>2</sup>, S.J. Pedersen<sup>3</sup>, X. Baraliakos<sup>4</sup>, P. Machado<sup>5</sup>, J. Sieper<sup>6</sup>, D. Poddubnyy<sup>6</sup>, S. Wichuk<sup>1</sup>, R.G. Lambert<sup>7</sup>, M. Østergaard<sup>8</sup>. <sup>1</sup>Medicine, University of Alberta, Edmonton, Canada; <sup>2</sup>Rheumatology, King Christian 10th Hospital for Rheumatic Diseases, Graasten; <sup>3</sup>Rheumatology, Gentofte Hospital, Copenhagen, Denmark; <sup>4</sup>Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany; <sup>5</sup>Rheumatology, University College London, London, UK; <sup>6</sup>Rheumatology, Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>7</sup>Radiology, University of Alberta, Edmonton, Canada; <sup>8</sup>Rheumatology, Copenhagen Center for Arthritis Research, Copenhagen, Denmark

**Background:** The diversity of MRI lesions in the sacroiliac joints of patients with axial spondyloarthritis (axSpA) has only recently been appreciated and consistent terminology, descriptions, and definitions have not yet been internationally accepted. The ASAS MRI group has generated updated consensus lesion definitions (ASAS\_MRI\_def<sup>®</sup>) and these now require validation in multi-reader exercises to support widespread adoption for clinical practice and research.

**Objectives:** To assess the reliability of detection of active and structural lesions as defined by (ASAS\_MRI\_def<sup>®</sup>) on MRI images from the ASAS Classification Cohort (ASAS-CC) in a multireader ASAS exercise.

**Methods:** ASAS\_MRI\_def<sup>®</sup> were recorded in an eCRF that comprises global assessment (lesion present/absent) and detailed scoring (SPARCC SIJ inflammation, SPARCC SIJ structural). MRI images were available in a variety of formats (DICOM (n=175), JPEG(n=71), DICOM film(n=32)) and sequences, axial and semicoronal orientations, from 278 of the 495 cases who had MRI performed in the ASAS-CC. Image quality was considered sufficient to record global data by 6 central readers in all cases. An additional reader assessed only images in DICOM format (n=175). Detailed SPARCC scoring data was based only on assessment of images in DICOM format. Detection of lesions assessed as

present/absent by global assessment was analysed using kappa. Reliability of detailed scoring was analysed by intraclass correlation coefficient (ICC).

**Results:** Reliability of detection of active and structural lesions was comparable and somewhat better when DICOM images were evaluated (table 1). The most frequently detected active lesion, subchondral inflammation, was detected to a comparable degree of reliability as the most frequently detected structural lesion, erosion. Fat metaplasia in the joint space (backfill) and ankylosis were also reliably detected despite low frequency of occurrence in this cohort. Mean ICC for detailed scores were BME-0.84, Erosion-0.55, Fatty lesion (any)-0.61, Fatty lesion (>1 cm depth)-0.55, Sclerosis-0.73, Fat metaplasia in joint space-0.36, Ankylosis-0.97, Bone bud-0.07.

**Abstract FRI0169 – Table 1.** Kappa values for detection of MRI lesions in the SIJ of patients in the ASAS-CC

	*Based on all images (n=278).	**Based on DICOM images (n=175).
	Mean of all reader pairs (95% CI)*	Mean of all reader pairs (95% CI)**
Active lesions typical of axSpA	0.73 (0.64-0.81)	0.70 (0.58-0.82)
Active lesions typical of axSpA (confidence ≥3) (1-4 scale)	0.77 (0.69-0.86)	0.80 (0.69-0.92)
ASAS positive MRI	0.74 (0.65-0.82)	0.73 (0.61-0.84)

## FRI0170 CONSENSUS DEFINITIONS FOR MRI LESIONS IN THE SACROILIAC JOINTS OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS: FIRST ANALYSIS FROM THE ASSESSMENTS IN SPONDYLOARTHRITIS INTERNATIONAL SOCIETY (ASAS) CLASSIFICATION COHORT

W.P. Maksymowych<sup>1</sup>, S.J. Pedersen<sup>2</sup>, X. Baraliakos<sup>3</sup>, P. Machado<sup>4</sup>, U. Weber<sup>5</sup>, J. Sieper<sup>6</sup>, S. Wichuk<sup>1</sup>, D. Poddubnyy<sup>6</sup>, M. Østergaard<sup>7</sup>, R.G. Lambert<sup>8</sup>. <sup>1</sup>Medicine, University of Alberta, Edmonton, Canada; <sup>2</sup>Rheumatology, Gentofte Hospital, Copenhagen, Denmark; <sup>3</sup>Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany; <sup>4</sup>Rheumatology, University College London, London, UK; <sup>5</sup>Rheumatology, King Christian 10th Hospital for Rheumatic Diseases, Graasten, Denmark; <sup>6</sup>Rheumatology, Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>7</sup>Rheumatology, Copenhagen Center for Arthritis Research, Copenhagen, Denmark; <sup>8</sup>Radiology, University of Alberta, Edmonton, Canada

**Background:** A broad spectrum of MRI lesions has been described in the sacroiliac joint (SIJ) of patients with axial spondyloarthritis and a recent consensus from the ASAS MRI group has culminated in updated lesion definitions (ASAS\_MRI\_def<sup>1</sup>). There has been no central reader evaluation of MRI scans from the ASAS Classification Cohort (ASAS-CC)<sup>1</sup> to determine the spectrum of MRI lesions in the SIJ in this cohort, to compare the frequencies of different lesion types, and to compare detection of lesions between central and ASAS-CC local site readers

**Objectives:** To determine the spectrum and compare the frequencies of active and structural lesions on MRI images from the ASAS-CC according to the consensus ASAS\_MRI\_def<sup>1</sup> update.

**Methods:** ASAS\_MRI\_def<sup>1</sup> were recorded in an eCRF that comprises global assessment (lesion present/absent) and detailed scoring (SPARCC SIJ inflammation, SPARCC SIJ structural). For global assessment, wording of lesions defining active and structural lesions typical of axSpA was the same as in the original ASAS-CC eCRF permitting comparisons between central and local site readers. MRI images were available in a variety of formats (DICOM (n=175), JPEG(n=71), DICOM film(n=32)) and sequences, axial and semicoronal orientations, from 278 of the 495 cases who had MRI performed in the ASAS-CC. Image quality was considered sufficient to record global data by 6 central readers in all cases. An additional reader assessed only images in DICOM format (n=175). Detailed SPARCC scoring data was based only on assessment of images in DICOM format. Comparison of active and structural lesion frequencies was assessed descriptively according to individual and majority of central readers data. Detection of active

lesions typical of axSpA in all available images from the ASAS-CC was compared between central and local readers.

**Results:** The percentage of cases with active lesions typical of axSpA recorded by central readers (28.4% by majority read) was lower than the 40% reported by local site readers in the ASAS-CC (table 1). This was similar to the frequency of structural lesions typical of axSpA (28.6% by majority read) (table 2). 11.2% had subchondral inflammation but not active lesions typical of axSpA but only 0.3% had active lesions typical of axSpA without subchondral inflammation. Erosion was the most frequently observed structural lesion (25.2%) followed by fatty lesion (19.8%). Results were very similar when only data from the 175 DICOM cases was analysed.

**Abstract FRI0170 – Table 1.** Frequencies of active MRI lesions in the SIJ in the ASAS-CC

Variable	Mean% (Range) of cases*	Number (%) of cases*
Active lesions typical of axSpA	31.5 (24.5-38.5)	79 (28.4%)
Active lesions typical of axSpA and level of confidence ≥3 (scale of 1-4)	22.4 (18.0-27.3)	58 (20.9%)
Active lesions typical of axSpA and meets ASAS definition for positive MRI	30.0 (22.6-37.4)	71 (25.5%)
Meets ASAS definition for positive MRI and level of confidence ≥3 (scale of 1-4)	23.1 (18.3-30.2)	58 (20.9%)
Subchondral inflammation	43.5 (38.5-51.1)	110 (39.6%)
Site of erosion cavity inflammation	8.9 (5.8-12.6)	10 (3.6%)
Capsulitis	4.0 (1.8-7.2)	6 (2.2%)
Joint Fluid	14.1 (6.8-20.5)	11 (4.0%)
Enthesitis	7.5 (1.8-12.2)	6 (2.2%)

(\*Individual data from 6 readers; majority reader (≥4) data).

**Abstract FRI0170 – Table 2.** Frequencies of structural MRI lesions in the SIJ in the ASAS-CC

Variable	Mean% (Range) of cases*	Number (%) of cases*
Structural lesions typical of axSpA	31.4 (23.5-39.9)	68 (28.6%)
Structural lesions typical of axSpA and level of confidence ≥3 (scale of 1-4)	20.8 (14.0-29.4)	46 (19.3%)
Subchondral sclerosis	24.2 (10.1-39.1)	36 (15.1%)
Erosion	27.9 (23.1-32.8)	60 (25.2%)
Fatty lesion (any)	23.5 (18.1-29.8)	47 (19.8%)
Fatty lesion (>1cm)	11.7 (8.0-15.6)	22 (9.2%)
Bone bud (yes)	2.1 (0.4-3.8)	1 (0.4%)
Fat metaplasia in joint space (yes)	8.1 (4.2-10.5)	11 (4.6%)
Ankylosis	1.1 (0.8-3.8)	5 (2.1%)

(\*6 readers; majority reader (≥4) data).

**Conclusions:** In this first central reader analysis of MRI images from the ASAS-CC we demonstrate similar frequencies of active and structural lesions typical of axSpA, erosion as a common lesion, some degree of false positive subchondral inflammation, and a lower frequency of active lesions typical of axSpA than noted by local site readers.

## FRI0171 WHICH IMAGING OUTCOMES FOR AXSPA ARE MOST SENSITIVE TO CHANGE? A 5-YEAR ANALYSIS OF THE DESIR COHORT

A. Sepriano<sup>1</sup>, S. Ramiro<sup>1</sup>, D. van der Heijde<sup>1</sup>, M. Dougados<sup>2</sup>, P. Claudepierre<sup>3</sup>, A. Feydy<sup>4</sup>, M. Rejnjerse<sup>5</sup>, D. Loeuille<sup>6</sup>, R. Landewé<sup>7</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; <sup>2</sup>Rheumatology, Hôpital Cochin; <sup>3</sup>Radiology, Hôpital Henri-Mondor; <sup>4</sup>Radiology, Hôpital Cochin, Paris, France; <sup>5</sup>Radiology, Leiden University Medical Centre, Leiden, Netherlands; <sup>6</sup>Rheumatology, Hôpital Brabois, Nancy, France; <sup>7</sup>Rheumatology, Amsterdam Rheumatology and Clinical Immunology Center (ARC), Amsterdam, Netherlands

**Background:** Several imaging outcomes have become available to assess inflammation and structural damage over time in patients with axial spondyloarthritis (axSpA). However, no formal comparison of their sensitivity to change has been made in the early phases of the disease.

**Objectives:** We aimed to compare the sensitivity to change of different MRI and radiographic scoring methods in patients with early axSpA.

**Methods:** Patients from the DESIR cohort fulfilling the ASAS axSpA criteria were included. Radiographs and MRI of the sacroiliac joints and spine were obtained at baseline, 1 year, 2 years and 5 years. Each film was scored by 2 or 3 readers in 3 'reading-waves' (wave 1: baseline; wave 2: baseline, 1 year, 2 years; wave 3: baseline, 2 years, 5 years). Outcomes measuring inflammation and structural damage both on MRI and radiographs in the spine and SIJ were assessed (table 1). The analysis of change captured over time was performed using generalised estimating equations (GEE) longitudinal models separately for each outcome, taking into account data from all readers and waves ('integrated analysis'). To allow

comparisons across outcomes, these were standardised (difference between the individual score and the mean of all scores divided by the standard deviation, per reader, wave and time-point) before running the models. The higher the standardised coefficient the more change in inflammation/damage is captured.

**Results:** In total, 345 patients were included (mean (SD) symptom duration: 1.6 (0.9) years; 53% males; 89% HLA-B27 positive). Inflammation on MRI-SIJ (according to both the ASAS definition of sacroiliitis and the continuous SPARCC score) was more sensitive to change as compared to inflammation on the spine that remained essentially unchanged regardless of the outcome (table 1). Structural damage on the SIJ was found to increase over time, but with a higher standardised yearly rate of change on MRI-SIJ (range: 0.015–0.274) as compared to X-SIJ (range: 0.043–0.126). Notably,  $\geq 3$  Fatty lesions on MRI-SIJ was the structural outcome in the SIJ with highest sensitive to change (0.274), while  $\geq 3$  erosions was the least sensitive (0.015). Spine structural damage slowly progressed over time but, in contrast to SIJ, radiographic outcomes (i.e.  $\geq 1$  syndesmophytes and mSASSS) were more sensitive to change than MRI structural outcomes.

**Conclusions:** Our data adds to the body of evidence showing that structural damage assessed in pelvic radiographs only has low sensitivity to change. MRI-SIJ is a promising alternative (especially fatty lesions) capturing more structural changes. In contrast, in detecting structural change in early axSpA radiographic outcomes outperform MRI outcomes.

#### FRI0166 CHARACTERISATION OF PHOSPHODIESTERASE 4 (PDE4) BLOCKADE IN THE SYNOVIUM OF PSORIATIC ARTHRITIS PATIENTS: A FOCUS ON SYNOVIAL INVASIVENESS AND T-CELL POLYFUNCTIONALITY

S.M. Wade<sup>1</sup>, M. Canavan<sup>1</sup>, T. McGarry<sup>1</sup>, S.C. Wade<sup>1</sup>, D.J. Veale<sup>2</sup>, U. Fearon<sup>1</sup>.

<sup>1</sup>Molecular Rheumatology, Trinity College Dublin, <sup>2</sup>Center for Arthritis and Rheumatic Diseases, St. Vincents University Hospital, Dublin, Ireland

**Background:** Owing to the multi-faceted nature of the pathogenesis of psoriatic arthritis (PsA), the development of multi-targeted agents has been an area of intensive research. Such agents include the phosphodiesterase 4 (PDE4) inhibitors, Rolipram and Apremilast, which elevate intracellular cAMP levels to modulate a number of anti-inflammatory mechanisms. However, the effect of PDE4 blockade within the complex inflammatory environment of the inflamed synovium remains to be elucidated.

**Objectives:** To characterise the effect of PDE4 blockade in PsA using *ex vivo* synovial whole tissue explants and synovial single cell suspensions reflective of the complex synovial micro-environment.

**Methods:** *Ex-vivo* PsA whole tissue synovial explants were cultured in the presence of PDE4 inhibitor, Rolipram, for 24 hour. The expression of pro-inflammatory mediators were quantified by ELISA and MSD multiplex. A 21 day synovial explant matrigel model was utilised to examine synovial fibroblast (SFC) invasiveness to allow for a long-term assessment. For the characterisation of synovial T-cells, synovial explants were digested and cultured in the presence of Rolipram for 8 hours, stimulated and stained for surface and intracellular T-cell markers. Cell surface expression of CD161 was used to identify Th17 lineage (CD161+Th17 and exTh17 cells) or non-Th17 lineage (CD161-) Th1 cells. SPICE analysis was utilised to determine the proportions of mono- and polyfunctional T-cells, which were correlated with disease activity scores.

**Results:** Rolipram treatment inhibited the spontaneous secretion of inflammatory mediators IL-6, IL-8, MCP-1 and MMP-1 (all  $p < 0.05$ ), with a parallel increase in IL-10 expression. Under DMSO control conditions, a significant increase in SFC outgrowths from PsA explants (indicative of SFC invasiveness) was observed from day 8–21 (all  $p < 0.05$ ), effects of which were significantly decreased in the presence of Rolipram (all  $p < 0.05$ ). A comparative analysis of T cells in PsA PBMC and synovial tissue revealed an enrichment of Th1 ( $p < 0.05$ ), Th17 ( $p = 0.06$ ) and exTh17 ( $p < 0.05$ ) cells in PsA synovial tissue, which displayed distinct polyfunctional cytokine profiles, in particular Th17 cells, as compared to matched PBMC. The frequency of polyfunctional triple positive GM-CSF/TNF/IL-17 and/or IFN $\gamma$  producing Th1 ( $r = 0.8$ ,  $p < 0.05$ ), Th17 ( $r = 0.6$ ,  $p < 0.16$ ) and exTh17 ( $r = 0.9$ ,  $p < 0.05$ ) cells positively correlated with PsA disease activity, suggesting an important role of T-cell polyfunctionality in PsA synovial pathogenesis. Analysis of synovial tissue cell suspensions and matched PBMC cultured in the presence of Rolipram showed a significant decrease in the proportion of these triple positivesynovial T cells compared to DMSO ( $p < 0.05$ ), suggesting that PDE4 blockade can effectively targets the polyfunctional hyper-pathogenic synovial T cells in PsA, particularly polyfunctional CD8 +T cells and Th17 lineage, Th17 and exTh17 cells.

**Abstract FRI0171 – Table 1.** Standardised rate of change of imaging outcomes over 5 years of follow-up in early axSpA patients from the DESIR-cohort who fulfil the ASAS axSpA classification criteria.

Imaging outcomes	Baseline score* (N=313-344)	Standardized rate of change/year†
<b>SACROILIAC JOINTS</b>		
<b>Inflammatory lesions (MRI-SIJ)</b>		
Sacroiliitis (ASAS criteria)	134 (39.2%)	-0.278

**Conclusions:** PDE4 blockade mediates broad anti-inflammatory mechanisms in PsA synovial tissue through the reduced expression of pro-inflammatory mediators, decreased invasiveness and reduced T cell polyfunctionality. We also demonstrate the feasibility of using *ex vivo* models to determine “*in situ* like” assessments of therapeutic agents and further our understanding of disease pathogenesis.

#### FRI0167 EXPRESSION LEVELS OF IL-17, IL-22 AND IL-23 RECEPTORS IN FOUR OSTEOBLAST MODELS AND THE EFFECTS OF IL-17, IL-22 AND IL-23 ON OSTEOBLASTS

J.-R. Zhang<sup>1</sup>, S.-M. Dai<sup>2</sup>. <sup>1</sup>Department of Rheumatology and Immunology, <sup>2</sup>Department of Rheumatology and Immunology, Shanghai Jiao Tong University Affiliated Sixth People's Hospital, Shanghai, China

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory joint disease that chiefly affects the sacroiliac joints and the spine. Radiographs reveal erosive changes at the corners of the vertebral bodies in the early stages of disease, and outgrowth of bony spurs known as syndesmophytes in the later stages. Some data imply a pivotal role of IL-23/IL-17 axis in the regulation of bone homeostasis. However, it remains unknown whether IL-17, IL-22 or IL-23 has any direct effects on osteoblasts or new bone formation in AS.

**Objectives:** To examine the expressions of IL-17, IL-22, and IL-23 receptors in four osteoblast models and the effects of IL-17, IL-22, and IL-23 on osteoblasts.

**Methods:** Gene expression levels of receptors, alkaline phosphatase (ALP), osteocalcin (OCN), and Runt-related transcription factor 2 (Runx-2), were

evaluated by RT-PCR and real-time RT-PCR. Proliferative responses and cell cycle analysis were detected by a CCK-8 assay and flow cytometry, respectively. ALP activity and ALP mass were detected by an ALP activity assay and ALP staining, respectively.

**Results:** In primary osteoblasts, only the IL-17 receptor was expressed. In C2C12, MC3T3-E1, and Saos-2 cells, the genes of IL-17, IL-22, and IL-23 receptors were not detectable. None of IL-17, IL-22, and IL-23 had an obvious effect on the proliferation of primary osteoblasts, but IL-17 exhibited an inhibitory effect on the gene expression of ALP, OCN, and Runx-2. The ALP activity and ALP mass of primary osteoblasts were downregulated by IL-17 treatment in a dose-dependent manner.

**Conclusions:** Primary osteoblasts constitutively express IL-17 receptors, but none of C2C12 cells, MC3T3-E1 cells, and Saos-2 cells express any receptors for IL-17, IL-22, and IL-23. IL-17 inhibits BMP-2-induced osteoblast differentiation.

### INFLAMMATION ON MRI OF THE SACROILIAC JOINTS IS HIGHLY PREDICTIVE OF STRUCTURAL DAMAGE IN AXIAL SPONDYLOARTHRITIS PATIENTS IN CLINICAL PRACTICE: DATA FROM THE ASAS AND DESIR COHORTS

A. Sepriano<sup>1</sup>, S. Ramiro<sup>1</sup>, R. Landewé<sup>2</sup>, M. Dougados<sup>3</sup>, D. van der Heijde<sup>1</sup>, M. Rudwaleit<sup>4</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Centre, Leiden; <sup>2</sup>Rheumatology, Amsterdam Rheumatology and Clinical Immunology Center (ARC), Amsterdam, Netherlands; <sup>3</sup>Rheumatology, Hôpital Cochin, Hôpitaux de Paris, Paris, France; <sup>4</sup>Rheumatology, Klinikum Bielefeld, Bielefeld, Germany

**Background:** The effect of MRI-detected inflammation on the development of radiographic damage at the sacroiliac joints (SIJ) level in patients (pts) with axial spondyloarthritis (axSpA) has been previously shown when images were scored by trained central readers<sup>1</sup>. Central reading decreases measurement error, but does not translate easily to what is usually done in clinical practice.

**Objectives:** To test the possible effect of MRI-SIJ inflammation on structural damage in X-SIJ, when both are assessed by local readers as in daily clinical practice.

**Methods:** Pts with axSpA (according to the treating rheumatologist) from both the ASAS and DESIR cohorts were included. MRI-SIJ and X-SIJ were obtained at baseline (BL), and at follow-up (ASAS: mean 4.4 years; DESIR: 5 years) and scored by local readers (rheumatologists/radiologists). Images were taken unblinded to other imaging information and clinical characteristics. Readers had the option to view the baseline image when scoring the follow-up image. Bone Marrow Oedema (BME) at MRI-SIJ was assessed either without a formal definition (ASAS-cohort) or according to the ASAS definition (DESIR-cohort) as present/absent. Structural damage in the X-SIJ was defined according to the mNY criteria. The% of structural net progression (number of 'progressors' minus the number of 'regressors' divided by the total number of pts) was assessed in subgroups according to CRP and BME status at BL. The effect of BME on MRI-SIJ on X-SIJ damage was evaluated in logistic regression models adjusted for potential confounders selected *a priori* on clinical grounds (gender, HLA-B27, CRP, symptom duration, variables available in both cohorts).

**Results:** In total, 150 (ASAS-cohort) and 421 (DESIR-cohort) pts had complete 5 year X-SIJ data available. Remarkably, but not unexpectedly, the% of improvements in X-SIJ' was impressive both in the ASAS- and DESIR-cohorts (10% and 5.7% respectively), yielding a total% of net progression that was higher in the former than in the latter (14.7% and 5.9%). Net progression in X-SIJ ranged from 0.0% to 33% and from 0% to 17.4% according to the presence of objective signs of inflammation at BL in the ASAS- and DESIR-cohorts, respectively (figure 1). In the multivariable analysis, the presence of baseline BME at MRI-SIJ both in the ASAS (OR=3.2 [95% CI: 1.3–7.9]), and DESIR cohorts (OR=7.4 [95% CI: 4.3–12.7]) was highly predictive of X-SIJ structural progression at follow-up (table 1).

**Abstract FRI0172 – Table 1.** Effect of inflammation on MRI-SIJ at baseline on X-SIJ structural damage at follow-up

Predictor Outcome	mNY
	OR (95% CI)
Sacroiliitis on MRI-SIJ (ASAS-cohort)	3.2 (1.3; 7.9) *
Sacroiliitis on MRI-SIJ (DESIR-cohort)	7.4 (4.3; 12.7) *

\* Adjusted for gender, HLA-B27, CRP, symptom duration.

**Abstract FRI0172 – Figure 1.** Net progression from mNY-negative to mNY-positive according to baseline objective inflammatory markers in the ASAS (A) and DESIR (B) cohorts (ASAS: N=125; 25 patients miss baseline MRI-SIJ; DESIR: N=398; 6 patients miss baseline MRI-SIJ and 17 patients miss baseline CRP).

**Conclusions:** Our results, obtained in two independent cohorts, show that despite the expected increased 'noise' (measurement error) invoked by local reading, inflammation on MRI-SIJ still clearly predicts the later development of radiographic damage in axSpA.

### IDENTIFICATION OF A TYPICAL PATTERN OF MRI LESIONS OF SACROILIAC JOINTS IN PATIENTS WITH OSTEITIS CONDENSANS ILII AS COMPARED TO AXIAL SPONDYLOARTHRITIS

D. Poddubny<sup>1,2</sup>, N. Gobejshvili<sup>1</sup>, T. Diekhoff<sup>1</sup>, H. Weineck<sup>1</sup>, M. Llop<sup>1</sup>, V. Rios Rodriguez<sup>1</sup>, J. Sieper<sup>1</sup>, K.-G. Hermann<sup>1</sup>. <sup>1</sup>Charité Universitätmedizin Berlin; <sup>2</sup>German Rheumatism Research Centre, Berlin, Germany

**Background:** Osteitis condensans ilii (OCI) is regarded as a non-inflammatory disorder that is believed to be induced, for example, by mechanical stress and mechanical instability of the sacroiliac joints (SIJ) related to pregnancy/delivery. OCI is being increasingly recognised as an important differential diagnosis for axial spondyloarthritis (axSpA), due to onset at young age, possible inflammatory character of back pain and recently described presence of subchondral bone marrow oedema on magnetic resonance imaging (MRI) of the SIJ. So far, no systematic comparison of MRI changes in the sacroiliac joints in patients with OCI and axSpA has been performed.

**Objectives:** To compare active and chronic inflammatory lesions of the SIJ as detected by MRI in patients with OCI and axSpA.

**Methods:** Using medical database search we identified n=103 patients aged ≥18 years who were diagnosed with OCI upon presentation with chronic back pain in the Early Spondyloarthritis Clinic of the rheumatology department in the Charité University Hospital between January 2010 and May 2015. These patients were contacted in order to obtain an informed consent and to complete a survey on the disease-related history. A total of 27 patients had evaluable MRIs of the SIJ in STIR and T1-weighted sequences, which were used for the current study. These patients were matched to 27 patients with definite axSpA according to the back pain duration. MRIs were scored according to the Berlin scoring system for osteitis, fatty degeneration, erosions, sclerosis and ankylosis independently by 3 trained and calibrated readers who were blinded for all clinical data including diagnosis. In addition, the preferential localization of lesions (ventral, mid, or dorsal part of the SIJ) was recorded.

**Results:** There were no differences either in the osteitis score or in the proportion of patients with presence of osteitis on MRI of the SIJ between OCI and axSpA patients (table 1). The fatty degeneration score was significantly lower in OCI as compared to axSpA, although the difference in the prevalence of the fatty lesions did not reach the level of statistical significance. There was a non-significant trend towards a higher sclerosis score in OCI patients. Importantly, there was a highly significant difference in the erosion score and in the prevalence of erosions: only 2 (7.4%) OCI vs. 18 (66.7%) axSpA patients had at least one erosion (table 1). Importantly, none of the OCI patients had high-grade (>5 erosions) erosive changes.

There were substantial differences concerning localization of the lesions: in OCI, ventral localization was recorded in 96% of the cases for osteitis, in 100% for fatty degeneration, and in 96% for sclerosis, while in axSpA, osteitis was preferentially localised in the ventral part only in 29% of the cases, fatty degeneration in 25%, sclerosis in 29%. Ankylosis and erosions were localised in the mid part in almost all cases.

**Abstract FRI0173 – Table 1.** Active and chronic lesions of the sacroiliac joints as detected by MRI in patients with osteitis condensans ilii (OCI) and with axial spondyloarthritis (axSpA).

MRI changes	OCI N=27**	axSpA N=27	p-value***
Osteitis score (0-24), mean±SD	3.6 ± 2.3	4.4 ± 4.1	0.89
Osteitis present, n (%)	25 (96.2)	23 (85.2)	0.351
Fatty degeneration score (0-24), mean±SD	2.0 ± 2.3	4.5 ± 6.7	<b>0.001</b>
Fatty degeneration present*, n (%)	14 (51.9)	20 (74.1)	0.158
Erosions score (0-6), mean±SD	0.2 ± 0.4	3.0 ± 2.3	<b>&lt;0.001</b>
Erosions present*, n (%)	2 (7.4%)	18 (66.7%)	<b>&lt;0.001</b>
Ankylosis score (0-2), mean±SD	0	0.3 ± 0.7	<b>0.040</b>
Ankylosis present*, n (%)	0 (0)	4 (14.8%)	0.111
Sclerosis score (0-2), mean±SD	1.4 ± 0.6	1.0 ± 0.8	0.055
Sclerosis present*, n (%)	24 (88.9)	19 (70.4)	0.175

The absolute lesion scores represent mean values of 3 readers. Lesions were considered to be present if the corresponding score was ≥1 in the opinion of at least two readers.

\* N=26 for osteitis. \*\* Derived from the Mann-Whitney U-test for the scale variable or from the Fisher's exact test for the categorical variables.

**Conclusions:** MRI of sacroiliac joints in OCI is characterised by preferential ventral localization of lesions (osteitis, fatty degeneration, sclerosis), absence of ankylosis and absence of extended erosive changes. Such a findings constellation should be taken into account as suggestive of OCI for the differential diagnosis of axSpA in clinical practice.

#### FRI0174 SPINAL RADIOGRAPHIC PROGRESSION IN EARLY AXIAL SPA: 5-YEAR DATA FROM THE DESIR COHORT

S. Ramiro<sup>1</sup>, D. van der Heijde<sup>1</sup>, A. Sepriano<sup>1</sup>, M. van Lunteren<sup>1</sup>, A. Molto<sup>2</sup>, A. Feydy<sup>2</sup>, M.A. D'Agostino<sup>3</sup>, D. Loeuille<sup>4</sup>, M. Dougados<sup>2</sup>, M. Rejnjerse<sup>5</sup>, P. Claudepierre<sup>5</sup>. <sup>1</sup>Leiden University Medical Center, Leiden, Netherlands; <sup>2</sup>Paris Descartes University; <sup>3</sup>Université Versailles-Saint Quentin en Yvelines Boulogne-Billancour, Paris; <sup>4</sup>University of Nancy, Nancy; <sup>5</sup>Université Paris Est Créteil, Créteil, France

**Background:** Spinal radiographic progression has been investigated in patients (pts) with r-axSpA, but not yet as thoroughly in early axSpA.

**Objectives:** To analyse the progression of spinal radiographic damage in pts with early axSpA.

**Methods:** Five-year follow-up data (baseline, 2 and 5 years) from the DESIR cohort, including pts with early axSpA, were used. Cervical and lumbar radiographs were centrally and independently scored by 3 readers (averaged scores), blind for chronological order and clinical characteristics, according to the mSASSS (0–72). Change scores for all available intervals were calculated. Pts were included if they had ≥1 mSASSS interval available (0–2 y, 2–5 y or 0–5 y). The development of new syndesmophytes (2 out of 3 readers) was calculated as a net change, i.e. subtracting the number of pts in whom an existing syndesmophyte ('noise') is no longer reported from those with a new syndesmophyte ('true progression'), divided by all pts. Two- and 5 year mSASSS progression and development of new syndesmophytes were assessed in each subgroup of pts according to the ASAS axSpA criteria and its arms at baseline (see figure 1). In addition, pts were grouped according to the fulfilment of mNYC and also to the presence of baseline syndesmophytes.

**Results:** In total, 549 pts (mean age 34 (SD 9) years, 46% males, 63% fulfilling ASAS axSpA criteria, baseline mSASSS 0.46 (1.54)) were included. Thirty-eight pts (7%) showed syndesmophytes at baseline, 42% of which were ASAS axSpA criteria negative. Mean mSASSS progression was 0.15 (0.94) at 2 years and 0.42 (1.77) at 5 years. 18% of the pts fulfilling the ASAS axSpA criteria showed a 5 year positive mSASSS change (>0), compared to 30% in those not fulfilling the criteria (figure 1). 26% of the pts fulfilling the imaging arm had a positive change: highest positive change in MRI-mNYC+ (34%), followed by MRI+mNYC+(29%) and lastly MRI+mNYC- (23%). Mean mSASSS progression was highest in the mNYC +MRI + group (1.34 (3.98)). Eleven percent of the pts fulfilling only the clinical arm of the ASAS criteria had a positive change in mSASSS at 5 years, mean change of 0.13 (0.65). Pts with baseline syndesmophytes (across all subgroups) had the highest progression: 2.69 (5.02) mSASSS-units. At 5 years, 7% of all pts had a net change of any new syndesmophyte; this was 6% for ASAS+pts, 9% for ASAS-, 10% for pts

fulfilling the imaging arm (18% for mNYC +MRI+) and 3% for pts fulfilling the clinical arm only. Seventeen percent of the mNYC +pts had a net change in new syndesmophytes as well as 42% of the pts with baseline syndesmophytes.

**Abstract FRI0174 – Figure 1.** Five-year mSASSS radiographic progression categories according to the subgroups of the ASAS criteria, arms of the ASAS criteria and fulfilment of mNYC at baseline.

The totals of some groups are higher than the sum of the subgroups due to missing data not allowing to classify patients into the subgroups.

**Conclusions:** Spinal radiographic progression, though limited in early axSpA, can be captured already at 2 years of follow-up. Progression is higher in pts fulfilling the mNYC and also in pts with baseline syndesmophytes. Almost half of the pts with early axSpA with a syndesmophyte at baseline develop further syndesmophytes over 5 years.

**Disclosure of Interest:** None declared

#### FRI0175 RATES AND PREDICTORS OF RADIOGRAPHIC SACROILIITIS PROGRESSION AFTER CENTRAL READING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS FROM THE ASAS COHORT: A 5-YEAR FOLLOW-UP STUDY

M. Protopopov<sup>1</sup>, F. Proft<sup>1</sup>, A. Sepriano<sup>2,3</sup>, R. Landewé<sup>4,5</sup>, D. van der Heijde<sup>3</sup>, J. Sieper<sup>1</sup>, M. Rudwaleit<sup>6</sup>, D. Poddubny<sup>1,7</sup>. <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>NOVA Medical School, Universidade Nova de Lisboa, Lisboa, Portugal; <sup>3</sup>Leiden University Medical Center, Leiden; <sup>4</sup>Amsterdam Rheumatology and Clinical Immunology Center, Amsterdam; <sup>5</sup>Zuyderland Medical Center, Heerlen, Netherlands; <sup>6</sup>Klinikum Bielefeld Rosenhöhe, Bielefeld; <sup>7</sup>German Rheumatism Research Centre, Berlin, Germany

**Background:** In patients with axial spondyloarthritis (axSpA), radiographic progression of sacroiliitis is relatively slow, with only few predictors identified. Recently, an analysis of data from Ankylosing Spondylitis Assessment Society (ASAS) Cohort, based on local assessment of X-Rays, revealed a surprisingly high rate of regression from radiographic axSpA (r-axSpA) to non-radiographic axSpA (nr-axSpA).

**Objectives:** To analyse the rates and predictors for radiographic progression of sacroiliitis in patients with axSpA from the ASAS Cohort, based on the central reading of radiographs.

**Methods:** Altogether 205 patients, who were included in the ASAS Cohort and diagnosed with axSpA by local rheumatologists, with baseline pelvic radiographs available for central reading, were included in the current study. Among them, 106 patients also had a pelvic radiograph at follow up (mean time to follow up 4.4±0.8 years). Images were independently assessed by 2 central readers (MP, FP), blinded for the chronology of the radiographs, according to the scoring system of the modified New York criteria (grade 0–4). In case of disagreement in classification (nr-axSpA or r-axSpA), the image was scored by an adjudicator (DP) that defined the final classification. In addition, we calculated a sacroiliitis sum score (0–8) based on scoring results of 2 (3) readers. The primary outcome was the proportion of patients with progression from nr-axSpA to r-axSpA at follow-up. Predictors of progression were investigated in univariable and multivariable logistic regression analyses.

**Results:** Among 205 patients, 82 (40%) were classified as nr-axSpA, and 123 (60%) as r-axSpA at baseline. Among 106 patients with available baseline and follow-up radiographs, 49 (46.2%) were classified as nr-axSpA, and 57 (53.7%) as r-axSpA at baseline. The agreement between two primary readers in classification (either nr-axSpA or r-axSpA) was moderate to substantial (κ=0.54 at baseline and

$\kappa=0.63$  at follow up); between local and central readers – poor to moderate ( $\kappa=0.18$  at baseline and  $\kappa=0.58$  at follow up). At follow up, 8 (7.5%) patients progressed from nr-axSpA to AS, while 6 (5.7%) were reclassified from AS to nr-axSpA, resulting in net progression of 1.9%. The sacroiliitis sum score increased in 43 (40.6%) patients, decreased in 21 (19.8%) and did not change in 42 (39.6%). Logistic regression analysis showed an association of active and chronic changes on MRI at baseline, already existing structural damage in the sacroiliac joints (sacroiliitis sum score) at baseline and younger age with higher odds for progression from nr-axSpA to r-axSpA.

**Conclusions:** There was a low but still detectable progression from nr-axSpA to r-axSpA after up to 5 years of follow-up in the ASAS cohort. Presence of active and chronic changes on MRI, initial structural damage on radiographs, and younger age at baseline were associated with a higher odds for progression from nr-axSpA to r-axSpA.

#### FRI0176 PERFORMANCE OF SPINAL AND SACROILIAC JOINT MRI FINDINGS IN PATIENTS WITH AXSPA

S. Lee<sup>1,2</sup>, I. Sari<sup>2,3</sup>, E.S. Tunc<sup>2</sup>, R.D. Inman<sup>2,4</sup>, N. Haroon<sup>2,4</sup>. <sup>1</sup>Radiology, Hanyang University Hospital College of Medicine, Seoul, Korea, Republic Of, <sup>2</sup>Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, Canada; <sup>3</sup>Rheumatology, Dokuz Eylul University School of Medicine, Izmir, Turkey; <sup>4</sup>Krembil Research Institute, University Health Network, University of Toronto, Toronto, Canada

**Background:** Early diagnosis of axial spondyloarthritis (AxSpA) is challenging, particularly in patients with normal sacroiliac joints (SIJs) on radiographs. Currently, magnetic resonance imaging (MRI) is considered as the most sensitive imaging modality for detecting early SpA even before radiographic structural lesions develop. However, there are controversial reports, particularly for the spine, regarding the diagnostic utility of MRI.

**Objectives:** To determine the diagnostic utility of spine and sacroiliac joint lesions assessed by MRI in patients with ankylosing spondylitis (AS) or non-radiographic AxSpA (nr-AxSpA) compared to chronic mechanical back pain (MBP).

**Methods:** We included 151 AS, 110 nr-AxSpA, and 37 MBP patients. Spine and SIJ MRIs were performed in all patients. Two independent readers blinded to clinical details of the patients, scored the MRI images. A third reader participated in disputed cases. On T1 weighted sequences, the following structural changes in SIJs were scored: sclerosis ( $\geq 5$  mm) and extensive sclerosis ( $\geq 10$  mm), erosions, <sup>1-2</sup> extensive erosions ( $\geq 3$ ), partial or complete fusion, and fat deposition. Presence in at least two consecutive slices was required for erosions and fusion. On STIR sequences, the following inflammatory changes in the SIJs were determined: ASAS-defined bone marrow oedema (BME) and SPARCC SIJ scores. For the spine, the following were defined: fat infiltration at the vertebral corner on T1 and the number of corner inflammatory lesions (CILs) on STIR. We calculated sensitivity, specificity, and likelihood ratios (LR) of the above-mentioned structural and inflammatory lesions for both AS and nr-AxSpA groups.

**Results:** There were 298 patients in the study: 151 AS (mean age: 39 (16–77) years; 62.3% male), 110 nr-AxSpA (mean age 36 (17–64) years; 45.5% male), and 37 MBP (mean age 38 (19–59) years; 40.5% male). Presence of erosion was the most sensitive SIJ-MRI finding for structural lesions in AxSpA (AS 97%, nr-AxSpA 89%). However specificity of this variable was low (19%). Evidence of fusion and extensive sclerosis were the most specific SIJ-MRI findings for structural abnormalities with poor sensitivity levels in both groups. On the other hand, presence of extensive erosions showed acceptable sensitivity (78% and 58%) and specificity (62%) values in both AS and nr-AxSpA. For inflammatory lesions of SIJ, both ASAS BME and SPARCC  $\geq 2$  had similar sensitivity and specificity values in AxSpA. The presence of SIJ fat and evident erosions was associated with a slight increase in Likelihood of AxSpA. Among spinal lesions, spinal fat was the most sensitive finding in AxSpA (67% and 58%) with limited specificity (40%). CILs had moderate to high specificity but low sensitivity. All spinal parameters had low positive LRs.

**Abstract FRI0176 – Table 1.** Performance of different MRI derived SIJ and spine lesions in AxSpA

#### FRI0177 ASSESSING THE VALUE OF WHOLE BODY MAGNETIC RESONANCE IMAGING AS TO CLINICAL EXAMINATION TO PREDICT REMISSION AND RELAPSE IN EARLY PERIPHERAL SPONDYLOARTHRITIS

T. Renson<sup>1</sup>, P. Carron<sup>1</sup>, S. Krabbe<sup>2</sup>, L. Jans<sup>3</sup>, A.-S. De Craemer<sup>1</sup>, M. de Hooge<sup>1</sup>, P. Jacques<sup>1</sup>, M. Ostergaard<sup>2</sup>, D. Elewaut<sup>1</sup>, F. Van den Bosch<sup>1</sup>. <sup>1</sup>Rheumatology, Ghent University Hospital, Ghent, Belgium; <sup>2</sup>Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; <sup>3</sup>Radiology, Ghent University Hospital, Ghent, Belgium

**Background:** Evaluation of disease activity and treatment response in peripheral spondyloarthritis (pSpA) is currently based upon clinical findings, laboratory tests and ultrasound examination. Whole-body magnetic resonance imaging (WB MRI) is a relatively new imaging technique that could offer additional information regarding the inflammatory status of joints, entheses and soft tissues.

**Objectives:** To determine A) the value of WB MRI, performed at baseline, in relation to clinical remission in pSpA and B) the value of subclinical inflammation, detected by WB MRI, at time of clinical remission in predicting flare after treatment withdrawal in pSpA.

**Methods:** Clinical REmission in peripheral SPondyloArthritis (CRESPA) is a placebo-controlled trial of golimumab treatment in 60 early (symptom duration  $< 12$  weeks) pSpA patients (pts). All pts underwent a modified WB MRI at baseline and at the time of clinical remission when treatment was withdrawn. The WB MRI was performed by scanning multiple locations individually (using different coils) in order to investigate SpA-specific locations in detail. Several anatomical sites of pelvis and lower limbs were evaluated for bone marrow oedema (BME), synovitis and soft tissue inflammation (STI) by 3 readers, giving a score of 0 (no abnormalities), 1 (mild), 2 (moderate) or 3 (severe). For each site a mean of the scores of the 3 readers was calculated. For each patient at each time point, we calculated a sum score for synovitis, STI and BME separately adjacent to a total sum score. Changes scores are baseline minus remission sum scores.

**Results:** Pts reaching clinical remission had significant lower baseline BME sum scores than the non-remission group (mean 1.86 vs. 2.89,  $p=0.024$ ). At the time of clinical remission 10/45 (22%) and 11/45 (24%) pts had residual talocrural and subtalar synovitis respectively. However, there was no statistically significant difference between patients who relapsed after treatment withdrawal and those who remained in remission concerning synovitis sum scores ( $p=0.497$ ) as well as BME sum scores ( $p=0.741$ ) and STI sum scores ( $p=0.131$ ) at time of clinical remission (table 1).

**Abstract FRI0177 – Table 1.** BME, synovitis and STI presence in early pSpA pts who relapsed and did not relapse after stopping golimumab therapy

	Patients relapsed (n=20)	Patients not relapsed (n=25)
BME at baseline	1.82 ( $\pm 2.29$ )	1.69 ( $\pm 1.62$ )
BME at follow-up	1.32 ( $\pm 1.12$ )	1.09 ( $\pm 1.18$ )
Change score BME	0.50 ( $\pm 1.36$ )	0.52 ( $\pm 1.42$ )
Synovitis at baseline	2.53 ( $\pm 3.11$ )	3.53 ( $\pm 3.04$ )
Synovitis at follow-up	1.13 ( $\pm 1.41$ )	1.44 ( $\pm 1.49$ )
Change score synovitis	1.50 ( $\pm 2.71$ )	2.16 ( $\pm 2.81$ )
STI at baseline	1.67 ( $\pm 1.81$ )	2.07 ( $\pm 2.38$ )
STI at follow-up	0.93 ( $\pm 0.75$ )	1.01 ( $\pm 1.12$ )
Change score STI	0.70 ( $\pm 1.34$ )	1.00 ( $\pm 2.06$ )

**Conclusions:** Early pSpA pts who reach clinical remission have less BME on baseline WB MRI compared to those with ongoing disease activity. At time of clinical remission, a substantial part of the participants showed residual ankle synovitis on MRI. However, residual inflammatory lesions detected by WB MRI did not differ significantly between pts who relapsed after treatment withdrawal and those in ongoing clinical remission.

#### FRI0179 INTEGRATED LONGITUDINAL ANALYSIS INCREASES PRECISION AND REDUCES BIAS: A COMPARATIVE 5-YEAR ANALYSIS IN THE DESIR COHORT

A. Sepriano<sup>1</sup>, S. Ramiro<sup>1</sup>, D. van der Heijde<sup>1</sup>, M. Dougados<sup>2</sup>, P. Claudepierre<sup>3</sup>, A. Feydy<sup>4</sup>, M. Rejniers<sup>5</sup>, D. Loeuille<sup>6</sup>, R. Landewé<sup>7</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Centre, Leiden, Netherlands; <sup>2</sup>Rheumatology, Hôpital Cochin, Hôpitaux de Paris, Paris; <sup>3</sup>Radiology, Hôpital Henri-Mondor, Créteil; <sup>4</sup>Radiology, Hôpital Cochin, Hôpitaux de Paris, Paris, France; <sup>5</sup>Radiology, Leiden University Medical Centre, Leiden, Netherlands; <sup>6</sup>Rheumatology, Hospital Brabois, Nancy, France; <sup>7</sup>Rheumatology, Amsterdam Rheumatology and Clinical Immunology Center (ARC), Amsterdam, Netherlands

**Background:** Evaluation of imaging is important in spondyloarthritis (SpA) research, but loss to follow up often jeopardises interpretation of the evaluation. The Interpretation may further be challenged by the fact that often different readers have contributed to scores, in multiple read 'waves'. A common approach is to evaluate patients (pts) with complete follow up (completers analysis), and aggregate scores of individual readers (eg. agreement  $\geq 2$  out of 3 readers). These approaches are not assumption-free, may cause non-random data loss, and may as such provide spurious estimates and loss of external validity.

**Objectives:** We aimed to investigate if the use of all data in an assumption-free manner (a so called 'integrated analysis') affects the precision of estimates for imaging outcomes in pts with axial SpA (axSpA), with completers analysis as reference standard.

**Methods:** Pts from the DESIR cohort fulfilling the ASAS axSpA criteria were included. Radiographs and MRIs of the SIJ and spine were obtained at baseline (BL), 1, 2 and 5 years. Each film was scored by 2 or 3 readers in 3 'reading-waves' (wave 1: BL only; wave 2: BL, 1, 2 years; wave 3: BL, 2, 5 years). Each outcome was analysed in two ways: i. according to a 'combination algorithm' ('2 out of 3' for binary and mean of 3 readers for continuous variables); and ii. per individual reader. The change of each outcome was analysed by generalised estimating equations (GEE) with 'time' as explanatory variable. Three analytical approaches were pursued: i) 'integrated-analysis' (including all pts with  $\geq 1$  score from  $\geq 1$  reader from all waves); ii) completers-only analysis (including only pts with complete 5 year follow-up, using scores from individual readers from wave 3); iii) aggregated completers analysis using a combination algorithm (the same as ii but using combined scores).

**Results:** In total, 413 pts were included (mean (SD) symptom duration: 1.6 (0.9) years) and 366 completed the 5 year follow up. An analysis with all data from different readers and 'waves' ('integrated analysis') was more inclusive, but did not result in a meaningful loss of precision (width of 95%CI) of the change-estimates as compared to both completers analyses (table 1). In fact, for low-incident outcomes (e.g.% of mNY-positive over 5 years), a similar incidence was 'captured', with more precision, by the 'integrated analysis' compared to the completers

analysis with combined scores (% change/year (95% CI): 1.1 (0.7; 1.5) vs 1.2 (0.5; 1.8), respectively). The same results were seen using continuous outcomes.

**Abstract FRI0179 – Table 1.** Change per year in the percentage of positive cases for binary imaging outcomes over 5-years of follow-up, according to 3 different analytical methods, in early axSpA patients fulfilling the ASAS axSpA criteria from the DESIR-cohort

	Integrated analysis	Completers analysis with individual readers scores	Completers analysis with combined scores for readers
Imaging outcomes	% change per year (95% CI) (N=399-411)	% change per year (95% CI) (N=342-364)	% change per year (95% CI) (N=338-364)
<b>SACROILIAC JOINTS</b>			
Sacroiliitis on MRI-SIJ (ASAS criteria)	-7.4 (-11.7; -3.1)	-5.4 (-8.9; -1.9)	-3.1 (-5.1; -1.2)
$\geq 3$ fatty lesions on MRI-SIJ	4.7 (2.7; 6.7)	3.3 (1.7; 4.9)	2.1 (1.1; 3.0)
mNY on X-SIJ (positive/negative)	1.1 (0.7; 1.5)	0.9 (0.5; 1.3)	1.2 (0.5; 1.8)
<b>SPINE</b>			
BME: $\geq 3$ lesions on MRI-Spine (ASAS criteria)	-0.8 (-2.3; 0.7)	-0.4 (-1.4; 0.5)	-0.1 (-1.2; 1.0)
$\geq 5$ fatty lesions on MRI-Spine	-0.2 (-0.9; 0.4)	-0.1 (-0.5; 0.2)	-
$\geq 1$ syndesmophyte on X-Spine	0.8 (0.5; 1.2)	0.5 (0.2; 0.8)	0.5 (0.3; 0.9)

**Conclusions:** An efficient and entirely assumption-free usage of all data from different readers and 'read-waves' does not compromise precision of the estimates of change in imaging parameters, and may yield increased statistical power for detecting changes with low incidence. In addition, integrated analysis may protect against attrition bias and avoid bias by 'convenient choices'.

#### FRI0180 DIAGNOSIS JOURNEY OF PATIENTS WITH ANKYLOSING SPONDYLITIS IN THE UNITED STATES

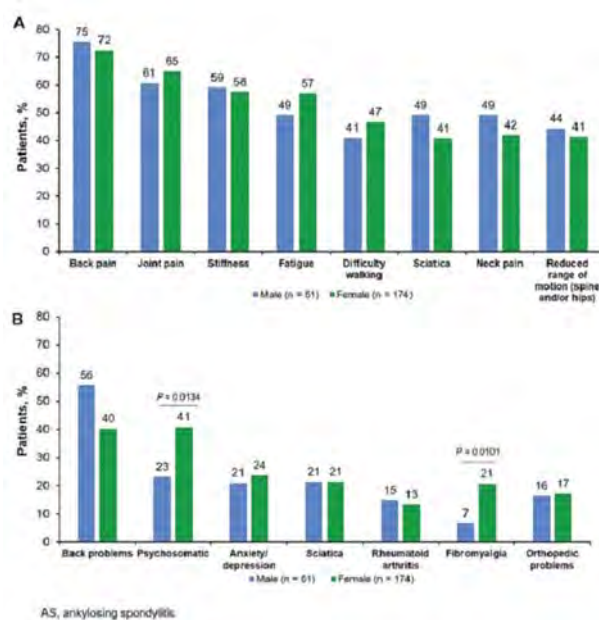

A. Ogdie<sup>1</sup>, W.B. Nowell<sup>2</sup>, R. Reynolds<sup>2</sup>, K. Gavigan<sup>2</sup>, S. Venkatchalam<sup>2</sup>, M. de la Cruz<sup>3</sup>, E. Flood<sup>3</sup>, E.J. Schwartz<sup>3</sup>, B. Romero<sup>3</sup>, Y. Park<sup>4</sup>. <sup>1</sup>Perelman School of Medicine at the University of Pennsylvania, Philadelphia; <sup>2</sup>Global Healthy Living Foundation, Upper Nyack; <sup>3</sup>ICON, Gaithersburg; <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA

**Background:** A US-based study demonstrated that patients with ankylosing spondylitis (AS) experience a significant delay (on average 14 years) from symptom onset to diagnosis of AS.<sup>1</sup> Understanding the diagnosis journey of patients with AS and identifying opportunities to reduce misdiagnosis and incorrect referral are crucial to reducing time to diagnosis, preventing irreversible joint damage, and preserving mobility.

**Objectives:** To describe the patient journey to AS diagnosis from the patient perspective and differences observed between females and males.

**Methods:** US adults aged  $\geq 18$  years with a self-reported diagnosis of AS were recruited through CreakyJoints, an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers. Respondents completed a web-based survey on socio-demographics, clinical symptoms, disease burden, and diagnosis history, which included symptoms that led to seeking care, time from symptom onset to seeking care and from seeking care to AS diagnosis, types of healthcare providers seen, and misdiagnoses. Survey questions were developed following analysis of qualitative interviews of patients with AS and clinical experts, as well as a targeted literature review. Survey results were compared between females and males using 2-sample *t* tests for continuous variables and chi squared tests for categorical variables.

