Results: The CR achievement rate at the last observational day by Boolean definition and Simple Disease Activity Index were 40.5% and 50.2%, respectively. The achievement rate of HAQ-DI ≤0.5, EQ5D ≥0.867 and FeR was 73.1%, 48.5%, and 46.7%, respectively. The differences in disease duration, stage, class and HAQDI at the time of the first interview, state of MTX, GCs and b/ts-DMARD use; and age at the last observational day for the achievement of FeR were statistically significant. The odds ratios, as determined by multiple logistic regression analysis of the above-mentioned results, were 1.034 (95% CI 0.982–1.088, p=0.202) for disease duration (per 1 year), 1.576 (95% CI 1.257–1.977, p<0.001) for HAQDI at first interview (per 0.5), 0.615 (95% CI 0.277–1.365, p=0.232) and 4.943 (95% CI 1.683–14.524, p<0.01) for GCs state (non-use vs temporal use and non-use vs continuous use, respectively), and 1.164 (95% CI 1.037–1.307, p=0.05) for age at last observational day.

Conclusions: HRQoL is important as they will influence future treatment strategy. Our results indicated the importance of functional assessment at first interview and demonstrated how to use GCs for the treatment of RA. Ageing always contributes to patients’ frailty, and it is unavoidable to it. To achieve FeR, functional assessment should be performed during the first interview and short-term use of GC is useful for prompt functional recovery, in consideration of ageing.

AB0311

DETERMINANTS OF NON-NOCICEPTIVE PAIN IN RHEUMATOID ARTHRITIS

T.M. Rocha, S. Pimenta, M. Bernardes, A. Bernardo, M. Barbosa, R. Lucas, L. Costa. Rheumatology, Centro Hospitalar de São João, Porto, Portugal

Background: A neuropathic component (NP) of Rheumatoid Arthritis (RA) pain was described in nearly a third of the patients. Radiographic damage is a reflection of cumulative disease activity and other pathophysiological processes. Some clinical predictors of NP were recently identified by our group, but association and adjustment for radiographic damage were not studied.

Objectives: To estimate the clinical predictors of NP in RA patients adjusting for their radiographic damage.

Methods: Cross-sectional study was performed with RA patients followed at our Rheumatology department. Patients with diagnosed neuropathy or non-RA risk factors for NP were excluded. Selected patients were evaluated in a medical visit. Demographic and clinical data were collected and two questionnaires were applied to assess NP: the Leeds Assessment of Neuropathic Symptoms (LANSS) and the painDETECT (PQD). Wrists, hands and feet radiographic studies from the previous 12 months were classified according to the modified van der Heijde Sharp’s method by one trained reader, blinded for patient clinical variables and treatment allocation. Univariate and multivariate logistic regression were performed adjusting for global radiographic score (GS). Significance level was set as <0.05.

Results: Ninety one RA patients were included. Seventy (77%) were women, with a mean (SD) age of 55.6 (10.8) years and median disease duration of 12 years; 84% patients were seropositive for Rheumatoid Factor and/or ACPA; 89% were treated with DMARDs and 41% with a biological DMARD (bDMARDs). The mean (SD) DAS28 4V CRP was 3.15 (0.77). The median joint erosion score was 28 (range: 3–143) and the median joint space narrowing (JN) was 46 (range: 10–133). Forty-two (46%) patients had LANSS NP (≥12) and 29% had a possible/likely NP in the PDG (≥12). JN was a significant negative predictor of LANSS NP (OR: 0.98, p=0.02); After adjusting for GS, gender was not associated with NP. Pain VAS, patient global activity and the tendon joint count were positive predictors of NP of both tests. Swollen joint count, ESR or CRP levels were not significantly associated with NP. DAS28 CRP was a significant positive predictor of NP by both tests (OR 1.89 for LANSS and OR: 2.06 for PDG, p<0.05); as well as the HAQ score (OR: 2.68 and OR: 4.85, respectively, p<0.05). Positivity for ACPA was a negative predictor of LANSS NP (OR: 0.31, p=0.048), as previously described. Current methotrexate treatment had lower odds of LANSS NP (OR: 0.35, p=0.04) but did not remain significant after adjustment for DAS28 CRP. Previous/current Hydroxychloroquine (HCQ) treatment was once more a significant negative predictor for NP (OR 0.11, p=0.04) and remained significant after adjustment for DAS28 CRP. Previous/current leflunomide (LFN) was newly a positive predictor of NP in both tests (OR: 3.41 for LANSS and OR: 2.95 for PDG, p<0.05), persisting after disease activity adjustment for LANSS NP. No other associations were found.

Conclusions: Consistently with our previous data, this study supports an association between NP and disease activity/function scores but not with objective inflammatory measures. Possible increased risk of NP in LFN treated patients was newly pointed and protective role of ACPA positivity and HCQ was reinforced.

AB0312

INFLAMMATORY ACTIVITY APPEARS WELL CONTROLLED IN MOST PATIENTS WITH RHEUMATOID ARTHRITIS (RA) IN CONTEMPORARY RHEUMATOLOGY CARE, BUT JOINT DAMAGE AND DISTRESS REMAIN AS PROBLEMS OF GREATER MagnITUDE THAN INFLAMMATION

T. Pincon, I. Castrejon, J.A. Block. Rheumatology, Rush University Medical Center, Chicago, USA

Background: Rheumatologists traditionally use quantitative measures such as swollen and tender joint counts and laboratory tests to assess inflammatory activity. However, structural damage to joints, as well patient distress seen as fibromyalgia, depression, etc., may be important clinical problems for many RA patients, but are described narratively in the medical record rather than estimated.
Physician global assessment of the status of patients with rheumatoid arthritis (RA) at their first visit to an academic routine care setting is explained as much by damage and distress as by inflammation. According to physician ratings: Should the structure of rheumatology care be modified?

T. Pinios, I. Castrejon, J.A. Block. Rheumatology, Rush University Medical Center, Chicago, USA

Background: A physician global assessment (DOCGL) on a 0–10 visual analogue scale (VAS) reflects inflammatory activity in patients who meet criteria for RA clinical trials, in which DOCGL is more efficient than laboratory tests or joint counts to distinguish active from control treatments. However, in routine clinical care, patients are not selected for inflammatory activity, and may have joint damage and/or distress (fibromyalgia, depression, etc.) as important clinical problems. Some rheumatologists consider damage and distress in assigning a 0–10 DOCGL; others consider only inflammation. One approach to resolve this matter is for physicians to estimate the proportion of DOCGL attributed to inflammation, damage, or distress (total=100%).

Objectives: To analyse a physician 0–10 VAS overall global assessment for estimates of the proportions attributed to inflammation, damage, or distress (total=100%).

Methods: Rheumatologists at one academic setting complete a 0–10 VAS for DOCGL, and estimates of the proportion of DOCGL attributed to inflammation, damage, and/or distress (total=100%). These scales were analysed in 38 new patients with RA seen between April and November 2017, using cross-tabulations to compare patients whose DOCGL was 0–4 vs 4–10 vs the proportion of inflammation, damage, or distress (total=100%) as 0%–40% or 41%–100%.

Results: Physician global assessment was 4–10 in 23/38 patients (61%) at first visit, and 0–4 in 15/38 (39%) (table 1). In all 38 patients, inflammation was rated as explaining 41%–100% of DOCGL in 11/38 (29%), compared to damage in 18/38 (47%), and distress in 6/38 patients (16%). Among the 23/38 patients with DOCGL 4–10, inflammation was rated as explaining 41%–100% of DOCGL in 6/23 (29%), versus 10/23 (43%) for distress. Therefore, inflammation appear to account for >40% of DOCGL only in a minority of new RA patients, which were explained more by either damage or distress (or both).

standing RA patients. It is very important to set treatment goal for those management.

Methods: The purpose of this study is to set treatment target using Timed Up and Go test (TUG) in relation to achievement of HAQ-DI remission (HAQ-DI <0.5) with joint surgery in lower limbs. 

Methods: Multicenter prospective observational cohort study was conducted among patients who underwent elective joint surgery for RA from April 2012 to March 2016 (Study registration: UMIN000012649). In this study, we collected data including age, sex, disease duration, drug therapies, and disease activity (DAS), TUG, and patient-reported outcome [HAQ-DI, EQ-5D (QOL), patient's global assessment (PtGA) and BDII-II (depression)] at baseline and at 6 or 12 months after the surgery. Association between TUG and achievement of HAQ remission and cut-off values for HAQ remission were also determined using logistic regression analysis with adjustment of age and sex and ROC curve, respectively.

Results: Totally, 139 patients with elective joint surgery in lower limbs were analysed. Mean age, disease duration, HAQ-DI and TUG were 65.4 years, 17.5 years, 1.022, and 12.7 s, respectively. Performed joint surgeries were total hip arthroplasty; 10.1%, total knee arthroplasty; 33.8%, total ankle arthroplasty or ankle fixation; 10.1%, and forefoot arthroplasty; 46.0%. The surgeries can significantly improve the outcome measures, including TUG, DAS, PtGA, pain, EQ-5D and BDII-II other than HAQ-DI. In this study, 45 of 139 patients (32.4%) had HAQ remission status at baseline. 18 of 94 patients (19.1%) who had HAQ-DI >0.5 can achieve HAQ remission with the surgery. Notably, TUG at last observation was significantly associated with achievement of HAQ remission even after adjustment for age, sex, and BDII-II (1 s increasing of TUG. OR:0.72, 95% CI: 0.53–0.97). The adjusted-TUG at last observation of patients with achievement of HAQ remission was 9.2 s (95% CI: 5.6–12.8) (figure 1). Cut-off of TUG at observation for achievement of HAQ remission was 9.2 s based on ROC analysis (figure 2). Importantly, We confirmed significant more improving of EQ-5D, HAQ-DI and TUG in patients who achieved TUG 9.2 s at last observation than in patients who did not (figure 3).

Conclusions: TUG was significantly associated with PRO; HAQ-DI and EQ-5D. The cut-off values of TUG (9.2 s) should be important to achieve good QOL and physical function for patients with joint surgery in lower limbs and could be suitable target for surgical procedure.

IS THERE A NEED TO RELOOK AT THE CUT OFFS OF RHEUMATOID FACTOR IN INDIAN POPULATION ?

V. Vasdev. Rheumatology and Clinical Immunology, Army Hospital R and R New Delhi, new delhi, India

Population specific cut offs of titers of Rheumatoid Factor (RF) in diagnosis of Rheumatoid arthritis (RA) and the role of anti citrullinated peptide antibodies (ACPA) remains unknown.

Objectives: To define cut offs for RF titres in diagnosis of RA in Indian population

Methods: RF titers of consecutive adult RA patients fulfilling ACR 1987 as well as ACR/EULAR 2010 criteria were compared with healthy normal and disease controls encountered in the rheumatology OPD of a tertiary care Armed forces Hospital using ROC-AUC analysis. Reclassification of disease phenotype as seropositive and seronegative RA using various the cutoffs was looked into and corresponding Anti-CCP titers in the subset of patients with RA was analysed.

Results: Overall 589 cases of RA (range: 18–69 years; 29.9% Females) were compared with age and sex matched 192 non RA and 51 controls. Mean (+SE) RF titers in RA cases was 107.7 IU/L (+ 6.17) while that in non RA disease cases was 29.3 IU/L (+ 6.08) and normal healthy controls 14.7 IU/L (0.43). ROC analysis revealed a cutoff titer of 20.3 IU/L (+ 0.74) with the best combination of sensitivity and specificity for a diagnosis of RA from non RA and healthy controls. With the currently used cutoffs of 60 IU/L in our centre as well as high titre RF as per ACR/EULAR 2010 criteria, subjects were seropositive in 286/589 (48.5%) cases. Cutoffs of 40 IU/L and 20 IU/L led to a label of seropositivity in 322 (54.7%) and 396 (67.2%) cases respectively. Simultaneous Anti-CCP was done in 480 (81.4%) cases: 363 (75.6%) of these were positive. Using a cutoff of 60 IU/L as seropositive RA, anti CCP positivity was noted in 246/286 (86%) cases while with a cutoff of 40 IU/L and 20 IU/L it was 278/322 (86.3%) and 334/396 (84.3%) respectively. The RF titers in 117 anti-CCP negative cases was >20,>40 and>60 IU/L in 62 (52.9%), 44 (37.6%) and 40 (34.1%) cases respectively.

Conclusions: In this observational study, patients with early RA at risk of inadequate response to MTX include only with high disease activity at baseline, and the level of ACPA titers or other baseline characteristics don’t predict it.
DO MECHANICAL AND INFLAMMATORY RHEUMATOLOGIC DISEASES LEAD TO THE SAME SLEEP DISORDERS?

W. Hamdi, M. Boudokhane, I. Cherif, D. Kaffel, K. Maatallah, M. Kchir.
Rheumatology, Kassab Institute, Tunisia, Tunisia

Background: Sleep disorders are frequent feature of chronic rheumatologic diseases. They are reported in inflammatory diseases as well as in mechanical disorders but they are not systematically assessed by clinicians. It is necessary to identify the factors associated to sleep problems in order to reduce their impact on patient’s quality of life.

Objectives: We aim to describe the sleep pattern in inflammatory and mechanical chronic rheumatologic diseases and to assess factors associated with sleep disorders.

Methods: We conducted a cross-sectional study during 1 year including Tunisian patients with chronic inflammatory rheumatism (rheumatoid arthritis: RA according to the criteria ACR 1987 and axial spondyloarthritis: AS according to modified NEW YORK criteria) and patients with mechanical disorders (chronic low back pain and primitive knee osteoarthritis). Sleep has been evaluated by the MOS-SS questionnaire. For each group specific disease parameters were assessed at the same time of the administration of the questionnaire.

Results: We collected 120 patients with chronic inflammatory rheumatism (group 1) and 80 patients with mechanical disorder (group2). Group 1 was composed of 70 RA and 50 SPA including 65 women and 55 men. The average age was 46.95 [18.75]. Group 2 was composed of 40 chronic low back pain and 40 primitive knee osteoarthritis including 48 women and 32 men. The average age was 51.95 [18.82]. Sleep disorders were frequent in both groups, but they were more noticeable in Group 1 patients than Group 2 patients 53.68% vs 26.38% (p=0.00). Risk factors for sleep disorders in rheumatoid arthritis were disease activity (p=0.00) and functional impairment (p=0.00). In patients with spondyloarthritis, risk factors for sleep impairment were disease activity (BASDAI (p=0.00), ASDAS vs (p=0.00) et ASDAS CRP (p=0.00)) and impaired quality of life (p=0.00). The factors involved in sleep disorders in chronic low back pain was the reduced lumbar spine mobility assessed by the finger-to-ground distance (p=0.00) and the schober index (p=0.01) and functional impairment assessed by Eiffel questionnaire (p=0.00). In patients with knee osteoarthritis the Lequesne index (p=0.008), the knee extension limitation (p=0.00) and the radiological damage (p=0.004) were associated to sleep impairment.

Conclusions: Our results illustrate the frequency of sleep disorders in chronic rheumatic diseases. They should not be underestimated in patients with mechanical disorders. A better control of the factors associated to sleep impairment for each disease should help promoting a better sleep quality in patients with chronic rheumatologic diseases.

ARE PATIENTS EXPERIENCING DIFFERENT SORT OF FATIGUE DEPENDING ON THE TYPE OF CHRONIC RHEUMATISM?

W. Hamdi, M. Boudokhane, I. Cherif, D. Kaffel, K. Maatallah, M. Kchir.
Rheumatology, Kassab Institute, Tunisia, Tunisia

Background: Fatigue is frequently reported by patients with inflammatory chronic diseases as well as in mechanical rheumatologic disorders. But it’s not recognized and treated as priority by clinicians. It is necessary to identify the frequency of this symptom and to determine it’s impact on the quality of life of patient.

Objectives: We aimed to assess ando compare the frequency and the intensity of fatigue between inflammatory and degenerative chronic rheumatologic diseases, and to identify the factors correlated with fatigue in these diseases.

Methods: We conducted a cross-sectional study during 1 year including Tunisian patients with chronic inflammatory rheumatism (rheumatoid arthritis: RA according to the criteria ACR 1987 and axial spondyloarthritis: AS according to modified NEW YORK criteria) and patients with mechanical disorders (chronic low back pain and primitive knee osteoarthritis). Fatigue was assessed by the chalder questionnaire including physical and mental fatigue. Results: The frequency of fatigue in patients with chronic inflammatory rheumatism (group 1) and 80 patients with mechanical disease (group2). Group 1 was composed of 70 RA and 50 AS including 65 women and 55 men. The average age was 46.95 [18.75]. Group 2 was composed of 40 chronic low back pain and 40 knee osteoarthritis including 48 women and 32 men. The average age was 51.95 [18.82]. Fatigue was more significantly observed in group 1 than in group 2: 8.40% vs 5.54% (p=0.000). Mental and physical fatigue was noted in 2.1% and 6.25% in group 1 and 1.0% and 4.49% in group 2, respectively. The risk factors for fatigue were in the RA theth swollen joint and swollen joint count, the DAS 28 and the HAQ. In AS, factors associated to fatigue were the visual scale of pain, BASFI, BASDAI, ASDAS, and CRP. In the chronic low back pain fatigue was associated by the functional impairment assessed by the Eiffel questionnaire. Finally knee in osteoarthritis fatigue was associated to Lequesne index and radiological stage.

Conclusions: Fatigue seems to be a frequent symptom in rheumatic diseases and mostly associated to severity and activity of the disease.

IMPAKT OF RHEUMATOID ARTHRITIS ON LIFE QUALITY: BEFORE AND AFTER TREATMENT

X. Grapton1, on behalf of CREER, P. Lemeslé2, on behalf of CREER, L. Arabián3, on behalf of CREER, V. Stróz3, on behalf of CREER on behalf of CREER.1 Private Rheumatology Practice, Colombes; 2Private Rheumatology Practice, Bois-Colombes; 3Private Rheumatology Practice, Clamart; 4Private Rheumatology Practice, Antony, France

Background: Life quality issues in rheumatoid arthritis (RA) are often spontaneously mentioned by patients or identified by rheumatologists. Besides classic follow up parameters like DAS28 we have to consider those issues to improve our patients life quality.

Objectives: Explore and quantify the impact of RA on life quality via everyday’s life and psychological items and the effect of treatment on them.

Methods: RA cases were collected by a group of 20 private practice rheumatologists in the Paris area. Basic informations about the patient and his disease were provided by his rheumatologist. Questionnaire including 12 themes and 41 items was filled in by the patient.

Results: 167 cases collected: 82% women, mean age 57 years, 56% moderate and 14% severe disease, 76% ACPA positive, 73% structural damage. Initial DAS28 4.7, Post treatment DAS28 2.7. Drugs: classic DMARDs 95%, corticostoids 73%, biological DMARDs 22%, combination therapy 76%. Life quality issues are spontaneously mentioned by 55% of the patients.

Disclosure of Interest: None declared

Abstract AB0321 – Figure 1. The absolute number of CD4+ Treg cells were reduced in peripheral blood of the all enrolled new-onset RA patients (n=57) (A). The reduction of peripheral CD4+ Treg cells from new-onset patients were negatively correlated with the levels of RF tested in these subjects (B). There was statistically significant difference in two titer groups of RF (C).

Conclusions: The absolute number of CD4+Treg cells in peripheral blood of new-onset patients with RA was significantly decreased compared with that in health controls. Furthermore, the reduction of peripheral CD4+ Treg cells was negatively correlated to the titers of RF, suggesting that RF contributes to the reduction of CD4 +Treg cells. The correlation of decreased CD4+ Treg and RF may be involved in the pathogenesis of poor prognosis in RA.

AB0321 NEGATIVE CORRELATION OF THE ABSOLUTE NUMBER OF CD4+CD25+FOXP3+REGULATORY T CELLS TO THE LEVELS OF RHEUMATOID FACTOR IN PERIPHERAL BLOOD OF NEW ONSET PATIENTS WITH RHEUMATOID ARTHRITIS

X. Jianfang1, C. Gao2, X. Li1, G. Liu1. 1Second Hospital of Shanxi Medical University, Taiyuan, China; 2Pathology, Brigham and Woman’s Hospital, Boston, USA

Background: Rheumatoid arthritis (RA) is a progressive immune-mediated disease that can culminate in joint destruction and early mortality. High levels of serum RF are associated with a worse prognosis in RA. The role of RA is not fully understood. Recently, our studies have found that the absolute number of peripheral CD4+CD25+Foxp3+ regulatory T (CD4+Treg) cells decreased in RA patients. Interestingly, regulatory T cell epitopes (Tregitopes) in IgG has been reported as the main component of intravenous immunoglobulin therapy (IVIG) and provide a new tool for tolerance induction and treatment of autoimmunity. J Clin Immunol 2013 Jan;33(Suppl 1):S43–9. doi:10.1007/s10875-012-9762-4 [Epub 2012 Sep 2. Review].

Disclosure of Interest: None declared

Before treatment, psychological well-being and housework ability are altered in more than 50% of the cases. Impact on economy, food and social life occurs in less than 25% of the cases. Life quality is mostly altered by pain (85%), then fatigue (75%) and handicap (58%).

We find a correlation between the severity of RA and the importance of the impact on psychological well-being, sexual life and hobbies.

After treatment, psychological well-being improves in 53% of the patients, and social life, work, getting about and sexual life in 45%–32%.

Items improved around 50% of the patients are in order; sleep, relation to other people, feeling excluded, social life, depression, sick leave, concentration problems, anxiety and shopping.

We find and improvement in a third of cases in house-keeping, going out, sports and libido.

72% of the patients feel a lack of listening by their families, even under treatment.

Conclusions: Treatment of RA, including drugs and associated measures, reduces the frequency of negative impact on life quality.

We observe that, when DAS28 drops by 43%, the frequency of RA related repercussions diminishes by 31% (14%–50%) on the chosen items. All the items are impacted by RA before treatment and stay impacted after treatment, but less frequently, except family relations. More than one patient of 2 gains correct sleep and almost half of them aren’t depressed or anxious anymore. Impact on social activity and house-keeping activity are less frequently improved.

Regarding these facts, the rheumatologist has to accomplish a tight follow-up and suggest, besides drug treatment, associated measures like physiotherapy, professional activity and environment adaptation and rest among others.

A qualitative evaluation of the improvement will be the subject of a further study.

Department of rheumatology, Shandong Provincial Hospital Affiliated to Shandong University, Jinan, 13. Department of Rheumatology, Chongqing Hospital of Traditional Chinese Medicine, Chongqing, 14. Shanghai Gothic Internet Technology Co., Ltd., Shanghai, 15. Suzhou AntiInflammatory Research Institute, Suzhou, China

Background: Combination therapy with DMARDs for treating RA is considered as standard of care. However, certain rates of adverse events (AEs) are unavoidable. The stigma is which drug should be stopped first once AEs emerge. The decisions made by clinicians are always empirically.

Objectives: To develop an algorithm for decision making on drug withdraw sequence in factoring combination events with combination therapy based on data mining and machine learning from the SSDM.

Methods: SSDM is an interactive mobile disease management tool, including the doctors’ and patients’ application system (App). The patients can input medical records and perform self-evaluation via App. The data synchronises to the mobiles of authorised rheumatologists through cloud and advices could be delivered. In order to develop the master algorithm, abnormal white blood cell (WBC) counts in blood were first targeted. WBC and medication data was collected, extracted, validated, and then based on Bayesian networks, data mining, modelling, calculating, analysing were performed. WBC under 4,000/ml is defined as leukocytopenia (LP), and over 10,000/ml as infection predisposing (IP).

Results: From Jun 2014 to Jan 2018, 4,731 RA patients from 486 centres registered in SSDM. 6,099 are male and 18,632 are female with mean age of 49.28 ±16.08 (18 to 99) years. 19 different drugs and 156 types of combination therapies are identified. Lab test results showed LP happened in 87 and IP in 123 treatment groups.

Abstract AB0322 – Figure 1. Bayesian network and data processing: patients’ number (black bold as blow showed) and the rate of either LP or IP in 15 regiments.

AB0323

RELATIONSHIP BETWEEN SERUM LEVELS OF LEPTIN & HOMEOSTYNE IN RHEUMATOID ARTHRITIS PATIENTS WITH OR WITHOUT EXTRA ARTICULAR MANIFESTATIONS

Y. Hussein Gazar. Rheumatology Department, Al-Azhar University, Cairo, Egypt

Background: Rheumatoid arthritis (RA) is a chronic, systemic disorder with unknown etiology, which is characterised by involvement of hand joints and deformations. Rheumatoid arthritis is characterised by synovial inflammation and hyperplasia. Chronic inflammatory process of the joints that progresses through different stages of increasing severity characterises rheumatoid arthritis.

Objectives: In this study we aimed to determine the relationship and correlation between serum homocystein and leptin levels in RA patients with rheumatoid arthritis (RA) without extra articular manifestation (non Ex RA)(GROUP-A) and RA patients with extra articular manifestation (ExRA) (GROUP B) and disease progression.

Methods: 80 patients diagnosed as rheumatoid arthritis (according TO ACR/EULAR 2010 classification criteria) (according TO ACR/EULAR 2010 classification criteria) and selected as follow: (Group A) 40 patients without extra articular manifestation (non ExRA) and (Group B) 40 patients with variable extra articular manifestation (ExRA).

Results: Significant differences were found between RA patients (group A+group B) and controls healthy group (group C) with regard to the mean levels of Hb, ESR, TNF-α, IL-6, and DAS-28 (p<0.05).

As regards to serum leptin, non significant level differences between healthy control group (20.43±8.73 ng/ml) and patient groups (group II and III) (22.43±7.73 ng/ml).

While A statistically significant higher mean level serum Homocystein concentration (p<0.05) was found in patients (group A) and B (11.79±8.72 μmol/L) than in control (group C) (8.8±1.58 μmol/L).

Significant differences were found between non ExRA (group A) and ExRA (group B) with regard to the mean levels of Hb, ESR, TNF-α and IL-6 (p<0.05). A statistically non significant differences in mean level of serum Leptin concentration (p>0.05) was found in group A (22.43±5.73 ng/ml) than in group B (24.43±5.73 ng/ml).

While a significant level mean of serum Homocystein concentration (P value>0.05) was found in Group B patients (19.43±1.08 μmol/L) than in group A (11.79±13.05 μmol/L) (P<0.05).

Positive significant correlations were detected between serum Homocystein and ESR, TNF-α, IL-6, and DAS-28 (p<0.05) in group A.

Conclusions: Serum leptin can’t be considered of value as an inflammation marker in monitoring RA patients.

Seum homocystein can be used as a marker for probability of extra articular compiliation of RA.

AB0324 DISTRIBUTION AND CLINICAL SIGNIFICANCE OF ANTI-HETEROGENEOUS NUCLEAR RIBONUCLEOPROTEIN A2 ANTIBODY IN CONNECTIVE TISSUE DISEASES
V. Wang, F. Mu, Y. Fang. Department of Rheumatology, Southwest Hospital, the Third Military Medical University, Chongqing, China

Background: The anti-heterogeneous nuclear ribonucleoprotein A2 (hnRNP-A2) antibody is specific for rheumatoid arthritis (RA). But, it is also reported that there is no significant difference between RA and systemic lupus erythematosus (SLE) in terms of the antibody.

Objectives: To investigate the distribution and clinical significance of anti-hnRNP-A2 antibody in connective tissue diseases.

Methods: Serum anti-hnRNP A2 antibody level was measured by solid-phase enzyme linked immunosorbent assay (ELISA) in 1464 patients with RA, 209 patients with SLE, 204 patients with arthralgic spondylitis (AS), 63 patients with mixed connective tissue disease (MCTD), 133 patients with undifferentiated connective tissue disease (UCTD), 60 patients with Sjogren syndrome (SS), 47 patients with polymyositis/dermatomyositis (PM/DM), and 45 patients with systemic sclerosis (SSc). The positivity rate of anti-hnRNP-A2 antibody was compared among various patient groups, and its correlation to clinical and laboratory parameters and its diagnostic significance were analysed.

Results: The positivity rate of anti-hnRNP-A2 antibody was 38.0% (556/1464), 36.8% (77/209), 3.9% (8/204), 52.4% (33/63), 17.3% (23/133), 5.0% (3/60), 4.3% (2/47), and 8.9% (4/45) in RA, SLE, AS, MCTD, UCTD, SS, PM/DM and SSc, respectively. The rate differed insignificantly between the RA, SLE and MCTD groups (p>0.05), but was significantly higher than in other disease groups (p<0.01). The titers of anti-hnRNP-A2 antibody were significantly higher in the RA, SLE, MCTD and AS groups (p<0.05), but differed insignificantly between the RA, SLE, MCTD groups (p>0.05). In RA patients, anti-hnRNP-A2 antibody weakly correlated negatively to anti-Cyclic citrullinated peptide (CCP) antibody (r=-0.135, p<0.01), but correlated insignificantly to age, course of disease, and its positivity rate is relatively high in RA, SLE and MCTD. It is not a marker of connective tissue disease.

Conclusions: Anti-hnRNP-A2 antibody can be found in various connective tissue diseases, and its positivity rate is relatively high in RA, SLE and MCTD. It is not a marker of connective tissue disease.

AB0325 CLINICAL OUTCOME OF 2 YEARS TREATMENT OF THE EARLY PHASE RHEUMATOID ARTHRITIS
Y. Sugimura1, T. Kashigawara2, M. Kobayashi3, H. Miyakoshi4, Y. Shimada4. 1Orthopedic Surgery, Nakadori General Hospital; 2Orthopedic Surgery, Akita City Hospital; 3Orthopedic Surgery, Hiraka General Hospital; 4Orthopedic Surgery, Akita University Graduate School of Medicine, Akita, Japan

Background: Few studies have reported long term clinical outcome of patients with early phase rheumatoid arthritis (RA).

Objectives: The objectives of this study were to investigate outcome of 2 years treatment for RA which was started less than 12 months after RA symptoms first appeared and to evaluate prediction factors of poorly controlled patients at 2 years.

Methods: From a total of 1663 RA patients registered in the Akita Orthopaedic Group on Rheumatoid Arthritis (AORA), 66 patients were treated within the first year of RA appearance, and enrolled in this study. Sex, age, RA disease duration, Steinbrocker’s stage, Steinbrocker’s class, medications and DAS28-ESR at the baseline and 2 years post-treatment were evaluated. Furthermore, we compared the group of remission (REM) or low disease activity (LDA) with the group of medium disease activity (MDA) or high disease activity (HDA) at 2 years.

Results: At the baseline, the patients included 13 males and 53 females. Mean age and RA disease duration were 59±8 years and 7±11 months, respectively. Fifty-four, 8, 0 and 0 patients were classified into Steinbrocker’s stage I, II, III, and IV, respectively. Thirty-nine, 25, 2 and 0 patients were classified into Steinbrocker’s class I, II, III, and IV, respectively. Thirty-seven (56%), 24 (36%), and 16 (24%) patients were treated with MTX, DMARDs, and PSL, respectively. In DAS28-ESR, 19 (29%), 13 (20%), 32 (48%), and 2 (3%) patients showed REM, LDA, MDA, and HDA, respectively. Forty-four patients were followed-up for 2 years. At 2 years, 30, 7, 5, and 2 patients were classified into Steinbrocker’s stage I, II, III, and IV, respectively. Thirty-one, 12, 1, and 0 patients are classified into Steinbrocker’s class I, II, III, and IV, respectively. In DAS28-CP, 33 (75%), 4 (9%), 7 (16%), and 0 (0%) patients showed REM, LDA, MDA, and HDA, respectively. Compared with the group of REM or LDA, the group of MDA or HDA had significantly older age (p=0.018), higher Steinbrocker’s stage (p=0.012) and higher DAS28-CP (p=0.049) at the baseline.

Conclusions: At 2 years, 75% of patients with early phase RA achieved REM. Older, higher Steinbrocker’s stage and higher DAS28-CP at the baseline could be prediction factors of poorly controlled patients at 2 years.

AB0326 MATRIX METALLOPROTEINASE-3 IS A GOOD PREDICTOR FOR JOINT DESTRUCTION ONLY IN MALE PATIENTS WITH RHEUMATOID ARTHRITIS
Y. Yamada1,2, K. Inui1, T. Okano1, K. Orita3, Y. Sugio4, K. Mamoto1, T. Koike3, M. Tada2, H. Nakamura1. 1Department of orthopedics surgery, Osaka City University; 2Department of orthopedics surgery, Yodogawa Christian Hospital, Osaka City; 3Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama; 4Center for Senile Degenerative Disorders (CSDD), Osaka City University; 5Department of orthopedics surgery, Osaka City General Hospital, Osaka City, Japan

Background: Serum level of matrix metalloproteinase-3 (MMP-3) is elevated by synovial inflammation. It destroys articular cartilage such as proteoglycans so that it has been used as a clinical biomarker of joint destruction in patients with rheumatoid arthritis (RA).

Objectives: The purpose of this study is to investigate a relation between radiographic progression, MMP-3 and other factors such as ultrasonography (US) findings.

Methods: 259 patients (213 women) with RA were enrolled in this study. Their baseline data such as age, sex, disease duration, use of glucocorticoid (GC) or DMARDs, disease activity (DAS28), laboratory data (MMP-3, CRP, RF and ACPA), and the Power Doppler (PD) score at digits and wrists by US were collected. The modified total Sharp score (mTSS), erosion score (ERN) and joint space narrowing (JSN) were examined at baseline and 1 year. Their changes from baseline to 1 year (Δ) were calculated. Relationship between baseline MMP-3 and other variables was examined. Predictors for joint destruction was investigated by multiple regression. Statistical analysis was separated by sex because upper limit of MMP-3 is different between men and women.

Results: MMP-3 showed no correlations with GC use, DAS28, CRP and mTSS. MMP-3 was correlated with ΔmTSS and ΔJSN only in men, but PD score only in women (table 1). Multiple regression analysis revealed that MMP-3 was correlated independently with ΔmTSS only in men, whereas PD score was correlated independently with ΔJSN in women. PD score, but not MMP-3, could predict joint destruction at 1 year in women (table 2).

Clinical Significance of Hormone-related (Isolated) Amyloidosis of the Islets of Langerhans – A Postmortem Clinicopathologic Statistical Study of 234 Rheumatoid Arthritis Patients

A. Apatly1, M. Béli2, 1Department of Rheumatology, St. Margaret Clinic; 2Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest, Budapest, Hungary

Background: "All forms of amyloidosis related to the circulation of blood are systemic, and all forms of amyloidosis not connected to the circulation are isolated (localised)."1 Systemic AA amyloidosis (AAa) – characterised by amyloid A deposition – is one of the major chronic complications of rheumatoid arthritis (RA), in most cases leading to renal and less frequently to cardiac insufficiency and death.2 Islet amyloidosis (IA) (islet amyloid polypeptide – IAPP – prohormone fragment deposition localised to islets of Langerhans) is an isolated (localised) form of amyloidosis of clinical (diagnostic) significance in adult type II diabetes mellitus (DM).

Objectives: The aim of this study was to determine the prevalence of AAa and IA in RA, to analyse the relationship between them, furthermore to evaluate the possible role of IA in DM in RA patients.

Methods: At the National Institute of Rheumatology 11 558 patients died between 1969 and 1998; among them 234 with RA, and all of them were autopsied. RA was confirmed clinically according to the criteria of the ACR.3 The diagnosis of DM based on clinical data. Tissue samples of pancreas were obtained from 234 patients. AAa and IA were diagnosed histologically, amyloid A and IAPP deposits were confirmed histochemically.4 The relationships between AAa and IA further more between IA and DM were analysed by Pearson’s chi-squared (χ²) test.

Results: AAa complicated RA in 32 (23.31%) of 150 patients. Hormone-related IA localised to the islets of Langerhans was observed in 15 (10.0%) of 150 pancreases; Clinically diagnosed DM was associated with RA in 31 (20.66%) of 150 patients. AAa was associated with LA in 2 (6.45%) of 31 cases. The relationship between AAa and IA was not significant, even the association’s coefficient was negative: -0.2381, χ²=0.0785, p<0.77. IA associated with clinically diagnosed DM in 8 (53.3%) of 15 patients. There was a positive and significant correlation between clinically diagnosed IA and DM (association’s coefficient: 0.6953, χ²=10.9475, p=0.0009). IA was present without the clinical diagnosis of DM in 2 (46.7%) of 15 patients. The relationship between IA and clinically not diagnosed DM was also positive and significant (association’s coefficient: 0.6037, χ²=6.8717, p<0.008).

Conclusions: Systemic or localised types of amyloidosis may exist simultaneously by side or may be present independently from each other. AAa and IA are independent phenomena based on the negative association’s coefficient and not significant relationship between them, and may coexist in RA. According to our interpretation the early stage of IA (involving only a few islets with minimal IAPP deposits) represents a clinically latent DM and the advanced stage of it is clinically manifest DM. The strong positive and significant correlation between IA and clinically manifest DM suggest close relationship between them. Based on the positive and significant correlation between IA and clinically not diagnosed DM, the IA may be a good indicator of potential DM in the latent stage of disease. This correlation may help recognise DM in its early stage. For this reason we recommend that all biopsy material and surgical specimens of pancreas to be tested for IA or IAPP deposition.

Cardiovascular Risk Evaluation in Long Standing Rheumatoid Arthritis: Real Clinical Data

A. Babaev1, E.V. Kalinina1, M.S. Zvonorenko1, H.S. Solodenko2, M. A. Osadchuk3. 1Volgograd State Medical University, Volgograd; 2M. Sehoven First Moscow State Medical University, Moscow, Russian Federation

Background: According to recent national and EULAR recommendation cardiovascular risk (CVR) in pts with RA should be evaluated using modified SCORE system. But a lot of investigations and real clinical data demonstrate that this system commonly down-estimates CVR in RA pts.

Objectives: Aim of our study was to compare standard CVR assessment and additional CVR evaluation on the basis of specific disease-associated risk factors (RF) and CV system investigations in long standing RA.

Methods: 118 pts (96 female, 22 male) aged from 34 to 74 years old (mean age 55.9±1.5±21) with long standing RA (duration >5 years) were observed. In all pts CVR was stratified according to modified SCORE. We have analysed pts medical cards and standard examination data to determine clinical features of RA and associated conditions to verify severity of CVR. In term to reveal asymptomatic CV disease pts had undergone additional investigations (echocardiography, Dopplerography of carotid arteries, ECG-monitoring).

Results: Conventional CVRF were registered in 110 (93.22%) pts. Age>45 (male),>50 (female) was in 85 (72.03%) pts, BMI>25 kg/m²; in 10.17%, elevated cholesterol level and/or dyslipidemia in 41.52%, AH with target organ damage was detected in 49.76%, T2DM in 11.8%, CKD 3 stage in 10.17%, history of MI was in 2 (1.69%) pts. According to modified SCORE for RA very high, high, moderate and low CVR was detected in 17.80%, 47.46%, 18.64%, 16.10% cases respectively. High activity of RA was diagnosed in 61.02%, and erosive arthritis in 84.75% pts. Inadequate disease-modifying treatment was qualified in 15.26% cases. Majority of pts (59.32%) received systemic glucocorticoids (GC) in daily doses from 2 to 12 mg of methylprednizolone, among these pts 14 (11.86%) have been taken GC in moderate and high dose for a long period. On the basis of instrumental data asymptomatic atherosclerosis of aorta and/or aortic valve and/or carotid arteries was detected in 44 pts (37.29%). Silent ischemia was revealed in 3 pts (2.54%). High disease activity and long term systemic GC treatment were associated with significantly high CV events in observed pts (p<0.05). Using obtained results we reassessed CVR in studied cohort. Revised data of CVR stratification suggest that 49 (41.53%) pts were in VH-CVR, 41 (34.75%) – in H-CVR, 16 (13.56%) in M-CVR and only 12 (10.17%) in L-CVR. The difference in pt ratio for CVR stratification was significant in accordance with χ² criterion.

Conclusions: Obtained data suggest that modified SCORE is not absolutely reliable tool for precise CVR stratification in long standing RA. Additional investigations to define asymptomatic atherosclerosis and coronary artery disease are required in term to prevent CV complications especially in pts with high active erosive RA treated with systemic GC.

Method of Evaluation of Cardiorespiratory System Neurovegetative Regulation in Rheumatologic Patients

A. Lebedeva, V. Marchenko, I. Mozhaya. Department of Research Institute of rheumatology and allergology, Pavlov First Saint Petersburg State Medical University, Saint Petersburg, Russian Federation

Objectives: To study the characteristics of cardiorespiratory system (CRS) neurovegetative regulation disorders and to define the correlation with disease activity.

Methods: 40 rheumatoid arthritis (RA) patients (14 m:30 f; median age 45±2.32), 18 ankylosing spondylitis (AS) patients (13 m:5 f; m.a. 39.6±2.44), 17 osteoporosis (OP) patients (3 m:14 f; m.a. 55±1±4.7), 50 healthy persons (HP, 25 m:25 f; m.a. 23.6±0.84) were studied. The diagnosis of RA, AS, OP were established by the current diagnostic and classification criteria. The cardiorespiratory system neurovegetative regulation was studied with the use of AB0327

Rheumatoid Arthritis – comorbidty and clinical aspects

AB0328

Cardiovascular Risk Evaluation in Long Standing Rheumatoid Arthritis: Real Clinical Data

AB0329

The Method of Evaluation of Cardiorespiratory System Neurovegetative Regulation in Rheumatologic Patients
Sporoarterio-cardiograph, that was able to synchronously analyse the variability of heart rate (HR), respiration (R), systolic (S) and diastolic (D) arterial pressure, respiratory phase structure, baroreceptor sensitivity and some other cardiohemodynamics parameters. Following parameters were calculated: spectrum of fluctuations total power (TP), the activity of suprasympathetic (VLF), sympathetic (LF), parasympathetic (HF), cortical (IC) and subcortical (SNCA) contours and sympathetic-vagus balance parameters (LF/HF) in regulation HR, R, S, D, baroreceptor sensitivity (BR), inhalation (Ti) and exhalation (Te) time (V. Marchenko, 2004). Results: Different severity dysregulation of CRPS at all levels is typical for the AS patients, which expresses in decrease of the variability of the basic contours of regulation of heart rate, respiration, systolic and diastolic blood pressure with a shift of sympathetic-vagal balance in favour of parasympathicotonia, reduction baroreceptor sensitivity. The heterogeneity of the analysed groups according to the parameter LF/HF_HR is shown. The ratio of patients with parasympathotony, normo- sympathetic in groups made up, respectively, in HP (34:48:18), RA (23:54:23), AS (55:28:17), OP (29:32:18). It is established that a significant number of AS patients had parasympathetic type of regulation, and the rest of the groups were dominated by patients with normotonic type of regulation. It is shown that in groups of patients neurovegetative regulation system was more stringent, as evidenced by the increase in their number of reliable correlations compared with the group of healthy individuals. The features of deregulation in each analysed group were established, the nature of which requires further analysis. Significant correlations (τ >0,45; p<0,029) between the parameters of the neurovegetative regulation of cardiorespiratory system on the one hand and the clinical and laboratory parameters of inflammatory activity (in the first place, DAS28, CRP, ESR) on the other hand in patients with RA; with parameters BASDAI, the activity of the inflammatory process (ESR, CRP) in patients with AS; densitometric parameters in patients with OP were identified. The close connection between vascular component and the activity of the inflammatory process is shown, which may be a manifestation of endothelial dysfunction.

Conclusions: Thus, the method of variability of cardiorespiratory allows to detect the neurovegetative dysregulation of the cardiorespiratory system in rheumatologic patients and can be recommended for the evaluation of the system of regulation in general, the possible role of its disorders in the pathogenesis of clinical manifestations of diseases, and assessing the dynamics of regulatory processes in the treatment of patients.

AB0330 OSTEOPOROSIS, SACROPENIA AND OSTEOSACROPENIA IN WOMEN WITH RHEUMATOID ARTHRITIS

A. Feklistov, N. Demin, N. Toroptsova. Nasorova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Rheumatoid arthritis (RA) is a systemic inflammatory disease associated with polyarthritis, progressive joint damage, and physical impairment that can lead to osteoporosis and sarcopenia, increasing the risk of fractures and leading to a greater loss of autonomy in RA patients.

Objectives: To assess the frequency of osteoporosis, sarcopenia and osteosarcopenia in women with RA.

Methods: 40 female patients with RA (mean age 63±7 years) and 40 female controls without RA (mean age 64±9 years) were enrolled in this study. Body composition and bone mineral density (BMD) in lumbar spine and proximal hip were assessed by using dual X-ray absorptiometry (DXA, Hologic Discovery A). Sarcopenia in women was defined as a skeletal muscle index (SMI) ≤5.67 kg/m² and osteosarcopenia – if sarcopenia and low BMD were present together.2 The participants performed Short Physical Performance Battery (SPPB) and handgrip strength was measured. Body mass index (BMI) and Disease Activity Score (DAS28) were calculated.

Results: Low BMD at least in one of measured area was found out in 19 (48%) RA persons and in 18 (45%) controls. Sarcopenia occurred in 10 (25%) RA patients and in 6 (15%) women without RA (p>0,05). Among them osteosarcopenia was found in 6 (15%) RA women and 2 (5%) controls. Skeletal muscle index (SMI) was lower in patients with RA (6.43±0.978) than in controls (7.01±1.64, p<0.05). In RA patients SMI had a positive correlation with BMI (r=0.58, p<0.05) and handgrip strength (r=0.34 for right, r=0.30 for left, p<0.05 for both). Sarcopenia was more common in RA patients who were overweight or obese according to their BMI (p<0.01). There was no correlation between SMI and DAS28, drug use, frequency of falls during the last year, SPPB in the RA group.

Conclusions: In RA patients 48% had osteoporosis and 25% – sarcopenia, among them 15% women – osteosarcopenia. The risk of sarcopenia and osteosarcopenia was higher in nonobese patients.

AB0331 INCIDENCE OF MALIGNANCY IN PSORIATIC AND RHEUMATOID ARTHRITIS PATIENTS LIVING IN NEWFOUNDLAND AND LABRADOR

A.F. Lewis1, I. Landels2, G. Mugford3, M. Khrash3. 1Clinical Epidemiology; 2Dermatology; 3Rheumatology, Memorial University of Newfoundland, St. John's, Canada

Background: Rheumatoid Arthritis (RA) and Psoriatic Arthritis (PsA) are reported to be associated with an increased risk of malignancy. Newfoundland and Labrador (NL) has one of the highest cancer rates in Canada. There is a paucity of literature on the prevalence of malignancy in NL patients with PsA and RA.

Objectives: Evaluate the incidence of malignancy in a cohort of PsA and RA patients and compare rates with the general population. Evaluate the impact of therapy of these two diseases.

Methods: Data was extracted from the charts of 200 PsA and 500 RA patients seen at a rheumatology clinic in St. John’s between 2011 and 2014. Statistical analyses were performed using SPSS version 21.0 for Windows (IBM Inc.). Person-time Rate (PYs) per 100,000, stratified by age and gender, were used to estimate overall cancer risk and proportions between the two cohorts. Observed rates were compared with Statistics Canada reported general NL rates.

Results: We identified 37 (5.3%) malignancies: 34 (91.8%) solid and 3 (8.1%) hematologic. Mean (SD) age was 58.4 (12.28) and age at diagnosis of disease was 46.8 (12.88). Four hundred and eighty (86.6%) were females. No difference was observed in rates between the study population and the NL general population (p=0.3217). The most common solid tumours were breast (21.6%) and skin (21.6%), followed by five bowel and lung cancers in equal proportions (13.5%). Distribution of cancers between the two cohorts were similar.

Conclusions: The results suggest there is no difference in the cancer rate between our cohorts and the NL general population. We acknowledge study limitations related to shorter duration of follow-up and lower sample size.

REFERENCES:

Disclosure of Interest: None declared

Background: The Charlson comorbidity index (CCI) is a prognostic scale, which gives a numerical value that indicates the burden of comorbidities in a patient. This index is obtained from the sum of 19 medical conditions that have been related to mortality and has been validated in several studies. Patients with rheumatoid arthritis (RA) are more at risk than the general population of developing comorbidities. However, these often go unnoticed despite the impact on the disease activity and to treatment response, as shown by different studies such as COMORA.

Objectives: To determine the prevalence of comorbidities in a cohort of patients with RA and estimate CCI.

Methods: Cross-sectional descriptive study, patients diagnosed with RA according to the EULAR/ACR 2010 classification criteria were included. All patients were followed up in a rheumatology service in a tertiary hospital. Comorbidities were obtained from the medical records. To measure comorbidities, CCI was calculated, the diagnosis of RA was not included in the index. We defined three categories of comorbidity according to CCI: 0 (no comorbidity, applied to patients with no previous record of conditions included in the CCI), 1 to 2 (moderate) and 3 or more (severe). Other comorbidities not included in CCI such as hypertension (HTN), dyslipidemias (DLP), thyroid disease (TD), osteoporosis (OP) were collected.

Results: 130 patients (103 women) were analysed; mean age was 58.6±12.9 years and disease duration 6.0±4.4 years. 82.8% were seropositive for rheumatoid factor (n: 83) and/or anti-CCP (n: 97). 44.6% had previous smoking history, 22 were current smokers. The most observed comorbidities in our cohort were: overweight and obesity (BMI ≥25; 63%), DLP (38.8%), HTN (31.5%), chronic kidney disease (32.3%; 6.9% >Stage III) and chronic lung disease (23.8%). Other diseases included TD (18.5%), OP (17.7%), diabetes mellitus (9.2%) and liver disease (9.2%). Five patients had a history of tumour (2 metastases) and 2 lymphomas.

Conclusions: ICADs correlate poorly with quality of life, assessed by SF12, but moderately with functional limitation, assessed by HAQ.

REFERENCES:

Disclosure of Interest: None declared
and 120 had anti-citrullinated peptide (anti-cci) positive. Erosions were present in 106 RA patients. The prevalence of neoplasms was similar in RA and non-RA groups (n=24 vs 23, p=0,8) and 5 of the neoplasms occurred in the RA-neoplasm group were due to the cancer. Of the 24 neoplasms in RA group, 9 appeared after the RA diagnosis was established (mean 10 years) and 17 before (mean 6,65 years). In RA patients correlation was found between male sex and neoplasm (p=0,04) as well as absence of RF rheumatoid factor and neoplasm (p=0,049). No correlation was found between the presence of neoplasm and anti ccpp presence or erosions (p=0,3 and p=0,51 respectively). In this study, the overall risk of neo-
plasms in patients with RA was not associated with conventional or biological DMARD’s. No differences were found between the type of tumour in RA patients vs non-RA, except for colon cancer, more prevalent in RA patients (p=0,03). Only 21 non-RA patients vs 19 RA patients were smokers and for so, it wasn’t possible to establish any correlations.

**Conclusion:** In this study when a prevalence of colon cancer in RA patients, as was found in other studies whatever, the increased risk for lung cancer and lymphoma often reported, was not found. It seems that male sex and the absence of rheumatoid factor are responsible for an increased risk. However we have several limitations: a very small sample, the population of the study was predominantly Caucasian. Further studies examining specific aspects such as treatments, smoking or other lifestyle factors needs to be investigated to understand the underlying mechanisms for the increased or decreased risk of specific cancers observed in patients with RA compared with the general population.

**ARE EULAR RHEUMATOID ARTHRITIS (RA) MANAGEMENT RECOMMENDATIONS APPLICABLE AT THE COUNTRY LEVEL? SIMILARITIES AND DIFFERENCES WITH THE RECENT FRENCH RA MANAGEMENT RECOMMENDATIONS**

C. Hua1,2, G. Daïen1, C. Gaujoux-Viala1,2, A. Cantarell3, M. Dubremetz2, M. Dougdous1, B. Fautrel1, X. Mariette1, N. Nayraf1, R. Cîrce1, A. Saraua2, G. Thibaud2, D. Wendling3, L. Gossec4, B. Combe5. 1Nîmes University hospital, Montpellier University, Nîmes; 2SFR Recommendations Working Group, Paris, France

**Background:** Recently, EULAR updated the rheumatoid arthritis (RA) management recommendations. 1 In 2018, the French Society of Rheumatology (SFR) updated their recommendations regarding the management of RA. 2 This gave us the opportunity to compare the recommendations.

**Objectives:** To update the 2014 French recommendations for the management of RA and to compare them to the EULAR recommendations.

**Methods:** The SFR approach was based on the literature and on expert opinion. A systematic literature review (SLR) was performed by 2 fellows, collecting data to answer 11 questions. The previous (2014) recommendations were updated by a committee including 11 rheumatologists, 2 patients and 1 healthcare professional, during a 1 day meeting in January 2018. The recommendations were compared to the recently issued EULAR recommendations.

**Results:** The SLR included 137 papers. The consensus process led to 4 over-
arching principles and 15 recommendations. The overarching principles empha-
sise the need for shared decisions between the rheumatologists and the patient and the importance of a global approach of RA including pharmaceutical and non-
pharmacological management. The recommendations address the diagnostic phase of RA, early initiation of disease-modifying antirheumatic drugs (DMARDs) and the usefulness of regular disease activity assessments through validated composite indices with a target of clinical remission or low disease activity. As first strategy, the expert committee recommends methotrexate (MTX). In case of intoler-
ance or inadequate response to MTX, treatment must be optimised. If unfavour-
able prognostic markers are present, adding a targeted treatment (either biologic or synthetic) can be proposed, at best in combination with MTX; if not, switching to another conventional synthetic DMARD (csDMARD) or combined csDMARDs therapy can be proposed. While waiting for csDMARDs efficacy, short term (less than 6 months) glucocorticoids (GC) can be proposed. Second-line and further treatments and management of remission are also addressed, as well as the importance of managing comorbidities and of non-pharmacological measures.

**Conclusions:** These recommendations are designed to improve the manage-
ment of RA and are concordant with the recent EULAR recommendations on sev-
eral items. Main differences concern the place of GC and of combined csDMARD therapy, as well as additional points on diagnosis, non-pharmacological mea-
ures, comorbidities and the importance of a global approach.

**AB0336 HEPATITIS B VIRUS REACTIVATION IN RHEUMATOID ARTHRITIS PATIENTS WITH HBSSAG-NEGATIVE/ANTI-HBC-POSITIVE STATUS**

C.-H. Ho1, M.H.A. Leung2.

1Department of Medicine; 2Queen Elizabeth Hospital, Kowloon, Hong Kong

**Background:** Hepatitis B virus (HBV) reactivation in rheumatoid arthritis (RA) patients with positive hepatitis B surface antigen (HBsAg+) is one of the treat-
ment-related complications. The risk of reactivation in patients with negative hep-
atitis B surface antigen but positive anti-hepatitis B core antibody (HBsAg+/anti-
Hbc-) is less well defined compared to their HBsAg+ counterparts.

**Objectives:** This retrospective, single centre study aimed to study the prevalence of HBV reactivation (defined as HBV DNA becoming detectable) among RA patients with HBsAg+/anti-Hbc+ status, and to investigate any factors predicting reactivation.

**Methods:** RA patients attending the rheumatologist specialist clinic in a local terti-
ary hospital between 1st January 2011 and 31st December 2016 were included if they had 0 HBsAg/anti-Hbc+ status and 0 undetectable HBV DNA at baseline. Demographic data, clinical parameters including treatments for RA and any use of antiviral prophylaxis, and laboratory results including anti-hepatitis B surface antibody (anti-HBs) and serial HBV DNA levels were obtained. Chi-square (or Fisher exact test if number was less than 5) was used for analysis of categorical varia-
bles. Student’s t-test and Mann Whitney test were used for analysis of parametric and non-parametric continuous variables respectively.

**Results:** Majority (80%) of the 107 included patients included were female and the mean age was 62.5-year-old (SD 12.09). All the patients were receiving dis-
ease modifying anti-rheumatic drugs (DMARDs), 43% of which (n=46) were on biological therapy (with or without concomitant synthetic DMARDs) and the remaining (n=61) were only on conventional synthetic DMARDs (B on monother-
apy, 53 on combination therapy). As antiviral prophylaxis was not mandatory in HBsAg/anti-Hbc+ patients according to local guideline, only 13 patients (12.1%) were on antiviral cover (12 on entecavir and 1 on lamivudine). Ten patients (9.3%) experienced HBV reactivation during their disease course. Three of them were on antiviral prophylaxis and four had positive anti-HBs. All of these reactivations were only transient low-grade viraemia with HBV DNA level <20 IU/ml. Spontaneous resolution of viraemia in less than 12 months’ time were observed in all of these patients. None of the reactivation resulted in any adverse clinical event including acute hepatitis, hepatic failure or mortality.

All among synthetic and biological DMARDs, only the use of methotrexate was found to be a significant predictor of HBV reactivation (p<0.05). Other parameters including age, the lack of antiviral prophylaxis, negative anti-HBs status and anti-
HBs titre did not predict HBV reactivation.

**Conclusions:** HBV reactivation among RA patients with HBsAg+/anti-Hbc+ status and undetectable HBV DNA at baseline was infrequent. Reactivation may occur in patients with positive anti-HBs or on antiviral prophylaxis, but was unlikely to be associated with adverse clinical outcome. The use of methotrexate was a predictor of HBV reactivation in these patients.

AB0337 ASSESSMENT OF NUTRITIONAL STATUS IN WOMEN WITH RHEUMATOID ARTHRITIS MEASURED BY DUAL ENERGY X-RAY ABSORPTIOMETRY

D. Reing1, C. Gómez Vaquero2, J.M. Nolla3. 1Rheumatology, Consorci Sanitat Integral; 2Rheumatology, Hospital Universitari de Bellvitge, Barcelona, Spain

**Background:** As many other chronic diseases, rheumatoid arthritis (RA) has been related to an impairment of the nutritional status of multifactorial etiology. Even if Body Mass Index (BMI) has traditionally been used, it is not always a valid method, and there are still lots of questions without answer in how to evaluate ideally the nutritional status in these patients. Only very few studies had evaluated it by Dual Energy X Ray Absorptiometry (DXA).

**Objectives:** 1) To evaluate the nutritional status in women with RA and to compare with a population of same age women without RA using DXA for the analysis of whole body composition, 2) differences between the prevalence of alterations of the nutritional status measured by DXA and by the classical methods used in clinical care, 3) relation of RA time of evolution, inflammatory activity, physical function and dietary intake on altered nutritional status evaluated by DXA.

**Methods:** Case-control study including 89 patients that were diagnosed with RA and a control group (100) composed by patients affected by other non-inflammtory rheumatic diseases as soft tissue diseases. All the clinical charts were revised in order to record the following data: age, BMI, RA duration, history, activity and disability, serum albumin, Dietary intake, Whole body DXA assessment and Skeletal muscle index (SMI).

**Results:** Mean age of patients was 62.8±9.3 years. Mean duration of RA was 13.7 ±9.3 years. Mean DAS28 was 3.7±1.4 and mean Health Assessment Questionnaire was 0.88±0.77. BMI of the patients was 27.43±5.16 and 27.78±3.98 in controls (p: ns). Albumin was within normal range in all patients. RA patients presented a statistically significant lower lean mass than controls in all locations and lower fat mass in limbs, along with a higher fat trunk. RA duration was found to be inversely correlated to BMI and lean mass and directly correlated with fat mass.

Neither BMI nor albumin correlated with DXA parameters. RA patients fulfilled criteria of sarcopenia in 44% of de cases vs 19% of controls (p: ns). Albumin was within normal range in all patients. RA patients fulfilled criteria of sarcopenia in 44% of de cases vs 19% of controls (p: ns). Albumin was within normal range in all patients.

AB0338 CLINICAL CHARACTERISTICS OF PATIENTS WITH RHEUMATOID ARTHRITIS WHO USED COMPUTER TERMINALS FOR SELF-ASSESSMENT OF DISEASE ACTIVITY AND QUALITY OF LIFE

E. Popovich1, V. Amirshadovana. 1V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Objectives:** To present the clinical features, pharmacotherapy, activity and quality of life in pts with rheumatoid arthritis (RA) who used computer terminals for self-assessment of pts with rheumatic diseases.

**Methods:** The study included 976 RA patients from the cohort of "TERMINAL" multicenter study, envisaging pts with RA and RA patients with RA (ACR criteria) older than 50 years. The study included 976 RA patients from the cohort of "TERMINAL" multicenter study, envisaging pts with RA and RA patients with RA (ACR criteria) older than 50 years.

**Results:** Mean age of patients was 62±8 years. Mean duration of RA was 13.7 ±9.3 years. Mean DAS28 was 3.7±1.4 and mean Health Assessment Questionnaire was 0.88±0.77. BMI of the patients was 27.43±5.16 and 27.78±3.98 in controls (p: ns). Albumin was within normal range in all patients.

AB0339 SARCOPENIA AND EARLY FRAILTY SYNDROME IN RHEUMATOID ARTHRITIS

E. Trujillo1, M.R. Garcia-Marreo2, M.I. Fuentes3, M.D.M. Trujillo3. 1Servicio de Reumatología, Hospital Universitario de Canarias, la Laguna; 2Gerencia de Atención Primaria, Tenerife; 3Funcanis, Fundación Canaria de Investigación, Canarias, Spain

**Background:** Sarcopenia and frailty are common in older persons and pose particular challenges for health and social care systems.

Sarcopenia, the loss of skeletal muscle mass, is a core component of physical frailty that together impact negatively on an individual’s capability to live independently.

Frailty is defined as a syndrome of physiological decline in late life, characterised by marked vulnerability to adverse health outcomes. Frail adults are less able to adapt to stressors such as acute illness or trauma than non-frail adults. This increased vulnerability contributes to increased risk for multiple adverse outcomes, including procedural complications, falls, institutionalisation, disability, and death.

Rheumatoid arthritis (RA) is a chronic disabling disease, which leads to functional limitations and diminishes health-related quality of life. The presence of comorbidity and polypharmacy are both related to RA severity.

**Objectives:** The aim of this study was to assess the prevalence of sarcopenia and frailty syndrome in patients with RA.

**Methods:** Cross-sectional, observational and descriptive study in patients with RA (ACR criteria) older than 50 years.

Sarcopenia was defined as per the European Working Group on Sarcopenia in Older People definition as Skeletal muscle mass index (SMI) ≤8.87 kg/m² in men and ≤6.42 kg/m² in women. Body composition analysis was performed using bioelectrical impedance analysis (BIA).

Frailty was measured according to the 5 criteria proposed by Fried, using the Frail scale, and it was considered fragile to the patient who met at least 3 and fragile to those who met at least 2.

Frail scale: Based on five items, reflecting performance, selfreports and common co-morbidities (Morrow JE et al. J Nutr Health Ageing 2012;16(7):601–8).

**Frail SCALE**

Did you feel worn out? or Did you feel tired? Ability to climb one flight of stairs

Ability to walk 100 m

Self-report of >5% wt loss

≤5 of: dementia; heart Disease; depression; arthritis; asthma; bronchitis/emphysema; diabetes; hypertension; osteoporosis; stroke.

**Results:** 283 consecutive RA patients were included, 83.4% were female. Mean age was 63.3 years and mean disease duration was 10.4 years. Mean number of comorbidities was 1.48, with systemic hypertension and obesity as the most frequent ones (33.8% and 26.4%, respectively). Polypharmacy was found in 96.8% and 64.7% received more than five drugs simultaneously.

31% presented some degree of sarcopenia. 21.5% met frailty criteria (42% in > 65 years old patients).

**Conclusions:** Prevalence of sarcopenia and frailty syndrome in this study was high. Rheumatologists should make an early detection of signs of frailty.

The screening and early detection of frailty can spur reforms to make routine care less hazardous, can focus on outcomes most relevant to patients and can aid in understanding effectiveness of health care interventions, including at the population level.

AB0340 ASSOCIATION BETWEEN MICROALBUMINURIA AND METABOLIC SYNDROME IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Baraka1, S. Abdel Monem2, R. El Tanawy1, A. Shoshan1, Y. Ismail2. 1Rheumatology, Rehabilitation and Physical medicine; 2clinical pathology, Benha Faculty of Medicine, Benha University, Cairo, Egypt

**Background:** Rheumatoid arthritis (RA) is an autoimmune, symmetrical polyarticular disease characterised by chronic inflammation of the synovial joints. Microalbuminuria (MA) occurs as a leakage of small amounts of albumin into the urine. Metabolic syndrome (MetS) describes risk factors for cardiovascular diseases such as dyslipidaemia, obesity, hypertension and diabetes.

Disclosure of Interest: None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3256
Objectives: The aim of this study was to detect the prevalence of MA in patients with RA and study its correlation with disease activity and severity. Our aim extends to identify the association of RA with MetS in rheumatoid arthritis.

Methods: This study was carried out on 30 adult RA patients, 30% male patients and 70% female patients (mean ± SD: 42.27±10.99 years). Their mean disease duration was 12.8±7.06 years. Twenty apparently healthy adults of matched age and sex served as a control group. All the patients were subjected to full history taking, full clinical examination, laboratory investigations and assessment of disease activity using DAS 28 Score. Urinary microalbumin level was measured in all subjects in early morning samples by the immunoturbidimetry method. MetS was assessed in all subjects according to Grundy’s criteria.

Results: The RA patients’ group had highly significantly (p<0.001) elevated mean values of urinary microalbumin and urinary albumin to creatinine ratio compared to the control group (63.9±2.57 mg/dl vs 21.95±13.88 mg/dl, 46.6 ±95.28 u/gmg vs 14.9±11.45 u/gmg respectively). The frequency of the metabolic syndrome according to Grundy’s criteria was 60% in the RA patients’ group. This frequency was highly statistically significant (p<0.001) compared to the control group (10%). The MetS was prevalent in 13/15 (87%) of RA patients with microalbuminuria (MA), while 5 normo-albuminuric RA patients (33%) had the MetS. A statistically significant difference was observed among these groups (p<0.05). On the other hand, 13/18 (72%) of RA patients with MetS had MA.

Although RA patients with MA had and increased mean values of disease duration, body mass index, waist circumference, fasting blood sugar, triglycerides, high density lipoprotein, DAS 28 and Larsen’s score, they had no statistically significant differences compared to normo-albuminuric patients. RA patients with the MA had a statistically significantly higher mean disease duration (p<0.004) than patients without the MetS. There were highly statistically significant positive correlations (p<0.001) of urinary microalbumin levels with disease duration, duration of morning stiffness, number of tender joints, number of swollen joints, ESR 1st hour, C-reactive protein, Larsen’s score, DAS 28, and A/CR.

Conclusions: RA and MetS are frequent in RA, particularly in those with long standing disease. Early detection of albuminuria allows early intervention with the goal of reducing inflammation development in RA, CV risk. MetS is frequent in RA patients with MA.

AB0343
MYOCARDIAL INVOLVEMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS EVALUATED BY TWO-DIMENSIONAL SPECKLE TRACKING ECHOCARDIOGRAPHY BEFORE AND AFTER 18 MONTHS OF TREATMENT WITH ANTI-TNF DRUGS

F. Atzeni1, L. Giartrurco1, L. Boccassini1, P. Sazzi-Puttini2, M. Turie2
1Rheumatology Unit, University of Messina, Messina; 2Cardiology Unit, “Beato Matteo” Hospital, GSD Hospitals, Vigevano (PV)

Background: Cardiovascular (CV) mortality and morbidity is increased in rheumatoid arthritis (RA). Studies found a more than two-fold higher prevalence of ischaemic heart disease in RA patients compared to controls. However, a number of studies indicate that RA is also associated with various non-atherosclerotic CV manifestations. The inflammatory processes in RA may affect different structures of the heart: the most characteristic lesions are conduction defects, but other less frequent manifestations are pericarditis, cardiomyopathy and valve disease.

Objectives: The aim of this study was to evaluate left ventricular myocardial function with two-dimensional speckle tracking echocardiography (STE), in addition to conventional Doppler and tissue Doppler echocardiography, in order to detect subclinical left ventricular myocardial dysfunction in patients with RA.

Methods: The study involved 30 outpatients who fulfilled the 2010 ACR/EULAR criteria for RA (11 males and 19 females; mean age 54.63±9.36 years, median disease duration 2 years), at baseline at after 18 months of treatment with anti-TNF drugs and 30 healthy controls matched in terms of age, gender and other anthropometric characteristics. All patients underwent a complete physical examination and routine laboratory analysis. CV risk profiles were assessed by means of standard ECG, conventional and stress trans-thoracic echocardography with the measurement of CFR, cardiac ultrasonography and pulse wave velocity (PWV). Two-dimensional echocardiographic images were obtained using the apical 4-chamber view at a high frame rate of 70–80 frames/s, and three cardiac cycles were stored in cine-loop format for off-line analysis using commercially available QLAB 9 software (Philips Medical System, USA) in order to assess global longitudinal strain (GLS).

Results: None of the patients showed any signs or symptoms of CV disease, pulmonary involvement, or any other complication. The results of the speckle tracking analysis were significantly different between the two groups, with GLS being significantly lower in the RA patients compared to healthy controls (GLS%: 18.51±6.63 vs 20.23±2.71; p<0.05). Right and left PWV (PWV right, m/sec: 7.52±1.64 vs 6.85±2.02; p=0.06 and PWV left, m/sec: 7.56±1.60 vs 6.83±2.11; p=0.07) and right and left coronary intima media thickness (cIMT) (cIMT right mm: 0.90±0.22 vs 0.75±0.13; p=0.05 and cIMT left, mm: median 0.89±0.18 vs 0.75±0.09; p=0.05) values were all higher in the RA patients and the differences of cIMT were statistically significant. Furthermore, a significant improvement in GLS in RA patients at 18 months of anti-TNF treatment was observed (GLS%: 18.51±6.63 vs 19.09±9.72; p<0.01).

Conclusions: GLS measured by means of speckle tracking echocardiography was impaired in RA patients in the absence of any clinical evidence of CV disease and echocardiographic evaluations negative. This data suggests an early myocardial alteration.

AB0344
DOES THE PRESENCE OF ILD INFLUENCE THE CHOICE OF DMARD AND BIOLOGIC THERAPY IN RHEUMATOID ARTHRITIS?

F. Coelli1, S. Siddiqui1, A. Himashi2, A. Bharadwaj3, S. Dubey2, F. Haynes1, G. Kodu2
1Rheumatology, University of Auckland; 2Rheumatology, Southern Cross University Hospital, Westcliff-On-Sea; 3Rheumatology, University Hospital Coventry and Warwickshire, Coventry; 4Rheumatology, Basildon University Hospital, Basildon, UK

Background: Interstitial lung disease (ILD) is a progressive fibrotic disease of the lung parenchyma. It is the only complication of rheumatoid arthritis (RA) reported to be increasing, accounting for around 7% of all RA deaths.1 Prediction of patients with RA-ILD is reported to be poor, with usual interstitial pneumonia (UIP) being the predominant pattern associated with poor survival.2 It is a challenge to determine specific pattern of ILD and formulate an appropriate treatment plan to achieve stabilisation. Early use of Methotrexate (MTX) and biologics in RA has improved outcomes and quality of life. However, this causes difficulty when RA patients develop ILD. There are reports of ILD with biologics and DMARDs, although it is difficult to establish a causal relationship or if an exacerbation of pre-existing ILD. There are no evidence based guidelines regarding introducing biologics in such patients and clinicians face a dilemma as to whether they should be denied.

Objectives: The aim of this retrospective study is to:
• Check the overall management of RA and ILD.
• Examine whether ILD diagnosis influences treatment of RA.

Methods: We reviewed 37 patients with RA-ILD from 3 hospitals (2001–2017). We collected data on demographics, clinical, Pulmonary function tests, imaging, time from diagnosis to treatment and outcomes.

Results: The majority developed ILD after RA except for 3 patients. Mean age of onset of RA was 67 years, 22 (60%) were female. 32 (87%) were RF or ACPA positive, 25 (68%) patients smoked. 29 (78%) patients had baseline PFTs. HRCT showed 13 had NSIP, 20 UIP and 4 were unclassified. Following the diagnosis of ILD, MTX was stopped in 16 patients, reduced in 3 and unchanged in 2. Leflunomide was stopped in 4 and SLZ stopped in 4, of which 1 had definite alveolitis. Infliximab was stopped in 2 patients.

Specific Treatment for ILD: 12 patients received Rituximab, of those 8 were for ILD and 4 for RA. 4 Patients continued Anti-TNF. 26 patients received steroids, 4 received MMF and 2 Cyclophosphamide. 2 received Abatacept for ILD with active RA and one received Etanercept. 3 were on Carboceystine, 2 on NAC and 3 on oxygen.

Outcomes: 20 ILD patients were stable and 8 (21%) progressed and died despite treatment. RA disease activity was low to moderate in 23 patients. RA progressed in 8 patients and 1 who received Etanercept was in remission. MTX was stopped in the majority of patients. Steroids were the commonest treatment for RA in the presence of ILD. Rituximab was the drug of choice for RA with severe ILD, followed by MMF and Cyclophosphamide. DMARDs such as HCO, Leflunomide and SLZ were used for RA in milder ILD and biologics were generally avoided.

Conclusions: There appears to be significant variation in the treatment of RA in the presence of ILD. However Rituximab seems to be the preferred option for severe ILD. There is a need for stratified and standardised guidance for management of RA-ILD.

DOES IRON DEFICIENCY CONTRIBUTE TO FATIGUE OF PATIENTS WITH RHEUMATOID ARTHRITIS WITHOUT ANAEMIA?

F. Vidal1, A. Gillibert2, M. Quillard3, P. Fandellone4, S. Poupin1, O. Vittecoq1, T. Lequerre1
1Rheumatology; 2Biostatistics; 3Biochemistry; 4Rheumatology, Rouen University Hospital, Rouen; 4Rheumatology, Amiens University Hospital, Amiens, France

Background: Iron deficiency (ID) without anaemia is a cause of fatigue, which is itself a recurring complaint of patients with rheumatoid arthritis (RA).

Objectives: The objective of this study was to determine the prevalence of ID in patients with RA without anaemia and to analyse the relationship between ID with fatigue, disease activity and depression.

Disclosure of Interest: None declared
INVESTIGATION OF ALEXITHMYA IN PATIENTS AFFECTED BY RHEUMATOID AND PSORIATIC ARTHRITIS: CROSS-SECTIONAL OBSERVATION

G.L. Fordi, M.S. Chimenti, P. Coniglario, J. Hitaj, M. Galluzzo, M. Talamonti, B. Kroegler, E. Greco, R. Penicone. Policlinico Tor Vergata, Rome, Italy

Background: Rheumatoid arthritis (RA) and Psoriatic arthritis (PsA) are chronic inflammatory diseases that lead to an overthrow of articular structure, functional limitation and disability. Alexithymia is a personality trait characterised by deficits in cognitive processing and regulation of emotions. A broad association between alexithymia and symptoms as depression, inflammation and pain has been demonstrated.

Objectives: to evaluate the prevalence of alexithymia in patients affected by Rheumatoid and Psoriatic arthritis.

Methods: We prospectively enrolled, from January to December 2017, patients affected by RA diagnosed according to the ACR revised criteria and PsA diagnosed according to the CASPAR criteria referred to the out-patients clinic of the Rheumatology Unit of Policlinico Tor Vergata, Rome. The 20-item Toronto Alexithymia Scale (TAS-20) was used to assess alexithymia. Disease activity, function and quality of life, clinimetric tests as well as ESR and CRP were assessed. Statistical comparisons were performed using Pearson’s Coefficient of Skewness, the unpaired t-Test and Mann-Whitney test.

Results: A total of 50 RA patients and 51 PsA patients were enrolled (table 1). The TAS-20 score showed that 38.6% (39/101) of patients had alexithymia, 26.7% (27/101) patients were in the borderline of alexithymia and 35.2% (35/101) patients had not alexithymia. A statistical significant association was observed between alexithymia and symptoms as depression, inflammation and pain has been demonstrated.

Abstract AB0346 – Table 1. Characteristics, therapies and clinimetric evaluation of the study population

Data are expressed as Mean ± Standard Deviation; csDMARDs: conventional synthetic disease-modifying antirheumatic drugs; bDMARDs: biological disease-modifying antirheumatic drugs; VAS: Visual Analogic Scale; GH: Global Health; percentages calculated for total population.

Conclusions: This study suggests that alexithymia assessment should be a part of the comprehensive care of patients with RA and PsA. We are in the process of extending this investigation on a larger sample population to improve our investigation field and to consolidate our dates.

BODY COMPOSITION IN PATIENTS WITH RHEUMATOID ARTHRITIS KAZAKH NATIONALITY

G. Gobudina, A. Tokarev, D. Mussabaeva. Kazakh Medical University, Almaty, Kazakhstan

Background: Chronic inflammation in rheumatoid arthritis (RA) leads to a decrease in fat and muscle mass (Baker J.F., Von Feldt J. Mostoufi-Moab S. et al., 2014 Low muscle mass in RA is considered as the main criterion of sarcopenia. Recently, much attention has been paid to various phenotypes of sarcopenia, among which osteopenic sarcopenia, sarcopenic obesity and osteosarcopic obesity (most unfavourable in terms of functional disorders) are distinguished. In the modern literature there are works devoted to changes in the composition of the body in the aspect of abdominal obesity and its influence on cardiovascular risk in RA (Croxson G.S., Myasoedova E., Davis J.M., 2011). Studies with the evaluation of muscle mass and sarcopenia in RA are few. In Kazakhstan, the composition of the human body was not studied.

Objectives: The purpose of the study was to study the body composition (muscle and fat mass) of patients with RA of Kazakhstan nationality using bioelectrical impedance analysis.

Methods: In our study we used Bioimpedance analyzer 101 (BIA 101, Italy). Bioimpedansometry was performed in 585 participants, including 295 patients with RA and 290 of their siblings.

Results: In patients with RA, in contrast to the comparison group (siblings), BMI (proband – 25.34±5.1, siblings – 24.86±4.45), the girth of the waist and hips were slightly higher than those of the siblings. The ratio of RT/OB in both groups was virtually the same. At the same time, a decrease in the lean mass was found

AB0348 GRIP POWER AND INDEPENDENT DAILY LIVING IN THE PATIENTS WITH RHEUMATOID ARTHRITIS

H. Ishikawa1, A. Abe1, T. Kojima2, M. Kojima2, N. Ishiguro2, S. Ino1, A. Murasawa1.
1Rheumatology, Niigata Rheumatic Center, Sibaita city, Niigata; 2Orthopedic Surgery, Nagoya University Hospital; 3Medical Education, Nagoya City University Hospital, Graduate School of Medicine, Nagoya city, Japan

Background: Grip power is known to be a simple and useful objective index that can be used in the self-assessment of disease activity in patients with rheumatoid arthritis (RA)1). However, the clinical significance of this physical function is unknown.

Objectives: The objective of this study was to clarify the relationship between the grip power and the level of activities of daily living (ADL).

Methods: The grip power was measured in 221 inpatients of our hospital with RA using a mercury dynamometer. The independence level (0: impossible, 1: incomplete and not practical, 2: practical but the means thereof are unusual, 3: normal) for 44 ADL items, including most daily activities was investigated. For each item, the site with the problem (shoulder, elbow, forearm, wrist, thumb, fingers, lower extremity and trunk) and cause of disability (pain, loss of power, decreased range of motion, abnormal prehensile pattern and fatigue) were investigated by interviewing the patient. There were 33 male and 188 female patients. The average age of the patients was 64.6 years, and the average duration of the disease was 13.3 years. Biological therapy had been given to 23% of the patients. The average grip power of the right and left hands was used.

Results: There were 14 items requiring others’ assistance (level 0 or 1) in more than 10% of patients. For these 14 items of ADL, the grip power increased with the increase in the independence level (p<0.001)2). The site with a problem was, in order of frequency, the fingers (26.1%), wrist (14.8%) and lower extremity (14.0%). The cause of disability was, in order of frequency, pain (38.8%), loss of power (32.8%) and a decreased range of motion (14.0%). The cause of disability was, in order of frequency, pain (38.8%), loss of power (32.8%) and a decreased range of motion. Based on the results of a step-wise regression analysis, the first factor, consisting mainly of “reaching function”, including “hair dressing”, “washing one's body”, “taking on and off one’s shoes”, “clipping nails”, “buttoning”, etc., was most strongly related to a loss of grip power and problems at the elbow, the shoulder and the wrist. The second factor, consisting mainly of the “prehensile function”, including “opening a plastic bottle”, “opening lids”, “squeezing towels”, etc., was most strongly related to a loss of grip power and problems at the wrist and the thumb. The third factor, consisting mainly of “activities involving changing body position and transfer”, including “getting in and out of the bathtub”, “standing and sitting”, etc., was most strongly related to age and problems with the lower extremities and at the elbow and the wrist. In the receiver operating characteristic (ROC) curve, the grip power with the maximum Youden index was 136.5 mmHg (11.8 kg) in females and 152.5 mmHg (13.5 kg) in males. Most activities were performed independently with the grip power more than 136.5 mmHg in females (figure 1). The explanatory variables for the grip power in the female patients were ageing; a long disease duration; a high disease activity score (DAS); and problems at the fingers, the thumb and the elbow; decreased flexion at the shoulder and a decreased range of forearm rotation.

AB0349 OTO-RHINO-LARYNGOLOGICAL MANIFESTATIONS OF RHEUMATOID ARTHRITIS

S. Zrour1, H. Mouanaa1,2, N. Kolsi1, H. Hachfi2, A. Arfa1, M. Juguirim1, I. Bejia1, T. Mongi1, M. Youness1, J. Koubaa1, N. Bergcaul1. 1Rheumatology Department of Monastir University Hospital, Monastir; 2Rheumatology Department of Mahdia University Hospital, Mahdia; ENT Department of Monastir University Hospital, Monastir, Tunisia

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disorder that can damage a wide variety of body systems. Ear, nose and throat (ENT) involvement is frequent but not often reported. The purposes of our work are to determine the prevalence of ENT involvement during RA and to evaluate its correlation with RA disease activity.

Objectives: The purposes of our work are to determine the prevalence of ENT involvement during RA and to evaluate its correlation with RA disease activity.

Methods: This is a cross-sectional study of 90 consecutive RA, followed at the Rheumatology department of Monastir Teaching Hospital in Tunisia, during 06 months (November 2016 to April 2017) and 46 matched volunteers. ENT clinical examination with tonal audiometry and thyroid tests (TSH, T4, anti-Thyroidperoxi-dase Ab (Anti TPO Ab) and Anti-Thyroglobulin Ab (Anti tig) were performed.

Results: ENT involvement prevalence was 78%. The most frequent functional signs were intermittent dysphonia in 50% and dysphagia in 42% of cases. The neck examination revealed painful larynx mobilisation in 58% cases and cervical lymph nodes in 7% of cases. Indirect laryngoscopy, performed in the 67% of symptomatic patients, noted inflammatory mucosa in 38% of cases and decrease in vocal cord mobility in 8% of cases. Seventy percent patients had temporomandibular Joint (TMJ) involvement. Tonal audiometry revealed 42% of cases of deafness: 27% sensorineural deafness, 13% conductive deafness and 2% cases mixed hearing loss. The ENT manifestations significantly associated to RA compared to the witness group (p<0.01) were intermittent dysphonia, dysphagia, painful larynx mobilisation, inflammatory nasal mucosa, painful TMJ and deafness. Active disease (DAS 28>3) was statistically associated with deafness (p=0.048) and TMJ involvement (p=0.009). Logistic regression study shows that RA duration over 10 years was associated to laryngeal dyspnea (OR=4.4, p=0.012, IC (95%) [1.377, 14.134]) and deafness (OR=3.8, p=0.03, IC(95%) [1.142, 12.882]). In the other hand, RA moderate functional handicap is a protective factor (OR=0.123, p=0.016, IC (95%) [0.076, 0.772]) of ENT involvement and biotherapy use was associated to thyroid involvement (OR=7.8, p=0.017, IC(95%) [4.31, 43.175]).

Conclusions: ENT involvement is a very common, usually asymptomatic extra-articular manifestation during RA. It is, mainly, TMJ involvement, deafness and dysphonia. The main relevant determinants are RA disease activity and duration.

AB0350 TEMPORO-MANDIBULAR JOINT INVOLVEMENT IN RHEUMATOID ARTHRITIS

S. Zrour1, H. Mouanna1, A. Arfa1, H. Hachi2, M. Jguiri1, I. Bejia1, T. Mongi1, M. Youness2, N. Bergaoui1, 1Rheumatology Department of Monastir University Hospital, Monastir; 2Rheumatology Department of Mahdia University Hospital, Mahdia, Tunisia

Background: Temporomandibular joint (TMJ) disorder in rheumatoid arthritis (RA) may be associated with significant osteoarticular destruction and may be responsible of significant functional impairment.

Objectives: We aimed in this study to determine the prevalence of TMJ involvement and its correlations with RA parameters.

Methods: We report a descriptive monocratic cross-sectional study of 90 consecutive RA, followed at the Rheumatology department of Monastir Teaching Hospital in Tunisia, during 06 months (November 2016 to April 2017) and 46 matched volunteers. Clinical assessment and stomatological examination were performed in all cases.

Results: Sixty-three RA patients out of 90 (70%) had TMJ involvement. TMJ painful mobilisation, mastication difficulties, swollen TMJ, dental malocclusion and limitation of mouth opening were noted in 55 (81%), 49 (74%), 20 (30.3%), 19 (29%) and 8 (12%) of cases, respectively. Compared with the control group, painful palpation of TMJ (p<0.000) was significantly associated with RA. In RA, TMJ disorder is more common in adults between 40 and 60 years of age, patients with HAQ>0.5 and a high total Vander Heijde Sharp radiographic score (SS). TMJ painful mobilisation is significantly associated with increased body mass index (BMI). Swollen TMJ is significantly associated with age (more frequent in elderly subjects), increased BMI, high RA disease activity (high DAS 28 ESR and/or DAS 28 CRP) and HAQ>0.5. Limitation of mouth opening is significantly associated with age (more common in elderly subjects), overweight, high methotrexate dose (20 mg/day), leflunomide and biotherapy use. Dental malocclusion was significantly associated with high doses corticosteroids (more than 5 mg/day). Mastication difficulties are significantly associated with more than 10 year RA duration, HAQ>0.5 and radiological impairment.

Conclusions: Temporomandibular disorder is frequent in RA (70%). TMJ disorder is observed especially in active (high DAS 28), serious (radiological impairment, HAQ>0.5) and advanced (more than 10 year duration) RA. Physicians must be careful to assess systematically TMJ in RA patients.

AB0351 DIFFERENTIAL PERCEPTION ABOUT THE CSDMARDS ON DRUG-INDUCED INTERSTITIAL LUNG DISEASE BETWEEN RHEUMATOLOGISTS AND NON-RHEUMATOLOGISTS

H. Kobayashi1,2, T. Okubo1, H. Oka1, A. Aoki1, 1Rheumatology, Tokyo Medical University Hachioji Medical Center, Tokyo; 2Internal Medicine, Aihara Hospital, Sagamihara, Japan

Background: As disease modified anti-rheumatic drugs (DMARDs) were the mainstay in the treatment of rheumatoid arthritis (RA), the opportunity for general physicians to also prescribe DMARDs has recently increased in Japan. After DMARDs were initiated by specialists, subsequent drug prescription by general physicians during remission should be expected. However, general physicians are more likely than rheumatologists to feel it difficult to accept patients taking even conventional synthetics (cs) DMARDs but not biologics and such discomforts may be potential barriers to cooperative management between specialists and general physicians. One of the reasons is because some csDMARDs such as methotrexate and leflunomide may induce pneumonitis or worsen RA-related pre-existing interstitial lung disease (ILD) as a rare but severe adverse event. To minimise the risk, rheumatologists may choose low-risk csDMARDs smartly when the patients are concomitant with risk factors on ILD.

Objectives: To measure the physicians’ perspective toward the risk of each csDMARD on drug-induced ILD and their attitude in prescribing the csDMARDs to a pre-existing ILD case.

Methods: A questionnaire was given in an internet survey to registered physicians who take care of more than ten patients with RA in Japan. Topics covered were i) how is the risk of each csDMARD for drug-induced lung injury compared to methotrexate, ii) which csDMARDs should be applied to a case with mild pneumonitis on the chest CT. Cross tabulation analysis and χ2 test as a statistical analysis was performed.

Results: A total 184 physicians consisting of 66 rheumatologists (36%) and 118 non-rheumatologists (64%) responded. The physicians’ mean age was 45 years old. The rheumatologists tended to belong to rheumatology and take care of more than 200 RA patients per month in university hospitals. The non-rheumatologists tended to belong to general medicine and manage less than 50 patients per month in their clinics. The csDMARDs except for methotrexate were more significantly prescribed by the rheumatologists. All rheumatologists but 24% of non-rheumatologists had managed RA patients with exacerbated ILD. On physicians’ perspective toward the risk of each csDMARD, the rheumatologists considered that LEF was equal to or higher than MTX and that cyclosporine A (CyA), tacrolimus (TAC), salazosulfapyridine (SASP) was relatively safer (Figure A.). In cases with pre-existing ILD, more rheumatologists agreed to use the csDMARDs except for methotrexate and leflunomide. (Figure B.)

Abstract AB0351 – Figure 1. A) Physician’s opinion about how is the risk of the following csDMARDs for drug-induced ILD compared to methotrexate. B) Physician’s opinion about if the following csDMARDs should be applied to a case with mild ILD on the chest CT.

Conclusions: We can find the gap of risk perception about each csDMARDs between rheumatologists and non-rheumatologist and the difference in attitude in prescribing to patients concomitant with risk factors. Considerable consensus and additional enlightenment to general physicians should be necessary.

SIGNIFICANCE OF OCCULT INFECTIONS IN INFLAMMATORY ARTHRITIS PATIENTS RECEIVING BIOLOGIC THERAPIES IN EAST LONDON

Background: Chronic hepatitis B virus (HBV) infection remains a significant global health problem. In high endemic areas like African and Asian countries, most infections occur from vertical transmission, whilst in western countries HBV is primarily acquired in adulthood. Either way, HBV can persist in infected hepatocytes lifelong, even if undetectable in the serum, allowing reactivation during immunosuppression. HBsAg carriers, those with detectable HBV viral load, or receiving concomitant corticosteroids are at greater risk. Most guidelines recommend screening for occult infections prior to starting biologic treatment including tumour necrosis factor (TNF) inhibitors, HCV, HIV and HBV infection.

Objectives: This study was carried out to estimate the prevalence of occult infections, particularly chronic HBV, in an East London rheumatology population receiving biologic therapies, and to evaluate the rate of HBV reactivation after starting treatment.

Methods: Inflammatory arthritis patients starting biologic therapies in Barts Health NHS Trust between August 2014 and August 2017 were identified from databases of Whipps Cross and Mile End Hospitals. Health records were reviewed focusing on HBV core antibody (HBcAb), HBV surface antigen (HBsAg), HBV DNA, HCV and HIV antibody status. Latent TB tests included IGRAs and ELI-Spot assays.

Results: 757 patients were included in the study. Of those, 51 (6.7%) were HBsAg positive. Of the remaining 706 patients, 82 (11.6%) were HBcAb positive and two patients had low level HBV viremia with detectable DNA antibody at baseline. 61% (n=31) of HBcAb positive patients were female, whilst 39% (n=20) were male, with median age of 58 years (IQR, 43–65). The ethnic distribution was the following: 43% asian (n=22; Bangladeshi or Pakistani), 29% african or Afro-caribbean black (n=15), and 18% white caucasian (n=8). The underlying rheumatological conditions included rheumatoid arthritis (59%), ankylosing spondylitis (33%) and psoriatic arthritis (8%). Fifteen patients (29%) received concomitant prophylactic anti-viral therapies (lamivudine, entecavir or tenofovir). After commencing biologic therapies, no HBV reactivation was noted in the HBcAb positive cohort. Intermittent mild transaminases were detected on monitoring blood tests in 22% (n=11). The rate of latent TB infection was 11.5%; HCV IgG was detected in three patients, whilst HIV infection was absent in our cohort.

Conclusions: Approximately 50% of the patient population of Barts Health NHS Trust is coming from minority ethnic groups. Likely because of the diversity of the population, the prevalence of chronic HBV infection (HBsAg and HBcAb positives) in our East London rheumatology population receiving biologic therapies was higher than the national average (0.8% vs. 0.3%, respectively). No HBV reactivation was observed in the follow up period indicating that the risk of reactivation is relatively low. Nevertheless, for patients with evidence of previous infection (HBcAb positive) careful surveillance continues to be recommended.

GENETICALLY PREDISPOSITION AND PRO-INFLAMMATORY DYSREGULATIONS – CONNECTING RHEUMATOID ARTHRITIS AND MENTAL DISORDERS

1Rheumatology Clinic, University of Medicine and Pharmacy, Cluj-Napoca, Romania; 23GENYO Centre for Genomics and Oncological Research, University of Granada, Granada; 4Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC), University of Cordoba; 5Maimonides Institute for Research in Biomedicine of Cordoba (IMIBIC); 6Reina Sofia University Hospital/University of Cordoba, Cordoba, Spain

Background: Depressive and anxiety disorders are reported as the more prevalent psychiatric comorbidities in chronic inflammatory diseases and their occurrence has been correlated with higher serum levels of cytokines and chemokines (IL-6, IL-1, IL-12, IL-18, TNF-α, and even TNF-R1 and TNF-R2). Some single nucleotide polymorphisms (SNPs) in TNF-α gene have been found to play a common part in pro-inflammatory alterations in patients with rheumatoid arthritis (RA) and depressive symptoms. Either way, RA is a depressive symptom. In RA patients.

Objectives: To investigate the possible influence of four single-nucleotide polymorphism in the tumour necrosis factor receptor II (TNFRII) genes and development of psychiatric disorders in patients with active RA. The second aim was to evaluate some correlation between these SNPs, the level of four chemokines and the incidence of mental disorders.

Methods: We included 89 Caucasian patients with active RA treated in a tertiary Department of Rheumatology from Cluj-Napoca. All demographic, clinical, and biological data and RA comorbidities were completed. The presence of depressions or anxiety was confirmed at the baseline by psychiatrist. Four potentially functional SNPs within TNFRSF1B (rs1061622, rs1062624, rs1061631, rs3397) were selected to be genotyped in all patients using PCR (KASPar) or asASys (Kbiosciences, Hoddesdon, Hertfordshire, UK) at the Centre for Genomics and Oncological Research (GENYO), Granada, Spain. Plasmaic levels of soluble tumour necrosis factor receptor II (sTNFRII), interleukin (IL)–6, monocyte chemotactic protein (MCP)–1 and vascular endothelial growth factor (VEGF) was quantified using cytofluorometry-based ELIAS technique in accordance with manufacturer’s instructions using FlowCytoMix kit (eBioscience, UAS).

Results: According to DAS28 (CRP) all the patient have active arthritis (5.87 ±0.6) with median disease duration of 9 (4–14) years. Most of the patients were diagnosed with depression (n=33), 84.8% were female. Anxiety was present at 21 subjects (80.9% female). In 3 cases these two mental disorders coexist. In a subgroup with depression the polymorphism rs1061631 (GG) was significantly associated with increased level of VEGF (p=0.007). A significant correlation was also found between the polymorphism rs3397 (CC/TT) and MCP-1 (p=0.01).

In a subgroup with anxiety the significant association was found between the polymorphism rs1061831 (GG) and the level of MCP-1 (p=0.04).

Conclusions: Pro-inflammatory dysregulation might be particularly relevant in some patients with RA and psychiatric illness. Amongst genetic factors that influence the susceptibility to the development of RA and psychiatric disorders some single nucleotide polymorphisms (SNPs) in TNF-α gene have been considered with increasing interest. Further investigation in a larger cohort is needed.

Disclosure of Interest: None declared

FACTORS OF THE POSITIVE OR NEGATIVE ANSWER ON THERAPY WITH DENOSUMAB IN WOMEN WITH RHEUMATOID ARTHRITIS AND OSTEOPOROSIS

I. Drydkina, P. Kovalenko, A. Snirnov, E. Nasonov. Nasonova Reumatologiches Research Institute, Moscow, Russian Federation

Objectives: To define a contribution of factors: anamnesis, clinical/laboratory markers, glucocorticoids (GC) intake, etc. on the response to therapy with denosumab (OP) and osteoporosis (OP).

Methods: 66 postmenopausal women (mean age 59.6±7.4) with RA (mean duration 17.7±10.4 years) and OP received s/denosumab 60 mg every 6 months pro 1 year. RF- positive were 72%, ACCP – 74% of patients. 34 (49%) continued GC. At baseline and after 12 months it was carried out the dual energy x-ray absorptiometry at 3 sites: lumbar spine (L1-L4), hip neck (HN) and distal forearm (DF) and different scoring systems for evaluating bone loss and bone erosion score - lower BMD in L1-L4 (at baseline and after treatment) - correlated with increase in JSN (p=0.036) – lower value of BMD dynamics (%) in DF. The erosion score was increased in 12% (n=8) patients, the joint space narrowing score (JSN) – in 9% (n=5) and the bone density score (BDD) – in 28% of cases.

Results: In DF positive (increase or stabilisation of BMD) was noted in 89% patients at L1-L4, 67% – at HN and 60% – at DF. The erosion score was increased in 12% (n=8) patients, the joint space narrowing score (JSN) – in 9% (n=5) and the bone density score (BDD) – in 28% of cases.

Conclusions: In women with rheumatoid arthritis and osteoporosis the denosumab response is associated with RF-positivity (p=0,02), the negative response on therapy is associated with RF-positivity (p=0,02), the negative response back correlates with increase in erosion score and total SVH score: r=−0,0360 (p<0,05).

In table 1 is shown the most significant factors, which influence on SVH score dynamics (increase) after 12 months of denosumab therapy.

Abstract AB0354 – Table 1. The factors which influence on SVH score increase (n=66), p<0.05.

<table>
<thead>
<tr>
<th>SVH score</th>
<th>The score increase is associated with</th>
</tr>
</thead>
<tbody>
<tr>
<td>Erosion score</td>
<td>- lower BMD in L1-L4 (at baseline and after treatment)</td>
</tr>
<tr>
<td>- higher cumulative GC dose</td>
<td>- back correlates with BMD increase in DF</td>
</tr>
<tr>
<td>- back correlates with bone alkaline phosphatase (BAP) base level</td>
<td>- correlates with increase in JSN</td>
</tr>
<tr>
<td>Joint space narrowing score (JSN)</td>
<td>- presence at patients in anamnesis a surgical menopause</td>
</tr>
<tr>
<td>- lower value of BMD dynamics (%) in DF</td>
<td>- correlates with increase in erosion score and total SVH score.</td>
</tr>
</tbody>
</table>
Conclusions: There was established that positive response on therapy with denosumab in BMD in NH and DF is associated with RF-positivity. The particular correlation of prehensile response in L1-L4 and RN is associated with GC intake (previous intake more than 3 months in the anamnesis), purpose of the GC after menopause onset. There was note that the increase of erosion score is associated with either lower BMD in L1-L4 (at baseline and after treatment) or back correlation with BMD increase in DF. Also the higher cumulative GC dose and back correlation with BAP base level were observed at patients with increased erosion score. The only factors that we could reveal in patients with increased JSN score were surgical menopause in anamnesis and lower value of BMD dynamics (% in DF) after treatment. In general it was a direct correlation between erosion score and JSN score.

Disclosure of Interest: None declared

THE RELATIONSHIP BETWEEN HAND PREHENSILE STRENGTH, CLINICAL ACTIVITY AND FUNCTIONAL CAPACITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

L.P. Guzmán Guzmán1, J.E. Navarro-Zarza2, G.A. Alonso-Silverio3, A. Alarcón-Paredes4, D. Jerez-Mayorga1, I. Parra-Rojas5; 1Facultad de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero; 2Hospital General; 3Facultad de Ingeniería, Universidad Autónoma de Guerrero, Chilpancingo, Mexico; 4Facultad de Ciencias de la Rehabilitación, Universidad Andres Bello, Santiago, Chile

Background: The hand is an anatomical structure with a large number of joints; its prehensile grasp capability constitutes a highly specialised biomechanical function. In rheumatoid arthritis (RA), the structures of the joint are damaged by the characteristic inflammatory process. The prehensile strength was obtained by the dynamometry method in the DAS28-ESR and HAQ-Di were recorded.

Methods: The prehensile strength was obtained by the dynamometry method from 105 AR patients, the maximum strength levels in the dominant and non-dominant hand were considered. The Disease Activity Score 28 joints using the erythrocyte sedimentation rate (DAS28-ESR) and HAQ-Di were recorded.

Results: The maximum prehensile strength, on average, was 14 kg, and the weak force category was more prevalent. The prehensile strength of both hands was negatively correlated with the HAQ-Di score and DAS28 index. In an adjusted logistic regression model, the “weak” strength category of the non-dominant hand was associated with “moderate clinical activity” in the DAS28 score (OR=8.59, p=0.02), while the category of “weak” strength of the dominant hand was associated with the presence of “some difficulty” of HAQ-Di score (OR=4.75, p=0.10).

Conclusions: The decrease in prehensile strength represents a marker associated with the presence of both the HAQ-Di and DAS28 index in the patient with RA, regardless of age, muscle mass, total fat or body mass. The measurement of the prehensile strength can be a useful and inexpensive tool to be considered in the clinical evaluation of the RA.

BUILDING A PATIENT-CENTRED CARDIOVASCULAR RISK REDUCTION PROGRAM FOR PATIENTS WITH INFLAMMATORY ARTHRITIS

L.Y. Navarro-Milan1, S. Young2, S. Shurbaji3, C. McDavid3, A. Cornelius-Schecter1, B. Johnson4; 1Weill Cornell Medicine, New York; 2Binghamton University, Binghamton; 3University of Alabama at Birmingham, Birmingham; 4Yale University, New Haven, USA

Background: Cardiovascular disease (CVD) is the most common cause of death among patients with inflammatory arthritis (IA) such as rheumatoid arthritis (RA), psoriatic arthritis (PsA) or ankylosing spondylitis (AS).

AB0357 THE SUPPORT OF MEDICAL CLERKS IN RHEUMATIC DISEASE CLINIC AIDS T2T PRACTICE FOR RHEUMATOLOGISTS AND IMPROVES DISEASE ACTIVITIES OF PATIENTS WITH RHEUMATOID ARTHRITIS

I. Matsuishi1, H. Motomura1, T. Hiraiwa1, S. Arai2, C. Ota2, T. Kimura1; 1Orthopaedic Surgery, University of Toyama; 2Orthopaedic Surgery, Sainou Hospital, Toyama, Japan

Background: With treat-to-target (T2T), the physician always has to evaluate disease activity and joint damage of rheumatoid arthritis (RA) patients exactly to maintain the activities of daily living of the patient for the long term. However, the amount of work required by physicians to complete T2T can be onerous, so the cooperation of medical staff is necessary to practice T2T.

Methods: In our rheumatic disease clinic, MCs have supported rheumatologists since April 2011. We individually evaluated 50 RA patients in May 2010 (before MC support); “preceding period”, April 2011 (1 year after the start of MC support: “early period”), April 2013 (3 years after the start of MC support: “middle period”), April 2015 (5 years after the start of MC support: “late period”) and April 2017 (7 years after the start of MC support: “last period”). We assessed the prevalence of T2T practice, disease activity, and drug use. When all components of the Simplified Disease Activity Index (SDAI) of patients had been listed in the medical record and radiography of hand and foot joints had been undertaken more than once a year, the medical examination was defined as “T2T practice”. Disease activity was assessed using the SDAI and Clinical Disease Activity Index (CDAI).

Results: Prevalence of T2T practice was 50%, 86%, 94%, 100% and 100% at preceding, early, middle, late and last periods, respectively. Prevalence of T2T practice increased after the start of MC support. Accordingly, disease activities improved gradually. SDAI remission was 30.8% in the preceding period, 28.5% in the early period, 30% in the middle period, 58% in the late period and 56% in the last period, respectively. CDAI remission improved towards the last phase, similar to that seen with the SDAI. The mean dose of methotrexate (MTX) increased gradually towards the last phase, but the prevalence of MTX use did not show a remarkable change. Prevalence of use of biological disease-modifying anti-rheumatic drugs did not increase during the study period.

Conclusions: MC support in rheumatic disease clinics aids T2T practice for rheumatologists. The disease activities of RA patients can be improved by MC support.

PHENOTYPES OF SECONDARY SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS

R. Yatsyshyn, I. Steka. Internal Medicine #1, Ivano-Frankivsk National Medical University, Ivano-Frankivsk, Ukraine

Background: Secondary sarcopenia may be caused by low physical activity, eating disorders, chronic inflammation. In patients with rheumatoid arthritis (RA), sarcopenia co-occurs with osteoporosis as well as obesity and, in most cases, both osteoporosis and obesity co-occur with sarcopenia. Therefore, 3 phenotypes of sarcopenia can be identified: sarco-osteo-sarcopenic, sarcopenic obesity, osteosarcopenic obesity.

Objectives: The aim of the research was to study the features of sarcopenia and her phenotypes in patients with RA. There were examined 40 women with stage II-III RA, Rtg stage II-III, functional limitation stage II. The patients average age was 40.7±2.25 years.

Methods: The algorithm for diagnosing phenotypes of sarcopenia recommended by the European Working Group on Sarcopenia in Older People (2019) was used. Body mass index was determined. Dynamometry (the measurement of hand-grasp strength using handgrip dynamometer) was performed and the evaluation of physical fitness. Serum levels of leptin and creatine phosphokinase MM (CPK MM) fraction were determined. The dual-energy X-ray absorptiometry DEXA (totocalculate a T-score) was performed.

Results: According to the results of laboratory tests and methods of evaluating functional muscle disorders, 87.5% of patients were diagnosed with sarcopenia. The mean values of dynamometry were within 18.3±0.7 kg being significantly lower as compared to healthy individuals – 28.3±0.5 kg. After the evaluation of physical fitness, the average score was 7.9±0.7, while in healthy individuals, it was 11.3±0.4. The mean CPK MM concentration was 175±2.34 U/L, while in healthy individuals, it was 144±3.5 U/L. The average T-score were within the limits (−2.0±0.6) and (−1.0±0.6). The mean DLCO concentration was 80% ±10% in healthy individuals.

Conclusions: RA leads to muscle metabolism disorders which result in the development of secondary sarcopenia. Therefore, a high-protein diet, physical exercise, namely aerobic exercise (swimming, cycling) and medical preparations that improve muscle metabolism should be included in therapeutic measures and preparations of calcium.

Disclosure of Interest: None declared

CLINIC PROFILE OF PATIENTS WITH RHEUMATOID ARTHRITIS AND PULMONARY AFFECTION IN A COHORT FROM A UNIVERSITY HOSPITAL

I. Casafont Solé1, A. Prior-Espariol1, S. Holgado1, J. Roca2, L. Mateu1, Y. García-Mira1, J. Camin1, G. Giné1, A. Riverol1, M. Martínez-Moll1, M. Aparicio1, A. Olivé1. 1Rheumatology, Epidemiology, Hospital Universitartrar Germans Trias i Pujol, Badalona, Spain

Background: Pulmonary affection is a serious complication in Rheumatoid Arthritis (RA) with an important impact on mortality and morbidity.

Objectives: To describe the clinical and radiographic characteristics of patients with RA in our centre, and specifically from those with interstitial lung disease (ILD).

Methods: Retrospective analysis of patients with RA and pulmonary affection from a University Hospital with a referral area of 85,000 inhabitants. Clinical, laboratory, imaging and pulmonary function test (PFT) data was recorded.

Results: Data from 85 patients, 37 (43.5%) male and 48 (56.5%) female, were recorded. The mean time from RA diagnosis to pulmonary disease was 9.2 years, with mainly erosive (58.8%) and seropositive (84.7%) patients. RA disease activity score 28 using C-reactive protein. The mean time from RA diagnosis to pulmonary disease was 9.2 years.

Conclusions: RA–ILD is a chronic, systemic inflammatory disease, which mainly affects synovial joints. Heart structural abnormalities are more prevalent in RA-patients than in general population, such as pericarditis, increased left ventricle mass and valvular disease.ILD affects approximately one third of RA patients in our area and is an undiagnosed entity. We consider that it is necessary to establish a screening program to diagnose and treat it early.

LEFT ATRIAL DILATION IS INCREASED IN PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY

1Rheumatology; 2Cardiology, Hospital Universitario Dr.-José E. Gonzalez, UANL, Monterrey, Mexico

Background: Rheumatoid arthritis (RA) is a chronic, systemic inflammatory disease, which mainly affects synovial joints. Heart structural abnormalities are more prevalent in RA-patients than in general population, such as pericarditis, increased left ventricle mass and valvular disease. Left atrial (LA) dilatation predicts atrial fibrillation and congestive heart failure. It also increases the risk of developing thromboembolic events.

Objectives: The aim of this study was to determine the prevalence of LA dilatation in RA-patients and compare it with matched controls.

Methods: An observational, cross-section, case-control study was designed. Patients who fulfilled 1987 ACR and/or 2010 ACR/EULAR classification criteria for RA, 40–75 years old, with no overlap syndromes or atherosclerotic cardiovascular disease were included. The control group was matched by age, gender and comorbidities. A standard transthoracic echocardiogram was performed by a board-certified cardiologist. LA structure alterations were evaluated according to the American Society of Echocardiography guidelines.

Results: A total of 63 RA-patients and 41 control subjects were included. Demographic characteristics are shown in table 1. LA dilatation, defined as a LA indexed volume (LAVI) >34 ml/m², was found in 9 (14.3%) patients of the RA-group, whereas no control subjects presented that condition (p=0.011). Mitral regurgitation was detected in 39 (62%) RA-patients and 7 (17%) control subjects (p<0.001).

Disclosure of Interest: None declared
Conclusions: LA dilation is more prevalent in RA-patients when compared to matched controls. Prospective studies are needed to evaluate the influence of this condition in cardiovascular outcomes.

REFERENCES:

Background: Despite the fact that genetic and serological risk factors have been studied in rheumatoid arthritis (RA), the symptoms phase of preclinical RA is poorly characterised. Taking into account the importance of early diagnosis and effective treatment for the prevention of structural damage and long-term disability in RA, it is important to find clinical or image variables that identify patients with clinically suspected arthralgias at risk of developing a chronic arthritis (CSA).

Objectives: To identify baseline clinical, immunological and ultrasound variables in patients with arthralgias clinically suspected of progression to chronic arthritis.

Methods: Longitudinal prospective study of patients with CSA and follow-up from November 2015 in pre-arthritis clinics. Patients were assessed at baseline and every 6 months until 2 years, with clinical, laboratory and ultrasound data using standardised protocols. The criteria for eligible patients for inclusion in the study were ≤12 months of symptoms onset, inflammatory arthralgias (predominance in nights or mornings, improvement during the day or with movement, and morning stiffness < 30 min), and the involvement of small joints of hands or feet. Patients with clinical synovitis at baseline visit, patients with fibromyalgia or osteoarthritis were excluded.

Results: Twenty-six patients were recruited in 26 months of the study (1 male, 25 female), with an average baseline age of 44.7±12.6 years, an average delay time of symptoms to first visit of 8.7±3.3 months, a mean follow-up time of 7.7±81 months an average body mass index (BMI) of 27.1±7.2. Five patients had familial background of autoimmune diseases in first degree relatives (RA, psoriasis, inflammatory bowel disease), 6 (23%) were seropositive (RF and/or ACPA), 7 (26.9%) had increased baseline acute-phase reactants (PAR), and 11 (47.8%) were smokers or former smokers. Most of the patients reported a progression of the arthralgias (55%) and a subjective joint swelling at some point (70%). Of 24 patients, 8 (33.3%) developed chronic arthritis (7 RA, 1 undifferentiated arthritis), with a longer follow-up (15.7±7.4 vs. 7.5±2.2 months, p=0.016), greater baseline HAQ (11.8±8.3 vs. 3.9±4.8, p=0.033) and higher percentage of moderate inflammatory activity in the baseline ultrasound (83.3% vs. 8.3%, p=0.004), compared to patients that didn’t develop arthritis. The patients of the group that developed arthritis had a trend towards a higher seropositivity (37.7% vs. 18.8%), a higher patient global disease assessment (45±29 vs. 30±27 on a 100 mm scale), higher patient pain scores (using a visual analogue pain 100 mm scale) (58±41 vs. 34±23) among patients who eventually developed arthritis, although not statistically significant. No differences were found with PAR, BMI, age, smoking habit or painful joint count at baseline visit.

Conclusions: In our pre-arthritis clinics of patients with clinically suspicious arthralgias, 33% progressed to arthritis, underlying the importance of these clinics. Functional disability and ultrasound at baseline visit are especially useful in predicting future progression to arthritis. It is necessary to recruit more patients in order to obtain more robust conclusions.

FACTORS ASSOCIATED WITH THE DEVELOPMENT OF ARTHRITIS IN PATIENTS WITH ARTHRALGIAS CLINICALLY SUSPECTED OF EVOLVING INTO ARTHRITIS: EXPERIENCE OF A PRE-ARTHRITIS CLINIC

Background: Despite the fact that genetic and serological risk factors have been studied in rheumatoid arthritis (RA), the symptoms phase of preclinical RA is poorly characterised. Taking into account the importance of early diagnosis and effective treatment for the prevention of structural damage and long-term disability in RA, it is important to find clinical or image variables that identify patients with clinically suspected arthralgias at risk of developing a chronic arthritis (CSA).

Objectives: To identify baseline clinical, immunological and ultrasound variables in patients with arthralgias clinically suspected of progression to chronic arthritis.

Methods: Longitudinal prospective study of patients with CSA and follow-up from November 2015 in pre-arthritis clinics. Patients were assessed at baseline and every 6 months until 2 years, with clinical, laboratory and ultrasound data using standardised protocols. The criteria for eligible patients for inclusion in the study were ≤12 months of symptoms onset, inflammatory arthralgias (predominance in nights or mornings, improvement during the day or with movement, and morning stiffness < 30 min), and the involvement of small joints of hands or feet. Patients with clinical synovitis at baseline visit, patients with fibromyalgia or osteoarthritis were excluded.

Results: Twenty-six patients were recruited in 26 months of the study (1 male, 25 female), with an average baseline age of 44.7±12.6 years, an average delay time of symptoms to first visit of 8.7±3.3 months, a mean follow-up time of 7.7±81 months an average body mass index (BMI) of 27.1±7.2. Five patients had familial background of autoimmune diseases in first degree relatives (RA, psoriasis, inflammatory bowel disease), 6 (23%) were seropositive (RF and/or ACPA), 7 (26.9%) had increased baseline acute-phase reactants (PAR), and 11 (47.8%) were smokers or former smokers. Most of the patients reported a progression of the arthralgias (55%) and a subjective joint swelling at some point (70%). REFERENCE:

frequencies occurring six months before/after their introduction, using medical files and phone inquiry.

**Results:** Twenty-three patients were included in this study. Data about RA treatments and SCD frequencies could be collected for 15 patients. Middle age at RA diagnostic was 32.9 years-old, sex ratio was 4.75:1.M. 74% of the patients were RF positive, 65% were ACPA positive. 74% of the patients had articular damages. Among them, 100% had severe carpal which appears to be the major radiological expression of RA in SCD patients, occurring sometimes without finger bone erosion. 100% received at least one specific drug for RA, 35% a biotherapy. There was no significant difference in the number of crisis before and after methotrexate introduction (p=0.1 or anti TNF alpha drugs (p=0.35) IC95% [1.26;0.51]. Methotrexate had to be stopped for 3 patients because of acute chest syndrome, which did not occur with anti TNF. No infection was noticed.

**Conclusions:** In conclusion, in SCD, RA occurs sooner in life course and to be more severe with a particular pattern: carpal and tarsite without finger bone erosion. The use of biotherapy appears to be safe, with a close monitoring.

**AB0364 REMARKABLE INTERNATIONAL VARIABILITY IN REASONS FOR NON-PARTICIPATION IN THE GLORIA TRIAL**

L. Hartman1, R. Bos2, F. Buttgereit2, M. Güler-Yuksel3, R. Ionescu5, M. Kok4, W. Lems3, M. Miculescu4, D. Opis-Belinski5, A. Pusztai6, E. Santos7, J. da Silva8, Z. Szekanecz2, K. Zeiner3, D. Zhang9, M. Boers1,9, Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, 2Rheumatology, Medical Center Leeuwarden, Leeuwarden, Netherlands, 3Department of Rheumatology and Clinical Immunology, Charité – University Medicine Berlin, Berlin, Germany, 4Department of Rheumatology and Clinical Immunology, Maasstad Hospital, Rotterdam, Netherlands, 5Department of Internal Medicine and Rheumatology, ‘St. Maria’ Hospital, University of Medicine and Pharmacy, Carol Davila’, Bucharest, Romania, 6Instituto Português de Reumatologia, Lisbon, Portugal, 7Department of Rheumatology, University of Debrecen Faculty of Medicine, Debrecen, Hungary, 8Reumatologia, Facultade de Medicina e Hospitais da Universidade de Coimbra, Coimbra, Portugal, 9Department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands

**Background:** GLORIA is an ongoing large pragmatic trial that examines harm, benefit and costs of low-dose glucocorticoids added to the standard treatment of RA patients of 65 years or older. The eligibility criteria are non-restrictive: RA, age >65 years, disease activity score (DAS28) of >2.6, and no current glucocorticoid treatment. Patients with comorbidity are expressly included, and the impact of trial procedures on normal care is minimal. Nevertheless, inclusion proves to be challenging. We have prospectively sampled all the reasons for ineligibility across a number of centres in different countries participating in the GLORIA trial.

**Methods:** Rheumatologists from 8 centres in Germany, Hungary, The Netherlands, Portugal and Romania screened the patient list of at least two full clinic days. For each patient, the eligibility and all possible reasons of exclusion were recorded.

**Results:** In total, 385 patients were screened. Of these patients, 15 (4%) were eligible to participate in the GLORIA trial. In Germany, Romania and Portugal (Lisbon) none of the screened patients proved eligible.

The most common reasons for ineligibility were inactive disease and age (both 58%) (table 1). Current glucocorticoid use was reported in 28%, 5% had a temporary reason (i.e. recent switch of therapy or glucocorticoid use), and 51% had more than one reason for ineligibility. We found remarkable differences between the sites in the distribution of the main reasons for ineligibility (table 1).

Of the eligible patients, 1 was already participating, 3 were included after this screening, and 2 were currently considering participation; 9 declined participation (most common reasons: fear of glucocorticoids, not interested to participate, preference for GC injections or declining additional therapy).

**Conclusions:** In this prospective study, we found remarkable differences between countries in reasons for non-participation in our ongoing GLORIA trial. The willingness of eligible patients to participate was low in this elderly population, despite the pragmatic design. Earlier studies also showed that it is challenging to include elderly patients in a clinical trial. Pre-screening of patients in potential sites can provide important information on the potential to recruit patients in a trial, but the actual willingness of patients to participate remains hard to predict.

**AB0365 THE INSULIN RESISTANCE, METABOLIC SYNDROME AND TYPE 2 DIABETES MELLITUS DEVELOPMENT RISK ASSESSMENT IN RHEUMATOID ARTHRITIS PATIENTS**

L. Konradjeva, T. Popkova, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** The insulin resistance (IR) is the known risk factor of type 2 diabetes mellitus (DM) and potential cardiovascular complications. But it’s not feasible in routine practice to calculate special indices to determine IR, as insulin levels monitoring is not a standard procedure in RA pts. Metabolic syndrome (MS) criteria and questionnaires designed to assess the risk of DM development can help to differentiate a subgroup of pts, requiring more accurate evaluation of their IR status.

**Objectives:** To determine how IR relates with MS and DM development risk assessment in RA patients.

**Methods:** A total of 46 RA pts (39 women, 7 men, 57 [39; 64] years old) without established disease were enrolled in the study, including 14 pts with IR and 32 pts without IR, matched by age and sex. IR was defined as Homeostasis Model Assessment of Insulin Resistance (HOMA-IR) index \(>2.77\). National Cholesterol Education Program/Adult Treatment Panel III (NCEP/ATPIII) and International Diabetes Federation (IDF) criteria were used to confirm MS. The abdominal obesity was determined as waist circumference (WC) >80 cm for women and >94 cm for men (by IDF), and WC >88 cm for women and >102 cm for men (by NCEP/ATPIII). If the total score of questionnaire Finnish Type 2 Diabetes Risk Assessment Form (FINDRISK) was >12, the DM development risk was considered as moderate or high.

**Results:** The body mass index was higher in pts with IR than in those without IR (28.5 [24.8; 32.5 kg/m\(^2\)] vs 22.4 [20.1; 25.4 kg/m\(^2\), p<0.001]). Abdominal obesity was documented in 100% pts with IR and in 41% pts without IR by IDF criteria (p=0.002), in 64% and 22% pts, respectively, by NCEP/ATPIII criteria (p=0.01). There were no differences in DAS28, CRP and ESR values and glucocorticoids users proportions, MS by IDF criteria was diagnosed in 57% pts with IR and 19% pts without IR (p=0.02), and MS prevalence by NCEP/ATPIII criteria was similar in both groups (36% vs 16%, respectively, p=0.2). Higher rates of moderate and high risk for DM development were found in pts with IR compared to pts without IR (71,4% vs 31,2%, p=0.03).

**Conclusions:** The FINDRISK and IDF questionnaires, but not the NCEP/ATPIII criteria of MS, can be helpful in selecting RA pts with potential IR. Abdominal obesity was the key factor indicative of IR in RA pts. On the other hand, IR may not be there even in the presence of several traditional DM risk factors. Therefore further clarification of potential contribution of RA-related risks is needed.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3264
Background: Rheumatoid arthritis (RA) is a chronic rheumatic inflammatory disease with a higher risk of developing some cardiovascular pathology compared to the general population. The presence of comorbidities in patients with RA represents an increase in the cost of care, work disability and hospital admissions.

Objectives: To describe clinical, epidemiological characteristics, frequency of comorbidities and their association with clinical and analytical characteristics in Paraguayan patients with rheumatoid arthritis.