**Results:** Among 235 respondents, 174 (74%) were female. Mean (SD) age of female and male respondents were 48.6 (10.6) and 53.1 (10.3) years, respectively. Although the majority (58% female and 54% male) sought medical care within the first year of symptom onset, female respondents reported a mean of 17.2 years since first symptom onset and 7.5 years since AS diagnosis; while male respondents reported a mean of 20.0 years since first symptom onset and 11.4 years since AS diagnosis. The most common symptoms that led to seeking medical care were back pain, joint pain, stiffness, and fatigue (figure 1A). During the diagnosis process, patients reported seeking medical care from a general practitioner (87%), rheumatologist (65%), orthopedist (27%), chiropractor (26%), and urgent care/emergency room doctor (21%) with no differences between females and males. The most commonly reported misdiagnoses were back problems (56%), psychosomatic (23%), and sciatica (21%) in males, while psychosomatic (41%), back problems (40%), and anxiety/depression (24%) were most common in females. Significantly higher proportions of females reported misdiagnoses of fibromyalgia (21% vs 7%) and psychosomatic (41% vs 23%) (figure 1B).

**Abstract FRI0180 – Figure 1.** Most common first symptom to prompt seeking care (A) and most common misdiagnoses (B) in patients with AS

**Conclusions:** The diagnostic process differs among males and females with AS. Our study findings highlight gender differences in initial symptom presentation, misdiagnoses, and time to diagnosis of AS.

#### FRI0181 TWELVE YEARS FOLLOW-UP OF PATIENTS WITH SPONDYLOARTHRITIS IN AN ENDEMIC CITY DEMONSTRATES HIGH RISK OF ACTIVE TUBERCULOSIS INFECTION

A. Morsch<sup>1</sup>, D. Silva<sup>1,2</sup>, G. Garziera<sup>1,2</sup>, M. Ferreira<sup>1</sup>, C. Kohem<sup>1,2</sup>, R. Xavier<sup>1,2</sup>, A. Gasparin<sup>1</sup>, C. Brenol<sup>1</sup>, R. Bohn<sup>2</sup>, N. de Andrade<sup>1</sup>, D. Vieccell<sup>1</sup>, F. Menegat<sup>1</sup>, P. Palominos<sup>1</sup>. <sup>1</sup>Hospital de Clínicas de Porto Alegre; <sup>2</sup>Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

**Background:** Anti-tumour necrosis factor (anti-TNF) agents can induce progression from latent tuberculosis infection (LTBI) to active tuberculosis (TB) in patient with rheumatic diseases<sup>1,2</sup>. In a high tuberculosis incidence setting, TB cases developed despite the screening and treatment for LTBI.

**Objectives:** To identify, in a high TB incidence setting, the TB incidence rate in patients with spondyloarthritis (SpA) during twelve years of follow-up.

**Methods:** Electronic medical records from patients attending the SpA Clinic between 2004 and 2016 in a public university hospital were reviewed. Patients were grouped in those exposed to anti-TNF therapy and those non-exposed. The tuberculosis incidence rate (IR) was calculated for both groups and expressed as number of events per 1 00 000 patients/year; the incidence rate ratio (IRR) associated to the anti-TNF therapy was calculated.

**Results:** A total of 274 patients were evaluated, 102 exposed to anti-TNF drugs and 172 non-exposed. All the 102 patients underwent screening for LTBI before anti-TNF therapy: 38.2% (n=39) were diagnosed with LTBI and underwent 6 months of isoniazid preventive therapy (IPT). The total follow up time (in patients/year) was 729 in the group exposed to anti-TNF and 1243 in the group non-exposed. Ten patients were diagnosed with TB: 4 exposed to anti-TNF therapy and 6 non-exposed. Among the 4 patients exposed to anti-TNF therapy who developed TB, three had negative screening for LTBI. The TB IR (per 1 00 000 patients/year) among those exposed to anti-TNF was 548, compared to 321 in non-exposed; the IRR associated with the use of anti-TNF drugs was 1.7.

**Conclusions:** In a region with high TB prevalence, patients with SpA exposed to anti-TNF drugs had a higher incidence of TB compared to those who have never been exposed to these drugs. Our data reinforces the American College of Rheumatology's recommendation that patients who live in endemic TB settings should be tested annually for LTBI.

**FRI0182** EROSIONS AT THE SACROILIAC JOINTS AND FATTY LESIONS AT THE SPINE ARE THE MOST DISCRIMINANT LESIONS FOR RECENT ONSET AXSPA RECOGNITION

A. Moltó<sup>1</sup>, L. Gossec<sup>2</sup>, M. Lefevre-Colau<sup>1</sup>, R. Beaufort<sup>1</sup>, V. Foltz<sup>2</sup>, J. Laredo<sup>3</sup>, P. Richette<sup>3</sup>, P. Dieudé<sup>4</sup>, P. Goupille<sup>5</sup>, A. Feydy<sup>1</sup>, M. Dougados<sup>1</sup>. <sup>1</sup>Cochin; <sup>2</sup>Pitié Salpêtrière; <sup>3</sup>Lariboisière; <sup>4</sup>Bichat, Paris; <sup>5</sup>CHU Tours, Tours, France

**Objectives:** To evaluate the performances of MRI (SIJ and Spine) structural lesions suggestive of axSpA for its recognition.

**Methods:** Observational cross-sectional national multicentre study. **Patients:** a) Recent onset axSpA patients: first, a sample of 100 patients representative in terms of imaging abnormalities of the global DESIR recent onset axSpA cohort based on the results of the previously published central reading of baseline films of DESIR were selected. b) Recent onset CBP patients: consecutive in- and out-patients consulting for recent mechanical CBP, initiating before the age of 45 y and with a maximum age of 50 y, in four tertiary care Hospitals were included in the study. **Imaging:** MRI scans (T2-STIR and T1 sequences) of the SIJ and cervico-thoracic and thoraco-lumbar spine were performed in both groups with identical protocol. **Central reading:** an experienced reader (AM) centrally read all MRI scans, blinded for clinical diagnosis. **Statistical analysis:** prevalence of lesions suggestive of axSpA was compared in both groups. Sensitivity, specificity and positive likelihood ratio (LR+) of each lesion were calculated.

**Results:** A total of 98 patients with recent onset CBP were included, and compared to 100 recent onset axSpA patients. Age and gender were comparable (mean (SD) 36.2 (9.9) vs. 32.2 (8.7)y, and 41.8% and 45% males, in the CBP vs. axSpA groups, respectively).

Prevalence of chronic lesions of the SIJ was significantly greater in the axSpA group. Presence of at least 3 subchondral bone erosions at the SIJ performed the best for axSpA discrimination. Prevalence of chronic lesions of the spine was comparable in the two groups. The presence of at least 5 fatty lesions was the most discriminant, with high specificity.

**Conclusions:** Presence of at least 3 erosions at the MRI-SIJ and at least 5 fatty lesions at the MRI-spine seemed to performed well for axSpA recognition.

**Disclosure of Interest:** None declared

**FRI0183** CLINICAL PERIPHERAL ENTHESITIS IN THE DESIR PROSPECTIVE LONGITUDINAL AXIAL SPONDYLOARTHRITIS COHORT

V. Nadon<sup>1</sup>, A. Moltó<sup>2</sup>, A. Etcheté<sup>2</sup>, L. Bessette<sup>3</sup>, L. Michou<sup>3</sup>, M.-A. D'Agostino<sup>4</sup>, P. Claudepierre<sup>5</sup>, D. Wendling<sup>6</sup>, M. Dougados<sup>2</sup>. <sup>1</sup>Institut Rhumatologie Montreal, Montreal, Canada; <sup>2</sup>Cochin, Paris, France; <sup>3</sup>CHUL, Quebec, Canada; <sup>4</sup>Ambroise-Paré, Boulogne-Billancourt; <sup>5</sup>Henri Mondor, Créteil; <sup>6</sup>CHU Besançon, Besançon, France

**Objectives:** 1) To describe the prevalence and characteristics of peripheral enthesitis in recent onset axial spondyloarthritis; 2) to estimate the incidence of peripheral enthesitis over time; 3) to determine the factors associated with the presence of peripheral enthesitis.

**Methods:** **Patients:** 708 patients with recent onset axial spondyloarthritis enrolled in the DESIR cohort (prospective multi-centre, longitudinal). **Data collected:** patients and spondyloarthritis characteristics at baseline with a specific focus on enthesitis and occurrence of peripheral enthesitis, during the five of years follow-up

**Results:** At inclusion, 395 patients (55.8%) reported peripheral enthesitis. The locations were mainly the plantar fascia (53.7%) and the Achilles tendon (38.5%). During the 5 year follow-up period, 109 additional patients developed peripheral enthesitis resulting in an estimated (Kaplan Meier technic) percentage of 71% (95% CI: 68–75). Variables associated with peripheral enthesitis in the univariate analysis were: older age, male gender, absence of HLA B27, MRI sacroiliitis and fulfilled Modified NY criteria, presence of anterior chest wall pain, peripheral arthritis, dactylitis, psoriasis, high BASDAI, BASFI, mean score ASAS and the use of NSAID. Only the history of anterior chest wall pain and of peripheral arthritis were retained in the multivariate analysis (Odds Ratio (OR)=1.6 [95% Confidence interval 1.6 [1.1–2.3], and OR=2.1 [1.4–3.0], respectively).

**Conclusions:** This study highlights the high prevalence of peripheral enthesitis in recent onset axial spondyloarthritis, and suggests that in combination with peripheral arthritis, enthesitis might have an impact on the burden of the disease.

**FRI0184** HIGH PREVALENCE OF HIDRADENITIS SUPPURATIVA, ESPECIALLY IN FEMALE AXIAL SPONDYLOARTHRITIS PATIENTS WITH HIGH DISEASE ACTIVITY AND POOR QUALITY OF LIFE

A. Rondags<sup>1</sup>, S. Arends<sup>2,3</sup>, F. Wink<sup>3</sup>, B. Horvath<sup>1</sup>, A. Spoorberg<sup>2,3</sup>.

<sup>1</sup>Dermatology; <sup>2</sup>Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen; <sup>3</sup>Rheumatology, Medical Center Leeuwarden, Leeuwarden, Netherlands

**Background:** Hidradenitis suppurativa (HS) is a chronic debilitating inflammatory skin disease. Although HS and axial spondyloarthritis (SpA) share common denominators in the pathogenesis and treatment, little is known about HS associated patient characteristics in axial SpA.

**Objectives:** To identify patient characteristics associated with HS in a large cohort of axial SpA patients.

**Methods:** In this cross-sectional study, a self-screening questionnaire based on validated diagnostic HS questions was sent to all axial SpA patients from the Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort. Verification of HS diagnosis was done by reviewing medical records for dermatologists diagnosis of HS and by telephone using another validated diagnostic HS question. These HS questions showed previously high sensitivity and specificity (92%–97%<sup>1</sup> and 97%<sup>2</sup>, resp.). Comparative analysis for axial SpA patients with versus without HS was performed. Multivariable logistic regression analysis of patient characteristics was performed to investigate independent predictors for HS in axial SpA.

**Results:** In total, 75.6% (449/592) questionnaires were eligible for analyses. Included patients had a mean age of 50±13 years, 63% were male, mean symptom duration was 23±13 years, and 78% were HLA-B27 positive. HS diagnosis could be confirmed in 41 of the 449 respondents, resulting in an estimated prevalence of 9.1%. Assuming that all non-responders never had HS, the minimal HS prevalence rate would be 6.9% (41/592).

In comparison to patients without a positive history of HS, these patients were more frequently female (54% vs. 35%, p=0.02), showed higher axial SpA disease activity (mean BASDAI 4.5 vs. 3.6, p=0.01 and ASDAS<sub>CRP</sub> 2.6 vs. 2.2 p=0.003), and worse quality of life (QoL) (median ASQoL 9.0 vs. 4.0, p<0.001). Also, a history of heel enthesitis and dactylitis was more prevalent (34% vs. 19%, p=0.03% and 15% vs. 6%, p=0.05, respectively). Multivariable analysis showed that a higher score on ASDAS was independently associated with HS (OR: 1.639, 95% CI 1.176–2.284).

**Conclusions:** In our cohort of axial SpA patients, HS is more prevalent than in the general population (6.9%–9.1% and ~1% resp.).<sup>3</sup> HS is associated with high ASDAS, especially in female patients experiencing poor QoL. Additionally, heel enthesitis and dactylitis seems also to be more prevalent in axial SpA patients with HS.

**FRI0185** FACTORS DETERMINING WORK INSTABILITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

A.S. Buche, L. Preston, N. Barkham. *Rheumatology, The Royal Wolverhampton NHS Trust, Wolverhampton, UK, Wolverhampton, UK*

**Background:** Work instability is defined as mismatch between the employee's ability to work and the employer's expectations<sup>1</sup>. 50% of Ankylosing spondylitis patient lose their job due to disease activity and 50% of those in job face work instability and job retention problem<sup>2</sup>. Work disability is preceded by a period of work instability, which can be measured by the Ankylosing spondylitis work instability scale (ASWIS)<sup>1</sup>.

**Objectives:** To determine the factors responsible for work instability in patients with Axial spondyloarthritis (axSpA).

**Methods:** Patients attending the Spondyloarthritis clinic at a UK centre from 2013 to 2017, were included, if in employment, and diagnosed with axSpA according to ASAS criteria. Number of patients having low (WIS  $\leq 10$ ) and moderate to high (WIS 11–20) and corresponding parameters were noted. Numerical values were analysed using Spearman rank test and categorical values using Pearson's test. Multiple regression analysis was done. P value  $\leq 0.05$  was considered significant.

**Results:** Of total 255 patients, 139 were in employment (54.5%), 97 were male and 42 were female. Mean age was 43.5 years (20–78 years). 59 patients in manual and 80 patients in non-manual job type, 52 had non-radiographic axSpA (nrSpA) and 87 had radiographic axSpA (rSpA). Mean diagnostic delay was 8 years (0–37 years). Mean ASWIS score was 10.43 (0–20). 75 patients (53.9%) were in Low WIS category and 64 (46%) in moderate to high WIS category. BASDAI and BASFI are found to be significantly correlating with WIS for the whole cohort.

Parameter	Spearman Rank Coefficient	p value
BASDAI	0.7633	0.00011*
BASFI	0.4250	0.00092*

Diagnostic delay, job type, comorbidities, extra articular features, HLAB27, CRP, Pain visual analogue scale (VAS), BASMI, smoking, alcohol and use of biologics were not found to be significant for the whole cohort.

In separate analysis for rSpA and nrSpA groups, the BASDAI and BASFI were of equal significance, but the Pain VAS strongly correlated with WIS in the nrSpA group only ( $r=0.62$ ) and the CRP correlated in the rSpA group only ( $r=0.64$ ).

**Conclusions:** Work instability is prevalent in axSpA, in all job types. Main factors contributing to work instability are disease activity (BASDAI) and function (BASFI). Drivers for work instability may be different in radiographic and non-radiographic patients. A prospective study will evaluate the impact of use of biologic on work instability.

#### CONCOMITANT CSDMARDS INFLUENCE CLINICAL RESPONSE TO TNF INHIBITORS ONLY IN OVERWEIGHT PATIENTS WITH AXIAL SPONDYLOARTHRITIS

B. Hernández-Breijo<sup>1</sup>, V. Navarro-Compán<sup>1</sup>, A. Martínez-Feito<sup>1</sup>, A. Jochems<sup>1</sup>, A. Villalba<sup>1</sup>, D. Peiteado<sup>1</sup>, E.L. Kneepkens<sup>2</sup>, P. Nozal<sup>1</sup>, G.J. Wolbink<sup>2</sup>, T. Rispens<sup>3</sup>, D. Pascual-Salcedo<sup>1</sup>, A. Balsa<sup>1</sup>, C. Plasencia-Rodríguez<sup>1</sup>. <sup>1</sup>Immunorheumatology research group, IdiPaz, University Hospital La Paz, Madrid, Spain; <sup>2</sup>Rheumatology, READE; <sup>3</sup>Immunopathology, Sanquin, Amsterdam, Netherlands

**Background:** In patients with axial spondyloarthritis (axSpA), the use of conventional synthetic disease-modifying anti-rheumatic drugs (csDMARDs), such as methotrexate (MTX) and sulfasalazine (SSZ), as well as the body mass index (BMI) have been associated with circulating TNFi levels. Recently, BMI has also been associated with TNFi clinical response but csDMARDs have not shown any significant clinical improvement for axial manifestations<sup>1</sup>. However, no study has assessed in the same population the influence of both factors -csDMARDs and BMI- on drug serum levels and clinical response

**Objectives:** To investigate the influence of csDMARD and BMI on circulating drug levels and clinical response to TNFi therapy in axSpA patients

**Methods:** A 1 year follow-up prospective observational study with two cohorts (Madrid and Amsterdam) including 180 axSpA patients treated with standard doses of infliximab (41%) or adalimumab (59%). Laboratory and clinical parameters were collected every 6 months. Patients were stratified by BMI: normal-weight (18.5–24.9 kg/m<sup>2</sup>) and overweight-obesity (>25.0 kg/m<sup>2</sup>). TNFi trough levels were measured by capture ELISA<sup>2</sup>. Clinical response to TNFi was defined as  $\Delta$ BASDAI  $\geq 2$ . The association between concomitant csDMARDs and BMI with drug levels and clinical response to TNFi at 1 year was analysed through multivariate log-regression models (odds ratio and 95% CI). The presence of significant interactions between covariates was tested and all models were adjusted for

age, gender, HLA-B27, disease duration, TNFi-type (for drug levels) and baseline BASDAI and CRP (for clinical response)

**Results:** Seventy-nine out of 180 patients (44%) received concomitant csDMARDs (MTX 14%, SSZ 20% and MTX +SSZ 10%), 78 (43%) patients were normal-weight and 102 (57%) overweight-obese. Mean (SD) age and disease duration was 47(13) and 11(9) years respectively, 59% were males, 73% HLA-B27 + and 78% had r-axSpA. Concomitant csDMARDs (OR: 3.82; IC 95%: 1.06–13.84) and being overweight-obese (OR: 18.38; IC 95%: 2.24–150.63) were independently associated with serum TNFi drug presence. Furthermore, a significant interaction between csDMARDs and BMI with clinical response was found. While the use of concomitant csDMARD contributed positively to achieve clinical response in overweight-obese patients (OR: 7.86; IC 95%: 2.39–25.78), no association was found for normal-weight patients (OR: 1.10; 0.33–3.58). Additionally, sensitivity analysis using remission status and ASDAS were performed and showed results along the same line

**Conclusions:** In patients with axSpA, TNFi drug persistence is positively influenced by the use of concomitant csDMARDs and especially by being normal-weight. However, TNFi clinical response is associated with the use of concomitant csDMARDs only in overweight-obese, but not in normal-weight patients. Based on this, the use of concomitant csDMARDs in patients with axSpA could be beneficial in overweight patients

**Background:** Cardiovascular disease (CVD) is the main cause of mortality and morbidity in patients with spondyloarthritis (SpA), partially explained by traditional CV risk factors (CVRF). Other non-conventional CVRF, probably related to chronic systemic inflammation, may be involved. In this sense, lipoprotein (a) [Lp (a)], a non-conventional risk factor with proatherogenic and thrombogenic properties, could be involved, since it seems to act as an acute-phase reactant, there are few data on this aspect in these patients.

**Objectives:** To evaluate the prevalence of hyperlipoproteinemia (a) in patients with SpA and analyse the possible related factors.

**Methods:** Analysis of the baseline visit of patients with ankylosing spondylitis (AS) and psoriatic arthritis (PsA) of the CARMA project (CARDiovascular in REumatology), a prospective cohort study of 10 years of follow-up, to evaluate the cardiovascular risk in chronic rheumatic inflammatory diseases, including rheumatoid arthritis, AS and PsA, followed in 67 Spanish rheumatology centres. A multivariate logistic regression model was performed, in which the dependent variable was hyperlipoproteinemia (a), defined as the plasma concentration of lipoprotein (a) [Lp (a)]  $\geq 50$  mg/dl. Sociodemographic factors and those related to the disease itself have been included as independent variables.

**Results:** 1459 patients were analysed, 738 with AS and 721 with PsA. Plasma concentrations of Lp(a) were available in 57.7% of the patients with AS and in 57.1% of the patients with PsA. A 19.2% (95% CI: 16.80–22.05) of the patients with SpA, 20.7% (95% CI: 16.91–24.82) of AS and 17.7% (95% CI: 14.15–21.75) of PsA, respectively, had hyperlipoproteinemia (a), without statistically significant differences with respect to the control group: 16.7% (95% CI: 13.23–20.86;  $p=0.326$ ). After adjusted for age and sex, only patients with AS were more likely to have hyperlipoproteinemia (a) than the control group (OR: 1.806, 95% CI: 1.177–2.771,  $p=0.007$ ). In the model adjusted for possible confounding factors, high values of apolipoprotein B in all patients, non-steroidal anti-inflammatories in AS, and sex (men) and kidney disease as comorbidity in PsA, were associated with a higher probability of presenting hyperlipoproteinemia (a).

**Conclusions:** Patients with AS have a higher percentage of hyperlipoproteinemia (a) compared to the control group. No specific factors of the disease have

been identified that are associated with hyperlipoproteinemia (a) in each of the analysed groups.

**FRI0188** **FACTORS ASSOCIATED WITH PATIENT-PHYSICIAN DISCORDANCE IN GLOBAL ASSESSMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: AN ASIAN PERSPECTIVE**

C. Wang<sup>1</sup>, W. Fong<sup>1</sup>, Y.H. Kwan<sup>2</sup>, J.K. Phang<sup>1</sup>, N.L. Lui<sup>1</sup>, Y.Y. Leung<sup>1</sup>, J. Thumboo<sup>1</sup>, P. Cheung<sup>3</sup>. <sup>1</sup>Department of Rheumatology and Immunology, Singapore General Hospital; <sup>2</sup>Program in Health Services and Systems Research, Duke-NUS Medical School; <sup>3</sup>Department of Rheumatology, Allergy and Immunology, National University Hospital Singapore, Singapore, Singapore

**Background:** Shared decision making between patients and physicians is important in the management of patients with axial spondyloarthritis. However patient's perspective on disease activity is not always similar to physician's perspective.<sup>1</sup> There are limited studies on patient-physician discordance, none of which is based on Asian population.

**Objectives:** To identify the factors associated with patient-physician discordance in patients with axial spondyloarthritis (axSpA) in an Asian population.

**Methods:** A cross-sectional study was conducted in 2 tertiary referral centres in Singapore. Patients who fulfilled ASAS 2009 criteria for axial spondyloarthritis (axSpA) were recruited. Sociodemographic, clinical, laboratory and patient reported outcomes (PROs) data were collected during study visits from 2014 to 2015. We performed univariate and multivariate logistics regression analysis to evaluate the factors associated with patient-physician discordance, which we defined as the absolute difference  $\geq 20$  mm between Patient Global Assessment (PGA) and Physician Global Assessment (PhGA).

**Abstract FRI0188 – Table 1.** Multivariate logistic regression analysis of patient-physician (PGA-PhGA) discordance with different variables.

Characteristics	PGA-PhGA	
	OR (95% CI)	p value
Current age	1.00 (0.98–1.02)	0.69
Education <sup>a</sup>	0.35 (0.12–0.98)	0.04
If post-secondary (6 years)		
Pain score	1.03 (1.01–1.05)	<0.01
BASFI	1.08 (0.94–1.25)	0.23
ASDAS CRP	0.82 (0.59–1.13)	0.23
Current Biologics use	2.63 (1.34–5.17)	<0.01

Abbreviations: ASDAS CRP: Ankylosing Spondylitis Disease Activity Score C-reactive protein; BASFI: Bath Ankylosing Spondylitis Functional Index

**Results:** 298 axSpA patients were included: 82% male, 81% Chinese, median age of 40 (range:20–78) years, median disease duration of 9 (range:0.1–48) years. 80% were on non-steroidal anti-inflammatory drugs and 23% were on biologics. In univariate logistic regression analysis, current age (OR:1.01, p=0.09), post-secondary education level (OR:0.34, p=0.02), pain score (OR:1.03, p<0.01), Bath Ankylosing Spondylitis Functional Index (BASFI) (OR:1.26, p<0.01), Ankylosing Spondylitis Disease Activity Score C-reactive protein (ASDAS-CRP) (OR:1.39, p<0.01) and current use of biologics (OR:1.80, p=0.05) were associated with patient-physician discordance. In multivariate logistic regression analysis, pain score (OR:1.03, p<0.01), post-secondary education level (OR:0.35, p=0.04) and current biologics use (OR:2.63, p<0.01) were associated with patient-physician discordance.

**REFERENCE:**

a with reference to pre-secondary

**Conclusions:** Higher pain score, lower education level and current biologics use were associated with greater patient-physician discordance. These factors should be taken into account during shared decision making.

**FRI0189** **PERIPHERAL MANIFESTATIONS IN SPONDYLOARTHRITIS: IMPACT ON PATIENT-REPORTED OUTCOMES (PROS) AND TREATMENT. DATA FROM ASAS-COMOSPA**

C. López-Medina<sup>1,2</sup>, A. Moltó<sup>1,3</sup>, M. Dougados<sup>1,3</sup>. <sup>1</sup>Rheumatology, Cochin Hospital, Paris, France; <sup>2</sup>Rheumatology, Hospital Universitario Reina Sofia/IMBIC/ Universidad de Córdoba, Córdoba, Spain; <sup>3</sup>Inserm (U1153), clinical epidemiology and biostatistics., PRES Sorbonne Paris-Cité, Paris, France

**Background:** Peripheral manifestations (arthritis, enthesitis and dactylitis) are frequent in patients with Spondyloarthritis (SpA)<sup>1</sup>. However, little is known regarding the impact of these manifestations on patients' disease perception and treatments.

**Objectives:** To evaluate the impact of the presence of peripheral manifestations on patient-reported outcomes (PROs) and treatment.

**Methods:** Data from the ASAS-COMOSPA study were analysed. Patients who reported peripheral arthritis were divided into three groups: current, past history and no history. The impact of the presence of peripheral arthritis on VAS-G (Global Visual Analogue Scale), BASDAI (Bath Ankylosing Spondylitis Activity Index), BASFI (Bath Ankylosing Spondylitis Functional Index), work and activity impairment was evaluated through the use of the ANOVA one factor test. Finally, NSAIDs, corticosteroids and DMARDs intake were compared among patients with and without peripheral articular involvement.

A similar statistical analysis was performed for enthesitis and dactylitis.

**Results:** Among the 3984 patients included in the ASAS-COMOSPA study, 1333 (33.5%), 718 (18%) and 1933 (48.5%) patients had current, past history and no history of peripheral arthritis, respectively. Patients with current peripheral arthritis showed higher levels in VAS-G, BASDAI, BASFI, as well as in work and activity impairment, in comparison to the other two groups, being these differences statistically significant (p<0.01). Patients with peripheral articular involvement at the time of the visit showed higher mean scores in all questions of the BASDAI questionnaire, in contrast to those with past history and/or no history (p<0.001). Impact on treatment is shown in table 1.

Regarding enthesitis, 642 (16.1%), 864 (21.7%) and 2478 (62.2%) patients had current, past history and no history of enthesitis, respectively. Patients with current enthesitis showed significant higher levels in all PROs against the other two groups of patients (p<0.05), as well as higher scores in all the BASDAI questions (p<0.001). Finally, 171 (4.3%), 447 (11.2%) and 3366 (84.5%) patients had current, past history and no history of dactylitis, respectively. The same results as the other two peripheral manifestations were obtained regarding impact on PROs and BASDAI questions.

**Conclusions:** The presence of any of the three peripheral manifestations at the time of the visit was associated to higher scores in all PROs. Patients with peripheral involvement showed greater use of NSAIDs, corticosteroids and DMARDs than those without peripheral manifestations.

### RELATIONSHIP BETWEEN FAECAL CALPROTECTIN, HLAB-27 AND ACUTE PHASE REACTANTS IN PATIENTS WITH SPONDYLOARTHRITIS WITHOUT PRIOR DIAGNOSIS OF INFLAMMATORY BOWEL DISEASE

C. Ramos Giraldez<sup>1</sup>, M. Espinosa Malpartida<sup>1</sup>, C. Merino Arguménez<sup>1</sup>, B. Ruiz Antorán<sup>2</sup>, J. Campos Esteban<sup>1</sup>, C. Barbadillo Mateos<sup>1</sup>, H. Godoy Tundidor<sup>1</sup>, B. Agudo Castillo<sup>3</sup>, Y. González Lama<sup>3</sup>, J.L. Andrés Sánchez<sup>1</sup>, J. Sanz Sanz<sup>1</sup>.  
<sup>1</sup>Rheumatology Service; <sup>2</sup>Clinical Pharmacology Service; <sup>3</sup>Gastroenterology Service, Hospital Universitario Puerta De Hierro Majadahonda, Madrid, Spain

**Background:** Faecal calprotectin (FC) is a biomarker of inflammatory bowel activity widely used in the diagnosis and follow-up of inflammatory bowel disease (IBD). Microscopic intestinal inflammation is described in approximately 50% of patients with spondyloarthritis (SpA), and it is associated with more severe disease.

**Objectives:** The purpose of this study was to describe the possible relationship between FC, HLAB27 and acute phase reactants in patients diagnosed of SpA without clinical suspicion or prior diagnosis of IBD.

**Methods:** Unicentric, cross-sectional observational study with prospective clinical data collection. We included consecutively selected patients in the Rheumatology Clinic diagnosed of SpA who fulfilled ASAS criteria and did not have digestive symptoms suggestive of IBD (chronic diarrhoea, rectal bleeding, perianal disease or chronic abdominal pain persistent/recurrent). Demographic, clinical and analytical data from SpA (Uveitis, HLAB27, acute phase reactants), treatments and FC were collected and a FC cut-off point >50 MG/kg was determined. For patients on NSAIDs suspension was recommended two weeks prior to collection of stool samples. The study was approved by the centre's Ethics Committee for Clinical Trials.

**Results:** Ninety-nine patients were included. 50% male, average age 46±11 years old. 3.7±2.5 BASDAI. 79% HLA-B27 positive, 31% had elevated levels of ESR, 9% elevated CRP (>10 mg/L). 49 patients (49.5%) had high levels of FC, with mean levels of 276 mg/kg (range 52–3,038). HLAB27 positive patients had significantly higher FC levels than HLAB27 negative patients (160 mg/kg vs 98 mg/kg; p<0.05). There were no differences in relation to the history of uveitis. Patients with high FC had significantly higher CRP levels than patients with normal FC (6.7 mg/L vs. 3.2 mg/L; p<0.05), in accordance with these results from the group of patients with CRP levels>10 mg/L, the percentage of FC elevation was 78% vs. 47% of patients with CRP <10 mg/L. There were no significant differences in relation to ESR.

**Conclusions:** Patients with spondyloarthritis (ASAS criteria), HLAB27 positive and elevated CRP have higher levels of faecal calprotectin, a biomarker of inflammatory bowel activity, which may indicate that inflammatory activity in SpA might be associated with subclinical intestinal inflammation.

### SIMILARITIES AND DIFFERENCES BETWEEN OSTEITIS CONDENSANS ILII AND AXIAL SPONDYLOARTHRITIS PATIENTS PRESENTING WITH CHRONIC BACK PAIN IN A RHEUMATOLOGY SETTING

D. Poddubnyy<sup>1,2</sup>, H. Weineck<sup>1</sup>, J. Listing<sup>2</sup>, T. Diekhoff<sup>1</sup>, K.-G. Hermann<sup>1</sup>, J. Sieper<sup>1</sup>.  
<sup>1</sup>Charité Universitätsmedizin Berlin; <sup>2</sup>German Rheumatism Research Centre, Berlin, Berlin, Germany

**Background:** Osteitis condensans ilii (OCI) is regarded as a non-inflammatory disorder, which is considered to be induced by mechanical stress (e.g., by pregnancy and delivery). The diagnosis is normally based on wide spread sclerosis of the sacroiliac joint without erosions or ankyloses on imaging. More recently, par-articular bone marrow oedema has been described on MRI, which can occur early but also intermittently later in the course of the disease. The clinical characteristics of OCI patientst have not been well described. To date, there are no published systematic data on the characteristics of OCI as compared to axial spondyloarthritis (axSpA).

**Objectives:** The objective of this matched case-control study was to investigate demographic, clinical, and lab characteristics of OCI as compared to axSpA.

**Methods:** Using medical database search we have identified n=103 patients aged ≥18 years who were diagnosed with OCI upon presentation with chronic back pain in the Early Spondyloarthritis Clinic of the rheumatology department in the Charité University Hospital between January 2010 and May 2015. These patients were contacted in order to obtain an informed consent and to complete a survey on the disease-related history. n=60 OCI patients who provided an informed consent and completed the survey were included in the final analysis. These patients were matched with a 1:2 ratio according to the back pain duration to patients with definite axSpA diagnosed in the same setting in order to compare demographic, clinical and lab characteristics.

**Abstract FRI0191 – Table 1.** Demographic, clinical and lab characteristic of OCI as compared to axSpA in the rheumatology setting.

Characteristics	OCI N=60	axSpA N=120	p-value
Age, years	40.3±10.0	39.4±11.3	0.51
Female sex, %	96.7%	41.7%	<0.001
Age at back pain onset, years	29.7±9.0	30.5±9.0	0.59
Back pain duration, years	9.0±7.9	8.9±8.0	n.a.*
HLA-B27 positive, %	35.2%	84.2%	<0.001
CRP, mg/l	2.1±2.1	11.3±27.6	<0.001
Elevated CRP (>5mg/l), %	7.1%	41.3%	<0.001
Inflammatory back pain, %	39.5%	92.3%	<0.001
Good response to NSAIDs, %	73.8%	76.9%	0.67
Peripheral arthritis, %	4.5%	12.5%	0.25
Enthesitis of the heel, %	4.8%	15.8%	0.11
Dactylitis, %	0%	5.0%	0.60
Uveitis, %	0%	11.7%	0.011
Psoriasis, %	5.6%	3.3%	0.68
Inflammatory bowel disease, %	1.8%	2.5%	1.00
Family history of SpA, %	32.7%	20.8%	0.12
BASDAI, NRS points (0-10)	4.6±2.0	4.0±2.0	0.17
BASFI, NRS points (0-10)	3.4±2.2	3.1±2.3	0.49
Menell's test positive, %	37.5%	62.5%	0.09
Patrick's test positive, %	45.8%	69.6%	0.07
Tenderness in the SIJ area, %	75.6%	66.7%	0.48
Schober's test, cm	4.2±0.9	4.6±2.1	0.63
Lateral spinal flexion, cm	15.6±5.0	15.3±4.5	0.83

\*Matching variable

**Results:** The main characteristics of the two groups are presented in the table. Most importantly, all but 2 patients with OCI were females and had a significantly lower prevalence of inflammatory back pain, lower level of CRP stressing a rather non-inflammatory nature of this condition. All patients were referred because of possible axial SpA, therefore SpA features, although being lower than in axSpA patients (table 1), were higher than can normally be expected in OCI patients. This is probably the reason why a statistical significance in comparison to axSpA was observed for uveitis only. There was no difference in age of back pain onset (but age <45 years was a referral parameter). Signs of sacroiliitis at physical examination were only slightly more frequent in axSpA; there were no differences in spinal mobility. The level of symptoms (BASDAI) and the perceived level of functional disability (BASFI) were comparable between groups. 83% of female patients with OCI reported a history of at least one pregnancy with a mean number of pregnancies of 3 (median=3, range 1–8).

**Conclusions:** OCI manifesting with chronic back pain starting prior to 45 years of age represents an important differential diagnosis for axSpA. A constellation of a female sex (with a history of pregnancies), negative HLA-B27 and negative CRP seems to be of differential diagnostic value as compared to axSpA.

FRI0192

### PREDICTORS OF SEVERE HIP INVOLVEMENT IN ANKYLOSING SPONDYLITIS: DATA FROM NATIONAL INPATIENT SAMPLE

P. Karmacharya<sup>1</sup>, D.R. Poudel<sup>2</sup>, P. Shrestha<sup>2</sup>, R. Dhital<sup>2</sup>, J.M. Davis III<sup>1</sup>.  
<sup>1</sup>Rheumatology, Mayo clinic, Rochester; <sup>2</sup>Reading Hospital and Medical Center, Reading, USA

**Background:** Hip involvement in ankylosing spondylitis (AS) is common (24%–36%), leading to worse functional outcomes. While some cases achieve long-term remission, few develop progressive joint destruction with 5%–8% requiring hip replacement. Although studies in the past have looked at factors associated with severe hip involvement, these remain debated.

**Objectives:** To investigate the factors associated with severe hip disease in patients with AS using a large inpatient US database.

**Methods:** Using the Nationwide Inpatient Sample (NIS) data from 2009–2011, we identified patients with AS based on International Classification of Diseases, Ninth Revision (ICD-9) code 720.0 (first 5 positions) and identified patients with hip surgery with ICD-9 procedural codes 800.5, 801.5, 802.5, 803.5, 804.5, 807.5, 808.5, 809.5, 812.1, 815.1, 815.2, 815.3 (any position). NIS is the largest publicly available all-payer inpatient care database in the United States, sponsored by

Agency for Healthcare Research and Quality as a part of Healthcare Cost and Utilisation Project. Univariate and multivariate binomial logistic regressions were used to derive odds ratio for predictors of hip surgery. Statistical analysis was done using STATA version 13.0 (College Station, TX).

**Results:** NIS database from 2009–2011 contained 3538 (weighted counts in the whole US population n=17,480) patients with AS. Out of those, 190 (weighted n=934) had hip surgery (5.36%). Multivariate binomial regression analysis after controlling for confounders (table 1) showed male sex (OR 2.52, CI 1.65–3.83, p<0.001) and peripheral enthesopathy (OR 8.64, CI 2.48–30.12, p<0.001) to be significantly associated with hip surgery in AS patients, and an inverse relationship with inflammatory bowel disease (IBD) (OR 0.35, CI 0.16–0.76, p=0.01) was seen.

AS with Hip Surgery	Odds Ratio	Standard error	p-value	95% CI	
				Lower limit	Upper limit
Age	1	0	0.46	0.99	1.01
Male sex	<b>2.52</b>	<b>0.54</b>	<b>&lt;0.001</b>	<b>1.65</b>	<b>3.83</b>
Non-white	1.11	0.25	0.65	0.71	1.74
Income quartile	1.33	0.21	0.07	0.97	1.83
CAD	0.6	0.16	0.06	0.35	1.02
CKD	0.65	0.31	0.36	0.25	1.66
DM	0.64	0.17	0.09	0.38	1.07
CHF	0.14	0.14	0.05	0.02	1.04
Current smoking	0.75	0.18	0.23	0.46	1.20
Obesity	1.24	0.35	0.46	0.71	2.16
Uveitis	1.04	0.77	0.96	0.25	4.43
IBD	<b>0.35</b>	<b>0.14</b>	<b>0.01</b>	<b>0.16</b>	<b>0.76</b>
Psoriasis	0.85	0.64	0.84	0.2	3.74
Peripheral enthesopathy	<b>8.64</b>	<b>5.5</b>	<b>&lt;0.001</b>	<b>2.48</b>	<b>30.12</b>
Constant	0.04	0.01	<0.001	0.02	0.06

**Conclusions:** Our study found male sex and patients with peripheral enthesopathy to have higher odds of severe hip disease requiring surgery among hospitalised AS patients and significantly lower odds with IBD. Previous studies showed an association with age at onset, delay in diagnosis, bilateral involvement, axial/enthesial disease and severe sacroiliitis. Some of these associations could not be analysed in our study due to lack of individual level patient data. Interestingly, epidemiological factors like smoking and obesity which have been linked to severe disease in PsA, were not found to have any significant association. Routine clinical hip exam and radiological imaging might help to identify high-risk patients. Early therapeutic strategies might be indicated for this specific population to prevent severe hip disease and need for hip replacement surgery.

**FRI0193** **PROGNOSTIC MARKERS IN AXIAL SPONDYLOARTHRITIS (PROMISE) – CROSS SECTIONAL EVALUATION OF SERUM BIOMARKERS IN AXSPA, MECHANICAL BACK PAIN AND HEALTHY CONTROLS**

E. Reilly<sup>1</sup>, C. Fisher<sup>2</sup>, R. Sengupta<sup>1</sup>. <sup>1</sup>Royal National Hospital for Rheumatic Diseases, Bath; <sup>2</sup>University College London, London, UK

**Background:** In recent years there has been increasing interest in biomarkers in axial spondyloarthritis, for diagnosis, disease prognostication, and to monitor treatment effect.<sup>1,2</sup> Many biomarkers have been evaluated, but the role each of these plays and how they may interact is unclear.

**Objectives:** Our aim was to evaluate a broad panel of serum biomarkers in a large mixed cohort of patients, with Ankylosing Spondylitis (AS), non radiographic axial Spondyloarthritis (nr-axSpA), mechanical back pain (MBP) and healthy controls (HC), in order to identify any potential biomarkers for diagnosis by assessing the differences between the groups.

**Methods:** Cross sectional evaluation of 46 serum biomarkers was undertaken by Myriad RBM using multiplexed immunoassays of Multi-Analyte Panels, in a cohort of patients from a tertiary referral centre, consented as part of the Bath Spondyloarthritis BioBank. Validated patient reported outcomes (including BASDAI, BASFI) and BASMI were completed. 50 HC blood samples were also collected at University College London for biomarker analysis.

**Results:** 331 patients were included in the study, of which 59.5% AS, 8.2% nr-axSpA, 15.7% mechanical back pain, 15.1% HC. 64.7% were male, mean age 44.2 years (SD 16.6), mean disease duration in the AS group of 22.4 years (SD 13.6) with 84% HLA B27 positive.

IL1 alpha and beta, IL1 receptor antagonist, IL2, 3, 4, 5, 7, 10, 15, 17, IL12 subunit p70, factor VII, GM-CSF, IFN gamma, MMP9, TNF beta were the only biomarkers not to show statistical differences across the diagnostic groups (table 1.). 12 biomarkers showed a statistical difference between genders (table 1, column 1, p value significance indicated with \*<0.05, \*\*<0.01 using Mann Whitney U, in addition to Factor VII\*).

**Abstract FRI0193 – Table 1.** Statistically significant serum biomarker results by diagnosis

**Conclusions:** Serum biomarkers have been shown to vary with gender and diagnosis. Further work is planned to evaluate their relationship to disease activity using outcome measures such as the BASDAI, and radiographic scoring, to better understand the role of each factor and combination of factors, and any causal link.

**FRI0194** **ANKYLOSING SPONDYLITIS DISEASE ACTIVITY SCORE (ASDAS) BASED ON A QUICK QUANTITATIVE CRP ASSAY PERFORMS SIMILARLY WELL TO ASDAS BASED ON CONVENTIONAL CRP IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

E. Proft<sup>1</sup>, B. Mucbe<sup>1</sup>, M. Schmidt<sup>1</sup>, L. Spiller<sup>1</sup>, V. Rios Rodriguez<sup>1</sup>, J. Rademacher<sup>1</sup>, A.-K. Weber<sup>1</sup>, S. Lüders<sup>1</sup>, M. Protopopov<sup>1</sup>, I. Spiller<sup>1</sup>, J. Sieper<sup>1</sup>, D. Podubnyy<sup>1,2</sup>. <sup>1</sup>Charité – Universitätsmedizin Berlin; <sup>2</sup>German Rheumatism Research Centre, Berlin, Germany

**Background:** The Ankylosing Spondylitis Disease Activity Score (ASDAS) is a composite index to assess disease activity in patients with axial spondyloarthritis (axSpA). According to the treat-to-target (T2T) recommendations for SpA, and the

ASAS/EULAR management recommendations for axSpA, the C-reactive protein (CRP)-based ASDAS is the preferred instrument for the assessment of disease activity in the process of making decision on modification of axSpA treatment in clinical routine. Currently, measurement of CRP by routine lab methods takes hours to days what seriously challenges the feasibility of T2T approaches in clinical routine and clinical studies.

**Objectives:** To compare the performance of the ASDAS based on a quickCRP assay (ASDAS-quick-CRP) with the ASDAS-routine-CRP and with the erythrocyte sedimentation rate (ESR)-based ASDAS in the assessment of disease activity in patients with axSpA.

**Methods:** This cross-sectional study was performed in patients referred with a suspicion of axSpA as part of the Identification of the Optimal Referral Strategy for Early Diagnosis of Axial Spondyloarthritis (OptiRef) study. Briefly, referred patients underwent a structured assessment of SpA features by a rheumatologist. CRP was measured in the central lab (routine turbidimetric assay, lowest detection level: 0.3 mg/L) and locally by ESR and a quantitative quick-CRP test (QuickRead go, Orion Diagnostica Oy, lowest detection level: 5 mg/L, test duration approx. 2 min.). If the quick-CRP was below the limit of detection, the value of 2 mg/L was used. In patients with the final diagnosis of axSpA, ASDAS-routine-CRP, ASDAS-quick-CRP and ASDAS-ESR were calculated.

**A**

		ASDAS-quick-CRP (n=46)			
		Inactive disease (<1.3)	Moderate disease activity (1.3-2.1)	High disease activity (2.2-3.5)	Very high disease activity (>3.5)
ASDAS-routine-CRP	Inactive disease (<1.3)	3 (6.5%)	0	0	0
	Moderate disease activity (1.3-2.1)	1 (2.2%)	9 (19.6%)	0	0
	High disease activity (2.2-3.5)	0	0	22 (47.8%)	2 (4.3%)
	Very high disease activity (>3.5)	0	0	0	9 (19.6%)

**B**

		ASDAS-ESR (n=44)			
		Inactive disease (<1.3)	Moderate disease activity (1.3-2.1)	High disease activity (2.2-3.5)	Very high disease activity (>3.5)
ASDAS-routine-CRP	Inactive disease (<1.3)	2 (4.5%)	1 (2.3%)	0	0
	Moderate disease activity (1.3-2.1)	0	7 (15.9%)	3 (6.8%)	0
	High disease activity (2.2-3.5)	0	1 (2.3%)	16 (36.4%)	5 (11.4%)
	Very high disease activity (>3.5)	0	0	2 (4.5%)	7 (15.9%)

**Abstract FRI0194 – Figure 1.** Comparison of the disease activity state ascertainment by ASDAS-routine-CRP vs. ASDAS-quick-CRP (A) and ASDAS-routine-CRP vs. ASDAS-ESR (B).

**Results:** A total of 132 patients referred with suspicion of axSpA had available routine and quick CRP levels; 46 patients of them were diagnosed with axSpA. Mean  $\pm$ SD routine/quick CRP serum levels were  $3.20 \pm 6.86$  mg/L and  $4.52 \pm 6.78$  mg/L, respectively, in the entire group, and  $7.09 \pm 10.18$  mg/L and  $8.22 \pm 10.11$  mg/L, respectively, in patients with axSpA. There was no significant difference ( $p=0.11$ ) in the mean values of ASDAS-CRP ( $2.76 \pm 0.97$ ) and ASDAS-quick-CRP ( $2.80 \pm 1.00$ ), while the ASDAS-ESR ( $2.90 \pm 1.02$ ) was significantly higher than ASDAS-routine-CRP ( $p=0.034$ ). In 43 of the 46 cases of axSpA (94%) the status scores for disease activity showed no difference between ASDAS-routine-CRP and ASDAS-quick-CRP – figure 1. Two patients were assigned to a higher and one to a lower disease activity category (DAC) according to ASDAS-quick-CRP as compared to ASDAS-routine-CRP. For ASDAS-ESR compared to ASDAS-routine-CRP, only 32/44 patients (73%) were assigned to the same DAC.

**Conclusions:** ASDAS-quick-CRP performed similarly well to ASDAS-routine-CRP with an agreement on the status score for disease activity of 94%, that was clearly better than the agreement of 73% between ASDAS-ESR and ASDAS-routine-CRP. With a duration of approximately 2 min the quick-CRP test is, therefore, feasible for immediate decision making as a part of clinical routine or clinical trials.

### CLINICAL CHARACTERISTICS OF 897 CHINESE ANKYLOSING SPONDYLITIS/SPONDYLOARTHRITIS REAL WORLD COHORT: DATA FROM A CHINESE COHORT WITH SMART MANAGEMENT SYSTEM FOR SPONDYLOARTHRITIS (SMSP)

X. Ji, J. Zhu, J. ZHANG, F. Huang on behalf of SMSP co-authors. *Rheumatology, Chinese PLA General Hospital, Beijing, China*

**Background:** With increasing global popularity of smartphone technology, there is a great opportunity for using mobile phone applications for disease management. Smart Management System for Spondyloarthritis (SpA) (SMSP) created a smart management system for SpA using eHealth technologies in China.

**Objectives:** The aim of this study was to report major characteristics of Chinese ankylosing spondylitis patients derived from a large, longitudinal and prospective database with SMSP.

**Methods:** SMSP was designated for multicenter, consecutive, and prospective cohorts, including patients' mobile terminal, the physician workstation system, and communication system. Patients' portal was used for self-assessment prior visiting clinics, short message consultation, monitoring symptoms between clinic visits as well as uploading/downloading medical records, while physician' portal was used for professional assessment at clinic, scheduled visits reminder, sending self-management strategies at intervals and making recommendations and delivering patient-specific guidance to the individual. In this preliminary analysis, all patients fulfilled the modified New York criteria. All data were collected online using SMSP.

**Results:** From April 2016 to June 2017, data were extracted online from the physician workstation system in 4 rheumatology centres across China. There was a total of 2790 times self-assessment of BASDAI, BASFI performed by patients (median times=3.1, from 1 to 14) and a total of 1960 evaluation performed by the physician at the clinic (median times=2.1, from 1 to 10).

A total of 897 AS patients (mean age:  $30.8 \pm 8.8$  years, male 82.7%, HLA-B27 positive rate 88.0%) were recruited in this baseline analysis. The median disease duration was 7.1 (0.01 to 39.63) years. A history or current symptoms suggestive of acute anterior uveitis, psoriasis, and inflammatory bowel disease were observed in 17.2%, 2.6%, 7.1% of the patients, respectively. Differences in symptom duration ( $\leq 5$  years, 5 years to 10 years and  $>10$  years) were analysed. Acute anterior uveitis and inflammatory bowel disease were detected significantly more frequently in patients with symptom duration of  $>10$  years (27.0%, 11.0%, respectively), shown in table 1.

According to the ASDAS, at the baseline visit, 20.1% of patients achieved inactive disease, 30.8% with moderate disease activity, 37.3% with high disease activity and 10.6% with very high disease activity. The most commonly used medication was NSAIDs (98.9%). The patients using biological DMARDs possessed a percentage of 15.5%. 12.8% of the patients used etanercept which was the most commonly used biological DMARDs. 64.7% of the patients used conventional synthetic DMARDs.

**Abstract FRI0195 – Table 1.** Demographics and baseline clinical characteristics of the total cohort

Characteristic	Durations $\leq 5$ years (n=292)	5 years $<$ Durations $\leq 10$ years (n=322)	Duration $> 10$ years (n=283)	P value

**Conclusions:** SMSM is an effective mobile interface to serve AS patients performing self-management as well as to supply physicians with valuable and reliable data with a minimal bias for online data collection and automatic quality controls. This large cohort may improve our knowledge of the characteristics, pathogenesis and natural course in Chinese patients with AS.

#### FRI0196 TRADITIONAL DXA UNDERESTIMATES BONE MINERAL DENSITY OF THE SPINE IN AXIAL SPONDYLOARTHROPATHY

G. Fitzgerald, T. Anachebe, F. O' Shea. *Department of Rheumatology, St James's Hospital, Dublin 8, Ireland*

**Background:** Axial spondyloarthritis (axSpA) is an inflammatory arthritis which can lead to new bone formation (syndesmophytes) and ankylosis of the spine. Osteoporosis is a recognised feature of axSpA, but can be challenging to diagnose. Traditional dual-energy x-ray absorptiometry (DXA) in the antero-posterior (AP) projection of the spine can overestimate bone mineral density (BMD) due to the presence of syndesmophytes, potentially under-diagnosing osteoporosis. There is a real need to find an accurate method to assess BMD in axSpA patients. Lateral DXA of the lumbar spine is unaffected by syndesmophyte formation and may be a promising tool.

**Objectives:** The aim of this study is to:

1. investigate different projections of DXA of the lumbar spine in axSpA patients
2. assess the effect of syndesmophytes on spine BMD.

**Methods:** AxSpA patients were assessed with clinical exam, questionnaires and laboratory investigations. The burden of syndesmophytes on lateral x-rays of the lumbar and cervical spine was assessed with the validated modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS) score, which ranges from 0–72 (higher scores indicate more severe disease). DXA was performed of the spine in both the AP and lateral projections. SPSS was used for statistical analysis.

**Results:** One hundred patients with axSpA were recruited: 78% (n=78) male, mean (SD) age 52<sup>12</sup> years, disease duration 26<sup>13</sup> years, 85% (n=85) fulfil modified New York criteria. The median (IQR) mSASSS score was 10.<sup>33</sup>

Lumbar spine BMD was lower when measured by lateral DXA rather than AP (0.76 v 1.11 g/cm<sup>2</sup>, p<0.01). Lateral DXA detected more cases of spinal osteopenia or osteoporosis than AP (21% v 44%, p<0.01). Lateral spine BMD reduced with longer duration of disease (r=-0.3, p=0.02), whereas AP spine BMD increased with age (r=0.3, p=0.01). Women had significantly more cases of osteoporosis at the lumbar spine than men when measured by lateral DXA (32% v 12%, p=0.02), but not by AP DXA.

A higher mSASSS, reflecting more syndesmophytes/new bone formation, was associated with a rising AP spine BMD (r=0.5, p<0.01), but had no effect on lateral spine BMD. The gap between AP and lateral spine BMD, i.e. when AP BMD was higher than lateral BMD, increased significantly (p<0.05) with increasing age (r=0.38), disease duration (r=0.37) and mSASSS (r=0.52). mSASSS was the strongest independent predictor of a difference between AP and lateral BMD measurements, suggesting that syndesmophyte formation interferes with AP DXA assessment of the spine.