Methods: Descriptive, cross-sectional study of a cohort of patients with established rheumatoid arthritis, followed in the Department of Rheumatology of the Hospital de Clinicas, epidemiological (i.e. sex, age, origin), clinical (i.e., comorbidities (i.e. HBP was defined as BP > 140/90), obesity BMI ≥ 30, dyslipidemia according to lip profile levels), time of evolution of the disease, DAS28, etc.), laboratory (i.e. RF, anti-CCP) and radiographic variables were recorded. Qualitative variables were expressed in frequencies and percentages and quantitative variables were characterised by their means and standard deviations. The comparison of clinical, epidemiological, serological variables was performed using the chi-squared test and the student test respectively for qualitative and quantitative variables. The statistical analysis was performed with the statistical program SPSS V.23.0.

Results: 177 patients with RA were included, 82.5% were women, with a mean age at onset of 44.8±13.8 years, mean disease duration of 8.6±8.3 years. 68.3% came from Asuncion and Gran Asuncion. 44.6% of the patients were married, the average number of children per patient was 3.55±2.2. Most of the patients (43.6%) were from social stratum 1–2, according to the GRAFFAR questionnaire. Family income with minimum salary or less was found at 55, 7% of patients with an average household income of 2.350,515±1.622,049 Guaranies. Most patients work at home, 54.5% were housewife, and only 11.9% had a university degree. Only 15.3% had extra-articular manifestations, mainly rheumatoid nodules. The average body mass index was 29.6±12.7. 75.9% were RF positive, with an average level of 224.7±201 UI/L. Methotrexate was the most frequent treatment (87%), only with DMARDs.

Conclusions: It is not clear if the use of SIS may be related to function and disability in RA. Forefoot SIS did not show correlation although hallux valgus, MTMP subluxation and 5th MTP exostosis may be related to foot function. Forefoot SIS and its items seem to be most correlated with function and disability in RA.

AB0367 THE OCCURRENCE OF ANTIBODIES DEPENDING ON THE DURATION OF RHEUMATOID ARTHRITIS

M. Volkova. BeMAPGE, Minsk, Belarus

Background: Recently heterogeneous nuclear ribonucleoproteins (hnRNPs) were identified as antigenic targets for autoantibodies in RA. Autoantibodies to RNP B1, B2 and heterogeneous complex A20 are the most studied and are referred to as ‘antigen RA33’. Clinical value of anti-RA33 in RA continues to be studied, so the question is about the diagnostic and pathogenic significance of these autoantibodies in patients with RA remains open.

Objectives: The aim of this study was to investigate the frequency of occurrence of anti – RA33y patients with RA and compare them with clinical manifestations and immunological parameters of disease.

Methods: The study included 139 patients with RA. The diagnosis was verified according to the classification criteria of ACR/EULAR 2010 Autoantibodies to RNP B1 IgG was assessed in samples of blood serum by enzyme immunoassay (ELISA; Medigen AG, Germany). A recombinant human RNP antigen B1 was used as the antigen, which was synthesised in the E. coli. cell line of the protein production. Anti-COP, RF and antibodies to S-a-antigen (anti-Sa) was evaluated by ELISA according to the manufacturer’s instructions (Euroimmun AG company, Germany). The results were expressed in relative units (U/ml). Statistical data processing was carried out using the software Statistica 7.0 (StatSoft, USA) and

Disclosure of Interest: None declared
Medcalc 12.5.0.0 (USA), including standard methods of parametric and nonparametric analysis. Differences were considered significant at p<0.05.

Results: Levels and frequency of occurrence of anti-RA33, anti-CCP, RF IgM and anti-Sa were analysed for the examined patients depending on disease duration. Patients were divided into two groups: patients with early RA (disease duration less than 12 months) and patients with established RA (disease duration over 12 months). In the analysis it was found that the incidence of anti-Sa in established RA are much higher in comparison with the early RA (77.98% vs. 52.00% respectively, p<0.05). The levels of anti-Sa autoantibodies were lower in early RA than in established RA 21.57 U/L; 95% CI 12.10–27.42 vs. 33.10 U/L; 95% CI 27.58–37.71 respectively, p<0.05). Frequency of occurrence of anti-CCP and RF IgM is no different in the early and developed stage of RA. The frequency of occurrence of anti-RA33 in early RA was higher than in established RA (52.00% vs. 32.45% respectively, p<0.05).

Conclusions: Thus, anti-RA33 is a perspective independent biomarker of RA which has its own potential. Further study of the anti-RA33 as a diagnostic biomarker of early stage RA is promising. Based on preliminary studies the anti-RA33 could have diagnostic and prognostic value in diagnosis and evaluation of patients with early RA, and its differentiation from other small joint disorders, particularly when the other serologic tests are negative.

To clarify the diagnostic and pathogenic value of anti-RA33 further research with a large sample size, comparison of immunological data with genetic factors, the results of other laboratory and instrumental studies, clinical manifestations of the disease are required. The obtained data will allow us to more thoroughly study the pathogenesis of RA and contribute to the search for new therapeutic options.

ADULT-ONSET STILL’S DISEASE TREATMENT PREDICTORS AT 1-YEAR FOLLOW-UP IN A SINGLE RHEUMATOLOGIC CENTRE EXPERIENCE

M. Giannotta, F. Cacciapaglia, M. Giannini, M. Nivuoi, R. Fanizzi, G. Lopalco, G. Laselva, C. Scioscia, F. Iannone. Department of Emergency and Organ Transplantation, Rheumatology Unit of Uniبار, Bar, Italy

Background: Adult-onset Still’s disease (AOSD) is a rare systemic inflammatory disorder mainly characterised by persistent high spiking fevers, evanescent rash, and joint involvement. Data on the efficacy of biologic therapy in the management of AOSD1 is increasing and represents a breakthrough in the management of patients with AOSD refractory to corticosteroids (CS) or conventional (c) DMARDs. Objectives: We aimed to evaluate possible predictor on the need to use a biologic agent in the management of AOSD patients.

Methods: In this retrospective monocentric study we evaluated AOSD patients followed in our outpatient’s clinic since 2010 with at least 1 year follow-up. Clinical manifestations, joint involvement, CS and c- or bDMARD use were main outcome measures. T-test or ANOVA and Chi-squared were used to compare continuous or categorical data, when appropriate, and the odds ratio (OR) for which condition had an influence on clinical outcome was calculated.

Results: We evaluated 28 AOSD patients (mean age 43±14 years; median disease duration 3 (95%CI 2.5–17.3) months). All patients at baseline were treated with a median CS of 18.7 (95%CI 14.3–24.8) mg/die prednisone equivalent dose, and median methotrexate (MTX) dose of 15 (95%CI 13.4–16.2) mg/week. After 1 year follow-up, in the 8 patients (28.6%) that needed to start a bDMARD (4 anti-IL1; 3 anti-IL6 and 1 anti-TNF), we observed that baseline joint involvement was the more prevalent manifestation of the disease with higher DAS28 compared to those patients still on CS + MTX (DAS28 3.8±1.2 vs 2.8±1.1, respectively p<0.03). Moreover, we showed that clinical manifestations of systemic involvement (e.g. fever, rash, organomegaly and anaemia) were associated with a protective risk to start a bDMARD at 1 year (OR 0.49 95% CI 0.2–0.76). Consistently, in those patients with concomitant elevated ESR (>20 mm/h), CRP (>15 mg/L) and ferritin (>250 ng/ml) levels at baseline, we observed a low risk to start a bDMARD at 1 year follow-up (OR 0.49 95% CI 0.18–0.87).

Conclusions: In our cohort about one third of AOSD patients required to be treated with a bDMARD at 1 year follow-up, mainly if joint involvement was the predominant clinical manifestation at disease onset. Systemic manifestations of the disease seem to benefit from high dose CS+MTX combination therapy. Further studies with more extensive cases are necessary.

LOW SERUM IGF1 IS ASSOCIATED WITH HIGHER CARDIOVASCULAR RISK IN THE MIDDLE-AGED ‘WOMEN WITH RHEUMATOID ARTHRITIS’ INDEPENDENTLY OF THE DISEASE RELATED PARAMETERS

M.C. Erlandsson1,2, S.T. Silversward1, M. Nadali1,2, R. Pullertet1, M. Bokarewa1,3,2

1, 2Rheumatology and Inflammation Research, GOTHENBURG UNIVERSITY; 3Rheumatology Clinic; 4Department of Clinical Immunology and Transfusion Medicine, Sahlgrenska university hospital, Gothenburg, Sweden

Objectives: To analyse the relation between serum levels of IGF1 and cardiovascular risk (CVR) in women with rheumatoid arthritis (RA).

Methods: The risk of dying of CV disease within 5 years was calculated using the strategy proposed by Pocock et al. BMJ 2001 in 185 women with RA (mean age 51.7 years) with previous history of CV events. The CVR and characteristics related to it were analysed with respect to serum IGF1. IGF1 levels below the median of the total cohort were considered low.

Results: The RA women with low IGF1 (n=91, mean 104 pg/ml) had significantly higher CVR compared to those with normal IGF1 (n=94, mean 194 pg/ml) with the predicted risk of 0.51% and 0.17%, respectively (p<0.05–0.01). Among the traditional CVR factors, the low IGF1 group was 10 years older (mean 56.8 vs. 46.9 y, p=0.05–0.1), lower in height (165 vs. 168 cm, p=0.013, 21% of the patients being <160 cm) and had high prevalence of hypertension (24% vs. 8.5%, p=0.004), while current smoking was similar between the groups (15% vs. 14%).

The low IGF1 group displayed the unfavourable metabolic profile with higher BMI (31 vs. 29 kg/m2, p=0.05), higher anaemia (13% vs. 9%, p=0.02), higher visceral fat area (mean 37.71 vs. 35%, p<0.05), and higher total and LDL cholesterol (p=0.0014 and p=0.0035, respectively). The levels of adiponectin (p=0.032) and HDL-cholesterol (p=0.25) tended to be higher in the low IGF1 group, which resulted in the comparable total cholesterol to HDL ratio between the groups. This could also explain that the prevalence of diabetes mellitus and metabolic syndrome were low.

With exception of the disease duration, the groups displayed no significant difference in the RA-related CVR factors such as the disease activity measured by DAS28 (3.29 vs 2.99), systemic inflammation measured by IL6 (mean 8.46 vs. 5.99 pg/ml) and IL1β (mean 19.47 vs. 23.1 ng/ml), and the prevalence of sero- positivity (91% vs. 92%). The prevalence of treatment with MTX monotherapy was higher in the low IGF1 group (56% vs. 39%, p=0.024), while the use of TNF- inhibitors and other biologic and synthetic anti-rheumatic drugs was similar within the groups.

Conclusions: Serum IGF1 levels in the normal range are associated with higher CVR in RA female patients. This increase in CVR seems to be independent of the RA-related characteristics. The combination of low height and hypertension argues for the important role of congenital factors in defining serum IGF1 levels in the studied RA women.

THE EFFECT OF CUMULATIVE EXPOSURE TO CIGARETTE SMOKING ON VASCULAR DAMAGE IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Aguilar-Zamora1, M. Robustillo-Villarino1, L. Montolio Chiva1, A.V. Orenes Vera1, A. Martínez-Ferrer1, E. Valls. Pascual1, D. Ybarra García1, A. Sendra García1, I. Torner Hernández1, V. Núñez Monje1, J.J. Alegre-Sancho1

1Rheumatology, Hospital Universitario Dr. Peset; 2Foundation for the promotion in health and biomedical research (FISABIO), Valencia, Spain

Background: Smoking is described as a classic cardiovascular (CV) risk factor and we also know the beneficial effect on the CV system of smoking cessation. However, there is contradictory data about its effect in patients with rheumatoid arthritis (RA). It is possible that the measure of cumulative exposure to tobacco expressed in pack-year gives us more information than the smoking status.

Objectives: To explore the relation between smoking exposure, measured in pack-year, and subclinical vascular damage, mortality and vascular events in patients with RA.

Methods: Observational ambispective study. We included, consecutively, RA patients controlled in a tertiary hospital. We gathered demographic (sex, age, body mass index [BMI], clinical (characteristics of RA, classic CV risk factors and history of vascular events) and analytical variables (CRP, ESR). We estimated the modified SCORE. We explored the extracranial branches of the carotid artery
AB0372  LEFT ATRIAL FUNCTION IN RHEUMATOID ARTHRITIS PATIENTS

M. Fawzy, S. bahoom, . Ashour, M. sheik, kaser el Aini, giza, Egypt

Background: Rheumatoid arthritis (RA) is a common autoimmune systemic inflammatory disease affecting approximately 1% of the worldwide population. The interaction of genetic and environmental factors results in a cascade of immune reactions, which ultimately lead to the development of synovitis, joint damage, and structural bone damage.1 The importance of the left atrium in cardiovascular performance has long been acknowledged. Quantitative assessment of left atrial (LA) function is laborious, requiring invasive pressure-volume loops and thus precluding its routine clinical use. In recent years, novel postprocessing imaging methodologies have emerged, providing a complementary approach for the assessment of the left atrium. Atrial strain and strain rate obtained using either Doppler tissue imaging or two-dimensional speckle-tracking echocardiography have proved to be feasible and reproducible techniques to evaluate LA mechanics.2

Objectives:
1. To screen cardiac affection in rheumatoid arthritis patients
2. To assess subclinical echocardiographic affection in RA patients

Methods: 30 healthy control, and 45 RA patient subjected to full clinical assessment, DAS 28 ESR score, full laboratory evaluation, conventional and tissue Doppler imaging (TDI) and strain (S) and strain rate (SR) analysis by two-dimensional speckle tracking of the left atrium.

Results: we found statistically significant difference in 2 Left atrial PEF, 2 Left atrial EI, 2 Left atrial TEF, TDI mitral lateral annulus e', TDI mitral lateral annulus a, Average SR E 1/s between patients and controls, and negative correlation between TDI lateral e', TDI lateral s, and Strain rate e and rheumatoid factor. There was negative correlation between 2LA PEF, 2LA EI, and 2LA TEF. Rheumatoid factor is correlated to strain rate e, and negatively correlated with left atrial passive emptying.

Conclusions: RA had alteration in left LV longitudinal myocardial function, left atrial expansion volume can be a predictor of AF in RA. RA patient had more left atrial stiffness. Our study concluded cardiac affection is more in seropositive RA patients.

NONTUBERCULOUS MYCOBACTERIUM INFECTIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS: A SINGLE-CENTRE EXPERIENCE IN JAPAN

M. Hayashi, K. Funamura, M. Maeda, T. Kanaromo. Departments Of Orthopedics Surgery And Rheumatology, Nagano Red Cross Hospital, Nagano, Japan

Background: Nontuberculous mycobacteria (NTM) infection has been increasing in both general population and immunocompromised patients in Japan. This study aimed to identify the incidence and clinical characteristics of NTM infections in patients with rheumatoid arthritis (RA).

Methods: We performed a cross-sectional analysis and assessed 11 RA patients, who were all female, complicated with NTM (mean age, 66.6 years) at our institute. We examined Steinbrocker Stage and Class, disease duration, positivity of anti-CCP antibody and rheumatoid factor, HAQ-DI, DAS28-ESR, NTM species, radiological features, methotrexate use and dosage, prednisolone use and dosage, biological agent use, and anti-NTM therapy.

Results: Average values obtained with SD were as follows: age (years), 66.6 ±8.0; Steinbrocker Stage I; II, III; IV, and 9, Class 1; 2; 2, 5; 3, 4; and 4, 0; disease duration (months), 27.4±26.9; positivity of anti-CCP antibody, 80.0%; positivity of rheumatoid factor, 100%; HAQ-DI, 1.35±0.72; DAS28-ESR, 3.61 ±0.90; detection by sputum culture, 81.8%; NTM species, M. avium, 8 cases and M. intracellulare, 3 cases; bronchiectasis, 90.9%; interstitial pneumonia, 0%; methotrexate use and dosage (mg/week): 63.6% and 7.4±3.4; prednisolone use and dosage (mg/day): 81.8% and 4.3±2.0; biological agent use, 45.5%; and anti-NTM therapy, 36.4%.

Conclusions: At our institute, RA patients complicated with NTM were longstanding, had high disease activities and worse HAQ-DI. In all five patients (45.5%) who were treated with biologics, 3 who had preceding episodes of NTM infection were treated with anti-NTM therapy before treatment with biologics, and the other 2 who had asymptomatic NTM infection after treatment with biologics were not treated with anti-NTM therapy thereafter. In RA patients who are treated with biologics, it is necessary to perform sputum cultures constantly to detect possible NTM infections. This finding is important in the management of RA complicated with NTM.

A SYSTEMATIC LITERATURE REVIEW OF OMEGA 3 IN THE TREATMENT OF RHEUMATOID ARTHRITIS

M. Prince1, M. Bulharn2. 1Lancaster Medical School, Lancaster University; 2Rheumatology, Royal Lancaster Infirmary, Lancaster, UK

Background: Many different elements and variations of diet in the management of rheumatoid arthritis (RA) have been studied over the years such as vegan or Mediterranean diets.

Objectives: This systematic literature review covers one food stuff, omega-3 polyunsaturated fats efficacy in the management of RA alongside or independent of conventional DMARD therapy.

Methods: A systematic review of the literature between 1966–2017 was conducted using MEDLINE, CINAHL and EMBASE databases, with key words ‘RA’ and ‘omega-3’ for English-language articles producing 209 hits. We then refined to publications within the last 10 years, giving 96 results. Only including clinical trials gave 12 hits pertaining to 8 trials.

Results: The table above shows a summary of the evidence found. In total, 751 were exposed to omega-3 versus 1733 controls with the smallest study being an RCT involving 13 people and the largest a case-control study with 1569 participants. A notable difference between these studies was the use of DMARD therapy as part of the inclusion or exclusion criteria. Another difference noted was the RA stage eligible for a trial. Some studies required a diagnosis of RA of <12 months whereas most required stable RA ongoing for >12 months.

Conclusions: This review concludes that omega-3 leads to clinical and statistically significant improvements in RA. There was a significant heterogeneity in the trials published with different inclusion criteria especially regarding disease duration and concomitant DMARD therapy. It would seem prudent to include dietary advice in our advice to patients when treating RA. Possible reasons for this evidence would include altering the microbiome.

RAPAMYCIN INDUCES REMISSION IN PATIENTS WITH NEWLY DIAGNOSED RHEUMATOID ARTHRITIS

M. Chen1, Z. Li1, H. Yao1, F. Hu1, J. Liang1, N. Yan1, H. Niu2, C. Gao3, X. Li3, C. Wang1. 1Rheumatology, the Second Hospital of Shanxi Medical University, Taiyuan, China; 2Pathology, Brigham and Women’s Hospital, Harvard Medical School, Boston, USA

Background: Rheumatoid arthritis (RA) is an autoimmune disease characterised by chronic inflammation of the joints. We found that there was an imbalance between Th17 and Treg cells in the patients with active refractory RA, reduced absolute number of Treg cells was found in these patients.

Objectives: To observe the medium-term curative effect of rapamycin in the treatment of 25 cases newly diagnosed rheumatoid arthritis.

Methods: Collecting 25 patients of newly diagnosed rheumatoid arthritis, which accorded with RA diagnosis standard of ACR in 1987. The patients were treated with rapamycin at a dose of 0.5 mg every 2 days for 24 weeks, then we observed the change of clinical improvement and immunological assessments after 24 weeks.

Results: There was 25 patients enrolled. After rapamycin treatment for 24 weeks, the mean DAS28 of them was decreased from 5.36 [1.42] to 3.45 [1.29](p<0.001). The absolute number of TregCD4+CD25+Foxp3+cells significantly higher than baseline—line (30.24 [14.44],46.64 [27.54], p=0.025). The absolute number of Th17 cells was not significantly different (6.40 [4.46],7.03 [5.60],p>0.05), and the same as the ratio of Th17/Treg cells (0.25 [0.18],0.19 [0.16]),p<0.05). Meanwhile, the mean dose of prednisone was decreased form 11.25 mg/d to 9.6 mg/d.

Conclusions: Rapamycin could induce the balance of Th17 cells and Treg cells, especially up-regulate the absolute number of Treg cells, thus induce remission in patients with newly diagnosed RA.

AB0377 ARE CO-MORBIDITIES DURING RHEUMATOID ARTHRITIS DIFFERENT FROM THOSE IN ANKYLOSING SPONDYLARThritis ?

Background: Patients with inflammatory rheumatic diseases are certainly not unscathed from a lot of comorbidities which may be due to the systemic inflammatory activity of rheumatic diseases themselves, immune dysfunction, or iatrogenic, they may also occur independently.

Cardiovascular morbidity remains one of the most important to detect and is increased during these diseases.

So are there significant differences between co-morbidities associated with rheumatoid arthritis (RA) and those with ankylosing spondylitis (AS)?

Objectives: To highlight the difference between comorbidities in RA and AS.

Methods: This is a retrospective study of 111 patients followed for RA ACR 1987 criteria), and 60 patients followed for AS, compiled between January 2005 and December 2016.

Results: The mean age of patients with RA was 51.04 years (18–80 years) with a sex ratio (M/F) of 0.18. The average duration of disease progression was 6.54 years (0–29 years). The mean age of patients with AS was 40.4 years (18–61) with a sex ratio (M/F) of 19. The average duration of disease progression was 16.8 years [1–45 years].

About cardiovascular comorbidities, 16.2% of patients with RA and 5.1% with AS were diagnosed with high blood pressure. Dyslipidemia was found in 2.7% of patients with RA and in 0% with AS. 31.5% with RA and 21.7% in AS have overweight and obesity was illustrated in 22.5% of RA and 11.7% of AS.

Heart and coronary failure were documented in 5.4% of RA and 1.7% of AS. Likewise renal failure in 3.6% of RA and 3.4% of AS. Diabetes was found in 18% of RA and 10% of AS. Hypothyroidism in 5.4% of RA and 1.7% of AS. Gout attack in 0.9% of RA and 0% with AS and osteoporosis in 21.3% of RA and 40% of AS.

Conclusions: Our study concluded at the frequency of comorbidities and mostly cardiovascular in rheumatoid arthritis compared with AS. Osteoporosis is also more common in our studied population with RA, although not rare with our patients with AS. This can be explained by the prescription of corticosteroid therapy in RA.

AB0379 MUSCULOSKELETAL INVOLVEMENTS IN GIANT CELL ARTERITIS

Background: Joint involvement is frequent in Giant cell arteritis (GCA), mostly polymyalgia rheumatica (PMR). The aim of this study was to describe clinical features of joint involvement in GCA.

Objectives: To compare patients according to the presence or not of PMR.

Methods: A retrospective and descriptive study of 96 patients with GCA diagnosed between 2000 and 2015. ACR 1990 criteria were used for the diagnosis of GCA. Clinical, biological and histological features were recorded and analysed.

Results: Joint involvements were noted in 67 patients with GCA (69.3%); 34 women and 33 men. Mean age at diagnosis was 72.4±6.36 years. PMR was diagnosed in 45 patients (46.8%) and revealed the disease in two patients. Neck pain was noted in 48 patients. Twenty one patients (21.8%) complained of peripheral arthralgias which revealed GCA in five cases. Joint manifestations were associated to cardinal symptoms of GCA: headache (97%), jaw claudication (62%), scalp tenderness (49.3%) and ophthalmologic manifestations (36.9%). Erythrocyte sediment rate and C-reactive protein were high in 89.2% and 82.7% of cases respectively.

Constitutional symptoms (60% vs 39.2%; p=0.042), jaw claudication (68.2% vs 47.1%; p=0.038) and neck pain (62.2% vs 39.2%; p=0.024) were significantly more frequent in patients with PMR. Peripheral arthralgias (29.8% vs 15.7%) were more frequent in patients with PMR without significant differences. Giant cell vasculitis on temporal arterial biopsy was more frequent in patients with PMR (57% vs 30%; p=0.037).

Corticosteroids were given in 97% of patients while methotrexate was used in 20.9%.

Conclusions: PMR in patients with GCA seem to be associated to different joint manifestations.

AB0380 DELAY IN TIME TO DIAGNOSIS INCREASES THE RISK OF SUFFERING CLASSIC CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Robustilio Villaringo, A. Sendra Garcia, J.J. Alegre Sancho, 1Rheumatology, Hospital Universitar Pr. Pieset i Alexandre; 2Rheumatology, Foundation for the Promotion of Health and Biomedical Research of Valencia (FISABIO), Valencia, Spain

Background: Rheumatoid arthritis (RA) is a chronic inflammatory disease that constitutes an independent cardiovascular risk factor (CVRF). In addition, patients with RA have a higher prevalence of CVRF than the general population.

Objectives: To assess whether delay in time to diagnosis of the disease may increase the risk of CVRF in patients with RA.

Methods: Patients diagnosed with RA, according to the EULAR/ACR 2010 classification criteria, were consecutively selected and recruited for a period of 12 months. Delay in time to diagnosis was calculated as the interval between the beginning of first joint symptoms and the diagnosis of RA with start of specific treatment. Furthermore, the presence or absence of arterial hypertension (AHT), dyslipidemia (DL) and diabetes mellitus (DM) were recorded. Whether its diagnosis was prior or subsequent to the diagnosis of the inflammatory disease was also recorded. SPSS version 17.0 software was used for statistical analysis, considering statistical significance for p<0.05.

Results: A total of 244 patients were studied, 73.8% (180) of whom were women and 26.2% (64) men. The mean age was 60.42 years (SD 13.24). Mean Delay in time to diagnosis was 2.1 years (SD 5.5). Mean age at diagnosis was 48.9 years (SD 15.7). Regarding classic CVRF, the percentage of patients with AHT, DL and DM before RA diagnosis were 17.6% (43), 6.1% (15) and 6.1% (15), respectively,
After RA diagnosis, 22.5% (55), 43.4% (106) and 3.3% (8) of patients were diagnosed with AHT, DL and DM diagnosis after RA diagnosis. A high inflammatory load, such as that accumulated in RA patients who have delayed the start of treatment, is associated with a higher probability of developing CVRF, which are associated with the appearance of vascular structural damage in the long term. These results are consistent with the effect of inflammatory cytokines on peripheral tissues (increased lipolysis in adipose tissue, increased insulin resistance, increased arterial stiffness).

AB0381 CLINICAL AND RADIOGRAPHIC CHARACTERISTICS OF AIRWAY DISEASE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Konda1,2, Y. Katsumata1, Y. Seto1,2, M. Hasegawa2, S. Sakai1, H. Katsura3, H. Yamanaka1. 1Institute of Rheumatology, Tokyo Women’s Medical University, Tokyo; 2Division of Rheumatology, 3Division of Respiratory Medicine, Tokyo Women’s Medical University Yachiyo Medical Center, Chiba; 4Department of Diagnostic Radiology, Saitama International Medical Center, Saitama Medical University, Saitama, Japan

Background: Airway disease (AD) has drawn attention both clinically and etiologically in rheumatoid arthritis (RA), but it is still poorly understood.

Objectives: We aimed to elucidate the clinical and radiographic characteristics of AD in patients with RA.

Methods: We retrospectively reviewed high-resolution computed tomography (HRCT) images and clinical data of 131 consecutive RA patients in whom HRCT were scanned for clinical purposes and screening. Overlap patients with other collagen tissue diseases and patients complicated with active infection or lung cancer were excluded. Patients who had a history of drug-induced lung disease, thoracic radiation, or exposure to dust were also excluded. HRCT images were analyzed independently by a pulmonologist and a radiologist in blind fashions, and cases of disagreement were discussed to reach a final consensus. AD was radiographically sub-categorised into 3 sub-groups: central AD, small AD, and middle lobe and lingular bronchiectasis. The associations between AD and interstitial lung disease (ILD) and each pair of the subtypes of AD were analysed by Fisher’s exact test. The risk factors for AD and subtypes of AD were identified by multivariate logistic regression analyses.

Results: The mean age of the patients was 65 years old, the mean disease duration of the patients was 123 months, 69% of the patients were women, and 42% of the patients had past/current histories of smoking. The mean Disease Activity Score 28 (DAS28)-erythrocyte sedimentation rate (ESR) value was 2.87, AD and ILD were observed in 53 (40%) and 36 (27%) patients, respectively, and both in 19 (15%) patients. AD and ILD were not significantly associated (p=0.11). Multivariate logistic regression analyses, rheumatoid factor (RF) was identified as risk factor for AD (odds ratio [OR] 2.7; 95% confidence interval [CI], 1.0 to 6.9; p=0.04). Central AD, small AD, and middle lobe and lingular bronchiectasis were observed in 45 (34%), 31 (24%), and 17 (13%) patients, respectively. Each pair of these 3 subtypes were significantly associated with each other (p<0.001 in all comparisons). By multivariate logistic regression analyses without considering the overlaps with multiple subtypes of AD in the same patients, age and RF were identified as risk factors for central AD: the OR for the age was 1.04 (95 CI, 1.00 to 1.09; p=0.04), and that of RF was 3.00 (95 CI, 1.1 to 8.5; p=0.034). In contrast, DAS28-ESR values were identified as a risk factor for central AD: the OR for DAS28-ESR values was 1.5 (95% CI, 1.0 to 2.4; p=0.0498). Lastly, no significant risk factor was identified for middle lobe and lingular bronchiectasis by the multivariate logistic regression analysis, although disease duration tended to be longer in the patients with middle lobe and lingular bronchiectasis than in those without AD (p=0.12). In contrast, smoking histories was not significantly associated with whole AD or any subtypes of AD.

Conclusions: Radiologically defined AD was frequent comorbidity in RA patients, and multiple subtypes of AD were observed and coexisted. Furthermore, AD may be related to the pathology of RA, and different AD subtypes may have distinct risk factors. Prospective studies with early RA patients were warranted to further clarify these findings and clinical impact of AD.

AB0382 RAPAMYCIN SELECTIVELY INCREASES CIRCULATING TREG CELLS AND MAINTAIN REMISSION OF PATIENTS WITH RHEUMATOID ARTHRITIS

N. Yao1, H. Yao1, F. Hu1, J. Liang1, H. Niu1, X. Li1, C. Gao2, C. Wang1. 1the Second Hospital of Shanxi Medical University, Taiyuan, China; 2Brigham and Women’s Hospital, Boston, USA

Background: It is thought that Rheumatoid arthritis (RA) arises from a breakdown in immunological self-tolerance. We have given direct evidence for this concept that absolute number of peripheral CD4+ Regulatory T-cells (Tregs) decreased in RA patients[1]. Furthermore, rapamycin can significantly induce immune tolerance through up-regulate Tregs and down-regulate Th17 cells[2].

Objectives: To investigate the effect of rapamycin on the absolute numbers of Th17 and Treg cells and on maintenance of disease remission in RA patients instead of DMARDs.

Methods: Thirty-two patients, who achieved remission (DAS28<2.6) by the treatment with two kinds of DMARDs for more than half a year, received rapamycin at a dose of 0.5 mg every other day for 12 weeks. Before and after treatment with rapamycin, the disease activity and immunological assessments of them were performed.

Results: In this study, BD Trucount tubes with the lyophilized pellet of a known number of internal counting beads were used for determining absolute counts of total CD4+ T-cells in peripheral blood and then calculating the absolute number of Th17 and CD4+ T cells.

Results: At week 12, 65.6% of the patients maintained remission (DAS28≤2.6). The DAS28 was increased from a median of 2.03 (at week 0) to 2.15 (at week 12) (p<0.05). The absolute number of Treg cells was increased significantly from a median of 22.16 (at week 0) to 32.19 (at week 12) (P=0.039). The absolute number of Th17 cells was decreased from a median of 0.58 (at week 0) to 0.56 (at week 12) (p<0.05). The ratio of Th17/Treg cells was also decreased from a median of 0.245 (at week 0) to 0.19 (at week 12) (p<0.05). At the same time, the mean dosage of prednisone decreased from 6.29 mg/d to 5.35 mg/d and that of DMARDs were also reduced from 93.75% to 56.25%.

Conclusions: Rapamycin was effective in the maintenance of remission of DAS28≤2.6 by increase of Treg cells and correcting the imbalance of Th17/Treg cells. Meantime, the mean dosage of conventional drugs such as glucocorticoid and DMARDs gradually decreased. In the future, rapamycin may replace current immunosuppressant for treatment of RA.

Disclosure of Interest: None declared

AB0383 CHANGES OF METABOLIC BIOMARKER LEVELS UPON ANTI-TNF THERAPY IN RHEUMATOID ARTHRITIS PATIENTS

N. Bođnar1, A. Pusztai1, E. Végó1, Á. Horváth1, S. Szántó1, G. Szűcs1, A. Hamar1, Á. Domján1, K. Hodosi1, I. Seres2, G. Kerekes3, Z. Szekanecz1. 1Department of Rheumatology, 2Department of Internal Medicine, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

Background: Rheumatoid arthritis (RA) has been associated with cardiovascular disease and metabolic syndrome. Numerous pro-inflammatory cytokines (e.g. TNF-α, IL-1, IL-6) are released, which cytokines cause increased reactive oxygen species (ROS) production and thereby contribute to the increased lipid peroxidation and reduction of many antioxidants. These processes not only lead to the deterioration of joints and other tissues but may also contribute to comorbidities, such as atherosclerosis.

Objectives: The aim of this study was to assess the effects of anti-TNF therapy on different metabolic markers, such as PON1 (paraoxonase 1), aroylsterase, chemerin and adiponectin. We also investigated whether these biomarkers correlated with various demographic, clinical and laboratory markers.
Methods: We treated 37 RA patients with either etanercept (ETN) or certolizumab pegol (CZP) in a 12 month follow-up study. Assessments were performed at baseline, and 3, 6 and 12 months after treatment initiation. Serum chemerin and adiponectin concentrations were measured by commercially available ELISA kits (R and D System, MN and USA). PON1 and alylesterase activities were measured by spectrophotometry. In addition, age, disease duration, disease activity (DAS28), CRP, anti-CCP, IgM rheumatoid factor and plasma lipid levels were also assessed. Arterial flow-mediated vasodilation (FMD), carotid intima-media thickness (cIMT) and arterial pulse-wave velocity (PWV) were assessed by ultrasound.

Results: Anti-TNF treatment resulted in a significant decrease in the levels of chemerin (p<0.001) and adiponectin (p=0.007) after 12 months. There were no significant changes in the levels of other metabolic biomarkers. We found the following correlations between the baseline values: the PON1 levels correlated with the age of patients (R=0.466, p=0.004). The adiponectin correlated with the disease activity (R=0.385, p=0.030), HDL-C (R=0.417, p=0.012) and the triglyceride levels (R=0.481, p=0.003). The total cholesterol correlated with the PWV (R=0.449, p=0.021) and the levels of the LDL-C (R=0.911, p<0.001). The baseline triglyceride correlated with the IgM rheumatoid factor (R=0.343, p=0.021); and the levels of LDL-C correlated with the PWV values (R=0.444, p=0.023).

Conclusions: Metabolic factors, such as certain adipokines, PON1 and alylesterase may play a role in oxidative stress and atherosclerosis associated with RA. Anti-TNF treatment may affect adipokine levels.

Disclosure of Interest: None declared

RHEUMATIC ARTHRITIS PATIENTS WITH VERY HIGH CARDIOVASCULAR RISK: POOR RESULTS IN CHANGES IN LIFESTYLE DURING FOLLOW-UP

N. Vegas-Revenga1, V. Portilla1, L.C. Dominguez-Casas1, J.L. Martín-Villar1, B. Atienza-Mateo1, M. Agudo1, J. Rueda-Gotor1, J.L. Hernández2, R. Blanco1, M. A. González-Gay1, A. Corrales1, 1Rheumatology; 2Internal Medicine, Hospital Universitario Marqués de Valdecilla, Santander, Spain

Background: Rheumatoid arthritis (RA) is associated with accelerated atherosclerosis, which results in high cardiovascular morbidity and mortality. The European Atherosclerosis Society recommends a strict control of cardiovascular (CV) risk factors, focusing in a healthy lifestyle, for the prevention of future CV events.

Objectives: Our aim was to assess the characteristics of healthy lifestyle in patients with RA and very high risk of CV events.

Methods: Prospective study that included a group of 113 patients, of whom 65 presented carotid plaques on carotid ultrasound study and, due to this, were categorised as having very high risk at the baseline visit. At this time, patients were informed about the risks associated to their disease and the high risk of having CV events, and were subsequently followed-up for 12 months.

Results: The results of the 65 patients at the last visit are shown in table 1. The average age was of 67 years, with a disease duration of 17 years and high prevalence of dyslipidemia (72%), HTA (62%) and obesity (40%). Data obtained at the basal and last visit (with an average difference of 5.5 years) were compared in table 2. At last follow-up none of the smokers at baseline had discontinued smoking. There were no significant differences in the body mass index (BMI) average. Nevertheless, there was increase in the number of patients with a BMI <30 (36% vs 31%). Only a few patients claimed to go on any type of diet (20%), although the majority (88%) had classic CV risk factors (DM, HTA, obesity or dyslipidemia) at baseline that required adequate diet regime. Yet, more than half of the patients (52%) made regular exercise (>3 times/week) and did not have a sedentary lifestyle (50%), despite having a mean age of 67 years and long disease duration at baseline. Poor control of diabetes mellitus (DM), was found in more than half of the patients.

Conclusions: Despite having been informed on the high risk of CV events, patients with RA included in the category of very high CV risk performed poor long-term control of factors that include a healthy lifestyle.

Disclosure of Interest: None declared

Comparative Assessment of BMD in Pre-, Postmenopausal Women and Man with Rheumatoid Arthritis (RA)

O. Garmish, A. Romanovskyi, T. Orfik, Institute of Cardiology, Kyiv, Ukraine

Background: RA doubles the risk of hip and vertebral fractures, regardless of the use of GCs, and disease activity is consistently associated with low BMD. But now, it is not clearly identified predictors of the individual risk of bone loss depends on sex and menopausal status patients with RA.

Objectives: To compare BMD in man, pre- and postmenopausal women with RA.

Methods: The study was performed on 145 patients: 117 women (mean age 45.4 ±13.0 years, mean disease duration 9.7±7.7 years, 41% (n=48) postmenopausal) and 28 man (mean age 46.4±16.9 years, mean disease duration 4.2±1.1 years) with RA. 91.6% have moderate/high disease activities by DAS 28. 68.4% women and 64.3% men received prednisolone ≤10 mg/day more than 3 months. 87% of patients received MTX. BMD was measured in 3 part of the skeleton: hip, lumbar spine, distal part of forearm. Female patients were divided in two groups by menopause: premenopausal (PreM) in mean age 36.9±13.3 years and postmenopausal (PM) in the mean age 57.6±5.9 years.

Results: BMD was decreased in 44.5% of women and 42.9% of man. BMD of hip, lumbar spine, distal part of forearm were respectively decreased in 26.1%, 28.3%, and 26.3%. In PreM women and 66.7%, 70.8%, 79.2% PM women. 39.3% of man had decrease BMD in the hip and 42.8% – in the lumbar spine. In women the age was high associated with BMD decrease, in man no association with age was found. In PreM women was not found association between BMD, disease duration, DAS28 and X-ray changes in hands and feet, only cortical index was correlated with BMD in all part of the skeleton. In PM women the disease duration was correlated with BMD in total hip and forearm, in man – with BMD in lumbar spine and hip neck (p<0.01). It was found association between BMD and X-ray stage by Steinbrocker in PM women and man. DAS28 was strong associated with low hip and forearm BMD in PM women and low spine BMD in men. According to dispersion analysis PM women with III-IV X-ray stages has significantly lower BMD in the hip (total: Z=2.16, p=0.04; neck: Z=2.81, p=0.01) and medium part of forearm (Z=2.92, p=0.001). Man had significantly lower BMD in all part of the skeleton since II X-ray stage (p<0.001) and negative correlation between BMD and presence of erosion.

Conclusions: A sexual differences in BMD loss was observed in different parts of the skeleton. In the man most affected part of the skeleton was spine and BMD changes were more likely to PreM women, had high association with disease activity by DAS28 and presence of erosion, and no association with age. In PreM women only cortical index had high predictive value for decrease BMD in all parts of the skeleton. Age, disease deration, duration of menopause, DAS28 and X-ray changes in hand and feet was strong associated with decreased BMD in the hip and forearm in PM women.

Comparative Assessment of BMD in Pre-, Postmenopausal Women and Man with Rheumatoid Arthritis (RA)

RELATIONSHIP BETWEEN EXTRA-ARTICULAR MANIFESTATIONS AND JOINT SURGERY IN RHEUMATOID ARTHRITIS

O. Saidane, M. Sellami, R. Barhoumi, A. Ben Tekaya, H. Ajlani, R. Tekaya, I. Mahmoud, L. Abdelmoula. Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia

Background: Extra-articular organ involvement is a serious condition in rheumatoid arthritis (RA) associated with increased mortality. These manifestations may affect the course of the disease, but could they accelerate the joint destruction and shorten the pre-joint surgical period?

Objectives: Our objective was to study the impact of extra-articular manifestations (EAM) on joint surgery during RA management.

Methods: It is a retrospective comparative study involving 500 RA patients (according to 1987 ACR or 2010 ACR/EULAR criteria) in rheumatology department between 2000 and 2014. The assessment of EAM was systematically done in RA diagnosis and during management. We compared 2 groups of RA patients according to the presence or not of EAM.

Results: We enrolled 422 women and 78 men with mean age of 53.3 years (21–83) and mean disease duration of 12 years (2–40). RA was Rheumatoid Factor positive and erosive in 71.4% and 90% cases respectively. A surgical procedure was considered necessary in 59 cases (11.8%). An EAM was diagnosed in more than a half of patients (62.4%) with a predominance of ocular and bone manifestation, mainly xerophthalmia (173 cases, 34.6%) and osteoporosis (120 cases, 24%). Secondary Sjögren’s syndrome was confirmed in 70 cases. Pulmonary manifestations related to RA were noted in 70 patients (14%), especially diffuse interstitial pulmonary in 48 cases (9.6%). Renal involvement was present in 45 patients, of which interstitial renal disease was the most common manifestation (29 patients, 64.4%), Rheumatoid nodules (4.6%) and small vessel vasculitis (0.6%) were the most frequent skin manifestations. A significantly higher incidence of joint surgery was noted in osteoporotic RA patients (OR=1.91; p=0.029). There was no significant correlation between joint surgery resort and other EAM (Table 1).

SLEEP DISTURBANCES IN INFLAMMATORY RHEUMATIC DISEASES

O. Addimanda1,2, M. Burati3, L. Baldelli1,3, G. Chiari1,2, G. Pignotti2, F. Proven1,2, M. Meliconi1,2, 1Department of Biomedical and Neuroromotor Sciences, University of Bologna; 2Medicine and Rheumatology Unit, Rizzoli Ortopaedic Institute, IRCCS; 3Neurology Unit, Institute of Neurological Sciences, Bellaria Hospital, Bologna, Italy

Background: Inflammatory rheumatic joint diseases such as Ankylosing Spondylitis (AS) and Rheumatoid Arthritis (RA) have recently been found to be associated with sleep disturbances especially obstructive sleep apnoea.1,2

Objectives: The aim of our study was to evaluate the occurrence of sleep disturbances, especially REM Sleep Behaviour Disorder (RBD), in inflammatory rheumatic diseases, (rheumatoid arthritis -RA and Spondyloarthritides –SpA).

Methods: We enrolled 103 consecutive patients affected by inflammatory rheumatic diseases [RA (64, 62.1%) or SpA (39, 37.9%)]. Patients underwent a neurologic and psychopathological assessment, including identification of sleep disorders by means of the Pittsburgh Sleep Quality Index (PSQI), the Berlin and the REM sleep behaviour disorder (RBD) questionnaires, a structured interview on sleep terrors and sleep paralysis, Beck Depression Inventory (BDI-II) and the Spielberger State-Trait Anxiety Inventory (STAI). Statistical analysis was performed using SPSS software.

Results: No significant differences were found between RA and SpA patients in age at diagnosis, disease duration, smoke habit, alcohol consumption, anaemic comorbidities (especially metabolic diseases, anxiety or depression), disease activity/remission and biologic Disease Modifying Antirheumatic Drugs use. No differences demonstrated in BDI-II, STAI, PSQI and RBD questionnaires; only the Berlin Questionnaire showed significant differences (17.2% in RA vs 35.9% in SpA, p=0.036). No differences in sleep paralysis (10.9% in RA vs 7.7% in SpA, p=0.74) and sleep terrors (37.5% in RA vs 20.5% in SpA, p=0.0826) which were found to be increased if compared with general population (2.6%).

Conclusions: Our data show an increased prevalence of sleep terrors in rheumatic patients when compared to the general population although no differences were highlighted between RA and SpA; also increased risk of sleep apnoea (Berlin Questionnaire) has been demonstrated in patients with SpA compared with RA.

HIPERTRIGLYCERIDEMIC-WAIST PHENOTYPE: A MARKER OF CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS PATIENTS

I.P. Guzmán Guzmán1, O. Zaragoza-García1, J.E. Navarro-Zarza2, J. Maldonado-Anuncio3, C. Castro-Alarcón3, I. Parra-Rojas1. 1Facultad de Ciencias Químico Biológicas, Universidad Autónoma de Guerrero, Chilpancingo, 2Hospital General, Chilpancingo, Guerrero, 3Universidad Autónoma de Guerrero, Chilpancingo, Mexico

Background: The risk of cardiovascular disease (CVD) is increased in rheumatoid arthritis (RA); about 50% of associated deaths in rheumatoid arthritis (RA) are attributed to CVD. Both traditional cardiovascular risk (CVR) factors and inflammation contribute to this risk. The hyperuricemia (HUC) and metabolic syndrome (MetS) are considered parameters of CVR, both closely related, and recently the hypertriglyceridemic-waist (HTGW) phenotype has been defined as well a marker to identify HUC in the general population.3

Objectives: To determine the prevalence of HTGW phenotype and to evaluate its association with CVR parameters among RA patients.

Methods: HTGW phenotype was defined as waist girth >102 cm in male and >88 cm in female and TG >150 mg/dl in 250 patients diagnosed with RA according to the ACR/EULAR 2010 criteria. The levels of uric acid >5.5 mg/dl defined HUC. The MetS and its individual components (NCEP-ATPIII) were evaluated as parameters of CV risk.

Results: We identified 51 AR patients (20.4%) with HTGW phenotype. Adjusting for covariates in a logistic regression model, it was observed that the HTGW phenotype is associated with the presence of HUC (OR=6.14, p<0.001), and MetS (OR=5.7, IC95%, 2.7–12.2, p<0.001).

Conclusions: HTGW is prevalent in RA patients from southern Mexico. The HTGW phenotype can be considered at low cost marker, used as a tool screening to predict high metabolic risk during the clinical course of the rheumatic disease.

RELATIONSHIP BETWEEN BODY MASS INDEX AND PERSONALITY IN AN EARLY ARTHRITIS COHORT OF PATIENTS

P. Moreno Fresnedo1, D. Martinez-Quintanilla Jiménez, N. García Castañeda, T. Velasco Ripoll, A.M. Ortiz García, I. González Álvaro. Rheumatology. HOSP. Universitario La Princesa, Madrid, Spain

Background: According to previously reported data from our early arthritis registry (PEARL, Princess Early Arthritis Register Longitudinal), patients with a higher BMI have higher scores in pain and disability scales. We also described some years ago that, in the same population, the structure of personality explored with the PANAS questionnaire (Positive and Negative Affect Scale) affects some outcomes in arthritis measures. Specifically, higher scores on the negative affect subscale associate higher scores in pain and disability scales.

Objectives: To analyse the relationship between BMI and the structure of the affect in the PEARL cohort.

Methods: PEARL registry includes patients with early arthritis (less than one year of duration), in whom, sociodemographic, disease related and treatment data are recorded in five protocolised visits. We analysed data from those patients in which the PANAS questionnaire data were available and whose classification, after 2 years of follow-up, were rheumatoid arthritis -according to the 1987 ACR classification criteria -- or undifferentiated arthritis. The structure of the affect was evaluated with the PANAS questionnaire administered in one single occasion. This questionnaire is used to evaluate the components of positive (PA) and negative affect (NA). It consists of 20 questions and the score obtained from its administration ranges between 10 and 50 points for each affect. The WHO definition was used for low weight, normal weight, overweight and obesity (BMI <18.5, 18.5–25, 25–30 or >30 kg/m² respectively). The statistical analysis were performed with ANOVA and Pearson’s correlation tests, as well as multivariate linear regression (including as independent variables sex, age and study level) using the Stata 12.1 software.

Results: We analysed the data of the 71 patients for whom PA values were available and of the 65 patients with NA values available. There was not a statistically significant relationship observed between PA and NA and BMI when analysed as a continuous variable (R=0.12, p=0.25 and R=0.1, p=0.36, respectively) or as a categorical variable. However, there was a non-significant trend to lower scores for both PA and NA in patients with a higher BMI (figure 1). The multivariate analyses, adjusted for sex, age and study level, also showed no statistically significant relationship between the BMI (analysed as continuous or categorical variable) and the PA and NA; but there was also a non-significant trend that sets a relationship between lower scores of both PA and NA and higher BMI values.

Conclusions: In our early arthritis registry there is no relationship between the BMI and the structure of the affect evaluated through the PANAS questionnaire. However, it is necessary to evaluate this relationship in a greater number of patients and in different populations before discarding this relationship definitely.

CLINICAL, SEROLOGICAL AND TREATMENT ANALYSIS OF RHUPUS SYNDROME: A RETROSPECTIVE MONOCENTRIC STUDY

P. Rottenberg1, F. Jouen2, I. Marie3,4, T. Lequerre1,4, O. Vittecoq1,4. 1Rheumatology; 2Clinical Immunology Laboratory; 3Internal Medicine, Rouen University Hospital; 4U1234, INSERM, Rouen, France

Background: Rhuspus syndrome is a rare condition in which rheumatoid arthritis (RA) features overlap with systemic lupus erythematosus (SLE) manifestations. Disease characterisation tends to improve, but some uncertainties remain, and therapeutic management has still to be defined.

Objectives: We aimed to perform a study of the patients followed at the Rouen University Hospital with rhupus diagnosis using both recent criteria and expert diagnosis, in order to perform an analysis of the clinical, radiological and biological characteristics, and to report the therapeutic procedures carried out.

Methods: We performed a retrospective research work covering a period of 10 years, using diagnosis code extraction for both RA and SLE from database of the medical information department, as well as biological data extraction concerning ACRA testing, anti-dsDNA and anti-RNP antibodies. Patients satisfying both ACR/EULAR 2010 and SLICC 2012 classification criteria for RA and SLE respectively, or with an expert diagnosis of rhupus were included. A screening of medical records was performed to collect clinical, biological and treatment data for each patient.

Results: Sixteen patients were identified and 12 fulfilled both classification criteria. RA most often preceded rhupus, and clinical analysis found a predominant articular pattern at initial and established disease, with erosive arthropathy (n=11). Skin involvement was the most frequent associated manifestation (n=12). Among other associated manifestations, serious events were reported, including active glomerulonephritis (n=2), ischaemic stroke (n=1) and myocardial infarction (n=1). Immunological profiles showed positivity for (n=14), anti-dsDNA (n=9) and ACPA (n=8). Ten patients required biological DMARD, in addition to conventional treatment. All types of RA approved bDMARD were used. Rituximab was the most prescribed (n=9) and the most effective, with sustained response in 5 patients.

Conclusions: Rhupus is a rare condition, with predominant articular pattern, but serious SLE-related manifestations can occur. In rhupus refractory to conventional treatment, biologics, and particularly rituximab, are a promising therapeutic approach.

Disclosure of Interest: None declared

Background: Patients with rheumatoid arthritis (RA) may have a higher risk of developing chronic kidney disease (CKD) compared with general population. However, the data on this risk are limited and not well-characterised.

Objectives: This systematic review and meta-analysis aimed to comprehensively investigate the risk of incident CKD among patients with RA by reviewing all available studies.

Methods: A systematic review was performed using MEDLINE and EMBASE database from inception to December 2017 to identify all cohort studies (either retrospective or prospective) that compared the risk of incident CKD in patients with RA versus individuals without RA. Adjusted point estimates were extracted from individual studies and the pooled risk ratio and 95% confidence interval (CI) were calculated using random-effect, generic inverse-variance method of DerSimonian and Laird. Visualisation of funnel plot was used for evaluation for publication bias.

Results: A total of 4 retrospective cohort studies with 1,627,981 participants were included. The risk of incident CKD was significantly increased among patients with RA with the pooled risk ratio of 1.52 (95% CI, 1.28–1.80). The statistical heterogeneity of this study was high with an I² of 82%. The forest plot of this systematic review and meta-analysis is shown as figure 1. The funnel plot was relatively symmetric and, thus, did not suggest the presence of publication bias in favour of positive studies.

Conclusions: In this study, the use of antimalarial drugs was associated with an increased risk to present disturbances of the cardiac rhythm/conduction in patients with established RA.

RHEUMATOID ARTHRITIS AND RISK OF INCIDENT CHRONIC KIDNEY DISEASE: A SYSTEMATIC REVIEW AND META-ANALYSIS OF COHORT STUDIES

P. Ungprasert1, S. Raksausk2, 1Rheumatology, Reina Sofia University Hospital/IMIBIC/University of Còrdoba, 2Rheumatology, University of Còrdoba, Còrdoba, Spain

Background: Cardiac involvement is present in 7% to 35% of patients with rheumatoid arthritis (RA). Anecdotal case series have associated the use of antimalarials with a history of ischaemic heart disease or an already diagnosed disturbance of the cardiac rhythm/conduction. During follow-up, an improvement in inflammatory and quality of life manifestations. RA is associated with a high risk of morbidity and premature death secondary to the earlier development of cardiovascular, lung diseases and malignancy, being cardiovascular disease secondary to accelerated atherosclerosis the main cause of morbidity and mortality in these patients.

Objectives: Main objective: To calculate the incidence of comorbidities and CV events in patients with recent onset RA. Secondary objectives:-To determine the clinical disease features according to baseline RA profile. To analyse the relationship between CV event and the different variables. To describe classic CV risk factors evolution throughout the follow-up.

Methods: We conducted a retrospective longitudinal observational study of 70 patients with recent onset RA according to ACR/EULAR 2010 or ACR 1987 criteria. We excluded individu-als with a history of ischaemic heart disease or an already diagnosed disturbance of the cardiac rhythm/conduction.

Results: A total of 37 cases of electrocardiographic disturbances were found in patients receiving antimalarials (51%), but only 18 cases (25%) in the control group (p=0.001), giving an odds ratio (OR) of 3.17 (95% CI, 1.57–6.42). P=0.001.

The average dose of hydroxychloroquine was 3.02±0.41 mg/kg, while the dose of chloroquine was 2.23±0.13 mg/kg. A history of prednisone consumption also was associated with an increased risk to present an electrical cardiac disturbance (p=0.005; OR 9.73, from 2.00 to 47.32).

Conclusions: This study, the use of antimalarial drugs was associated with an increased risk to present disturbances of the cardiac rhythm/conduction in patients with established RA.

Disclosure of Interest: None declared
parameters (DAS28, ESR, CRP and HAQ) was observed (p<0.05). Likewise, the % of hypertensive and dyslipidemic patients increased during follow up (p<0.05), while the levels of cholesterol, triglycerides, glucose and diabetic patients remained similar. The presence of CV event was related to high levels of ESR, male sex and hypertension, (p<0.05).

Conclusions: • The incidence of cardiovascular event in our recent onset RA cohort resembles that previously described in the literature, with the majority occurring during the first 5 years of follow-up. • The development of hypertension and dyslipidemia occurs mainly during the first 5 years of follow-up. • The presence of a cardiovascular event was related to male sex, high blood pressure and high ESR levels.

AB0395
CORRELATION BETWEEN CARDIOVASCULAR RISK CALCULATORS IN A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS

Background: EULAR recommends for patients with rheumatoid arthritis (RA) a cardiovascular (CV) risk assessment at least once every five years. Several risk calculators are available but most of them are based on data from general population, so they may underestimate the risk of RA patients. To obtain a more accurate estimation they should be adapted for RA by a 1.5 multiplication factor, unless the instrument includes RA as a variable. To date, there are no studies analysing the concordance and correlation of different CV risk calculators in Spanish population.

Objectives: To analyse concordance and correlation of CV risk calculated using different tools and to determine the proportion of CV risk factors in a cohort of patients with RA.

Methods: We performed a cross-sectional study including patients with RA according to ACR/EULAR 2010 criteria, treated in a tertiary hospital. Individuals with previous CV events, diabetes and chronic kidney disease were excluded.

Ten-year CV risk was obtained with the following calculators: Framingham-body mass index (FRS-BMI), Framingham-lipids (FRS-L), SCORE CV risk calculator (SCORE) and the Expanded CV Risk Prediction Score for RA (ERS-RA). A 1.5 multiplying factor was used to adapt the results for RA patients in those which didn’t include it in their models. CV risk was categorised as low or high using 10% as a cut-off for FRS-BMI and FRS-L and 5% for SCORE y ERS-RA. Correlation was evaluated using Spearman correlation coefficient (Rho) and concordance with weighted kappa.

Results: We included 88 patients (18 male), 87.5% Caucasian, mean age 56.9±10.6 years, mean disease duration 5.8±3.3 years. 67% and 76% had positive RF and ACPA respectively and 15% presented extra-articular manifestations (rheumatoid nodules, interstitial lung disease, pleuropericarditis). Regarding CV risk factors: 14.8% were active smokers, 60.2% were overweight or obese, 25% had hypertension, 47.8% had dyslipidemia. The median CV risk predicted at 10 years was 15% (1.5–70.20) for FRS-IMC, 11.8% (1.2–54.0) for FRS-L, 1.5% (1.1–16.5) for SCORE and 6% (0.6–27.8) for ERS-RA. 64 patients were categorised as low risk and 22 as high risk for ERS-AR. No significant differences were observed in the means of risk obtained by the different calculators or in the risk categories according to ERS-RA when stratified by disease duration (more or less than 5 years).

For the correlation between ERS-RA and FRS-BMI, FRS-L and SCORE, Spearman’s Rho coefficients were 0.84, 0.79 and 0.80, (p<0.005).

For the concordance between ERS-RA vs FRS-BMI a weighted k=0.29 (CI95:0.15–0.42) was obtained. For ERS-AR vs FRS-L, k=0.34 (CI95:0.19–0.50) and for ERS-AR vs SCORE, k=0.70 (CI95:0.52–0.87).

Conclusions: A strong correlation was observed between the CV risk calculators evaluated and good agreement only between ERS-AR and SCORE. Additionally, overweight, obesity and dyslipidemia were the most prevalent comorbidities.

Disclosure of Interest: None declared

AB0396
RELATIONSHIP BETWEEN PATIENT GLOBAL ASSESSMENT AND PAIN ASSESSMENT IN THE DISEASE ACTIVITY INDEXES IN RHEUMATOID ARTHRITIS, AND ITS CORRESPONDENCE WITH SONOGRAPHIC ALTERATIONS
R. Menor Almagro, R.M. Martínez, E.M. Rubio, M.M. Fernández. Rheumatology, Hospital Universitario Virgen del Rocío, Seville, Spain

Background: Disease activity indexes in rheumatoid arthritis (RA) provide information of different parameters in a single value. It is very useful in the evaluation of the disease activity and its progression. The subjective component of these indexes can modify the index final value.

Objectives: The aim of our study was to describe the relation between the patient global assessment (PGA) and pain assessment (PA) with the sonographic alterations in AR.

Methods: Transversal study describing the ultrasonographic changes and disease activity indexes in AR. We included patients with RA according to ACR/ EULAR classification criteria. They were sent by their usual clinician, in random selection. They were reviewed in the same day by a rheumatologist and blind sonographer. PGA, PA, HAC, tender and swollen joint count, CDAI, SDAI and DAS28 were evaluated. The ultrason were realyzed by grey scale and doppler in 12 joints (wriists, second to fifth MCF and fifth bilateral MTF).

Results: A total of 48 patients had PGA ≤50 and 37 PGA ≥50. The mean age was 53±11.7 for group 1 and 56.5±10.2 for group 2, women 64.6% and 83.8% respectively. The positive rheumatoid factor resulted in 72.9% vs 73%. The evaluation of the disease in months presented a median of 96 (47.2–132.7) vs 108 (48–138). p=0.564. The Body Mass Index in the groups was 26.6 (23.5–29.7) and 26 (22.6–30.0), p=0.647, and the tobacco consumption of 11 patients group 1 and 12 group 2 (p=0.397). No significant difference was found in the treatment at the time of the evaluation with methotrexate, median of 10 (0–15) vs 7.5 (0–15), p=0.350, or corticosteroids 1.4 (0–23) vs 2.5 (0–4), p=0.005. 23 patients in the group 1 and 19 in the group 2 were in biological therapy. The results referring to the patient’s assessment of their disease, acute-phase reactants, clinical examination, ultrasound and disease activity indexes are presented in table 1.

Conclusions: Disease activity indexes in AR have been established as a very useful measure, both in the homogenization of the results obtained in the research and in the daily clinical practice. In our study, we observed the modification in the values of disease activity indexes due to PGA and PA, even those in which its contribution is less decisive than other parameters, as it happens in the DAS 28. Those variables no relacionated in their value with the patient assessment of his disease status did not show statistical significance between the groups. The patients’ valuation about activity of their AR and the modification of the indexes in which it participates in our study were not concordant with the echographic alterations found in grey scale and doppler echo.

PREVALENCE AND FACTORS ASSOCIATED WITH DEPRESSION AMONG PATIENTS AFFECTED BY CHRONIFIC INFLAMMATORY ARTHRITIS: PRELIMINARY RESULTS OF A SINGLE-CENTRE EXPERIENCE IN ITALY

S. Pezzato1, S. Tomassi2, E. Fracassi1, A. Gioello1, C. Cairmi1, F. Martins3, M. G. Gatta2, D. Cristofalo2, C. Boneto2, M.L. Marognoli1, S. Tosato1, A. Carletto1
1Rheumatology, Reumatologia – AOU Verona; 2Section of Psychiatry, Department of Neurosciences, Biomedicine and Movement Sciences, University of Verona, Verona, Italy

Background: Depression and anxiety disorders are more common in chronic inflammatory arthritides (CIA) than in the general population.1 In rheumatoid arthritis (RA), depressive and anxiety symptoms have been associated with disease activity and pain perception,1 physical disability,2 health care costs,3 and mortality.4 To our knowledge, data on the prevalence of depression in Italian patients with RA are scarce.

Objectives: To estimate the prevalence and factors associated with depression among patients affected by RA.

Methods: During an one year period, patients affected by RA have been consecutively enrolled. For each patient demographics and disease characteristics were recorded: the Hospital Anxiety and Depression Scale (HADS) was administered. HADS is a validate questionnaire to assess depressive and anxiety symptoms in patients affected by somatic disorders admitted to general hospital. An HADS >11 was considered diagnostic for depression.

Results: The table summarises the main results. We recruited 231 patients affected by RA, finding a prevalence of depression of 19.9% (95% CI 9.4%–28.5%). Overall, patients with depression, when compared with patients without, were older, more frequently females, with a lower education, higher physician global assessment and patient global assessment, more comorbidities. In particular, they had any cardiovascular, neurologic or musculoskeletal issue (p=0.018, p=0.032, p=0.014, respectively) and more often used glucocorticoids or NSAIDs.

Conclusions: These preliminary results suggest that more than one every seven patients with RA could suffer from depression, thus depression might be undiagnosed in a significant number of patients. Comorbidities, anti-inflammatory medications and both physician- and patient-driven evaluation of disease burden were the most striking factors associated with depression in this cohort of patients with RA.

INVESTIGATION OF PREOPERATIVE INTRANASAL COLONISATION IN ORTHOPAEDIC SURGERY PATIENT WITH RHEUMATOID ARTHRITIS

S. Tsuji1, J. Hashimoto1, T. Noguchi2, S. Neta1, K. Yachi2, M. Saito1, S. Ohshima1, Y. Saeki3, Department of Rheumatology and Allergology, 1Department of Orthopaedic Surgery, 2Department of Clinical Research, National Hospital Organization, Osaka Minami Medical Center, Kawachinagano City, Osaka, Japan

Objectives: Coagulase-negative staphylococci (CoNS) is listed as the major SSI causative organism in the field of orthopaedic surgery, but detailed report on the presence or absence of methicillin-resistant CoNS of intranasal colonisation is not found.

Methods: In 13 months from July 2016 to the end of July 2017, 1000 cases of consecutive cases in which nasal cavity culture was performed within one month prior to hospitalisation for patients scheduled for our orthopaedic surgery. 223 men, 777 women, average age 66.4 years old, 197 cases of RA patients, 803 cases except RA patients.

The method of intranasal culture is as follows. After culturing for 18 hours at 37 °C using blood agar medium (daily water) and CHROMagar MRSA selective medium (Kanto Kagaku), identification of bacterial species of the genus Staphylococcus grown and cultivation of drug susceptibility tests. It was carried out by BD Phoenix according to the method of the Association (CLSI).

Results: The results of intranasal culture showed that S. aureus, S. epidermidis, CoNS (excluding S. Epidermidis) and culture negative were 18.2%, 27.8%, 7.8%, and 23.9%, respectively. MRSA, MRSE and MRCoNS (excluding MRSE) with methicillin resistance were 3.2%, 22.1% and 1.7%, respectively and 27.0% of methicillin resistant bacteria were found to exist.

Conclusions: Methicillin-resistant Staphylococcus was found to be 27.0% intra-nasal colonisation of patients in orthopaedic surgery. Especially in RA patient, it was high rate of 38.6%. In the future, we need to consider the selection of perioperative preventive antibacterial drugs.

AUDIT OF INFLUENZA AND PNEUMOCOCCAL VACCINATIONS IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGICS

S. Selvan, Rheumatology, Basildon and Thurrock NHS Foundation Trust, Essex, UK

Background: Rheumatoid arthritis (RA) patients are at increased risk of pneumococcal and influenza disease secondary to a deficient immune system and immunosuppressive medications.1 Despite the possible reduction in vaccine efficacy in RA, prophylactic vaccination in preventing pneumococcal pneumonia and influenza in RA patients should be routinely advised and practised.2 EULAR guidelines recommend that influenza and pneumococcal vaccinations should be strongly considered for all patients with RA.2

Objectives: To study pneumococcal and influenza vaccination rates in a cohort of RA patients on biologic medications.

Methods: We undertook a prospective audit of RA patients on biologics attending routine rheumatology clinics in a DGH over a 6 week period. A proforma was given to patients, and data was collected on medications, comorbidities, Disease Activity Score (DAS) and vaccination status for influenza and pneumococcus.

Results: Of the 25 patients audited, 17 (68%) were female and 8 (32%) were male. The average age of patients included was 59 years (range 37–75), 18 (72%) patients were seropositive, and 7 (28%) were seronegative. The patients included had the following comorbidities; 14 (56%) none, 6 (24%) thyroid disease, 1 (4%) osteoporosis, 1 (4%) hypertension, 1 (4%) type 2 diabetes, 1 (4%) interstitial lung disease.

On reviewing their medications, 7 (28%) patients were on an Etanercept biosimilar (Benpali), 2 (8%) on Tocilimab, 2 (8%) on Rituximab, 9 (36%) on Adalimumab, 2 (8%) on an Infliximab biosimilar (Remsima), 2 (8%) on Etanercept, and 1 (4%) on Certolizumab. In addition to their biologic agent, all 25 patients were on Methotrexate. 2 patients (8%) were also on Sulphasalazine, and 2 (8%) were on Hydroxychloroquine additionally. The average DAS CPR score was 2.7.

8 (32%) patients had received both influenza and pneumococcal vaccinations, and 9 (36%) patients had neither. On analysing the vaccination rates individually, 16 (64%) patients were up to date with influenza and 7 (28%) were up to date with pneumococcal. Of the 9 patients that had neither vaccination, 5 (20%) patients were unaware of their requirement, and 3 (12%) felt they were too well to receive them. 1 (4%) patient was unsure whether they could have the vaccination as they had been recruited into a research trial.

REFERENCES:

Disclosure of Interest: None declared
Conclusions: Only 32% patients had received both influenza and pneumococcal vaccinations. The uptake rate for influenza vaccination was reasonable at 64%, however the rate for pneumococcal vaccination was only 28%. Vaccination assessment should be performed routinely for all RA patients in clinic and in particular those on biologic medications to reduce the risk of developing these infections in this high risk cohort.

AB0400 HIGH PREVALENCE OF COMORBIDITIES IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SOUTH AFRICA
S. Botha-Scheepers, A.G.A. Mohammed, A. Gcelu, B. Hodkinson. Medicine/Rheumatology, Groote Schuur Hospital/University of Cape Town, Cape Town, South Africa

Background: Patients with rheumatoid arthritis (RA) are at increased risk to develop comorbidities. Data on the prevalence of comorbidities in RA patients in South-Africa is lacking.1 Poorly controlled joint inflammation, common use of glucocorticoids and nonsteroidal anti-inflammatory drugs, a high prevalence of smoking and obesity, together with a high burden of infectious diseases may be important risk factors for comorbidities in this population.

Objectives: To assess the prevalence of comorbidities in RA patients in Cape Town, South-Africa and the association with disease activity and DMARD use using the METEOR (Measurement of Efficacy of Treatment in the Era of Outcome’ in Rheumatology) database.

Methods: This is an ongoing cross-sectional study. Data from 109 RA patients from regular clinic visits at Groote Schuur Hospital in Cape Town, South Africa have been entered in the Meteor database (from December 2016). The Meteor database is a free online tool that was developed to improve the management of patients with autoimmune inflammatory rheumatic diseases. The tool is currently widely used in other countries, but has it not yet been described in any African countries. Information on the following parameters were reported: demographics, disease duration, disease activity (CDAI), current DMARDs use and comorbidities.

Results: The mean age (SD) was 57.6 (14.7) years, disease duration (SD) 14.1 (14.6) years, female 86.7%, RF positive 85.1% and ACPA positive 80.4%. The average (SD) CDAI was 13.1 (9.8) and 49.3% were smokers. Current DMARDs used was Methotrexate (72%), Sulphasalazine (29%), Chloroquine (67%), Low dose corticosteroids (47%), Leflunomide (11%), Etanacept (1%), but no other biological agents (0%). At least one comorbidity was present in 69% of the patients, two in 40%, three in 26%, four in 13% and five in 2% of the patients. The most frequently observed comorbid diseases were hypertension (45.5%), tuberculosis (TB) (11.1%), Diabetes Mellitus Type 2 (10.9%) and osteoarthritis (10.9%). Other diseases included hypercholesterolemia (7.1%), gastro-esophageal reflux disease/peptic ulcer (6.1%), COPD/emphysema (6.1%), HIV (4.0%), hypothyroidism (4.0%), ischaemic heart disease (3.0%), liver disease (3.0%), DVT/pulmonary embolism (3.0%), malignancies (3.0%), asthma (2.0%), discolipidemic erythematous (2.0%), interstitial lung disease (1.0%), anaemia (1.0%), rheumatic heart disease (1.0%), cerebrovascular accident (1.0%) and depression (1.0%).

Conclusions: This study shows a high prevalence of comorbidities among patients with RA in South Africa. In particular, hypertension, TB and osteoarthritis were very common. More patients will be included in this study in the next few months. Furthermore, we will assess the association between comorbidities, disease activity and DMARD use. The METEOR tool offers the unique opportunity to study daily practice care as well as research questions in real life setting in a South African clinic. This study will provide information that is necessary to address the burden of comorbidities in patients with RA in South Africa.

AB0402 RECENT ONSET RHEUMATOID ARTHRITIS HAVE AND INCREASED LEFT ANTERIOR DESCENDING CORONARY ARtery WALL THICKNESS: EVIDENCE OF SUBCLINICAL CORONARY ARtery DISEASE
S. Hannawi1, I. Al Salmi2, H. Hannawi1. 1Rheumatology, Ministry of Health and Prevention of UAE; 2Cardiology, Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

Background: Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease of the joints with several extra-articular features. Cardiovascular disease (CVD) mortality accounts for 40–50% of all deaths in RA. Apart from atherosclerotic heart disease other cardiac abnormalities had been found to be prevalent in RA; including, pericarditis, heart failure, coronary vasculitis and valve disease.

Objectives: Due to scarcity of data regarding cardiac disease in the Middle East population, we studied echocardiographic features in RA patients compared to their age, sex, and traditional CVD risk factors matched controls.

Methods: In a cross-sectional study, we recruited 39 RA patients meeting the 1987 revised criteria of RA and 37 age, sex and traditional CVD risk factors matched controls. Standard trans-thoracic echocardiography examination was carried out by a specialties cardio-sonographer who was blinded to the status of the participants. Left ventricular dimensions, wall geometry, ejection fraction, diastolic parameters, right ventricular size and function, valve structure and function, pericardium, pulmonary pressures and aortic root dimensions were assessed by echocardiography. t-test and chi-2 test were used to compare the echocardiographic findings between the two groups. P value of<0.05 was considered significant.

Results: Thirty-nine RA patients (34 F, 4 M) and 37 controls (32 F, 5 M) were studied. Among RA, 27 (69%) were RF positive. The two groups were similar in terms of age (p=0.86), gender (p=0.71), and traditional cardiovascular risk factors. No significant difference was found between RA and the controls in term of left ventricular ejection fraction, wall geometry, diastolic parameters, right ventricular size and function, valve disease, pulmonary pressures, pericardium and aortic root dimensions. However, left ventricular end-diastolic diameter (43.1±1.14 vs. 39.5±0.84 mm respectively, p=0.01), end-systolic diameter (24.3±0.70 mm vs. 26.9±0.96, respectively, p=0.03) and Left ventricular mass index (79.8±3.11 vs. 63.6±3.15, respectively, p=0.01) were significantly higher in RA patients than in the controls.

Conclusions: Patients with rheumatoid arthritis have higher left ventricular end-diastolic and end-systolic dimensions, and greater left ventricular mass index compared to their age, sex and traditional CVD risk factors-matched controls. As the increase in the left ventricular mass index is a predictor of cardiac sudden death, echocardiography might be a simple non-invasive tool for cardiac risk screening in RA.

Factors Contribute to the Level Uric Acid in Rheumatoid Arthritis

S. Hannawi1, I. Al Salmi2, H. Hannawi3. 1 Rheumatology, Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates; 2 The Royal Hospital, Muscat, Oman; 3 Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

Background: Uric acid (UA) is a strong correlate of renal dysfunction in rheumatoid arthritis (RA), even in the absence of crystal deposition, by causing endothelial dysfunction, intrarenal vascular disease and renal impairment. In hyper or normo-uricemia RA, UA was the strongest independent predictor of GFR, even after adjustments for most of the potential confounding factors. Additionally, in RA patients UA had been found to be an independent predictor of hypertension and cardiovascular disease (CVD).

Objectives: This study aimed to investigate what could be the determinants of the UA level in RA patients.

Methods: RA patients with no clinically evident gout, CVD, thyroid disease, liver or renal disease were studied. Serum UA was obtained for all the patients. Renal function parameters, RA disease characteristics, inflammatory markers, and traditional CVD risk factors relation to uric acid level was examined using simple linear regression analysis. To test for the independence association between uric acid and the variables of interest, multiple model was built for the same dependent and independents variables. Statistical significance was accepted at p-value<0.05.

Results: The study recruited 86 consecutive patients meeting the 1987 RA revised ACR criteria, attending routine outpatient clinics at the Department of Rheumatology. Basic demographics and clinical characteristics of were obtained. Of the total 86 patients, 10 (11%) were men and 76 (89%) were women. The mean age of the participants was 47±14 years, with mean RA duration of 68±87 months. 64 out of 86 participants (74%) had rheumatoid factor positive. The mean UA value was 255±86 umol/l (NR: 180–340). The mean GFR, calculated using modified MDRD (Modification of Diet in Renal Disease) formula was 133±2 mll/min/1.73m².

Using univariate analysis revealed a positive linear relationship between uric acid level and each of the age of the participants (p=0.016, CI: 0.31, 2.92), age at RA symptoms onset (p<0.04, CI: 0.025, 0.039), age at RA diagnosis (p<0.03, CI: 0.101, 2.565), systolic blood pressure (p=0.04, CI: 0.054, 2.167), diastolic blood pressure (DBP) (p=0.02, CI: 0.322, 3.777), monocytes absolute count (p=0.014, CI: 2.510, 4.801), monocytes percentage (p=0.005, CI: 34,599, 193,959), cholesterol level (p=0.008, CI: −39,934, −2.286), Triglyceride level (p=0.04, CI: 0.064, 56.546), urea level (p=0.001, CI: 9,356, 28.743), creatinine (p=0.001, CI: 2,345, 3,960), urinary microalbumin (p=0.024, CI: 0.0296, 0.399), urinary microalbumin/creatinine ratio (p=0.006, CI: 0.791, 4.616), and ferritin level (p=0.025, CI: 0.044, 0.633).

As well, univariate analysis revealed a negative linear relationship between UA level and GFR (p<0.001, CI: −1.127,−0.486).

Building a multiple model, including the entire variable with significant association with the UA in the univariate analysis showed that the UA level in RA is determined by GFR, microalbumin creatinine ratio, cholesterol level, monocytes count and DAS score. The adjusted R² of the model was 54

Conclusions: Whether serum uric acid is merely a marker that reflects the integration of co-morbidities and subclinical renal impairment or a true risk-causative factor for CVD outcome remains as an important question, therefore it is important to know the determinant of UA level and control it.

Apelin Concentrations are Associated with a Reduced Left Atrial Volume Index and Improved Systolic Function in Patients with Rheumatoid Arthritis

S. Gunter1, C. Robinson1, L. Tsang1, P.H. Desselin2, A.M. Millen3. 1 Cardiovascular Pathophysiology and Genomics Research Unit, University of Witwatersrand, Johannesburg, South Africa; 2 Free University Brussels, Brussels, Belgium

Background: We recently reported that apelin concentrations are associated with reduced atherosclerosis and plaque vulnerability as well as improved aortic function in rheumatoid arthritis (RA)1,2. These relations were influenced by RA characteristics1,2. Besides protecting against atherosclerosis, apelin is also a vasodilative peptide that improves cardiac contractility. In this regard, patients with RA experience a 2-fold increased risk of developing heart failure3. RA patients often demonstrate diastolic dysfunction and heart failure with a preserved ejection fraction (HFpEF). Traditional cardiovascular risk factors do not fully explain the increased heart failure incidence in this population. Metabolic risk factor driven inflammation is highly implicated in HFpEF.

Objectives: This study aimed to determine whether apelin can impact left ventricular function in RA and whether disease characteristics can modify this potential effect.

Methods: Relationships of apelin concentrations with echocardiographically determined markers of systolic and diastolic function including stroke volume, endocardial fractional shortening, midwall fractional shortening, ejection fraction, relative wall thickness, left ventricular mass, mitral inflow (E/A), filling pressure (E’/e’) and left atrial volume index (LAVI) were determined in multivariable regression models among 169 patients without established cardiovascular disease.

Results: In demographic characteristic adjusted analysis, rheumatoid factor (RF) positivity, joint deformity counts, and CRP were associated with increased apelin concentrations (p=0.01, 0.02 and 0.05, respectively). Apelin was associated with a reduced LAVI [ln(SE)=−4.6 (2.2); p=0.04] but not with E/A, lateral e’ or E’/e’ (p>0.05 for all). RA characteristics including disease duration, CRP, erythrocyte sedimentation rate (ESR), RF positivity, and joint deformity counts did not impact apelin concentration-diastolic function marker relationships (interaction p values>0.05). Apelin levels were associated with increased endocardial fractional shortening [ln(SE)=−5.99 (2.97); p=0.04] and midwall fractional shortening [ln(SE)=−6.92 (3.0); p=0.03]. The ESR and anti-citrullinated peptide antibody (ACPA) status impacted the apelin level-endocardial fractional shortening relationships (interaction p=0.05 and 0.01, respectively). In stratified analysis, apelin concentrations were associated with improved endocardial fractional shortening in those with [ln(SE)=1.41 (3.9); p=0.001] but not without an ESR >12 mm/hr (median value), and in those with [ln(SE)=8.2 (3.7); p=0.03] but not without ACPA positivity.

Conclusions: In RA, apelin concentrations are associated with a reduced LAVI irrespective of RA activity and severity characteristics. Apelin concentrations are also associated with improved endocardial fractional shortening in patients with RA, particularly in those with high-grade inflammation and ACPA positivity. Whether apelin can improve left ventricular systolic and diastolic function in RA merits further exploration in longitudinal studies.

Clinical Features and Problems of Elderly Onset Rheumatoid Arthritis in Ultra-Ageing Society – Single Centre Retrospective Cohort Study

T. Kurasawa, Y. Okada, A. Shibata, S. Saito, K. Chino, A. Okuyama, H. Takei, T. Kondo, K. Amano. Department of rheumatology and clinical Immunology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan

Background: Japan is the ultra-ageing society ahead of any other country in the world, which ageing rate (the ratio of the population aged 65 and older to the total population) was reported to be 27.3% on October 1, 2016. The rate of aged patients, who followed up at the division of rheumatology in Saitama medical centre, had exceeded 40%.

Objectives: The aim of our study is to reveal recent clinical features and problems of elderly onset rheumatoid arthritis (EORA) patients for better management.

Methods: Patients had a diagnosis by 1987 classification criteria or 2010 ACR/EULAR criteria. We firstly listed up RA patients who followed up our hospital from April 1 to September 30, and above aged 65 years old as of September 30. Then we retrospectively collected clinical information of EORA patients who onset
above 60 years old, diagnosed and made starts of treatment in our hospital, and observed more than 6 months, from medical records.

Results: One hundred eighty eight EORA patients were enrolled in this study. Female were 116 (62.0%). Mean observation period from first visit until September 30, was 68 months. Rheumatoid factor positive rate was 67.0%. Anti-CCP antibody-positive was 68.2% (107/157), and most of them (65.5%, 70/107) had high antibody titer over 100 U/mL. At the time of diagnosis, average CRP was 3.1 mg/dL. Respiratory complications were seen in 26.1% (49 cases), including 28 intestinal lung disease, 10 COPD/emphysema, 7 non-tuberculous mycobacteriosis/obselete tuberculosis, and 6 bronchectasis. Other complications were diabetes 16.5% (past 25 cases, new 6), hypertension 38.3% (past 66, new 6), and hyperlipidemia 23.9% (past 33, new 12). Histories of cerebrovascular or cardio-vascular events were seen in 10.6% (20 cases), and history of malignancy was seen in 6.9% (13 cases). During observation period, newly developed malignancy was seen in 14 cases (14.1/1000 person-years), including 4 MTX related lymphoproliferative disorders (MTX-LPD), 3 gastrointestinal cancer, 3 gynaecological cancer, 2 lung cancer, and so on. Infectious adverse event were occurred in 35 patients (35.3/1000 person-years). From the point of treatment, corticosteroids were prescribed in 32%, csDMARDs 88%, and biological DMARDs (BIO) 47%. Of 89 EORA patient treated with BIO, average DAS28-ESR was 5.77, and HAQ-DI 1.48 at the baseline. Twenty-nine cases were started to treat with BIO as monotherapy, 13 cases as switching to BIO from csDMARDs, and 47 as addition BIO to csDMARDs. During observation period, reasons of cessation of the first BIO were remission in 21, adverse events in 19 (7 infections, 6 injection-site/infusion reaction, 3 malignancies, and so on), insufficient response in 16, and patient’s hope in 2.

Conclusions: RF/anti-CCP antibody positive rate was lower than general RA population, but slightly higher than previous reports on EORA.1,2 BIO could be discontinued in 24% of 89 patients who received BIO because of remission. On the other hand, the frequency of infection and malignancy was still higher in EORA patients. So it is necessary to adjust anti-rheumatic therapy for poor prognostic cases, and we should be careful to follow up EORA patients.

AB0406 SIGNIFICANT ASSOCIATION BETWEEN REnal FUNCTION AND AREA OF AMYLOID DEPOSITION IN Kidney biopsy SPECIMENS IN both AA AMYLOIDOSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS AND AL AMYLOIDOSIS

T. Kuroda1, Y. Ito1, N. Imai1, Y. Nozawa1, H. Sato1, T. Nakastue1, Y. Wada1, M. Ueno2, M. Nakano3, I.N. Narta1, 1Division of clinical nephrology and rheumatology, Niigata University, Niigata; 2University Health Center, Joetsu University of Education, Joetsu; 3Faculty of Medicine, Niigata University, Niigata, Japan

Background: The kidney is a major target organ for systemic amyloidosis, which results in proteinuria and an elevated serum creatinine level. The clinical manifestations and precursor proteins of amyloid A (AA) and light-chain (AL) amyloidosis are different, and the renal damage due to amyloid deposition also seems to differ.

Objectives: The purpose of this study was to clarify how the difference in clinical features between AA and AL amyloidosis are explained by the difference in the amount and distribution of amyloid deposition in the renal tissues.

Methods: A total of 119 patients participated: 58 patients with an established diagnosis of AA amyloidosis (AA group) and 61 with AL amyloidosis (AL group). We retrospectively investigated the correlation between clinical data, pathological manifestations, and the area occupied by amyloid in renal biopsy specimens. In most of the renal specimens the percentage area occupied by amyloid was less than 10%. For statistical analyses, the percentage area of amyloid deposition was transformed to a common logarithmic value (Log10%amyloid).

Results: The sex-, age-, and Log10%amyloid-adjusted analyses showed that systolic blood pressure (SBP) was higher in the AA group. In terms of renal function parameters, serum creatinine, creatinine clearance (CrCl) and estimated glomerular filtration rate (eGFR) indicated significant renal impairment in the AA group, whereas urinary protein indicated significant renal impairment in the AL group. Pathological examinations revealed amyloid was predominantly deposited at glomerular basement membrane (GBM) and easily transferred to the mesangial area in the AA group, and it was predominantly deposited at in the AL group. The degree of amyloid deposition in the glomerular capillary was significantly more severe in AL group. The frequency of amyloid deposits in extraglomerular mesangium was not significantly different between the two groups, but in AA group, the degree amyloid deposition was significantly more severe, and the deposition pattern in the glomerulus was nodular. Nodular deposition in extraglomerular mesangium leads to renal impairment in AA group. There are significant differences between AA and AL amyloidosis with regard to the renal function, especially in terms of CrCl, eGFR and urinary protein, even after Log10%amyloid was adjusted; showing that these inter-group differences in renal function would not be depend on the amount of renal amyloid deposits.

Conclusions: These differences could be explained by the difference in distribution and morphological pattern of amyloid deposition in the renal tissue.

AB0407 THE IMPACT OF DEPRESSION ON SOCIAL CONTACTS OF PATIENTS WITH REUMATOID ARTHRITIS

T. Jankovic, J. Zvekic Svorcan. Rheumatology, Faculty of Medicine, University of Novi Sad Special Hospital for Rheumatic Diseases, Novi Sad, Serbia

Background: Rheumatoid arthritis (RA) affects the psychological and emotional state of the patient, leading to a significant reduction in the quality of life and social contacts.

Objectives: Assess the occurrence and degree of depression in RA patients and their impact on quality of life and social contacts.

Methods: The study involved 110 patients, 78.4% women and 22.6% men, with RA of median age 58.7. The average disease duration was 13.6 years. 68% of patients were treated with methotrexate monotherapy (MTX), 32% by combination of MTX and other DMARD. The disease activity in patients was determined by the index DAS28, the functional status -HAQ-DI questionnaire. The intensity of the pain was determined using a visual analogue scale for VAS pain (0–100 mm). The degree of radiological changes was determined based on the classification by Steinbrocker. Patients completed a questionnaire related to the quality of social relationships. The degree of depression was determined using Bäck scale for depression.

Results: The incidence of depression had 65.4% of the patients. A mild degree of depression was observed in 26.4%, moderate 24%, expressive 13% while 2% of the patients had a more severe degree. There was a significant statistic correlation between the degree of depression with age, the duration of the disease, the high degree of DAS28, HAQ-DI, VAS pain and the degree of radiological changes. By analysing the quality of life and social contact, patients in 62% were supported by a close family and a spouse, 28% of their close relatives, 7% of the wider family, while 3% of the patients lived alone.

Conclusions: Depression is the most common and most important psychological state that occurs in patients with RA. It is important to recognise and start treatment on time, which should be based on a multidisciplinary approach. In addition to family support, overall social support also takes a significant place.

ANALYSIS OF THE CORRELATION OF COMPOSITE INDICATORS OF ACTIVITY OF THE DISEASE AND THE CONCORDANCE BETWEEN THE DIFFERENT STATES OF ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Fontana, B. Ferreira Althoff, C. Janson Ferreira, Y. Alfarro, G. Ricardo Werner de Castro, I. Alves Pereira, Rodovia Antonio Luís de Moura Gonzaga, Unisul Pedra Branca, Florianópolis, Brazil

Background: Rheumatoid arthritis (RA) is an inflammatory joint disease of systemic involvement and varied evolution, which uses different disease evaluation scores. It is essential that these instruments be evaluated according to the disease, so that the treatment algorithms can be applied independently.

Objectives: To analyse a correlation of disease activity indexes (ICADs) and a concordance between different states of activity in patients with Rheumatoid Arthritis.

Methods: Cross-sectional study based on 100 patients of outpatient care from a multicenter prospective cohort study. Approved by CEP UNISUL. Statistical analysis by the SPSS 18.0 program, using the Pearson Correlation Coefficient and McNemar-Bowker Concordance, considering significance level p < 0.05.

Results: Majority female patients (86%), with an average age of 54 years, who were active in their jobs (53%) and had a positive rheumatoid factor in 65%. The average values of the ICADs were DAS-28 (3.6), DAS-28 PCR (3.0), SDAI (13.4), CDAI (12.5) and RADAI (3.5), respectively. Many were classified with moderate disease activity of the disease. The degree of correlation was very strong (>0.8) and strong (>0.5) in most ICADs and a concordance of remission DAS-28PCR ranged from 41.3% to 54.3% with the other ICADs.

Conclusions: The ICADs presented a strong correlation with each other, as well a level of similarities in the classification of the different degrees of activity. These results confirm that in different patients with RA, the ICADs serve to define active disease and to aid in the treatment strategy, so it is not imperative to use only a single evaluation score.

DIAGNOSIS OF LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS, A PROSPECTIVE MONOCENTRIC STUDY

Background: Respiratory involvement in rheumatoid arthritis (RA) is the most common extra-articular localisation, affecting 50% of patients, even though only 5% become symptomatic. Lung pathology as RA related interstitial lung disease is associated with significant morbidity and mortality. Involvement of the respiratory system seems frequent but remains underestimated because of the absence of guidelines about its detection in patients with RA.

Objectives: This study aimed at determining the prevalence of respiratory involvement among symptomatic and asymptomatic patients with rheumatoid arthritis managed in a university hospital.

Methods: We conducted a prospective observational study from May 2017 to January 2018 at the Strasbourg University Hospital. The patients included were over 18 years of age, had rheumatoid arthritis according to the ACR/EULAR 2010 criteria and signed informed consent. They responded to a self-administered questionnaire about their medical history, cardiorespiratory symptoms and life-style. Epidemiological, clinical and radiological data were assessed. All of the patients had a chest computed tomography (CT) and respiratory function tests (RFT). A collection of salivary flow and a test of Shirmer were carried out, to investigate the presence of a sicca syndrome. Chest CTs were interpreted by a radiologist specialised in lung area.

Results: We included 102 successive patients, 73 women and 29 men. The average disease duration was 34 years. 60 patients were seropositive for rheumatoid factor and 68 for anti-CCP. 59 patients had bone erosions. The average disease activity score (DAS28-CRP) at inclusion was 3.5, 49 patients had associated Sjögren’s syndrome. 22 were active smoker. 43 patients were taking long-term corticosteroid therapy. 96 patients were treated with conventional DMARD treatment, 28 with anti-TNF alpha therapy, 28 with rituximab, 16 with tocilizumab, 12 with Abatacept, 2 with JAK selective inhibitors, and 16 patients were under Rituximab treatment. Of the 87 RFT performed, 39 were abnormal: 14 reported an obstructive syndrome, 8 a restrictive syndrome, 32 peripheral expiratory braking, suggestive sign of bronchiolitis, and 24 a decrease in the DLCO. Of the 91 chest CTs, 42 revealed lung nodules (42%), 15 of which were more than 6 mm; 29 interstitial syndrome (29%), among which 5 were non-specific interstitial pneumonitis (PINS), 3 common interstitial pneumonitis (PiC), and the other were non specific interstitial syndrome. 2 chest CT showed pleural effusion and 1 pulmonary nodule. 44 patients had coronary calcifications, among whom 32 had no lipid-lowering therapy.

Conclusions: Pulmonary systemic assessment of RA patients show high prevalence of respiratory involvement: 42% of patients had lung nodules and 29% had an interstitial syndrome. Detection of interstitial lung disease may raise questions about RA treatment such as anti-TNF alpha therapy. Rheumatologist should be more aware of respiratory involvement in RA patients and RFT, a non-invasive test, might be useful at diagnosis and follow-up.

MISSING THE BIG PICTURE? AN AUDIT OF HAND XRAYS IN BIOLOGIC TREATED RHEUMATOID ARTHRITIS PATIENTS

U. Habbii, A. Sahnii, M. Lloyd, B. Barberii, J. Cameron, S. Melathi, D. Christidis, J. Wajedii, A. Mistli, S. Cooper, 1.Rheumatology, 2Radiology, Frimley Park Hospital, Frimley, UK

Background: Rheumatoid arthritis (RA) treatment is target driven. The aim is to ease burden may currently be relatively neglected.

Methods: 100 random biologic treated patients from our biologics database were selected for analysis. We used patient letters and our digital imaging system (PACS) for further information. Our PACS has records running back to 2004.

Results: Mean age was 58 years. 77% were female. Mean duration of RA was 10.6 years (range 0.9–44 years). 46 were currently receiving etanercept; 17 tocilizu- zumab; 16 adalimumab; 14 certolizumab; 5 rituximab and 3 abatacept. 61 patients were current prednisolone users. The mean duration of biologic treatment was 4.8 years. 44 patients had received more than one biologic drug; 17 more than two. Mean DAS was 3.4; 72 patients had had previous documented hand XRs; 25 (34%) of these had erosions. The mean duration since the last hand XR was 37 months. 27 patients had had 2 previous hand XRs; 11 had had 3; 4 had had 4 and 2 had had 6 previous XRs. In 19 cases hand erosions appeared to have progressed in the patients who had had more than one XR. 44 patients had had previous foot XRs; 15 (34%) had erosions. 26 patients had had more than one foot XR. 36 patients had had previous joint ultrasound (US); in 17 (47%) US suggested active synovitis. The mean duration since the last US was 17 months.

Conclusions: Our patients had relatively high disease activity despite biologic treatment, over half were also on steroids and significant numbers had had several biologic switches. Despite this only around two thirds of patients had had previous hand XRs documented over an average of 10 years RA duration, and there was a long average time since the last imaging. US rates were lower, but scans were more recent, perhaps suggesting a more modern trend to US over XR. Less than half of patients had had foot XRs. Although there was a lower rate of foot XRs the rate of erosions was similar in hand and foot XRs, suggesting similar patterns of joint damage. Interestingly, despite erosions being a hard end point in most treatment trials, NICE guidance only suggests XR early in RA in ‘people with persistant synovitis’ and EULAR guidance suggests assessing for ‘structural damage’ without specifying time intervals. Although newer imaging techniques may be more sensitive, XRs remain cheap, quickly accessible and allow objective assessment, particularly in long term patients being assessed for biologic switches. Our audit suggests that this well established and useful measure of disease burden may currently be relatively neglected.
AB0411  RISK OF REACTIVATION OF HEPATITIS B VIRUS IN RHEUMATOID ARTHRITIS PATIENTS WHO RECEIVED LONG-TERM LOW DOSE CORTICOSTEROID THERAPY

W. Jeong1, J. Kim1, E.-J. Park2, B.-C. Song3, 1Rheumatology, Jeju National University Hospital, Jeju-Si, Jeju; 2Rheumatology, National medical center, seoul; 3Hepatology, Jeju National University Hospital, Jeju-Si, Korea, Republic of Ireland

Background: It is well known that the use of corticosteroids results in increased viral replication and elevated ALT in patients with hepatitis B virus. The use of high dose corticosteroids for more than 4 weeks usually results in hepatitis worsening after cessation of steroids. However, few studies have investigated the effect of low dose corticosteroids on hepatitis B virus (HBV) reactivation.

Objectives: The aim of this study is to investigate the reactivity of HBV in rheumatoid arthritis (RA) patients treated with long term low dose corticosteroids and its risk factor.

Methods: Patients with HBsAg positive who were diagnosed with RA and who received prednisolone of less than 10 mg/day over four weeks and immunosuppressive agent were selected at four university hospitals in South Korea between June 1996 and March 2017. Medical records and laboratory data were retrospectively analysed and multivariate analysis was performed.

Results: One hundred forty five patients were included in the study and 26 (17.9%) patients were reactivated with HBV. Mean age at diagnosis of RA was 50.7 years and 41 (28.3%) patients were male. Baseline characteristics including sex, age and laboratory findings at diagnosis of rheumatoid arthritis were not significantly different in patients with HBV reactivation compared to those without HBV reactivation. The average daily dose of prednisolone was 3.6±5.2 mg and the mean duration of prednisolone was 5.1±5.05 years and the average cumulative dose of prednisolone was 5821.6±7021.3 mg. Eleven (42.3%) of 26 HBV reactivated patients were reactivated within one year after prednisolone administration and the period from the start of prednisolone administration to the reactivation was 4.0±5.77 years on average. The duration of prednisolone administration, mean daily dose of prednisolone, and cumulative prednisolone dose and administration of methotrexate, tacrolimus, tumour necrosis factor inhibitor and hydroxychloroquine did not significantly affect HBV reactivation in both univariate and multivariate analyses. However, the administration of leflunomide showed a significant difference in the reactivation of HBV (adjusted odd ratio 3.76; p=0.04).

Conclusions: The hepatitis B virus can be exacerbated by spontaneous viral reactivation, so it is difficult to conclude that hepatitis is caused by the administration of steroids. In this study, the administration of low-dose steroids did not affect the reactivation of HBV. However, leflunomide increased the risk of HBV reactivation when the effects of other disease modifying antirheumatic drug (DMARD) were corrected. Therefore, a prospective study is needed to evaluate the effect of DMARDs on HBV reactivation in the long-term administration of low-dose corticosteroids in RA patients.

AB0412  DYNAMICS OF QUANTITATIVE BODY COMPOSITION INDICES BY THE METHOD OF DUAL-ENERGY X-RAY ABSORPTIOMETRY (DRA) IN PATIENTS WITH EARLY RA DEPENDING ON THE ACHIEVED ACTIVITY OF THE DISEASE

V. Gorbunova, T. Popkova, L. Kondratyeva, A. Smirnov, E. Nasonov. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Background: Adipose tissue as an active endocrine organ. In pts with RA the redistribution of body fat mass. Using BMI and WC do not allow to distinguish between fat and lean (muscle) mass. Performing dual-energy X-ray absorptiometry allows to specify the quantitative composition of the body (mass of adipose tissue and muscle) in pts with early RA.

Objectives: to compare the indicators of the quantitative composition of the body in groups of RA pts with different disease activity before and after the beginning of treatment.

Methods: included 37pts with early RA(ACR/EULAR2010), 57 [46.5, 62] yrs, duration of disease 6 [5.5, 15.5] months, IgMRF seropositive antiCCP, with high RA activity(DAS285 [5.1, 6]), SDAI 32.4 [22.4, 42], CDAI 29 [19.7, 39.5]. After inclusion in the study, all pts started receiving MTX 10 [10–15 mg/week], after 12 weeks, with ineffective MTX, ADA 40 mg2 weeks was prescribed. The quantitative composition of the body was determined initially and after 6mths by means of DXA using the apparatus Hologic, analysing the following parameters: the total, of fat and lean mass.

Results: By the 24th week of therapy, 13 (35%) pts with early RA received combined therapy(ADA, MTX), 24 (65%) pts with RA monotherapy MTX. Depending on the activity of RA(DAS28)by the 24th week of therapy, pts are divided into 2groups: I(n=18) pts with remission/low activity, II(n=19) with moderate/high RA activity (table 1). Initially, the groups differed in fat mass: this index was higher in the group of pts with moderate/high activity persisting, compared with the group of pts with remission/low activity of RA:30.2 kg versus 19.4 kg. In the I group of pts before the treatment and after 6mths of therapy, a statistically significant decrease in muscle mass was observed: from 45.2 kg to 41.6 kg. A decrease in the mass of adipose tissue after 24 weeks of therapy was noted in the Igroup of pts with RA: from 30.2 kg to 28.2 kg. The difference in the indices between the groups by the 6th month of therapy was noted for the mass of adipose tissue. This composition of the body score was also higher in pts with moderate and high RA activity, compared to the group of pts with remission/low RA activity: 28.2 kg versus 19.9 kg (p<0.05 in all cases).

AB0413  NODULAR POLYARTERITIS AS AN UNFORESEEABLE ADVERSE REACTION IN RA PATIENT TREATED WITH TOFACITINIB

V. Muravyev1, S. Radenska-Lopovok2, V. Lebedeva1, S. Alamankina1, Federal State Budgetary Institution «Research Institute of Rheumatology» under the Russian Academy of Medical Sciences; 1M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Tofacitinib basic prescribing information and guidelines for medical use do not provide any description of such adverse drug reaction (ADR) as vasculitis, in particular polyarteritis nodosa. We present a clinical case of vasculitis emerging during tofacitinib therapy.

Objectives: demonstration of an unexpected reaction to tofacitinib

Demonstration of an unexpected reaction to tofacitinib

Methods: A 59 y.o. RA female patient was hospitalised in December 2016 due to eruption of indurated nodules on her hips and legs producing sharp pain, ulceration of nodules on the legs, painful hip and ankle joints, and morning stiffness lasting for about one hour.

Results: Seropositive RA was diagnosed in this patient in April 2004 with subsequent DMARD with methotrexate (MT) at 7.5 mg/week. The remission achieved
Background: Oxytocin (OXT), also referred to as a happy hormone, has been associated with various psychiatric disorders, including depression. However, the relation between serum oxytocin levels and disease activity, depressive state, activity of daily life (ADL), and quality of life (QOL) in RA remains unclear. Histopathology of skin and subcutaneous fat biopsy samples is presented on figure 1a,1b. Histopathology data suggests the presence of cutaneous and subcutaneous fat productive and destructive vasculitis and acute, predominantly lobular, panniculitis; such structural changes are usually present in cutaneous polyarteritis nodosa and other systemic vasculitis. The usual relationship between this ADR and tofacitinib therapy was assessed as probable using Naranjo scale.

Conclusions: development of vasculitis (polyarteritis nodosa) in RA patient can be caused by tofacitinib.

Disclosure of Interest: None declared

AB0414

RELATIONSHIP BETWEEN SERUM OXYTOCIN LEVELS AND DEPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Miyaw, T. Kasama, K. Sanada, 1Division Of Rheumatology, Department Of Medicine; 2Department of Psychiatry, SHOWA UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan

Background: Oxytocin (OXT), also referred to as a happy hormone, has been associated with various psychiatric disorders, including depression. However, the relationship between depression and rheumatoid arthritis (RA) has not yet been clarified.

Objectives: The objective of this study was to investigate the relationship between serum oxytocin levels and disease activity, depressive state, activity of daily life (ADL), and quality of life (QOL) in RA.

Methods: This study included 119 RA patients. We measured the following variables: baseline characteristics including age, sex, disease duration, smoking history, body mass index, prednisolone dose, and methotrexate (MTX) dose, serum levels of rheumatoid factor, matrix metalloproteinase-3, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) level. The disease activity of RA was assessed using the Simplified Disease Activity Index (SDAI); depression was assessed using the Hamilton Depression Rating Scale (HAM-D); ADL were assessed using the Health Assessment Questionnaire; and QOL was assessed using the 36-Item Short Form Health Survey (SF-36). Serum OXT levels were determined by enzyme-linked immunosorbent assay. The subjects were divided into two groups according to the higher or lower of the serum OXT levels, and a retrospective study was performed.

Results: The serum OXT levels were correlated with the disease duration (r=0.443, p=0.000). Weak correlations of MTX dose (r=0.208, p=0.030), swollen joint count (SJC) (r=-0.306, p=0.001), ESR (r=-0.245, p=0.010), CRP (r=-0.283, p=0.003) and the mental component summary (MCS) score (r=-0.196, p=0.041) of SF-36. The binomial logistic analyses findings were as follows; younger age (p=0.0209, odd ratio: 0.96, 95% CI: 0.94–0.99) and longer disease duration (p=0.0053, odd ratio: 1.08, 95% CI: 1.02–1.13). Other items did not correlate to the serum OXT levels included with the HAM-D score.

Conclusions: The serum oxytocin levels were correlated with longer disease duration and younger age.

Rheumatoid arthritis – biological DMARDs

AB0415

DISEASE FLARES AMONG EARLY RHEUMATOID ARTHRITIS PATIENTS TREATED WITH CONTINUED METHOTREXATE EITHER ALONE OR IN COMBINATION WITH ADALUMAB

A. Kavanya, R. van Voellenhoven, P. Sunkureddi, Y. Zhang, J. Subotchi, J. Smolen, 1Division of Rheumatology, Allergy, and Immunology, University of California San Diego, La Jolla, USA; 2Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands; 3University of Texas Medical Branch, Galveston; 4AbbVie Inc., North Chicago, USA; 5Division of Rheumatology, Department of Medicine, Medical University of Vienna and Hietzing Hospital, Vienna, Austria

Background: Some rheumatoid arthritis (RA) patients (pts) may experience flares in their disease even after reaching stable low disease activity (sLDA), but the consequences of even temporary elevations in disease activity are poorly understood.

Objectives: The purpose of this analysis was to explore the rates of flares after reaching sLDA in pts treated to target with either methotrexate (MTX) monotherapy or adalimumab combination therapy (ADA+MTX).

Methods: This post hoc analysis included pts from the randomised, double-blind, double-period OPTIMA trial achieving sLDA [DAS28(CRP) <3.2 at weeks (wks) 22 and 26] at the end of period 1 (P1). In P1, pts were randomised to receive ADA +MTX or placebo (PBO) +MTX for 26 wks. Pts on ADA +MTX achieving sLDA were randomised to receive PBO +MTX (ADA Withdrawal) or continue on ADA +MTX (ADA Continuation) for an additional 52 wks in period 2 (P2). Pts who achieved sLDA on PBO +MTX in P1 continued their treatment in P2 (MTX Continuation). Pts achieving sLDA in each treatment group were categorised based on whether they experienced a flare (change in DAS28(CRP) ≥0.6 at consecutive visits and DAS28(CRP) ≥3.2); the proportion of pts experiencing flares and time to flare were assessed. For each group, mean change from wk 26 to wk 78 in disease activity [DAS28(CRP)], functional (HAQ-DI) and structural (mTSS) measures were analysed.

Results: In pts achieving sLDA at the end of P1, flare rates in P2 differed based on initial treatment assignment (ADA Continuation: 11.7% [95% CI: 11.9–12.4]; MTX Continuation: 22.4% [22.8–23.0]). Interestingly, flare rates in pts randomised to withdraw ADA on initial treatment assignment (ADA Continuation: 11.7% [11.7–12.7]; MTX Continuation: 22.4% [22.8–23.0]) were numerically similar to the MTX Continuation group. The mean time to flare was 193, 191, and 177 days in the ADA Withdrawal, ADA Continuation, and MTX Continuation groups, respectively. During P2, the mean DAS28(CRP) scores were predictably higher in pts who flared compared with those who did not across treatment groups. In pts experiencing flares in P2, disease activity and functional measures worsened from wk 26 to wk 78 as compared with pts without flares (table 1). Of the individual DAS28(CRP) components, pt global assessment of disease activity (PtGA) showed the greatest worsening. There were small differences in radiographic progression between pts experiencing flares compared with pts without flares.

</table>

*Flare was defined as change in DAS28(CRP) >0.6 at consecutive visits and DAS28(CRP) >3.2.

LDA—low disease activity; DAS28(CRP)>28 joint disease activity score based on C-reactive protein; ADA=adalimumab; MTX=methotrexate; HAD-DI=health assessment questionnaire disability index; mTSS=modified total Sharp score.

Conclusions: In early RA pts achieving sLDA, flares were generally infrequent; however, they were more prevalent in pts receiving PBO+MTX compared with ADA+MTX. Flares were numerically associated with higher disease activity, functional deterioration, and higher PGA, underscoring its impact on health-related quality of life and the importance of preventing flares as a therapeutic outcome.

Mota1, 1Universidade de Brasilia, UnB-Brasil, Brasilia; 2Universidade de São Paulo, São Paulo; 3Hospital for Special Surgery-Well Cornell Medicine, New York; 4AbbVie, Chicago; 5Analysis Group, Inc., Boston, USA

Background: As biosimilars are approved and commercialised for rheumatic diseases, patients may be switched from original biologic treatment to biosimilars due to perceived cost savings between the two biologic products. However, in the short term, non-medical switching (NMS) may require additional patient education, office visits, lab/imaging tests, and additional administrative support which could lead to substantial costs.

Objectives: To estimate the short-term costs associated with NMS from original biologics to biosimilars.

Methods: An economic model was constructed including two components: the administrative burden for NMS program set-up and support, and the provider burden for initiating and managing NMS. Administrative burden was modelled at the center-level and considered staff time for program set-up, patient education, scheduling, documentation, and departmental meetings from pre-NMS planning to post-NMS implementation (<1 year). The provider burden was modelled at the patient-level and considered the expected additional provider time needed and extra laboratory/imaging tests when managing NMS from the time of switching until 3 month post NMS implementation. Model inputs for the administrative burden came from the literature and for provider burden from survey of physicians. Literature was used to inform both the total number of rheumatology patients that underwent NMS and the unit cost associated with provider/staff time and laboratory/imaging tests.

Results: From a rheumatology centre perspective, setting up an NMS program and the subsequent administrative support was estimated to cost £19 617 per centre, attributed to general overhead (40%), pharmacist time (26%), consultant time (21%), and nurse time (13%). After the set-up, provider burden for initiating and managing NMS was estimated to be £113 per switched patient. Assuming 5000 patients with relevant rheumatoid conditions in a centre, 572 stable patients with RA, PsA or AS were estimated to switch to biosimilars. The overall short-term cost associated with NMS was estimated to be £84 174 for the entire centre, with 23% attributed to the NMS program set-up and support, and 77% attributed to extra provider time and monitoring (on average £147 per switched patient).

Conclusions: Switching stable patients with a rheumatic condition from original biologics to biosimilars could have considerable short-term costs for a centre. Additional real world studies are needed to better weigh the potential saving vs. cost associated with NMS.

Mota1, 1Universidade de Brasilia, UnB-Brasil, Brasilia; 2Universidade de São Paulo, São Paulo; 3Hospital for Special Surgery-Well Cornell Medicine, New York; 4AbbVie, Chicago; 5Analysis Group, Inc., Boston, USA

Background: Rheumatoid arthritis (RA) is a chronic disease, characterised by inflammatory involvement of the synovial joints. The “treat to target” concept is well established in the rheumatologic community, however, in many patients, especially in developing countries, its implementation is not feasible. Considering the high costs of treatment com of RA and the limited national epidemiological data available on this disease, we sought to describe the profile of use of biological drugs in Brazilian patients with RA to help the decision-making process by public health managers.

Objectives: To describe the frequency and time of use of biological drugs in Brazilian patients with rheumatoid arthritis.

Methods: The REAL – RA in real life in Brazil – is a multicenter prospective cohort study, with twelve-month follow-up period. To be included in this study, consecutive patients from 11 tertiary rheumatology centres had to meet the 1987 ACR and the limited national epidemiological data were used as secondary sources. The present study present data taken from the participants’ initial assessment. This research was approved by the Ethics Committees of each centre.

Results: A total of 1125 patients were analysed. 89% were women with a mean age of 56.6 years. The main clinic data were: DAS 28 (median)=3.52, HAQ (median)=0.87 and CDAI (median)=9. 1022 (90.84%) used synthetic DMARDs.
and 406 (36.09%) biologic therapy. The frequency of use of the biologic therapy was: abatacept (73 patients/6.49%), etanercept (66/5.87%), tocilizumab (60/5.33%), adalimumab (54/4.8%), infliximab (50/4.44%), rituximab (49/4.36%), golimumab (37/3.29%), certolizumab (17, 1.5%). The time of use of the biological drugs is presented in Table 1.

Conclusions: The therapeutic profile of this cohort of Brazilian RA patients shows some interesting results. The relatively high number of patients on biologics, compared to other studies, may be related to the fact that the centres involved were reference centres, probably dealing with more difficult cases.

AB0419

THE EFFECT OF CONCOMITANT METHOTREXATE ON SERUM TNF INHIBITORS LEVELS AND CLINICAL RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS: DOSE IS DEPENDENT AND GREATER THAN OTHER DMARDs

A. Martinez-Feito, C. Plasencia, V. Navarro-Compan, B. Hernández-Breijo, M. A. González, I. Monjo, L. Nuño, P. Nozal, D. Pascual-Salcedo, A. Balasa, ImmuNo-Rheumatology Research Group, University Hospital LA PAZ, Madrid, Spain

Background: Several factors influence on the pharmacokinetics(PK) of TNF inhibitors(TNFi). One of the most relevant influencing factors is the development of antidrug-antibodies(ADA), which is associated with low circulating drug levels and loss of clinical efficacy. Previous studies, mostly about Adalimumab (Ada), have demonstrated a beneficial effect of concomitant use of methotrexate(MTX) in patients(pts) under TNFi therapy by reduction of immunogenicity. There are other csDMARDs(OD) as lefunomide, hydroxychloroquine or sulfasalazine which may have also an effect on PK.

Objectives: To investigate the effect of csDMARDs on the presence of serum TNFi levels and on the clinical response during the first year of Ada or Infliximab (Ixf) treatment in RA pts. Secondly, to evaluate if MTX has a dose-dependent effect on these outcomes.

Methods: This is an inception cohort including pts with RA starting Ixf or Ada in a tertiary hospital since 1999. At baseline, 6 and 12 months clinical(DAS28, EULAR response and dDAS28) and serological(drug and ADA levels) parameters were measured. Patients were clustered according to the use of concomitant csDMARDs at baseline in three groups: i) TNFi monotherapy(ii) TNFi +MTX (iii) TNFi +OD. Pts within the TNFi +MTX group were also classified according to the MTX dose:MTX <15 mg/week(TNFi +MTX <15) and MTX >15 mg/week(TNFi +MTX >15).

Results: A total of 92 RA pts(Ada(n=25) or Ixf(n=67)) under TNFi were included. The number and percentage of pts in each group were as follows: TNFi monotherapy:12 pts(13%); TNFi +MTX, 59 pts(64%); TNFi +OD, 21 pts(23%). The number and percentage of pts receiving any dose of MTX, the percentage of them with drug levels after 12 months(71%) was numerically higher than in the other groups(20% in TNFi +OD and 9% in TNFi monotherapy,p=0.1). However, after stratifying pts by MTX dose, we observed that circulating drug levels at 12 months were more frequent in higher dose of MTX(54% of the pts with TNFi +MTX >15) compared to patients with TNFi +MTX <15 (17%), with TNFi +OD (20%) and with TNFi monotherapy (9%);p=0.002. According to EULAR response, pts treated with TNFi +MTX(81%) achieved more frequently a good response compared with the other groups (11% on TNFi +OD and 8% on TNFi monotherapy, p=0.6). Moreover, differences on clinical response were observed depending on MTX dose. While 58% with TNFi +MTX >15 were good EULAR responders, 23% with TNFi +MTX <15 achieved this. Overall, the best effect on clinical response was observed in the group of MTX; p=0.4. Finally, the TNFi median survival time(mst) was significantly higher in pts with TNFi +MTX than in pts with TNFi +OD or on TNFi monotherapy(5 years vs 2 years vs 2.15 years, respectively;p=0.03). Analysing by MTX dose, drug survival was superior for high (>15) and low MTX doses(<15) (median 5.2 and 3.3, respectivelycompared to OD and TNFi monotherapy although the difference was not statistically significant:p=0.09.

Conclusions: In RA pts under Ixf or Ada treatment, the presence of TNFi in serum, the clinical response and the TNFi survival are influenced by MTX but not by OD. Moreover, a MTX dose-dependent effect is closely associated with these outcomes.

FREQUENCY OF DISEASE FLARE AND STUDY OF THE CD4+CD25HIGHCD127LOW-/ TCELL POPULATIONS AFTER DISCONTINUATION OF ANTI-TNF THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS: PERSISTENT REMISSION

A. Lo Monaco1, C. A. Scire1, F. Cassiano2, V. Tisato2, P. Secchierno2, M. Govoni1.

1Department of Medical Sciences-Section of Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna di Ferrara; 2Department of Morphology, Surgery and Experimental Medicine and LTTA Centre, University of Ferrara, Ferrara, Italy

Background: Rheumatoid arthritis (RA) patients in a prolonged remission status represent a population whose future management has yet to be established. Treg cell function in patients with active RA is assumed to be impaired, a trend that seems to be reversed by TNFα antagonist therapy (aTNF). Theoretically a deeper remission may be represented by an immunological resetting of immune system, a condition which could enable to consider the possibility of a drug-free remission.

Objectives: To evaluate the incidence of disease flare after cessation of aTNF in pts in remission together with reconstitution of the CD4+CD25highCD127low/- Tcell subset after those patients in the same remission status with persistent low CD4+CD25highCD127low/- Tcell population, assuming the Treg populations as a markers of deep remission allowing a better selection of those patients at low-risk of flare after aTNF withdrawal.

Methods: inclusion criteria: patients with RA (>18 years) fulfilling the 1987 ACR classification criteria treated with aTNF and synthetic DMARDs for at least 12 months, in remission (DAS28<2.6/DAS44<1.6)+6 months, without glucocorticosteroid. Exclusion criteria:<18 years, glucocorticosteroids within the three months before; another inflammatory disease other than RA; ongoing infections. Intervention: aTNF levels withdrawal with continuation of DMARDs previously associated (MTX or LFN); a 24 months of follow up was performed. Serial clinical and instrumental evaluation, blood sampling and radiographs have been performed according to the scheduled protocol. Treg population and several cytokines/chemokines/ growth factors were analysed (Human Cytokine/Chemokine Panel I, Millipore).

Results: 23 patients were included, mean age 53 years (SD 12.3), 68% RF +, 52% ACPA +, DAS28 medium 1.41 (SD 0.48); average duration of illness 9.62 years (SD ±5.73). During the 24 month post-suspension follow-up, for a total of 267 person-months, 11 patients presented a flare, for a flare rate of 3.74/100 person-months (CI95% 1.79–6.88). The average observed exacerbation time from aTNF withdrawal was 14.6 months (SD 3.93). None statistical predictive value of Treg levels regarding disease outcome after aTNF withdrawal was observed (95% CI) 1.38 (0.82–2.30). None significant correlation among cytokines concentrations and disease status/Treg levels was observed. A correlation was observed between the presence of a synovitis with PD1+ at the baseline and the loss of remission [HR 7.062 (1.64–30.41, p=0.009);* higher values were exclusion criteria]. All 3 patients with positive US (PD1) who had flare-up were asymptomatic at baseline.

Conclusions: 47.8% of pts maintained aTNF-induced remission at 24 months continuing only sDMARDs therapy (MTX). Only in 1 case reintroduction of Adalimumab did not allow to regain clinical remission, which was obtained using another therapeutic target (anti-CTLA4). The presence of a residual synovitis, although mild (PD1), was correlated with the risk of exacerbation. Further results will be discussed.
Drug survival on certolizumab and predictors thereof in patients with rheumatoid arthritis, psoriatic arthritis, and axial spondyloarthritis from the apulian bioupe registry

A. Serranes1, G. Carlozzi2, R. Bucci2, F. D’Onofrio3, P.C. Falaffone5, S. Lopriore3, A. Marsico1, N. Maruotti4, D. Mazzotta2, M. Muratore1, L. Quarta1, L. Sarto1, C. Zuccaro1, F. Iannone3, *Rheumatology Unit, ASL Taranto; 2Rheumatology Service, ASL LE Casarsano; 3Rheumatology Hospital Unit, Foggia; 4UOC Reumatologia Universitaria, University of Foggia; 5Rheumatology Outpatients, “A. Pennino” Hospital, Binodì; 6DETO – Rheumatology Unit, University of Barletta; 7UOC Reumatologia Universitaria, University of, Foggia; 8O.U. of Rheumatology, “V. Fazzi” Hospital, Lecce; 9O.U. of Rheumatology, ASL Barletta, Italy

Background: In BIO.PU.RE. Registry are collected data from patients being treated with Biologics from rheumatologic centres in Apulia (Southern Italy).

Methods: We analysed longitudinal data of consecutive patients, affected with RA, PsA or axial-SPa starting a treatment with certolizumab (CTZ) in the time frame from 1st January 2011 to 30th June 2017. Demographic and disease related characteristics were collected at baseline and at last observation visit. Primary endpoint was the persistence on CTZ, and secondary endpoint was the search of baseline predictors of drug survival and clinical outcomes. Drug survival was evaluated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs, 95% confidence intervals (CI)) of drug discontinuation or achievement of low-disease/ remission in RA, and minimal disease activity (MDA) in PsA at last visit, adjusted for patient’s age at baseline was weakly correlated to the achievement of low disease/ remission in RA, while co-medication with MTX was significantly associated to the achievement of MDA (HR 3.82, 95 CI 1.26–11.54, p=0.01) in PsA. Globally, the causes of discontinuation were: ineffectiveness (n=94, 27.2%), adverse event (n=40, 11.8%), pregnancy (n=1, 0.3%), remission (n=3, 0.9%), others (n=13, 3.8%).

Cost effectiveness analysis of modified dosing regimen of biological therapy in chronic inflammatory disorder: an observational study

B.D. Pandey1, M. Goyal2, M.M. Thakar3, A.K. Vishwakarma4, 5Rheumatology, Fortis Hospital, NOIDA, Uttar Pradesh; 2Rheumatology, Goyal Hospital, Udaipur, Rajasthan; 3Medicine, JIPMER, Puducherry; 4Pharmacy, Shri Jagdishprasad Jhabvala Tibrewala University, Jungharuan, Rajasthan, India

Background: Cost of biologics in rheumatology is a prime concern in India. Due to lack of reimbursement system, a majority of the patients need to pay from their pocket for the therapy.