**Conclusions:** AP DXA of the spine is affected by a higher burden of syndesmophytes (new bone formation), raising concerns that traditional DXA assessment

may miss cases of osteoporosis. We suggest that lateral DXA of the spine may be a more accurate tool to detect osteoporosis in axSpA patients.

#### FRI0197 ASSOCIATION OF THE ELECTROCARDIOGRAPHIC DISTURBANCES WITH AORTIC ROOT DILATION IN PATIENTS WITH ANKYLOSING SPONDYLITIS

H.S. Park<sup>1</sup>, A. Laiz<sup>1</sup>, C. Alonso<sup>2</sup>, S. Jeria Navarro<sup>1</sup>, A. García-Guillén<sup>1</sup>, M. Millán<sup>1</sup>, P. Moya<sup>1</sup>, B. Magallares<sup>1</sup>, I. Castellvi<sup>1</sup>, C. Diaz-Tome<sup>1</sup>, S. Fernandez<sup>1</sup>, J. Casademont<sup>3</sup>, H. Corominas<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Cardiology; <sup>3</sup>Internal Medicine, H.U. Sant Pau, Barcelona, Spain

**Background:** Ankylosing spondylitis (AS) is a disease with very characteristic extraarticular organ involvements. Cardiac conduction disturbances and aortic root diseases are some of the most particular manifestations of this disease<sup>1</sup>. The most frequent conduction disturbances are atrioventricular blocks (AVB), bundle branch blocks (BBB) and intraventricular conduction disturbances (IVCD)<sup>2</sup>. The prevalence of AVB is 3% and 8% for IVCD in the general population<sup>3</sup>. In some cross-sectional studies of the AS population<sup>4,5</sup> the prevalence was reported to be around 4.6%–9% for AVB and 4%–29% for IVCD. Some studies propose that there may be a relation between the conduction disturbances and the inflammation of the aortic root due to disease activity<sup>6,7,8</sup>.

**Objectives:** This study aims to evaluate association between the electrocardiographic alterations (AVB, BBB, IVCD) and aortic root dilation in patients with AS.

**Methods:** Out of a registry of 118 patients from a spondyloarthritis consultation, we selected patients with AS according to New York criteria. We included those patients who had undergone an electrocardiography (EKG) and an echocardiography, in order to rule out heart disease or to check up because of long term AS. Demographical and clinical data (cardiovascular risk factors, past heart disease, presence of arthritis, enthesitis, dactylitis, uveitis and HLAB27) were collected. The EKG were reevaluated looking for IVCD, AVB or BBB by a blinded arrhythmologist. Echocardiographical data about aortic root dilation were collected using aortic root diameter adjusted by body surface area. We carried out chi squared analysis as well as a comparison of proportions. We summarised descriptive data of our sample in table 1.

**Results:** Out of 118 patients, 38 patients met inclusion criteria. Fourteen of them (36.8%) were women. The average age was 60.3 years old and mean disease duration was 19.62 years.

Conduction disturbances were present in 12 (31.5%) patients of whom 4 were AVB (10.5%), 5 BBB (13.2%) and 3 IVCD (7.8%). Aortic root dilation was found in 6 (15.8%) of the 38 patients.

The conduction disturbances showed a statistically significant association with aortic root dilation (chi square p=0.02). In comparison of two proportions, the prevalence of aortic root dilation in abnormal EKG group (0.67 IC95% 0.36%–0.97%) was significantly higher than normal EKG group (0.6 IC95% 0.36%–0.97) p=0.02.

Abstract FRI0197 – Table 1

Variable	Number (patients)/Proportion (%)
Women	14 / 36.84%
B27	29 / 80.56%
Arthritis	14 / 36.84%
Enthesitis	13 / 34.21%
Uveitis	5 / 13.16%
Aortic root dilation	12 / 31.5%
Aortic insufficiency	12 / 31.5%
Exsmoker	23.68%
Smoker	34.21%
Hypertension	21 / 56.76%
Dyslipemia	22 / 59.49%
Diabetes	10 / 27.02%
Valve disease	2 / 5.55%
Ischaemic disease	7 / 29.44%
AVB	4 / 10.52%
Left BB	1 / 2.63%
Right BB	3 / 7.89%
Anterior BB	1 / 2.63%
Intraventricular conduction disturbances	3 / 7.89%

**Conclusions:** The prevalence of aortic root dilation and conduction disturbances was higher in our sample than in the general population. In our

sample the presence of aortic root dilation and conduction disturbances (AVB, BBB, IVCD) had a statistically significant association. The principal limitations of this study are the small sample size and the retrospective nature in patient selection.

### WHICH FACTORS INFLUENCE PSYCHOLOGICAL WELL-BEING OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS? – DATA FROM A CROSS-SECTIONAL SURVEY LINKED TO INSURANCE CLAIMS

I. Redeker<sup>1</sup>, F. Hoffmann<sup>2</sup>, J. Callhoff<sup>1</sup>, H. Haibel<sup>3</sup>, J. Sieper<sup>2</sup>, A. Zink<sup>1,4</sup>, D. Poddubnyy<sup>1,3</sup>. <sup>1</sup>Epidemiology Unit, German Rheumatism Research Centre, Berlin; <sup>2</sup>Department of Health Services Research, Carl von Ossietzky University, Oldenburg; <sup>3</sup>Department of Gastroenterology, Infectiology and Rheumatology; <sup>4</sup>Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin, Berlin, Germany

**Background:** Psychological well-being is considered an important determinant of quality of life. Importantly, well-being is related not only to medical factors, but also to social and economic factors.

**Objectives:** The aim of this study was to examine the psychological well-being of patients with axial spondyloarthritis (axSpA) and its determinants.

**Methods:** A stratified random sample of subjects with a diagnosis of axSpA (International Classification of Diseases, Tenth Revision, [ICD-10] code M45) was drawn from German health insurance data to whom a postal questionnaire was sent asking about disease-related, psychological, and lifestyle factors as well as socioeconomic status. Additional information to verify the axSpA diagnosis was collected. The psychological well-being was assessed by the World Health Organisation Well-Being Index (WHO-5), which is considered a sensitive and specific screening tool for depression. The following established cut-offs on the WHO-5 were applied: >50: good well-being, no depressive symptoms, 29–50: mild depressive symptoms, ≤28: moderate-to-severe depressive symptoms. Information on comorbidities, drug prescriptions and non-pharmacological treatment was retrieved from claims data and linked to the questionnaire data.

**Results:** A total of 1736 persons with a confirmed axSpA diagnosis were included; mean age was 55.8 years and 46.3% were female. We found a mean WHO-5 score of 44.70 in axSpA subjects, which is considerably below the WHO-5 score of 69.95 reported among the population in Germany aged 41 to 60 years.<sup>1</sup> Using the cut-offs on the WHO-5, 533 persons (31%) were found to have moderate-to-severe depressive symptoms, 479 (28%) had mild depressive symptoms, and 724 (42%) had a good well-being. Persons with moderate-to-severe depressive symptoms had higher disease burden of axSpA, lower household income and reported more often a lack of exercise and a perception of suffering from stress (table 1). Multivariable logistic regression revealed that higher disease activity of axSpA, higher level of functional impairment, lower income, self-reported stress and lack of exercise, and younger age were associated with moderate-to-severe depressive symptoms.

**Abstract FRI0198 – Table 1.** Main demographic, disease-related, lifestyle and socioeconomic characteristics of patients and axSpA.

FRI0199

### FUNCTIONING CATEGORIES BY ASAS HEALTH INDEX IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS AND CONCOMITANT FIBROMYALGIA

I. Shapoval, M. Stanislavchuk, L. Perebetskiy, G. Movchan. *Internal Medicine Chair #1, National Pirogov Memorial Medical University, Vinnytsya, Ukraine, Vinnytsya, Ukraine*

**Background:** Ankylosing spondylitis (AS) is a chronic rheumatic disease that characterised by prevalent inflammatory spinal involvement. Concomitant fibromyalgia (FM) can significantly modify this condition. In 2014, ASAS Health Index and Environmental Factors (ASAS HI/EF) appeared as new tool to assess the health status of patients with spondyloarthritis, able to describe the total impairments, restrictions and functional limitation due to AS.<sup>1</sup>

**Objectives:** The aim of this study was to evaluate the functional status of patients with active AS with concomitant FM by the functioning categories of ASAS HI.

**Methods:** The study included 72 patients with AS according to the modified. New York criteria (1984) Fifty-nine were male (81.94%), average age 39.5±11.72 (M ±SD) years. FM was diagnosed by modified criteria of the American College of Rheumatology (2010) The disease activity we assessed by Ankylosing Spondylitis Disease Activity Score (ASDAS-ESR). We used Ukrainian version of ASAS HI/EF.<sup>2</sup> Functional categories were established as recommended.<sup>3</sup> We categorised patients into 3 functioning categories: normal functioning (ASAS HI ≤4), moderate impairment of functioning (>4 and ≤8) and severe impairment of functioning (ASAS HI >8).

**Results:** Twenty patients met the criteria for FM (27.78%). Disease activity according to the ASDAS-ESR in patients with AS and AS with concomitant FM was almost the same: 3.58±0.84 and 3.98±0.91. However, ASAS HI in patients with AS and FM was significantly higher than in patients with AS (7.3±1.22 vs. 5.8±1.84).

According to ASAS HI we divided all patients into functioning categories. 10 of 52 patients with AS (19.23%) had normal functioning, 39 (75%) were classified as patients with moderate impairment of functioning and 3 (5.77%) had severe impairment of functioning. In the group AS +FM patients with normal function were not found, while others were distributed in a ratio of 2:1–13 (65%) patients with moderate and 7 (35%) with severe impairment of functioning. It was revealed relationship between ASAS HI and disease activity ( $r=0.549$ ).

**Conclusions:** Concomitant FM impairs the functional status in patients with AS. High and very high disease activity in patients with AS is associated with functional disability according to ASAS HI functioning categories. ASAS HI is reliable and sensitive clinical tool for determining impairment of functioning in patients with AS.

#### FRI0200 INSIGHT INTO THE QUALITY OF LIFE OF PATIENTS WITH ANKYLOSING SPONDYLITIS: REAL-WORLD DATA FROM A US-BASED LIFE IMPACT SURVEY

J.T. Rosenbaum<sup>1,2</sup>, L. Pisenti<sup>3</sup>, Y. Park<sup>4</sup>, R. Howard<sup>5</sup>, <sup>1</sup>Oregon Health and Science University; <sup>2</sup>Legacy Devers Eye Institute, Portland, OR; <sup>3</sup>UCB, Inc, Smyrna, GA; <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ; <sup>5</sup>Spondylitis Association of America, Van Nuys, VA, USA

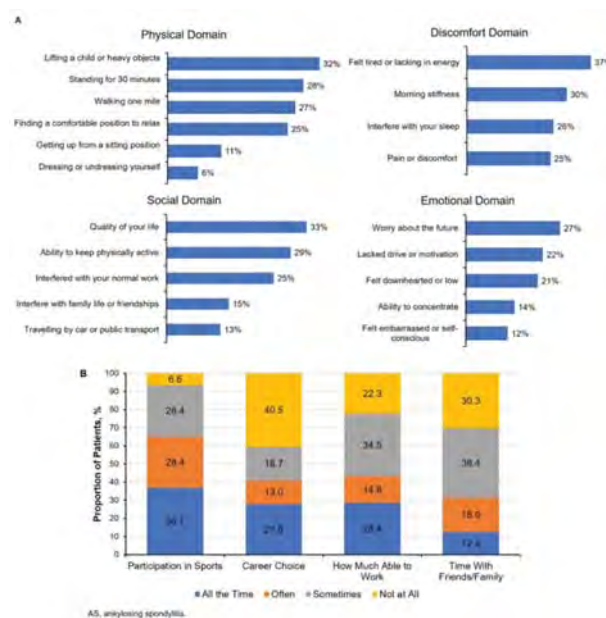

**Background:** While severe pain and stiffness are common hallmarks of ankylosing spondylitis (AS), disease progression is slow and not always visible; however, the quality of life (QoL) of patients with AS is still significantly impacted.

**Objectives:** To assess patient-reported impact of AS on QoL in the physical, discomfort, social, and emotional domains among US patients with AS in a real-world setting.

**Methods:** Descriptive data on demographics and QoL were collected from a random sample of patients associated with the Spondylitis Association of America (SAA). QoL measures were based on the Evaluation of Ankylosing Spondylitis Quality of Life (EASi-QoL) questionnaire (scale, 0–80, with higher score indicating more severe impact).<sup>1</sup> Between July 7 and December 31, 2017, 820 interviews were conducted with SAA contacts, including 720 completed via web survey (from 7750 emails) and 100 via follow-up over the phone (from 10 784 phone calls made to 5000 unique numbers). Of 820 participants who completed the survey, 716 self-reported receiving a diagnosis of AS from their doctor and were included in this study. Participants were queried on the impact of AS on their QoL within the day of survey participation with regard to the physical domain, and within the past week prior to participation with regard to the discomfort, social, and emotional domains. A 3:1 (male to female) weighting was performed to reflect the known

clinical prevalence that men are three times more likely to have AS compared to women.

**Results:** The mean age of the 716 respondents was 55.5 years; 46.9% were male. The most common locations of pain reported were the lumbar spine (86.8%), neck (84.1%), and hip joint (80.2%). The mean total EASi-QoL score was 28.9; overall, 34.7%, 31.7%, and 34.7% of respondents, respectively, reported low (EASi-QoL score 0–17), medium,<sup>18–35</sup> and high (≥36) impact of AS on QoL. Physical aspects of the disease contributed the most impact, with 41.9% of respondents reporting high impact of AS on the physical domain (EASi-QoL score ≥10). The proportion of respondents reporting high impact of AS (ie, the top 2 levels of impairment for each question) in the 4 QoL domains is shown in figure 1A. In several QoL aspects, AS impacts were reported more frequently by female vs male respondents, respectively, including lifting a child or heavy objects (43.2% vs 27.8%), worrying about the future (37.3% vs 23.5%), feeling tired or lacking in energy (46.4% vs 33.4%), sleep interference (32.7% vs 23.2%), trouble keeping physically active (35.9% vs 26.7%), standing for 30 min (34.9% vs 26.1%), and travelling by car or public transport (19.2% vs 10.5%). AS also impacted their lifestyle, as shown in figure 1B.

**Abstract FRI0200 – Figure 1.** (A) Proportion of respondents with AS reporting top two levels of impairment by their disease across 4 domains of disease, and (B) Patient-reported impact of AS on lifestyle. AS, ankylosing spondylitis.

**Conclusions:** Negative impacts in all QoL domains were reported, with a mean overall EASi-QoL score of 28.7. Gender differences were also pronounced in several aspects, including lifting a child or heavy objects, and worrying about the future. Incorporating subjective measures of disease via patient-reported outcomes should be considered with evaluation of disease progression.

**FRI0201 HEALTHY INDIVIDUALS AT INCREASED RISK FOR AXIAL SPONDYLOARTHRITIS WOULD CONSIDER USING MEDICATION IN A PREVENTIVE SETTING**

J.J. de Winter<sup>1</sup>, H.M. De Jong<sup>1</sup>, P.T. Nieuwkerk<sup>2</sup>, I.E. van der Horst-Bruinsma<sup>3</sup>, D. L. Baeten<sup>1</sup>, M.G. van de Sande<sup>1</sup>. <sup>1</sup>Clinical immunology and rheumatology, <sup>2</sup>Medical Psychology, Academic Medical Center, <sup>3</sup>Rheumatology, VU medical center, Amsterdam, Netherlands

**Background:** Axial spondyloarthritis (axSpA) is a chronic inflammatory disease with a diagnostic delay of 5–10 years. Treating the disease in the pre-clinical phase before the disease becomes clinically manifest is not yet clinical practice, although initiatives to diagnose axSpA in an early phase such as the SPondyloArthritis Caught Early (SPACE) cohort and the pre-SpA cohort might enable early or even pre-clinical detection and thus treatment of SpA. Possibly, very early treatment might be able to stop the disease process hereby preventing the development of irreversible structural damage or, ideally, even disease onset.

**Objectives:** To study the willingness of individuals with an increased risk for SpA to use medication in a preventive setting.

**Methods:** Healthy first degree relatives of HLA-B27 positive axSpA patients from the Pre-SpA cohort completed a questionnaire consisting of different hypothetical scenarios varying in 1) the risk of developing axSpA, 2) the occurrence and nature of possible side effects, and 3) the effectiveness of the medication. Moreover, the survey included multiple choice questions about participants' perception towards SpA and preventive medication.

**Results:** The response rate was 81.5% (106 out of 130). Figure 1 shows the comparison of the different scenarios. The percentage of individuals willing to use preventive medication causing no side effects varied between 63.2% (with 30% SpA risk) and 91.5% (with 70% SpA risk). The percentage of individuals willing to use this medication varied between 27.4% (with 30% SpA risk) and 51.9% (with 70% SpA risk) if the preventive medication would possibly cause infections. This percentage was 32.1% (with 30% SpA risk) if the medication would possibly cause mild side effects. The percentage of individuals willing to use preventive medication that would cause a delay in onset of SpA of 10 years (with 70% SpA risk) was 72%. The willingness of individuals to use preventive medication was negatively influenced by their own risk assessment of developing SpA ( $B=0.16$ ,  $p=0.001$ ) and was not primarily influenced by costs (0.9%) or the route of administration (0%).

**Conclusions:** 1. Individuals at increased risk for SpA would consider using preventive medication.

2. Their willingness to use preventive medication is largely influenced by the formal likelihood to develop SpA, by their own perception of the disease and by the likelihood of side effects.

3. Their willingness to use preventive medication is not primarily influenced by costs and the route of administration.

**FRI0202 INERTIAL MOTION SENSORS USING THE VIMOVE® SYSTEM IS A VALID METHOD TO ASSESS SPINAL MOBILITY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

I.C. Aranda-Valera<sup>1</sup>, J.L. Garrido-Castro<sup>2</sup>, I. Martinez-Sanchez<sup>2</sup>, C. Gonzalez<sup>2</sup>, P. Gardiner<sup>3</sup>, P.M. Machado<sup>4</sup>, E. Collantes<sup>1</sup>, on behalf of iMaxSpA Study Group. <sup>1</sup>HU Reina Sofia; <sup>2</sup>IMIBIC, Cordoba, Spain; <sup>3</sup>WHSC, Londonderry; <sup>4</sup>UCL, London, UK

**Background:** Spinal mobility measures are recommended for the assessment axial spondyloarthritis (axSpA). Simple, low-tech tools as goniometers and metric tapes are commonly used, resulting in high variability and low accuracy of the measurements. More recently, advanced technological systems have facilitated the measurement of human mobility with high precision, such as motion capture systems like the UCOTrack and its index, the UCOASMI, validated for use in axSpA patients. The development of inertial measurement units (IMUs) has produce wearable, cheap and self-contained devices that can measure motion usually using triads of gyroscopes, accelerometers and magnetometers. Some of the mobility angles measured using motion capture systems can also be measured using IMUs placed in pre-defined anatomical locations.

**Objectives:** To evaluate the validity of IMUs using the ViMove® system for measuring spinal mobility in patients with axSpA.

**Methods:** We recruited 20 patients with axSpA from the HU Reina Sofia of Cordoba. The UCOTrack was used as the gold-standard system to obtain mobility measurements. UCOTrack measurements were compared with ViMove® measurements, a system that includes two IMU sensors located in the lumbar spine (pelvis and L1- figure 1) or in the neck (occiput and T3). Conventional metrology measures and patient-reported outcomes were also collected.

**Results:** The table presents the measurements obtained at the L1 and occiput levels. UCOTrack and ViMove® measurements were very similar, with Root

Mean Square Errors (RMSE) less than 10° and Variation Coefficients (VC) less than 10%. We found high intraclass correlation coefficients (ICC) between the two systems (0.84–0.99). Measurements with both systems correlated strongly and significantly with BASMI (0.60–0.92) and BASFI (0.51–0.84), but not with BASDAI.

Type of measurement	UCOTrack®	ViMove®	VC	RMSE	ICC
<i>Lumbar (L1)</i>					
Anterio flexion	103.6 (17.3)	99.0 (17.4)	4.4%	6.57	0.93
Extension	24.6 (9.3)	22.3 (9.6)	9.4%	4.22	0.90
Left rotation	27.7 (10.4)	27.4 (11.0)	1.1%	1.83	0.99
Right rotation	26.8 (10.4)	25.3 (10.1)	5.6%	3.14	0.95
Left lateral flexion	70.7 (13.9)	72.6 (16.6)	2.7%	8.71	0.84
Right lateral flexion	68.4 (15.4)	67.6 (16.7)	1.2%	7.87	0.88
<i>Cervical (occiput)</i>					
Flexion	50.9 (12.5)	52.3 (12.8)	2.8%	2.73	0.98
Extension	43.1 (16.0)	39.3 (14.4)	8.8%	5.44	0.94
Left rotation	66.1 (20.2)	63.8 (20.5)	3.5%	9.13	0.90
Right rotation	62.1 (19.2)	64.7 (21.7)	4.2%	9.72	0.89
Left lateral flexion	34.3 (15.8)	32.9 (15.5)	4.1%	7.77	0.88
Right lateral flexion	34.7 (15.9)	34.0 (16.3)	2.0%	7.10	0.90

All measures are expressed in degrees.

**Conclusions:** The ViMove®, an IMU based system, is a valid method to assess spinal mobility in patients with axSpA. There was excellent agreement between ViMove® and UCOTrack and a strong correlations with conventional metrology (BASMI) and patient-reported physical function (BASFI). IMU systems are more feasible than motion capture systems because they do not require a motion laboratory and results can be obtained more quickly in an objective and quantitative way. The ViMove® system has potential for use both in the clinical and research setting and further evaluation of its reproducibility and sensitivity to change should be undertaken.

**FRI0203 THE LINK BETWEEN COPD AND ANKYLOSING SPONDYLITIS: A POPULATION BASED STUDY**

K. Sharif<sup>1</sup>, A. Watad<sup>2</sup>, S. Tiosano<sup>2</sup>, Y. Yavne<sup>2</sup>, D. Comaneherster<sup>3</sup>, A. Cohen<sup>4</sup>, H. Amital<sup>2</sup>. <sup>1</sup>Sheba medical centre, Tel aviv; <sup>2</sup>Sheba Medical Centre; <sup>3</sup>Clalit; <sup>4</sup>Clalit health services, Ramat Gan, Israel

**Background:** Ankylosing spondylitis (AS) is one of the most common and severe subtypes of the spondyloarthropathies. Extra-articular involvement among AS patients, including lung disease, has been described widely. Chronic obstructive pulmonary disease (COPD) has been linked to several autoimmune diseases, however, very few studies have investigated the association between AS and COPD.

**Objectives:** To assess whether an association exists between AS and COPD.

**Methods:** A population-based cross-sectional study was conducted using data retrieved from the largest electronic medical records database in Israel, the Clalit Health Services (CHS). Patients were defined as having AS or COPD when there was at least one such documented diagnosis in their medical records. The proportion of COPD was compared between AS patients and controls. A logistic regression model was used to estimate the association between AS and COPD in a multivariate analysis adjusted for age, gender and smoking status

**Results:** The study included 4076 patients with AS and 20 290 age- and sex-frequency matched controls. The proportion of COPD in AS patients was higher than in controls (46% vs. 18%, respectively,  $p < 0.001$ ). Multivariate logistic regression demonstrated a robust independent association between AS and COPD (OR 1.225,  $p = 0.031$ ).

**Abstract FRI0203 – Table 1.** Interactions between COPD, covariates by strata and AS

	ALL n=24 366	Controls n=20 290	AS n=4076	OR	P
COPD	628 (2.58%)	431 (2.12%)	197 (4.83%)	2.34 [1.97;2.78]	<0.001

**RADIOGRAPHIC PROGRESSION OF SPONDYLOARTHRITIS PATIENTS AFTER 13 YEARS OF FOLLOW UP: DATA FROM THE REGISPONSER DATABASE**

L. Pérez Sánchez<sup>1,2,3</sup>, P. Font<sup>1,2,3</sup>, C. López<sup>1,2,3</sup>, L. Bautista<sup>1,2,3</sup>, L. Ladehesa<sup>1,2,3</sup>, I. Gómez<sup>1,2,3</sup>, A. Escudero<sup>1,2,3</sup>, E. Collantes<sup>1,2,3</sup>, M.C. Castro<sup>1,2,3</sup>. <sup>1</sup>Reina Sofia University Hospital; <sup>2</sup>IMIBIC; <sup>3</sup>University of Cordoba, Cordoba, Spain

**Objectives:** To describe the radiographic evolution after 13 years of follow-up in a monographic consultation of patients with Axial Spondyloarthritis (EspAax) included in REGISPONSER at the Reina Sofia University Hospital in Córdoba.

**Methods:** Seventy eight SpA patients from the REGISPONSER registry were analysed in an observational study, which were evaluated for the first time in the year 2004–2005. The last x-rays analysis of the cervical and lumbar spine, pelvis and hips were recorded. Two independent observers evaluated the radiographs and calculated the BASRI index. The interobserver concordance was studied using Cohen's Kappa statistic. Finally, radiographic progression was assessed using the McNemar test.

**Results:** Sixty one SpA patients were radiographically evaluated at baseline and after 11 (1.7) years of follow-up. A complete radiographic study was recorded in 38 of them. The baseline characteristics, including BASRI values, as well as the treatment received are listed in table 1. The strength of the interobserver concordance in the radiographic analysis was considerable in hips ( $k = 0.77$ ,  $p < 0.001$ ) and almost perfect at the levels of the cervical spine ( $k = 0.88$ ,  $p < 0.001$ ), lumbar spine ( $k = 0.87$ ,  $p < 0.001$ ) and sacroiliac joints ( $k = 0.84$ ,  $p < 0.001$ ). The BASRIs and BASRII scores were 7.5 (2.9) and 8.8 (4.1) respectively. Moreover, during the follow-up, the BASRII was increased in 1.23 ( $p = 0.014$ ). Individual analysis of the different components of BASRI, showed that 42.1% of SpA patients got worse regarding the score corresponding to the cervical spine ( $p < 0.001$ ), 28.9% to the lumbar spine ( $p = 0.057$ ), 15.8% to the hip ( $p = 0.754$ ) and no worsening was found in sacroiliac ( $p = 0.500$ ).

**Abstract FRI0204 – Table 1.** Baseline characteristics and current treatment of the cohort N=38 for the radiographic study.

Type of SpA N(%)	AS 38 (100%)	BASRIs baseline Mean (DS)	6.44 (2.91) 7.60 (3.96)	Current treatment NSAIDs N(%)
				Daily treatment: 22 (57.9%)
		BASRII baseline Mean (DS)		Casual treatment: 13 (34.2%)
				Response: 35 (92.1%)
				Type: - 18 COX-2 selective (51.4%)
				- 7 Diclofenac (18.4%)
				- 5 Indomethacin (13.2%)
				- 5 Others(13.2%)
Time of evolution Diagnosis-inclusion in the registry Mean (DS) years	11 (7.1)	Degree of sacroiliitis Me (RI)	4 ( <sup>2-4</sup> )	Current treatment N (%) cDMARDs - Sulfasalazine 1 (2.7%)
Sex	34 (89.5)	Degree of cervical spine Me (RI)	1 (0-2)	- Methotrexate 1 (2.7%)
Male				Current treatment N(%) bDMARDs
Female	4 (10.5)			10 (26.3%) - 4
N(%)				Golimumab (10.5%)
				- 3 Etanercept (7.9%)
				- 1 Adalimumab (2.6%)
				- 1 Infliximab (2.6%)
				- 1 Secukinumab (2.6%)
Age Mean (DS) years	58.2 (7.9)	Degree of hips Me (RI)	1 (0-2)	

**Conclusions:** This study provides information related to the structural progression of patients followed in a monographic consultation of SpA after 13 years of follow-up. Radiographic evolution was significantly noticed in relation to the total score of the BASRI. However, analysing the individual scores it seems that the cervical spine was the segment where there was greater radiographic progression. We did not find worsening of BASRI in sacroiliac due to the fact that the most of patients already had an advanced degree of sacroiliitis in the first visit of the registry.

### COMPARISON OF WORK DISABILITY, DEPRESSION AND QUALITY OF LIFE IN PATIENTS WITH ANKYLOSING SPONDYLITIS VS. PSORIATIC ARTHRITIS: INTERIM RESULTS FROM THE COMPLETE STUDY

M. Khraishi<sup>1</sup>, L. Bessette<sup>2</sup>, B. Haraoui<sup>3</sup>, B. Florica<sup>4</sup>, Y. Setty<sup>5</sup>, M. Teo<sup>6</sup>, V. Rempel<sup>7</sup>.  
<sup>1</sup>Memorial University of Newfoundland, St. John's; <sup>2</sup>Laval University, Centre Hospitalier de l'Université Laval, Quebec; <sup>3</sup>Centre Hospitalier de l'Université de Montréal, Montréal; <sup>4</sup>University of Toronto, Toronto; <sup>5</sup>Grey Bruce Health Services, Owen Sound; <sup>6</sup>University of British Columbia, Penticton; <sup>7</sup>AbbVie Corporation, Montreal, Canada

**Background:** Ankylosing Spondylitis (AS) and Psoriatic arthritis (PsA) are chronic progressive inflammatory diseases associated with severe pain and joint damage which may negatively impact patient reported outcomes (PRO), such as ability to work, depression and quality of life (QoL).

**Objectives:** To assess differences in PROs between patients with active AS and PsA requiring change in their treating regimen.

**Methods:** Patients eligible for the COMPLETE studies are anti-TNF $\alpha$  naïve adults, with active AS or PsA who require change in their regimen per the treating physician. Here, baseline data from patients enrolled between Jul/2011-Jun/2017 were included. PROs included the WLQ, BDI, and SF-12. Disease activity was classified as active/severe vs low/moderate based on BASDAI ( $\geq 4$  vs  $< 4$ ) for AS and based on DAS28 ( $\geq 5.1$  vs  $< 5.1$ ) for PsA. PsA patients were further stratified as per BSA  $\geq 3\%$  vs  $< 3\%$ . Differences between AS and PsA in WLQ, SF-12, and BDI were assessed with multivariate generalised linear models.

**Results:** 528 AS and 317 PsA (41% with BSA  $\geq 3\%$ ) patients were included. Upon multivariate adjustment, AS patients showed a trend towards higher scores in the SF-12 Physical Functioning subdomain compared to PsA patients with BSA  $< 3\%$  ( $p=0.069$ ) at baseline (table 1). Furthermore, PsA patients with BSA  $\geq 3\%$  had significantly higher scores in the SF-12 Role Functioning (Physical) subdomain ( $p=0.031$ ) and showed a trend towards higher scores in the SF-12 Mental Health subdomain ( $p=0.085$ ) compared to those with BSA  $< 3\%$ . No differences were observed between groups in any of the remaining SF-12 subdomains, WLQ, or BDI.

In terms of other determinants of PROs, high/very high disease state was associated with significantly higher BDI and worse scores in all WLQ and SF-12 dimensions and female gender was found to be a significant predictor of higher BDI scores and lower scores in the SF-12 physical functioning, vitality, social functioning and mental health subdomains.

Abstract FRI0205 – Table 1. PROs by disease type

Assessment	Parameter	AS (n=528)*	PsA w/BSA $\geq 3\%$ (n=130)*	PsA w/BSA $< 3\%$ (n=187)*
BDI	Total Score	12.6	13.8	13.7
WLQ	Mental Interpersonal Demands	24.9	27.2	26.7
	Output Demands	29.8	32.8	34.7
	Physical Demands	36.3	39.9	38.9
	Time Demands	37.8	41.1	42.0
SF-12	Productivity Loss Score	8.0	8.5	9.1
	General Health	50.2	49.8	45.3
	Physical Functioning	46.1	43.1	38.2
	Role Functioning (Physical)	43.0	47.9	39.2
	Bodily Pain	40.3	43.4	43.9
	Vitality	36.2	38.4	33.6
	Social Functioning	59.5	58.9	57.5
	Role Functioning (Emotional)	64.4	63.0	57.9
	Mental Health	56.7	58.6	52.2
	Physical Component Summary Scale	24.6	24.7	24.6
	Mental Component Summary Scale	18.9	18.9	18.8

\*Least square means adjusted for age, gender, disease duration, and disease activity.

**Conclusions:** AS and PsA affect multiple aspects of patients' lives without significant differences between the two diseases. Higher disease severity is associated with depressive symptoms and greater impairment in daily activities and work productivity. The impact of disease activity and treatment response over time on PRO will be evaluated in future analyses.

### GENDER DIFFERENCES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE ATLAS-2017

M. Garrido-Cumbrera<sup>1,2</sup>, D. Gálvez-Ruiz<sup>1</sup>, P. Zarco<sup>3</sup>, O. Braçe<sup>1</sup>, V. Navarro-Compán<sup>4</sup>.  
<sup>1</sup>Universidad de Sevilla, Sevilla; <sup>2</sup>CEADE; <sup>3</sup>Rheumatology, Foundation Hospital of Alcorcón; <sup>4</sup>Rheumatology, Hospital Universitario La Paz, IdiPaz, Madrid, Spain

**Background:** Recent data suggest gender differences on clinical manifestations, treatment access, and impact of the disease in patients with Axial Spondyloarthritis (axSpA). However, more data to confirm this hypothesis are needed.

**Objectives:** To assess gender differences on the physical, social, and psychological impact of the disease in patients with axSpA.

**Methods:** A sample of 680 axSpA patients was interviewed as part of the Spanish Atlas-2017 project. This aimed to promote early referral, improve healthcare, and the use of effective treatments in patients with axSpA. Among the recorded data, the following variables were collected: sociodemographic, smoking habits, degree of functional limitation in 18 daily activities (0–3 none, little, some, moderate), spinal stiffness level at cervical, thoracic, and lumbar spine (0–3 none, little, some, moderate), disease activity through BASDAI (0–10), risk of severe psychiatric illness using General Health Questionnaire – GHQ-12 (0–12), treatment received (NSAIDs and biological therapy), and disability. Differences for all of these variables between patients who are part of support group associations (associated-patients) and those who are not (non-associated patients) were tested using Mann-Whitney or Chi-square tests.

**Results:** In total, 323 (47.5%) men and 357 (52.5%) women participated in the survey. Compared with men, women reported a longer delay in diagnosis. Additionally, despite having a shorter disease duration, women reported significantly higher disease activity, worse functionality, and a higher risk of severe psychiatric illness than men. On the other hand, male patients had been treated more frequently with biological therapies and were significantly more likely to have had their disability legally recognised.

Abstract FRI0206 – Table 1. Sociodemographic and clinical outcomes of the disease characteristics stratified for the patient gender

	Men (mean $\pm$ SD or %)	Women (mean $\pm$ SD or %)	P
Age	48.1 $\pm$ 10.89	43.40 $\pm$ 10.29	<0.001
Marital Status (Married)	76.5%	66.9%	<0.05
Study Level (University)	31.9%	41.5%	<0.01
Smoker	56%	51.5%	0.2
Patient Association Membership	53.9%	35.6%	<0.001
Diagnostic Delay	7.85 $\pm$ 7.02	9.18 $\pm$ 8.19	0.07
Disease Duration	23.98 $\pm$ 12.48	17.91 $\pm$ 11.09	<0.001
HLA-B27 (Positive) (n=507)	83.4%	71.4%	0.001
Treatment			
- NSAIDs (without biology)	26.9%	32.5%	0.1
- Biology (with or without NSAIDs)	39.9%	33.1%	<0.06
BASDAI (n=442)	5.10 $\pm$ 2.14	5.88 $\pm$ 2.14	<0.001
Stiffness (High) (n=540)	44.4%	29.2%	<0.001
Functional Limitation (0–54) (n=605)	24.63 $\pm$ 13.10	30.55 $\pm$ 12.65	<0.001
GHQ-12 (n=474)	5.30 $\pm$ 4.52	6.19 $\pm$ 4.41	0.02
Inability to Work (n=344)	55.4%	33.3%	<0.001

**Conclusions:** Gender differences are observed regarding the impact of the disease in patients with axSpA. While women report a higher physical and psychological impact of the disease, men are more frequently legally recognised as disabled.

### THE INCORPORATION OF THE ANTERO-POSTERIOR LUMBAR SPINE VIEW IN THE MODIFIED STOKES ANKYLOSING SPONDYLITIS SPINE SCORE ONLY MARGINALLY IMPROVES DETECTION OF RADIOGRAPHIC SPINAL PROGRESSION IN AXIAL SPONDYLOARTHRITIS

M. Llop<sup>1</sup>, V. Rios Rodríguez<sup>1</sup>, J. Sieper<sup>1</sup>, H. Haibel<sup>1</sup>, M. Rudwaleit<sup>2</sup>, D. Poddubnyy<sup>1,3</sup>. <sup>1</sup>Rheumatology, Charité Universitätsmedizin, Berlin; <sup>2</sup>Internal Medicine and Rheumatology, Klinikum Bielefeld Rosenhöhe, Bielefeld; <sup>3</sup>German Rheumatism Research Centre, Berlin, Germany

**Background:** The modified Stokes Ankylosing Spondylitis Spine Score (mSASSS) is considered currently as a gold standard of assessment of structural damage in the spine in patients with axial spondyloarthritis (axSpA). However, mSASSS takes into account only structural damage visible on lateral radiographs of the cervical and lumbar spine. Antero-posterior (AP) views might be able to detect structural damage not visible on lateral ones.

**Objectives:** To evaluate the performance of the extended mSASSS score including AP lumbar radiographs compared to the conventional mSASSS in detection of radiographic spinal progression in patients with axSpA.

**Methods:** A total of 210 patients with axSpA, 115 with ankylosing spondylitis and 95 with non-radiographic axSpA, from the German SPondyloarthritis Inception Cohort (GESPIC) were included in the analysis based on the availability of spinal radiographs (cervical spine lateral view, lumbar spine lateral and AP views), at baseline and year 2. Two trained readers independently scored lateral cervical and lumbar spine images according to the mSASSS system (0–72). In addition, left and right, upper and lower vertebral corners of vertebral bodies visible on lumbar AP radiographs (lower Th12 to upper S1) were assessed according to the same scoring system ranging from 0 (no abnormality) to 3 (bridging syndesmophyte). Thus, the extended mSASSS had a total range from 0 to 144. The reliability and the sensitivity to detect radiographic spinal progression of the extended mSASSS as compared to the conventional mSASSS were evaluated. Following definitions for progression were used: change of the absolute scores, change of  $\geq 2$  points, development of new syndesmophytes, and development of new syndesmophytes or growth of the existing syndesmophytes after 2 years.

**Results:** The reliability of both scores was excellent with intraclass correlation coefficients (ICCs) of 0.927 and 0.926 at baseline and 0.933 and 0.920 at year 2 for the extended and conventional mSASSS, respectively. The mean  $\pm$  SD score at baseline was 4.25 $\pm$ 8.32 and 8.59 $\pm$ 17.96 for mSASSS and extended mSASSS, respectively. The change score between baseline and year 2 was 0.73 $\pm$ 2.34 and 1.19 $\pm$ 3.73 for mSASSS and extended mSASSS, respectively (table 1). With the extended mSASSS score as compared to the conventional one, new syndesmophytes after 2 years were detected in 4 additional patients (1.9%), new syndesmophytes or progression of existing syndesmophytes – in 5 additional patients (2.4%), and progression by  $\geq 2$  points in the total score – in 14 additional patients (6.7%) – table 1.

**Abstract FRI0207 – Table 1.** Comparison of the conventional and extended mSASSS for the detection of radiographic spinal progression in patients with axSpA (n=210)

	Conventional mSASSS (range 0-72)	Extended mSASSS (range 0-144)
Mean score at baseline, mean $\pm$ SD	4.2 $\pm$ 8.3	8.5 $\pm$ 17.9
Mean score at year 2, mean $\pm$ SD	4.9 $\pm$ 9.5	9.7 $\pm$ 20
Mean change score, mean $\pm$ SD	0.7 $\pm$ 2.3	1.1 $\pm$ 3.7
Smallest detectable change	2.9	4.5
Standardized response mean	0.3	0.3
Change of $\geq 2$ units, n (%)	30 (14.3)	44 (21)
Total number of syndesmophytes at baseline, mean $\pm$ SD	0.9 $\pm$ 2.6	1.9 $\pm$ 5.2
Total number of syndesmophytes at year 2, mean $\pm$ SD	1.1 $\pm$ 3.0	2.2 $\pm$ 5.9
Development of new syndesmophytes, n (%)	16 (7.6)	20 (9.5)
Development or progression of syndesmophytes, n (%)	18 (8.6)	23 (11)

mSASSS, modified Stokes Ankylosing Spondylitis Spinal Score

**Conclusions:** The incorporation of the AP radiographs of the lumbar spine in the assessment of structural spinal damage provided only a relatively small improvement of detection of radiographic spinal progression in axSpA.

### ANKYLOSING SPONDYLITIS QUALITY OF LIFE: DEFINING MINIMAL CLINICALLY IMPORTANT CHANGE

N. Richard<sup>1,2</sup>, N. Haroon<sup>1,2</sup>, G.A. Tomlinson<sup>1,2</sup>, I. Sari<sup>1,2</sup>, Z. Touma<sup>1,2</sup>, R. D. Inman<sup>1,2</sup>. <sup>1</sup>University Health Network; <sup>2</sup>University of Toronto, Toronto, Canada

**Background:** The Ankylosing Spondylitis Quality of Life (ASQoL) is a readable and simple to complete questionnaire relating to health-related quality of life (HRQoL) in ankylosing spondylitis (AS) and it has been shown to be a reliable and valid outcome measure<sup>1</sup>. Despite that this tool was used in various research settings over the last decade, the Minimal Clinically Important Difference (MCID) remains to be defined.

**Objectives:** Our objective is to define the MCID of ASQoL in subjects with axial spondyloarthritis(axSpA).

**Methods:** All subjects seen at the Spondylitis Clinic of the Toronto Western Hospital between July 2003 and January 2018 with a diagnosis of axSpA [AS or non-radiographic axSpA (nr-axSpA)] were included in this study. The ASQoL comprises 18 questions, and answers are dichotomized into yes/no. The weighted score for each item is 1 and poor HRQoL is associated with higher scores. The Medical Outcomes Study Short Form-36 (SF-36) is an instrument to assess for health status. Subjects completed ASQoL and SF-36 at the same time during yearly visits in the clinic. To determine MCID for ASQoL the SF-36 question 2 (SF-36 Q2: “compared to one year ago, how would you rate your health in general now?”) was used as an anchor measure. The answer to this question was incorporated in a 5 point Likert scale: “much worse”(–2 points), “somewhat worse”(–1 point), “about the same”(0 point), “somewhat better”(+1 point), “much better”(+2 points). An important change on the anchor was determined as +2 for improvement and –2 for worsening on the Likert scale. MCID was determined based on the optimal threshold that discriminated between change and no change (improvement or worsening) using receiver operating characteristic (ROC) curve analyses.

**Results:** A total of 1328 subjects were seen during the follow-up period. Of these, 66.2% were male, 75.3% were Caucasian, 61.8% had college or more education and the proportion AS/nr-axSpA was 84%/16%. At baseline, the mean age was 38.7 years and the mean disease duration was 14.9 years. On follow-up visit, patients who reported “much worse”, “somewhat worse”, “about the same”, “somewhat better” and “much better” had a mean change in ASQoL of respectively 3.85, 1.30, –0.24, –0.94 and –3.45 (table 1). Differences between mean change in ASQoL were statistically significant(p<0.02). The area under the ROC curve was 0.72 (95% CI 0.66–0.79) for subjects who worsened and 0.69 (95% CI 0.66–0.72) for those who improved. The ROC curve analyses showed that for thresholds of –2.5 and –3.5 points in deterioration there was a sensitivity/specificity of 0.536/0.841 and 0.474/0.890, respectively. Similarly, cut-offs of +2.5 and +3.5 points in improvement showed a sensitivity/specificity of 0.464/0.825 and 0.389/0.883, respectively.

SF-36 Q2	Mean ASQoL change	Standard deviation
Much improved (+2)	–3.45	4.98
Somewhat better (+1)	–0.94	3.87
About the same (0)	–0.24	3.23
Somewhat worse (–1)	1.30	4.20
Much worse (–2)	3.85	4.94

\* p-value<0.02 between all groups

**Conclusions:** We identified the MCID for ASQoL; a 3 points change for both improvement and worsening. Defining MCID will enhance the clinical utility of ASQoL in the management of patients with axSpA.

**FRI0209** **RECOMMENDATIONS FOR ACQUISITION AND CONSIDERATIONS FOR INTERPRETATION OF MRI OF THE SPINE AND SACROILIAC JOINTS IN THE INVESTIGATION OF AXIAL SPONDYLOARTHRITIS IN THE UK**

T. Bray, A. Jones, M.A. Hall-Craggs, A. Bennett, P.G. Conaghan, A. Grainger, R. Hodgson, C. Hutchinson, M. Leandro, P. Mandl, D. McGonagle, P. O'Connor, R. Sengupta, M. Thomas, A. Toms, N. Winn, H. Marzo-Ortega, P.M. Machado. *MRI Working Group, British Society for Spondyloarthritis, BRITSA, UK*

**Background:** The use of magnetic resonance imaging (MRI) has been instrumental in the early recognition and characterisation of axial spondyloarthritis (axSpA). However, a recent survey in the UK showed that there is diverse practice in the use of MRI and limited knowledge of MRI features suggestive of axSpA among radiologists.<sup>1</sup>

**Objectives:** To develop clinical practice recommendations for the acquisition and interpretation of MRI of the spine and sacroiliac joints (SIJs) in the investigation of axSpA through a collaboration between rheumatologists and radiologists.

**Methods:** A working group comprising 9 rheumatologists and 9 musculoskeletal radiologists with an interest in axSpA was established. The EULAR standardised operating procedures were followed.<sup>2</sup> Two working group meetings were held, the first to define the scope of the exercise and the second to review the results of the Systematic Literature Review that informed the recommendations. An anonymised Delphi process was used to formulate the final set of recommendations. The level of evidence and strength of recommendation was added to the recommendations. The level of agreement by working group members was assessed using a numerical rating scale.

**Results:** A total of 2 overarching principles and 7 recommendations were formulated (figure 1). The first 3 recommendations address the MRI acquisition protocol, namely anatomical areas to be scanned and sequences to be used. The remaining 4 recommendations address the interpretation of active and structural lesions of the spine and SIJs.

OP1	The diagnosis of axSpA is based on clinical, laboratory and imaging features.
OP2	Some patients with axSpA have isolated inflammation of the SIJs or spine.
Rec1	When requesting an MRI for suspected axSpA, imaging of both the SIJs and the spine is recommended.
Rec2	T1-weighted and fat-suppressed, fluid sensitive sequences (including STIR, fat-saturated T2 or Dixon methods) are recommended when requesting an MRI for suspected axSpA.
Rec3	The minimum protocol when requesting an MRI for suspected axSpA should include sagittal images of the spine with extended lateral coverage and images of the SIJs which are coronal to the joint.
Rec4	In the SIJs, the presence of bone marrow oedema, fatty infiltration or erosion is suggestive of the diagnosis of axSpA. The presence of more than one of these features increases the diagnostic confidence of axSpA.
Rec5	In the spine, the presence of multiple corner inflammatory lesions and/or multiple corner fatty lesions increases the diagnostic confidence of axSpA.
Rec6	In the SIJs and/or spine the presence of characteristic new bone formation increases the diagnostic confidence of axSpA.
Rec7	The full range and combination of active and structural lesions of the SIJs and spine should be taken into account when deciding if the MRI scan is suggestive of axSpA or not.

**Abstract FRI0209 – Figure 1.** Overarching principles (OP) and recommendations (Rec)

**Conclusions:** A UK joint rheumatology and radiology consensus on the most appropriate MRI acquisition protocol and interpretation of images in the investigation of axSpA was achieved. This consensus will help standardise practices and ensure prompt and effective patient management in the diagnosis and treatment of axSpA.

**FRI0210** **EXTRA-ARTICULAR MANIFESTATIONS ARE ASSOCIATED WITH WORSE QUALITY OF LIFE AND CLINICAL OUTCOME IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS**

R. van der Meer<sup>1</sup>, S. Arends<sup>1,2</sup>, S. Kruidhof<sup>1</sup>, R. Bos<sup>2</sup>, H. Bootsma<sup>1</sup>, F. Wink<sup>2</sup>, A. Spoorberg<sup>1,2</sup>. <sup>1</sup>*Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen*; <sup>2</sup>*Rheumatology, Medical Center Leeuwarden, Leeuwarden, Netherlands*

**Background:** In the 1960s, the association between axial spondyloarthritis (SpA) and extra-articular manifestations (EAMs), acute anterior uveitis (AAU),

inflammatory bowel disease (IBD) and psoriasis, was first reported. Still, knowledge of axial SpA disease outcome associated with the development of EAMs is scarce.

**Objectives:** To investigate the prevalence and 4 year incidence of EAMs and to explore associations of newly developed EAMs with disease outcome after 4 years of follow-up in a large cohort of axial SpA patients.

**Methods:** All consecutive patients fulfilling the modified New York criteria for AS or the ASAS criteria for axial SpA from the prospective observational Groningen Leeuwarden Axial Spondyloarthritis (GLAS) cohort with a baseline visit between November 2004 and December 2011 were included in the analyses. Baseline and follow-up data of EAMs from the GLAS database were verified in the medical records. EAMs were only recorded and used for analyses when a description of the diagnosis by an ophthalmologist, gastroenterologist or dermatologist was present. Prevalence and 4 year incidence of EAMs was calculated and comparative analyses regarding disease outcome was performed.

**Results:** 421 axial SpA patients were included with a mean age of 43.4±12.5 years, 65% were male, mean symptom duration was 17.4±11.7 years, 78% were HLA-B27 positive, mean ASDAS was 3.3±1.1 and 66% started TNF- $\alpha$  inhibitors at baseline. Of the 421 patients, 132 (31.4%) had a positive history of one or more EAMs: 104 (24.8%) AAU, 40 (9.5%) IBD, and 18 (4.3%) psoriasis. Of the 362 patients with 4 year follow-up data, 57 (15.7%) patients developed an EAM: 48 (13.3%) patients AAU, of which 13 (3.6%) had a first episode, 7 (1.9%) patients developed IBD, and 3 (0.8%) patients developed psoriasis.

Patients who developed a new EAM without a history of EAMs at baseline had higher ASQoL (mean 10.0 vs. 5.9, p=0.001), larger occiput to wall distance (median 6.3 vs. 2.0, p=0.021) and also the modified Schober test was more limited (mean 12.6 vs. 13.6, p=0.014) after 4 years of follow-up. The difference found for BASFI was not statistically significant (mean 4.4 vs. 3.4, p=0.12).

**Conclusions:** The prevalence rates of EAMs in our cohort are similar as found in other axial SpA studies. The 4 year incidence of EAMs was relatively low, possibly due to the relatively large proportion of patients starting TNF- $\alpha$  inhibitors at baseline. However, these axial SpA patients showed worse quality of life and clinical outcome than patients without a newly developed EAM.

**FRI0211** **ASSOCIATION OF NEUROPATHIC-LIKE PAIN CHARACTERISTICS WITH CLINICAL AND RADIOGRAPHIC FEATURES IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

S.-H. Lee, H.-R. Kim, K.-A. Lee. *Konkuk University Medical Center, Seoul, Korea, Republic Of*

**Background:** Ankylosing spondylitis (AS) is a chronic progressive inflammatory disorder that mainly involves the axial skeleton and causes chronic back pain. It is not unusual for patients with AS to have symptoms similar to neuropathic pain. There were several studies showing that various rheumatic diseases, including rheumatoid arthritis, primary Sjogren syndrome, and fibromyalgia, had neuropathic pain components. However, the existence of neuropathic pain in patients with AS has not been well investigated. The painDETECT questionnaire (PD-Q) is a relatively simple and self-administered screening tool for determining neuropathic pain and has high sensitivity, specificity, and positive predictive accuracy values.

**Objectives:** The aim of this study was to investigate the neuropathic pain component in patients with AS using PD-Q, and to assess the relation between neuropathic pain and disease characteristics of AS.

**Methods:** A single-centre prospective study was performed on 105 patients. The patients with AS completed three questionnaires: PD-Q, Beck depression inventory (BDI), and Euro Quality of life (EQ-5D) questionnaires. Patients were classified into three groups according to the PD-Q scores: nociceptive pain (NoP) (score <13), mixed pain (MP) (score 13–18), and neuropathic (NeP) (score >18) pain. Fifteen patients (14.3%) were classified in the NeP group, 22 patients (21.0%) in the MP group, and 68 patients (64.7%) in the NoP group. The questionnaires and clinical and radiographic findings were analysed.

**Results:** Patients with NeP and MP scored worse on Bath ankylosing spondylitis disease activity index (BASDAI), BDI, modified Stoke Ankylosing Spondylitis Spine Score, pain-visual analogue scale (VAS), EQ-5L index, and showed an increased prevalence of enthesitis and peripheral arthritis (table 1). There were no differences in objective inflammatory markers. PD-Q scores positively correlated with pain-VAS, BASDAI, BDI, and inversely correlated with EQ-5D index (figure 1). Presence of enthesitis, BDI, age, and pain VAS score independently associated with PD-Q scores.

**Conclusions:** The findings showed a neuropathic pain component in AS. Neuropathic pain in AS was associated with age, high disease activity, radiographic progression, enthesitis, peripheral arthritis, depression, and low quality of life.

#### FRI0212 THE RELATIONSHIP BETWEEN ANTI-TNF THERAPY USE AND METABOLIC SYNDROME IN PATIENTS WITH ANKYLOSING SPONDYLITIS

A. Ferhatosmanoğlu<sup>1</sup>, S. Çelik<sup>2</sup>, N. Alpay Kanitez<sup>2</sup>, N. Caf<sup>1</sup>, S. Yılmaz-Oner<sup>2</sup>, C. Bes<sup>2</sup>. <sup>1</sup>Physical Medicine and Rehabilitation, Istanbul Physical Medicine and Rehabilitation Research and Training Hospital, <sup>2</sup>Rheumatology, University of Health Sciences, Bakırköy Dr. Sadi Konuk Training and Research Hospital, Istanbul, Turkey

**Background:** Ankylosing spondylitis (AS) is an inflammatory disease associated with accelerated atherosclerosis and the presence of metabolic syndrome (MetS) features. TNF- $\alpha$  is considered as one of the factors responsible for favouring insulin resistance and dyslipidemia, which are important features of the metabolic syndrome.

**Objectives:** In this study, we aimed to investigate the relationship between anti-TNF therapy and metabolic syndrome rate in patients with ankylosing spondylitis (AS).

**Methods:** AS patients who visited the outpatient rheumatology clinic between 2016 February and May were included in to the study. Systolic and diastolic blood pressures, body mass index (BMI), waist-hip circumference were measured. Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), fasting blood sugar, cholesterol panel were evaluated. MetS was defined by abdominal obesity, elevated blood pressure, elevated glucose, high triglycerides and reduced high-density lipoprotein cholesterol according to National Cholesterol Education Program's Adult Treatment Panel III report (NCEP ATP III) criteria. Duration of disease and use of anti-TNF was recorded. Bath Ankylosing Spondylitis Functional Index (BASFI) – Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) measurements were performed to assess the disease activity and functional capacities. Patients were divided into two groups as anti-TNF treated and anti-TNF naive. For comparisons between groups statistical analyses included descriptive statistics, *t*-tests and one-way ANOVA.

**Results:** A total of 223 patients were analysed. Of the total 223 patients, 78 (35%) were receiving anti-TNF therapy. Age distribution was similar in between groups. In the group receiving anti-TNF therapy, the number of male patients was higher (75.6% vs. 58.6%) and the duration of disease was longer (145.2 $\pm$ 90.8 vs 103.3 $\pm$ 97.1). Serum lipid levels, glucose, ESR, CRP, BASFI, BASDAI measurements, BMI and blood pressures were not significantly different in between the groups. MetS was present in 26 (33.3%) of 78 patients receiving anti-TNF and 29 (20%) of 145 patients in anti-TNF naive group. The effect of TNF- $\alpha$  inhibitor use on MetS was independent from the gender.

**Conclusions:** Patients with AS who received anti-TNF therapy were found to have a higher incidence of MetS than those who did not. Suppression of the catabolic effect of inflammation with treatment may have been effective in this result.

**Disclosure of Interest:** None declared

#### FRI0213 THE PERFORMANCE OF 12 FLARE DEFINITIONS INCLUDING THE ASSESSMENT OF SPONDYLOARTHRITIS INTERNATIONAL SOCIETY (ASAS)-ENDORSED DEFINITION OF CLINICALLY IMPORTANT WORSENING IN ASDAS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS TREATED WITH ADALIMUMAB FOR 5 YEARS

S. Juul Pedersen<sup>1</sup>, I.J. Sørensen<sup>1</sup>, A.G. Loft<sup>2</sup>, J. Hindrup<sup>1</sup>, G. Kollerup<sup>1</sup>, G. Thamsborg<sup>1</sup>, K. Asmussen<sup>1</sup>, O. Hendricks<sup>1</sup>, J. Nørregaard<sup>1</sup>, M. Østergaard<sup>1</sup>. <sup>1</sup>Rigshospitalet, Copenhagen; <sup>2</sup>Aarhus Hospital, Aarhus, Denmark

**Background:** In 2016 the Assessment of Spondyloarthritis International Society (ASAS) published proposals for 12 definitions of ‘flare’ (ref. 1) for patients with axial spondyloarthritis (axSpA). The definitions are based on pain, BASDAI and ASDAS (see table 1). In January 2018, ASAS published the ASAS-endorsed definition of clinically important worsening based on ASDAS ( $\Delta$ ASDAS $\geq$ 0.9) (ref. 2).

**Objectives:** The aim of this study was to describe the frequency of ‘flares’ as detected by the 12 flare definitions including the ASAS-endorsed definition.

**Methods:** Data from an investigator-initiated double-blinded randomised placebo-controlled trial of adalimumab versus placebo of 12 weeks with a 5 year open-label extension (NCT00477893, ref. 3) were used for this study. The number of patients experiencing a flare at each visit according to the 12 ASAS ‘flare’ definitions was recorded for 20 study visits performed from two weeks after initiation of treatment and to year 5.

**Results:** 52 patients started treatment and 41 (79%) patients completed the 5 year follow-up visit. The total number (percentage) of study visits where pain, BASDAI and ASDAS flares could be calculated was 879 (84.5%), 875 (84.1%) and 842 (81.0%), respectively. The mean (SD) number of patients with a flare per visit ranged from 0.7 (1.2) to 3.8 (2.2) and the median (inter-quartile-range (IQR)) from 0 (0–1) to 5 (3–7) (table 1). The mean number of patients per visit with a flare was significantly higher when the definition “change in ASDAS $\geq$ 0.6” ( $p<0.0001$  to  $p=0.001$ , *t*-test) and “change ASDAS $\geq$ 0.6 AND observed ASDAS $\geq$ 1.3” ( $p<0.0001$  to  $p=0.04$ ) were applied, and the mean number of patients was significantly lower when the BASDAI flare definitions were applied ( $p<0.0001$  to  $p=0.02$ ).

**Abstract FRI0213 – Table 2.** Patients per study visit fulfilling a ‘flare’ definition

Flare definition	Mean (SD)	Median (IQR)	Min-max	Number	Percent
$\Delta$ pain $\geq$ 2 AND final value $\geq$ 4	2.7 (1.7)	2 (1–4)	0–6	53	6.0
$\Delta$ pain $\geq$ 3	1.6 (1.0)	1 (1–2.75)	0–3	31	3.5
If observed value is $\geq$ 4: $\Delta$ pain $\geq$ 2 points. Otherwise: $\Delta$ pain $\geq$ 3 points	2.9 (1.7)	2.5 (1.25–4)	0–6	57	6.5
$\Delta$ BASDAI $\geq$ 2 points	1.9 (2.0)	1 (0–3)	0–7	37	4.2
$\Delta$ BASDAI $\geq$ 2 points AND final value $\geq$ 4	1.2 (1.9)	0 (0–1.75)	0–6	23	2.6
$\Delta$ BASDAI $\geq$ 3 points	0.8 (1.2)	0 (0–1)	0–4	15	1.7
$\Delta$ BASDAI $\geq$ 3 points AND final value $\geq$ 4	0.7 (1.2)	0 (0–1)	0–4	14	1.6
If observed value is $\geq$ 4: $\Delta$ BASDAI $\geq$ 2 points. Otherwise: $\Delta$ BASDAI $\geq$ 3 points	1.2 (1.9)	0.5 (0–1.75)	0–6	24	2.8
$\Delta$ ASDAS $\geq$ 0.6	5.0 (2.5)	5 (3–7)	0–9	100	11.9
$\Delta$ ASDAS $\geq$ 0.9 (endorsed by ASAS)	2.9 (2.2)	2.5 (1–4.75)	0–8	58	6.9
$\Delta$ ASDAS $\geq$ 1.1	2.1 (1.6)	1.5 (1–4)	0–5	42	5.0
$\Delta$ ASDAS $\geq$ 0.6 AND observed ASDAS $\geq$ 1.3	3.8 (2.2)	4 (2–5)	0–8	75	8.9

**Conclusions:** The frequency of flares as detected by the 12 ASAS flare definitions for patients with axial spondyloarthritis differed substantially. The ASAS-endorsed definition performed well.

**FRI0214** **CLINICAL EVALUATION CORRELATES POORLY WITH ULTRASOUND AND MAGNETIC RESONANCE IMAGING OF JOINTS AND ENTHESES IN EARLY PERIPHERAL SPONDYLOARTHRITIS**

T. Renson<sup>1</sup>, P. Carron<sup>1</sup>, S. Krabbe<sup>2</sup>, L. Jans<sup>3</sup>, A.-S. De Craemer<sup>1</sup>, M. de Hooge<sup>1</sup>, P. Jacques<sup>1</sup>, M. Ostergaard<sup>2</sup>, D. Elewaut<sup>1</sup>, F. Van den Bosch<sup>1</sup>. <sup>1</sup>Rheumatology, Ghent University Hospital, Ghent, Belgium; <sup>2</sup>Copenhagen Center for Arthritis Research (COPECARE), Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark; <sup>3</sup>Radiology, Ghent University Hospital, Ghent, Belgium

**Background:** Enthesitis is a hallmark of spondyloarthritis (SpA), which occurs in 30% to 50% of psoriatic arthritis patients (pts).<sup>1</sup> Evaluation of tenderness at the site of an enthesitis with a standard palpation approach remains the gold standard for detection of enthesitis. However, inter- and intra-observer variability is rather high. All existing clinical enthesitis scoring systems lack validity. Imaging could avoid these drawbacks.

**Objectives:** To compare the performance of ultrasound (US) and magnetic resonance imaging (MRI) with clinical examination (CE) of joints and entheses in peripheral (p)SpA.

**Methods:** Clinical Remission in peripheral SPondyloArthritis (CRESPA) is a placebo-controlled trial of golimumab treatment in 60 early (symptom duration <12 weeks) pSpA pts. CE included tender and swollen joint count, dactylitis and enthesitis (evaluation of palpation tenderness) count. All pts underwent Power Doppler (PD)US of entheses and knee, talocrural (TC) and subtalar (ST) joints. Synovitis was scored according to the OMERACT-EULAR-US composite PDUS scale, giving a score of 0–3 for each joint. Enteseal sites were evaluated for hypoechoogenicity and intraenthesitis Doppler signal and were scored on a scale of 0–3. Modified whole-body MRI was performed at baseline. Bone marrow oedema (BME), synovitis and soft tissue inflammation (STI) were scored (scale 0–3) by 3 readers at several anatomical sites of pelvis and lower limbs. For each site a mean of the scores of the 3 readers was calculated.

**Results:** Abstract FRI0214 – Table 1. Prevalence of synovitis and enthesitis on CE, US and MRI

Joints/entheses	CE	US	MRI
Hip joint	3/60 (0)	-	4/60 <sup>1</sup>
Knee joint	21/60 <sup>6</sup>	25/60 <sup>6</sup>	24/60 <sup>7</sup>
Talocrural joint	14/60 <sup>1</sup>	9/60 <sup>1</sup>	24/60 <sup>13</sup>
Subtalar joint	7/60 <sup>2</sup>	10/60 <sup>12</sup>	15/60 (0)
Quadriceps tendon	10/60 <sup>2</sup>	9/60 <sup>1</sup>	4/60 (0)
Superior patellar ligament	8/60 <sup>2</sup>	8/60 <sup>1</sup>	7/60 <sup>1</sup>
Inferior patellar ligament			6/60 <sup>1</sup>
Achilles tendon	14/60 <sup>2</sup>	11/60 <sup>2</sup>	17/60 <sup>4</sup>
Plantar fascia	15/60 <sup>1</sup>	7/60 <sup>1</sup>	17/60 <sup>3</sup>

Prevalence of bilateral involvement is indicated between brackets.

Synovitis detected by US and MRI was most prevalent at knee joints (table 1). A discrepancy was noted between TC synovitis detected by CE, US and MRI. Enthesitis was most prevalent at Achilles tendon and plantar fascia. Regarding enthesitis, agreement between CE and US ranged from no (kappa –0.082) to moderate agreement (kappa 0.562). The highest agreement was observed at the enteseal sites of Achilles tendon (left 0.511, right 0.350) and plantar fascia (left 0.321, right 0.507). MRI did not correlate better with CE than US (kappa from –0.077 to 0.446). The correlation between MRI and US was overall poor and only in the Achilles tendon moderate (range –0.106 to 0.656).

**Conclusions:** There was a weak agreement between CE and imaging in detecting enthesitis. In general, US detects less enthesitis compared to CE, while MRI detects more.

Autónoma de GDL, GDL, Mexico; <sup>17</sup>NIHR LBRC and LIRMM, UoL, Leeds, UK

**Background:** In the last three decades, major advances in the spondyloarthritis (SpA) field have been achieved leading to new terminology. Whilst this terminology is well established in English, there is concern about the disparity of translated words and acronyms in Spanish, which is used by more than 437 million people in 21 countries.

**Objectives:** To develop a consensus to standardise the use of the Spanish terms, abbreviations and acronyms employed in the field of SpA.

**Methods:** An international task force was created comprising of all ASAS Spanish-speaking native members representing 5 countries, the executive committee members of GRESSER, two methodologists, two linguists from Real Academia Nacional de la Medicina Española (RANM) and two patients from CEADE. First, a literature review spanning the last 15 years was performed to identify the conflicting terms/abbreviations/acronyms. This review examined available written sources in Spanish including manuscripts, ICF and ICD, guidelines, recommendations and consensus. A three-round Delphi method including a face-to-face meeting, then followed. The recommendations from the RANM based on the Panhispanic dictionary in medical terms were consistently followed throughout the process.

**Results:** Consensus was reached for 44 terms, abbreviations or acronyms related to the field of SpA. A Spanish translation was accepted for 6 terms and 6 abbreviations to name the disease or its subgroups (SpA, axSpA, nr-axSpA, pSpA, AS, r-SpA, PsA) and for 6 terms and 4 abbreviations related with the disease (enthesitis, sacroiliitis, IBP, MRI-SIJ, BME, mNY). Additionally, it was agreed not to translate into Spanish 15 acronyms because they are very well established (ASDAS, BASDAI, BASFI, BASMI, mSASSS, RASS, BASRI, BAS-G, ASQoL, PsAQoL, MASES, MASEI, PASI, PARS, ASAS). However, when mentioning these acronyms, it is recommended that the following structure is used: type of variable in Spanish and acronym and expanded form in English. With regards to the terms or abbreviations attached to 7 acronyms (ASDAS-CI, ASDAS-MI, ASAS-HI, ASASpr, ASAS 5/6, ASAS20, ASAS40 improvement criteria), it was agreed to translate only the expanded form and a translation was also selected for all of them.

**Conclusions:** A consensus in Spanish nomenclature for SpA has been developed by ASAS group. The implementation of this consensus across the Spanish-speaking community will be of substantial benefit, avoiding misunderstandings and time-consuming processes.

Bukowski<sup>6</sup>, H. Jones<sup>6</sup>, I. Logeart<sup>7</sup>, L. Marshall<sup>6</sup>, R. Pedersen<sup>6</sup>, A. Szumski<sup>8</sup>, B. Vlahos<sup>6</sup>, M. Dougados<sup>5</sup>. <sup>1</sup>University of Alberta, Edmonton, Canada; <sup>2</sup>Université Paris Est Creteil, Creteil, France; <sup>3</sup>Leiden University Medical Center, Leiden; <sup>4</sup>Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; <sup>5</sup>Paris Descartes University, Hôpital Cochin, Paris, France; <sup>6</sup>Pfizer, Collegeville, USA; <sup>7</sup>Pfizer France, Paris, France; <sup>8</sup>inVentiv Health, Princeton, USA

**Background:** Sacroiliac joint (SIJ) structural damage may be evaluated using MRI, CT scan or radiographs.

**Objectives:** A post-hoc analysis of SIJ images from EMBARK (NCT01258738) and DESIR (NCT01648907) evaluated: <sup>1</sup> association between presence/absence of erosion on MRI and presence/absence of erosion or sacroiliitis on radiographs

at BL and Wk 104;<sup>2</sup> association between decrease/increase in erosion score on MRI and decrease/increase in erosion or sacroiliitis grade on radiographs, BL to Wk 104.

**Methods:** All patients had early axSpA. EMBARK: 12 wks double-blind placebo-control, then 92 wks open-label etanercept. DESIR: patients had no history of biologics and received no biologics for 104 wks. MRI images from both studies: combined, anonymized, and read per patient; radiographs combined, anonymized, read separately from MRI. Readers unaware of: image chronology, original cohort. Three experienced readers individually reviewed T1 weighted MRI using SpondyloArthritis Research Consortium of Canada SIJ Structural Score; 3 different readers assessed radiographic sacroiliitis using mNY grade; all were at level of each joint surface. Lesion presence/absence or decrease/increase recorded per patient if  $\geq 2$  of 3 readers agreed. Statistical analyses:  $\kappa$  coefficient of agreement, McNemar's test for discordance asymmetry.

**Results:** 224 patients had MRI and radiographs. At BL, concordance for presence or absence of erosion in 162/224 (72.3%) ( $\kappa=0.42$ ), table 1. Discordance: erosion more frequent on MRI (21.4%) than radiographs (6.3%;  $p<0.0001$ ). Wk 104 data similar to BL. Decrease in erosion more frequent than increase only on MRI; significantly more frequent on MRI than radiographs. Decrease in erosion on MRI significantly more frequent than decrease in sacroiliitis grade.

**Abstract FRI0216 – Table 1.** Concordance between MRI and Radiographs, BL and Wk 104; and Change BL to Wk 104

	N	Present/ Present n (%)	Absent/ Absent n (%)	Absent/ Present n (%)	Present/ Absent n (%)	$\kappa$ (95% CI)	P-value*
BL Erosion: MRI/ radiographs	224	50 (22.3)	112 (50.0)	14 (6.3)	48 (21.4)	0.42 (0.30– 0.53)	<0.0001

## FRI0217 DIAGNOSTIC ASCERTAINMENT OF AXIAL SPONDYLOARTHRITIS IN PATIENTS PRESENTING WITH UNDIAGNOSED BACK PAIN: WHAT IS THE IMPACT OF MRI IN RHEUMATOLOGICAL PRACTICE?

R.G. Lambert<sup>1</sup>, R. Carmona<sup>2</sup>, J. Yeung<sup>3</sup>, J. Chan<sup>4</sup>, L. Martin<sup>5</sup>, S. Aydin<sup>6</sup>, D. Mosher<sup>5</sup>, A. Masetto<sup>7</sup>, S. Keeling<sup>8</sup>, O. Ziouzina<sup>5</sup>, S. Rohekar<sup>9</sup>, J. Paschke<sup>10</sup>, A. Carapellucci<sup>10</sup>, W.P. Maksymowych<sup>9,10</sup>. <sup>1</sup>Radiology, University of Alberta, Edmonton; <sup>2</sup>St. Joseph's Healthcare Hamilton, Hamilton; <sup>3</sup>James Yeung Rheumatology, Richmond; <sup>4</sup>Artus Health Clinic, Vancouver; <sup>5</sup>University of Calgary, Calgary; <sup>6</sup>Ottawa Hospital, Ottawa; <sup>7</sup>Université de Sherbrooke, Sherbrooke; <sup>8</sup>Medicine, University of Alberta, Edmonton; <sup>9</sup>Lawson Health Research Institute, London; <sup>10</sup>CaRE Arthritis Ltd., Edmonton, Canada

**Background:** In current rheumatology practice, the circumstances that prompt clinicians to order MRI in patients with suspected axSpA are unclear. In addition, the manner and degree to which MRI changes diagnostic ascertainment of axSpA in patients presenting with undiagnosed back pain has not been formally studied.

**Objectives:** 1. To determine whether any particular patient demographic and/or disease characteristics are associated with rheumatologist ordering of MRI. 2. To assess the impact of MRI evaluation on diagnostic ascertainment of axial SpA in patients presenting with undiagnosed back pain.

**Methods:** The multicenter Screening for AxSpA in Psoriasis, Iritis, and Colitis (SASPIC) Study is aimed at early detection of axial SpA in consecutive patients presenting with undiagnosed back pain to the rheumatologist. Consecutive patients with any one of psoriasis, iritis, or colitis diagnosed by the relevant specialist undergo routine evaluation by a rheumatologist. The rheumatologist determines the presence/absence of axial SpA and the degree of confidence in the diagnosis (–10 (definitely not SpA) to +10 (definite SpA) on a NRS) at 3 consecutive stages: 1. After the clinical evaluation; 2. After the results of labs (B27, CRP) and radiography; 3. After the results of MRI. Differences in patient demographics and/or disease characteristics between those who did or did not have MRI were assessed by chi-square and t-tests. We assessed the degree of diagnostic reclassification after each step at the categorical level (axial SpA yes/no) and also according to the degree of confidence.

**Results:** 244 patients (51.6% male, mean age 34.6 years, mean age at symptom onset 27.4 years, mean back pain duration 7.1 years, B27 +37.2%) were referred with AAU (29.9%), psoriasis (21.7%), Crohn's colitis (32.8%), ulcerative colitis (19.3%). A diagnosis of axSpA was made in 67.5% after stage 1 clinical evaluation and in 56.4% at stage 2 after review of the labs and radiography. MRI evaluation varied across sites (mean(range): 73% (16.7%>100%) of patients), ordered in 141 patients, and significantly more frequently in those with probable inflammatory type back pain (probability >5 (0–10 scale) ( $p=0.04$ ), when radiography was mNY- ( $p=0.005$ ) and in those without Crohn's colitis ( $p=0.001$ ). No differences in ordering of MRI were noted according to age, gender, disease duration, back pain severity, NSAID response, B27 status, or CRP level. In patients with completed MRI scans, a diagnosis of axSpA was made in 70.5% after stage 1 clinical evaluation, in 56.4% after review of the labs and radiography, and in 47.3% after MRI review. 24 (18.6%) were recategorized from SpA to non-SpA and 4 (3.1%) from non-SpA to SpA. Confidence in diagnostic categorization was increased after MRI.

Stage of Assessment	axSpA present n (%)	Mean (SD) confidence	axSpA absent n (%)	Mean (SD) confidence
1. Clinical only	n=91 (70.5)	5.5 (2.4)	n=38 (29.5)	3.4 (3.2)
2. Clinical plus labs and radiography	n=81 (62.8)	5.9 (2.9)	n=48 (37.2)	5.1 (3.6)
3. Clinical, labs, radiography, plus MRI	n=61 (47.3)	7.5 (2.9)	n=68 (52.7)	7.5 (2.5)

**Conclusions:** In a setting of undiagnosed back pain and higher risk for axial SpA, use of MRI is primarily driven by negative radiography. MRI was primarily helpful in ruling out SpA and reducing false positives.

**Disclosure of Interest:** None declared

**FRI0218** VALIDATION OF ASSESSMENTS IN SPONDYLOARTHRITIS INTERNATIONAL SOCIETY (ASAS) MRI LESION DEFINITIONS IN AXIAL SPONDYLOARTHRITIS: DATA FROM THE ECHOGRAPHY IN SPONDYLOARTHRITIS COHORT (ECHOSPA)

W.P. Maksymowych<sup>1</sup>, D. Loeuille<sup>2</sup>, S. Wichuk<sup>3</sup>, J. Paschke<sup>4</sup>, O. Judet<sup>5</sup>, M. Breban<sup>6</sup>, M.-A. D'Agostino<sup>6</sup>, R.G. Lambert<sup>7</sup>. <sup>1</sup>Rheumatology, University of Alberta, Edmonton, Canada; <sup>2</sup>Rheumatology, CHRU Vandoeuvre les Nancy, Nancy, France; <sup>3</sup>Medicine, University of Alberta; <sup>4</sup>CaRE Arthritis, Edmonton, Canada; <sup>5</sup>Radiology; <sup>6</sup>Rheumatology, Ambroise Paré Hospital, Boulogne-Billancourt, France; <sup>7</sup>Radiology, University of Alberta, Edmonton, Canada

**Background:** The diversity of MRI lesions in the sacroiliac joints of patients with axial spondyloarthritis (axSpA) has only recently been appreciated and consistent terminology, descriptions, and definitions have not yet been internationally accepted. The ASAS MRI group has generated updated consensus lesion definitions and these now require validation to support widespread adoption for clinical practice and research.

**Objectives:** To assess the distribution by diagnosis, reliability of detection, and construct validity of active and structural lesions as defined by the ASAS-MRI group on MRI scans from the ECHOSPA cohort.

**Methods:** Consecutive outpatients with age <50 years and symptoms >3 months suggestive of SpA (inflammatory back pain, peripheral arthritis or inflammatory arthralgia, enthesitis or dactylitis, uveitis with B27 positivity, a family history of SpA) were enrolled in the prospective French ECHOSPA cohort. MRI scans from 412 of the 470 recruited cases were available for evaluation by 2 readers and an adjudicator. ASAS\_MRI\_def<sup>n</sup> were recorded in an ASAS consensus-derived eCRF that comprises global assessment (active and/or structural lesion typical of axSpA present/absent) and detailed scoring of individual lesions (SPARCC SIJ inflammation, SPARCC SIJ structural). Definite lesions were defined according to confidence  $\geq 3$  (0–4 scale). Reliability of detection of lesions assessed as present/absent by global assessment was analysed using kappa and detailed scoring of SIJ quadrants by intra-class correlation coefficient (ICC). For construct validity we calculated optimal cut-offs for bone marrow oedema (BME) and erosion that defined active and structural lesion typical of axSpA, respectively.

**Results:** At baseline, mean age of the 412 cases with MRI scans was 39.3 years, mean duration of symptoms was 2.5 years, 41.3% were HLA-B27 positive, and 63.2% were female. Active and structural lesions typical of axSpA were present in 9.7% and 10.8%, respectively, and ASAS positive MRI in 9.3%. Subchondral BME (13.6%) and erosion (9.4%) were the most frequent active and structural lesions, respectively. Active but not structural lesions were present in 3.0% while the converse was evident in 4.0%. AxSpA was diagnosed at baseline in 88.1% and all categories of active and structural lesions were higher in those with axSpA. Substantial  $\kappa$  values (95% CI) were evident for detection of these lesions with comparable reliability for active and structural lesions: active lesion (0.76 (0.65–0.88)), ASAS positive MRI (0.78 (0.66–0.89)), structural lesion (0.76 (0.65–0.87)). Detailed scoring per SIJ quadrant that reflect expert opinion as to what constitutes an active or structural lesion typical of axSpA are provided in the table 1.

Abstract FRI0218 – Table 1

Number of SIJ Quadrants	Active Lesion Typical of AxSpA	
	Sensitivity	Specificity
BME Score $\geq 2$	100%	90.27%
BME Score $\geq 3$	100%	95.14%
BME Score $\geq 4$	97.5%	96.76%
	Structural Lesion Typical of AxSpA	
	Sensitivity	Specificity
Erosion Score $\geq 2$	84.09	99.15
Fat metaplasia $\geq 2$	27.27	98.02
Backfill $\geq 2$	11.36	100
Ankylosis $\geq 2$	4.55	99.72

**Conclusions:** SPARCC BME score of  $\geq 3$  and Erosion Score  $\geq 2$  may optimally reflect active and structural lesions typical of axSpA, respectively. MRI lesions defined by the ASAS-MRI group can be reliably detected.

**Disclosure of Interest:** None declared

**FRI0219** ANALYSIS OF THE DIFFERENT VALUE OF MAGNETIC RESONANCE IMAGING CHANGES IN THE SACROILIAC JOINTS FOR A DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS AS JUDGED BY RHEUMATOLOGISTS AND RADIOLOGISTS

X. Baraliakos, A. Ghadir, M. Fruth, U. Kiltz, J. Braun. *Rheumazentrum Ruhrgebiet, Herne, Germany*

**Background:** A classification of axial spondyloarthritis (axSpA) by the imaging arm of the ASAS criteria relies partly on the detection of a bone marrow oedema (BME) in the magnetic resonance imaging (MRI) of the sacroiliac joints (SIJ) suspicious of SpA.<sup>1</sup>

**Objectives:** To evaluate different types of MRI changes possibly relevant for a diagnosis of axSpA as judged by radiologists taking the rheumatologist's diagnosis as gold-standard.

**Methods:** Consecutive patients <45 years were included if they presented in a specialised rheumatologic centre with chronic low back pain (duration >3 months). Patients underwent a complete diagnostic workup including MRI of the SIJ. All clinical and laboratory information including images but no radiological reports was available for experienced rheumatologists to make a diagnosis of axSpA or non-axSpA. In parallel, two experienced musculoskeletal radiologists, blinded to patients' demographics and symptoms (except for back pain) evaluated all MR images without knowledge of the rheumatologist's diagnosis, by quantification of BME, fat metaplasia, erosions, sclerosis and ankylosis based on the Berlin SIJ score. The radiologists also stated whether the patient is likely to have axSpA or not, solely based on MRI findings.

**Results:** A total of 100 patients were recruited. The rheumatologist diagnosed axSpA in 54 patients (mean age 31.5 $\pm$ 8.0 years, 77.8% HLA-B27+, mean symptom duration 36.4 $\pm$ 42.0 months), while 46 patients were diagnosed as non-specific back pain (age 33.6 $\pm$ 7.1 years, 17.4% HLA-B27+, mean symptom duration 25.5 $\pm$ 31.6 months). According to the radiologists, 38 patients were identified as axSpA, 34 of which were also diagnosed as axSpA by the rheumatologist (overall agreement with the clinical diagnosis: 63%), and 4 patients were thought to have axSpA by the radiologist but not by the rheumatologist (disagreement with the clinical diagnosis: 8.7%). Similarly, the quantification of MRIs showed higher scores in patients diagnosed as axSpA by the rheumatologist (Tab.1). Only few patients had sclerosis or ankylosis.

From the radiologist's perspective, the calculated odds ratio (OR) for identification of axSpA by MRI only was 3.1 (95% CI:1.4–7.1) for the presence of BME, 3.5 (95% CI:1.4–9.0) for fat metaplasia, 2.8 (95% CI:1.1–7.0) for erosions, 2.0 (95% CI:0.7–5.5). For the combination of BME and any structural change, the OR was 3.7 (95% CI:1.6–8.5).

Tab. 1: Mean/median scores $\pm$ standard deviation for inflammatory and chronic lesions based on the Berlin SIJ score

	Lesion type	axSpA	non-SpA	p-value
Mean $\pm$ SD	Total score	12.3 $\pm$ 11.8	4.4 $\pm$ 4.8	p<0.001
	BME	3.3 $\pm$ 3.8	1.1 $\pm$ 1.5	p=0.001
	Fat metaplasia	3.4 $\pm$ 5.4	1.0 $\pm$ 3.0	p=0.004
	Erosions	3.2 $\pm$ 5.8	0.7 $\pm$ 2.1	p=0.011
Median	Sclerosis or Ankylosis	0	0	

**Conclusions:** This study reveals a discrepancy between the rheumatologist's and the radiologist's identification of axSpA, confirming that a diagnosis of axSpA in daily practice should not rely on imaging findings only. Nevertheless, the overall specificity of the radiologists was acceptable, although the sensitivity was relatively low. These data suggest also that not only BME but also fat metaplasia and erosions are of value to diagnose axSpA, beyond classification. The combination of MRI changes seems to enhance the discriminative diagnostic performance.

## Crystal diseases, metabolic bone diseases and bone diseases other than osteoporosis

FRI0220

### ULTRASOUND IN ASSESSMENT OF DISEASE COURSE IN GOUT: THE 24 MONTH SINGLE-CENTRE PROSPECTIVE OBSERVATIONAL STUDY

E. Norkuviene<sup>1</sup>, M. Petraitis<sup>1</sup>, I. Apanaviciene<sup>1</sup>, S. Ottaviani<sup>2</sup>, A. Baranaukaite<sup>1</sup>.<sup>1</sup>Rheumatology, Lithuanian University of Health Sciences, Kaunas, Lithuania;<sup>2</sup>Rheumatology, Hôpital Bichat, APHP, Paris, France

**Background:** Today, despite the great potential of ultrasound (US) in gout, there is lack of longer duration US follow-up studies in this disease.

**Objectives:** The aim was to evaluate the 24 month's treatment effect of urate-lowering therapy on gout-specific US lesions and to determine the most representative target for US follow-up in gout.

**Methods:** A 24 month prospective observational single-centre study was carried out. Patients with gout diagnosis, confirmed by identification of monosodium urate crystals, with at least one tophus in the joint or tendon or one double contour sign (DC) on US, were selected for the study. The serum uric acid (SUA) level was assessed every three months. US evaluations of 36 joints and four tendons (m. triceps and patellar) were performed every six months starting from the baseline, by one rheumatologist, blinded to the SUA levels and clinical data. Outcomes were: change in US features (tophus, DC count and tophus size) in joints and tendons according median of SUA level during the follow up period from M3 to M24. Two stages of SUA levels were defined: high,  $\geq 360 \mu\text{mol/l}$ ; and low,  $< 360 \mu\text{mol/l}$  (considered as within the treatment target). Correlations between US findings modifications in different locations, and between US findings modifications and SUA levels, were estimated by the Pearson correlation coefficient.

**Results:** We included 40 gouty patients (mean  $\pm$ SD age 54.1 $\pm$ 9.7 years, 90.0% males, disease duration 8.5 $\pm$ 8.8 years). Mean  $\pm$ SD baseline SUA level was 504.8  $\pm$ 32.9  $\mu\text{mol/l}$ .

Among the 31 completers at M24, 21 (71%) achieved median SUA  $< 360 \mu\text{mol/l}$ . On month 24 the global number of patients with DC and tophus was reduced from 91% to 32% and from 100% to 64%, respectively. A total of sixty-four percent of patients in the study had not reached the US cure (DC or T being still found in at least one joint or tendon) after two years of treatment in the group with the median of SUA less than 360  $\mu\text{mol/l}$ . The comparison of crystal clearing process in joints and tendons showed an excellent correlation of mean percentage change in total tophus number ( $r=0.900$ ) and size ( $r=1.0$ ) in joints and tendons, investigating 21 gout patients who participated in all five US study visits during the 24 months of follow-up. A strong positive correlation was observed between the changes of tophus size in left and right first MTP joints ( $r=0.718$  [95% confidence interval: 0.370; 0.875],  $p<0.001$ ) also between the changes of tophus size in toe and total intra-articular tophus size, measured by US ( $r=0.726$  [95% confidence interval: 0.347; 0.925],  $p<0.001$ ) on month 24 (compared to month 0). It was found a negative correlation between the mean SUA during 24 months follow up and the reduction in tophus size on month 24 ( $r=0.602$ )

**Conclusions:** Only one third of patients with median SUA  $< 360 \mu\text{mol/l}$  were free of US gout signs after 2 years of treatment. Due to positive link between the change in tophus size in the first MTP joint and changes in the whole intraarticular urate pool, also tendons, the tophaceous deposition in the first MTP joint could be the most representative target for follow-up morphological analysis in gout clinical trials or monitoring the disease's activity in clinical practice with US.

### GOUT IS ASSOCIATED WITH AN INCREASED RISK OF CANCER – A NATIONWIDE COHORT STUDY INCLUDING OVER 70,000 GOUT PATIENTS

K. Zobbe<sup>1,2</sup>, D. Prieto-Alhambra<sup>3,4</sup>, R. Cordtz<sup>1,2</sup>, L. Møllekjær<sup>5</sup>, P. Højgaard<sup>1,2</sup>, L. E. Kristensen<sup>1</sup>, L. Dreyer<sup>1,2,6</sup>, <sup>1</sup>The Parker Institute, Bispebjerg and Frederiksberg Hospital, Frederiksberg; <sup>2</sup>Center for Rheumatology and Spine Diseases, Rigshospitalet/Glostrup, Hellerup, Denmark; <sup>3</sup>GREMPAL Research Group, Idiap Jordi Gol and CIBERFes, Universitat Autònoma de Barcelona and Instituto de Salud Carlos III, Barcelona, Spain; <sup>4</sup>Centre for Statistics in Medicine, NORDMIS, University of Oxford, Oxford, UK; <sup>5</sup>Danish Cancer Society Research Center, Copenhagen; <sup>6</sup>Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark

**Background:** In addition to the possible carcinogenic effect of chronic inflammation, gout patients may experience increased risk of cancer due to additional risk factors such as obesity, diabetes, sedentary lifestyle, smoking and increased alcohol consumption. There is limited data on the association between gout and different cancer types. We investigated the incidence of cancer among Danish gout patients compared to national cancer rates.

**Methods:** All patients diagnosed with gout in the period 1978–2015 according to the Danish National Patient Registry (including in- and outpatient hospital contacts) were linked with The Danish Cancer Registry to identify incident cancers. Follow-up for cancer started at date of first gout diagnosis and ended at date of cancer, death, emigration or end of 2015, whichever came first. Standardised incidence ratios (SIR) were calculated using sex and 5 year age and calendar-specific incidence rates for first primary cancers in the general population in Denmark.

**Results:** We observed 6205 first primary cancers among 70 591 gout patients. Compared to an expected number of 5308 in the general population, this corresponded to a SIR for any-cancer of 1.17 (95% confidence interval (CI): 1.14–1.20). SIRs were highest for cancer sites associated with smoking, obesity and excess alcohol consumption: mouth/tongue, pharynx, oesophagus, liver, pancreas, lung, pleura and kidney (table 1). Excess risks were also observed for colorectal cancer, breast cancer, endometrial cancer, multiple myeloma and other types of leukaemia but not for Hodgkin and Non-Hodgkin lymphomas.

**Conclusions:** Gout patients are at risk of cancer, especially cancer types associated with smoking, obesity and excess alcohol consumption, but also multiple myeloma and leukaemia. It is unknown if uric-acid lowering therapy and/or lifestyle changes reduce this risk.

Observed number (Obs) of incident cancers and standardised incidence ratios (SIRs) among 70 591 patients with gout.

**FRI0222 ASSOCIATION BETWEEN BLOOD LEAD LEVELS AND GOUT: THE UNITED STATES NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY 2007–2014**

T.T. Cheung, M.F. Tsoi, B.M.Y. Cheung, W.C.S. Lau. *Medicine, The University of Hong Kong, Hong Kong, Hong Kong*

**Background:** Lead is a heavy metal with no physiological role in humans. It is well known that excessive exposure to lead is associated with cardiovascular, gastrointestinal and neurological complications. However, recent studies have demonstrated that lead can increase the tubular reabsorption of urate, resulting in hyperuricaemia and the development of gout.

Although blood lead levels are dropping in the US general population, the association between low blood lead levels and gout remains inconclusive.

**Objectives:** To evaluate the relationship between serum blood lead levels and the development of gout in the US general population.

**Methods:** Adult participants with blood lead measurements and self reported gout in NHANES 2007–2014 were included in the analysis.

Results were analysed using SPSS complex sample module version 22. Logistic regression with sample weight adjustment was used to study the association between blood lead levels and gout. Odds ratio (OR) and 95% confidence interval (95% CI) were estimated. Sub-group analysis was conducted in participants with blood lead level <5 µg/dL.

**Results:** 18837 adult participants were included in the analysis. 18 270 participants had blood lead levels below 5 µg/dL (The current reference range for acceptable blood lead levels in healthy persons without excessive exposure to environment source of lead).

The prevalence of gout increased with blood lead levels. In the total population, the odd ratio of gout was 4.96 in subjects with blood lead levels above 2.21 µg/dL. After adjusting for body mass index, hypertension, renal function and use of diuretics, the odd ratio of gout was 2.65 which remained significant.

The subgroup analysis of subjects with blood lead levels below 5 µg/ml showed similar findings. The risk of gout is increased when blood lead levels are higher than 1.43 µg/dL.

**Abstract FRI0222 – Figure 1.** (A) Prevalence of gout according to quintiles of blood level. (B) Association between quintiles of blood lead level and gout at blood lead level <5µg/dL

**Conclusions:** Low blood lead levels are associated with gout. The risk of gout is increased when the blood lead level is higher than 1.43 µg/dL. Therefore, measures should be taken to minimise the environmental exposure to lead.

**FRI0223 IS PERFORMANCE OF THE 2015 ACR/EULAR GOUT CLASSIFICATION CRITERIA AFFECTED BY DISEASE DURATION AND GENDER? RESULTS FROM AN ITALIAN MULTICENTRE STUDY FOCUSED ON THE MANAGEMENT OF CRYSTAL-INDUCED ARTHRITIDES (ATTACK STUDY)**

N. Ughi<sup>1</sup>, A. Zanetti<sup>1</sup>, P. Frallonardo<sup>2</sup>, A. Hoxha<sup>3</sup>, M. Lorenzin<sup>3</sup>, A. Ariani<sup>4</sup>, F. Ceccarelli<sup>5</sup>, M.A. Cimmino<sup>5</sup>, C. Scirocco<sup>5</sup>, B. Raffener<sup>7</sup>, A. Bortoluzzi<sup>8</sup>, A. Di Matteo<sup>9</sup>, F. Furini<sup>8</sup>, M. Manara<sup>1</sup>, F. Salaffi<sup>9</sup>, G. Carrara<sup>1</sup>, C.A. Scire<sup>1</sup>, R. Ramonda<sup>3</sup>.  
<sup>1</sup>Epidemiology Unit, Italian Society for Rheumatology, Milan; <sup>2</sup>Universita' degli Studi di Padova; <sup>3</sup>Universita' degli Studi di Padova, Padova; <sup>4</sup>AOU di Parma, Parma; <sup>5</sup>Sapienza Universita' di Roma, Roma; <sup>6</sup>Universita' di Genova, Genova; <sup>7</sup>Ospedale di Bolzano, Bolzano; <sup>8</sup>AOU Sant'Anna, Ferrara; <sup>9</sup>Universita' Politecnica delle Marche, Ancona, Italy

**Background:** Gout is a common form of arthritis, but early disease and phenotypes related to gender<sup>1</sup> may favour diagnosis misclassification, unless monosodium urate (MSU) crystals are searched for in synovial fluid (SF). The 2015 ACR/EULAR gout classification criteria<sup>2</sup> were validated in Rheumatology and primary settings,<sup>3</sup> and the impact of disease features on performance were observed,<sup>4</sup> yet little studied.

**Objectives:** To assess the performance of the 2015 ACR/EULAR gout criteria in a cohort of crystal-induced arthritides stratified by disease duration and gender in a real-life setting in Italy.

**Methods:** In/outpatients referring to Rheumatology Units for acute arthritis were enrolled into an ongoing multicentre cohort study designed for achieving improvement in the management of crystal-induced arthritis (ATTACK) by the Italian Society for Rheumatology. Gout was defined as MSU +SF (gold standard), irrespective of the clinical diagnosis, and the ACR/EULAR criteria were applied as full (all domains) and clinical-only set excluding imaging and SF analysis. To classify a patient as having clinical gout, the sufficient criterion (MSU +SF) was ignored and cutoff score ≥8 was used. Overall sensitivity and specificity were calculated. Disease duration (early if <2 years) was considered and gender effect explored.

**Results:** Of 199 adult patients (65±12 years, 75% male, 96% Caucasian) recruited in 11 hospitals, complete SF analysis and ACR/EULAR score were obtained in 105 (53%). MSU+ were 62/105 (59%), 47/62 (76%) were non-tophaceous and 25 (40%) early diseases. Calcium pyrophosphate (CPP) was the most prevalent crystal in non-MSU+. Details on performance (95% confidence intervals) are shown in table and on a receiver operating characteristic plot (figure 1).

**Abstract FRI0223 – Table 1**

	Sensitivity%		Specificity%	
	Full	Clinical-only	Full	Clinical-only
Overall n=105	76 (63–86)	71 (58–82)	95 (86–99)	81 (67–92)
<2 years n=49	48 (28–69)	40 (21–61)	100 (86–100)	92 (73–99)
≥2 years n=56	95 (82–99)	92 (78–98)	89 (67–99)	68 (44–87)
Male n=74	77 (64–87)	74 (60–85)	94 (71–100)	65 (38–86)
Female n=31	60 (15–95)	40 (5–85)	96 (80–100)	92 (75–99)

Overall good performance and high specificity of full and clinical-only sets were observed. In early disease criteria had high specificity, but low sensitivity, while performance was stable in longstanding gout. Specificity (clinical-only) and sensitivity were low when criteria were applied to males and females, respectively.

**Conclusions:** The overall performance of the 2015 ACR/EULAR gout criteria was good, particularly for the purpose of enrolling into trials. The impact of disease duration was confirmed and should be considered for misclassification issues as well as in clinical practice. Exploratory findings on gender effect seem relevant and deserve further studies.

**FRI0224 MANAGEMENT TO REDUCING LIVER FUNCTION IMPAIRMENT WHEN INITIATING FEBUXOSTAT FOR GOUT BASED ON THE PREDICTION NOMOGRAM**

J. Yu. *Rheumatology, Distinct Health Care, Shenzhen, China*

**Background:** Febuxostat is now used widely as urate-lowering therapy in gout, The most common adverse effects of which is liver function impairment (LFI). However, it is still not known in what conditions will the LFI happen.

**Objectives:** To identify the potential factors associated with LFI and establish an effective prediction nomogram, and also to determine whether febuxostat with stepwise dose increase useful in reducing LFI in patients with high risk calculated basing the nomogram.

**Methods:** Part A: A retrospective study was performed among patients with gout. Nomogram was established based on logistic regression. The internal validation was performed via the area under the receiver operating characteristic (ROC) curve (AUC). Part B: In the follow-up prospective study, patients were divided into high-risk (>30%) group (stepwise dose increase of febuxostat from 10 to 40 mg/day) and low-risk (≤30%) group (fixed-dose febuxostat 40 mg/day) calculated basing the nomogram. Incidence rate of LFI were analysed.

**Results:** Part A: 306 subjects were recruited. LFI happened in 38 subjects after initiating fixed-dose febuxostat 40 mg/day. The logistic regression multivariate analysis indicated that age, use of alcohol, chronic renal insufficiency (CRI), medication use of statin and fatty liver were significantly associated with LFI. The AUC was 0.8424 (95% CI: 0.765–0.920). Part B: 108 subjects were recruited. LFI happened in 3/46 in high-risk group and 4/62 in low-risk group. The incidence rate of LFI after management basing prediction nomogram (7/108, 6.48%) was lower than previous study (38/306, 12.42%), with statistically difference (P<0.05).

**Abstract FRI0224 – Table 1.** Multivariate logistic regression analysis of variables (P<0.05) predicting LFI.

Variable	P value	Adjusted OR (95% CI)
Age	0.004	1.062 (1.020–1.106)
Gender	0.507	0.569 (0.109–2.996)
Chronic renal insufficiency (%)	0.038	5.905 (1.100–31.701)
Hypertension (%)	0.359	0.573 (0.174–1.884)
Coronary artery disease (%)	0.906	0.907 (0.181–4.552)
Hyperlipidemia (%)	0.638	1.395 (0.349–5.573)
Statin use (%)	0.021	6.608 (1.324–32.970)
Fatty liver (%)	0.024	6.005 (1.268–28.438)
Alcohol use (%)	0.028	2.882 (1.119–7.420)

The nomogram allows the user to obtain the probability of liver function impairment risk when initiating febuxostat. As an example, locate the patient's age and draw a line straight upward to the "Points" axis to determine the score associated with that age. Repeat the process for each variable, and sum the scores achieved for each covariate, and locate this sum on the "Total Points" axis. Draw a line straight down to determine the likelihood of liver function impairment. CRI – chronic renal insufficiency.

**Abstract FRI0224 – Figure 1.** Prediction nomogram for liver function impairment in gout treated with febuxostat.

The nomogram allows the user to obtain the probability of liver function impairment risk when initiating febuxostat. As an example, locate the patient's age and draw a line straight upward to the "Points" axis to determine the score associated with that age. Repeat the process for each variable, and sum the scores achieved for each covariate, and locate this sum on the "Total Points" axis. Draw a line straight down to determine the likelihood of liver function impairment. CRI – chronic renal insufficiency.

Internal validation using the receiver operating characteristic (ROC) curve. The area under the ROC curve was 0.8424, 95% confidence interval (95% CI: 0.765-0.920).

**Abstract FRI0224 – Figure 2.** Validation of the nomogram.

Internal validation using the receiver operating characteristic (ROC) curve. The area under the ROC curve was 0.8424, 95% confidence interval (95% CI: 0.765–0.920).

**Conclusions:** Predictors including age, use of alcohol, CRI, medication use of statin, and fatty liver, were combined to construct a nomogram. And the current nomogram might help to distinguish gouty patients with high-risk LFI when initiating febuxostat and avoid unnecessary adverse events. Stepwise dose increase of febuxostat in patients with high-risk calculated basing the nomogram effectively reduced incidence rate of LFI.

#### FRI0225 ELECTRONIC CONSULTATION UTILITY IN THE MANAGEMENT OF GOUT

J. Chang<sup>1</sup>, M. DiFiore<sup>1</sup>, M. Wong<sup>2</sup>. <sup>1</sup>Internal Medicine, University of California, Irvine, Orange, <sup>2</sup>Rheumatology, University of California, Irvine/Tibor Rubin VA Medical Center in Long Beach, Long Beach, USA

**Background:** Gout is the most prevalent inflammatory arthritis in adults worldwide. Although it can be managed by primary care physicians (PCPs), complex cases often require rheumatology consultation. The average wait time for an initial rheumatology clinic visit varies from 38 days to 47 weeks after diagnosis. Utilising electronic consults (E-consults) allows for a swift two-way communication between referring and rheumatology physicians (pre-consult exchange). Rheumatologists can then triage patients to electronic management versus face-to-face rheumatological evaluation to provide timely insight to improve patient care.

**Objectives:** To analyse the effectiveness of gout management via E-consult compared to PCP or rheumatology management at the Veteran's Affairs Medical Centre in Long Beach (VALB), CA, USA.

**Methods:** A retrospective study of 171 VALB gout patients from 2009 to 2014 was constructed. Patients were placed into groups based on modes of management: PCP (n=48), direct rheumatology (n=67), or E-consult management (n=56). Electronic medical records were reviewed for a 24 month period from the first gout flare or E-consult date. The read-out for management effectiveness included change in frequency of gout flares, related emergency department (ED) and PCP visits, renal function (creatinine clearance, CrCl), and serum uric acid levels (sUA).

**Results:** Of the 56 E-consults, 43 cases were resolved electronically and 13 were converted to face-to-face rheumatology visits. The wait time for recommendations from E-consults was 2.1±4.6 days, and face-to-face rheumatology visits was 22.9±20.1 days after pre-consult exchange, vs 43.1±56.9 days for direct rheumatology consults. Both E-consult and rheumatology clinic patients had more gout attacks and related ED visits at baseline (p=0.08). They were also more likely to be treated with allopurinol, colchicine, febuxostat and corticosteroids than with NSAIDs alone (p<0.05). The number of gout attacks, and hence related PCP and ED visits, were significantly reduced when patients were managed by either a rheumatologist clinically or E-consult compared to PCP alone (p<0.05), with significant decrease in sUA and improved CrCl (p<0.001). Efficacy of E-consult management was comparable to rheumatology visits in the first 12 months, but at 18 months, direct rheumatology management superseded E-consults.

**Conclusions:** Gout management can be optimised when patients with uncontrolled disease are referred to rheumatology or E-consults within the first 12 months of active disease, and be transitioned to PCP management thereafter if disease is stable. E-consult serves as a reasonable alternative in managing gout with a shorter wait time for recommendations and rheumatology appointments. E-consults are an efficient means to address straight-forward clinical questions from PCPs, to expedite referrals to the rheumatology clinic.

#### FRI0226 ASSESSMENT OF THERAPY ADHERENCE AND TREATMENT RESULTS IN GOUT PATIENTS WHO ATTENDED SCHOOLS FOR PATIENTS AND IN THOSE WHO DID NOT

M. Eliseev, O. Zhelyabina, M. Chikina, S. Vladimirov, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Gout is a poorly controlled disease despite the availability of effective treatment methods. One of the main reasons for its poor control is patients' low adherence to treatment, including due to insufficient knowledge of treatment principles.

**Objectives:** To assess adherence to therapy and results of treatment in gout patients who attended schools for patients and in those who did not.

**Methods:** All patients with crystal-verified gout were interviewed and invited to attend School for gout pts. Totally 301 pts with gout were observed, 36 (10%) females and 264 (90%) males, mean age 54.5±12.7 y., mean disease duration 9.02±1.12 y., with the gout diagnosis verified at average 48.71<sup>±12.60</sup> months after the onset, the target UA level <360 µmol/l initially was in 72 pts (24%).

All patients were divided into 3 groups: Group 1 included 111 (36%) patients who refused to attend the school, Group 2 included 90 (30%) patients who consented but failed to come, Group 3 consisted of 100 (34%) patients who attended the School (- 100 (34%).

The data from the questionnaires were used for baseline and on-treatment assessments of the following: patient's attitude to the disease, patient's compliance to treatment, satisfaction with quality of life, the fact of taking urate-lowering therapy, UA level control, achievement of the UA level of <360 µmol/l.

**Results:** In all 3 groups, after the visit to the doctor, the number of the patients taking urate-lowering therapy who reached the target level of uric acid, significantly increased, the maximum values were noted in the group who attended the School for gout pts. The UA target level achievement results in Group 2, of those who agreed to attend the School but never did for various reasons, were better than in Group 1 and comparable to that in Group 3. Table 1 presents the results of questionnaire survey at baseline and after one year.

Better adherence to treatment was noted in patients with poorer quality of life and a rational attitude toward their disease. The patients who report satisfaction with quality of life often decided to refuse to take their medications, visited the doctor less often and more seldom achieved the UA target level.

**Abstract FRI0226 – Table 1.** Parameters at baseline and after one year

parameters	Group 1 (patients who refused to attend the school), n=111		Group 2 (patients who consented but failed to come), n=90		Group 3 (patients who attended the school), n=100	
	baseline	after 1 year	baseline	after 1 year	baseline	after 1 year
Did not take urate lowering therapy, n (%)	86 (79%)	38 * (35%)	55 (62%)	12 (12%)	56 (56%)	8 (8%)
Monitored the level of UA, n (%)	62 (56%)	76 * (69%)	68 (75%)	72 (80%)	62 (62%)	90 (92%)
Achieved the target UA level<360 µmol/l, n (%)	8 (33%)	56* (51%)	14 (15%)	62 (69%)	13 (13%)	87 (87%)
Satisfied with the quality of life, n (%)	84 (67%)	85 (77%)	42 (47%)	75 (83%)	62 (62%)	95 (95%)
Not satisfied with the quality of life, n (%)	26 (33%)	5 (5%)	48 (53%)	3 (4%)	38 (38%)	3 (3%)

\*p<0,05 between the baseline and one-year

**Conclusions:** Patients' attendance of the School for gout pts increases their adherence to urate-lowering treatment and promote better quality of life. However, treatment adherence in gout patients largely depends on mental approach. Patients who are more actively involved in their health care achieve better results regardless of the source of information.