Disclosure of Interest: None declared

Severe Infections in Rheumatoid Arthritis (RA) Are Related to the Use of Biologic DMARDs, Assessment of Real-Life Patients

**Objectives:** Our objective was to estimate the cost-effectiveness in patients with the chronic inflammatory disorder on biological therapy with modified dosing regimens in patients of a tertiary care clinic.

**Methods:** In this retrospective observational study, data were captured from patients’ record in a tertiary care centre located in North India who received biological therapy in rheumatology care practice between 1 January 2013 and 31 December 2017. Modification in the dosing pattern was carried out in the patients and cost of therapy were estimated. These patients, who carried out the therapy, were monitored for any safety outcomes for up to 72 weeks.

**Results:** During the study period, 342 patients received modified dosing of biologicals indicated for rheumatoid arthritis and spondyloarthritis. The cost comparison of biologics is shown in table 1. Among all, 44 (12.86%) patients got reimbursement/claims from central and state government agencies. There were 73 (21.34%) patients who were followed up to 72 weeks (minimum possible) of the period for safety assessment. These patients achieved remission or low disease activity and after six months, mean DAS28 (mean ±SD) was 2.26±0.83, B23DAI (mean ±SD) was 2.32±0.98 and DAPSA (mean ±SD) was 3.11±1.05. A total 11 (3.21%) cases of known adverse events including hematruia (1.05% patient with etanercept), pneumonia (4.34% patient with tocilizumab), sinustitus (3.63% patient with infliximab), mild fungal infection (1.81% patient with infliximab) and urinary tract infection (5.26% patient with adalimumab) were reported. One patient (1.05% patient with rituximab) diagnosed with tuberculosis and diabetes after 37 months of initiation of rituximab and one case of hospitalisation was seen due to community-acquired pneumonia in the patient receiving infliximab. Two cases of mortality were reported in patients receiving etanercept after 18 months (due to clinical parkinsonism with aspirational pneumonia) and adalimumab after one month (reason unknown). After modified dosing, the patients tend to remain on therapy with no new safety signal.

IL-6 Receptor Blockade Induced a Different Immune Response in Rheumatoid Arthritis Patients With and Without Remission

**C. Diaz-Torre 1, A. Estrada 2, M.A. Ortiz 3, P. Moya 4, C. Marquez 5, D. de la Fuente 6, V. Torrente 7, J. Ramirez 8, D. Reina 9, M. Moreno 10, E. Casado 11, N. Busquets 12, M. Pujol 13, M.V. Hernandez 14, P. Santó 15, S. Ros 16, E. Garcia-Casares 17, H. Corominas 18, S. Vidal 19, J. de Agustín 20. 1Bio-eco group from ECOCAT, Societat Catalana de Reumatologia; 2Immunologia., Institut de Recerca Sant Pau, Barcelona, Spain

**Background:** Tocilizumab (TCZ) is a humanised antibody that blocks IL-6 receptor. Despite its effectiveness in rheumatoid arthritis (RA), there are patients that do not respond to the IL-6R blockade. The immune characteristics that would explain this lack of response are not known.

**Objectives:** Our aim was to determine the tocilizumab-induced changes in CD4+ T cells of patients that achieve, or not, remission at 12 m.

**Methods:** Prospective, multicenter study in 47 RA patients treated with TCZ during one year following standard clinical practice. Demographic, disease and treatment characteristics were collected at each visit. Ultrasound (US) grey scale and power doppler were assessed for joints and tendons using a semiquantitative scale from 0–3 points. Phenotyping of T lymphocytes was determined by flow cytometry and the plasma cytokine concentration was quantified by ELISA.

**Results:** Forty seven patients were treated with a mean age of 54±11 y and 85% were women. Years of disease were 13±8. We segregated patients according to their lack of response to the IL-6R blockade. The immune characteristics that would explain this lack of response are not known.

**Conclusions:** b-DMARDs use in our setting, combined with low dose methotrexate, reach higher frequency of severe infections than s-DMARDs, irrespective of comorbidities, steroid use or disease characteristics including disease activity.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3552
cells decreased in the remission group. The analysis of T cells classified according to chemokine receptors showed that memory (29.1±4.0 vs 22.7±2.7 10^5 cells/ml; p=0.06) and naive (22.6±4.1 vs 17.2±2.8; p=0.01) CD4+ and CD8+ T cells decreased in the remission group but not in the non-remission group. Since the expression of chemokine receptors defines the different Th subpopulations, we analysed them in the two groups of patients. Th1 tended to decrease in the remission group (3.5 ±0.7 vs 2.5±0.4; p=0.06) and Th9 decreased significantly in both groups (R: 5.0 ±0.8 vs 2.5±0.3; p=0.006 and Non R: 5.1±0.8 vs 3.1±0.4; p=0.001). In regard to the cytokines produced by CD4 + T lymphocytes, IL-17 (2.1±1.1 vs 1.2±0.5 ng/ml; p=0.04) and VEGF (0.5±0.2 vs 0.3±0.1 ng/ml; p=0.05) but not IL-6 and IL-22 changed significantly in the remission group. Interestingly, IL-17 and VEGF correlated with US findings before the initiation of the treatment (grey scale R=0.378, p=0.01 and R=0.322, p=0.03; power Doppler R=0.415, p=0.004 and R=0.320, p=0.03 respectively).

Conclusions: Tocilizumab induced changes in specific subsets of CD4 + T cells and their inflammatory associated cytokines in the remission group.

Disclosure of Interest: None declared

AB0425 PREVALENCE AND RISK FACTORS OF SERIOUS INFECTIONS IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING THE BIOLOGIC/TARGETED SYNTHETIC DMARDS: A PROPENSITY SCORE ANALYSIS FROM THE HONG KONG BIOLOGICS REGISTRY

C.C. Mok, R. Wan, B. Fong, on behalf of The Hong Kong Society of Rheumatology. Medicine, Tuen Mun Hospital, HK, Hong Kong

Objectives: To study the prevalence and risk factors for serious infections in rheumatoid arthritis (RA) patients receiving the biologic/target synthetic (b/ts) DMARDs.

Methods: Patients who fulfilled the EULAR/ACR criteria for RA and were ever treated with b/tsDMARDs were included. Withdrawal of b/tsDMARDs due to serious adverse events (SAEs) and serious infections (SIs) was analysed. Demographic data, medical comorbidities and concomitant use of glucocorticoids were included in the propensity score analyses. The propensity score for SIs was calculated and patients were stratified according to quintiles of propensity to SIs. Cox regression was performed, with SIs yes/no as the endpoint.

Results: Up to December 2017, 2355 courses of b/tsDMARDs were used in 1355 patients. The commonest causes of SIs were pulmonary tuberculosis (41%), severe pneumonia (33%), soft tissue infection (6.8%), atypical TB (7.7%) and tofacitinib (2.7%). After a follow-up of 5056 patient-years, 1433 courses of b/tsDMARDs were terminated (7.7%) and tofacitinib (2.7%). Among those b/tsDMARD courses terminated due to either inefficacy or serious adverse events (SAEs), the rate of SIs only in the three quintiles of patients with lower propensity to SIs. The rate of SIs was 1.17/100 patient-years for b/tsDMARD users compared to 1.00/100 patient-years for csDMARD users (HR 1.19 [0.96–1.48]; p=0.09). Among all patients, the most common causes of SIs were pulmonary tuberculosis (41%), severe pneumonia (33%), soft tissue injury (6.8%) and atypical TB (7.7%). The change in DAS28 score was also non-significantly greater in the combination group (−1.95±1.26 vs −1.68±1.56; p=0.30). The difference in 6 month efficacy between the combination and monotherapy groups was greater in anti-TNF users. The overall cumulative withdrawal rate of the b/tsDMARDs due to either inefficacy or serious adverse events (SAEs) was 1.55 at 3 years and 0.47 at 5 years. The anti-TNF biologics had a significantly higher withdrawal rate than the non-TNF biologics (hazard ratio [HR] 1.83 [1.56–2.14]; p<0.001). In Cox regression models, monotherapy of the b/tsDMARDs was not significantly associated with drug withdrawal due to inefficacy (HR 0.95 [0.53–1.71]; p=0.87) or SAEs (HR 1.27 [0.51–3.19]; p=0.61) after adjustment for age, sex, anti-TNF (vs non-TNF) biologic use, previous use of b/tsDMARDs (vs first time use) and DAS28 at baseline. Separate analyses of the anti-TNF and non-TNF biologics showed no significant association between the combination and monotherapy of the b/tsDMARDs due to inefficacy or SAEs after adjustment for age, sex, previous use of b/tsDMARDs and disease activity at baseline (HR 1.02 [0.56–1.80]; p=0.99 for anti-TNF and HR 1.20 [0.47–3.08]; p=0.70 for non-TNF biologics, respectively).

Conclusions: Monotherapy of b/tsDMARDs was used in 8.7% of our RA patients in real life practice, probably due to intolerance, inefficacy or non-compliance to the csDMARDs. Short-term efficacy tended to be better with b/tsDMARDs/csDMARDs combination, especially in the anti-TNF biologics, but the long-term drug retention rate was similar between b/tsDMARD monotherapy and combination therapy with the csDMARDs.

Disclosure of Interest: None declared

AB0426 EFFICACY OF MONOTHERAPY OF THE BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL WORLD DATA FROM THE HONG KONG BIOLOGICS REGISTRY

C.C. Mok, R. Wan, B. Fong, on behalf of The Hong Kong Society of Rheumatology. Medicine, Tuen Mun Hospital, HK, Hong Kong

Objectives: To report the prevalence and efficacy of biologic DMARD (bDMARD) monotherapy in real life treatment of rheumatoid arthritis (RA).

Methods: RA patients registered in the Hong Kong Biologics Registry who were receiving bDMARD monotherapy (without concomitant conventional synthetic DMARDs [csDMARDs] except low dose prednisolone) were identified. The efficacy (clinical response and drug retention rate) of bDMARD monotherapy was compared with bDMARD combination therapy (with csDMARDs) using statistical testing.

Results: From December 2007 to April 2017, 2123 courses of bDMARDs/csDMARDs were used in 1250 RA patients (83% women, mean age at therapy 53.8±12.7 years). Among 1881 courses of therapies with complete data, 164 (8.7%) was monotherapy at baseline. Low dose prednisolone (<10 mg/day) was used in 56% of these courses. In the combination group, the commonest csDMARDs used in combination with bDMARDs were methotrexate (79%), sulphasalazine (27%), hydroxychloroquine (25%) and leflunomide (21%). The bDMARDs/csDMARDs most frequently used as monotherapy were tocafitinib (14.3%), tocilizumab (11.6%) and abatacept (11.2%). Overall, the non-TNF was more commonly used as monotherapy (11.2%) than the anti-TNF bDMARDs (7.4%). At 6 months of bDMARD/csDMARD therapy, the DAS remission rate was non-significantly higher in the bDMARD monotherapy group (11% vs 5%; p=0.42). The change in DAS28 score was also non-significantly greater in the combination group (−1.95±1.26 vs −1.68±1.56; p=0.30). The difference in 6 month efficacy between the combination and monotherapy groups was greater in anti-TNF users. The overall cumulative withdrawal rate of the bDMARDs/csDMARDs due to either inefficacy or serious adverse events (SAEs) was 0.55 at 3 years and 0.47 at 5 years. The anti-TNF biologics had a significantly higher withdrawal rate than the non-TNF biologics (hazard ratio [HR] 1.83 [1.56–2.14]; p<0.001). In Cox regression models, monotherapy of the bDMARDs was not significantly associated with drug withdrawal due to inefficacy (HR 0.95 [0.53–1.71]; p=0.87) or SAEs (HR 1.27 [0.51–3.19]; p=0.61) after adjustment for age, sex, anti-TNF (vs non-TNF) biologic use, previous use of bDMARDs (vs first time use) and DAS28 at baseline. Separate analyses of the anti-TNF and non-TNF biologics showed no significant association between the combination and monotherapy of the biologics with the drug withdrawal due to inefficacy or SAEs after adjustment for age, sex, previous use of bDMARDs and disease activity at baseline (HR 1.02 [0.56–1.80]; p=0.99 for anti-TNF and HR 1.20 [0.47–3.08]; p=0.70 for non-TNF biologics, respectively).

Conclusions: Monotherapy of bDMARDs was used in 8.7% of our RA patients in real life practice, probably due to intolerance, inefficacy or non-compliance to the csDMARDs. Short-term efficacy tended to be better with bDMARDs/csDMARDs combination, especially in the anti-TNF biologics, but the long-term drug retention rate was similar between bDMARD monotherapy and combination therapy with the csDMARDs.

Disclosure of Interest: None declared

conventional DMARD-experienced ABA- and TOF-treated pts. Treatment-related death was not analysed in an NMA due to insufficient data. 

Results: Thirty-one randomized controlled trials (n=13,978) were included for data extraction. Of these, ABA and TOF were examined in 16 and 15 trials, respectively. There were no head-to-head comparisons of ABA vs TOF. Most of the trial population were Caucasian (48%–98% across trials), had an average age ranging from 40 to 60 years and were predominantly female (60%–90%). Of the trials, 26 included a US population and 5 a non-US population. Out of 11 studies reporting treatment-related mortality, one study reported four deaths for pts on TOF 5 mg (n=321) within a 1 year follow-up. No such deaths were reported for ABA pts. The NMAs showed no significant differences in the risk of TRAEs for pts on TOF 5 or 10 mg compared with ABA with/without MTX (TOF 5 mg+MTX vs ABA+MTX: risk ratio [RR] 1.1, 95% CI: 0.77, 1.5; TOF 10 mg vs ABA: RR 1.1, 95% CI: 0.78, 1.6). These findings remained consistent for the risk of total AEs and serious infections.

Abstract AB0427 – Figure 1. PRISMA Diagram Showing Study Selection

*One reference identified manually from a ClinicalTrials.gov record

1Wrong publication date cut-off: meeting abstract published before 2015

Conclusions: Without head-to-head trials, the data available to make comparisons between abatcept and TOF are limited. Even after conducting an SLR and NMAs, precision is lacking in estimating differences. Additional studies, such as real-world observational analyses with larger patient samples and higher incidence of measured outcomes, are needed to further examine the safety differences of abatcept vs TOF.

AB0428

PREFERENCES IN THE USE OF BIOLOGIC DRUGS AND ADVERSE EVENTS IN PATIENTS WITH RHEUMATIC DISEASE FROM A NATIONAL BIOLOGICS REGISTRY IN MEXICO

D. Xibillé1, S. Carillo2, S. Siciski3, F. Izaguirre4, A. Ramos5, S. Durán6, M. Saavedra1, L. Barile7, G. Olvera8,1, SSM, Cuernavaca; 2Hospital 1 Oct, ISSSTE, México; 3UMAE 71 IMSS, Torreón; 4CMN 20 Nov, ISSSTE, México; 5CMN NE 25 IMSS, Monterrey; 6CIRO SC, Guadalajara; 7HE CMN La Raza, IMSS; 8Colegio Mexicano de Reumatología, México, México

Background: National registries of biologic drugs have proven to be valuable tools in following patients with rheumatic disease and some outcomes in real-life situations.

Objectives: The objective of this study was to describe Mexican Rheumatologists’ preferences when treating patients with biologic drugs and to analyse factors associated to the use of this therapy.

Methods: Data from patients undergoing biologic treatment in México is gathered into the BIOBADAMEX online database, which is part of the BIOBADAMERICA initiative and based on the BIOBADASER Phase 3 platform. Phase 3 in México started gathering patient data in 2014 and to date has information on 216 registries. The database collects information such as gender, age, diagnosis, disease duration, biologic treatment, DMARD treatment, concomitant therapy, motives for discontinuation of biologics, comorbidities, adverse event (AE) severity, infection site and germ involved. Descriptive statistics were applied on the data collected from April 2016 to January 2018.

Results: We analysed data on the use of 267 biologic treatments in 216 patients. Most of them received biologic therapy through socialised medical insurance programs which may have led to bias. 89.1% of patients were female, mean age 49 ±15.2 (4–85) years, 42.5% belonging to the <50 group. 69.9% of patients in the registry have RA, 12.5% AS and 5.5% PsA. Mean disease duration is 11±8.9 (0–58) years. The most commonly used biologic overall is Abatacept (15.3%), followed by Adalimumab (15.8%), Tocilizumab (11.2%), Certolizumab (10.1%), Golimumab (8.6%), Infliximab (8.2%), Etanercept biosimilar (7.4%), Etanercept (6.3%), Inflix, including JAK inhibitors and Benifylida (1.1%). All others, including IL6 inhibitors, are used in <1% of patients. The preference for first biologic drug was Etanercept (32.4%), followed by Adalimumab (12%), Infliximab (8.3%), Tocilizumab and Certolizumab (5.5% each) and Abatacept (2.7%). Most treatments were stopped due to lack of efficacy (60%), disease remission (7%), other causes (20%), AE (4.4%), with the rest of the causes affecting 3% of patients. The most commonly used DMARD were Methotrexate (49.8%), steroids (33.3%) and Lefunomide (23.2%). Comorbidities were present in 87 patients (40%), the most common being Hypertension (13.4%), Diabetes (7.8%) and Dyslipidemia (6.9%). Non-lymphoma neoplasms were reported in 1.3%. 25% of AE were considered serious but most (70%) were mild. Only 6 patients reported infections with the most common sites being the skin (33.3%), urinary tract (16.6%) and middle-ear (16.6%). The causal germ was often undetermined (60%).

Conclusions: When using biologic drugs, TNF inhibitors are the most commonly used initial mechanism of action for the treatment of rheumatic diseases in the BIOBADAMEX registry. Upon treatment failure, patients undergo a switch to another mechanism of action, mainly using Abatacept. Adverse events and infections related to the use of biologics are infrequent, but 40% of patients present chronic comorbidities.

AB0429

NO DIFFERENCE IN EFFECTIVENESS WITH EITHER ETAÑERCEPT ORIGINATOR OR BIOSIMILAR AS FIRST LINE BIOLOGIC TREATMENT FOR RHEUMATOID ARTHRITIS

D. De Cock1, R. Davies1, L. Kearsley-Fleet2, K. Watson3, K. Hrych1,2, on behalf of the BSRBR-RA contributor group. 1Arthritis Research UK Centre for Epidemiology, Manchester University; 2Manchester Academic Health Science Centre, Central Manchester NHS Foundation Trust, Manchester, UK

Background: Biosimilars and their reference agents have been shown to be equivalent in clinical trials. In the United Kingdom, etanercept biosimilars (E-TA-B) are, since 2016, a first-line treatment option for the management of severe rheumatoid arthritis (RA) defined as no response to 2 or more csDMARDs. However, real world data, including how it compares to the etanercept originator (E-TA-O) are lacking.

Objectives: This study aims to compare the short-term effectiveness of etanercept originator with its biosimilar in patients with RA when used as a first biologic following csDMARDs.

Methods: This study included patients with RA registered with the British Society for Rheumatology Biologics Registers for RA (BSBR-RA) at the point of starting either ETA-O or ETF-A between 2011 as their first biologic. Baseline information is collected at drug start and includes demographic and clinical data. Follow-up (FU) data are captured every 6 months and include details on therapy changes, current disease activity, and development of any adverse events. The primary outcome of this study is effectiveness as calculated by change in the 28 joint count disease activity score (DAS28). Only patients with a complete DAS28 at baseline and their 1st FU were included in the final analysis of this study. Hazard ratios (HR) comparing drug survival and risk of first serious adverse event (SAE) between ETA-O and ETA-B patients were calculated using Cox regression.

Results: Between January 2010 and 11 December 2017, 1217 and 412 patients, starting ETA-O or ETA-B respectively were recruited and had ≥1 FU available. Complete DAS28 data at baseline and 1st FU were available for 740 ETA-O patients and 177 ETA-B patients. Patient characteristics were similar between the 2 cohorts (Table). After adjusting for baseline differences, no difference between groups was seen in DAS28 (p=0.1) or remission status (p=0.1) at 1st FU.
Nine (5%) and 48 (6%) of ETA-B and ETA-O patients had stopped their respective treatments by the 1st FU. The adjusted hazard ratio for stopping ETA-O versus ETA-B over this time period was similar (HR=0.8 (0.4-1.6); p=0.5). Risk of SAEs associated with treatment response were identified using univariate and multivariable logistic regression analyses. Baseline factors included the clinical, laboratory, imaging, and anamnestic data.

Conclusions: In the UK, etanercept biosimilars are now frequently used as first-line biologic in RA patients. These short-term follow-up data demonstrate in routine clinical care that ETA-B appears to be equivalent to ETA-O in terms of short-term effectiveness, drug survival and safety.

SUBJECTIVE ASSESSMENTS OF PATIENTS WITH RHEUMATOID ARTHRITIS REPORTED THAT BIO-HOLIDAY THERAPY BROUGHT THEM FINANCIAL AND PSYCHOLOGICAL IMPROVEMENTS

E. Torikai1, D. Suzuki1, M. Suzuki2, Y. Matsuyama2.1Department of Rheumatology, Iwata city hospital, Iwata; 2Department of Orthopaedic surgery, Hamamatsu university school of medicine, Hamamatsu, Japan

**Background:** At EULAR 2016 and 2017 we reported that it is possible to maintain disease activity, radiographic progression, physical function, and bone metabolism status in rheumatoid arthritis (RA) patients with clinical disease activity index (CDAI) remission using the biologic agents (Bio)-holiday therapy. Currently, in RA therapy, subjective assessment of patients as well as objective assessment of doctors is becoming more important.[1]. How does the patient think about Bio-holiday therapy?

**Objectives:** We conducted questionnaire survey in RA patients with CDAI remission who underwent Bio-holiday therapy or Bio-continue therapy to evaluate the benefits of their therapies and to clarify the number of patients concerned about flare-up.

**Methods:** The first and second survey comprised 9 and 11 questions, respectively; each provided predefined answers. In the first survey, we questioned 85 RA patients in CDAI remission: those treated with any DMARDs. We asked them whether a patient who underwent Bio-holiday therapy or Bio-continue therapy was assured of retreatment with Bio in case of a flare-up.

**Results:** Patients in both groups were equally satisfied with the improvement of their disease activity and progression of ADL. Reduction of the anxiety living, which are important for patients with CDAI remission. Interestingly, improvement of emotional depression is the higher in BH group than in BC group. Anxiety regarding high medical expenses was lower than that in BC group. Anxiety regarding flare-up was equal to that in BC group as patients were assured of retreatment with Bio in case of a flare-up.

**Conclusions:** Patients in both groups were equally satisfied with the improvement of their disease activity and progression of ADL. Reduction of the anxiety regarding treatment costs and flare-up in Bio-holiday therapy also helped to improve psychological aspects. Therefore, we recommended Bio-holiday therapy for RA patients with CDAI remission.

EARLIER AGE AT THERAPY INITIATION IS ASSOCIATED WITH BETTER RESPONSE TO TOCILIZUMAB THERAPY IN PATIENTS WITH JUVENILE IDIOPATHIC POLYARTHRITIS

E. Alexeeva1,2, T. Dvoryakovskaya1,2, M. Spoloshenko1, R. Denisova1, K. Isayeva1, A. Mamutova1, V. Gladkikh3,4, A. Moskaliev3,4, 3National Medical Research Center for Children’s Health; 4Sechenov First Moscow State Medical University (Sechenov University, Moscow, 2EOL Labs Ltd, Department of Biostatistics; 4Institute of Computational Mathematics and Mathematical Geophysics SB RAS, Novosibirsk, Russian Federation

**Background:** The use of therapy with anti-cytokine biologics in routine practice has significantly increased the percentage of children showing good response to therapy and reduced the time to achieve pharmacological remission. Nevertheless, the problem related to selecting the optimal drug for a certain patient still remains to be solved.

**Objectives:** This study was aimed at identifying clinical and laboratory parameters associated with response to tocilizumab (TOC) therapy in patients with RF-negative polyarticular JIA.

**Methods:** The prospective study to assess TOC efficacy involved 55 patients with RF-negative polyarticular JIA aged 9.42 years (IQR 5.96–13.42), with females (85.5%) predominating was conducted at the National Medical Research Centre of Children’s Health (Moscow). Treatment efficacy was evaluated using the ACRPedi criteria; Wallace’s criteria were used to assess whether a patient had reached inactive disease or remission. The potential baseline characteristics associated with treatment response were identified using univariate and multivariate logistic regression analyses. Baseline factors included the clinical, laboratory, and anamnestic data.

Disclosure of Interest: None declared
Results: TOC therapy showed high efficacy in children with RF-negative polyarticular JIA: 81.8/87.3/47.3/23.6% of patients reached the ACR30/50/70/90 criteria for the end of follow-up, respectively. The median time of achieving at least 30% improvement from baseline (ACR30) was 1 month (IQR 1:3).

Univariate analysis showed that earlier age at initiation of Tocilizumab therapy, higher physician’s global assessment score using the 100-point Visual Analogue Scale, and longer morning stiffness were the factors associated with reaching ACR90. Younger age at therapy initiation, greater number of swollen joints and joints with limited range of motion, and history of using fewer biologicals are the factors associated with reaching inactive disease and remission. However, multivariable analysis showed that only earlier age at initiation of TOC therapy was a statistically significant factor associated with reaching the best response to therapy in all the models.

Conclusions: Earlier initiation of TOC therapy is associated with higher chances for reaching ACR90 and pharmacological remission in patients with RF-negative polyarticular JIA. Further studies in larger cohorts are needed to identify the optimal age at therapy initiation.

THE INFLUENCE OF BODY MASS INDEX ON THE Efficacy of TUMOUR NECROSIS FACTOR BLOCKING THERAPY AND Disease Activity in Patients with RHEUMATOID ARTHRITIS

E.N. Mole1, K. Zoupidou1, A. Alexoudis1, E. Koutsantoni2, C. Stfontouris2, S. Gazi1. 1Department of Rheumatology, General Hospital of Attica “KAT”; Kifisia; 2Department of Rheumatology, General Hospital of Athens “Evaggelismos”, Athens, Greece

**Background:** The impact of Body Mass Index (BMI) on efficacy of TNF blocking therapy in Rheumatoid Arthritis (RA) patients and therefore on control of the disease is an important question.

**Objectives:** The aim of this study is to determine the influence of BMI on the efficacy of TNF blocking therapy in terms of disease activity in patients with RA.

**Methods:** A retrospective, observational study of 168 consecutive RA patients who received subcutaneously (SC) TNF blocking treatment (adalimumab, etanercept, golimumab and certolizumab pegol). Their follow-up data, for at least 26 weeks, and their baseline BMIs were available. The WHO definition for normal weight, overweight and obesity was applied, whereas clinical response was compared by BMI subgroups.

**Results:** The average BMI was 26.8±3.4 kg/m² and the baseline Disease Activity Score in 28 joints (DAS28 [ESR]) was high at 5.72±0.84. Mean age was 53.4±12.58 years and 135 (80.36%) were female. The median disease duration was 13.01±8.57 years. Overall, patients with normal weight responded better to treatment regimen, followed by overweight and obese subgroups. After a follow-up period of 26 weeks, the obese group had significantly higher DAS28 (ESR) and Health Assessment Questionnaire (HAQ) than either normal or overweight subgroups (3.26±0.84 vs 2.61±0.82, p<0.001, 0.42±0.002 vs 0.07±0.01 vs 0.17±0.01, p<0.001 respectively). Furthermore, obesity was significantly associated with a decreased tendency of achieving week 26 remission, based on DAS28 (<2.6) p<0.002 and normal HAQ (<0.5) p=0.003.

**Conclusions:** Patients with RA and higher BMIs demonstrated a diminished clinical response after 26 weeks of SC-administered TNF-blocking treatment compared with their counterparts with lower BMIs.

THE TREATMENT PATTERN OF TOCILIZUMAB in PATIENTS with RHEUMATOID ARTHRITIS in CHINA: A MULTICENTER OBSERVATIONAL STUDY

F. Zhang, on behalf of Lijun Wu, Lingli. Dong, Yasong. Li, Changhong. Xiao, Xiaofei. Shi, Yan. Zhang, Qin. Li, Yi. Liu, Bin. Zhou. Peking Union Medical College Hospital, Beijing, China

**Background:** Tocilizumab (TCZ) is a humanised monoclonal antibody targeting interleukin-6 receptor. Since TCZ Label for RA has been issued in many countries, administration patterns and dose modifications for managing adverse events (AEs) seems differ depending on clinical opinion. Few data are available from real world practice in China.

**Objectives:** To observe in routine clinical practice the treatment patterns of TCZ in RA patients with regard to persistence on drug and adherence to the licensed label recommendations.

**Methods:** This a 6 month non-interventional, multi-centre study enrolled patients with moderate to severe RA diagnosed per revised 1987 ACR criteria (age >18 years) and being treated with TCZ. Data was recorded during routine visit. The primary variable was the proportion of patients on TCZ treatment after 6 months.

**Results:** Of 407 patients from 23 centres in China, 396 were eligible, including 330 (83.3%) women. The mean age was 49.1±13.44 years. The mean RA diagnosis course was 5.4±6.24 years. Among 396 patients, 250 (63.1%) were RF positive, 235 (59.3%) were anti-CCP positive and 123 (31.1%) had anaemia (Hb <90 g/L). Of eligible patients, 293 (74.0%) completed the study. The primary reason of premature termination was treatment costs (n=49, 12.4%). There were 37 (9.3%) patients received anti-TNF biologics previously and 330 (83.3%) received concomitant DMARDs, of which 84 (21.2%), 149 (37.7%) and 97 (24.5%) received single, 2 or >3 types of DMARDs, respectively. Methotrexate (n=255, 64.4%) and Leflunomide (n=184, 46.5%) were the most commonly used DMARDs. A total of 126 and 197 patients received corticosteroids or nonsteroidal anti-inflammatory drugs (NSAIDs), respectively. During 6 months observation, 21.0% and 67.7% had TCZ dose modification or discontinuation, respectively. At month 3 and month 6, 161 (40.7%) and 102 (25.8%) kept TCZ treatment, respectively. The mean frequency of TCZ usage was 3.7±1.62. Effectiveness of TCZ was analysed in patients who were still using TCZ at month 6. The mean score of total TJC (28-joint count) at baseline and at month 6 was 11.2±8.0 (n=63) and 2.3±4.12 (n=77), respectively; mean change from baseline was –9.5±8.02 (n=53). The mean score of total SJC (28-joint count) at baseline and at month 6 was 8.0±8.81 (n=63) and 1.7±3.35 (n=77), respectively; mean change from baseline was –6.5±7.2 (n=53). The mean score of DAS28 at baseline and at month 6 was 6.13±1.33 (n=56) and 2.79±1.39 (n=66); mean change from baseline was –3.45±1.48 (n=46). Patients in low disease activity (DAS28 <3.2) or remission (DAS28 <2.6) in those who still using TCZ at month 6 was 63.6% and 51.5%. The mean change in TJC (28-joint count) from baseline to month 6 was 9.09±5.58 (n=34) and 40.74±15.81 (n=28), respectively. One patient died of severe pneumonia.

**Conclusions:** This was the first real-world study in RA patients treated with TCZ in China. The results show that Chinese RA patients have long disease history. TCZ was frequently used in combination with DMARDs, especially with >2 types of DMARDs. Compared with the dose recommendations, shorter treatment duration and longer dose interval of TCZ were found in China. TCZ demonstrated effectiveness in treatment of Chinese RA patients in real-life clinical practice with manageable safety profile.

**Acknowledgements:** This study was sponsored by Shanghai Roche Pharmaceuticals Limited.

CONSOLIDATED LONG-TERM SAFETY of INFliximab IN INFLAMMATORY ARTHRITIS FROM A PROSPECTIVE, OBSERVATIONAL REGISTRY

D. Choquette1, P. Rahmani2, A. Chow1, R. Farawa1, W. Olzynski3, E. Rampaakis4, O. Asin-Milan5, B. Osborne6, A.J. Lehman7, Nangle7. 1Institut de Rhumatologie de Montreal, Montreal, QC; 2Memorial University, St-Johns; 3Credit Valley Rheumatology, Mississauga; 4McMaster University, Hamilton; 5Polmed Research Inc, Saskatoon; 6JSS Medical Research, Montreal; 7Lijun Wu, Lingli. Dong, Yasong. Li, Changhong. Xiao, Xiaofei. Shi, Yan. Zhang, Qin. Li, Yi. Liu, Bin. Zhou. Peking Union Medical College Hospital, Beijing, China

**Background:** Lysed data on inflammatory arthritis patients treated with infliximab (IFX), golimumab and ustekinumab. Patients specifically treated with IFX were recruited from July 2002 to June 2015 and followed up to June 2017.

**Objectives:** The objective of this abstract is to document the final consolidated safety data from the BioTRAC IFX cohort.

Disclosure of Interest: None declared

Methods: Treatment was prescribed by the physician per actual clinical practice or standard of care for rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA); there was no randomised assignments to treatment. There were no restrictions on the use of concomitant medications. At enrolment (baseline) and approximately every 6 months thereafter, information was collected to assess safety, clinical outcomes, quality of life, comorbidities, pharmacoeconomics and treatment regimens.

Results: A total of 1390 patients were enrolled and used for this analysis. The proportion of patients by indication was 59.2% for RA (n=890), 25.9% for AS (n=389) and 7.4% for PsA (n=111). The mean (SD) exposure was 3.10 (3.26) years for a sum of 4290.25 patient-years. Treatment with IFX was generally safe, with AEs and SAEs being reported for 64.3% and 19.5% of patients, respectively. The incidence rate of AEs and SAEs was 116.0 and 11.2 events per 100 pt-ys, respectively. More specifically, 338 SAEs were reported by 189 (21.2%) RA patients [SAEs/100 pt-yrs: 11.7], 150 SAEs were reported by 60 (15.4%) AS patients [SAEs/100 pt-yrs: 10.5] and 28 SAEs were reported by 22 (19.8%) PsA patients [SAEs/100 pt-yrs: 8.82]. The most commonly reported AE identified was arthralgia, viral upper respiratory tract infection, upper respiratory tract infection and nausea. For SAEs, the most commonly reported SOC (≥3% of patients) was “Infections and infestations” (5.3% (n=73); 2.16 SAEs/100 pt-ys) and “Neoplasms benign, malignant and unspecified” (5.5% (n=49); 1.24 SAEs/100 pt-ys) which occurred at similar rates to the general RA patient population and included two lymphomas (0.1%; 0.05/100 pt-ys). Across 3 closely monitored categories of AEs, a total of 302 closely monitored AEs were reported by 293 (21.1%) patients, including cancer (3.7%), lack of efficacy (17.1%) and tuberculosis (0.2%). A total of 21 deaths were reported during the study in 18 RA, 1 AS and 2 PsA patients. Cause of death included MACE (x5), lung cancer (x2), pulmonary fibrosis (x2), pneumonia (x2), respiratory failure, bronchitis, intestinal cancer, thyroid cancer, intestinal gangrene, disseminated TB, septic shock, procedural complication and drowning. The cause of death was not known for one patient.

Conclusions: The results of this longitudinal observational study showed that treatment with IFX was well tolerated in people living with AS, PsA and RA over a 15 year period in a real-world setting.

AB0437

ADALUMUMAB THERAPY RESULTS IN SUSTAINED RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS OVER 5 YEARS: THE GERMAN NONINTERVENTIONAL AGIL STUDY

F. Behrens1, M. Schmalzing2, M. Koehm3, E.C. Schwaneck2, G. Gregor3, T. Mosch1,3, H. Burkhardt1, H. P. Tony1,2,3, R. Rheumatology, Goethe-University Frankfurt, Frankfurt am Main; 2Rheumatology/Immunology, Universitätshospital Würzburg, Würzburg; 3AbbVie Deutschland, Wiesbaden, Germany

Background: Observational studies provide important insights into therapeutic response during daily clinical practice, including data on the effects of long-term treatment.

Objectives: To evaluate treatment responses in rheumatoid arthritis (RA) patients during 5 years of adalimumab (ADA) therapy.

Methods: We analysed data from a large German multicenter observational study of patients with active RA who initiated ADA therapy during routine clinical care (the AGIL study). Outcomes of interest included Disease Activity Score-28 joints (DAS28), DAS28 therapeutic response as assessed by the statistical critical difference (dcr),1 Health Assessment Questionnaire-Disability Index (HAQ-DI), and patient-reported global health and pain.

Results: A total of 4283 patients had data available for analysis at baseline. The mean age was 55.2 years, 74% of patients were female, the mean disease duration was 9.3 years, and 26% had received previous treatment with one or more biologic drugs. At month 60, 726 patients (17%) of patients remained in the study. During the 5 year study, 41.3% of patients were lost to follow-up, 22.3% discontinued due to lack of effectiveness (about half within the first 6 months), and 4.0% discontinued due to adverse events. Mean values in patients treated with ADA showed a rapid response to treatment by both objective and patient-reported measures. Responses were maintained over 5 years in patients remaining on therapy (table 1). ADA was well tolerated and no unexpected safety signals were observed.

Abstract AB0437 – Table 1. Therapeutic response to ADA in the AGIL study. Values are presented as mean (standard deviation) unless otherwise indicated

Conclusions: The AGIL study is one of the largest observational cohorts to provide long-term data on ADA therapy. Both objective and subjective measures support the effectiveness and safety of ADA in patients with RA during 5 years of therapy. Approximately 43% of patients experienced a therapeutic response to treatment at 6 months as assessed by statistical methods (DAS28-dcr),1 and this level of response increased to 60% at 5 years in patients remaining on therapy. About one-third of patients recovered full functional ability (HAQ-DI remission) at the 6 month and subsequent visits. Our data indicate that ADA is an effective and safe long-term therapy in RA patients who continue on treatment.

AB0438

SAFETY OF TNP BLOCKERS IN CASE OF NON-ALCOHOLIC FATTY LIVER DISEASE AND CIRRHOsisA SYSTEMATIC REVIEW

F. Verhoeven1,2, D. Weil-Verhoeven3, T. Thevenot3,4, C. Prati1,2, V. Di Martino3,4, D. Wendling1,4, R. Rheumatology, CHRUL de Besançon; 2EPID, Université de Bourgogne Franche Comté; 3Hepatology, CHRUL de Besançon; 4EA 4266 EPILAB, Université de Bourgogne Franche Comté, Besançon, France

Background: The management of inflammatory rheumatisms and psoriasis has largely evolved over the last 15 years with the emergence of biotherapies whose main adverse effect is the increased infection risk. The prevalence of metabolic syndrome is increasing and has been estimated at 30% in patients with rheumatoid arthritis with an excess of 45% compared to healthy subjects. One of the major complications of the metabolic syndrome is the Non Alcoholic Fatty Liver Disease (NAFLD), which prevalence is 25% in the global population, and 30% in a cohort of patients with rheumatoid arthritis. The main complication of NAFLD is

Scientific Abstracts 1381
the development of cirrhosis, known to increase infectious risk. Surprisingly, there are no data on the safety of TNF antagonists in patients with chronic inflammatory disease and NAFLD or cirrhosis.

Objectives: To assess infectious and liver safety of the main TNF blockers used in chronic inflammatory diseases in patients with cirrhosis or NAFLD.

Methods: A systematic review of the literature, following the Prisma recommendations, was conducted on the PubMed and Embase databases with the following keywords: "adalimumab", "infliximab", "etanercept", "certolizumab", "golimumab". The search terms "AND" liver cirrhosis, "AND" non alcoholic fatty liver disease. We selected only studies including patients treated with TNF blockers and with cirrhosis or ultrasurally characterised NAFLD. We excluded animal models and non-English articles.

Results: We identified 39 articles and only 11 fulfilled the inclusion criteria. 9 Case Reports have reported the tolerance of TNF-blockers in patients with cirrhosis and one controlled study (44 patients) assessed the safety of etanercept in case of NAFLD. One study (7 patients) investigated the impact of infliximab in refractory autoimmune hepatitis. The cause of cirrhosis was primary biliary cholangitis (5 cases), alpha1 antitrypsin deficiency (4 cases) and post hepatitis B cirrhosis (2 cases). All cirrhosis were compensated. Inflammatory diseases requiring the introduction of TNF blocker were rheumatoid arthritis (n=5), psoriatic arthritis (n=4), ulcerative colitis (n=2) and psoriasis (n=44). The TNF-blockers prescribed were adalimumab in 2 patients, infliximab in 11 patients and etanercept in 49 patients. The duration of treatment ranged from 6 to 24 months. For the 9 cirrhotic patients with an inflammatory disorder, no infection was reported and two of them (2 cases of primary biliary cholangitis) even had an improvement in liver function secondary to the introduction of biotherapy. For the 7 patients receiving infliximab to treat autoimmune hepatitis, 5 patients presented recurrent infections. For patients with NAFLD, no infectious event was reported and an improvement of the hepatic biological parameters was observed, suggesting an improvement in liver function.

Conclusions: The results of this review suggest that in case of compensated cirrhosis, TNF-blockers were not deleterious for the liver and did not increase the infectious risk. In case of auto-immune cirrhosis, TNF-blockers increased the infectious risk. In case of NAFLD, TNF-blockers might improve liver function and prevent fibrosis.

ETHNIC MINORITIES EXPERIENCE INFREQUENT BIOLOGIC SWITCH DESPITE ACTIVE RHEUMATOID ARTHRITIS DISEASE

G. Kerr1, on behalf of EMRAC, C. Sweering2, S. Hochberg3, J. Udé3, Y. Yazici2, on behalf of Ethnic Minority Rheumatoid Arthritis Consortium.

Washington, DC New York University, New York, USA

Background: The expanded therapeutic modalities in rheumatoid arthritis (RA) provide options to achieve low disease activity or remission. Yet, in routine care, the frequency and choice of switching of biologic DMARD (bDMARD) amongst ethnic subsets when there is inefficacy, is unknown.

Objectives: To evaluate frequency and choice of biologic switch in ethnic RA subsets.

Methods: Patients enrolled in the Ethnic Minority RA Consortium (EMRAC), with at least one followup visit with data collected included clinical outcomes assessed by RAPID3 tender/swollen joint counts; medication use (prednisone, methotrexate, other DMARD), and bDMARD (Tumour Necrosis factor inhibitors (TNFi) and non-TNFi). Minimally clinical improvement (MCI) in RAPID3 was defined as a decrease of ≥3.2 points during followup. Differences between medication usage, biologic switch, and RAPID3 improvement between race and ethnicity groups while on biologics, was investigated.

</table>

TNF: adalimumab, certolizumab, etanercept, golimumab, infliximab.

Non-TNF: abatacept, anakinra, tocilizumab, tofacitinib, rituximab.
Results: 1040 subjects with 3719 follow-up visits spanning an average of 63.2 weeks were analysed. African Americans and Hispanics comprised 24% and 13.5%, respectively. Compared to Whites, African Americans had significantly less education (p<0.001 for both), significantly less biologic use (p<0.001 for both) and significantly less TNF use (p<0.001 for both). African Americans had significantly higher RAPID3 scores at enrollment than Whites as well (p=0.018).

Switching between TNFi and non-TNFi was recorded in only 9 subjects, with 7 subjects switching from TNFi to non-TNFi. There was no statistical difference between race/ethnic groups in frequency of bDMARD switching, nor within bDMARD class (TNFi class, p=cc; non-TNFi class, p=bb). bDMARD treatment led to MCI in RAPID3 in 101 (38%) subjects and in more African Americans (29 [48%]) and Hispanics (12 [41%]) than in Whites (49 [37%]) (but not statistically significant).

Conclusions: In our cohort, disparity was seen in bDMARD use between race and ethnic groups but had similar and infrequent biologic switch. Based upon these data, efforts to eliminate biologic use disparity remains paramount and supersedes concerns regarding disparity in biologic switching.

AB0443

THE EFFECTS OF DENOSUMAB FOR RHEUMATOID ARTHRITIS PATIENT

I. Yoshi. Rheumatology and Musculoskeletal Medicine, YOSHII HOSPITAL, Shimanto City, Japan

Background: Denosumab (dMAB), an anti-receptor activator of nuclear factor kappa-B ligand (RANKL) monoclonal antibody, is now popular anti bone absorption suppressant for osteoporosis. Recently, this drug has indicated for rheumatoid arthritis (RA) treatment, for expectation for suppressant in joint destruction. However, except of the effect on joint deformation, anti inflammation effect is not evident in randomised control trial (RCT), although rich case series for OP in RA patient is already collected in clinical practice.

Objectives: Aim of this study is to investigate effects of dMAB on RA, and evaluate other effects but joint destruction suppression.

Methods: In 352 patients who have been treated with dMAB, RA patients who have been treated with dMAB consecutively for more than 1 year, were picked up for this study. Patient who have had experience of biologic disease modifying anti rheumatic drug (bDMARD) or targeted synthetic DMDARD, had been eliminated. In whom bone mineral density (BMD) in lumbar spine (LS), femoral neck (FN), and greater trochanter (GT), and tartrate-resistant acid phosphatase 5b (TRACP5b), 28-joints disease activity score with C-reactive protein (DAS28-CRP), Health Assessment Questionnaire Disease Index (HAQ-DI), yearly progression of Sharp/van der Heijde score (dSHS), and bone erosion score (dBE), and pain score with visual analogue scale (PS-VAS) were measured, and their mean values were compared between 6 months before start (BEF) and 6 months after start (AFT) statistically with paired T-test. Statistically significant level was set less than 1%.

Results: One hundred and three patients, in whom 100 were female and three were male, were donated in this study. All of them had been supplemented with Denotas Chewable Combination Tablets (Daichi Sankyo Co., Ltd., Tokyo, Japan), which is medical compound with calcium and natural vitamin D3. Average age at start was 71.17 years old, and disease duration of RA at start was 7.42 years. Glucocorticoid was administered in 45 patients (44.7%), and methotrexate was administered in 72 patients (69.9%). BMD demonstrated from 74.03 (%YAM) to 77.32 in LS, whereas from 69.79 to 69.63 in FN, and from 71.99 to 74.27 in GT, from BEF to AFT, respectively. BMD of LS and GT at AFT demonstrated significant increase, while FN demonstrated no significant difference. TRACP5b demonstrated 489.3 at BEF, while 255.3 at AFT. TRACP5b at AFT demonstrated significant less value than at BEF. Disease activity, namely DAS28-CRP, tendererness joint count (TJC), swollen joint count (SJC), patient’s global assessment (PGA), evaluator’s global assessment (EGA), CRP, pain score with visual analogue scale (PS-VAS), HAQ-DI, GS, and pain score with visual analogue scale (PS-VAS) were measured, and their mean values were compared between 6 months before start (BEF) and 6 months after start (AFT) statistically with paired T-test. Statistically significant level was set less than 1%.

Conclusions: The effect of dMAB on RA is suggested suppression of dBE, BMD increase in LS and GT, improvement of DAS28-CRP, and may have decrease of PS-VAS.

AB0444

DESCRIPTION IN REAL-WORLD OF THE EFFICACY AFTER SWITCHING FROM INTRAVENOUS TO SUBCUTANEOUS ADMINISTRATION OF TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS. THE ROSSWITCH STUDY

Rheumatology, University Hospital, Lille; Rheumatology, General Hospital, Armentières; Rheumatology, University Hospital, Amiens; Rheumatology, General Hospital Victor Provo, Roubaix; Rheumatology, Institut François Calot, Berck-sur-Mer; Rheumatology, University Hospital Maison Blanche, Reims; Clinical Operations, Roche SAS, Boulogne Billancourt; Medical, Chugai Pharma France, Paris La Défense; Rheumatology, Private Practice, Valenciennes; Rheumatology, University Hospital Roger Salengro, Lille, France

Background: It has been proven, in a pivotal RCT, that SC tocilizumab (TCZ) was non-inferior to IV TCZ. However the switch from IV to SC TCZ has not been evaluated to date in a large real-world study.

Objectives: The main objective was to assess the maintenance of efficacy of SC TCZ 6 months (M6) after switching from IV to SC formulation in patients with rheumatoid arthritis (RA) in real-world. Secondary objectives were: characteristics of pts and RA, efficacy of TCZ at M12, TCZ retention rates at M6 and M12 for Switch and 2.9±2.1 months in No-Switch pts. Mean DAS28 at Switch was 2.1±1.1 in Switch and 2.9±1.6 in No-Switch pts. 81.9% and 59.5% of the pts were in DAS28 remission/LDA, 18.1% and 28.6% in MDA, 0% and 11.8% in HAD in Switch and
Therapeutic maintenance of abatacept in physician-reported behaviours and maintenance in remission/LDA category

* Permanent discontinuation of TCZ considered as failure.

Using the IPTW for balancing on baseline characteristics between groups, similar proportions were observed at both M6 and M12. TCZ retention rates at M12 were 78% (95% CI 72.4–86.2) and 80% (95% CI 74.5–85.9) for Switch and No-Switch groups respectively. In the 208 pts with a DAS28 >3.2 at inclusion, multivariate analysis showed no parameters associated to the switch. Conversely in the 108 pts with a DAS28 >3.2 at inclusion, rheumatoid nodules (OR=4.7, 95% CI [1.23–18.55], p=0.024) and duration of IV TCZ before inclusion (OR=1.37, 95% CI [1.08–1.73], p=0.009) were significantly associated to the switch.

Conclusions: The RIoSwitch study showed the maintenance of efficacy at 6 and 12 months in RA pts switching from IV to SC TCZ. Similar efficacy and therapeutic retention rates were observed for No-Switch pts. No factor was associated with the switch in pts in remission/LDA at inclusion suggesting that patient’s personal appreciation was preponderant in the choice of the switch.

Objectives: Study the therapeutic maintenance, associated factor with maintenance at 12 months and reasons for abatecept (ABA) stop in daily practice.

Methods: Retrospective multicentric study, from the RIC Nord de France network, of patients treated for rheumatoid arthritis who received at least one ABA treatment between January 2008 and July 2016. We studied the therapeutic maintenance at 12 months, according to the number of previous bDMARDS and according to the date of initiation (group 1: from 2008 until 31/07/2010 (ABA authorised in anti-TNF failure) and group 2 from 01/08/2010 (ABA authorised in anti-TNF failure) and group 2 from 01/08/2010 (ABA authorised in anti-TNF failure)). Therapeutic maintenance was evaluated using the Kaplan-Meier approach to switch. Conclusions: The RIoSwitch study showed the maintenance of efficacy at 6 and 12 months in RA pts switching from IV to SC TCZ. Similar efficacy and therapeutic retention rates were observed for No-Switch pts. No factor was associated with the switch in pts in remission/LDA at inclusion suggesting that patient’s personal appreciation was preponderant in the choice of the switch.

PHYSICIAN-REPORTED BEHAVIOURS AND TREATMENT TRENDS OF TUMOUR NECROSIS FACTOR INHIBITOR USE: CYCLING VERSUS SWITCHING IN FIVE EUROPEAN COUNTRIES: FRANCE, GERMANY, ITALY, SPAIN AND THE UK

J.R. Curtis1,2, E. Sullivan3, J. Kershaw2, S. Blackburn2, S. Mahaj4, S. Boklage4,5

1University of Alabama at Birmingham, Birmingham, USA; 2Adelphi Real World, Manchester, UK; 3Sanofi, Bridgewater; 4Regeneron Pharmaceuticals, Inc., Tarrytown, USA

Background: Previously, most biologics prescribed for treating rheumatoid arthritis (RA) were tumour necrosis factor inhibitors (TNFi) and it was common practice to prescribe a second TNFi after failure of the first. Biologics with different mechanisms of action (MOA) have become available and 2016 European League Against Rheumatism guidelines recommend cycling to another TNFi or switching to a biologic with a new MOA following failure of the first TNFi.

Objectives: Describe the proportion of patients in 5 EU countries who, after failure of a first TNFi, cycle to a second TNFi (‘TNFi cycling’) vs switch to a treatment with a different MOA (‘Switch’), and identify patient characteristics and physician attitudes associated with TNFi cycling vs switching.

Methods: Data were from the Adelphi Disease Specific Programme (DSP), a cross-sectional survey conducted in 2017 in France, Germany, Italy, Spain and the UK. Rheumatologists prospectively completed records about the next 10 patients with RA who consulted them during the study period; records captured treatment history and clinical details. Patients were included in the analysis if they had been prescribed at least 2 different biologics, their first was a TNFi and their second was known. Patients were assigned to 2 cohorts: ‘TNFi cycling’ patients received a TNFi at first- and a different TNFi at second-line; ‘Switch’ patients received a TNFi at first-line and a non-TNFi at second-line. Bi-variate comparisons of groups were conducted using nonparametric tests as appropriate.

Results: Of the 517 patients (74% women) who were included, the mean age was 61.4±13.3 years. There were 76% positive anti-CCP. ABA was used as monotherapy in 176 patients (34%) and 22% of patients were naïve to bDMARDS. The mean DAS 28-VA at initiation of ABA was 4.7±1.3.

Therapeutic maintenance at 12 months was 68%, this rate is similar to Pan-European Registry. The rate of CRP at initiation seems to have an impact on the maintenance of ABA at 12 months.

REFERENCE:

Disclosure of Interest: None declared

Conclusions: Despite evidence from literature suggesting that RA patients have a better treatment response switching to a non-TNFi after initial TNFi inadequate response and despite the majority of physicians in our study believing that there is a class effect with TNFis, regarding efficacy and safety, 46.5% of patients still cycled to a second TNFi rather than switched to a non-TNFi as second-line therapy.

REFERENCE:

Acknowledgements: Research sponsored by Sanofi and Regeneron Pharmaceuticals, Inc.

Background: Patients with rheumatoid arthritis (RA) often receive methotrexate (MTX) in combination with biologics; however, MTX may be discontinued due to intolerance or to reduce the medication burden once disease control is achieved. Whereas previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO) for the treatment of RA, patient-reported outcomes (PROs) after MTX withdrawal in patients achieving good clinical response (GCR) to TCZ +MTX have not been evaluated. PROs are important measures when determining response to therapy in patients with RA with respect to health-related quality of life (HRQOL).

Objectives: This study evaluated PROs between patients with RA who achieved low disease activity with TCZ +MTX and then continued or discontinued MTX in the COMP-ACT trial (NCT01855789).

Methods: US patients with RA who were inadequate responders to MTX were enrolled; initial combination therapy included MTX (≥15 mg/week orally) plus TCZ 162 mg subcutaneous either weekly (qw) or every 2 weeks (q2w). Patients who achieved DAS28-ESR≤3.2 at Week 24 were randomised 1:1 to receive TCZ-MONO or continue TCZ +MTX until week 52 (double-blind). Changes in PRO scores were measured between Week 24 and Weeks 40 and 52, and included patient global assessment of disease activity (PtGA; VAS), 0–100 mm), pain (VAS), Health Assessment Questionnaire Disability Index (HAQ-DI, 0–3) and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue.

Results: Of the 296 randomised patients (TCZ +MTX, n=148; TCZ-MONO, n=148), 74.8% were women, mean age was 55.5 years, mean RA duration was 6.8 years and mean DAS28-ESR was 6.3 at baseline. At Week 24 (randomization), PRO scores were similar between the randomised treatment groups. The mean changes in PGA, pain, HAQ-DI and FACIT-fatigue scores from Week 24 to Weeks 40 were similar between the TCZ +MTX and TCZ-MONO groups (table 1). The proportion of patients with HAQ-DI <0.5 was similar between the groups at Week 24 (randomization), and remained similar at Weeks 40 and 52.
Impact of Therapeutic Patient Education on Safety Skills and Infectious Events of Patients Treated by Biological DMARDs in Rheumatology: A Bi-centric Study

L. Franger1, M. Ardizzone1, L. Spana1, D. Orfeol1, N. Affl1, L. Arnaud2, J. E. Gottenberg2, J. Sibilia3, C. Sortes4,3, Service de Rhumatologie, GHR Mulhouse Sud Alsace, Mulhouse, 2Service de Rhumatologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

Background: Patients treated with biologic DMARDs have to be aware of the specific adverse events and have to be able to manage their treatments in case of infectious diseases. Therapeutic Patient Education aims to enable patient to acquire these safety skills.

Objectives: To assess the impact of Therapeutic Patient Education on safety skills and management of infectious events in patients treated with biologic DMARDs in rheumatology.

Methods: Bi-centric analytical study comparing safety skills and infectious events between two cohorts of patients (TPE and TPE-naïve). Safety skills were assessed by an auto-assessment called “Biosecure”, rated on a scale from 0 to 100. This assessment explores several dimensions of treatment management and was validated for assessment of safety skills in patients treated with biologic DMARDs in rheumatology in a preliminary study. Infectious events and their management were self-reported by patients. A cluster analysis aimed to separate patients into working group based on their shortcomings (on the basis of their answers to the Biosecure Assessment).

Results: 414 patients answered the assessment. The median Biosecure Score was 70.98/100 (IQR: 60.97–84.63). 47% attended Therapeutic Patient Education. The median Biosecure Score was significantly higher in the TPE group than in the TPE-naïve group (74.88 versus 67.20/100; p<0.05). Regarding the observance to treatment, activity scores, vaccination rates or incidence of infectious events, there were no significant differences between the groups TPE and TPE-naïve. Nevertheless, there were more treatment interruption for infectious events in the TPE-group, suggesting that TPE could lead to better management of treatment during infectious events.

Conclusions: Therapeutic Patient Education could provide better safety skills and better treatment management in patients treated with biologic DMARDs in rheumatology. Prospective studies may confirm the impact of TPE on treatment management during infectious events. Further studies may assess the impact of TPE on incidence of serious infectious events.

AB0452 BIOLOGICAL THERAPY ADVERSE EVENTS IN BIOBADAGUAY REGISTRY

M. Franco1, Z. More1, M.G. Avila-Pedretti2, S. Cabrera-Villabala1, I. Acosta-Colman1, P. Babak1, P. Melgarejo1, G. Elizaur1, P. Delgadillo1, D. Cordovilla Montero1, J. Losanto2, L. Román1, E. Paredes1, J. Mazzoleni1, P. de Abreu4, on behalf of BIOBADAGUAY 1Rheumatology, Hospital Central del Instituto de Previsión Social; 2Rheumatology, Hospital de Clínicas, Asunción, Paraguay; 3Rheumatology, Instituto Nacional de Reumatología, Montevideo, Uruguay; 4Rheumatology, Sociedad Paraguaya de Reumatología, Asunción, Paraguay

Background: BIOBADAGUAY is the Paraguayan/Uruguayan registry of adverse events (AE) in patients with inflammatory rheumatic conditions under biologic therapy (BT).

Objectives: To determine the frequency and severity of AE in patients under BT from the BIOBADAGUAY registry.

Methods: Prospective, observational study of undetermined length to verify the efficacy, safety, and survival of the BT. The methodology applied is available at https://biobadaguay.ser.es. For the present study epidemiological and clinical variables, BT, type and severity of AE were analysed. The incidence rate (IR) was calculated as the total number of adverse events per 1000 patients/year and the incidence rate ratio (IRR) was analysed using the Poisson regression model.

Results: 778 BT were analysed (56.6% adalimumab, 23.7% etanercept, 9.6% tocilizumab, 5.7% rituximab, 3.5% infliximab, 0.5% golimumab, 0.38% abatacept). In these, 330 AE were observed, 256 (77.6%) mild and 74 (24.4%) severe. The global IR of AE was 143.9 (95% CI, 128.8 – 160.8) and 32.6 (95% CI, 25.3 – 40.5), 111.6 (95% CI, 98.4 – 126.2) for severe and mild respectively. The most frequent AE in BT was fever (17.9% (95% CI, 13.0 – 23.3)) and for global, severe and mild respectively. Out of the 39 severe AE, respiratory infections were the most frequent in 43.6% of the cases. 5 tuberculosis, 6 malignancies and 6 deaths were observed.

When analysing the IR according to diagnosis, Idiopathic Juvenile Arthritis (JIA) was associated with a higher IR of global AE when comparing to the other diagnosis (IRR=2.3 [95% CI, 1.6 – 3.4] p=4.27 × 10–6, RA diagnosis was significantly associated with a higher risk of severe AE (IRR=2.20 [95% CI, 1.2 – 4.1] p=1.17 × 10–2), tocilizumab was significantly associated with a higher incidence of global AE (IRR=2.69 [95% CI, 1.90–3.82] p=3.13 × 10–8) and severe ones (IRR=3.34 [95% CI, 1.81–6.1] p=1.10 × 10–4). Adalimumab was significantly associated with a lower rate of global AE (IRR=0.6 [95% CI, 0.4–0.8] p=1.86 × 10–4).

Conclusions: AE were mild in general and infections were the most frequent. In the present study, it was found that JIA and treatment with tocilizumab presented a higher IR of AE while RA presented a higher rate of severe AE.

AB0453 BIOLOGICAL THERAPIES RETENTION RATE IN TWO SUDAMERICAN COUNTRIES. DATA FROM BIOBADAGUAY REGISTRY

M.G. Avila-Pedretti1, P. Melgarejo1, M. Franco1, Z. More1, J.G. Elizaur1, P. Delgadillo1, I. Acosta-Colman2, S. Cabrera1, D. Cordovilla Montero1, J. Losanto2, L. Román1, E. Paredes1, J. Mazzoleni1, P. de Abreu4, on behalf of BIOBADAGUAY 1Rheumatology, Hospital Central del Instituto de Previsión Social; 2Rheumatology, Hospital de Clínicas, Asunción, Paraguay; 3Rheumatology, Instituto Nacional de Reumatología, Montevideo, Uruguay; 4Rheumatology, Sociedad Paraguaya de Reumatología, Asunción, Paraguay

Background: The retention rates (RR) of biological therapies (BT) have been extensively studied in European countries and the United States, but there is a lack of information about them in emerging populations.

Objectives: To analyse BT retention rates and variables associated to them at the BIOBADAGUAY registry.

Methods: Patients with a chronic inflammatory arthritis enrolled in the Paraguay-Uruguay biological registry (BIOBADAGUAY) between 2015 and 2017 where included in the study. Phase I of the study was focused in the global RR analysis and association with clinical and epidemiological variables. In phase II we analysed BT retention rate according to different discontinuation motives and association with clinical and epidemiological variables. Survival analysis was performed using Kaplan-Meier estimators and proportional hazard regression models.

Results: A total of 778 BTs where included in the study (etanercept n=184, adalimumab n=440, rituximab n=44, infliximab n=75, and others n=8). The underlying diagnosis associated to these BTs were rheumatoid arthritis (RA;58.2%), juvenile arthritis (JIA; 14.2%), ankylosing spondylitis (SA; 12.5%), psoriatic arthritis (PA; 8.0%), juvenile idiopathic arthritis (JIA; 14.2%), ankylosing spondylitis (SA; 12.5%), juvenile idiopathic arthritis (JIA; 14.2%), ankylosing spondylitis (SA; 12.5%), juvenile idiopathic arthritis (JIA; 14.2%).

In phase I we found that mean survival times were 322 (±17.9), 315 (±22.32), 289 (±8.52) and 233 (±16.69) weeks for AS, PA, RA and JIA respectively. The survival association analysis has shown that JIA diagnosis (p=2.26 × 10–4, HR=1.80 [95%CI, 1.32–2.46]), corticosteroids (p=1.54 × 10–2, HR=1.98 [95% CI, 1.06–3.70]), and previous BT (p=3.32 × 10–2, HR=1.43 [95% CI, 1.03–1.98]) were variables significantly associated with a lower BT retention.

In phase II, we stratified the survival analysis by cause of discontinuation. We found that corticoids (p=9.48 × 10–4, HR=2.02 [95% CI, 1.33–3.06]), female gender (p=3.46 × 10–2, HR=1.86 [95% CI, 1.01–2.72]) and previous BT (p=2.56 × 10–2, HR=1.72 [95% CI, 1.07–2.78]) were associated with lower BT retention due to ineffectiveness. When we analysed withdrawn according to adverse events, we found that RA (p=0.80 × 10–2, HR=1.83[95% CI, 1.07–3.15]), previous BT (p=4.83 × 10–2, HR=1.76[95% CI, 1.00–3.09]) and age (p=7.14 × 10–5, HR=1.05 [95% CI, 1.02–1.05]) were significantly associated with therapy discontinuation. In the group of treatments with discontinuation due to remission, we found that JIA diagnosis (p=7.93 × 10–8, HR=30.58 [95% CI 8.77–106.71]), age (p=7.83 × 10–6, HR=4.27-0.06);
HR 0.83,[C 95% 0.76–0.90]) and gender (p=4.36 × 10−2; HR 1.66,[C 95% 1.01–2.72]) were associated to discontinuation due to remission.

Conclusions: Our results show that different sets of clinical and demographical variables are significantly associated to biological therapy survival depending on the discontinuation cause.

BIOTHERAPIES SURVIVAL IN ADULTS AND JUVENILE ONSET ARTHRITIS. DATA FROM BIOBADAGUAY REGISTRY

M. O. Avila-Pordetti1, Z. Morel1, N. Cabrera2, S. Cabrera-Villalba1, I. Acosta Colman1, P. Bambak1, P. Melgarejo1, G. Elizaur1, M. Franco1, P. Delgado1, D. Cordovilla Montero1, J. Losanto1, L. Roman1, E. Paredes2, J. Mazzoleni1, P. de Abreu1, on behalf of BIOBADAGUAY.

1Rheumatology, Hospital Central del Instituto de Previsión Social, 2Rheumatology, Sociedad Paraguaya de Reumatología, Asunción, Paraguay, 3Rheumatology, Hospital de Clínicas, Asunción, Paraguay

Background: Survival of biological therapies (BT) may be considered as an indicator of efficacy and safety of the drug. BT survival have been studied mainly in adult’s patients, whereas only few studies have been focused on paediatric population to date.

Objectives: To analyse and compare BT survival in adults and juvenile onset arthritis patients from BIOBADAGUAY registry.

Methods: Patients with a chronic inflammatory arthritis enrolled in the Paraguayan-Uruguayan biological register (BIOBADAGUAY) between 2015 and 2017 where included. For this study, patients were divided in two groups: 1. Adults with anychronic inflammatory arthritis and 2. Patients with juvenile idiopathic arthritis (JIA). To compare the groups according to BT, only the first biotherapy was considered.

Survival analysis was performed using Kaplan-Meier estimators and proportional hazard regression model. First we analysed global BT survival in both groups; secondly we compare BT survival between groups.

Results: From 776 BTs(etanercept n=184, adalimumab n=440, rituximab n=44, infliximab n=27, tocilizumab n=75, and others n=8), 556 where identify as first line BTs. Of these, only adalimumab and etanercept were included in the study due to sufficient number prescriptions in both groups for the analysis.

We found a mean survival time for adults of 289 (±20.7 SD) weeks for etanercept and 287 (±6.6 SD) weeks for adalimumab. In JIA patients the mean survival were 243 (±26.0 SD) and 216 (±24.0 SD) weeks for etanercept and adalimumab respectively.

When comparing survival between groups, we found that JIA presented more discontinuation of BT when compare with adult patients (p=4.4 × 10−4; HR=0.51 [95% CI, 0.35–0.73]). Similar results were observed when analysing only etanercept (p=3.92 × 10−2; HR=0.50 [95% CI, 0.32–0.79]) or adalimumab (p=1.20 × 10−3; HR=0.48 [95% CI, 0.30–0.75]).

Conclusions: In our study we have analysed mean BT survival between adults and JIA at the BIOBADAGUAY registry. When we compared both groups of patients it was observed that JIA patients presented more BT discontinuation but due to remission.

IMPACT OF ONE-YEAR TREATMENT WITH BIOTECHNOLOGIC DRUGS ON WORK DISABILITY AND ACTIVITY IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

1Rheumatology, Hospital de Clínicas, Asuncion, Paraguay, 2Division of Rheumatology, Yonsei University College of Medicine, Seoul, Korea, Republic of Ireland, 3Rheumatology, Hospital of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy, 4Spedali Civili, Brescia, Italy, 5Città della Salute e della Scienza, Ospedale Mauriziano, Torino, Italy, 6ASO.SS. Antonio e Biagio e C. Amico, Alessandria, Italy, 7L. Sacco Hospital, Milan, Italy, 8School of Economics and Management, LIUC University, Castellanza, Italy

Background: Disease activity significantly impacts on work ability of patients with Rheumatoid Arthritis (RA). Biologic agents can control disease activity, but their effects on productivity outcomes were not adequately investigated in Italian population.

Objectives: Aim of the study was to evaluate the impact of biologic therapy on work productivity outcomes in a cohort of biologic-naïve patients with active RA from northern Italy.

Methods: This is a multicentre prospective study on patients with active RA in working age (18–65 years), scheduled to undergo their first biologic treatment. Demographics and clinical data were collected at baseline and at 6 and 12 months, together with productivity outcomes assessed with the RA-specific work productivity survey (WPS-RA)1 and the Health and Labour Questionnaire (HLQ)2. Primary outcome was the productivity loss or gain after 1 year of treatment.

Results: We included 100 patients from 7 rheumatology centres in northern Italy with active RA [mean DAS28: 5.1 (SD 0.9), median SDAI: 25.2 (IQR 18.7–33.2)]. Most of them were females (85%), with a mean age of 49.1 (SD: 10.3 years) and a median disease duration of 7 (IQR: 3–14) years. Patients were treated with TNF-inhibitors (68%), Abatacept (24%) or Tocilizumab (8%). At baseline 39 patients were unemployed. After 1 year of treatment, 85 patients were still on follow-up, with an improvement in all indexes of disease activity [mean DAS28: 2.8 (SD 1.3), median SDAI: 5.1 (IQR 1.9–12.9)]. A significant reduction in number of days of work missed (absenteism) and of reduced productivity (presenteeism) was observed in employed subjects, as well as a significant decrease in number of days missed of household work and social activities in all the study population (table 1).

EFFICACY AND SAFETY OF SWITCHING FROM ETANERCEPT REFERENCE PRODUCT TO LBEBC0101 (ETANERCEPT BIOSIMILAR) COMPARED WITH CONTINUING LBEBC0101 IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y.W. Song1, H. Matsuno2,3, M.C. Park1, M. Tomomitsu4, S. Shin5, J. Lee6, on behalf of LBEBC0101 Research Group.

1Seoul National University Hospital, Seoul, Korea, Republic of Ireland, 2Tokyo Medical University, Tokyo, 3Matsuno Clinic for Rheumatic Diseases, Toyama, Japan, 4Division of Rheumatology, Yonsei University College of Medicine, Seoul, Korea, Republic of Ireland, 5Mochida Pharmaceutical Co., Ltd, Tokyo, Japan, 6LG CHEM, Seoul, Korea, Republic of Ireland

Background: LBEBC0101 is a newly developed biosimilar of etanercept (ETN). As rheumatoid arthritis (RA) treatment is a long-standing process in the clinical practice, the long-term safety and efficacy of anti-TNF inhibitors have been studied and reported. Clinical studies have been conducted to evaluate the efficacy and safety of biosimilar after switching from their originator drug.2

Objectives: To evaluate the long-term efficacy, safety, and immunogenicity of switching from the ETN reference product (RP) to LBEBC0101 or continuing LBEBC0101 in patients with RA.

Methods: This multicenter, single-arm, open-label extension study enrolled patients with RA who had completed the 52 week treatment period of the
randomised, double-blind, parallel-group, Phase III study for LBE0101 (NCT02357069). Patients who were deemed requiring continuous treatment for RA upon the investigator’s discretion and agreed to participate in this study were allowed for participation. All patients received LBE0101 50 mg/ml once a week for 48 weeks with the stable dose of methotrexate regardless of the randomization group in the Phase III study. Efficacy, safety and immunogenicity were assessed up to Week 100. Data were analysed for patients who continued to receive LBE0101 for 100 weeks (maintenance group) and for those who had received ETN-RP for 52 weeks and then switched to LBE0101 for 48 weeks (switch group).

Results: A total of 148 patients were enrolled in this study: 70 patients continued to receive LBE0101 and 78 patients switched to receive LBE0101 from ETN-RP. DAS28-ESR score in the full analysis set were maintained in both groups from week 52 up to week 100 (from 3.068 to 3.103 in maintenance group vs. from 3.161 to 3.079 in switch group). Response rates at week 100 for maintenance and switch groups, respectively, were 79.7% vs. 83.3% for ACR20, 65.2% vs. 66.7% for ACR50 and 44.9% vs. 42.3% for ACR70. The incidences of adverse events were comparable between the groups (70.0% for maintenance vs. 66.7% for ACR50% and 44.9% vs. 42.3% for ACR70. The incidences of adverse events were comparable between the groups (70.0% for maintenance vs. 66.7% for ACR50% and 44.9% vs. 42.3% for ACR70). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 1.3% for switch group, respectively).

Conclusions: The efficacy and safety of LBE0101 were comparable in both maintenance and switch groups. The efficacy of LBE0101 was well sustained over 100 weeks.

**AB0457**

**CLINICAL EQUIVALENCE IN EFFICACY BETWEEN ABP 501 AND ADALIMUMAB IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS: A TIPPING POINT SENSITIVITY ANALYSIS**

Background: ABP 501 is the first approved biosimilar to adalimumab. Patient withdrawals from clinical trials can result in missing data, which may lead to loss of statistical power and bias of the treatment difference estimate. Therefore, it is critical to examine the potential effects of missing data and analyse the sensitivity of the results under various assumptions on the mechanism of missing data.

Objectives: To examine and confirm the robustness of the clinical similarity conclusion between ABP 501 and adalimumab reference product (RP) through tipping point sensitivity analyses on ACR20 at week 24, the primary endpoint of the phase 3 study in patients with rheumatic arthritis.

Methods: The primary analysis for this trial has been previously published. The proportions of patients achieving ACR20/50/70 responses with last observation carried forward imputation at weeks 2, 4, 8, 12, 18 and 24, were similar between ABP 501 and the RP over time. Tipping point sensitivity analyses were used to estimate the difference between ABP 501 and the RP with varying assumptions on the outcomes in patients who withdrew from the study early and those who completed the study.

Results: The table 1 displays the results of tipping point analyses on the primary endpoint of ACR20 at week 24. There were no scenarios in which the 90% confidence interval (CI) failed to rule out a 12% loss/increase in the ACR20 response.

Abstract AB0457 – Table 1. Tipping point analysis results for RD (90% CI) of ACR20 at week 24

<table>
<thead>
<tr>
<th>Tipping Point</th>
<th>RD (90% CI)</th>
<th>p Baseline</th>

<th>p Baseline</th>
<th>Week 12</th>
<th>Week 24</th>
<th>p</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.000</td>
<td>0.250</td>
<td>0.500</td>
<td>0.750</td>
<td>0.999</td>
<td>0.000</td>
<td>0.250</td>
<td>0.500</td>
<td>0.750</td>
</tr>
</tbody>
</table>

| 0.000 | 0.250 | 0.500 | 0.750 | 0.999 | 0.000 | 0.250 | 0.500 | 0.750 | 0.999 |

Conclusions: The tipping point sensitivity analyses support the findings of the key efficacy analyses in the phase 3 RA study and confirm that the effects of missing data would not change the conclusion of clinical similarity between ABP 501 and the RP.

**AB0458**

**EFFICACY AND B-CELL DEPLETION WITH VERY LOW DOSE RITUXIMAB (BIOSIMILAR) IN SERO-POSITIVE DMARD RESISTANT RHEUMATOID ARTHRITIS: A 24 WEEK STUDY**

N.S. Jain1, S. Pandya2, D. Shukla2, P. Srivastava2. 1Department of Rheumatology; 2Department of Rheumatology, VS Hospital Ahmedabad, Ahmedabad, India, India

Background: Very low dose Rituximab (RTX) (100 mg) has been variously used in autoimmune diseases like ITP and rheumatoid arthritis (RA). As cost of treatment is an important issue in resource poor setups, we decided to study efficacy of very low dose RTX in patients with RA.

Objectives: 1) To study clinical efficacy of very low dose RTX in DMARD refractory RA. 2) To study B cell depletion with very low dose RTX.

Abstract AB0458 – Table 1. Demographic profile and response to very low dose Rituximab

</tbody>
</table>

Methods: Prospective open labelled study. Biologic naive, conventional DMARD refractory, sero-positive RA patients ACR 2010 criteria) with high disease activity (DAS 28 ESR) were included after informed consent.

Arm 1: Total 4, weekly 100 mg doses (total dose 400 mg) of a RTX biosimilar were infused.

Arm 2: Single 100 mg RTX infusion.
Efficacy was assessed using standard outcome measures for RA (including RAPID3) at week 24. B cell depletion (CD19 levels in peripheral blood by flow cytometry) was studied at baseline, week 1 and week 12.

**Results:** Total number of patients in Arm 1 = 14 and in Arm 2 = 13.

In Arm 1: 28% (4/14) achieved EULAR remission while 78% (11/14) had EULAR good response. In Arm 2: 70% (9/13) had EULAR good response. All patients achieved complete B-cell depletion (defined as <0.01%) at week 1 after just single dose of 100 mg RTX remained so at 6 weeks only to start rising again at week 12.

There were no adverse events noted. Steroid doses were reduced in most patients at follow up visits with delta change in steroid dose 2.2 mg/day. Results comparable with other studies using both low dose and conventional dose of RTX. Limitations of the study includes small sample size and short follow-up.

**Conclusions:** Very Low dose RTX is efficacious in conventional DMARD refractory RA patients. Single dose (100 mg) is as good as 400 mg up to week 24. Complete B cell depletion can be achieved even with 100 mg RTX as early as week 1.

**AB0459**

**REMISSION RATE OF TOCILIZUMAB IN CONTROLLED TRIALS AND OBSERVATIONAL STUDIES: SYSTEMATIC REVIEW OF RHEUMATOID ARTHRITIS**

**Background:** In concept the state of remission constitutes a clinical condition in which no active disease is present. Target of rheumatoid arthritis (RA) is achievement to remission. Tocilizumab (TOC) is a humanised monoclonal antibody that binds to the interleukin-6 receptor.

**Objectives:** The aim of this study was to assess the remission rate of TOC for the treatment of RA patients in randomised controlled trials (RCTs) and longitudinal observational studies (LOS).

**Methods:** In January 2017, a systematic Review (SR) was performed in PUBMED MEDLINE. Publications were identified using the MedSch terms: (“rheumatoid arthritis and Tocilizumab”) with a limitation to “humans”, “all adults: 19 + years”, “English” and “clinical trials”. All available studies describing the remission rate of TOC were recruited to SR. Retention rate of TOC were calculated according to route (SC or IV), dosage (4 mg/kg vs 8 mg/kg), monotherapy or combination with methotrexate. Of the 662 publications identified by the literature search, 42 were recruited in the analysis. Retention rates of TOC at 12–16 weeks, 24–32 weeks, 48–52 weeks, 2, 3, 5 and 5 years were analysed. Open label extension period of RCTs included to LOS. The causes of withdrawal of TOC were recorded as ineffectivity, adverse event, and others.

**Results:** Of the 34 studies, 13 (38%) were RCTs and 21 (62%) were LOSs. Totally 12 043 patients (9834 (81%) female) were pooled to analysis that 6190 patients (51%) were from RCTs. The mean age was 53 years and mean disease duration was 9 years. Seropositivity was 73.6% for rheumatoid factor and 72.2% for ACA. Overall, 5493 (54.6%) of patients were biologic-naïve. TOC was used as monotherapy (2469/6077, 35.4%), or concomitant with methotrexate (8037/11429, 70.3%). Available baseline DAS-28 score, CDAI, SDAI and HAQ-DI score were 6.2, 32.1, 33.3, and 1.49 respectively. Remission rate of TOC according to different remission criteria. Remission achieved both RCTs and real life results. Moreover, remission rate of TOC in LOSs was comparable with other biologic DMARDs, as well.

**Conclusions:** These systematic literature results show that treatment with TOC has a high likelihood of inducing a clinically important benefit in terms of different remission criteria. Remission achieved both RCTs and real life results. Therefore, TOC can be used as a first-line agent in conventional DMARD refractory RA patients.

**AB0460**

**LONG-TERM DRUG SURVIVAL OF ETANERCEPT VS OTHER TNF INHIBITOR THERAPIES IN PATIENTS WITH RHEUMATOID ARTHRITIS**

P. Enev1, B. Vlahos2, P. Szczypka3, M. Thakur4, H.E. Jones4, J. Woolcott2, P. V. Santos Esteves6, A. Gibotsky5, C. Rolland3, G. Citrea2, L. Marshall4, L. Musculoskeletal Biomedical Research Centre LTHT, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, UK; 2Pfizer, Collegeville, USA; 3Pfizer Ltd, Walton Oaks; 4Pfizer, Sandwich, UK; 5Well Medical College, New York, USA; 6Envision Pharma Group, Horsham, UK; 7Consultantios Reumatologicos, Buenos Aires, Argentina

**Background:** TNFα inhibitors have profoundly altered outcomes for patients with rheumatoid arthritis (RA) since they were introduced >15 years ago, by reducing disease activity and radiographic progression and improving quality of life. As a chronic disease, RA often requires life-long treatment, understanding drug survival in real-world settings can be beneficial in optimising disease management.

**Objectives:** To compare the long-term drug survival of adalimumab (ADA), certolizumab pegol (CZP), etanercept (ETN), golimumab (GLM), and infliximab (IFX) in patients with RA based on systematic literature review (SLR).

**Methods:** In this SLR, the goal was to identify full-text articles containing registry data or systematic reviews on TNFα inhibitors, following Cochrane dual-reviewer methodology. Searches were conducted in November 2017 with no date restriction, using Embase®, MEDLINE®, the Cochrane Central Trials Register and Database of Systematic Reviews, other Cochrane Library databases, and PubMed. Outcomes extracted included drug survival data that were analysed and reported using Kaplan-Meyer or Cox regression methods.

**Results:** Of 3888 non-duplicated publications initially identified, 3299 were excluded based on titles or abstracts and 344 based on full-text screening, leaving 26 publications published between 2005 and 2017 included in the analysis. The number of studies (range of sample size) for each drug were: ADA: 15 (25–2349), ETN: 17 (20–3892), IFX: 21 (26–2898), GLM: 4 (2–88) and CZP: 1 (NA). Among the analysed studies, the mean disease duration in years (range) was: ADA: 10.7 (8.2–15.1); ETN: 15.9 (5.0–18.5); IFX: 14.2 (8.5–19.3); CZP: 10.3 (NA); GLM: 8.9 (8.1–11.5) and mean baseline DAS28 (range) was: ADA: 5.0 (4.2–5.9); ETN: 5.2 (4.3–6.3); IFX: 5.3 (4.1–6.4); CZP: 4.7 (NA) and GLM: 4.7 (4.1–5.1). Trends for survival rates of first-line ETN were slightly higher than ADA at time points >36 months; ADA and ETN had higher survival rates than IFX at >48 months (figure 1).
Conclusions: Long-term survival rates for ADA, ETN, and IFX were similar and relatively high for treatment periods up to 36 months. After 36 months, there was a noticeable decline in drug survival for all three TNFi inhibitors. Heterogeneity in study size and design may contribute to the range of survival data for each agent.

AB0461 EXPERIENCE WITH SUBCUTANEOUS ABATACEPT IN ROUTINE CLINICAL PRACTICE: 6-MONTH INTERIM ANALYSIS OF A 2-YEAR, PROSPECTIVE, NON-INFERIORITY, MULTICENTRE STUDY IN PATIENTS WITH RA

R. Alten; X. Mariette; M. Buch; R. Caporali; R.-M. Filip; A. Forster; H. Griffiths; M. Nuroomahamed; Y. Patel; P. Peichl; R. Sannaris; C. Chauvet; J. Heitzman; J. Hetzmann; C. Rauch; S.E. Connelly; P. Flesch; H. Altmann; S. Matar; I. Meier; M. Thakur; H. Jones; L. Marshall; G. Citera; C. Rolland; G. Connolly; R. Alten; F. Forster; S. Connelly; M. Thakur; H. Jones; L. Marshall; G. Citera; C. Rolland.

Background: ASCORE (Abatacept SubcutaneOus in Routine clinical practiceE; NCT02090556) is an ongoing, prospective, non-inferiority, multicentre study of patients (pts) with RA receiving SC abatacept (ABA). In a similar real-world setting, IV ABA retention was >86% at 6 months (M).

Objectives: To present baseline (BL) pt characteristics and 6M interim retention rates and clinical outcomes for SC ABA by biologic (b)DMARD treatment line.

Methods: Pts (≥18 years) with active, moderate-to-severe RA, naïve to ABA and who initiated SC ABA 125 mg weekly were enrolled across 10 countries (March 2013–January 2017) in 2 cohorts: biologic-naïve pts and pts who had failed ≥1 prior bDMARD. In some countries, an IV loading dose was administered according to local practice. Demographics and disease characteristics at SC ABA initiation were recorded. The retention rate (95% CI) of SC ABA over 6M was estimated by Kaplan–Meier analysis. Good/moderate EULAR response rates based on DAS28 (ESR, otherwise CRP), low disease activity (LDA) or remission according to DAS28 (ESR), CDAI, SDAI and Boolean criteria were assessed at 6M.

Results: Of 2943 pts enrolled, 2785 (94.6%) were evaluable: 1155 (41.5%) bio-logic naïve; 718 (25.8%) had failed 1; and 912 (32.7%) had failed ≥2 prior biologicals. At BL, there was a higher proportion of females and pts with longer disease duration among those who had failed ≥2 vs 1 or no prior bDMARDs; disease activity was similar across treatment lines; CRP was higher in biologic-naive vs - failure pts; 402 (48.4%) biologic-naïve pts had erosive disease vs 261 (53.7%) or 390 (63.8%) who had received 1 or ≥2 prior bDMARDs, respectively. Probability of overall SC ABA retention at 6M was 0.88 (95% CI 0.86, 0.9); retention was higher in pts receiving ABA as a first or second vs later bDMARD (figure 1). At 6M, 335 pts had discontinued ABA, 172 (51.3%) of whom due to inefficacy and 146 (41.8%) due to safety. At 6M, among pts continuing ABA, good/moderate EULAR response rates were 83.5%, 75.1% and 72.0% for biologic-naive pts and pts with 1 and ≥2 prior bDMARD failures, respectively. DAS28 (ESR), CDAI or SDAI/LDA/ remission, or Boolean remission rates were higher with earlier vs later treatment lines. The safety profile was consistent with IV ABA studies.1.2

UP TO 5-YEAR RETENTION OF ABATACEPT IN BELGIAN PATIENTS WITH MODERATE-TO-SEVERE RA: PROSPECTIVE DATA FROM THE REAL-WORLD ACTION STUDY

1UZ KU Leuven, Leuven, Belgium; 2Bristol-Myers Squibb, Princeton, USA; 3Hôpital Erasme, ULB, Brussels; 4Grand Hôpital de Charleroi, Charleroi; 5AZ Damaisan, Oostende; 6ASZ Aalst, Wetteren, Belgium; 7Excelya, Boulogne-Billancourt; 8Bristol-Myers Squibb, Rueil-Malmaison, France; 9Bristol-Myers Squibb, Braine-L’Alleud; 10CHU Sart Tilman, Liège, Belgium

Background: With its specific mechanism of action, abatacept (ABA) has shown good efficacy, acceptable safety and is well tolerated in patients (pts) with RA in randomized clinical studies.1 2 In a chronic disease such as RA, the long-term efficacy and safety of treatment are crucial and require validation in a real-world setting.

Objectives: To explore long-term safety and retention in pts with RA treated with IV ABA in routine clinical practice in the Belgian cohort of the AbataCePT In Ou-tNe clinical practice (ACTION) study.

Methods: ACTION is a noninterventional, multicentre, prospective, longitudinal study of pts (aged >18 years) with established active moderate-to-severe RA, who initiated IV ABA in routine care. In Belgium, reimbursement criteria require failure with 2 conventional synthetic DMARDs and DAS28 (CRP) >3.7. The primary study objective was retention rate estimated using the Kaplan–Meier method.

Results: Overall, 135 Belgian pts from 16 sites (6 [4.4%] first-line biological and 129 [95.6%] second or further line) were enrolled between October 2010 and December 2012. Of these, 131 were evaluable for effectiveness analysis. Pts had a mean (SD) disease duration of 10.5 (9.7) yrs and were at high risk of disease progression: 25.4% of the evaluable pts had erosions (n=33/130), 71.6% were anti-cyclic citrullinated peptide positive (n=63/88) and 78.7% were RF positive (n=79/103). Overall, pts showed high disease activity at baseline according to mean (SD) DAS28 (ESR) 5.21 (1.02), DAS28 (CRP) 4.72 (1.09), CDAI 28.5 (11.1), SDAI 29.9 (11.9) and HAQ-DI score 1.23 (0.65). Patient and Physician Global Assessment of disease were mean (SD) 65.3 (20.95) and 58.02 (21.77), respectively. The overall retention rate (95% CI) was 76% (68.8, 82.5), 64% (54.8, 71.5) and 34% (22.6, 45.4) at 12, 24 and 60 mths, respectively. When temporary discontinuations (>84 days, n=24) were not included in the number of events, retention rates were 80% (72.0, 85.9), 73% (64.0, 79.4) and 51% (40.1, 61.0) at 12, 24 and 60 mths, respectively (Fig). Average DAS28 (CRP) before discontinuation and at restart was stable (3.37 [1.03] vs 3.73 [1.78], respectively [n=12]), suggesting that a temporary discontinuation of >2 consecutive ABA infusions does not seem to have a major clinical consequence. Pts who discontinued ABA due to lack of efficacy (n=37) had significantly shorter disease duration, higher CRP, higher number of prior DMARDs at baseline, mean DAS28 (CRP) of 3.61 (1.17) and DAS28 (ESR) of 4.66 (1.35) at discontinuation. Overall, ABA was generally well tolerated and no new safety signals were identified.

Abstract AB0462 – Figure 1. Treatment Retention Rate Over Time (Mths) in Study Population Evaluable for Effectiveness.

Conclusions: These real-world data demonstrate an acceptable safety profile for abatacept in Belgian pts with a stable retention rate of up to 5 years in a difficult-to-treat population. A temporary discontinuation also seems feasible.

A REVIEW OF THE OUTCOMES OF WOMEN WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH BIOLOGIC AGENTS ATTENDING THE SHEFFIELD COMBINED OBSTETRICS AND RHEUMATOLOGY CLINIC 2002 TO 2013

R. Smith1, R. Kilding1, K.-P. Kuef1, F. Fairlie2, R. Jokhi3, T. Bonnett4, M. Smith5, M. Akiti6.

1Rheumatology Department, Obstetrics and Gynaecology, Royal Hallamshire Hospital, Sheffield, UK

Background: Women with RA have increased risk of complications including preeclampsia, low birth weight babies and Caesarean sections compared with unaffected women.1 Higher levels of disease activity have a negative influence on birth weight.2 More women are being treated with biologic agents, and there is growing evidence for their safe use in pregnancy.3

Objectives: To assess disease activity during pregnancy, and to review foetal and maternal outcomes.

Methods: Retrospective review of case notes.

Results: Between 2002 and 2013, 17 women with RA treated with biologic agents attended the combined clinic. 13 were treated with Etanercept, 2 Adalimumab, 1 Tocilizumab and 1 Rituximab. 13 were in combination with disease modifying anti-rheumatic agents (DMARDs). There were 17 pregnancies, 2 women stopped their biologic prior to conception; 14 stopped on confirmation of pregnancy. 12 women had active disease during pregnancy. All had some form of steroid treatment, 3 had a DMARD introduced, and 1 restarted Etanercept at 20 weeks. There were 14 live births and 2 first trimester miscarriages. There was 1 elective Caesarean section, 7 spontaneous deliveries, and 5 inductions, 3 of which proceeded to Caesarean. Data is missing for 2 women. 10 babies were born at term, 3 were pre-term and data is missing for 2. 2 babies weighed less than 2500 g and 2 more than 4500 g. Data is missing for 3 babies. The low birth weight babies were also pre-term, had cardiac abnormalities and required admission to the neonatal unit. Both mothers had stopped Etanercept at confirmation of pregnancy. Both flared during pregnancy.

6 women developed complications: hypertension, diabetes, proteinuria, cervical incompetence, and hypothyroidism. 4 of these had active disease during their pregnancies, 2 babies had intrauterine growth restriction, 2 cardiac abnormalities and 1 macrosomia. All had mothers who flared during pregnancy.

Conclusions: Our group of patients is small, but the outcomes are comparable to those of women with RA. There is no discernible increase in adverse events due to biologic use. In 2014 product recommendations were to stop biologics prior to conception.4 Since 2016 the British Society for Rheumatology has advised that Etanercept and Adalimumab are compatible with use in the first and second trimesters. Tocilizumab and Rituximab should still be stopped prior to conception.3 Local practice has changed to reflect this guidance, and the next step in this project is to review the data from more recent pregnancies to determine whether more prolonged use of biologics improves disease control and in turn foetal and maternal outcomes.

SAFETY AND DURATION OF BIOLOGIC TREATMENT IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

S. Garrate Corral, A. Garcia Fernandez, P. Moran Alvarez, F.J. Bachiller Corral. Rheumatology, Hospital Ramon y Cajal, Madrid, Spain

Background: Several differences may be expected between young and elderly patients with rheumatoid arthritis (RA), safety and efficacy results are variable in the different previous studies. 1,2

Objectives: To compare the duration and safety of biological treatment in patients with RA depending on the age of onset of therapy, in a Spanish tertiary centre.

Methods: We conducted a retrospective observational study of patients with a diagnosis of RA who were receiving biological treatment. They were diagnosed between February 1980 and February 2017, on the basis of criteria ACR/EULAR 2010 or 1987 ACR criteria. The information was obtained from review of medical records. We divided the patients in two groups according to the age of the onset of treatment: elderly group (>65 years) and young group (<65 years).

Results: 140 patients were included. At the beginning of the treatment 89 were under 65 years and 51 older (65–74 years: 28 patients, >75 years: 23). The average duration of the disease from diagnosis until the beginning of the biological treatment was 103±91 months in young patients and 142±86±109.5 months in elderly patients (p=0.023). We detected no differences between both groups at baseline characteristics, except for comorbidities and sex. DAS28PCR prior to biological therapy was 5.20±1.44 in young patients and 5.14±0.813 in elderly (p=0.37).

Duration of the treatment was similar in both groups. Suspension of biological treatment occurred in 50 young patients (56%) and 30 elderly patients (58%) (table 1). The causes are detailed in table 2. Adverse effects were more frequent in the elderly but without statistical significance. There were 9 cases of cancer in elderly patients (17.3%) and 4 cases in young patients (4.6%) p: 0013. The average diagnosis of cancer prior to the introduction of biological treatment was 5.8±7.1 years.

Conclusion: Our study corroborate that biological treatment has similar duration and safety in elderly and young patient. 1,2

Disclosure of Interest: None declared
Methods: A retrospective observational study was conducted including patients with RA treated in a tertiary hospital between June 2006 and May 2017 who had received at least one RTX cycle. At RTX initiation we analysed: age, sex, comorbidities and Charlson score, disease duration, presence of rheumatoid factor (RF)/anti-citrullinated protein antibodies (ACPA), disease activity (DAS28), acute phase reactants (CRP, ESR), previous biological treatments; concomitant treatment (csDMARD/glucocorticoids (GC)). Serum Ig levels before every RTX cycle, the number of RTX cycles and adverse events (AE), including serious and opportunistic infections were also analysed. Results: We included 53 patients (86.8% women, mean age 55.5±13.5 years), 58% with a Charlson score ≥3. Mean disease duration was 16±9.1 years; 84.9% and 92.5% were RF and ACPA positive, respectively.

Before starting RTX, 81% of patients had received other biologic drugs (58.5% ≥2); 88% received concomitant csDMARD, (52% methotrexate and 32% lefunomide) and 81% were treated with GC (median dose 10 mg, P25–75: 5–10 mg). The median number of RTX cycles received per patient was 5 (P25–75: 2–6). 80 AE were reported: 12 infusion reactions, 8 cases of neutropenia, 51 infections (18 respiratory, 8 urinary, 4 skin and soft tissues, 8 gastrointestinal, 4 cases of non-disseminated herpes zoster, 1 bacteremia, 2 septic shock and 6 other) of which 19 were serious. and 5 malignancies (2 melanomas, 2 cervix, and 1 bladder) were also notified. No opportunistic infections were reported.

Ig levels were obtained for 41 subjects: 7, 5 and 1 patients had low levels of IgG, IgM and IgA, respectively. Patients who developed infections received a greater number of RTX cycles (p<0.0002) and had more frequently low levels of serum IgG during follow-up (p<0.044) than those who did not have infections. Conclusions: Long-term exposure to RTX showed a good safety profile with a low incidence of serious infectious and no opportunistic infections. Factors associated with the development of infections were the number of cycles received and low serum levels of IgG at any point during follow-up. SUSTAINED CLINICAL RESPONSE IN REFRACTORY RHEUMATOID ARTHRITIS PATIENTS WITH A LOW-DOSE RITUXIMAB RETREATMENT REGIMEN

S.D.L.C. Rodríguez García, R. Castellanos-Moreira, M.V. Hernandez-Miguel, A. Cuervo, V. Ruiz-Esquide, J. Ramírez, O. Camacho, J.D. Cañete, J. Gomez Puerta, R. Sanmartí. Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain

Background: The standard dose of rituximab (RTX) in rheumatoid arthritis (RA) is two intravenous (iv) 1 g infusions, separated by two weeks. Recently, the efficacy of a low-dose regimen (LDRTX) has been shown to be safe and effective in rheumatoid arthritis patients. We aimed to evaluate the long-term sustained effectiveness of a low-dose of RTX in daily clinical practice.

Methods: Observational retrospective study including all RA patients treated on a tertiary hospital who had received at least one cycle of RTX, at the standard dose, between June 2006 and May 2017. We selected those patients who achieved a good or moderate EULAR response and were then treated with a low-dose regimen (1 g). Variables analysed: age, sex, disease duration, presence of ACPA (anti-CCP2) and rheumatoid factor (RF), glucocorticoid (GC) and conventional synthetic DMARD (csDMARD) use and dosage before and after RTX treatment, number of biologic DMARD (bDMARD) used prior to initiating RTX. Disease activity was measured using DAS28 index (prior to first RTX infusion, at low-dose regimen initiation and at last follow-up visit).

Results: 53 patients received, at least, one cycle of 2 g RTX, 70% achieved a good or moderate EULAR response and were stepped-down to a low dose treatment regimen. Baseline characteristics of patients receiving low-dose RTX were: mean age 56.4±10.9 years; 13.5% male, mean disease duration 12.7±9.8 years, 91.9% RF and 97.3% ACPA +; mean DAS28 prior to RTX initiation 5.79 ±1.17. 73% of patients had received other bDMARDs before RTX, 48% 2 or more. 92% were on csDMARDs, 51.4% methotrexate (MTX) and 37.8% lefunomide (LEF) and 86.5% were receiving concomitant GC (median dose 10 mg, P25–75: 5–10 mg). 73% of subjects received only one standard cycle before RTX dose reduction. Mean DAS28 decreased significantly between the first visit on 1 g RTX vs the last follow-up visit (4.08 vs 3.04; p<0.001). Additionally, 11 patients (8 MTX, 3 LEF) were able to reduce csDMARD dosage, 56.3% of patients receiving GC at the initiation of low-dose retreatment were able to reduce the dose (median 10 mg vs 5 mg; p<0.0001), and 28% discontinued GC therapy.

After a mean follow-up of 3±1.8 years, RTX was withdrawn in 10 patients: 8 due to adverse events (recurrent infections in 4) and 2 cases due to loss of efficacy. Conclusions: A sustained clinical response was observed with the 1 g retreatment of RTX after a long-term follow-up period.

CLINICAL AND ULTRASONOGRAPHIC EFFECTIVENESS IN TWO COHORTS OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT: A REAL LIFE STUDY

S. Parisi, M.C. Ditto, M. Scarati, M. Priora, C.L. Peroni, E. Fusaro. Rheumatology Unit, AOu Città della Salute e della Scienza di Torino. Turin, Italy

Background: Synovitis in Rheumatoid Arthritis (RA) is a phenomenon related to the development of erosions and progressive structural damage; early synovitis improvements are successfully associated with long-term clinical and structural outcomes.

Objectives: The aim of this study was to evaluate the efficacy of abatacept in two cohort of patients treated with Abatacept as the first and second or third line of treatment.

Methods: We evaluated patients affected by RA (according to ACR 2010 criteria) and were divided into two groups:

Group A: patients with moderate or severe active RA, non-responders to Methotrexate (MTX), bDMARDs naïve, treated with Abatacept 125 mg wk;

Group B: patients with moderate or severe active RA, non-MTX and anti-TNF responders, treated with Abatacept 125 mg wk;

The concomitant treatment with MTX was maintained unchanged in those patients who were taking it at stable doses before the start of the study (10–15 mg/week for ≥28 days); concomitant therapies such as low-dose systemic CS (prednisone ≤7.5 mg/day) and NSAIDs have been maintained for at least 4 weeks if stable. The activity of RA was calculated with the DAS28-CRP according to the clinical practice protocol (week 0,4,12,24). The Ultrasound (US) evaluation of the synovitis was done according to the Omeract criteria (Grey Scale and PDUS score: 0 to 3).

Results: We recruited consecutively 34 patients with RA, 16 pts (male n=4, 25,00%) took Abatacept as the first line (Group A), and 18 pts (males n=5, 27.7%) took Abatacept as followed by another anti-TNF drugs (Group B). The mean age was 57.2±10.7 years (median 60, range 45–72); mean of DAS28 at baseline was 4.8±0.9 (median 4.7; range 3.9–5.6); mean duration of the disease was 15.3±5.7 years (median 10; range 3–22). Tab.1

A constant improvement of the DAS28 score is shown in both groups examined until the end of the follow up, resulting respectively -3.0 for Group A (p<0.05) and -4.21 (p<0.05) for Group B. The total PDUS score decreased in both groups from week 4, with a mean change (95% CI) compared to baseline of −0.8 (range −1.4 to −0.2) and progressive mean significant improvement until follow-up (Gr.A p<0.05; Gr.B p<0.05). No serious adverse events or infections were observed. Patients with ACPA positive showed a greater improvement trend compared to other patients in both groups (p=0.068), Figure 1.

CONCLUSIONS: The treatment with Abatacept, administered in the first or second or third line, has shown significant efficacy in reducing the synovial inflammation in patients with RA, monitored with clinical and ultrasonographic outcome. Moreover, we have not demonstrate statistically significant differences between two groups into the timing of improvement.

AB0469 Efficacy and safety of Interleukin 6 inhibitors in rheumatoid arthritis: a systematic literature review

T. Oto1, E. Loza2, R. Samart3, J. Tornero Molina1,1 Instituto de Salud Musculoesquelética;2 Instituto de Salud Musculoesquelética, Madrid;3Rheumatology, Hospital Universitari Clínic, Barcelona;4Rheumatology, Hospital de Guadalajara, Guadalajara, Spain

Background: Interleukin 6 (IL-6) inhibitors constitute a therapeutic option for patients with rheumatoid arthritis (RA). Currently, apart from Tocilizumab (TCZ), we have data from other drugs targeting the IL-6 pathway.

Objectives: To review published evidence on safety and efficacy of IL-6 inhibitors in RA.

Methods: We performed sensitive systematic literature searches in Medline and Cochrane (up to October 2017), screened EULAR and American College of Rheumatology meeting-abstracts. An expert librarian designed the strategies that included Mesh and text word terms. The search was limited to human RA, adults and the English and Spanish language. The inclusion criteria were: 1) RA patients on IL-6 Inhibitors including TCZ, sarilumab (SAR), olarikizumab, sirukumab and clazakizumab; 2) Placebo and an active comparator were accepted as comparators; 3) Articles including typical efficacy and safety variables such as DAS-28, radiographic progression or the infections rate; 4) Only meta-analyses, systematic reviews and clinical trials were selected. Two reviewers screened the titles and abstracts of the retrieved articles independently. They also collected the data from the studies included by using ad hoc standard forms. All collection was double by article and independent. Subsequently, a secondary manual search of the bibliography of the articles that were finally included was performed. Evidence tables were produced. The quality was evaluated with the Oxford 2009 scale.

Results: We included 64 articles of moderate-high quality, variable duration, between 12 and 108 weeks. These articles analysed more than 8000 patients with RA, most of them with established RA (although there are data on early RA), with high disease activity and severity criteria. More than a half of the studies are of TCZ. IL-6 inhibitors were effective both in the short and long term in terms of clinical remission, RA activity, radiographic progression, function, fatigue, bone metabolism, morning stiffness, pain, quality of life, or anaemia. They also decreased and even normalised CRP values in a rapid and sustained manner. The efficacy of blocking IL-6 has been seen in RA refractory to DMARD or anti-TNFα and in MTX-naive patients, as well as in the intravenous and subcutaneous formulations (TCZ). TCZ and SAR are more effective than adalimumab in monotherapy. In general, no statistically significant differences were found between combined therapy and monotherapy. In terms of safety, the rate of adverse events increased over time and with the concomitant use of DMARDs. Infections and hypersensitivity reactions were the most frequent adverse events and infections the most frequent serious adverse events. IL-6 inhibitors were associated with a rapid and subsequently sustainable increase in serum lipid parameters, although this was not associated with a higher prevalence of cardiovascular events and related mortality, nor was it associated with neoplasms. Transtilamine elevations were generally mild and without serious disorders. The incidence of gastrointestinal perforations was very low, and it was associated with a previous history of diverticulitis.

Conclusions: IL-6 inhibitors are effective to control RA activity and symptoms and to prevent radiographic damage in different disease profiles, with an acceptable safety profile.

AB0470 Influence of using adalimumab in complex treatment on frequency of eyes involvement in patients with JIA

T. Marushke1, O. German, J. Golubovska. National Academy of postgraduate education named after P.L. Shupik, Kyiv, Ukraine

Background: Extra-articular organs involvement in JIA is frequent and mostly includes rheumatoid uveitis in ANA-positive oligoarthritis. In Ukraine almost 10% of children with JIA during systematic ophthalmologic examination have signs of ocular involvement. Early treatment with biological agents can influence inflammation progression in eyes of the JIA patients.

Objectives: Objective of the study was to investigate the frequency of recurrences of uveitis in patients with JIA and eye involvement on methotrexate alone and methotrexate with adalimumab.

Methods: There were 23 patients with JIA and rheumatoid uveitis involved into the study. Mean age was 9.6 (4–16) years. Among them there were 14 (61%) girls and 9 (39%) boys. Serological characteristic included 17 (74%) patients with positive ANA, and 3 (13%) children with positive HLA-B27. All patients received 15 mg/m2/week of SC methotrexate. During onset and recurrence of uveitis all children received glucocorticoids with slowly tapering dosage (from 1 mg/kg/day to 0.2–0.1 mg/kg/day) until uveitis remission. Of 23 patients 11 (47.8%) received adalimumab in standard doses. Study were hold for 5 years during which every child were investigated by ophthalmologist every 3 months irrespectively of clinical status.

Results: During 5 year follow up in “methotrexate” group (n=12) there were 15 episodes of uveitis recurrence (0.25 episodes per patient/year). Of them 10 (66.6%) were revealed only by ophthalmological assessment and had no obvious clinical signs (subclinical uveitis). Same time only 2 episodes of uveitis recurrence were registered in “methotrexate +adalimumab” group (0.04 episodes per patient/year) (p<0.05).

Conclusions: Adding adalimumab to methotrexate in complex treatment of patients with JIA and eyes involvement allows decreasing frequency of both clinically evident and subclinical recurrences of rheumatoid uveitis.

Disclosure of Interest: None declared

AB0471 Biosimilar medicine is acceptable to patients if recommended by a rheumatologist in an Australian tertiary RA cohort

T. Koutsvitanickan1,2, D. Wang1,3, S. Raghunath1,2, L. Kyi1, N. Walpole1, S. Pignataro2, S. Morton2, E. Morand1,2, M. Letch1,3,1University of Sydney, Sydney;2Monash Health;3Monash University, Melbourne, Australia

Background: Advancement in biological disease-modifying antirheumatic drugs (bDMARDs) has greatly improved the prognosis of patients with rheumatoid arthritis. Their high costs, however, pose a significant health-economic challenge. Biosimilars are being adopted in Australia and worldwide to improve affordability and access to treatment. While the predominant focus of current literature has been on physicians’ awareness and confidence of biosimilars, an effective introduction of biosimilars requires an understanding of patient acceptance of these products.

Objectives: To investigate patient awareness and attitudes to biosimilar medicine in a tertiary hospital RA clinic.

Methods: A cross-sectional study of 127 patients with rheumatoid arthritis was performed in Melbourne, Australia. A brief education on biosimilars was provided. Patients rated concerns regarding biosimilar efficacy, side-effect profile, operation
of the medication, and general attitude towards the new medication on a ten-point scale.

Results: 45.2% of our cohort have received biological DMARDs. Although only 5.6% have some knowledge of biosimilars, 75.4% would accept biosimilars if their rheumatologist recommends it, with only 5.6% refusing to switch. 19% of patients were unsure. Of those refusing biosimilars, the main concerns related to efficacy and general concerns about change. In our RA cohort, 61.9% took generic medicines regularly and 84.6% of these they would also be comfortable taking biosimilars. In those refusing generic medicines, nearly two-thirds would still accept biosimilars. 15.8% and 12.7% of patients had great concerns about the efficacy and safety profile of biosimilars, respectively. 26.2% were significantly worried that their physician may be unaware if they were receiving the biosimilar or reference product.

Conclusions: Despite being unfamiliar with biosimilars, most patients in our cohort would be comfortable taking biosimilars if recommended by their rheumatologist, highlighting the role of trust in doctor-patient relationships. Of patients usually refusing generic medicines, nearly two-thirds would still accept biosimilars. Almost a quarter of the patients were unsure about the use of biosimilars and many patients indicated that they would like more information regarding these products. This patient group offered the opportunities to improve the uptake rate of biosimilars by allaying their concerns through information-education strategies. The current legislation in Australia allows pharmacists to substitute biological DMARDs in consultation with the patient without informing the prescriber. This concerns nearly all (89%) prescribers in Australia. The majority of patients in our study were not concerned, whilst approximately one quarter were worried about unrecognised switching. A successful introduction of biological DMARDs is likely to improve patient access to effective biological therapy and to ensure sustainability of the healthcare budgets.

Abstract AB0472 – Table 1. Baseline and change in pharmacodynamic parameters, and safety in studies 6R88-RA-1309 and PDY14191

Conclusions: The pharmacodynamic and safety profiles observed after a single-dose of sarilumab SC or IV/SC tocilizumab IV or SC in patients with rheumatoid arthritis (RA) in studies 6R88-RA-1309 and PDY14191 were comparable to those observed in non-Japanese patients.

Disclosure of Interest: None declared

Abstract AB0472 – Figure 1

Background: Two studies (PDY14191 [NCT02404558]: randomised, open-label, non-Japanese patients; 6R88-RA-1309 [NCT02097524]: randomised, open-label, non-Japanese patients) assessed the pharmacodynamic profiles of two monoclonal antibody blockers of IL-6R, sarilumab and tocilizumab.

Objectives: To evaluate the pharmacodynamics of absolute neutrophil count (ANC), C-reactive protein (CRP), IL-6, soluble IL-6 receptor (sIL-6R), and safety after a single dose of subcutaneous (SC) sarilumab, or intravenous (IV) or SC tocilizumab in patients with RA.

Methods: 30 Japanese patients (PDY14191) were randomised: 1:1:1:1 ratio receiving a single injection with SC sarilumab 150 mg or SC tocilizumab 162 mg without background medication. 101 non-Japanese patients (6R88-RA-1309) were randomised: 1:1:1:1 and received a single dose of SC sarilumab (150 or 200 mg) +/− methotrexate (MTX), or IV tocilizumab (4 or 8 mg/kg)+MTX. Pharmacodynamic and safety outcomes were assessed through Week 6.

Results: Baseline demographics were comparable between studies. The use of background medication was lower in non-Japanese patients (mean 36 vs 57 kg). Although there were numeric differences in baseline pharmacodynamic parameters between the two studies, onset of effects on ANC, CRP, IL-6, and sIL-6R during the first week after a single drug dose were similar regardless of drug, dose, or route of administration in both studies. Within both studies, maximal effects on ANC and CRP nadir and on IL-6 and total sIL-6R peaks were comparable for sarilumab and tocilizumab (Table 1). The pharmacodynamic response was more prolonged with IV tocilizumab. Time for pharmacodynamic effects to return to baseline was consistent with the dosing intervals for SC sarilumab (q2w), and IV (q4w) and SC (q2w) tocilizumab. The safety profiles of sarilumab and tocilizumab were generally similar and both drugs were associated with laboratory effects consistent with their mechanism of action (ie, decrease in neutrophil count). There was a dose-dependent effect on ANC<1.0 Giga/L in study 6R88-RA-1309 and numeric differences in ANC<1.0 Giga/L between sarilumab and tocilizumab in PDY14191. The decrease in ANC was not associated with increased risk of infections.
AB0474

THE CLINICAL EFFECTIVENESS AND COST SAVINGS OF TAPERING BIOLOGIC DMARDS IN PATIENTS WITH INFLAMMATORY ARTHRITIS AT A UK DISTRICT GENERAL HOSPITAL

W.P. Lee, R. Manhas, V. Sebbage, S. Kyle. Rheumatology, North Devon District Hospital, Barnstaple, UK

Background: Biologic DMARDs (bDMARDs) have led to substantial improvement in clinical outcomes for treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial/periarticular spondyloarthritis (SpA), making remission a realistic target. Current guidelines suggest clinicians should consider tapering after achieving remission in RA.1 Nevertheless, the optimal approach for tapering bDMARDs remains unknown and un-standardised across conditions.2

Objectives: To evaluate the tapering strategies on 3 major rheumatological disease entities (RA, PsA, SpA), the number of patients successfully tapered and the total cost saving from successful tapering.

Methods: The study was conducted at North Devon District Hospital in Barnstaple, UK and includes all bDMARDs users up until 31st December 2017. The tapering strategy was identified from hospital notes. Patients who are deceased, lost to follow-up or discontinued bDMARDs due to contraindication or adverse effects were excluded. Successful tapering is defined as patient on tapered dose or had their biologics withdrawn and remains at target treatment level (RA: DAS-28 <2.6; PsA:<3 tender joints and <3 swollen joints; SpA: BASDAI <4).

Results: There are a total of 298 patients: 174 RA; 59 PsA; 57 SpA; 8 other diagnoses. 94 patients (31.5%) had attempted tapering: 52 RA, 16 PsA, 22 SpA, 60 (20.1%) successfully tapered their bDMARDs: 34 RA (56.7%); 13 PsA (21.7%); 13 SpA (21.7%). Out of 34 RA, 30 seropositive; 4 seronegative; 24 co-prescribed with synthetic DMARDs, 10 on monotherapy. Out of 13 PsA, 8 co-prescribed with synthetic DMARDs; 5 on monotherapy. 59 tapered by increasing interval of subcutaneous treatment. Only 1 RA patient tapered its IV dose of tocilizumab. This patient is excluded from the final analysis.

Conclusions: Tapering is a feasible strategy for a proportion of patients with rheumatological disease entities (RA, PsA, SpA), the number of patients successfully tapered and the total cost saving from successful tapering.

DISEASES: AN UPDATED REVIEW FROM REGULATORY DOCUMENTS AND CONFIRMATORY CLINICAL TRIALS

V. Strand1, J. Goncalves2, T.P. Hickling3, H. Jones4, L. Marshall5, J. Isaacs6
1Stanford University School of Medicine, Palo Alto CA, USA; 2IMed-Research Institute for Medicines, Faculdade de Farmácia da Universidade de Lisboa, Lisboa, Portugal; 3Biomedicine Design, Pfizer, Andover, MA; 4Immuno and Immunology, Pfizer, Collegeville, PA, USA; 5NHIR Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle upon Tyne, UK

Background: Several biosimilars have been approved for the treatment of rheumatic diseases by the European Medicines Agency (EMA) or the US Food and Drug Administration (FDA).

Objectives: To summarise immunogenicity data from regulatory documents or confirmatory trials of biosimilars approved by the EMA or FDA for the treatment of rheumatic diseases.

Methods: EMA Public Assessment Reports (EPARs), FDA Clinical Summaries, PubMed records, and EULAR and ACR abstracts were searched for immunogenicity data from confirmatory trials of approved TNFα or CD20 inhibitor biosimilars in patients with rheumatic diseases. Data collected included the proportion (%) of patients positive for anti-drug antibodies (ADAbs) among all patients and the proportion (%) of patients with neutralising antibodies (nAbs) among ADA-positive patients.

Results: We identified 10 biosimilars approved by the EMA or FDA: three each for adalimumab (BI 695501, SB5, and ABP 501) and infliximab (CT-P13, and infliximab-dxbq) and two each for etanercept (GP2015 and SB4) and rituximab (CT-P10 and GP2013). The duration of treatment periods in the 16 identified trials (which varied in design and methodology of ADA/nAb detection) ranged from 12 weeks to 102 weeks. Across treatment groups in all trials, 0% to 62% of patients were ADA-positive, of whom 0% to 100% were also nAb-positive. The lowest proportions of ADA-positive (0%–13%) and nAb-positive patients (0%–3%) were observed in the trials of etanercept and its biosimilars, and the highest in the trials of infliximab and its biosimilars (ADAbs: 20%–62%; nAbs: 88%–100%). Consistent with the biosimilar designation, the proportions of ADA- and nAb-positive patients in individual trials were similar between the originator and biosimilar products. Of note, in a 52 week trial of etanercept and its biosimilar SB4, the incidence of ADAs by Week 52 was significantly lower with SB4 than with etanercept (1% [3/299] vs 13% [39/296], p<0.001). However, as noted in the SB4 EPAR, this difference, which was not reflected in the incidence of nAbs and efficacy or safety of etanercept, may have been due to an ADAb assay bias in samples collected at Weeks 4 and 8, when 37/39 ADAbs in the etanercept group and 2/3 in the SB4 group were detected.

Conclusions: Immunogenicity of the approved biosimilars is generally similar to that of originator products. For ETN, which has been associated with relatively low ADAb levels, there was a discrepancy in ADAb incidence compared with its biosimilar SB4, but those differences were transient and did not affect clinical activity or safety.

THE INFLUENCE OF SWITCHING FROM ETANERCEPT ORIGINATOR TO ITS BIOSIMILAR ON EFFECTIVENESS AND THE IMPACT OF SHARED DECISION MAKING ON RETENTION AND WITHDRAWAL RATES

W.D. Mäskens1, S.A.A. Rongen-van Dar1,2, E. Adang3, P.L. van Riel1,2, J.Q. Healthcare, Radboud UMC, Nijmegen; 2Rheumatology, Bernhoven, Uden; 3Health Evidence, Radboud UMC, Nijmegen, Netherlands

Background: With biological patents expiring, biosimilars are becoming a realistic, less costly alternative to their originator. The data from numerous randomised clinical trials support that it is safe, effective and cost saving to switch to a biosimilar. However, real world data about efficacy, safety, and cost-effectiveness of such a switch are lacking. Since shared decision making (SDM) is a key factor in the treatment of rheumatic diseases, a non-mandatory open label transitioning from Etanercept originator to its biosimilar was performed at the rheumatology department of Bernhoven.

Objectives: The first goal of this study was to investigate the effect of switching from Etanercept originator to its biosimilar on the effectiveness of treatment. The second aim was to analyse the effect of SDM on the 1 year retention rates and reasons for withdrawal in daily clinical practice.

Methods: All patients with rheumatoid arthritis (RA), axial spondyloarthritis (SpA) and psoriatic arthritis (PsA) that were using Etanercept originator between 01–06–2016 and 23–10–2017 were informed by letter of the possibility to switch to its biosimilar. During the next outpatient visit with their rheumatologist the possibility to switch was discussed. Patients had the opportunity to ask questions regarding biosimilars and the switch to a biosimilar. If patients agreed the switch was made, with the reservation that they could switch back to the originator if they encountered difficulties with the biosimilar.

Using the registry of the rheumatology department at Bernhoven data were collected on disease activity (DA), medication use and adverse events from the moment of switch till 23–10–2017. As measure for DA the DAS28 was used for RA and PsA, the ASDAS was used for SpA. Stop reasons for biosimilars were verified using the health record system of the hospital. Reasons for change in disease activity and discontinuation of biosimilar treatment were assessed.

Results: Between 01–06–2016 and 23–10–2017 80% (69 patients) of the Etanercept originator users switched to its biosimilar. These patients switched to biosimilar after a median time of 5.1 (IQR 2.6–8.3) years. By 23–10–2017, median follow-up of 307 (IQR 196–357) days, the mean DA did not significantly differ from the DA at baseline, 3.1 (95%CI 2.5–3.7) vs. 2.8 (95%CI 2.5–3.1). At end of follow-up 25% of the patients had discontinued their treatment and either switched back to originator (18%), switched to another biological (3%) or stopped treatment with biologics (4%).

Reasons for switching back to originator were adverse events (58%), lack of effect (17%) and “adverse event and lack of effect” (25%). Only one serious adverse event was reported. This was a drug hypersensitivity reaction. After the patient was recovered, the originator was restarted without any difficulties.

Conclusions: An open label non-mandatory switch from Etanercept originator to its biosimilar showed that around 80% of the patients is willing to perform this switch. Switching did not affect effectiveness of treatment during one year follow-up. 75% of patients were eligible to continue biosimilar therapy. In the 69 patients that switched only one serious adverse effect occurred.

INHIBITION OF LARGE JOINT DESTRUCTION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB

Y. Hirang, K. Hattori, R. Yamada, Rheumatology, Toyohashi Municipal Hospital, Toyohashi, Japan

Background: Rheumatoid arthritis (RA) causes not only inflammation of small joints, such as hands and feet, but also inflammation of large joints. Destruction of large joints is correlated with impairments of physical activity in RA patients more than destruction of small joints is. We experience strong inhibitory effect of inflammation in synovial joints, not only small joints but also large joints, by treatment with tocilizumab (TCZ), an antibody to IL-6 receptor in RA patients in daily clinical practice. Although inhibitory effects of small joint destruction by TCZ is well known, inhibitory effects of large joint destruction is unknown.

Objectives: This retrospective study investigated inhibitory effect of large joint destruction by TCZ treatment in RA patients.