**RISK FACTORS FOR SKIN REACTIONS TO ALLOPURINOL IN THE KINH POPULATION OF VIETNAM**

T. Bardin<sup>1,2</sup>, L.G. Le<sup>3</sup>, T.M.K. Buy<sup>1</sup>, A.D. Do<sup>4</sup>, H. Le<sup>5</sup>, M.D. Do<sup>3</sup>, V.A. Hoang<sup>3</sup>, A. N. Le<sup>6</sup>, Q.D. Nguyen<sup>1</sup>, N.H. Le<sup>1</sup>, P. Richette<sup>2</sup>, M. Resche-Rigon<sup>7</sup>, T.P. Mai<sup>8</sup>.

<sup>1</sup>French-Vietnamese Gout Research Center, Vien Gut general clinic, Ho Chi Minh City, Viet Nam; <sup>2</sup>Rheumatology, Hôpital Lariboisière, Paris, France; <sup>3</sup>Center for Molecular Biomedicine, University of Medicine and Pharmacy; <sup>4</sup>Physiology, Pathophysiology and Immunology, Pham Ngoc Thach University of Medicine; <sup>5</sup>Tropical Disease; <sup>6</sup>Scientific research, Cho Ray Hospital, Ho Chi Minh City, Viet Nam; <sup>7</sup>Biostatistics, Hôpital Saint Louis, Paris, France; <sup>8</sup>Physiology, University of Medicine and Pharmacy, Ho Chi Minh City, Viet Nam

**Background:** Allopurinol (ALLO) exposes to mild (M) and severe (S) cutaneous adverse reactions (CARs). SCARs have been associated with HLA\*B58 01 with various strength of across ethnicities. Little is known about ALLO tolerance in Vietnam (VN).

**Objectives:** The aim of this ongoing prospective study was to investigate risk factors, including HLA\*B-58 01, for MCARs and SCARs in the predominant Kinh ethnicity of VN

**Methods:** All included patients were Kinh Vietnamese. SCARs were recruited at Ho Chi Minh City hospitals, MCARs from the same departments and from the Vien Gut clinic at HCMC (specialised in gout care), and tolerant gouty patients (no skin reaction after at least 3 months from the last increment in ALLO dose) at the Vien Gut clinic. Clinical data were prospectively collected and HLA\*B-58 01 typing used the PG5801 DNA detection kit (Pharmigene-Taiwan). Fisher exact test for categorical variables and Kruskal/Wilkinson test for quantitative variables were used for statistics.

**Results:** 10 patients experienced a non-fatal SCAR. Toxic necrotic epidermolysis, Stevens-Johnson syndrome and mixed syndrome were diagnosed in 1, 8 and 1 patients respectively. 54 patients stopped ALLO because of MCAR. 112 ALLO tolerant patients were recruited. Table 1 shows the main features of interest in the 3 groups. The Odds ratio of HLA\*B-58 01 positive patients to develop SCARs was calculated at 171.2 (95% CI: 20; 7889)

**Abstract FRI0227 – Table 1.** Features associated with MCARs and SCARs

	SCARs (n=10)	MCARs (n=54)	Tolerant (n=112)	P value Global test	P value SCARs vs tolerant	P value MCARs vs tolerant
No Gout n (%)	5 (50%)	53 (98%)	112 (100%)	p<0,0001	p<0,0001	p=0,33
Females n (%)	2 (20%)	0	0	p=0003	p=0006	p=1
Age Mean (CI)	55 (CI :12)	47 (CI :12)	46 (CI :12)	p=0012	p=0,04	p=0,73
History of MCAR to ALLO	1/7 (14%)	1/52 (2%)	0	p<0,0001	p=0006	p=0,32
Diuretic intake n/known (%)	2/9 (22%)	1/52 (2%)	0	p=0002	p=0.005	p=0,32
ALLO dose/d Mean (CI)	345 mg/j (CI :142)	259 mg/j (CI :119)	356 mg/j (CI :114)	p<0,0001	p<0,0001	p=0.51
ALLO titration n (%)	0	49 (91%)	112 (100%)	p<0,0001	p<0,0001	p<0,0001
GFR<60 ml/ min n/known (%)	2/6 (33%)	1/51 (0.2%)	1/88 (0.01%)	p=0008	p=0,01	p=1
HLA-B*5801	10 (100%)	3 (5,6%)	6 (5,3%)	p<0,0001	p<0,0001	p=1

**Conclusions:** HLA\*B-58 01 was significantly associated with SCARs to ALLO in the VN Kinh population. Other known factors but not high ALLO dose were also associated. The only association with MCARs was lack of ALLO titration.

**URATE CORRELATES TO CORONARY ARTERY CALCIFICATION BUT NOT TO INTIMA MEDIA THICKNESS**

M.I. Dehlin<sup>1</sup>, P. Drivelegka<sup>1</sup>, V. Sigurdardottir<sup>1</sup>, O. Angerås<sup>2</sup>, L.T. Jacobsson<sup>1</sup>, H. Forsblad d'Elia<sup>3</sup>. <sup>1</sup>Dept of rheumatology and inflammation research, Institution of Medicine, Sahlgrenska Academy, University of Gothenburg; <sup>2</sup>Department of Molecular and Clinical Medicine, Sahlgrenska Academy, Gothenburg; <sup>3</sup>Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå, Sweden

**Background:** Hyperuricemia is closely associated to cardiovascular disease (CVD) although it has not been definitively established whether it is a marker or a causative agent. Serum urate (SU) is strongly linked to the metabolic syndrome, hypertension, hyperlipidemia, kidney failure and higher BMI and higher levels are seen in men compared to women. Coronary artery calcification (CAC) is associated with future risk of atherosclerotic CV events in addition to the traditional cardiovascular risk factors (CVRF). CACs are present in atherosclerotic arteries and can be quantified and scored non-invasively by computed tomography. Carotid intima media thickness (CIMT) is a method of estimating atherosclerosis by assessing the level of arterial thickening present. CIMT can be used as a noninvasive marker of atherosclerotic disease with increasing CIMT linked to an increased risk of subsequent CV events. In the present study we have examined the relation between CACs, CIMT and SU in 1040 male and female with no history of myocardial infarction or stroke.

**Objectives:** To examine the association between SU and CAC and CIMT respectively in men and women separately.

**Methods:** We identified 1106 (552 males) individuals who were screened for traditional CVRFs, such as hypertension (HT), dyslipidemia (DL), diabetes mellitus (DM), smoking, physical activity (PA), educational level (EDU), socioeconomic status (SES), BMI, high sensitive CRP (hsCRP), kidney function by eGFR (eGFR). CACs, reflecting calcification of coronary arteries, was determined according to Agatston<sup>1</sup>. CIMT was calculated as the mean of CIMT of the left and right coronary artery. We measured SU and related quartiles of it to CACs and CIMT with multiple logistic regression analyses adjusting for traditional CVRFs. CAC was defined positive if  $\geq 1$ . CIMT was defined positive for  $\geq 75$  percentile. All study participants with a history of CVD (n=68, 44 male) were excluded.

**Results:** Of the 1106 participants, 68 were excluded due to history of CVD rendering a study population of 1040 individuals (508 males) with a mean age of 57.7 and 57.5 for male and female respectively. Age, BMI, EDU, SES, smoking status, PA, hsCRP, HT and DL showed no differences between sex while presence of CAC and diabetes was twice as common in men (table 1) and 65% of men displayed an eGFR below 90 mL/min compared to 12% of women (table 1a b). The three upper quartiles of SU (>306  $\mu\text{mol/L}$ ) all significantly ( $p<0.05$ ) predicted presence of CACs in male when adjusting for HT, DL, DM, smoking, PA, EDU, SES, BMI, hsCRP, eGFR and age in multivariate logistic regression, but not in women (table 2). CIMT showed no correlation to SU in men nor women.

**Abstract FRI0228 – Table 1.** Prevalence of gout I WSHCR by 2012–12–31, age above 20 years in total and by age and sex

Variables	Male, n=508	Female, n=532
Age, years, mean, (SD)	57.7(4.4)	57.5(4.3)
BMI, mean, (SD)	27.7(4.1)	26.8(4.9)
hsCRP (mean, SD)	2.2(3.4)	2.4(3.8)
CAC positive (%)	293(58%)	137(26%)
eGFR >90 ml/min	180(35%)	467(88%)
eGFR 60-90 ml/min	316(62%)	60(11%)
eGFR <60 ml/min	12(2%)	5(1%)
Smoking status, never	215(42%)	237(45%)
Smoking status, previous	206(41%)	191(36%)
Smoking status, active	86(17%)	102(19%)
Hypertension (%)	160(32%)	178(33%)
Diabetes mellitus (%)	39(8%)	21(4%)
Dyslipidemia (%)	144(28%)	121(23%)

**Conclusions:** CDS should be considered and craniocervical junction exposed in the context of acute cervical or occipital pain with stiffness and elevated inflammation markers not only in patients previously diagnosed with CPPD, but rather in diverse clinical settings. Particularly, CDS should be recognised as a possible alternative diagnosis in older patients referred with suspicion to giant cell arteritis because of new headache and elevated ESR/CRP. While generally believed to be a rare phenomenon, CDS was seen in 24 patients in 400-bed general hospital within 2 years and is probably widely underdiagnosed.

#### FRI0231 STUDY OF URATE TRANSPORTERS IN PRIMARY HYPERURICEMIA AND GOUT

B. Stiburkova<sup>1,2</sup>, K. Pavelkova<sup>1,3</sup>, J. Bohata<sup>1,3</sup>, K. Kozakova<sup>1,3</sup>, L. Petru<sup>1,3</sup>, J. Zavada<sup>1</sup>, K. Pavelka<sup>1</sup>. <sup>1</sup>Institute of Rheumatology; <sup>2</sup>Department of Pediatrics and Adolescent Medicine, First Faculty of Medicine, Charles University and General University Hospital in Prague; <sup>3</sup>Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic

**Background:** The urate transporters are one of the main genetic determinants of serum uric acid concentrations.

**Objectives:** In this study we investigated the effects of non-synonymous allelic variants of urate transporters in a cohort of patients with primary gout and/or asymptomatic hyperuricemia.

**Methods:** The cohort consisted of 165 gout patients (151 men, 14 women); 58 hyperuricemic individuals (39 men/19 women); 115 normouricemic controls were used for comparison. Gouty arthritis was diagnosed according to the 1977 preliminary criteria of the American College of Rheumatology. Coding regions of *ABCG2*, *SLC2A9*, *SLC22A11*, *SLC22A8*, *SLC17A3*, and *SLC17A1* genes were amplified and sequenced directly. To estimate the functions of the identified non-synonymous allelic variants, we used the protein prediction algorithms.

**Results:** In *ABCG2* gene, we detected nine non-synonymous variants (two common, seven rare including one novel): p.V12M, p.Q141K, p.R147W, p.T153M, p.K360del, p.F373C, p.T434M, p.S476P and p.D620N. The p.Q141K (rs2231142) variant had a significantly higher minor allele frequency (0.23) in the gout patients compared to the European-origin population (0.09) and was significantly more common among gout patients than among normouricemic controls (OR=3.15, p<0.0001). In addition, patients with non-synonymous *ABCG2* allelic variants had an earlier onset of gout (41.5 vs. 48 years, p=0.0478) and a greater likelihood of a familial history of gout (42% vs. 26%, OR=2.02, p=0.043)<sup>1</sup>. We identified novel intron variant c.689+1G>A which is associated with two abnormal splicing variants, leading to premature introduction of the stop codon, mislocalized *ABCG2* signal on plasma membrane and no urate uptake activity<sup>2</sup>.

In *SLC2A9* gene, seven missense variants were identified (six common, one rare): p.A17T, p.G25R, p.T275M, p.D281H, p.V282I, p.R294H, and p.P350L. In

*SLC17A3*, the analysis revealed common allelic variants p.A100T and p.G279R. Rare non-synonymous variants p.V202M and p.R343L were found in *SLC22A11*. Only one common missense variant p.T269I was identified in *SLC17A1*. In *SLC22A8* sequencing revealed three rare variants: p.R149C, p.V448I and p.R513G. The precise impact of *SLC22A11*, *SLC22A8*, *SLC17A3*, and *SLC17A1* in the context of hyperuricemia and gout in our cohort is unclear and will be further studied include functional characterisation of selected dysfunctional variants.

**Conclusions:** Genetic variants of *ABCG2*, common and rare, increased the risk of gout and had a significant effect on earlier onset of gout and the presence of a familial gout history. Genotyping the rare variants of *ABCG2* along with its common variants is essential for evaluating the individual risk for gout.

#### FRI0232 ULTRASONOGRAPHIC FEATURES OF GOUTY DACTYLITIS OF THE HANDS

C.A. Guillen-Astete<sup>1</sup>, B. Laso-Jimeno<sup>2</sup>. <sup>1</sup>Rheumatology Department; <sup>2</sup>Ramon y Cajal University Hospital, Madrid, Spain

**Background:** Dactylitis is a manifestation of gout that can occur on debut or throughout the course of the disease, although it is usually considered a sign of chronicity or a hallmark of long-term disease. Classically, the synovitis or tenosynovitis mediated by the deposit of microcrystals has been interpreted as an inflammatory effect due to proximity. The etiological prevalence based on imaging studies is unknown.

**Objectives:** To determine the prevalence of different ultrasonographic features of dactylitis of the hands in patients with gout.

**Methods:** A cross-sectional study was conducted based on a registry of ultrasound images of patients with gout and clinical dactylitis either in debut or throughout evolution. The selection of patients followed strictly clinical criteria based on the corresponding medical reports. All images were obtained in a medium-high gamma GE equipment and were obtained by the same operator over three years. Given that no comparisons were planned, no masking of the clinical situation of the patients was made in the eyes of the interpreter. The interpretation of findings was dichotomous in the determination of synovitis, tenosynovitis and enthesopathy according to EULAR definition criteria. The identification of tophi was made according to the definition of Avila Fernandes et al. (doi: 10.1007/s00256-010-1008-z) The overlapping of findings was counted independently at the moment of establishing the prevalence.

**Results:** We included images of 66 patients diagnosed with gout and with dactylitis of at least one finger at the time of the ultrasound evaluation. The mean age of the patients was 59.2 SD 4.3 years. Sixty-two patients were male. Of the total number of patients, 60 had tenosynovitis of the flexor tendinous apparatus (90.9%). Four of these patients also presented tenosynovitis of the tendinous extensor apparatus. No patient presented only extensor tenosynovitis. Enthesopathy was identified in 6 patients (9.1%), in no case did enthesopathy occur with power Doppler signal. Synovitis was identified in 43 patients (65.1%). Of these, in 13 patients a grade I was registered and in 26 a power Doppler signal was demonstrated. Tophi were identified in 16 patients (24%).

**Conclusions:** CONCLUSIONS: This is, as far as we know, the first iconographic study of gouty dactylitis based on ultrasound. According to our results, tenosynovitis of the flexors is the most frequent finding in gouty dactylitis while enthesopathy is rather rare. The presence of significant synovitis is the second most frequent finding while tophi as conditioning agents of synovitis were the least frequent finding. We understand that the knowledge of the echographic characteristics of gouty dactylitis can serve as a clinical guide when making therapeutic decisions in cases where this clinical sign lasts despite the control of other manifestations.

**FRI0233 DOES GOUT PROTECT FROM PARKINSON'S DISEASE: A CASE-CONTROL STUDY FROM AN URBAN POPULATION**

C. Diaz-Torne<sup>1</sup>, M.A. Pou<sup>2</sup>, F. Orfila<sup>3</sup>, S. Jeria<sup>4</sup>, S. Fernandez<sup>4</sup>, H. Park<sup>4</sup>, I. Castellvi<sup>4</sup>, H. Corominas<sup>4</sup>. <sup>1</sup>Unitat de Reumatologia, Hospital de la Santa Creu i Sant Pau; <sup>2</sup>EAP Encants. ICS; <sup>3</sup>IDiAP Jordi Gol. ICS; <sup>4</sup>Unitat de Reumatologia, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Background:** It has been demonstrated that hyperuricemia protects from Parkinson's disease (PD), but this relation is controversial in patients with gout. Inflammatory properties of urate monosodium(UMS) crystals deposition that appears when uric acid(UA) levels exceed its solubility faces antioxidant and neuroprotective features of soluble UA. Both, UMS crystals deposition and hyperuricemia coexist in gouty patients.

There is several data that demonstrates that hyperuricemia protects from Parkinson's disease (PD). Results from different studies about the relation between them are controversial. Inflammatory properties of the urate crystals faces antioxidant and neuroprotective features of soluble UA. Both, UMS crystals and hyperuricemia coexist in gouty patients.

**Objectives:** To study if gout protects from Parkinson disease in a mediterranean urban population.

**Methods:** Primary care based matched case-control study. It has been carried out using the electronic clinical record database from the public health (Institut Català de la Salut) of the city of Barcelona. The database contains anonymous data from almost 1 million and a half people. Just people that were 40 years or older were studied. Were considered cases patients with a PD diagnose, or taking high specific anti-Parkinson's drugs (like l-dope, rasagiline, selegiline...), between 2006 and 2016. For every case we randomly selected four controls matched by gender and age. Data on risk factors was also collected for each individual (diabetes mellitus, hypertension, hypercholesterolemia and tobacco consumption before the PD diagnose), as well as age and gender. A multivariate logistic regression model was used to study the association of gout and PD adjusted by the presence of other risk factors. Adjusted Odds Ratios (aOR) and their 95% CI are provided.

**Results:** 21 789 persons with a PD diagnose and 87 156 controls were included. Mean age was 75.5 (SD 10.9) years. 55.6% were females. 2.5% of PD patients had a previous gout diagnose, compared to 4.8% of controls (p<0.001). Multivariate Logistic regression model showed for gout: aOR=0.55 (0.50–0.61). Diabetes mellitus: aOR=1.18 (1.14–1.23); hypertension: aOR=0.7 (0.72–0.77); tobacco: aOR=0.55 (0.52–0.58); high cholesterol levels: aOR=0.60 (0.58–0.61).

**Conclusions:** Gout shows a protective effect on the development of Parkinson's disease, pointing that the antioxidant and neuro protective effect of UA seems to overcome its inflammatory properties in gouty patients.

Gout shows a protective effect on the development of Parkinson's disease, pointing that the antioxidant and neuro protective effect of UA seems to overcome its inflammatory properties in gouty patients.

**FRI0234 SEL-212: SELECTIVE MITIGATION OF ANTI-DRUG ANTIBODIES AGAINST PEGSITICASE TO CONTROL SERUM URIC ACID IN HYPERURICEMIC SUBJECTS**

E. Sands<sup>1</sup>, A.J. Kivitz<sup>2</sup>, L. Johnston PhD<sup>1</sup>, W. DeHaan<sup>3</sup>, T.K. Kishimoto<sup>1</sup>. <sup>1</sup>Selecta Biosciences, Watertown; <sup>2</sup>Altoona Center for Clinical Research, Duncansville, PA; <sup>3</sup>480 Arsenal Way, Selecta Biosciences, Watertown, USA

**Background:** We previously reported initial Phase 2 study results for 60 gout patients treated with SEL-212, a novel combination treatment comprised of pegsiticase (pegylated uricase) co-administered with a synthetic vaccine particle encapsulating rapamycin (SVP-R).<sup>1</sup> SEL-212 was well-tolerated, mitigated the formation of anti-drug antibodies, and enabled sustained control of serum uric acid (sUA) levels in most subjects.<sup>1</sup> In this ongoing study, new treatment cohorts involving higher SVP-R dose levels and extended combination regimens were introduced.

**Objectives:** To assess the tolerability and impact on sUA levels and ADA formation of escalated and expanded doses of SEL-212, designed to be the first non-immunogenic uricase therapy for refractory gout.

**Methods:** Patients with symptomatic gout ( $\geq 1$  tophus, gout flare within 6 months or gouty arthropathy) and elevated sUA ( $\geq 6$  mg/dL) were enrolled to SEL-212 treatment (n=6–12 pts/cohort) of fixed doses of pegsiticase (0.2 mg/kg or 0.4 mg/kg) alone or co-administered with SVP-R (0.05, 0.08, 0.1, 0.125, and 0.15 mg/kg). SEL-212 was infused in 28 day cycles x3 doses followed by challenge with pegsiticase alone on 28 day cycles x2 doses. In addition, 2 cohorts were added that

extended the combination treatment with SVP-R to all five q28 doses of pegsiticase. ADAs and sUA were assessed at baseline and 7, 14, 21, and 30 days after each dose to Day 140. Safety was monitored continuously.

**Results:** As previously reported, 5 of 6 patients dosed with pegsiticase alone developed ADAs after a single dose, correlating with loss of sUA control by 30 days. The addition of SVP-R to pegsiticase showed a dose-dependent inhibition of ADAs, enabling prolonged control of sUA levels. At a mid-dose of 0.1 mg/kg SVP-R, combined with either 0.2 or 0.4 mg/kg pegsiticase, the majority of patients showed sustained control of sUA through 18 weeks. However, control of ADAs and sUA tapered off in some patients by week 20, after two injections of pegsiticase alone. Preliminary results of treatment at increased SVP-R doses (0.125–0.15 mg/kg) are consistent with Phase 1b data indicating that higher doses of the SVP-R will increase the percentage of patients that remain ADA free. These results also suggest that extending treatment to 5 doses of SVP-R and pegsiticase may enable more subjects to complete the 5 month treatment with sustained reductions in sUA. In addition to mitigating immunogenicity, patients treated with SVP-R experienced a low rate of gout flares, with less than 25% of patients experiencing flares during the first month after treatment, despite profound drop in sUA level, and continued reduction was observed during months 2–5. SEL-212 has been generally well tolerated at clinically active dose levels and infusion reactions observed with repeat dosing were reduced with increasing doses of SVP-R.

**Conclusions:** SEL-212 has been well tolerated, mitigated immunogenicity, and sustained control of sUA levels. Escalation of the SVP-R component of SEL-212 may enhance the duration of sUA and ADA suppression without increased risk.

**FRI0235 EFFECT OF SERUM URIC ACID (SUA) ON GOUT FLARES (GF) AND TOPHI RESOLUTION IN GOUT PATIENTS. POOLED POST HOC ANALYSIS OF CLEAR 1 & CLEAR 2 TRIALS**

F. Perez-Ruiz<sup>1</sup>, P. Richette<sup>2</sup>, R.G. Karra<sup>3</sup>, I. Wild<sup>3</sup>, H. Hagedorn<sup>3</sup>, P. Kandaswamy<sup>3</sup>, T. Bardin<sup>2</sup>. <sup>1</sup>Rheumatology Division of Cruces Hospital and University of the Basque Country, Baracaldo, Spain; <sup>2</sup>Université Paris Diderot, Paris, France; <sup>3</sup>Grünenthal GmbH, Aachen, Germany

**Background:** Gout is caused by crystal deposition due to persistent hyperuricemia. EULAR<sup>1</sup> and other guidelines recommend a target sUA of <5–6 mg/dL (0.30 to 0.36 mmol/L) depending on severity. Despite physiological plausibility and abundant literature evidence there is an absence of consensus among physicians on the targets and necessity of long term urate lowering therapy (ULT)<sup>2</sup>.

**Objectives:** To investigate the effects of sUA and target sUA <5–6 mg/dl with respect to the occurrence of GF, flares requiring treatment (GFRT) and the percent change in the area of tophi (TR) from baseline irrespective of treatment arms.

**Methods:** Data of 1213 patients (PT) was pooled from CLEAR trials<sup>3&4</sup>, two randomized, double-blind, placebo-controlled Phase 3 studies that evaluated Lesinurad 200/400 mg daily in combination with allopurinol vs allopurinol. Prophylaxis for flares was given from baseline to month (M) 5. PT who met the sUA target of <5–6 mg/dl at M 6 and 12 were compared against those not on target with respect to the TR from baseline using a Wilcoxon test. In addition, the mean sUA measurements for PT with or without GFs and GFRT was compared at M 6 and 12 using a t-test.

**Results:** PT with sUA on target <5–6 mg/dl showed a larger decrease (increase in percent reduction) in area of tophi with a difference of 27.9%, and 17.3% at M 12 only compared to the PT not on target (table 1). The mean sUA levels were 0.227 mg/dL lower for PT with GF and 0.389 mg/dL lower for PT with GFRT compared to PT without GF and GFRT at M 6 (table 2), but not at M 12.

**Abstract FRI0235 – Table 1.** Percent Change from baseline Area of tophi vs. SUA on target <5–6 mg/dL at M 6 and 12

§ Number of PT with a target tophus at baseline was small. # Wilcoxon test with H0: Mean ranks in categories are equal

**Abstract FRI0235 – Table 2.** Mean sUA at M 6 and 12 by occurrence of GF and GFRT

Mean sUA mg/dL (95% CI) M6	p-value#	Mean sUA (95% CI) M12	p-value#
GF Yes	5.94 (5.80–6.07)	5.92 (5.79–6.06)	
GF No	5.71 (5.51–5.92)	5.91 (5.64–6.17)	
Difference	0.22 (–0.01–0.47)	0.01 (–0.28–0.31)	0.91
GFRT No	5.91 (5.79–6.03)	5.93 (5.80–6.05)	
GFRT Yes	5.530 (5.23–5.83)	5.83 (5.41–6.25)	
Difference	0.38 (0.06–0.71)	0.09 (–0.34–0.53)	0.65

# T-test with H0: No difference in means

**Conclusions:** These results confirm that sUA on target <5–6 mg/dl is essential for TR, and longer the control better the TR. The lower mean sUA levels for PT with GF and GFRT was observed at M6 and not at M 12, maybe owing to the fact that flares are common during the first months of ULT initiation and then taper off and urate deposits were more fragile and not completely dissolved. Also M 6 and 12 may not be optimal to observe statistically significant differences between treatments with respect to TR, GF and GFRT.

#### ASSOCIATIONS BETWEEN COMORBIDITY AND URATE DEPOSITION IN SUBJECTS WITH ASYMPTOMATIC HYPERURICEMIA: A PILOT STUDY

G. Kerr<sup>1,2</sup>, S. Dowell<sup>3</sup>, A. Wells<sup>4</sup>, R. Haddad<sup>5</sup>, P. DeMarco<sup>2,6</sup>, J. Joseph<sup>2,7</sup>, J. Ude<sup>1</sup>, S. Hochberg<sup>1</sup>, J. Huang<sup>8</sup>, D. Nashel<sup>2,7</sup>. <sup>1</sup>VAMC/HUH; <sup>2</sup>Georgetown University Hospital; <sup>3</sup>Howard University, Washington; <sup>4</sup>Rheumatology/Immunotherapy, Franklin; <sup>5</sup>The Hospital for Special Surgery, New York; <sup>6</sup>Arthritis and Rheumatism Associates, PC, Wheaton; <sup>7</sup>VAMC; <sup>8</sup>MedStar Health Research Institute, Washington, USA

**Background:** Hyperuricemia is common and along with comorbidities, is increasing in prevalence. Though often asymptomatic and hence, under diagnosed, it may be associated with subclinical urate deposition. Ultrasound (US) imaging can detect urate deposition in individuals with asymptomatic hyperuricemia (ASU).

**Objectives:** To evaluate the association of comorbidities with urate deposition via US in ASU.

**Methods:** ASU was defined as serum urate (sUA) >6 mg/dl; sUA <6 mg/dl served as controls. Demographic (age, gender, BMI), comorbidity (CM – [hypertension (HTN), hyperlipidemia (HLD), diabetes mellitus (DM), cardiovascular (CVD) and renal disease (CKD)], diuretic/aspirin use, dietary data (alcohol, red meat, seafood) were collected. Ultrasonography (US) of joints (knee/MTP), tendons (triceps, quadriceps/patella, Achilles) was performed via standard procedure, OMERACT parameters of urate deposition documented, and images read by an Expert ultrasonographer blinded to sUA category. Correlations between sUA levels and MSK urate deposition with comorbidities, medication and dietary risk factors were analysed by 2-stage multivariable logistic regression model with propensity score weighting.

**Results:** Of 95 predominantly non-Hispanic Blacks (mean age 59.7 years, BMI ~32 kg/m<sup>2</sup>), ASU subjects (n=71, median sUA=8.0) were older men, with more frequent HTN, CVD, CKD, alcohol ingestion versus controls. In multivariate analyses adjusting for demographic characteristics, BMI, CKD, and alcohol use were positively associated with sUA >6 mg/dl; while HTN, CVD, and CKD were positively associated with sUA >8 mg/dl. Adjusting for comorbidities, sUA >8 mg/dl was significantly associated with urate deposition at knee (OR=3.20; p=0.03), quadriceps and Achilles tendons (OR=4.14; p<0.01), OR=9.51; p<0.01, respectively) but not at 1 st MTP (OR=2.14; p=0.06). A sUA >6 mg/dl alone, however, did not predict urate deposition.

**Conclusions:** Presence of HTN, CVD and CKD are associated with higher levels of sUA and increases the risk of urate deposition in ASU patients. Identifying a subset of ASU patients that may benefit from urate lowering therapy requires

further stratification and long term follow up for incident gouty arthritis in order to alter current urate lowering treatment guidelines.

FRI0237

#### PEGLOTICASE TREATMENT SIGNIFICANTLY DECREASES MEAN ARTERIAL BLOOD PRESSURE IN PATIENTS WITH CHRONIC GOUT

H. Choi<sup>1</sup>, R. Johnson<sup>2</sup>, A. Yeo<sup>3</sup>, P. Lipsky<sup>4</sup>. <sup>1</sup>Massachusetts General Hospital, Boston; <sup>2</sup>University of Colorado, Aurora; <sup>3</sup>Horizon Pharma, Lake Forest; <sup>4</sup>AMPEL BioSolutions LLC, Charlottesville, USA

**Background:** There are significant correlations between serum uric acid (sUA) and blood pressure (BP) in individuals with and without gout.<sup>1</sup> Limited data suggest that lowering sUA may decrease BP<sup>2</sup>, but no consistent effect has been noted.<sup>3</sup> Recent guidelines suggest the need for more aggressive management of increased BP.<sup>4</sup>

**Objectives:** To determine the impact of persistent, very low sUA levels on BP in subjects with chronic refractory gout treated with pegloticase, a recombinant uricase conjugated to polyethylene glycol approved for chronic refractory gout that decreases sUA to <1 mg/dL.

**Methods:** This analysis used results from two, 6 month randomised clinical trials (RCTs) in which subjects were treated with 8 mg pegloticase every 2 or 4 weeks (q2w or q4w) or placebo.<sup>5</sup> sUA responders maintained sUA <6 mg/dL.<sup>5</sup> Sitting BP was measured at each visit and estimated glomerular filtration rate (eGFR) was determined at baseline and after 3 and 6 months.

**Results:** Serial BP measures were obtained in 173 subjects during the course of the RCTs. Significant reductions in mean arterial pressure (MAP) from baseline to 6 months were noted in q2w responders (p=0.0029) (figure 1), whereas reductions in MAP in other groups were not significant. Notably, 18/29 (62.1%) of q2w sUA responders experienced persistent reductions in MAP (p=0.01 compared to other groups). Changes in both systolic and diastolic BP paralleled the change in MAP. Of the q2w sUA responders exhibiting persistent decreases in MAP, there were no significant differences in baseline age, gender, race, body mass index, history of hypertension, gout duration, MAP, sUA, cholesterol, eGFR, or urinary UA/creatinine ratio compared with those who did not lower MAP. There were no significant changes in eGFR in sUA responders to pegloticase treatment over the course of the study and there was no significant correlation between change from baseline MAP and eGFR in these subjects (p=0.43).

**Abstract FRI0237 – Figure 1.** \*Significantly different from baseline (GLM adjusted for multiple comparisons)

**Conclusions:** Responders to biweekly pegloticase experienced significant reductions in MAP that were independent of changes in renal function.

### FRI0238 THE LEVEL OF LEPTIN IN PATIENTS WITH GOUT AND ITS ASSOCIATION WITH THE GOUT ACTIVITY SCORE

I. Orlova, M. Stanislavchuk. Department of Internal Medicine #1, National Pirogov Memorial Medical University, Vinnytsya, Ukraine

**Background:** Leptin is a cytokine-like hormone mainly produced by adipose tissue. Its role in inflammation, obesity, diabetes mellitus, and cardiovascular pathology is well known.<sup>2</sup> Most of these pathological conditions usually accompany gout, but role of leptin in gout remains on the discussion.

**Objectives:** To determine the level of leptin in patients with gout and evaluate its association with the disease activity.

**Methods:** Study involved 151 patients with gout (100% men), aged (mean  $\pm$  SD) 52.4 $\pm$ 9.2 years, with a disease duration 8.9 $\pm$ 6.6 years. In 51 (33.7%) was diagnosed tophaceous gout. Control group was represented by 31 healthy subjects. Diagnosis of gout was based on the ACR/EULAR 2015 criteria. The disease activity was determined by the Gout Activity Score (GAS),<sup>2</sup> the intensity of the pain – by the visual analogue scale (VAS<sub>pain</sub>). Leptin in serum was determined by ELISA.

**Results:** The level of leptin in patients with gout was 2 times higher compare to those in the control group (6.6 $\pm$ 4.3 vs 3.0 $\pm$ 1.4 ng/ml). The number of attacks in the last year was 3.9 $\pm$ 2.7, number of affected joints was 8,1 $\pm$ 5.4, and uric acid in serum (sUA) was 8.1 $\pm$ 2.0 mg/dl. Mean value of VAS<sub>pain</sub> in gout patients was 5.4  $\pm$ 2.4 cm, and disease activity by GAS – 5.9 $\pm$ 2.1. Regarding GAS we divided our patients in three groups: low activity (GAS <25 th percentile), moderate activity (between 25th and 75th percentile) and high activity (>75 th percentile). In 36 patients with high disease activity (GAS >7.4) the level of leptin was the highest (11.7 $\pm$ 4.7 ng/ml), whereas in patients with moderate activity (GAS 4.5–7.4; n=77) and in patients with low disease activity (GAS <4.5; n=38) it was 5.3 $\pm$ 2.6 ng/ml and 3.9 $\pm$ 1.4 ng/ml, respectively. The difference in leptin levels between all groups was significant (p<0.01). The level of leptin correlated with the number of gout attacks (r=0.41), number of affected joints (r=0.55), sUA (r=0.39), VAS<sub>pain</sub> (r=0.35), and GAS (r=0.69).

**Conclusions:** Association of increased leptin level with high gout activity may indicate possible pathogenic role of leptin in gout. GAS is reliable and sensitive clinical tool for determining disease activity in patients with gout.

### FRI0239 ABSOLUTE NUMBERS OF PERIPHERAL TH17 AND TH2 CELLS INCREASED IN PATIENTS WITH GOUT

J. Yuan<sup>1</sup>, L. Zhao<sup>2</sup>, J. Luo<sup>2</sup>, C. Gao<sup>3</sup>, X. Li<sup>2</sup>, H. Gao<sup>2</sup>, L. Shang<sup>1</sup>, Q. Li<sup>1</sup>. <sup>1</sup>The second hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Department of Rheumatology, The second hospital of Shanxi Medical University, Taiyuan, China; <sup>3</sup>Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, USA

**Background:** Gout is generally considered as an acute or chronic inflammatory disease of the joints due to deposition of crystals of monosodium urate (MSU). However, crystals of MSU do not always elicit inflammation in joints, suggesting that the immunological basis is required for the development of gouty arthritis. Although T helper 17 (Th17) and regulatory T cell subsets in CD4 +T cells have been reported to play a key role in autoimmune diseases, their status in peripheral blood of gout patients are rare studied.

**Objectives:** Our present study is to explore whether the absolute numbers of peripheral CD4 +T subsets, especially Th17 cells and CD4 +CD25+FOXP3T regulatory (Treg) cells, is abnormal in gout.

**Methods:** A total of 72 patients with gout (70 male/2 female) and 41 age-sexual-matched controls were recruited from the Second Hospital of Shanxi Medical University (from March 1 st in 2016 to July 30th in 2017). Of these, 72 patients were categorised as acute gout who had redness, swelling, warmth and pain at the same time (Group1; n=18) or as acute gout without redness and warmth (Group2; n=52). All patients fulfilled 2015 Gout classification criteria developed by the American College of Rheumatology (ACR) and the European League Against Rheumatism (EULAR). Patients with a history of other autoimmune diseases, nephropathy, cancer, infectious processes, or hematopathy were excluded. The detail medical histories were collected, comprehensive laboratory examinations were performed, and then the differences between the patients and controls were investigated. The concentrations of CD4 +T cell subsets (the absolute numbers of Th1, Th2, Th17 and Treg cells) in peripheral blood were measured by flow cytometry combined with internal standard beads and then the ratios of Th1/Th2 and Th17/Treg were calculated.

**Results:** The duration of their disease was 46.73 $\pm$ 54.92 (Group1), or 61.54  $\pm$ 70.51 (Group2) months. The white blood cells (WBCs) and neutrophils in gout blood were significantly higher than those in controls (P<0.01) and ESR in Group1 was obviously increased (p=0.033). Levels of Total T lymphocyte counts (CD3 +CD19-), Total B lymphocyte counts (CD3-CD19+) and Helper T cells (CD3 +CD4+) were increased in Group2 (all p<0.05). Nevertheless, there was no difference between Group1 and healthy controls. The absolute number of peripheral Th2 in gout (both Group1 and Group2) was higher than that in healthy controls (p=0.001). Most importantly, the absolute number of peripheral Th17 cells was significantly increased in gout patients in Group2 (p=0.006) while, in Group1, the absolute number of Treg cells decreased despite no statistical significance (P>0.05).

**Abstract FRI0239 – Table 1.** Lymphocyte subsets of Gout Patients & Normal Persons

a. Total B lymphocyte counts (CD3-CD19+) were increased in Group1 compared with Group2 (p=0.037).

c. Total T and B lymphocyte counts (CD3-CD19+) were increased in Group2 compared with healthy controls. (all p < 0.05)

**Abstract FRI0239 – Table 2.** CD4+ T cell subsets of Gout Patients & Normal Persons

	Group1	Group2	Normal	F	P-values
N	18	52	41		
Th1 cells,IFN- $\gamma$ (cell/ $\mu$ L)	63.24(126.68)	115.03(183.53)	125.72(99.01)	1.610	0.447
Th2 cells,IL-4 (cell/ $\mu$ L)	12.92(16.62)	11.38(11.16) <sup>a</sup>	7.44(5.88) <sup>a</sup>	12.379	0.002
Th17 cells,IL-17 (cell/ $\mu$ L)	6.79(12.77)	13.07(9.37)	7.48(5.87) <sup>a</sup>	7.131	0.028
Treg cells, CD4+CD25+FoxP3+ (cell/ $\mu$ L)	23.62(28.06)	30.25(20.53)	30.22(16.72)	2.032	0.362
Th1/Th2, IFN- $\gamma$ /IL-4	3.14(7.66)	3.95(14.49) <sup>a</sup>	16.17(20.13) <sup>a</sup>	16.288	0.000
Th17/Treg, IL-17/CD25+FoxP3	0.29(0.83)	0.40(0.43)	0.24(0.20) <sup>a</sup>	6.986	0.030

b. the absolute number of peripheral Th2 cells was significantly increased in gout patients in Group1 compared with healthy controls (p=0.012)

c. the absolute number of peripheral Th2 and Th17 cells was significantly increased in gout patients in Group2 compared with healthy controls (all p < 0.05)

**Conclusions:** The increase of peripheral Th2 and Th17 cells led to an imbalance of CD4 +T cell subsets may correlate with gouty inflammation in an undefined way. The elevation of Th2 and Th17 cells may serve as important reference indices for gout attack and a target of gout treatment. Moreover, Th17 may contribute to the persistence of the disease.

### CLINICAL TRIAL TO DETERMINE WHETHER ALTERING THE REGIMEN OF PEGLOTICASE ADMINISTRATION CAN INCREASE THE FREQUENCY OF SUBJECTS HAVING SUSTAINED LOWERING OF SERUM URATE

K. Saag<sup>1</sup>, M. Feinman<sup>2</sup>, H.S. Baraf<sup>3</sup>, R. Fleischmann<sup>4</sup>, A. Kavanaugh<sup>5</sup>, P. Lipsky<sup>6</sup>.  
<sup>1</sup>University of Alabama at Birmingham, Birmingham; <sup>2</sup>ACME Research, Orangeburg; <sup>3</sup>Center for Rheumatology and Bone Research, Wheaton; <sup>4</sup>University of Texas Southwestern, Dallas; <sup>5</sup>University of California San Diego, LaJolla; <sup>6</sup>AMPEL BioSolutions LLC, Charlottesville, USA

**Background:** Pegloticase is a pegylated recombinant mammalian uricase approved for treatment of persons with chronic gout refractory to standard urate-lowering therapy.<sup>1</sup> Despite initial profound reduction of serum urate (sUA), patients may lose the urate lowering effect of pegloticase owing to the development of anti-drug antibodies.<sup>2</sup> As a result, only 42% of treated patients had sustained urate lowering in the registration trials, and infusion reactions (IRs) occurred in 26% receiving the biweekly dosing regimen compared to 5% of placebo-treated patients.<sup>1</sup> Examination of pegloticase pharmacokinetics<sup>2</sup> indicated that the biweekly regimen may not maintain sufficiently high levels of drug during the first 2 weeks of therapy, possibly contributing to immunogenicity.

**Objectives:** To determine whether an additional dose of 8 mg of pegloticase 1 week after the initial dose and 1 week before the subsequent dose might be sufficient to maintain high serum pegloticase levels and contribute to the development of high zone tolerance and a more persistent urate lowering effect. (NCT02598596)

**Methods:** This is a multi-centre, open-label trial enrolling patients with chronic gout whose sUA was not maintained  $\leq 6$  mg/dL. Background urate lowering therapy was discontinued and patients were treated with 3 weekly doses of 8 mg pegloticase followed by biweekly administration of 8 mg of pegloticase for a total of 10 doses over 17 weeks. After the first administration, dosing was only permitted if the sUA was  $\leq 6$  mg/dL. Standard infusion and gout flare prophylaxis were required. The primary outcome was the maintenance of sUA at  $\leq 6$  mg/dL throughout the treatment period.

**Results:** 50 patients have been enrolled with a mean age of  $59.8 \pm 16.3$  years. Of the 50 patients, 31 (62%) completed all study activities, 7 were non-compliant, 8 withdrew consent, 2 were discontinued by the PI and 2 were discontinued for an adverse event (AE). Patients have received a total of 315 infusions to date. Only 1 patient had a mild IR (0.3% of infusions) that did not meet the criteria for anaphylaxis. 38 patients reported at least 1 AE, the most common being a gout flare (52%). 8 patients (16%) reported severe AEs, including 5 with gout flares. Of the 50 evaluable patients, there were 22 responders (44%), 21 nonresponders (42%) and 7 patients were not evaluable (14%). It is notable that responders had significantly higher trough levels of pegloticase than nonresponders 1 week after the initial infusion (1.45 ug/ml, n=22 vs 1.02 ug/ml, n=21, p=0.02) that persisted throughout the trial, supporting the contention that higher levels of drug are required to promote tolerance and response.

**Conclusions:** The tolerization regimen of pegloticase treatment is well tolerated. Only one IR was noted as administration of pegloticase was avoided in those with a sUA  $> 6$  mg/dL. The tolerization regimen may be associated with a somewhat higher frequency of patients achieving a persistent urate lowering effect. Trough levels of pegloticase separated responders from nonresponders throughout the trial and may be useful to develop an optimal treatment regimen.

### THE EFFECT OF FEBUXOSTAT ON INFLAMMATORY AND CARDIOVASCULAR BIOMARKERS IN HYPERURICEMIC HYPERTENSIVE PATIENTS

L. McLean<sup>1</sup>, L. Gunamardhana<sup>2</sup>, U. Thienel<sup>3</sup>, J. Wu<sup>4</sup>, G. Smithson<sup>5</sup>. <sup>1</sup>Takeda, La Jolla, CA; <sup>2</sup>Takeda, Deerfield IL; <sup>3</sup>RRD LLC, Rockville MD; <sup>4</sup>Takeda, Deerfield; <sup>5</sup>Takeda, Boston MA, USA

**Background:** Hyperuricemia (HU) is associated with hypertension (HTN) and adverse cardiovascular (CV) events. Potential mechanisms include endothelial xanthine oxidoreductase (XO) activity, direct effects of circulating soluble urate, and inflammation from crystal deposits. A phase 2 double-blind placebo (PBO)-

controlled randomised trial tested the ability of 6 weeks treatment with the selective XO inhibitor febuxostat (FBX) to reduce blood pressure in hyperuricemic HTN patients who had no history of gout. A planned subgroup analysis showed reduction of systolic blood pressure (SBP) by 6.7 mmHg (95% CI 0–13.3) as assessed by 24 hour ambulatory BP measurement (ABPM) in HTN subjects with normal renal function (eGFR  $\geq 90$ ).<sup>1</sup>

**Objectives:** To explore mechanistic links between HU and CV disease we examined the effect of treatment with FBX on inflammatory and vascular biomarkers.

**Methods:** Entry criteria included ABPM SBP of  $\geq 130$  and  $\leq 165$  mmHg; taking  $\leq 2$  BP drugs at baseline; and baseline serum urate (sUA) of  $\geq 420$   $\mu$ M. 121 subjects were randomised 1:1 to FBX 80 mg OD or PBO for 6 weeks. Serum and whole blood mRNA samples were taken at screening (d-21), d1 pre-treatment, after 3 w and after 6 w of FBX/PBO.

Soluble markers were measured using a 50-analyte multiplex array (from Myriad RBM HuMAP panel v1.6) and included mediators previously implicated in gout and in CV associations with HU, including CCL2 (MCP-1), CXCL8 (IL-8), E- and P-selectins, cystatin C, ICAM-1, IL-6, leptin, MMPs, MPO, SerpinE1 (PAI-1), TNF $\alpha$ , VCAM-1 and vWF. Additional candidates (angiotensin (AT)-II, hsCRP, insulin) were measured by ELISA. RNAseq was done on the Illumina HiSeq2000 platform with 20–30 million 50 bp paired-end reads and analysed for fold change vs baseline.

**Results:** Serum urate was reduced by a mean of 190  $\mu$ M at week 6 in FBX-treated subjects and 0  $\mu$ M with PBO. Nominally significant differences in change from baseline between PBO and FBX were noted in ICAM-1 (PBO –9.5, FBX +7.0 ng/ml at w6; uncorrected p=0.006) and SerpinE1 (–4.1, +30.9; 0.004). There was no baseline association between sUA and key markers on univariate, multiple linear regression analyses, or principle component regression.

Nonparametric analysis showed marginally significant differences between FBX and PBO in the changes in CRP (unadjusted p=0.26 at w3, 0.018 w6), ICAM-1 (0.023, 0.063) and LOX-1 (0.356, 0.044). The effect of FBX was not significant for other soluble mediators including AT-II, CCL2, CRP, CXCL8, insulin, or MMPs.

Many mRNA transcripts of interest (including CXCL8, SERPINE1) showed low levels in blood and no association between fold-change and reduction in sUA. Changes in CST3, MIF, S100A8 and S100A9 expression were associated with change in sUA.

**Conclusions:** In these HU HTN subjects without gout no significant relationship was found between sUA and inflammatory or CV markers at baseline. FBX effects on these biomarkers are sporadic, expected when evaluating many markers in a relatively small sample. These findings do not support a direct role for soluble urate in HU-associated HTN or CV disease. Limitations include the non-gout population studied, the relatively narrow range of baseline BP, and short treatment duration.

FRI0242

### IMPAIRMENT IN THE RATES OF INCIDENCE, MORTALITY, STAYS AND ANNUAL COSTS OF HOSPITALIZATIONS FOR GOUT IN THE SPANISH NATIONAL HEALTH SYSTEM

M. Hernández Hurtado<sup>1</sup>, M. Á. Martínez Huedo<sup>2</sup>, A. Balsa Criado<sup>3</sup>, D. Peiteado López<sup>3</sup>, E. De Miguel Mendieta<sup>3</sup>. <sup>1</sup>Medical student, Universidad Autónoma de Madrid; <sup>2</sup>Teaching and investigation unit., Hospital Universitario La Paz; <sup>3</sup>Rheumatology Department, Hospital Universitario La Paz- IdiPaz, Madrid, Spain

**Background:** Gout is the most common inflammatory articular disease in adults concerning a 1%–2% of the general population, and even a 4%–5% in older than 70 years. Recently, it has been reported an increase of the prevalence of gout, especially in developed countries.

**Objectives:** The principal purpose of our study is to describe the clinical and epidemiological characteristics of hospitalised patients with diagnosis of gout in Spain including mortality, comorbidities and healthcare costs in the last decade

**Methods:** Retrospective observational study based on data from the Database of Hospital from the Spanish National Health Service. The study was conducted in patients over eighteen years old with any gout diagnosis as principal or other diagnosis, who were admitted in the hospital between the years 2005–2015. The clinical characteristics analysed were sex, age, costs and length of hospital stay. Comorbidities as diabetes, congestive heart failure, acute myocardial infarction and cerebrovascular disease were identified with *International Classification of Diseases, ninth revision, common modification* (ICD-9-CM).

**Results:** The study cohort included 192.037 patients with gout, 82.6% of those were males. There was a progressive increase in the number of hospitalised patients with gout from 12 851 patients in 2005 to 23 318 in 2015; this was associated with an increase in mortality, reaching its highest value in 2015 with a 4.9% of gout hospitalised patients. The average age at death in 2015 was 79.2 years and 85.16 years in male and female respectively, an age slightly lower than in the general population. The average cost in these hospitalised patients was 4931 €, reaching a peak of 5384 € in the last year. The hospital stay reached its lowest numbers in 2015 with an average of 8.9 days per patient. These comorbidities had statistical association with an added mortality risk in cerebrovascular disease (odds ratio [OR] 1.57, 95% confidence interval [CI] 1.46–1.49), liver disease (OR 2.61 95% CI 2.34–2.9), kidney disease (OR 1.34 95% CI 1.28–1.41), dementia (OR 2.13 95% CI 1.88–2.42). On the contrary, in type 2 diabetes (OR 0.92 95% CI 0.87–0.96), we found a statistically significant lower mortality risk. Furthermore, it was found a statistically reduced mortality risk in females (OR 0.85 95% CI 0.8–0.9)

**Abstract FRI0242 – Table 1.** Incidence, mortality, stays and annual costs of hospitalisation for gout of the Health National System

Year	Number of patients	Mortality Number (%)	Average hospital stay (SD)/cost (SD)	Cost/year In millions €
2005	12 850	532 (4.1%)	11.00/4219	54.2
2006	13 163	479 (3.6%)	10.63/4269	56.2
2007	13 896	544 (3.9%)	10.46/4459	61.6
2008	15 292	601 (3.9%)	10.58 4838	74
2009	16 172	630 (3.9%)	10.33/4997	80.8
2010	16 803	658 (3.9%)	9.96/5205	87.5
2011	18 482	781 (4.2%)	9.62/5385	99.5
2012	19 179	897 (4.7%)	9.21/5247	100.6
2013	20.777	926 (4.5%)	9.09/5166	107.3
2014	22.105	991 (4.5%)	8,94/5080	112.3
2015	23.318	1139 (4.9%)	8,90/5384	125.5
<b>Total</b>	<b>192.037</b>	<b>8178 (4.3%)</b>	<b>9,74/4999</b>	<b>959.5</b>

**Conclusions:** In Spain we have a progressive increase in the hospital admissions for gout, higher mortality rates and higher healthcare costs. This shows the need for changes in prevention and management of gout disease.

## FRI0243 ANAKINRA FOR CALCIUM PYROPHOSPHATE CRYSTAL ARTHRITIS: AN EFFICIENT, SAFE ALTERNATIVE TREATMENT

M. Thomas, M. FORIEN, E. PALAZZO, P. DIEUDÉ, S. OTTAVIANI.  
*Rheumatology, Hôpital Bichat, Paris, France*

**Background:** Calcium pyrophosphate (CPP) deposition is a frequent joint disease with increased prevalence in older people in whom treatment of acute CPP arthritis with conventional therapies such as colchicine, corticosteroids or non-steroidal anti-inflammatory drugs (NSAIDs) could be contraindicated or not used at an optimal dose. As recommended in gout, anakinra might represent an alternative treatment for acute arthritis. In contrast, the relevance of anakinra in acute CPP arthritis has not given much attention.

**Objectives:** We further aimed to analyse the efficacy and safety of anakinra in acute CPP arthritis in a large cohort.

**Methods:** We retrospectively included all patients receiving anakinra for acute CPP arthritis between January 2011 and 2017. Medical history data were collected including hypertension, diabetes mellitus, cardiovascular disease, history of gastroduodenal ulcer, renal impairment and concomitant treatments including anticoagulants or antiplatelet drugs. The following data were collected before and 4 days after the first anakinra injection: swollen joint count (SJC), tender joint count (TJC), pain score on a visual analogue scale (VAS, 0–100 mm) and C-reactive protein (CRP) level. A good response was defined according the evaluation of the physician or documentation in the chart of the phrase “good response” after anakinra treatment.

**Results:** We included 33 patients (24 women; mean age 79.2±12.8 years). Mean duration of acute arthritis 13.2±12.9 days. CPP arthritis was confirmed by the presence of CCP crystals in synovial fluid in 28/33 (84.8%) patients. For the remaining 5 patients, the diagnosis was confirmed by CPP deposition features seen on imaging. Corticosteroids, NSAIDs and colchicine were previous treatments, without significant improvement in 12 (36.4%), 7 (21.2%) and 18 (54.5%) patients, respectively. The mean dose of corticosteroids was 20.8±8.2 mg/day. Among the 33 patients, 32 had a documented visit at day 4. The number of good responders was 27 (81.8%). At day 4, patients showed decreased mean VAS

pain score (from 64.8±26.5 to 21.2±19.7 mm, p<0.0001), TJC (5.8±5.0 to 1.0±1.0, p<0.0001), SJC (3.9±2.7 to 0.9±1.0, p<0.0001) and CRP level (116.1±71.6 to 26.0±23.1 mg/L, p<0.0001). Anakinra was well tolerated. Only one patient had pneumonitis that was resolved with oral antibacterial agents.

**Conclusions:** Our results suggest that anakinra could be a relevant alternative for managing acute CPP arthritis, leading to rapid relief of inflammatory symptoms, with a good tolerance.

## FRI0244 LIFE STYLE FACTORS AND COMORBIDITIES IN GOUT PATIENTS COMPARED TO THE GENERAL POPULATION

M.J. Dehlin<sup>1</sup>, L. Scheepers<sup>1</sup>, A. Landgren<sup>1</sup>, L.T. Jacobsson<sup>1</sup>, U. Lindström<sup>1</sup>, E. Klingberg<sup>1</sup>, U. Bergsten<sup>2</sup>. <sup>1</sup>Dept of rheumatology and inflammation research, Institution of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, <sup>2</sup>RandD Department, Region Halland, Halmstad, Sweden

**Background:** Gout is the most common inflammatory arthritis and relatively much is known regarding its pathogenesis. It is clear that life style factors play a significant role in developing and maintaining disease.

**Objectives:** This study aimed to analyse lifestyle factors in prevalent gout patients by sex compared to age matched controls from the general population.

**Methods:** All patients above 18 years of age with an ICD 10-diagnosis of gout from Jan 2015 through Feb 2017 listed at any of twelve randomly selected primary health care centres or the rheumatology department at Sahlgrenska University hospital in the Western Sweden Health Care Region (WSHCR) were identified. They were sent a questionnaire, regarding demographics, life style factors such as smoking status, alcohol consumption, physical activity, body mass index (BMI); categorised into 4 levels in the analyses) and comorbidities such as diabetes and hypertension. All responders aged 18–84 years were matched to five control individuals, without gout, by sex and age. Control individuals were selected from a random sample of 52 348 individuals aged 16–84 years who participated in the National Public Health survey in Sweden year 2015 This survey is a national study on health, lifestyle and living conditions. Alcohol consumption was categorised as none and any with/without binge drinking behaviour. Binge drinking was (liberally) defined as consuming more than four (women) or five glasses (men) on any occasion.

Conditional logistic regression models were used to compare cases and controls with regard to lifestyle factors and comorbidities. Multivariate analyses were also performed, including BMI, smoking status, alcohol consumption, and physical activity.

**Results:** Of the 1589 invited gout patients, 868 responded and 79.7% were male. Non-responders were more often young men. Mean age was 69.3 (std:10.5) years for men and 71.8 (std: 9.9) years for women with gout.

Male gout patients were in multivariate analyses more likely to be overweight (OR 1.67 (95% CI: 1.31–2.14)), obese (OR 2.20 (95% CI: 1.64–2.94)), have binge drink behaviour (OR 3.32 (95% CI: 2.39–4.62)), and had lower levels of physical activity compared to controls (table 1). Current smoking habits did not differ between male gout patients and controls.

Female gout patients were in multivariate analyses more likely to be overweight (OR 1.87 (95% CI: 1.05–3.33)), obese (OR 3.62 (95% CI: 1.96–6.72)), and have binge drink behaviour (OR 4.28 (95% CI: 1.92–9.53)), but not did differ with regard to current smoking habits or physical activity compared to controls.

In bivariate analyses, comorbidities such as diabetes and hypertension, were significantly more common in gout patients among both sexes.

**Abstract FRI0244 – Table 1.** Prevalence of lifestyle factors and comorbidities between gout patients and sex-age matched healthy controls.

More than 5 hours	24.7	18.5	0.76	(0.66 to 0.87)	0.87	(0.66 to 1.14)	31.7	30.9	1.02	(0.79 to 1.31)

\* Multivariate analyses including BMI, alcohol consumption, smoking status and physical activity per week.

**Conclusions:** Compared to the general population, patients with gout were more often obese (in particular women) and had higher occurrence of binge drinking behaviour (in particular men). The lower level of physical activity (men) and normal frequency of smoking among gout patients may be a consequence of the high comorbidity rates.

**FRI0245** **PREDICTORS FOR CLINICALLY DIAGNOSED GOUT – 30 YEARS FOLLOW-UP IN THE MALMÖ PREVENTIVE PROJECT COHORT, SWEDEN**

M.C. Kapetanovic<sup>1</sup>, P. Nilsson<sup>2</sup>, C. Turesson<sup>3</sup>, M. Englund<sup>4</sup>, N. Dalbeth<sup>5</sup>, L. Jacobsson<sup>6</sup>. <sup>1</sup>Department of Clinical Sciences Lund, Lund University, rheumatology, Lund; <sup>2</sup>Lund University, Malmö, Sweden; Internal Medicine and Skåne University Hospital, Internal medicine; <sup>3</sup>Lund University, Department of Clinical Sciences, Malmö, Lund University and Skåne University Hospital, rheumatology, Malmö; <sup>4</sup>Department of Clinical Sciences Lund, Lund University, Clinical Epidemiology Unit, Orthopaedics, Lund, Sweden; <sup>5</sup>University of Auckland, Department of Medicine, Auckland, New Zealand; <sup>6</sup>Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

**Background:** Gout is the most common form of inflammatory arthritis worldwide. Hyperuricemia is a crucial risk factor. The relative importance of other risk factors is slightly more controversial.

**Objectives:** Our aim was to identify predictors for clinical gout cohort from a population survey, the Malmö Preventive Project (MPP) – a large-scale screening and case finding program in Malmö, Sweden.

**Methods:** A total of 33 346 individuals (67% men, mean age 46 years, mean follow-up 28 years) were screened 1974–1992. The survey included: A Questionnaire (alcohol consumption, smoking); A Physical Examination and Laboratory tests. The Malmö modification of Michigan alcoholism screenings test (Mm-MAST) was used to identify alcohol risk consumption (Mm-MAST score  $\geq 2$ ). Subjects were followed to date of first gout diagnosis, death, migration from area, or December 2014. All gout diagnoses given at visits to physicians in primary or specialised care were identified by linking MPP cohort to regional Skåne Healthcare Register and to National Patient Register. Possible risk factors/markers at baseline associated with incident gout were analysed using Cox-regression models.

**Results:** In total, 1275 individuals (3.8%); 1014 men (4.5%) and 261 women (2.4%) were diagnosed with gout. In both sexes, baseline s-UA  $>405$  (age-adjusted) was the strongest factor associated with incident gout. Higher age, higher BMI, higher s-triglycerides, hypertension and smoking were also associated with gout in both sexes. Mm-MAST score  $\geq 2$  was associated with gout only in men while higher ESR was associated with gout only in women (table 1).

**Conclusions:** In this large cohort of middle-age individuals, hyperuricemia, higher age, hypertriglyceridemia and higher BMI were associated with incident gout in both sexes. Alcohol risk consumption predicted gout only in men. Higher ESR, as a possible marker of chronic inflammation, was a significant predictor only in women.

**Disclosure of Interest:** None declared

**FRI0246** **INVESTIGATING THE EFFECT OF SERUM URATE LEVELS ON GOUT FLARE RATES IN A LARGE-SCALE U.S. ADMINISTRATIVE CLAIMS DATABASE**

P. Herzog<sup>1,2</sup>, A.-C. Fu<sup>1</sup>, J. Lim<sup>1,3</sup>, D.C. Taylor<sup>1</sup>. <sup>1</sup>Ironwood Pharmaceuticals, Inc., Cambridge; <sup>2</sup>Columbia University Mailman School of Public Health, New York; <sup>3</sup>Tufts University School of Medicine, Boston, USA

**Background:** Reducing patients' serum urate (sUA) levels has long been the focus of gout treatments. Current evidence suggests that sUA levels  $\geq 6.0$  mg/dL significantly increase a subject's risk of an acute gout attack or "flare."

**Objectives:** To investigate the effects of sUA levels on gout flare rates (GFLR) over a 5 year period in a large-scale US commercial claims database.

**Methods:** Truven MarketScan administrative claims data from 2010 to 2015 were used for this analysis. The study population was patients with gout whose index gout diagnosis was defined as first gout diagnosis. Index sUA date (IsD) was defined as the sUA result closest to, but not preceding, a subject's index gout diagnosis. Patients were included if they had continuous health plan enrollment during the year prior to and after their IsD. Patients without an sUA result after their index gout diagnosis were excluded. Three sUA comparison groups were created based on mean sUA values calculated from sUA measurements at IsD through follow-up. Person-time was defined as time between IsD to the end of continuous enrollment or to the end of the study period, whichever came first. Gout flares were determined via a published algorithm Halpern 2009 combining health care visits and prescriptions by using ICD9/10, HCPCS, and NDC codes. Subjects' annual GFLR were calculated as their number of flares per person-time. Mean GFLR were calculated for each sUA comparison group. A generalised linear model was developed to investigate the effect of sUA levels on GFLR after adjusting for demographics and regions.

**Results:** 15 140 subjects were included in the analysis. Most subjects were male (78%) and from the south (47%) with a mean age of 52 years. Mean sUA was 6.9 mg/dL (min=1.4, max=17.5) where 58% of patients had sUA between 6.0 and 9.0 mg/dL. Subjects were followed for 2.1 years on average. sUA  $\geq 6.0$  and  $<9.0$  mg/dL (Group 2), and sUA  $\geq 9.0$  mg/dL (Group 3) were both associated with increased gout flare rates compared to sUA  $<6.0$  mg/dL (Group 1). Group 3 had 1.540 times of the annual flare rate of Group 1. Male sex and increasing age were associated with increased GFLR. North central, south, and west US regions were all positively associated with GFLR in relation to the northeast (table 1).

\*HR is calculated per 1 SD or for dichotomous covariates (yes vs. no)

**Abstract FRI0246 – Table 1.** Generalised linear model for association between sUA level and gout flare rates (n=15,140)

Variable	Rate Ratio	95% CI	p-value
Group 2: sUA $\geq 6.0$ and $<9.0$ mg/dl <sup>1</sup>	1.179	(1.143, 1.216)	<0.001
Group 3: sUA $\geq 9.0$ mg/dl <sup>1</sup>	1.540	(1.475, 1.608)	<0.001
Sex: Male	1.374	(1.326, 1.424)	<0.001
Age	1.012	(1.010, 1.014)	<0.001
North central <sup>2</sup>	2.198	(2.114, 2.285)	<0.001
South <sup>2</sup>	1.382	(1.339, 1.425)	<0.001
West <sup>2</sup>	2.038	(1.935, 2.145)	<0.001

<sup>1</sup> versus  $<6.0$  mg/dl (Group 1)<sup>2</sup> versus northeast

**Conclusions:** These results suggest that higher sUA levels are associated with higher flare rates and that sUA level may be an indicator of GFLR. This finding may encourage health providers to prioritise reducing sUA levels in gout patients to reduce the frequency of gout flares and improve gout management.

FRI0247

### GOUT CHARACTERISTICS AND ITS ASSOCIATION WITH THE PRESENCE OF CARDIOVASCULAR DISEASE: A CASE-CONTROL STUDY

S.J. Lopez Salguero, M. Andrés Collado. *Reumatología, Hospital General Universitario Alicante, Alicante, Spain*

**Background:** Gout is an independent risk factor for any type of cardiovascular disease (CVD). The exact mechanism behind remains to be elucidated, but persistent crystal-related inflammation is presumed as a key factor.

**Objectives:** The aim of this study was to assess whether gout characteristics that may indicate a more severe disease and higher inflammatory load are associated with the presence of CVD.

**Methods:** Case-control study, performed at baseline of an inception cohort including consecutive crystal-proven gout patients seen at a rheumatology unit. Gout features (time since first attack, number of attacks, number of joints affected, pattern of presentation, tophi) were registered after interview and physical exam. Presence and duration of CVD (which included coronary heart disease, heart failure, stroke or peripheral artery disease) was registered after interview and records review. Those patients who have suffered from CVD prior to the onset of gout were excluded. Other cardiovascular risk factors, as well as clinical and laboratory variables, were also registered. Odds ratios with 95% confidence intervals (95% CI) for each gout feature were calculated between patients with and without CVD, using a multiple logistic regression model to adjust for confounders.

**Results:** The inception cohort includes 308 patients; 54 were excluded for this study because gout onset occurred after CVD, so finally 254 cases were analysed. Mean age was 61.4 years (SD 13.9), being 225 (88.6%) men. Regarding gout, median duration was 5 years (IQR 1–12), median number of reported attacks was 5 (IQR 2–14) that had involved a median of 3 joints (IQR 2–5); presenting attack was monoarticular in 77.4% cases, oligoarticular in 16.7%, and polyarticular in 6%, and 58 patients (22.8%) showed tophi at enrolment. A total of 32 patients (12.6%) had suffered from CVD at enrolment. Table 1 shows the results of logistic regression analysis: time since first attack and polyarticular presentation of gout both significantly associated with the presence of CVD, while other variables showed no association. After multivariate analysis, time since first attack persisted associated with CVD, while polyarticular involvement showed a trend towards signification.

### Association between gout features and cardiovascular disease

	Simple regression		Multiple regression	
	OR (95% CI)	p	aOR (95% CI)*	p
<b>Gout duration</b>	1.07 (1.03–1.10)	<0.001	1.06 (1.02–1.11)	0.005
<b>Number of attacks suffered</b>	1.00 (0.99–1.00)	0.561	-	-
<b>Number of involved joints</b>	1.09 (0.96–1.22)	0.177	-	-
<b>Joint pattern at presentation</b>				
<b>i. Monoarticular</b>	1. (ref)	-	1.0 (ref)	-
<b>ii. Oligoarticular</b>	2.30 (0.93–5.72)	0.073	1.71 (0.44–6.65)	0.440
<b>iii. Polyarticular</b>	3.56 (1.02–12.32)	0.045	5.33 (0.92–30.78)	0.061
<b>Tophi</b>	1.64 (0.73–3.69)	0.234	-	-

\*aOR: adjusted OR for age, gender, hypertension, diabetes, dyslipidemia, smoking background, obesity, and renal failure.

**Conclusions:** Time since first attack and likely a polyarticular presentation, two variables that may estimate crystal and inflammatory load in gout patients, are independently associated with the presence of CVD, adding evidence to the role of persistent inflammation on its development.

FRI0248

### VALIDITY OF RANDOM URINARY URIC ACID-TO-CREATININE RATIO FOR ESTIMATING 24-HOUR URINE URIC ACID EXCRETION IN PATIENTS WITH GOUT

S. Choi<sup>1</sup>, S.-J. Moon<sup>2</sup>, E.-J. Kang<sup>3</sup>, K.-H. Lee<sup>4</sup>. <sup>1</sup>Internal Medicine, Chung-Ang University College of Medicine, Seoul; <sup>2</sup>Internal Medicine, Catholic Kwandong University College of Medicine, Incheon; <sup>3</sup>Internal Medicine, Busan Medical Center, Busan; <sup>4</sup>Internal Medicine, Dongguk University College of Medicine, Goyang, Korea, Republic Of

**Background:** Gout is one of a heterogeneous group of diseases related to hyperuricemia. The measurement of 24 hour urinary uric acid excretion is frequently used to evaluate disease status and select drugs that lower uric acid level. However, 24 hour urine collection is inconvenient and frequently unreliable, due to errors in collection. Therefore, a simpler alternative to the 24 hour urine collection is needed.

**Objectives:** We investigated the utility of the random urine uric acid-to-creatinine (UA/CR) ratio in predicting 24 hour urine uric acid excretion in patients with gout.

**Methods:** Ninety patients with gout without any use of uric acid lowering agents were enrolled in this study. The mean age was 50.0±16.7 years old and the male patient was 90.0% (81/90) of all participants. For the evaluation of uric acid excretion and renal function, patients were collected 24 hour urine. Random urine uric acid and creatinine specimens were gained on the same day of 24 hour urine collection. Chronic kidney disease was defined as a creatinine clearance (Cr) level of less than 60 ml/min/1.73m<sup>2</sup> measured in 24 hour urine collection sample. Excretion of more than 600 mg of uric acid in the 24 hour urine sample was defined as uric acid over-excretion.

**Results:** Mean serum uric acid level was 7.73±1.89 mg/dl, and the mean 24 hour uric acid excretion was 666.5±236.2 mg. The random urinary UA/CR ratio showed positive correlation with 24 hour urine uric acid excretion ( $\gamma=0.398$ ,  $p<0.001$ ). Correlation between these two variables was also found in the patients with chronic kidney disease ( $\gamma=0.762$ ,  $p=0.028$ ). In the linear regression analysis, absolute 24 hour urine uric acid excretion was estimated to be 581 × (random urinary UA/Cr)+432 ( $p<0.001$ , adjusted  $R^2=0.398$ ). The best cut-off value for the random urinary UA/Cr ratio to distinguish between uric acid over-excretion and normal uric acid excretion was 0.342, with a sensitivity of 74.1%, specificity of 66.7%. The areas under the curves (AUCs) of the random urine UA/CR ratio was 0.763 [95% confidence interval (CI), 0.665–0.861,  $p<0.001$ ].

**Conclusions:** The random urine UA/CR ratio correlated with 24 hour urine uric acid excretions in patients with gout. The best cut-off random urine UA/CR ratio value to discriminate uric acid over-excretion was 0.342, with a sensitivity of 74.1% and a specificity of 66.7%. The random urine UA/CR ratio would be a useful

predictor to detect patients with urinary uric acid underexcretion, who could then be treated with uricosuric drugs.

### FRI0249 AUDIT OF THE MANAGEMENT OF GOUT -ARE WE DOING IT RIGHT?

T.J. Khan, S. Kamath, E. Roddy. *Rheumatology, Haywood Hospital, Stoke-On-Trent, UK*

**Background:** Gout is the most prevalent inflammatory arthritis, affecting 2.5% of adults in the UK. However, management is often inadequate in both primary and secondary care, with only 45% of patients achieving target serum urate (SUA) level <360µmol/L over 12 months in UK rheumatology clinics. A better understanding of how well gout is managed in different areas of our service (discharge to GP, general rheumatology follow-up clinics, and specialist gout clinic) will inform service redesign.

**Objectives:** To compare the management of gout in the rheumatology service against the 2007 British Society for Rheumatology (BSR) and 2006 European League Against Rheumatism (EULAR) gout guidelines, and the NICE febuxostat technology appraisal (TA164).

**Methods:** We retrospectively audited all new out-patient referrals with gout seen in our department over a 12 month period (January-December 2015). Data were collected by electronic review of case notes and completion of a structured proforma. Three mutually exclusive groups were compared: those seen once in rheumatology and discharged to GP (group1), followed-up in general rheumatology clinics (group2), or followed-up in a specialist gout clinic (group3). Follow-up SUA levels were specifically compared to EULAR (<360µmol/L) and BSR (<300µmol/L) treatment targets.

**Results:** 150 new consecutive gout referrals (50 per group) were included in the audit: 83% were male and mean age was 62 years. Gout was diagnosed by monosodium urate crystal identification in 16 (11%) and 25% had tophi. 43 (29%) patients were already on ULT, and 107 (71%) patients were newly commenced on ULT. Prophylactic medications were co-prescribed in 86% (130) cases. 44 patients were taking diuretics; diuretics were advised to be stopped or reduced in 12% cases. Nearly all patients starting allopurinol commenced a daily dose of ≤100 mg (99% cases). Of the patients started on a uricosuric/febuxostat, 92% had taken allopurinol previously. Of the 15 patients commenced on febuxostat, 3 (15%) had ischaemic heart disease (IHD) or cardiac failure. Chronic kidney disease (CKD) stage 3 (group1 28%, group2 22%, group3 34%), CKD stage 4/5 (2%, 2%, 10%), IHD/cardiac failure (30%, 30%, 40%), clinically evident tophi (16%, 18%, 42%) and previous allopurinol intolerance (10%, 14%, 24%) were more common in group 3 than groups 1 and 2. After 12 months, only 90 (60%) patients achieved target <360µmol/L (group1 42%, group2 64%, group3 62%) and 47 (31%) patients achieved target SUA <300µmol/L (group1 20%, group2 34%, group3 36%).

**Conclusions:** Allopurinol starting dose, use of prophylaxis, and use of allopurinol first-line concurred well with national and international guidelines. We achieved target SUA levels more commonly than the UK national average in a recent national rheumatology audit. Patients discharged to the GP with a management plan prior to achieving a target SUA level achieved target less frequently suggesting that rheumatologists should follow patients in order to ensure treatment is escalated until the target SUA level is achieved.

### FRI0250 BELIEFS ABOUT MEDICINES AMONG GOUT PATIENTS - DATA FROM THE NOR-GOUT STUDY

T. Uhlig<sup>1</sup>, L.F. Karoliussen<sup>1</sup>, J. Stjærne<sup>2</sup>, E.A. Haavardsholm<sup>1</sup>, T.K. Kvien<sup>1</sup>, H. B. Hammer<sup>1</sup>. <sup>1</sup>*Rheumatology, Diakonhjemmet Hospital, Oslo;* <sup>2</sup>*Rheumatology, Betanien Hospital, Skien, Norway*

**Background:** Low adherence to medication is a concern in gout where urate lowering therapy (ULT) is indicated to prevent disease severity and comorbidities. The beliefs patients have about medication may impact on the success of achieving these treatment goals.

**Objectives:** To study which factors were associated to beliefs about medicines in patients with a recent gout attack and a need for ULT.

**Methods:** Baseline data from a prospective observational study were used in patients with crystal-proven gout who presented after a recent gout flare with insufficiently treated serum urate (sUA) level (>360 µmol/L/>6 mg/dl). In these patients a treat-to-target approach was planned to meet the treatment target (sUA <360 µmol/L, or <300 µmol/L if clinical tophi). Assessment included demographic and clinical data, baseline serum urate levels, medication, self-administered

comorbidity questionnaire (SCQ), physical function (HAQ), and SF-36 mental (MCS) and physical component summaries.

The Beliefs in Medicines Questionnaire (BMQ)<sup>1</sup> assesses patient beliefs about medicines on four subscales: necessity and concerns specific for the patient, and generally on overuse and harm. Respondents indicated their degree of agreement with each individual statement about medicines on a 5-point Likert scale, (1=strongly disagree to 5=strongly agree). Scores within the four subscales (necessity, concerns, overuse, harm) were summed (ranges 5–25 and 4–20). Calculation of the necessity-concerns differential gave the relative importance for the patient for taking medicines.

**Results:** 163 patients were included at baseline, 93.3% men, 90.5% caucasian, mean (SD) age 57.0 (14.1) years, disease duration 8.0 (7.7) years). Mean sUA level was 487 (SD 82) µmol/L at baseline, body mass index 28.9 (4.7) kg/m<sup>2</sup>, comorbidity score (SCQ) 3.6 (3.2), and physical function (HAQ) 0.35 (0.55). 18.8% (n=28) had tophi, and 30.1% (n=43) were using allopurinol.

Scores for the BMQ subscales (SD) were for necessity 16.8 (4.3), concerns 13.7 (5.0), overuse 10.6 (2.7), and harm 9.5 (2.4). The specific necessity-concerns differential was 3.1 (5.7), with median 2.5. Patients expressing higher versus lower beliefs in importance of medication (necessity-concern higher than median) demonstrated in bivariate comparisons statistically significant differences (table 1). The level of serum urate was not associated with any BMQ subscale.

In logistic regression analyses, also adjusting for age and gender in the final model, high beliefs in the relative importance of medication were independently associated with not using allopurinol medication (OR 0.41, 95% CI 0.18–0.94), with higher BMI (OR=1.11 per unit, 95% CI 1.02–1.20), and better mental health (SF36 MCS) (OR 1.04 per unit, 95% CI 1.01–1.08).

	High belief (>median)	Low belief	p-value
BMI	29.6	28.2	0.048
Comorbidity score (SCQ)	2.3	4.4	0.02
Taking allopurinol	25.8%	37.9%	0.09
SF36 MCS	50.8	47.1	0.03
BMQ overuse	9.9	11.4	0.001
BMQ harm	8.9	10.2	0.001

**Conclusions:** Unexpectedly, using allopurinol medication was inversely associated with high beliefs, whereas higher BMI and better mental health were positively associated with high beliefs in the importance of medication in gout patients. These findings do not allow conclusions on causality, and beliefs in medicines in gout patients should also be studied longitudinally and in relationship to therapy response.

### FRI0251 PREVALENCE OF GOUT AND THE USE OF URATE LOWERING AGENTS IN US GENERAL POPULATION NHANES 2007–2016

T.T. Cheung, M.F. Tsoi, B.M.Y. Cheung, W.C.S. Lau. *Medicine, The University of Hong Kong, Hong Kong*

**Background:** The prevalence of gout has been increasing worldwide. Previous study using National Health and Nutritional Examination Survey (NHANES) showed an increase of 1.2% in the prevalence of gout in the US general population from 1988 to 2007. However, it is unknown if this trend continued over the past decades. Therefore, we would like to determine the prevalence of gout in the US general population using NHANES 2007 to 2016. In addition, the use of urate lowering agents among patients with gout was analysed.

**Objectives:** To estimate the prevalence of gout and the use of urate lowering agents using the National Health and Nutritional Examination Survey from 2007 to 2016

**Methods:** Adult participants in NHANES 2007–2016 were included in the analysis. NHANES is a continuous national survey conducted by the US Centres for Disease Control and Prevention and is designed to evaluate the health and nutritional status of adults and children in the US. They are based on a representative sample of the non-institutionalised US civilian population. Each participant represents approximately 50000 Americans.

The primary outcome was self-reported gout. Factors associated with gout, such as body weight, drinking habit, history of chronic kidney disease, use of aspirin and thiazide diuretics were evaluated. Prescriptions of allopurinol, febuxostat or probenecid were retrieved from the NHANES dataset to evaluate the use of urate lowering agents among patients with gout.

Results were analysed using SPSS complex sample module version 22. Multiple regression was used to analyse the difference in prevalence of gout and utilisation of urate lowering agents.

**Results:** 23482 adults participants were included in the analysis. There was no further increase in the prevalence of gout in the general US population. The prevalence was 3.82% and 3.84% in NHANES 2007–2010 and 2011–2016, respectively (p=0.966).

Although there is a decreasing trend in the serum urate levels among patients with gout, the utilisation of urate lowering agents remained low. Only 28.2% and 29.4% of patients with gout were prescribed urate lowering agents in 2007–2010 and 2011–2014, respectively.

Among patients with gout, history of chronic kidney disease and use of thiazide diuretics are the most significant negative predictors for achieving the therapeutic target of SUV <6 mg/dL (Odds ratio of 0.23 and 0.41, respectively). Use of aspirin was not a significant predictor for treatment failure.

NHANES survey cycle	2007-2010	2009-2010	2011-2012	2013-2014	2015-2016	P-value

% of patients on NSAIDs	7.0 (5.8-8.2)	6.6 (5.4-7.8)	7.8 (6.6-9.0)	7.3 (6.1-8.5)	0.276
% of patients on colchicine	0.5 (0.3-0.7)	0.6 (0.4-0.8)	0.6 (0.4-0.8)	0.7 (0.5-0.9)	0.097

	10 years analysis	5 years analysis
OR		
95% CI		
10-15	0.72 (0.27-1.79)	0.71 (0.45-1.10)
15-20	0.48 (0.20-0.93)	0.48 (0.24-0.93)
20-25	0.44 (0.22-0.91)	0.44 (0.22-0.91)
25-30	0.56 (0.26-0.99)	0.56 (0.26-0.99)
30-35	1.20 (0.24-6.04)	1.20 (0.24-6.04)
35-40	0.58 (0.22-0.94)	0.41 (0.24-0.71)
40-45	0.72 (0.30-1.47)	0.59 (0.27-1.47)
45-50		0.73 (0.40-1.35)

**Conclusions:** The prevalence of gout in the US general population has not increased over the past 10 years. Although the use of urate lowering agents among patients with gout remained low, the percentage of patients with gout achieving the therapeutic target has increased over the past 10 years.

History of chronic kidney disease and use of thiazide diuretics are the most significant negative predictors for treatment success.

**FRI0252 TESTING FOR A CAUSAL ROLE OF MITOCHONDRIAL VARIATION IN THE DEVELOPMENT OF GOUT**

T.R. Merriman<sup>1</sup>, A. Shaikat<sup>1</sup>, A. Gosling<sup>1</sup>, M. Bixley<sup>1</sup>, N. Dalbeth<sup>2</sup>, L. Stamp<sup>3</sup>, E. Matisoo-Smith<sup>1</sup>, J. Harre Hindmarsh<sup>4</sup>, L. Joosten<sup>5</sup>, T. Jansen<sup>6</sup>, M. Janssen<sup>6</sup>, A.-K. Tausche<sup>7</sup>, P. Riches<sup>8</sup>. <sup>1</sup>University of Otago, Dunedin; <sup>2</sup>University of Auckland, Auckland; <sup>3</sup>University of Otago, Christchurch; <sup>4</sup>Ngati Porou Hauora Charitable Trust, Te Puia Springs, New Zealand; <sup>5</sup>Radboud University Medical Centre, Nijmegen; <sup>6</sup>VieCuri Medical Centre, Venlo, Netherlands; <sup>7</sup>University of Dresden, Dresden, Germany; <sup>8</sup>University of Edinburgh, Edinburgh, UK

**Background:** Mitochondria execute critical roles in diverse cellular pathways. As a danger signal mitochondria induce inflammation in response to stress through NLRP3 inflammasome activation, central to gout development. We recently reported association of reduced mtDNA copy number (CN) with prevalent gout in New Zealand Māori and Pacific (Polynesian) populations<sup>1</sup>. However the cause-effect relationship is unknown. This could be evaluated by testing for association with gout using nuclear genetic variants that associate with mtDNA CN.

**Objectives:** 1) Genome wide association study (GWAS) for mtDNA CN to identify nuclear and mitochondrial loci controlling mtDNA copy number 2) test any such loci for association with gout.

**Methods:** The mtDNA CN GWAS comprised 1340 Eastern Polynesian (EP), 816 Western Polynesian (WP) and 4579 European samples (New Zealand, Germany, The Netherlands, Scotland) genotyped on the Illumina CoreExome v24 array. 343 mitochondrial single nucleotide polymorphisms (SNPs) were evaluated. As

previously described<sup>2</sup> the median of the absolute difference in X and Y probe intensities was used as a measure of mtDNA CN, and additional 10 000 randomly selected autosomal SNPs were used to calculate the principal components (PCs). A mtDNA CN GWAS was run on chromosomes 1–22 and the mitochondrial genome using Plink 1.9 .v2, adjusting for the first 10 PCs, age and sex followed by association analysis with gout adjusting by age, sex and the first 10 PCs generated from a separate set of 3000 autosomal SNPs.

**Results:** The association of reduced mtDNA CN with gout in the EP and WP groups was reproduced but there was no evidence of association of mtDNA CN with gout in Europeans. Two genome-wide significant (p<1x10<sup>-7</sup>) variants *MUC17 rs78010183* (T-allele) and *SLC16A8 rs75640043* (T-allele) were associated with increased mitochondrial CN in EP and WP, respectively, and mitochondrial variant *rs3928306* was associated with mtDNA CN (p=4.49x10<sup>-12</sup>) in Europeans. *MUC17 rs78010183* also associated with increased mtDNA CN in Europeans, with the T allele also increasing CN (β=0.06, p=1.07x10<sup>-4</sup>). The T-allele of *rs78010183* was associated with gout in Europeans (OR=9.32, p=5.53x10<sup>-3</sup>) and the *SLC16A8 rs75640043* T-allele was associated with gout in the WP group (OR=6.85, p=5.50x10<sup>-3</sup>). The mitochondrial variant *rs3928306* A-allele (very rare in Polynesian) was not associated with gout in Europeans (OR=1.09, p=0.36).

**Conclusions:** That genetic variants associated with mitochondrial copy number also associate with gout provides evidence for a potential causal role of mitochondrial copy number in gout. However, the nuclear genetic variants support a causal relation of increased mtDNA CN with gout, conflicting with our previous observational report of association of reduced mtDNA CN with gout<sup>1</sup>.

**FRI0253 TRENDS FOR GOUT IN ADULTS IN AN URBAN AREA FOR A 5-YEAR PERIOD: INCIDENCE, PREVALENCE AND HOSPITALISATION RATES**

V. Dostanko<sup>1</sup>, V. Yagur<sup>1</sup>, V. Apanasovich<sup>1</sup>, N. Dostanko<sup>1</sup>, A. Rekun<sup>2</sup>. <sup>1</sup>2-d Department of Internal Medicine, BSMU; <sup>2</sup>Rheumatology Department, 9-th Minsk City Clinical Hospital, Minsk, Belarus

**Background:** Gout is one of the most common arthritis nowadays which has a great influence on patient's quality of life, course and outcomes of cardiovascular and renal pathology.<sup>1</sup> Some recent papers demonstrate that the prevalence of gout has risen over the last decades and underline the scarcity or lack of epidemiologic data in different countries as well as the notable variations among them.<sup>2,3</sup>

**Objectives:** We estimated incidence, prevalence and hospitalisation rates for gout in Minsk (the Republic of Belarus) for the 5 year period (2011–2015).

**Methods:** Minsk is a typical urban area which is considered to be representative for the urban population of the whole country. The data on the new onset gout and the first visit for gout in a corresponding year were collected from all rheumatologic services of Minsk for the 5 year period from January, 1 of 2011 to December, 31 of 2015. Only patients older than 18 years old with the diagnosis of gout according to the ICD-10 (M10) were included. The data on age and sex structure of the population of the Republic of Belarus were obtained from the annual Statistical bulletins of the National Statistical Committee of the Republic of Belarus. Hospitalisation rates were calculated on the base of statistical reports on discharges for the corresponding year.

**Results:** There were no significant differences in age and sex structure of the population in Belarus and Minsk for the study period. The size of the adult population, incidence and prevalence of gout, hospitalisation rates and duration of hospitalizations for gout for the corresponding years in Minsk are presented in the table 1. According to these data the gout incidence for the 5 year period changed from 25.0 (CI 95% 24.7–25.2) to 35.5 (CI 95% 35.3–35.8) per 100 000 adults, the gout prevalence for the period 2011–2015 also increased from 178.9 (CI 95% 178.3–179.5) to 290.3 (CI 95% 289.6–291.0) per 100 000 adults (p<0.001 for both trends). There were 2688 hospitalizations in Minsk for gout for the study period. The mean age of hospitalised patients was 57.3±10.3 years (median 58.0; range 25–87), 91.4% were men (92%; 87.8%–94.9%). It is worth noting that 45.6% of hospitalised patients were at the age 55–65% and 90.2% were under 70 years old with sharp decrease of hospitalizations after 65 years of age. Hospitalisation rates

also increased from 28.7 to 38.2 per 100 000 adults ( $p < 0.001$ ). The mean duration of hospitalisation was  $12.5 \pm 2.7$  days (13 days; 2–26 days) and increased from 11.6 to 12.7 ( $p = 0.03$ ).

**Abstract FRI0253 – Table 1**

	2011	2012	2013	2014	2015
Population size in Minsk, adults	1537880	1555210	1568320	1585480	1598120
Incidence per 100 000	25.0	26.2	35.3	38.0	35.5
Prevalence per 100 000	179	228	248	255	290
Hospitalisation rate per 100 000	28.7	36.8	33.5	33.9	38.2
Hospitalisation duration, days	11.6	12.5	13.1	12.7	12.7

**Conclusions:** We revealed significant increase in incidence, prevalence as well as hospitalisation rates for gout in adults in Minsk (the Republic of Belarus) for the 5 year period (2011–2015) in 1.4, 1.6 and 1.3 times, correspondingly.

#### CLINICAL FEATURES AND RISK FACTORS FOR DEVELOPING GOUT ATTACKS DURING ANTI-TUBERCULOSIS MEDICATION: A CASE-CONTROL STUDY IN SOUTH KOREA

<sup>1</sup>Y.-J. Ha, S.W. Chung<sup>2</sup>, J. Lee<sup>3</sup>, E.H. Kang<sup>1</sup>, Y.J. Lee<sup>1</sup>, Y.W. Song<sup>3</sup>. <sup>1</sup>Division Of Rheumatology, Department Of Internal Medicine, Seoul National University Bundang Hospital, Seongnam; <sup>2</sup>Division Of Rheumatology, Department Of Internal Medicine, Incheon Sarang Hospital, Incheon; <sup>3</sup>Division Of Rheumatology, Department Of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of

**Background:** Gout is a form of inflammatory arthritis that develops in some people with hyperuricemia. Several drugs may induce hyperuricemia and gout attack. Some anti-tuberculosis (TB) medications are also known to increase uric acid level and trigger acute gout attack. However, there have been no well-described studies for gout during anti-TB therapy.

**Objectives:** To investigate the clinical features and risk factors of gout attacks following anti-TB treatment in South Korea.

**Methods:** We conducted the case-control study including 49 patients who developed gout attack following anti-TB medications and 147 age- and sex- matched TB controls without gout attack. Demographic, clinical features and laboratory findings of patients with gout attacks following anti-TB medication were analysed and compared to those of controls in order to establish risk factors associated with gout attack during anti-TB treatment.

**Results:** The mean age was  $67.7 \pm 13.2$  years and 39 patients (79.6%) were male. Twenty-four patients (49.0%) had a previous history of gout. The mean time interval to develop gout attack from the initiation of anti-TB therapy was  $4.13 \pm 4.49$  months. The attacks tended to involve lower extremity joints (43/49, 87.8%), especially the ankle and the first metatarsophalangeal joint. Factors associated with experiencing gout attack during anti-TB medication were higher body mass index (BMI,  $23.7 \pm 3.6$  vs  $21.8 \pm 3.6$ ,  $p = 0.003$ ), higher pre-treatment uric acid level ( $7.2 \pm 2.5$  vs  $6.2 \pm 1.7$  mg/dL,  $p < 0.001$ ), previous history of gout (49.0% vs 1.4%,  $p < 0.001$ ), absence of dyslipidemia (4.1% vs 16.3%,  $p = 0.008$ ), and decreased renal function (eGFR  $63.6 \pm 27.5$  vs  $82.6 \pm 29.9$ ,  $p = 0.003$ ). In multivariate model, higher BMI, chronic kidney disease (CKD, eGFR  $< 60$  ml/min/1.73m<sup>2</sup>), previous history of gout, and pre-treatment hyperuricemia (uric acid  $\geq 6.8$  mg/dL) were

found to be independent risk factors for gout attack following anti-TB medication (table 1).

**Abstract FRI0254 – Table 1.** Multivariate analysis of risk factors for post-TB medication gout

	Odds ratio	95% CI	p-value
Body mass index (BMI)	1.202	1.029–1.403	0.020
Previous history of gout	71.39	12.790–398.467	<0.001
Chronic kidney disease (eGFR $< 60$ ml/min/1.73m <sup>2</sup> )	2.794	1.012–7.719	0.047
Pre-treatment hyperuricemia (Serum uric acid $\geq 6.8$ mg/dL)	4.866	1.770–13.378	0.002

**Conclusions:** TB patients with obesity, history of gout, pre-treatment hyperuricemia, and CKD have higher risk for having gout attack following anti-TB medication. When starting anti-TB therapy in TB patients with these risk factors, physicians should pay attention to the development of gout attack and educate the patients.

FRI0255

#### INJECTION OF CD40 DNA VACCINE AMELIORATES THE AUTOIMMUNE PATHOLOGY OF NON-OBESE DIABETIC MICE WITH SJOGREN'S SYNDROME

Y.-B. Zhou<sup>1</sup>, X. Yuan<sup>1</sup>, Q.-K. Wang<sup>1</sup>, H. Zhang<sup>1</sup>, G.-S. Wang<sup>1</sup>, X.-P. Li<sup>1</sup>, Y.-P. Wang<sup>2</sup>, X.-M. Li<sup>1</sup>. <sup>1</sup>Rheumatology and Immunology, The First Affiliated Hospital of University of Science and Technology of China, Hefei, Anhui, China; <sup>2</sup>Westmead Institute for Medical Research, the University of Sydney, Westmead 2145 NSW, Australia

**Background:** In the patients with primary Sjögren's syndrome (pSS), overexpression of CD40 was reported. The increased CD40 expression contributes to enhance CD40-CD40L interaction and promotes the inflammatory response in various ways.

**Objectives:** To investigate whether CD40 DNA vaccine could inhibit the immune response and slow the disease progression of SS in non-obese diabetic (NOD) mice.

**Methods:** Female 8-week-old NOD mice were randomly divided into 3 groups. CD40 DNA vaccine group received pTaget CD40 DNA vaccine at a weekly dose of 50 ug for 4 weeks. Vector and NS group were administered an equivalent amount of empty vector or NS. Serum anti-CD40 antibody was measured by ELISA. Lymphocytes infiltration in the salivary glands was monitored by focus score (FS) calculation. Salivary CD40 was stained by immunohistochemistry. Splenic lymphocyte phenotypes were analysed by flow cytometry. CD40, TNF- $\alpha$  and IL-6 levels in the salivary glands were detected by PCR. Serum ANA was monitored by immunofluorescence.

**Results:** 1) CD40 DNA vaccination induced anti-CD40 antibody response We found the positive rate on anti-CD40 antibody in vaccine group was 80% at week 6% and 100% at week 10, which was significantly increased compared with that in nonvaccinated ones ( $p < 0.05$  and  $p < 0.01$ , respectively)

2) Expression of CD40 decreased in salivary glands in vaccine group

At week 10, CD40 expression on ductal epithelial and endothelial cells in NOD mice of vaccine group was significantly decreased positive staining. CD40 mRNA expression level showed a significant reduction compared to vector group ( $0.51 \pm 0.31$  vs.  $1.56 \pm 0.53$ ,  $p < 0.05$ ).

3) Down-regulation of lymphocytes infiltration in the salivary glands of mice in vaccine group

At week 10, infiltration of lymphocytes was inhibited in treated group while increased in control group ( $F=5.275$ ,  $P < 0.05$ ). FS was significantly decreased in vaccine group as compared to NS group ( $2.00 \pm 1.73$  vs.  $11.33 \pm 5.51$ ,  $P < 0.05$ ).

Average weight of wet salivary gland and the ratio of average salivary gland weight to body weight of NOD mice in vaccine group were significantly lower than that in control groups ( $p < 0.05$  and  $p < 0.05$ , respectively).

4) CD40 DNA vaccine reduced the expression of TNF- $\alpha$  and IL-6 in the salivary glands

In vaccine group, the expression level of TNF- $\alpha$  mRNA in salivary glands were declined significantly as compared to baseline ( $0.41 \pm 0.25$  vs.  $0.98 \pm 0.16$ ,  $p < 0.05$ ) and IL-6 mRNA expression was down-regulated compared with control groups at week 10 ( $p < 0.05$ ;  $p < 0.01$ , respectively).

5) Disturbances in spleen DC and plasma cell subpopulations

At week 6, the total numbers of CD11c<sup>+</sup>DC decreased as compared with two control groups ( $p < 0.05$  and  $p < 0.05$ , respectively). CD11c<sup>+</sup>DC and CD19<sup>+</sup>CD138<sup>+</sup>plasma cells were significantly reduced compared to basal level ( $p < 0.01$  and  $p < 0.05$ , respectively).

6) Level of ANA reduced in the vaccine group

At week 10, the expression of ANA in HEp-2 cells is strong positive (++++) in both control groups, but only positive (+) in vaccine group.

**Conclusions:** These findings indicate that CD40 DNA vaccine can downregulate the expression of proinflammatory cytokines of TNF- $\alpha$  and IL-6, decrease the percentage of DCs and plasma cells, ameliorate the pathologic change in NOD mice with SS, and thus inhibit the autoimmune inflammation.

FRI0256

#### EFFECTS OF ANIFROLUMAB ON OXIDATIVE STRESS AND MACROPHAGE ACTIVATION: NOVEL BIOMARKERS AND IMPACT OF TYPE I INTERFERON BLOCKADE IN SYSTEMIC LUPUS ERYTHEMATOSUS

X. Guo<sup>1</sup>, S. Wang<sup>1</sup>, L. Wang<sup>2</sup>, L.K. Roskos<sup>1</sup>, W.I. White<sup>1</sup>. <sup>1</sup>MedImmune; <sup>2</sup>AstraZeneca, Gaithersburg, USA

**Background:** Type I interferons (IFNs) drive several aspects of systemic lupus erythematosus (SLE) etiology and pathophysiology. Anifrolumab, a fully human anti-IFN- $\alpha$  receptor monoclonal antibody, substantially reduced disease activity compared with placebo in a Phase IIb study of SLE patients.<sup>1</sup> Previous results indicated beneficial effects of anifrolumab on dysregulated lymphocyte, neutrophil, and complement systems in SLE.<sup>2</sup> However, the impact of type I IFN blockade remains to be fully elucidated.

**Objectives:** We characterised biomarkers for oxidative stress and macrophage activation in SLE and assessed downstream effects of anifrolumab on those two key disease pathways.

**Methods:** In the MUSE study,<sup>1</sup> 305 patients with moderate to severe SLE were randomised in a 1:1:1 ratio to receive placebo or anifrolumab (300 or 1,000 mg) every 4 weeks for 48 weeks. A four-gene expression assay was used to define type I IFN gene signature (IFNGS) test status. In our study, four protein biomarkers were measured in sera of healthy controls (HCs) and SLE patients with samples available at baseline, and 85, 169, and 365 days after administration, using a multiplex luminex immunoassay. Wilcoxon rank-sum test was used to evaluate baseline protein concentrations and posttreatment changes between different groups.

**Results:** Two oxidative stress biomarkers, peroxiredoxin 4 (PRDX4) and aldose reductase (AKR1B1), were found in greater serum concentrations in 195 SLE patients than in 20 HCs ( $p < 0.01$ ). Their increased concentrations were associated with greater SLEDAI scores and abnormal anti-dsDNA concentrations ( $p < 0.05$ ). PRDX4 concentrations were greater for IFNGS test-high ( $n=144$ ) vs IFNGS test-low ( $n=51$ ) patients ( $p < 0.01$ ), whereas AKR1B1 was not associated with type I IFNGS-test status. Anifrolumab suppressed PRDX4 in IFNGS test-high patients compared with placebo ( $p < 0.05$ ). In contrast, no significant changes were observed for AKR1B1 after anifrolumab treatment. Folate receptor 3 (FOLR3) and CD163 are markers of activated macrophages, the former of which has not been characterised in SLE. Our results demonstrated greater concentrations of both FOLR3 and CD163 in IFNGS test-high than in IFNGS test-low patients and HCs, along with significant associations with SLEDAI score and anti-dsDNA concentrations. Anifrolumab reduced serum concentrations of both FOLR3 and CD163 in IFNGS test-high but not IFNGS test-low patients vs. placebo ( $p < 0.05$ ). Moreover, cellular enumeration data demonstrated anifrolumab-induced upregulation of

monocyte count in IFNGS test-high patients, which may result from reduced activation, apoptosis, and/or tissue infiltration of monocytes/macrophages.

**Conclusions:** Our results identified PRDX4 as an oxidative stress marker and FOLR3 as a macrophage activation marker associated with disease activities and type I IFNGS test status in SLE. Anifrolumab administration elicits reduced oxidative stress and decreased monocyte/macrophage activation, which may contribute to the clinical efficacy of anifrolumab in SLE patients.

#### THE STAT4 SLE RISK ALLELE RS7574865[T] IS ASSOCIATED WITH INCREASED IL-12-INDUCED IFN-GAMMA PRODUCTION IN T CELLS FROM SLE PATIENTS

N. Hagberg<sup>1</sup>, M. Joelsson<sup>1</sup>, D. Leonard<sup>1</sup>, S. Reid<sup>1</sup>, M.-L. Eloranta<sup>1</sup>, J. Mo<sup>2</sup>, M. Nilsson<sup>2</sup>, A.-C. Syvänen<sup>3</sup>, Y.T. Bryceson<sup>4,5</sup>, L. Rönnblom<sup>1</sup>. <sup>1</sup>Department of Medical Sciences, Rheumatology and Science for Life Laboratories, Uppsala University, Uppsala; <sup>2</sup>Respiratory, Inflammation and Autoimmunity, IMED Biotech Unit, AstraZeneca, Gothenburg; <sup>3</sup>Department of Medical Sciences, Molecular Medicine and Science for Life Laboratories, Uppsala University, Uppsala; <sup>4</sup>Department of Medicine, Center for Hematology and Regenerative Medicine, Karolinska Institutet, Karolinska University Hospital Huddinge, Stockholm, Sweden; <sup>5</sup>Department of Clinical Sciences, Broegelmann Research Laboratory, University of Bergen, Bergen, Norway

**Background:** Genetic variants in the transcription factor *STAT4* are associated with increased susceptibility to systemic lupus erythematosus (SLE) and a more severe disease phenotype.

**Objectives:** This study aimed to clarify how the SLE-associated intronic *STAT4* risk variant rs7574865[T] affects the function of immune cells in SLE.

**Methods:** Peripheral blood mononuclear cells (PBMCs) were isolated from 52 SLE patients in remission (SLEDAI-2K $\leq$ 4). *STAT4* and *STAT1* protein levels and phosphorylation status in response to interferon (IFN)- $\alpha$ , IFN- $\gamma$ , or interleukin (IL)-12 were determined, before and after pre-activation of cells with phytohaemagglutinin (PHA) and IL-2, in CD56<sup>dim</sup> NK cells, CD56<sup>bright</sup> NK cells, B cells, CD4<sup>+</sup> T cells, CD8<sup>+</sup> T cells and monocytes by flow cytometry. The frequency of IFN- $\gamma$ <sup>+</sup> cells upon IL-12 or PMA (phorbol 12-myristate-13-acetate) stimulation and the frequency of T-bet<sup>+</sup> cells was determined in PHA/IL-2 pre-activated cells. Cellular responses and phenotypes were correlated with *STAT4* risk allele carrier status (rs7574865[T], 21 homozygous protective, 22 heterozygous and 9 homozygous risk) using an additive linear regression model. Janus kinase inhibitors (JAKi) selective for TYK2 (TYK2i, Compound 35) or JAK2 (JAK2i, BMS-911543) were evaluated for inhibition of IL-12 or IFN- $\gamma$ -induced activation of SLE PBMCs.

**Results:** In resting PBMCs, the *STAT4* risk allele was neither associated with protein levels of *STAT4* or *STAT1*, nor cytokine-induced phosphorylation of *STAT4* (pSTAT4) or *STAT1* (pSTAT1). However, following PHA/IL-2-activation, CD8<sup>+</sup> T cells from *STAT4* risk allele carriers displayed increased levels of *STAT4* ( $p=0.04$ ), resulting in increased pSTAT4 in response to IL-12 ( $p=0.003$ ) and IFN- $\alpha$  ( $p=0.04$ ). Analysis of T cell subsets revealed that the effect was seen in CD45RA<sup>+</sup>CD57<sup>-</sup> naïve and CD45RA<sup>+</sup>CD57<sup>+</sup> memory CD8<sup>+</sup> T cells, but not in CD45RA<sup>+</sup>CD57<sup>+</sup> memory or CD45RA<sup>+</sup>CD57<sup>+</sup> effector CD8<sup>+</sup> T cells. A slight increase in *STAT4* protein levels and IL-12-induced pSTAT4 was also observed in CD4<sup>+</sup> T cells from *STAT4* risk allele carriers ( $p=0.08$  and  $p=0.09$ , respectively). *STAT4* risk allele carriers displayed an augmented IL-12-induced IFN- $\gamma$  production in CD8<sup>+</sup> and CD4<sup>+</sup> T cells ( $p=0.03$  for both), whereas PMA-induced IL-12 production was normal ( $p=0.31$  and  $p=0.10$ , respectively). T-bet expression was not correlated to the *STAT4* genotype. The TYK2i and the JAK2i efficiently blocked IL-12 and IFN- $\gamma$ -induced activation of PBMCs from *STAT4* risk patients, respectively.

**Conclusions:** T cells from SLE patients carrying the *STAT4* risk allele rs7574865 [T] display an augmented response to IL-12 and IFN- $\alpha$ . This subset of patients may benefit from JAKi treatment.

### FRI0258 COMPARISON OF ELISA AND MULTIPLEX TECHNIQUES FOR QUANTIFYING A URINE BIOMARKERS PANEL FOR LUPUS NEPHRITIS IN CHILDREN

E.M. Smith<sup>1,2</sup>, M.W. Beresford<sup>1,2</sup>. <sup>1</sup>Paediatric Rheumatology, Alder Hey Children's NHS Foundation Trust; <sup>2</sup>Women and Children's Health, Institute of Translational Medicine, University of Liverpool, Liverpool, UK

**Background:** A urine 'biomarker panel' comprising alpha-1-acid-glycoprotein (AGP), ceruloplasmin (CP), transferrin (TF) and lipocalin-like-prostaglandin-D synthase (LPGDS) has been shown to cross-sectionally perform to an 'excellent' level for Lupus Nephritis (LN) identification in children.<sup>1</sup> Quantification of all four biomarkers by enzyme linked immunoabsorbant assay (ELISA) techniques is time consuming and costly. Therefore, novel methods of biomarker panel quantification are required to facilitate future urine biomarker led monitoring studies.

**Objectives:** The main objective was to compare the ability of ELISA and multiplex biomarker quantification techniques to differentiate active versus inactive LN when the biomarkers are considered individually and in combination.

**Methods:** The urinary biomarkers were quantified by both ELISA and a newly developed, custom multiplex platform in participants of the UK Juvenile Systemic Lupus Erythematosus (JSLE) Cohort Study. Multiplex assay development involved identification of appropriate antibody pairs, assessment of JSLE urine sample matrix effects and range finding in JSLE patient samples. Patients were categorised as having active LN (renal domain BILAG score of A, B and previous histological confirmation of LN) or inactive LN (renal BILAG score D or E). Firth's penalised binary regression with AUC ROC analysis was used to compare the ability of multiplex and ELISA assays to detect active LN disease state univariately and in combination.