Methods: Toyohashi RA database (TRAD) was used. TCZ was initiated in 65 RA patients in our institute, 31 cases (23 female and 8 male) who continued TCZ over 2 years were utilised in this study. Baseline characteristics and time course of disease activity were investigated. Delta-modified Sharp score (ΔmTSS) per year was used to evaluate small joint destruction. ARASHI score (2) was used to evaluate large joints destruction. Shoulders, elbows, hips, knees and ankles were evaluated using ARASHI score.

Results: Treatment continuation rate of TCZ was 86.3% at one year and 77.7% at two years in whole 65 cases (Kaplan-Meier methods). Baseline characteristics of 31 cases was as follows. Average age: 56 years old. Average RA duration: 6.6 years. Concomitant rate of MTX: 74.2%. Concomitant rate of prednisolone:
MILD AND MODERATE HEPATIC IMPAIRMENT HAVE NO CLINICALLY RELEVANT IMPACT ON UPADACITINIB PHARMACOKINETICS: RESULTS FROM A DEDICATED PHASE 1 STUDY

M.-E.F. Mohamed, S. Coppola, T. Feng, A.P. Lacerda, A.A. Othman, AbbVie, North Chicago, USA

Background: Upadacitinib is a selective Janus kinase 1 (JAK1) inhibitor being developed for the treatment of several inflammatory diseases, including rheumatoid arthritis (RA). Upadacitinib efficacy was demonstrated in Phase 2 studies in RA. Crohn’s disease, atopic dermatitis, in addition to three completed Phase 3 trials in RA. Upadacitinib is a non-sensitive substrate for hepatic metabolism by cytochrome P450 3A; however, 38% and 24% of upadacitinib immediate-release dose are eliminated unchanged in faeces and urine, respectively. Since, there is a potential for upadacitinib use in some patients with hepatic impairment, evaluation of impact of hepatic impairment on upadacitinib exposure is of key clinical relevance.

Rheumatoid arthritis – non biologic treatment and small molecules

ABSTRACT

Figure 1. Evaluation of large joint destruction using ARASHI score during two-year tocilizumab treatment

Conclusions: Over 90% of large joints was not destructed during two-year TCZ treatment. Improvement was frequently observed in knees and elbows. Major reasons of improvement of joint destruction were stabilisation of joints by osteophyte formation and repair of bone erosions.

Objectives: To evaluate the effect of mild and moderate hepatic impairment on the pharmacokinetics of upadacitinib.

Methods: This was a Phase 1, open-label study in subjects with mild (n=9) or moderate (n=6) hepatic impairment, according to the Child-Pugh classification, and demographically-matched healthy subjects (n=6). Subjects received a single 15 mg dose of upadacitinib extended-release formulation under fasting conditions. Blood samples for upadacitinib assay were collected over 120 hours after administration. Upadacitinib maximum observed plasma concentration (Cmax), area under the plasma concentration curve (AUC), and terminal phase elimination half-life (t1/2) were calculated using non-compartmental analyses. Analyses of covariance were conducted to estimate upadacitinib exposure in subjects with hepatic impairment relative to subjects with normal hepatic function.

Results: There was no statistically significant difference in upadacitinib Cmax or AUC in subjects with mild and moderate hepatic impairment compared to subjects with normal hepatic function. One subject with moderate hepatic impairment showed significantly lower upadacitinib exposures than subjects with normal hepatic functions and was excluded as an outlier to ensure a conservative estimate for effect of hepatic impairment on exposure. Upadacitinib exposure ratio central values [and 90% confidence intervals] in subjects with mild and moderate hepatic impairment were 1.28 [0.91–1.79] and 1.24 [0.87–1.76] for AUC and 1.04 [0.77–1.39] and 1.43 [1.05–1.95] for Cmax, respectively, compared to subjects with normal hepatic function. Upadacitinib terminal elimination half-life (harmonic mean pseudo standard deviation) was 7.99±4.60 and 4.14±1.46 in subjects with mild and moderate hepatic impairment relative to 8.93±4.87 in subjects with normal hepatic function. Upadacitinib was generally well tolerated by the subjects in the study.

Conclusions: Mild and moderate hepatic impairment result in only a very limited effect on upadacitinib plasma exposures (<30% increase in upadacitinib AUC). Therefore, in clinical trials, dose adjustments in subjects with mild or moderate hepatic impairment are not warranted.

CHARACTERISATION OF THE EFFECT OF RENAL IMPAIRMENT ON UPADACITINIB PHARMACOKINETICS

M.-E.F. Mohamed, S. Coppola, T. Feng, J. Anderson, A.A. Othman, AbbVie, North Chicago, USA

Background: Upadacitinib is a selective inhibitor of Janus kinase 1 (JAK1) which is currently being evaluated for the treatment of several autoimmune disorders, including rheumatoid arthritis (RA). Although renal elimination plays a minor role in upadacitinib clearance (<20% of upadacitinib dose is eliminated unchanged in urine), a considerable number of RA patients have renal dysfunction. As such, characterisation of the effect of different degrees of renal impairment on upadacitinib plasma exposures is important for this patient population.

Objectives: The objective of this study was to assess the pharmacokinetics of upadacitinib in subjects with mild, moderate, and severe renal impairment compared to subjects with normal renal function.

Methods: This Phase 1 study was conducted in 24 adult subjects, who were assigned to one of four groups (six subjects per group) according to the estimated glomerular filtration rate (eGFR) as calculated by the Modification of Diet in Renal Disease (MDRD) equation: normal renal function (eGFR of >90 mL/min/1.73 m²), mild renal impairment (60–89 mL/min/1.73 m²), moderate renal impairment (30–59 mL/min/1.73 m²), and severe renal impairment (15–29 mL/min/1.73 m²). Subjects received a single 15 mg dose of upadacitinib extended-release formulation under fasting conditions. Blood samples for pharmacokinetic assessments were collected for 120 hours post-dosing. The effect of renal impairment on upadacitinib plasma exposures was assessed through regression analysis as well as analysis of covariance across the renal impairment categories.

Results: The point estimates for upadacitinib plasma exposure ratios [90% confidence interval] in subjects with mild, moderate, and severe renal impairment were 1.00 [0.96–1.04], 1.23 [1.11–1.36], and 1.41 [1.29–1.55] for Cmax, respectively, relative to subjects with normal renal function. In this analysis, one subject with moderate renal function showed exposures significantly lower than subjects with normal renal function.
Folic Acid Supplementation Delays Clinical Similar Efficacy of Tofacitinib on Disease Activity in Patients with Rheumatoid Arthritis

Methods: A. Mohr Drewc,1 C. Brockb,2 S.E. Rasmussen3, M. Pfeffer Jensen4.1 Department of Rheumatology, Aarhus University Hospital, Aarhus;2Mech-Sense, Department of Medical Gastroenterology, Aalborg University Hospital, Aalborg, Denmark

Background: Rheumatoid Arthritis is a prevalent, autoimmune disease causing joint destruction and severe physical disability. In various studies the vagal nerve has been postulated to play a role in modulation of systemic inflammation.

Objectives: Our aim was to investigate the effect of transcutaneous stimulation of the vagal nerve (t-VNS) in patients with rheumatoid arthritis. We hypothesised that stimulation of the vagal nerve and thereby enhanced parasympathetic tone would increase the activity of the vagal nerve and improve experienced clinical pain.

Methods: Sixteen patients with rheumatoid arthritis and flare (DAS28-CRP>3.2) and twenty without flare were recruited. Three bilateral electrical stimulations of the vagal nerve were done with a handheld device for 4 days. Cardiac vagal tone (CVT) was assessed with linear vagal scale (LVS) and DAS28-CRP were collected on the 1st, 2nd and 5th day.

Results: Cardiac vagal tone was significantly lower in patients with flare in comparison to patients without flare (3.2 vs. 4.9 LVS, p<0.03), t-VNS did not alter CVT in patients with flare, however decreased CVT in patients without flare (baseline: 4.9, 2nd day: 3.8 LVS, p<0.03). A decrease in DAS28-CRP in patients with flare was seen in response to t-VNS (baseline: 4.2, 5th day: 3.9, p<0.03), due to decrease in CRP (baseline: 8.2, 5th day: 6.0 mg/L, p=0.02) and number of swollen joints (baseline: 5.4, 5th day: 4.4, p<0.01) and tender joints (baseline: 3.7, 5th day: 2.8, p<0.02) in RA patients with flare. A negative association between baseline CVT and baseline DAS28-CRP was found in all RA patients, showing that lower CVT was associated to higher disease activity.

Conclusions: Baseline CVT was lower in RA patients with flare, possibly due to higher level of inflammation, and the observed decrease in DAS28-CRP was not associated to CVT modulation.

REFERENCES:
In this research, we sought to investigate patients with RA and rheumatoid arthritis (RA). It is notable that although MTX has severe potential side effects, the frequency of patient follow-up and changes regarding daily life. The main questionnaire was filled by the patients in the hospital and physicians filled the on-line questionnaire. Following Fayet et al., the data were collected from rheumatoid arthritis patients (n=98) and physicians (n=82) through a questionnaire that included questions regarding the effects of MTX, MTX administration, drug interaction, side effects, information about the side effects of MTX, drug interactions and the need for contraception. Consequently, had insufficient information regarding MTX. Notably, patients are lack of information about the side effects of MTX, drug interactions and the need for contraception. Hence, we recommend that patients’ knowledge should be increased with and without previous ≥1biologics at weeks 0,12 and 24 (table 2) Remission rate was(43%)at week 60(observed data) (table 2) A total of 9 adverse events (sinfection,3allergic rx,2 rash)were observed during the followup period. The findings showed that patients with RA, who used MTX frequently, had insufficient information regarding MTX. Notably, patients are lack of information about the side effects of MTX, drug interactions and the need for contraception. Hence, we recommend that patients’ knowledge should be increased with and without previous ≥1biologics at weeks 0,12 and 24 (table 2) Remission rate was(43%)at week 60(observed data) (table 2) A total of 9 adverse events (sinfection,3allergic rx,2 rash)were observed during the followup period. The findings showed that patients with RA, who used MTX frequently, had insufficient information regarding MTX. Notably, patients are lack of information about the side effects of MTX, drug interactions and the need for contraception. Hence, we recommend that patients’ knowledge should be increased with and without previous ≥1biologics at weeks 0,12 and 24 (table 2) Remission rate was(43%)at week 60(observed data) (table 2) A total of 9 adverse events (sinfection,3allergic rx,2 rash)were observed during the followup period.

**PHYSICIANS’ AWARENESS ON THE USE OF METHOTREXATE BY RHEUMATOID ARTHRITIS PATIENTS**

B.N. Coskun1, B. Yengiz2, Y. Pehlivan3, E. Dalkılıç2, 1Rheumatology, Ilker Celikcan Physical Therapy and Rehabilitation; 2Rheumatology, Uludag University, Bursa, Turkey

**Background:** Methotrexate (MTX) is an anchor drug used in the treatment of rheumatoid arthritis (RA). It is notable that although MTX has severe potential side effects, most of these side effects could be prevented. Patients should be informed very well regarding MTX and prescriptions should be prepared carefully.

**Objectives:** In this research, we sought to investigate patients with RA and also physicians, awareness regarding use of MTX, which is under-researched.

**Methods:** Following Fayet et al., the data were collected from rheumatoid arthritis patients (n=98) and physicians (n=82) through a questionnaire that included questions regarding the effects of MTX, MTX administration, drug interaction, side effects, the frequency of patient follow-up and changes regarding daily life. The questionnaire was filled by the patients in the hospital and physicians filled the on-line questionnaire.

**Results:** 23% patients responded correctly about that MTX is drug modifying anti-rheumatic drugs (DMARD). 88% of the patients stated that they used MTX weekly, only 16% of the patients were able to explain the reason why they used folic acid, was reducing the toxicity of MTX and only 5% reported that folic acid did not increase the efficacy of MTX. 95% did not know that trimethoprim should not be combined with MTX. 11% were familiar with haematologic risks. 7% were aware of hypersensitivity pneumonitis. 42% had information regarding laboratory tests. 20% were concious concerning the need for contraception. 33% noted that alcohol consumption must be limited. The striking findings physicians responded wrongly was that according to 51% physicians, MTX leads to cancer. Surprisingly, approximately 30% physicians responded wrongly concerning surgery protocol.

**Conclusions:** The findings showed that patients with RA, who used MTX frequently, had insufficient information regarding MTX. Notably, patients are lack of information about the side effects of MTX, drug interactions and the need for contraception. Hence, we recommend that patients’ knowledge should be increased regarding MTX. Physicians should be provided with training to raise awareness proper use of MTX.
Background: Systemic lupus erythematosus (SLE) is a heterogeneous autoim- mune disease characterised by immune system hyperactivation leading to the production of autoantibodies and immune attack on multiple organs including the skin and kidneys. High levels of type I interferons (IFNα/β) alter the activation state of immune cell populations and have been identified as a risk factor for SLE. Anti- body blockade of the interferon alpha receptor (IFNAR) has demonstrated clinical efficacy in a Phase 2b study in SLE, and validates targeting this pathway in SLE.

Methods: FIL was tested in the NZB/W F1 model of lupus at two concentrations (0.05% and 0.1%) formulated in chow and administered from weeks 28–40. Cyclophosphamide (CP) was used as a positive control at 5 mg/kg, once daily. Efficacy was determined by changes in proteinuria, renal histopathology, and survival. Splenic cell populations were analysed by flow cytometry at study completion. pSTAT1 signal was assessed using blood pSTAT1 assay and PK exposure data were used to assess target coverage.

Results: In the NZB/W model, FIL was shown to decrease dose-dependent decrease in proteinuria with a concomitant reduction in BUN levels, renal inflammation, improved glomerular morphology, and increased survival (table 1). Diseased mouse glomeruli showed increased protein casts, interstitial inflammation, and vascu- larized p-values comparing changes between treatment and placebo groups: *p<0.05

Conclusions: FIL demonstrated efficacy in the NZB/W F1 murine model of lupus with an alteration of splenic immune cell subsets affected by type I IFNs toward non-diseased levels. This data provides the basis for the evaluation of FIL as monotherapy in the currently ongoing Phase 2 studies in lupus-related diseases.

AB0486  SUBCUTANEOUS METHOTREXATE DISCONTINUATION IN PATIENTS WITH RHEUMATOID ARTHRITIS
G. Grindeyeva, Y. Muraviev. Federal State Budgetary Institution «Research Institute of Rheumatology» under the Russian Academy of Medical Sciences, Moscow, Russian Federation

Background: Safety of methotrexate (MT) therapy remains the most important issue of early rheumatoid arthritis (RA) therapy.

Objectives: A prospective evaluation of most common causes of MT discontinuation in RA patients with disease duration <3 years.

Methods: An open 1 year study included 106 patients with active RA meeting ACR/EULAR 2010 or ACR 1987 (DAS28 >3.2) criteria, naïve to subcutaneous (SC) MT. All pts were administered SC MT, starting with 10–15 mg/week dose, and following 5 mg up-titration each 1–2 weeks (to max 30 mg/week) until achieving the target (minimal or minimum disease activity) or emergence of adverse reactions (AR). Pts monthly monitoring procedures included physical examination, blood analysis and biochemistry panel. T. Woodworth et al. inventory was used to assess the severity of ARs, and Naranjo scale was used to assess causal relationship of MT with an AR.

Results: Totally 12 (11%) MT discontinuations for the period of >3 weeks were analysed. Permanent discontinuation occurred in 9 pts (8%), and temporary (from 4 weeks to 4 months) in 3 pts. 83% of all cases of withdrawal took place during the first 3 months. In 3 patients MT was discontinued because of an AR and inefficacy. Combination of drug failure with AR was the reason for permanent SC MT discontinuation in 3 pts.

The causes led to SC MT discontinuation were: skin reactions in 3 pts(25%), “after-dose reactions”– in 2 (17%), allergic rash– in 2 (17%), diarthroea– in 2 (17%), elevated liver enzymes– in 3 (25%), leukopenia – in 1 (8%), breast abscess– in 1 (8%). Some patients manifested multiple ARs. Two ARs (17%) were serious (grade 4 severity). Grade 3 ARs were documented in 4 cases (30%), Grade 2 ARs – in 4, and Grade 1 (mild) ARs – in 2 (17%) pts.

Skin lesions became the underlying cause for SC MT discontinuation, such as active dermatitis (n=1) and lichenoid skin reaction (n=1).

Totally 11 (11%) MT discontinuations for the period of >3 weeks were analysed. Permanent discontinuation occurred in 9 pts (8%), and temporary (from 4 weeks to 4 months)– in 3 (3%). 83% of all cases of withdrawal took place during the first 3 months. In 3 patients MT was discontinued because of an AR and inefficacy. Combination of drug failure with AR was the reason for permanent SC MT discontinuation in 3 pts.

The causes led to SC MT discontinuation were: skin reactions in 3 pts(25%), “after-dose reactions”– in 2 (17%), allergic rash– in 2 (17%), diarthroea– in 2 (17%), elevated liver enzymes– in 3 (25%), leukopenia – in 1 (8%), breast abscess– in 1 (8%). Some patients manifested multiple ARs. Two ARs (17%) were serious (grade 4 severity). Grade 3 ARs were documented in 4 cases (30%), Grade 2 ARs – in 4, and Grade 1 (mild) ARs – in 2 (17%) pts.

Skin lesions became the underlying cause for SC MT discontinuation, such as active dermatitis (n=1) and lichenoid skin reaction (n=1).

Conclusions: Skin reactions were the most common cause for SC MT discontinuation. Therapeutic failure as the leading cause for drug discontinuation was not documented in a single patient.

AB0488  DISEASE ACTIVITY AT ONE YEAR AFTER ADDITION OF IGuratimOd OR SULFASALAZINE TO METHOTRExATE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: PROPENSITY SCORE ANALYSIS
K. Tokunaga1, A. Shiraishi2, H. Oshikawa1, N. Hagino3, S. Tohma4. 1Department of Rheumatology, JAPANESE RED CROSS KUMAMOTO HOSPITAL, Kumamoto-City Higashi-ku; 2Emergency Department, Kameda Medical Center; 3Department of Rheumatology, Teikyo University Chiba Medical Center, Chiba; 4Department of Rheumatology, Tokyo National Hospital, National Health Organization, Tokyo, Japan

Background: Igarutimod (IGU) is a small-molecule disease-modifying anti-rheumatic drug (DMARD) that has been shown to suppress inflammation via the inhibition of nuclear factor-kappa B activation in vitro. The efficacy of combination therapy with IGU and methotrexate (MTX) has been demonstrated in comparison with that of placebo in rheumatoid arthritis (RA). However, its efficacy in comparison with other DMARDs such as sulfsalazine (SSZ) has not been elucidated.

Objectives: To assess the disease activity at one year after addition of IGU in comparison with SSZ to MTX in typical clinical practice.

Methods: We analysed data from 16,988 RA patients registered in a large database (NinJa: National Database of Rheumatic Diseases by iR-net in Japan) from April 2012 to March 2017. In this study, we compared the two groups who received IGU or SSZ in addition to methotrexate in the earlier year. We excluded patients who started receiving biologic DMARDs, and IGU or SSZ the year prior to the study period, and those whose regimens were changed to other DMARDs such as tacrolimus and bucillamine.

Baseline characteristics were compared using the t test, Wilcoxon test, or chi-square test. Fisher analysis was conducted for both outcomes. The predicted probability of IGU treatment was calculated by fitting a logistic regression model using all clinically relevant variables as presented in table 1. Moreover, to reduce the effect of treatment-selection bias and potential confounding in this observational study, we performed rigorous adjustment for significant differences in the baseline characteristics of patients with propensity-score matching using the following algorithm: 1:1 optimal match with ±0.2 caliper and no replacement. We used the standardised difference to measure covariate balance, whereby a standardised mean difference of >0.1 represents meaningful imbalance. The outcome of interest was defined as the difference in DAS28-ESR between baseline and week-24. All analyses were performed using all clinically relevant variables as presented in table 1.

Results: The group that received IGU in addition to MTX included 113 patients; the other group that received SSZ in addition to MTX included 244 patients. Table 1 shows the results of the pre- and post-propensity score matching of patients’ characteristics. One hundred and nine patients were compared in each group after score matching. The remission rates of DAS28-ESR in the following year was 45.0% (49/109 patients) and 54.1% (59/109 patients; p=0.22), and drug retention rate was 79.8% (87/109 patients) and 78.9% (86/109 patients; p=1.00), in the IGU and SSZ groups, respectively.

AB0487  MULTICENTER 24-WEEK STUDY TO ASSESS THE EFFICACY AND SAFETY OF TACROLIMUS IN ACTIVE RHEUMATOID ARTHRITIS PATIENTS
J. Hur1, S. Hong2, S. Kim3, G. Kim4, S. Cho5. 1Internal medicine, Eulji university college of medicine; 2Internal medicine, Kyunghee university school of medicine, Seoul; 3Internal medicine, Ulsan university college of medicine, Ulsan; 4Internal medicine, Kook san university college of medicine, Busan; 5Internal medicine, Korea university college of medicine, Ansan, Korea, Republic of Ireland

Background: Rheumatoid arthritis (RA) is characterised by persistent synovitis and structural joint damage with T cell-driven inflammation. Tacrolimus suppresses activation of T cells through the inhibition of calcineurin.

Objectives: We evaluated the efficacy and safety of tacrolimus in Korean active RA patient who had inadequate response to disease-modifying anti-rheumatic drugs (DMARDs) including Methotrexate (MTX).

Methods: During the study period from Aug. 2012 to Jan. 2016 in this open labelled, multicenter study, 115 patients were enrolled with DAS28 >3.2. Patients received tacrolimus during 24 weeks. The initial dose was 1 mg once daily and was increased to 3 mg by every 4 weeks. The disease activity and safety was assessed.

Results: Data from 97 patients were evaluated in full set analysis. At week-24, EULAR response rate were 83.5% (81 of 97) with improvements from week-16 in 74.2% (72 of 97). Mean DAS28-ESR was continuously decreased of 5.64 at baseline, 4.14 (±1.22, p<0.001) at week-16 and 3.66 (±1.39, p<0.001) at week-24. Efficacy rates according to SDAI were 89.7% (87 of 97) and KHAQ-20 score decreased of 2.42 (±4.37, p<0.001) from baseline 7.27 (±4.59) at week-24. Mean ESR was decreased of 10.97 (±24.16, p<0.001) at week-16, -14.77 (±24.57, p<0.001) at week-24 from baseline 46.05 (±23.22). Mean CRP was decreased of 2.86 (±7.85, p=0.0578) at baseline to 1.34 (±3.02, p=0.0367) at week-24. In serious adverse events (6 of 108, 5.6%), two cases (pneumonia, high glucose level) were related with tacrolimus and recovered with treatment.

Conclusions: This study demonstrated the efficacy of add on tacrolimus therapy to MTX in patients with active RA patients.

Disclosure of Interest: None declared
Abstract AB0488 – Table 1. Patients’ Characteristics in Full and Propensity Score-Matched Cohorts according to Initiation of Igaruatimod or Sulfasalazine

CRP: C reactive protein; IGU: iguratimod; mHAQ: The modified Health assessment questionnaire; MTX: methotrexate; PPA: patient’s global assessment; PSL: prednisolone; SD: standard deviation; SJC: swollen joint count; SSZ: sulfasalazine; TJC tender joint count

Conclusions: Combination therapy with IGU or SSZ and methotrexate for rheumatoid arthritis did not show a significant difference in disease activity. Further studies are needed.

AB0489	TOFACITINIB IMPROVES LEFT VENTRICULAR MASS AND CARDIAC OUTPUT IN RHEUMATOID ARTHRITIS PATIENTS WITH CHRONIC HEART FAILURE

K. Kume1, K. Amano1, S. Yamada1, T. Kanazawa1, K. Hatta1, N. Kuwabara2.

1Rheumatology, Hiroshima Clinic, Hiroshima; 2Medical Research, EP Sogo, Nagoya, Japan

Background: Rheumatologists need to develop primary and secondary prevention strategies for cardiovascular disease (CVD) in rheumatoid arthritis (RA) patients. We reported tofacitinib (Tofa) improved left ventricular mass index (LVMI) in patients with rheumatoid arthritis. We have experienced RA patient with chronic heart failure (CHF). We couldn’t use some TNF blockers in RA patients with CHF. There is no evidence that Tofa effects on left ventricular (LV) morphology and function in RA patients with CHF.

Objectives: To study the effect of Tofa on LV morphology and function in chronic synthetic (cs) DMARDs resistant active RA patients with CHF, in a cohort study design.

Methods: RA patients with CHF were eligible if they had active disease despite treatment with cs DMARDs. Consecutive 24 patients with moderate to severe active RA patients (DAS28 >3.2) despite cs DMARDs were received Tofa plus cs DMARDs. LV morphology and function was assessed with cardio-MRI at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data were collected at regular visits.

Results: 21 patients completed 24 weeks. New York heart association functional classification (NYHA) class 1 is 12 cases, class 2 is 7 cases, and class 3 is 2 cases respectively. Left ventricular mass index (LVMI) was attenuated significantly by Tofa (week 0 week24: 9.02±5.8 g/m²; p=0.02). Cardiac output (CO) was attenuated significantly by Tofa (week 0 week24: -0.42±1.2 l/min). DAS28 and CRP improved significantly by Tofa (week 0 week24: DAS28: -2.16±0.95; CRP: 15.1±5.7 mg/L) (p<0.05). Surprisingly, the change of disease activity (DAS 28 and CRP) is no correlation with the change of LVMI or CO in this study. Observationally, 2 cases significantly improved right ventricular mass as well as left ventricular mass (10% improved right ventricular index from baseline).

Conclusions: Tofa improved LVMI and CO in active RA despite cs DMARDs with CHF. Tofa improves LVMI and CO independently of its effects on disease activity. Tofa might be improved right ventricular mass. JAK-STAT pathway might be an important role of LV hypertrophy. Tofa, JAK-STAT pathway blocking, may prevent cardiovascular morbidity and mortality in RA with CHF.

AB0490	EVALUATION OF INHIBITORY FACTOR OF RADIOGRAPHIC PROGRESSION BY IGURATIMOD ADD-ON THERAPY IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSES TO DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

K. Katayama1, Y. Kori1, T. Okubo1, R. Fukas1, Y. Makino1, H. Ito1, 1Orthopedic Surgery, Katayama Orthopedic Rheumatology Clinic, Asahikawa; 2Rheumatology, Sapporo Rheumatology and Immunology Clinic, Sapporo; 3Radiology, Katayama Orthopedic Rheumatology Clinic; 4Pharmacology, Sei-en Pharmacy, Medicine, Asahikawa Medical University; 5Orthopedic Surgery, Asahikawa Medical University, Asahikawa, Japan

Background: Igaruatimod (IGU) is one of csDMARDs (Conventional synthetic Disease modified anti-rheumatoid arthritis drug) for RA patients in Japan. It was reported to suppress the production of inflammatory cytokines by inhibiting NFKb pass-way. IGU add-on therapy was efficient in patients with RA who were previously designated MTX-monotherapy inadequate responders (MTX-IR). The efficacy of IGU add-on therapy in bDMARDs (Biological DMARD)-IR patients was also reported. In this study, we showed disease activity and safety, and showed also radiographic evaluation for the first time by adding IGU.

Objectives: To obtain DAS28-ESR and adverse event data about adding IGU on RA patients with poor response to csDMARDs and/or bDMARDs in single-centre, open label and retrospective study. Furthermore, to show the radiological evaluation after one year.

Methods: Clinical and radiographic efficacy was assessed by disease activity score of 28 joints (DAS28) ESR (n=68) and the modified total Sharp score (mTSS) (n=44), respectively. We evaluated which factors are important in determining a progression of clinical response and mTSS. For safety, adverse events (AE) were investigated on all patients (n=89).

Results: 89 RA patients were recruited, and male was 28% (n=25). Mean age was 61.5 years old and mean of disease duration was 87 months. Main csDMARDs were MTX (72%). The mean dose of MTX was 7 mg/week (The average dose in Japan). Observational period was 13 months (range, 1 to 30). DAS28-ESR changed from 4.3±1.1 to 3.6±1.2 after adding IGU for 6 months (p<0.0001). The relation with the predictive factors before treatment and the response by using Igaruatimod, CRP, ESR, swelling joint, DAS28-ESR, CDAI and
POSSIBLE LINKAGE BETWEEN INTESTINAL BACTERIA COMPOSITION CHANGES AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH NATURAL MILK ANTIBODIES AGAINST ENTERIC BACTERIA AND THEIR TOXINS

K. Katayama, Orthopedic Surgery, Katayama Orthopaedic Rheumatology Clinic, Asahikawa, Japan

Background: A growing body of research has indicated potential association between dysbiosis or imbalance of intestinal bacterial flora and RA. Previously, we demonstrated the natural milk antibody preparation containing high levels antibodies against pathogenic enteromicrobes and their toxins seems to be effective in a certain RA subset in an open labelled pilot study.1

Objectives: To investigate the effects of natural milk antibodies (Ab) on intestinal bacteria composition, and consequent therapeutic effect on disease activity of RA by multicenter randomised double blind clinical trial (UMIN CTR: 000009492).

Methods: Eighty-seven patients with RA with disease activity score of ≥28 joints with ESR (DAS 28-ESR) values above 3.2 were divided into 3 groups (29 patients each), and treated with 600 mg of Ab, 300 mg of Ab plus 10 g of skim milk (probiotics), and 20 g of skim milk alone, respectively, for 12 weeks. The therapeutic effects of milk antibody treatment were determined by DAS28-ESR, swollen joint count (SJC), tender joint count (TJC), and visual analogue score (VAS). The biological effects of milk antibodies were examined by serum and faecal LPS concentration, and faecal bacterial composition changes before and after the treatment. Bacteria composition changes was determined by quantitative PCR of bacterial 16S rRNA.

Results: A significant reduction in DAS28-ESR values from 4.6 to 4.1 was observed at 4th week in Ab 300 mg plus skim milk group (figure 1). Importantly, this effect was lasted through until 12th week (p<0.01), but DAS28-ESR values gradually returned to original levels after discontinuation of the treatment. On the other hand, neither high dose of milk antibody (600 mg) nor 20 g of skim milk had little effect on DAS28-ESR. Characteristic effect of milk antibody treatment observed in the Ab 300 mg plus skim milk group was the improvement of SJC, TJC, and Pain VAS. No severe adverse events have been observed. Enteric microbiome analysis before the treatment indicated lower Bacteroides fragilis (less than 1/100 compared to healthy adults) and higher Staphylococcus aureus population (1000x higher) in patients with RA, indicating a dysbiosis in RA. The DAS28-ESR value reduction in the Ab 300 mg group was associated with an increase in the Lactobacillus population. In contrast, the improvement of Pain VAS was associated with an increase in the B. fragilis population. Possible improvement in the intestinal barrier function was assumed by the reduction of serum and faecal LPS concentration ratio in the Ab 300 mg groups.

Conclusions: Adding IGU to csDMARDs with poor response in RA patients is effective, but AE should be considered. Radiographic progression by Iguratimod might be inhibited in early phase of RA.

JAK-INHIBITION WITH PEFICITINIB AND FILGOTINIB IN FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS

M. Diller1, M.-L. Hülsen1, R. Hassel1, S. Rehart2, U. Müller-Ladner1, E. Neumann1. 1Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus-Liebig-University, Gießen; 2Dept. of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt, Germany

Background: With the approval of the Janus kinase inhibitors (JAKi) Tofacitinib and Baricitinib for the treatment of rheumatoid arthritis (RA) in the European Union (EU), the opportunities for a successful therapy were extended by a new substance class. Other JAKi like Peficitinib and Filgotinib are currently examined in clinical trials. Peficitinib is a pan-JAKi, whereas the other substances differ clearly in the capability to block the four members of the Janus kinase family. It is unclear, if the new substances offer an additional benefit in RA treatment in comparison to the approved JAKi.

Objectives: This study characterised the effect of the different JAKi on inflammatory response of activated fibroblast-like synoviocytes from patients with RA (RA-FLS).

Methods: RA-FLS were isolated from synovial tissue of patients with RA undergoing joint replacement surgery. The cells were pretreated for 2 h with different concentrations of JAKi or vehicle control and then stimulated with IL1-β (10 or 20 ng/ml) or Oncostatin M (OSM, 100 ng/ml). After the indicated time (17–24 h), the supernatants were collected and the concentrations of IL-6 and MMP-3 were measured by ELISA. An assay combining the measurement of cell viability, cytotoxicity and apoptosis was performed to exclude effects of JAKi caused by cell toxicity.
Results: To detect the most effective JAKi in blocking the inflammatory response induced by IL-1β, RA-FLS were first pretreated with different JAKi for 2 hour with concentrations of 1 μM and 10 μM and then additionally stimulated with IL-1β (20 ng/ml) for 18 hour. Even at the highest concentration of 10 μM Tofacitinib and Baricitinib did not change the IL-6 levels, whereas Peficitinib and Filgotinib reduced the IL-6 release at 10 μM. Tofacitinib and Baricitinib reduced the cytokine release if the RA-FLS were stimulated with OSM, a factor directly inducing the JAK-dependent IL-6-pathway (n=3).

To obtain a dose-response curve for the clinically relevant range of concentrations between 0.01 μM and 5 μM, RA-FLS were pretreated with Filgotinib and Peficitinib for 2 hour and then stimulated with IL-1β (10 ng/ml) for 17 hour. In contrast to Filgotinib, Peficitinib at 5 μM caused a reduction of IL-6 levels of 66% compared to control with IL-1β (p<0.01, n=5). The MMP-3 release was decreased by both substances at 5 μM: In comparison to the control with IL-1β, Peficitinib caused a reduction of 92% (p<0.0001, n=5) whereas Filgotinib only reduced the levels by 43% (p<0.05, n=3). Furthermore, Peficitinib at 1 μM decreased the MMP-3 release by 46% (p<0.01).

The treatment with Peficitinib did not affect the viability, cytotoxicity or apoptosis of RA-FLS (n=3). Therefore, the effects of Peficitinib on the inflammatory response were not caused by cell death.

Conclusions: Peficitinib reduced the release of proinflammatory cytokines and of matrix metalloproteinases after activation of RA-FLS with IL-1β and appeared to be superior to Tofacitinib and Baricitinib in targeting the pro-inflammatory and matrix destructive properties of RA-FLS.

AB0493 EFFECTIVENESS OF SUBCUTANEOUS PRESENTATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Villanear1, M. Rivero2, D. Buitrago-García3, M. Cabrera1, P. Santos-Moreno4.  
1Health Services; 2Pharmaceutical Chemist; 3Epidemiology; 4Rheumatology, Biomab, Center For Rheumatoid Arthritis, Bogota, Bogota, Colombia

Background: Methotrexate (MTX) is one of the most used drugs for the treatment of rheumatoid arthritis (RA) and has become the gold standard of therapy. It can be given via oral, intramuscular or subcutaneous (SC). MTX is a highly effective therapy for patients with RA; however, oral MTX has been associated with gastrointestinal intolerance diminishing the adherence of patients to treatment and increasing the switching to biological therapy. Thus, the use of SC methotrexate can improve its efficacy compared to oral MTX.

Objectives: The aim was to determine the effectiveness and safety of SC MTX in patients with rheumatoid arthritis.

Methods: We performed a retrospective descriptive analysis; our main goal was to provide real-life data regarding effectiveness of SC MTX in patients with RA. We excluded patients who were in remission. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3 months. We excluded patients who were in remission. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3 months. We achieved remission in 33% of patients according to DAS28% and 29% according to CDAI, while at 12 months mean DAS28 was 3.28±1.12. Clinical disease activity CDAI at baseline had a mean of 9.6±7.2 and at 12 months 7.8±7.5. We achieved a statistical significance between disease activity at baseline compared to disease activity at 12 months (p<0.005). It was not observed major complaints with SC MTX, only 5% of the patients reported some mild and transient discomfort at the local application site.

Conclusions: Subcutaneous MTX is an effective and safe alternative for the treatment in patients with RA and intolerance to oral MTX, and could be a good option to prevent a premature switching to biological therapy.

Disclosure of Interest: None declared

AB0494 USABILITY OF A PRE-FILLED PEN FOR SELF-ADMINISTRATION OF SUBCUTANEOUS METHOTREXATE

M. Hattesohl1, M. Tribanek, K. Gescher. MEDAC GMBH, Wedel, Germany

Background: Methotrexate (MTX) is the first-line DMARD for the treatment of rheumatoid arthritis (RA). It is also of high significance in the treatment of psoriasis arthritis (PsA) and psoriasis vulgaris (PsV).1,2 Studies in RA patients found that there are advantages in terms of bioavailability and efficacy when MTX is administered subcutaneously (SC) as compared to orally.3,4 Since the introduction of MTX pre-filled syringes, patients are principally enabled to self-administer methotrexate subcutaneously, however not all patients are able to use syringes easily. Auto-injection using a pre-filled pen can facilitate administration by the patient. Results of a comparative crossover study showed that SC self-injection with a pre-filled pen is mainly preferred to a pre-filled syringe with regard to use, acceptability, and satisfaction.5,6

Objectives: The aim of this practice documentation was the evaluation of the usability of a MTX pre-filled pen under everyday clinical conditions.

Methods: This multicentric non-interventional practice documentation, which took place from 2013 to 2015 in Germany, was open to naïve patients and to those who had already been treated with the pre-filled pen in accordance with the approved indications. Usability was evaluated by the patient and the physician through assessment of the individual steps of two self-injections in an interval of approximately 12 weeks (V1, V2) and through a final overall assessment using ordinal scales. Data analysis was carried out descriptively by means of standard statistical methods. Calculation of a total usability score allowed for comparison of V1 and V2.

Results: The 478 participating patients had a mean age of 56±13.7 years, 57.1% were female; 39.3% suffered from RA, 34.7% from PsV, 23.4% had PsA, and 12.6% were diagnosed with other conditions. 87.7% received treatment with the pre-filled pen for the first time, and 61.5% had previously received MTX. The individual steps of self-injection, removing of a protective cap, placing the device onto the skin, pressing the injection button, removing the pen, and ergonomics of the pen, were rated as “very good” and “good” by more than 90% of patients as well as of physicians in both visits. Comparing V1 and V2, usability was assessed to be even better at the second visit (p<0.0001 in the total score). Injections were carried out accurately by more than 93% of the patients.

Conclusions: Auto-injection with a pre-filled pen enables patients to self-administer subcutaneous MTX easily and comfortably in routine clinical practice.

Post-marketing surveillance of tofacitinib in Japanese patients with rheumatoid arthritis: An interim report of safety data

N. Tamura1, M. Kuwana1, T. Atsumi2, S. Takeda1, M. Harigai1, T. Fujii1, H. Matsuno1, T. Mimori1, S. Morohama1, K. Nomura1, Y. Endo1, N. Sugiyama1, T. Hiroshi1, Y. Morishima1, N. Yoshi1, T. Makag1, T. Juntendo University, Tokyo; 2Nippon Medical School, Tokyo; 3Hokkaido University, Sapporo; 4Kagoshima University, Kagoshima; 5Tokyo Women’s Medical University, Tokyo; 6Wakayama Medical University, Wakayama; 7Matsumo Clinic for Rheumatic Diseases, Toyama; 8Kyoto University, Kyoto; 9Hakkeikai Medical Institution, Shizuoka; 10The University of Tokyo, Tokyo; 11Matsuno Clinic for Rheumatic Diseases, Shizuoka; 12Yamagata University Faculty of Medicine, Yamagata, Japan

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Efficacy and safety of tofacitinib have been shown in patients (pts) with RA in global Phase (P)2, P3 and a long-term extension (LTE) study and in 2 P2 and 1 LTE study in Japanese pts.

Objectives: To evaluate safety of tofacitinib following drug approval in Japanese pts with RA using all-case post-marketing surveillance (PMS) data.

Methods: An interim analysis (IA) of safety data from an ongoing 3 year PMS study was conducted (5 Nov 2017 data-cut). All Japanese RA pts receiving tofacitinib were prospectively registered in the PMS study. All adverse events (AEs) were collected during tofacitinib treatment. Follow-up surveillance after discontinuation was conducted for serious infection events (SIEs; 1 year), malignancy and death (3 years). For all AEs and serious AEs, 6 month IA data was used. For AEs of special interest, all-period data (up to 36 months) was used to calculate cumulative incidence rates (IRs; pts with events/100 pt-yrs [yrs]) over time for herpes zoster (HZ) and SIEs during treatment +28 days and for malignancies during the full observation period.

Results: Overall, 3929 tofacitinib-treated pts with 1704.1 pt-yrs of exposure were included in the 6 month IA of safety: 80.5% were female, mean age was 62.7 years, with 32.6% of pts: 70 years. Of these, 892 pts (22.7%) discontinued treatment, mainly due to AEs (351 pts; 8.9%) or lack of effectiveness (335 pts; 8.5%). At least one AE was observed in 1313 pts (33.4%); infections were observed in 493 pts (12.5%). The most frequent AEs were HZ (145 pts; 3.7%) and abnormal hepatic function (72 pts; 1.8%). SAEs occurred in 287 pts (7.3%); the most frequent SAEs were HZ (24 pts; 0.6%) and pneumonia/bacterial pneumonia (33 pts; 0.8%). SAEs occurred in 130 pts (3.3%). Malignancy (all causality) was reported in 25 pts (0.6%). Lymphoma/lymphoproliferative disorder occurred in 5 pts (0.1%) and breast cancer in 3 pts (0.08%). There were 21 deaths (0.5%) during the 6 month period. The most common causes of death (including pts with multiple causes listed) were infection (6 cases) and malignancy (5 cases). For AEs of special interest from all-period data the IR of HZ (serious and non-serious) was 6.81 (264 pts; 3876 pt-yrs) and the IR of SIEs was 5.38 (212 pts; 3941 pt-yrs) and the IR of malignancy was 1.25 (61 pts; 4874 pt-yrs).

Conclusions: This IA of tofacitinib PMS in Japan did not reveal any new or unex- pected safety signals vs the tofacitinib RA clinical trials. IRs for HZ and malignancy was similar to IRs in clinical trials of tofacitinib in Japanese RA pts and the SIE IR was within the range reported in PMS of biologic treatments. Continuous monitoring of SAEs is required until the final PMS results.

T2Z with subcutaneous methotrexate in very early rheumatoid arthritis (RA)

N. Chichasova1, 2, G. Imantienė1, E. Nasonov1, 2

1Nasonova State Institute of Rheumatology; 2Federal State Autonomous Educational of Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation, Moscow, Russian Federation

Objectives: Adherence to foundations T2Z and education of patients (pts) according to T2Z Connect program increase possibility of favourable outcome of RA.

Methods: In open prospective 36 months study of efficacy and safety of subcutaneous methotrexate (MT) 74 pts with definite very early RA (ACR/EULAR 2010) were included: mean age was 45.2±15.9, mean duration of RA – 5.2±3.48 months, mean DAS28 – 5.68±1.99 (max 7.06, min 4.44), RR positivity 73% and ACCP positivity 77% of pts. 3 pts had joint erosions. FK II had 43% and III–53% of pts. Education conducted by program T2Z Connect. Initial dose of MT was 15 mg/week, all pts used 5–10 mg/week folic acid and NSAIDs in therapeutically dose according to comorbidities, systemic glucocorticoids (GC) were not prescribed. 72 pts completed 12 months of treatment, 54–24 months, 29–36 months.

Results: In 88% of pts improvement was observed in first 4–5 weeks. After 3 months low disease activity (LDA) was registered in 18 pts, in over pts therapy wasn’t corrected in view with clear tendency to decrease of RA activity, intraarticular injection of GC was performed in 3pts. Changes of DAS28 are in the table 1. After 6 months moderate disease activity was in 49% of pts, LDA – in 51%. After 12 months of study in all pts target of treatment was achieved: LDA in 81% of pts and remission (ACR/EULAR 2010) in 19%; after 24 months 57% and 43% respectively, after 36 months – 36% and 64% respectively (18 pts without treatment). The minimal radiographic progression was observed in 18 pts (24%, mean erosion’s score 1.63±1.02), that wasn’t cause of firm decrease of functional ability in pts. 3 women with remission after 18 and 20 months of treatment with MT became pregnant and gave birth to normal newborns. Withdraw MT because of AE was in 2 pts (flu-syndrome).

Effectiveness, Tolerability, and Safety of Tofacitinib in Rheumatoid Arthritis: A Retrospective Analysis of Real-World Data from the St. Gallen and Aarau Cohort

R. Mueller1, F. Popo1, F. Mattow1, M. Durniss1, A. Souza2, H. Schutze-Koos3, P. Hasler2, J. von Kempis1, 1Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen; 2Division of Rheumatology, Kantonsspital Aarau, Aarau; 3herita AG, Gränichen, Switzerland; 4Rheumaeinheit, University of Munich, München, Germany

Background: Tofacitinib is an oral JAK inhibitor indicated for the treatment of RA. Efficacy and safety of tofacitinib have been shown in several randomised clinical studies.

Objectives: The study presented here aimed to assess the clinical tolerability and effectiveness of tofacitinib among patients with RA in real life.

Methods: Consecutive patients between June 2013 and April 2017 with RA who fulfilled the American College of Rheumatology/EULAR 2010 criteria were analysed in a prospectively designed analysis of retrospective data. Patients were initiated on tofacitinib 5 mg bid. The primary objective was to analyse safety of tofacitinib in a real life cohort. Safety was assessed by the reasons to stop tofacitinib. The follow up period was 1 year.

Results: Overall, 144 patients were treated with tofacitinib. 84.9% of the patients were naive to biologics. The mean follow up was 1.22 years (range 10 days to 62 months). Rate of MTX was elevated from 57% to 62%, and dose (mean ± SD) was increased from 9.8±3.2 to 11.6±3.7 mg/w (p<0.0001) for uses only, whereas PSL was suppressed from 56% to 26%, and decreased from 2.0±1.3 to 0.8±1.8 mg/d (p=0.0004) for all patients. SDMARDs were used for 16 patients, and newly initiated for 2 patients. Although not significant, median CDAI, SDAI, and DAS28 were suppressed from 5.7 to 3.8, 6.2 to 3.9, and 2.92 to 2.77, and remission rate were increased from 24% to 39%, 27% to 41%, and 36% to 41%, respectively.

Conclusions: GCs could be reduced or withdrawn without deterioration with appropriately increased MTX. Moreover, disease control rather showed improved tendency.

Evaluation of the Effectiveness of Metabolism in the Hepatic Toxicity Due to Methotrexate in Patients with Rheumatoid Arthritis

S. Parisi, M.C. Ditto, M. Scarrati, M. Priora, F. Enrico, Rheumatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy

Background: Methotrexate inhibits the metabolism of purines resulting in the accumulation of adenosine; it also inhibits the activation of T cells and suppresses the expression of intercellular adhesion molecules for T cells. Side effects may show up during the treatment and among them there is hepatic toxicity, characterised by an increase of AST and ALT; such increase is usually asymptomatic but may lead to a suspension of the treatment. Metabolism (MTDX) is a drug which is used in order to treat both acute and chronic alcohol intoxication; it also prevents the inactivation of ATP from acetaldehyde and pyrogallatic acid. MTDX also showed to improve hepatic function markers and to decrease oxidative stress leading to a protective effect against radicals.

Objectives: The aim of this preliminary study was to evaluate the possible effect of MTDX on hepatic function in patients affected by RA in therapy with MTX.

Methods: The study involved the recruitment of patients affected by RA in treatment with MTX; a following random selection of a subgroup of patients who took MTDX (500 mg twice a day for 28 days, from the 5th to the 8th week of therapy with MTX) was performed. All the patients underwent a 12-week-follow up in which these parameters were evaluated: demographics, blood tests required for MTX in accordance with datasheets (especially AST and ALT), CRP, ESR, ACPA, numbers of swollen and tender joints, concomitant medications (NSAIDs and steroids) and the degree of disability (HAQ, table 1).

Results: 24 patients affected by RA (20 women), with an mean age of 51.3 years (+/-1.4) and mean MTX dose of 13.2±3.2, were recruited. 70.3% took GC with a medium dosage (3.72±2.7). Among these 24, 13 patients were underwent MTDX 500 mg twice a day for the 5th to the 8th week of therapy with MTX) was performed. All the patients underwent a 12-week-follow up in which these parameters were evaluated: demographics, blood tests required for MTX in accordance with datasheets (especially AST and ALT), CRP, ESR, ACPA, numbers of swollen and tender joints, concomitant medications (NSAIDs and steroids) and the degree of disability (HAQ, table 1).

Comparison of Hepatic Functions between two groups

Conclusions: In summary, the patients who were treated with TOF + MTX had significantly lower AST and ALT levels than those treated with TOF alone. This study suggests that the combination of TOF + MTX may be a safe and effective treatment option for RA patients.

Abstract AB0501

Efficacy and safety of tofacitinib (TOF) in patients with rheumatoid arthritis 52 weeks in clinical practice

T. Arakawa1, K. Kojima1, S. Kurushima1, Y. Tsuchi1, N. Kawachi1, N. Inamoto2, K. Ichinose1, K. Terada3, K. Eguchi3, Y. Ueki1, A. Kawakami4, Rheumatic Disease Center, Sasebo Chuo Hospital, Sasebo; 2Unit of Translational Medicine, Department of Immunology and Rheumatology, Nagasaki Graduate School of Biomedical Sciences, Nagasaki; 3Sasebo Chuo Hospital, Sasebo, Japan

Objectives: There are few long-term experience of TOF for Rheumatoid arthritis (RA) patients in clinical use. We evaluated 52 and 104 weeks efficacy and safety of TOF in patients with rheumatoid arthritis in clinical practice.

Methods: We enrolled 77 RA patients started to treat with TOF between December 2013 and November 2016 in our hospital. All patients received 5 mg of TOF twice daily. We evaluated clinical disease activity in composite measures (including Disease Activity Score 28 (DAS28) – Erythrocyte (ESR), – C-reactive protein (CRP), Simple Disease activity Index (SDAI) and Clinical Disease Activity Index (CDAI)) every three months and adverse events (AEs) during 52 and 104 weeks after treatment with TOF. We estimated the drug survival rate with Kaplan-Meier survival analysis.

Results: The mean age of patients was 66.3 years and the duration of disease was 15.4 years. Fifty-four (74.0%) patients have positive rheumatoid factor (RF) and 59 (78.7%) patients have positive anti-citrullinated protein antibodies (ACPA). Twenty-three patients were biologic-naive and fifty-four patients have ever been treated with biologic DMARDs of whose mean number is 2.6 prior to TOF. Regarding the last biologic DMARDs: 14 patients have treat with TNF inhibitor (infliximab, etanercept, adalimumab, golimumab, certolizumab-pegol), 30 patients with tocilizumab and 10 patients with abatacept. Twenty-three (29.9%) patients were treated with TOF without methotrextate (MTX) twice daily. We evaluated clinical disease activity in composite measures (including DAS28-ESR, DAS28-CRP, SDAI and CDAI) were 5.15, 4.07, 23.3 and 21.5 respectively. The Drug survival rate at 24 weeks is 84.4% and that at 52 weeks is 70.2%. Eleven patients were stopped to treat with TOF due to adverse events (n=5) and lack of efficacy (n=7). Analysed by last observation continued forward (LOC) method, the mean of DAS-ESR decreased to 3.52 at 24 week and 3.59 at 52 week. CDAI decreased from 21.5 to 7.94 at 24 week and 7.93 at 52 week. Sixteen (20.8%) patients were remission as which defined less than 2.6 in DAS-ESR and 13 (16.9%) were low disease activity (LDA) as which defined less than 3.2 in DAS-ESR. In 23 patients without MTX, 6 (26.0%) and 5 (21.7%) have achieved remission and LDA at 52 W respectively. The adverse events due to which the patients had to be stopped to treat with TOF occurred in 20.6% of patients in initial 52 weeks. Infection was the most frequent AE to TOF, especially herpes zoster (7 patients). Six patients experienced herpes zoster within 6 month after treat with TOF. All of them could restart almost of them with TOF.

Conclusions: Our study shows that TOF can be much effective clinically and have longer-lasting effectiveness. In our patients, herpes zoster was almost as frequent as reported in the phase III trials in Japan and we could restart almost of them with TOF.

ADVERSE EVENTS WITH TREATMENT REGIMENS OF RHEUMATOID ARTHRITIS (RA) REPORTED BY PATIENTS APPLYING SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILES TOOLS: A COHORT STUDY OF RA PATIENTS IN CHINA

Background: Hepatic, hemolitic and other adverse events (AE) during treatment in RA patients are unavoidable. And monitoring AE in long-term treatment is quite necessary as a part of chronic disease management. SSDM is a smart mobile tool to help patients upload their therapeutic regimen, lab test records and report AEs. Our previous study showed that patients in China can master the application of SSDM after training.

Objectives: To determine and compare the incidence of adverse events during treatment of RA with different therapeutic regimens, focusing on mono and combination therapy.

Methods: The SSDM includes interfaces of both physicians’ and patients’ application. Patients were educated to enter the data of lab test records and treatment regimens once a month, all data can be synchronised automatically to the author’s database.

Results: From Aug 2014 to Jan 2018, a total of 7048 RA patients from 480 centres in China were entered in the cohort study. These patients contributed more than 12 600 patient-years (PY) of total followup. The mean age was 48.8 ±16.08 (18 to 99) years and the median disease duration was 23.27 months. The treatment regimens include mono or combination of leflunomide(LEF), MTX, hydroxychloroquine (HQC), sulfasalazine(SSZ), glucocorticoid(GC), biologic DMARD, Tripterygium wilfordii, meloxicam, celecoxib, iguratimod, etc. In this database the five most common treatment regimens is LEF monotherapy (3801 PY), MTX monotherapy (1321 PY), LEF +MTX (1086 PY), HCQ monotherapy (715 PY), LEF +HQC (576 PY). The incidence rate of hepatic events was lower for LEF +MTX combination therapy (39 events/1000 PY) than LEF +HCQ combination therapy (84 events/1000 PY). The incidence rate of leukopenia was lower for LEF monotherapy (42 events/1000 PY) and MTX monotherapy (39 events/1000 PY) than LEF +MTX combination therapy (84 events/1000 PY). The incidence rate of leukopenia was lower for LEF monotherapy (42 events/1000 PY) and MTX monotherapy (39 events/1000 PY) than LEF +MTX combination therapy (84 events/1000 PY).

Conclusions: The findings show that mono or combination of csDMARDs are the most commonly used drugs in Chinese RA patients. And AEs may be well described in this patient report database because of the large sample sizes and empowering patient themselves. RA patients can get better safety in the long-term treatment via SSDM.

AB0502

DRUG SURVIVAL ANALYSIS OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Karakoc1, I. Ercan2, 1Rheumatology Clinic, Biyozif Medical Centre; 2Biosistatlcs, Uludag University Medical Faculty, Bursa, Turkey

Background: The drug survival rate of tofacitinib in patients with Rheumatoid Arthritis (RA) has not been reported so far.

Objectives: To determine the tofacitinib drug survival rate and the factors that may affect it in patients with RA from a single rheumatology clinic.

Methods: We have retrospectively analysed the track records of RA patients to whom tofacitinib was prescribed between June 2014 to December 2017. Descriptive analysis includes sex, duration of disease, autoantibody association, smoking, major trauma exposure, initiation in DMARD/Anti-TNF resistant patients, monotherapy/use in combination with DMARD. According to the duration of the disease, the patients were grouped as early (0–4 year), established (5–10 year), and late RA (>10 year).

Drug survival was estimated using Kaplan-Meier survival analysis, and the independent variables that may affect the discontinuation were investigated by log-rank test and modelled by Backward Stepwise Cox regression analysis.

Tofacitinib was prescribed to patients who were resistant to at least three different types of csDMARDs. Low-dose Steroid (below 10 mg) and NSAID drugs were used as needed.

Results: During the study period, 192 (163 F, 85%) patients were prescribed tofacitinib in our clinic. Median age was 56±8–61 years, the median age at onset was 45±12 years, and median disease duration was 10±4–14 years. In this study, the ratio of RF and anti-CCP positivity were 63% and 60%, respectively. 33% of patients were seronegative. The patients with a smoking history were 26%, and exposure to major trauma was 16%. 15% of patients were early, 31% established, and 54% late RA.

Tofacitinib was prescribed in 92 (48%) bio-naive and 100 (52%) bio-experienced patients. It was used as monotherapy in 112 (58%) and in combination with csDMARDs in 80 (42%).

The drug survival rates in Kaplan Meier analysis were 77% at 3rd, 69% at 6th, 62% at 12th, 54% at 18th and 49% at 24th, 49% at 30th months. Tofacitinib was discontinued in 51 (27%) patients due to no response and in 22 (11%) patients due to side effects. None of the independent variables in regression analysis showed a relationship to tofacitinib discontinuation (p>0.05). During the follow-up period, one patient had breast cancer, and one had recurrent pneumonia. There were no tuberculosis or shingles cases reported. Two patients died from pulmonary thromboembolism.

Conclusions: We found that drug survival rates of tofacitinib in RA patients were 77% at 3rd month, 69% at 6th month, 62% at 12th month, 54% at 18th month and 49% at 24th month, 49% at 30th months. The main cause of discontinuation of the drug was inefficiency and the loss of efficiency. We could not find any link between the predetermined independent variables and the drug discontinuation. This result raises questions about why the drug loses its efficacy in some patients in time, and how this could be preventable.

Acknowledgements: One of the theories of autoimmunity is that Damage-Associated Molecular Patterns (DAMPs) may give rise to autoimmune inflammation. We were curious about how many of patients suffered from major trauma, which was defined as accidents terminated with fractures and dislocations or falls from a height of at least three metres.

Mosca12, M. Pelusi13, M. Piga14, C. Sciri11, E. Silvagni15, A. Tincani16, P. Tomietto17, S. Truglia18, M. Zeli19, G. Bentissas13, M. Govoni20, 1University of Ferrara, Cona (Ferrara), Italy; 2Atikon University Hospital, Athens, Greece; 3State University of Campinas, Campinas, Brazil; 4University of Pisa, Pisa; 5Epidemiology Unit, Italian Society of Rheumatology, Milano; 6Sapienza University of Rome, Rome; 7University of Udine, Udine; 8University of Padova, Padova; 9University of Brescia, Brescia, Italy; 10Dalhousie University, Halifax, Nova Scotia, Canada; 11University of Cagliari, Cagliari; 12AOU Ospedali Riuniti di Trieste, Trieste, Italy; 13University of Crete, Heraklion, Greece

Background: The treatment of neuropsychiatric systemic lupus erythematosus (NPSSLE) is extremely challenging and only a few clinical trials have been performed to establish optimal management.

Objectives: To describe the therapeutic approach and the short-term outcome of a multi-centre cohort of patients with NPSSLE, enrolled at the time of the first NP event.

Methods: This is a retrospective cohort study. All NP events were defined according to American College of Rheumatology (ACR) case definition and divided into 3 clusters: central/diffuse (C/D), central/local (C/F) and peripheral (P). A validated attribution algorithm was used to determine the attribution of all NP events. Demographic variables, global SLE disease activity (SLEDAI-2K), cumulative severe organ damage (SLICC/ACR Damage Index (SDI)) and treatment adopted for NP manifestations were collected. The clinical outcome of all NP events was determined by a physician-completed seven-point Likert scale (1=patient demise, 2=much worse, 3=moderate worse, 4=no change, 5=improved, 6=much improved, 7=resolved). The relationship between the variables of interest and the outcome was analysed by crude and adjusted logistic models and reported as Odds Ratio (OR) and 95% confidence intervals (95% CI).

Results: 461 SLE patients with at least one NP event were included. 91.8% of patients were female, mean (SD) age 35.4 (13.6) years. 19.7% (91) of events were observed at diagnosis of SLE, 13.4% (62) before and 66.8% (308) after the diagnosis. 111 events (24.1%) were C/F, 286 (62%) C/D and 64 (13.9%) P. 198 (42.9%) of all NP events were attributed to SLE. The overall probability of immunosuppressive therapy was 28.4% (95% CI 24.3–32.8), 38.7% (95% CI 29.6–48.5) in C/F, 21.3% (95%CI 16.7–26.5) in C/D and 42.2% (95%CI 16.7–26.5) in P manifestations. The probability of immunosuppressive therapy was 47.9% (95% CI 40.8–55.2) in attributed events. The one-year outcome was available in 355 patients. Physician assessment indicated resolution (76 patients) or improvement (150 patients) in 49% (226/461) of cases. The crude and adjusted OR of attributed NP events and immunosuppressants on a favourable outcome is illustrated in Figure 1. The multivariable logistic regression analysis was done adjusting for age at diagnosis of SLE [OR 0.96, 0.94–0.98] = p<0.001, female gender [OR 0.97, 0.33–2.7] = p=0.959, SDI [0.85, 0.68–1.08] = p=0.202, SLEDAI-2K [1.06, 1.01–1.11] = p=0.008 and type of event (F/C [REF], C/D [0.37, 0.16–0.83] = p=0.016, P [0.54, 0.21–1.42] = p=0.215).

EFFICACY OF PROLONGED MAINTENANCE MONOTHERAPY WITH RITUXIMAB IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: THREE-YEAR FOLLOW-UP

A. Tominshia1, E. Rodionova1, T. Satonova2, V. Vasiliev1. 1Nasonova Research Institute of Rheumatology, Research Institute of Ophthalmic Diseases, Moscow, Russian Federation

Background: There are currently no effective systemic therapies of primary Sjögren’s syndrome (pSS); however, open label series have suggested that rituximab may be beneficial for systemic and glandular manifestations.

Objectives: To estimate clinical efficacy and safety of prolonged maintenance B-cell targeted monotherapy for pSS.

Methods: 25 with pSS ACR-EULAR criteria, 2016 were included in this research. Indications for treatment were significant immunological activity (high titres of rheumatoid factor (RF) and/or anti-nuclear antibodies) and/or hypogammaglobulinaemia in 20 patients, parotid enlargement (lymphoma was excluded) – 5, arthritis – 3, lymphadenopathy – 3, severe keratoconjunctivitis sicca in 7, of them corneal...
AB0506 HYDROXYCHLOROQUINE HAS NO PROTECTIVE EFFECT ON THE DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN 704 PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: A NATIONWIDE POPULATION-BASED STUDY

B.-C. Hsu, K.-T. Tang. Department of Allergy, Immunology, and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

Background: Hydroxychloroquine (HCQ) has been proposed to be associated with later onset of systemic lupus erythematosus (SLE) and is widely used in patients with primary Sjögren’s syndrome (pSS) which may evolve to SLE. We want to explore the potentially protective role of HCQ in the development of SLE among patients with pSS.

Objectives: This study was conducted to assess whether exposure to HCQ in pSS patients is associated with a reduction in the development of SLE.

Methods: This retrospective cohort used claims data from the National Health Insurance Research Database (NHIRD) in Taiwan. Patients with incident Sjögren’s syndrome (SS) from 2000 to 2010 in the Registry of Catastrophic Illness Database (RCIPD) of the NHIRD, which was certified by two rheumatologists, were identified. The date when SS was diagnosed in the RCIPD was defined as the index date. Those who were diagnosed as having SLE, rheumatoid arthritis, polymyositis, dermatomyositis, or systemic sclerosis in the RCIPD before the index date were excluded. Other exclusion criteria included patients who were diagnosed as having SLE in the RCIPD within one year after the index date, patients who withdrew from the NHIRD within one year after the index date, and patients who used oral, intramuscular, or intravenous corticosteroids, methotrexate, azathioprine, leflunomide, sulfasalazine, cyclosporine, tacrolimus, mycophenolate, mercaptopurine, or cyclophosphamide for more than or equal to 90 days within one year before or after the index date. The included SS patients who used HCQ for more than or equal to 90 days within one year after the index date were eligible to HCG group. The study endpoint was defined as newly-diagnosed SLE in RCIPD or withdrawal from NHIRD during the 14 year follow-up period (January 1st, 2000 to December 31st, 2013).

Results: A total of 7004 pSS patients were identified. The mean follow-up time was 6.9 years in the HCG group (n=4282) and 7.0 years in the non-HCG group (n=2722). There were 22 newly-diagnosed SLE (0.5%) in the HCG group and 16 (0.6%) in the non-HCG group. The overall event rate of SLE was 8.78/10,000 person-years in the HCG group and 9.83/10,000 person-years in the non-HCG group (adjusted hazard ratio 0.97, 95% confidence interval 0.50–1.88, in a Cox proportional hazard model).

Conclusions: There is no protective effect of HCQ on the development of SLE in patients with pSS.

Fixed, low-dose hydroxychloroquine versus weight-adjusted dose in systemic lupus erythematosus patients with low activity
J.L. Cellejas-Rubio1, D. Sanchez-Cang1, R. Rios-Fernandez2, M. Moreno-Higuera3, G. Fatou del Prado1, S. Velasco-Fuentes1, M. Trigo-Rodriguez1, N. Faro-Minguez1,1 Unidad de Enfermedades Autoinmunes Sistemicas; 2 Servicio de Medicina Interna, Hospital Campus de la Salud, Granada, Spain
Background: Optimal hydroxychloroquine (HCQ) dose to reduce ocular toxicity risk is 5 mg/kg or actual weight daily, according to new recommendations. In systemic lupus erythematosus patients (SLE) with low or no disease activity, fixed low-dose HCQ might be equally effective in relieve prevention weight-adjusted doses, thus resulting in lower cumulative dose.

Objectives: Our aim was to compare a fixed dose of HCQ 200 mg daily with a weight-adjusted dose (5 mg/kg of actual weight daily) in SLE patients with low activity.

Methods: SLE activity was assessed using the SLE Disease Activity Index (SLEDAI-2K), the Safety of Oestrogen in Lupus Erythematosus National Assessment (SELENA)-SLEDAI and the Physician Global Assessment (PGA, 0–3 scale) in each visit. Low-activity SLE (LLDAS) was defined according to Franklyn et al: 1) a SLEDAI-2K score ≤4, 2) no new SLE-related activity events compared with the previous visit, 3) a PGA score ≤1, 4) prednisone dose ≤7.5 mg daily and 5) stable doses of maintenance immunosuppressant therapy. LLDAS was evaluated at baseline and months 3 and 6. In order to adjust doses to weight, and given the impossibility of fractionating HCQ tablets, the adjusted dose was calculated for every week. For example, for 62 kg patient, the calculated dose would be 5 mgx52 kg=260 mg daily, which would mean 1820 mg weekly. Therefore, the patient would receive 400 mg daily for 2 days and 200 mg daily for 5 days every week. A relapse was defined as an increase of SLEDAI scores >3, according to current recommendations.

Results: A total of 50 LLDAS patients were compared, 25 with a fixed dose and 25 with a weight-adjusted dose. No significant differences regarding body weight between groups were observed: 52 kg (41–58.5 kg) vs. 51 kg (44–55 kg). Baseline activity scale scores were not significantly different. No patient relapsed on follow-up in either of both groups. Finally, the mean HCQ cumulative dose at 6 months was reduced by approximately 9.6 grams.

Conclusions: In LLADS patients, a fixed HCQ dose of 200 mg daily may be as effective as the weight-adjusted dose in preventing disease relapses, thus resulting in a decrease in the HCQ cumulative dose and, therefore, a reduction of the risk of ocular toxicity.

Fixed, low-dose hydroxychloroquine versus weight-adjusted dose in systemic lupus erythematosus patients with low activity
J. Lickliter1, D. Bomba2, J. Anden2, A. Fan2, C.J. Kirk2, J. Wang2, 1Nucleus Network, Melbourne, Victoria, Australia; 2Kezar Life Sciences, South San Francisco, California, USA
Background: Proteasome inhibition is a standard of care for plasma cell malignancies. Bortezomib targets the constitutive proteasome and immunoproteasome, and is effective in the treatment of Systemic Lupus Erythematosus (SLE) and lupus nephritis (LN), but is associated with hematologic (e.g. thrombocytopenia) and constitutional (e.g. peripheral neuropathy) adverse events (AEs).

Objectives: We report the safety, pharmacokinetics (PK), pharmacodynamics (PD) and immunomodulatory effects of KZR-616, a first-in-class selective inhibitor of the immunoproteasome, in healthy volunteers (HV) following single and repeat subcutaneous (SC) administration.

Methods: Cohorts (6 drug:2 placebo) received single or 4 weekly SC doses. Safety assessments, PK and PD were measured to Day 7 (SAD) or Day 28 (MAD). SAD cohorts included 7.5, 15, 30 and 60 mg (SC). MAD cohorts included 30 and 60 mg, and 2 intrasubject escalation cohorts with 1 dose at 30 mg and 3 doses at 45 mg. PK was measured by LC/MS2. PD was measured using enzymatic and active site binding assays. Inflammatory cytokine release was measured following ex vivo stimulation of whole blood in HV receiving placebo or 45 mg KZR-616.

Results: 32 HV (24:8) were enrolled in 4 SAD cohorts. The most common AEs were injection site reactions (ISRs), which were generally mild and transient. No clinically-significant (CS) laboratory or ECG abnormalities and no dose limiting toxicities were observed in the SAD subjects. Following SC administration, drug exposure increased dose proportionally and was characterised by rapid absorption (Tmax15–30 min) and clearance (T1/2 ~2 hours). Inhibition of the immunoproteasome exceeded 80% at >30 mg with significant recovery noted over 7 days. Constitutive proteasome inhibition was <37% in all cohorts.

40 HV (30:10) were enrolled in 5 SC MAD cohorts. In the initial cohort of 60 mg, a systemic drug reaction (chills, elevated heart rate, nausea) occurred ~8 hours after the first dose in 4 subjects. Dosing for this cohort was stopped. Subsequent cohorts (initiated at 30 mg) received prophylactic treatment with antihistamines and prednisolone 1 hour prior to the first and second dose. No similar AEs occurred with the dosing of 45 mg, but laboratory or ECG abnormalities were seen in the remaining MAD cohorts. ISRs did not appear to increase in severity or frequency with repeat dosing. There were no AEs of peripheral neuropathy, and 45 mg was well tolerated across 3 cohorts.

Consistent PK was noted following repeat administration and no drug accumulation was observed. At 45 mg, inhibition of 2 key subunits of the immunoproteasome, LMP7 and LMP2, was ~95% and ~70%, respectively. Reduced ex vivo stimulated production of multiple cytokines (IL-23, IL-6, TNF-a, IL-17) was noted in subjects receiving repeat administration of 45 mg KZR-616.
Conclusions: The educational intervention and outcomes measurement were funded through an independent educational grant from GlaxoSmithKline Global.

**IMPROVING KNOWLEDGE OF SLE DISEASE FLARES AND TREATMENT OPTIONS AMONG RHEUMATOLISTS AND PRIMARY CARE PROVIDERS: EFFECT OF AN ONLINE EDUCATIONAL INTERVENTION**

F. Jackson; D. Blatherwick, K. Badal. Medscape Education, New York, USA

**Background:** With a significantly higher mortality in patients affected by systemic lupus erythematosus (SLE) developing chronic disease, prevention is a major goal in management. Flares are a common feature throughout the course of SLE and can result in organ damage. As a result, clinician knowledge on how to prevent, recognise, and treat flares is crucial.

**Objectives:** Determine whether an online educational intervention could effectively address a knowledge gap and an underlying educational need in the areas of SLE disease management among rheumatologists and primary care providers (PCPs).

**Methods:** An online educational intervention focusing on SLE disease management was made available online, intended for rheumatologists and PCPs who treat patients with SLE. The intervention consisted of a 30 min video presentation by a recognised expert in the treatment of SLE. Synchronised slides supported the presentation. The educational impact was assessed by comparing participants' responses to 3 repeated-pair, multiple-choice pre- and post-intervention questions. The impact on self-reported confidence was also assessed through a separate, 5-point Likert-scale question. Data were collected from 9/28/2017 through 11/29/2017. Statistical analysis included a paired t-test comparing mean pre-intervention and post-intervention scores, McNemar’s $\chi^2$ statistic for measuring changes in responses to individual questions, and Cramer’s V to determine the overall impact of the intervention.

**Results:** Analysis of pre- versus post-intervention responses demonstrated a significant (p=0.05) improvement in overall knowledge in both rheumatologists (79% to 87%, n=118) and PCPs (61% to 73%, n=253). The overall impact of the intervention was similar in both groups (V=0.106 for rheumatologists and V=0.123 for PCPs). This intervention resulted in increased knowledge surrounding several specific areas of SLE, such as pathophysiology, relationship between disease activity and organ damage, and selection of SLE therapies (see table 1).

**Abstract AB0510 – Table 1**

<table>
<thead>
<tr>
<th>Topic area</th>
<th>Rheumatologists (n=118)</th>
<th>PCPs (n=253)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pathophysiology</td>
<td></td>
<td></td>
</tr>
<tr>
<td>9% (75% to 84%)</td>
<td>23% (40% to 63%, p=0.06)</td>
<td></td>
</tr>
<tr>
<td>Relationship between disease activity and organ damage</td>
<td>8% (84% to 92%, p=0.05)</td>
<td>5% (70% to 75%, p=0.197)</td>
</tr>
<tr>
<td>Treatment selection</td>
<td>7% (79% to 86%, p=0.173)</td>
<td>6% (74% to 80%, p=0.093)</td>
</tr>
</tbody>
</table>

The intervention resulted in a 4% shift in self-reported confidence in addressing flare symptoms among rheumatologists, and a 26% shift among PCPs.

**Conclusions:** Participation in an online video educational intervention with synchronised slides was associated with significant overall improvement in knowledge levels of rheumatologists and PCPs in several important aspects of SLE management. Based on assessment of residual gaps, future directions for education should be tailored to specific learner groups including case-based reinforcement of knowledge and competence among rheumatologists, and additional foundational education for PCPs in the areas of pathophysiology and disease progression.

**THE EFFECT OF MILNACIPRAN ON FATIGUE IN A CLINICALLY STABLE LUPUS COHORT**

E.P. Katsaros¹, F. Dong², I. Moldovan². ¹Internal Medicine, ²Graduate College of Biomedical Sciences, Western University of Health Sciences, Pomona; ³Internal Medicine, Loma Linda University, Loma Linda, USA

**Background:** Systemic lupus erythematosus (SLE) is a chronic multi-system autoimmune disease impacting the physical wellbeing and health related quality of life (HRQoL) of patients. Fatigue occurs in up to 90% of SLE patients and affects their HRQoL. The purpose of this pilot study is to determine the effect of milnacipran, a norepinephrine and serotonin reuptake inhibitor used to treat fibromyalgia, on fatigue in clinically stable SLE patients with widespread pain (WSP). To date, no clinical trials have demonstrated efficacy for the primary treatment of fatigue and WSP in adult SLE patients.

**Objectives:** The objective is to determine the effect of milnacipran on fatigue in a clinically stable lupus cohort.

**Methods:** SLE patients, 18 years and older, with fatigue, WSP and on more than 4 weeks of stable therapy were recruited for a 15 week prospective, double-blind, placebo-controlled study. Patients were randomised at a 1:1 ratio to receive 14 weeks of milnacipran 50–100 mg twice a day or placebo. Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index (SLE-DAI). Measurements of fatigue, pain and a patient’s general impression of change from baseline were assessed at baseline and week 14 using the Fatigue Severity Scale (FSS), the Short-Form McGill Pain Questionnaire (SF-MPQ), and the Patient’s Global Impression of Change (PGIC) respectively.

**Results:** A total of 14 patients were included in the final analysis with seven patients in each group. Upon entry and throughout this study, both groups had low disease activity (mean SLEDAI <3.5 at week 0 and week 14). Fatigue as measured by FSS in the intervention group improved from 5.70 at week 0 to 5.14 at week 14 and improved in the placebo group from 5.90 to 5.59 respectively (Delta=0.56, 0.31 for the intervention and placebo group, respectively, p=0.70). Pain as measured by the SF-MPO changed in the treatment group from 20.80 at week 0 to 18.80 at week 14, and in the placebo group from 15.40 to 13.20 respectively (Delta=2.00, 2.20 for the intervention and placebo group, respectively, p=0.97). The patient’s Global impression of change was greater in the intervention group than the placebo group (0.67, 0.49, p=0.21).

**Conclusions:** Although results were not significantly different in this pilot study, improvement in fatigue and the patient’s impression of global change appeared to be greater in the intervention group than the placebo group even though lupus activity remained low in both groups and the difference in pain between the two groups was nearly identical. Therefore, milnacipran may improve fatigue independently of disease activity and pain in lupus patients. Future randomised controlled trials of the drugs effect with larger cohorts are needed to confirm these findings.

**OCCURRENCE AND CONSEQUENCES OF ANTI-DRUG ANTIBODIES TO RITUXIMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS**

F. Faustini¹, I. Paradis², N. Dunn², M. Ryner², A. Fogdell-Hahn², I. Gunnarsson¹.

¹Medicine, Unit of Rheumatology; ²Clinical Neuroscience, Center for Molecular Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

**Background:** Anti-drug antibodies (ADA) to rituximab (RTX) have been reported to a limited extent in rheumatoid arthritis (RA, 4%–11%) and in multiple sclerosis (MS, 26%–37%), in the latter being associated with incomplete B-cell depletion. In SLE, data on the clinical significance of ADA are lacking.

**Objectives:** To define the frequency and consequences of ADA to RTX in a SLE population by setting a disease specific threshold using a sensitive ADA method.

**Disclosure of Interest:** None declared

Methods: SLE patients fulfilling the 1982 ACR classification criteria who received RTX treatment at the Karolinska University Hospital during the years 2001–2015 were included. Stored serum samples obtained prior to and after six months from initiation of treatment were analysed for the detection of ADA using a GSK-developed and validated electrochemiluminescence assay. Disease specific screening and confirmation cut-off for SLE samples (1.44 AU and 29% respectively) were used. Clinical and laboratory data were retrieved from electronic medical charts. SLE activity was measured using SLE disease activity index 2000 (SLEDAI-2K).

We defined treatment response according to the SLE responder index (SRI).2

Results: Thirty-eight patients (89.5% females, median age 35.0 years; IQR: 27.7–55.0) were included in this retrospective analysis. The median disease duration was 6.2 years (IQR: 2.1–11.6) and the baseline median SLEDAI-2K was 6.9 (IQR: 7.0–16.5). The indications for RTX were active lupus nephritis (65.8%), arthritis (13.2%), haematological manifestations (7.9%), or mucocutaneous involvement (2.6%). Twenty-six patients (68.4%) received RTX according to the lymphoma regimen (375 mg/m² at day 1, 7, 14, 28) while 12 (31.6%) according to the arthritis regimen (2 infusions at a dose of 1 g, 14 days apart). Intrahepatic corticosteroids and cyclophosphamide were given in 65.8% and 63.2% of the patients, respectively.

ADA were detected in 18 patient samples (47.4%) at follow-up and stratified into reactive samples (confirmed positive but with a titer <2 AU/mL; n=3), low positive (2–10 AU/mL; n=6), medium positive (11–50 AU/mL; n=4), and high positive (>51 AU/mL; n=5).

We found no association between the occurrence of ADA and either SRI response (p=0.26, Fisher exact test) nor the concomitant use of high dose IV 6-methylprednisolone (p=0.56, c² test) or IV cyclophosphamide (p=0.11, c² test). At follow-up, patients positive for ADA had higher levels of CD19 +B cells (median: 0.03 × 10⁹ cells/L; IQR: 0.01–0.13) compared to negative patients (median: 0.01 × 10⁹ cells/L; IQR: 0.005–0.01; p=0.007, Mann-Whitney test).

Conclusions: ADA to RTX in SLE are more frequent than in RA and MS and occur irrespective of treatment response and corticosteroids, but are associated with higher counts of CD19 +B cells at follow-up. Such finding could reflect either incoincident B-cell activation in ADA positive patients, or earlier repopulation. Further studies should address the relation between ADA titters and clinical outcomes as well as immunological consequences.

AB0514 THE EFFECT OF HYDROXYCHLOROQUINE ON REDUCING PROTEINURIA IN STABLE SLE PATIENTS

H. Takahashi, Y. Nasa, E. Takamasa, S. Sugiy, Y. Yokogawa, Rheumatology, Tokyo Metropolitan Tama Medical Hospital, Fucyu Tokyo, Japan

Background: It is thought that hydroxychloroquine (HCQ) reduces proteinuria by preventing endothelial dysfunction in mouse models, but the effects in systemic lupus erythematosus (SLE) patients are not known.

Objectives: To investigate the effects of HCQ on proteinuria in stable SLE patients.

Methods: This was a single-centre, prospective cohort study. We included stable SLE patients who met the updated or revised American College of Rheumatology 1997 criteria for SLE or the 2012 Systemic Lupus International Collaborating Clinics criteria, and had no active organ dysfunction that needed an increase in immunosuppressive therapy. The subjects (HCQ group) were SLE patients with proteinuria >0.2 g/gCr who started HCQ between 11/1/2015 and 8/1/2017. The controls (non-HCQ group) were SLE patients with proteinuria >0.2 g/gCr seen between 10/1/2015 and 10/1/2016 and 10/1/2016 and 10/1/2017. Reduction in proteinuria over 6 months in the HOC and non-HCQ groups was compared. The following patients were excluded from the analysis: those who had proteinuria of other aetiologies (diabetic nephropathy, etc.), those who increased the prednisolone (PSL) dose or started immunosuppressive agents, angiotensin converting enzyme inhibitors, or angiotensin II receptor blockers beginning 1 month before the observation period started until its end. Improvement was defined as a reduction in proteinuria >0.1 g/gCr. The statistical analysis was performed with the t-test and chi-square test.

Results: There were no significant differences in disease duration, sex, Systemic Lupus Erythematosus Disease Activity Index, or the use of immunosuppressants at baseline between the HOC (n=16) and non-HOC (n=14) groups. The respective mean PSL dose at baseline was 5.9±2.8 and 3.3±3.8 mg in the HOC and non-HOC groups (p=0.042). Patients in the HOC group were younger (mean 47±12 vs. 63±14 years, p=0.005). The kidney pathology of the HOC group was 6.25, 25, 6.25, 6.25, and 6.25% class I to V, respectively, compared with 7.14% class IV, 14.2% class V, and 14.2% class IV-V in the non-HOC group. The other patients were diagnosed with lupus nephritis clinically.

Proteinuria was significantly lower in the HOC group than in the non-HOC group (p=0.036). The mean proteinuria at baseline and 6 months later was 0.501±0.276 and 0.331±0.274 g/gCr, respectively, in the HOC group, and 0.587±0.409 and 0.717±0.720 g/gCr in the non-HOC group. The proportion of patients who improved in the HOC and non-HOC groups was 68.7% (11/16) and 28.5% (4/14), respectively (p=0.028).

Conclusions: HCQ may reduce proteinuria in SLE patients. This suggests that HCQ administration protects the kidneys of SLE patients.

Disclosure of Interest: None declared

AB0515 B AND T LYMPHOCYTES MODIFICATIONS AFTER BELIMUMAB TREATMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

F. Regola1, S. Piantoni1,2, R. Reggi1, R. Kumar1, L. Andreoli1, F. Franceschini1, A. Tincani1, P. Airo1,2, Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia, Molecular and Translational Medicine, University of Brescia, Brescia, Italy

Background: B- and T-cell hyper-activation is one of the pathogenic mechanisms of systemic lupus erythematosus (SLE). SLE patients have a severe defect in the B cell tolerance check, resulting in high numbers of autoreactive mature naïve B-cells (CD19 +CD27−IgD+ and of peripheral transitional B-cells (CD19 +38high24high). On the other hand, in patients with active SLE a reduced thymic output with a decreased number of recent thymic emigrants T-cells (RTE; CD4 +38high24high). On the other hand, in patients with active SLE a reduced thymic output with a decreased number of recent thymic emigrants T-cells (RTE; CD4 +38high24high) was demonstrated, whereas repeated antigenic stimulation drives modifications in T-cells subpopulations, with enhanced differentiation into effector memory cells (CCR7−CD45RA−).

Belimumab is a monoclonal antibody against soluble BlyS used in the treatment of severe SLE. Although B cells are the main target of this treatment, a BlyS-dependent T-cell activation pathway has also been demonstrated. However, few data are available on the effects of belimumab on circulating B- and T-cell subsets.

Objectives: The aim of this study was to characterise B- and T-cell phenotype in a cohort of patients with SLE, and to analyse their modifications during belimumab therapy.

Methods: Phenotypic analysis of peripheral blood B and T lymphocyte subsets was made by flow-cytometry in 14 SLE patients before the first infusion of belimumab, and after 12 months of treatment. SLEDAI-2K score was used to determine disease activity: a score >4 indicated high disease activity. Sex and age-matched healthy controls were enrolled for the comparisons.

Results: At baseline, SLE patients had lower numbers of B- (82 vs 153 cell/µl; p=0.05), T- CD4+ (365 vs 1131 cell/µl; p<0.01), T- CD8+ (340 vs 516 cell/µl; p=0.03) than healthy donors. After treatment there was a decrease of total B lymphocytes (82 vs 19 cell/µl; p=0.01), and particularly of naïve (45 vs 19% of CD19+; p=0.01) and transitional cells (1 vs 0.2 cell/µl; p=0.03). The absolute number of unswitched memory B cells decreased (2.2 vs 1.4 cell/µl; p=0.05), whereas the percentage of switched memory B cells increased (16 vs 44% of CD19+; p<0.01). The absolute number of CD19 +effector memory cells was also reduced (61 vs 53 cell/µl; p=0.05), as well as percentages of RTE (20 vs 10% of CD4+; p=0.01). After 1 year therapy in the only 2 patients with persistent high disease activity the percentages of transitional B cells and unswitched memory cells were higher than in 7 patients in which an initially high disease activity decreased below SLEDAI=6 (9% vs 1%; p=0.03; and 29% vs 6%; p=0.04, respectively).

Conclusions: The effects of belimumab on B cell subpopulations are likely to be directly explained by the blockage of soluble BlyS. On the other hand, the effects on the phenotype of T cells are modest and it cannot be excluded that they are indirectly explained by the reduction of disease activity obtained through the therapy. The number of certain circulating B cell subsets might be a marker of response to treatment.

AB0515  SPANISH SOCIETY OF RHEUMATOLOGY (SER) RECOMMENDATIONS ON PRIMARY ANTIPHOSPHOLIPID SYNDROME (APS), IN A PATIENT WITH OBSTETRIC APS, WHICH TREATMENTS ARE MORE EFFECTIVE? SYSTEMATIC REVIEW

H. Sánchez Pérez1, M. Nishishiyama Aquino2, C. Pereda3, P. Diaz del Campo Fontecha4, M. Martínez Zamora5. 1Rheumatology, Hospital Universitario de Canarias, La Laguna; 2Programa de doctorado en Ciencias de la Educación y el Deporte de la Facultad de Psicología, Ciencias de la Educación y de l’Esport Blanquerna, Institut Traumatològic Quirín, Barcelona; 3Rheumatology, Hospital Mediterráneo, Ámera; 4Unidad de Investigación, Sociedad Española de Reumatología, Madrid; 5Servicio de Obstetricia y Ginecología, Hospital Clinic, Barcelona, Spain

Background: Pregnancy complications and poor obstetric prognosis are part of the manifestations of APS. The obstetric APS (O-APS) includes 3 or more early miscarriages, 1 or more intrauterine foetal deaths, prematurity secondary to preeclampsia or placental insufficiency, intrauterine growth retardation and HELLP syndrome among others. There is disagreement among different published studies regarding the need of preconceptional or primary thromboprophylaxis (treating with anticoagulant/antiaggregant drugs in the presence of specific autoantibodies but without previous clinical events) and the most effective and safest drug to use, as well as which treatment should be chosen in the case of secondary thromboprophylaxis (treating in the presence of autoantibodies and recurrent miscarriages or previous obstetric complications).

Objectives: To evaluate the available scientific evidence on which treatments are the most effective and safest in O-APS.

Methods: A systematic review (SR) was performed to evaluate the efficacy and safety of different interventions (Aspirin (ASA), Heparin, Antimalarials, Immunglobulin IV (IVIG), others) in pregnant women with O-APS. We included SR, randomised clinical trials (RCTs) and comparative cohort studies. Result measures on morbidity (prematurity, low birth weight, need for intensive care, impaired cognitive development, preeclampsia, eclampsia, HELLP, abruptio placenta) and mortality included both the newborn and the pregnant woman. A peer review selection and analysis of the studies was carried out (SP, H, NA, MB).

Results: 788 citations were identified (Medline, EMBASE, CENTRAL). May 2017. We included 17 studies: 5 SR, 5 RCTs and 7 cohort studies. Results are shown on the table 1 below.

<table>
<thead>
<tr>
<th>Drugs</th>
<th>Efficacy</th>
<th>Level of evidence</th>
</tr>
</thead>
<tbody>
<tr>
<td>ASA placebo</td>
<td>Inconclusive</td>
<td>1+</td>
</tr>
<tr>
<td>ASA + Heparin</td>
<td>The combination is more effective than ASA on its own in order to achieve better obstetric results in women with O-APS</td>
<td>1+, 1a, 1b</td>
</tr>
<tr>
<td>IVIG</td>
<td>Comparing IVIG with ASA+heparin is favourable to this combination: it is easier to use and has a lower cost</td>
<td>1+</td>
</tr>
<tr>
<td>Corticoids</td>
<td>There is not enough evidence available.</td>
<td>1a, 2-</td>
</tr>
<tr>
<td>Statins</td>
<td>There is not enough evidence available.</td>
<td>2+</td>
</tr>
</tbody>
</table>

Conclusions: In women with O-APS:
- Secondary thromboprophylaxis: The combination of ASA + Heparin is more effective than ASA monotherapy.
- With regards to the use of IVIG, corticosteroids and statins: NO representative conclusions can be drawn from published studies
- Pre-conceptional thromboprophylaxis, primary thromboprophylaxis: NO representative conclusions can be drawn from published studies.

AB0516  THERAPEUTIC STRATEGIES AND PROGNOSIS IN CHINESE PATIENTS WITH SEROLOGICALLY ACTIVE CLINICALLY QUIESCENT SYSTEMIC LUPUS ERYTHEMATOSUS

H. Huang1,2, L. Mou1, Y. Hao3, Z. Zhang4, W. Zhou1. 1Rheumatology and Clinical Immunology Department, Peking University First Hospital; 2Rheumatology and Clinical Immunology Department, First Hospital of Tsinghua University, Beijing, China

Background: SACQ patients with SLE appears to account for 6%–12% of all patients with SLE, but there is disagreement about whether such patients are indeed clinically stable, especially in Chinese patients. And there is no conclusion as to what kind of treatment should be taken for such patients.

Objectives: The aim of our study was to identify the frequency and outcome of SACQ patients with SLE. And we tried to find out potential predictors of flare.

Methods: 682 patients with systemic lupus erythematosus who were followed up for more than 6 months at Peking University First Hospital from January 2007 to December 2015 were summarised. SACQ was defined as an at least a 6 month period with persistent serologic activity and without clinical activity and could be taking a daily dose of prednisone or equivalent less than 7.5 mg. Serologically quiescent clinically quiescent (SQCQ) patients and serologically active clinically active (SACA) patients served as control groups. Data including demographics, initial symptoms, duration to SACQ, treatments before and after SACQ, and characteristics of the flare group were analysed.

Results: Of the 682 patients, 170 were SACQ patients (24.9%), 187 were SQCQ patients, and 325 were SACA patients (47.7%). SQCQ patients (38.61±15.08 years old) were older at study start than did SACQ patients (38.61±15.08 years vs. 32.09±14.35 years, p=0.000), but there was no significant difference between that of SACQ and SACA patients. 56 of the 170 SACQ patients (32.9%) experienced flare. Corticosteroids (OR 1.323, 95% CI 1.135 to 1.542; p=0.000) was an independent risk factor for flare, while antimalarials (OR 0.040, 95% CI 0.004 to 0.418; p=0.007) and immunosuppressants (OR 0.321, 95% CI 0.153 to 0.673; p=0.003) were protective factors.

Conclusions: SLE patients with SACQ remained relatively stable, with 32.9% of patients relapsed. The group of flare patients took greater use of corticosteroids than non-flare ones, whereas antimalarials and immunosuppressants agents were protective factors.

AB0517  INVASIVE ASPERGILLOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY FOCUS ON CLINICAL CHARACTERISTICS AND RISK FACTORS OF IN-HOSPITAL MORTALITY

H. Ning1, C.-Y. Tsai2. 1Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital; 2Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital, Taipei, Taiwan, Province of China

Objectives: To analyse the clinical features and outcomes of patients with invasive aspergillosis (IA), the mortality risk factors and all-cause mortality in patients with systemic lupus erythematosus (SLE) in single centre of Taiwan.

Methods: A retrospective study was performed to identify the mortality risk factors associated with IA in patients with systemic lupuserythematosus (SLE). We reviewed the medical records of patients with SLE who were diagnosed with invasive aspergillosis between Jan. 2006 and Jun. 2017 from Taipei Veterans General Hospital in Taiwan. Clinical and laboratory parameters as well as treatment outcomes were analysed.

Results: Twenty-one patient diagnosed with proven (n=4; 19.04%) and probable (n=17; 80.96%) invasive aspergillosis according to revised definition by European Organisation for Research and Treatment of Cancer/Invasive Fungal Infections Cooperative Group and the National Institute of Allergy and Infectious Diseases Mycoses Study Group (EORTC/MSG) Consensus Group were enrolled in the study and separated into survivors(n=7; 33.33%) and non-survivors (n=14;
Efficacy of Belimumab for Primary Sjögren Syndrome: Results of a Systematic Review of the Literature

Background: Belimumab is a human monoclonal antibody that inhibits B-cell activating factor shown to be efficacious in systemic lupus erythematosus. In other B cell mediated autoimmune disease such as primary Sjögren’s syndrome (pSS) the efficacy is unclear.

Objectives: To evaluate the efficacy of belimumab in patients with pSS.

Methods: A systematic literature review was performed (EMBASE, MEDLINE and Cochrane) as part of the Spanish Rheumatology Society’s Recommendations for the Use of Biological Therapies in Primary Sjögren’s Syndrome. Inclusion criteria was defined as: Population: patients with pSS according to American-European Consensus Criteria 2002 Intervention: belimumab; Control: synthetic or biologic DMARDs, corticosteroids, ursodeoxycholic acid or placebo; Outcome: efficacy in dryness, glandular and extraglandular manifestations. Studies with <10 patients or <3 months of follow up were excluded. Two reviewers independently selected the articles and evaluated the quality of the evidence following SIGN guidelines.

Results: 3 articles were included out of 13. All of them published results from the same study at different timepoints. The study design was experimental but with a small sample size and no control group or randomization.

The study of De Vita et al 2015 compared clinical and lab variables of W52 with 12 months of follow up after interrupting belimumab. A significant decrease in ESSDAI in 9 out of 13 patients (3.5±3.7 vs 7.0±5.7; p<0.01) was observed as well as in RF (52 vs 69U; p<0.01), IgM (131.9 vs 165 mg/dl; p<0.04) and BlYs (1304 vs 2882 pg/ml; p<0.01).

Conclusions: Published evidence to determine the efficacy of belimumab in primary Sjögren is limited and poor. Belimumab seems to be effective to reduce systemic activity, parotid enlargement, dryness, lymphadenopathies, articlar manifestation, fatigue and B cell biomarkers.

AB0519 IMPACT OF HIGHER BODY MASS INDEX (BMI) IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Săulescu, D. Opris Belinski, A. Vorangiu, L. Groseau, S. Daia-Iliescu, D. Mazilu, M. Negru, V. Stoiar, V. Bojinci, A. Balanescu, C. Constantinescu, R. Ionescu. Internal Medicine and Rheumatology, UMF Carol Davila, SF. Maria Hospital, Bucharest, Bucharest, Romania

Background: Systemic lupus erythematosus (SLE) patients may have nutritional changes triggered by disease itself or by treatment with possible implication for patients prognosis.

Objectives: The main focus of the study was to evaluate nutritional status and its impact in a SLE cohort with disease duration of at least 1 year.

Methods: 105 SLE patients admitted in St. Maria Clinical Hospital in 2017 were enrolled. Inclusion criteria were represented by disease evolution of at least 1 year. All patients agreed to participate in this observational study. Data about demographic, clinical or serological characteristics, but also activity (SLEDAI), damage accrual (SLICC damage index SDI) and treatment or complications (osteoarthritis, cataract, glaucoma, etc) were collected. Nutritional status was evaluated by calculating Body Mass Index (BMI) for each patient. A descriptive and analytical statistics was performed with SPSS.

Results: 99 females and 6 males were enrolled. Mean age at SLE diagnosis was 34.39. SD 11.34. BMI was calculated as ratio of body weight to squared height (kg/m²). According to BMI, 5% of patients were underweight (BMI <18.5), 56% had normal weight (BMI 18.5–25), 25% were overweight (BMI 25–30) and 14% were obese (BMI >30). Increased BMI was correlated with longer disease duration (p 0.001, r 0.30) and older age (p 0.001, r 0.35), but these correlation loose the strength for patients older than 40 years (p 0.04, r 0.19), suggesting a more pronounced weight gain at the beginning of the disease. Quality of sleep was significantly altered in patients with abnormal BMI (p 0.005, r 0.35). As expected, overweight and obese patients had a sedentary life style (p<0.01). Higher BMI was correlated also with higher SDI score (p 0.026, r 0.35) and higher number of complications related to chorticotherapy per patient (p 0.0001, r 0.45).

Conclusions: SLE patients have an increased risk for higher BMI, especially patients younger than 40 years, in the first years after diagnosis. Optimising weight in our SLE patients should be in our focus in order to limit number of complications, damage accrual and lifestyle patterns that negatively impact their life.

AB0520 ASSESSMENT OF ANTI-MÜLLERIAN HORMONE LEVELS IN SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH IMMUNOSUPPRESSOR

J. Yu, Rheumatology, Distinct Healthcare, Shenzhen, China

Background: Systemic lupus erythematosus (SLE) is a chronic immune-mediated inflammatory disease that affects predominantly females during childbearing age. Fertility in SLE patients is considered to be normal but several factors, such as disease activity, renal involvement and treatment with immunosuppressors may negatively influence fertility.

Objectives: To investigate the ovarian reserve of patients with SLE by measuring anti-müllerian hormone (AMH) levels, and compare the AMH levels before and after treatment with immunosuppressors.

Methods: This was a self-control study performed on newly diagnosed premenopausal female SLE patients fulfilled the 1997 American College of Rheumatology (ACR) criteria. Serum concentrations of AMH in peripheral venous blood were measured using a human AMH ELISA kit (MSKBIO, Wuhan, China) before and after treatment with immunosuppressors.

Results: 45 patients were recruited. AMH serum levels reduced after treatment in the cyclophosphamide (CTX) group (n=6) and leflunomide (LEF) group (n=7), P<0.05. AMH serum levels did not differ before and after treatment in the mycophenolate (MMF) group (n=11), tacrolimus group (n=8) and methotrexate (MTX) combined with cyclosporin A (CsA) group (n=13), p>0.05.

Conclusions: In this self-control study, the AMH serum levels reduced after 6 month treatment of CTX or LEF, indicating CTX and LEF might negatively influence ovarian reserve function. AMH serum levels did not differ after 6 month treatment of MMF, tacrolimus or combined use of MTX and CsA, indicating these immunosuppressors might be relatively safe for ovarian reserve function.

AB0521 SAFETY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF SINGLE DOSES OF A BSPECIFIC ICOSL AND BAFF INHIBITOR, AMG 570, IN HEALTHY SUBJECTS

Background: Autoimmune diseases, including systemic lupus erythematosus (SLE), are associated with dysregulation in both T cell and B cell responses. Targeting the activity of both cell types simultaneously holds promise as a treatment for autoimmune disease. AMG 570 is a bispecific molecule targeting both T cell and B cell activity through neutralisation of the inducible costimulator ligand (ICOSL) and the B cell activating factor (BAFF).

Objectives: To investigate the safety, tolerability, pharmacokinetics, and pharmacodynamics of AMG 570 in healthy subjects after single subcutaneous doses.

Methods: This ongoing, double-blind, randomised, placebo-controlled trial has enrolled healthy subjects (age ≥18 years) into escalating single-dose cohorts. Eight participants were enrolled into each cohort and were randomised 3:1 to receive either AMG 570 or placebo across six cohorts of increased dose level. The primary endpoint of the study was treatment-emergent adverse events (AEs). Secondary endpoints included pharmacokinetics and pharmacodynamics (eg, receptor occupancy of ICOSL, changes in B cell subpopulations, and serum immunoglobulin levels).

Results: As of an ad hoc interim analysis on October 5, 2017, 48 participants were enrolled and received one dose of investigational product (either AMG 570 or placebo). 73 AEs were reported; all were mild (n=56) to moderate (n=14) in severity (3 injury AEs had no grade reported). Upper respiratory tract infection and injection site erythema were the most commonly reported AEs. No drug-related serious adverse events were reported. No severe, life-threatening, or fatal AEs were reported. AMG 570 demonstrated nonlinear pharmacokinetics consistent with cell surface target (ICOSL) interaction. In the highest dose tested, AMG 570 achieved greater than 90% mean ICOSL receptor occupancy on circulating B cells 8 days after dosing, and high levels (>85% mean ICOSL receptor occupancy) were observed 29 days after dosing. AMG 570 led to a reduction in circulating naïve B cells and an increase in circulating memory B cells. No apparent changes were observed in serum IgM or IgG.

Conclusions: Overall, AMG 570 was safe and well tolerated by healthy subjects. AMG 570 demonstrated pharmacodynamic activity consistent with ICOSL and BAFF neutralisation.

Disclosure of Interest: L. Cheng Grant/research support from: This project was supported by a grant from the Health and Family Planning Commission of Shenzhen Municipality (20161037) and a grant from the Traditional Chinese Medicine Bureau of Guangdong Province (20161228).

TACROLIMUS IN REFRACTORY LUPUS NEPHRITIS: A PROSPECTIVE MULTICENTRIC STUDY CARRIED OUT IN CLINICAL PRACTICE SETTING

M. Lareo1, M. Zen1, L. Iaccarino1, A. Tincani1, L. Andreoli2, F. Conti2, F. R. Spinelli2, G. De Marchi3, S. De Vita4, A. Doria1.
1Rheumatology Unit, Department of Medicine-DIMED, University of Padova, Padova; 2Rheumatology and Clinical Immunology Unit, Ospedale Civile, Brescia, Brescia; 3Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome; 4Clinic of Rheumatology, Department of Medical and Biological Sciences, University Hospital “Santa Maria della Misericordia”, Udine, Italy

Background: The efficacy of tacrolimus (TAC) in lupus nephritis (LN) has been recently demonstrated in several randomised controlled trials in asian cohorts. Nevertheless, data on real-life experience and long-term safety of TAC are still lacking.

Objectives: To assess efficacy and safety of TAC in SLE patients with refractory LN in a multi-centric prospective cohort.

Methods: Adult SLE patients with refractory LN from 4 Italian centres were prospectively followed for at least 12 months. Clinical and serological variables and previous/concomitant medications were collected at baseline, 3, 6, 12 months after starting TAC. Renal response was assessed by using EULAR/ERA-EDTA definitions. Adverse events (AEs) included non-infectious and infectious AEs; they were defined severe (SAE) when hospitalisation and/or death and/or life-threatening manifestations occurred. Data were analysed using SPSS (v.24.0).

Results: Thirteen SLE patients (8 females, 5 males, mean age 33.7±10.2, mean disease duration 11.9±5.9) were enrolled (table 1). Concomitant medications included: prednisone (100%), mycophenolate mofetil (92.3%), hydroxychloroquine (53.8%), azathioprine (7.7%), belimumab (7.7%) and cyclosporine (7.7%). The average number of previous immunosuppressants taken by each patient was 3.15±1.9. Six-months renal response was achieved by 5/13 patients (38.5%): complete renal response (CRR) in 2/13 (50.0%) and partial renal response (PRR) in 2/13 (50.0%). One patient achieved complete renal response (CRR) in 2/13 (50.0%) and partial renal response (PRR) in 2 patients (40.0%). Twelve-months renal response occurred in 4/13 patients (30.8%): CRR in 2/13 (50.0%) and PRR in 2/13 (50.0%). One patient achieved CRR at 6 and 12 months; one patient achieved PRR at 6 months and CRR at 12 months. Six patients (46.1%) discontinued TAC after an average follow up period of 10.2±7.8 months. Causes of discontinuation were: 3 non-inflammatory non-SAEs, 1 flare, 1 non-inflammatory SAE, and 1 non-response. Concerning AEs, no severe infections or deaths occurred.

METFORMIN COMBINED WITH CONVENTIONAL THERAPY INCREASES ABSOLUTE NUMBER OF REGULATORY T CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Hao1, Z. Liang1, X. Jing1, X.Q. Liu1, C. gao1, X. li1, J. chen1. The Second Hospital of Shanxi Medical University, Taiyuan, China; Brigham and Women’s Hospital, Harvard Medical School, Boston, USA

Background: Systemic lupus erythematosus (SLE) is multisystem and multiorgan autoimmune diseases and the main treatment is hormone combined with immunosuppressant and biological agents. Since the conventional treatment regimens have not achieved expected effects, it is of great practical value to search for good efficacy, lower side-effects, and low-cost drugs. Recently, we have found that the absolute number of CD4+CD25+FoxP3+ regulatory T (CD4+ Treg) cells reduced in SLE. Metformin, a basic hypoglycemic drug, has been shown to increase the number of Treg cells and decrease the number of Th17 cells.[1,2,3]

Objectives: To observe the clinical efficacy of metformin on the treatment of SLE and levels of CD4+ Treg and Th17 cells.

Methods: Twenty-three patients with SLE were enrolled in this study. They fulfilled the ACR 1997 standard, their average age was 32.22±8.18 years, and duration was 51.41±15.52 months. These patients were administered metformin (250 mg Bid) combined with conventional therapy for 6 weeks. At week 0 and week 6, the absolute numbers of Th17 cells and Treg, the symptoms, and laboratory indicators were collected.

Results: After metformin treatment combined with conventional therapy, average absolute number of Treg cells in 23 patients increased significantly from 20.20 (20.28) (week 0) to 25.76 (25.11) (week 6) (p=0.075) while that of Th17 cells increased slightly from 5.29 (6.43) (week 0) to 5.57 (6.05) (week 6) (p=0.956), which led to reduce average ratio of Th17/Treg from 0.25 (0.31) (0 week) to 0.19 (0.23) (6 weeks) (p=0.147). The treatment attenuated the symptoms of the patients and meantime, the dose of prednisone was decreased. At week 6, metformin combined with interleukin-2, the dosage of prednisone in SLE patients were decreased from 23.7±19.41 mg(±0 week) to 20.4±17.03 mg(±6 weeks) (p=0.548).

Abstract AB0523 – Figure 1

Conclusions: Our findings suggest metformin can effectively up-regulate Treg cells as well as increase Th17 to a certain extent, which restores the balance of Th17/Treg cells in SLE, metformin combined with conventional therapy can reduce the dosage of glucocorticoid, but the long-term effect needs further investigation.

HOW DO WE TREAT DRYNESS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME? A NATIONWIDE STUDY IN SPAIN FROM THE SJÖGREN’S REGISTRY

1Rheumatology, Hospital Infanta Sofia, Madrid; 2Research Unit of the Spanish Society of Rheumatology; 3Rheumatology, Hospital Puerta de Hierro Majadahonda, Madrid; 4Rheumatology, Hospital Marques de Valdecilla, Santander; 5Rheumatology, Hospital Germans Trias i Pujol, Barcelona; 6Rheumatology, Hospital Marina Baixa, Alicant, Spain

Background: Primary Sjögren syndrome (pSS) is a systemic autoimmune disease whose main characteristic is the involvement of the exocrine glandular system. Thus, its most common clinical manifestation is eye and mouth dryness. No currently evidence-based therapy for pSS is mainly limited to symptomatic drugs for dryness.

Objectives: To describe the dryness treatment in a cohort of primary Sjögren Syndrome patients.

Methods: SJÖGREN’S registry is a multicentre descriptive cross-sectional study of pSS patients, fulfilling European-American criteria, from 33 Spanish rheumatology departments. Data were collected by reviewing clinical records and interviewing the patients. Informed consent was obtained and local ethics committees approved the study. Variables were analysed by descriptive statistics using means, medians and ranges. Chi square test was used to compare categorical variables. A p<0.05 was considered significant.

Results: Four hundred and thirty seven patients were included (female 95%; median age 58 years). Ninety four per cent of the patients complained of daily, persistent, troublesome dry eyes for more than 3 months, 92% had sensation of sand in the eyes, 16% developed corneal ulcer. Ninety four per cent of the patients complained of dry mouth for more than 3 months and 27% had dental loss. The most frequent ocular dryness treatments were tear substitutes (96%), followed by lubricating ophthalmological ointments (46%), autologous sera solutions (14%), topical corticosteroids (13%), topical cyclosporine (6%). Comparing patients with and without ocular dryness, only pilocarpine and lubricating eye ointment were used significantly with more frequency in symptomatic patients (p<0.05); tear substitutes was used significantly with more frequency in symptomatic patients only in the subgroup of patients that used tear substitutes more than 3 times a day. The most frequent oral dryness treatments were chewing gums or candies without sugar (85%), followed by pilocarpine (56%), special toothpaste (22%), mucolytic agents (20%), saliva substitutes (19%), lubricating oral gel (13%) xyitol (11%) and fluoride (11%). Comparing patients with and without oral dryness, chewing gums or candies without sugar, xyitol and fluoride were not used significantly more frequently in symptomatic patients. In contrast, saliva substitutes, lubricating oral gel, pilocarpine, mucolytic agents and specific toothpaste were used significantly more frequently in symptomatic patients (p<0.05). The median in ESSPRI (Eular Sjögren’s Syndrome Patient Reported Index) in SJÖGREN’S cohort was 5.3 (2.5-7.5, 3.67-7). Only topical corticosteroids and pilocarpina were used significantly more frequently in patients with a dryness VAS: 5 in ESSPRI index.

Conclusions: Despite the high number of symptomatic patients, the use of dryness treatments is limited in pSS patients. Chewing gums or candies without sugar, xyitol and fluoride remain underutilised in this cohort. Despite the dryness VAS score, patients do not seem to use all the symptomatic therapeutic options available.

IMBALANCE IN ELASTIN-ELASTASE SYSTEM LEADING TO CLINICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOUS

O. Emelyanova1, O. Rusanova1, I. Gontar1, L. Maslakova1, N. Emelianov2.
1Federal State Budgetary Institution «Research Institute of Clinical Ind Experimental Rheumatology named after A.B. Zborovsky»; 2Federal State Medical Budgetary Institution of Higher Education “Volgograd State Medical University” of the Ministry of Healthcare of the Russian Federation, Volgograd, Russian Federation

Background: It is believed that in systemic lupus erythematosus antibodies induce a disturbance in the elastin-elasticase metabolism, which yields altered soluble isoforms followed by triggering of autoimmunity mechanisms, which damage the elastin-containing tissues.

Objectives: Studying antibody formation in the elastin-elasticase system in patients with systemic lupus erythematosus (SLE) using magnetocontrollable adsorbents with an immobilised form of corresponding antigen.

Methods: Sera from 30 donors and 65 SLE patients were studied. Antibodies to elastin and elastase were determined using ELISA test and magnetocontrollable adsorbents with an immobilised form of corresponding antigen.

Results: We analysed changes in the content of antibodies to elastin and elastase in patients with SLE of varying severity assessed using SLAM, SLEDAI scale, and criteria by V.A. Nasonova.
The greatest elastin antibody titer was noted in patients with SLE grade III (57.1%, 4 people), with grade II – in 42.5% (17 people), and with grade I – in 33.3% (6 people). The elastin antibody titer in SLE patients being admitted to hospital was reliably higher than in donors (p<0.001).

An analysis of the findings showed that patients with vascular lesions demonstrated a significant elevation of elastin antibodies (p<0.05).

Besides studying elastin antibodies, we analysed elastase antibodies. Elevated elastase antibodies were revealed in 72.2% of SLE patients with grade I of the condition; in 80.0% with grade II, and in 85.7% of patients with grade III. The titer of elastase antibodies in SLE patients admitted to hospital was reliably higher than in the control group (p<0.01). The highest elastase antibody titer was noted when the skin and joints are affected, and vasculopathy is present.

Conclusions: The regularities revealed by pathogenetic method can be accounted for by considerable B-clone expansion in SLE patients as the condition progresses. From the point of view of immunology, hyperproduction of elastin and elastase autoantibodies is noted, which results in autoimmune lesion of the ligamentous apparatus, joints, skin and vessels where this protein is naturally present.

S100 PROTEINS ARE NOVEL BIOMARKERS FOR THE EFFICACY OF HCQ TREATMENT TO SKIN LESION IN SYSTEMIC LUPUS ERYTHEMATOSUS

R. Wakiya, K. Ueeda, T. Kameda, S. Nakashima, M. Izumkawa, H. Shimada, A. Kondo, M. Kato, T. Miyagi, N. Kadowaki, H. Dobashi. Department of internal medicine, Division of hematology, rheumatology and respiratory medicine, Kagawa University, Kagawa, Japan

Background: Systemic lupus erythematosus (SLE) is deeply associated with not only acquired immunity but also innate immunity throughout toll like receptors (TLRs) signalling. Among many TLRs, TLR7 and TLR9 were reported to be closely associated with IFN-α production which contributed the pathogenesis of SLE. On the other hand, several reports demonstrated that S100A8 and S100A9 proteins which was known as one of damage-associated molecular patterns (DAMPs), were associated with disease activity of lupus nephritis. These proteins were also shown to reflect the treatment response by immunosuppressive therapy for SLE. 1, 2 However, there is no report about the effect of hydroxychloroquine (HCQ) on S100A8 and S100A9 proteins expression.

Objectives: To find a new biomarker of treatment with HCQ, we focused on expression of S100A8 and S100A9 proteins in SLE.

Methods: We enrolled all SLE patients treated with HCQ in the absence of additional immunosuppressive therapy more than 3 months in our institute from Jan 2016 to Dec 2017. Serum levels of S100A8 and S100A9 proteins were measured by ELISA(CircuLex ELISA Kit, MBL) at the screening, 3 months and 6 months after HCQ administration. Disease activity of SLE was measured using the SLENA-SLEDAI 2011 Cutaneous disease activity was evaluated by Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI). Immunological activity was examined by the levels of complement (C3, C4, CH50), anti-dsDNA anti-body and counting blood cell.

Results: 61 patients were enrolled in this study, HCQ was administered 48 cases with usual dose(based on ideal weight), 15 cases with low dose than usual dose with low dose HCQ. On the other hand, serum levels of S100A8 and S100A9 proteins were significantly elevated in SLE patients with renal lesion(p<0.02). These proteins were significantly decreased by the treatment with HCQ regardless of the HCQ dose(p<0.0001). The changes of serum S100A8 and S100A9 proteins during HCQ treatment(for 3 months) were significantly associated with changes of CLASI

Abstract AB0527 – Figure 1. S100A8 and S100A9 proteins associated with CLASI score. Compared with SLE patients of 50% and less rate of change of CLASI activity, those of more than 50% rate of change of CLASI activity significantly decreased serum levels of S100A8 and S100A9 proteins after administration of HCQ. There were no SLE patients whose skin lesion got worse during HCQ treatment in this study.

Conclusions: HCQ reduced the expression of serum S100A8 and S100A9 proteins, which reflected SLE disease activity especially in skin lesion. The measurement of S100A8 and S100A9 proteins is novel predictive biomarker for the efficacy of HCQ treatment on skin lesion in SLE patients.

CONCOMITANT MEDICATION IN SYSTEMIC LUPUS ERYTHEMATOUS (SLE) PATIENTS TREATED WITH BELIMUMAB IN CLINICAL PRACTICE SETTINGS: RESULTS FROM THE OBSERVE STUDY IN SWITZERLAND

J. von Kempis1, S. Dütsch2, N. Reuschling3, D. Schlaer4, F. Vallielan3, R. Villiger5, P.M. Villiger6, R.B. Mueter7. 1Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen; 2GlaxoSmithKline AG, Münchbuchsee; 3Division of Rheumatology, Hirslanden, Basel; 4Universität Hospital Zürich, Zürich; 5Department of Rheumatology, Inselspital Bern, Bern, Switzerland

Background: Systemic lupus erythematosus (SLE) is a complex and potentially severe autoimmune disease. Belimumab is the latest drug, and the first biologic medication among belimumab users in Switzerland.

Methods: OBSERVE Switzerland (GSK 201232) was a retrospective, multi-centre observational cohort study collecting data on the use of belimumab therapy in routine care of SLE Patients in Switzerland. SLE patients were included who had started therapy with 10 mg/kg belimumab/4 weeks at least six months before documentation. All patients were included regardless of treatment discontinuation during the study period. All statistical analyses were descriptive for both categorical and quantitative data.

Results: 53 SLE patients with belimumab as part of their routine treatment were analysed for this study. 81% of the patients were female, the mean age was 46.7 years and the mean BMI was 25.4 kg/m². The reasons to initiate belimumab were severe autoimmune disease. Belimumab is the latest drug, and the first biologic medication among belimumab users in Switzerland.

CLASI was improved by the treatment with HCQ independent of HCQ dose. However, the effect of HCQ on SLENA-SLEDAI and immunological biomarker was shown in the patients treated with usual dose HCQ, not shown in those treated with low dose HCQ.
AN AUDIT FOR SCREENING OF OSTEOPOROSIS AND ITS MANAGEMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S.A. Syed, K. Sunmboye, S. Shaffu. Rheumatology, University Hospitals of Leicester, NHS Trust, Leicester, UK

Background: Systemic lupus erythematosus (SLE) is an autoimmune, multi-system, chronic inflammatory condition. It is managed with long-term immunosuppressive therapy which includes steroid use. SLE is therefore considered an independent risk factor for osteoporosis.

Objectives: This clinical audit was undertaken to evaluate the screening of osteoporosis in patients diagnosed with SLE and assess adherence to national guidelines for the management of patients with low bone mineral density (BMD) on prolonged steroid therapy.

Methods: We studied 64 SLE patients seen at the Leicester Royal Infirmary. Demographic and clinical data was collected from the clinic letters. Steroid use for a cumulative period of over 4 weeks per year was considered significant and used for BMD screenings. BMD measurements were taken using dual X-ray absorptiometry. Osteoporosis was defined by a T score less than or equal to -2.5 SD in at least one region of measurement.

Results: Of the 64 patients studied, 54 (84.4%) were female and 10 (15.6%) male with an age range of 23 to 86 years and mean age of 47.45 years. Steroids were used in 46 (71.9%) patients while 18 (28.1%) patients did not receive any steroids. Twenty-one (32.8%) patients had DEXA scans and whilst 43 (67.2%) had not. Of those who had received steroids, 20 (43.4%) patients underwent DEXA scans and 26 (56.5%) did not. Osteoporosis was diagnosed in 3 (14.3%) patients out of the 21 scanned. The therapies used are summarised in figure 1.

Conclusions: Studies have shown that SLE is an independent risk factor for low BMD and use of corticosteroids is already a well-recognised risk for osteoporosis. Our study has shown that a large section of patients (43.8%) did not receive any form of bone protection although, a significant proportion (71.9%) were on oral steroids. Although a small section of those scanned demonstrated osteoporosis (14.3%), many patients were already initiated on bisphosphonates without a DEXA. There was also no exclusion criteria set for young patients (age <45 years) or those who were newly diagnosed. Despite this, our study demonstrates the need for robust guidelines for the screening and management of bone health in patients with SLE in order to improve morbidity and mortality rates in this patient cohort.

TREATMENT OUTCOME IN LUPUS NEPHRITIS PATIENTS TREATED WITH MYCOPHENOLATE MOFETIL: FINDINGS FROM REAL-WORLD CLINICAL PRACTICE

S.M. Jung1, D. Kim1, H.W. Kim2, S.-W. Lee1, J.J. Song1, Y.-B. Park1. Internal Medicine, Yonsei University College of Medicine; Internal Medicine, Seoul National University Bundang Hospital, Seoul, Korea, Republic of Ireland

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease often characterised by the development of glomerulonephritis. There is a growing interest in the use of mycophenolate mofetil (MMF) as induction therapy and maintenance therapy for lupus nephritis.2–3

Objectives: This study aimed to evaluate the therapeutic outcome of MMF in lupus nephritis from real-world clinical practice, and identify the predictors for failure of remission after MMF treatment.

Methods: Korean patients with pathologically proven lupus nephritis class III, IV, and V were recruited from nephrology clinic in Severance Hospital, Yonsei University College of Medicine between Nov 2011 and Aug 2017 Patients who treated with MMF for at least 3 months were included in the analysis. The probability of remission after MMF therapy, and the difference between patients who achieved remission or failed to achieve remission were analysed using Kaplan–Meier analysis and Cox proportional hazards model.

Results: Of 153 patients with lupus nephritis, 116 patients were included in this study. Seventy two patients continued MMF until the last follow-up. The mean age of patients was 34.2 years, and the median duration of SLE was 5.7 months. Anti-dsDNA antibody was positive in 82.8% of patients, and 9.5% of patients showed a histological class with pure V pathology. Mean protein/creatinine ratio in spot urine was 4.6, and active urinary sediment was found in 82.8% of patients. During median follow-up period of 5 years, 80% of patients achieved clinical remission of lupus nephritis. Median time to remission was 4.2 months (IQR 0.9–9.1). Risk factors for failure of remission were nephrotic-range proteinuria and seronegativity of anti-dsDNA antibodies.

Conclusions: This study shows the real-world data on MMF treatment in patients with lupus nephritis. Patients with risk factors for failure to remission may require more intensive treatment and management.

AB0531 DECISION TO INITIATE IMMUNOSUPPRESSION IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

Background: There is limited data available (case series, small clinical trials and expert opinion) regarding the need to initiate immunosuppressive therapy in patients with primary Sjögren syndrome (pSS).

Objectives: The aim of this study is to determine the factors that correlate with physician’s decision to start immunosuppressive therapy in pSS patients.