**Results:** Biomarker analysis was undertaken on 54 JSLE patients (13 active, 41 in-active). Assessment of each biomarker univariately demonstrated similar AUC values regardless of the biomarker quantification technique; LPGDS (ELISA AUC 0.826, multiplex AUC 0.829), TF (ELISA AUC 0.829, multiplex AUC 0.996), CP (ELISA AUC 0.901, multiplex AUC 0.983), AGP (ELISA AUC 0.934, multiplex AUC 0.979) (see table 1). Combining the multiplex biomarker data in the same order as the original ELISA based study<sup>1</sup> led to a similar progressive increase in AUC as biomarkers were added to the model (optimal model including AGP +CP + LPGDS+TF ELISA AUC=0.951, multiplex=0.995). For all biomarker combinations, the multiplex-derived AUC was higher than the ELISA AUC.

Abstract FRI0258 – Table 1. AUC values generated looking at each biomarker univariately

Individual biomarkers	ELISA AUC	Multiplex AUC
LPGDS	0.826	0.829
TF	0.829	0.996
CP	0.901	0.983
AGP	0.934	0.979

Abstract FRI0258 – Table 2. Comparison of biomarker combination AUC ROC values

Biomarker combinations	ELISA AUC	Multiplex AUC
AGP	0.880	0.979
AGP+CP	0.937	0.986
AGP+CP+LPGDS	0.942	0.985
AGP+CP+ LPGDS+TF	0.951	0.995

**Conclusions:** This new LN urine biomarker panel multiplex assay has been shown to display a comparable ability for active LN disease state identification as compared to existing ELISA techniques. The major advantage to this approach is that it reduces cost, processing time and the volume of sample required, as compared to ELISA techniques, representing a key enabler for future clinical studies.

### FRI0259 IN VITRO INDUCED REGULATORY T-CELLS CAN AMELIORATE SEVERITY OF PRISTANE INDUCED LUPUS (PIL)

B. Jacobs<sup>1</sup>, H. Leiss<sup>2</sup>, I. Gessl<sup>2</sup>, A. Puchner<sup>2</sup>, J. Smolen<sup>2</sup>, G. Stummvoll<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, Providence Saint Vincent Medical Center, Portland, USA; <sup>2</sup>Department of Rheumatology, Medical University of Vienna, Vienna, Austria

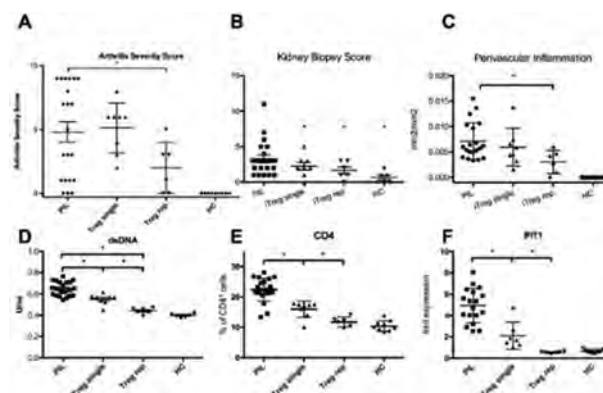

**Background:** Pristane induced lupus (PIL) is an established murine model of induced systemic lupus erythematosus (SLE). Mice develop specific autoantibodies and show symptoms of SLE including arthritis, glomerulonephritis and haemorrhagic pulmonary capillaritis.

**Objectives:** To investigate the therapeutic effects of *in vitro*-induced regulatory T cells (iTreg) in the murine model of PIL.

**Methods:** BALB/c mice were injected i.p. with 0.5 ml of pristane (PIL) or PBS (control). Naive CD4<sup>+</sup> thymocytes were sorted and cultured and cell suspensions with >80% CD4<sup>+</sup>FoxP3<sup>+</sup> cells (iTreg) were injected i.v. (i) once when PIL was induced (5 × 10<sup>6</sup> iTreg (iTreg-single)) or (ii) every 4 weeks (1 × 10<sup>6</sup> iTreg, iTreg-rep). Mice were monitored for paw swelling and grip strength. After 8 months, histological analysis quantified cartilage degradation, number of osteoclasts, extent of inflammation and bone erosion. Glomerulonephritis and pneumonitis were quantified using the kidney biopsy score and a histomorphometric image analysis system; inflammatory tissue was analysed by tissue cytometry. Serum levels of auto-antibodies were measured by ELISA. Frequencies of B cells, activated and regulatory CD4<sup>+</sup> T cells and Th1, Th2, Th17 cells were measured by flow cytometry. FlowCytomix Pro was used to measure serum cytokines. RT-qPCR was used to measure expression levels of interferon (IFN)-signature and T-cell subset related as well as inflammation-associated genes.

**Results:** Monthly injections of 1 × 10<sup>6</sup> iTreg reduced the clinical and histological severity of PIL-arthritis. This was seen by a higher mean grip strength, less mean paw swelling, retardation of symptom onset and a lower summative arthritis severity score (figure A). There was significant reduction of arthritis severity in all histological parameters and in the percentage of affected mice with erosive arthritis (33% of iTreg-rep mice vs 62% of PIL-mice). A single boost of 5 × 10<sup>6</sup> iTreg could not prevent joint manifestation, however a slight retardation in 'loss of grip strength' and significantly less erosive area was seen. In regards to cellular composition of the inflammatory tissue in paws, a significantly increased relative amount of CD4<sup>+</sup>Foxp3<sup>+</sup> cells was seen in the iTreg-rep group compared to PIL group.

Repeatedly injected mice (iTreg-rep) had significantly less renal disease (glomerular activity score) (figure B) and pulmonary involvement (perivascular inflammatory area) (figure C) compared to PIL. iTreg-rep mice had significantly lower serum levels of disease-associated auto-antibodies (figure D). Upon restimulation, splenic CD4<sup>+</sup> cells in iTreg-rep showed a less pronounced Th1, Th2 and Th17 response as well as lower percentages in B- and activated T-cells, whereas the percentage of Treg was higher than in all other groups (figure E). FlowCytomix analysis showed reduced cytokine production after repeated iTreg administration. Correspondingly, iTreg-rep showed decreased expressions of IFN-signature-, T-cell subset- and inflammatory cytokine related genes (figure F).

**Conclusions:** Repeated injections of iTreg ameliorate the clinical, histological, serological as well as the genetic severity of PIL-manifestations. A single boost of iTreg at time of disease induction does not prevent manifestations, but retards the

onset of symptoms. Thus iTreg have significant positive effects on PIL, which may have consequences for future approaches in treating SLE.

### POLYMORPHISMS OF STAT4 AND MIR146A PREDICT THE ACHIEVEMENT OF 5 YEARS REMISSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C. Perricone<sup>1</sup>, C. Ciccacci<sup>2</sup>, F. Ceccarelli<sup>1</sup>, G. Mettola<sup>1</sup>, I. Leccese<sup>1</sup>, F.R. Spinelli<sup>1</sup>, C. Alessandri<sup>1</sup>, C. Politi<sup>2</sup>, A. Latini<sup>2</sup>, G. Novelli<sup>2</sup>, G. Valesini<sup>1</sup>, P. Borgiani<sup>2</sup>, F. Conti<sup>1</sup>. <sup>1</sup>Lupus Clinic, Rheumatology, Department of Internal Medicine, Sapienza University of Rome; <sup>2</sup>Department of Biomedicine and Prevention, Section of Genetics, University of Rome "Tor Vergata", Rome, Italy

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with a complex pathogenesis in which genes and environmental factors interact leading to a protean clinical picture. Treat-to-target recommendations have identified 'remission' as a target in SLE, since achievement of remission improves the outcome and is associated with decreased damage progression. Nonetheless, predicting factors for the achievement of remission are lacking. It is likely that genes associated with SLE pathogenesis may influence the disease course.

**Objectives:** Thus, our aim was to analyse previously identified loci associated with SLE in a cohort of SLE patients to evaluate their influence on remission achievement.

**Methods:** We recruited 117 Italian SLE patients. A panel of 34 SNPs in 19 genes involved in immune response, autophagy and inflammation, was selected. SNPs genotyping was performed by allelic discrimination assay by TaqMan assays (Applied Biosystems, Foster City, CA, USA) and ABI PRISM 7000. The main clinical/laboratory features (including injury index and disease activity) were collected on an electronic platform. Remission was defined according to Zen et al.<sup>1</sup> and evaluated over 5 years. A genotype/phenotype correlation analysis was performed.

**Results:** The variant alleles of rs7574965 (STAT4) ( $p < 0.001$ ) and rs2910164 (MIR146a) ( $p = 0.031$ ) were significantly associated with lack of achievement of 5 years remission in SLE. Specifically, patients carrying the C allele of MIR146a were less likely to achieve 5 years remission ( $p = 0.01$ , OR 0.235, 95% CI 0.074–0.752) as well as to achieve remission after 1, 2 and 3 years of evaluation ( $p = 0.002$ ,  $p = 0.001$ ,  $p = 0.002$ , respectively). Among the clinical and laboratory features, 5 years remission was less likely to be achieved by patients who had arthritis in their clinical history ( $p = 0.007$ ), and who tested positive for anti-dsDNA ( $p = 0.005$ ). In a multinomial logistic regression analysis, arthritis ( $p = 0.022$ , Exp(B) = 0.255, 95% CI 0.079–0.820), anti-dsDNA ( $p = 0.003$ , Exp(B) = 0.166, 95% CI 0.051–0.537) and MIR146a rs2910164 gene variant ( $p = 0.046$ , Exp(B) = 0.250, 95% CI 0.064–0.974) were confirmed to be independent risk factors for unachieved 5 years remission (table 1).

Abstract FRI0260 – Table 1

REMISSION	Exp (B)	Exp (B) 95% CI	
		Lower	Upper
Arthritis	0255	0079	0,82
anti-dsDNA	0166	0051	0537
STAT4	0354	0,11	1139
mir146A	0,25	0064	0974

**Conclusions:** We describe for the first time the contribution of STAT4 and MIR146a SNPs as predicting factors for the achievement of 5 years remission in SLE. No genetic study has been performed so far in SLE, while a genetic profile of patients may be useful to predict the disease outcome.

### ASSESSMENT OF AUTOPHAGE FUNCTION IN SYSTEMIC LUPUS ERYTHEMATOSUS IN RESPECT OF HYPERLIPIDEMIA AND IMMUNOSUPPRESSIVE DRUGS

A.S. Hamada<sup>1</sup>, M.I. aref<sup>1</sup>, W.A. salahdin<sup>2</sup>. <sup>1</sup>Clinical Immunology, Al Azhar University Hospital, Cairo; <sup>2</sup>Rheumatology, Benha University Hospital, Benha, Egypt

**Background:** Autophagy is an orchestrated homeostatic process to eliminate unwanted proteins and damaged organelles. Lipid turnover, as well, is controlled by autophagy through a process described as lipophagy. Defective lipophagy has been already linked to important metabolic disorders such as fatty liver, obesity and atherosclerosis.

**Objectives:** Assessment of autophagy focusing on lipids regulation in untreated newly diagnosed systemic lupus Erythematosus (SLE) patients and after three months of treatment with immunosuppressive drugs.

**Methods:** Subjects in this study have been divided into three groups. Group 1 included 60 newly diagnosed SLE patients before receiving any treatment, group2 included the same subjects of group 1 after three months of treatment with immunosuppressive drugs and group 3 included 30 healthy donors of matched age and sex as a control group. For each subject, disease activity was assessed by (SLE-DAI) score, lipid profile was measured in addition to evaluation of lipids uptake, enhanced phagocytosis and intracellular killing ability of monocytes and neutrophils using Sudan Black B stain and Nitroblue tetrazolium stain mixed with latex particles coated with antibodies. Microscopic pictures were captured and quantified by ImageJ.

**Results:** 95% of patients were females(57/60) with mean of age(39.7±8.6). Mean of SLEDAI score in group 1 was (18.6±3.4) decreased in group 2 (3 months after treatment) to (10.4±4.2). There was a positive correlation between total cholesterol, LDL and triglycerides and disease activity(SLEDAI score) ( $r = 0.677$ ,  $r = 0.603$  and  $r = 0.718$ ; respectively). On the contrary, There was a negative correlation between HDL and disease activity( $r = -0.396$ ). Furthermore, there was a negative correlation between lipid content of cells and intracellular killing and disease activity( $r = -0.258$  and  $r = -0.324$ ; respectively). After 3 months, 100% of patients were taking Corticosteroids and Hydroxychloroquine(60/60).18.3% of patients received Azathioprine(11/60), 40.0% received Cyclophosphamide(24/60) and 15% received Mycophenolate(9/60) besides Corticosteroids and Hydroxychloroquine. Comparing group 2 to group 1, there was significant increase in cholesterol, LDL and triglycerides ( $p = 0.027$ ,  $p = 0.021$  and  $p = 0.017$ ; respectively) while HDL showed insignificant difference( $p = 0.0740$ ). Lipid content in cells and intracellular killing significantly decreased( $p = 0.0322$  and  $p = 0.0271$ ; respectively).

**Conclusions:** Autophagy is deficient in patients with SLE aggravated by immunosuppressive drugs so they are more susceptible to infections and dyslipidemia. Consequently, lipid lowering drugs are definitely required to decrease comorbidity.

### MONITORING DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS WITH DIGITAL ELISA QUANTIFICATION OF SERUM INTERFERON- $\alpha$

S. Mouries-Martin<sup>1</sup>, A. Mathian<sup>1</sup>, K. Dorgham<sup>2</sup>, H. Devilliers<sup>3</sup>, F. Cohen-Aubart<sup>1</sup>, L. N. Garrido Castillo<sup>2</sup>, J. Haroche<sup>1</sup>, M. Hie<sup>1</sup>, M. Pineton De Chambrun<sup>1</sup>, M. Miyara<sup>1</sup>, M. Pha<sup>1</sup>, D. Lê Thi Huong<sup>1</sup>, F. Rozenberg<sup>4</sup>, G. Gorochov<sup>5</sup>, Z. Amoura<sup>1</sup>. <sup>1</sup>French National Referral Center for Systemic Lupus Erythematosus, Antiphospholipid Antibody Syndrome and Other Autoimmune Disorders, Service de Médecine Interne 2, Institut E3M, Assistance Publique-Hôpitaux de Paris (APHP), Groupement Hospitalier Pitié-Salpêtrière; <sup>2</sup>Inserm UMRS1135, Centre d'Immunologie et des Maladies Infectieuses (CIMI-Paris), Sorbonne Universités, UPMC Univ Paris 06, Paris; <sup>3</sup>Centre Hospitalier Universitaire de Dijon, Hôpital François-Mitterrand, Service de Médecine Interne 2 et Centre d'Investigation Clinique, Inserm CIC 1432, DIJON; <sup>4</sup>Service de Virologie, Assistance Publique-Hôpitaux de Paris (APHP), Hôpital Cochin; <sup>5</sup>Inserm UMRS1135, Centre d'Immunologie et des Maladies Infectieuses (CIMI-Paris), Assistance Publique-Hôpitaux de Paris (APHP), Groupement Hospitalier Pitié-Salpêtrière, Paris, France

**Background:** To date, anti-dsDNA–Ab titration, better achieved with the Farr test, has been used to monitor global disease activity in systemic lupus erythematosus (SLE). Indeed, anti-DNA–Ab-positivity is associated with overall SLE activity. However, the sensitivity and specificity of that association are relatively low. The close association between Interferon alpha (IFN $\alpha$ ) expression and SLE activity suggests that monitoring this cytokine might help physicians better evaluate

disease activity. Unfortunately, no reliable simple or standardised assays to quantify IFN $\alpha$  are available in routine clinical practice. The new single-molecule array (Simoa) assay, also called digital ELISA, enables direct IFN $\alpha$  quantification at attomolar (i.e. fg/mL or 10<sup>-15</sup> moles/mL) concentrations corresponding to 5,000-fold-increased sensitivity over commercial ELISAs.

**Objectives:** We hypothesised that serum-IFN $\alpha$  levels determined with this new standardised assay would be a better biomarker of SLE activity than the Farr test, still considered the "gold standard" for this purpose. The primary objective of this study was to characterise the relationship between digital ELISA-determined serum-IFN $\alpha$  concentrations and clinically assessed SLE activity. We also compared that assay to a functional, sensitive biological assay (bioassay), based on IFN $\alpha$  antiviral properties, used routinely in our institution for 30 years.

**Methods:** IFN $\alpha$  concentrations in serum samples from 150 consecutive SLE patients and 68 healthy donors in a cross-sectional study were determined with the digital ELISA and the bioassay. For SLE patients, clinical characteristics, Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), therapeutic regimen, Farr assay, C3 levels and other usual biological parameters were recorded on the day of the blood draw.

**Results:** Based on healthy blood donors, the abnormal serum-IFN $\alpha$  level threshold value was 136 fg/mL. Next, using receiver operating characteristics curves for an SLE-patient series, widely heterogeneous for disease activity and organ involvement, the threshold IFN $\alpha$  value associated with active disease was 266 fg/mL. The digital ELISA-assessed serum-IFN $\alpha$  level was a better biomarker of disease activity than the Farr test: its specificity, positive likelihood ratio and positive-predictive value better discerned active SLE and a flare. The digital ELISA was more sensitive than the bioassay to detect low-abnormal serum-IFN $\alpha$  concentrations and patients with low disease activity. In multivariate analyses, abnormal digital ELISA-determined IFN $\alpha$  concentrations were significantly associated with SLE-specific fever, active mucocutaneous lupus, active lupus nephritis and anti-Sm Abs but no other anti-ribonucleoprotein Abs (i.e., anti-Ro/SSA 52, anti-Ro/SSA 60, anti-La/SSB and anti-RNP).

**Conclusions:** Direct serum-IFN $\alpha$  determination with a highly sensitive assay might improve monitoring of clinical SLE activity and selection of the best candidates for anti-IFN $\alpha$  treatment.

#### CHARACTERISATION OF EPITHELIUM-ASSOCIATED FCRL4+ B CELLS FROM PAROTID GLANDS OF PATIENTS WITH SJÖGREN'S SYNDROME USING SINGLE CELL RNA SEQUENCING

G.M. Verstappen<sup>1</sup>, J.A. Ice<sup>2</sup>, H. Bootsma<sup>1</sup>, S.A. Pringle<sup>1</sup>, E.A. Haacke<sup>1,3</sup>, F. K. Spijker<sup>4</sup>, C.J. Lessard<sup>2,5</sup>, F.G. Kroese<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; <sup>2</sup>Arthritis and Clinical Immunology Research Program, Oklahoma Medical Research Foundation, Oklahoma City, USA; <sup>3</sup>Pathology; <sup>4</sup>Oral and Maxillofacial Surgery, University of Groningen, University Medical Center Groningen, Groningen, Netherlands; <sup>5</sup>Pathology, University of Oklahoma Health Sciences Center, Oklahoma City, USA

**Background:** A subset of B cells expressing the inhibitory Fc receptor-like protein 4 (FcRL4) is found in salivary gland lesions of patients with primary Sjögren's

syndrome (pSS). FcRL4 +B cells are associated with ductal epithelial cells forming lymphoepithelial lesions (LEL), in particular within parotid glands<sup>1</sup>. Furthermore, FcRL4 is expressed by mucosa-associated lymphoid tissue (MALT) lymphoma B cells.

**Objectives:** We aimed to investigate, by single cell and bulk RNA sequencing, how the gene expression profile of FcRL4 +B cells differs from FcRL4-negative naive and memory B cells in salivary gland tissue from pSS patients. We hypothesised that FcRL4 +B cells contribute to LEL formation and are prone to lymphomagenesis.

**Methods:** Parotid gland biopsies of 5 pSS patients without MALT lymphoma were obtained. Single cell suspensions were prepared by mechanical disruption and enzymatic digestion. The cells were incubated with anti-CD19, anti-CD27 and anti-FcRL4 antibodies, and sorted as single cells or 5 cells per well based on the following definitions: CD19 +CD27-FcRL4- ('naive'), CD19 +CD27+FcRL4- (memory) and CD19 +FcRL4+ (FcRL4+). Library preparation was done using an in-house SMARTseq2 protocol and sequencing was done on an Illumina HiSeq2500.

**Results:** Samples from 4 pSS patients passed quality control and were included. A total of 160 single cells and 360 cells in bulk were included in the analysis. Genes identified by differential expression were subjected to gene pathway analysis. Both in single cell and bulk samples, multiple genes coding for integrins, such as *ITGAX* (CD11c), were significantly upregulated in FcRL4 +B cells. Gene Ontology pathways that showed the highest upregulation in FcRL4 +B cells (both single cell and bulk) were receptor binding, GTPase and protein kinase pathways. Analysis of bulk samples further revealed that expression levels of genes encoding for Src tyrosine kinases, genes involved in the NF- $\kappa$ B pathway, *CXCR3*, and *TNFRSF13B* (TACI), among others, were significantly upregulated in FcRL4 +B cells, compared with either naive or memory B cells. Expression levels of *CD40* were significantly decreased in FcRL4 +B cells.

**Conclusions:** FcRL4 +B cells in salivary glands of pSS patients show upregulation of genes involved in homing and cell adhesion, consistent with their tissue location close to the epithelium. FcRL4 +B cells also show increased levels of transcripts that induce inflammation and B cell survival. These cells exhibit all characteristics of chronically stimulated CD11c+memory B cells, and we speculate that FcRL4 +B cells contribute significantly to the epithelial damage seen in the glandular tissue of pSS patients.

#### ROLE OF P-GP IN PATHOGENIC CONVERSION OF TH17 CELLS IN LUPUS NEPHRITIS LEADING TO GLUCOCORTICOID RESISTANCE

A. Jaiswal<sup>1</sup>, M.K. Rai<sup>2</sup>, V. Agarwal<sup>2</sup>, N. Prasad<sup>1</sup>. <sup>1</sup>Department of Nephrology; <sup>2</sup>Department of Clinical Immunology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India

**Background:** Th17 cells and cytokine IL-17 are mainly involved in autoimmunity. Recently IL-17/IFN- $\gamma$  double-positive Th17 cell were found to be allied with inflammatory diseases. P-glycoprotein (P-gp) +ve Th17 cells are refractory to steroid. P-gp on lymphocyte effluxes out steroid and prevents its action. We conducted this study with hypothesis that P-gp positive IL-17/IFN- $\gamma$  double +ve Th17 are one of key pharmacokinetic and pharmacodynamic modulator liable for steroid resistance in lupus nephritis (LN).

**Objectives:** We planned to study the frequency of P-gp expressing pathogenic Th17 cells in steroid responsive and non-responsive steroid patients.

**Methods:** We analysed the frequency of pathogenic IL-17/IFN- $\gamma$  double-positive Th17 lymphocytes and P-gp expression on their surface by flowcytometry in responsive (n=52; mean age 34.06 $\pm$ 10.84) and non-responsive (n=25; mean age 37.29 $\pm$ 13.73) patients. We also included 10 age and sex matched healthy controls. All patients were biopsy proven LN.

**Results:** We found a significant increase in the frequency of Th17 (p=0.001); Th17 (p=0.006) and IL-17/IFN- $\gamma$  double positive Th17 (p=0.006) and IL-17/IFN- $\gamma$  double-positive Th17 (<0.001) cells in non-responsive as compared to responsive patients and healthy controls (p<0.001). Of the total Th17; Th17 and pathogenic Th17; 78.45%; 72.37% and 95.8% cells expressed P-gp on their surface in non-responsive; 45.0%; 30.27% and 30.1% cells expressed P-gp in responsive group; and 30.91%; 15.51% and 15.62% in healthy control respectively.

**Conclusions:** Higher frequency of IL-17/IFN- $\gamma$  doublepositive Th17 cell with P-gp expression may be associated immunological and pharmacological factor for steroid resistance in LN.

#### FRI0265 ANGIOGENIC T CELLS IN PRIMARY SJÖGREN'S SYNDROME: A DOUBLE-EDGED SWORD

A. Alunno<sup>1</sup>, M. Manetti<sup>2</sup>, O. Bistoni<sup>1</sup>, S. Cipriani<sup>1</sup>, L. Ibba Manneschi<sup>2</sup>, R. Gerli<sup>1</sup>.

<sup>1</sup>Department of Medicine, Rheumatology Unit, University of Perugia, Perugia;

<sup>2</sup>Department of Experimental and Clinical Medicine, Section of Anatomy and Histology, University of Florence, Florence, Italy

**Background:** Angiogenic T cells (Tang) have been recently identified within colonies of endothelial progenitor cells (EPCs) as mediators of endothelial repair. Both Tang and EPCs are reduced in rheumatoid arthritis and this contributes to persistent endothelial damage and eventually increased cardiovascular risk. In primary Sjögren's syndrome (pSS), EPCs are expanded but no data are currently available about Tang.

**Objectives:** Aim of this study was to assess Tang (CD3 +CD31+CXCR4+) in peripheral blood (PB) and target organs of pSS as well as the association with EPCs (CD34 +CD133+VEGFR-2+) and clinical and serological features of the disease.

**Methods:** Thirty-six pSS patients and 20 sex- and age-matched healthy donors (HD) were enrolled. Phenotypic analysis of peripheral blood mononuclear cells was performed by flow cytometry using FITC, Pe, Pe-Cy7 or AlexaFluor647 labelled anti-human CD3, CD31, CXCR4, CD4, CD8, CD28, CD34, CD133, VEGFR-2, and IL-17 antibodies. Minor salivary gland (MSG) biopsies from 8 pSS patients were studied and compared to samples from 12 patients with sicca symptoms and either non-specific chronic sialadenitis (NSCS) or normal parenchyma (n=6 each). MSG sections were subjected to immunofluorescence staining to assess the presence of CD3 +CD31+CXCR4+Tang cells and the expression of the CXCR4-ligand CXCL12/SDF-1 chemokine.

**Results:** Circulating Tang were expanded in pSS compared to HD and were directly correlated to EPCs. Both Tang and EPCs directly correlated with disease activity as calculated with the EULAR Sjögren's syndrome disease activity index (ESSDAI). Over 60% of Tang lacked CD28 revealing a senescent phenotype. Only a small proportion of Tang displayed either CD4 or CD8, the majority of Tang being therefore CD4-CD8- double negative (DN). A subset of Tang produced IL-17 and the highest proportion of IL-17-producing cells was observed among DN cells. Immunofluorescence analyses revealed the exclusive presence of infiltrating Tang cells along with increased expression of CXCL12/SDF-1 in pSS MSGs compared to either NSCS or normal MSGs.

**Conclusions:** Circulating Tang cells are expanded in pSS, display a senescent phenotype, are mainly CD4-CD8- DN and produce IL-17. Moreover, Tang cells home to and infiltrate MSGs in pSS, presumably through the SDF-1/CXCR4 chemotactic axis. Our data suggest that besides their positive effect together with EPCs in endothelial repair, Tang cells may contribute to disease pathogenesis.

Alarcon<sup>5</sup>, J.O. Pers<sup>4</sup>, C. Lopez-Pedraza<sup>1</sup>, on behalf of PRECISESADS Clinical Consortium and Precisesads Flow Cytometry Collaborative Group. <sup>1</sup>GC-5/Rheumatology, Reina Sofia Hospital-Imibic, Cordoba; <sup>2</sup>FIMABIS-Virgen de la Victoria Hospital, Malaga; <sup>3</sup>Radiology, Reina Sofia Hospital-Imibic, Cordoba, Spain; <sup>4</sup>Université de Brest, Brest, France; <sup>5</sup>Genyo, Granada, Spain

**Objectives:** This study, developed within the IMI-JU project PRECISESADS framework, aimed to determine the enrichment on CD14 +and CD16+ monocyte subpopulations in SLE, APS and APS +SLE patients, and to investigate their role in the pathogenesis of these diseases.

**Methods:** The frequencies of monocyte subpopulations in the peripheral blood of 54 healthy donors and 46 SLE patients included in the PRECISESADS study (preliminary data) were determined by flow cytometry. A second cohort of 21 APS +SLE patients and a third cohort of 19 APS patients were included. Clinical profile,

proinflammatory circulating mediators, and peroxide levels were analysed. Carotid intima media thickness (CIMT) was evaluated as atherosclerosis marker

**Results:** The CD14 +CD16+ (non-classical) monocyte subset was reduced in SLE patients. Their frequencies were negatively associated with the positivity for anti-dsDNA, anti-SSB, anti-SSA and anti-U1RNP autoantibodies, as well as with renal involvement, which might reflect a recruitment process of this subset in renal tissues. Correlation studies further indicated a link between the reduced frequency of non-classical monocytes and increased levels of circulating inflammatory mediators. Conversely, SLE patients with a previous history of thrombosis displayed a significant increase in circulating CD14 +CD16+ monocytes in relation to those without previous thrombotic manifestations. These results prompted us to evaluate the proportion and profile of this inflammatory subtype in parallel cohorts of SLE +APS and APS patients, on which thrombosis constitute the main clinical disorder.

SLE +APS patients showed enrichment in intermediate (CD14 ++CD16+) and non-classical monocytes, associated with the positivity for anti-dsDNA antibodies and the presence of atheroma plaques. Correlations among the frequency of those monocyte subsets and inflammatory mediators, and circulating cytokines, were also demonstrated. Yet, SLE +APS patients with renal involvement displayed reduced proportion of circulating intermediate and non-classical monocytes, suggesting that, as in the case of SLE patients, circulating CD16 +cells might have migrated to the kidney.

In APS patients we also saw enrichment of the CD16 +inflammatory subsets, associated to recurrent thrombotic events and a pathologic CIMT, pointing out that such subsets are associated with CVD. The scores of various markers related to autoimmunity, oxidative stress and prothrombotic molecules further correlated with the proportions of intermediate and non-classical monocytes.

**Conclusions:** Circulating CD16 +monocytes might constitute an important subpopulation of proinflammatory cells, whose frequency might identify APS, APS +SLE and SLE patients suffering thrombosis, atherosclerosis and organ involvement.

#### FRI0267 CHARACTERISATION OF THE MOLECULAR PROFILE OF ALTERED GENES AND PATHWAYS IN MONOCYTES OF ANTIPHOSPHOLIPID SYNDROME PATIENTS RELATED TO THEIR ATHEROTHROMBOTIC STATUS. EFFECTS OF IN VIVO UBIQUINOL SUPPLEMENTATION

C. Perez-Sanchez<sup>1</sup>, M.A. Aguirre<sup>1</sup>, L. Perez-Sanchez<sup>1</sup>, M. Luque-Tevar<sup>1</sup>, N. Barbarroja<sup>1</sup>, P. Ruiz-Limon<sup>1</sup>, Y. Jimenez-Gomez<sup>1</sup>, I. Arias de la Rosa<sup>1</sup>, M. C. Abalos<sup>1</sup>, P. Segui<sup>1</sup>, J.M. Villalba<sup>1</sup>, E. Collantes<sup>1</sup>, M.J. Cuadrado<sup>2</sup>, C. Lopez-Pedraza<sup>1</sup>. <sup>1</sup>IMIBIC/Reina Sofia Hospital/University of Cordoba, Córdoba, Spain; <sup>2</sup>St Thomas Hospital, London, UK

**Objectives:** This study was undertaken to: 1. Characterise monocytes molecular profile of altered genes and pathways involved in the pathology of APS. 2. To evaluate the role of antiphospholipid antibodies in the regulation of these processes. 3. To investigate the short-term effects of *in vivo* ubiquinol (reduced coenzyme Q10 [Qred]) supplementation on the modulation of genes related to inflammation and thrombosis in this autoimmune disorder.

**Methods:** Monocytes from peripheral blood of 60 subjects, including 30 APS patients and 30 healthy donors (HDs) were purified by negative immunomagnetic selection (Miltenyi). Total RNA was extracted from 6 subjects –as exploratory cohort- and microarray studies were performed in an Agilent G4112F platform (Whole Human Genome Microarray 44 k). Functional categorization of the altered gene signature and molecular pathways and networks was carried out using the Ingenuity Pathway Analysis Software (IPA). The most differentially expressed genes were validated by RT-PCR in monocytes purified from all the subjects recruited to the study. Correlation and association studies were performed with clinical and analytical variables. The effects of antiphospholipid antibodies (aPL) were also evaluated by *in vitro* studies. The short-term effects of *in vivo* Qred supplementation on the monocyte gene profile were further analysed.

**Results:** Gene expression array identified 518 altered genes in monocytes from APS patients in relation to the control group ( $p < 0,05$  and fold change  $> 2$ ). IPA analysis showed that the main canonical pathways integrated by these genes were leukocyte adhesion, diapedesis and extravasation signalling, interleukin and cytokine signalling, as well as oxidative stress production and antioxidant response. This analysis further identified that the most relevant diseases in which these altered genes are involved were inflammatory and cardiovascular diseases (44%), as well as reproductive (42%), neurological (11%), renal (1%) and ophthalmic diseases (2%). The alteration of several of these genes was validated by RT-PCR and protein analysis, and associated to clinical parameters of APS patients, including thrombotic recurrences and early atherosclerosis. *In vitro* studies

demonstrated the specific modulation of several genes by direct effect of aPLs. *In vivo* Qred supplementation of APS patients for one month significantly improved the monocytes' atherothrombotic gene profile, reversing the altered expression of a number of genes related to thrombosis, atherosclerosis, inflammation, oxidative stress, and intracellular signalling.

**Conclusions:** 1. Gene expression profile allowed the identification of relevant genes and pathways altered in monocytes of APS patients, which are associated with the pathogenesis of the disease and modulated, at least partially, by aPLs. 2. We have branded novel and specific mRNAs related to CVD in APS monocytes, further modified by effect of *in vivo* Qred supplementation.

### FRI0268 GLUCOCORTICOID-INDUCED LEUCINE ZIPPER (GILZ) REPRESENTS A CHECKPOINT LIMITING TYPE I INTERFERON (IFN) PRODUCTION IN SLE

C.T. Nataraja, E.F. Morand, J. Thomas, J. Harris, S.A. Jones. *Department of Medicine, Monash University, Melbourne, Australia*

**Background:** Glucocorticoids (GC) remain the mainstay of treatment in Systemic Lupus Erythematosus (SLE). Type I interferons (IFN), produced by plasmacytoid dendritic cells (pDC) in response to Toll-Like receptors (TLR) ligands, are critical to SLE pathogenesis, but are not suppressed by GC. Glucocorticoid-Induced Leucine Zipper (GILZ) is an endogenous anti-inflammatory protein induced by GC. Beaulieu et al., 2010 However, whether GILZ regulates IFN production in SLE is not known.

**Objectives:** To test the hypothesis that GILZ inhibits the production of Type I IFN in SLE.

**Methods:** We performed *in vitro* analysis on pDC and bone marrow-derived DC (BMDC), and *in vivo* studies, of WT and GILZ<sup>-/-</sup> mice using stimuli of TLR7 (Imiquimod), TLR7/8 (Resiquimod) and TLR9 (CpG). IFN was measured using a IFN luciferase assay, and other cytokines with ELISA. IFN-stimulated gene signatures (ISG) were measured using qPCR. To determine whether GILZ regulates IFN in human SLE, we mined a public gene expression dataset GSE10325. Becker et al., 2013

**Results:** Deletion of GILZ resulted in excess pDC secretion of IFN in response to TLR7 ( $p=0.0012$ ) and TLR9 ( $p=0.01$ ) stimulation, and BMDC secretion of IFN, IL-6 and TNF $\alpha$  in response to TLR7 ( $p=0.0039$ , 0.017, 0.033), TLR7/8 ( $p=0.001$ ,  $<0.0001$ ,  $<0.0001$ ) and TLR9 ( $p=0.005$ ,  $<0.0001$ , 0.0034) stimulation respectively. Dexamethasone (DEX) induced GILZ in WT pDC and BMDC, and TLR stimulation suppressed GILZ expression in BMDC, but TLR-stimulated GILZ<sup>-/-</sup> cell failed to suppress IFN in response to DEX. Moreover, GILZ deficiency was associated with increased ISG in naïve spleen cells, naïve BMDCs and TLR7/9 stimulated pDC of GILZ<sup>-/-</sup> mice compared to WT mice. Correspondingly, increased IFN was seen in GILZ<sup>-/-</sup> mice in response to TLR7/8 stimulation *in vivo*. In GSE10325, we show that lower expression of GILZ was associated with high ISG (*IFI44*, *IFI44L*, *RSAD2*, *IFI27*) ( $p=0.0021$ ) in SLE patient peripheral blood B cells, and GILZ mRNA was negatively correlated with IFN signature ( $r=-0.63$ ,  $p=0.017$ ) which in turn positively correlated with disease activity (SLEDAI2k) ( $r=0.77$ ,  $p=0.002$ ).

**Conclusions:** GILZ is an endogenous regulator of increased IFN production in response to TLR stimulation *in vitro* and in mice, and is negatively correlated with ISG in human SLE. This suggests that GILZ negatively regulates type I IFN production and GILZ based therapy may be a potential therapeutic strategy that could reduce steroid dependence in SLE.

### FRI0269 DEFICIENCY OF GLUCOCORTICOID-INDUCED LEUCINE ZIPPER (GILZ) DISINHIBITS IFN PATHWAYS AND EXACERBATES NEPHRITIS IN THE LYN-DEFICIENT MURINE MODEL OF LUPUS

C.T. Nataraja, E.F. Morand, J. Thomas, J. Harris, S.A. Jones. *Department of Medicine, Monash University, Melbourne, Australia*

**Background:** Systemic lupus erythematosus (SLE) is a multi-system autoimmune disease of unknown etiology. Lyn-deficient mice develop lupus-like autoimmunity due to hyperactive B cells resulting in excess IL-6 production, and cyclical exacerbation of inflammation by further activation of B and T cells. Tsantikos et al., 2010 C57BL/6 mice deficient in glucocorticoid-induced leucine zipper (GILZ), an intracellular protein involved in glucocorticoid effects on immunity, develop lupus-like autoimmunity and excess B cell activation. Jones et al., 2016. However, the effect of GILZ in lupus-prone mice is unknown.

**Objectives:** We aim to test the hypothesis that GILZ modulates autoimmunity in the lyn deficient murine model of lupus.

**Methods:** We generated GILZ-deficient mice on a lyn-deficient background (GILZ-lyn double knock out (DKO)) and compared them to WT and lynKO mice. The effects of GILZ deficiency on spleen weight, nephritis, Type I interferon-induced genes (ISG) and autoantibodies were examined.

**Results:** We observed heightened lupus-like autoimmunity in GILZ-lyn DKO mice, compared to LynKO, that include increased spleen weights ( $p=0.041$ ) and more severe glomerulonephritis, especially segmental necrosis. A panel of ISG (*ifi44*, *usp18*, *oas3*, *cxcl10*, *isg15*, *mx1*, *irf7*, *stat1* and *ifit3*) and an overall ISG score was significantly increased ( $p=0.0023$ ) in GILZ-lyn DKO mice compared to LynKO. In contrast, serum autoantibodies (dsDNA, Sm, histone, Jo-1, Scl-70, SSA, SSB, U1RNP, Ro52,) were not increased in GILZ-lyn DKO mice compared to LynKO mice.

**Conclusions:** In LynKO lupus-prone mice, spleen weight, glomerulonephritis, and ISG profiles were significantly exacerbated by GILZ deficiency, while autoantibody titres were unaffected. This suggests that endogenous GILZ exerts an inhibitory effect on IFN pathways, in this lupus model. Therefore, GILZ potentially regulates the cycle of inflammation in SLE by inhibiting IFN responses

downstream of autoantibodies. A GILZ-based treatment could be a potential therapeutic strategy in SLE.

#### FRI0270 IDENTIFICATION OF NOVEL DYSREGULATED INTERFERON-INDUCIBLE NON-CODING RNAs IN SJÖGREN'S SYNDROME

N. Means<sup>1,2</sup>, J.A. Ice<sup>1</sup>, I. Adriano<sup>3</sup>, A.M. Stolarczyk<sup>1</sup>, M.L. Joachims<sup>1</sup>, A. Rasmussen<sup>1</sup>, J.M. Guthridge<sup>1</sup>, J.A. James<sup>1,2</sup>, R.H. Scofield<sup>1,2,4</sup>, K.L. Sivits<sup>1,2</sup>, C. J. Lessard<sup>1,2</sup>. <sup>1</sup>Oklahoma Medical Research Foundation; <sup>2</sup>University of Oklahoma Health Sciences Center, Oklahoma City; <sup>3</sup>Henry Ford Health System, MI; <sup>4</sup>Department of Veterans Affairs Medical Center, Oklahoma City, USA

**Background:** Sjögren's syndrome (SS) is a chronic, heterogeneous disease with hallmark features of auto-inflammation and autoantibody production. Upregulation of type I and II interferon-stimulated genes (ISGs), known as the "Interferon (IFN) Signature" is correlated with anti-Ro titers and has been observed both in the salivary glands and peripheral blood of SS patients. Within the 2 p25.2 genomic interval, the long non-coding RNA (lncRNA) negative regulator of the interferon response (*NRIR*) has been identified as inducible by type I IFN and is responsible for the downregulation of the ISGs *CMPK2* and *RSAD2*.<sup>1</sup>

**Objectives:** We sought to identify additional unannotated ISGs lncRNAs that are differentially expressed (DE) in SS patients utilising correlated expression of *RSAD2*.

**Methods:** We evaluated and compared the transcriptome of anti-Ro(+) patients (n=27) and healthy controls (n=27) using RNA-seq with DE defined as q<0.05 and a fold change (FC) ≥2 or ≤0.5. qRT-PCR was used to validate DE with primers specific for each RNA of interest. To understand the biological relevance of these transcripts, we performed *in vitro* time-course experiments to compare the transcriptional changes of unstimulated cells and cells stimulated with either PMA/ionomycin (PMA/I) or universal type I IFN for 36 hours measuring 7 time points.

**Results:** One of the most overexpressed type I ISGs in the SS Ro(+) is *RSAD2* (FC=8.05, p=3.29x10E-07). Because of its role in the type I IFN pathway, pairwise correlation coefficients between all DE transcripts and *RSAD2* for SS Ro(+) patients were calculated. In total, we found 223 transcripts exhibiting correlation with *RSAD2* expression (Pearson's r>+0.70 or <-0.60), including *NRIR* (FC=2.72, p=5.87x10E-03) and *CMPK2* (FC=2.53, p=3.58x10E-03). Of the 223 transcripts, 14 DE expressed lncRNAs correlated with *RSAD2* expression. Several antisense ncRNAs situated nearby to other type I ISGs correlated with *RSAD2*, including: *AC099063.1* (FC=2.51), *AC004551.1* (FC=3.35), and *AP001610.1* (FC=4.12). We confirmed upregulation of these lncRNAs by qRT-PCR from the independent replication (14 Ro(+) and 36 controls) cohort (p=2.49x10E-02, 8.63 × 10E-06, 1.17 × 10E-04, respectively). Based on the locations of the lncRNAs to type I ISGs, HSB-2 cells were stimulated with PMA/I or universal type I IFN. Using qRT-PCR to measure the protein coding genes *MX1*, *OAS1*, and *GBP5* along with the lncRNAs, *AC099063.1* (*GBP5-AS1*), *AP001610.1* (*MX1-AS1*), and *AC004551.1* (*OAS123-AS1*) showed coordinated regulation with their protein coding counterparts with both stimuli.

**Conclusions:** Given the importance of the IFN signature to disease pathogenesis in the autoantibody positive patients, it is critical that we better understand how this complex pathway is coordinately regulated. Since one critical function of lncRNAs is to regulate the genome, characterising the mechanisms by which these 14 identified by this study regulate the ISG coordinately could result in new diagnostic and/or therapeutic options.

#### FRI0271 DIMETHYL FUMARATE INHIBITS UBE2L3 MEDIATED TLR7 SIGNALING AND AUTOREACTIVE B CELL DEVELOPMENT IN SLE

D. Mauro<sup>1</sup>, V. Tsang<sup>1</sup>, I. Lucey-Clayton<sup>1</sup>, F. Rivellese<sup>1</sup>, S. Pagani<sup>1</sup>, F. Alam<sup>1</sup>, E. Pontarini<sup>1</sup>, A. Nerviani<sup>1</sup>, A. Pakozdi<sup>2</sup>, R. Rajakariah<sup>2</sup>, D. Pyne<sup>2</sup>, T.J. Vyse<sup>3</sup>, C. Pitzalis<sup>1</sup>, M.J. Lewis<sup>1</sup>. <sup>1</sup>Experimental Medicine and Rheumatology, Queen Mary University of London; <sup>2</sup>Rheumatology Department, Mile End Hospital, Barts Health NHS Trust; <sup>3</sup>Medical and Molecular Genetics, King's College London, London, UK

**Background:** Genetic studies have identified a single *UBE2L3* risk haplotype which is associated with SLE and multiple autoimmune diseases, and leads to increased expression of *UBE2L3* in eQTL studies. The E2 ubiquitin-conjugating enzyme *UBE2L3* regulates NF-κB activation through regulation of the Linear Ubiquitination Chain Assembly Complex (LUBAC). Thus *UBE2L3* regulates CD40-driven B cell activation. The *UBE2L3* risk allele correlates with circulating plasmablast and plasma cell expansion in SLE individuals.

**Objectives:** To determine the effect of *UBE2L3* and linear ubiquitination on TLR7 signalling, and test the effect of Dimethyl Fumarate (DMF), which has recently been shown to inhibit *UBE2L3*, on B cell and plasmablast differentiation in SLE.

**Methods:** Confocal microscopy, immunoprecipitation and western blot were used to assess linear ubiquitin chain accumulation in TLR7-HEK293 cells after TLR stimulation by Resiquimod. The effect of *UBE2L3* and LUBAC on TLR7 signalling was dissected by the use of *UBE2L3*/LUBAC overexpression, dominant negative mutants and shRNA silencing, measuring NF-κB reporter activity, IkappaBalpha phosphorylation, gene expression by qPCR and IL-8 secretion. DMF was administered *in vitro* to human B cells isolated from SLE patients (n=15) and controls and cultured with Resiquimod and/or IFNα for 5–7 days. B cell viability/proliferation, plasmablast differentiation were analysed by 10-colour flow cytometry. Supernatants were assayed for immunoglobulin secretion and autoantibody production.

**Results:** TLR7 stimulation led to intracellular accumulation of linear ubiquitin chain comparable to TNFα. *UBE2L3* and LUBAC co-overexpression enhanced TLR7 driven NF-κB activation and led to increased NF-κB target mRNA expression and increased secretion of IL-8. The effect was specific to *UBE2L3* compared to other E2 enzymes. Dominant negative mutant *UBE2L3*(C86S) or HOIP (C885S) or *UBE2L3*/HOIP shRNA suppressed the response to TLR7 stimulation. DMF showed a dose-dependent inhibition of TLR7-mediated NF-κB activation. In primary SLE and healthy B cells, DMF suppressed proliferation of switched and unswitched CD27+ memory B cells and blocked plasmablast differentiation. DMF profoundly inhibited immunoglobulin secretion and anti-nuclear autoantibodies production in response to TLR7 and IFNα stimulus.

**Conclusions:** Our data demonstrate that linear ubiquitination and *UBE2L3* regulate TLR7 activation of NF-κB. *UBE2L3* silencing or pharmacological antagonism of *UBE2L3* by DMF suppressed the response to TLR7 activation. Excessive TLR7 signalling has been linked to SLE development and enhanced B cell autoreactivity. Thus our data identify a novel mechanism by which the *UBE2L3* risk haplotype contributes to SLE susceptibility. DMF suppressed plasmablast differentiation and inhibited TLR7 and IFNα induced autoantibody production. These results support a role for repositioning DMF (currently used to treat multiple sclerosis) in the treatment of SLE.

#### FRI0272 PHARMACODYNAMIC EFFECTS OF ATACEPT TREATMENT IN A CYNOMOLGUS MONKEY KLH ANTIGEN CHALLENGE MODEL

E. Samy<sup>1</sup>, A. Bender<sup>1</sup>, Y. Wu<sup>1</sup>, V. Castagna<sup>2</sup>, E. Bertotti<sup>2</sup>, R. Boggio<sup>2</sup>, A. Paoletti<sup>2</sup>, S. Riva<sup>2</sup>, P. Schneider<sup>3</sup>, P. Haselmayer<sup>4</sup>, J. DeMartino<sup>1</sup>. <sup>1</sup>EMD Serono Research and Development Institute, Inc. (a business of Merck KGaA, Darmstadt, Germany), Billerica, USA; <sup>2</sup>Istituto di Ricerche Biomediche Antoine Marxer RBM SpA (an affiliate of Merck KGaA, Darmstadt, Germany), Colliere Giacosa, Italy; <sup>3</sup>Department of Biochemistry, University of Lausanne, Lausanne, Switzerland; <sup>4</sup>Merck KGaA, Darmstadt, Germany

**Background:** Atacept is an antagonist of the B cell regulatory factors BlyS (B lymphocyte stimulator) and APRIL (a proliferation inducing ligand). It is capable of binding to all known conformations of BlyS and APRIL and is thus expected to modulate the maturation, differentiation, and effector function of B cells. We aimed to define the relationship between atacept drug exposure and pharmacodynamic (PD) effects *in vivo*. Here, we report results of our study examining the effects of atacept on the immune response in a keyhole limpet hemocyanin (KLH) challenge model in cynomolgus monkeys.

**Methods:** Cynomolgus monkeys (*Macaca fascicularis*) were injected with KLH on Day -33, and on Day 1 received the first dose of either atacept (0.3, 3, or 30 mg/kg) or vehicle followed by a KLH challenge. Animals were dosed weekly (Day 1, 8, 15) and were subsequently monitored for 2 weeks before the study ended on Day 29. Clinical signs, total and free drug levels, peripheral blood B and

T cell subpopulations, and total and KLH-specific immunoglobulin (Ig) levels were monitored. Additionally, gene expression in blood was analysed using the NanoString nCounter platform.

**Results:** Atacept was well-tolerated at all dose levels tested. All animals in the treatment arms had quantifiable levels of atacept in serum throughout the study. Reduction of serum IgM and IgG was detected 7 days after treatment, with a continuous reduction in the mean serum IgM and IgG levels observed until Day 29 (table 1). In animals treated with 3 and 30 mg/kg atacept, a significant decrease in serum anti-KLH IgG levels was observed versus vehicle-treated controls, beginning at Day 11 (table 2). A minor reduction in absolute CD3-CD20+, IgD +B cell numbers was seen in response to treatment, but no changes in T cell subsets were detected. Changes in gene expression following atacept treatment were predominantly observed in B cell-related and Ig genes.

**Abstract FRI0272 – Table 1.** Mean% reduction of total IgM and IgG relative to baseline

Mean reduction	Day 8			Day 29		
	0.3 mg/kg	3 mg/kg	30 mg/kg	0.3 mg/kg	3 mg/kg	30 mg/kg
IgG	7.1	14.2	16.3	10.6	27.2	46.3
IgM	9.1	17.1	22.3	21.5	52.3	64.1

**Table 2** Mean% reduction of KLH-specific IgM and IgG relative to vehicle group

Mean reduction	Day 11			Day 29		
	0.3 mg/kg	3 mg/kg	30 mg/kg	0.3 mg/kg	3 mg/kg	30 mg/kg
KLH-specific IgG	17.3	55.2	49.7	39.4	78.8	71.5
KLH-specific IgM	15.1	33.4	40.1	40.4	67.8	66.6

**Conclusions:** This study showed that atacept modulates B cell responses, IgM and IgG levels, and Ig isotype switching in a KLH-antigen-challenged cynomolgus monkey model, thus supporting its use in the treatment of antibody-mediated diseases. Additionally, gene expression PD markers identified in this study will be used in subsequent clinical trials as exploratory PD readouts.

#### RNA SEQUENCING DETECTION OF GENE DYSREGULATION IN EPITHELIAL SORTED CELLS FROM SALIVARY GLAND TISSUE REVEALS INTERESTING PATHWAYS INVOLVED IN SJÖGREN'S SYNDROME PATHOPHYSIOLOGY

E. Rivière<sup>1</sup>, N. Tchitchek<sup>1</sup>, G. Nocturne<sup>1,2</sup>, S. Boudaoud<sup>1</sup>, J. Pascaud<sup>1</sup>, A. Virone<sup>1</sup>, A. Thai<sup>3</sup>, N. Allaire<sup>3</sup>, B. Jagla<sup>4</sup>, M. Mingueneau<sup>5</sup>, X. Mariette<sup>1,2</sup>. <sup>1</sup>Immunology of viral infections and autoimmune diseases, IDMIT, CEA – Université Paris Sud – INSERM U1184, Le Kremlin Bicêtre and Fontenay aux Roses; <sup>2</sup>Rheumatology, Université Paris Sud, Le Kremlin Bicêtre, France; <sup>3</sup>Immunology Research, Biogen, Cambridge, USA; <sup>4</sup>Biomarker Discovery Platform UtechS CB and Hub de Bioinformatique et Biostatistiques C3BI, Institut Pasteur, Paris, France

**Background:** Primary Sjögren's syndrome (pSS) is a chronic autoimmune disorder characterised by lymphocytic infiltrates and destruction of the salivary glands. Several lines of evidence support the hypothesis that salivary gland epithelial cells (SGECs) are not only the target of autoimmunity in pSS patients but may also play a role for its initiation and maintenance.

**Objectives:** To establish high-resolution molecular maps of SGEC from pSS patients compared to controls using RNASeq analysis.

**Methods:** Patients had pSS according to 2016 EULAR/ACR criteria and controls had sicca symptoms without any antibodies and with normal lip biopsy. SGEC, B, T CD4 and CD8 lymphocytes were sorted from salivary gland biopsies from 9 pSS patients and 4 controls, using a FACS ARIA cell sorter. Total RNASeq profiling was performed using MiSeq (Illumina). For SGEC subset, 4 samples were excluded due to a contamination by B lymphocytes, thus analysis was performed on 5 pSS and 4 controls using R software, to identify transcriptional differences

between pSS and control SGEC. Functional Enrichment analysis was performed using Ingenuity Pathway Analysis software.

**Results:** In SGEC, 495 genes were differentially expressed between pSS and controls. 280 genes were up-regulated, and 215 genes were down-regulated. Enrichment analysis (table 1) highlighted IL-7 signalling pathways (including IL-7, STAT5A, STAT1 genes) and interferon signalling (including OAS1, IFIT3, IFI6, TAP1 genes). Other genes potentially involved in immune responses and interactions between SGEC and lymphocytes were significantly up-regulated, including bone marrow stromal cell antigen 2, HLA-DRA, BAFF-R and IL-23 A (table 2). These results need to be confirmed by RT qPCR. However, consistent results have already been obtained in our laboratory, showing that IL-7 serum level is increased in pSS patients compared to controls and that SGECs produce IL-7 after interferon stimulation. The analysis of the non-coding RNA part and the other sorted cells subtypes is ongoing.

**Abstract FRI0273 – Table 1.** Pathways identified as statistically over-represented with Ingenuity Pathways Analysis in epithelial cells from pSS patients compared to controls

Pathway	-log p-value
Primary Immunodeficiency Signalling	4,08
Interferon Signalling	3,52
B Cell Development	2,89
Role of JAK2 in Hormone-like Cytokine Signalling	2,73
IL-7 Signalling Pathway	2,51

**Abstract FRI0273 – Table 2.** Selection of genes differentially expressed between pSS and controls in SGEC

Gene Symbol	log2 fold-change	p-value
IL-7	2.56	0.002
BST2	4.08	0.0002
HLA-DRA	1.84	0.0372
IL-23 A	3.59	0.0155
BAFF-R	4.94	0.0097

**Conclusions:** Immune interactions between SGEC and B or T lymphocytes could represent a key in the understanding of the initiation and/or maintenance of autoimmunity in pSS. Our study highlights the key role of epithelial cells in activation of immune cells. *In vitro* experiments are needed to confirm these results and elucidate the molecular mechanisms.

FRI0274

#### ELEVATED REACTIVITY OF CD38<sup>HIGH</sup> B CELLS AGAINST BAFF CONTRIBUTES TO IGG OVERPRODUCTION IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

E. Ishioka-Takeji, K. Yoshimoto, K. Suzuki, H. Yasuoka, K. Yamaoka, T. Takeuchi. Keio University School of Medicine, Tokyo, Japan

**Background:** Primary Sjögren's syndrome (pSS) is often accompanied by hypergammaglobulinemia and production of autoantibodies, such as anti-Ro/SSA and anti-La/SSB antibodies. These serological aberrations suggest that abnormally activated B cells play a key role in the pathogenesis of pSS. We have previously reported that the proportion of peripheral CD38<sup>high</sup>IgD<sup>+</sup> B cells among CD19<sup>+</sup> B cells is significantly elevated in pSS patients and positively correlated with serum anti-Ro/SSA, anti-La/SSB titer, total IgG, and the European League against Rheumatism (EULAR) Primary Sjögren's syndrome disease activity index (ESSDAI). B cell activating factor belonging to TNF family (BAFF) is a well known cytokine which promotes differentiation, proliferation and survival of B cells. It has been reported that serum BAFF level is increased in pSS patients compared to HC and that BAFF is also highly expressed in salivary glands. Based on these background, it is conceivable that BAFF plays a pivotal role in the pathogenesis of pSS.

**Objectives:** To elucidate the involvement of BAFF in IgG overproduction in pSS.

**Methods:** Peripheral CD19<sup>+</sup> B cells were prepared from pSS patients (n=16) and gender-matched HC (n=10) by using CD19-microbeads. The cells were stimulated *in vitro* with an anti-IgM antibody, recombinant human CD40 ligand and recombinant human IL-4 ('multiple stimulation') with or without recombinant human soluble BAFF (rhsBAFF) for 96 hours. The amount of IgG produced by the cells in the culture supernatants was measured by ELISA. The proportion of B cell subsets, characterised by anti-CD19, anti-IgD and anti-CD38 antibodies, and the expression level of a BAFF receptor (BR3) in the subsets were analysed by FACS. Disease activities of the pSS patients were quantified based on the ESSDAI scores. The serological data of the patients were collected by clinical records.

**Results:** IgG production by CD19<sup>+</sup> B cells *in vitro* upon multiple stimulation was significantly increased in pSS patients as compared to HC (p=0.015). Notably, the IgG production was further enhanced by the addition of rbsBAFF to the culture, and that enhancement was significantly higher in pSS patients than HC (p=0.011). Moreover, the proportion of CD38<sup>high</sup>IgD<sup>+</sup> B cells among CD19<sup>+</sup> B cells was significantly and positively correlated with not only serum IgG level (p<0.0001), but also the amount of IgG produced *in vitro* by the multiple stimulated CD19<sup>+</sup> B cells (p=0.042). The mean fluorescence intensity of BR3 expression in CD38<sup>high</sup>IgD<sup>+</sup> B cells was significantly higher in pSS patients than HC (p=0.029), whereas no significant difference was observed between pSS and HC for total CD19<sup>+</sup> B cells.

**Conclusions:** Our results suggest that CD38<sup>high</sup>IgD<sup>+</sup> B cells, which are known as activated B cells, highly react to BAFF in pSS patients as compared to HC. Our findings may shed light on the mechanism of B cell activation triggered by BAFF during the pathogenesis of pSS.

### FRI0275 ALTERED PROTEIN TYROSINE PHOSPHATASES ACTIVITY AND DISEASE SPECIFIC EXPRESSION PATTERN OF CD45 AND CD148 ON VARIOUS LYMPHOCYTE SUBSETS IN AUTOIMMUNE DISEASES

E. Szelinski<sup>1,2</sup>, S. Fleischer<sup>2</sup>, S. Weibenberg<sup>1,2</sup>, K. Reiter<sup>1</sup>, T. Dörner<sup>1,2</sup>.

<sup>1</sup>Department of Rheumatology and Clinical Immunology, Charité; <sup>2</sup>German Rheumatism Research Center Berlin (DRFZ), Berlin, Germany

**Background:** Previous studies demonstrated impaired B cell receptor (BCR) response in patients with systemic lupus erythematosus (SLE). Besides diminished cytokine production upon TLR9 stimulation<sup>1</sup> it was found that phosphorylation of Syk<sup>2</sup> and downstream Ca<sup>2+</sup> flux was reduced upon BCR stimulation. This led to the hypothesis of a "post activation" state of peripheral B cells (BCs) in autoimmunity which might be related to altered protein tyrosine kinase (PTK) versus phosphatase (PTP) activities. Prior studies in SLE showed enhanced PTP but not ser/thr phosphatase (PSP) activities in BCs.<sup>3</sup> Receptor PTPs (RPTPs) CD45/CD148 are described as regulators of initial steps of BCR signalling by regulating Lyn which phosphorylates CD79 ITAMs and thus activates Syk.<sup>4</sup>

**Objectives:** This study aimed at testing the hypothesis that altered phosphatase activity (PA) is a hall mark of autoimmunity. So, expression of RPTPs CD45/CD148 were compared on lymphocyte subsets in patients with rheumatoid arthritis (RA), primary Sjögren's Syndrome (pSS), SLE and healthy donors (HD). To check whether increased global PA is restricted to BCs of patients with SLE, the study extended analysis to T cells (TCs) and studied patients by including cohorts of RA and pSS.

**Methods:** Peripheral blood samples were analysed for expression of CD45 and CD148 in patients and HDs using flow cytometry (n(HD/RA/pSS/SLE)=13/8/18/22). PTP and PSP activities were analysed in isolated BCs and TCs lysates from patients and HD using a protein activity assay (n(HD/RA/pSS/SLE)=21/6/13/10).

**Results:** Compared to HDs CD45 expression is significantly enhanced on peripheral monocytes and CD3<sup>+</sup>/CD4<sup>-</sup> as well as CD3<sup>+</sup>/CD4<sup>+</sup> TCs from patients with RA. Further, CD3<sup>+</sup>/CD4<sup>-</sup> TCs of patients with RA express more CD148 (Tb1 1). In patients with SLE, CD148 expression is decreased on CD148<sup>+</sup> memory B cells. In addition, this study confirmed that enhanced PTP activity is characteristic of SLE BCs since TCs of any of the cohorts and BCs of patients with RA and pSS showed PTP and PSP activities comparable to HD.

**Abstract FRI0275 – Table 1.** Significant differences found in RA and SLE compared to HD.

		CD45	CD148		PTP activity	PSP activity
RA	monocytes	↑ 0.0354	ns	TCs	ns	ns
	CD3 <sup>+</sup> /CD4 <sup>-</sup>	↑ 0.0325	↑ 0.0451		ns	ns
	CD3 <sup>+</sup> /CD4 <sup>+</sup>	↑ 0.0277	ns		ns	ns
	naïve BCs	ns	ns		ns	ns
	memory BCs	ns	ns		ns	ns
SLE	monocytes	ns	ns	TCs	ns	ns
	CD3 <sup>+</sup> /CD4 <sup>-</sup>	ns	ns		ns	ns
	CD3 <sup>+</sup> /CD4 <sup>+</sup>	ns	ns		ns	ns
	naïve BCs	ns	ns		ns	ns
	memory BCs	ns	↓ 0.0054		BCs	↑ PTP = 0.0122 ↑ PSP = 0.0055

↑: significantly increased; ↓: significantly decreased; ns: not significant; PTP/PSP, phosphotyrosine 1/2

**Conclusions:** This study identified characteristic differences of PTP activities in BCs from patients with SLE compared to HD which were not identifiable by an enhanced CD45 or CD148 expression on PBMCs and did not correlate with disease activity. This suggests intrinsic abnormality in SLE BCs. While there is evidence that abnormal PTP is present in SLE BCs, further studies are needed to identify underlying individual PTPs to further analyse their pathogenic and potential therapeutic relevance. Among the tested autoimmune conditions increased

CD45 expression on TCs and monocytes was specific to RA, which might indicate disease dependent patterns of PTP/PSP expression.

### FRI0276 ABERRANT DISTRIBUTION OF CD3+CD56+ NKT-LIKE CELLS IN PATIENTS WITH SJÖGREN'S SYNDROME

H. Chen, L. Zhao, W. Xu, Z. Chen, J. Sun, F. Zhang. Rheumatology, Peking Union Medical College Hospital, Beijing, China

**Background:** CD3<sup>+</sup>CD56<sup>+</sup> NKT-like cells are a subset of T cells co-expressing NK cell markers, and bridge innate and adaptive immunity. However, the phenotype and the potential role of NKT-like cells in the pathogenesis of Sjögren's Syndrome (SS) remains elusive.

**Objectives:** To elucidate the distribution of CD3<sup>+</sup>CD56<sup>+</sup> NKT-like cells in peripheral blood and labial salivary gland (LSG) of SS patients, as well as the immune function of NKT-like cells in SS patients.

**Methods:** SS patients (n=110) and healthy controls (HC, n=94) were enrolled. Peripheral CD3<sup>+</sup>CD56<sup>+</sup> NKT-like population, proliferation and apoptosis potential, surface chemokine receptors and proinflammatory cytokines secretion were quantified by flow cytometry. The infiltration of NKT-like cells in LSG was examined by immunofluorescence. Serum and tissue levels of CX3CL1 were detected by ELISA and immunohistochemistry, respectively. *In vitro* transwell migration assay was used to examine the chemotaxis of NKT-like cells induced by chemokines. NKT-like cells were stimulated with CX3CL1 and were quantified the TNF-α and IFN-γ secretion by flow cytometry.

**Results:** Peripheral CD3<sup>+</sup>CD56<sup>+</sup> NKT-like cells from SS patients were significantly lower than those from HC (3.09%±2.35% vs 5.37±4.06%, p<0.001), which was negatively correlated with ESSDAI (r=-0.523, p=0.009) and serum RF level (r=-0.586, p=0.015). The proliferation rate (35.1%±10.69% vs 36.4±10.75%, p=0.812) or apoptosis rate (13.01%±12.15% vs 12.48±5.28%, p=0.338) of NKT-like cells from SS and HC were comparable. However, NKT-like cells infiltrations into LSG were observed in SS patients but were rarely presented in HC. Serum level of CX3CL1 (936.8±99.82 vs 887.8±82.77 pg/ml, p=0.015) and epithelial CX3CL1 of LSG were higher in SS patients than those in HC. CX3CR1 were expressed on NKT-like cells from both SS and HC (68.25%±22.38% vs 70.06±17.34%, p=0.777). Furthermore, migration assay showed that CX3CR1 promoted NKT-like cells chemotaxis with a dose-dependent manner. Functionally, NKT-like cells from SS patients expressed higher level of CD69 (10.97%±6.75% vs 2.69±1.82%, p<0.0001). Peripheral NKT-like cells from both SS patients and HC secreted high level of TNF-α (70.29%±22.74% vs 81.33±10.76%, p=0.137) and IFN-γ (62.42%±16.66% vs 64.34±14.50%, p=0.759), and low level of IL-4 (4.39%±3.42% vs 2.64±1.90%, p=0.131) and IL-17 (0.30±0.28 vs 0.31±0.30, p=0.967). Importantly, CX3CL1 promoted TNF-α and IFN-γ production by NKT-like cells *in vitro*.

**Conclusions:** NKT-like cells were aberrantly depleted in peripheral blood and accumulated in LSG in patients with SS, which was driven by CX3CL1- CX3CR1 axis. NKT-like cells from SS were activated and secreted high level of TNF-α and IFN-γ, which were further promoted by CX3CL1. Thus, NKT-like cells were implicated in the pathogenesis of SS, which might be a potential therapeutic target for SS.

FRI0277

### METFORMIN REDUCES SALIVARY GLAND INFLAMMATION BY CONTROLLING B CELL DIFFERENTIATION AND REGULATING BALANCE OF TH17 AND TREG CELL IN NON-OBESSE DIABETIC MICE

J.-W. Kim<sup>1</sup>, S.-M. Kim<sup>2</sup>, J. Lee<sup>1</sup>, S.-K. Kwok<sup>1</sup>, J.H. Ju<sup>1</sup>, S.-H. Park<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, School of Medicine, The Catholic University of Korea; <sup>2</sup>Rheumatism Research Center, Catholic Research Institute of Medical Science, The Catholic University of Korea, Seoul, Korea, Republic Of

**Background:** Sjögren's syndrome (SS) is a systemic autoimmune disease that affects exocrine glands and lymphoid organs. B cell hyperactivity and imbalance between T helper 17 (Th17) cells and regulatory T (Treg) cells are involved in pathogenesis of SS. Metformin, a commonly used anti-diabetic drug, is found to have immunomodulatory effect via AMP-activated protein kinase enhanced inhibition of mTOR-STAT3 signalling.

**Objectives:** We examined the therapeutic effect of metformin on SS by using animal model of SS, non-obese diabetic (NOD) mice.

**Methods:** Metformin (50 mg/kg) or vehicle (saline) was given per oral every day from 11 weeks after birth until 20 weeks. Salivary flow rate (SFR) was addressed on every 2 or 3 weeks between 11 weeks and 20 weeks. Histologic analyses of salivary gland and spleen were performed on week 20. Expression of Inflammatory cytokine was determined by immunohistochemistry analysis and real-time PCR. Flow cytometry was performed with peripheral blood to examine Th17 and Treg cells and germinal centre (GC) B cell populations. Serum immunoglobulin level was measured by enzyme-linked immunosorbent assay. Splenic cells of NOD mice were treated with metformin or vehicle *in vitro* and cultured for 3 days.

**Results:** SFRs of metformin-treated mice recovered, whereas SFRs of those treated with vehicle declined. Histologic examination of salivary gland showed decreased infiltration of lymphocytes and reduced expression of IL-6 and TNF-alpha in metformin-treated mice. Relative expression of IL-6, TNF-alpha, and IL-17 mRNA in salivary gland and spleen also declined in metformin-treated mice. Flow cytometric analysis revealed decreased Th1 and Th17 cells and increased Treg cells in peripheral blood of mice treated with metformin. In addition, GC B cells and immunoglobulin levels were reduced in peripheral blood of mice treated with metformin. Decreased Tfh cells and increased Tfr cells were observed from *in vitro* cultures of splenic cells treated with metformin.

**Conclusions:** Metformin controls B cell differentiation and keeps balance between Th17 and Treg cells in NOD mice, in addition to reducing lymphocytic infiltration and inflammatory cytokine expression in salivary gland. Metformin has potential therapeutic effects on SS.

FRI0278

### ALTERATIONS IN MEMORY AND VISIO-SPATIAL LEARNING IN A PRISTANE-INDUCED LUPUS BALB/C MICE

J. Luciano Jaramillo, F. Sandoval Garcia, E.A. Martinez Garcia, M. Vazquez Del Mercado, B.T. Martin Marquez. *Universidad de Guadalajara, Guadalajara, Mexico*

**Background:** Neuropsychiatric lupus is a condition that occurs in 30%–40% of systemic lupus erythematosus (SLE) patients and is associated with the presence of autoantibodies in central nervous system (CNS). The pristane-induced lupus in BALB/c mice is an experimental model that presents clinical and immunological similarities to SLE pathogenesis and it can be proposed as model to analyse affectations in visio-spatial learning and memory.

**Objectives:** To evaluate short and long term visio-spatial learning and memory in Balb/c pristane-induced lupus using Barnes maze test.

**Methods:** Fourteen female Balb/c mice were studied: 4 controls (single intraperitoneal injection of 0.5 mL NaCl 0.9%), 5 treated with pristane (single intraperitoneal injection of 0.5 mL pristane) and 5 treated with pristane plus lipopolysaccharide (LPS) 3 mg/kg 4 months post-administration of pristane. Short and long term visio-spatial learning and memory was evaluated in all groups at 7 weeks after the administration of LPS using Barnes maze test. The test consists of 3 phases: adaptation phase, acquisition phase and test phase. The short-term memory was evaluated during the acquisition phase (4 tests per day, D1-D4) and the long-term memory was evaluated 48 hour after the last test of the acquisition phase. Primary and total errors, primary and total latencies were analysed. The

results are shown as a mean ±SD. Kruskal-Wallis and Mann-Whitney U test was used for statistical analysis.

**Results:** All mice treated with pristane showed higher latencies to find the target hole in Barnes maze compared with controls during the short-term memory test (STP, D1-D4). In the long-term memory test (LTP) the highest latency in seconds (s) was observed in the pristane plus LPS group (64.6±59.1 s) followed by the pristane group (62.4±69.6 s) in comparison control group (7±3.6 s).

**Abstract FRI0278 – Figure 1.** Total. Latency in Barnes maze test. Total latency in seconds between mice groups (pristane, pristane + LPS and control) in STP (A) and LTP tests (B) in Barnes's maze

**Conclusions:** The increased latencies in the groups pristane plus LPS and pristane with respect to controls suggests that the autoantibodies produced in this model could be involved in alterations of the CNS, modifying the learning and memory processes. These results also suggest that pristane may have the potential to alter the permeability of the blood-brain barrier by itself. However, more experimental studies are needed to confirm the results obtained in this study.

FRI0279

### DECREASED SPHINGOSIN-1-PHOSPHATE RECEPTOR 1 (S1P1) EXPRESSION IN ENDOTHELIAL PROGENITOR CELLS (EPCs) FROM SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) PATIENTS

J. Romo-Tena<sup>1</sup>, D. Gómez-Martín<sup>1</sup>, L.P. Blanco<sup>2</sup>, C. Carmona-Rivera<sup>2</sup>, R. Carazo-Vargas<sup>1</sup>, J. Alcocer-Varela<sup>1</sup>, M.J. Kaplan<sup>2</sup>. <sup>1</sup>*Immunology and Rheumatology, Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán", Mexico City, Mexico;* <sup>2</sup>*Systemic Autoimmunity Branch, National Institute of Arthritis and Musculoskeletal and Skin Diseases, National Institutes of Health, Bethesda, MD, USA*

**Background:** SLE patients display an elevated cardiovascular risk when compared to the general population. <sup>1</sup> Interferon-alpha (IFN-α) appears to drive atherogenesis in SLE at least in part, by promoting abnormal phenotype and function of EPCs. <sup>1</sup> S1P1 is considered crucial for vasculogenesis and has been shown to attenuate IFN-α autoamplification by promoting IFN receptor 1 (IFNAR1) degradation. <sup>2,3</sup>

**Objectives:** To characterise S1P1 expression in EPCs from SLE patients and its putative association to type I IFNs effects on vasculogenesis.

**Methods:** SLE subjects that fulfilled SLE ACR classification criteria were recruited. Healthy controls were selected based on age and gender. Disease activity was assessed by SLEDAI-2K index. EPCs were quantified by flow cytometry in PBMC subsets as those cells that coexpress CD133<sup>+</sup>/CD34<sup>+</sup> in the CD3/CD56/CD79b<sup>-</sup> gate. <sup>1</sup> S1P1 expression was quantified in that subset. Control PBMCs were cultured in endothelial cell (EC)-enrichment medium for 2 weeks. Differentiated ECs were characterised by immunofluorescence (IF) as those cells that coexpress UEA-1 lectin and take up acetylated LDL. <sup>1</sup> These cells were stimulated with recombinant IFN-α in the presence or absence of the S1P1 agonist CYM-5442 and the S1P1 antagonist W-146 to assess the effect of this pathway on EC differentiation and type I IFN induced gene expression. <sup>3</sup>

**Results:** SLE and matched healthy controls (n=36/group) were compared. Demographic and clinical characteristics are depicted in table 1.

**Abstract FRI0279 – Table 1.** Demographic and Clinical features.

	Mean±SEM
Age (years)	32.2±1.35
Female (%)	34 (94.44)
Time since SLE diagnosis (months)	103.36±13.46
Time since remission (months)	16.6±3.07
SLEDAI-2K (points)	9.41±1.15

SLE patients displayed decreased absolute EPC numbers when compared to controls (2463.43±450.07 vs 39457.65±9063.34 EPCs/ml, p<0.001). Decreased EPC numbers negatively correlated with SLEDAI-2K (r=-0.405, p=0.026). S1P1 expression was decreased in lupus EPCs when compared to controls (48.27±1.55 vs 60.89±1.66%,

$p < 0.001$ ) and this was independent of disease activity. Recombinant IFN- $\alpha$  decreased EPC differentiation in healthy control cells ( $32.44 \pm 0.09$  vs  $79.69 \pm 0.27\%$ ,  $p = 0.001$ ), and this was attenuated in the presence of CYM-5442 and exacerbated in the presence of W-146. Moreover, type I IFN regulated genes were modulated by these compounds.

**Conclusions:** The S1P1 pathway is involved in the regulation of EPC differentiation by type I IFNs. Defects in S1P1 signalling pathway in lupus EPCs may contribute to the development of endothelial dysfunction in SLE.

### FRI0280 A MOLECULAR NETWORK FOR FATIGUE IN PRIMARY SJÖGREN'S SYNDROME

K. Bårdsen<sup>1</sup>, C. Brede<sup>2</sup>, I. Kvivik<sup>1</sup>, J.T. Kvaløy<sup>1,3</sup>, K. Jonsdottir<sup>1</sup>, A.B. Tjensvoll<sup>4</sup>, P. Ruoff<sup>5</sup>, R. Omdal<sup>6,7</sup>. <sup>1</sup>Research Department, <sup>2</sup>Department of Medical Biochemistry, Stavanger University Hospital, <sup>3</sup>Department of Mathematics and Physics, University of Stavanger, <sup>4</sup>Department of Neurology, Stavanger University Hospital, <sup>5</sup>Centre for Organelle Research (CORE), University of Stavanger, <sup>6</sup>Clinical Immunology Unit, Stavanger University Hospital, Stavanger, <sup>7</sup>Department of Clinical Science, University of Bergen, Bergen, Norway

**Background:** Fatigue is a common phenomenon in primary Sjögren's syndrome (pSS) and other chronic inflammatory diseases, cancer, and neurodegeneration. The underlying mechanisms for fatigue are not completely understood, but increasing evidence point to a biological basis for the phenomenon.

**Objectives:** Following the sickness behaviour hypothesis for fatigue, where pro-inflammatory cytokines and particularly interleukin 1 $\beta$  (IL-1 $\beta$ ) related signalling are essential, we wished to investigate how molecules that influence IL-1 $\beta$  activity may influence fatigue through complex networks (IL-1 $\beta$ , IL-1Ra, IL-1RII, IL-6 and S100B). We also hypothesised that the neuropeptide hypocretin-1 (Hcrt1), a regulator of sleep and wakefulness, could be an element in a network for fatigue.

**Methods:** In cerebrospinal fluid (CSF) from 49 patients with pSS, Hcrt1 was measured by RIA and the other proteins by ELISA. Fatigue was rated using the fatigue visual analogue scale (fVAS), and results analysed by univariate-, multiple regression, and principal component analysis (PCA).

**Results:** It was not possible to measure IL-1 $\beta$  due to very low concentrations in CSF. In simple univariate regression analysis with fatigue as a dependent variable a significant association was observed for depression ( $R^2 = 0.20$ ,  $p < 0.01$ ), and pain ( $R^2 = 0.23$ ,  $p < 0.01$ ) and the biochemical variable IL-1Ra ( $R^2 = 0.09$ ,  $p = 0.04$ ). In multiple regression with fVAS as dependent variable a model was obtained with depression, pain, and IL-1Ra as significant contributors ( $R^2 = 0.37$ ;  $p < 0.001$ ). In PCA two significant components were revealed (figure 1a). The first component (PC1) was dominated by variables related to IL-1 $\beta$  activity. The second component (PC2) showed a negative correlation between IL-6 and Hcrt1. fVAS was then introduced as an additional variable. In this new model fVAS correlated with the IL-1 $\beta$  related variables on PC1 and to a lesser degree with Hcrt1 on PC2 (figure 1b).

**Abstract FRI0280 – Figure 1.** a) PCA of biochemical variables only. b) PCA of biochemical variables including fatigue. Biplot illustrates scores of individuals and variables for PC1 and

PC2. Individual's scores are illustrated by dots. Arrows illustrate correlations of the variables to the components. Longer arrows mean higher correlation and arrows close to a component has higher contribution in generation of the component.

**Conclusions:** The main findings in this study indicate a functional network in which several IL-1 $\beta$  related molecules in CSF influence fatigue in addition to the clinical factors depression and pain. The neuropeptide Hcrt1 seem to participate in fatigue signalling, but probably not through the IL-1 pathway.

### FRI0281 TRANSCRIPTOMIC PROFILING OF PDCs FROM PATIENTS WITH PSS IDENTIFIES CONSISTENTLY ALTERED GENE NETWORKS THAT INDICATE AN ACTIVATED PHENOTYPE AND ENHANCED ANTI-VIRAL STATE

M.R. Hillen<sup>1,2</sup>, A. Pandit<sup>1,2</sup>, S.L.M. Blokland<sup>1,2</sup>, S.A.Y. Hartgring<sup>1,2</sup>, K.M.G. Van der Wurff-Jacobs<sup>2</sup>, A.A. Kruize<sup>2</sup>, M. Rossato<sup>1,2</sup>, J.A.G. van Roon<sup>1,2</sup>, T. R. D. J. Radstake<sup>1,2</sup>. <sup>1</sup>Laboratory of Translational Immunology, <sup>2</sup>Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht University, Utrecht, Netherlands

**Background:** Primary Sjögren's syndrome is an autoimmune disease characterised by lymphocytic infiltration of the exocrine glands and dryness of mouth and eyes. Type-I interferons (IFN) are thought to play an important role in pSS pathogenesis and plasmacytoid dendritic cells (pDCs) are capable of producing high levels of IFN. These cells infiltrate the salivary glands of pSS patients and their numbers correlate with local IFN-production.

**Objectives:** To understand the molecular mechanisms behind systemic dysregulation of pDCs, we performed RNA sequencing on pDCs isolated from peripheral blood of patients with pSS, non-Sjögren's sicca (nSS) and healthy controls.

**Methods:** We established two independent cohorts (each  $n = 31$ ), of patients and controls. pSS patients ( $n = 25$ ) were classified according to the 2002 AECG criteria. nSS patients ( $n = 20$ ) presented with dryness complaints without a known cause, did not have any generalised autoimmune disease, and did not fulfil the classification criteria for pSS. Healthy donors ( $n = 17$ ) were included as control group. Peripheral blood pDCs were isolated using MACS and RNA sequencing was performed for both cohorts.  $\pm 20$  million paired-end sequencing reads per sample were obtained using Illumina HiSeq 2500 platform.

**Results:** 8556 genes were differentially expressed ( $p$ -value  $< 0.05$ ) between all three groups in the discovery cohort. Of these, 3144 genes were also differential in the replication cohort. We generated gene modules from both cohorts and found 5 gene clusters comprising 1259 genes that were consistently dysregulated in both analyses. Pathway analysis showed that the 5 modules contain genes associated with cellular activation, including a group of genes involved in IFN-signalling and viral sensing, as well as regulation of intracellular transport. Generally, pDCs from patients with nSS displayed an intermediate phenotype.

**Conclusions:** We mapped transcriptomic differences in circulating pDCs from patients with nSS and pSS and identified gene clusters that are robustly replicated in two independent cohorts. We found 5 gene clusters that are dysregulated in patients with pSS and indicate enhanced cellular activation, including IFN-signalling and viral sensing which are key pathways in pSS pathogenesis. nSS patients showed similar transcriptomic dysregulation at an intermediate level. These data can help us better understand the role of pDCs in pSS.

### FRI0282 MILK FAT GLOBULE EPIDERMAL GROWTH FACTOR 8 ON MONOCYTES IS A NOVEL BIOMARKER OF DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

M. Ushikubo<sup>1,2</sup>, S. Saito<sup>2</sup>, J. Kikuchi<sup>2</sup>, M. Takeshita<sup>2</sup>, K. Yoshimoto<sup>2</sup>, H. Yasuoka<sup>3</sup>, K. Yamaoka<sup>2</sup>, N. Seki<sup>4</sup>, K. Suzuki<sup>2</sup>, H. Oshima<sup>1</sup>, T. Takeuchi<sup>2</sup>. <sup>1</sup>Department of Connective tissue disease, National Hospital Organization Tokyo Medical Center, <sup>2</sup>Division of Rheumatology, Keio University School of Medicine, <sup>3</sup>Division of Rheumatology, School of Medicine Keio University, Tokyo, <sup>4</sup>Research Unit/Immunology and Inflammation, Mitsubishi Tanabe Pharma Corporation, Yokohama, Japan

**Background:** Milk fat globule epidermal growth factor 8 (MFG-E8) is an apoptosis-related secreted protein. It has been reported that MFG-E8 deficient or excess mice developed a systemic lupus erythematosus (SLE)-like autoimmune disease due to impaired clearance of apoptotic cells,<sup>1</sup> suggesting that abnormal expression of MFG-E8 is involved in the pathogenesis of SLE. Since elevated serum MFG-E8 level has been found in SLE patients,<sup>2</sup> it may possibly provide the

classification of the disease by pathological conditions.<sup>3</sup> However, the association with MFG-E8 expression and clinical features of SLE patients is not fully understood.

**Objectives:** To clarify the clinical significance of MFG-E8 in SLE, we analysed the correlation between the expression level of MFG-E8 in circulating phagocytic leukocytes and clinical parameters of the patients.

**Methods:** A multi-centre, exploratory and prospective SLE cohort was established. Among SLE patients who visited our division from May 2015 to March 2017 and satisfied the 1997 revised criteria, patients with one or both of BILAG A or B, or with SLEDAI-2K $\geq$ 4 and clinical symptoms were defined as active SLE. These patients were then matched with randomly selected patients by age, gender, history of nephritis, and daily glucocorticoid dose as an inactive SLE group. Age and sex matched healthy controls (HC) were also recruited. The expression level of MFG-E8 in monocytes and its concentration in serum of the patients were measured by FACS and ELISA, respectively. The clinical parameters of the patients were collected from their clinical records.

**Results:** A total of 108 cases were enrolled, consisting of 36 active (mean age: 44.2 $\pm$ 18.6, female: 80.6%, nephritis: 69.7%), 38 inactive SLE and 24 HC cases. The absolute number and the proportion of MFG-E8 positive-monocytes to total monocytes were significantly higher in the active SLE group ( $p<0.01$ ), whereas serum MFG-E8 level showed no significant difference among the group. Importantly, the proportion was also significantly correlated with SLEDAI-2K, serum levels of anti-ds-DNA antibody and complement and C1q (table 1). Notably, elevated proportion of MFG-E8-positive monocytes to total monocytes was observed in the patients with cutaneous or musculoskeletal involvement or leukocytopenia. In addition, the proportion of MFG-E8-positive monocytes to total monocytes significantly decreased from the baseline in active SLE patients after 6 months treatment and increased concordantly with disease activity in 6 refractory cases. Then we further analysed the accuracy to discriminate between active and inactive SLE patients and found that the proportion of MFG-E8 monocytes showed significant accuracy of disease activity, which is equivalent to serum levels of anti-ds-DNA antibody, complement and C1q, by receiver operating characteristic curve analysis (figure 1).

**Abstract FRI0282 – Table 1.** Correlation with SLEDAI and serological markers (Spearman's rho)

		#	Number of MFG-E8 positive monocyte	Proportion of MFG-E8 positive monocyte	Serum MFG-E8
a) Activity	SLEDAI-2K	74	0.570**	0.634**	-0.110
b) Serological markers	CH50	51	-0.503**	-0.591**	0.049
	Anti-ds-DNA antibody	74	0.425**	0.449**	-0.027
	C1q	69	0.526**	0.568**	0.001

\*  $p<0.05$ , \*\*  $p<0.01$  by Spearman's correlation coefficient

**Abstract FRI0282 – Figure 1.** Receiver operating characteristic curve analysis for discriminating active from inactive SLE

**Conclusions:** Our study indicate that the proportion of MFG-E8-positive monocytes to total monocyte in peripheral blood was positively associated with disease activity of SLE and may be a novel mechanistic biomarker to determine the disease activity.

**FRI0283 DYNAMIC CONTRAST ENHANCED MRI (DCE-MRI) DEMONSTRATES HIPPOCAMPUS PERMEABILITY IN SLE**

M. Mackay, B. Diamond, D. Eidelberg, A. Hoang, P.C. Sanelli. *The Feinstein Institute for Medical Research, Manhasset, USA*

**Background:** Cross-reactive, anti-dsDNA/N-methyl d-aspartate receptor antibodies (DNRAb) have been implicated in the pathogenesis of cognitive impairment in SLE. The mouse model demonstrates selective effects of DNRAb on hippocampal neurons following blood brain barrier (BBB) breach. <sup>1</sup> We previously identified abnormal hippocampal glucose hypermetabolism in SLE patients that correlated with serum DNRAb titers and poor performance on neuropsychological (NP) testing.<sup>2</sup> However, little is known about how antibodies access brain in humans.

**Objectives:** BBB permeability (BBBP) in SLE and healthy control (HC) subjects was evaluated with DCE-MRI. We hypothesised that brain areas with abnormal hypermetabolism<sup>2</sup> in SLE subjects would also demonstrate altered BBBP.

**Methods:** 6 SLE subjects with no history of NP symptoms and 6 HCs were recruited (all female). All subjects underwent NP testing and DCE-MRI on a 3.0 tesla magnet (Siemens Healthineers, GERMANY). MRI sequences were acquired according to standard protocols; permeability imaging used DCE technique with axial 3D-SPGR T1-WI sequences and 80 cine phases using TR=25 ms, TE=3.8 ms, FOV=24 mm, and matrix size of 128x256. Magnevist Gadolinium contrast (Bayer Healthcare, GERMANY) was dosed IV at 0.1 mmol/kg, at 5cc/sec following a 5 s delay. Post-processing of images into BBBP parameters of K-trans (mL/100 gm/min) and VE (mL/100 gm) was performed using Olea Sphere 2.2, 2.3 (Olea Medical, France) with the Tofts extended permeability model. This technique was standardised with the arterial input function centred in the cavernous ICA segment for all subjects.

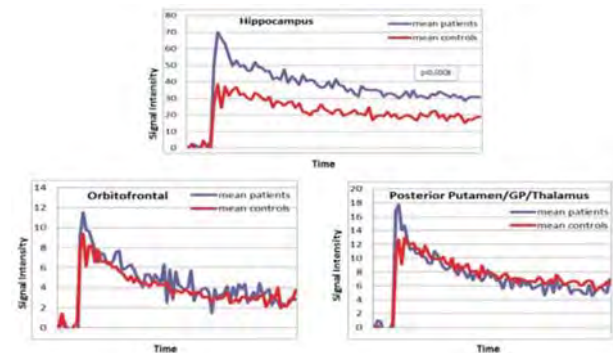

**Analyses:** Regions-of-interest (ROI) from previously identified hypermetabolic regions (hippocampus, orbitofrontal cortex, posterior putamen/globus pallidus/thalamus) were selected. Mirror ROIs were placed in bilateral MRI cerebral hemispheres for sampling at same brain levels. Regional DCE curves were generated to compare permeability phases. T-tests were used to evaluate demographic and NP testing differences.

**Results:** SLE subjects performed significantly worse than HCs on cognitive testing (table 1). Mean DCE curves (figure 1) show perfusion (initial spike) and permeability phases of contrast in the sampled tissues. Compared to HCs, SLE subjects demonstrate significantly increased signal in the permeability phase in the hippocampus, indicating leakage of contrast into the extravascular space.

**Abstract FRI0283 – Table 1.** Subject characteristics and neuropsychological testing scores

	Healthy Control (n=6)	SLE (n=6)	p
Age	35.04 $\pm$ 9.6	38.0 $\pm$ 13.2	.669
NP Testing*			
Matching Grids	40.9 $\pm$ 9.7	25.8 $\pm$ 9.2	.023
Match to Sample	35.4 $\pm$ 13.5	16.4 $\pm$ 5.9	.01
Continuous Processing	86.3 $\pm$ 13.9	65.6 $\pm$ 5.5	.013

\*Automated Neuropsychological Testing Metric: resulted as throughput scores that represent efficiency as a function of accuracy and time

**Abstract FRI0283 – Figure 1.** Dynamic Contrast Enhanced MRI Curves show increased hippocampus permeability in SLE

**Conclusions:** This is the first report of increased BBBP in SLE subjects that is specific to the hippocampus; a region that we have previously reported to have abnormal resting metabolism in SLE subjects. These data, including the abnormal NP testing, support the murine model of autoantibody-mediated cognitive impairment following disruption of the BBB. The results also suggest that DCE-MRI may be an effective, non-invasive tool to measure BBBP and its role in neuropsychiatric SLE pending confirmatory studies with increased sample size.

#### FRI0284 ALTERED PATTERNS OF HISTONE ACETYLATION POINT TO MECHANISMS OF TRANSCRIPTIONAL DYSREGULATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

B. Anić<sup>1</sup>, A. Blažeković<sup>2</sup>, D. Bosnić<sup>1</sup>, M. Sentić<sup>1</sup>, M. Mayer<sup>1</sup>, M. Cerovec<sup>1</sup>, K. Gotovac Jerčić<sup>2</sup>, F. Borovečki<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, Division for Clinical Immunology and Rheumatology, University Hospital Centre Zagreb; <sup>2</sup>Department for Functional Genomics, University of Zagreb School of Medicine, Zagreb, Croatia

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease designated by a heterogeneous course and systemic nature. It arises as a result of complex pathways, as well as the interaction of genetic and environmental factors, leading to the altered reactivity of the immune system that culminates in autoantibody formation. Epidemiological studies have shown an important role of the genetic component in the emergence of SLE and genome-wide association studies have identified more than 50 SLE-associated risk loci, pointing to a complex genetic background.

**Objectives:** The aim of the study was to further elucidate the genetic mechanisms influencing the development of SLE.

**Methods:** We performed chromatin immunoprecipitation experiments to ascertain the levels of histone acetylation in peripheral blood mononuclear cells collected from 5 recent onset and treatment naive SLE patients compared to 5 age and gender matched controls.

**Results:** The analysis revealed 16 379 significantly enriched genomic regions in control patients compared to 39 204 significantly enriched genomic regions in SLE patients. Among the SLE specific regions several pathways were significantly enriched including the adaptive immune system pathway, cytokine signaling in immune system, disease of immune system and inflammation mediated by chemokine and cytokine pathway.

**Conclusions:** The collective data point to a significant alteration of histone acetylation patterns in SLE patients possibly mediated by the DNA specific autoantibodies. The results of the study offer additional insight into the genetics of SLE pointing to putative mechanisms of transcriptional dysregulation.

#### FRI0285 DETECTION OF OLIGOCLONAL B-CELL POPULATIONS BY SPECTRATYPING ANALYSIS IN THE RENAL TISSUE OF PATIENTS WITH ACTIVE LUPUS NEPHRITIS

P. Sfikakis<sup>1</sup>, K. Kolovou<sup>2</sup>, M. Roumelioti<sup>1</sup>, D. Paleologou<sup>1</sup>, M. Tektonidou<sup>1</sup>, C. Kyrtsou<sup>1</sup>, J. Boletis<sup>1</sup>, P. Panayiotidis<sup>1</sup>, S. Marinaki<sup>2</sup>. <sup>1</sup>First Department of Propaedeutic and Internal Medicine; <sup>2</sup>Nephrology Department and Renal Transplantation Unit, Medical School, National and Kapodistrian University of Athens, Athens, Greece

**Background:** Previous studies have shown, using polymerase chain reaction (PCR), cloning, sequencing and analysis of rearranged immunoglobulin heavy-chain (Ig-V<sub>H</sub>/D<sub>H</sub>/J<sub>H</sub>) genes, that clusters of clonally-related sequences are commonly found in the peripheral blood of patients with active lupus nephritis.

**Objectives:** Using an easy-to-perform method such as spectratyping analysis, to test the hypothesis that clonal B-cell populations are present in the renal tissue of lupus nephritis patients, induced perhaps as a result of local (auto)antigenic stimulation.

**Methods:** Genomic DNA extracted from renal biopsy samples from 18 patients with active lupus nephritis and 24 control patients with other (auto)immune-mediated glomerular diseases, as well as DNA from 25 paired peripheral blood samples, was subjected to multiplex PCR for the detection of Ig-V<sub>H</sub> clonal rearrangement. PCR products were analysed by capillary electrophoresis according to the Biomed-2 standard guidelines for the definition of clonal B cell populations. Immunohistochemistry using the B-cell-specific L-26 antibody was also performed in available renal samples.

**Results:** Electrophoregrams of PCR products derived from patients with biopsy proven active lupus nephritis revealed the presence of oligoclonal B-cell populations among polyclonal B-cells in renal tissue of 6/18 patients. No associations with clinical or histology class were evident. Oligoclonal B-cell populations were also found in renal samples derived from patients with untreated focal segmental glomerulosclerosis (6 of 7), minimal change disease (1 of 3), membranous nephropathy (1 of 3) and IgA nephropathy (3 of 4), and not in patients with pauci-immune vasculitis (n=4) or membranoproliferative glomerulonephritis (n=3). Oligoclonal B-cell populations were not found in any of the paired peripheral blood samples derived from 13 patients having renal B-cell oligoclonality, suggesting the existence of local (auto)antigens leading to clonal expansion rather than B-cell transfer through peripheral circulation. Finally, spectratyping analysis identified polyclonal or oligoclonal B-cells in all renal tissues in the absence of detectable B-cells by immunohistochemistry in the same samples.

**Conclusions:** These novel findings show that spectratyping analysis can detect oligoclonal B-cell expansions in renal tissue from patients with active lupus nephritis and other (auto)immune-mediated glomerular diseases. Whether this standardised method can identify individual patients who could benefit from therapeutic B cell depletion deserves further study.

#### FRI0286 RANK-L IS EXPRESSED BY SALIVARY GLAND EPITHELIAL CELLS IN PRIMARY SJOGREN'S SYNDROME: A NOVEL ACTOR IN ECTOPIC LYMPHOID STRUCTURE NEOGENESIS

P.-M. DURET<sup>1</sup>, R. VEBER<sup>2</sup>, R. FELTEN<sup>1</sup>, F. MONNEAU<sup>2</sup>, C. MUELLER<sup>2</sup>, J. SIBILIA<sup>1</sup>, H. DUMORTIER<sup>2</sup>, J.-E. GOTTENBERG<sup>1</sup>. <sup>1</sup>Rheumatology, Strasbourg University Hospital; <sup>2</sup>Molecular and Cellular Biology, IBMC, Strasbourg, France

**Background:** Tertiary Lymphoid Organs (TLOs) are observed in target tissues of various immune-mediated inflammatory diseases (IMIDs) such as salivary glands in primary Sjögren's syndrome<sup>1</sup> (pSS). TLOs are mimicking secondary lymphoid organs (SLOs) architecture and strikingly share common features with lymph nodes.<sup>2</sup> SLOs organogenesis is coordinated by a complex stromal network that has not been fully characterised in TLOs yet. Although RANK-L (Receptor Activator of NF-κB Ligand) has been recently involved as a pivotal cytokine in precocious steps of lymph nodes development,<sup>3</sup> notably through a stromal cell expression, its contribution in TLOs neogenesis remains unclear.

**Objectives:** To characterise stromal cells subsets within TLOs arising in the salivary glands and to determine whether RANKL is expressed or not in the target tissue of pSS.

**Methods:** Stromal cells and RANK-L expression were analysed in TLOs from salivary glands by immuno-fluorescence on frozen sections in the NZB/NZW F1 mouse model and in minor salivary gland biopsies of patients fulfilling 2016 ACR-EULAR Sjögren's syndrome criteria and by flow-cytometry after enzymatic digestion of NZB/NZW F1 salivary glands. RANK-L expression has also been assessed by Real Time quantitative Polymerase Chain Reaction (RT-qPCR) and immunofluorescence on primary cultures of salivary gland epithelial cells (SGECs) with or without IL-1b or Interferon alpha (INF-α) stimulation.

**Results:** Most of SLOs stromal cells populations: Fibroblastic Reticular Cells (FRCs), Follicular Dendritic Cells (FDCs), Lymphatic Endothelial Cells (LECs), Blood Endothelial Cells (BECs) and High Endothelial Venules (HEVs) were identified in salivary TLOs of both NZB/NZW F1 mice and patients with pSS. FRCs were the dominant subset in salivary TLOs and their proportion correlated with the degree of lymphocytic infiltration (r=0,7 ; p=0,007). In SLOs, RANK-L was mainly expressed by MRCs, whereas, none of them could be detected in salivary TLOs. However, despite the absence of MRCs in TLOs, RANK-L was still expressed by

a few T-cells within the infiltrates and strikingly by epithelial cells. Furthermore, RANK-L expression by SGECS in primary cultures was increased after INF- $\alpha$  or IL-1 $\beta$  stimulation.

**Conclusions:** To our knowledge, this is the first report of a RANK-L contribution to primary Sjögren's syndrome. These results suggest that RANK-L could be an important actor of ectopic lymphoid neogenesis. RANK-L inhibition might represent, in the future, a relevant immuno-modulatory strategy in primary Sjögren's syndrome.

#### FRI0287 SEROLOGIC EVIDENCE OF VIRAL REACTIVATION AND INCREASED DISEASE ACTIVITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

R. Wood, L. Guthridge, E. Thurmond, C. Guthridge, H. Chen, W. deJager, S. Macwana, R.L. Boum, S. Kamp, R. Lu, C. Arriens, E.F. Chakravarty, A. Thanou, J. Merrill, J. Guthridge, J.A. James. *Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, USA*

**Background:** Systemic lupus erythematosus (SLE) is a clinically heterogeneous disease oftentimes characterised by a waxing and waning disease course. However, mechanisms of disease flare remain elusive.

**Objectives:** This study examined relationships between SLE disease activity, immune pathways, and serologic evidence of viral exposures and reactivation within molecular subsets of SLE patients.

**Methods:** Serial or single samples of plasma, serum and RNA (n=290) were collected from 184 adult SLE patients who met ACR classification and cohort-matched controls (n=49). Disease activity was assessed by modified SELENA-SLEDAI. Immune pathways were evaluated by modular transcriptional analysis of Illumina Beadchip Microarray gene expression data, as well as by plasma soluble mediators (n=32) by multiplex, bead-based assay and ELISAs. This information was used to subset patients into seven molecular-defined categories by random forest modelling. Viral seropositivity and antibody concentrations were detected by ELISA for antibodies against EBV-Viral Capsid Antigen (VCA) (IgG and IgA), EBV-Early Antigen (EA) (IgG), Cytomegalovirus (CMV) (IgG), and Herpes Simplex Virus (HSV-1) (IgG).

**Results:** Serologic evidence of EBV reactivation was more common in SLE patients compared to controls, as measured by antibodies against EBV-EA [IgG] (40% vs 13%; OR=4.57, p=0.0006) or EBV-VCA [IgA] (36% vs 17%; OR=2.70, p=0.019). No differences were noted in CMV or HSV1 seropositivity rates between patients and controls. IgG responses against EBV-VCA were nearly universal among these adult patients and controls; however, concentrations of EBV-VCA IgG were higher in SLE patients compared to controls (ISR=4.44 vs 3.52; p=0.0021), as were EBV-VCA IgA and EBV-EA IgG antibody responses. In cross sectional analysis, SLE patients with higher disease activity (SLEDAI  $\geq 6$ ; n=126) had higher concentrations of EBV-EA IgG than patients with lower (n=166) disease activity (ISR=0.822 vs 0.540; p=0.033). SLE patients with serologic evidence of EBV reactivation by EA IgG responses had higher levels of interferon associated molecules, IP10 (p=3.4 $\times 10^{-14}$ ), BLYS (5.5 $\times 10^{-5}$ ), and IL-10 (p=0.00013). HSV1 IgG positive SLE patients also showed higher levels of IP10 (2.2 $\times 10^{-7}$ ). Antibody responses toward EBV-EA were enriched in molecularly defined patient clusters with higher expression levels of interferon and inflammatory modules, as well as with interferon and inflammatory soluble mediators. Patients within these clusters were also more likely to have major organ involvement, such as renal or neurologic disease.

**Conclusions:** Serologic evidence of EBV reactivation is more common in SLE patients compared to healthy controls. EBV-EA IgG responses are elevated in SLE patients with active disease and correspond with increases in interferon-associated mediators. This study provides serologic evidence suggesting a possible role for viral reactivation in SLE disease activity.

#### FRI0288 THYMIC STROMAL LYMPHOPOIETIN (TSLP) BIOLOGICAL EFFECTS ON HUMAN PERIPHERAL BLOOD B LYMPHOCYTES IN PRIMARY SJÖGREN'S SYNDROME

S. Gandolfo<sup>1</sup>, M. Bulfoni<sup>2</sup>, C. Fabro<sup>1</sup>, E. Doriguzzi Breatta<sup>1</sup>, L. Quartuccio<sup>1</sup>, C. Di Loreto<sup>2</sup>, D. Cesselli<sup>2</sup>, S. De Vita<sup>1</sup>. <sup>1</sup>*Clinic of Rheumatology, University Hospital of Udine*; <sup>2</sup>*Institute of Anatomic Pathology, University Hospital of Udine, Udine, Italy*

**Background:** Thymic stromal lymphopoietin (TSLP) is an epithelial lymphopoietic cytokine belonging to interleukin (IL)–7 family, acting as a B-cell growth factor. A pathogenetic role of TSLP in primary Sjögren's syndrome (pSS) and pSS-related B-cell lymphoproliferation has been recently indicated.<sup>1</sup>

**Objectives:** to investigate the biological effects of TSLP on human peripheral blood B lymphocytes in pSS.

**Methods:** Peripheral blood B lymphocytes from 15 pSS patients, stratified according to their lymphoproliferative status (fully benign, fbSS: n=5; myoepithelial sialadenitis, MESA: n=5; B-cell non-Hodgkin lymphoma, NHL: n=5) and from 5 healthy blood donors (HBDs) were isolated by immunomagnetic negative selection and cultured with three different stimuli: i) TSLP; ii) combination of TSLP and IL-4; iii) combination of CD40 functional grade monoclonal antibody and IL-4. B-cell activation status was evaluated by flow cytometry, by analysing the expression of surface IgM after stimulation. An ELISA assay was also performed to assess the immunoglobulins (Ig) production in the B-cell culture supernatants after the exposure to the three different stimuli.

**Results:** peripheral blood B lymphocytes isolated from fbSS patients were significantly activated by the combination of TSLP and IL4 (p=0.0218), as well as by the classic co-stimulation of antiCD40 plus IL4 (p=0.044), but not when TSLP was used alone. This pattern of responsiveness was observed also in HBDs. By contrast, the peripheral B-cells of NHL pSS patients were significantly activated by the TSLP alone (p=0.0157), without the necessity of other additional stimuli. A similar response to TSLP alone was observed also in MESA B-cell cultures but with no significance. As concerns Ig production in culture supernatants of peripheral B-cells, in fbSS patients we observed a significant increase of Ig production both after the exposure to TSLP plus IL4 (p=0.0417) and after the stimulation with antiCD40 plus IL4 (p=0.0293), but not with TSLP alone. By contrast, TSLP alone induced Ig production both in MESA (p=0.0368) and in NHL peripheral B-cells (p=0.0268). Unexpectedly, the combined stimulus of TSLP plus IL4 did not produce any significant effect in both these subgroups, and was less effective than TSLP alone also in stimulating B-cell surface IgM expression.

**Conclusions:** human peripheral blood B-cells from pSS patients showed an increased responsiveness to TSLP, however with significant differences. In HBDs and in fbSS, TSLP induced a significantly higher B-cell activation and immunoglobulin production only with the addition of IL4, whereas in NHL TSLP alone was sufficient. In addition, IL-4 co-stimulus induced a lower activation than TSLP alone in NHL. Overall, also functional tests support a role of TSLP as an important driver of B-cell stimulation and lymphoma progression in pSS. Interactions of TSLP with other B-cell stimulating factors also deserve particular attention.