Methods: Subjects with pSS diagnosed according to the classification criteria in use at the time of their first presentation, were included in a monocentric cohort. A retrospective analysis was performed. The EULAR Sjögren’s Syndrome Disease Activity Index (ESSDAI) at onset and Sjögren Syndrome Damage Index (SSDI) at the last evaluation were calculated. Treatment was given according to the physician’s decision. Laboratory tests and Ultrasoundography (US) of major salivary glands were performed in all cases. The data was analysed using Windows Excel.

Results: Corticotherapy was prescribed in 26/30 cases (86.6%), mean duration 50.65 months. Immunomodulatory treatment with hydroxychloroquine was given in 26/30 cases (86.6%). Immunosuppressive treatment was required in 10/30 patients (33.3%): azathioprine 7 (23.3%) cases, methotrexate 3 (10%) cases. The mean ESSDAI score was 6.83±SD 1.8. In 19 (63.3%) cases disease activity was moderate or high (ESSDAI >5). The mean damage score value (SSDI) was 3.1±SD 1.2. There was a moderate correlation between the activity score ESSDAI and the damage score SSDI (r=0.41, p<0.05). The physician’s decision to start immunosuppression correlated significantly with the presence of hypergammaglobulinemia (r=0.4, p<0.05). The duration of immunosuppressive treatment correlated moderately with specific Sjögren’s US pattern of salivary glands (r=0.40, p<0.05). In contrast, immunosuppressive treatment duration did not correlate with the activity and damage scores (ESSDAI and SSDI).

Conclusions: An important number of patients received corticotherapy, immunomodulatory agents and immunosuppressive treatment. The decision to initiate and maintain immunosuppressive therapy correlated with hypergammaglobulinemia and specific Sjögren’s US changes. The damage score (SSDI) does not correlate with immunosuppressive therapy duration.

AB0533 PATTERN OF DRUG USE IN SYSTEMIC LUPUS ERYTHEMATOSUS IN REAL WORLD CLINICAL PRACTICE

T. Costa¹, M. Eusébio², S. Falcao³, F. Araújo², P. Nero⁴, L. Inês⁵, M. Rodrigues⁶, D. Jesus⁶, S. Barreira⁶, C. Maceda⁶, M. Cabral⁶, G. Seqüeira⁶, J. Branco⁶, M. Santos⁶. ¹Hospital Egas Moniz; ²Sociedade Portuguesa Reumatologia; ³Hospital S. Antão; ⁴Hospital CUR Descobertas, Lisboa; ⁵Centro Hospitalar Universitário, Coimbra; ⁶Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Centro Académico de Medicina, Lisboa; ⁷Hospital Fernando Fonseca, Amadora; ⁸Centro Hospitalar Universitário de Algave, Faro; ⁹Hospital Garcia de Orta, Almada, Portugal

Background: Pharmacological treatment for systemic lupus erythematosus (SLE) is aimed at reducing disease activity, preventing flares and minimising the damage. The use of medication varies widely and therapeutic strategies are well defined only for certain organ manifestations. Hydroxychloroquine is the standard treatment for most SLE patients during the entire disease course, while immunosuppressants are recommended for those with severe organ involvement. Belimumab is the only biological currently licensed for SLE, although others are used off-label in clinical practice.

Objectives: To describe the real-world patterns of drug use in SLE patients, and their relationship with disease phenotype.

Methods: Observational study of adult SLE patients registered in the Rheumatic Diseases Portuguese Registry, who have clinical diagnosis of SLE, followed for at least 1 year and with available data on medication, which was retrieved. Sociodemographic and clinical characteristics were compared among treatment groups defined as: group 1 antimalarials and/or glucocorticoids; group 2 immunosuppressants (azathioprine (AZA)/mycophenolate mofetil (MM)/methotrexate (MTX)) and glucocorticoids; group 3 biologics, immunosuppressants and/or antimalarials and/or glucocorticoids. To assess possible differences

between the groups, univariate regression analyses were made. In all analyses significance level was set at 0.05.

Abstract AB0533 – Table 1. Sociodemographic and clinical characteristics according to treatment groups

Results: A total of 824 SLE patients were included, mean age of 47.3±14.4 years, 92.3% female. The mean age at first symptoms was 31.6±14.1 and at SLE diagnosis of 34.1±14.3 years. On their last assessment, 678 (82.9%) were being treated with antimalarials, 463 (56.2%) glucocorticoids, 343 (41.6%) immunosuppressants (149 AZA, 99 MM, 67 MTX, 14 cyclosporine, 11 cyclophosphamide, 3 leflunomide), 53 (6.4%) biologics (32 rituximab, 21 belimumab) and 26 (3.2%) were off medication. The sociodemographic and clinical characteristics according to treatment groups are shown in table 1. Gender distribution was similar across groups. A high prevalence of women, Caucasians, non-smokers, acute cutaneous lupus and arthritis was found in all groups. Patients in group 1 had lower disease activity measured by SLEDAI, less organ damage measured by SLICC and lower physician’s global assessment. In group 2 patients were younger and had higher prevalence of renal involvement. Patients in group 3 had higher SLEDAI score and damage, higher prevalence of mucocutaneous, articular, neurologic and hematologic involvement and more use of glucocorticoids.

Conclusions: Almost all SLE patient with established disease were chronically medicated, most with antimalarials and/or glucocorticoids. As expected, group 1 had less severe disease. Patients under immunosuppressants had a higher frequency of renal involvement, which denotes a targeted therapeutic strategy. In routine clinical settings biologics are rarely used, being restricted to patients with very active SLE and multiple clinical manifestations.

PROPORTION OF SJÖGREN’S SYNDROME PATIENTS REFERRED TO ORAL SPECIALISTS AT A RHEUMATOLOGY TERTIARY CENTRE AND FACTORS ASSOCIATED WITH THEIR REFERRAL

G. Levinson1, U. Ahmed1, C. Curtin1,2. 1UCL; 2Department of Rheumatology, UCLH, London, UK

Background: Ideally all patients with Sjögren’s Syndrome (SS) and symptoms of mouth dryness should be assessed by an oral specialist (OS) team at 3–6 monthly intervals for optimisation of their treatment for xerostomia and minimisation of the risk of dental loss1. However, in reality specialist input is not always offered.

Objectives: To determine the proportion of SS patients at a rheumatology tertiary centre who were referred to OS and evaluate if any factors were associated with referral.

Methods: We retrospectively collected data about 105 patients with primary or secondary SS who attended outpatient clinics in October – November 2016, including duration of symptoms and years since diagnosis, presence of SS associated symptoms, medications trialled to date, and serological, imaging and histological patient features. We have also assessed proportion of patients referred to OS, as well as the medication recommended by the OS. p<0.05 was considered significant.

Results: In our cohort, 58.1% of SS patients were referred to an OS. We compared patient demographics and various disease features (table 1) in SS patients who were referred to OS and those who were not.

Disclosure of Interest: None declared

EFFECT OF METFORMIN ON THE ABSOLUTE NUMBER OF CD4 T CELL SUBSETS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

X. Sun1, H. Yao1, J. He2, G. Chai1, L. Wei1, J. Xie1, C. Gao3, X. Li1, J. Li3.
1Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China; 2Pathology, Brigham and Women’s Hospital, Harvard Medical School, Boston, USA

Background: Primary Sjögren’s syndrome is a chronic inflammatory autoimmune disease characterised by the infiltration of lymphocytes into exocrine glands such as the salivary gland and lacrimal gland. Although its etiology and pathogenesis is unclear at present, we consider immune dysfunction plays a significant role in the process. A lot of studies have confirmed that the formation of Treg and Th17 cells interact between each other, and their balance can affect the immune response results, notably reflected in various autoimmune and inflammatory diseases, including primary Sjögren’s syndrome. However, there are few studies on the absolute number of CD4+ T cells in peripheral blood of patients with primary Sjögren’s syndrome. In addition, metformin can affect the balance of Th17/Treg cells through the AMPK-mTOR pathway.

Objectives: To explore whether metformin can affect the balance of Th17/Treg cells in peripheral blood of patients with primary Sjögren’s syndrome, and then be applied in the treatment of pSS patients.

Methods: The number of Treg cells (28.74 (21.22,38.68) vs 34.05 (30.14,42.31), P=0.023) significantly increased after the treatment. At the same time, there was a significantly decrease in the ratio of h17/Treg cells (0.25 (0.08,0.44) vs 0.18 (0.04,0.32), P=0.014). Besides, after the treatment the absolute number of Th17 cells were increased, but it was not statistically significantly (4.5 (3.64,14.23) vs 7.87 (2.37,19.89), P=0.835). In addition, the clinical symptoms of the metformin group were obviously improved, while the dosage of prednisone, leflunomide or hydroxychloroquine reduced significantly.

Results: The number of Treg cells (28.74 (21.22,38.68) vs 34.05 (30.14,42.31), P=0.023) significantly increased after the treatment. At the same time, there was a significantly decrease in the ratio of h17/Treg cells (0.25 (0.08,0.44) vs 0.18 (0.04,0.32), P=0.014). Besides, after the treatment the absolute number of Th17 cells were increased, but it was not statistically significantly (4.5 (3.64,14.23) vs 7.87 (2.37,19.89), P=0.835). In addition, the clinical symptoms of the metformin group were obviously improved, while the dosage of prednisone, leflunomide or hydroxychloroquine reduced significantly.

Conclusions: Metformin can increase the absolute number of Treg cells and decrease the ratio of Th17/Treg cells in the peripheral blood of patients with PSS, while reducing the use of hormones and DMARDs drugs. And it may be one of the mechanisms adopted in the treatment for pSS.

RAPAMYCIN ATTENUATES SYMPTOM AND RESTORES THE BALANCE OF TH17/TREG IN REFRACTORY PRIMARY SJÖGREN’S SYNDROME

Z. Hao1, M. Mia01, Y. Guo1, X. Zhang, X. Li1, C. Gao1, X. Wang1.
1The Second Hospital of Shanxi Medical University, TaiYuan, China; 2Harvard Medical School, Boston, USA

Background: Primary Sjögren’s syndrome (pSS) is one of the more common rheumatological diseases. Despite continued advances, the use of conventional drugs or biologic agents in patients with pSS did not provide expected efficacy and a targeted treatment of pSS is not available at present. We have shown that absolute number of peripheral CD4+CD25+FOP3+ regulatory T cells (Tregs) decreased in pSS patients. And rapamycin is an inhibitor of mTOR that can decrease Th17 cells but increase regulatory T cells (Tregs).

Objectives: To observe the effect of rapamycin on Th17/Treg cell balance in patients with refractory pSS.

Methods: Twenty-eight refractory SS patients (26 women and 2 men) and 93 health controls were enrolled, with a mean duration of 76.64±49.66 months and mean age of 52.39±10.62 years. They fulfilled the 2002 PSS international classification criteria and were treated with glucocorticoid and immunosuppressant for more than one year, but had not yet reached the disease relief. After the eligible patients are given rapamycin in combination with conventional therapy at 0, 12, 24 weeks, we respectively collect the clinical symptoms, blood routine, urine routine, ESR, the absolute number of Th17 and Treg cells, the ratio of Th17/Treg, and the dosage of corticosteroids and immunosuppressant. Allèvement criteria: no clinical symptoms, inflammation normal range, no organ damage.

Results: The absolute number of Treg cells decreased significantly in peripheral blood of PSS patients compared with that of healthy controls. By rapamycin combined with conventional therapy, flow cytometry showed the absolute number of Treg cells in refractory SS patients was increased from 25.51 cells/μl (at week 0) to 27.88 cells/μl (at 12 weeks) and 29.6 cells/μl (at 24 weeks) (P=0.05) respectively. The ratio of Th17/Treg decreased from 0.38 (at week 0) to 0.21 (at 12 weeks) and 0.22 (at 24 weeks) (P=0.05). There was no significant difference in the usage of prednisone, whereas 5 patients gradually stopped using CTX at 24 weeks. Also, the dose of hydroxychloroquine and leflunomide were markedly diminished.

Conclusions: Our results suggest that rapamycin combined with the conventional treatment greatly alleviated symptoms of patients with pSS, and gradually reduced the use of DMARDs. The absolute number of peripheral Tregs decreased in pSS patients and restored by this combined therapy. It still needs to be further confirmed by large sample studies.

SLE, Sjögren’s and APS – clinical aspects (other than treatment)

INCREASED BODY MASS INDEX MAY NOT BE A RISK FACTOR FOR THE DEVELOPMENT OF LUPUS NEPHRITIS

Y.P. Chock1, A. Danve1, on behalf of Yale University School of Medicine, M. Petri2, W. Fu3.
1Yale University School of Medicine, Connecticut; 2Johns Hopkins University, Baltimore, USA

Background: Studies have indicated that elevated body mass index (BMI) increases risk of Chronic Kidney Disease (CKD). Obesity is a low grade inflammatory state which leads to CKD by glomerulosclerosis. Systemic Lupus Erythematosus (SLE) is associated with high leptin levels and dyslipidemia. We hypothesised that obese SLE patients may be at increased risk of nephritis.

Objectives: We studied BMI as possible predictor for development of lupus nephritis (LN) in SLE.

Methods: We performed a retrospective cross sectional study on a longitudinal lupus cohort. Patients were enrolled from year 1987 to 2015. We compared demographics, clinical information, labs between patients with and without LN (table 1) and between patients with SLE with and without obesity. Mean and standard
deviations were reported for continuous variables. Number and percentages were shown for categorical variables and chi-square test was utilised for comparison.

Results: Total of 1362 patients with SLE fulfilling revised ACR criteria were included; 60.9% were Caucasian and 32.8% African American. 596 had biopsy-proven LN however 524 patients were excluded because they had proteinuria before or at cohort entry. Only first available BMI were analysed: 32.7% were obese (BMI >30 kg/m²), 27.2% overweight (BMI: 25–29.9 kg/m²), 37.5% normal (BMI: 18.5–24.9 kg/m²) and 2.6% underweight (BMI <18.5 kg/m²). 39.4% (537) patients were on steroids at first BMI measurement. Results are described in table 1.

BMI measured as continuous (p=0.51) and categorical variables (overweight patients were on steroids at first BMI measurement. Results are described in table 1.

Methods: A total of 14 SLE patients without RP (ACR criteria) (mean age 53±14 SD years, mean disease duration 7±4 years), 14 PRP patients (LeRoy and ACR/EULAR 2013 criteria) (mean age 53±17 years, mean RP duration 6±5 years) and 14 HS (mean age 50±17 years) were enrolled during the winter period. Nailfold videocapillaroscopy (NVC) and laser speckle contrast analysis (LASCAL) were performed in the three groups of patients. The absolute nailfold capillary number (CN) per linear millimetre at first distal row was assessed by NVC. Blood perfusion (BP) was detected by LASCAL at the level of fingertips, perilungal areas, dorsum and palm of both hands and face. The average BP was calculated as perfusion units (PU). Patients were not taking vasodilator drugs since at least one month. Statistical analysis was performed by non parametric tests.

Results: SLE patients showed a positive correlation between BP and nailfold CN in all areas of hands (p<0.0001), but no statistically significant correlation was observed between BP and nailfold CN at the level of face (p=0.10). In both PRP and HS no statistically significant correlation was observed between BP and nailfold CN in all examined areas (p=0.70 and p=0.20, respectively). SLE patients showed a statistically significant lower nailfold CN than both PRP and HS (median 9.1 vs 10.3 vs 11.0, respectively, p<0.0005). Conversely, no statistically significant difference of nailfold CN was observed between PRP and HS. PRP patients showed a statistically significant lower BP than both SLE and HS at the level of fingertip (median 90, 114, 187 PU, respectively, p<0.0001), perilungal (median 74, 100, 141 PU, respectively, p<0.0001), dorsal (median 61, 72, 128 PU, respectively, p<0.0001), and palm areas (median 76, 96, 124 PU, respectively, p<0.0001). Conversely, PRP, SLE and HS patients showed similar BP values at the level of face (median 141, 139, 137 PU, respectively, p=0.30).

Conclusions: This study demonstrates a correlation between morphological and functional microvascular features in SLE patients. SLE patients without RP have a subclinical microangiopathy, showing lower nailfold CN and BP than HS. Versely, PRP patients show only a functional dysfunction, having a lower peripheral skin BP than both SLE patients and HS. The clinical value of this new finding is undergoing further analysis.

**CORRELATION BETWEEN MORPHOLOGICAL AND FUNCTIONAL MICROVASCULAR DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS**

A. Sulli,1 B. Ruoaro,1 C. Pizzorni,1 V. Smith,2 S. Paolino3, M. Pendolino1, L. Vemi1, M. Cutolo1.1 Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium

Background: Numerous articles have investigated peripheral microcirculation in primary Raynaud’s phenomenon (PRP).1–3 However, reports that analyse peripheral microcirculation in systemic lupus erythematosus (SLE) are scanty.4,5

Objectives: The aim of this study was to investigate possible correlations between morphological and functional aspects of microcirculation in different skin areas of the hands and face in SLE patients and to compare the results with PRP patients and healthy subjects (HS).

Methods: A total of 14 SLE patients without RP (ACR criteria) (mean age 53±14 SD years, mean disease duration 7±4 years), 14 PRP patients (LeRoy and ACR/EULAR 2013 criteria) (mean age 53±17 years, mean RP duration 6±5 years) and 14 HS (mean age 50±17 years) were enrolled during the winter period. Nailfold videocapillaroscopy (NVC) and laser speckle contrast analysis (LASCAL) were performed in the three groups of patients. The absolute nailfold capillary number (CN) per linear millimetre at first distal row was assessed by NVC. Blood perfusion (BP) was detected by LASCAL at the level of fingertips, perilungal areas, dorsum and palm of both hands and face. The average BP was calculated as perfusion units (PU). Patients were not taking vasodilator drugs since at least one month. Statistical analysis was performed by non-parametric tests.

Results: SLE patients showed a positive correlation between BP and nailfold CN in all areas of hands (p<0.0001), but no statistically significant correlation was observed between BP and nailfold CN in all examined areas (p=0.70 and p=0.20, respectively). SLE patients showed a statistically significant lower nailfold CN than both PRP and HS (median 9.1 vs 10.3 vs 11.0, respectively, p<0.0005). Conversely, no statistically significant difference of nailfold CN was observed between PRP and HS. PRP patients showed a statistically significant lower BP than both SLE and HS at the level of fingertip (median 90, 114, 187 PU, respectively, p<0.0001), perilungal (median 74, 100, 141 PU, respectively, p<0.0001), dorsal (median 61, 72, 128 PU, respectively, p<0.0001), and palm areas (median 76, 96, 124 PU, respectively, p<0.0001). Conversely, PRP, SLE and HS patients showed similar BP values at the level of face (median 141, 139, 137 PU, respectively, p=0.30).

Conclusions: This study demonstrates a correlation between morphological and functional microvascular features in SLE patients. SLE patients without RP have a subclinical microangiopathy, showing lower nailfold CN and BP than HS. Conversely, PRP patients show only a functional dysfunction, having a lower peripheral skin BP than both SLE patients and HS. The clinical value of this new finding is undergoing further analysis.

Since the majority of patients with SLE are double positive, differences between the two subspecificities of Ro (52 and 60) could not be analysed. On the other hand, no differences were found in cardiac conduction according to the treatments received, the activity or damage indexes, or the analytical or clinical characteristics of the patients.

Conclusions: The study results show that there are no differences in cardiac conduction according to the presence of anti-Ro antibodies in SLE patients. Thus, the cardiac screening in SLE patients with anti-Ro positive antibodies seems not helpful in clinical practice.

HEPCIDIN AND INTERFERON-A IN SYSTEMIC LUPUS ERTHEMATOSUS PATIENTS

D.G. Archimandriti1, A.T. Tzallas2, T.-E. Memi3, P. Spyrou1, A.A. Drosos1, P. V. Voulgar1, 1Rheumatology Clinic, Department Of Internal Medicine, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, 2Department of Computer Engineering, School of Applied Technology, Technological Educational Institute (TEI) of Epirus, Kostakoli, 47100, Arta, Greece, 3Department of Internal Medicine, 1Rheumatology Clinic, Department Of Internal Medicine, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, Ioannina, Greece

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease where interferon (IFN)-α is considered to play a central role in its pathogenesis. Anaemia of chronic disease (ACD) in SLE is common. Hepcidin may contribute to anaemia by limiting iron availability for erythropoiesis.

Objectives: The aim of the study was to evaluate the frequency of MS in a cohort of patients with pSS.

Methods: One hundred and twenty-one patients with pSS had been evaluated and followed up in the outpatient Rheumatology Clinic at predefined times since 1994. All patients were classified according to the 2016 ACR-EULAR criteria for SS. During follow-up, the clinical, laboratory and imaging findings were all recorded. In addition, Magnetic Resonance Imaging and electrophysiological studies as well as spinal fluid analysis were performed when indicated. The diagnosis of MS was based on the 2010 revised McDonald criteria.

Results: Seven patients were diagnosed as having MS. All patients with MS were female. Mean age at the time of MS diagnosis was 65.6±5.6 years, while pSS has been diagnosed at the mean age of 54±3.2 years. Mean time of MS development was approximately 10 years after the pSS diagnosis. pSS patients who developed MS had severe sicca symptoms without other extraglandular manifestations and had positive Ro (SSA) antibodies and a positive minor salivary gland biopsy. pSS patients with MS development were treated appropriately in the Neurology department with biological medications with some improvement of the sicca symptoms.

Conclusions: We found that 5.8% of pSS patients as having MS. This percentage of patients clearly indicates the possibility for the coexistence of a second autoimmune disease with similar if not common pathogenetic mechanisms. Thus patients with pSS should be evaluated carefully and screened appropriately for MS when indicated.

MULTIPLE SCLEROSIS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME

E. Kaltsonoudis1, E. Pelechas1, S. Kontsitsiotis2, P.V. Voulgar1, A.A. Drosos1, 1Rheumatology Clinic, Department Of Internal Medicine, 2Neurology Clinic, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, Ioannina, Greece

Background: Imaging and histopathologic studies in patients with primary Sjögren’s Syndrome (pSS) have demonstrated matter lesions which are indistinguishable from those observed in multiple sclerosis (MS).

Objectives: The purpose of this study was to evaluate the frequency of MS in a cohort of patients with pSS.

Methods: One hundred and twenty-one patients with pSS had been evaluated and followed up in the outpatient Rheumatology Clinic at predefined times since 1994. All patients were classified according to the 2016 ACR-EULAR criteria for SS. During follow-up, the clinical, laboratory and imaging findings were all recorded. In addition, Magnetic Resonance Imaging and electrophysiological studies as well as spinal fluid analysis were performed when indicated. The diagnosis of MS was based on the 2010 revised McDonald criteria.

Results: Seven patients were diagnosed as having MS. All patients with MS were female. Mean age at the time of MS diagnosis was 65.6±5.6 years, while pSS has been diagnosed at the mean age of 54±3.2 years. Mean time of MS development was approximately 10 years after the pSS diagnosis. pSS patients who developed MS had severe sicca symptoms without other extraglandular manifestations and had positive Ro (SSA) antibodies and a positive minor salivary gland biopsy. pSS patients with MS development were treated appropriately in the Neurology department with biological medications with some improvement of the sicca symptoms.

Conclusions: We found that 5.8% of pSS patients as having MS. This percentage of patients clearly indicates the possibility for the coexistence of a second autoimmune disease with similar if not common pathogenetic mechanisms. Thus patients with pSS should be evaluated carefully and screened appropriately for MS when indicated.

AB0543
CORRELATION BETWEEN SYSTEMIC LUPUS ERTHEMATOSUS DISEASE ACTIVITY AND OCULAR SIGNS IN OPHTHALMOLOGICALLY ASYMPTOMATIC PATIENTS

S.A. Fouad1, S.M. Esmat Mahmoud Ali2, A.R.L. Rozk Alnaggar1, S. Mahfouz1, M. Essam1, H. El-Gendy1, 1Internal Medicine Department, 2Ophthalmology, Kasr Al Einy hospital, Cairo University, Giza, Egypt

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease involving different organs and systems. Ocular manifestations of lupus may manifest as a presenting feature of the disease or as a complication that can be sight threatening. Almost any part of the eye and visual pathway can be affected by inflammatory or thrombotic processes yet ophthalmological assessment in those patients may be delayed.

Objectives: Detection of various ocular pathologies in ophthalmologically asymptomatic SLE patients using Optical Coherence Tomography (OCT). Fundus Fluorescein angiography (FFA), and fundus examination, in addition to studying the
role of between detected ocular changes and SLE disease activity assessed by SLEDAI score.

Methods: 26 ophthalmologically asymptomatic SLE patients recruited from Kasr Alainy hospital, Cairo University, and were subjected to comprehensive ocular assessment in the form of the measurement of visual acuity, fundus examination, FFA, and OCT. Hypertensive, diabetic and renal impairment patients were excluded.

Results: SLE patients were 25 females and 1 male, age mean of 25.15 (±8.6) years, SLEDAI mean 14 (±8.3), duration of illness mean 27 (±42.3) months, FFA showed that 38 out of 52 eyes (73%) had signs of pathological changes in the form of splinter haemorrhages, venular occlusion, diffuse mottling and optic nerve leakage and also degenerative changes which indicate chronicity, in the form of hyperfluorescence areas outside the arcades and pre-papillary areas and capillary drops. Besides; OCT detected changes in 67.3% of the examined eyes with 26.9% revealing degenerative thinning. There was significant correlation between disease activity and changes detected by FFA (p value 0.017), but neither the fundus findings nor the OCT pathological changes had correlation with disease activity. On the other hand, there was significant correlation between OCT changes and prolonged use of hydroxychloroquine more than 5 years (p value 0.032) and steroid intake for more than 3 months (p value 0.039). There was no correlation between FFA or OCT changes and proteinuria or anti-phospholipid antibodies.

Conclusions: FFA is can detect early retinopathy changes in patients of SLE which cannot be detected by fundus examination. FFA changes are correlating with disease activity. On the other hand, there was no correlation between OCT changes and disease activity. OCT is more sensitive to detect changes from hydroxychloroquine and steroids intake.

IS LUPUS MORE PREVALENT IN WORLD’S MOST STRESSED COUNTRIES?

A. Almahkour, D. Pyne, A. Pakozdi, R. Rajkaria, A. Cove-smith, M. Lewis, on behalf of Barts Lupus Center. BARTS NHS TRUST, London, UK

**Background:** A number of studies have implicated psychological stress as a trigger for autoimmune diseases. In a questionnaire study involving 120 lupus patients emotional stress was selected in over 75% cases as a trigger for their disease. The role of stress as a trigger in lupus however is controversial. Here we study whether there is an association between the prevalence of lupus in various countries and their reported stress measures.

**Methods:** We undertook a literature review of the reported prevalence of lupus in various countries across the world. We then recorded the reported stress index in those countries from Bloomberg’s study, which utilised seven equally weighted variables: homicide rates, GDP per capita income inequality, corruption perception, unemployment, urban air pollution and life expectancy to rank 74 countries according to stress levels. Pearsons correlation was used to measure association between national stress indices and lupus prevalence.

**Results:** Results are presented in graph 1. Prevalence data was only available in the literature for limited countries. Of the countries studied no correlation was found between national stress indices and lupus prevalence.

**Conclusions:** Conclusions: We found no association between a country’s prevalence of lupus and the measured stressfulness of its living environment.

CRYOglobulinemia in Systemic Lupus Erythematosus: Clinical and Immunological Features

A. Barrera-Vargas1, F. J. Antiga-Lopez2, J. Rangel-Patiño2, R. Rosado-Canto2.

Immunology and Rheumatology, Internal Medicine, Hematology, Nephrology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

**Background:** Systemic lupus erythematosus (SLE), as the prototype of systemic autoimmune diseases, has a wide array of clinical manifestations. An association between cryoglobulinemia and certain clinical and immunological features of SLE has been proposed, and there are various physiopathologic pathways that could be involved in this relationship. Although the presence of cryoglobulinemia in SLE patients may be related to specific disease features and could even have prognostic value, this association has not been addressed thoroughly.

**Objectives:** To describe clinical and immunological characteristics in SLE patients with cryoglobulinemia.

**Methods:** We performed a retrospective, case-control study, in which we included all patients with a cryoglobulin determination between January 2005 and December 2016 in a third level referral centre in Mexico City. Patients with SLE and a positive cryoglobulin test (cryocrit >1%) were included in the case group, whereas SLE patients with a negative cryoglobulin determination were considered controls. We studied demographic, clinical and immunological characteristics at the time of the positive cryoglobulin result, as well as three months earlier, and 6 and 12 months later.

**Results:** Thirty-six SLE patients had a cryoglobulin determination throughout the study period. Ten patients had cryoglobulin levels (>1%) and were included in the case group, whereas 26 patients with a negative determination were included as controls. Mean age was 37.7±18.3 in cases and 41.7±19.3 in controls. 70% of cases and 88.5% of controls were women.

Among subjects with cryoglobulinemia, the cryocrit was 1% in 9 patients, and 3% in one. Regarding clinical and immunological characteristics, a positive lupus anticoagulant and a history of vasculitis were more frequent in patients with serum cryoglobulins (p=0.004 and 0.04, respectively). At the time of the cryoglobulin measurement, patients in the case group had lower levels of C3 and C4 (p=0.026 and p=0.003, respectively), and serum albumin (p=0.028). They also had a higher prevalence of serositis (p=0.021) and peripheral oedema (p=0.034), as well as a higher SICC Damage Index score (p=0.014) than controls.

Regarding follow-up, patients in the case group had a higher SLEDAI score after six and twelve months (p=0.009 and 0.034, respectively). Also, after 12 months they had a higher prevalence of renal activity (p=0.004) and lower C4 levels (p=0.001). Among patients with renal activity, 20% of cases and 55% of controls had achieved complete remission after 12 months.

**Conclusions:** Serum cryoglobulins in SLE patients were associated with positive lupus anticoagulant and hypocomplementemia. Cryoglobulinemia was also associated with specific disease manifestations, such as serositis and vasculitis, and with damage accrual. At follow-up, patients with cryoglobulinemia had a higher prevalence of renal activity, as well as an increased disease activity overall. Whether cryoglobulins could be used as a biomarker for renal activity or worse renal prognosis remains to be determined, and larger prospective studies will be needed to address this possibility.

LYMPHADENOPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL RELEVANCE AND HISTOLOGICAL SUBTYPES

A. Berba1, M. Estevaez2, M. Freire3, E. González4, L. González-Vázquez5, I. Carballo6, B. Sopena7, on behalf of CEAG (Círculo de Estudios en Enfermedades Autoinmunes de Galicia).

1Medical Student, Faculty of Medicine., University of Santiago de Compostela, Santiago de Compostela (A Coruña); 2Systemic Diseases Unit; 3Systemic Diseases Unit, CHUVI, Vigo; 4Systemic Diseases Unit, CHOU, Ourense; 5Department of Medicine, POIVISA, Vigo; 6Systemic Diseases Unit, Hospital Clínico Universitario de Santiago de Compostela (CHUS), Santiago de Compostela (A Coruña), Spain

**Background:** Lymphadenopathy (LAP) in Systemic Lupus Erythematosus (SLE) has lymphadenopathy (LAP) at diagnosis or at follow-up. The prevalence of LAP in SLE was 39% in the oldest recorded series, 12% in the 1993 EUROLUPUS series and 16% in the last two decades its prevalence was not mentioned. However, the presence of LAP and their histological type may have clinical relevance.

**Objectives:** To study the prevalence and histologic characteristics of LAP in a cohort of patients with definite SLE and evaluate its relationship with clinical manifestations.

**Methods:** All patients diagnosed with SLE according to the 1997-ACR criteria at the Autoimmunity Units of three different hospitals since 2005 were followed looking for lymph node enlargement at every consult. The moment when LAP was detected, the concomitant clinical symptoms, SLE manifestations and laboratory variables were recorded. The group of patients with and without LAP were compared. A tissue sample was obtained when indicated. All patients agree to participate in the study.

**Results:** 103 patients with definite SLE were included in the study. Valuable LAP (>10 mm) was found in 28 patients (27%). The gender and age of SLE patients with or without LAP was similar (80% vs 78% females, and 34±15 vs. 40±28 years respectively). LAP was detected at the time of SLE diagnosis in 54% of patients. Fever was significantly more frequent in patients with LAP (60% vs 5%, p=0.01) like dermopathy (86% vs. 60%; p=0.05) and serositis (45% vs 16%; p=0.01). High titers of anti-dsDNA antibodies (71% vs. 42%; p=0.05) and hypocomplementemia (89% vs. 60%; p=0.05) were also more frequent in patients with LAP. A total of 28 tissue samples were obtained in 17 patients (FNA 6, Ultrasound-guided biopsy 6 and surgical excision in 17). The histopathological study showed: Reactive lymphadenitis 20, histiocytic necrotizing lymphadenitis in 6 and Non-Hodgkin Lymphoma in 2 (B-cell lymphoma on methotrexate treatment, and a Burkitt lymphoma). All 6 patients with SLE and histiocytic necrotizing lymphadenitis have cutaneous involvement but none of them developed lupus nephritis.

**Conclusions:** Patients con SLE and lymphadenopathy had significantly more fever, cutaneous lesions and serositis. High levels of anti-dsDNA antibodies and hypocomplementemia were more frequent in these patients. In some occasions malignancy could be the cause of lymphadenopathy.

AB0548
ANTIBODY TO PURINNUCLEOSOID PHOSPHILILASE CAN BE USED AS AN ADDITIONAL MARKER OF INFECTIOUS COMPLICATIONS WITH SYSTEMIC LUPUS ERYTHEMATOSIS

Background: Purine nucleoside phosphorylase (PNP, EC 2.4.2.1) plays a leading role in the assimilation of nucleosides and nucleotides by the cell, as well as in maintaining the immune status of the organism. Patients with PNP deficiency are highly susceptible to various infections, in view of the fact that the decreased activity of PNP is closely related to the insufficiency of cellular immunity.

Objectives: Study of the possibility of using the level antibodies to purine nucleoside phosphorylase as an additional marker of infectious complications in patients with systemic lupus erythematosus (SLE).

Methods: The study included 60 patients with SLE (women – 91.7%, mean age 36.3±15.27 years, average duration of the disease 7.96±7.35 years) with different clinical manifestations (SLEDAI activity 8.93±5.74, ECLAM activity 5.30±2.79, damage index SICCI/ACR 1.95±1.71). Antibodies to PNP (anti-PNP) were determined in our indirect ELISA test using the immobilised form of the enzyme as an antigen.

Results: The presence of infectious complications in SLE patients was assessed by characteristic clinical manifestations and was considered to be confirmed when the causative agent was recognised and/or the serological analyses are positive. Infections were diagnosed in 38.3% of patients, the most frequent localization was the urinary system (n=12; 52.2%) and female genitalia (n=5; 21.7%).

Conclusion: In the presence anti-PNP in the blood serum of patients with SLE we have often noted infectious complications (p=0.025, criterion ¥2 and less often lung damage (p=0.17) (when compared with a group of patients with SLE seronegative for the presence of anti-PNP).

AB0549
CAN THE OVERALL THROMBOTIC RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS BE DETERMINED? THE COMBINED ROLE OF CLASSIC CARDIOVASCULAR FACTORS AND ANTIPHOSPHOLIPID ANTIBODIES

Background: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory disorder. Antiphospholipid syndrome (APS) is a thrombotic disorder associated with the presence of antiphospholipid antibodies (APA) and increased cardiovascular risk (CVR). Framingham (FRM) and SCORE (Systematic Coronary Risk Evaluation) scales are available CVR assessment systems. aGAPSS (adjusted Global Antiphospholipid Syndrome Score) combine positive APA and CVR factors, which was suggested to determine the thrombotic risk in persistently positive APA (PPAPA) patients.

Objectives: To determine the role of the thrombotic factors in SLE patients, considering CVR factors and APA. To access the application of different thrombotic risk scales.

Methods: A retrospective cohort study of 84 patients with SLE followed in an outpatient setting of a Portuguese central hospital was performed. The study evaluated patient gender, current age, age at diagnosis, duration of illness, presence of another autoimmune disease (AID), CVR factors (obesity (OB), diabetes (DB), arterial hypertension (AH), dyslipidemia (DL), smoking (SM)), presence of APA, treatment, dose and duration of steroids. The FRM, SCORE and aGAPSS scores were calculated. The data was analysed using SPSS and considered significant if p<0.05.

Results: Table 1 characterises the study population. Male patients had a higher prevalence of AH (p=0.022), DL (p=0.047), and SM (p=0.001), with a risk of 11%–20% in the FRM scale and a risk of 5%–14% in the SCORE (p=0.000). Female patients had a higher prevalence of another AID (p=0.014) and treatment with disease-modifying antirheumatic drugs (p=0.014). FRM scale reveals a risk of 11%–20% in the presence of AH and >20% in SM (p=0.001). The SCORE scale reveals a risk of 5%–9% in the presence of AH (p=0.003) and 10%–14% in DL (p=0.024). When the risk is 6%–20% in the FRM scale, the risk is lower in SCORE (p=0.000). APA does not correlate with an increased CVR. All APA are associated with another AID, APS and PPAPA. The aGAPSS associates a score of 7–12 if another AID is present (p=0.000); 4–9 with APS;>7 with PPAPA (p=0.000); 4–6 with DB (p=0.039), DL (p=0.002) and AH (p=0.000)>7 with lupus anticoagulant (LA);>7 with anticardiolipin antibodies (aCL) and >12 with anti-β2-glycoprotein-I antibody (antiβ2GPI) (p=0.000).

Conclusions: This study highlights the existence of thrombotic factors in SLE. Their risk is even more elevated when another AID is present. The FRM and SCORE scales reflects the CVR. In SLE patients both the CVR factors and the presence of APA must be evaluated. Therefore, not only should the FRM scale be calculated, but also the global thrombotic risk, using the aGAPSS, must be accessed.

AB0550  CLINICAL-EPIDEMIOLOGICAL FEATURES OF PATIENTS WITH A LATE-ONSET LUPUS IN A TERTIARY CARE HOSPITAL

A. Crespo Colmar, C. Moriano, M. Garjo, C. Iglesio, I. González, A. López, E. Díez, C. Ávarez, M. Martín, E. Valdepe, T. Pérez. Rheumatology Department, University Health Care Complex of León, León, Spain

Background: Different frequency of clinical and serological manifestations has been detected according to the age of onset of the patients with Systemic lupus erythematosus (SLE). According to the literature, senile SLE manifests between 6% and 18% of the patients with lupus.

Objectives: 1. To identify and analyse the clinical-serological and epidemiological features of senile SLE in our environment.
2. To determine the average survival time and mortality in these patients, identifying its main cause.

Methods: Observational retrospective study of 319 patients diagnosed with SLE (according to ACR 1992 and SLICC 2012 criteria) at the Hospital of León between 1997–2017 and with an age of onset ≥65 years, obtaining a total of 88 patients with senile SLE.

Results: The mean age at diagnosis was 75.4±12.1 years, with a female/male ratio of 2.4. The most frequent manifestations were as joint (63.2%) and haematological manifestations in the form of leuco-lymphopenia (55.9%). The hemolytic anaemia only appeared in 2.9% of the cases and the thrombocytopenia in 25.36.8% of patients showed photosensitivity and 29% had other cutaneous manifestations, being the malar erythema the most prevalent type (60%), followed by the discoid lupus erythematosus (20%) and the subacute lupus (15%). Alopecia was only observed in 4.4%. Lupus nephritis was detected in the form of proteinuria in 4.4% of the patients, and only one patient had microscopic haematuria. Lung involvement was uncommon (8.8%), taking precedence the UIP (33.3%) over the rest of the pulmonary manifestations. Only 11.1% of the patients with senile SLE had serositis, being in the form of pleuritis in 75% of the cases, pericarditis in the 37.5% and ascites in the 12.5%. Regarding the neurological involvement, 5 patients showed polyneuropathy and 1 had chorea. Likewise, the frequency of Sjögren, Raynaud and secondary antiphospholipid syndrome was of 16.7%, respectively.

The most important serological findings were: 97.3% ANA; 44.1% DNA and 20.6% hypocomplementemia, with 54.4% of the patients having serological activity at the onset, having hypocomplementemia only in 1 out of 5 cases. The most important serological findings were: 97.3% ANA; 44.1% DNA and 20.6% hypocomplementemia, with 54.4% of the patients having serological activity at the onset, having hypocomplementemia only in 1 out of 5 cases. Only 5.9% had anti-Sm. Antiphospholipid antibodies were positive in 41.2% of the patients, 14 died (20.59%), mostly due to infectious etiology (35.7%) and 14.28% of the patients showed polyneuropathy and 1 had chorea. Likewise, the frequency of serositis, being in the form of pleuritis in 75% of the cases, pericarditis in the 37.5% and ascites in the 12.5%. Regarding the neurological involvement, 5 patients showed polyneuropathy and 1 had chorea. Likewise, the frequency of serositis in the form of pleuritis in 75% of the cases, pericarditis in the 37.5% and ascites in the 12.5%. Regarding the neurological involvement, 5 patients showed polyneuropathy and 1 had chorea. Likewise, the frequency of serositis, being in the form of pleuritis in 75% of the cases, pericarditis in the 37.5% and ascites in the 12.5%.

Conclusions: The late–onset SLE prevails in our environment, one of every 5 patients diagnosed with SLE in our consulting room is older than 65 years.

• It is found most often in women and it is confirmed a lower male/female ratio than expected.
• Joint and haematology manifestations and cutaneous involvement in the form of malar erythema define the clinical profile of our patients with senile SLE, with the renal involvement or the presence of serositis being uncommon.
• Half of the patients had serological activity at the onset, having hypocomplementemia only in 1 out of 5 cases.
• Infections were the first cause of mortality in our sample with an average survival time of around 13 years.

AB0551  OBSTETRICAL MORBIDITY RELATED TO ANTI-SSA ANTIBODIES: DATA FROM A FRENCH MONOCENTRIC RETROSPECTIVE STUDY

L. Plaça1, F. Carr2, L. Carballon2, P. Nicaise3, A. Bénit2, O. Fan1, A. Melekian1. 1: Internal Medicine; 2: Obstetrics and Gynecology, Jean Verdier hospital; 3: Auto-immunity and hypersensibility, Bichat hospital; 4: Obstetrics and Gynaecology, Jean Verdier hospital, Paris, France

Background: Obstetrical morbidity is an issue among autoimmune diseases patients. Anti-SSA positivity is well known for it’s effect on fetus and risk of congenital heart block but no evidence has been yet found for its effect on obstetrical morbidity.

Objectives: To investigate anti-SSA positivity effect among a large monocentric cohort of obstetrical morbidity patients and to evaluate the efficacy of different treatment regimens.

Methods: All women who were seen from January 2010 to January 2015 in Jean Verdier University Hospital for obstetrical morbidities were retrospectively included. All patients had been tested for anti-nuclear antibodies and anti-SSA/Ro and anti-SSB/La antibodies.

Results: We included 244 women (median age 34 years [interquartile range 21–53]) with 869 pregnancies overall. In 27 (11%) patients with anti-SSA antibodies, the median age at the time of pregnancy was 29.5 (17–40) years, with mean number of 3.66 pregnancies per woman. For these 27 patients, 83/99 pregnancies (84%) had an adverse obstetrical outcome: fetal loss (n=65; at a median of 20 (4–38) weeks of gestation), preterm delivery (n=59), pre eclampsia (n=45), congenital heart block (n=22). In comparing women with obstetrical antiphospholipid syndrome and unexplained adverse complications, there was no major difference in frequency of recurrent miscarriages, preterm deliveries, preeclampsia or fetal loss. Among factors associated with obstetrical outcome and fetal loss, aspirin and hydroxychloroquine treatments were significantly associated with a favourable obstetrical outcome: odds ratio 0.65 [95% confidence interval 0.01:0.37] and 0.15 [0.02: 0.98] (p=0.04).

Conclusions: Women with unexplained recurrent obstetrical complications should be screened for anti-SSA antibodies. The benefit of aspirin and hydroxychloroquine treatment to improve the obstetrical outcome should be confirmed in prospective studies.

Disclosure of Interest: None declared

AB0552  THE CLINICAL AND LABORATORY FEATURES OF ANTIPHOSPHOLIPID ANTIBODY POSITIVE PATIENTS WITH OR WITHOUT SYSTEMIC LUPUS ERYTHEMATOSUS

A. Yazıcı1, A. Ommar2, S. Yilmaz2, S. Yavuz3, K. Ayar1, E. Kasapoglu4, B. Kısıakoğlu5, A. Cefle1, D. Erkan1. 1: Rheumatology, Kocaeli University School of Medicine, Kocaeli, Turkey; 2: Rheumatology, Numune Hospital, Ankara; 3: Rheumatology, Bilim University School of Medicine, Istanbul; 4: Rheumatology, University of Health Sciences Yüksek İhtisas Training and Research Hospital, Ankara; 5: Rheumatology, Medicalpark Hospital, Gaziantep, Turkey; 6: Barbara Volcker Center for Women and Rheumatic Diseases, Hospital for Special Surgery, Weill Cornell Medicine, New York, USA

Background: A multicenter antiphospholipid antibody (aPL) clinical database was created in 2016 with the participation of six rheumatology centres around the country. The purpose has been to better define aPL-related clinical manifestations and management strategies; and also to establish a resource for future clinical studies.

Objectives: In this first analysis, we compared the clinical and laboratory features of aPL-positive patients with and without systemic lupus erythematosus (SLE).

Methods: The demographic, clinical, laboratory, treatment characteristics of the aPL-positive patients with/without other systemic autoimmune diseases (SAID) are recorded at enrollment according to a predefined protocol. The inclusion criteria are positive aPL (lupus anticoagulant test [LA], antiphospholipid antibody [aCL], and/or anti β2-glycoprotein-I antibody [aβ2GPI]) based on the Updated Sapporo Antiphospholipid Syndrome (APS) Classification Criteria at least twice within one year prior to enrolment. For the purpose of this analysis, we only included aPL-positive patients without other autoimmune diseases (primary aPL/APS) and aPL-positive SLE patients (SLE-aPL/APS).

Results: As of January 2018, 105 aPL-positive patients were recruited (mean age: 42.6±10.1 [min-max: 19–70]; 83 [79%] female; and 67 [84%] with another SAID). Ten patients were excluded from the analysis due to their SAID history other than SLE. Of the remaining 95 patients, 38 (40%) had primary aPL/APS, 57 (60%) fulfilled the ACR SLE Classification Criteria; 42 (44%) had thrombotic APS (TAPS) (8 arterial, 24 venous, and 8 both); 21 (22%) had obstetric APS (OAPS); 22 (23%) had both TAPS and OAPS (7 arterial, 14 venous, and 1 both); and 10 (11%) had no TAPS/OAPS. Fifty percent of the patients had history of at least one non-criteria aPL-manifestation. Demographics, clinical and laboratory manifestations, and medications were similar between primary aPL/APS and SLE aPL/APS patients except increased frequency of autoimmune hemolytic anemia, aCL IgG, and hydroxychloroquine use in SLE aPL/APS patients (table 1).

Disclosure of Interest: None declared

Conclusions: The analysis of our multicenter aPL database demonstrates that the frequencies of thrombosis and pregnancy morbidity are similar between aPL-positive patients with or without SLE. Half of the patients in both groups had history of at least one “non-criteria” aPL-manifestation; only autoimmune hemolytic anemia was more frequent in aPL-positive patients with SLE.

AB0553 CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHEMATOSUS AMONG VARIOUS AGE GROUPS: COMPARISON BETWEEN JUVENILE ONSET, ADULT ONSET, AND LATE ONSET SYSTEMIC LUPUS PATIENTS FROM A SINGLE TERTIARY CENTRE, EGYPT

B.M. Medhat, N. Sobhy, B. Eissa, Rheumatology and Rehabilitation department, Faculty of Medicine-Cairo University, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is a complex autoimmune disease with several factors affecting the characteristics of the disease, including age of onset which is one of these major factors.1

Objectives: To highlight the differences in disease characteristics among various age groups in an Egyptian cohort from a single tertiary centre.

Methods: Information in this study was derived from medical records of patients admitted to the Rheumatology department in Cairo University from December 2015 to June 2017. All patients fulfilled the SLICC classification criteria of 2012.2 Demographic, clinical and serologic characteristics of all patients were recorded. Age of onset was defined as the age at the time of development of manifestations; upon which patients were divided into 3 groups: juvenile onset (SLE: onset ≤16 years), adult onset: (ASLE: onset 17–50), and late onset lupus (LSLE: onset >50) patients.

Results: The study included 369 patients, of which 44 (11.96%) were males and 324 (88.04%) were females. The mean age of onset of the cohort was 24.04 ±10.15 (7–63) years, while the mean disease duration was 65.6±58.4 (0.5–408) months. The study included 75/369 (20.3%) JSLE, 283/369 (76.6%) ASLE, and 10/369 (2.7%) LSLE patients. The median age of onset of JSLE patients was 13 (11–15), 23 (20–30) in ASLE patients, and 54 (52–58) years in the LSLE group. The median disease duration in JSLE patients was 78 (36–125), 36 (24–84) in ASLE patients, and 12 (9–38) months in LSLE patients. Apart from arthritis, malar rash, and nephritis, there were no differences between the three groups. The prevalence of arthritis was highest among ASLE patients and lowest in JSLE (p=0.004) patients, with LSLE patients showing a comparable prevalence of arthritis to ASLE (p=0.5) and JSLE (p=0.3) patients. On the other hand, JSLE patients showed the highest prevalence of malar rash (p=0.006), as opposed to both ASLE (p=0.04) and LSLE (p=0.004) patients; yet ASLE patients showed a substantially high prevalence of malar rash when compared to LSLE patients (p=0.03). Nephritis was most common in JSLE patients (p=0.007) and least common in LSLE patients. Although there was no statistical difference in the prevalence of nephritis between JSLE and ASLE patients (p=0.1), both groups showed a higher prevalence of nephritis than LSLE patients (p=0.002 and p=0.01 respectively).

Conclusions: Adult onset SLE patients showed the highest prevalence of arthritis. On the other hand, JSLE patients showed the highest prevalence of nephritis as opposed to LSLE patients with the lowest prevalence, indicating a predilection towards a more severe disease in the former group.

Abstract AB0554 – FACTORS AFFECTING QUALITY OF LIFE IN INDIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

B. Pinto1, S. Grover2, M. Rath1, A. Dhooaria1, A. Sharma1. 1Internal Medicine, 2Psychiatry; 3Nephrology, PGIMER, Chandigarh, India

Background: SLE has a profound impact on Quality of Life (QoL). In addition to disease activity and damage, other factors such as fatigue, fibromyalgia and psychosomatic comorbidities also influence QoL.3 However, there is lack of data in the form of comprehensive assessment of all these factors in the same cohort.

Objectives: To assess the quality of life and its correlates among patients with SLE.

Methods: Using a cross-sectional study design, 144 patients with SLE were assessed for disease activity and damage by using SELENA –SLEDAI and SLICC/ACR damage Index (SDI), depression (by using Patient Health Questionnaire-9 (PHQ9), anxiety (by using Generalised Anxiety Disorder 7 (GAD7)), fatigue (by using Fatigue severity scale (FSS)) and fibromyalgia (as per ACR 2010 criteria). QoL was assessed using a generic QoL scale – Short Form 36 (SF-36).2 Statistical analysis was done using STATA version 14.

Results: The study sample included 140 females and 4 males. Mean age of the participants was 32.48 (SD-7.26) years and the mean duration of illness was 3.92 (SD-3.76) years. The mean SELENA SLEDAI and SDI was 3.42±2.04 and 0.26 ±0.65 respectively. Prevalence of depression (PHQ9 ≥10) and anxiety (GAD7 ≥10) was 25% and 22.9% respectively, Fatigue (FSS ≥4) was present in 51.4%. Physical domains of SF36 were affected more often than the mental domains, 71.5% of the respondents had scores less than 50 in Physical component Summary (PCS) and 61.1% in Mental Component Summary (MCS) of SF36. No correlation was found between disease activity and damage and various domains of SF36. Depression, anxiety and fatigue had a significant negative correlation with all the domains of SF36 (table 1). On multivariate regression only fatigue was an independent predictor of PCS of QoL.

*p<0.05; **p<0.001
Conclusions: Fatigue, depression and anxiety have a greater influence on QoL in SLE than disease activity and damage. Of these, fatigue appears to be the most important variable which influences QoL.

AB0555
IS HIGHER FITNESS ASSOCIATED WITH BETTER HEALTH-RELATED QUALITY OF LIFE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS?  
1Department of Physical Education and Sport, 2Department of Personality, Evaluation and Psychological Treatment, University of Granada; 3Systemic Autoimmune Diseases Unit, Department of Internal Medicine, “Virgen de las Nieves” University Hospital, Granada; 4Department of Education, University of Almería, Almería, Spain

Background: Patients with systemic lupus erythematosus (SLE) present reduced health-related quality of life (HRQoL). As an adjunct to traditional medical therapy, higher levels of physical fitness seem to be associated with better symptomatology and HRQoL. However, a comprehensive characterisation of the association of different components of physical fitness with the different dimensions of HRQoL in this population is lacking and would provide valuable information for the design of prospective studies.

Objectives: The aim of this study was to investigate the association of different physical fitness components (flexibility, muscle strength and cardiorespiratory fitness (CRF)) with the dimensions of HRQoL.

Methods: This cross-sectional study included a total of 70 women with SLE (age 42.5 ± SD 13.9). The back scratch test, 10 s chair stand test and 6 min walk test (n=49) (from the Senior Fitness Test battery) as well as the handgrip strength test were used to assess physical fitness. The median value of each fitness test [flexibility (0.125 cm), upper muscle strength (24.2 kg), lower muscle strength (15 repetitions) and CRF (575 metres)] was used to consider high (>median value) or low (<median value) fitness. HRQoL was assessed through the 36-item Short Form Health Survey (SF-36). Partial correlation was used to examine the association of physical fitness components with all dimensions of the SF-36. For those dimensions significantly associated with fitness, analyses of covariance comparisons were used to estimate the differences in HRQoL between patients with low and high fitness level. All analyses were controlled for age, body mass index, depression and fatigue.

Results: Flexibility was correlated with physical function, social functioning and physical component (r(pearson between 0.28 and 0.50; all p<0.05) with differences between groups of low and high muscle strength (upper and lower body) in all those dimensions (p<0.05). CRF was correlated with physical function and physical component (r(pearson between 0.39 and 0.65; all p<0.01) with differences in physical function and physical component between groups of low and high CRF (p<0.05).

Conclusions: The main findings of the present study suggest that flexibility, muscular strength and cardiorespiratory fitness are associated with different dimensions of HRQoL, particularly with those related to self-reported physical health, in women with systemic lupus erythematosus. Future prospective research should assess the predictive role of fitness regarding disease activity and function.

THE DIAGNOSTIC AND PREDICTIVE SIGNIFICANCE OF NAILFOLD VIDEO CAPILLAROSCOPY IN CTD PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION

B. Jiang, X. Xu, K. Zhou, C. Wang, L. Geng. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: Pulmonary arterial hypertension (PAH) is a serious complication of connective tissue diseases (CTD), defined as an elevation in mean pulmonary artery pressure 25 mmHg at rest. The 1 year, 3 year survival rates of CTD-PAH are only 69% and 30%, respectively. Therefore, to early prediction and diagnosis of PAH is very critical for prolonging survival of CTD patients. Nailfold video capillaroscopy (NVC), is an imaging technique for the study of microcirculation. Until now, capillary abnormalities in systemic sclerosis (SSc) are well documented, but rare study focus on the association between the abnormality of capillary with PAH in CTD patients.

Objectives: Through estimating the correlation of the abnormality of nailfold capillary with pulmonary arterial hypertension (PAH) and other organs injury to find out its importance on early diagnosis and prediction for PAH in the patients with connective tissue disease (CTD).

Methods: Nailfold video capillaroscopy (NVC) was performed using a videocapillaroscope to test the fingers capillaries of 123 hospitalised CTD patients with and without PAH. The parameters of NVC were estimated including: the inter, outer and top loop diameter, loop number, misshaped or giant capillaries, flowing speed, haemorrhage, erythrocyte aggregation, et al. The organ involvement like interstitial lung disease (ILD) and cardiovascular complications were also considered. Mann-Whitney test was used to estimate the difference.

Results: 1) The number of capillary loops in patients with SSc was much lower, but morphologic score, liquid score, and total score were all higher than other CTD patients (Tab). 2) The loop number was significantly decreased but abnormal scores of morphology, liquid, diameter, misshaped loop number, flowing speed, erythrocyte aggregation were increased in CTD-PAH patients especially in SLE-PAH compared with non-PAH patients (Fig). 3) ILD relates the abnormality of peripheral circulation such like capillary malformation, decreased loop number, diameter and blood flow, increased haemorrhage, but the influence of PAP may be larger than ILD. 4) Down-regulated loop number, increased morphology, liquid and total score, and abnormal diameter, malformation, erythrocyte aggregation were found in CTD patients with cardiovascular complications, especially in CTD-PAH patients and SLE patients. 5) Age doesn’t directly influence the capillaries of CTD patients, but in young and middle age patients, the difference between PAH and non-PAH groups were more evident.

Abstract AB0556 – Table 1. Comparison of number of nail fold capillaries in patients with various CTD

Abstract AB0556 – Figure 1. Loop number and other indexes of nail fold capillaries in patients with various CTD and CTD-PAH with non-PAH CTD
HAEMATOLOGICAL INVOLVEMENT (CYTOPENIA) AT THE TIME OF THE DIAGNOSIS IS ASSOCIATED WITH LESS SEVERE OCULAR INVOLVEMENT IN PATIENTS WITH PRIMARY SJOGREN SYNDROME

**Background:** In patients with primary Sjogren Syndrome (pSS), haematological involvement – autoimmune cytopenia, might be present at the time of the diagnosis or can develop in time after the characteristic glandular involvement. (1-3)

**Objectives:** The objective of the study is to evaluate the correlation between gllandular involvement (ocular) and presence of cytopenia in patients diagnosed with pSS.

**Methods:** A retrospective analysis was performed on a cohort of patients diagnosed with primary Sjogren Syndrome under surveillance in one Rheumatology Centre between 2009 and 2016. The documented cases have been diagnosed according to the 2002 American-European Consensus group classification criteria, the 2012 ACR criteria or 2016 ACR/EULAR Classification Criteria for pSS.

The EULAR Sjogren’s Syndrome Disease Activity Index (ESSDAI) was calculated for all patients. Ocular assessment and follow-up were performed in collaboration with the same ophthalmologist. The data was analysed using Windows Excel SPSS 20.0.

**Results:** 30 female patients diagnosed with pSS were included in the study. The mean age at the time of diagnosis was 52.1 years±SD 9.1. The ESSDAI was calculated for all patients at baseline: 5 (17%) patients presented high disease activity (ESSDAI >14), 14 (46%) patients moderate disease activity (5 ≤ ESSDAI <14) and 11 (37%) patients low disease activity (ESSDAI <5). The domain weight for the study group was obtained a statistically significant correlation between ocular involvement and disease activity as evaluated by ESSDAI. In the clinical case series, Spearman’s rank correlation coefficient between haematologic (autoimmune cytopenia), and biological markers (hypocomplementemia) and ocular involvement were calculated. A strong negative correlation was found between autoimmune cytopenia and glandular manifestations (ocular involvement-xerophthalmia) (r=−0.60; p<0.05). Another strong negative correlation was obtained between hypocomplementemia and severe ocular involvement (corneal ulceration) (r=−0.59, p<0.05), respectively.

**Conclusions:** Patients diagnosed with primary Sjogren Syndrome that presented at disease’s onset cytopenia and hypocomplementemia had a less severe ocular involvement.

THE PREVALENCE OF NON-CRITERIA ANTIPHOSPHOLIPID ANTIBODIES IN ANTI-PHOSPHOLIPID SYNDROME

C. Li1, L. Zhu1, Z. Wang1, Y. Sun2, R. Mu1, Z. Li1, 1 Peking University People’s Hospital, Beijing, 2Department of Neurology, Beijing General Hospital, Peking University Health Science Center, Beijing, China

**Background:** Antiphospholipid syndrome (APS) is an autoimmune disease characterised mainly by arterial and/or venous thrombosis, recurrent pregnancy morbidity, with the presence of a variety of heterogeneous circulating antiphospholipid antibodies. However, there are a group of APS patients with persistently negative antiphospholipid antibodies. It is necessary to validate new specific antibodies to better recognition of these APS patients.

**Objectives:** To explore the clinical significance of non-criteria antiphospholipid antibodies in a large cohort of Chinese patients with anti-phospholipid syndrome (APS).

**Methods:** Serum samples were obtained from 214 APS patients, 122 disease control including systemic lupus erythematosus, sjogren syndrome, ankylosing spondylitis, rheumatoid arthritis, osteoarthritis and 50 healthy control. Antiphospholipidase/serine(igA/igG/igM)(APS), anti- phospholipidtyehanolamine(igA/igG/igM)(aPE), anti-prothrombin-antibodies (igA/igG)(aPT), - annexin V-antibodies (igA/igG/igM)(aAnxV), anti-phospholipid antibody(igA/igG/igM)(aPL), anti-oxLDL antibody(igA/igG/igM)(aoxLDL) were tested by ELISA kits(HUMAN Diagnostics Products, Germany) and IgG/IgM APL were tested by ELISA(Louisville APL Diagnostic, USA). The Chi-square (q2) test was used to examine the difference of frequencies of antibodies in APS patients and patients with other diseases. Spearman correlation analysis was performed to investigate the relationship between aPS/PT and other clinical/laboratory parameters.

**Results:** The prevalence of aPS IgG, aPS IgM, aPT, aPE, aAnxV, aPL, aoxLDL and IgG APL, IgM APL were 44.8%, 22.4%, 46.3%, 9.8%, 17.8%, 44.4%, 22.4%, 45.3% and 22.9%. The specificity of the antibodies were 82.6%, 95.3%, 96.0%, 99.4%, 95.3%, 92.4%, 95.3% and 94.8%. The highest positive predictive values of these antibodies were aPE, aPS, aPT, aPL and APL were associated with thrombotic events and oxLDL, aPS, aPL, IgG, IgM, IgT, aPT, aoxLDL, APH, and APH were correlated with anti-cardiolipin antibody (ACL), aPS IgG, aPS IgM, aPE, aoxLDL and were associated with J2-GP1 antibody. APL IgG, APL IgM and PS Ig were the highest prevalence in both ACL and lupus anticoagulant (LAC) negative patients. aPT has the highest prevalence in ACL and J2-GP1 negative patients and APL IgG and aPS IgG were the highest two antibodies in LAC and J2-GP1 negative patients and aPT has the highest prevalence in seronegative APS patients.

**Conclusions:** Non-criteria aPLs have a good diagnostic value in APS and were associated with thrombotic events.

PATIENTS WITH RHEUMATOID ARTHRITIS AND LUPUS HAVE SIMILAR PREVALENCE OF PERIODONTITIS – A CROSS-SECTIONAL SURVEY

C. Ciurtin1, M. Orlandi2, J. Bakshi1, J. Guinot1, B. Bernstein1, F. D’Autil1
1Rheumatology, University College London; 2Oral Health, Eastman Dental Hospital, London, UK

Background: Periodontitis (PD) is a chronic inflammatory disease of the gingival tissues triggered by a dysbiotic microflora and causing the loss of soft and hard tissues surrounding the dentition. Over the last two decades, PD has been linked to a systemic inflammatory response and an increased risk of other comorbidities including cardiovascular diseases and diabetes. Numerous observational studies have confirmed an association between PD and rheumatic diseases. Some evidence suggests an association with rheumatoid arthritis (RA) and a beneficial effect of periodontal treatment on RA outcomes. Scarce evidence instead exists on the association between PD and Systemic Lupus Erythematosus (SLE). The main aim of this study was to evaluate the prevalence of PD in RA and SLE.

Methods: We conducted a cross-sectional survey of consecutive eligible outpatients with RA and SLE attending the Rheumatology Department at UCLH. PD diagnosis was estimated administering a validated self-reported questionnaire. Medical histories, cardiological risk factors and assessment of standard biomarkers of inflammation and RA activity were collected as part of the outpatients’ visit.

Results: 86 patients affected by RA and 122 by SLE and 5 presenting both diseases were recruited and agreed to complete the questionnaire. PD was detected in 100 patients of the overall survey (47%), 38 (44%) patients with RA and 59 (48%) patients with SLE had prevalent PD. There was no statistically significant difference in the prevalence of PD between the two patients’ groups (p=0.575). PD was associated with diagnosis of diabetes (p=0.023), hypertension (p=0.004) and hypercholesterolemia (p<0.0001). Diagnosis of PD was associated with increased levels of C-reactive protein (CRP) (2.8±3.3 vs 4.0±4.4, p=0.03) in the whole population. In RA patients PD was associated with increased CRP (3.2±3.2 vs 5.2±4.4, p=0.014) and ESR (9.8±10.0 vs 18.3±16.6, p=0.008).

Conclusions: Prevalence of PD is similar in both RA and SLE (approximately 45%) and to the UK national estimates (Adult Dental Survey 2009). PD could contribute to an increased inflammatory profile in patients with RA and SLE. Our data highlight the need of assessing oral health needs of patients with rheumatic diseases.

INFECTIONS IN NEWLY DIAGNOSED SPANISH PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM THE RELES COHORT

C. Gonzalez-Echayare1, M. Garcia1, G. Espinosa2, G. Ruiz-Irastorza2, on behalf of Autoimmune Diseases Group GEAS. 1Internal Medicine Department, BioCruces Health Research Institute, Cruces University Hospital, 2Autoimmune Diseases Unit, Internal Medicine Department, Cruces University Hospital. Bilbao, 3Department of Autoimmune Diseases, Hospital Clinic, Barcelona, Spain

Background: Infections continue to be an important source of morbidity and mortality in systemic lupus erythematosus (SLE).1 Susceptibility to infections is thought to be due to a combination of disease related factors and immunosuppression, however differential contributions during disease course has not been yet studied.

Objectives: Using data of patients from the longitudinal inception cohort Registro Español de Lupus Eritematoso Sistémico (RELES), we aimed to analyse how predictors of infection change during the course of the disease.2

Methods: Two hundred and eighty-two patients from the RELES cohort were included. Markers of lupus activity, average prednisone doses and use of immunosuppressive drugs were compared between patients with and without infections within the first and second year of disease. For the analysis, drugs given during the first month of follow-up were considered for infections during the first year and medications given during the first year were considered for infections during the second year.

Results: Nineteen patients (6.4%) had a documented episode of infection during the first year of follow-up and 16 patients (5.67%) during the second year. The following variables were associated with infections during the first year: hypocomplementemia at diagnosis (p=0.01), nephritis at diagnosis (p=0.03), SLEDAI score (p<0.01), average dose of prednisone higher than 30 mg/day (p=0.01), methylprednisolone pulses (p=0.05) and mycophenolate use (p=0.02). The independent variables in the final model were hypocomplementemia (OR 4.41, 95% CI 0.96–20.2) and average dose of prednisone higher than 30 mg/day (OR 6.60, 95% CI 1.3–32.4). The following variables were predictors of infections during the second year in the univariate analysis: average dose of prednisone higher than 7.5 mg/kg (p=0.05), methylprednisolone pulses (p=0.07), duration of therapy with antimalarials (p=0.09), mycophenolate use (p=0.01) and cyclophosphamide use (p=0.05). The independent variables in the final model were average dose of prednisone higher than 7.5 mg/day (OR 4.5, 95% CI 0.99–21) and duration of therapy with antimalarials as a protective factor (OR 0.99, 95% CI 0.99–1.00).

Conclusions: Patients with high baseline activity are at a higher risk of infection during the first months but intensive lupus therapy, specifically with medium-high doses of prednisone, is the strongest predictor of infectious events. Continued use of antimalarials protects from infections.

EXTRAGLANDULAR MANIFESTATIONS IN PATIENTS WITH PRIMARY SJÖGREN SYNDROME IN A TERTIARY HOSPITAL IN MADRID

C.M. Pijoan Moratalla, C. Sobrino-Grande, C. De la Puente-Bujodos. Rheumatology, Hospital Ramón y Cajal, Madrid, Madrid, Spain

Background: Primary Sjögren syndrome (pSS) is a chronic autoimmune disorder characterised by generalised dryness. In a variable percentage of cases (up to 50%) patients can present extraglandular disease, which frequently determines the prognosis.

Objectives: To determine the frequency of both glandular and extraglandular disease in patients with SSSp seen in a tertiary hospital in Madrid and to compare them with the frequency observed in the large cohorts (SER and EULAR).

Methods: A descriptive, observational cross-sectional study was conducted. We included patients with diagnosis of pSS according to the ACR/EULAR Classification criteria (2016) attended in our Rheumatology Unit from 2012 to 2017. A database was created, including clinical and epidemiological data and a descriptive analysis was carried out comparing the results with those obtained in the Sjögren-SER project and EULAR group.

Results: 106 patients with pSS were included. 92.5% were female (98), with a mean age at diagnosis of 45 years (range: 32–58). Frequency of exocrine gland disease is shown in table 1. Dry eye was the most frequent symptom (91%), with nearly half of them presenting ocular complications. 69.8% complained of dry mouth and 18.9% associated complications such as dysphagia and oral candidiasis. 16 patients (15%) suffered from recurrent parotiditis and 13 (12.3%) from salivary gland enlargement. Glandular disease also included xerosis (25%), dyspia (11.3%), upper respiratory tract dryness (12.3%) and atrophic chronic gastritis (14%). Frequency of extraglandular disease is shown in table 2. Chronic fatigue was the most frequent symptom, similar to the observed in both cohorts (50.9%). followed by arthralgia which was less frequent than in the Spanish cohort (40.6% vs 34.5%). 35 patients suffered from inflammatory arthritis and 3 cases associated fibromyalgia, less than the expected (2.8% vs 14.6% and 22%–33%). Sixteen patients suffered from interstitial lung disease, this being the higher than the observed in both cohorts (15.1% vs 6.64% and 5%). Fewer patients suffered from depression compared with the EULAR group (24.5% vs 40%). Both peripheral neuropathy and renal disease were diagnosed in a percentage of patients similar to the expected (11.3% vs 8.92% y 1.88% vs 1.83% respectively). 7 patients had autoimmune thyroid disease. Finally, 5 patients (4.7%) developed lymphoma, 3 of them being MALT lymphomas of the parotid gland.
which is higher than the observed in the Spanish cohort but it is within the EULAR range. The frequency of Raynaud’s phenomenon, cutaneous vasculitis, lymphadenopathy, splenomegaly and pericarditis were similar to those observed both in the Spanish national group and EULAR cohort.

Abstract AB0562 – Table 1. Exocrine Gland Disease

Conclusions: Extraglandular disease in SS, although less frequent than sicca symptoms, have a special relevance when it comes to patient management. In our study the frequency of both glandular and extraglandular disease was similar to the observed in Sjögren-SER and EULAR groups although there were some differences. Fibromyalgia was less frequent in our group, whereas intestinal lung disease and peripheral neuropathy were more prevalent.

Changes in Health Related Quality of Life in Renaissance Cohort of Russian Patients with Systemic Lupus Erythematosus

E. Aseeva, L. Vorobyova, S. Soloviev, G. Koliubaeva, S. Glukhova. Intensive Care Department, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; Rheumatology department, National Center of Cardiology and Internal Medicine named after Academician M. Mirnaimov, Bishkek, Kyrgyzstan.

Background: The Lupus Quality of Life (LupusQol) is recommended to assess health related quality of life (HRQOL) in systemic lupus erythematosus (SLE). Objectives: The aim of the current study was to assess HRQOL in the first year observation in cohort of patients with systemic lupus erythematosus in Russian Federation (RENAISSANCE).

Methods: The LupusQol-Russian was administered to a cohort of 128 Russian patients affected with SLE at baseline and follow up visit up to 12 months. Disease activity was evaluated by the SLE disease activity index - 2000 (SLEDAI-2K), and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI) at baseline and follow up visit.

Results: 128 patients (118 (92%) women; aged 33.02±11.04 years, mean disease duration 100.08±84.3 months) were included. At baseline mean SLEDAI 2K was 11.2±8.5, mean SDI – 1.3±1.6, mean daily prednisolone 16.8±10.9 mg/day). For 12 months all patients received standard therapy according SLEDAI 2K and their clinical manifestations (prednisolone 100%, Hydroxychloroquine 72.4%, Mycophenolate mofetil 25%, Cyclophosphamide 12.5%, Rituximab 27.3%, belimumab 12.5% pts). At follow up visit SLEDAI 2K score significantly improved up to 6.9±6.93 (p<0.000029), SDI significantly worse up to 1.7±1.9 (p<0.04), P value of mean prednisolone significantly reduced up to 12.2±7.3 mg/day (p=0.04). All 8 subscales LupusQol showed improvement in the 12 months versus baseline (table 1). Spearman’s correlation with SLEDAI 2K was obtained for Physical health (r=0.13), Pain (r=0.16), Planning (r=0.21), Intimate relationship (r=0.17). Burden to others (r=0.16), Emotional health (r=0.13), Body image (r=0.21).

Table 1. Changes in LupusQol domains in the first year observation in cohort of patients with systemic lupus erythematosus in Russian Federation (RENAISSANCE).

Anti-Phospholipid Antibodies Sero-Negativization in Systemic Lupus Erythematosus Patients Treated with Belimumab

E. Rubini, M. Radin, I. Cecchi, D. Roccatello, S. Sciascia. Università Degli Studi di Torino, Turin, Italy.

Background: Belimumab is a monoclonal antibody that blocks the B-lymphocyte stimulator, preventing it to bind its receptor on B-lymphocyte’s surface, thus avoiding B-cell activation. Despite some benefits showed in murine models of anti-phospholipid syndrome (APS), the use of belimumab in this condition needs further investigation.

Objectives: To investigate changes in the anti-phospholipid antibodies (aPL) profile in Systemic Lupus Erythematosus (SLE) patients treated with belimumab.

Methods: We retrospectively collected data from patients who attended the S. Giovanni Bosco Hospital, Turin, Italy. Inclusion criteria comprised: a) fulfilled ACR criteria for SLE; b) persistent aPL positivity (confirmed 3 occasions over a time >24 months before belimumab treatment); c) previous or ongoing belimumab therapy.

Results: This retrospective study included 3 patients with diagnosis of SLE (median age 39 (range 33–51); male:female 2:1). Table 1 resumes the characteristics of patients. All 3 patients received belimumab because of SLE flares. Before the treatment, Patient#1, classified as SAPS, presented a persistent triple positivity for lupus anticoagulant (LA), high-titer aCL IgG isotype (>200 GPL) and anti-β2GPI: protein 1 antibodies (>50 GPL) (anti-β2GPI) IgG isotype. Patient#2 was persistently positive for IgG aCL and IgM anti-β2GPI (both >20–30 GPL and MPL, respectively; cut-off >7U), and had a history of pregnancy morbidity. Patient#3, classified as SAPS, presented positivity of LA and IgG aCL (10–20 GPL).

After 12 months since belimumab was started, a marked reduction of aPL was noticed, as follows. Patient#1 became negative for antiβ2GPI, while his aCL titre significantly decreased. Anti-β2GPI and aCL both turned negative in Patient#2. After being on belimumab for one year, she planned a pregnancy and she stopped the treatment; after 8 months since suspension, IgG antiβ2GPI antibodies were detectable (cut-off >3.5 U). Patient#3 was persistently negative for aCL while being on belimumab. When he discontinued the therapy, IgG aCL antibodies returned positive. Figure 1 illustrates aPL titres of the 3 patients in relationship with belimumab therapy.

Conclusions: Despite its limitations, this pilot study is the first report of aPL negativization after starting therapy with belimumab. The clinical relevance of these findings should be investigated in prospective multicenter studies.

CLINICAL SIGNIFICANCE OF THE DETECTION OF HLA-DRB1 ALLELES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

E. Belolipetskaya1, I. Beliaeva1, V. Mazurov1, S. Lapin2, G. Tkachenko2, V. Gusova2, O. Inamova3, North-Western State Medical University named after I. I. Mechnikov, 2 St. Petersburg State Medical University named after I. P. Pavlov, 3 Clinical Rheumatological Hospital No: 25, Saint-Petersburg, Russian Federation

Background: Associations between clinical manifestations of systemic lupus erythematosus (SLE), presence of antiphospholipid antibodies (aPL) and HLA-DRB1 alleles have been established, these associations however need clarification.

Objectives: Clarify the associations between clinical features of APS in patients with SLE and the presence of aPL and the HLA-DRB1 alleles.

Methods: 79 SLE patients were enrolled in the study (MF: 7/72; mean age 11.0 years, range (18,0;78,0). The main group consisted of 41 aPL carriers (28 of them with antiphospholipid syndrome (APS), a comparison group consisted of 38 aPL-negative SLE patients. The groups were comparable in age, duration and SLE activity. ELISA was used to test for aPL. Lupus anticoagulant (LA) was evaluated using the DRVIV test method. The HLA-DRB1 alleles were identified using HLA-typing.

Results: While comparing both groups, HLA-DRB1*03 allele was found significantly less frequently in aPL-carriers group (p=0.04). In aPL-negative group HLA-DRB1*08 allele was present significantly more often (p=0.002), both HLA-DRB1*03 and*15 alleles were found significantly less often (p=0.008) in comparison with the aPL-negative group.

SLE patients with HLA-DRB1*16 allele were more likely to develop an early pregnancy loss (OR=2,9, p=0.04) and in comparison with aPL-negative group. The presence of HLA-DRB1*11 allele both early pregnancy loss and fetal loss occurred less often (OR=0.18, p=0.04; OR=0.29, p=0.04) compared with other alleles. The highest level of anti-double-stranded DNA was found in patients with HLA-DRB1*13 allele (Me=54, [17.0, 290.0 IU/ml], p=0.005), and lowest level was in patients with HLA-DRB1*04 (Me=0.15, [0.0; 14.2 IU/ml], p=0.005).

In the group of aPL carriers significant correlations between the HLA-DRB1*08 allele and elevated level of antiphospholipid antibodies (aCL) IgM (r=-0.42, p=0.005) and anti-annexin V antibodies IgG (r=0.3, p<0.01), between HLA-DRB1*04 allele and elevated level of aCL IgG (r=0.31, p=0.008), between the HLA-DRB1*12 allele and an elevated level of anti-annexin V antibodies IgM (r=0.31, p=0.01) were found.

Correlations between HLA-DRB1*16 allele and early pregnancy loss (r=0.37, p<0.001), between HLA-DRB1*11 allele and fetal loss (r=0.30, p<0.001) were observed.

Conclusions:
1. HLA-DRB1*08 allele is a risk factor for the development of APS in SLE patients.
2. HLA-DRB1*03 and *15 alleles were more often detected in aPL-negative SLE patients.
3. The presence of HLA-DRB1*16 and *11 alleles in SLE patients is a risk factor for the development of obstetric complications.
4. In the group of aPL carriers significant correlations between HLA-DRB1 alleles and elevated levels of aPL were found.
5. SLE patients with HLA-DRB1*01 were less likely to develop any obstetric complications.

KNOW YOUR VACCINES – A CLINICAL AUDIT ON THE UPTAKE OF VACCINATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

E.E. Varughese, M. McCartney, K. Sunnboye, S. Shaflu. Rheumatology, University of Leicester- Leicester Royal Infirmary, Leicester, UK

Background: Systemic Lupus erythematosus (SLE) is a multi-system autoimmune disease with an increased mortality and morbidity rate compared to the controlled population. One of the commonest causes of mortality and morbidity in SLE is infection. This is a result of not only the immunosuppressive effect of the disease process itself but also treatment involving disease modifying anti-rheumatic drugs (DMARDs). In fact, corticosteroids and immunosuppressants increase the risk of opportunistic infection, in addition to the more common pathogens.

Vaccines provide long lasting protective immunity against microbial pathogens and prevent clinically relevant infections. Recommended vaccinations in SLE patients include H. Influenza, Pneumococcal, Hepatitis A and B, and Human Papilloma Virus (HPV). Influenza vaccines are given annually and a Pneumococcal booster dose is given at 5 years following the initial vaccine.

Objectives: To assess whether, in routine clinical practice, patients with SLE are immunised against preventable disease according to EULAR recommendations and to assess the level of patient awareness.

Methods: A questionnaire was designed to assess the degree of compliance with current recommendations adapted from the EULAR-recommended vaccinations in patients with autoimmune inflammatory rheumatic diseases on DMARD therapy. The questionnaire enquired into the awareness and uptake of the influenza B, pneumococcal and Hepatitis B vaccines. They were sent out by postal mail, with an enclosed stamped address envelope, to all SLE patients within the university hospitals of Leicester (UHL) NHS trust identified via the rheumatology patient database. Questions included awareness of the need to have vaccinations whilst on DMARDs. The audit was conducted over a three month period and the results were compiled in Microsoft excel.

Results: Of the 396 SLE patients within UHL, 86 responded. Among the patients studied 38% were on DMARD therapy, an equal proportion claimed they were not and 23% were unclear if they were on DMARD therapy. Approximately 60% were unaware of the need for vaccinations and only 27.9% acknowledged awareness for the need of the 3 vaccines mentioned above. Fifty-six (60%) patients had the influenza vaccine yet only 26 (28%) and 15 (21.8%) had the Pneumococcal and Hepatitis vaccines respectively.

Conclusions: The increased infection rate in SLE can be reduced through vacciniation. This highlights the importance of increasing both physician and patient awareness. Although the sample size was small, the above audit has revealed that current local practice, with regards to ensuring that all SLE patients are appropriately vaccinated, requires improvement. This can be achieved through patient and healthcare worker education, and also creating a checklist that can be added to the clinic notes. Working together with our primary care colleagues will also help bridge the divide between compliance and non-compliance. Such measures will aim to improve mortality and morbidity in SLE patients.

SECURE VACCINE FOR SLE PATIENTS – A CLINICAL AUDIT ON THE UPTAKE OF VACCINATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

AB0567

AB0566

RELATIONSHIP BETWEEN THE LEVELS OF VITAMIN D AND THE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS IN DOMINICAN REPUBLIC

Background: 25 (OH) D is a steroid prohormone that participates in calcium homeostasis and bone health. Nonclassical functions of this vitamin have been described in a variety of cells of the innate and adaptive immune system. Currently, the immunomodulatory role of 25 (OH) D in Systemic Lupus Erythematosus (SLE) continues in debate. In addition, a correlation between non-optimal levels of 25 (OH) D and disease activity has been observed. In the SLE, there is a high prevalence of non-optimal levels of vitamin D. A prevalence of 25 (OH) D insufficiency of 15% to 75% is reported.9

Objectives: To determine the relationship between vitamin D levels and disease activity in SLE.

Methods: It is a prospective, cross-sectional study, in all patients who attended the rheumatology clinic of the Hospital Docente Padre Billini in the period August – October 2017, where the levels of vitamin D and activity of the disease were measured with SELENA-SLEDAI (≥3 without activity, 3–12 moderate activity, ≥12 high activity). Vitamin D deficiency is defined as serum levels of 25 (OH) D <10 ng/ml, insufficiency levels serum levels of 25 (OH) D of <30 ng/ml inclusion criteria; all patients with at least 18 years of age who met the SLE SLICC 2012 classification criteria were included with determination of vitamin D and calcium.

Results: 45 patients who met criteria SLICC 2012 were included. 97.7% (44) were women. The most frequent age range was 31–45 years. 24.4% (11) had decreased calcium values. The vitamin D values were insufficient in 77.7% (30) of the patients and deficient in 4.4% (2) According to SELENA-SLEDAI 77.7% (35) had no activity of the disease, 20% (9) had moderate activity and 2.2% (1) had
high activity. Of the patients who reported disease activity, only 13.3% had insufficient vitamin D. There is no significant difference between patients who have vitamin D values greater than or less than 20 ng/ml. In both groups, the majority had SELENA-SLEDAI in low activity.

Conclusions: The vitamin D levels were not associated with an increase in disease activity in our study patients. Although our country is an island, the use of sunscreen and avoid sunbathing is something common, it causes to find low levels of vitamin D, not only in patients with SLE, where avoiding sunbathing is a recommendation, but also in other pathologies in some countries that come to our service. We believe that vitamin D levels should be measured in the general population, to have a reference range and study their influence on health.

AB0570 ASSOCIATION BETWEEN SLEDAI-2K DOMAINS AND ORGAN DAMAGE ACCRUAL
1. Monash University, Melbourne, Australia. 2. Information Technology. 3. Faculty of Medicine Nursing and Health Sciences, Monash University, Melbourne, Australia

Background: Prevention of permanent organ damage is a key goal of SLE management. Overall disease activity measured by SLE Disease Activity Index (SLEDAI-2k) is a risk factor for damage, but the contribution of organ-specific activity to damage risk has not been enumerated.

Objectives: We sought to determine the degree to which organ domains of SLEDAI-2k are associated with damage accrual.

Methods: A dataset of SLE patients (2007–2017) at the Australian Lupus Registry was studied. Variables collected at each visit included all domains of SLEDAI-2k, Physician Global Assessment, and medications. Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI) was recorded annually and each visit was labeled “damage transition” or “no-damage transition” based on whether SDI increased at the subsequent annual measure. The association of risk of SDI increase with SLEDAI-2k domains was assessed using multivariable logistic regression analysis adjusted for confounding by medication use.

Results: 5538 visits from 266 patients (86.5% female, 47.4% Caucasian, 66% with prednisolone exposure, the effects of some domains were attenuated, but pericarditis (odds ratio (OR)=4.06, 95%CI=1.69–9.83), pyuria (OR=1.94, 1.47–2.56), arthritis (OR=1.71, 1.35–2.16), and rash (OR=1.43, 1.20–1.60), alopecia (OR=1.43, 1.10–1.86) and leukopenia (OR=1.36, 1.03–1.78) remained significant. No other SLEDAI-2k domains showed a significant association, in part due to infrequent occurrence. SLEDAI-2k domains weightings were not congruent with the respective risk of damage accrual.

Conclusions: In study, only some SLEDAI-2k domains were significantly associated with organ damage accrual. Re-appraisal of weightings in SLE disease activity scores based on their association with outcome is potentially warranted.

AB0571 FACTORS RELATED TO ALEXITHYMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS
F. Basta, D.P.E. Margiotta, G. Dolcin, V. Batani, A. Vemuccio, M. Vadacca, A. Aletta. Universita Campus Bio-medico di Roma, Rome, Italy

Background: Alexithymia describes the difficulties of people in identifying, differentiating and articulating emotions of others and themselves and in discriminating those from bodily sensations, with a limited fantasy and a concrete, externally oriented cognitive style.1 A high prevalence of alexithymia has been found in patients with a variety of health conditions, including SLE.2 Previous authors identified mood states and quality of life as the main factors related to alexithymia in Systemic Lupus Erythematosus (SLE).

Objectives: Aim of our study was to assess the impact of clinical, immunological, psycho-social factors on the presence of alexithymia in Systemic Lupus Erythematosus (SLE).

Methods: We consecutively enrolled 104 patients in a cross-sectional study. Alexithymia was assessed using the Toronto Alexithymia scale (TAS-20). We also evaluated symptoms of mood disorders using BDZ and HAM-H, quality of life using MOS-SF36, sleep disorders with PSQI and physical activity using IPAQ.

Results: The mean (standard deviation) TAS-20 score was 49.5 (15.6). The prevalence of alexithymia (TAS-20 >>61) was 28%. Alexithymic patients (TAS-20 > 61) were significantly older (p<0.0005), presented more severe depressive and anxiety symptoms (p<0.0001), a higher score of sleep disorders (p<0.0001), a reduced Faci-Fatigue score (p=0.0007), reduced SF-36 mental and physical component summary scores (p=0.0001 and 0.004) and increased daily sedentary time (p=0.002). In the multiple logistic regression analysis the variables associated to the presence of alexithymia were age (OR 1.07, p=0.02) and the score of depressive symptoms (OR 1.15, p=0.02).

Conclusions: About a third of SLE patients presented a dysfunctional processing of emotion. It is necessary to carefully consider the symptoms of mood disorders to optimise SLE patient management.

AB0572 CORRELATION OF 24 HOURS URINARY PROTEINQUANTIFICATION WITH RANDOM SPOT URINE PROTEIN/CREATININE RATIO IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS
F. Elbadawi, M. Khamasha, J. Alsaleh. Rheumatology Department, Dubai Hospital, Dubai, United Arab Emirates

Background: Proteinuria is an important signal of Lupus nephritis. The standard method of proteinuria quantification is 24 hours urine collection. The ongoing practice of using spot urine sample to determine the ratio between protein and creatinine excretion is a convenient, alternative method of proteinuria estimation is not without limitation and criticism questioning its accuracy.

Objectives: Given the cumbersome expressed by some patients on collecting 24 hours urine for protein quantification, our aim was to determine the correlation between spot urine protein-to-creatinine ratio (PCR) and 24 hour urinary protein (UP) in patients with active Lupus nephritis.

Methods: The active patients included in the analysis was 53 attending Dubai Hospital shared Rheumatology/Nephrology clinic during the period of June 2016 till Dec 2017. All diagnosed to have systemic lupus erythematosus who either had flare with proteinuria or newly diagnosed as Lupus nephritis. . Suspicion of active Lupus nephritis was evidenced by active urine sediment and 24 hours UP quantification of more than 0.5 gm or more than 1.0 gm regardless to urine sediment. Paired baseline urine samples were obtained and results included in the final analysis. Most of the patients underwent ultrasound guided kidney biopsy to classify the nephritis according to ISN/RPS 2003 classification, unless contra-indicated or patient refused to give consent. We used Minitab 18.1 software to determine the Spearman’s correlation coefficient (r), and it is significance. P-Value <0.05 was considered statistically significant.
Influence of smoking and obesity on the risk of developing primary Sjögren’s syndrome: a population-based cohort study

G. Maciel1, L. Servill1, C. Nanni1, C. Crowson2, E. Matteson3, D. Cornec4, A. Beni1, T. Maciel Hospital Montevideo, Uruguay; 2Department of Rheumatology, Hospital de Prato, Prato, Italy; 3Mayo Clinic, Rochester MN, USA; 4Rheumatology Department, Brest Teaching Hospital, Brest, France; 5Immunology, Rheumatology, Allergy and Rare Diseases Department, San Raffaele Scientific Institute, Milan; and Rheumatology Department, Santa Chiara Hospital, Trento, Italy

Objectives: Cigarette smoking and obesity have been identified as risk factors for developing several autoimmune diseases, and may be protective for others. This study explored the role of these risk factors in primary Sjögren’s syndrome (pSS).

Methods: A cohort of Olmsted County, Minnesota residents diagnosed with pSS between January 1, 2000 and December 31, 2015 was identified based on individual medical record review. Each of the cases was matched to 3 age- and sex-matched comparators without pSS randomly selected from Olmsted County residents, indexed to the date of pSS diagnosis. Smoking status was divided into three categories of current smoker, ex-smoker and never smoker. The body weight and height closest to date of diagnosis/index date (±1 year) were used. Obesity was defined as a body mass index (BMI) ≥30 kg/m².

Results: 106 incident cases of pSS and 318 controls were identified. The odds ratio (OR) of pSS comparing current smokers with never smokers was 0.34 (95% confidence interval (CI): 0.14, 0.85; p<0.05), while the OR for former smokers compared to never smokers was 1.27 (95% CI, 0.80, 2.03). Smoking status was not associated with an anti-citrullinated antibody, anti-SSA, anti-SSB or rheumatoid factor positivity (p>0.05). The OR of pSS comparing obese subjects with non-obese subjects was 0.79 (95% CI, 0.48, 1.30), while the OR of pSS for BMI analysed as a continuous variable was 0.97 (95% CI, 0.94, 1.01).

Conclusions: In this population-based study, current smokers have a lower risk of developing pSS while BMI does not affect this risk.

Renal activity patterns and therapeutic approaches in lupus nephritis observations in 5 Mexican rheumatology centres

G. Pickens1, D.A. Herrera-van Oostdam1, F. Irazoqui-Palazuelos2, S. Cerpa-Cruz2, M.A. Saavedra-Salinas3, C. Mendoza-Pinto3, C. Abud-Mendoza4.

1Rheumatology, Hospital Central Dr. Ignacio Morones Prieto, San Luis Potosí; 2Rheumatology, Centro Médico Nacional ‘20 de Noviembre’, Ciudad de México; 3Rheumatology, Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara; 4Rheumatology, Hospital de Especialidades Centro Médico Nacional “La Raza”, Ciudad de México; 5Rheumatology, Hospital General Regional Numero 36 ‘San Alejandro’, Puebla, Mexico

Background: Lupus nephritis (LN) develops in 40–60% of Systemic Erythematous Lupus (SLE) patients; 45% don’t achieve complete response or eventually relapse and 10–20% progress to end stage renal disease.

Objectives: Describe renal activity patterns and therapeutic schemes employed in 5 Mexican Rheumatology Centres.

Results: Retrospective analysis of renal activity in 193 patients with LN with >6 months follow-up. If follow-up was ≤1 year, response was classified as complete (CR), partial (PR) or no response (NR). If follow up was >1 year, response was classified as one of the following patterns: persistent inactive (PI), relapsing-rematting (RR), chronic active (CA) and mixed.

Results: Biopsy was available in 166 subjects (86.01%): class IV (42.77%), III (23.49%), V(10.24%), II(9.03%). The most prevalent schemes were CYC+MMF 46.6%, only CYC 18.13%, only MMF 12.4%, CYC+MMF+ TAC 9.84%. Thirty eight patients had follow-up ≤1 year with the following response: CR 16 (42.1%), NR 13 (34.21%) y PR 9 (25.7%). One hundred and fifty five patients had >1 year follow-up with the following activity patterns: PI 55 (35.48%), RR 38 (24.51%), CA 31 (20%), mixed 31 (20%).

We then compared patients whose therapeutic schemes were classified as the National Institutes of Health regime (n=109) (as considered by the treating physician) to those with different therapeutic schemes. We observed a higher final GFR (100±39.2 SD VS 87±37.9 SD, p=0.029) and more frequent CYC use (106 ±100 SD VS 37±49.3 SD, p<0.0001) in the NIH group. There weren’t statistically significant concerns on renal response or activity patterns. Although treating physicians stated they had used the NIH regime in 57.9%, 64.3% actually received CYC+MMF and 11.4% CYC+MMF+ TAC. We then compared the group that received CYC monotherapy to the groups that received CYC+MMF and CYC+MMF+ TAC and did not observe any statistically significant differences.

Conclusions: The most prevalent renal activity patterns were those that translated intermittent of continuous activity (64.51%). Strict adherence to the original NIH regime is questionable, most subjects actually received CYC+MMF at some point. We did not observe any statistically significant superiority of renal outcomes of combination therapy over CYC monotherapy. Limitations: preliminary initial analysis, heterogeneous information and missing data.

Clinical analysis of 22 cases of systemic lupus erythematosus complicated with hemophagocytic lymphohistiocytosis

Objectives: To investigate the clinical features of hemophagocytic lymphohistiocytosis (HLH) in systemic lupus erythematosus (SLE).

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2018-eular.6023

Scientific Abstracts
Methods: Twenty – two cases of systemic lupus erythematosus complicated with hemophagocytic syndrome were retrospectively analysed. The clinical manifestations, laboratory tests and prognosis were collected.

Results: Twenty-two patients with systemic lupus erythematosus complicated with hemophagocytic syndrome developed fever in 22 patients, including 18 with hyper-pyrexia, 20 with hypertemic, 20 with cytopenia, 10 with splenomegaly, 6 with hyperglycemia, 5 cases of hypofibrinogenemia, 14 cases of bone hemophagocytic occurred in the bone wear, nk cell activity decreased or absent in 7 cases, 15 cases of hyperferritinemia, mostly bilateral arterial, 22 cases of liver function abnormalities/ hepatic insufficiency in 11 cases, ultrasound showed 10 cases of cardiac involvement, MRI showed 5 cases of cumulative brain. 22 patients were diagnosed with high-dose glucocorticoid, 9 cases of hormonal impact, 17 cases of human immunoglobulin immunosuppression in 9 cases, 4 cases of ganciclovir, 1 cases of acyclovir, 1 case of relying on Park Glycosides. 21 cases showed 10 cases of cardiac involvement, MRI showed 5 cases of cumulative brain. One of them had encephalopathy, mostly bilateral arterial stump, liver function abnormalities/hepatic insufficiency in 11 cases, ultrasound showed 10 cases of cardiac involvement, MRI showed 5 cases of cumulative brain. The clinical diagnosis is easy to miss. When patients with SLE continue to have high fever, splenomegaly, blood cells decrease, phagocytosis occurs in bone wears, coagulation dysfunction should be combined with vigilance HLH, Improve the relevant inspection. High-dose glucocorticoid combined with immunosuppressive agents, human immunoglobulin therapy can effectively improve the prognosis.

Conclusions: Neurological manifestations of SLE in the majority of Kyrgyz patients were mainly caused by CNS lesions (68.75%), mostly in the form of neuropsychiatric disorders (50.65%), with a predominance of psychosis with visual and auditory hallucinatory syndrome (87.18%).

CHARACTERISTICS OF VALVULAR HEART DISEASE IN A MONOCENTRIC MALAYSIAN LUPUS COHORT

H. Jing1, S.G. Ong, S.S. Md Sani. Medicine, Kuala Lumpur Hospital, Kuala Lumpur, Malaysia

Background: Valvular heart disease (VHD) is one of the commonest cardiovascular manifestations of autoimmune disease, including systemic lupus erythematosus. Its prevalence ranges from 18% to 74%, with predominantly regurgitant lesions and valvular thickening. The cause of such abnormalities is yet unclear. There have been very few such studies performed in Asian patients, and only one in Malaysian patients to date.

Objectives: We sought to evaluate the valvular abnormalities of a multicentric cohort of lupus patients and also examine the association of these abnormalities with potentially related factors.

Methods: The medical records of all patients with SLE who had attended the Rheumatology Clinic of Kuala Lumpur Hospital between January 2008 and December 2016 were reviewed. All patients fulfilled the 1997 updated ACR criteria for SLE. Transthoracic echocardiographic examinations as part of their standard of care were performed by trained technicians using a standardised protocol. Multivariable logistic regressions were conducted to determine factors associated with valvular abnormalities in these patients.

Results: There were 207 patients in this study. VHD was found in 67.1% of patients: they were asymptomatic and did not have murmurs. The main abnormalities were tricuspid regurgitation (TR) (45.4%), mitral regurgitation (MR) (40.6%) and valvular thickening (19.2%). The majority of cases comprised mild TR (37.2%), mild MR (25.1%) and mitral valve thickening (10.6%). There were more patients with moderate to severe MR compared to TR (15.5% vs 8.2%). Median pulmonary artery systolic pressure was 23.0 mmHg (IQR 13.2). Risk of VHD was higher in patients with lower C3 levels (<0.83 g/l) (OR 3.36, 95% CI 1.74–6.66), MR (83.3%) and mitral valve (MV) thickening (58.3%) were the commonest abnormalities in patients with APS. Having APS greatly increased the risk of MR (OR 10.1, 95% CI 1.65–77.95) and mitral valve thickening (OR 16.30, 95% CI 3.93–73.84). Risk of mitral valve thickening was increased by presence of lupus anticoagulant (OR 20.82, 95% CI 1.42–177.6), anti-cardiolipin antibody (OR 5.24, 95% CI 1.42–177.6), anti-J2GPI antibody (OR 6.35, 95% CI 1.18–37.14) and diabetes (OR 7.85, 95% CI 1.43–40.24). Risk for MR was increased by presence of lupus anticoagulant (OR 3.55, 95% CI 1.10–12.43). Hypertension was associated with an increased risk for developing aortic regurgitation (OR 4.70, 95% CI 1.67–13.44). Anti-histone antibody positivity appeared to protect against development of MR (OR 0.84, 95% CI 0.34–2.14).

Conclusions: More than half of our patients had VHD, with regurgitant lesions and valvular thickening being the commonest abnormalities. Our finding of the association of MR and mitral valve thickening with APS and individual antiphospholipid autoantibodies concurs with earlier studies. However, what was unusual about our cohort was that TR was the prevalent abnormality and the association of VHD with low C3. We suggest that all patients with SLE have at least one echocardiogram, especially the patients with APS or antiphospholipid antibodies.

ANALYSIS OF CLINICAL FEATURES AND RISK FACTORS OF IN-HOSPITAL MORTALITY IN CYТОMEГALOVIRUS (CMV) DISEASES WITH SYSTEMIC LUPUS ERYTHEMATOSUS

H. Ming1, C.-Y. Tsai2. 1Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital, *Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital, Taipei, Taiwan, Province of China

Background: Cytomegalovirus (CMV) is known as a major cause for life-threatening complications in immunocompromised hosts, including status post allogeneic bone marrow transplantation, solid organ transplantations, and acquired
immunodeficiency syndrome (AIDS). The reactivation of CMV depends on the immune status of host. Systemic lupus Erythematosus (SLE) often requires steroid and immunosuppressive agents to induce remission and lower disease activity. This study presents the clinical presentations, laboratory characteristics, medical profile (including steroid, immunosuppressive agents, and biological agents) and clinical outcomes in SLE patients with diagnosis of CMV diseases. Further, we attempted to investigate the mortality risk factor in these patients.

**Objectives:** To analyse the clinical features, the mortality risk factors and all-cause mortality of Cytomegalovirus (CMV) diseases in patients with systemic lupus erythematosus (SLE) in single centre of Taiwan.

**Methods:** A retrospective study was performed to investigate the clinical features and identify the mortality risk factors associated with CMV diseases in patients with systemic lupus erythematosus (SLE). We reviewed the medical records in patients with SLE who were diagnosed with CMV diseases between Jan, 2006 and Dec. 2016 from Taipei Veterans General Hospital in Taiwan. Clinical and laboratory parameters as well as treatment outcomes were analysed.

**Results:** Fifty-six patients diagnosed with CMV diseases were enrolled in the study and separated into survivors (n=24) and non-survivors (n=32) groups. All patients in CMV disease demonstrated significantly high incidence of CMV pneumonia (71.43%). The higher SLEDAI-2000 score (p=0.009, HR=1.154, 95% CI 1.037–1.285), percentage of recent pulse therapy (p=0.013, HR 4.569, 95% CI 1.313–15.902), and plasmapheresis during hospital course (p=0.005, HR 6.905, 95% CI 1.637–29.122) was more common characteristics in non-survivor group than in survivor group. Non-survivors had significantly higher percentage of pancytopenia (p=0.001, HR=9.667, 95% CI 2.307–40.511), CMV-positive PCR of blood and bronchoalveolar lavage fluid (Blood: p<0.001, HR 15.000, 95% CI 3.932–57.223, BAL fluid: p=0.021, HR 6.176, 95% CI 1.151–33.151), and presence of concurrent infections (bacteremia: p=0.026, HR 4.833, 95% CI 1.122–20.824, other fungal infections:p<0.001, HR 11.424, 95% CI 2.722–47.952) than survivors. Septic shock (n=10, 41.2% of non-survivor group) is the most common cause of in-hospital mortality in CMV diseases.

**Conclusions:** The recent pulse therapy, pancytopenia, and concurrent infections are risk factors of in-hospital mortality in CMV diseases of patients with Systemic Lupus Erythematosus. The serological data of non-survivor groups showed negative findings of CMV immunoglobulin M (IgM) with detection of CMV DNA by polymerase chain reaction (PCR) was observed in CMV diseases. The pulmonary haemorrhage and acute respiratory distress syndromes (ARDS) were the factors of in-hospital mortality in CMV pneumonia.

**Conclusions:** MSGB in our PSS patients demonstrated an association between T lymphocytes, B lymphocytes and CD4/CD8 ratio. The infiltrate is mostly based on CD4 more than CD8 T cells. Other significant findings were the association between CD8 T lymphocytes and Chisholm-Mason scale grade ≥3, regardless of the number of infiltrates. No correlation or colinearity was observed with the number of infiltrates by immunological analysis and the Chisholm-Mason grade reported by the pathology analysis.

CONGENITAL HEART BLOCK AND MATERNAL PREGNANCY OUTCOMES IN WOMEN WITH POSITIVE ANTI-RO AND ANTI-LA AUTOANTIBODIES: A SINGLE CENTRE-STUDY

**Background:** The fetal Congenital Heart Block (CHB) is thankfully a rare occurrence. It can develop during pregnancy in women with Rheumatic Diseases who have positive autoantibodies anti-RO/La.

**Objectives:** To evaluate the efficacy of hydroxychloroquine (HCO) treatment and the monthly control in a multidisciplinary unit of Rheumatic Diseases and pregnancy on the pregnancy outcomes in women with positive anti-RO/La.

**Methods:** Descriptive, prospective, longitudinal and open study of 28 pregnant patients with positive anti-RO/La. They were attended in a specialised multidisciplinary unit of Rheumatic Diseases and pregnancy and 46 pregnancies were developed with no complications. The following variables were collected: age, maternal pathology, presence of anti-Ro52, anti-Ro60 y anti-La, prior abortions, prior babies born with CHB, result of fetal echocardiograms, treatment during pregnancy, obstetric outcomes births/abortion, pregnancy length and maternal/fetal complications.

**Results:** 28 pregnant women were included in the study. 64.3% were diagnosed with Systemic Lupus Erythematosus, 21.4% with Sjögren’s syndrome, 10.7% with undifferentiated connective tissue and 3.6% with rheumatoid arthritis. Our patients were an average of 32.2±5.34 years old and the 35% were older than 35 years. 46 pregnancies were developed during the monitoring with an average of 1.61±0.74 pregnancies per patient. Before the inclusion in our unit, the following fetal history was collected: 1 baby with CHB and 11 abortions. Nevertheless, during the multidisciplinary evaluation and treatment there was no baby developing CHB and only 2 abortions occurred during the first trimester. The positivity of anti-Ro52, anti-Ro60 y anti-La was 89.3%, 32% and 29% respectively. Besides, 2 patients had triple positive autoantibodies and 6 patients double positive autoantibodies. 18% of our patients were diagnosed with lupus nephritis and 29% were diagnosed with secondary antiphospholipid syndrome and/or thrombophilia. The immunosuppressive therapy received during the 46 pregnancies is specified in figure 1. Also, 50% pregnant women received treatment with acetylsalicylic acid, 24% with low-molecular-weight heparin and 41% with corticoid. The mean gestational age was 38 weeks and 11% births were caesarean. 11% babies were preterm with an average birth weight of 2871.6±494.8 grams. 87% of our patients did not have complications in the puerperium. All of our patients were monitored with periodic fetal echocardiograms from the 16th week of gestation and none had a baby with CHB or neonatal lupus (100% of the babies were born healthy).

**Conclusions:** Our results demonstrate that both treatment with hydroxychloroquine and close control in a multidisciplinary unit are effective in the prevention of congenital heart block development, in the decrease in the number of abortions and in a reduction of maternal and fetal morbidity and mortality. The multidisciplinary evaluation is essential in women diagnosed with rheumatic diseases with high obstetric risk.

**DOI:** 10.1136/annrheumdis-2018-eular.3267

PREGNANCY OUTCOMES IN WOMEN WITH ANTIPHOSPHOLIPID SYNDROME AND THROMBOPHILIA TREATED IN A MULTIDISCIPLINARY UNIT

**Background:** The Antiphospholipid Syndrome (APS) and Thrombophilia predominantly affect women of fertile age, so their pregnancies should be considered high obstetric risk. These pregnant women need close monitoring in a multidisciplinary unit.

**Objectives:** To evaluate the efficacy of the treatment on the pregnancy outcomes of women with APS and thrombophilia from a Spanish cohort.

**Methods:** Descriptive, prospective, longitudinal and open study of 88 pregnant patients with primary and/or secondary APS and thrombophilia assisted in a specialised multidisciplinary unit of Rheumatic Diseases and pregnancy (integrated by Gynaecologists, Haematologists and Rheumatologists). The following variables were collected: age, maternal pathology, presence of antiphospholipid antibodies, thrombotic episodes and prior abortions, number of childbirths, treatment during pregnancy, obstetric outcomes births/abortion and pregnancy length and maternal/fetal complications.

**Results:** 88 pregnant women were included in the study. 44 patients were diagnosed with thrombophilia (mostly, Heterozygotes for MTHFR gene), 33 with primary or secondary APS and 11 patients were diagnosed with both APS and thrombophilia. 140 pregnancies were developed during the monitoring: 61% of women had a single birth, 30% had two births and 9% had three births. Abortions registered before and during inclusion in our unit are specified in figure 1. Before the inclusion in our unit, 52% patients had 1 or 2 abortions, 25% had 3 abortions and 23% had 4 or more abortions. 10% patients had presented a previous thrombosis. Our patients were an average of 33.6±5.5 years old and the 44.3% were older than 35 years. Among the 44 patients with APS: 50% presented positivity to Lupus Anticoagulant (LA), 25% had triple positive antiphospholipid antibodies (LA, anticardiolipin antibodies and anti-ß2-glycoprotein) and 27% had double positive autoantibodies. As for the treatment received during the 140 pregnancies: 50% pregnant women received treatment with prophylactic doses of low-molecular-weight heparin (LMWH) together with acetylsalicylic acid (ASA), 26% were treated in monotherapy with LMWH and 9% in monotherapy with ASA. 10 patients diagnosed with thrombophilia, with an average of 5.3±1.5 abortions per patient, received treatment with LMWH, ASA and intravenous gammaglobulin. All patients who received LMWH during pregnancy also received LMWH after birth for 6 weeks. The mean gestational age was 38 weeks with an average birth weight of 3058.5±595.6 grams. 13% babies were preterm and 32% births were caesarean. 87% of our patients did not have complications in the puerperium.

**Conclusions:** Our results demonstrate that both treatment with hydroxychloroquine and close control in a multidisciplinary unit are effective in the prevention of congenital heart block development, in the decrease in the number of abortions and in a reduction of maternal and fetal morbidity and mortality. The multidisciplinary evaluation is essential in women diagnosed with rheumatic diseases with high obstetric risk.

Abstract AB0580 – Figure 1. Immunosuppressive therapy received during the 46 pregnancies (%)

Abstract AB0581 – Figure 1. Abortions before inclusion (n) and during inclusion (n)
Conclusions: The treatment is effective in the prevention of abortions. Our results demonstrate a decrease in the number of abortions and a larger number of term pregnancies since the inclusion of patients with high risk pregnancies in our unit. The multidisciplinary evaluation is essential to prevent complications in women diagnosed with APS and thrombophilia in order to reduce adverse pregnancy outcomes and exacerbations of the mother’s pathology.

SOLUBLE TRIGGERING RECEPTOR EXPRESSED ON MYELOID CELLS-1 (STREM-1) AND ADRENOMEDULIN ARE ELEVATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

I. Jeremić1, N. Stojanovic1, Z. Stanoevic2, B. Jovanovic2, J. Tosic2, S. Vidić2, A. Isaković1. 1Institute of Rheumatology, Belgrade; 2Institute of Biochemistry, Belgrade; 2Clinical Centre of Serbia, Belgrade, Serbia

Background: Adrenomedulin is a peptide firstly isolated from human phaeochromocytoma with vasodilatory effects. Secretion of adrenomedulin is modified by inflammatory cytokines and it may be important as a suppressor of lupus nephritis activity. Triggering receptor expressed on myeloid cells-1 (TREM) is a member of immunoglobulin superfamily clearly elevated in inflammatory conditions. Some subgroups of patients with systemic lupus erythematosus-SLE may have especially elevated levels of s-TREM.

Objectives: The aim of this study was to examine adrenomedulin and s-TREM levels in patients with SLE and healthy controls and to assess their relation with SLE disease activity index-SLEDAI

Methods: Serum samples from 50 SEL patients and 40 healthy blood donors were analysed. Serum levels of adrenomedulin, s-TREM, complement components C3 and C3, and anti-dsDNA antibodies were measured

Results: Patients with SLE had higher adrenomedulin (9.8±4.5 vs. 15.3±7.2 pg/mL, p<0.05) and s-TREM (11.7±4.1 vs. 20.3±13.1 pg/mL) (p<0.05) levels. s-TREM showed correlation with anti-dsDNA antibodies (r=-0.405, p<0.05) and SLEDAI score (r=0.386, p<0.001). In multivariate analysis s-TREM did not appear as an independent predictor of SLEDAI score, while only anti-dsDNA antibodies were significant in multivariate analysis.

Conclusions: Increased adrenomedulin and s-TREM are found in lupus sera. Despite of correlation with SLEDAI score, s-TREM is not better then anti-dsDNA antibodies as a predictor of SLE disease activity.

NEOPLASIA PREVALENCE IN PRIMARY SJÖGREN’S SYNDROME IN HISPANIC PATIENTS

J.C. Riega-Torres1, J. Hermosillo-Villafranca1, G. Hernandez-Molina2, R. Barbosa-Cobos3, C. Skinner-Taylor4, M. Garza-Elzondo1, A. Garcia-Garcia1, E. Flores-Huerta1. 1Servicio de Reumatología e Inmunología Clínica, Departamento de Medicina Interna, Hospital Universitario “Jose E. Gonzalez”, Monterrey, 2Coordination of Rheumatology and Immunology, Instituto Nacional de Ciencias Médicas y Nutrición “Salvador Zubirán”; 2Servicio de Reumatología, Júarez de México/México/Centro Médico ABC, Mexico, Mexico

Background: A rheumatic disease may be a casual factor in the pathogenesis of a neoplastic disease, as in other cases, cancer may lead to the development of paraneoplastic rheumatic manifestations that may be the only initial symptoms 1. Lazarus et al. demonstrated in its cohort study with 112 patients that 22% of patients who developed neoplasia during the study, the most prevalent was lymphoma with 34.6%, followed by breast cancer with 19.2%, 11.5% of basal cell cancer and 7.7% cases of cervical uterine cancer.

Objectives: To determine the prevalence of cancer in patients with Sjögren’s syndrome, and to compare demographic characteristics in Patients with Primary Sjögren Syndrome

Methods: Cross-sectional, observational study was conducted in which 393 patients were included, of which 221 (52%) came from the institutional medical center of mexico and nutrition “Salvador Zubirán”, 92 (23.4%) from the university hospital “José E González” and 80 (20.6%) of the juarez Mexico hospital/ABC medical centre whom fulfilled the diagnosis of SS according to the 2002/2012 criteria of the american college of rheumatology/european league against rheumatism. Bivariate analysis was performed, normality was demonstrated using the K.S test, the student’s T test was used for the numerical variables and the chi2 test for the categorical ones, and no difference was found between the characteristics of patients with or without cancer.

Results: We include 393 patients, the majority were women (n=377, 95.9%) with an average age of 56.4 (±13.60), of these 23 (5.85%) had some type of neoplasm regardless of their malignancy, the most prevalent was lymphoma with 9 cases (34.6%), followed by breast cancer with 5 (19.2%), 3 (11.5%) of basal cell cancer and 2 (7.7%) cases of cervical uterine cancer

Abstract AB0583 – Figure 1. Neoplasia prevalence in primary sjögren syndrome in Mexican-Mextizo patients

Conclusions: We confirmed lymphoma as the most prevalent neoplasia in a cohort of non-Caucasian pSS patients. We observed the presence of non-hematological malignancy 60.86% of our patients, whether it risk is increased in pSS population still needs to be addressed.

PAEDIATRIC VS ADULT ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: THE SIMILARITIES AND DIFFERENCES; A STUDY FROM A TERTIARY CARE CENTRE FROM NORTHERN INDIA

L. Duggal

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with myriad of systemic features. While the disease manifestations and therapy remain same for both paediatric onset (cSLE) and adult onset SLE (aSLE), disease manifestation and burden of disease differs in the two populations.

Objectives: To study disease profile within 6 months of disease onset and burden of disease by SLEDAI of cSLE and aSLE to understand the similarities and differences and to compare with those from around the world

Methods: Retrospective review done of 100 aSLE and cSLE patients, from June 2015 to June 2016, fulfilling SLEICC criteria. Demographic data, clinical profile and ds burden at onset(highest of 1st 6 mths of ds onset) by SLEDAI 2K were recorded on a predesigned proforma

Results: The incidence of skin involvement (acute and chronic cutaneous lupus, alopecia) serositis more in aSLE. Oral mucositis, neuropsychiatric SLE(NPSLE) and lupus nephritis(LN) more common in cSLE.LN was also higher in cSLE from other centres around the world as compared to aSLE. Of statistical significance were non SLEICC features like fatigue, Raynaud phenomenon and fatigue in aSLE. cSLE significantly differed in higher incidence of non SLEICC features like fever, vasculitic rash and in laboratory features like leucopenia, low complements, dsDNA positivity and antiphospholipid antibody(APLA) positivity. Although APLA antibodies were frequent in cSLE, thrombotic events were rare. On the other hand, thrombotic events were significantly associated with aSLE. Median SLEDAI at onset was higher in cSLE than aSLE. The higher incidence of LN in cSLE than aSLE was similar from the inception cohort from Toronto. The mean SLEDAI at onset was also similarly higher in cSLE. The Spanish SLE registry also reported similar findings.

Abstract AB0584 – Table 1

Conclusions: This study showed significant difference in initial systemic involvement and onset of presentation in aSLE and cSLE. cSLE present with more subtle features and seldom have a classic presentation with malar rash, oral mucositis and alopecia which oft herald aSLE. cSLE and aSLE though being the same disease often have a varied spectrum of presentation and the generalist and the treating teams need to be aware of these for prompt recognition of the disease and optimum therapy

A LUPUS LOW DISEASE ACTIVITY STATE IS ASSOCIATED WITH REDUCED FLARE, LOWER ORGAN DAMAGE ACCRUAL, AND BETTER QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J-H Kang, K.-E. Lee, D.-J. Park, S.-S. Lee. Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of Ireland

Objectives: To identify the potential predictors of a lupus low disease activity state (LLDAS), and the relationship between LLDAS and disease flare, organ damage, and quality of life in Korean patients with systemic lupus erythematosus (SLE).

Methods: The study followed 181 SLE patients from a single centre for three years. LLDAS was defined as follows.1 SLE Disease Activity Index (SLEDAI) – 2K<4, with no activity in major organ systems,2 no new lupus disease activity compared with the previous assessment,3 SLEDAI Physician Global Assessments,1 a current prednisolone (or equivalent) dose ≤7.5 mg daily; and well-tolerated standardized maintenance doses of immunosuppressive drugs. We assessed data annually and divided 4 groups according to the number of LLDAS: LLDAS=0, 1, 2, and 3. Univariate and multivariate analyses were performed to identify predictors of LLDAS.

Results: Of the 181 patients, 16.0% attained LLDAS on three consecutive years. Each group shows as follows: no LLDAS (n=30); LLDAS=1 (n=60), LLDAS=2 (n=62), and LLDAS=3 (n=29). The patients who had higher number of LLDAS had shorter duration of symptoms, lower anti-histone antibody positivity, lower cumulative prescribed dose of prednisolone at baseline, lower mean PQA, lower mean SLEDAI at onset was higher in cSLE than aSLE. The higher incidence of LN in cSLE than aSLE was similar from the inception cohort from Toronto. The mean SLEDAI at onset was also similarly higher in cSLE. The Spanish SLE registry also reported similar findings.

Abstract AB0585 – Table 1

Conclusions: Attaining LLDAS was associated with an improved outcome, as represented by a decreased rate of disease flare, lower organ damage accrual, and better quality of life in Korean patients with SLE.

CURRENT IMPACT OF ETHNICITY ON RENAL HISTOLOGY AND OUTCOME OF LUPUS NEPHRITIS

J. Nosser1,2, W. Raymond2, A. Kang1, D. Wong2, M. Ognejovic2, A. Chakera1,3

1Rheumatology, Sir Charles Gairdner Hospital, Nedlands, Australia; 2Pathology, PathWest Laboratory Medicine, Nedlands; 3School of Medicine, University of Western Australia, Crawley, Australia

Background: Lupus Nephritis (LN) remains a serious complication of Systemic Lupus Erythematosus (SLE) and continuous worldwide demographic changes as well as new mechanistic insights and treatment options necessitate regular updating of our knowledge of LN.

Objectives: To investigate the current relevance of demographic, clinical and histological characteristics as outcome predictors in patients with Lupus Nephritis.

Methods: A retrospective single centre cohort study of all SLE patients undergoing a first renal biopsy for LN evaluation between 1997–2017 in a metropolitan hospital in Western Australia with a 750,000 catchment area. Demographic, laboratory and treatment data were collected at baseline and at last follow-up using a predefined form and histological findings (ISN class) were re-evaluated. Kaplan Meier survival estimates for patient and renal survival were tested by log-rank test.

Results: The final study cohort included 90 SLE patients (age 31.5 years, 88% female, time since SLE diagnosis 0.7 years). Renal biopsies were performed in 30 patients. Of the 30 patients, 19 (63.3%) were of Aboriginal (n=11) and other ethnicity (n=7, mainly SubSaharan Africans). The annual LN incidence estimate was 0.6/100,000. There were no significant differences across subgroups regarding renal (overall median 14) and nonrenal SLEDAI (median 4) scores, proteinuria (median PCR 300 mg/mmol), presentation with raised serum creatinine (31% overall), anti-dsDNA Ab (89%) or hypoalbuminaemia (88%) or presence of proliferative (Class III/IV: 66%) or membranous (Class V:19%) LN. Corticosteroid (86%), immunosuppressive (97% overall) and
anthypertensive drug (69%) use were similar across ethnic subgroups (all p>0.2). After a mean follow-up of 95 months, eight patients (9%) had died, six (7%) received renal replacement therapy and five (6%) had developed CKD. Five and ten years patient survival was similar for Asian and Caucasian patients (95%) and poorest in Aborigines (81% and 70%) (p=0.016) with no impact of gender, ISN class, full house IF findings or PCR >300. Renal 5 and 10 year survival (endpoint RRT) was 100% for Asian, 100% and 96% for Caucasian vs 86% and 64% for Aborigines(p=0.02). PCR >350 predicted worse renal survival (p=0.03), which was not influenced by gender, increased baseline creatinine, ISN class, A/A/C/C subclass or presence of full house IF deposits.

Conclusions: Asian patients have similar clinical and histological LN findings and experience equally good renal and patient outcomes as Caucasian patients in Western Australia, where the incidence rate of LN is comparable with Europe. Whether the grim outlook for Aboriginal patients relates to intrinsic differences in LN pathophysiology and/or socioeconomic circumstances deserves further study.

Disclosure of Interest: None declared

J. Kikuchi1, M. Ushikubo2, S. Saito1, H. Yasuoka1, K. Yamaoka1, H. Tsujimoto2, M. Sugahara3, T. Takeuchi1. 1Division Of Rheumatology, Department Of Internal Medicine, Keio University School of Medicine; 2Department of Connective tissue disease, National Hospital Organization Tokyo Medical Center, Tokyo; 3Research Unit-Immunology and Inflammation, Mitsubishi Tanabe Pharma Corporation, Kanagawa, Japan

Background: Herpes virus infections (HVIs) including cytomegalovirus infections (CMVs) and herpes zoster (HZ) remains as major complications during treatments with immunosuppressant (IS) in patients with autoimmune diseases.3,4 Previous reports have suggested the associations between virus infections and characteristics of T cells.3,4

Objectives: To elucidate the characteristics of peripheral immune cells associated with risk factors of HVIs during induction therapies in patients with active lupus nephritis (LN).

Methods: Standardised peripheral immunophenotyping was performed using flow cytometry in active LN and ANCA-associated vasculitis (AAV) patients starting induction therapy and also in inactive LN patients with maintenance therapy between April 2015 to April 2017. The definition of HVIs was the infection necessary to administer anti-viral agents.

Results: Sixty-two LN patients and 11 AAV patients were enrolled. Among 30 active LN patients, 27 were analysed except for 3 patients (2 died and 1 withdrawn consent). Mean age was 41.7 years, 9 patients (33%) had newly-onset, and mean SLE disease activity index (SLEDAI) was 19.3. All active LN patients were treated with prednisolone (PSL) (mean 51.7 mg/day) and 25 were treated with an additional IS (cyclophosphamide [CYC];13, mycophenolate mofetil;8, tacrolimus;5, rituximab [RTX];1). Six (22.2%) patients developed HVIs (5 CMVs and 1 HZ) within 3 months following induction therapy. None of the 32 LN patients in maintenance phase (mean age, 54.8; SLEDAI, 2.5; PSL 2.5 mg/day) developed HVIs during the mean 2.8 years-observational period. Two (18.2%) AAV patients developed HVIs within 3 months following induction therapy. All AAV patients (mean age, 63.4) were treated with PSL (mean 41.8 mg/day) and 10 with IS (CYC;5, RTX;3, azathioprine;1, methotrexate;1).

Among active LN patients, univariate analysis revealed that older age, lower proportions of naïve CD8 + T cells, higher proportions of effector CD8 + T cells and HLA-DR + regulatory T cells (Tregs) at baseline and lower naïve CD8 + T cells at month 3 associated with HVIs (p=0.011, p<0.001, p=0.009, p=0.024, p<0.001 respectively). Unexpectedly, lymphocyte count, IgG titer, usage of CYC at baseline, renal response and change in SLEDAI at month 3 did not associate with HVIs. Multivariate analysis revealed that low proportions of naïve CD8 + T cells and high proportions of HLA-DR + Tregs at baseline were the only detectable independent risk factor for HVIs (p=0.014).

Among AAV patients, univariate analysis showed that older age, lower proportions of naïve CD8 + T cells, higher proportions of Tregs at baseline associated with HVIs. However, multivariate analysis showed no independent risk factor for HVIs among them.

Conclusions: Our results suggest that active LN patients with low proportion of naïve CD8 + T cells and high HLA-DR + Tregs at the time of induction therapy should be closely monitored for HVIs. The different results between LN and AAV implicated the different risks of HVIs by immunophenotyping. Larger prospective study is desired to confirm our results.

AB0589

RELEVANCE OF B AND T CELL SUBSETS TO LUPUS FLARE IN KOREAN PATIENTS WITH SYSTIMIC LUPUS ERYTHEMATOSUS

J.H. Koh1, N. Lee2, W.-U. Kim3. 1Division of Rheumatology, Department of Internal Medicine, Pusan National University Hospital, Pusan; 2Center for Integrative Rheumatoid Transcriptomics and Dynamics, The Catholic University of Korea; 3Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary’s hospital, the Catholic university of Korea, Seoul, Korea, Republic of Ireland

Background: Systemic lupus erythematosus (SLE) is a systemic autoimmune disease with heterogeneous clinical manifestations and is characterised with autoactive T cells and autoantibody overproduction by activated B cells.

Objectives: The aims of this study were to characterised T-cell and B-cell subpopulation phenotype in Korean patients with SLE, and to elucidate the association between lymphocyte subpopulation and lupus activity.

Methods: We used multicolor flow cytometry to analyse subsets of peripheral blood B-cells (defined by CD19, IgD, CD27, and CD38) and T-cells (CD3, CD4, CD8, CD45RA,CCR7) in 26 patients with SLE and 22 age- and sex-matched healthy subjects. Baseline and 6 month follow-up SLE disease activity index (SLEDAI) was recorded, and SLEDAI score >6 was considered as lupus flare-up. Lymphocyte phenotype was also compared between stable disease and lupus flare-up.

Results: The number of B cells and CD8+ T cells were not different between SLE patients and healthy subjects; however, non-switched memory (NSwM) B cells was decreased in SLE patients. Double negative (DN) T cells, CD4+ T cells and its subset [naive, central memory (CM), effector memory (EM) and terminally differentiated effector memory (TEMRA) cells] were decreased in SLE patients compared to healthy controls. Patients with lupus flare-up showed significantly decreased CD4+ and DN T cells, whereas CD4+EM T cells were increased in patients with lupus flare up, compared to stable SLE. SLEDAI was correlated with DN T cells (p=0.728, p<0.001), CD4+CM T cells (p=0.544, p=0.004), CD4+EM T cells (p=0.697, p<0.01) and CD8+EM T cells (p=0.408, p=0.039). Six (23%) patients experienced lupus flare and a patient presented still high disease activity at 6 month follow-up visit. Interestingly, these patients showed the low number of DN T cells, CD4+EM and TEMRA cells at baseline when they were stable.

Conclusions: Biassed differentiation of T-cells was associated with lupus flare and aggravation of SLE 6 months later. Understanding T cell subset enables accurate stratification of lupus flare-up and personalised approach.

A VALIDATION STUDY OF THE PREGNANCY MORBIDITY QUESTIONNAIRE (PMQ) IN WOMEN WITH ANTIPHOSPHOLIPID ANTIBODIES AND PREGNANCY MORBIDITY

K. Schreiber1,2, S. Koder3, C. Ay9, I. Pabinger5, S. Jacobsson6, 1Department of Rheumatology and Haemophilia, Guy’s and St Thomas’ Hospital, London, UK; 2Copenhagen Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Copenhagen, Denmark; 3Clinical Division of Haematology and Haemostaseology, Department of Medicine I, Medical University of Vienna, Vienna, Austria

Background: The presence of antiphospholipid antibodies (aPL) is associated with pregnancy complications. There is a lack of validated pregnancy questionnaires to assess previous pregnancy morbidity reliably in aPL positive patients. We therefore designed the pregnancy morbidity questionnaire (PMQ).

Objectives: To validate the pregnancy morbidity questionnaire (PMQ) in the prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS) cohort.

Methods: The Vienna Lupus Anticoagulant and Thrombosis Study (LATS) is an ongoing, single-centre, biobank-based, prospective observational cohort study enrolling patients (age >18 years) who are persistently positive for lupus anticoagulant (LA) (two positive tests at least 12 weeks apart) with or without a history of thrombosis or pregnancy complications1. The cohort currently consists of 150 patients (mean age: 41.3 years, female gender: n = 122 (81.3%), history of thrombosis or pregnancy complications: n = 111 (74.0%)). Of these 150 women, 15 were approached at their follow up visit and invited to fill out the PMQ. The PMQ consists eight questions outlined in table 2.

Results: Twelve women agreed to participate, of whom nine had a previous history of pregnancy and/or pregnancy complications. Patient characteristics are shown in table 2. PMQ results are outlined in table 2.

Conclusions: Our aim was to validate the PMQ in the prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS) cohort. Patients were able to recall their pregnancy history in great detail over a period of more than three decades. Our PMQ may provide a tool to assess previous pregnancy morbidity in patients with antiphospholipid antibodies.

SLE RESponder INDEX (SRI) UNDERESTIMATES IMPAIRMENT IN HAND STRENGTH, DEXTERITY AND ACTIVITIES OF DAILY LIVING PERFORMANCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

K. Mahmoud1,2, A. Zayat1,2, M.Y. Md Yusof1,2, E. Hensor1,2, P.G. Conaghan1,2, P. Emery1,2, E. Vital2,1. Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, University of Leeds; 2NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, LEEDS, UK

Background: Musculoskeletal (MSK) manifestations are common in SLE. Many recent clinical trials were negative or had small benefits vs. placebo. SRI is a common primary endpoint but has not been independently validated. Ultrasound is an objective measure of synovitis validated in inflammatory arthritis.

Objectives: To compare the responsiveness of clinical outcome measures with ultrasound in MSK-SLE.

Methods: 20 SLE patients meeting SLICC 2012 criteria with inflammatory MSK symptoms were studied with clinical assessment (BILAG2004, SLEDAI-2K over 30 days, patient and physician VAS, symptomatic, tender and swollen joint counts in 28 joints) and MSK ultrasound (grey scale and power Doppler scores, number of abnormal joints) at 0, 2, and 4 weeks after 120 mg IM depomedrone. Change in each variable was measured using Wilcoxon matched pairs and effect sizes(r=2/sqrt(2*n)) compared using Cohen (1988) criteria. Changes were compared for SRI responders and non-responders.

Results: All patients were ANA positive, CCP negative and female. At baseline, 15/20 had clinical synovitis. The others had either ultrasound synovitis (GS in 18/20, PD in 17/20) or >60 min EMS. 19/20 patients scored 4 points on SLEDAI for musculoskeletal involvement, BILAG scores were A in 7/20, B in 8/20, and C in 5/20. MSK-SLEDAI score improved in 9/20 at 4 weeks, MSK-BILAG improved in 16/20. For changes, see table 1.

19 patients with MSK-SLEDAI=4 at baseline were grouped into SRI-4 responders (n=9) and non-responders (n=10). There were large effect sizes for improvement in TJC and SJC in responders (r=−0.505 and −0.492 respectively) and medium effect sizes in non-responders (r=−0.365 and −0.301). For ultrasound, large effect sizes for improvements in both grey scale and power Doppler were observed in both responders (r=−0.517 and −0.564) and non-responders (r=−0.629 and −0.596).

Conclusions: In MSK-SLE, ultrasound was the variable most consistently sensitive to change. All commonly used clinical variables significantly improved by week 4 but there was variation in responsiveness between them. BILAG-2004 and physician VAS had similar responsiveness to ultrasound. SRI-4 underestimated response, with substantial objective improvements in synovitis in SRI-4 non-responders. Developing organ-specific outcome measures may improve the ability to measure treatment effects in SLE clinical trials.

IMPAIRMENT IN HAND STRENGTH, DEXTERITY AND ACTIVITIES OF DAILY LIVING PERFORMANCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A CROSS-SECTIONAL STUDY

K. Keramtsidou1, C. Anagnostou1, A. Galanos1, P. Stilakis1, M.G. Tektondiou1, 1First Department of Propaedeutic and Internal Medicine, Medical School, National and Kapodistrian University of Athens; 2General Hospital of Elefssis ‘Thriasio’; 3Medical School, National and Kapodistrian University of Athens, Athens, Greece

Background: Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease affecting multiple systems. To date a small number of studies have assessed the hand function and performance of daily activities in SLE1.

Objectives: To examine the grip and pinch hand strength, the dexterity, and the performance of Activities of Daily Living (ADL) in SLE patients compared with healthy controls.

Methods: 197 SLE patients (48,03±12.76, 88.3% female) and 100 healthy controls (47,87±12.77, 86% female), matched by age and gender, were enrolled in the study. Both groups were assessed by hand grip and pinch grip strength, dexterity and ADL performance tests. Hand grip strength was measured by Jamar dynamometer, and pinch grip strength by pinch gauge, in both hands. Dexterity was measured by Purdue pegboard test. Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire and Health Assessment Questionnaire (HAQ) were used in order to determine the difficulties in ADLs.

Results: Hand grip strength, both lateral and jaws pinch grip strength, and dexterity, were significantly impaired (p<0.001) in both hands of SLE patients compared to healthy subjects (table 1). DASH questionnaire (19.78±20.93 vs 2.42±2.9, p<0.001) and Health Assessment Questionnaire score (HAQ) (0.41±0.52 vs 0.03 ±0.52, p<0.001) were also significantly different between SLE patients and healthy controls.

Background: Fatigue is an important issue in systemic lupus and has a major impact on quality of life of the patients. Data are controversial about the factors associated with this complex symptom.1

Objectives: To identify the factors associated with fatigue and severe fatigue in patients with systemic lupus erythematosus (SLE) in a large cohort using a multivariate model to precise the importance of each parameter in this multidimensional symptom.

Methods: We used the LLBR data base, a German French data base of SLE patients. All patients fulfilled the 1997 ACR criteria for SLE. The Fatigue Scale for Motor and Cognitive Functions (FSMC) was used to assess fatigue and severe fatigue. The depression and anxiety were measured with Hospital Anxiety and Depression Scale (HADS). Tests were performed at sampling.

Results: A total of 570 patients were included (89.1% female). The median age was 42 years (QR25–75: 34–52). The median value of the SELENA-SLEDAI was 2 (QR25–75: 0–4) and 136 patients had a SELENA-SLEDAI score >6. Fatigue was reported by 386 patients (67.7%) including severe fatigue by 209 (36.7%). In univariate analysis among the individual components of the SLEDAI arthritis (p=0.003) and oral ulcers (p=0.002) were associated with severe fatigue. In multivariate analysis fatigue was strongly associated with anxiety (OR: 4.49 [95%CI: 2.60–7.77], p<0.0001) and depression (OR: 4.72 [95%CI: 1.39–16.05], p=0.01). It was also associated with age at sampling (OR: 1.01 [95%CI: 1.00–1.03, p=0.03] per 1 year increase), SLEDAI (OR: 1.05 [95%CI: 1.00–1.12, p=0.043] per 1 SLEDAI point increase) and glucocorticoids treatment (OR: 1.54 [95%CI: 1.00–2.38, p=0.04]). It was not associated with physical activity. Severe fatigue was strongly associated with depression (OR:6.87 [95%CI: 3.12–15.11], p<0.0001) and anxiety (OR: 3.80 [95%CI: 2.46–5.87], p<0.0001) but not with SLEDAI or physical activity.

Conclusions: Fatigue is a common symptom in SLE patients and is strongly associated with anxiety and depression. While remission remains an important therapeutic target, these manifestations should also be taken care of with psychological counselling and pharmacological intervention, when needed.

ANTIPHOSPHOLIPID SYNDROME (HUGHES SYNDROME) IS A DISEASE WITH PROTEAN FACES: MULTIDISCIPLINARY APPROACHES ON SERBIAN COHORT OF APS PATIENTS

L. Stojanovich, A. Djikovic, N. Stanisavljevic, G. Bogdanovic, M. Zdravkovic. Internal medicine department, University Hospital Center Bezanska Kosa, Belgrade, Serbia

Background: Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterised by thrombophilitic state and circulating antiphospholipid antibodies (aPL) including anti beta2GPI.

Objectives: Since than it became one of the most systemic conditions. In the last three and half decades, a variety of clinical manifestations involving almost all organs and tissues (cardiac, pulmonary, neurological, renal, cutaneous, haematologic, gastrointestinal, ocular, skeletal and endocrinologic), have been described associated with antiphospholipid antibodies (aPL).

Methods: Our study comprises a total of 608 patients: 420 primary APS (PAPS) patients and 188 SLE patients with secondary APS (SAPS). aPL analysis included detection of aCL, aß2GPI, and LA.

Results: Thrombosis was diagnosed in 46.5% patients, with higher prevalence in PAPS compared to SAPS patients: 51.2% and 38.3%, respectively, p=0.045. Pseudoinfective endocarditis was observed in 12.8% secondary APS patients and 3.1% in primary APS patients (p=0.004). 30% of the patients with high levels of aCL IgG antibodies had valve thickening and dysfunction, as compared to 4.1% without valve abnormalities (p=0.002). Presence of ß2GPI IgG was significantly related to stroke, and overall ß2GPI (IgG and IgM) positivity was significantly related to TIA in SAPS patients. Valvarul manifestations were significantly related to TIA in both groups of patients and were independent risk factors for TIA in SAPS (OR 3.790 CI 1.597–8.998 p=0.003: table 2). In PAPS, epilepsy correlated with ß2GPI-IgM, migraine with aCL-IgM, thrombocytopenia with aCL-IgM, aCL-IgG, anti ß2GPI-IgG and LA. Livedo reticularis was more prominent in PAPS with high levels of aCL-IgG. Skin ulcerations were more prevalent in aCL-IgM positive SAPS patients and epilepsy more frequently had high levels of anti ß2GPI-IgG in SAPS.

Conclusions: In this cross-section analysis of a large cohort of APS patients we analysed that APS patients can be presented with a wide variety of thrombotic
and nonthrombotic manifestations. The key the success is multidisciplinary approach in all time of patient’s life. Antiphospholipid syndrome is really a disease with protean faces.

THE IMMUNE COMPLEXES OF IgG/IgM BOUND TO B-2-GLYCOPROTEIN I ARE ASSOCIATED WITH LIVEDO RETICULARIS, THROMBOCYTOPENIA AND SICCA IN APS PATIENTS

D. Pérez1, L. Stojanovich1, L. Naranjo2, N. Stanisavljevic2, G. Bogdanovic2, M. Serrano1, A. Serrano1. 1Immunology, Hospital Universitario 12 de Octubre, Madrid, Spain; 2Internal medicine, Bečanaška Kosa; University Medical Center, Belgrade, Serbia

Background: Several manifestations strongly associated with APS have been excluded as classification criteria.1 2

Objectives: The aim of this study was to investigate correlation between circulating immune-complexes of IgG or IgM antibodies bound to B2GPI (B2G-CIC and B2M-CIC) and clinical manifestations in Serbian cohort of APS patients.

Methods: A total of 57 patients with APS were evaluated: 35 with PAPS and 22 patients with SAPS. Mean age was 47 (6.1 ± 1 years; 36 (63.2%) were women. All patients have met the 2006 revised Sydney criteria for APSQuantification of B2G-CIC and B2M-CIC levels was performed as previously, for detect B2G-CIC was used anti-human IgG HRP-conjugate and for B2M-CIC human IgM HRP-conjugate, both from INOVA (INOVA Diagnostics Inc., San Diego, CA, USA).

Results: In our cohort Serbian APS patients the prevalence of CIC was 19.29% (11/57); 8 patients with B2M-CIC and the remain 3 patients with B2G-CIC. Livedo reticularis was diagnosed with higher prevalence in patients with CIC compared with patients without CIC; 63.6% and 23.9%, respectively (OR: 5.57, p=0.01). In patients with CIC, thrombocytopenia and leukenkemia were more prominent; 54.4% vs 17.4% (OR: 5.70, p=0.01) and 45.5% vs 13.0% (OR: 5.56, p=0.01), respectively. Ophthalmic sicca was more prevalent in patients with CIC; 54.4% vs 8.7% (OR: 12.6, p<0.001). Although complement consumption was more frequent in patients with CIC (figure 1).

Figure 1. Mean levels of C3 (A) and C4 (B) complement in groups. Mean levels of C3 (115.6±9.2 mg/dL and 140.9±4.3 mg/dL, group-1 and group-2 respectively) and mean levels of C4 (140.9±4.3 mg/dL and 30.8±1.6 mg/dL, group-1 and group-2 respectively).

Conclusions: B2G-CIC and B2M-CIC are strongly associated with clinical manifestations related to APS. Widening the APS spectrum is indispensable to better understand this syndrome.

CHANGES IN THE THYROID HORMONES IN PATIENTS WITH SJÖGREN’S SYNDROME IN DOMINICAN REPUBLIC

Background: Sjögren’s syndrome (SS) is an autoimmune chronic where there is a B-cell activation and lymphocytic infiltration of exocrine glands, this can be primary or secondary and characterised by xerostomia, xerophthalmia and extra-glandular manifestations.1 Thyroid involvement is frequent in patients with SS sharing histological and antigenic characteristics2. 10–24% of patients with SS have thyroid involvement, the most common are Hashimoto’s thyroiditis or Grave’s disease are the most frequent autoimmune syndromes. Some reports indicated that Hashimoto’s Thyroiditis and Grave’s disease has an incidence of 4.2% and 3.4% in the patients with SS respectively. A study showed that in patients with SS 45% had changes in the values of thyroid hormones and 24% autoimmune thyroiditis.3–5

Objectives: The aim of this study was to determine the changes in the thyroid hormones in patients with Sjögren’s syndrome.

Methods: A cross-sectional study. The information was collected from the digital records of Hospital Docente Padre Billini Rheumatology department during the period October 2017–January 2018. Inclusion criteria: age ≥18 years old, patients with Sjögren’s syndrome according to ACR/EULAR 2016 criteria. Excluded patients who did not thyroid test during the study and patients who have a thyroid disorder under treatment. The data was analysed using SPSS V23 Windows 10.

Results: 79 cases were reviewed, of which 51 met the inclusion criteria. 98% were women, average age of 45 years, 9.8% had hypothyroidism and 3.9% hyperthyroidism by laboratory tests. 82.3% were euthyroid. 82.3% had anti TPO and anti Tg, 96% Schirmer test + and 37.2% positive biopsy report for SS.

Conclusions: In our study, we found that 9.8% of patients with Sjögren’s syndrome could be associated with subclinical hypothyroidism and 3.9% with hyperthyroidism what can mask the clinical manifestations at the time of diagnosis. The screening in high-risk patients such as patients with autoimmune disorders remains important.

SIGNIFICANCE OF NON CRITERIA ANTI-PHOSPHOLIPID ANALOGUES IN THE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ASSOCIATED WITH ANTI-PHOSPHOLIPID SYNDROME

M. Drudlewská1, A. Majdan2, M. Majdan1. 1Department of Rheumatology and Connective Tissue Diseases; 2Chair of Oncology, Medical University, Lublin, Poland

Background: Systemic Lupus Erythematosus (SLE) is a chronic inflammatory autoimmune disease in which the uncontrolled activation of the immune system leads to overproduction of autoantibodies (Ab) with different mechanisms of action. Coexistence of anti-phospholipid antibodies (aPL) significantly increases the risk of thromboembolic complications and worsens the clinical course and prognosis of SLE.

Objectives: The aim of study was to investigate correlation between circulating immune-complexes of IgG or IgM antibodies bound to B2GPI (B2G-CIC and B2M-CIC) and clinical manifestations in Serbian cohort of APS patients.

REFERENCES:

Disclosure of Interest: None declared

Methods: The study involved 70 (52-female and 18-male) patients treated in the Department of Rheumatology and Connective Tissue Diseases. All patients fulfilled the SLICC classification criteria of SLE (46/70 pts fulfilled clinical and laboratory criteria of Antiphospholipid Syndrome (I group SLE/APS-46pts) and 24/70 pts (II group SLE/aPL (+) – 24) - they had criteria antibodies but did not display clinical criteria symptoms of APS. In the whole study group the mean age was: 38.5±12.9 years (range 18–71), the duration of the disease was 8.3±6.5 years (range 0–37). The presence of Ab was detected in patients’ serum using the commercially available tests: aPL-immunodot assay Anti-Phospholipid 10 Dot, for the qualitative detection of IgG or IgM antibodies. Statistical data analysis was performed using Statistica v13.0.

Results: In the study group of 70 patients we detected the presence of the following aPLs: a-cardiolipin IgM – 33.7%, IgG – 50%; a-phosphatidic acid IgM – 17.5%, IgG – 11.2%; a-phosphatidylcholine IgM and IgG – 0; a-phosphatidylethanolamine IgM and IgG – 0; a-phosphatidylglycerol IgM – 4.4%, IgG – 10%; a-phosphatidylinositol IgM-11.2%, IgG-10%; a-phosphatidylserine IgM-31.2%, IgG-48.7%; a- annexin V IgM – 20%, IgG – 10%; a-b2-GP I IgM-33.7%, IgG-30%; a-prothrombin IgM – 51.4%, IgG-30%.

The following non-criteria symptoms of APS were present: nephropathy in 27.1%, hypertension-41.1%, livedo reticularis 11.4%, convulsions/chorea-5.7%, thrombocytopenia-20% of the study group.

No statistically significant differences in the frequency of occurrence of individual non-criteria aPLs, as well as non-criteria clinical symptoms of APS have been found in the examined subgroups of SLE/SAPS and SLE/aPL (+) patients.

Conclusions: The prevalence of non-criteria aPLs in SLE and APS pts is similar found in the examined subgroups of SLE/SAPS and SLE/aPL (+) patients.

The prevalence of non-criteria clinical symptoms of APS was present: nephropathy in 27.1%, hypertension-41.1%, livedo reticularis 11.4%, convulsions/chorea-5.7%, thrombocytopenia-20% of the study group.

RELATION BETWEEN THE DEFICIT/DEFICIENCY OF VITAMIN D AND THE DEPRESSION/ANXIETY IN PATIENTS WITH LUPUS IN THE DEPARTMENT OF RHEUMATOLOGY OF THE HOSPITAL OF CLINICS

M. A. Vazquez 1, N. Orta 1, V. Martinez 1, L. Roman 1, K. Bauman 1, M. Melo 1, E. Acosta 1, M. Duarte 1, L. Acosta Colman 1, C. Central, Hospital de Clínicas San Lorenzo, C. Central, Instituto de Investigación en Ciencias de la Salud San Lorenzo, Asunción, Paraguay

Background: It has been postulated that low concentrations of 25-hidroxivitamin D serum [25 (OH) D] is associated with a greater prevalence of depression. People with deficient levels of vitamin D are more likely to experience mood disorders such as depression and anxiety. The vitamin D plays a role in the release of neurotransmitters such as serotonin and dopamine which is why is interesting the study of this in patients with systemic lupus erythematosus, who are discouraged from sun exposure.

Objectives: To evaluate the IOP values and the presence of increased excavation of 50 SLE patients.

Methods: Observational study of longitudinal court based in a questionnaire according to the scale HADS (Hospital anxiety and Depression Scale) and the dosages of vitamin D performed on patients who entered the LUPUS PY cohort with prior informed consent. The dosage of vitamin D realised by chemiluminescence. Data and samples were taken in week 0 and week 24 and the prevalence of depression and anxiety and its association with vitamin D deficiency and insufficiency were identified. Patients with vitamin D deficiency or insufficiency were supplemented with vitamin D. For the descriptive analysis of the quantitative variables, average and SD were used, for the qualitative frequencies and percentages. For the analysis of association the test x 2 was used. The value of the p considered statistically significant was less than 0.05.

Results: In relation to the characteristics of the studied cohort, we can see that 90.5% were female, with an average age of 33±10.2 years. At week 0 the average value of vitamin D concentration was 31.8±10.2 ng/ml. It is found that 4.48% of patients had depression and 33.69% of patients have anxiety. In the week 24 the value of the average of vitamin D was of 31.1±13.6 ng/ml. It was observed in this week that 6% of patients presented depression and 12% of patients anxiety. In the analysis of association there was no association between vitamin D deficits and the presence of depression or anxiety of these patients both at the week 0 as a week 24 post vitamin D supplementation such, and as seen in table 1.

Abstract AB0599 – Table 1. Deficit and insufficiency of vitamin D associated with the depression and anxiety in patients with SLE.

Conclusions: A significant percentage of patients with deficient or insufficient vitamin D were found, as well as a considerable percentage had depression or anxiety, although no association was found between the state of this vitamin and the alterations of the studied mood. More studies are required that include more patients in order to obtain more conclusive results.

RELEVANCE OF OPHTHALMOSCOPIC EVALUATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: UNDERESTIMATION OF INTRAOCULAR PRESSURE VALUES

M.C.D.F. Salgado 1, A.D.C. M. Paiva 1, Y.D.F. B. Chagas 1, J.L.P. Vaz 1, F.C. Freire 1, L.M. Arêas 2, F.C. Freire 1, V. Vigneron 1, Y.D.F. B. Chagas 1, J.L.P. Vaz 1, A. Vaz 1, V. Vigneron 1, 1General Medicine, ophthalmology, Federal University of Rio de Janeiro State, Rio De Janeiro, Brazil

Background: The evaluation of the size of the optic nerve papilla in ophthalmoscopy is an important tool for the diagnosis of glaucoma in individuals who do not present elevated intraocular pressure (IOP) levels. The calibration of the IOP is performed through Goldmann’s tonometry, which consists of flattening the central cornea with a tonometer. Patients with Systemic Lupus Erythematosus (SLE) have circulating autoantibodies and immune complexes that alter corneal biomechanics, resulting in underestimated IOP values.

Objectives: To evaluate the IOP values and the presence of increased excavation in patients with SLE, reinforcing the importance of ophthalmoscopy in this population.

Methods: Descriptive study. Analysis of IOP measurement and papillary excavation of 50 SLE patients.

Results: All patients had IOP values within the normal range (8–21 mmHg). In a total of 100 eyes evaluated, four (4%) had increased papillary excavation.

Conclusions: Type I collagen is essential for the maintenance of biomechanical parameters and resistance of the cornea. At the corneal level, the activation of the complement system results in the lysis of type I collagen fibres, reducing corneal thickness and resistance. Therefore, IOP values for tonometry will be reduced and underestimated. Comparing the IOP values of SLE patients and healthy volunteers, there are lower results (p<0.001) in lupus patients. In the present study, no patient had IOP changes. However, 4% of the eyes revealed increased excavation. These findings reflect the results of Yazici at al, and reinforce the importance of ophthalmoscopy in the screening of glaucoma in SLE patients.

ENTHESES ULTRASONOGRAPHY IN TUNISIAN PRIMARY SJÖGREN’S SYNDROME PATIENTS

K. Ben Abdelghani, M. Chammakhi, A. Fazaa, K. Ouenniche, S. Kassab, S. Chekili, A. Lataar. Rheumatology, Mongi Slim Hospital, La Marsa, Tunisia

Background: Primary Sjögren’s Syndrome is an autoimmune disease characterised by dryness of the eyes and the oral cavity. Musculoskeletal manifestations are common. However, the underlying mechanism remains often unknown.

Objectives: The aim of the current study was to describe subclinical enthesis involvement in patients with Primary Sjögren’s Syndrome via ultrasound, to calculate a modified Madrid sonography enthesis index and to compare it with a group of healthy controls.

Methods: The study was conducted in the rheumatology department of Mongi Slim hospital in Tunisia, between June 2015 and December 2017, including 29 patients with Primary Sjögren’s Syndrome and 25 healthy sex- and age-matched controls. Cases were defined according to the American-European Consensus Criteria for Sjögren’s Syndrome. All the included subjects underwent an enthesis ultrasonography examination (Esaote MyLab 60 machine and a 13–18 MHz linear array transducer) by a rheumatologist experimented in ultrasound. Five enthesis locations bilaterally (distal Achilles tendon, distal and proximal patellar ligaments, distal quadriceps, and brachial triceps tendons) in each patient were explored. The following elemental lesions of enthesis were evaluated: thickening, presence of calcifications, erosions, enthesophytes, loss of fibrillar pattern and power Doppler signal. The calculated index was compared by Mann-Whitney U test between cases and controls. The significance level was set at 5%.

Results: In our study population, the median age was 53.2±11.3 years and the median body mass index was 29.6±4.4 kg/m². All included subjects were female. The ultrasound abnormalities in the Primary Sjögren’s Syndrome were as follows: erosions in 19.2% of cases, enthesophytes in 16.4% of cases, calcifications in 6% of cases, hypoechogeneity in 2.8% of cases, thickening in 2.4% of cases, power Doppler signal in 1.6% of cases and loss of fibrillar pattern in 1.2% of cases. The total enthesis index was 4.96±2.9 allowing cases and 5.72±2.92 among healthy control subjects with no statistically significant difference. Considering each affected enthesis, cases had no significantly higher scores than controls.

Conclusions: Our study did not find a significant enthesis involvement among patients with Primary Sjögren’s Syndrome that could explain the chronic indefinable pain. The diagnosis of an associated fibromyalgia should be kept in mind.

Disclosure of Interest: None declared

ANTHROPHOSPHOLIPID SYNDROME COMPONENTS IN PATIENTS WITH CORONARY HEART DISEASE

M. Nazarova1, M. Stanislavchuk2, L. Burdeina3. 1PhD-student of the internal medicine chair #1; 2Professor, the head of the internal medicine chair #1; 3PhD of the internal medicine chair #1, National Pirogov Memorial Medical University, Vinnytsia, Ukraine

Background: Antiphospholipid antibodies (aPL), such as anticardiolipin antibodies (aCL), are the immunological markers of the antiphospholipid syndrome (APS).1 The aPL are found in association with venous and/or arterial thrombosis. Myocardial infarction (MI) is usually related to atherosclerosis and thrombosis of coronary arteries.2 The clinical significance of aPL in MI, however, has not yet been well established.

Objectives: To evaluate the presence and levels of aPL in patients with history MI.

Methods: 50 patients (100% male) with average age 49.5±6.09 (M±SD) years with history of MI were examined. Serum IgG aPL (anti-cardiolipin, -phosphatidylserine, phosphatidylinositol, -phosphatidylacetate) were determined by enzyme-linked immunosorbent assay (ELSSA).

Results: IgG isoforms of aPL were detected in 26 (52%) patients with the history of MI and 24 patients were negative. The average age (M±SD) of aPL positive patients was 44.1±5.00 years and of aPL negative patients was 47.7±4.83 years (p=0.01). The difference comprises more than 3.5 years.

Patients with recurrent MI (two and more) had higher level of IgG aPL than patients with one MI (18.0±7.53 vs. 11.5±4.21 GPL-U/ml). The difference is significant (p=0.005).

Conclusions: Determined younger age of the first MI in aPL positive patients and higher level of IgG aPL in patients with recurrent MI indicate the possible involvement of the autoimmune factor in the pathogenesis of MI. This proves the necessity for further research in this direction.

REFERENCES:
Conclusions: Our results demonstrated that the frequency of IQRs on ECGs would be greater in SLE patients with high disease activity.

AB0604
INITIAL CLINICAL AND IMMUNOLOGICAL FACTORS ASSOCIATED WITH MANIFESTATIONS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME: A SINGLE CENTRE RETROSPECTIVE STUDY
M. Tsukamoto1,2, K. Suzuki1, T. Takeuchi1.
1Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; 2Department of Rheumatology, National Tokyo Medical Center, Tokyo, Japan

Background: Primary Sjögren’s syndrome (pSS) is a prototypical systemic autoimmune disease that manifests various signs and symptoms. Although a few studies have focused on these manifestations over the long term,1,2 the association of initial clinical and immunological factors with subsequent longer-term manifestations has not been fully elucidated.

Objectives: To identify initial clinical and immunological factors associated with manifestations in patients with pSS.

Methods: A retrospective review was performed on pSS patients followed over a 10 year period at our department. Clinical and immunological data, including levels of serum immunoglobulin (Ig) and autoantibodies, were collected and statistically analysed.

Results: A total of 224 patients diagnosed with pSS who had met the classification criteria3 were enrolled. Among them, 201 patients were diagnosed with pSS at our hospital. Of these, we followed the 91 patients who continued to visit our hospital over 10 years. Of the other 110 patients, 69 suddenly interrupted treatment, 20 visited different hospitals, and 13 interrupted treatment at our department and visited dentistry or ophthalmology departments. During observation, 7 patients were newly diagnosed with rheumatoid arthritis in addition to SS and one patient died. We then analysed the 91 patients who continued to visit. Of these, 88 were female and 3 were males. Average age was 52 years. 72 and 33 patients had anti-SS-A and/or -SS-B antibodies, respectively. 15% of patients used corticosteroid and/or immunosuppressant treatment. 10% of patients took traditional Chinese medicine. On follow-up for 10 years, titers of IgG, A and M were significantly decreased, whereas complement levels were elevated. The proportion of patients with extraglandular involvement decreased from 90% to 73%, whereas 14% of patients had new extraglandular organ involvement. The frequency of extraglandular involvement at 10 years was high in patients with hyper IgG at the initial test (39% vs 85%, p<0.01). The frequency of extraglandular organ involvement at 10 years was high in patients who were RF-positive at diagnosis (3% vs 15%, p<0.05). 9% of patients developed malignancies. 29% of patients without RF at the initial test had RF during the 10 years observation. The presence of dry eyes, mouth, or other ocular findings did not change during follow-up in pSS patients.

We then created a multivariate model of predictors for malignancies, extraglandular involvement and extraglandular organ involvement with possible variables at diagnosis. Age, anti-centromere antibody, hyper IgG and anaemia were identified as possible variables at diagnosis. 20% of patients with RF and hyper IgG at diagnosis were candidates for the development of extraglandular involvements in the future.

AB0605
PROCALCITONIN MIGHT BE USED FOR DISCRIMINATING INFECTIONS FROM INCREASED DISEASE ACTIVITY IN PRIMARY SJÖGREN SYNDROME
B. Arican Tarim1, M.E. Tezcan1, A. Orcun2, O. Keskin1.
1Internal Medicine; 2Rheumatology; Biochemistry, University of Health Sciences, Kardial Training and Research Hospital, Istanbul, Turkey

Background: Procalcitonin is a polypeptide which is secreted as a response to bacterial stimulus and accepted as an early and sensitive marker of infection. In healthy subjects procalcitonin should be <0.1 ng/mL. In case of infection it may rise over 0.5 ng/mL. Its level in inflammatory diseases usually does not reach to such high levels as in infections. Differentiating infection and disease activation may be confusing in autoimmune diseases. For this purpose, there were several studies that evaluated the role of procalcitonin for excluding infection on suspicion of increased autoimmune disease activity.2

Objectives: As far as we know, there is no study in literature that evaluated procalcitonin levels in patients with primary Sjögren’s syndrome (pSS). Our aim is to evaluate procalcitonin levels in pSS and determine whether we can use it as a marker to differentiate infection from disease activation.

Methods: The following two groups of patients were included in the study: Forty-eight patients with pSS, who met ACR 2012 Classification Criteria for Sjögren’s Syndrome, and fifty-three subjects as control group who have no chronic diseases. Patients with possible infection were excluded according to their clinical evaluation and laboratory data. Then, serum procalcitonin levels were compared between the groups. Finally, we evaluated the correlation between disease activity, measured by Sjögren’s syndrome disease activity index (SSDAI) and procalcitonin levels.

Results: Procalcitonin levels in pSS group were found statistically higher than control group, whereas it was still in normal ranges (p<0.01). Furthermore, no correlation was found between disease activation and the procalcitonin levels (p=0.63).

</tbody>
</table>

Statistically significant P values were shown bold. Numerical variables were summarised by median [interquartile range]

Conclusions: Procalcitonin levels were found higher in pSS patients. But, none of the patients had clinically significant increase in procalcitonin. We thought that with careful clinical evaluation, procalcitonin would be an indicator for differentiating infection from disease activation in pSS patients.

NEUROPSYCHIATRIC LUPUS IN A SAMPLE OF EGYPTIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOUS: PREVALENCE AND CLINICAL CHARACTERISTICS

M. Fissa, B.M. Medhat, A. Moghazy. Department of rheumatology and rehabilitation, Cairo University, Cairo, Egypt

Background: Neuropsychiatric (NP) lupus is common among patient with systemic lupus erythematosus (SLE). It occurs in about 30%–56% of all SLE patients. However, the diagnosis of neuropsychiatric SLE (NPSLE) remains difficult. Neuropsychiatric lupus (NPL) can present with a wide variety of clinical manifestations.

Objectives: The aim is to determine prevalence of NPSLE among a sample of Egyptian SLE patients from a single centre and to describe its features and characteristics.

Methods: The study included 301 adult SLE patients from Cairo University Hospital. The patients were classified according to the Systemic Lupus International Collaborative Clinics (SLICC) criteria for SLE. Neuropsychiatric manifestations were recorded using the ACR NPSLE nomenclature and case definitions (1999) Global Disease activity was quantified by the SLE Disease Activity Index 2000 (SLEDAI-2K) at first and at last visit of the patient. Systemic Lupus International Collaborative Clinics/ACR Damage Index (SLICC/ACR-DI) was used to measure damage. The period of data collection took 4 months. The collected data included demographic, clinical, serologic data and medications.

Results: 301 SLE patients (87.4%) females and (12.6%) males with mean age 30.7±9.2 years and disease duration 72 months (2–268) were included. 101 (33.5%) were diagnosed as having NPSLE. The highest NP manifestation in frequency is headache (55.4%) followed by psychosis (33.7%) then seizures (21.8%). NP manifestation is the onset of the disease in 42.6% of all NPSLE patients. Compared to non-NPSLE group, NPSLE group is significantly older at onset of disease and have longer disease duration (p=0.05). They are significantly more active at the onset of the disease than non-NPSLE and have significantly more disease damage (p=0.05). Regarding clinical manifestations of lupus: NPSLE are significantly higher in frequency of discoid rash, cutaneous vasculitis, serositis, secondary anti-phospholipid syndrome (APS), associated avascular necrosis of the joints and osteoporosis (p<0.05). Anti-cardiolipin IgM ant bodies are significantly more frequent in NPSLE group (p<0.05). Notably, frequency of psychosis, superior sagittal thrombosis and cerebrovascular disease were significantly higher in NPSLE with positive APS than those with negative APS (p<0.05).

Conclusions: NPL is common in SLE, its prevalence is about 30% in Egyptian SLE patients. NPSLE patients may present diverse clinical manifestations most commonly headache, psychosis and seizures. NPL is different from non-NPL and presence of APS has an impact on clinical presentation of NP involvement in the patients.

CLINICAL PROFILE OF FILIPINO PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

A.-T.M. Santiago1, M. Tee1, C. Tee2. 1IM-Rheumatology; 2Pediatric Rheumatology, University of the Philippines Philippine General Hospital, Manila, Philippines

Objectives: To determine the clinical profile of Filipino SLE patients when we examined them and their case records, as part of a nationwide genetic study on SLE conducted from October 2015 to March 2017.

Methods: Outpatient and inpatient with connective tissue diseases from Department of Rheumatology of the Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

Background: Plasma Lp-PLA2 has both anti-inflammatory and pro-inflammatory activity in vascular-related pathologies and is an independent risk predictor for coronary heart disease and stroke because of its important role in atherosclerosis and thrombosis. However, vasculitis is a common pathological feature of connective tissue disease.

Objectives: Therefore, the aim of this study was to investigate the association of plasma Lp-PLA2 level with antinuclear antibody (ANA) titer, karyotype, anti-cardiolipid antibody (ACA) and anti-Jo-2/GP1 antibody and lupus anticoagulant (LA, including PT-1gG and PT-1mg).

Methods: Outpatient and inpatient with connective tissue diseases from Department of Rheumatology of the Third Affiliated Hospital of Sun Yat-sen University from 2015 to 2016 were randomly selected. Venous blood was collected, plasma Lp-PLA2 level was measured by Elisa method. ANA titer and karyotype were detected by indirect immunofluorescence assay. ACA, anti-Jo-2/GP1 antibody, PT-1gG and PT-1mg were detected by Elisa method. SPSS23.0 statistical software was used for statistical analysis.

Results: A total of 175 patients with connective tissue disease including 38 males (21.59%) and 138 females (78.41%) were enrolled in this study, and the average age was 42.22±17.31 years. The mean plasma level of Lp-PLA2 was (363.96 ±203.19 ng/ml). There was no significant difference in Lp-PLA2 level between different genders (p=0.072), and Lp-PLA2 level have no correlation with age (p=0.098). The ANA titer were classified as negative (35.80%), weakly positive 1:100 (11.93%), positive 1:100 (18.75%), positive 1:320 (12.50%), positive 1:1000 and positive 1:3200 (9.66%). There was no significant difference in plasma Lp-PLA2 level between different titers of ANA (p=0.088). ANA karyotypes
included nucleolar type (0.88%), centromere type (3.54%), cytoplasm type (7.96%), homogeneity (29.20%) and granularity (58.41%). Also, there was no significant difference in plasma Lp-PLA2 level between different karyotypes (p=0.400). Anti-2GP1 antibodies were classified as negative (<20 U/ml, 91.48%) and positive (>20 U/ml, 8.52%). Plasma Lp-PLA2 level did not differ significantly between anti-2GP1 antibody negative and positive patients (p=0.449). Lupus anticoagulant PT-IgG and PT-IgM were classified as negative (<18 U/ml) and positive (>18 U/ml). PT-IgM were all negative and there was no significant difference in plasma Lp-PLA2 level between PT-IgG negative (96.59%) and positive (3.41%) patients (p=0.279).

Conclusions: Plasma Lp-PLA2 level in patients with connective tissue disease have no significant correlation with age, gender, ANA titer, karyotype, ACA, anti-β2GP1 antibody and LA. The role of plasma Lp-PLA2 in connective tissue disease may be different from APLA.

AB0610 CORRELATION BETWEEN TRADITIONAL CARDIOVASCULAR RISK INDEXES AND ARTERIAL STIFFNESS IN PATIENTS WITH GENERALISED LUPUS ERYTHEMATOSUS

M. Vázquez-Del-Mercado1,2, A. Llamas García1, A. Coldovar-Gabrieli2, E. Gómez-Bañuelos1, D.A. Victoria-Rios, J.J. Lopez-Blasi, K.J. Arrona-Rios1, F.D.J. Perez-Vazquez2, G. Diaz-Rubio2, F. Grover-Paz2. Servicio de Reumatología 004086 PNPC CONACYT, Hospital Civil de Guadalajara Dr. Juan I. Menchaca; Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético; Instituto de Terapéutica Experimental y Clínica, Universidad de Guadalajara, Guadalajara, Mexico

Background: Cardiovascular disease (CVD) is the leading cause of late death in patients with systemic lupus erythematosus (SLE). SLE is related with up to 50 fold risk of CVD. SLE is recognised as an independent cardiovascular risk factor (CVR). However, traditional scales underestimate the CVR in SLE.

Objectives: Determine the correlation between traditional CVR scores (Framingham, systematic coronary risk evaluation (SCORE), atherosclerotic cardiovascular disease (ASCVD) and arterial stiffness (AS)) in an open population of SLE, assessing AS by pulse wave velocity (PWV), vascular damage through cardiovascular risk in SLE.

Methods: Patients with SLE of 18 years old and older, diagnosed according to SLICC 2012 criteria. Informed written consent. AS was determined by PWV, CAVI, ABI, and qIMT. CVR was evaluated by Framingham, SCORE and ASCVD. Correlation between qualitative variables will be done through the X2 test or the Fisher exact test. For comparison of the quantitative variables with normal distribution Student’s T and ANOVA tests were done. The correlation coefficient (r) of Pearson was calculated. Variables with a p<0.2 value were included in a multiple linear regression model to evaluate the influence of the disease variables on CVD risk.

Results: Out of 95 children with cSLE, 48 patients (42 females and 6 males) who attained the age of majority, were included in the study. Mean age at the time of diagnosis was 13.5 years (range 6–18), and the mean disease duration was 11 years. Mean SLEDAI-2K was 19.25 (range 0–42) in childhood and 7125 (range 0–30) in adulthood. In adulthood, thirty-two patients (66.67%) showed improvement, three (6.25%) disease progression, six (12.5%) had the same disease activity and seven patients (14.58%) were in remission. 13 children (27%) had organ damage at the last follow up with mean SDI 0.43 (0–6) and 20 patients in adulthood (41.67%) had organ damage with SDI 0.75 (0–6). Cataract, erosive arthritis and avascular necrosis were the most common organ damage in both groups. The most common presenting symptoms in childhood were musculoskeletal (predominantly arthritis) occurring in 34 children (70.83%), mucocutaneous (rash) noted in 31 (64.58%) and fever in 21 patients (43.75%). Of different laboratory tests the most common were positive antinuclear antibodies (ANA) screen (95.83%) and hypocomplementaemia (75%). Proteinuria was noticed in 26 children (54.17%). Similarly, in adulthood the most common symptoms were arthritis in 20 (80.83%) and rash in 8 patients (16.67%). Alopecia, headaches and visual disturbances were represented with 12.5% each. ANA screen was positive in 27 patients (56.25%) and hypocomplementaemia present in 22 patients (45.83%).

Conclusions: The total of SLE patient were 44 (100%), with a mean age of 34±12 years old. Thirty six women (82%). The mean evolution time was 6±5 years. Smoke was registered in 16% (7 cases). Systolic blood pressure 110±14, diastolic blood pressure 73±11 mmHg. Body mass index 28.4±9.1, total cholesterol 186 ±47, triglycerides 143±67, cHDL 42.9±15, cLDL 57±27 mg/dL. Erythrocyte sedimentation rate of 17±14 mm/br, Reactive protein 7.1±4.8 mg/L. Anti dsDNA antibodies were present in 47.7% of the cases. Secondary antiphospholipid syndrome in 13.6%. Mean SLEDAI 8 (range 0–32), mean SLICC 1 (range 0–6). C3 levels 83.6±21.4, C4 19.5±18.8 mg/dL. The most important correlations found were with qIMT and age 0.651 (p<0.001), BMI 0.513 (p 0.001), cRPr 0.351 (0.033), cLDL 0.400 (0.01), Framingham score was able to predict CVD up to 44.8% the measurement of PWV, ASCVD in 30% and SCORE up to 22%.

Conclusions: Traditional scores (Framingham, SCORE, ASCVD) underestimate cardiovascular risk in patients with SLE. The most important finding is that qIMT was able to correlate more than age, to BMI and cLDL in SLE patients. Disclosure of Interest: None declared

AB0611 DISEASE ACTIVITY AND ORGAN DAMAGE IN PATIENT WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS, FROM CHILDHOOD TO ADULTHOOD: A RETROSPECTIVE STUDY OVER THE LAST 25 YEARS

E. Hosticka1, M. Novoselec1, M. Sestan1, N. Cekada1, M. Ftekovic1, I. Padjen2, M. Sentic2, B. Anic3, M. Jeluscic1. 1Department of Paediatrics; 2Department of Internal Medicine, University Hospital Centre Zagreb, University of Zagreb School of Medicine, Zagreb, Croatia

Background: Although clinical symptoms and immunological findings are common in both children and adults with systemic lupus erythematosus (SLE), children generally have a more severe clinical presentation at the time of diagnosis with a larger number of affected organs, a much more aggressive clinical course and greater chance of developing organ damage over time.

Objectives: To compare the SLEDAI-2K disease activity index in patients with SLE at the time of diagnosis with SLEDAI-2K in the same patients in adulthood and to compare of the SLICC/ACR damage index (SDI) in patients with cSLE at the last follow up in childhood with SLICC/ACR of the same patients in adulthood.

Methods: This retrospective study included children who were diagnosed with cSLE, according to the ACR 1997 and SLICC 2012 criteria, in the period from 1991–2016 at the Referral Centre for Paediatric and Adolescent Rheumatology Republic of Croatia, Department of Paediatrics, University Hospital Centre Zagreb and who by the end of March 2017 reached the age of majority at 18 and continued their treatment at the Department of Internal Medicine, University Hospital Centre Zagreb.

Results: Out of 95 children with cSLE, 48 patients (42 females and 6 males) who attained the age of majority, were included in the study. Mean age at the time of diagnosis was 13.5 years (range 6–18), and the mean disease duration was 11 years. Mean SLEDAI-2K was 19.25 (range 0–42) in childhood and 7125 (range 0–30) in adulthood. In adulthood, thirty-two patients (66.67%) showed improvement, three (6.25%) disease progression, six (12.5%) had the same disease activity and seven patients (14.58%) were in remission. 13 children (27%) had organ damage at the last follow up with mean SDI 0.43 (0–6) and 20 patients in adulthood (41.67%) had organ damage with SDI 0.75 (0–6). Cataract, erosive arthritis and avascular necrosis were the most common organ damage in both groups. The most common presenting symptoms in childhood were musculoskeletal (predominantly arthritis) occurring in 34 children (70.83%), mucocutaneous (rash) noted in 31 (64.58%) and fever in 21 patients (43.75%). Of different laboratory tests the most common were positive antinuclear antibodies (ANA) screen (95.83%) and hypocomplementaemia (75%). Proteinuria was noticed in 26 children (54.17%). Similarly, in adulthood the most common symptoms were arthritis in 10 (20.83%) and rash in 8 patients (16.67%). Alopecia, headaches and visual disturbances were represented with 12.5% each. ANA screen was positive in 27 patients (56.25%) and hypocomplementaemia present in 22 patients (45.83%).

Conclusions: At the time of diagnosis in childhood, disease activity is very high while in adulthood there is a significant decrease in disease activity. Higher disease activity in childhood is related to the development of the organ damage in adulthood.

INFRINGEMENT OF THE BLOOD LIPID SPECTRUM IN CHILDREN AND ADOLESCENTS WITH SLE AND THEIR PREDICTIVE VALUE FOR THE FURTHER COURSE OF THE DISEASE

N.S. Shevechenko 1, 2, L.F. Bogmat 3, I.M. Bessonova 2, 3, V.V. Nikonov 2
1department of pediatrics No2, V. N. Karazin Kharkiv National University;
2department of cardiorheumatology, Institute of Children and Adolescents Health Care;
3department of pediatrics, V. N. Karazin Kharkiv National University, Kharkiv, Ukraine

Background: Infractions of the lipid blood spectrum, or so-called dyslipidemia, are common in adults suffering from SLE and ranges from 36% to 60%.

The aim of the study was to clarify the prognostic importance of the role of storage of metabolic shifts in children with SLE on the background of treatment for the course of the disease.

Methods: A total of 35 people aged 7–18 years with SLE who were ill for more than one year and received complex therapy with glucocorticoids and immunosuppressive drugs were examined. The average age of the patients was 173.56 ±14.17 months; the total duration of the disease was 48.45±3.18 months. General clinical trials included the complex included autoantibodies, disease activity, drugs. Total cholesterol (TCh), triglycerides (TG), high density lipoprotein cholesterol, low-density lipoprotein cholesterol, apolipoprotein B, ApoA-I and lipoprotein-α were evaluated. The state of the blood coagulation system was also studied: fibrinogen of the blood, prothrombin index, thrombin time, active partial thrombin time, d-dimer, international normalised ratio.

Results: The presence of atrogenic dislipoproteinemia in 60.0% of ill children and adolescents on SLE in children and adolescents, disorders in the system of hemostasis in 25.0% was established. The data on the presence of interconnection of blood triglycerides with glomerular filtration rate (n=−0.892; p<0.05) and activity of transaminases (alanine transaminase) (x=0.848; p<0.05).

As a result of multiple regression analysis with step-by-step exclusion of minor variables, serum creatinine serum levels in patients with SLE depend on the level of TG of blood with high predictive accuracy: blood creatinine=−0.0672884 +0.0127034 * TG; R=69.79%; R²=62.34%; p<0.05.

A multivariable regression analysis also proved that the level of circulating immune complexes in patients with SVF significantly depends on the level of total cholesterol, complement and TG by the formula: CIC=1,4442789+0.1889767 * TCh – 1,51503 * complement +0.35538 * TG; R=94.25%; R²=90.02%; p<0.01.

The mean indices of state of the blood coagulation system indices for children and adolescents on SLE in children and adolescents, disorders in the system of hemostasis in 25.0% was established. The data on the presence of interconnection of blood triglycerides with glomerular filtration rate (n=−0.892; p<0.05) and activity of transaminases (alanine transaminase) (x=0.848; p<0.05).

As a result of multiple regression analysis with step-by-step exclusion of minor variables, serum creatinine serum levels in patients with SLE depend on the level of TG of blood with high predictive accuracy: blood creatinine=−0.0672884 +0.0127034 * TG; R=69.79%; R²=62.34%; p<0.05.

* The percentages have been rounding

Conclusions: Europe participate in more than a quarter of Lupus clinical studies and Spain is the third European country participating in those clinical studies. New treatment development studies are the main CT performed worldwide and the percentage is even higher in Spain. Regarding the study phase, the distribution of CT in Europe and Spain are similar although phase I studies in Spain are less frequent.

From all studies registered, the majority are non-industry sponsored studies. In Europe and in Spain the situation is the opposite, as 87.3% of the studies are pharma-sponsored studies.

**AB0615**

**CHANGES IN SOMATOSENSORY EVOKED POTENTIALS IN PATIENTS WITH PRIMARY SJÖGREN’S SYNDROME**

E. Dzialkowski1, A. Sebastian2, M. Wieczorek3, E. Kusinska1, M. Waliszewska-Prostol4, P. Wieland5, E. Jmna1, 1Department of Neurology, 2Department of Rheumatology and Internal Medicine, Wroclaw Medical University, 3Department of Geoinformatics and Cartography, Institute of Geography and Regional Development, Wroclaw, Poland

**Background:** Primary Sjögren’s syndrome (pSS) is a chronic autoimmune disease, which, in addition to impaired function of exocrine glands, can affect other organs including nervous system.

**Objectives:** The aim of the study was to establish whether in patients with pSS without central nervous system (CNS) involvement, the function of the central portion of the sensory pathway can be challenged.

**Methods:** In 33 patients diagnosed with pSS without clinical features of CNS damage and normal head CT scan, somatosensory evoked potentials (SEP) were studied. The results were compared to other clinical parameters of the disease, particularly to immunological status. The control group consisted of 20 healthy volunteers selected with respect to age and sex.

**Results:** Mean latency of all components of SEP were considerably prolonged in patients compared to the control group. Mean interpeak latency N20-P13 (duration of central conduction TT) did not differ significantly between the groups. However, in the study group, mean amplitude of N20P22 and N13P16 was significantly higher compared to healthy individuals. In patients with PSS, significant differences in SEP parameters depending on duration of the disease, duration of arthralgia and presence of SSA and SSB antibodies were noted. No significant differences in mean SEP parameters were observed with respect to skin lesions, xerophthalmia, current joint pain and swelling, focus score, levels of C3 and C4 complement components, ESR, CRP and presence of Ro52 antibodies.

**Conclusions:** The authors confirmed central nervous system involvement often observed in patients with pSS. They also showed dysfunction of the central sensory neuron as a difference in amplitude of cortical response, which indicates subclinical damage to the CNS.

**THE CORRELATION BETWEEN FOCUS SCORE AND ULTRASONOGRAPHY OF MAJOR SALIVARY GLANDS IN PRIMARY SJÖGREN SYNDROME**

A. Sebastian1, J. Sikoci2, A. Halor3, P. Wierd1, 1Department of Rheumatology and Internal Medicine, 2Department of General and Paediatric Radiology, 3Division of Pathomorphology and Clinical Cytology, Department of Pathomorphology, Wroclaw Medical University, Wroclaw, Poland

**Background:** Currently, the role of salivary gland ultrasonography (SGUS) in the diagnosis of primary Sjögren’s syndrome (pSS) is being determined. So far, in none of the proposed classification criteria for pSS SGUS is taken into consideration. The most recent analyses of patients show that SGUS can prove to be useful in the identification of even early forms of pSS.

**Objectives:** We analyzed the SGUS changes in patients with pSS and its correlations with focus score (FS) of major salivary glands and immunological and laboratory profile.

**Methods:** We included 68 patients with pSS in the mean age of 51, based on the classification criteria from 2002.

**Results:** In 33 (48%) patients were abnormal findings in major salivary glands detected (table 1). Scattered hypoechoic changes of different size were the most common observed changes in SGUS, mainly in parotid glands.

**ACROSS-SECTIONAL STUDY OF NAILFOLD MICROVASCULAR CHANGES IN INDIAN PATIENTS WITH RNP+ LUPUS AND MCTD USING NAILFOLD VIDEOCAPILLAROSCOPY**

P.P. Chebbi1, R. goel1, R. althai2, G. mahasampath2, D. danda1, 1Clinical Immunology and Rheumatology, 2Biostatistics, Christian Medical college, Vellore, India

**Background:** Nailfold capillary changes (NFC) may objectively predict the systemic microvascular abnormalities in SLE patients with positive Anti U1-RNP antibody.

**Objectives:** To study nailfold microvascular changes (NFVC) in SLE patients with RNP+ and compare them with NFVC changes observed in patients with RNP negative SLE and Mixed connective tissue disease (MCTD).

**Methods:** Nailfold videocapillaroscopy (NFC) examination (Optilimedscope, 200X) was performed in consecutive patients satisfying classification criteria of...
SLE with or without Anti-U1 RNP positivity. Patients satisfying criteria for MCTD were recruited as disease controls. Individual NFC parameters were analysed by a blinded assessor. Changes in three groups were compared using non-parametric tests. Ordinal logistic or linear regression were used wherever applicable to assess any independent association of NFC changes with disease groups.

**Results:** Total of 81 patients were studied, of which 28 had SLE with RNP+ (age 30.0±10.37; 26 females), 26 had SLE without RNP positivity (age 29.42±9.20; 25 females) and 26 had MCTD (age 37.0±9.86; 25 females). Capillary density was significantly reduced in MCTD as compared to RNP+ SLE patients (5.1±1.69/ mm vs 7.25±1.38/ mm, p=0.001), as well as in RNP+ SLE as compared to RNP negative SLE patients (7.25±1.38/mm vs 8.92±1.13/mm, p=0.001). Conversely, patients with RNP+ SLE had more frequent giant capillaries, enlarged capillaries and ramified/branched capillaries as compared to RNP negative SLE patients (p=0.047, 0.01 and 0.029 respectively). However, there was no statistical difference in number of haemorrhages among these groups. These changes were more severe in patients with MCTD as compared to RNP+ SLE. Ordinal logistic regression showed more severe reduction in capillary density in patients with RNP+ SLE as compared to RNP negative SLE (OR=9.5, p=0.007) independent of the presence of Raynaud’s, ILD and disease duration.

**Conclusions:** Presence of anti-U1 RNP antibody is associated with micro-vascular abnormalities in SLE as detected by NFVC. Patients with MCTD have more profound abnormalities as compared to RNP+ SLE patients.

**Disclosure of Interest:** None declared

**PREVALENCE OF HYPOVITAMINOSIS D IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND THE RELATIONSHIP WITH SLEDAI 2K IN PATIENTS TREATED IN TWO RHEUMATOLOGY SERVICES, BOGOTA 2017**

R.A. Guzman Moreno, L.G. Piñeros, J. Garcia, L.M. Pombo, A. Teheran, J. Bustillo, K.A. Guzman Moreno, V. Cadavid, M.C. Mejía. Inmuno Reumatologia and Internal Medicine, IDEARG. Fundación Universitaria Juan N Corpas, Bogota, Colombia

**Background:** Vitamin D is a steroid hormone with pleiotropic effects on physiological processes. Among others, immune system regulation and their analogues prevent symptom development of autoimmune diseases such as SLE. A previous research in a colombian clinic found a prevalence of hypovitaminosis D of 87% in healthy population, but hypovitaminosis D is higher in SLE patients than healthy controls.

**Objectives:** To establish the prevalence of hypovitaminosis D in patients with SLE and relationship with SLEDAI – 2K.

**Methods:** A cross sectional study was carried out. 80 medical records with a diagnosis of SLE o CIE-10 M30-M36 were identified and we included patients 18 years of age who meet at least 4 of the 11 criteria to diagnoses of SLE for medical record. The analysis included means, DS and Kruskall Wallis with p-value<0.05.

**Results:** The majority of patients are women (94%), with an average age of 39.9 years, married (41%), with secondary education (56.7%) and different occupations. It was found that the patients with higher activity, had lower vitamin D levels. Additionally, if the patient had lupus nephritis, vitamin D levels decreased even more.

**Conclusions:** Patients with active systemic lupus erythematosus, (SLE) have hypovitaminosis D more frequently and we noticed that patients with renal involvement have the lowest levels of vitamin D, which justifies a later analysis.

HIGH RISK OF MISTAKEN CLASSIFICATION OF PRIMARY ANTIPHOSPHOLIPID SYNDROME AS SYSTEMIC LUPUS ERYTHEMATOSUS: ACCORDING TO THE SLICC CRITERIA: ANALYSIS OF A COHORT OF 214 ANTIPHOSPHOLIPID PATIENTS

APHP, PARIS, France

Background: The diagnosis of systemic lupus erythematosus (SLE) is based on the association of clinical and biological manifestations and on clinical experience. In 2012, a major revision by the Systemic Lupus International Collaborating Clinics (SLICC) group sought to improve their sensitivity and specificity. In replications, the SLICC classification produced fewer errors than the previous version; its higher sensitivity but lower specificity meant that some patients could be classified with SLE although they had another disease. In fact, the distinction between PAPS, APS associated with SLE, and isolated SLE may be difficult in some cases because the two diseases share some clinical and biological manifestations.

Objectives: To assess the limitations of the SLICC (Systemic Lupus International Collaborating Clinics) classification criteria for systemic lupus erythematosus (SLE), in patients with primary antiphospholipid syndrome (PAPS).

Methods: Retrospective study of a cohort of APS patients (Sydney criteria). We successively excluded patients with at least one “SLE-specific” manifestation (biopsy-proven SLE nephropathy, arthritis, cutaneous, or neurologic SLE manifestations, pericarditis, autoimmune haemolytic anaemia, oral and nasal ulcers, non-scarring alopecia, and lupus anticoagulant), any other autoimmune connective tissue disease, and/or any antinuclear antibodies>1/320. Careful file review confirmed PAPS among the remaining patients. We then assessed the number of SLICC criteria each patient met.

Results: Among these 214 APS patients, we excluded 85 with at least one SLE-specific manifestation, 8 with another connective tissue disease, and 21 with antinuclear antibodies>1/320, leaving 100 patients with primary APS. Among them, 28% met at least 4 SLICC classification criteria including one clinical and one immunological criterion (antiphospholipid antibodies, aPL, by definition) and could thus theoretically be classified with SLE. Fourteen had an arterial phenotype (50%), 9 a history of catastrophic APS (32%), and 18 a triple-positive profile for aPL (64%). None had developed SLE during a median follow-up of 12 [5.5–17] years.

Conclusions: Because 28% of our patients with longstanding and strictly defined PAPS could be mistakenly classified as SLE, they were at risk of deleterious therapeutic management. We therefore suggest that any future classification for SLE should specifically require at least one SLE-specific criterion for patients with aPL.

EPIDEMIOLOGY, CLINICAL CHARACTERISTICS AND THERAPY APPROACHES OF A RETROSPECTIVE COHORT OF PAEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS IN A TERTIARY CENTRE

R. M. Alcobendas, S.M. Loza, A.R. Camba, C.U. Gascon. Pediatric Rheumatology, university hospital La Paz, Madrid, Spain

Background: Systemic lupus erythematosus (SLE) is a chronic autoimmune disease that involves multiple systems, including the skin, musculoskeletal, renal, neurological, haematologic, cardiovascular and respiratory systems.

Objectives: The aim of this study was to characterise the patients with systemic lupus erythematosus living in Malta, in terms of age of disease onset, BMI, comorbidities, drug history, disease activity, damage and other factors including fatigue, sleep quality, depression, anxiety and vitamin D level.

Methods: The study consisted of a cross-sectional cohort study of all known SLE patients, over the age of 18, living in Malta. 92 patients who fulfilled the SLICC classification criteria for SLE, gave informed consent and an interview was carried out. Fatigue, anxiety, depression, sleep quality and disability were assessed respectively by filling in the following questionnaires: Fatigue Severity Scale (FSS), Hospital Anxiety and Depression Scale (HADS), Pittsburg Sleep Quality Index (PSQI) and modified Health Assessment Questionnaire (mHAQ).

Results: 92.4% of SLE patients studied were female. Table 1 summarises the characteristics of the SLE patients. 23.9% of SLE patients were in remission (SLEDAI-2K 0), while 52.2% had a low disease activity (SLEDAI-2K 1–5) at the time of the interview. 20.7% and 3.3% had a moderate (SLEDAI-2K 6–10) and high (SLEDAI-2K 11–19) disease activity respectively. A significant negative correlation was noted between function measured by mHAQ and SLEDAI (R=0.417, p=0.000). 56.5% were noted to have an abnormally high level of fatigue (FSS >3.7), 6.5% were noted to have depression (HADS D>10) and 35.9% had anxiety (HADS A>10). 55.4% were noted to have poor sleep quality (PSQI >5) and 26.1% had an abnormal level of function (mHAQ >0.3). 15.2% were found to have vitamin D deficiency and 27.2% were vitamin D insufficient.

CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN MALTA: A POPULATION BASED CROSS-SECTIONAL COHORT STUDY

R. Magro, A.A. Borg. Rheumatology, Mater Dei Hospital, Msida, Malta

Background: Systemic Lupus Erythematosus (SLE) is an autoimmune disorder that involves multiple systems, including the skin, musculoskeletal, renal, neurological, haematologic, cardiovascular and respiratory systems.

Objectives: The aim of this study was to characterise the patients with systemic lupus erythematosus living in Malta, in terms of age of disease onset, BMI, comorbidities, drug history, disease activity, damage and other factors including fatigue, sleep quality, depression, anxiety and vitamin D level.

Methods: The study consisted of a cross-sectional cohort study of all known SLE patients, over the age of 18, living in Malta. 92 patients who fulfilled the SLICC classification criteria for SLE, gave informed consent and an interview was carried out. Fatigue, anxiety, depression, sleep quality and disability were assessed respectively by filling in the following questionnaires: Fatigue Severity Scale (FSS), Hospital Anxiety and Depression Scale (HADS), Pittsburgh Sleep Quality Index (PSQI) and modified Health Assessment Questionnaire (mHAQ).

Results: During the study period, 38 patients were identified (ratio female: male: 3/1). The mean age at the onset of disease was 11.5 years (range 6–17). All had (caucasian origins, except 5 coming from South America, 2 from India and 1 from Africa. Onset of the disease took place in spring in 22 (58%) patients, while in 10 (26%) patients onset was in summer, 5 (13%) in autumn and only one (3%) in winter season.

The most frequently clinical manifestations found at the debut were cutaneous involvement (66%, predominantly in the form of a malar rash), renal (65%) and joint (60%, 46% arthralgia and 52% polyarthralysis). Other manifestations were fever (50%), cytopenias (39%), asthenia (36%), serositis and neurological clinic (both deep vein thrombosis in the lower limbs).

Regarding treatment, all patients required corticosteroids. Therapy with acetylsali- cylic acid was indicated in all patients with APS-associated immunology. Only 6 patients received treatment with corticosteroids and hydroxychloroquine exclusively. Nineteen (50%) patients initially received azathioprine therapy, being necessary to switch to mycophenolate mofetil for lack of response in eleven, receiving the last treatment 20 patients finally (52%). Eighteen patients (47%) received cyclophosphamide therapy, 16 of them as a consequence of their renal involvement. In addition, biologic therapy (ruximab and belimumab, respectively) was used in two refractory patients.

Conclusions: As widely already reported, SLE is a disease that affects predomi- nantly women. Moreover, as it has been previously described in the literature the most frequently initial manifestations found in c-SLE are cutaneous, renal and articular. However, a large variability of onset symptoms exists, thus c-SLE should be ruled out in patients with multisystemic involvement.

Disclosure of Interest: None declared

Conclusions: This is the first population based study on SLE to be carried out in Malta. The prevalence of SLE in Malta is estimated to be 25.5 patients per 100,000 and the estimated incidence is 1.05 patients per 100,000 per year. A high frequency of obesity and vitamin D deficiency and insufficiency were noted in SLE patients. Other unmet needs include an uncontrolled disease activity, fatigue, poor sleep quality and anxiety.

PREGNANCY OUTCOME IN SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY

R Dumitru1, C. Vasiliu2. 1Infertility and gonadal pathology, National Institute of Endocrinology „C.I. Parhon“; 2Obstetrics and Gynecology, Bucharest Emergency University Hospital, Bucharest, Romania

Background: Pregnancy represents a challenge for patients with systemic lupus erythematosus. One of the major risk is the occurrence of a flares during pregnancy. The influence are mutual, and the risk of complications depend mostly on the disease activity in the last 6–12 months before pregnancy. Therefore, these patients need a multidisciplinary approach, the obstetrician should collaborate with the rheumatologist and nephrologist.

Objectives: To determine the associations between disease activity and pregnancy outcomes, and the risks factors that predict pregnancy complications and flares.

Methods: We present a retrospective study conducted between January 2010 and December 2015. We enrolled 35 pregnant patients, diagnosed with SLE with flare.

Results: Of 569 patients 92.6% were females and 4.7% males with mean age at diagnosis 24.6 years. The majority of SLE patients had more severe dyslipidemia. The blood TG, TC, LDL, ApoB levels were positively correlated to serum creatinine, urea nitrogen, uric acid. The blood levels of TG, TC, LDL, ApoB were positively correlated to serum total protein, albumin, globulin. The level of serum ANGPTL4 was positively correlated to HDL and ApoA1 as well as sTNFRA and sTNFRB with TG.

Conclusions: Dyslipidemia in SLE was significantly correlated with SLEDAI and kidney involvement. The circulating levels of sTNFRA, sTNFRB and ANGPTL4 were associated with dyslipidemia in SLE.

Disclosure of Interest: None declared

SYSTEMIC LUPUS ERYTHEMATOSUS IN EGYPTIAN COHORT OF PATIENTS: A MULTICENTER STUDY

S.A. Elbakry1, N. Alfiri2, S.A. Hussein3, N. Mohmannad3, I.H. Bassouyni3, N.F. Abou Eleze3. 1Department of internal Medicine-Rheumatology Division, Ain Shams University-Cairo-Egypt, Cairo; 2Department of internal Medicine-Rheumatology Division, Alexandria University Hospitals-Alexandria, Alexandria; 3Rheumatology and Rehabilitation Department; Faculty of Medicine, Cairo University; 4Community and Public Health Department Faculty of Medicine, Ain Shams University-Cairo-Egypt, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease that mainly affects females in the reproductive age. The disease presents with a diverse spectrum of clinical and immunological manifestations which has been studied in many countries and ethnic groups. Data from North Africa especially Egypt are minimal.

Objectives: To study the clinical and immunological characteristics of an Egyptian cohort with SLE and compare it with data from MENA region and international data.

Methods: In this retrospective study, data of 569 SLE patients who fulfilled the modified American College of Rheumatology (ACR) criteria for the diagnosis of SLE were collected from three tertiary care centres in Cairo and Alexandria from the period of January 2014 to December 2017. Disease activity was assessed by using the SLE disease activity index (SLEDAI). The data collected included serum lipid (TG, TC, LDL, HDL, ApoA1, ApoB), renal function (proteinuria, albuminuria, creatinine, blood urea nitrogen, uric acid), liver function (Alanine transaminase [ALT], glutamic oxalacetic transaminase [AST]), total protein, albumin, globulin, blood system (lymphocyte, white blood cell [WBC], platelet[PLT], haemoglobin[HB]).

Results: Compared with the healthy controls, the level of serum TG, TC, LDL, ApoB were significantly increased, while HDL and ApoA1 were decreased. The serum levels of LDL and ApoB were positively correlated to SLEDAI, while HDL and ApoA1 were negatively correlated to SLEDAI. The patients with lupus nephritis had more severe dyslipidemia. The blood TG, TC, LDL, ApoB levels were positively correlated to serum creatinine, urea nitrogen, uric acid. The blood levels of TG, TC, LDL, ApoB were positively correlated to serum total protein, albumin, globulin. The level of serum ANGPTL4 was positively correlated to HDL and ApoA1 as well as sTNFRA and sTNFRB with TG.

Conclusions: Dyslipidemia in SLE was significantly correlated with SLEDAI and kidney involvement. The circulated levels of sTNFRA, sTNFRB and ANGPTL4 were associated with dyslipidemia in SLE.

Disclosure of Interest: None declared

DYSLIPIDEMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS: CORRELATION WITH DISEASE SEVERITY AND CYTOKINES

S. Huang1, Z. Zhang2, on behalf of Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, S. Wu1, J. Qi1, D. Wang1, G. Yao1, L. Sun3.

Department of Rheumatology and Immunology, Drum Tower Clinical Medical College of Nanjing Medical University, Nanjing, China

Objectives: The patients with systemic lupus erythmatosus (SLE) are obviously at high risk of cardiovascular disease (CVD) and the relationships between disturbed lipid metabolism and lupus activity remain to be elucidated. We evaluated dyslipidemia in association with disease severity, organ involvement and cytokines in patients with SLE.

Methods: Outpatients with SLE (n=105) and healthy controls (n=75) were recruited in this study. The concentrations of plasma tumour necrosis factor receptor factors A(sTNFRA), tumour necrosis factor receptors B(sTNFRB) and adipokine angiopeptin-like 4 (ANGPTL4) were measured by ELISA. The clinic and laboratory data were collected from patient records using electronic data processing. The data collected included serum lipid (TG, TC, LDL, HDL, ApoA1, ApoB), renal function (proteinuria, albuminuria, creatinine, blood urea nitrogen, uric acid), liver function (Alanine transaminase [ALT], glutamic oxalacetic transaminase [AST]), total protein, albumin, globulin, blood system (lymphocyte, white blood cell [WBC], platelet[PLT], haemoglobin[HB]).

Results: Compared with the healthy controls, the level of serum TG, TC, LDL, ApoB were significantly increased, while HDL and ApoA1 were decreased. The serum levels of LDL and ApoB were positively correlated to SLEDAI, while HDL and ApoA1 were negatively correlated to SLEDAI. The patients with lupus nephritis had more severe dyslipidemia. The blood TG, TC, LDL, ApoB levels were positively correlated to serum creatinine, urea nitrogen, uric acid. The blood levels of TG, TC, LDL, ApoB were positively correlated to serum total protein, albumin, globulin. The level of serum ANGPTL4 was positively correlated to HDL and ApoA1 as well as sTNFRA and sTNFRB with TG.

Conclusions: Dyslipidemia in SLE was significantly correlated with SLEDAI and kidney involvement. The circulated levels of sTNFRA, sTNFRB and ANGPTL4 were associated with dyslipidemia in SLE.

SYSTEMIC LUPUS ERYTHEMATOSUS IN EGYPTIAN COHORT OF PATIENTS: A MULTICENTER STUDY

S.A. Elbakry1, N. Alfiri1, S.A. Hussein3, N. Mohmannad3, I.H. Bassouyni3, N.F. Abou Eleze3. 1Department of internal Medicine-Rheumatology Division, Ain Shams University-Cairo-Egypt, Cairo; 2Department of internal Medicine-Rheumatology Division, Alexandria University Hospitals-Alexandria, Alexandria; 3Rheumatology and Rehabilitation Department; Faculty of Medicine, Cairo University; 4Community and Public Health Department Faculty of Medicine, Ain Shams University-Cairo-Egypt, Cairo, Egypt

Background: Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease that mainly affects females in the reproductive age. The disease presents with a diverse spectrum of clinical and immunological manifestations which has been studied in many countries and ethnic groups. Data from North Africa especially Egypt are minimal.

Objectives: To study the clinical and immunological characteristics of an Egyptian cohort with SLE and compare it with data from MENA region and international data.

Methods: In this retrospective study, data of 569 SLE patients who fulfilled the modified American College of Rheumatology (ACR) criteria for the diagnosis of SLE were collected from three tertiary care centres in Cairo and Alexandria from the period of January 2014 to December 2017. Disease activity was assessed by using the SLE disease activity index (SLEDAI).

Results: Of 569 patients 92.6%were females and 4.7% males with mean age at presentation 26.3±8.8 years and median disease duration four years (min 0.08–max 30 years). The main presenting symptom was musculoskeletal (arthritis/ arthralgia) in 44.1% followed by fever in 39.4% and nephritis in 14.2%. Renal affection was present in 374 patients (65.7%) and renal biopsy was done in 268 patients with the most common is class III and IV lupus nephritis (18.3% and 14.1% respectively) (table 1). Antinuclear antibodies (ANA) was positive in all patients and immunofluorescence pattern was done in 256 patients; homogeneous
pattern was the most common followed by speckled (29.9% and 13.4% respectively). Anticardiolipin antibodies was positive in 71.2% while lupus anticoagulant was detected in 50.8% (table 2). Mean SLEDAI was 13.38±9.75 with proteinuria in 58.9%, increased binding to DNA in 54.9% and low complement in 45.5%.

CLINICAL FEATURES OF SYSTEMIC LUPUS ERYTHEMATOSUS IN MALES

S. Sayhi, T. Ben Achour, N. Bousssetta, B. Arlaoui, N.E.H. Gueddich, F. Ajji, B. Louzir, on behalf of research unit UR 17DN02. Internal medicine, Military hospital, Tunis, Tunisia

Background: Systemic lupus erythematosus (SLE) is an autoimmune disease that primarily affects the adult woman. Male involvement is rare.

We report a series of men with systemic lupus in order to specify the particularities of the different manifestations of SLE in men.

Objectives: we aim to describe the clinical feature of male tunisien patients presenting SLE

Methods: This is a retrospective study of male lupus patients hospitalised in internal medicine for a period of 9 years. All patients are Tunisian and meet the lupus criteria established by the ACR.

Results: Twenty-one patients with male lupus were enrolled in a total of 97 systemic lupus (gender-to-sex ratio 3.6). The mean age at diagnosis was 34 years (range: 14 to 84 years). A family lupus in one case. The clinical manifestations are dominated by joint damage (95%) with non-erosive arthritis in 9 cases and arthralgia in 12 cases, followed by cutaneous manifestations (erythema vespertilo=71%, photosensitivity=41%, Raynaud (25%). Pericarditis was found in 37.5% and pleurisy in 23%. Venous thrombosis was only observed in 4 cases associated with anti-cardiolipin antibodies in one case, and complicated by pulmonary embolism in one case. Sixteen patients had progressive nephropathy (permanent proteinuria >0.5g/24 hours with mean proteinuria of 3.2g/24 hours and extremes of 0.7 and 8g/24 hours) of which 9 underwent kidney biopsy puncture. Membranoproliferative glomerulonephritis was observed in 4 cases, segmental and focal in 3 cases, mesangial and extramembranous, each in one case. Two patients had progressed to end-stage renal disease requiring hemodialysis. Concerning haematological involvement, anaemia, observed in 50% of cases, was haemolytic in 12.5% of cases. Leukopenia and lymphopenia were each scored in 46% of cases. Sixteen patients 16 were put on chloroquine, all patients were placed on high dose corticosteroids for an average of 25 months with boli in 7 cases, combined with cyclophosphamide (700 mg/month IV) in 4 patients cases in patients with proliferative glomerulonephritis. The evolution was enamelled with flares in 11 cases, 2 of which had progressed to end-stage renal failure. Aspetic osteonecrosis of the femoral head was observed in one patient after 1 year of corticosteroid therapy. Complete remission was observed in 3 patients with a follow-up of 14, 24, and 144 months and one patient died as a result of peritonitis.

Conclusions: Systemic lupus is a disease essentially of adult women and rarely affects humans. The prevalence of the disease in the female gender suggests the intervention of a hormonal factor. In favour of the deleterious role of estrogens, lupus relapses are triggered by pregnancy, the peri and postpartum, as well as the oestroprogestative pill. The most common manifestations in humans in our study were renal impairment including membranoproliferative glomerulonephritis and segmental and focal glomerulonephritis complicated by renal failure in two patients. These data join those of the literature. The same is true for hemolytic anaemia.

LES is rare in men, nevertheless it correlates with a higher mortality in front of the association most frequent with the renal involvement which imposes a better knowledge of these clinical and laboratory particularities.

PHYSICAL ACTIVITY BY SELF-REPORTED PHYSICAL ACTIVITY AND LUPUS NEPHRITIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S.-K. Kim, J.-Y. Choe, S.-H. Park, H. Lee. Catholic University of Daegu School of Medicine, Daegu, Korea, Republic of Ireland

Background: Physical activity is found to be associated with clinical status such as disease activity, organ damage, disability, fatigue, and quality of life in systemic lupus erythematosus (SLE).

Objectives: The aim of this study was to identify the association between physical activity and disease activity and organ damage in patients with SLE.

Methods: A total of 415 patients with SLE were consecutively enrolled from KOREan lupus Network (KORNET) registry. This registry assessed clinical features, disease activity Systemic Lupus Erythematosus Disease Activity Index 2000 [SLEDAI-2K], and disease damage (Systemic Lupus International Collabo rating Clinics/American College of Rheumatology [SLICC/ACR] damage index [SDI]) at the enrollment of study. Self-reported physical activity was measured by International Physical Activity Questionnaire (IPAQ). Statistical analyses were used by Mann-Whitney U test and multivariate logistic regression analysis.

Results: There is significant difference of vigour activity between patients with lupus nephritis (n=93) and without lupus nephritis (n=322) (p=0.012), but not moderate and walking activities. In contrast, the differences of each physical activity,
walking, moderate, and vigorous intensity, according to SLEDAI-2K and SDI were not found. In addition to high PCS of SF-36 (p=0.006) and SLEDAI-2K (p=0.038), less vigorous physical activity were related with lupus nephritis (p=0.033). However, the risk of CVD was not associated with physical activity of SLE.

Conclusions: This study showed that lupus nephritis had less vigorous physical activity. It implicates that SLE-related organ damage might be associated with levels of physical activity.

AB0629 INFECTIONS IN HOSPITALISED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A PROSPECTIVE OBSERVATIONAL STUDY FROM A TERTIARY CARE CENTRE IN SOUTHERN INDIA
S. Alur1, M.M. Thabań2, V.S. Negi1, S. Sistia3, Medicine; 2Clinical Immunology; 3Microbiology, Jawaharlal Institute of Post Graduate Medical Education and Research, Puducherry, India

Background: Infections are one of the main causes of morbidity and mortality in SLE. The high prevalence of infection is attributed to use of immunosuppressive agents and disease activity. There is paucity of literature from India on infections, types of infections, predictors and outcome.

Objectives: To determine the frequency, types and determinants of major infections in hospitalised patients with SLE.

Methods: Patients with SLE (2012 SLICC-ACR criteria) aged >13 years, admitted to Clinical Immunology and Medicine wards were included. Clinical evaluation for major organ involvement of SLE, disease activity was assessed by SLEDAI-2K. Whenever there was a suspicion of infection appropriate work up to find the etiology of infections was done. Major infection was defined as presence of either one of the following a) sepsis b) pneumonia, or pyelonephritis, or endocarditis, or meningitis. c) skin or soft tissue infection requiring hospital admission for treatment d) Infection requiring IV antibiotic therapy. The diagnosis of infection was made by compatible clinical, microbiological and imaging criteria.

Results: From December 2016 till January 2018, 63 (55 women and 8 men) were included; Mean age was 28.8±9.8 years; mean SLEDAI-2K was 14.6±7.03. Median duration of hospital stay was 14 days; range 2–64 days. Disease manifestation (including present and ever present) were arthritis/arthritis in 51 (81%), skin disease 56 (88.9%), myositis 10 (15.9%), lupus nephritis 35 (55.6%), CNS lupus 14 (22.2%), serositis 14 (22.2%), cardiac involvement 13 (20.6%), APS 3 (4.8%). At the time of enrollment thrombocytopenia was present in 13 (20.6%), and leukopenia 11 (17.5%). Twenty-three of 63 (36.5%) had infections (table 1), 14/23 (60.8) were microbiologically proven, remaining (39.2%) were confirmed by compatible clinical features and imaging.

Seven of 63 (11.1%) died; 5 (21.7%) in the infection group versus 2 (5%) in no infection group, p=0.08 OR 5.58 [CI 0.98–31.7]. Thirty-four of 63 (54%) had fever on admission; 17/23 (74%) patients with infection had fever compared to 17/40 (42.5%) in no infection group, p=0.02 [OR=3.8, CI 1.2–11.7]. There was no association of lupus nephritis, CNS lupus, leukopenia, receipt of cyclophosphamide, rituximab, methylprednisolone pulse therapy with occurrence of infection.

AB0629 PREVALENCE OF ASYMPTOMATIC VERTEBRAL FRACTURES IN POSTMENOPAUSAL WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS
S. Shkireeva1, 2, O.M. Lesnyak1, E.G. Zotkin2. 1North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg; 2Research Institute of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation

Objectives: To investigate the prevalence of vertebral fractures and to identify risk factors associated with vertebral fractures in postmenopausal women with systemic lupus erythematosus (SLE).

Methods: 86 consecutive postmenopausal women with SLE were included in this study. Bone mineral density (BMD) measurements of the hip and spine were performed using the dual energy X-ray absorptiometry (DEXA). Vertebral fracture assessment (VFA) was done for detection vertebral fractures using a method described by Genant. Accumulated damage was scored using the SLIC/ACR damage index (SDI).

Results: Vertebral fractures were defined in 42 (48.8%) postmenopausal women with SLE. Half of all patients with SLE (n=22, 25.6%) had asymptomatic vertebral fractures which were diagnosed only in this study. Every patient had 1.7 vertebral fractures on average (from 0 to 4). Distribution of vertebral fractures along the spine showed one peak at Th7. Univariate analyses of variables associated with fractures were longer duration of postmenopausal status in women with SLE, longer glucocorticoid intake, higher cumulative dose of glucocorticoids, lower SDI, lower BMD of the spine. Multivariate analysis showed longer duration of postmenopausal status in women with SLE (odds ratio 4.05, p=0.007), cumulative dose of glucocorticoids ≥60000 mg of prednisone (odds ratio 3.68, p=0.009), SDI ≥7 (odds ratio 2.94, p=0.028) and low BMD (T-score ≥−2.0) of the spine (odds ratio 2.48, p=0.015) were significantly associated with vertebral fractures in the thoracic and/or lumbar spine.

Conclusions: Vertebral fractures were occurred in 48.8% of postmenopausal women with SLE and half of them were asymptomatic. The current method using DEXA to predict the presence of vertebral fracture has limited value and there is a need for assessment of bone quality. Vertebral morphometry in patients with SLE is recommended and early therapeutic intervention is necessary to prevent vertebral fractures in postmenopausal women with SLE.

AB0630 EXPRESSION OF TNF-Α AND IL-6 IN SYSTEMIC LUPUS ERYTHEMATOSUS: RELATIONSHIP WITH DISEASE ACTIVITY
T.A. Pansikina, T.V. Popkova, A.A. Novikov, E.L. Nasonov. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Cytokines play an important role in the pathogenesis of SLE. TNF-α, IL-6 are the cytokines with suggested proinflammatory and immunoregulatory actions in the pathogenesis of SLE with differential effects on B or T cells, as well as on programmed cell death. Fas/APO-1 and Fas ligand (FasL) are involved in the apoptosis. FasL is a marker of apoptosis, it induces cell apoptosis when binds to Fas/APO-1. Both are expressed in membrane-associated and soluble forms (sFas/APO-1 and sFasL), sFasL/APO-1 is known to inhibit the apoptosis via blocking the binding of Fas/APO-1 to FasLs/FasLs.

Objectives: We evaluated the levels of IL-6 and TNF-α and their possible association with disease activity, apoptosis markers.

Methods: The study included 52pts (89% female, age 30.0 [26.5–44.5] years (median [interquartile range 25–75%])) with SLE ACR, 1997 and 20 controls (100% female without any rheumatic and infectious diseases, age 30.0 [25.0–39.5] years). SLE-related factors, including disease duration, clinical features, SLE Disease Activity Index (SLEDAI 2K) and Systemic Lupus International Collaborating Clinics (SLICC) damage index were evaluated in parallel with relevant laboratory findings, autoantibodies. Serum levels of IL-6 and TNF-α (pg/ml), sFas/
IS HYPERHOMOCYSTEINEMIA (HHC) ADDITIONAL RISK FACTORS OF PRIMARY APS DOMAINS EVALUATION OF PRIMARY ANTI PHOSPHOLIPID SYNDROME

T.M. Reshetnyak1,2, N.V. Seredavkina1, E.L. Nasonov1, L.I. Patrushev3. Vascular Rheumatology, V.A. Nasonova Research Institute of Rheumatology, Russian Medical Academy of Postgraduate Education, 2Shemyakin-Ovchinnikov Institute of Biogenic Chemistry of RAS, Moscow, Russian Federation

Background: HHC may be additional factor of thrombosis in SLE patients

Objectives: To assess the role of HHC as additional risk factors in development of vascular complications in SLE and antiphospholipid syndrome (APS).

Methods: A total of 125 patients (24 M and 101 F, mean age 38±13 years and the disease duration 14±11 years) were divided into three groups: 1 group – SLE patients (n=51); group 2 – SLE + APS patients (n=49); group 3 – primary APS patients (n=25). Homocystein (Hc) was assayed by high performance liquid chromatography. DNA diagnostics by the method of polymerase chain reaction was used to determine gene mutation C677T methylenetetrahydrofolate (MTHFR) reductase in 93 out of 125 patients.

Results: Hc (HC >15 mcg/L) was diagnosed in 82 of 125 (66%) patients: in 39 of 51 (76%) SLE patients (p<0.01) and in 53 of 74 (71.6%) SLE + APS patients (n=49) vs. 10 of 25 (40%) primary APS patients (n=25), 0.001). Elevated level of Hc was registered in 43 of 55 (78%) SLE patients with thromboses vs. 9 of 19 (47%) aPL-positive SLE patients without thromboses (p=0.03). HC occurred significantly more frequently in patients with arterial thromboses (in all 14 patients) than in patients with venous thromboses – in 16 of 23 (69.9%) pts (p=0.03) and in the absence of thromboses (p=0.04). HHC was associated with thromboses of cerebral (in 90%), peripheral arteries (in 84%) and myocardial infarction (in 79%) vs. 47% of patients without thromboses (p=0.005; p=0.04, p=0.04 respectively). Mutation of C677T MTHFR was in 33.3% of SLE patients, in 57.7% – of SLE +APS and in 63.2% – PAPS. Mutation C677T in the gene MTHFR was detected in 57% of examined patients, 20% of them had homozygous variant and 80% are heterozygous. Patients with a homozygous C677T MTHFR gene were at risk of developing arterial thrombosis.

Conclusions: More than 50% APS pts had elevated level of HC as additional, thrombogenic factors. Correlation between HHC and APS, primarily arterial, in APS patients gives grounds for the role of HHC in development of vascular complications in SLE and APS pts.
AB0633

MEASURING WHAT MATTERS TO LUPUS PATIENTS: TRANSLATING PATIENT VIEWS INTO NOVEL PATIENT-REPORTED OUTCOMES

S. Cleanthous1, A. Regnaut6, M. Schneider9, C. Gordon4, S. Bartlett5, S. Cano1, T. Morel10; 1Modus Outcomes, Cambridge, UK; 2Modus Outcomes, Lyon, France; 3Policlinic and Hiller Research Unit of Rheumatology, UKD, Heinrich-Heine-University, Düsseldorf, Germany; 4University of Birmingham, Birmingham, UK; 5McGill University, Montreal, Canada; 6UCB Pharma, Brussels, Belgium

Background: The 2010 U.S. FDA guidance1 on systemic lupus erythematosus (SLE) acknowledged that improvements in clinical outcome measures in patients with SLE may not always translate to improvements in how patients feel or function and encourages the use of patient-reported outcome instruments (PROs) to assess changes in outcomes that matter most to patients. Fatigue, identified by patients as their chief complaint during the Lupus Patient-Focused Drug Development (PFDD) meeting2, is not optimally measured by existing PROs3. There is a need for new patient-centred outcome measures as they are pivotal to PFDD. To address this, UCB has been conducting a multi-faceted, patient-centric, mixed methods research programme including evidence generated from >2100 SLE patients.

Objectives: There were three main objectives of the programme: 1) identify what concepts are most important to measure for SLE patients when evaluating treatment benefit; 2) critically evaluate the extent to which these concepts are captured by existing PROs; and 3) explore the opportunity to develop and evaluate new conceptually-based PROs in SLE.

Methods: There were three stages: 1) development of a preliminary treatment benefit conceptual model related to SLE including disease symptoms and impacts (generated from literature review, and patient and clinician input); 2) formal comparison of i) the conceptual model and the content validity (qualitative review) of existing SLE PROs and ii) psychometric properties (ie. SF-36, FACIT-F, and LupusQoL in the discontinued EMBOBY Phase 3 studies for epratuzimab); 3) development of new conceptually-based PROs in SLE (figure 1).

Results: A preliminary treatment benefit conceptual model in SLE was developed. Among the many symptoms and disease impacts reported by SLE patients, physical fatigue, mental fatigue (‘brain fog’), sudden fatigability, joint/muscle stiffness and pain, skin symptoms and mobility difficulties featured as most troublesome. The content validity of 10 widely used PROs was found to be limited when compared to this conceptual model. Psychometric analysis (based on Rasch Measurement Theory) confirmed the limitations of the SLE PROs used in the EMBOBY studies and suggested post-hoc reconceptualisation would improve the ability of the scales to detect clinical change. This led to the development of five new conceptually-based SLE PROs (ie. fatigue, pain, mobility, symptom severity, and emotional state), which are currently being explored in >500 SLE patients in a Phase 2b dapirolizumab pegol study (NCT02840765) and two cross-sectional, non-interventional, observational studies. Data on the new PROs are currently being assessed at several sites in the USA, Latin America, UK and Germany and will be available in the coming months.

Conclusions: New, well-defined and reliable PROs to better capture the patient perceptions of the symptoms and impact of SLE are needed. UCB has developed five new PROs which offer the promise of improved patient-centred outcome measurements in SLE and other autoimmune diseases.

CHARACTERISATION OF SLE PATIENTS WHO UNDERWENT CARDIOVASCULAR SURGERY

T. Kawamoto1, S. Matsushita2, H. Amano1, K. Minowa1, Y. Asai1, K. Yamaji1, A. Amano1, N. Tamura1. 1Internal medicine and rheumatology, Cardiovascular Surgery, Juntendo University School of Medicine, Tokyo, Japan

Background: SLE is characterised by alternate occurrences of flares and remissions throughout its course. During these flares, immune complexes are excessively produced and deposited in affected tissues. Previous reports suggest that immune complexes deposited in the blood vessels, atrioventricular valves, and heart tissue may require heart surgery. Although, the characteristics of patients in whom tissue injuries progress and ultimately require surgery have not been clarified.

Objectives: Heart diseases are categorised in valvular disease, ischaemic heart disease, and aortic aneurysm. This study was conducted to determine whether there was a correlation between the activity of SLE and the progress and aggravation of heart disease in each category.

Methods: Of the 2707 patients who were diagnosed with SLE at Juntendo University Hospital from 2012–2017, 35 underwent cardiac surgery. Six patients met the exclusion criteria, and thus, 29 patients were included. Patients with infectious endocarditis and those in whom SLE had not been diagnosed prior to surgery were excluded. Indices for SLE activity were anti-DNA Ab and CH50. Peak and bottom values of these indices before surgery were recorded, and the values obtained during the pre-surgery 180 day period were compared with those that had been determined prior to this period.

Results: The mean disease duration at the time of cardiac surgery was 24.2 years. The cardiac diseases were heart valve disease (V) in 10, ischaemic heart disease (I) in 7, and aortic aneurysm (A) in 12 patients. The integrated values obtained by the activity indices, anti-DNA Ab, and disease duration were 14 020 for V, 32 966 for I, and 29 444 for A. Thus, there was a tendency for values to be slightly lower in the heart valve disease category. The peak/bottom values for CH50 and anti-DNA Ab in the pre-surgery 180 day period were different from those obtained prior to this period. Investigation of anti-phospholipid antibodies indicated that the rates of positive result for either aCLβ2GPI, anti-CL antibodies, or LA were 60% for V, 28% for I, and 33% for A, and thus, higher in the heart valve disease category. All patients were treated with steroids, and five patients (17.2%) of the 29 used immunosuppressants. This rate tended to be lower than the previous frequency of the combined use of immunosuppressive drugs at our hospital (onset: 18.4%, first flare 33.3%).

Conclusions: There is a possibility that the long-term duration of SLE may lead to cardiac disease requiring surgery. The integrated value for DNA Ab was lower in the heart valve disease category; therefore, the presence of anti-phospholipid antibodies may be a risk factor for valvular disease. The low frequency of combined use of immunosuppressants in SLE patients with cardiovascular manifestations requiring surgery, suggest the possibility that treatment with a single steroid may require heart surgery.

AB0635 ANTI-PHOSPHOLIPID ANTIBODIES IN LUPUS MYOCARDITIS

V. Dhir1, A. Gawalkar1, J. Aihuwala2, A. Bahl2, S. Sharma3, A. Sharma3, S. Jain1.
1Internal Medicine (Rheumatology Unit); 2Hematology; 3Cardiology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

Background: Myocarditis in lupus is an uncommon clinical manifestation, with unknown pathogenesis.1 Suggested etiologies include Immune-complexes, cell mediated damage and anti-phospholipid antibodies. The latter may affect the myocardial function microthrombi in cardiac vessels or direct cytotoxicity.2 Previ-ously, small studies have suggested an association between antiphospholipid tests as myocarditis.

Objectives: To evaluate whether myocarditis in SLE is associated with antiphos-pholipid positivity.

Methods: This was a cross-sectional study in which patients fulfilling SLICC criteria 2012 for SLE or Alarcon Segovia criteria for MCTD were included after consent. Patients were recruited as ‘Cases’ if they had myocarditis/cardiomopathy defined by poor generalised contractility and/or dilation of all chambers or reduced ejection fraction on echocardiography without any obvious cause. Those with regional wall motion abnormalities or pulmonary artery hypertension (moderate or severe) were excluded. Controls were age (±2.5 years) and disease duration (±25%) matched patients of SLE without any abnormality on echocardiography. Serum titers of anticardiolipin antibodies and b2 GP1 (both IgG and IGM) were measured by commercial ELISA kit. Lupus anticoagulant was detected by Dilute Russell Viper Venom Test (dRVVT) with both screening (prolonged) and confirmation steps (shortening on higher phospholipid content, ratio >1.2) on doubly centrifuged, platelet poor plasma. Proportions were compared using chi-square test (or Fischers exact test) and continuous variables by Mann-Whitney U test.

Results: A total of 51 patients were recruited in this study that included 21 cases and 30 controls. All had SLE, except 1 case was of MCTD (among cases). There was no difference in mean ±SD age (33.3±14.7, 32.8±12.4 years, p=0.9) or median (interquartile range) disease duration (30.4–45.6 vs 15.3–45 months, p=0.6) between groups. Mean ejection fraction of Cases was 31.7% (±9.3%) while controls was 30.3% (±8.3%). Disease activity cSLEDAI scores, but the time adjusted cWAS scores (1.9 vs 1.2, p=0.9) and the frequency and risk of overall damage accrual (SDi=0, n=60) associated with HC was similar as for HC patients (OR 1.08, p=0.20).

Conclusions: This study did not find any significant association between anti-phospholipid antibodies (single time or persistent) with cases of lupus myocarditis.

AB0636 DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS NOT RELATED TO SUSTAINED HYPOCOMPLEMENTEMIA

W.O. Raymond2, L. Tyack1, G. O. Ellertsen2, J. Nossent2. 1School of Medicine and Pharmacy, University of Western Australia, Perth, Australia; 2Molecular Inflammation Research Group, Department of Clinical Medicine, Arctic University, Tromso, Norway

Background: Hypocomplementemia (HC) represents a significant clinical finding in Systemic Lupus Erythematosus (SLE) as it suggests complement activation by immune-complexes, which can initiate inflammation. As disease activity contributes to damage accrual in SLE patients, we investigated the role of HC as a predictor of subsequent organ damage.

Objectives: To evaluate whether myocarditis in SLE is associated with antiphospholipid antibodies.

Methods: Longitudinal cohort study of 102 SLE patients with HC defined as a C3 and/or C4 levels below cut off during median follow-up of 13.8 years (IQR 7.0, 23.1). Disease activity was scored by time averaged SLEDAI-2K without the sero-logical components (cWAS), fibres by SELENA-SLEDAI and damage accrual by SLICC-DI. Analysis included comparisons between normocomplementemic (HC) patients, and multivariate logistic and Cox regression modelling determined the predictive value of HC on organ damage.

Results: HC occurred in 2/3 of patients overall and was more frequent due to low C3 (97%) than low C4 (54%). HC patients had a higher prevalence of anti-dsDNA Ab (72% vs 36%, p<0.01) and aPL (74% vs 40%, p<0.01), but HC concurred with anti-dsDNA presence in only 36% of cases. HC patients had higher maximum cSLEDAI scores, but the time adjusted cWAS scores (1.9 vs 1.2, p=0.9) and the frequency and risk of overall damage accrual (SDi=0, n=60) associated with HC was similar as for HC patients (OR 1.08, p=0.20).

Conclusions: Low complement levels occur in 2/3 of SLE patients but have neg-ligible impact on time averaged disease activity and damage accrual in SLE. Discrepancies between low C3, low C4 and anti-dsDNA Ab Occurrence indicate that in SLE alternative complement activation occurs frequently and requires further translational study.

AB0637 HAEMATOLOGICAL INVOLVEMENT OF PRIMARY SJOGREN’S SYNDROME PATIENTS IN A SINGLE CENTRE STUDY OF 232 CHINESE CASES

X. Wang, Z. Wu, Y. Liang, F. Cheng, R. Feng, X. Fang, S. Yang, B. Gong, J. Tang. Department of Rheumatology, Tongji Hospital, Tongji University School of Medicine, Shanghai, China

Background: Primary Sjogren’s syndrome (pSS) is a common systemic auto-immune disease, characterised by lymphocytic infiltrated of the secretory glands and different extraglandular manifestations. Besides haematological disorders are prevalent but not well recognised in patients with pSS.

Objectives: Our aim is to determine the existence of cytopenia at diagnosis or during follow-up of our pSS patients as well as the associated factors.

Methods: A cohort of pSS patients that had been followed-up in the Department of Rheumatology, Tongji hospital of Tongji University, from 2011 to 2017 was retrospectively assessed. Clinical and laboratory findings about the patients were recorded.

Results: Out of 232 pSS patients composing the cohort, cytopenia was already present in 55.60% (n=129) at the time of diagnosis. Anaemia was detected in 30.17% (n=70), leucopenia in 37.5% (n=87), neutropenia in 22.41% (n=52), and thrombocytopenia in 26.72% (n=62) of patients. The proportion of patients with cumulative cytopenia was 6.47% (n=15). Cumulative cytopenia was disease-related in 5.60% (n=13) and medication-related in 0.86% (n=2) of the patients. In patients with cytopenia at the time of diagnosis, erythrocyte sedimentation rates (ESR) were higher (p=0.001), C3 and C4 hypocomplementemia was more preva-lent (p=0.001, p=0.060), and they were positive for anti-SSB at a greater propor-tion (p=0.059). Hyperglobulinemia, C3 hypocomplementemia, positive anti-SSA and anti-SSB might increase the incidence of anaemia in pSS, with OR of 2.700, 2.042, 1.537 and 1.901, respectively. In addition, logistic regression analy-sis suggest C3 hypocomplementemia might be associated with different types Leukopenia (p=0.01), while abnormal Transaminase and C4 hypocomplemente-mia are independent risk factors for thrombocytopenia with a OR of 4.171 (1.516–11.480) and 5.697 (1.662–19.523). Cytopenia in pSS patients not only at di-a-gnosis or during follow-up, was always easy to ameliorated, but several cases led to unfavourable outcome.

Abstract AB0635 – Figure 1

Conclusions: This study did not find any significant association between anti-phospholipid antibodies (single time or persistent) with cases of lupus myocarditis.

Disclosure of Interest: None declared
Conclusions: The most common haematological disorders in pSS patients are leukopenia, and cytopenia in pSS patients might be related to disease activity.

AB0639 CLINICAL SIGNIFICANCE OF ESR IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Xu, X. Feng, L. Sun on behalf of Jiangsu Lupus Collaborative Group. The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

Background: During the process of systemic lupus erythematosus (SLE), disease flair and infection are often accompanied by each other and always pose a major challenge to clinical treatments. Although erythrocyte sedimentation rate (ESR) has been tested in SLE patients for many years, there is still a lack of consensus on its value.

Objectives: To validate the value of ESR in Chinese SLE patients at the time of their first admission and to determine whether it is related to a poor outcome.

Methods: Clinical data of patients with ESR tested on their first admission were extracted from our SLE database; (Feng et al. PLoS ONE 2016;11(12): e0168619) and analysed for the relation with disease activity (SLEDAI), infection status, organ involvements and survival situation. To determine the risk of ESR for long-term mortality, cumulative survival was illustrated with the Kaplan-Meier plot and factors were compared using the Log-rank test.

Results: Totally 1225 patients were included in this study, of which 92.2% were female and the median age at admission was 34.3 years. The most often seen organ involvements were mucocutaneous (66.4%), musculoskeletal (55.0%), renal (51.7%) and hematologic (45.2%) respectively. ESR levels were correlated with SLEDAI scores ($r=0.145$, $p<0.001$), but not elevated in patients with infections. Patients with cardiopulmonary, renal or hematologic impairments had higher ESR levels ($p<0.05$). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement. The ten year survival rates for patients with elevated ESR was 80.57%, lower of that 88.62% for patients with normal ESR ($p<0.01$) (figure 1).

Conclusions: High ESR levels in SLE patients are associated with active disease and specific organ involvements, and may predict a poor prognosis. It should be checked routinely for the monitoring of SLE patients.

Disclosure of Interest: None declared

Abstract AB0639 – Figure 1. Cumulative survival rates for patients with elevated or normal ESR at first admission

Figure 1

AB0639 RISK OF MORTALITY IN SJOGREN’S SYNDROME AFTER 1ST ADMISSION

Y.-C. Chen. Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China

Background: The long-term prognosis of patients with SS is unclear. Population-based studies have shown conflicting evidence regarding relative mortality in SS.

Objectives: There is conflicting evidence regarding prognosis in patients with SS (pSS). The aim of this study was to estimate the risk factors of mortality in patients with SS through a in hospital review.

Methods: Through a review of databases through October 2002 till 2016, we identified cohort studies reporting relative risk (compared with standardised population), risk factors and causes of mortality in patients with SS.

Results: We identified 695 (83.2% females) with SS, of whom 88 patients died over a median average follow-up of 13 years. Leading causes of mortality were infections; Risk factors associated with increased mortality were advanced age at diagnosis [HR 1.045 (95% CI 1.024, 1.067), male sex [RR 2.18 (95% CI 1.45, 3.27)], associated with SLE [HR 2.448 (95% CI 1.108, 5.406), diabetis [HR 1.986 (95% CI 1.125, 3.505)].

Conclusions: After first admission, the risk factor for mortality include old age, associated with SLE and diabetes. These require close follow-up.

AB0640 IMPLAUSIBLE ANTI-SMITH ANTIBODY IS NOT IMPLAUSIBLE TO AUTOIMMUNE DISEASE IN CHINESE POPULATION USING THE EUROIMMUNE LINE IMMUNOASSAYS

Y. Wu, Y. Meng. Department of Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China

Background: Anti-Sm antibody is important test for lupus. In China, many labs detected anti-Sm using Euroimmun line immunoassays (LIA) kit, which mixture with purified Sm and RNP antigens as target antigens in Sm/RNP band and purified Sm antigens in Sm band. On the instruction, anti-Sm results should be determined according to the 2 bands. That is divided as true anti-Sm positive cases (having positive Sm and Sm/RNP bands) and implausible cases (having Sm band without Sm/RNP band), the value of implausible anti-Sm is not very clear now.

Objectives: We aimed at investigating the clinical value of the implausible anti-Sm in Chinese population.
Results: Implausible anti-Sm were evidenced in 271/1208 (22.42%) of all positive anti-Sm cases. Among patients with positive anti-Sm, 177 cases have definite diagnoses (65.31%, 177/271), with autoimmune diseases accounting for 68.36% (121/177), of whom 96 had systemic lupus erythematosus (SLE) (79.34%). In addition, there are 5 implausible cases with rheumatoid arthritis (RA), 3 with Sjogren syndrome (SS) and 10 with mixed connective tissue diseases (MCTDs). The titer of antinuclear antibodies (ANA) in patients with implausible anti-Sm is lower than ones with true anti-Sm. Implausible group have the same gender ratio, mean onset age and frequency of autoantibodies with true group. The prevalence of one of NAIDs, kidney disease, was significantly lower in implausible group than in true group (X2=3.841, p=0.05).

Conclusions: Implausible anti-Sm have great diagnostic value in AIDs just as true anti-Sm. Patients with implausible anti-Sm have less incidence of evolving to autoimmune injury and kidney injury. Patients with implausible anti-Sm but without autoimmune diseases may be potential autoimmune disease victims.

CORRELATION BETWEEN PHYSICIANS AND PATIENTS IN THE ASSESSMENT OF DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Naka1,2, N. Yokokawa1, H. Takahashi1, E. Takamatsu1, S. Sugii2, First Department of Internal Medicine, Kansai Medical University, Osaka; 2Department of Rheumatic Diseases, Tokyo Tama Medical Metropolitan Hospital, Tokyo, Japan

Background: In the assessment of systemic lupus erythematosus (SLE), labora-
tory data and clinical findings have been more focused than patient-reported out-
comes which reflect quality of Life. Previous studies showed discrepancy between patients and physicians in assessments of disease activity in SLE.1 The Systemic Lupus Activity Questionnaire (SLAQ), a lupus disease activity index which consisted of only patient reported outcomes, and SLE Disease Activity Index 2000 (SLEDAI-2K) were poorly correlated.2

Objectives: We aimed to investigate the correlation between SLAQ and SLEDAI-
2K scores in those who had discordance between patients’ VAS and physicians’ VAS or not.

Methods: Both SLEDAI-2K and SLAQ were routinely measured at every outpa-
tient visit in all SLE patients. We analysed the data between 9/12/2017 and 12/31/2017. Patients were divided into concordance [patients’ VAS-physicians’ VAS] <25 or discordance group [patients’ VAS-physicians’ VAS] ≥25. We measured correlation between SLAQ score vs SLEDAI-2K or SLEDAI-2K-nolab scores by Spearman’s correlation in the concordance group and the discordance group. Comparison between the concordance group and the discordance group were performed using chi-squared test for categorical variables and Student t-test, Welch’s t-test or Mann-Whitney U test for continuous variables.

Results: Total 130 patients were analysed; 91% of female, a mean age (SD) of 44.71 years, steroid use of 91%, immunosuppressant use of 54%, HCQ use of 70%, Median SLAQ, SLEDAI-2K and SLEDAI-2K-nolab scores were 4 [IQR: 2–7.1], 4 [IQR: 2–4] and 0 [IQR: 0–2], respectively. Among them, 86 (66%) were classi-
fied in the concordance group. The SLAQ scores were weakly correlated with the SLEDAI-2K scores (r=0.228, p=0.009), and with SLEDAI-2K-nolab scores (r=0.352, p<0.001). In the concordance group, the SLAQ scores correlated with SLEDAI-2K scores (r=0.327, p=0.002) and SLEDAI-2K-nolab scores (r=0.523, p<0.001). The pain VAS and RAPID3 in the discordance group were significantly higher than those in the concordance group (30.77±26.54 vs. 10.71±14.31, p=0.001, 8.11±5.87 vs. 2.97±3.23, p<0.001, respectively). In the discordance group, the SLAQ scores were not correlated with SLEDAI-2K scores (r=–0.029, p=0.849) and with SLEDAI-2K-nolab scores (r=–0.083, p=0.957).

Conclusions: The correlation between SLAQ vs SLEDAI-2K or SLEDAI-2K-
nolab scores was exhibited in the concordance group. Musculoskeletal pain may be associated with the discordance between patients’ and physicians’ assessment.

GLUCOCORTICOID INTAKE, HYPERGLYCEMIA AND OSTEOPOROSIS IN PATIENTS WITH AUTOIMMUNE DISEASES

Y. Jiang, G. Du, X. Wu, X. Yie, M. Zhao, Z. Liao, J. Gu, Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

Background: Autoimmune diseases (AID) are often treated with glucocorticoids. Glucocorticoids have a number of substantial side effects in human body, including hyperglycemia and osteoporosis.

Objectives: Our study was to investigate the use of glucocorticoid in patients with autoimmune diseases and its negative influence on blood glucose and osteoporosis in the patients who receiving glucocorticoid treatment.

Methods: Patients with autoimmune diseases were enrolled from July to Decem-
ber in 2017 in rheumatology department of the Third Affiliated Hospital of Sun Yat-
Sen University. Demographic information, family history, past medical history, and clinical information were collected by two rheumatologists, including years of hav-
ing glucocorticoids for treatment, largest dose of methylprednisolone, current dose of glucocorticoids. Blood glucose, glycosylated haemoglobin, and bone min-
eral density was required. The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis.

Results: Of all the 75 patients, 15 (20%) were male patients. 14.7% had primary education, while 26.6% received education in university. Numbers of the patients were stated as follows. Lupus, 29; rheumatoid arthritis, 4; Sjogren’s syndrome, 10; systemic sclerosis, 10; myositis, 4; mixed connective tissue disease, 1; auto-
immune hepatitis, 1; vasculitis, 5; other diseases, 11. Mean age was 40.29±14.64 years. Mean disease duration was 4.74±6.62 years. 3 (4%) patients had family history of diabetes. 3 (4%) patients had past medical history of diabetes. Mean duration of taking glucocorticoids was 3.30±4.40 years. Mean disease duration was 4.74±6.62 years. 3 (4%) patients had family history of diabetes. 3 (4%) patients had past medical history of diabetes. Mean duration of taking glucocorticoids was 3.30±4.40 years. 13 (17.3%) of the patients underwent high dose of glucocorticoid intravenous pulse (120 mg to 1000 mg of methylprednisolone). Current dose of glucocorticoids was 5.30±3.96 tablets of methylprednisolone. Mean blood glucose was 4.61±0.92 mmol/L. Mean glycosy-
lated haemoglobin was 5.65±0.84. 2 patients were found to have diabetes in this study. 5 other patients were found to have higher blood sugar than normal range (3.9–6.1 mmol/L, according to our laboratory). 14 (18.7%) of the patients had osteoporosis according to BMD scores. In 17 patients who had receiving gluco-
corticoids for more than five years, 3 (17.6%) patients were found to have higher
blood sugar than normal range and 5 (29.4%) patients were found to have osteoporosis.

Conclusions: Glucocorticoids have substantial side effects in hyperglycemia and osteoporosis in the patient receiving glucocorticoid treatment. More years of taking glucocorticoids could lead to more hyperglycemia and osteoporosis. We should evaluate side effects of glucocorticoids in the patients with AIDs.

**AB0644**

**FT3 STRONGLY CORRELATES WITH LIPID PROFILES AND DISEASE ACTIVITY IN SLE PATIENTS**

Z. Chen1, X. Zhang1, L. Liu1, S. Huang1, H. Wang1, L. Sun1, 1Department of Rheumatology and Immunology, The Second Affiliated Hospital of South China University of Technology, 2Department of Rheumatology, The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

**Background:** Dyslipidemia is prevalent in Systemic Lupus Erythematosus (SLE) patients and associated with lupus nephritis. Non-thyroidal illness syndrome (NTIS) frequently occurs in some autoimmune diseases. The incidence of dyslipidemia and NTIS in SLE patients vary in different studies and the association of NTIS and dyslipidemia in SLE patients has not yet elucidated.

**Objectives:** To investigate the frequency of dyslipidemia and NTIS in SLE patients and their association with laboratory parameters and SLE disease activity index (SLEDAI). To further explore the association between FT3 and blood lipid profiles in SLE patients.

**Methods:** This cross-sectional and prospective study included 271 patients fulfilled the ACR criteria for SLE. Forty-one patients who had a history of thyroid disease and/or familial hyperlipidemia and/or other rheumatologic diseases, and those took lipid-lowering agents or thyroid medications are excluded. Detailed laboratory parameters were collected and SLEDAI were assessed by qualified specialists of Rheumatology.

**Results:** Frequencies of dyslipidemia and NTIS in SLE patients are 61.8% and 57.2%, respectively. Laboratory indices such as BUN (p<0.005), uric acid (p<0.001), CRP (p<0.001), ESR (p<0.001) and SLEDAI (p<0.05) are significantly increased in SLE patients with dyslipidemia than non-dyslipidemia. Compared to euthyroid SLE patients, SLE patients with NTIS showed substantially elevated 24 hour urine protein (p<0.001), fasting blood glucose (p<0.001), BUN (p<0.001), serum creatinine (p<0.001), uric acid (p<0.005), CRP (p<0.005), ESR (p<0.001) and SLEDAI (p<0.01). Moreover, triglyceride (p<0.01), total cholesterol (p<0.01), LDL (p<0.01) and ApoB (p<0.001) levels are markedly higher in SLE patients with NTIS than euthyroid ones, while HDL levels obviously decreased in the former group (p<0.01). More notably, the lower FT3 patients showed more severe lipid profiles and significantly higher 24 hour urine protein (p<0.001), BUN (p<0.001), serum creatinine (p<0.001), uric acid (p<0.005), and SLEDAI (p<0.05) than patients with normal FT3. FT3 levels are negatively correlated with triglyceride (r=-0.263, p<0.0001), total cholesterol (r=-0.295, p<0.0001), LDL (r=-0.273, p<0.0001) and positively correlated with HDL (r=0.180, p<0.01).

**Conclusions:** Dyslipidemia and NTIS are prevalent in SLE patients and strongly correlates with disease activity. SLE patients with NTIS are more likely to combine with dyslipidemia. FT3 levels significantly correlates with lipid profiles and FT3 may plays a protective role in dyslipidemia.

**PREGNANCY OUTCOMES OF PLANNED PREGNANCY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE MULTICENTER STUDY**

Z. Zhao1, D. Chen1, M. Cao1, X. Cai1, J. Zhang2, 1Department of Rheumatology, 2Department of Rheumatology and Geriatrics, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou First People’s Hospital, The Second Affiliated Hospital of South China University of Technology, 3Department of Rheumatology, The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

**Background:** Compared with the general population, patients with SLE are still at high risk of adverse pregnancy outcomes (APOs). A number of studies have shown that patients with SLE are more likely to develop fetal complications, including fetal loss, preterm birth and IUGR, compared to healthy women.

**Objectives:** To investigate the fetal and maternal outcomes, as well as predictors for APOs in women with SLE who conceived when disease was stable, the so called “planned pregnancy”.

**Methods:** A retrospective multicenter study of 243 patients with SLE who underwent planned pregnancy was performed. APOs in fetus and mothers were recorded.

**Results:** The average age at conception was 28.9±3.9 years. Duration of SLE prior to pregnancy was 4.4±4.3 years. Fetal APOs occurred in 86 (86/243, 35.4%) patients. Preterm births, intrauterine growth retardation (IUGR), fetal distress, and fetal loss accounted for 22.2%, 14.8%, 11.1%, and 4.9%, respectively. Forty-two preterm infants (42/54, 77.8%) were delivered after the 34th week of gestation. All the preterm infants were viable. Fifty-two patients (52/243, 21.4%) had disease flares, among which 45 (45/52, 86.5%) cases were mild, 6 (6/52, 11.5%) were moderate and 1 (1/52, 1.9%) was severe. Fifty-two disease flares (21.4%) occurred, among which 8 disease flares occurred during the first-trimester, 15 during the second-trimester, and 29 during the third-trimester. Disease activity was mild in 45 (45/52, 86.5%) patients, moderate in 6 (6/52, 11.5%), and high in 1 (1/52, 1.9%). Disease flares were mainly presented as active lupus nephritis (41/52, 78.8%), thrombocytopenia (10/52, 19.2%), and skin/mucosa lesions (9/52, 17.3%). Pregnancy-induced hypertension (PIH) occurred in 29 patients, among which 3 were gestational hypertension and 26 were preeclampsia. Multiple analyses showed that disease flares (OR 8.1, 95% CI 3.8–17.2, p<0.001) and anti-cardiolipin antibodies positivity (OR 7.4, 95% CI 2.5–21.8, p<0.001) were associated with composite fetal APOs.

**Conclusions:** Planned pregnancy improved fetal and maternal outcomes, preventing as lower rate of fetal loss, more favourable outcomes for preterm infants as well as less severe disease flares during pregnancy. Our research reinforced the importance of planned pregnancy, which allowed women with SLE to conceive in a proper time monitored by multidisciplinary experts.

**Vasculitis**

**AB0645**

**ANCA VASCULITIS: THE EXPERIENCE AND TRENDS IN PATIENT CARE FROM A SINGLE CENTRE**

A. Bankole1, K. McCoy2, B. Year3, G. Verma, Gita3, 1Medicine, Virginia Tech Carilion School of Medicine, Roanoke; 2Medicine, Centra Medical Group Bedford; 3Postdoctoral, USA

**Background:** ANCA-associated vasculitis [AVV] is a small-medium vessel vasculitis that presents in a multi-systemic fashion, and is associated with significant mortality. Outcomes have improved with the introduction of immunosuppressive medications [ISM], the evidence supporting the initial choice ISM in AVV is limited, and may be influenced by health disparities related to social factors.

**Objectives:** The objective of this study was to compare various factors known to influence management and outcomes in AVV. Factors including, patient demographics, socioeconomic, clinical presentations, and medication choices were reviewed in relation to outcomes within the cohort.

**Methods:** This was a retrospective, single centre, hospital-affiliated cohort study. A list of all patients seen by the Rheumatology service between 2011 and 2016 with a diagnosis of AVV was generated. A review of the 3000 charts confirmed 77 patients that met the 1990 American College of Rheumatology criteria for AVV. General demographic data including age, gender, zip code, and median household income as well as disease related data including serology, disease manifestation, and treatment were obtained through a chart review and recorded in the database. Supplemental socioeconomic information for each patient zip code was obtained from the United States Government Census website.

**Results:** In our cohort the anti-proteinase 3 [PR3] antibody was the most common positive antibody. There was a relationship between PR3 positivity rate
and body mass index [table 1]. Given the low number of non-Caucasians we were unable to comment on the relationship between antibody and race. Medication choice and mortality were independent of mean household income. Rituximab was the most commonly prescribed ISM [44%]. The median age of rituximab exposure patients was 65 years and 60 years for unexposed patients. There was no significant relationship between age and medication choice. Rituximab was prescribed 60% of the time in renal AAV [p=0.01] and 53% of the time in pulmonary AAV [p<0.01]. Other commonly prescribed medications in the cohort included Mycophenolate [20%], Methotrexate [24%] and Cyclophosphamide [28%].

The overall mortality rate was 17% [13/75] (figure 1). There was no significant difference in the mortality rate of patients 65 years and older [23%, 9/39] compared to patients 64 and younger [11%, 4/36; p=0.17]. The mortality rate was also independent of median household income.

BMI: body mass index, PR3: proteinase 3, MPO: Myeloperoxidase

Conclusions: There was no relationship between age, sex, income, immunosuppressive therapy, and mortality in our AAV cohort. The mortality rate was higher in more severe disease and rituximab was more commonly used in such cases as well as in older patients. The limitations of the study include this being a hospital-based cohort, where social demographics may have less of an impact. There was a lack of racial diversity, though the cohort did reflect the general demographics in southwest Virginia.

AB0647 TAKAYASU’S ARTERITIS IN ITALY: CLINICAL PRESENTATION, DIAGNOSTIC DELAY AND VASCULAR PATTERNS

A. Tomellini, C. Campochiaro, S. Sartorelli, C. Sembenini, S. Franchini, F. Motta, D. Vanni, G. Cavalli, E. Baldissera, L. Dagna. Unit of Rheumatology, Immunology, Allergy and Rare Diseases (UnIRAR), San Raffaele Scientific Institute, Milan, Italy

Background: Takayasu arteritis (TA) is a large vessel vasculitis. At disease presentation TA patients may present with inflammatory symptoms, sometimes associated with vascular pain. As arterial lesions ensue, more characteristic features may be found, such as limb claudication, decreased or absent pulses, vascular bruits, discrepancies in blood pressure. Initial symptoms are often non-specific, early detection of TA is challenging and patients at diagnosis frequently have established damage.

Objectives: To describe symptoms presentation and vascular involvement in a large cohort of Italian TA patients. To assess the diagnostic delay associated with symptoms and arteries involved at presentation.

Methods: Data from 114 TA patients diagnosed according to ACR classification criteria at our tertiary centre were retrospectively collected. Signs and symptoms subsequently attributed to TA, age at first symptom onset, and age at diagnosis were analysed. The diagnostic delay was calculated. Arteries involved before the diagnosis were identified. Non-parametric statistical tests were used.

Results: The cohort included mostly female patients (104; 91.2%). Mean age at first symptom subsequently attributed to TA was 30.5 years (±13.1). Age at presentation of first TA related symptom was 18–40 years in 88 (59.6–18 years in 20 (17.5%); 40 years in 26 (22.8%); mean diagnostic delay = 65.6 months (±98.5). Diagnostic delay was >1 year in 75 patients (65.8%). The most frequent finding before diagnosis was raised inflammatory markers (82.4%), the least common pulmonary hypertension (2.8%). The features significantly associated with a diagnostic delay >1 year were arthritis, hypertension, previous vascular surgery. The mean diagnostic delay (months) was significantly higher in patients with raised inflammatory markers (8.4±4.9 vs 100.5±151.8±0.8, p=0.0005), cardiomyopathy (5.1±5.7 vs 34.2±3.2, p=0.034) and in patients who had upper limb claudication (11.0±13.2 vs 65.4±47.7, p=0.002). Data about arteries involved before diagnosis were available for 86 patients (75.4%). They were: subclavian in 43 (50%), carotid in 38 (44.2%), renal in 19 (22.1%), abdominal aorta in 18 (20.9%), ascending aorta in 15 (17.4%), axillary in 12 (14%), vertebral in 11 (12.6%), superior mesenteric in 10 (11.6%), thoracic aorta in 10 (11.6%), aortic arch in 9 (10.5%), celliac triad in 9 (10.5%), brachiocephalic in 8 (9.3%), iliac in 8 (9.3%), coronary in 6 (7%), femoral in 6 (7%), pulmonary in 5 (5.8%), brachial in 3 (3.5%), popliteal in 2 (2.3%) patients. There was no significant difference in the arteries involved between patients diagnosed <1 year and >1 year from symptoms onset. Mean diagnostic delay was not significantly different according to the arteries involved.

Conclusions: In Italy TA diagnosis is burdened with an important diagnostic delay. In our cohort it seems that the presence of both specific and non-specific symptoms is associated with delayed recognition of TA. Moreover, the need for vascular surgery in young women should rise the concern about TA.

AB0648 CORRELATES OF FATIGUE IN ANCA-ASSOCIATED VASCULITIS

A. Masiak1, K. Nowicka-Sauer2, A. Hajduk1, B. Grygiel-Górniak3, M. Komomicaśk4, Z. Zdregowski1, 1Department of Internal Medicine, Connective Tissue Diseases and Genetics; 2Department of Family Medicine, Medical University of Gdańsk, Gdańsk; 3Department of Rheumatology and Internal Medicine, Medical University of Karol Marcinkowski, Poznań; 4Department of Nephrology, Transplantology and Internal Diseases, Medical University of Gdańsk, Gdańsk, Poland

Background: Fatigue is a common symptom among patients with ANCA-associated vasculitis (AAV) identified as the greatest burden of their disease. 1, 2 Research revealed associations between fatigue and bio-psychosocial factors but not with clinical factors.

Objectives: To assess fatigue and its correlates among patients with granulomatisis with polyangiitis (GPA) and microscopic polyangiitis (MPA).

Methods: 37 patients (44% women; mean age 52.3 years; range 18–85) with GPA (27 patients) and MPA (10 patients) hospitalised in 3 clinical centres completed Multidimensional Fatigue Inventory-20 (MFI-20).3 Anxiety and depression were assessed by the Hospital Anxiety and Depression Scale (HADS). Socio-demographic data including age, sex, education, marital and occupational status were recorded. Disease characteristics included its’ duration, severity, activity, organ involvement and laboratory data.

Results: The mean age was 52.3 years (range 18–85 years), and the mean disease duration was 43.1 months (range 1–246). 4 patients had limited type of the disease, 13 – early systemic, 16 – systemic and 4 – severe type of the disease. 75% of patients had active disease as defined by Birmingham Vasculitis Activity Score, BVASv3 (mean BVASv3 in active patients 12.2). 8% of patients were not taking steroids. 40.5% of patients had CRP >5 mg/l, 43% had anaemia, 10% – thrombocytosis and 43% had renal insufficiency. Mean score of MFI-20 was 57 points (range 31–100). There were no differences in MFI-20 overall score between groups according to sex, education, marital and occupational status. No significant associations between fatigue and disease-related factors as well as steroid dose were observed. Depression (r=0.79, p<0.00000) and anxiety (r=0.63, p<0.00002) were strongly correlated with MFI-20 overall score.

Abstract AB0648 – Table 1. Socio-demographic characteristics of the study sample.

<table>
<thead>
<tr>
<th>Variable</th>
<th>n (%)</th>
</tr>
</thead>
</table>
| Education primary    | 6 (16)
| occupational         | 3 (8) |
| secondary            | 12 (32)
| higher               | 16 (43)
| Marital status       |       |
| married              | 29 (78)
| divorced             | 3 (8) |
| free state           | 4 (11) |
| widower              | 1 (3) |
| Occupational status  |       |
| employed             | 18 (49)
| unemployed           | 3 (8) |
| pensioner            | 8 (22) |
| annuitant            | 5 (13) |
| student              | 3 (8) |

Conclusions: Since fatigue was not related to clinical characteristics, tiredness declared by the patient should not be interpreted as a symptom of active disease. There were no connexions between fatigue and socio-demographic variables. The strong association between fatigue and depression and anxiety levels indicates the necessity to supplement the standard drug therapy and/or cognitive-behavioural therapy aimed at reducing anxiety and improving mood.

AB0649 USE OF BIOLOGICAL DMARDS IN PATIENTS WITH PRIMARY VASCULITIS: RESULTS FROM TURKBIO REGISTRY

A. Yazici1, A. Celebi1, E. Dalkılıç1, Y. Pehlivan2, G. Can3, B. Goker4, A. Tufan1, S. Senel5, S.S. Koca6, S. Akar7, N. Akkoç7, F. Oenə9, Rheumatology, Kocaeli University School of Medicine, Kocaeli, 2Rheumatology, Uludag University School of Medicine, Bursa, 3Rheumatology, Dokuz Eylül University School of Medicine, Izmir, 4Rheumatology, Gazi University School of Medicine, Ankara, 5Rheumatology, Kayseri University School of Medicine, Kayseri, 6Rheumatology, First University School of Medicine, Elazığ, 7Rheumatology, Katip Çelebi University School of Medicine, 8Rheumatology, Private Practice, 9Rheumatology, Dokuz Eylül University School of Medicine, Izmir, Turkey

Background: Untreated, The systemic vasculitides can be devastating, with high rates of morbidity and mortality. Recently, most of biological agents have been evaluated in clinical trials, and management of systemic vasculitis has been revolutionised over the last decade. 1, 2

Objectives: Here, we report the frequency of using and switching rate of biological agents in different types of primary vasculitis patients.

Methods: TURKBIO registry is the Turkish version of Danish DANBIO rheumatological database which has been established in 2011. All patients with primary vasculitis who received biological agents registered in TURKBIO registry between dates of October 2011 and January 2018 were included in this study. The demographic data, the date of starting to use biological drug, frequency of using and switching biological agents were collected.

Results: As of January 2018, 108 primary vasculitis patients were recruited (mean age: 38.4±10.9 [min-max: 19–67]; female 48%); 48 patients (44%) of them had Behcet’s disease (BD), 35 (32%) had Takayasu arteritis (TA), 24 (22%) had granulomatosis polyangiitis, and one of them had microscopic polyangiitis. The most commonly used biological agents in current treatment were as follows: 75% of patients received infliximab (INF) and 15% received adalimumab (ADA) in BD patients; 48.6% received tocilizumab (TCZ), 22% received INF and 20% received ADA in TA patients; all patients with granulomatosis with polyangiitis (GPA) were treated with rituximab. The switching rate was 54% in TA patients, 27% in BD patients, and 4% in GPA patients. The most frequent switching was found at INF (28/76) and ADA (9/23) which was the most commonly used agent in TA and BD. The lowest switching rate was TCZ (2/17) in TA patients (table 1).

Conclusions: This is the first evaluation of primary vasculitis patients who used biological agents from TURKBIO registry. According our data, there was high switching rate with anti-TNF agents in TA patients. The limitation of this study was the low number of the patients with primary vasculitis who used biological agents.

FREQUENCY OF PULMONARY HYPERTENSION IN BEHÇET’S DISEASE

B. Aramgil1, M. Oksuf2, Y.Z. Sener2, A. Sarlı1, A. Erden1, G.K. Yardımci1, L. Kılıç1, U. Kalyoncu1, Ö. Karadağ1, S. AprasBilgen1, S. Kıraz1, I. Ertenli1, A. Akdoğan1, U. Kalyoncu1, O. Karadağ1, S. AprasBilgen1, S. Kıraz1, I. Ertenli1, A. Akdoğan1.

Hacettepe University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Hacettepe University Faculty of Medicine, Department of Cardiology, Ankara, Turkey

Background: Behçet’s disease (BD) is a systemic vasculitis that involvement of pulmonary arteries can be seen. The aim of this study was to determine the frequency and the causes of pulmonary hypertension (PH) in patients with BD.

Methods: We studied consecutively 154 BD patients who fulfilled the International Study Group criteria for diagnosis of BD. All patients were evaluated with transthoracic echocardiography (TTE) for the presence of PH. BD patients were categorised according to the involved organs in 5 groups: group 1 mucocutaneous and articular, group 2 ocular, group 3 vascular, group 4 gastrointestinal and group 5 neurologic involvements. The presence of PH was defined as estimated sPAB ≥40 mmHg, by TTE. Every subject evaluated by a detailed medical history and physical examination was performed. Additional laboratory results were obtained from hospital file records.

Results: The mean age (SD) and the median (min–max) disease duration of the patients were 41.8±12.6 years and 126 (6–540) months respectively. PH was detected in 17 (11%) BD patients. Only 9 (52%) patients were symptomatic (NYHA FC ≥2). Left sided heart disease (Group II: 9 (52%) patients) was the leading cause of PH. Four (23%) patients had group IV PH and 75% (3/4) were symptomatic. Diastolic dysfunction (DD) was found in 32 (20.8%) patients and only 1 patient had systolic dysfunction. The number of patients with DD was significantly higher in patients with PH as compare to patients without PH (8 (47.1%) vs 24 (17.6%), p=0.005). There were no difference in demographic and clinical features of patients with and without PH. Only acneciform lesion was more frequently in patients without PH as compare to patients with PH, p=0.047 (table 1). There were no differences in frequency of PH in BD groups (table 2).

PET/MR IN LARGE-VESSSEL VASCULITIS: CLINICAL VALUE FOR THE DIAGNOSIS AND ASSESSMENT OF DISEASE ACTIVITY

C. Laurent1, L. Ricard1, I. Buvat2, O. Fain2, A. Mekinian1, M. Sousman2, on behalf of French PET–inflammation Network.1 Internal Medicine, Hôpital Saint-Antoine; 2Nuclear Medicine, Hôpital Avicenne, Paris, France

Background: The diagnosis and the activity determination could be challenging in large- vessel vasculitis (LVV).

Objectives: The aim of this study was to analyze the value of hybrid PET/MR in LVV.

Methods: All consecutive patients with LVV who underwent PET/MR were included. PET/MR patterns were defined as inflammatory in the case of positive PET (grade=3) and abnormal MR (stenosis and/or wall thickening) and fibrous in the case of negative PET (grade=1 or 2) and abnormal MR.

Results: Thirteen patients with median age at 67 years (23–87 years) and 10 (77%) females were included, and underwent 18 PET/MR scans. Eleven PET/MR performed at diagnosis (n=4) or relapse (n=7) and 7 in patients in remission. 8/18 (44%) had PET/MR inflammatory pattern and 3/18 (17%) had fibrous pattern. PET/MR were normal in 2/10 (20%) cases of TA versus 5/8 (62%) cases of GCA
Predicting Relapses in Autoimmune Large-Vessel Vascularitis – Towards Personalised Immunosuppressive Treatment Stewardship

P.S. Fuchs1, M.B. Bigler2, C. Küng2, T. Manigold3, M. Aschwanden4, D. Staub4

Background: Giant cell arteritis (GCA) is an autoimmune disease of the large arteries. Treatment consists in long-term immunosuppression with glucocorticoids (GC). About half of the patients have disease flares (relapses) despite standard therapy. Tocilizumab (TCZ), an anti-IL6 receptor antibody, is highly effective in GCA patients with remission (p=0.003).

Objectives: Here, we tested whether the initial clinical presentation and/or immunological findings might predict a GCA patient subset with poor response to GC.

Methods: We performed a chart review on 113 patients from our prospective cohort over the first two years after diagnosis. All had a follow-up of at least three months (median follow-up 24 months, IQR 12.6–24). Clinical findings at diagnosis, routine labs (at 0, 1, 3, 6, and 12 months) and therapy information (drug and dose) were extracted from the electronic database.

Results: Relapses were defined as the presence of GCA-related symptoms (ischaemic pain, polymyalgia (PMR)) and/or elevated systemic inflammation parameters (CRP, ESR) that responded to an increase in GC-dose. GC receptor (GCR) expression are risk factors for relapses in GCA. Low GCR expression combined with absence of lymphocytopenia during high dose GC therapy points at a constitutional steroid-resistance in relapers. Whether patient stratification based on these parameters allows to safely adapt (‘personalise’) the intensity and/or duration of GCA treatment needs to be tested in a prospective clinical trial.

Conclusion: Patients with fever at initial presentation had a 2.2-fold (CI 1.1–4.4) higher risk to relapse. Relapers’ received in this period (1747 mg vs. 1710 mg, p=0.4). Relapers had lower GCR expression levels, as assessed by flow cytometry.

Clinical Profile and Risk Factors of Infections in Patients with Anca-Associated Vasculitis (AAV) – 18-Year Data from a Single Tertiary Centre

C.-H. Hs Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong

Background: Despite advances in the treatment of AAV, there are still considerable morbidities related to treatment-related complications. Infection is one of the most commonly encountered problems in patients on immunosuppressive therapy.

Objectives: This single centre, retrospective study reviewed the clinical features and investigated the risk factors for infections among patients with AAV.

Methods: 104 patients with AAV diagnosed between January 2000 and December 2017 in a tertiary hospital were included. Demographic data and clinical parameters were reviewed. Logistic regression was performed to identify factors predicting infections.

Results: Around two-thirds of the 104 patients included were female (63.5% n=66). Mean age at diagnosis was 64.4-year-old. The majority (65.4%, n=68) had microscopic polyangiitis (MPA), 19.2% (n=20) had granulomatosis with polyangiitis (GPA) and 15.4% (n=16) had eosinophilic granulomatosis with polyangiitis (EGPA).

Conclusion: Infections were less frequent in EGPA patients compared to their counterparts with MPA and GPA (37.5% vs 61.8%–65%). Most infections were bacterial and multiple-drug resistant organisms were the causative agents in 8 patients. Two had neutrophic sepsis. Three had M. tuberculosis and five had herpes zoster. One had concomitant VZV and pneumocystis jirovecii pneumonitis.

Agreement between 18-FDG PET/CT and Clinimetric Takayasu Activity Scores

D. Hernandez-Lopez1, L.A. Martinez-Martinez1, D. Jimenez-Arenas2, B. Rivera-Brazo3, E. Hernandez-Lemus4, J.A. Barragan-Garías4, V. Guerrero-Lanz1, M. E. Soto-Lopez1, Instituto Nacional de Cardiología Ignacio Chavez-PET/CT Unit, School of Medicine at National Autonomous University of Mexico; 2Instituto Nacional de Medicina Genómica; 3Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico

Background: The 18-FDG PET/CT is an objective tool employed for the diagnosis of Takayasu arteritis and also is used for the assessment of disease activity of this vasculitis. There are few clinimetric scores developed for Takayasu clinical activity assessment such as the Indian Takayasu Clinical Activity Score (ITAS2010/ITAS.A), the National Institutes of Health criteria (NIH score) from USA and the Mexican effort by Dabague-Reyes (DR score). The validity and
utility of 18-FDG PET/CT to measure the disease activity by studying wall enhancement compared to the cliniometric assessment has been slightly studied.

Objectives: To explore the agreement between 18-FDG PET/CT and the cliniometric tests for the estimation of Takayasu activity in one national reference centre.

Methods: The clinical records of patients that had performed an 18-FDG PET/CT were consecutively included. The required information to fulfill the ITAS2010, ITAS.A, NIH and DR were gathered from clinical charts. The cut-off points we used are the following: SUVmax >2.1 for 18-FDG PET/CT, for ITAS2010 >2.1 points, for ITAS.A >4 points, for NIH >2 points and for DR >5 points. Kappa index was calculated, comparing SUVmax with all the cliniometric measures. As an exploratory exercise, ROC curves were performed. A p value less than 0.05 was considered statistically significant.

Results: Thirty six clinical records were reviewed. There was enough information to score ITAS2010 in 31 patients, ITAS.A in 28 patients, NIH and DR in 35 patients each. In our patients, moderate agreement was observed between 18-FDG PET/CT and DR score (Kappa=0.542, p=0.001). A tendency of weak agreement was observed with the NIH score (Kappa=0.215, p=0.086) and ITAS.A (kappa=0.351, p=0.063). There was no agreement with ITAS2010 (Kappa=0.107, p=0.519). Significant AUC were observed with DR (AUC=0.817, p=0.005) and NIH (AUC=0.756, p=0.025); however, this results were not obtained with ITAS2010 (AUC=0.675, p=0.124) and ITAS.A (AUC=0.697, p=0.083).

Conclusions: There was no strong agreement between 18-FDG PET/CT and any of these activity indices. On the other hand, these data suggest that the best disease activity tool in Mexican patients were DR and the NIH scores. Comparative studies in other populations are warranted.

AB0656 CRYOGLOBULIN EVALUATION: ANALYSIS OF INTRA-LABORATORY AND INTER-LABORATORY VARIABILITY

D. Campioli1, P. Natali1, D. Debbia3, A. Spinella2, G. Sandri2, C. Cerami3, L. Scichilone3, F. Fontana3, M.T. Mascia3. 1Department of Laboratory Medicine; 2Chair and Rheumatology Unit, University of Modena and Reggio Emilia, Policlinico of Modena, Modena, Italy; 3Chair and Nephrology Unit, University of Modena and Reggio Emilia, Policlinico of Modena, Modena, Italy

Background: Cryoglobulins (CRG) are immunoglobulins that precipitate in serum at temperatures below 37°C and resolubilize upon warming. The main reasons of interest of a clinical pathologist in the study of cryoglobulinemia are: 1) lack of standardisation in the preanalytical, analytical and postanalytical phases of the process (classification and reporting); 2) peculiarities of physiopathological mechanism 3) important clinical consequences. Vermeersch et al. studied these issues in 2008. To assess current practice in the detection, analysis, and reporting of cryoglobulins, a questionnaire was sent to 140 laboratories. They showed that only 38% of laboratories used standard procedures of analysis. Consequently, they concluded that standardisation was needed for cryoglobulin detection to avoid missed diagnoses and improve the comparability of results. Sargur et al. in 2010 reviewed the classification and clinical features of cryoglobulins and suggested “best practice” guidelines for laboratory detection and identification of cryoglobulins. They particularly highlighted the relevance of preanalytical and analytical phases: maintenance of the sample at a stable temperature of 37°C, especially throughout the initial steps (collection and transportation); centrifugation and separation methods; cryoprecipitate quantification; cryoprecipitate washing techniques; immunochromatization of cryoprecipitates especially through immunofluorimetric techniques (considered the “gold standard”).

Objectives: To verify and assess the variability of laboratory processes of CRG.

Methods: We checked laboratory databases of Hospital and University (Lab A and B) of Modena with long tradition in the cryoglobulin analysis (more than 6000 tests from 2002 to 2017). Concerning CRG testing, 734 patient samples were studied in both laboratories. We compared our results according to Broeuf classification into subgroups: type I, II and III. Therefore, we evaluated intra-laboratory variability, compared to previous or more frequent results. Finally, we studied inter-laboratory variability based on non-concordant laboratory reports.

Results: In the following table, we have represented the comparison between labs about the same patient cohort in 734 patient samples:

<table>
<thead>
<tr>
<th></th>
<th>I type (n)</th>
<th>II type (n)</th>
<th>III type (n)</th>
</tr>
</thead>
<tbody>
<tr>
<td>Lab A</td>
<td>21</td>
<td>242</td>
<td>108</td>
</tr>
<tr>
<td>Lab B</td>
<td>42</td>
<td>270</td>
<td>108</td>
</tr>
<tr>
<td>Chir.</td>
<td>p=0.0016</td>
<td>p=0.0004</td>
<td>Ns</td>
</tr>
</tbody>
</table>

Intra-laboratory variability: 14% Lab A, 16% Lab B (ns). Inter-laboratory variability: non-concordance in 25% of cases, considering 133 patients studied in both laboratories (Chi-square test).

Conclusions: No data about variability in CRG analysis are reported in literature. National and international guidelines are not explicative enough. Furthermore, many doubts about classifications are established. Our experience is unique but limited in two laboratories. Given the variability of testing conditions used in different laboratories and the lack of test standards and reference values, we confirm the need of further investigations into standardisation of CRG testing. New guidelines are fundamental, in order to optimise all phases of CRG research (pre and post analysis) and to ensure correct diagnosis and adequate treatments of the associated diseases.

AB0657 CYCLOPHOSPHAMIDE-SPARING ROLE OF AN INTENSIFIED B-CELL DEPLETION PROTOCOL IN ANCA-ASSOCIATED VASCULITIS: A CASE-CONTROL STUDY

D. Roccatello1,2, R. Fenoglio3, D. Rossi4, M. Radin1, L. Cecchi5, S. Murgia5, S. Baldovino1, E. Rubini5, S. Sciascia6. 1Chair of Immunopathology and Rare Diseases, University of Turin, Torino, Italy

Background: The management of ANCA-associated-vasculitis (AAV) requires the use of immunosuppressive drugs with potential toxicity. Recently, two trials demonstrated the efficacy of Rituximab (RTX) for the therapy of AAV.

Objectives: To explore the agreement between 18-FDG PET/CT and the clinimetric assessment has been slightly studied. Thirteen patients received an intensified protocol of B-cell depletion therapy (IBCDT) consisting of 4-weekly infusions of 375 mg/sm RTX followed by 2 infusions after 1 and 2 months, 3 pulses of methylprednisolone followed by prednisone tapered to 5 mg/day in three months and 2 pulses of 10 mg/kg CYC, without further maintenance therapy. Thirteen patients treated with 2 mg/kg/day CYC followed by azathioprine as a maintenance therapy served as controls.

Results: A significant improvement (p<0.05) of B-VAS, ESR, CRP and ANCA was observed in the IBCDT-group at 3, 6 and 12 months, with decrease of mean creatinine values from 4.81±5.4 mg/dl to 2.21±3.9 mg/dl. When compared to controls, no difference was observed in terms of complete and partial response. However, the IBCDT regimen achieved a 1 gm/month reduction of CYC cumulative dose (p<0.001).

Conclusions: In the treatment of this sample of severe AAV patients, the IBCDT protocol appeared to be noninferior to CYC-based regimen. Notably, the IBCDT regimen allowed a significant reduction of CYC cumulative dose.

Disclosure of Interest: None declared

AB0658 DIFFERENT ORBITAL MANIFESTATIONS OF GRANULOMATOSIS WITH POLYANGIITIS. COMPARATIVE STUDY

D. Iemalova1, I. Abramova2, P. Novikov2. 1Institute of Eye Diseases of Russian Academy of Medical Sciences; 2Rheumatology, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

Background: Ophthalmic manifestations are typical for granulomatosis with polyangiitis (GPA), and occur in 28.6%–60% of patients. In 8% of cases they lead to permanent visual loss. According to different studies orbital lesion develops in 5%–30.6% of GPA patients and is considered to be the second most prevalent ophthalmic manifestation after conjunctivitis/episcleritis.

Objectives: To study clinical features of different orbital manifestations of GPA.

Methods: 74 GPA patients with orbital involvement were studied and compared. 3 types of orbital involvement were proposed: orbital mass (45 patients),

PREVALENCE AND CLINICAL FEATURES OF CRANIAL AND EXTRACRANIAL GIANT CELL ARTERITIS

E. Fernández1, I. Monjo1, L. Coronel2, D. Benavent1, A. Balsa1, E. De Miguel1.
1Rheumatology, Hospital Universitario La Paz, Madrid, 2Rheumatology, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife, Spain

Background: Giant cell arteritis (GCA) is the most common systemic vasculitis in adults. Although it typically affects the cranial branches derived from the aortic arch, there is increasing evidence of the damage occurring to large vessel extracranial arteries, which is usually misdiagnosed. This subset of large vessel extracranial GCA may have specific clinical features that could hinder the diagnosis, which highlights the need for a different treatment and follow-up.

Objectives: To analyse the frequency and clinical and analytical features in cranial and extra-cranial GCA.

Methods: An observational retrospective descriptive study analysing data from patients with GCA who was performed in our hospital. Colour duplex sonography (CDS) studies were carried out in the last 29 months were reviewed. Standardised CDS images from the frontal and parietal branches of the temporal superficial artery (TA) and axillary artery (AX) with GCA compatible image with intra or extracranial involvement (hypoechoic, homogeneous and circumferential thickening of the artery wall ≥0.34 mm in TA, and ≥1 mm in AXE, respectively), SPSS version 23 were used to analyse a total of 29 variables.

Results: Out of the 119 patients that were tested in our fast track GCA clinic, with standardised CDS of TA and AXE, 22 had GCA. All GCA patients were hall sign in CDS. From them, 7 had large vessel involvement (31.8%), from whom 6 were mixed and 1 had exclusively extra-cranial involvement. Mean age at diagnosis was 76±9.7 SD in the extracranial GCA arteritis and 79±5.7 SD in the cranial GCA. The extracranial subset had a greater number of men than the cranial (28.6% and 26.6%, respectively) and suffered usually more fewer (28.5%±6.6%, respectively), constitutional syndrome (85.7%±40%), respectively or polymyalgia rheumatica (42.8%±40%). However, they suffered more frequently from headache (85.7% vs 93.3%) and jaw claudication (28.5% vs 33.3%). None of them suffered from visual impairment or central nervous system involvement; both did appear in the cranial GCA group in 13.3% and 6.6%. In the blood tests, mean ±standard deviation was: ESR 87.6±38 mmh in cranial GCA and 89.5±19.5 SD mmh in extracranial GCA, CRP 65±57.6 and 82.6±48.4 mg/L and Hb 11.4±1.3 and 12.1±1.3/dl, respectively. Patients with large vessel involvement met ACR criteria in 80% opposite 92.8% from those with solely cranial GCA. AT biopsy was performed in 7 patients in the cranial subset and 2 in the extra-cranial group and none in the second one. CT-PET was performed in 2 patients with cranial GCA with negative results, and in 4 with large vessel involvement, testing positive in 50%. Despite the large differences, the statistical analysis didn’t reach statistical significance due to the small sample size.

Conclusions: One third of the patients in our study had large vessel involvement, making axillary vessel CDS an important tool for the clinical exam of this disease. These patients tend to be younger and start more often with fewer or general syndrome and less with GCA typical symptoms like headache, jaw claudication or visual loss.

AB0660
THE ROLE OF ANTI-NEUTROPHIL CYTOPLASTIC AUTOANTIBODY SPECIFICITY FOR MPO OR PR3 IN PHENOTYPE OF ANCA ASSOCIATED VASCULITIS: KNOWING THE AUTOIMMUNITY IN LATIN AMERICA

E. Cañe, M. Cañe, H.B. Cabrera, D. Jaramillo-Arroyav, A.L. Vanegas-Garcia, G. Vásquez-Duque, M. Restrepo-Escobar, L.A. González-Naranjio, J. Hernández-Zapata, C.H. Muñoz-Vahal, 1Grupo de Reumatología Universidad de Antioquia, Medellin; 2Universidad CES, Medellin; 3Medicina Interna, Universidad de Antioquia; 4Universidad CES; 5IPS Universitaria Clínica León XIII, Medellin; 6Grupo de Reumatología Universidad de Antioquia, Medellin; 1Hospital Universitario San Vicente Fundación, Medellin, Colombia

Background: Antineutrophil cytoplasmic antibodies (ANCA) are present in up to 90% granulomatosis with polyangiitis, 80% microscopic polyangiitis and 70% eosinophilic granulomatosis with polyangiitis. MPO-ANCA has been associated with vasculitis limited to the kidney, chronic renal damage and less frequent gastrointestinal or respiratory tract involvement. PR3-ANCA are characterised by destructive lesions of the ear, nose and throat, alevolar haemorrhage, combination of upper and/or lower respiratory tract involvement with renal compromise and increased number of relapses. The frequency of pulmonary involvement is similar in both serotypes, and most ANCA associated vasculitis (AAV) patients are diagnosed between ages 50 and 70 years.

Objectives: To describe differences in clinical profiles of patients with AAV regarding ANCA specificity against MPO or PR3 in a Colombian based adult population

Methods: All medical records of patients with a diagnosis of AAV in two high complexity hospitals in Medellin, Colombia from January 1, 2014 to December 31, 2016 were reviewed. The clinical and demographic characteristics were abstracted and analysed with descriptive and inferential statistics in SPSS.

Results: Of 59 cases of AAV, 44 were positive for MPO or PR3-ANCA with male predominance (65.5% men vs 34.5% women) and similar age at diagnosis (47 years in MPO-ANCA vs 50 in PR3-ANCA). MPO-ANCA group had a greater number of men and weight loss (34.8% vs 20%), arterial hypertension (34.5% vs 26.7%), hematuria (34.5% vs 26.7%), proteinuria (31% vs 26.7%), creatinin higher than 5.6 mg/dL (20.7% vs 13.3%), myalgias (13.8% vs 0%) pachymeningitis (7% vs 0%) and skin compromise. PR3-ANCA patients had more arthritis/arthropathy (40% vs 31%), escleritis (33% vs 13.8%), epispilitis (13.3% vs 0%) and uvelitis (10% vs 7%).

Conclusions: In this Latin American population ANCA specificity affected the phenotype of clinical disease. MPO-ANCA patients had more constitutional symptoms, renal and central nervous system compromise while PR3-ANCA patients showed more articural and ocular involvement.

ASSESSMENT OF DAMAGE AND PROGNOSIS IN PATIENTS WITH ADULT IGA VASCULITIS: RETROSPECTIVE MULTICENTERED COHORT STUDY

F. Altunbas-Oner1, A. Omma2, A. San2, G. Gazeli1, D. Üsküdar Cansu2, A. Yazıcı2, A. Cefe1, C. Bes3, Ö. Karadağ3, H. Direkseven1. 1Rheumatology, Marmara University, School of Medicine, Istanbul, 2Rheumatology, Ankara Numune Research and Training Hospital, 3Rheumatology, Hacettepe University, School of Medicine, Ankara, Turkey

Objectives: Iga Vasculitis is a leukocytoclastic vasculitis involving small vessels with depositions of immune complexes containing IgA. IgA Vasculitis is a predominantly paediatric vasculitis. There is limited data for the prognosis of adult IgA Vasculitis, with also no damage assessment. In this study, we aimed to evaluate

Disclosure of Interest: None declared

Disclosure of Interest: None declared

Disclosure of Interest: None declared

the clinical characteristics, treatment, outcome and damage of patients with adult IgA Vasculitis.

**Methods:** We assembled a retrospective cohort of patients with adult IgA Vasculitis from tertiary Rheumatology Centres in Turkey. The demographics, clinical characteristics, treatment and outcomes of patients were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS), prognostic Five Factor Score (FFS) and vasculitis damage index (VDI) were calculated.

**Results:** The study included 103 (male/female: 67/36) patients with adult IgA Vasculitis. The mean age was 42.6±17 years. Infection history within 6 weeks before presentation was present in 40 (38.8%) patients (32 upper respiratory tract, 3 urinary tract, 2 gastrointestinal, 3 cutaneous). Cutaneous manifestations and arthritis/arthralgia were the most common clinical manifestations (table 1). 92 (89.3%) patients were treated with oral glucocorticoids (GC). Pulse GC treatment was also given to 29 (28.1%) patients. As additional immunosuppressive agents, azathioprine was given to 36 (34.9%) and pulse cyclophosphamide to 12 (11.8%). Fifty-nine patients (58.2%) had follow-up of mean 35.6 months. Eleven (18.6%) patients relapsed during follow-up. While 5 relapses were major, six of them were minor relapses. At the last visit, disease status was evaluated as active or treatment failure by the treating physician in 7 (11.8%) patients. The rate of chronic renal failure was 8.3% (n=5). Mortality was 1.6% (n=1) during follow-up, due to pneumonia. The mean VDI score was 0.2 in the last visit. Twelve (20.3%) patients had at least one damage item at the end of follow-up period.

**Conclusions:** Our results showed that approximately one fifth of patients with adult IgA Vasculitis had relapses during follow-up and had at least one damage item at the end of follow-up period. Although, 31% of patients had FFS ≥1, the mortality observed was to be very low in the present study.

**AB0663**

**18F-FDG-PET/CT DISEASE DISTRIBUTION IN A LARGE VESSEL VASCULITISCOHORT – SUPPORTS VASCULAR ULTRASOUND AS A SCREENING AND DIAGNOSTIC TOOL**

**Background:** Subsets of GCA have extensive vascular involvement, termed Large Vessel GCA (LV-GCA), seen in 12%–37% depending on imaging used. These patients have higher relapse rates and are more often refractory to glucocorticoids (GC), requiring steroid-sparing treatment to minimise GC toxicity and vascular complications. Diagnosis is reliant upon imaging, given the relative inaccessibility of tissue for histological analysis beyond temporal artery biopsy (TAB). If axillary and subclavian arteries are often affected, vascular ultrasound could be an effective screening tool.

**Objectives:** To determine disease distribution in the Southend Large Vessel Vasculitis (LVV) cohort, particularly levels of axillary and subclavian involvement.

**Methods:** The cohort has sixty-five patients (2010–2017), from which sixty 18F-FDG-PET/CT scans were performed. They were retrospectively examined by two vascular radiologists. Vascular involvement was determined by consensus opinion from other evidence (ultrasound, computed tomography). Of these, four were on concurrent GC (7–12 mg prednisolone), raising the possibility of “false negatives”. Nineteen scans were positive despite GC (1–80 mg prednisolone). Higher doses tended to be of short duration, being unable to postpone due to clinical necessity, but exceeded the 3 day limit at which FDG signal starts to attenuate.

**Results:** 6/46 patients with GPA diagnosis presented SGS (13%). 83% women, mean age of 37.8 years (DS ±14.8). Mean time between the presentation of the GPA and the diagnosis of SGS:18 months. Most frequent clinical manifestations of SGS: dyspnea (83%), stridor (83%), dysphonia (50%), cough (33%), bronchospasm (16%). One patient presented SGS as initial manifestation of the disease. Mean BVAS:14. Two patients presented such complication with evidence of systemic manifestations. Re stenosis was observed in one patient. Treatment: IV CYC 83%, oral CYC 16%, methylprednisolone (MP) 83%, oral steroids, plasma exchange (16%) in each one. Endoscopic intervention and balloon dilatation33%, and intralesional Mitomycin 16%.

**Conclusions:** 13% patients with GPA presented SGS, being in the majority of cases associated with other manifestations of the disease. However, 67% had no signs of systemic involvement (localised disease). Local treatment was necessary in only 33% because there was a good response to IS in 67% of the cases.

AB0664

LIFE EXPECTANCY IN PATIENT WITH GIANT CELL ARTERITIS (GCA): IMPACT OF VISION LOSS

G.S. Breuer1,2,3, V. Pollorak1,2,3, R. Nesher4, G. Nesher2,3,1 1Hebrew University, School of Medicine; 2Medicine; 3Rheumatology, Shaare Zedek Medical Center, Jerusalem; 4Ophthalmology, Meir Medical Center, Kfar Saba, Israel

Background and purpose: Several epidemiologic studies reported increased mortality in patients with GCA, while others found that the overall survival was essentially identical to that of the general population. Those studies used different methods to calculate the mortality rates.

Objectives: In this retrospective study we evaluated longevity in a group of GCA patients using specific gender and age-matched life expectancy tables.

Methods: Medical records of patients diagnosed with GCA in one Medical Centre between 1980–1999 were reviewed for clinical parameters at the time of diagnosis and during the first year of treatment, and for time of death and cause of death. For each patient the observed survival was compared with the specific age and gender-matched life expectancy tables of the Israeli Central Bureau of Statistics.

Results: 87 patients (51 females, 36 males) were included, their mean age at the time of GCA diagnosis was 73.9±8.4 and 75±8.1 years, respectively. The calculated mean life expectancy for this group of patients, from the time of diagnosis, was 14.1±6 years for females and 12±5.2 for males. However, the actual survival was significantly shorter, 7.5±6.2 years (p<0.001) in females, and 7.7±7.3 years (p=0.005) in males. Survival was not significantly affected by the intensity of immunosuppression (p=0.15) in females. The leading causes of death were cardiovascular/cerebrovascular diseases, in 43% of the patients, slightly exceeding the respective rate in the age-matched general population (40%, p=0.8), and infectious diseases, in 37% of the patients, significantly exceeding the respective rate in the age-matched general population (22%, p=0.015).

Conclusion: Infectious diseases were often the cause of mortality in this group of GCA patients, relative to the background population. Survival following GCA diagnosis was significantly shorter than expected, especially in patients presenting with vision loss.

INTERSTITIAL LUNG DISEASE AMONG PATIENTS WITH GIANT CELL ARTERITIS

H. Tamaki1, T. Jinta1, M. Okada1. 1Immuno-Rheumatology Center, St. Luke's International Hospital; 2Pulmonary Medicine, St Luke's International Hospital, Tokyo, Japan

Background: Lately interstitial lung disease (ILD) has been recognised more and more as a manifestation of primary systemic vasculitis, particularly among patients with microscopic polyangiitis (MPA), which is predominantly a disease of the elderly in Japan. Another primary systemic vasculitis that occurs frequently in...
the elderly is Giant Cell Arteritis (GCA) and one of the unusual manifestations of GCA includes non-productive cough that can occur in about 10% of patients. It is specified that vasculitis of the area in the area of cough receptors results in this manifestation. There have been only anecdotes about the association of GCA with ILD and it is unknown whether ILD is truly prevalent in patients with GCA.

**Objectives:** Here we systematically reviewed chest images of patients with GCA and investigated the prevalence of CT scan abnormality consistent with ILD among patients with GCA.

**Methods:** Single centre retrospective chart review was conducted at St. Luke’s International Hospital in Tokyo. The charts of patients with the diagnosis of GCA who were seen from March 2004 till August 2017 were extracted. The clinical data were obtained. Pulmonary images were reviewed by one of the authors, who is a pulmonologist and characteristics of the pulmonary lesions based on computed tomography (CT) of the lung were recorded.

**Results:** Forty-six patients had a diagnosis of Giant Cell Arteritis. Thirty-nine of them had a chest CT scan. The mean age of the patients was 69±17 years and 27 patients (58%) were female. Ten patients (26%) had abnormality in the CT scan. The abnormality included linear infiltrates beneath the posterior aspect of the pleura in the lung bases (n=9), ground glass opacities (n=3), honeycombing (n=3), and reticulonodular infiltrates (n=2). Two patients received prednisolone for ILD, ILD of whom were stable. No patients died during the median follow up of 14.5 months.

**Conclusions:** Chest CT abnormality consistent with mild ILD was prevalent among patients with GCA. The prognosis of these patients appears to be favourable and these patients responded to prednisolone.

**Disclosure of Interest:** None declared

**PREGNANCY OUTCOMES IN A TERTIARY TAKAYASU ARTERITIS CARE CENTRE**

I.E. Szabo1, M.M. Tamas1,2, L. Damian1, I. Filipescu1,2, I. Dobrota1, S. Rednic1,2, 1Department of Rheumatology, Emergency Clinical County Hospital, 2Department of Rheumatology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania

**Background:** Fertility and pregnancy are concerning issues in women of childbearing age with Takayasu arteritis (TA). Available data on the management and expected events in TA during pregnancy are sparse and inconsistent among study populations. Conflicting reports exist on both favourable pregnancy outcomes as well as increased fetal or maternal complications.

**Objectives:** To assess the obstetric and maternal outcomes in a tertiary centre TA cohort.

**Methods:** 15 female patients fulfilling the American College of Rheumatology 1990 criteria for the classification of TA were included in this retrospective study. Data regarding number of pregnancies, disease characteristics and pregnancy-related events were gathered from medical records. Disease extent was classified according to Numano classification criteria for TA: type I (4 patients, 26.6%), type II (4 patients, 26.6%), type III (4 patients, 26.6%), type IV (3 patients, 20%), type IV (2 patients, 13.3%), type IIa (1 patient, 6.6%), type IIb (1 patient, 6.6%). The prevalence of obstetric and maternal complications was evaluated in women before or after TA diagnosis. 6 patients were further excluded due to the paucity of information concerning pregnancy outcomes.

**Results:** A total of 15 pregnancies were identified in 9 patients, with 9 (60%) occurring before TA diagnosis – group 1, and 6 (40%) occurring concomitant with or after TA diagnosis – group 2. In the first group the extent of arterial involvement was mostly consistent with type I (6 pregnancies, 66.6%). No fetal or maternal complications were observed in this group. Type III TA was most commonly encountered (4 pregnancies, 66.6%) in group 2. Only 1 patient from the second group had more than 1 pregnancy after TA diagnosis. Active disease (National Institutes of Health/NIH score >1) was reported in 2 (33.33%) pregnancies in the second group. Cardiovascular events occurred exclusively during 2 (33.3%) pregnancies exhibiting active disease. One patient suffered severe aortic regurgitation and gestational hypertension during pregnancy, while the second patient experienced worsening of preexisting hypertension. These required steroid dose increase and addition of antihypertensive drugs. There were no obstetric events in group 2.

**Conclusions:** Most TA pregnancies are uneventful, bearing favourable feto-maternal outcomes. However, pregnant TA patients with active disease, have higher risk of developing maternal complications, especially cardiovascular events. In this setting, close monitoring and disease remission should be maintained during pregnancy.

TREATMENT OF THROMBOTIC EVENTS IN BEHÇET DISEASE: A SYSTEMATIC LITERATURE REVIEW

Rheumatology, Gregorio Marañon General Hospital, Madrid, Spain

Background: Behcet’s disease (BD) is a systemic disease which etiopathogenesis is largely unknown. It is characterised by a wide variety of clinical manifestations. Venous disorder is a serious manifestation being potentially life-threatening. There is little evidence on the management of the venous complications in BD.

Objectives: To perform a systematic literature review on the treatment used in venous thrombotic events in BD.

Methods: The objective was reformulated according to the PICOC approach. Several synonyms for the main components (i.e. Behcet, thrombosis, treatment) were used. Search limits were applied for humans. The literature search was performed in Medline and Embase from databases inception to 1st November 2017. Only articles in English and Latin languages were retained. We excluded abstracts, reviews and letters. From the selected studies, data about the venous involvement and treatments were retrieved using a predefined data collection form.

Results: The literature searched in 1552 articles, of which 632 were captured in Medline and 920 in Embase. Figure 1 shows the study flow-chart for article selection. The main reasons for article exclusion after full-text review were the lack venous involvement and the lack of explanation of venous involvement treatment. 28 articles reporting 1904 patients were included in qualitative analysis. The mean (range; SD) duration of 6 (1.2–9.3) 2.7 years. Superficial thrombosis was evaluated in 6 (21.4%) articles, profund thrombosis in 19 (67.9%) articles, cerebral and 7 (25%), inferior or superior cava vein in 15 (53.6%) and Budd-Chiari syndrome in 8 (28.6%) articles. Table 1 shows the treatments described in the selected articles. Treatment response was evaluated in 20 (71.4%) articles; in 7 of these treatments response was evaluated in a subjective way. In total, 52 (2.7%) deaths were reported in relation to BD. In 319 (16.7%) patients, partial efficacy or recurrence of thrombosis was reported. Considering the heterogeneity of the reported data and the variability in the measures of treatment response, predictors of mortality risk cannot be analysed. However, in the reviewed articles, a higher mortality rate was observed in patients with hematological involvement due to Budd-Chiari syndrome. We have also observed a higher risk for the development of venous thrombosis in patients with patenia phenomenon and male sex. Two studies suggested that immunosuppressive treatment concomitant with anticoagulant treatment is associated with a lower risk of thrombosis relapse compared with anticoagulant treatment alone.

Background: Uveitis is the most common ocular manifestation in Behçet’s Disease (BD), which can cause irreversible blindness.1-2

Objectives: To assess efficacy, safety and cost-effectiveness of adalimumab (ADA) therapy optimisation in a series of patients with uveitis due to BD.

Methods: Multicenter study of 74 ADA-treated patients with BD uveitis refractory to conventional immunosuppressants. Following remission, optimisation was performed by increasing the ADA dosing interval. Comparison between optimised and non-optimised group was performed.

Results: Ocular remission was achieved in 65 (86.6%) patients after a median ADA duration of 6–12 months. ADA was optimised in 23 cases. In the remaining 42 ADA was maintained at 40 mg/sc/2 weeks. No baseline differences were found at ADA onset between the optimised and non-optimised groups. Ocular outcomes were similar after a mean ±S.D. follow-up of 34.7±13.3 and 26±21.3 months in the both groups (table 1). Adverse effects were seen in non-optimised group (lymphoma, pneumonia, local reaction and bacteremia). Mean ADA treatment costs were lower in the optimised vs non-optimised group (6101.25 € / patient/year vs 12339.48).

Disclosure of Interest: None declared

Abstract AB0669 – Table 1

Conclusions: OA optimisation in BD uveitis refractory to conventional therapy is effective, safe and cost-effective.

FIRST DOCUMENTATION OF RS3PE AFFECTING THE HANDS ON 18F-FDG WHOLE BODY PET/CT IN POLYMYALGIA RHEUMATICA

C.E. Owen1,2, A.M. Poort3,2, L.P. Yap1, J.J. Leung1,2, D.F. Lieuw1,2, S.T. Lee1,2,3, A. M. Scott1,2,3, R.R. Buchanan1,2,1. Rheumatology, Austin Health, Heidelberg VIC; 2Medicine, University of Melbourne, Parkville VIC; 3Molecular Imaging and Therapy; 4Radiology, Austin Health; 5Olivia Newton-John Cancer Research Institute, Heidelberg VIC, Australia

Background: Remitting seronegative symmetrical synovitis with pitting oedema (RS3PE) syndrome describes a clinical entity characterised by distal synovitis with pitting oedema, the absence of rheumatoid factor (RF) and an excellent response to glucocorticoid therapy. Most frequently associated with polymyalgia rheumatica (PMR), tenosynovial sheath inflammation represents the magnetic resonance imaging (MRI) hallmark of this condition, with concomitant joint synovitis also present in some cases. More recently, diffusely increased 18F-fluoro-deoxyglucose (18F-FDG) uptake was visualised at the wrist joint and hand in a distinctive volar distribution. Therapy response to glucocorticoid therapy is effective, safe and cost-effective. We report the first documentation of RS3PE affecting the hands on 18F-FDG whole body PET/CT in a patient with PMR.

Methods: Patients with newly diagnosed PMR were prospectively recruited as part of the Melbourne Predictors of Relapse in PMR (MPR-PMR) study. A standard physical examination was carried out with specific focus upon the presence of peripheral synovitis and pitting oedema. In patients with findings suggestive of RS3PE, clinical photography was undertaken. All study participants underwent a whole body PET/CT scan including dedicated views of the hands using the Multi-detector T/F machine prior to prednisolone commencement. To precisely identify anatomic correlates of abnormal 18F-FDG uptake in patients with RS3PE, MRI of the wrist and hand was performed using a 1.5 Tesla magnet.

Results: 3/35 patients (0.86%) were noted to have distal synovitis and pitting oedema of the hands at enrolment. Mean age was 70.9±10.1 years, two patients were male, and all were Caucasian. RF and anti-citrullinated peptide autoantibodies were negative in all cases. On whole body PET/CT, intense 18F-FDG uptake was visualised at the wrist joint and hand in a distinctive volar distribution. MRI of the wrist and hand in two participants (contraindicated in the third)
confirmed flexor tenosynovitis (white arrows) and intercarpal synovitis (yellow arrow) in keeping with RS3PE syndrome.

Abstract AB0671 – Figure 1

Conclusions: On whole body PET/CT, RS3PE syndrome is associated with a distinctive volar pattern of abnormal $^{18}$F-FDG uptake at the wrist and hand, which correlates with flexor tenosynovitis and intercarpal synovitis as previously described on MRI.

AB0672
$^{18}$F-FDG WHOLE BODY PET/CT AS A DIAGNOSTIC TEST FOR POLYMYALGIA RHEUMATICA IN PATIENTS WITH NORMAL INFLAMMATORY MARKERS

C.E. Owen1,2, E. Martin3, A.M. Poort2, J.L. Leung1,2, D.F. Liew1,2, S.T. Lee2,3,4, A. M. Scott2,3,4, R.R. Buchanan1,2, R.F. Buchanan1,2, Rheumatology, Austin Health, Heidelberg VIC; 4Medicine, University of Melbourne, Parkville VIC; 5Molecular Imaging and Therapy, Austin Health; *Olivia Newton-John Cancer Research Institute, Heidelberg VIC, Australia

Background: Despite abnormal C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) being required in the 2012 EULAR/ACR classification criteria, 7%–20% of polymyalgia rheumatica (PMR) patients possess normal inflammatory markers at diagnosis.1 A characteristic pattern of $^{18}$F-fluorodeoxyglucose ($^{18}$FDG) uptake is seen on whole body position emission tomography/computed tomography (PET/CT) in PMR, hence this imaging modality may be a useful diagnostic test in this clinical scenario.

Objectives: To report the utility of whole body PET/CT for diagnosing PMR in patients with normal inflammatory markers and compare the clinical and radiologic characteristics of this subgroup with patients from the Melbourne Predictors of Relapse in PMR (MPR-PMR) study.

Methods: Patients presenting with clinical features of PMR according to the 2012 EULAR/ACR classification criteria but normal CRP and ESR underwent $^{18}$FDG PET/CT as part of their diagnostic work-up. A whole body scan from skull vertex to feet (including dedicated hand views) was performed using the Phillips TlF machine prior to prednisolone commencement. Qualitative and semi-quantitative (standardised uptake value maximum [SUVmax]) scoring of abnormal $^{18}$FDG uptake was undertaken. Newly diagnosed and untreated PMR patients who underwent the same $^{18}$FDG PET/CT protocol as part of the MPR-PMR study were used as the comparator group. Statistical analysis was conducted using Stata 13.1 (StataCorp, College Station, TX, USA).

Results: Three patients with normal inflammatory markers (Median CRP 1 [0.9–2], median ESR 61–7) underwent $^{18}$FDG PET/CT. Mean age was 60.15±7.55 years, two patients (66.67%) were male and all were Caucasian. Shoulder and hip pain was present in all cases, but only one patient reported peripheral joint involvement. Median early morning stiffness (EMS) was 30 min.11–16 On whole body PET/CT, characteristic $^{18}$FDG uptake was visualised in each patient at the shoulder capsule, trochanteric bursae and adjacent to the ischial tuberosities, with hip capsule involvement similarly present in 2/3. When compared with 35 patients from the MPR-PMR study, there were no statistically significant differences in the clinical characteristics nor the distribution or intensity of abnormal $^{18}$FDG uptake between the two populations.

Conclusions: In patients with suggestive clinical features but normal inflammatory markers, whole body PET/CT may be utilised to confirm a diagnosis of PMR.

ANCA-ASSOCIATED VASCULITIS AND INFECTIONS: RETROSPECTIVE ANALYSIS IN A REFERRAL CENTRE

J. Álvarez Troncoso, Z. Iannaccone, E. Álvaro Valiente, C. Busca Arenzana, L. Ramos Ruperto, G. Daroca Bengoa, J. Vasquez Manau, F. Amalich Fernández, J.J. Ríos Blanco. Internal Medicine, Hospital Universitario La Paz, Madrid, Spain

Background: The antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) are rare multisystem autoimmune diseases of unknown cause, characterised by inflammatory cell infiltration causing necrosis of blood vessels. The AAV comprise granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA). The AAV are autoimmune diseases with potentially severe systemic involvement that require prolonged immunosuppressive therapy. Infection is a frequent complication in AAV and is associated with increased morbidity and mortality.

Objectives: The aim of this study was to define epidemiology, ANCA patterns, treatments, infections and outcomes of a series of 39 patients with AAV.

Methods: We retrospectively analysed 39 patients diagnosed with AAV between 1995 and 2017 from the Internal Medicine Department of a Spanish referral centre.

Results: A total of 39 patients were reviewed. 23 female (58.9%). Mean age at diagnosis was 55.6 years. Median time delay to diagnosis was 7.6 weeks. Median follow-up was 91.3 months. Most frequent AAV was MPA with 16 patients (46.2%), followed by GPA with 11 (28.2%) and EGPA with 10 (25.6%). 6 patients (15.4%) had a concomitant autoimmune disease: Systemic sclerosis,2 Antiphospholipid syndrome,2 Lupus1 and Sjögren.1 Only 2 patients (5.1%) had previous infection with hepatitis C virus. Regarding the treatments, all patients received corticoids (bolus 24 patients, 61.5%), 29 (74.4%) cyclophosphamide, 10 (25.6%) rituximab, 19 (48.7%) azathioprine and 1 (2.6%) methotrexate. 16 patients presented post-treatment lymphopenia, 5 pancytopenia, and 15 hypogammaglobulinemia. 21 patients (53.8%) presented any infection after the diagnosis. The most frequent were bacterial infections (15 patients), presenting 9 patients with sepsis criteria (7 due to gram-negative organisms), 9 opportunistic infections were described: 3 infections by cytomegalovirus, 5 by tuberculosis and 1 by Mycobacterium avium. There were no cases of Pneumocystis jiroveci despite the fact that only 16 patients (41%) performed primary prophylaxis. The factors associated with increased risk of infections were: lymphopenia, pancytopenia and increased BVAS (p<0.05). 6 patients had died at the time of the study (3 associated with infections, 2 with neoplasms and 1 directly with AAV). The Charlson index performed at the time of the study was the best predictor of mortality (p<0.01).

Conclusions: Infections were a frequent complication in patients with AAV and one of the main causes of mortality. Risk factors were lymphopenia, pancytopenia and increased BVAS. Bacterial infections were the most frequent but opportunistic infections must be taken into account.

RESULTS: In this study, 53 patients (50.48%) with TAK were had As. The duration of disease in TAK patients with As significantly longer than non-As group (p=0.003, 95%CI: 1.431–14.494). More important, the LDL-C/HDL-C ratio was above the predicted cut-off value 3.038, the incidence of As increased by 2.945 times every 5 years (p=0.003, 95%CI: 1.431–6.062). History of hypertension has more risk to As (OR=4.088, 95%CI: 1.153–14.494). Logistic regression showed the age above 40 years old is risk factor of As in TAK patients. In disease activities, there were no differences in Kerr score and ITAS between 2 groups. The traditional risk factors of As in two groups were compared, and serum level of CRP in TAK with As patients lower than non-As (p=0.011). Levels of serum lipids in 2 groups of TA patients. There were no differences in TG, CHD, HDL-C and LDL-C between TA patients with atherosclerosis (As) and non-atherosclerosis (non-As).

Conclusions: Our study showed the duration of disease and LDL-C/HDL-C more higher in TAK patients with As than without As. Age ≥40 years old, the duration of disease, hypertension, TG/HDL-C and HDL-C/HDL-C ratios were the risk factors of As in TAK patients.

RHEUMATOID FACTOR POSITIVITY IS RELATED TO CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGITIS
J. Inamg, Y. Kaneko, Y. Ohta, T. Takeuchi. Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

BACKGROUND: Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), which is characterised by vasculitis with allergic features such as asthma and eosinophilia. Although rheumatoid factor (RF) positivity is known to be as high as 37%–50% in AAV patients the clinical significance of RF-positivity remains unknown.

OBJECTIVES: To investigate clinical features in patients with RF in EGPA.

METHODS: Consecutive patients who were diagnosed with EGPA between January 2008 and January 2018 in Keio University Hospital were enrolled. Clinical information was collected from medical records retrospectively. We divided patients into 2 groups according to RF positivity, and compared clinical features.

RESULTS: Seventeen patients were enrolled in the study. The mean age was 57.4 years old, and 82% were female. Among them, 11 patients were RF positive (RF positive group) and 6 patients were negative (RF negative group). The female rate tended to be higher in the RF positive group than the negative group (82% vs 50%, p=0.087). While the Birmingham Vasculitis Activity Score was comparable between the two groups (21.5 vs 17.3, p=0.329), general symptoms (fever and weight loss) and gastrointestinal lesions were more frequent in the RF positive group (55% vs 17%, p=0.072; 45% vs 17%, p=0.03) and central nervous involvement was less frequent (18% vs 67%, p=0.024). No patient with negative RF presented with arthralgia/arthritis. The count of eosinophils and IgA levels at diagnosis were significantly higher in the RF positive group than the RF negative group (1570/µL vs 4751/µL, p=0.009; 238 mg/dL vs 162 mg/dL, p=0.048). Interestingly, ANCA positivity was negatively correlated with RF positivity. MPO-ANCA was positive in 27% of the RF positive group and in 66% of the RF negative group, and PR3-ANCA was positive in none of the RF positive group and 17% of the RF negative group. Double negative was more frequent in RF positive group (73% vs 33%, p=0.060).

Conclusions: RF positivity was associated with clinical and serological characteristics in patients with EGPA, suggesting different pathogenesis or immunological disturbances is related.

AB0676  Efficacy of rituximab therapy against anti-neutrophil cytoplasmic antibody-related hypertrophic pachymeningitis: A case series

K. Kobayashi1, D. Nakagomi2, S. Hana1, M. Yamagata3, T. Sugiyama4, H. Kawashima5, M. Hiroguri6, T. Kasuya7, S. Furuta8, K. Ikeda9, H. Nakajima10, K. Kitanura3. 1. Third Department of Internal Medicine, University of Yamashini, Chuo city, Yamashini; 2. Department of Rheumatology, National Hospital Organization, Shimoshizu Hospital; 3. Department of Internal Medicine, Narta Red Cross Hospital; 4. Department of Allergy and Clinical Immunology, Chiba University Hospital, Chiba, Japan

Background: Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides presents with various symptoms. ANCA-associated hypertrophic pachymeningitis (HP) is a very rare pathology.

Methods: Seven patients were identified by retrospective chart review from local registries at four Hospitals in Japan. All patients met Chapel Hill 2012 Consensus Conference definitions of ANCA-associated vasculitides and were complicated with HP. We assessed the dose of prednisolone, CRP, and MRI findings of HP before and after RTX administration.

Results: Three female and 4 male were evaluated. Median age was 66 years old. Four cases had HP at the onset of vasculitis. Relapse of HP before RTX administration was found in 2 cases. RTX was used as an initial treatment in one patient. Daily dose of prednisolone and CRP were significantly decreased from baseline levels 24 weeks after RTX treatment. Evaluation of HP by contrast MRI showed improvement in six of seven cases. No relapse after RTX treatment was observed during the follow-up period of 24 weeks. Severe adverse effects were not found in any patients.

Conclusions: Our case series highlight the efficacy of RTX against patients with difficult-to-treat ANCA-related HP. Future studies in this context in a prospective manner are definitely required to establish the B-cell depletion therapy by RTX as a treatment option for ANCA-related HP.

treatment for SD. No prognostic factors were found to correlate with PUK relapses and final visual acuity/ocular perforation.

Conclusions: Conclusions: RA and ANCA-vasculitis are the SD more frequently associated with PUK. Visual outcomes are poor in less than 50% of patients despite of topical and systemic GC/biologic therapy. SD-PUK may emerge previous to the SD diagnosis or with the associate SD in remission.

AB0679 LEVEL OF SERUM 25(OH)D WITH DISEASE ACTIVITY OF A COHORT STUDY

L. Hu, Department of Rheumatology and Immunology, Beijing Anzhen Hospital, Capital Medical University., Beijing, China

Background: Takayasu’s arteritis (TAK) is a chronic large vessel vasculitis primarily involving the aorta and its major branches. TAK has been considered a rare disease that affected mostly young Asian women[1]. Its pathogenesis is still under investigation. However, some studies have demonstrated that immune disorder results in TAK. Especially cellular immunity plays a vital role in TAK. Recently, some studies shown that Vitamin D can regulate immune system in rheumatological diseases, such as SLE, RA and so on [2]. The relationship between Vitamin D and disease activity of TAK has not been reported yet. This study focuses on identifying the role of Vitamin D in pathogenesis of TAK through studying the correlation of serum 25(OH)D level and the disease activity of TAK.

Objectives: To evaluate the level of serum 25-hydroxyvitamin D in patients with Takayasu’s Arteritis (TAK)

Methods: Totally 57 untreated TA patients (TA group) and 51 healthy people (control group) were enrolled. The level of serum 25(OH)D were measured and compared between groups. The correlations of 25(OH)D level with related indicators were analysed.

Results: Lower concentrations of serum 25(OH)D were detected in TAK patients compared with healthy subjects [11.91±5.26 ng/ml versus (17.64±8.85 ng/ml) (p<0.01). In all patients with TAK, serum 25(OH)D correlated negatively with erythrocyte sedimentation rate (ESR), interleukin (IL)–6 (r=−0.321, p=0.022; r=−0.322, p=0.031). There was no correlation between serum 25(OH)D level and NIH score. ITAS2010 score, ITAS,A score, anti-tumour necrosis factor (TNF)-a antibody. TAK Patients with therapy showed a significantly higher serum level of 25(OH)D compared with that before therapy [(10.74±3.49) ng/ml versus (18.66±8.03) ng/ml] (p<0.01). After therapy, the changes of 25(OH)D level present a positive correlation with the changes of NIH score, ITAS2010 score and ITAS,A score.

Conclusions: We observed a high prevalence of vitamin D deficiency in patients with TAK. The 25(OH)D levels in serum was negatively correlated with ESR and IL-6. Levels of 25(OH)D were improved after therapy. The changes of 25OHD level correlation to Disease Activity of Index.

AB0680 NON OPHTHALMOLOGICAL NEUROLOGIC ISCHAEMIC MANIFESTATIONS OF GIANT CELL ARTERITIS

L. Coronel Tarancón1, L. Monó2, E. Fernández2, A. Balsa2, E. De Miguel2.
1Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife; 2Hospital Universitario La Paz, Madrid, Spain

Background: Giant cell arteritis (GCA) is a very infrequent cause of stroke. It is diagnosed in 0.15% of brain infarctions. On the other hand, in scientific literature there are very little patients with ischaemic brain infarctions that describes stroke as the clinical presentation of GCA. It might suggest that it is a underdiagnosed condition.

Objectives: To check the frequency of stroke as presentation symptom of GCA and other findings related with it.

Methods: Retrospective observational study of 123 consecutive patients diagnosed of GCA in our hospital. We reviewed the past medical history to obtain sings, symptoms and ultrasound parameters of the first medical evaluation. We searched for: age, sex, hypertension, diabetes, dyslipidemia, anterior ischaemic optic neuropathy (AION), headache, visual disturbances, Polymyalgia Rheumatica (PMR), jaw claudication, general symptoms, non ophthalmal brain ishaemic symptoms, disease outbreak and laboratory test: erythrocyte sedimentation rate (ESR), C reactive protein (CRP), Haemoglobin (Hb). For the analysis we divided the sample into two groups: a). Neurological symptoms b). Other presentations.

For statistical comparisons, we used SPSS version 17.0. Descriptive analysis and comparison was performed of the two groups. X2 was used for qualitative values and means comparisons for quantitative.

Results: Of our 123 patient’s cohort: 37 patients (30.08%) suffered from ischaemic events of the internal carotid artery, 25 patients (20.32%) of AION and 12 patients (9.8%) presented with neurological symptoms different from AION.

Out of the 12 patients with non ocular ischaemic sympotms of the central nervous system: 5 (44.66%) were diagnosed of transitory ischaemic accident (TIA), 4 (33.33%) of stroke, 2 (16.66%) of VI cranial nerve paresis, one the patients that presented with III and VI par paresis suffered also from TIA, at last, one patient presented ischaemic phenomena related with small-vessels vasculitis and one patient with dizziness due to cerebellum affection.

Conclusions: No patient was presented with PMR or jaw claudication. 3 (25%) patients died during the follow up in the neurologic symptoms group in comparison with 11 (9.90%) of the non neurological (p 0.11).

AB0681 BIOPSY RESULTS FROM PATIENTS WITH SUSPECTED GRANULOMATOUS POLYANGITIS (A DECADE (2005–2015), ALEATORISED SAMPLE ANALYSIS OF CLINICOPATHOLOGICAL CORRELATION

L.F. Flores-Suarez1, H. Echeagaray2, G. Tona-Acedo2, R.M. Rivera-Rosales3, N. Ruíz4, A. Castroena-Maldonado4. 1Primary Systemic Vasculitides Clinic; 2Department of Otorhinolaryngology, Head and Neck Surgery; 3Department of Pathology, Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico

Background: The diagnostic yield of airway biopsies in granulomatous with polyangitis (GPA) is usually less than 50%.

Objectives: To review the histologic diagnostic yield of airway biopsies sent with a suspected GPA diagnosis in a single-centre devoted to respiratory diseases by use of previously published criteria. Also, to know the interobserver variability among in-house pathologists, correlate signs and symptoms with GPA positive histologic findings, and with additional paraclinical data, apply the algorithm proposed by the European Medical Agencies (EMA) to know if a higher number of biopsies confidently supported a GPA diagnosis.

Methods: From 137 airways biopsies during a decade (2005–2015), fifty were randomly selected for the second review by an expert pathologist. Thereafter, with the incorporation of antineutrophil cytoplasm autoantibodies (ANCA) the EMA algorithm was applied. Demographic data were descriptively analysed, and
results expressed according to their distribution. Categorical data, expressed in percentages, were analysed with χ² test and variance analysis. The associations of independent variables were analysed with one-tail exact Fisher test. Simple logistic regression was used for variable associations. The interobserver correlation was tested with calculation of the kappa coefficient.

Results: A poor interobserver correlation was found among pathologists (kappa = 0.19), and no airway sign or symptom was predictive of a positive GPA biopsy. Several pitfalls were noticed: lack of adequate clinical information on files (including clinical); incomplete relevant information sent to pathologists and inadequate tissue sampling. Nevertheless, in patients with generalised disease, a 2.6 probability to obtain a diagnostic GPA airway biopsy was found. After expert pathologist’s review, and applying Devaney et al and Travis et al proposed criteria, from 16 initial GPA diagnoses, the number increased to 25. It further raised to 35/50 randomised biopsies when ANCA results were incorporated, and the EMA algorithm was applied.

Conclusions: Carefully retrieved clinical, endoscopic and serological data, coupled with systematic histopathologic sample review in patients with a GPA suspicion shall be incorporated in an orderly fashion in order to increase the diagnostic yield of this malady, especially in patients with the limited form of the disease.

AB0682 RISK FACTORS ASSOCIATED WITH RELAPSE OF ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

Background: Several factors increasing the risk of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitides have been reported. These include pulmonary and cardiovascular lesions, PR3-ANCA positivity in patients with granulomatosis with polyangiitis, and persistent PR3-ANCA positivity or an increase in the titer of such antibodies.

Objectives: We aimed to identify potentially novel factors predicting relapse in patients with ANCA-associated vasculitides.

Methods: We reviewed data on 73 patients (61 with microscopic polyangiitis [MPA], 12 with granulomatosis with polyangiitis [GPA]; 46 females) treated in our centre from 1998 to 2017 for whom medical histories were available. All achieved at least one remission after induction therapy. Relapse was defined as novel organ involvement or a need for therapy intensification. Follow-up continued to the first relapse or for as long as possible if no relapse was noted.

Results: The median age at disease onset (interquartile range) was 74 years (range: 67–80 years). The relapse rate was 42.5% (MPA 41%, GPA 50%), thus not significantly different between the two groups (p=0.75). The median follow-up duration was 23 months (range: 11–65 months) and the median time to relapse was 18 months (range: 10.5–54 months). Although pulmonary and cardiac lesions reportedly increased the relapse rate, neither contributed significantly to the rate in this study. Furthermore, ANCA positivity after remission and increases in ANCA levels prior to relapse did not significantly increase the relapse risk. In terms of medical histories recorded at the time of first onset of disease, the frequency of diabetes, dyslipidemia, coronary artery disease, and cerebral infarction did not differ significantly between patients who did and did not relapse. However, in MPA patients, a history of hypertension was significantly less in those who relapsed (p=0.01). In a multiple logistic regression analysis adjusted for sex and age, history of hypertension was a significant predictor of fewer relapse (odds ratio: 0.23; 95% confidence interval 0.07–0.69, p=0.009).

AB0683 TREATMENT WITH STATINS IN PATIENTS STUDIED BY FDG-PET/CT FOR POSSIBLE LARGE VESSEL VASCULITIS IS ASSOCIATED WITH A LOW VASCULAR SCORE

M.A. Cimmino1, F. Iannuzzi1, D. Camellini1, S. Morbelli1, M. Cutolo1, G. Sambuceti1, 1Department of Internal Medicine; 2Autoimmunity Laboratory; 3Division of Nuclear Medicine, University of Genova, Genova, Italy

Background: Polymyalgia rheumatica (PMR), giant cell arteritis (GCA), and fever of unknown origin (FUO) may show large vessel vasculitis (LVV) when studied with FDG-PET/CT. Statins, widely used to lower cholesterol concentrations, have shown anti-inflammatory activity in both the atherosclerotic plaque and in rheumatoid arthritis.

Objectives: To test the hypothesis that the concomitant treatment with statins induces a low uptake of the vessels in patients with PMR, FUO and GCA.

Methods: Consecutive patients with a diagnosis of PMR, GCA or FUO underwent a thorough clinical examination, including drug history, and a PET/CT scan. Arterial uptake of FDG was scored relative to liver uptake as 0=no uptake present, 1=lower than liver uptake, 2=similar to liver uptake, 3=higher than liver uptake. The values of each district were summed to obtain a total vascular score (TVS). A further semi-quantitative analysis of FDG uptake was carried out, drawing regions of interest (ROIs) on the theoretical arterial wall and within the left ventricular chamber (blood-pool, BP). Arterial FDG uptake was quantified by calculating the mean standardised uptake value (SUV) within each ROI and the results expressed as the ratio between mean SUV value of each ROI and BP ROI (SUV/BP).

Results: 129 patients were included, 87 women, with median age of 74 years (range 50–92). 95 patients were diagnosed with PMR, 13 with GCA, 16 with both PMR and GCA and 5 patients presented with FUO. 37/129 patients (28.7%) were assuming glucocorticoids (GC) at the time of examination. The mean interval between onset of symptoms and PET/CT was 85 days (range 4–1957 days), LTV was present in 75 patients (58.2%) when a cut-off ≥ 2 was used and 32 patients (24.8%) had a score of 3.

Twenty/129 patients (15.5%) were treated with statins for hypercholesterolemia. The median TVS was significantly lower in these patients when compared with those not treated with statins (8 [range 1–27] vs. 12 [range 0–42], p=0.02). This difference was present at the ascending aorta (p=0.017), the aortic arch (p=0.023), and the femoral arteries (p=0.025). The analysis of SUV was not
significant (p=0.45). As expected, the arterial calcium load, corresponding to the extent of vessel calcification, was higher in patients treated with statins (14 [range 2–35] vs. 8 [range 0–35]; p=0.012). However, calcium load did not correlate with the TVS, whereas it inversely correlated with SUVs (p=0.03). At multiple regression, assumption of statins was not predicted by sex, type of diagnosis, GC treatment or presence of LVV at PET/CT. Only age predicted statin therapy (p=0.04), but age was not associated with LVV (p=0.23). Among clinical features, only fever was significantly less frequent in patients treated with statins (p=0.03).

Conclusions: With the limits of an observational retrospective study, our data suggest that treatment with statins may lower arterial uptake in patients studied for LVV. This finding was seen using the theoretically more subjective TVS but not with SUV analysis. We feel that the latter is more easily influenced by the presence of calcific plaques, as suggested by its inverse correlation with arterial calcium load. The role of statins in tempering arterial inflammation deserves further studies.

### A REVIEW OF TEMPORAL ARTERY BIOPSIES AT A DISTRICT GENERAL HOSPITAL

M.A. Yusuf, M. Al-Zaza, T. Walton, Colchester Hospital University NHS Trust, Colchester, UK

Background: Giant cell arteritis is the most common vasculitis in the western world in the over 50 population. The morbidity associated with its natural progression and treatment is significant. No single investigation has been identified to accurately confirm or reject its diagnosis, though for some years biopsy of the superficial temporal artery has been carried out to support the diagnostic process. More recently, doppler ultrasound of the artery has gained prominence, though its widespread use is limited.

Temporal artery biopsy (TAB) is a significant use of resources, involving a surgeon and their team, as well as a histopathologist. It is an invasive procedure with the risks that this entails. It behaves the referring doctor to ensure that the probability of a positive result is as high as practicable.

Objectives: To determine the factors providing the highest likelihood of a positive TAB result.

Methods: The notes of all patients undergoing a TAB during a 3 year period 2013–2016 were requested from the Medical Records department at a district general hospital. The first 100 of these were reviewed by the authors. Each set of notes was examined for the following:

- Demographics (sex, age)
- The first department the patient was referred to (Rheumatology/Ophthalmology/Neurology/direct from the General Practitioner to Vascular Surgery)
- Period of time from symptom onset to biopsy
- Period of time on steroids to biopsy
- Initial dose of steroids prescribed
- Pre-treatment CRP
- Pre-treatment CRP
- Presence of symptoms (headache/jaw claudication/polymyalgia rheumatica)
- Other causes for a raised ESR
- The pre-test probability of a positive TAB result as assessed by the reviewer
- TAB result as reported by local histopathologist
- Evidence of the biopsy result impacting treatment

Results: Of the 100 TABs reviewed, 16 yielded positive results (16%). A breakdown of the notes review for these patients is included in the following table:

</tbody>
</table>

Conclusions: This study has shown that less than a fifth of TAB’s conducted during this period at our district general hospital yielded a positive result. There is scope to improve this yield significantly if we identify candidates for TAB better.

There was no positive result for any of the 16 patients less than 58 years of age. The majority had a raised CRP and ESR, though one patient had a CRP of 2. This reflects the need for vigilance before discounting GCA as a diagnosis.

One patient had a positive TAB even after 28 days of prednisolone 40 mg daily. The majority (14/16) had their biopsy within 3 weeks of steroid initiation, indicating that a short delay in biopsy does not rule out a positive result.

This study will help us develop a local pathway including Ophthalmology, Neurology, Vascular Surgery and Primary Care to improve the yield of positive TAB. This will improve patient experience as well as ensure appropriate use of resources.

### THE INCIDENCE OF GIANT CELL ARTERITIS IN SLOVENIA – PROSPECTIVE STUDY

N. Potočnik Pureau1, A. Hocevar1, R. Jestež, Ž. Rotar1, J. Piščem2, M. Hawlin3, A. Fakiriš, M. Tomšečič1.1. Dept. of Rheumatology, University Medical Center Ljubljana; 2Institute of Pathology, Faculty of Medicine, University of Ljubljana; 3Department of Ophthalmology, University Medical Center Ljubljana, LJUBLJANA, Slovenia

Background: Giant cell arteritis (GCA) represents the most common vasculitis in adults over age of 50 years in Europe. Recently the diagnostic options greatly improved with the implementation of imaging techniques such as colour Doppler ultrasonography (CDS) and positron emission tomography-computed tomography (PET/CT).

Objectives: The aim of our single centre prospective study was to determine the incidence of GCA in well-defined Slovenian region, based on the temporal artery (TA) biopsy (TAB) and/or the result of CDS and/or PET/CT.

Methods: The study was conducted at University medical centre Ljubljana (UMC Ljubljana), that represents the only secondary/tertiary centre in a region, serving a population of 3 239 residents aged 50 years or more (1 76104 females and 1 47193 males). Patients with suspected GCA are referred either to the Department of Rheumatology, or in case of severe visual disturbances, to the Department of Ophthalmology. In the analysis we included all GCA cases diagnosed between 1 January 2012 and 31 December 2017. The diagnosis of cranial GCA (c-GCA) was established with the help of American College of Rheumatology (ACR) 1990 classification criteria, positive TAB and/or TA CDS. Cases of extracranial large vessel vasculitis (lv-GCA) were diagnosed using CDS of branches of the aortic arch and/or PET-CT.

Results: During the six-year observation we identified 169 new GCA cases (66.3% females), with a median (IQR) age of 75.1 (68.6–80.0) years. Forty-two (24.8%) patients had lv-GCA, and the others had c-GCA. One-hundred and thirty-nine patients (24 lv-GCA and 115 c-GCA) fulfilled ACR 1990 classification criteria. The others patients had positive arterial CDS or PET-CT (18 CDS, 9 CDS and PET-CT, 3 PET-CT). TAB was performed in 119 patients and was positive in 88.2%. Clinical characteristics of our GCA cases are presented in table 1. The estimated annual incidence rate of GCA was 8.7 per 100 000 adults aged ≥50 years (95% CI 7.5–10.1), in c-GCA 6.5 per 100 000 adults aged ≥50 years (95% CI 5.5–7.8) and in lv-GCA 2.2 per 100 000 aged ≥50 years (95% CI 1.6–2.9).

Legend: GCA giant cell arteritis; lv-GCA extracranial large vessel GCA; c-GCA cranial GCA; PMR polymyalgia rheumatica; TA temporal artery; T TA tenderness or decreased pulse; TAB temporal artery biopsy; CDS colour Doppler sonography; ESR erythrocyte sedimentation rate; ACR American College of Rheumatology; median (interquartile range).

Conclusions: GCA is the most common vasculitis in adults aged 50 years or above, with an annual incidence rate of 8.7 per 100,000. c-GCA is nearly 3 times more common than lv-GCA.

ARTERIAL ANEURYSMS IN BEHÇET’S DISEASE: A RETROSPECTIVE DESCRIPTIVE ANALYSIS AND LONG-TERM OUTCOME

N.H.A. El Ghobashy, A. El-Garf, K. El-Garf. Rheumatology, Cairo University, Cairo, Egypt

Background: Behçet’s Disease (BD) was described in 1937 after Hulusi Bechet; as a triad of recurrent aphthous and genital ulcers together with iridocyclitis.1-3 Arterial disease is seen in 3%-5% of the patients.4-5 Thrombosis and/or aneurysmal formation are common sequelae mainly false aneurysms.1 In spite of the fact that BD is not uncommon in the clinical practice in Egypt; the paucity of data that looked specifically to the arterial aneurysms in the Egyptian patients with BD had prompted the present study.

Objectives: Arterial aneurysm in Behçet’s disease is a rare manifestation of Behçet’s disease. The prevalence of Arterial aneurysm in Behçet’s disease change the course of disease and it is an ominous sign and a challenge for rheumatologists.

Methods: A retrospective review of files of 160 patients admitted and followed up in the rheumatology department, Cairo University Hospitals between 2004–2017 was done. We looked specifically for the prevalence of arterial aneurysms. Demographic characteristics of patients with aneurysms, clinical presentation, and associated clinical features were noted.

Results: Twenty-seven (16.8%) patients had arterial aneurysms. All of them were males and the onset of development of the aneurysm is usually under the age of 40 years. 74% of the patients developed aneurysm 3.2±3.0 years after their disease onset. Apart from the oro-gential ulcers; deep venous thrombosis was the most common associated manifestation. Pulmonary artery was the most common artery involved in 12 (44.4%) of patients, followed by the abdominal aorta in 4 (14.8%). Surgical intervention was done for 11 (40.7%) patients; all of them received cyclophosphamide pulses before surgery except one. Four (14.8%) patients in this study died.

Conclusions: Arterial aneurysms are common in Egyptian patients with BD. The profile of Egyptian BD patient that is susceptible for development of arterial aneurysm is a male patient, under the age of 40 years, smoker with relatively short disease duration.

DOES ANTI-GLOMERULAR BASEMENT MEMBRANE (ANTI-GBM) ANTIBODY POSITIVITY CORRELATE WITH RELAPSE IN PATIENTS WITH ANTI-GBM DISEASE?

N. Dno, A. Katz, J. Sedo, R. Haj-Ali.1 Rheumatology, Cleveland Clinic Foundation, Cleveland, USA

Background: Anti-GBM disease is characterised by rapidly progressive glomerular nephritis with or without pulmonary haemorrhage. It is usually monophasic in nature and disease severity correlates with antibody titer. The disease is mediated by pathogenic antibodies directed against the non-collagenous region of the c3 chain of type IV collagen.

Despite the known pathogenicity of anti-GBM antibodies, and the correlation of disease severity with their titres, there is conflicting reports on whether anti-GBM antibody positivity correlates with disease relapse on long term follow up.

Objectives: To assess for correlation of anti-GBM antibody positivity and disease relapse in patients with anti-GBM disease.

Methods: Patients seen in one single academic centre between 1997 and 2017 were initially screened for the presence of anti-GBM disease by ICD 9/10 code for anti-GBM disease or Goodpasture’s syndrome. 435 patients were identified. Patients were then included in the study if the diagnosis was confirmed by a board certified nephrologist or nephrologist at our institution and had positive anti-GBM antibodies and/or biopsy results consistent with a diagnosis of anti-GBM disease. The primary endpoint of this study was anti-GBM antibody positivity at the time of relapse. All charts were reviewed for baseline demographics, clinical manifestations, anti-GBM antibody and anti-neutrophil cytoplasmic antibody (ANCA) positivity at the time of initial presentation; these were compared between those with relapsing and non-relapsing disease. Results were analysed using a two tailed standard t-test. These same characteristics were also examined the relapsing cohort at the time of relapse.

Results: 40 patients were confirmed as having anti-GBM disease at our institution. Mean follow up from disease onset to the date of last follow up was 56.2 months. 8 patients had relapsing disease and 32 patients had non-relapsing disease. Baseline characteristics and clinical manifestations were similar between groups (table 1). Patients with relapsing disease had a statistically higher incidence of ANCA co-positivity as compared to non-relapsing patients (62.5% vs. 21.7% respectively p-value: 0.03).

Conclusions: In patients with relapsing disease, only 14.7% (1/7 tested patients) had positive anti-GBM antibodies at the time of their relapse.

Abstract AB0687 – Table 1. Clinical features and laboratory values at baseline and at the time of relapse of Anti-GBM disease

Values are expressed as mean (range) or percent

PULMONARY AND THORACIC VASCULAR FINDINGS OF BEHÇET’S DISEASE AT COMPUTED TOMOGRAPHY

N. Isiksalan Özbülbül1, D. Üsküdar Cansu, C. Cökmaz,2 Radiology, Internal Medicine, Rheumatology, Eskişehir Osmangazi University, Eskişehir, Turkey

Background: Behçet disease is a multisystemic and chronic inflammatory disorder with unknown etiology. Pulmonary involvement is relatively infrequent.

Objectives: To investigate the pulmonary parenchymal changes and thoracic vascular abnormalities due to Behçet’s disease at computed tomography.

Methods: 21 patients diagnosed with a diagnosis of Behçet’s disease between 2004–2017 were evaluated. Clinical, laboratory, and thoracic computed tomography findings were retrospectively evaluated. Also, the immunosuppressive treatments of the patients were documented.

Results: 18 of the patients (85.7%) were male. The mean age of the patients was 44.4±11.7 years. Onset age of the disease was 32.4±6.4 years, length of follow up was 8.1±2.3 years. 13 of the patients (61.9%) had hemoptysis at the time of initial diagnosis of Behçet’s disease. 14 of the patients (66.6%) showed vascular involvement except pulmonary system. Pulmonary artery aneurysm was observed in 9 patients (%42.8). Pulmonary artery thromboembolism was observed in 15 patients (71.4%). Thoracic computed tomography demonstrated that 5 patients (23.8%) with pulmonary infarct, 4 patients (19%) with pulmonary consolidation, 5 patients (23.8%) with ground-glass opacity in the lung representing pulmonary haemorrhage, 2 patients (9.5%) with pleural effusion, 7 patients (33.3%) with non-specific parenchymal changes, and one patient with focal atelectasis. Also, one of the patients had intracardiac thrombus. Five of the patients were smokers.

Conclusions: Aneurysm of the pulmonary artery with or without thrombosis is the most common manifestation of Behçet’s disease. Pulmonary vasculitis and thrombosis of pulmonary vessels result in infarction, hemorrhage, focal
atelectasis. Thoracic computed tomography can clearly demonstrate the pulmonary and vascular abnormalities of Behçet’s disease.

AB0689 EXTRAVASCULAR MANIFESTATIONS OF TAKAYASU ARTERITIS: HISTORICAL COHORT STUDY IN KOREA
O.C. Kwon1, S.-W. Lee2, Y.-B. Park2, W.J. Seo3, J.S. Oh4, S. Hong1, C.-K. Lee1, B. You1, Y.-G. Kim1
1Division of Rheumatology, Department of Medicine, University of Ulsan, College of Medicine, Asan Medical Center, 2Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, 3Division of Rheumatology, Department of Medicine, Seoul Veterans Hospital, 4Clinical Research Center, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of Ireland

Background: Takayasu arteritis (TAK) is systemic disease characterised by large vessel involvement. Although the vascular characteristics of TAK are well characterised, there is no well-organised study demonstrating the extravascular manifestations of TAK.

Objectives: To evaluate the characteristics of extravascular manifestations of TAK, and to identify the association between vascular and extravascular manifestations of TAK.

Methods: TAK patients from two independent cohorts who fulfilled the 1990 ACR classification and encoded M314 according to ICD-10 code between January 2012 and October 2017 were included in the study. The characteristics of the patients were retrospectively collected from the electronic dataset. A radiologist reviewed CT scans of all included patients to evaluate the pattern of vascular involvement and presence of sarcroilitis. Clinical findings including uveitis, skin lesion, oral ulcer, arthritis, and inflammatory bowel disease (IBD) were reviewed. Logistic regression analysis was performed to evaluate the association between vascular and extravascular manifestation.

Results: A total of 268 TAK patients were included. Mean age at diagnosis was 41.2±14.2 years and 236 (88.1%) were female. The most commonly involved vessel was common carotid artery (176 [65.7%]), and the most common type of vascular involvement was type V (120 [44.8%]). Extravascular manifestation of TAK was common carotid artery (176 [65.7%]), and the most common type of vascular involvement was type V (120 [44.8%]). Extravascular manifestation of TAK was observed in 25% of patients, being alveolar haemorrhage frequently associated with presence of sarcroilitis. Clinical findings including uveitis, skin lesion, oral ulcer, arthritis, and inflammatory bowel disease (IBD) were reviewed. Logistic regression analysis was performed to evaluate the association between vascular and extravascular manifestation.

Conclusions: Extravascular manifestations of TAK are not rare and observed in up to one-fifth of patients. The most common extravascular manifestation was arthritis including sacroilitis (11.9%). Type IIb vascular involvement pattern and high ESR were significantly associated with arthritis in TAK.

AB0690 DIAGNOSTIC VALUES OF ENDOTHELIN-1 IN PATIENTS WITH SYSTEMIC NECROTIZING VASCULITIS
L. Petelytska1, O. Iaremkenko1, K. Iaremkenko2, Bogomolots National Medical University; 1Oleksandriivska City Clinical Hospital, Kyiv, Ukraine

Background: Systemic necrotizing vasculitis (SNV) is characterised by destructive and inflammatory changes in the vessels. Binding of autoantibodies and immune complexes on the surface of endothelial cells stimulates the synthesis of endothelin-1 (ET-1), which leads to activation of macrophages and adhesion of neutrophils, remodelling of the vascular wall and its damage.

Objectives: To evaluate the serum level of ET-1 in patients with SNV and the possibility of its using for the diagnosis of SNV and involvement of individual organs.

Methods: The study included 36 patients with SNV (polyarthritis nodosa – 8, AAV, associated vasculitis – 28) and healthy controls (n=26). Clinical characteristics of patients were calculated according to the Birmingham Vasculitis Activity Score (BVAS). All patients had active disease (BVAS >11). The serum levels of ET-1 (pmol/L) were determined by immunoassay analysis using the kits of Biomedica. The outcomes of this study were the differences in marker levels between patients with active SNV and healthy controls, patients with different forms of vasculitis, with varying degrees of BVAS activity, with involvement different organs and systems estimated by analysis of the absolute changes in marker levels and the areas under receiver operating characteristic (ROC) curves (AUC).

Results: The level of ET-1 (Mn) in the general group of patients with SNV was 0.31±0.24 and did not differ significantly from the control group (0.27±0.10, p>0.05). At the same time, in patients who did not receive at screening glucocorticoids and immunosuppressive agents (n=9), it was significantly elevated (0.62±0.58, p=0.03). However, ROC analysis indicated the moderate sensitivity (67%) and the low specificity (48%) of ET-1 for diagnosis of SNV. There were no significant differences in the levels of ET-1 between patients with different forms of vasculitis and with varying degrees of BVAS activity. In the analysis of the values of the ET-1 depending on the involvement of different organs and systems, it was found that only in patients with kidney involvement (n=15) its level (0.40±0.33) was significantly higher compared with patients without kidney involvement (0.23±0.22, p=0.04) and control group (p=0.01). ROC analysis showed that the AUC for ET-1 is 0.75±0.10 (p=0.004), which indicates acceptable capacity for ET-1 differentiated groups of patients with kidney involvement and patients without kidney involvement (sensitivity – 80.0%, specificity – 78.3%).

Conclusions: The serum levels of ET-1 were elevated in patients with SNV with kidney involvement (48% compared to healthy controls and 43% compared with patients without kidney involvement), which can be used for diagnostic purposes.

Disclosure of Interest: None declared

AB0691 INSTERTITIAL LUNG DISEASE AND MICROSCOPIC POLYANGIITIS IN CHILEAN PATIENTS

Background: Microscopic Polyangiitis (MPA) is an ANCA associated vasculitis (AAV), associated with p-ANCA (perinuclear) fluorescence pattern and anti-myeloperoxidase (MPO) specificity. Most frequently involved organs are kidney (80%–100%), peripheral nervous system and skin (30%). There is Pulmonary involvement in 25%–35% of patients, being alveolar haemorrhage frequently described. Interstitial lung disease (ILD) has also been recognised.

Objectives: The aim of our study is to report the characteristics of MPA Chilean patients with ILD and to compare it with other series.

Methods: Retrospective study. Patient diagnosed between 2007 and 2016 at the Hospital Clínico Universidad de Chile, with ILD, defined as interstitial lung disease on CT scan with Usual Interstitial Pneumonia (UIP) or Non Specific Interstitial Pneumonia (NSIP) pattern, and MPA were included. Demographic, clinical, laboratory and mortality data were plotted. Data from other series were compared with our results. Other causes that could explain the pulmonary involvement were excluded.

Results: From 94 patients with AVV, 36.1% were MPA, being 16 patients with ILD. All were Hispanic, median age 65.3 years, 22 (62.5%) female (table 1). Common manifestations were constitutional symptoms (100%), weight loss (88.7%) and fever (68.7%). All patients had anaemia, high ESR (mean 84 mm/hr. range 33–120) and CRP (8–22 times above upper normal limit). All patients were ANCA-positive. In 10 cases ILD was diagnosed concomitantly with MPA and in 6 was 0.5 to 15 years before. 4 patients developed pulmonary haemorrhage. Images patterns were 10 UIP and 5 NSIP. All patients received corticosteroid as induction therapy, 15 also received cyclophosphamide. One patient plasmapheresis, and one received Rituximab after a relapsed. Azathioprine was used as...
Maintenance therapy. Four patients died during follow-up. Table 2 shows data from other worldwide region compared with our data.

Abstract AB0691 – Table 1. Characteristic of chilean patient with ILD an MPA

Conclusions: Among chilean patients there are more females, have a more NSIP pattern, and less mortality that other worldwide series.

BELIMUMAB IN COMBINATION WITH AZATHIOPRINE FOR REMISSION MAINTENANCE IN GRANULOMATOSIS WITH POLYANGIITIS AND MICROSCOPIC POLYANGIITIS: EFFECT ON BIOMARKERS

D. Jayne1, D. Blockmans2, R. Luymans3, B. Jf4, Y. Green4, L. Haï5, D. Roth6, R. B. Henderson6, P.A. Meded7, 8University of Cambridge, Cambridge, UK;
9University Hospital Gasthuisberg, Leuven, Belgium; 10Bntrah Research Centre, University of Oxford, Oxford; 11GSK, Stockley Park; 12GSK, Stevenage, UK; 13GSK, Collegeville, PA; 14University of Pennsylvania, Philadelphia, PA, USA

Background: GPA and MPA (related types of ANCA-associated vasculitis [AAV]) are organ-/life-threatening systemic vasculitides. B cells and increased circulatory BLyS (a B cell survival factor) are implicated in AAV pathogenesis, suggesting a role for BLyS in these vasculitides. BEL is an anti-BLyS human monoclonal antibody.

Objectives: Examine the effects of BEL plus azathioprine (AZA), on biomarkers in patients with AAV for remission maintenance following standard induction (IND) with glucocorticoids (GC) and CYC or RTX.

Methods: This double-blind, placebo-controlled, multicentre study (BEL115466/C21) randomised (1:1) patients (≥18 years) with new/relapsing AAV following IND (oral or IV CYC or RTX), to AZA 2 mg/kg/day and oral GC, plus IV BEL 10 mg/kg or PBO (Days 0, 14, 28 and every 28 days until completion). Remission was defined as Birmingham Vasculitis Activity Score <0, plus GC ≤10 mg/day. The study was truncated after initiation (n=300 to 100) due to revised AAV standard of care (SoC) affecting recruitment. Biomarker endpoints (serum Igs, B cells and ANCA [anti-MPO/PR3]) were measured at baseline (BL) and thereafter. Summaries by IR were post hoc; no analyses were performed.

Results: At BL, RTX patients had B cell counts≤LLQ. CYC patients had notably low BL B cell counts; the lowest were in oral-CYC patients. Circulating memory B cells (CD20+CD27+) increased rapidly with BEL, then gradually returned to BL (CYC); no major changes occurred with PBO. BEL had no impact on the proportion of naive CD20+CD27– B cells vs PBO, post CYC IND. The number of RTX patients with quantifiable data was low; partial reconstitution occurred in a minority of patients (PBO 2/13; BEL 4/14) and did not translate into vasculitis relapses. Overall LG levels declined more noticeably with BEL vs PBO; suggesting BEL affects antibody-secreting cells. ANCA patients were similar between groups (PBO 32/50; BEL 30/49). No trends in change in ANCA status over time occurred, regardless of IR. Individual patient data showed no apparent trends between ANCA titres and AAV activity.

Conclusions: Choice of IR for active AAV affects B cell dynamics. BEL pharmacodynamics, effects occurred in patients with AAV receiving SoC. Given the small sample size and high variability, data must be interpreted with caution.

DEMOGRAPHIC, CLINICAL, LABORATORY AND IMAGING CHARACTERISTICS OF AN INCIDENCE COHORT OF 93 PATIENTS WITH LARGE VESSEL GCA

P. Macchioni1, 2, L. Boiard1, G. Restuccia1, F. Muratore1, P. Mancuso2, M. Catanos1, C. Salvare1, 3Ospedale Santa Maria Nuova; 4Epidemiology, Ausl Reggio Emilia, Reggio Emilia, Italy

Background: Few study have evaluated the clinical and imaging data of patients with large vessel GCA (LVGCA).

Objectives: To evaluate clinical, demographic and imaging data of an inception cohort of 93 patients with LVGCA recruited in Reggio Emilia (Northern Italy)

Methods: All patients with incident large vessel GCA diagnosed between 1 January 2005 and 31 December 2016 in the Reggio Emilia area, were identified by capture and re-capture checking of computerised discharge diagnosis codes (ICD10) and using outpatients databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital as well

Conclusions: Choice of IR for active AAV affects B cell dynamics. BEL pharmacodynamics, effects occurred in patients with AAV receiving SoC. Given the small sample size and high variability, data must be interpreted with caution.

AB0693
as by examining the Reggio Emilia district database for rare diseases. To be included in the study, patients must satisfy the following 2 criteria: Age at disease onset > 50 years; evidence of large-vessel vasculitis by clinical criteria, angiogra-
phy, MRA, CTA, PET/CT and/or ultrasonography. Demographic, clinical, labora-
tory and imaging data collected at first visit were retrieved from patients records.

Results: There were 93 incident cases of LV GCA (66 women, 71%) during the
study period. Mean ± SD age at diagnosis was 72.1 ± 9 years. The three most
prevailing signs were: systemic in 49 pts (52.7%), GCA cranial symptoms in 30 pts (41.9%) and PMR in 35 pts (37.6%). Peripheral ischaemic
symptoms were observed only in 8 pts (8.6%). Forty four pts had temporal artery biopsy and 70.5% resulted positive. At US examination the three most common
involved arteries were: common carotid artery (59.2% pts), subclavian artery (53.3% pts) and axillary artery (49.3 pts). At PET/CT scan examination the most
common involved arteries were: thoracic aorta (72.1% pts), subclavian artery (61.8% pts) and abdominal aorta (58.8% pts). Celiac trunk and mesenteric artery
were involved in 18.4% of pts and renal artery in 10.2% of pts.

Conclusions: In an inception cohort of LVGCA systemic manifestations had the
highest prevalence among presenting symptoms. Imaging studies demonstrated
an high prevalence of aortic and subclavian involvement.

AB0694 GIANTE CELL ARTERITIS EPIDEMIOLOGY IN LA REUNION: A RETROSPECTIVE CASES SERIES

O. Bichet1, T. Deltombe1, A. Foucher2, C. Roussin2, A. Randrianjohany3, A. Gerber1, P. Pouteau1, L. Raffray1. Internal Medicine, CHU de La Réunion, Saint Denis;1Internal Medicine, CHU de La Réunion, Saint Pierre;2Internal Medicine, CH Gabriel Martin, Saint Paul,3Internal Medicine, Groupe Hospitalier Est Réunion, Saint Benoît, France

Background: Giant Cell Arteritis (GCA) is the most common vasculitis in people
over 50 years, with incidence varying according to geographic location. In Europe, the average incidence is 10–30 per 100,000 inhabitants over 50 years, whereas in Africa and Asia it is approximately 1.5 per 100,000.

Objectives: To define the GCA epidemiology in La Réunion, a French overseas terri-
ory in South West Indian Ocean characterised by several ethnic groups and
 Genetic admixture.

Methods: Retrospective study between January 2005 and August 2017 in the 4
main hospitals of La Réunion. Patients were identified through hospital informatics
databases and practitioner records. A definite diagnosis of GCA was considered
for patients fulfilling ACR criteria and/or by assessment by a trained rheumatolo-
 gist. Incidence and prevalence calculation was based on French national census
data.

Results: Sixty patients were included, of which 60% were women. Mean age at
diagnosis was 73.7 years, with a mean delay to diagnosis of 6.8 months. Cases
met an average of 3.7/8 ACR criteria, and 78% had >2 criteria. The mean annual
incidence was 2.33 per 100,000 inhabitants older than 50 years (203,000), with
95% confidence interval (CI) of 1.74–2.92. The prevalence at the end of study
period was 24 cases per 100,000 (IC: 18–30). There was no seasonal variation
regarding disease onset. Clinically, patients complained of asthenia and head-
ache in 75%, fever in 33% and ophthalmologic damage for 32% of the cases, of
which 5 had anterior ischaemic optic neuropathy. Polyvalgiala rheumatica was
associated in 42% of all cases. Total blood cells counts were usually within normal
values, whereas mean CRP was 115 mg/L. Anicteric cholestasis was a common
finding: mean GGT=78 IU/L (n=42) and alkaline phosphatase=107 IU/L (n=104).

Radiological examinations contributed to diagnosis in only 9/31 cases. Temporal
artery biopsy was performed in 91% of patients and showed specific histological
features of GCA in 55%. Corticosteroid regimen was introduced in 59 patients (1
died the day after the biopsy) and mean treatment duration was 26 months, for a
total dose of 10.6 g. Antiplatelet therapy was given in 47% of patients. One patient
in three experienced one or more relapses.

Conclusions: This is the first study to describe GCA in La Réunion, and more
generally in Indian Ocean. It shows an incidence 4–12 times lower than in most
European countries with white ancestry background. This discrepancy could be
explained by the contribution of the various ethnic groups of La Réunion, espe-
cially those coming from parts of the world characterised by a lower GCA inci-
dence (Africa, India, South East Asia). A shorter life expectancy may also account
for this observation, assuming that GCA incidence increases with age. Sex ratio
and age at diagnosis were similar to European studies, as well as clinico-biologi-
cal features, response to treatment and side effects. Some limitations of our study
should be taken in consideration: inclusions of hospitalised patients only, infor-
matics record limits and retrospective design that did not afford for ethnic back-
ground determination.

AB0695 PREDICTIVE FACTORS OF LONG-TERM CLINICAL OUTCOME IN BECHET’S SYNDROME PATIENTS WITH OCULAR INVOLVEMENT: DOES ACTUALLY THE DISEASE TEND TO GROW DIM OVER TIME?

R. Tajriri1, M. Figus2, C. Possarelli2, A. D’Ascanio1, R. Nei1, C. Tani1, C. Baldini1, M. Mosca1.1Department of Clinical and Experimental Medicine, University of Pisa, Rheumatology Unit, 2Department of Surgical, Medical, Molecular Pathology and Emergency, University of Pisa, Pisa, Italy, 3Ophthalmology Unit, Pisa, Italy

Background: Behçet’s syndrome (BS) is a multisystemic, chronic relapsing inflammatory disease classified among the vasculitides. Eye involvement represent
one of the most serious manifestation of BS and occurs in half of all patients. It
seems more frequent and severe among young males and, unluckily, it still repre-
sents a significant cause of morbidity.

Objectives: The aims of the study were: to study the relapse rate of BS patients
with ocular involvement and to identify factors able to predict long-term outcome
behaviour.

Methods: Among a cohort of 118 patients with a diagnosis of BS according to
the ISG criteria, 62 patients (37 males and 25 females; mean age at the onset 38±5
years) with ocular involvement were prospectively studied. The probability of clini-
cal relapse after remission of the first ocular attack was calculated using the
Kaplan-Meier method. Predictors of long-term outcome were identified by univari-
ate analysis using the log-rank test and by multivariate analysis using Cox propor-
tional hazards regression models.

Results: The mean time between the first initial symptoms of BS and the onset of
eye lesions was 2.2±2 years. The number of ocular attacks were the following: 43
posterior uveitis, 27 anterior uveitis, 26 retinal vasculitis, while panuveitis devel-
oped in 18 subjects. The cumulative relapse rates at 1 year, 3 years, and 5 years
after remission of the first ocular attack were 41%, 31%, and 28%, respectively.

On multivariate analysis, a younger age (<30 years) at the onset of ocular involve-
ment, male sex and medical treatments other than biological agents represent
independent predictive factors for more early relapses in BS patients with ocular
involvement.

Conclusions: The relapse rate seems to be more frequent in the first years of
diseases, and probably it could be related to the fact the disease tend to grow dim
over time. As literature data suggest, younger age and male sex still represent
predictive factors of poor long-term clinical outcome.

AB0696 CLINICAL CHARACTERISTICS AND OUTCOME OF PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS (GPA) ACCORDING TO ANCA POSITIVITY AND SPECIFICITY

R. Solans-Laque;1, J. Pioz2, M. Rodriguez-Carballeira1, B. Frutos2, L. Saez2, F. Pasquali3, J. Oristrell4, E. Fonseca5, G. Fraile6, on behalf of REVAS-GEAS

(SEMI). 1Autoimmune Diseases Unit, Internal Medicine Department, Vall-Hebron
Hospital, Barcelona; 2Internal Medicine, H La-Paz, Madrid; 3Internal Medicine, H-Mutua, Terrassa; 4Internal Medicine, H Fuenlabrada, Madrid; 5Internal Medicine, H Miguel-Servet, Zaragoza; 6Internal Medicine, H Marina-Baxa, Alicante; 7Internal Medicine, H Parc-Tauli, Sabadell; 8Internal Medicine, H Cabueñes, Asturias; 9Internal Medicine, H Ramon-Cajal, Madrid, Spain

Background: GPA is a necrotizing granulomatous vasculitis associated with
ANCA that usually involves ENT, lung and kidneys. ANCA are mostly directed against proteinase 3 (PR3), although in few cases are directed against myeloperoxidase (MPO) or negative.

Objectives: To analyse the phenotype, clinical course and outcome of patients
with GPA according to ANCA positivity and specificity

Methods: multicenter retrospective-longitudinal study that included patients diag-
nosed with AAV between Jan 1995 and Jan 2016 in 21 Hospitals from Spain
(REVAS-Study). We analysed the clinical characteristics, treatment and outcome,
depending on the ANCA positivity and specificity. Statistical analysis was per-
formed using SPSSvs.20

Results: 221 patients with GPA were included:162 with PR3-ANCA, 36 with MPO-ANCA, and 23 with negative-ANCA. The mean-age at disease onset was
higher in patients with MPO-ANCA (69±16.5 years) than in patients with PR3-
ANCA (50±15.6) and negative ANCA (48±14.5),<0.006. Compared to
patients with PR3-ANCA, patients with MPO-ANCA presented a lower prevalence of toxic syndrome (42.9% vs. 55.6%, p=0.021), arthralgias (34.3% vs. 59.9%, p<0.001), arthritis (8.6% vs. 26.5%, p=0.026), pulmonary involvement (cavitary infiltrated nodules, p=0.007 and p=0.05), and anaemia (57.1% vs. 77.8%, p=0.05). Renal disease was less severe in patients with MPO-ANCA (creatinine ≥1.5 mg/dL 14.3% vs. 30.4%, p<0.04). Subcutis obliteris and sensoryneural deafness were more frequent in patients with MPO-ANCA (20% vs. 6.8%, p=0.05% and 34.3% vs. 18%, p=0.03). The mean BVSAS at baseline was lower in patients with MPO-ANCA (19.6±8.9) and negative ANCA (12.5±6.7) than in patients with PR3-ANCA (19.6±8.9), p=0.029. Patients with negative ANCA had less frequently toxic syndrome, fever, arthritis, subcutis obliteris, kidney disease, and peripheral neuropathy, and more frequently orbital masses. Disease relapses were less frequent in patients with MPO-ANCA than in patients with PR3-ANCA (37.1% vs. 48.8%, p=0.04), but more frequent than in patients with negative ANCA (20.8%), p=0.002. Patients with MPO-ANCA and negative ANCA received less frequently oral corticosteroids, MRA and chemotherapy. None of these differences were found related to death in patients with MPO-ANCA and PR3-ANCA. Patients with negative ANCA had the lower mortality.

Conclusions: A small percentage of patients with GPA present MPO-ANCA or negative ANCA. In our series, patients with MPO-ANCA were older at the disease onset, presented limited or less severe organic disease than patients with PR3-ANCA, lower percentage of relapses and lower requirement of aggressive thera-
pies. Patients with negative ANCA had the best prognosis. Our findings are similar to those recently published, although our patients with MPO-ANCA were older. Classification of GPA patients considering ANCA specificity can improve the treat-
ment stratification and reduce adverse events.

AB0697 GIANT CELL ARTERITIS WITH NORMAL INFLAMMATORY MARKERS AT DIAGNOSIS
R. Solans-Llangue 1, E. Fonseca 2, B. Escalaíte 2, A. Martinez-Zapico 4, G. Fraile 2, M. Perez-Conesa 3, M. Abella 3, M. Monteagudo 3, on behalf of REVAS-Study (GEAS-SEMI). 1Autoimmune Diseases Unit. Internal Medicine Department, Vall Hebron University Hospital, Barcelona; 2Internal Medicine, H Cabuérniga, Asturias; 3Internal Medicine, H Lozano-Blesa, Zaragoza; 4Internal Medicine, H Central, Asturias; 5Internal Medicine, H Ramon y Cajal, Madrid; 6Internal Medicine, H Miguel-Servet, Zaragoza; 7Internal Medicine, H La Ribera, Alzira; 8Internal Medicine, H Parc-Taulí, Sabadell, Spain

Background: GCA is an inflammatory vasculitis affecting medium and large-sized arteries, that can result in arteritic anterior ischemic optic neuropathy. C-reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) are usually elevated at GCA diagnosis, but inflammatory-marker negative disease does occur.

Objectives: To analyse the clinical and histological findings of patients with biopsy-proven GCA and negative inflammatory-markers at diagnosis.

Methods: multicenter-longitudinal retrospective study that included patients with biopsy-proven GCA recruited at 10 hospitals from Spain (REVAS Study). Statistical analysis was performed using SPSS vs. 21.

Results: 418 patients: 290 (69.4%) females (ratio F/M: 2.3/1) were included. The mean age at diagnosis was 75.5±7 (53–92). The most frequent symptoms at diag-
nosis were recent onset headache (81%), toxic syndrome (47%) and rheumatic polyarthritis (44.5%). Jaw claudication, cranial hyperesthesia and amaurosis fugax were reported in 31.8% and 16.3% of patients, respectively. A total of 84 patients suffered permanent vision loss. Fourteen patients (3.3%) had nor-
mal ESR (<20 mm/L) and CRP (<5 mg/dL) at diagnosis. No significant differences were found related to age at disease onset in these patients. Most patients (85%) reported headache; 42.9% jaw claudication, 28.6% cranial hyperesthesia and 42% rheumatic polyarthritis. Fever was less frequent in patients with negative inflammatory-markers (7.7% vs. 40.4%, p=0.020), as well as renal disease (21.4% vs. 51.5%, p=0.031). In contrast, patients with negative inflammatory-
markers had more frequently amaurosis fugax (35.7% vs. 16.8%, p=0.03) and optic ischaemic neuropathy (50% vs. 18.7%, p=0.009). Temporal arteries were abnormal (thickened and/or pulse less) in 78.6% of patients with negative inflam-
matory-markers vs. 37% of patients with elevated ESR and/or CRP. Anaemia was less common in patients with negative inflammatory-markers (29.6% vs. 81.5%, p<0.001, mean haemoglobin 12.9±1.1 g/dL). No significant differences were found related to temporal artery biopsy findings, although patients with normal ESR and CRP showed giant cells in 74.3% of cases vs. 62%.

Conclusions: typically patients with GCA present with elevated inflammatory-
markers (ESR and CRP) at disease onset. However, a few percentages of patients (4%–5%) have normal ESR and CPR at diagnosis. In our series, 3.3% of patients had negative inflammatory-markers at diagnosis. These patients had fewer constitutional symptoms and more visual symptoms (amaurosis fugax and permanent visual loss) than patients with elevated ESR and/or CRP. Our result are similar to those published in the laiterature. Abnormal temporal arteries on physical examination may help to diagnosis

AB0698 A COMPARISON OF THE EFFECTIVENESS OF MYCOPHENOLATE MOFETIL OR METHOTREXATE IN COMBINATION WITH PREDNISOLONE VERSUS PREDNISOLONE ALONE IN THE TREATMENT OF LARGE VESSEL VASCULITIS
R. Smith, R. Kilding, K.-P. Kuet, M. Akil, J. Maxwell. Rheumatology Department, Royal Hallamshire Hospital, Sheffield, UK

Background: The mainstay of treatment for large vessel vasculitis is glucocorticoids. Immuno-suppressants, including mycophenolate mofetil (MMF) and methotrexate (MTX) are used as steroid-sparing agents. A previous study at our centre showed MMF to have a steroid sparing effect in 97% of patients and to reduce C-reactive protein (CRP) in 80%.

Objectives: This study was undertaken to compare the efficacy of MMF or MTX combined with prednisolone or prednisolone alone in the treatment of large vessel vasculitis.

Methods: Patients with large vessel vasculitis (LVV) confirmed on postiron emis-
ion tomography (PET) scan and those meeting ACR criteria for a diagnosis of giant cell arteritis (GCA), treated with prednisolone alone, prednisolone with MMF or prednisolone with MTX, were identified over a period of 3 years. Prednisolone was adjusted and with a minimum follow up of 24 months were included in a retrospec-
tive single centre study. CRP and prednisolone doses were recorded at baseline, after 3, 6, 9, 12, 18 and 24 months of treatment and area under the curve (AUC) calculated for CRP and prednisolone doses. Median AOC prednisolone dose for patients treated with MMF or MTX was then compared with that of patients treated with prednisolone alone. A quantile regression model was also constructed to compare prednisolone dose between the 3 treatment groups, adjusted for CRP.

Results: 65 patients were included in the study, 41 with GCA and 24 LVV. 49 were female and 16 male. Mean age at diagnosis was 68; range 21 to 87. 37 patients were treated with prednisolone alone: 35 had GCA and 2 LVV. 20 were treated with MMF and prednisolone: 4 with GCA and 16 LVV. 8 were treated with MTX and prednisolone: 2 had GCA and 6 LVV. The AOC for prednisolone and CRP were not normally distributed across the cohort, and non-parametric meth-
ods were therefore used for comparisons. Median AOC prednisolone dose for the prednisolone only group was 68.0, (interquartile range (IQR) 17.7, n=37), for the MMF treated group 70.8 (IQR 28.7, n=20) and for the MTX treated group 67.8 (IQR 20.4–8). Median AOC CRP was highest in the group treated with predniso-
lone alone (58.9, IQR 34.5) compared to MMF (43.8, IQR 26.5) and MTX (49.3 IQR 67.5) but there were no statistical differences between median AOC predni-
solone dose or CRP in either the unadjusted or regression models.

Conclusions: No significant difference was shown between the groups. MMF is as effective as MTX and prednisolone alone in the treatment of LVV. However there are limitations to the study. The patient group was small. There was no ran-
donisation to treatment group; treatment choice was based on clinician prefer-
ence. There was potential bias in that patients perceived to be more difficult to

Disclosure of Interest: None declared
Background: Prednisone therapy, Thalidomide, azathioprine, anti-TNF-alpha inhibitors are presently used in resistant mucocutaneous lesions of Behçet’s Disease (BD). In this study, we used only ambulatory Benzathine Penicillin (BP), without being preceded by high doses of penicillin infusion. This Study confirm the value of BP in the treatment of refractory ulcers of BD and point out a probable role of Streptococcus on the pathogenesis of BD.

Objectives: This open Study confirm the value of BP in refractory oral, genital, and skin ulcers of BD. We propose to use BP when ulcers of BD are resistant to colchicine 1.5 mg/day and to add BP in the recommendations of EULAR for the treatment of resistant cases of mucocutaneous involvement.

Methods: 15 patients with BD (12 patients fulfilled all criteria for BD) had Giant (mean size of ulcer superior to 1 cm), or Multiple oral, genital, skin ulcers received BP at the dose of 2.4 million units in intramuscular injection; 3 intramuscular injections with an interval of 3 weeks between injection. Colchicine at the dose of 1 mg/ day was maintained. Serology of syphilis was negative. Patients had seen 15 days, 3 months and 1 year after the starting treatment.

Results: This study started in 2012, in a private office and comprised 15 patients: 9 males; 6 females. Arthritis was observed in 11 patients, uveitis in 6 cases. BP was used in 8 patients with oral ulcers (4 Giants and 4 multiples), Genital ulcers in 3 patients (2 multiple and 1 Giant), oral and genital ulcers (Multiples) and cutaneous aphthosis in 2 patients 0.2 weeks after the first injection of BP, recovery from ulcers was achieved. BP was administrated a second time with success, i.e., in 9 patients who have developed resistant ulcers, after 1 to 3 years of recovery: One patient with panuveitis treated with azathioprine in 2013 and interferon alpha in 2015 and interferon alpha in 2015 and 2017, developed refractory ulcers: Excellent efficacy of BP was observed in this patient.

Conclusions: In this study, we confirm the recovery from refractory oral, genital and cutaneous ulcers (Giant, Multiple) in these 15 patients with BP. We recommend using more frequently BP and we propose to add BP in the recommendations of EULAR for the treatment of resistant cases of mucocutaneous involvement because treatment with BP is rather easy in outpatients, it is efficient, it has a low cost and have few side-effects.

**AB0701** COMPARISON OF THE NEW ACR/EULAR CLASSIFICATION CRITERIA OF ANCA-ASSOCIATED VASCULITIS WITH THE EMA ALGORITHM IN CLASSIFICATION OF VASCULITIS

S. Li1, Q. Zhang2; 1Department of Rheumatology and Immunology, Peking University International Hospital; 2Department of Rheumatology and Immunology, The First affiliated hospital of Chinese PLA general Hospital, Beijing, China

**Objectives:** A new set of classification criteria for ANCA-associated vasculitis (AAV) was presented in 2017's ACR annual scientific meeting. In order to evaluate this new set of classification criteria, we conducted the current study to compare it with the EMA's consensus algorithm for classification of systemic vasculitides proposed by Watt et al. in our centre.

**Methods:** One hundred and twenty-two Chinese patients with clinically diagnosed as AAV in our centre during the past 15 years were retrospectively studied. We compared the new set of ACR/EULAR's classification criteria for AAV, with the EMA's consensus algorithm with surrogate parameters, in the same cohort of patients with primary systemic vasculitides.

**Results:** Applying the EMA's consensus algorithm with surrogate parameters, the diagnoses were EGPA (n.3), GPA (n.55), microscopic polyangiitis (MPA) (n.47), drug related AAV (n.2), and unclassified (n.5). Using the new ACR/EULAR's classification criteria for AAV, the diagnoses were EGPA (n.8), GPA (n.33), MPA (n.65), overlap with EGPA and GPA (n.2), overlap with GPA and MPA (n.8), and unclassified (n.7) (See the below picture).

**Conclusions:** The new 2017 ACR/EULAR classification criteria for AAV and Watts algorithm were all useful methods to classify patients with systemic vasculitides. The Watts' algorithm can classify all patients into a single category, with more GPA patients, less unclassified patients and without overlapping diagnosis, in comparison, the new 2017 ACR/EULAR classification criteria classified more MPA patients, more unclassified and more overlapping patients.

**AB0702** ALKALINE PHOSPHATASE AS A PREDICTOR OF GIANT CELL ARTERITIS – A RETROSPECTIVE ANALYSIS OF CLINICAL FEATURES AND TEMPORAL ARTERY BIOPSY FINDINGS

S. Varier, C. Li; Rheumatology, Royal Surrey County Hospital, Surrey, UK

**Background:** Giant cell arteritis (GCA) is the most common large vessel vasculitis in the United Kingdom and Northern Europe. Inadequate treatment and delay in diagnosis can lead to serious and life-threatening consequences.

**Objectives:** This study looks at whether the presence of a raised alkaline phosphatase (ALP) to degree of clinical features and suspicion of GCA is weak and of low correlation with severity of clinical presentation.

**Methods:** Retrospective multicenter cohort study.

Information was retrospectively gathered on patients who underwent TABs following a clinical working diagnosis of GCA. Only patients who fulfilled the American College of Rheumatology (ACR) classification criteria and had ALP measured within 4 weeks of undergoing TAB were included in the study. Once patients were identified, further information was extrapolated including the values of other serum markers taken, and presenting clinical features.

**Results:** Our cross-sectional sample population who fulfilled the inclusion criteria reflected typical GCA patients: 147 (65.9%) were female and mean age was 73.1 years (SD 10.5). TAB was positive in 54 patients (24.2%). Two patients (3.7%) who had a positive TAB had completely normal serum markers. We were unable to comment on variables, which could have contributed to this but they likely represented already administered aggressive glucocorticoid treatment at time of serum measurement or atypical presentation of GCA. Raised ALP sensitivity at the current cut off value was very low (14.8%) but with high specificity (90.5%), which was reinforced following ROC curve analysis. Pearson coefficient analysis suggested that there was a weakly associative relationship between raised ALP and degree of clinical suspicion (Correlation 0.346, Sig 0.01)

**Conclusions:** Patients with a higher level of clinical suspicion and TAB positivity were more likely to have a raised ALP. However, the association strength was weak. ALP is suggested to be highly specific for TAB positivity. The association of raised ALP to degree of clinical features and suspicion of GCA is weak and of low significance, likely a reflection of the limitations of this study. Further robust research may further evaluate this observed relationship.

**AB0703** LONG TERM FOLLOW-UP OF BEHÇET’S SYNDROME PATIENTS TREATED WITH CYCLOPHOSPHAMIDE

1Istanbul University, Cerrahpasa Medical School; 2Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; 3Cleveland Clinic, Department of Hematology and Oncology, Taussig Cancer Institute; 4Cleveland Clinic, Department of Internal Medicine, Cleveland, USA

**Background:** Cyclophosphamide (CYC) remains an important treatment option for Behçet’s syndrome (BS) patients with life-threatening conditions such as arthralgic aneurysms. However, several adverse events may occur with CYC and this has led to increased use of biologic agents such as rituximab in other vasculitides.

**Objectives:** The aim of this study is to delineate the outcome and short- and long-term adverse events with CYC use among BS patients.

**Methods:** We conducted a retrospective chart review of all BS patients treated with oral or intravenous CYC between 1976 and 2006. Patients were called and a standard form was used for collecting demographic characteristics, CYC indication, cumulative dose of CYC and short-term serious adverse events necessitating the cessation of therapy and/or requiring hospitalisation and long-term adverse events (malignancy and infertility), and outcome.

**Results:** We identified 198 (M/W: 184/14) BS patients who had received CYC. After a median follow up of 17 (IQ: 9–26) years after the initiation of CYC therapy, 52 (26%) patients had died within a median duration of 4–12 years, 33 (17%) were lost after a median follow-up of 9 (3.5–14) years, and 113 (57%) were contacted. CYC was prescribed for vascular involvement in 132 (67%) patients, eye involvement in 52 (26%), central nervous system involvement in 5, both vascular and eye involvement in 7 and both vascular and central nervous system involvement in 2 patients. The median duration of CYC use was 12 (IQ:4–24) months and median cumulative dose was 13.5 (IQ:5–49) gr. Among the 52 patients who died, reasons for death were vascular involvement in 26, malignancies in 7, infections in 5 (5 bacterial infections, 1 additional tuberculosis), neurologic involvement in 2, ischaemic stroke in 1, traffic accident in 1, and secondary amyloidosis in 1, esophageal variceal bleeding in 1, and unknown in 5 patients. Sixteen (8%) patients experienced serious adverse events associated with short-term CYC use and 1 of them died due to infection. Among these adverse events, haemorrhagic cystitis occurred in 7 patients, infections in 4 (1/4 died), leukopenia, acute myocardial
infection, anaphylic reaction, azosperma, liver toxicity, and severe nausea in 1 patient each. Overall, 16 malignancies were observed in 14 (7%) patients after a median follow up of 25 (IQR:15–26) years. The malignancies were bladder carcinoma (n=4), lung adenocarcinoma (n=3), prostate adenocarcinoma (n=2), carcinoma of unknown primary origin, pancreas adenocarcinoma, t-MDS-AML, lymphoma, colon adenocarcinoma, squamous cell carcinoma and thyroid papillary carcinoma. Among the 113 patients, we were able to question regarding infertility, 67 patients (59%) had children, 22 (19.5%) did not wish to have a child and 24 (21.5%) tried to have a child, but was not able to.

Conclusions: Short term serious adverse events occurred in 8% of the patients during CYC treatment. During long term follow-up malignancies occurred in 7% and infertility in 21.5% of the patients. These results underline the need for safer and effective alternatives to CYC for serious organ involvement in BS, similar to that in other vasculitides.

CLINICAL-ANALYTICAL CHARACTERISATION OF 52 DIAGNOSED PATIENTS OF BEHÇET DISEASE WITH INCLUSION OF PAEDIATRIC CASES IN A SPANISH TERTIARY HOSPITAL

S. Zegarra Mondragon, A. Alia-Jimenez, C. Bouronce Alaiuna, A. Boteanu. Rheumatology, Hospital Ramon y Cajal (Spain), Madrid, Spain

Background: Behçet’s disease (BD) is a chronic and recurrent inflammatory disease of unknown etiology, classified into polygenic autoinflammatory diseases or variable vessel vasculitis. It has a wide spectrum of symptoms with a very variable range of severity, from mucocutaneous involvement to neurological manifestations, systemic vasculitis and severe ocular manifestations. About 5.4%–7.8% of Behçet’s cases have a paediatric debut.

Objectives: To evaluate and compare the clinical and laboratory manifestations of a series of 52 patients, adults and children, diagnosed with BD according to the classification criteria of the International Study Group of BD (ISGDB-1990).

Methods: Retrospective cross-sectional observational study, which included 43 adult patients and 9 paediatric patients diagnosed with BE in the Rheumatology Department of a Madrid tertiary hospital. The clinical-analytical characteristics of both groups were evaluated, as well as the correlation of HLA-B51 with the described symptomatology.

Results: The mean age at diagnosis of BD was 36.9±11.8 years in adults and 11.4±5.1 years in children. 27.3% of adults and 11.1% of children with BD were male, with oral ulcers close to 90% in both groups. Contrary to what was reported in other series, genital ulcers were more frequent in children (77.8% versus 65.9% of adults), as was the presence of uveitis (44.4% in children compared to 22.7% in adults) and neurological manifestations (22.2% in children versus 6.8% in adults). Joint involvement was also more frequent in children (88.9% versus 52.3% in adults), as well as fever (44% in children versus 14% in adults); being these two manifestations the only parameters that were associated in a statistically significant way with their presentation in the paediatric age in BD. In contrast, skin involvement and vascular manifestations were more frequent in adults. The positivity of HLA-B51 did not correlate statistically with any clinical manifestation, but those who had it had a mean age at diagnosis of 26.5 years compared to a mean of 39 years in those who did not present this genetic marker.

Conclusions: Behçet’s disease presents with a wide spectrum of clinical manifestations, potentially serious, ranging from skin lesions to neurological or vascular manifestations. In our series, patients diagnosed at paediatric age most frequently had systemic manifestations (fever), arthritis or severe clinical manifestations such as neurological involvement or uveitis. Limitations: a small number of paediatric cases included in our study.

AB0705

LONG-TERM OUTCOMES AND PROGNOSTIC FACTORS ASSOCIATED WITH AORTIC VALVE SURGERY IN PATIENTS WITH TAKAYASU ARTERITIS AND AORTIC VALVEREGURITATION

S.H. Nam1, O.C. Kwon2, W.J. Seo3, Y.-G. Kim1, C.-K. Lee1, B. Yoo1, S. Hong1

1Internal medicine, Asan Medical Center, 2Internal medicine, Veterans Health Service Medical Center, Seoul, Korea, Republic of Ireland

Background: Some patients with Takayasu arteritis (TA) have aortic valve (AV) involvement, which can lead to aortic regurgitation (AR). However, data on the long-term outcomes, including survival of TA patients with AR, are lacking. Moreover, previous studies were limited to patients who underwent AV surgery.

Objectives: This study aimed to characterise the long-term outcomes and clinical characteristics of TA patients with AR regardless of whether they underwent surgical intervention.

Methods: Medical records of patients with TA between January 1995 and December 2015 were retrospectively reviewed. AR was diagnosed using transthoracic echocardiography. Poor outcomes were defined as all-cause death and major adverse cardiac and cerebrovascular events (MACCE). Multivariate analysis was performed to determine the factors affecting poor prognosis in the surgical group.

Results: Of the total 105 patients with TA and AR, 41 (39.0%) underwent AV surgery. Among patients who underwent AV surgery, inflammation values (Erythrocyte sedimentation rate, 62.0±31.8 mm/hr vs. 39.16±28.4 mm/hr; C-reactive protein, 3.66±4.1 mg/dL vs. 0.92±1.7 mg/dL; AR degree (3.56±0.7 grade vs. 2.08±1.0 grade), and sinus diameter (37.24±5.7 mm vs. 33.22±4.5 mm) were significantly higher than in those who did not undergo AV surgery. Long-term survival and freedom from MACCE were not significantly different between the groups (10 year survival, 84.3% vs. 79.4%; p=0.827; 10 year event-free survival, 51.8% vs. 71.2%; p=0.29). Twelve of the 41 patients who underwent AV surgery had a poor outcome during follow-up (median, 92.5 months; IQR, 54.5–183.5), and eight of them had a recurrence of AR requiring reoperation. Multivariate Cox analysis revealed that coronary disease [hazard ratio (HR), 4.234; 95% confidence interval (CI), 1.381–12.979; p=0.012], LV dysfunction [HR, 3.387; 95% CI, 1.143–10.042; p=0.028], and impaired renal function (HR, 19.983; 95% CI, 3.480–114.731; p=0.001) were significant risk factors associated with poor outcomes at follow-up (table 1).

Table 1 – Multivariate analysis of predictive factors of poor outcomes in patients with Takayasu arteritis who underwent aortic valve surgery

<td>0.001</td>
</tr>
</tbody>
</table>

*coronary disease: severity is more than moderate stenosis
**LV dysfunction: EF <50%

Conclusions: In patients with TA with AV involvement, there were no significant differences between long-term survival rate and event-free survival (MACCE) among those who had or had not undergone AV surgery. In the surgical group, the prognosis was poor when coronary artery disease, LV dysfunction, and renal impairment were present at the time of surgery.

OCULAR PRESENTATION IN GRANULOMATOSIS WITH POLYANGIITIS (GPA) PATIENTS: RELATION TO AUTOANTIBODIES AND DISEASE ACTIVITY

T.A. Gheita1, E.M. Abd El-Latif2, 1Rheumatology and Clinical Immunology, Faculty of Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo; 2Ophthalmology, Faculty of Medicine, Alexandria University, Alexandria, Egypt

Objectives: To study the disease characteristics, autoantibodies and activity in granulomatosis with polyangiitis (GPA) patients with ocular manifestations.

Methods: 46 GPA patients visiting the ophthalmology clinic were included. Ocular manifestations, clinical and slit lamp examination were performed. The Birmingham Vasculitis Activity Score (BVAS) was recorded. Laboratory investigations were recorded and the antineutrophil cytoplasmic antibody (ANCA) performed.

Results: The median age of the patients was 44.5 (32–63) years, 22 males:24 females and disease duration 6.5 (1–16) years. Ocular manifestations were present in all patients; 12 (26.1%) had episcleritis/scleritis with perforation in 3 (6.5%), keratoconjunctivitis in 33 (71.7%) – acute infiltrative stromal keratitis in 11, peripheral ulcerative keratitis in 15 and sclerosing keratitis in 11 patients. Uveitis was present in 11 (23.9%) and retinal changes included vasculitis, exudates and haemorrhage was present in 7 (15.2%). 43 (93.5%) of the patients had blurring of vision and vision loss was present in 2 (4.3%). Glaucoma was present in 4 (8.7%). Impaired visual acuity was noted in 4 (8.7%). Impaired color vision was noted in 2 (4.3%). Ankylosing spondylitis (n=3), lupus erythematosus (n=1), and rheumatoid arthritis (n=1) were associated with keratoconjunctivitis (p=0.04). Clinical activity assessed by BVAS showed a significant correlation with anti-PR3 (p<0.001) and anti-MPO (p<0.001).

Conclusions: Ocular involvement must be considered in all GPA patients and referral to an experienced ophthalmologist is mandatory for proper management and the improved outcome of such a rare systemic disease. ANA and RF positivity may raise suspicion for KC or uveitis respectively. There was a remarkable association between uveitis and disease activity.
FOUR DISTINCT CLINICAL PHENOTYPES OF SWITCHING FROM ORIGINATOR INFLIXIMAB TO THE USE OF TEMPORAL ARTERY BIOPSIES (TAB) IN NEUROPATHY.

T. Shirai, H. Fujiy, Y. Shirota, T. Ishi, H. Harigae. Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan

Background: Polyarteritis nodosa (PAN) is a necrotizing arteritis of medium-sized arteries. PAN is divided into systemic and cutaneous PAN (cPAN). cPAN is further classified as mild cPAN or severe cPAN, which presents with ulcer, necrosis, or neuritis. However, it is sometimes difficult to distinguish between severe cPAN and systemic PAN, and their optimal management are still unclear. The aim of this study is to evaluate clinical characteristics of patients with necrotizing arteritis of medium and small artery.

Objectives: To evaluate the clinical characteristics of patients with necrotizing arteritis of medium-sized arteries in order to further clarify the subtypes of PAN.

Methods: Forty-nine patients diagnosed with necrotizing arteritis of medium-sized arteries between 2008 and 2017 at our institution were enrolled to this study. Patients with evidence of glomerulonephritis or vasculitis in arterioles, capillaries, or venules, which are hallmarks of small-vessel vasculitis, were excluded. Clinical backgrounds, laboratory findings including inflammatory markers and antineutrophil cytoplasmic antibodies (ANCA), affected organs, treatments, and rates of relapse and death were evaluated.

Results: Among 49 patients, 11 patients (22%) presented with systemic vasculitis. Organ involvement was diverse and ranged from central nervous system to cutaneous manifestations. The remaining 38 patients were diagnosed as cPAN and further classified as mild cPAN (16 patients) or severe cPAN (22 patients: ulcer type, 9; neuritis type, 9; both, 4). There was one case of cPAN which resulted in renal damage. The clinical characteristics of mild cPAN included female pre-dominance (87.5%) and younger age (median, 32), and patients tend to have normal inflammatory markers and laboratory findings. Those of systemic PAN included older age (median, 69), higher levels of inflammatory markers, lower levels of serum proteins, and organ damage. Nonspecific elevation of autoantibodies is frequently observed. Particulary, 54.5% of systemic type possessed MPO-ANCA though the titers were significantly lower than those of microscopic polyangiitis, suggesting non-specific elevation of MPO-ANCA in Japanese population. Severe cPAN manifested with intermediate phenotypes, and inflammatory activities were significantly correlated with age (p<0.001). Although the mortality rates were indistinguishable, the relapse rates of cPAN (ulcer type) were significantly lower than those of other types (88.9%, Figure). The mean doses of prednisolone (PSL) used to treat mild cPAN, severe cPAN, and systemic type were 18.5, 38.6, and 39.1 mg/day, respectively. Immunosuppressants were used in 20% of mild cPAN, 90.9% of severe cPAN, and 72.7% of systemic PAN patients. Most patients with cPAN (ulcer type) were initially treated by corticosteroid monotherapy, and immunosuppressive agents were added when they relapsed. Considering its high relapse rate, it might be reasonable to select combination therapy with cyclophosphamide for severe cPAN (ulcer type) as is proposed in nonsystemic vasculitic neuropathy.

Conclusions: The clinical characteristics of mild cPAN, severe cPAN (ulcer type), severe cPAN (neuritis type), and systemic PAN were distinct from each other. Particularly, patients with severe cPAN (ulcer type) had higher relapse rates, thus indicating the importance of combination therapy in this patient cohort.

THE USE OF TEMPORAL ARTERY BIOPSIES (TAB) IN DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH GIANT CELL ARTERITIS (GCA). A RE-AUDIT IN RHEUMATOLOGY IN THE BELFAST HEALTH AND SOCIAL CARE TRUST (BHSCT)

U.A. Lavery, E. Banks, M. McHenry, NHS, Belfast, Ireland

Background: Patients should meet at least 3/5 American College of Rheumatology (ACR) criteria for a diagnosis of GCA. British Society of Rheumatology (BSR) guidelines on the management of GCA from 2010 emphasise the importance of early referral for specialist management. TAB should be considered depending on local experience and availability of other imaging modalities. Biopsy should be at least 10 mm in length and ideally done within 14 days of presentation. TABs performed in BHSCT over a three-year period were audited in 2014.

Objectives: We re-audited the Rheumatology TAB referrals in the BHSCT from August 2016 to August 2017 to assess how biopsies influenced the management of patients with GCA in comparison to the previous audit.

Methods: Histopathology based LabCentre search detected 36 TABs within the given period. A retrospective audit was carried out with the use of Electronic Care Record and 16 of these patients were Rheumatology based TAB referrals. A pro-forma was used to aid data collection.

Results: Female/Male ratio was 2.2:1, age range was 61–91 with a mean age of 76. 94% of patients presented with headache. Of those patients referred for biopsy, 100% already fulfilled 2 of ACR criteria, compared with only 80% in previous audit. TAB was positive in 25%. In those with a positive biopsy, 75% had an ESR >50. All patients were on steroid treatment at the time of biopsy. In 42% of patients with a negative biopsy, steroids were rapidly reduced. 100% of patients with a positive biopsy continued on steroids. 68% of biopsies were greater than 10 mm compared with 38% in the previous audit. 68% of patients had a TAB within 14 days of commencing on steroids, with 31% having biopsy within 7 days of commencing steroids. 63% of patients developed steroid related complications. In 56% of patients the biopsy result changed patient management.

Conclusions: The percentage of appropriate referrals for biopsy (based on the ACR criteria) has improved compared with the previous audit. The length of biopsy improved. 32% of patients were waiting longer than 2 weeks for biopsy but some of these patients presented late to the rheumatology team. Biopsy results changed management in 56% of patients. Areas for consideration include improvement in time to biopsy and biopsy length.

SWITCHING FROM ORIGINATOR INFLIXIMAB TO BIOSIMILAR INFLIXIMAB: EFFICACY AND SAFETY IN A COHORT OF PATIENTS WITH ESTABLISHED BEHÇET’S DISEASE

V. Veneto1, G. Lopalco1, L. Cantarini2, C. Fabiani3, M. Nivon1, F. Cacciapaglia1, M. Galeazzi2, G. Lapadula1, F. Iannone1, 1Department of Emergency and Organ Transplantations, Rheumatology Unit, University of Bari “Aldo Moro”, Bari; 2Department of Medical Sciences, Surgery and Neurosciences, Rheumatology Unit, Policlinico “Le Scotte”, University of Siena, Siena; 3Department of Ophthalmology, Humanitas Clinical and Research Center, Rozzano, Italy

Background: Infliximab (IFX) has been proved to be effective in several organ involvement of Behçet’s Disease (BD). A recent report describing rapid loss of efficacy of biosimilar IFX after switching from originator IFX suggests the necessity to exercise caution regarding the automatic substitution of originator IFX with biosimilar IFX in patients achieving remission with originator IFX.

Objectives: The purpose of the present study was to describe our experience with biosimilar IFX CT-P13 in patients affected with BD, who were switched from originator IFX.

**INTERFERON A2A FOR THE TREATMENT OF REFRACTORY BEHÇET’S DISEASE UVEITIS**

W. Zheng1, J. Shi1, C. Zhao2, J. Liu1, J. Zhou1, F. Gao2, M. Zhang2.

1Rheumatology and Clinical Immunology, 2Ophthalmology, Peking Union Medical College Hospital, BEIJING, China

**Background:** Behçet’s Disease uveitis (BDU) mostly involved bilateral panuveitis and retinal vasculitis, which are very challenging to treat. Interferon α2a (IFNα 2a) has been shown to have comparable effectiveness and tolerance profiles for BDU as tumour necrosis factor (TNF) inhibitors in a number of studies with a much lower cost. IFNα–2a treatment combined with corticosteroids without immunosuppressants was common in previous studies. We herein report a cohort of highly refractory BDU patients who experienced recurrence despite aggressive treatment with multiple immunosuppressants at their therapeutic doses.

**Objectives:** To investigate the efficacy and safety of IFNα2a treatment in combination with corticosteroids and immunosuppressants in patients with refractory BDU.

**Methods:** Clinical records of refractory BDU patients who underwent IFNα2a treatment in our centre between 2015 and 2017 were retrospectively reviewed. IFNα2a was initially given 3.0 million IU (MU) subcutaneously daily for 4 weeks, on the basis of conventional corticosteroid and immunosuppressive therapy. The dosage was gradually tapered down to 3.0 MU three times or even once per week for maintenance. Primary outcome measure was success rate and changes in ocular relapse rates before and after initiation of IFNα2a treatment. Disease activity, corticosteroid- and immunosuppressive agent-sparing effects and potential side effects were considered to be secondary outcomes.

**Results:** A total of 26 patients (23 males and 3 females) were included, with a median disease course of 41 months (range 5–168) before IFNα2a treatment. No major organ involvement except for ocular inflammation was noted. Concomitant medical conditions include chronic hepatitis B virus infection in 2 patients, pulmonary tuberculosis in 1 patient who was treated with antibacterial agents in the meanwhile. Prior to IFNα2a therapy, the median minimum dosage of corticosteroids was 20 (range 15–45) mg/day prednisone or equivalent, and 17 patients (65.4%) were treated with at least two immunosuppressive agents. Four received short terms of TNFα inhibitor therapy but stopped due to economic burden. Severe side effects related to previous therapies including femoral head necrosis and secondary hypertension were observed in some patients. Treatment success of IFNα2a was achieved in the majority of the patients (24/26, 92.3%). During a mean follow-up of IFNα2a therapy for 13.6±6.0 months, the median rate of uveitis relapse decreased notably from 8 per patient-year (range 2–12) to 0 per patient-year (range 0–6) (p=0.000008). Oral corticosteroids were successfully decreased in 20 cases (76.9%) and completely discontinued in 2 patients (7.7%), with the median minimum dosage reduced from 20 mg/day (range 15–45) to 15 mg/day (range 0–50) (p=0.008221). Moreover, immunosuppressive agents were cut down on types and dosage in 15 (57.7%) and 23 patients (88.5%), respectively, and were totally quitted in 5 cases (19.2%). Slight elevated liver and renal function parameters were detected in one and two patients, respectively. No other severe adverse events occurred. The serum autoantibodies were all negative during treatment with IFNα2a.

**Conclusions:** IFNα2a, in combination with corticosteroids and immunosuppressants, was effective and relatively safe in refractory BDU, with a potential steroid- and immunosuppressive agent-sparing effect.

**Disclosure of Interest:** None declared

**TOLICIZUMAB FOR SEVERE/REFRACTORY VASCULAR BEHÇET’S DISEASE**

W. Zheng1, Y. Ding2, J. Liu1, J. Shi1, C. Li1, Y. Zhao1, X. Zeng1.
1Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, BEIJING; 2Rheumatology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

**Background:** Vascular Behçet’s Disease (BD) is a common yet severe complication of BD. Despite aggressive conventional therapy, vascular BD remains as one of the leading causes of morbidity of BD. Tocilizumab (TCZ), an IL-6 receptor antagonist, is an emerging biological agents for neurologic BD or ocular BD, however, the efficacy of TCZ for vascular BD is unknown.

**Objectives:** To elucidate the efficacy and safety of TCZ for severe/refractory vascular BD.

**Methods:** We retrospectively analysed the clinical data of vascular BD patients treated with TCZ in our centre between 2014 and 2017.

**Results:** Seven patients (6 males and 1 female) were enrolled, with a mean age and median course of 32.9±9.1 years old and 72 months (range 54 to 138), respectively. Multiple arterial lesions were documented in all patients, including arterial aneurysm (n=5), stenosis (n=4), occlusion (n=3), and multiple venous thrombosis were documented in two patients. Recurrent aneurysms together with
ELIGIBILITY OF PATIENTS WITH GIANT CELL ARTERITIS FOR ENTRY INTO A PROSPECTIVE RANDOMISED CONTROLLED TRIAL: A SINGLE-CENTRE EXPERIENCE

W.A. Schmidt¹, K. Hofheinz¹, S. Burger¹, V.S. Schäfer²,³, A. Juche¹. Medical Center for Rheumatology Berlin-Buch, IMMANUEL KRANKENHAUS BERLIN, Berlin; Medical Klinik III, University of Bonn, Bonn, Germany

Background: The interest in pharmaceutical trials in giant cell arteritis (GCA) is increasing. Trial recruitment may be more challenging in GCA than in other rheumatic diseases because of a higher proportion of elderly patients who are additionally faced with a new diagnosis when being considered for trial participation.

Objectives: To analyse the eligibility of newly diagnosed and flaring GCA patients for trial participation between August 2016 until trial termination in October 2017 were included. The trial was prematurely terminated by the sponsor based on the decision to discontinue development of sirukumab in autoimmune diseases. Analysis of variance, two-sided Fisher’s exact and Pearson’s chi-squared tests were applied for calculating statistical significance.

Results: Ninety-five patients were pre-screened. Fifteen of these patients were screened and only 12 of the 95 (13%) pre-screened GCA patients were eligible for trial participation. Conclusions: Many newly diagnosed or relapsing GCA patients were not eligible for a trial due to concomitant diseases, failing inclusion criteria or declined consent. Eligible patients were younger, and more had relapsing disease.

Disclosure of Interest: None declared

AB0713 INTERFERON-ALPHA FOR THE MANAGEMENT OF LOWER EXTREMITIES DEEP VEIN THROMBOSIS IN BEHÇET’S SYNDROME: A CASE SERIES

V. Ozgürel, G. Hatermi, F. Cetinkaya, K. Tascilar, S. Uğurlu, E. Seyahi, H. Yazıcı, M. Melikoglu. Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey

Background: Lower extremity deep vein thrombosis (LEDVT) is a disabling complication of Behçet’s syndrome (BS). Relapses and frequent and cause permanent disability due to post-thrombotic syndrome.1 The management of LEDVT in Behçet’s syndrome (BS) consists mainly of azathioprine (AZA) and corticosteroids (CS) as first-line agents.2 Interferon-α (IFN) has been used with good results in the management of eye involvement of BS. However data regarding its efficacy for vascular involvement has been scarce.3

Objectives: To analyse the eligibility of newly diagnosed and flaring GCA patients for trial participation.

Methods: All patients with newly diagnosed or relapsing GCA considered for trial participation between August 2016 until trial termination in October 2017 were included. The trial was prematurely terminated by the sponsor based on the decision to discontinue development of sirukumab in autoimmune diseases. Analysis of variance, two-sided Fisher’s exact and Pearson’s chi-squared tests were applied for calculating statistical significance.

Results: 33 pts with LEDVT (26 M/7 F) were prospectively followed for a mean of 40.7±13.4 mo. Among these IFN was started in 18/33. In 2 pts IFN was started at the first episode of LEDVT due to co-existing uveitis. Seven pts were treated with IFN due to LEDVT relapses under AZA. In the remaining 9 pts, the reasons for switching from AZA to IFN were adverse events with AZA (n=2), relapse of superficial thrombophlebitis (n=4), leg ulcers due to severe post-thrombotic syndrome (n=2) and eye involvement (n=1). Among 17 pts treated with IFN mainly for vascular involvement during a mean follow-up of 29±20 mo, 3 pts already had good recanalisation when starting IFN. In the remaining 14 pts, 13 (93%) had good recanalisation under IFN. Two pts (11%) experienced relapses. One of the 2 pts who had a relapse had poor recanalisation despite IFN. In contrast, among the 29 pts treated with AZA, only 13 (45%) had good recanalisation and 13 (45%) pts experienced relapses. Nine of the 13 pts who had relapses under AZA had poor recanalisation. Overall we observed 23 LEDVT relapses in 15 pts. Relapse rates were 29%, 37% and 45% at 6, 12 and 24 months respectively. The only adverse event with interferon-alpha causing drug withdrawal was nephritis in 1 patient.

Conclusions: Relapse rate for LEDVT in BS is high despite AZA treatment. IFN seems to be a promising agent for preventing LEDVT relapses and achieving good recanalisation, an important predictor of relapse. The small number of pts and the lack of a parallel control group are the limitations of this prospective study.

MONOCYTES TO LYMPHOCYTES RATIO IS CORRELATED WITH DISEASE ACTIVITY IN BEHÇET’S DISEASE

V. Huang, S. Zheng, T. Li, F. Feng, W. Deng, O. Huang, Z. Huang, Z. Huang, X. Pan. Department of Rheumatology and Immunology, Guangdong Second Provincial General Hospital, Guangzhou, China

Background: Behçet’s disease (BD) is a complex, inflammatory multisystem disorder. Since the lack of universally recognised pathognomonic laboratory test, the diagnosis relies heavily on clinical findings. Currently, the Monocytes to lymphocytes ratio (MLR), Neutrophils to Lymphocytes ratio (NLR), Platelets to Lymphocytes ratio (PLR) and Red blood cell Distribution Width(RDW) have been demonstrated as a assessment of disease severity in many rheumatism diseases. Nevertheless, to our knowledge, only a few studies have investigated MLR, PLR, RDW in patients with BD.

Objectives: The aim of this study is to determine MLR, NLR, PLR and RDW in BD and to investigate their relationships with disease activity.

Methods: A total of 37 patients with BD fulfilling the criteria of the International Study Group for BD and 37 age and gender-matched healthy controls were enrolled in the study retrospectively. MLR, NLR, PLR, RDW, C-reactive protein (CRP) level and Erythrocyte Sedimentation Rate (ESR) level were evaluated. The correlation between the variables were tested with Pearson correlation. Area Under Curve (AUC) value, specificity, and the optimal cut-off values were determined using Receiver Operating characteristic Curves (ROC). According to the optimal cut-off values, BD patients were divided into low-value group (<the optimal cut off value) and high value group (>the optimal cut off value). The patient’s clinical characteristics between the two group were compared.

Results: The MLR, NLR, PLR and RDW were (0.37±0.24), (2.91±1.95), (155.09±28.01) and (13.07±1.19) in control group, the difference was significant (P<0.05; r=0.394, P<0.05). RDW was not correlated with ESR and CRP. ROC curves results showed that the AUC of MLR, NLR, PLR and RDW for BD were 0.841(CI95%: 0.748–0.935), 0.815(CI95%: 0.712–0.918), 0.720(CI95%: 0.699–0.840), 0.633(CI95%: 0.505–0.765), MLR yielded a highest AUC. In addition, the optimal cut off value of MLR for BD was 0.23, with the specificity of 73.0% and sensitivity of 83.8%. In 37 BD patients, 14 belong to low MLR group, 23 belong to high MLR value group. The comparison results show that high MLR value group have higher CRP level and higher incidence of genital ulceration (P<0.05).

Conclusions: MLR was elevated in BD patients as compared to control group, having a close relationship with disease activity.

Giant Cell Arteritis is Comorbid with Tuberculosis

V. Zhaong, D. Wang, Y. Yin, X. Zeng, 1, 1General Internal Medicine, Peking Union Medical College Hospital, Beijing, 1Neurology, Nanfang Medical College Hospital, Guangzhou, China

Background: Giant cell arteritis (GCA) is a medium- and large-vascular vasculitis with an onset age after 50 years, whereas Takayasu arteritis (TA) is a rare large- vessel vasculitis with an onset age younger than 40 years. The association between TA and tuberculosis (TB) was suggested. However, the association between GCA and TB was rarely reported.

Objectives: To understand the association between TA and TB

Methods: Clinical data between November 1998 and October 2017 at PUMCH, Beijing, China, were retrospectively reviewed. Ninety-one patients diagnosed with GCA were included in the study. Precise clinical data were collected and analysed.

Results: A total of 20 patients (22.0%) had a history of active tuberculosis and received anti-tuberculosis therapy. On comparing the clinical features of the patients with TB and those without TB, obvious weight loss (p<0.011), lower percentage of dyslipidemia (p<0.042), higher percentage of anti-phospholipid (p<0.010), and lower white blood cells (p<0.006) were noted in the TB group.

Conclusions: This study demonstrated that the percentage of TB history in patients with GCA was higher than that in the general population. The definite association between TB and GCA remains unknown. Hence, further studies are required to elucidate the mechanisms underlying TB in the pathogenesis of GCA. Clinicians should recognise the possibility of comorbid TB in patients with obvious weight loss and relatively lower white blood cell count.

Scleroderma, myositis, and related syndrome

AB0716  AN AUTOPSY CASE OF SYSTEMIC SCLEROSIS WITH SEVERE INTESTINAL INVOLVEMENT AND LITERATURE REVIEW

A. Aoki¹, H. Hiranoto¹, H. Kobayashi¹, T. Okubo¹, Y. Umeyabayashi¹, H. Oka¹, Dept. of Rheumatology; Dept. of Pathology; Dept. of Dermatology, Tokyo Medical University Hachioji Medical Center, Tokyo, Japan

Background: The gastrointestinal tract (GIT) is the second most common internal organ affected by systemic sclerosis (SSc). The rate of SSc patients who develop severe GIT symptoms is lower than 10%, although various degrees of chronic intestinal pseudo-obstruction (CIFO) may occur in as many as 40% of cases (1,2).

Objectives: To report an autopsy case of SSc with severe intestinal involvement and review the associated literature.

Methods: We will present the clinical features and autopsy findings of a SSc patient and literature concerning Japanese SSc autopsy cases associated with severe intestinal involvement, found Igaku-chuo and Pub-med on Internet.

Results: A 69-year-old Japanese woman was diagnosed with diffuse cutaneous SSc from skin sclerosis, Raynaud’s phenomenon, and mild interstitial pneumonia in January 2013. The antinuclear antibody was positive (1:160, speckled pattern), but the specific antibodies, including the anti-RNP, topoisomerase I, and centromere antibodies, were negative. In August 2015, at the age of 71, she was hospitalised for vomiting and abdominal pain. Plain abdominal radiograph showed dilatation of the small bowel with air-fluid levels. Abdominal CT revealed large dilatation of the small bowel in the absence of any mechanical obstruction. These findings were consistent with CIFO. Her symptoms soon improved by decomposition with a long intestinal tube. But she experienced frequent relapse of CIFO.

Conclusions: Vasculopathy in SSc involves small vessels, and it precedes fibrosis. The cases in the literature are summarised in table 1. Vascular damage and/or oedema damage in the both of upper lobes of the lungs. Vasculopathy was also seen in the lungs and heart. The cases in the literature are summarised in table 1. Vascular damage and/or smooth muscle atrophy were presented in all cases.

Abstract AB0716 – Table 1. Autopsy cases of systemic sclerosis associated with severe gastrointestinal symptoms in Japan

M, male; F, female; yr, years; mo, months; GIT, gastrointestinal tract; IP, interstitial pneumonia; CIFO, chronic intestinal pseudo-obstruction; PCI, pneumatosis cystoides intestinales; 1) Intimal proliferation and narrowing of the small arteries

Conclusion: Vasculopathy in SSc involves small vessels, and it precedes fibrosis. The triggering event of vasculopathy is unknown, but the narrowing of intestinal arteries causing hypoxia might be responsible for dysmotility of GIT.

REFERENCES:

(Raynaud’s phenomenon, pulmonary interstitial involvement, digital ulcers, digestive alterations, presence of scleroderma renal crisis) and activity index variables (modified Rodnan score, HAQ-DI, SGA-VAS).

Results: Four patients were included (75% women). The median age at the time of the AHStS was 36.5 years (range 27–51). In all cases, the initial diagnosis was diffuse cutaneous ES, refractory to corticosteroids and at least one DMARD. Prior to autologous hematopoietic stem-cells transplantation, the clinical manifestations were a) severe Raynaud’s phenomenon (100%) with significant joint and cutaneous involvement; b) digital ulcers (50%); c) interstitial lung disease (50%) and d) sclerodermal renal crisis (25%). In 3 of the cases (75%) the antitopoisoeraser antibodies were positive. The conditioning treatment for the autologous hematopoietic stem-cells transplantation was cyclophosphamide at high doses (50 mg/kg x 4 days) and anti-thymocyte globulin. In 3 patients (75%) there were slight post-transplant complications (febrile neutropenia, diarrhea) after a median follow-up of 6.5 years (range 1–15).

The response to AHStS is summarised in table 1. All patients showed values <1 in the Health Assessment Questionnaire on the Disability Index (HAQ-DI), in 75% with a modified Rodnan skin score (mRSS) lower than 7.

CLOSE TEMPORAL ASSOCIATION BETWEEN SILICONE COSMETIC SURGERY AND SYSTEMIC SCLEROSIS ONSET

A. Suli, S. Paolino, E. Alessandrini, B. Ruauro, M. Pendolino, M. Cutolo, C. Pizzorni.
Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genova, Italy

Background: The pathogenesis of systemic sclerosis (SSc) still remains unclear. However, it is increasingly thought to result from interactions between environmental factors and epigenetic features leading to the onset and progression of SSc in genetically susceptible patients. Case reports of women with silicone breast implants who developed SSc have been published, but several case-control series and prospective studies in connective tissue diseases (including SSc) failed to find an increased risk of SSc associated with silicone cosmetic surgery. How-ever, several biases may be recognised in these studies, i.e. heterogeneous cohorts of enrolled patients not selective for SSc, non homogenous either disease duration or disease stage at study entry. For these reason the possible effect of silicone implants as immune adjuvants is not clear.

Objectives: Retrospective study to find out patients who developed SSc after cosmetic surgery.

Methods: The clinical files of 110 female patients with systemic sclerosis were reviewed and collected. Clinical data at the time of diagnosis and study onset, disease duration or disease stage at study entry. For these reason the possible effect of silicone implants as immune adjuvants is not clear.

Objectives: To show evidence of the transfer of systemic sclerosis by allogeneic bone marrow transplantation (BMT).

Methods: In this report we describe a patient with T acute lymphoblastic leukemia who underwent BMT and developed systemic sclerosis.

Results: 34-year-old man in complete remission from a T acute lymphoblastic leukemia treated with allogeneic BMT from his mother in February of 2012.

First seen in November 2017 for digital ulcers that appeared one year before. He presented two necrotic ulcers: one on the second finger of the left hand and other on the third finger of the right hand (IMAGE 1). He was admitted to receive intravenous prostaglandins and complete the study. After the BMT he developed Raynaud’s phenomenon and in the examination he only presented facial and corporeal telangiectasia, attributed before to chronic graft versus host disease (cGVHD).

SYSTEMIC SCLEROSIS AND CANCER DEVELOPMENT. A SINGLE-CENTRE EXPERIENCE

E. Pelechas, E. Kaltsonoudis, P.V. Voulgari, A.A. Drosos, Rheumatology Clinic, Department Of Internal Medicine, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, Ioannina, Greece

Background: Systemic Sclerosis (SSc) is an autoimmune connective tissue disease with multisystem involvement, and sometimes devastating results. In bibliography there are reports that scleroderma patients present a higher incidence of risk for cancer when compared with the general population. However, different estimates have been reported.

Objectives: The purpose of the present study was to evaluate the frequency of cancer development (CD) in a cohort of patients with SSc.

Methods: Patients that fulfilled the 2013 American College of Rheumatology/European League Against Rheumatism criteria for SSc and were followed up since 1999, were included. Date of disease onset, disease duration, autoantibodies, age, pulmonary hypertension, comorbidities and the type of CD have all been taken into account, during the period 1991–2016.

Results: Seventy-nine SSc patients have been included. 46 with limited (lcSSc) and 33 with diffuse cutaneous Systemic Sclerosis (dcSSc). Six of them, (7.6%) developed different types of cancer. Most of them were adenocarcinoma. More specifically, 2 developed pulmonary adenocarcinoma (1 with lcSSc and 1 with dcSSc), 1 follicular carcinoma of the thyroid gland (lcSSc), 1 colocolical adenocarcinoma (lcSSc), 1 B-cell lymphoma (MALT lymphoma), and 1 prostate adenocarcinoma (lcSSc). Five out of six were female patients. Mean age at the time of cancer diagnosis was 66.8-years-old, while SSc has been diagnosed at the mean age of 49.4 years. Mean time of developing any type of cancer was 15.8 years after SSc diagnosis. The diagnosis of cancer was done the last 20 months. All patients were non-smokers, had gastro-oesophageal reflux disease and pulmonary fibrosis, while 4/6 had also pulmonary hypertension and were under treatment with phosphodiesterase 5 inhibitors and bosentan. Scleroderma patients with CD have been referred to the corresponding oncology clinic for further treatment.

Conclusions: The present study on SSc and CD provides data showing a potential association between the two entities. We found a high frequency of cancer development in patients with SSc (7.6%). Thus, a careful monitoring and screening is required when physicians follow-up scleroderma patients.

AB0721

TRANSFER OF SYSTEMIC SCLEROSIS AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION

Background: It is accepted that donor-derived immunity is transferred with allogeneic bone marrow transplantation (BMT). We aimed to study the incidence of SSc in a cohort of BMT recipients and to analyse the clinical features of these cases.

Objectives: To show evidence of the transfer of systemic sclerosis by allogeneic BMT.

Methods: In this report we describe a patient with T acute lymphoblastic leukemia who underwent BMT and developed systemic sclerosis.

Results: 34-year-old man in complete remission from a T acute lymphoblastic leukemia treated with allogeneic BMT from his mother in February of 2012.

First seen in November 2017 for digital ulcers that appeared one year before. He presented two necrotic ulcers: one on the second finger of the left hand and other on the third finger of the right hand (IMAGE 1). He was admitted to receive intravenous prostaglandins and complete the study. After the BMT he developed Raynaud’s phenomenon and in the examination he only presented facial and corporeal telangiectasia, attributed before to chronic graft versus host disease (cGVHD).
The analysis showed ANA 1/640 centromere pattern, anticytokerin antibodies, reumatoid factor (RF) (852 UI/mL) and C3 of 86.4 mg/dL. Previously to the BMT he had negative ANA, but we do not know the rest of the previous autoimmunity. On the videocapillaroscopy we observe an active scleroderma pattern (IMAGE 2–3).

He was diagnosed with systemic sclerosis based on Raynaud’s phenomenon, digital ulcers, anticytokerin antibodies and abnormal nailfold capillaries. He had not familiar background of connective tissue diseases, but his mother presented Raynaud’s phenomenon since she was thirty. So we studied her. She presented facial telangiectasia, puffy fingers and fingerpitting scars and the same autoantibodies: ANA 1/320 centromere pattern, anticytokerin antibodies, RF (159 UI/mL) and consumption of C3 (74.3 mg/dL) and C4 (7.6). We do not have previous autoimmune studies of her. On the videocapillaroscopy we observed a late scleroderma pattern (IMAGE 4–5).

She was also diagnosed with systemic sclerosis, based on Raynaud’s phenomenon, puffy fingers, fingerpitting scars and facial telangiectasia, anticytokerin antibodies and abnormal nailfold capillaries.

Conclusions: Experimental animal studies and human clinical reports have described the transfer of immune-mediated diseases from affected donors to unaffected recipients, because of that the importance of screening this diseases in the donor before a BMT.

To our knowledge, this will be the first described case of transmission of systemic sclerosis by this mechanism. However, other explanations should also be taken into consideration. This include recipient’s own persistent intrathymic lymphocyte population that may produce autobody and autoimmunity in the context of cGVHD. However, this last hypothesis is not supported since there is a familiar background and presence of anticytokerin antibodies.

CAPILLAROSCOPY AND PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW
A_Vanhaecke1,2, V. Smith1,2, K. Melsen1,2, S. Paolino3, Y. Piette2, A. Sulli2, A. C. Trombetta3, F. De K eyser1,2, E. Van de V erde1,2, M. Cuto1, on behalf of the EULAR study group on microcirculation in Rheumatic diseases. 1Department of Internal Medicine, Ghent University; 2Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; 3Research Laboratory and Academic Division Of Clinical Rheumatology, Department Of Internal Medicine, Ircs San Martino Aou, University Of Genoa, Genoa, Italy; 4Department of Cardiology, Ghent University Hospital, Ghent, Belgium

Background: At this very moment, no systematic review evaluating the role of nailfold videocapillaroscopy (NVC), with standardised definitions, in pulmonary arterial hypertension (PAH) has been published.

Objectives: To systematically identify and review all available literature evaluating the role of capillaroscopy in PAH in SSc, according to the definitions of the EULAR study group on microcirculation in Rheumatic diseases.

Methods: A systematic literature search was performed in Pubmed, EMBASE and Web of Science. All retrieved articles were screened on title, abstract and full-text level. Reference lists and google scholar were additionally searched. Original research papers that documented an association between NVC and PAH (confirmed on right heart catheterization [RHC]) in SSc were included. Subsequently, NVC parameters were subdivided in quantitative (density, dimension, morphology and haemorrhages), semi-quantitative (NVC score) and qualitative assessment (presence of scleroderma pattern, severity of scleroderma pattern and worsening of scleroderma pattern) according to the definitions of the EULAR study group on microcirculation in Rheumatic diseases.

Results: The systematic search identified 215 unique search results, of which 171 references were withheld after title screening. Abstract screening resulted in 51 references, only 19 were eligible for full-text review. Finally, 9 references were included in the final analysis after full-text screening (n=7) and bibliographic and google scholar search (n=2) (see table 1).

Regarding cross-sectional studies, density has been evaluated in 5 studies, with no unequivocal results for mean density; avascular score has been unequivocally included in the final analysis after full-text screening (n=7) and bibliographic and 171 references were withheld after title screening. Abstract screening resulted in

SEROPREVALENCE OF EPSTEIN-BARR VIRUS AND CYTOMEGALOVIRUS IN SYSTEMIC SCLEROSIS PATIENTS: PRELIMINARY RESULTS
A.C. Trombetta1, V. Tomatis1, E. Alessandri1, S. Paolino1, C. Pizzorni1, M. Ghio1, B. Ruaro1, M. Patane1, E. Gotelli1, F. Goegan1, A. Sulli1, V. Smith2, M. Cuto1
1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, Ircs Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy; 2Department of Rheumatology, University Hospital of Ghent, Ghent, Belgium

Background: Epstein-Barr Virus (EBV) and cytomegalovirus (CMV) are among the most diffused virus in humans, with prevalence of 90% and 80% respectively in adult immunocompetent population. Hypothesis for a role of EBV and CMV in systemic sclerosis pathogenesis was reported.

Methods: A total of 49 patients (44 females and 5 males, age 65,6±9 years, 34 with limited cutaneous involvement and 14 with diffused cutaneous involvement) diagnosed according to the 2013 ACR/EULAR criteria were randomly enrolled on the videocapillaroscopy we observe a late scleroderma pattern (IMAGE 4–5).

She was also diagnosed with systemic sclerosis, based on Raynaud’s phenomenon, puffy fingers, fingerpitting scars and facial telangiectasia, anticytokerin antibodies and abnormal nailfold capillaries.

Conclusions: Experimental animal studies and human clinical reports have described the transfer of immune-mediated diseases from affected donors to unaffected recipients, because of that the importance of screening this diseases in the donor before a BMT.

To our knowledge, this will be the first described case of transmission of systemic sclerosis by this mechanism. However, other explanations should also be taken into consideration. This include recipient’s own persistent intrathymic lymphocyte population that may produce autobody and autoimmunity in the context of cGVHD. However, this last hypothesis is not supported since there is a familiar background and presence of anticytokerin antibodies.

Disclosure of Interest: None declared

Conclusions: This systematic literature review, on behalf of the EULAR study group on microcirculation in Rheumatic diseases, is the first to investigate unequivocal associations between (incident) PAH and capillaroscopic alterations in a standardised way. Unequivocal associations were found in cross-sectional studies between avascular score, morphology, NVC score and severity of scleroderma pattern and PAH and in longitudinal studies between capillary loss and worsening of scleroderma pattern and incident PAH.

(p=0.04). Finally, higher CMV-IgG correlated with diffused cutaneous SSC form (p=0.023) and nephropathy (p=0.036).

Conclusions: The seroprevalence of EBV and CMV positivity was found significantly higher in the sample of SSC patients. EBV seropositivity (VCA-IgG) was present nearly in the totality of patients (98%). Of relevance, the high presence of CMV-IgG (93%) and CMV-IgM (44.9%) in SSC patients: the last correlated linearly with higher pulmonary arterial pressure values. EBV and CMV infections, among the supposed triggers in several autoimmune diseases, might also play a role in SSC patients, at least with progressive disease.

CARDIO-PULMONARY DISEASE MANAGEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS: CARDIO-RHEUMATOLOGY CLINIC AND PATIENT CARE STANDARDISATION PROPOSAL
A. Spinelli1, F. Lumetti1, A.V. Mattioli1, F. Coppì1, R. Rosario2, E. Cocchiara1, M. Colaci, C. Ferrì, G. Salvarean3, D. Giuggii4, C. Salvarean1, D. Giuggii4, 1Scleroderma Unit, Chair of Rheumatology; 2Department of Surgical, Medical and Dental Department of Morphological Sciences related to Transplant, Oncology and Regenerative Medicine; 3Chair of Cardiology; University of Modena and RE, Modena; 4Internal Medicine Unit, University of Catania, Catania; 5Scleroderma Unit, Chair of Rheumatology, University of Modena and RE, Modena, Italy

Background: Systemic sclerosis (SSc) is a chronic connective tissue disease characterised by endothelial dysfunction, dysregulation of fibroblasts with excessive fibrosis of the skin and internal organs and autoimmune abnormalities. Cardio-pulmonary manifestations are common in SSc and their detection in the early stage of the disease as well as their careful follow-up are mandatory in order to counteract their impact on the overall disease outcome. Despite the need of establishing a proper methodology, literature provides few reports about this issue.

Objectives: To evaluate the activity of our Cardio-Rheumatology Clinic in order to optimise diagnostic management of cardio-pulmonary disease in SSc patients.

Methods: We retrospectively analysed data from 350 consecutive SSc patients referred to our University-based Rheumatology Centre and SSc Unit (F/M:308/42; ic/dcSSc 45/305; mean age 50.8±14.7 years; mean disease duration 10.9±7.0 years). All patients underwent general and cardio-pulmonary assessment, in particular they were evaluated in the Cardio-Rheumatology Clinic. The following parameters were considered: physical examination; past and current drugs; blood tests, in particular Erythrocyte sedimentation rate-ESR, C-reactive protein-CRP, CPK enzymes, troponin, NT-pro-BNP, d-dimer, serum autoantibodies, 25-OH-vitamin D; capillaroscopy; pulmonary function tests; high resolution scan of the lungs (HRCT); standard electrocardiogram (ECC) and 24 hour Holter ECG monitoring. Doppler echocardiography; cardiac stress test; coronary angiography and right heart catheterization (RHC); cardiac MRI and CT; vascular ultrasound (intima-media-thickness, carotid-femoral and brachial-ankle pulse-wave-velocity). The clinicians decided to perform these examinations according to clinical picture and current methodologies.

Results: In the last 12 months we assessed 300 patients with 1st-level screening (cardio-rheumatologic evaluation, standard ECG, Doppler echocardiography, pulmonary function tests, thoracic imaging). Among 2nd-level, 30 procedures of 24 hour Holter ECG and 15 RHC tests were performed. Cardiac MRI, coronary CT angiography and vascular ultrasound were assessed, when requested, as 3rd-level examinations (30 procedures). After 1 year we observed a mean time of 10±5 days between request and clinical cardio-rheumatologic evaluation, 20±12 days to perform 1st-level screening, 25±15 days to execute the 2nd-level examinations. Figure-1 shows Cardio-Rheumatology algorithm for the management of SSc cardio-pulmonary disease.

Conclusions: The activity of our Cardio-Rheumatology Clinic optimises the cardiology-pulmonary SSc assessment, determining an early detection of these harmful complications with reduced waiting times which are critical issues. Screening algorithms are useful to stratify the risk and to establish the most appropriate diagnostic-therapeutic protocols, improving outcome of scleroderma patients. The development of a cardio-pulmonary risk score and the standardisation of a patient care approach, according to international quality indexes, could represent further tools to optimise SSc management.

AB0725
SEVERE DYSPHAGIA “POOR PROGNOSTIC MARKER” IN IDIOPATHIC INFLAMMATORY MYOPATHIES
A.C. Costi, L. Garcia, C. Pena, A. Testi, P. Sansinianea, R. Aguila, M. Pera, S. Velloso, F. Savy, M. Garcia. Reumatología, HIGA San Martín, La Plata, Argentina

Background: In Idiopathic Inflammatory Myopathies (MI), 18%–20% of patients have dysphagia.

Objectives: To evaluate the frequency of dysphagia in patients with MIL, association with other manifestations of the disease, treatment and evolution.

To evaluate clinical characteristics and evolution of severe dysphagia.

To compare clinical characteristics and evolution of mild-moderate versus severe dysphagia.

Methods: Retrospective, observational study. Patients with a diagnosis of MIL were included according to modified classification criteria of Bohan and Peter. Demographic, clinical and complementary studies were recorded. Serious dysphagia was considered: contraindication of oral feeding. Descriptive statistics were performed. Chi2 test, Student’s t-test or Mann Whitney as appropriate.

Results: We included 91 of 106 patients evaluated from 1992 to 2017: 76% female, mean age at diagnosis 45±14 years. 53% presented dysphagia: mild/moderate 62.5% (30/48 pts), severe 37.5% (18/48). Idiopathic dermatomyositis was the most frequent MIL in these patients (71%). In patients with dysphagia, proximal muscle weakness was 90%, weakness of neck muscles 45%, weakness of respiratory muscles 27%.

A significant association was found between dysphagia and weakness of respiratory muscles, weak neck muscles, glucocorticoid pulses, gammaglobulin, respiratory infections and death. (Data not shown in the summary).

In patients with severe dysphagia, we observed a significant association with the requirement for mechanical ventilation, hospitalisation in an intensive care unit, serious infections and death (table 1).

When comparing mild-moderate dysphagia vs severe dysphagia, a statistically significant association was found with neck muscles weakness, respiratory muscle weakness, glucocorticoid pulses, gamma globulin use, requirement for mechanical ventilation, hospitalisation in an intensive care unit, severe infections and mortality (table 2).

Conclusions: This was the first multicentre Portuguese study about ILD in SSc. In our cohort, ILD occurred in about 30% of the pts and was associated with a mortality rate of 3.4.13

Our results confirm that some variables are associated with pulmonary disease development, and thus its identification may help the clinician to detect pts with a higher risk of early ILD.

AB0726 INTERSTITIAL LUNG DISEASE IN SCLERODERMA PATIENTS – A PORTUGUESE PORTRAIT

A.C. Duarte1, A. Cordeiro1, T. Santiago2,3, M.J. Salvador2,3, M.J. Santos1.

1Rheumatology, Hospital Garcia de Orta, Almada; 2Rheumatology, Centro Hospitalar e Universitário de Coimbra; 3Faculty of Medicine, University of Coimbra, Coimbra, Portugal

Background: Systemic sclerosis (SSc) is characterised by inflammation and fibrosis of skin and internal organs. Lung involvement, particularly interstitial lung disease (ILD), is a major cause of morbidity and a leading cause of SSc-related mortality.

Objectives: To characterise SSc patients (pts) with ILD and identify possible predictors for its development.

Methods: A multicenter prospective cohort study using the Rheumatic Diseases Portuguese Register/Scleroderma database was performed. All patients fulfilled ACR/EULAR 2013 classification criteria for SSc. Demographic and clinical data until 15th January 2018 were collected as well as pulmonary function tests (PFTs), including diffusion capacity of carbon monoxide (DLCO). ILD was defined by fibrosis in chest x-ray and/or high-resolution computed tomography (HRCT) scan. Disease progression was defined by an increase from baseline in the area of ground glass imaging and/or reduction of more than 15% in DLCO or 10% in forced vital capacity in pts with stablished ILD. We performed a descriptive analysis of SSc cohort. Logistic regression analysis was used to identify variables independently associated with ILD.

Results: A total of 146 pts were included, 88.4% female, with a mean age of 61.5 ± 14.4 years (yrs) and mean disease duration of 14.3 ± 11.3 yrs. Limited cutaneous SSc (lSSc) was present in 64.1%, diffuse cutaneous SSc (dSSc) in 22.2%, and overlap SSc in 3.4%. Most pts (64.1%) had limited cutaneous SSc (lSSc), 26 (22.2%) diffuse cutaneous SSc (dSSc), 83.5% of them were female; 45.2% had dSSc and 42.9% lSSc. Anti-Scl70 (OR: 0.02 95% CI 0.00–0.42) and current/previous smoking habits (group 1 ERS/ECS 2013 classification) was present in 6.3% of pts with ACA, Osseous involvement was the second commonest manifestation and occurred in 57.1% of pts with ACA, although this association was not statistically significant. ACA seemed to have a protective effect for interstitial lung disease (ILD) (OR: 0.027 95% CI 0.004–0.213).

Anti-Scl70 positivity was associated with dSSc phenotype (OR: 9.29 95% CI 3.26–26.5) and ILD (OR: 10.39 95% CI 3.86–27.92).

During follow-up, disease progression occurred in 17 pts (40.1%), 3 of them under immunosuppression. Death occurred in 7 pts with ILD, 5 of them with direct relation to lung disease, 14.4 years after the diagnosis.

Conclusions: Anti-Scl70 antibody; anti-Scl70 – antitopoisomerase I; IcSSc – limited cutaneous systemic sclerosis; dSSc – diffuse cutaneous systemic sclerosis; PAH – pulmonary arterial hypertension; GI – gastro-intestinal; MS – muscle-skeletal

Legend: ACA – antitopoisomerase antibody; anti-Scl70 – antitopoisomerase I; IcSSc – limited cutaneous systemic sclerosis; dSSc – diffuse cutaneous systemic sclerosis; PAH – pulmonary arterial hypertension; GI – gastro-intestinal; MS – muscle-skeletal
Anti-U1RNP was associated with muscle-skeletal manifestations (OR: 10.7 95%, CI 9.92–20.44) and with overlap syndromes (OR: 15.2 95%, CI 4.7–29.1). Pts with anti-Th/To and anti-RNA-polymerase III had lcsScSs subtype. Vascular manifestations, oesophageal involvement and calcinosis cutis were the main manifestations, respectively. Table 1 shows detailed clinical manifestations and antibody profile.

Conclusions: In our cohort, ACA and anti-Scl70 were the commonest antibodies and were associated with lcsScSs and dlsScSs phenotype, respectively. ACA positivity conferred a higher risk of vascular disease and had a protective effect for ILD, while anti-Scl70 was associated with ILD. Pts with anti-U1 RNP and anti-PM/Scl had mainly muscle-skeletal manifestations. This study confirms an association between immunological profile and clinical manifestations, reinforcing the importance of antibody profile and raising awareness for possible disease complications. Larger national studies would be desirable, specially for a better understanding of major organ involvement associated with least common antibodies.

AB0728 NAILFOLD CAPILLAROSCOPY IN SYSTEMIC SCLEROSIS – SIX YEARS IN REVIEW

A.C. Duarte, A. Cordeiro, M.J. Santos. Rheumatology, Hospital Garcia de Orta, Almada, Portugal

Background: Microvascular dysfunction is a dynamic process that is crucial in systemic sclerosis (SSc) pathogenesis. Nailfold capillaroscopy(NCP) is a rapid, non-invasive exam that illustrates the early capillary changes in SSc and monitor their evolution. It is extremely useful in clinical practice and has been recognised in 2013 ACR/EULAR classification criteria for SSc.

Objectives: Evaluate the prevalence and evolution of NCP scleroderma pattern in SSc patients and analyse possible associations with disease-phenotype.

Methods: NCP of SSc patients followed in our centre were reviewed; clinical and demographic features were collected. A descriptive analysis was performed and nonparametric tests compared patients with and without SSc pattern.

Results: In total, 70 out of 117 SSc patients had at least 1 NCP available during the last 6 years. Most of these patients(62.9%) had limited cutaneous SSc, 21.4% diffuse cutaneous SSc, 11.4% very early diagnosis SSc and 4.3% overlap syndromes; mean disease duration was 10.7±9.6 years.

At the moment of the first NCP, 46 patients(39.4%) had a scleroderma pattern, 12 (10.3%) had non-specific(NS) NCP abnormalities and 12 had a normal NCP. During the 6 years follow-up, NCP changed in 5 patients as illustrated in figure 1. However, none had concomitant development/worsening of other clinical manifestations.

At the end of the follow-up, 49 (70%) patients had a NCP scleroderma pattern. Early pattern was present in 13 (26.5%) patients, active pattern in 21 (42.9%), active/late pattern in 3 (6.1%) and late pattern in 12 (24.5%). When comparing patients with and without scleroderma specific patterns (table 1), the presence of scleroderma pattern was associated with the presence of current/previous digital ulcers/OR 1.49 95% CI 1.17–1.92. However, this difference was not confirmed between the different scleroderma patterns.

Regarding, major organ involvement, although there were no statistical differences between both groups, patients with scleroderma pattern had a higher prevalence of oesophageal involvement.

Abstract AB0728 – Figure 1. Progression of nailfold capillaroscopy alterations during follow-up

Conclusions: This study demonstrates how NCP can illustrate the dynamic vascular damage in SSc. In our data, a NCP scleroderma pattern was significantly associated with a higher number of digital ulcers and these patients had a higher percentage of oesophageal involvement.

In daily clinical practice, NCP is useful not only for corroborating SSc diagnosis, but also for monitoring endothelial injury and potential macrovascular/systemic damage. Although our sample was too small to demonstrate specific associations between specific NCP alterations and internal organ involvement, some studies have already identify NCP patterns as predictive factors for organ damage.

AB0729 QUALITY OF LIFE ASSESSMENT IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION: A LONGITUDINAL STUDY

A.L.C. Guimarães1, K. Costa-Pereira2, J.B. Elias2, D.A. Moraes2, E.A. Oliveira-Cardoso1, J.T. Garcia1, M.C. Oliveira1, V. Leopoldo2, A.F. Zombrilli2, M.T. Costa2, M. Vasconcelos2, M.C. Oliveira2,1Ribeirão Preto School of Philosophy, Sciences and Literature; 2Division of Clinical Immunology, Ribeirão Preto Medical School, Ribeirão Preto School of Nursing, University of Sao Paulo, Ribeirão Preto, Brazil

Background: Autologous Hematopoietic Stem Cell Transplantation (AH SCT) has been explored as a therapeutic option for patients with systemic sclerosis (SSc) that do not respond to conventional treatment.

Objectives: To investigate changes in quality of life of severe and rapidly progressive SSc patients treated with AH SCT.

Methods: This is a longitudinal and comparative study. Patients were evaluated before (n=27) and at 6 (n=27) and 12 months (n=21) after AH SCT. The Generic Questionnaire for Evaluation of Quality of Life Medical Outcomes Study 36 Item Short-Form Health Survey (SF-36) was applied individually, face-to-face, under patient written consent. This questionnaire evaluates eight domains: physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), social functioning (SF), vitality (VT), role-emotional (RE) and mental health (MH).

Results: Participants were females (n=24), with mean age of 33 years (standard deviation, SD=10.33) and mean time from diagnosis of 34.4 months (SD=34.89). Before AH SCT, the mostly impaired aspects were: PF (mean=8.33, SD=18.34), and RP (mean=38.52, SD=21.56), while MH (mean=61.63, SD=15.46) and SF (mean=56.87, SD=27.17) were mostly preserved. At 6 and 12 months post-AH SCT, there was significant improvement of the SF-36 scores in the following domains: PF (6 months, p<0.01, 12 months, p<0.01); RP (6 months, p<0.01, 12 months, p<0.01); BP (6 months, p<0.01, 12 months, p<0.01); GH (6 months, p<0.01, 12 months, p<0.02); VT (6 months, p<0.01, 12 months, p<0.01); MH (6 months, p<0.01, 12 months, p<0.01). The SF domain showed significant increase only at 12 months (p=0.02). The only domain in which there was no significant change was RE.

Conclusions: Increases in the physical components of quality of life are more evident in the initial periods that follow AH SCT, while improvements in mental state, which are also associated with social aspects, are detected on longer follow-up. These data reinforce the relevance of AH SCT upon patient quality of life, signalling the importance of psychotherapeutic evaluations and follow-up.

AB0730  COMPARISON OF A SINGLE-CENTRE IDIOPATHIC INFLAMMATORY MYOPATHY COHORT FROM ARGENTINA WITH THE EUROMYOSITIS INTERNATIONAL REGISTRY

A.S. Braillard Poccard, R. Gomez, M. Pino, M. Garcia Carrasco, D. Dubinsky, Hospital de Clínicas “José de San Martín”, Ciudad Autónoma de Buenos Aires, Argentina

Background: The idiopathic inflammatory myopathies (IIM) are rare systemic autoimmune diseases that affect the muscle and other organs. Traditionally, IIM encompasses polymyositis (PM) and dermatomyositis (DM), but progressively inclusion body myositis (IBM), Immune-mediated necrotising myopathy (IMNM), the antisyntethase syndrome (ASS) and connective tissue diseases-ovler myositis (CTD-OM) have been recognised within the IIM spectrum.

Objectives: To compare the clinical characteristics and treatment in a IIM cohort from an Argentinian university hospital with the international IIM cohort EUROMYOSITIS.

Methods: Descriptive, retrospective study. IIM patients defined by expert opinion followed in our centre between October 2005 and October 2017 were included. ASS was defined by the presence of arthritis, Raynaud’s phenomenon, mechanic hands, elevated CK, muscle weakness, interstitial lung disease and/or presence of antisyntethase antibodies and, as in EUROMYOSITIS, patients with IIM with positive antisyntethase antibodies were reclassified as ASS. CTD-OM was defined as patients with IIM fulfilling classification criteria for other CTD.

Demographic data, accumulated clinical features, time interval between disease onset and diagnosis, IIM subtype, treatment and presence of neoplasm were evaluated.

Ethnicity was defined using the same classification as in EUROMYOSITS.

Results: 58 patients were included: DM 24, PM 4, ASS 10, CTD-OM 20. 89.6% of antisynthetase antibodies were reclassified as ASS. CTD-OM was explained by our mostly Hispanic population and/or by frequent Systemic Sclerosis overlap in our patients. It’s important to remark that the ethnic variety defined as Hispanic in EUROMYOSITIS has a complex composition in Latin America, due to interbreeding.

No difference was found in terms of most frequent treatments between both cohorts. However, use of IVlg was more frequent in our patients.

To our knowledge, this is the first comparative report of an Argentinian single-centre IIM cohort and an international multi-centre cohort.

Disclosure of Interest: None declared

Conclusions: DM was the most frequent IIM subtype in both cohorts. In our group, CTD-OM was second and ASS was third.

Muscle weakness was found less frequently in our DM and AAS than reported in EUROMYOSITIS. However, calcinosis was more frequent. This could be explained by our mostly Hispanic population and/or by frequent Systemic Sclerosis overlap in our patients. It’s important to remark that the ethnic variety defined as Hispanic in EUROMYOSITIS has a complex composition in Latin America, due to interbreeding.

No difference was found in terms of most frequent treatments between both cohorts. However, use of IVlg was more frequent in our patients.

To our knowledge, this is the first comparative report of an argentinian single-centre IIM cohort and an international multi-centre cohort.

AB0731  TREATMENT ALGORITHMS FOR SYSTEMIC SCLEROSIS ACCORDING TO EXPERTS

A. Fernández-Codina1,2, K.M. Walker3, J.E. Pope1, on behalf of Scleroderma Algorithm Group. 1Medicine, Rheumatology Division, University of Western Ontario, London, Canada; 2Internal Medicine, Systemic Autoimmune Diseases Unit, Hospital Universitari Vall d’Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain; 3Rheumatology Division, The Ottawa Hospital, University of Ottawa, Ottawa, Canada.

Background: Treatment for many aspects of systemic sclerosis (SSc) lacks agreement.

Objectives: To generate SSc treatment algorithms endorsed by high percentage of SSc experts.

Methods: Experts from the Scleroderma Clinical Trials Consortium and the Canadian Scleroderma Research group (n=170) were asked whether they agreed with SSc algorithms (from 2012). A further 2 consensus rounds refined agreement; 62 (36%), 54 and 48 experts completed surveys.

Results: For scleroderma renal crisis (SRC), 82% of the experts agreed (1st line ACEi, 2nd and 3rd adding CCB or ARB). Pulmonary arterial hypertension (PAH) had 61% agreement. For mild PAH, PDE5i, then endothelin receptor antagonists plus PDE5i, then prostanooids; while for severe PAH prostanooids were first-line, Raynauds’ phenomenon (RP) had 78% of agreement [mild (1st CCB, 2nd adding PDE5i, 3rd ARB or switching to another CCB, 4th prostanooids), severe (1st CCB, 2nd adding PDE5i, 3rd ERA, 4th prostanooids)]. Digital ulcer (DU) treatment had 69% agreement (1st CCB, 2nd PDE5i). Interstitial lung disease (ILD) had 65% agreement including induction (Mycophenolate mofetil (MMF) then intravenous cyclophosphamide then rituximab) and maintenance (1st line MMF). Skin involvement had 71% agreement. For a modified Rodnan skin score (mRSS) of 24 1st MTX, 2nd MF, and for mRSS 32 1st MTX, 2nd low dose glucocorticoids, 3rd hydroxychloroquine, 4th rituximab or tocilizumab. Cardiac and gastrointestinal algorithms had >75% agreement. The evolution of the agreement rates is shown in table 1:

Abstract AB0731 – Table 1

Algorithms for SSc treatment Agreement 2012 (%) Agreement 2017 (%)
Scleroderma renal crisis 69 82
Pulmonary arterial hypertension 45 81
Raynaud’s phenomenon 66 78
Digital ulcers 58 69
Interstitial lung disease 64 65
Gastrointestinal involvement NA 77
Skin involvement 56, 40, 36† 71
Inflammatory arthritis 45 79
Cardiac involvement NA 75

Conclusions: Total agreement for SSc algorithms was considerable. These SSc algorithms may guide treatment.

AB0732  Efficacy and safety of rituximab in systemic sclerosis: French retrospective study and literature review

M. Thébaut1, D. Launay2, S. Rivière3, T. Mahévas1, S. Bellakhall4, E. Hachulla4, O. Faín1, A. Mekinian1, Mdédecine Interne, Hôpital Saint-Antoine AP-HP, Paris; 2Mdédecine Interne, Hôpital Claude Huyné CHU Lille, Lille, France; 3Mdédecine Interne, Hôpital des Forces de Sécurité Intérieure, La Marsa, Tunisia

Background: Intestinal lung disease occurs in 42% of diffuse SSC patients and have a major impact on the overall survival.1 Cyclophosphamide and mycophenolate mofetil can allow the lung disease stabilisation.2–3 Recently several case-reports and little series reported the efficacy of rituximab in SSC, showing a possible improvement of pulmonary involvements.5–6 Large studies are lacking to determine the factors associated with rituximab response, the maintenance regimen and the long term efficacy of rituximab in SSC.

Objectives: To describe safety and efficacy of rituximab in patients with systemic sclerosis.

Methods: We included 13 patients with systemic sclerosis treated with rituximab and pooled with 40 additional patients from the literature. SSC rituximab untreated patients were matched to rituximab treated ones.

Results: Thirteen patients who received rituximab and 26 rituximab-untreated patients were included. In comparison to 26 patients who did not received rituximab, FVC changes were not significantly different, whereas DLCO improved in 13 of 24 (54%) months of follow up in dSSc who received rituximab (gain of 12.1% ± 19) at M12 (p=0.04). Pooled analysis of 53 patients (40 literature patients and 13 from personal series) showed significant improvement of median mRSS from 18.8 ± 33 at baseline to 9.5 ± 19 at M6 (p=0.007), 13.8 ± 19 at M12 (p=0.008) and 10.5 ± 19 at the last follow-up (p=0.002). FVC increased from 71% ± 40 at baseline to 84% ± 52 at M12 (p=0.001). DLCO increased from 58% ± 68 at M0 to 65% ± 75 at M12 (p=0.04).

Conclusions: Our personal data and pooled literature analysis suggest the efficacy of rituximab in the subset of diffuse SSC in particular in skin and interstitial disease involvements. The safety of rituximab seems to be reasonable and similar to previous data in other autoimmune diseases.

AB0733  Association of haematological parameters with disease manifestations, activity, and severity in patients with systemic sclerosis

M.E. Yayılgı, U. Ilgın2, İ.E. Okatan1, E. Uslu Yurtseven1, M. Toruğutlu Dinçer1, E.G. Aydemir Gülbükçası1, S. Sezer1, T.M. Turgay1, G. Kankılı1, A. Ates2, 1Department of Rheumatology, Ankara University Faculty of Medicine, Ankara; 2Department of Rheumatology, Trakya University Faculty of Medicine, Edirne, Turkey

Background: Neutrophil-to-lymphocyte ratio (NLR), monocyte-to-lymphocyte ratio (MLR), eosinophil-to-lymphocyte ratio (ELR), basophil-to-lymphocyte ratio (BLR), and mean platelet volume (MPV) may potentially reflect inflammatory status in systemic autoimmune diseases.

Objectives: The aim of this study is to investigate the association of NLR, MLR, ELR, BLR and MPV with disease manifestations, activity and severity in patients with systemic sclerosis (SSc).

Methods: 59 patients with SSc and 50 healthy controls were included in the study. All patients were diagnosed according to the 2013 ACR/EULAR systemic sclerosis classification criteria. Adult patients with SSc and healthy controls were compared in terms of NLR, MLR, ELR, BLR and MPV.

Results: SSc and control groups had similar ages and genders. Neutrophil-to-lymphocyte ratio was lower in SSc group compared to controls (p<0.001). SSc group also have higher NLR and MLR (table 1). There were no significant differences in ELR and BLR ratios between SSc patients and controls. Patients with active disease (2.9 [IQR 2.13], p=0.042), pulmonary hypertension (PHT), digital ulcers, and tendon friction rubs (TFR) had higher NLRs (table 2). MLR was also higher in dcSSc patients (0.28 [IQR 0.73] compared to lcsss (0.2 [IQR 0.48]) (p=0.045), and there were also significant associations with disease manifestations like digital ulcers, tendon friction rubs (table 2). MLR was positively correlated with mRSS (rho=0.35 p=0.009), Valenti (rho=0.453 p=0.001) and Medsger (rho=0.283 p=0.036) scores. According to capillaroscopy images, patients with late stage findings had higher ELRs and patients with normal findings (0.27 [IQR 0.3] vs 0.15 [IQR 0.04], p=0.001). Patients with digital ulcers (p=0.02) and arthritis (p=0.013) had higher ELRs and patients with tendon friction rubs has higher ELRs (p=0.014) and BLRs (0.036) compared to those without. There was no significant relation between MPV and disease manifestations (table 2). There were no relationships between dysmotility and haematological parameters.

AB0734
SERUM IL-35 LEVELS IN SYSTEMIC SCLEROSIS AND RELATIONSHIP WITH CLINICAL FEATURES

M.E. Yayla1, M. Torgutaş1, I.E. Okatan1, E. Eruş Yurteri1, O. Küçükşahin2, A. B. Keleşoğlu Dinçer1, E.G. Aydemir Gölükşüş2, S. Sezer1, E. Uş1, T.M. Turgay1, G. Kınik1, A. Ateş1. 1Department of Rheumatology, Ankara University Faculty of Medicine, 2Department of Rheumatology, Yıldırım Beyazıt University Faculty of Medicine, 3Department of Clinical Microbiology, Ankara University Faculty of Medicine, Ankara, Turkey

Background: Interleukin (IL)–35 is a member of the IL-12 family. Studies show that IL-35 is an important anti-inflammatory cytokine and suppresses effector T cell activity. Systemic sclerosis (SSc) is a chronic disease characterised by vascular damage, autoimmunity and fibrosis.

Objectives: In this study, we aimed to evaluate serum IL-35 level in SSc patients and its potential relation with disease findings.

Methods: Fifty-five SSc patients and 25 healthy controls were included in the study. All patients were diagnosed according to 2013 ACR/EULAR systemic sclerosis classification criteria. Serum IL-35 was measured using a commercial ELISA kit (Cloud-Clone Corp., Wuhan, China).

Results: SSc patients and healthy controls had similar ages and genders. The mean of serum IL-35 level was significantly higher in SSc patients (8.2±1.3 pg/ml) than in healthy controls (6.9±0.7 pg/ml) (p < 0.001). Serum IL-35 levels were similar in lcSSc (n=44) and dcSSc (n=11) groups (8.3±1.2 and 8.0±1.6 pg/ml, respectively). There were no significant differences between serum IL-35 level and disease duration, modified Rodnan skin score, Valentini disease activity score, Medsger disease severity score, erythrocyte sedimentation rate and C-reactive protein (CRP) levels. Serum IL-35 levels between patients treated with or not vasodilating agents such as calcium channel blockers, endothelin receptor antagonists and prostaglandin analogues, and also immunosuppressive drugs did not differ significantly.

Conclusions: It has been reported that serum IL-35 level is higher in SSc patients than healthy volunteers and is associated with interstitial lung disease. In our study, the level of IL-35 was higher in SSc patients than healthy controls. There is no relationship between clinical parameters and IL-35 levels, this may be due to small sample size. Our results suggest that IL-35 may have a role in the pathogenesis of SSc. Further investigations are needed in large sample size of SSc patients.

NAILFOLD CAPILLARY COUNTS CORRELATE MOST WITH COMPLICATIONS OF SYSTEMIC SCLERODERMA IN JAPANESE PATIENTS

A. Kondo1, H. Dobashi1, T. Kameda2, M. Izumikawa3, S. Nakashima4, H. Shimada5, R. Wakuya5, M. Kato6, N. Kadokawa7. 1Kagawa university, Kita, Japan; 2Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa university, Kita, Japan

Background: Connective tissue diseases (CTD) patients have various clinical manifestation including pulmonary hypertension (PH) and digital ulcer (DU). Especially, Raynaud’s phenomenon (RP) is one of the common symptoms. On the other hand, “abnormal nailfold capillaries” are important as the findings that suggest RP associated with CTD. They are included in one of the items of classification criteria for Scleroderma (SSc) in 2013 Classification Criteria for Systemic Sclerosis (ACR/EULAR)1. Recently, some reports presented the usefulness of nailfold capillarscopy (NFC) in SSc2,3. NFC findings showed enlarged/giant capillaries, fresh or old haemorrhages, avascular areas, ramified/bushy capillaries. These findings are known as “scleroderma pattern” features. Additionally, there are some reports that nailfold capillary density in SSc related with DU, PH and interstitial pneumonia (IP).

In this study, we clarify the association between nailfold capillary density and clinical manifestation by analysis of the case in our institution.

Objectives: To clarify the association between nailfold capillary density and clinical manifestation.

Methods: We enrolled Japanese SSc patients from May 2016 to May 2017 in our institution. We measured total nailfold capillary count per 1 mm from second to fifth finger by NFC “OptiPFX Capillarscopy Clinic 1.7.x”. In addition, we investigated relationship with NFC findings and clinical manifestation such as current and previous DU, PH and IP.

Results: We enrolled 42 SSc patients. Total nailfold capillary counts significantly decreased, especially in SSc patients with previous DU (n=41; p=0.0054), and PH (n=3; p=0.0023). In addition, there is significant difference between DU and existence of giant capillaries (p=0.0019 p=0.0464), existence of avascular areas (p=0.0057 p=0.0063). On the other hand, there is no significant difference between IP, PH and other “scleroderma pattern” features.

Conclusions: Our study revealed that total nailfold capillary counts were associated with PH and DU in SSc patients. We suggest that nailfold capillary density may most predict complications with SSc patients.

AB0736
SYSTEMIC SCLEROSIS SINE SCLERODERMA: CHARACTERISTICS OF A SOUTH INDIAN COHORT FROM A TERTIARY CARE CENTRE

B. Chilukuri1,2, S. Chinnadurai2, B. Mahendran3, R. Ramamoorthy3. 1Department of Rheumatology, Paravathy Hospital, 2Institute of Rheumatology, Madras medical college, Chennai; 3Department of Rheumatology, KIMS Hospital, Trivandrum; 4Department of Rheumatology, SRMC, Chennai, India

Background: Systemic Sclerosis is a complex disorder characterised by autoimmunity, vasculopathy and fibrosis. The hallmark of Systemic Sclerosis is skin thickening. Systemic Sclerosis sine scleroderma is a variant of Systemic sclerosis which shares visceral, serological and vascular manifestations but lacks skin thickening. Systemic Sclerosis sine scleroderma still remains a rarely reported subtype of Systemic Sclerosis unlike commonly reported limited cutaneous and diffuse cutaneous types.

Objectives: Aim of this study was to analyse the characteristics of patients with Systemic Sclerosis sine scleroderma from a cohort of Systemic Sclerosis patients.

Methods: This study was done at Institute of Rheumatology, Madras Medical College, Chennai, India. It was a retrospective observational study (January 2006 to November 2016). Patients satisfying ACR/EULAR 2013 classification criteria for Systemic Sclerosis were included in this study. Patients withOverlap syndrome, MCTD, UCTD, children and pregnant women were excluded. Poomoghim criteria was used for diagnosis of Systemic Sclerosis sine scleroderma.Absent skin
AMINAPHTONE INCREASES SKIN BLOOD PERFUSION AND IMPROVES CLINICAL SYMPTOMS IN PATIENTS WITH RAYNAUD’S PHENOMENON INDEPENDENTLY FROM DIFFERENT TREATMENT BACKGROUNDS

B. Ruaro, C. Pizzorni, E. Gotelli, J. Alsheyyab, E. Alessandri, A. Sulli, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy

Background: Aminaphtone is a vasoactive drug that was recently demonstrated to improve both peripheral blood perfusion (BP) and clinical symptoms of Raynaud’s phenomenon (RP) in patients with either primary or secondary RP to systemic sclerosis (SSc).1–2

Objectives: The aim of this study was to evaluate possible interferences of different treatment backgrounds on both skin BP and RP-related clinical symptoms in patients treated with aminaphtone, during a six-month follow-up.

Methods: Forty-six patients with active RP were enrolled during routine clinical assessment after informed consent (11 primary RP, mean age 49±19 SD years, mean RP duration 6±3 years; and 35 secondary RP to systemic sclerosis, mean age 61±17 years, mean RP duration 11±9 years). Aminaphtone was orally administered 75 mg twice daily in addition to current treatments, and all patients were on a stable drug regimen for at least two months, which remained unmodified during the follow-up. All patients were taking cardioaspirin. Six groups of treatment backgrounds were identified: 1) no further treatments (12 patients); 2) hydroxychloroquine (2 patients); 3) colchicine (5 patients); 4) methotrexate (3 patients); 5) cyclosporine A (6 patients); 6) mycophenolate (6 patients); 7) proton-pomp inhibitors (12 patients). Blood perfusion was measured by Laser Speckle Contrast Analysis (LASCA)3 at the level of fingertip, periangual areas, dorsum and palm of hands, and face at baseline (T0), after one (T1), four (T4), twelve (T12) and twenty-four (T24) weeks of treatment. Raynaud’s condition score (RCS) and both frequency and duration of Raynaud’s attacks were assessed at the same time. Statistical analysis was performed by non-parametric tests.

Results: During aminaphtone treatment, a progressive statistically significant increase of blood perfusion, as well as an improvement of RP clinical symptoms (decrease of RCS, frequency and duration of RP attacks/day), were observed in all above reported seven groups of RP patients with different treatments backgrounds from T0 to T12 in all skin areas (p<0.01). There were no statistically significant difference between the seven groups of patients concerning skin BP at different times (p>0.60). The results were similar in both primary and secondary (SSc) RP patients (p=0.40). Aminaphtone administration had to be stopped in 2 patients due to headache, and one patient was lost during follow-up.

Conclusions: This study demonstrates that the increase of skin blood perfusion and the improvement of RP clinical symptoms is not influenced by different treatment backgrounds in RP patients treated with aminaphtone. These preliminary results should be further confirmed by a randomised blind clinical trial.

IMPROVEMENT OF DERMAL THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH ENDOTHELIN RECEPTOR ANTAGONIST: LONG TERM STUDY BY HIGH FREQUENCY ULTRASOUND

B. Ruaro1, A. Sulli1, C. Pizzorni1, M. Ghio1, V. Smith2, V. Tomatis1, M. Cutolo1.
1Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium

Background: Systemic sclerosis (SSc) is a connective tissue disorder characterised by skin involvement, which may be evaluated by both modified Rodnan skin score (mRSS) and skin high frequency ultrasound (US).1–6 Endothelin-1 (ET-1) seems implicated in the development of dermal fibrosis in SSc.5 Bosentan, a dual ET-1 receptor antagonist seems effective in reducing skin fibrosis in SSc patients.6,7

Objectives: The aim of this study was to evaluate by US the long-term effects of bosentan on dermal thickness (DT) in SSc patients, in combination with long-term cyclic intravenous iloprost versus iloprost monotherapy.

Methods: Thirty-eight SSc patients were enrolled during their standard treatment for digital ischaemia. At baseline (T0), 19 patients already receiving bosentan, during a six-month follow-up.

Conclusions: The most common pattern of Systemic Sclerosis sine scleroderma observed in our cohort was Oesophageal dysfunction (78%) followed by lung involvement in the form of interstitial lung disease (52.1%) and pulmonary hypertension (47.8%). Renal involvement was not observed in any of the patients. Most common autoantibody detected among patients with Systemic Sclerosis sine scleroderma was anti-centromere antibody (78.2%) followed by anti-scl70 antibody (21.8%). Nine patients (39.1%) received pulse cyclophosphamide therapy and 3 patients received rituximab therapy in view of interstitial lung disease.

Abstract AB0736 – Figure 1

Conclusions: The most common pattern of Systemic Sclerosis sine scleroderma observed in our cohort was Oesophageal dysfunction + Raynauds Phenomenon + Anti-centromere antibody positivity + Interstitial lung disease with or without pulmonary hypertension which are usually the characteristics of limited cutaneous type of Systemic Sclerosis. Hence Systemic Sclerosis sine scleroderma could be a subset of limited cutaneous type without the phenotypic skin involvement.

Disclosure of Interest: None declared
months), continued the treatment for further 4 years (T4) (ILO group). Other 19 patients, although they continued the same cyclic intravenous iloprost treatment as before (BP group), received bosentan 125 mg twice a day for 4 years (ILO + BOS group), due to digital ulcers. DT was yearly evaluated by both US (18 MHz probe, MyLab 25, ESAOTE, Italy) and mRSS at the level of the usual seven skin areas (zygoma, fingers, dorsum of hands, forearms, upper arms, chest, abdomen, thighs, legs, and feet). Non-parametric tests were used for the statistical analysis.

Results: A statistically significant decrease of DT, measured by US, was observed in the ILO+BOS group from T0 (median DT 1.135 mm) to T4 (median DT 1.088 mm) (p=0.01). No statistical significant variation of mRSS was observed during the follow-up in this group of patients (median mRSS at T0 12.5±1 at T4 11.5±1, p=0.70). Conversely, in ILO group, a statistically significant increase of DT was observed after four years, as measured by US (median DT at T0 1.070 and at T4 1.258, p=0.0001), as assessed by mRSS (median mRSS at T0 4.5±1 and at T4 8.5±1, p=0.0001). Temporal increase of transaminases was managed by temporary bosentan discontinuation.

Conclusions: In this open study, the long-term treatment with ET-1 receptor antagonist in combination with iloprost seems to be associated with a decrease of DT in SSc patients, in contrast to the treatment with iloprost alone. DT evaluated by US over long term seems to be more susceptible to change than by mRSS.

LONGITUDINAL ASSESSMENT OF NAILFOLD CAPILLARY NUMBER, PERIPHERAL BLOOD PERFUSION AND DERMAL THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS OVER A PERIOD OF 5 YEARS
B. Ruaoro1, A. Sulli1, C. Pizzorni1, V. Smith2, E. Gotelli3, J. Alshayyab4, A. C. Trombetta1, M. Cutolo1.1 Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; 2Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium.

Background: Several studies demonstrated the relationship between blood perfusion (BP), dermal thickness (DT) and nailfold microangiopathy (“Early”, “Active” and “Late”) videocapillaroscopic patterns) in patients with systemic sclerosis (SSc).1,3,5

Objectives: The aim of this study was to evaluate the changes of BP and DT, during a follow-up of 5 years, in SSc patients with persistent “Late” NVC pattern at baseline, as well as to confirm the correlations among microvascular damage extent, absolute nailfold capillary number (CN), BP and DT, during the follow-up.

Methods: Twenty-three female patients affected by SSc according to the LeRoy criteria2 (mean age 63±4 SD years, mean disease duration 6±4 SD years) during the follow-up. The most advanced “Late” NVC pattern of microangiopathy at baseline (T0), were enrolled and followed for five years (T5), after informed consent. Laser speckle contrast analysis (LASCA), skin high frequency ultrasound (US), modified Rodnan skin score (mRSS), and nailfold videocapillaroscopy (NVC) were yearly performed. Blood perfusion (BP), assessed by LASCA at the level of fingertips, palmar areas, dorsum and palm of both hands, was calculated as perfusion units (PU).5,3 Dermal thickness (DT) was assessed by both US and mRSS in the same above reported areas.5 The microangiopathy evolution score (MES) and the CN per linear millimetre at first distal row were evaluated by NVC.5,3 Patients were receiving a wide range of drugs, including vasodilators, immunosuppressive agents and endothelin receptor antagonists. Statistical analysis was performed by non-parametric tests.

Results: A progressive statistically significant decrease of both BP (p<0.0001) and nailfold CN (p<0.0001) values was observed from T0 to T5 at the level of all areas, as well as a progressive statistically significant increase of DT (p<0.0001), mRSS (p<0.0001) and MES (p<0.01) values. The progressive decrease of BP positively correlated over time with the worsening of nailfold CN (p=0.03, r=0.62), MES (p=0.05, r=0.62), mRSS (p=0.002, r=0.72) and DT (p=0.002, r=0.64).

Conclusions: Microvascular damage with progressive reduction of nailfold capillary number was found, in a five-year follow-up, associated with progressive functional microvascular damage and DT worsening in the present cohort of SSc patients showing a persistent “Late” NVC pattern.

AB0740
EVALUATION OF HAND DERMAL THICKNESS AND PERIPHERAL BLOOD PERFUSION IN SYSTEMIC SCLEROSIS PATIENTS

B. Ruaoro1, A. Sulli1, T. Santiago2,3, J.A. Pereira da Silva2,3, C. Pizzorni1, V. Tomatis1, M. Cutolo1.1 Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; 2Rheumatology Department, Centro Hospitalar e Universitário de Coimbra; 3Faculty of Medicine, University of Coimbra, Coimbra, Portugal.

Background: Systemic sclerosis (SSc) is characterised by progressive skin involvement. The modified Rodnan Skin Score (mRSS) is the gold standard to assess skin damage, but it has significant limitations. Recently, several studies demonstrated the utility of skin high frequency ultrasound (US) as an alternative.

Objectives: The aim of this study was to identify possible correlations between peripheral blood perfusion (BP) and ultrasound dermal thickness (US-DT) at level of hand and finger in SSc patients.

Methods: Sixty-seven patients, satisfying the 2013 ACR/EULAR SSc criteria (mean age 64±9 SD years, mean disease duration 6±4 SD years) were enrolled. BP was measured as perfusion units (PU) by laser speckle contrast analysis (LASCA) at the level of dorsal region of hands. In a second time, different regions of interest (ROIs) were created at level of dorsal of the middle phalax of 3rd fin- ger and dorsum of hand bilaterally and the average BP was scored as perfusion units (PU), as previously reported.1,2 Both skin high frequency US and mRSS were used to evaluate DT at the above mentioned skin sites. The same examinations were performed in 65 healthy subjects.

Results: BP was negatively correlated with both US-DT (p=0.0005) and mRSS (p=0.007) in SSc patients at the finger sites, but not at the level of dorsum of the hands. In healthy subjects, there was no statistically significant correlation between BP and DT as evaluated by both US and mRSS at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects (p<0.0001). No statistically significant difference in BP values was observed between SSc and healthy subjects at the dorsum of hands.

Conclusions: This study demonstrates a negative correlation between BP, as evaluated by LASCA and DT, as evaluated by both US and mRSS, in the 3rd fin- ger of SSc patients. Additionally, the results confirm a reduced finger BP in SSc patients when compared to healthy subjects.

AB0741
T-REG AND TH17 LEVELS IN PATIENTS WITH SYSTEMIC SCLERODERMA
D. Üsküdar Cansu1, H. Üsküdar Tekeli2, C. Korkmaz3.1 Internal Medicine, Rheumatology, 2 Internal Medicine, Hematology, Eskişehir Osmangazi University, Eskişehir, Turkey.

Background: Regulatory T-cells (T-reg) may play an inhibitory role in the development of autoimmune diseases (AID) by suppressing the immune response to autoreactive T impaired or decreased T-reg and/or increased Th17 cells may be responsible for the development of AID. However, studies about the association of T-reg and systemic scleroderma (SSc) are limited and conflicting.

Objectives: Our aim is to determine whether there is a relationship between T-reg and Th17 levels and disease activation in patients with SSc.
Methods: 17 patients with SSc who met 2013 ACR/EULAR SSc criteria were included in the study. Clinical and laboratory parameters, Rodnan skin scores, Valentinelli disease activity index, were evaluated in current and previous recent hand X-rays, blood T-regs (CD4+CD25+, CD4+FOXp3+T reg, CD4+CD25+FOXp3+T reg) and Th17 (IL-17-producing T cells) were studied. Age and sex matched 11 subjects were included as healthy control (HC) in this study.

Results: Fifteen of seventeen patients were female, median age was 52.8±9.36 years, median disease duration was 5.41±4.51 years. While skin involvement and Raynaud’s phenomenon were determined in all of the patients, esophageal involvement was determined in 13 of the patients (76.5%), digital ulcer in 2 patients (11.7%), and lung involvement in 14 (94.1%) patients. Median ESR level was 31.29±12.7 mm/hour, median CRP level was 0.57±0.474 mg/dl, median Valentinelli disease activity index was 3.23±1.53. The medications of the patients during the follow up period were as: nifedipine n=15 (88.2%), hydroxychloroquine n=14 (82.4%), corticosteroids n=14 (82.4%), azathioprine n=10 (58.6%), mycophenolate mofetil n=1 (5.9%), cyclosporine n=7 (41.2%). In comparison of SSc and HC, all the T-reg cell levels were significantly higher in SSc group than HC (p<0.001, p<0.0001 and p<0.0001, respectively). Although the levels of CD4+ CD25+ T cells in SSc group were high compared to HC, it was not significant (p=0.100). A positive correlation between CD4+IL-17-cell and CRP (r=0.613, p=0.009), a negative correlation between CD4+CD25-T reg cell levels and dosage of corticosteroid (r=0.513, p=0.035), a negative correlation between CD4+CD25+T reg cell levels and platelet levels (r=0.560, p=0.019) and a negative correlation between CD4+CD25+FOXp3+T reg cell levels and platelet levels (r=0.500, p=0.041) were determined.

Conclusions: In a cross-sectional study, it is rather difficult to explain the meaningful increased T-reg cell in SSc patients. These results may be due to modification of the cells by immunosuppressive treatment. It might be more meaningful to evaluate T-reg cell before and after the treatment.

AB0744 A “LOST-TO-FOLLOW-UP” AUTOANTIBODY FOR THE DIAGNOSIS OF AUTOIMMUNE DISEASE: PREVALENCE AND CLINICAL CHARACTERISTICS OF ANTI-NOR90/ HUFB POSITIVE PATIENTS

C. Koutsianas1, K. Levasseur2, M. Rutter1, C. Webber2, M. Boyce2, K. Douglas1, Department of Rheumatology, The Dudley Group NHS Foundation Trust, Dudley; 2Department of Rheumatology, Worcestershire Acute Hospitals NHS Trust, Worcester; 3Department of Immunology, The Dudley Group NHS Foundation Trust, Dudley, UK

Background: Anti-nuclear antibody (ANA) patterns in indirect immunofluorescence testing (IFT) have been valuable in the diagnosis of autoimmune diseases. A pattern of speckling with fluorescent mitotic dots is considered to represent autoantibodies against nucleolar organising regions (NORs). Anti-NOR90 antibody targets the human upstream binding factor (hUBF) which activates RNA polymerase I-activated ribosomal RNA transcription. They have been anecdotally associated with systemic sclerosis (SSc), Sjögren syndrome (pSS) and rheumatoid arthritis (RA).

Objectives: To analyse the prevalence and clinical characteristics of patients found to be anti-NOR90 positive by immunology at The Dudley Group NHS FT (DGH) which also serves Worcestershire Acute Hospitals NHS Trust (WAH).

Methods: Clinical letters and electronic patient records of anti-NOR90 positive patients identified in the DGH immunology laboratory between July 2016 and October 2017 were reviewed. Advice was sought regarding ethical approval and consent; this was deemed unnecessary for this clinical survey. Anonymized patient data was collected on Excel. Anti-NOR90 was tested for when the characteristic ANA pattern was observed and as part of an extended SSc blot (profile- LINE SSc (Nucleoli) profile (IgG) – EUROMMUN).

Results: We identified 11 anti-NOR90 positive patients among 8000 positive ANA results (estimated prevalence 0.013%). Patient demographics, diagnoses and immunity are illustrated in Table 1. Patients were in their vast majority female (10/11, 91%) and had a median age of 63 (IQR:53–74) years. The median anti-NOR90 titre was 111 (IQR:14–139) units. Six (54.5%) had a confirmed diagnosis of rheumatoid arthritis. The most common clinical features were Raynaud’s phenomenon (83.6%), sicca symptomology (36.4%) and polyarthri- tis (36.4%).Interstitial lung disease (ILD) and oesophageal dysmotility (OD) were predominant clinical features in two cases (SSc, pSS). In general, patients lacked skin involvement (scleroderma, telangectasias, calcinosis).

Conclusions: Literature regarding anti-NOR90 auto-antibodies has been scarce and in the age of automated IIFT ANA testing, it is plausible that their specific nucleolar pattern is frequently missed. In our survey, they were observed in the context of several rheumatic diseases and linked to Raynaud’s, sicca symptoms and polyarthri- tis. Studies in larger relevant patient cohorts are needed to further clarify their clinical value.

AB0745 MECHANICS OF EARLY VENTRICULAR IMPAIRMENT IN SYSTEMIC SCLEROSIS AND THE EFFECTS OF PERIPHERAL VASCULOPATHY

C. Trouttel1, V.-K. Bournia1, S. Panopoulos2, A. Goumiakakizis2, D. Beldemos2, M. G. Tektonidou1, A.D. Protopopou1, P.P. Stikakis1, 1First Department of Propaedeutic and Internal Medicine/Joint Rheumatology Program, “Laikon” Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens; 2Cardiology Department, Tzanio Hospital, Piraeus, Greece

Background: Multiple mechanisms commonly lead to severe cardiac involvement in systemic sclerosis (SSc), an autoimmune disease characterised by microvascular lesions, systemic inflammation and fibrosis.

Objectives: To examine the mechanisms of right and left ventricles (RV, LV) at the early stage of possible impairment and test the hypothesis that peripheral arterial hemodynamics are associated with early LV compromise.

Methods: Ninety-five asymptomatic SSc patients free of cardiovascular disease (88% women, 53±14 years) and 54 apparently healthy controls matched for age, gender, arterial hypertension, dyslipidaemia, and diabetes mellitus underwent echocardiography, including multilayer speckle-tracking, and tonometry-based pulse wave analysis of the peripheral arteries; 68 SSc patients were prospectively assessed after 32±7 months. Indices of ventricular and arterial structure and function, as well as LV-arterial coupling, were calculated.

Results: At baseline, patients presented RV diastolic/systolic impairment, as well as LV remodelling and diastolic/systolic impairment in terms of reduced deformation parameters versus controls. No association was evident between RV and LV strain within individual patients, whereas by multivariate analysis including age, gender, and SSc characteristics we found that the global longitudinal strain of RV free wall was associated only with the presence of diffuse skin involvement (b=−2.63, p=0.042) and both global longitudinal and circumferential strain of LV were correlated only with disease duration (b=0.14, p=0.001 and b=0.17, p=0.032, respectively). Both RV and LV abnormalities progressed independently during follow-up. Moreover, in the absence of differences in aortic stiffening and LV-arterial coupling between patients and controls, arterial pressure wave reflections assessing small vessel function and/or microcirculation were abnormal in SSc patients and strongly correlated with impaired indices of LV diastolic function and remodelling.

Conclusions: These novel findings show the mechanics of RV early impairment in SSc that develops and progresses independently from the concomitant LV impairment, which, in turn, may be influenced by peripheral microvascular abnormalities in the absence of macrovascular damage.

AB0746 FREQUENCY AND CLINICAL ASSOCIATION OF RARE ANTIBODIES IN A LARGE CONNECTIVE TISSUE DISEASE COHORT

C. Campochiaro, C. Clark, L. Host, A. Sari, S. Nihayanova, C. Fonseca, C. Denton, V. Olgi, Centre for Rheumatology and Connective Tissue Diseases, The Royal Free Hospital, London, UK

Background: Connective tissue diseases (CTDs) are characterised by the presence of specific antibodies (Abs). These are useful in diagnosis and prognostic stratification. Rare Abs have been reported, but their clinical significance is currently not clear.

Objectives: To assess the diagnosis, and frequency of clinical features within each rare antibody subgroup in our CTD cohort

Methods: The immunology results for 5828 patients obtained over the past 17 years and patients positive for 1 of the rare Abs (Jo-1, PONAXR, PL-4, PL-7, PL-12, SRP, Ku, Mi-2, EJ, SL, PMSc, RNP, Th/Tu, NoMa-1, Os1) and hrRNPL were identified. Diagnosis and frequency of major organ involvement were reported.

Results: 758 patients (12.5%) were positive for at least 1 rare Abs. Clinical information confirming a diagnosis of a CTD was available for 514 patients. The most frequent rare Ab in our cohort was PMSc (3.1%). The majority of patients had clinical features of overlap syndromes (33.8%), the 2nd most common diagnosis was systemic sclerosis (SSc) (31.1%). Interstitial lung disease (ILD) was more commonly seen in patients with PL-7+ (82.4%), PL-12+ (75%), Jo-1+ (70.8%) and SRP+ (66.7%).ILD was not reported in PCNA+ or PL+ and hrRNPL+.

Pulmonary arterial hypertension (PAH) was most frequently seen in patients with XRF (31.8%). Inflammatory myositis (IM) was found in all Jo+ and SRP+ patients, and in the majority of PL-7+ (88.2%) patients. Inflammatory arthritis was commonly reported in patients with PCNA+ (57.1%), NoMa-1+ (50.0%) and rRNPL+ (40%). Renal involvement was classified as either glomerulonephritis (GNM) or sclero- derma renal crisis (SRC). GMM was more common in patients with rRNPL+ (60%), PL-4+ (45.4%) and PCNA+ (42.9%) patients. SRC was diagnosed in patients with SLE (3.2%), PMSc (5.5%) and Th/Tu+ (2.5%) (table 1).

**CALPROTECTIN LEVELS IN SYSTEMIC SCLEROSIS ASSOCIATED WITH INCREASED FAECAL GLYCOXIDATION PRODUCTS.**

**C. Caimmi**1, E. Bertoldo1, A. Venturini1, P. Caramaschi1, L. Fruillon2, R. Ciccioppo2, S. Brunelli2, L. Idolazzi1, D. Gatti1, O. Vapiana1, M. Rossini1, V. De Martino1, D. Gatti1, D. Sassi1, A. Pizziccolo1, P. Carascia1, L. Fruillon2, R. Ciccioppo2, S. Brunelli2, L. Idolazzi1, D. Gatti1, O. Vapiana1, M. Rossini1.

**Background:** Systemic sclerosis (SSc) is characterized by a complex pathogenic network that includes aberrations in the gut microbiota, which has been related to the disease activity in SSc. Faecal calprotectin (FC) is a method to evaluate gut inflammation and could be used as a marker of gut dysbiosis.

**Objectives:** To assess FC in a large cohort of SSc patients and to evaluate associations with clinical features.

**Methods:** A cross-sectional study was performed in 1928 SSc patients (53.7 ± 14.7 years, p = 0.027). Regarding subtypes, PAI was significantly more frequent in limited cutaneous SSc (48%, p = 0.004) and pre-SSc (47%, p < 0.001). To this end, Sjögren’s syndrome was by far the most common association (55%), followed by global autoimmune thyroid disorders (31%), autoimmune liver disorders (17%), and mixed connective tissue disease (12%). Clinical features are shown on table 1.

**Results:** Median levels of FC were 80 µg/g (157 µg/g). FC affected 35 patients (27.1%). The analysis was performed in the 110 cases with FC levels < 275 µg/g, in order to correct for a possible dysbiosis in triggering a pathologic immune response leading to ILD. It may also be that increased FC simply reflects a more severe disease but this still doesn’t explain why only ILD was found to be linked with FC. Is it because lung is a filter of molecule (i.e. antigens, cytokines, metabolites, etc.) produced in the gut? Further studies with longitudinal evaluation are warranted.

**Abstract AB0747**

**INTERSTITIAL LUNG DISEASE IS INDEPENDENTLY ASSOCIATED WITH INCREASED FAECAL CALPROTECTIN LEVELS IN SYSTEMIC SCLEROSIS**

**C. Caimmi**1, E. Bertoldo1, A. Venturini1, P. Caramaschi1, L. Fruillon2, R. Ciccioppo2, S. Brunelli2, L. Idolazzi1, D. Gatti1, O. Vapiana1, M. Rossini1.

**Background:** Interstitial lung disease (ILD) is one of the leading cause of death in systemic sclerosis (SSc).

**Objectives:** The aim of this paper was to evaluate the relationship between faecal calprotectin (FC) and ILD.

**Methods:** 129 outpatients with SSc were enrolled. Data about disease characteristics, in particular lung involvement, were collected and FC was measured.

**Results:** Eighty-seven patients (67.4%) had a limited subset with a mean disease duration of 13.3 (7.1) years. Anti-Scl70 antibodies were found in 35 (27.1%) patients. GI tract involvement was severe/end stage in 3 cases (2.4%). ILD affected 35 patients (27.1%). Median levels of FC were 80 µg/g (157 µg/g). FC was found to be higher in patients with a moderate/severe/end stage score for gastrointestinal tract (p = 0.046) and on steroids (p = 0.015). In addition, it positively correlated with age (p = 0.001).

**Conclusions:** Our data from a large CTD cohort suggest that rare Abs associate with distinct features in particular ILD and inflammatory myositis. A majority of these patients fulfill the criteria for overlap syndrome and SSC.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5842
Conclusions: PAI in SSc is a frequent condition that special attention in these patients. We found a rather higher prevalence compared with those published in the literature, even though the distribution of those associated disorders was similar. In our cohort, there were no remarkable differences between both groups concerning clinical manifestations (although not always statistically significant). Finally, certain circumstances should make us aware of a possible associated condition to SSc.

AB0749 DON’T FORGET THE CAREGIVERS OF PATIENTS WITH SYSTEMIC SCLEROSIS
M. Boonstra1, D.F. Stoop1, T.W. Huizinga1, T.P. Vliet Vlieland2, J.K. de Vries-Bouwstra1.
1Department of Rheumatology, 2Department of Orthopedics, Leiden University Medical Center, Leiden, Netherlands

Background: Systemic sclerosis (SSc) is a disease with considerable physical and psychosocial impact. Previous studies among partners of patients with other chronic diseases, such as Parkinson’s and stroke, showed that 6%–25% of caregivers experience high levels of stress related to caregiving. To our knowledge, the burden experienced by caregivers of patients with SSc has not been determined so far.

Objectives: To evaluate perceived strain, quality of life and health care needs among SSc caregivers.

Methods: During a patient information meeting, companions of SSc patients were invited to complete 3 questionnaires: 1. The Caregiver Strain Index questionnaire (CSI), in which a score >7 indicates high care burden, 2. Short Form-36 (SF-36): a measure of self-reported Quality of Life (QoL) and 3. a self-designed questionnaire on the needs and preferences for caregiving support. Caregivers with and without high care burden were compared regarding their general characteristics and Qol.

Results: Thirty-six SSc caregiver filled out questionnaires (n=31 completed the CSI questionnaire). Respondents were mostly women (64%), on average 62 years old (SD 14), 35% (n=11) had a paid job, and 50% (n=18) suffered from chronic disease. The majority was in a spousal relationship (75%) with the SSc patient and 56% of patients had been diagnosed with SSc more than 5 years ago. Nineteen percent of patients (n=7) needed daily personal caregiving and 25% (n=9) was transport-dependent. Median CSI was 2 (range 0 to 5), and 6/31 (19%) perceived high care burden (CSI >7). Caregivers with high care burden were significantly more often involved in daily personal caregiving of the patients (3/6 vs. 2/25). Although not statistically significant, all caregivers perceiving a high burden were spouses, while the remaining caregivers had varying relationships with SSc patients. SF-36 summary scale scores were similar in both groups (table 1).

AB0750 RHEUMATIC DISEASES WITH LUNG INVOLVEMENT AND PSYCHOLOGICAL STATUS
D. Abduljaniev, N. Shamсудdиноva, G. Nurulina, E. Kирilloва, E. Макарицева, A. Краснов, A. Суриков. Kazan State Medical University, Kazan, Russian Federation

Objectives: assess the impact of psychological status indicators on lung function in patients with rheumatic diseases with lung lesions

Methods: A study of 30 patients with diagnoses of systemic scleroderma (SSD) – 14 patients, systemic vasculitis (VB) – 10, rheumatoid arthritis (RA) – 6 patients. The average age of the patients was 56.5±10.59 (from 22 to 77 years). All patients had high activity of the underlying disease and received pathogenetic therapy in the form of pulse therapy for HA – 19 patients, high doses of HA (1 mg/kg) per os – 11 patients; were hospitalised in connexion with the first detected lung lesions or signs of progression of the existing lung injury (increased dyspnea, reduced exercise tolerance). Patients are consulted by a cardiologist to exclude the cardiac genesis of symptoms. All patients underwent a standard clinical examination, in addition they performed: high-resolution RCT of lung (64-slice CT system Philips Diamond Select Brilliance), a 6 min walk test. Evaluation of lung function was carried out using spirometry, bodipletizmography, diffusing “single breath”.

The following scales were used to assess the psychological status: State-Trait Anxiety Inventory (STAI) personal and situational anxiety assessment, symptomatic questionnaire SCL-90-R (English Symptom Check List-90- Revised), anxiety and depression, the Toronto Alexitmic Scale (TAS)

AB0748 RHEUMATIC DISEASES WITH LUNG INVOLVEMENT AND MULTIVARIATE ANALYSIS

Variables Multivariate analysis

Calcinosis 1.62 1.23 p < 0.001
Raynaud’s Phenomenon 2.72 1.87 p < 0.001
Gender 2.72 1.87 p < 0.001
Gastrointestinal involvement 1.32 1.02 p < 0.001
Age at diagnosis 1.01 1.00 p < 0.001

We found no significant differences concerning capillaroscopy patterns, or causes of death, neither SSc-related nor non-SSc-related.

Finally, a multivariate analysis with logistic regression was performed to evaluate the risk factors for PAI, which are shown on the table 2.

Abstract AB0749 – Table 1. Characteristics of caregivers of SSc patients with and without high care burden (CSI >7).

THE EPSTEIN-BARR VIRUS INFECTION IN SYSTEMIC SCLEROSIS

G. Efthymiou, C. Líasikos, E. Marou, E. Dardiots, V. Tismourtou, T. Scheper, W. Meyer, D.P. Boodanog, G. Hadjidjegoüir, L.I. Sakkas, 1Rheumatology and Clinical Immunology, 2Neurology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece, 3Institute of Immunology, EUROMMUN, Lübeck, Germany

Background: Epstein-Barr virus (EBV) infection has been considered trigger of various autoimmune diseases, including systemic sclerosis (SSc), mainly due to studies investigating cross-reactive responses amongst EBV and disease-specific autoantibodies. Metabolic assessment of antibody reactivities to the most immuno- dominant EBV antigens in SSc has not been performed.

Objectives: To assess ab reactivity against EBV viral capsid antigens (VCA), early antigens (EA) and EBNA-1 in SSc, and investigate their clinical relevance.

Methods: Sera from 59 SSC patients, who presented 31 diffuse SSC (dcSSc) and 28 limited SSC (lcSSc), 43 matched multiple sclerosis (MS) as controls and 32 matched healthy controls (HC) were tested for IgG anti-EBV VCA, EA and EBNA-1 by immunoblotting, using EBV whole SDS extract as antigen substrate.

Results: Percentages of EA and EBNA-1 reactivities were significantly higher in SSC patients compared to HC (EA: 33.9% vs. 3.1%, p=0.001; EBNA1: 89.8% vs. 68.8%, p=0.012), but were comparable between SSC and MS. These differences remained when SSC was divided in dcSSc and lcSSc (EA: 32.3% in dcSSc and 35.7% in lcSSc, P dublín vs HC=0.002, P dublín vs HC=0.001, EBNA-1: 92.9% in lcSSc, P dublín vs HC=0.020). VCA positivity was comparable between SSC or its two subgroups and MS or HCs. Also, triple positivity for all three antigen categories was observed more frequently in SSC, dcSSc and lcSSc compared to HCs (32.2% in SSC, 29% in dcSSc and 35.7% in lcSSc vs 3.1% in HC, p=0.001, p=0.004 and p=0.001, respectively). Anti- EA was present more frequently in SSC patients with calcinosis compared to those without (75% vs 27.5%, p=0.014) and tended to be more frequent in patients with pulmonary fibrosis compared to those without (47.8% vs 25%, p=0.071).

Conclusions: Antibodies against EBV appear to be more frequent in SSC than in healthy controls, and equaly prevalent with MS, a disease known to be associated with anti-EBV antibody responses and a known risk factor for MS. Whether an EBV-specific response is also an initiating trigger of SSC remains to be investigated.

AB0751

COMPARATIVE STUDY OF SYSTEMIC SCLEROSIS WITH OTHER AUTOIMMUNE DISEASES FOR HEALTH-RELATED QUALITY OF LIFE

F.H. Pad1, V. Strand2, Y.J. Oh3, H. Kwon4, Y.W. Song1, E.B. Lee5, 1Seoul National University Hospital, Seoul, Korea, Republic of Ireland; 2Stanford University, California, USA; 3Gangnam Sungshin Hospital, Seoul, Korea, Republic of Ireland

Background: Systemic sclerosis (SSc) is a rare autoimmune disease characterized by fibrosis of the skin and multiple internal organ involvement. Previous studies reported a poorer health-related quality of life (HRQoL) in patients with SSc compared to the general population. However, very little is known about HRQoL of SSc as compared to other systemic autoimmune diseases, including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjogren’s syndrome (SJS).

Objectives: To compare the HRQoL of patients with SSc and other systemic autoimmune disease and general population.

Methods: HRQoL was captured by the Korean short form-36 health survey version 2 (SF-36), short form-6D (SF-6D) and level version of EuroQol five-dimensional (EQ-5D) descriptive system (EQ-5D-3L). Between March and July 2017, consecutive patients with SSc, and randomly chosen patients with RA, SLE and SJS were recruited from the outpatient rheumatology clinics of Seoul National University Hospital, and were asked to answer SF-36 and EQ-5D. Disease activity of RA was evaluated by Disease Activity Score 28-ESR (DAS 28-ESR), SLE by Systemic Lupus Erythematosus Disease Activity Index-2k (SLEDAI-2k), and SJS by EULAR Sjögren’s syndrome disease activity index (ESSDAI). For patients with SSc, Korean version of Health Assessment Questionnaire Disability Index (HAQ-DI) and Systemic sclerosis HAQ-DI (SSc HAQ-DI) were also evaluated. Demographic, clinical, laboratory information were obtained through a medical chart review. Data on representative Korean healthy controls were obtained from a study of psychometric properties of the Korean SF-36 v2 for assessing the general population, which was performed on six hundred healthy controls aged 14-80 years.

Results: A total of 480 patients with SSc (n=120), RA (n=120), SLE (n=120) and SJS (n=120) and 600 healthy controls were included. The demographic features of patients were similar to the known features of each rheumatic disease group. Patients with rheumatic diseases had significantly lower SF-36 scores (p<0.001 in all domains), SF-6D scores (p<0.001), EQ-5D-3L index scores and EQ-VAS (p<0.001) than the healthy controls; adjustments for age and sex did not change those results. Patients with SSc showed significantly lower scores in the mental component summary scores compared with patients with RA (age and sex-adjusted scores, 43.0±20.9 vs 48.9±20.9; p<0.001). Specifically, domain of mental health was lower in SSc patients than RA patients (age and sex-adjusted scores, 61.3±1.8 vs 71.7±1.8; p<0.001). Among the physical domains scores, SSc
Background: Raynaud’s phenomenon (RP) is frequently associated with the presence of scleroderma or other connective tissue diseases (CTD). Identify the presence of secondary RP is important to perform an adequate therapeutic management and to achieve the early control of these patients. Nailfold capillaroscopy is safe, economic, and relatively easy to perform and has proven to be useful in identifying patients with secondary RP.

Objectives: To assess a long-term follow-up primary RP patient’s series.

Methods: Retrospective observational study of a wide and unselected series of patients diagnosed as primary RP from a single university hospital from January 2012 to August 2017. Patients were classified as primary RP after the presence of CTD at the onset was excluded.

Conclusions: HRQoL of patients with systemic autoimmune diseases is significantly worse and affects all health domains in comparison to healthy controls. Patients with SSc have poorer HRQoL than patients with other rheumatic diseases. Specifically, SSc patients have more impaired mental health than RA patients, and the perception of an individual’s general health is also poor compared to RA.

SKIN SCORE PROGRESSION AFTER DISCONTINUATION OF MYCOPHENOLATE TREATMENT IN SYSTEMIC SCLEROSIS PATIENTS

F.A. Mendoza1, C.P. Lee Ching1, S.A. Jimenez2. 1Scleroderma Center and Division of Rheumatology; 2Scleroderma Center and Jefferson Institute of Molecular Medicine, THOMAS JEFFERSON UNIVERSITY, Philadelphia, USA

Background: Rapid progressive skin involvement in diffuse Systemic Sclerosis (rp-dcSSc) is associated with higher mortality and internal organ involvement. Treatment with Mycophenolate Mofetil (MMF) has been shown to halt the progression of the disease. However, the optimal duration of therapy is unknown and has not been studied. We follow up a known cohort of rp-dcSSc patients treated with MMF after discontinuation of therapy.

Objectives: To describe the progression of skin involvement in rp-dcSSc patients after discontinuation of MMF.

Methods: Twenty-five previously untreated consecutive patients with recent-onset (<24 mo) rp-dcSSc received MMF as the only disease-modifying therapy. Their Modified Rodnan skin score (mRSS) and Pulmonary function tests were followed after discontinuation of MMF after 2 years of treatment. Patients were followed up every 3–6 months. Therapy was re-initiated if their mRSS increased more than 20% or worsening respiratory symptoms with progression of restrictive lung disease were reported.

Results: Six patients lost follow up after terminating the open label trial with MMF. From the 19 patients followed up after MMF discontinuation, 26.3% required to resume MMF. All these patients required to resume MMF within 6 months after discontinuation. Two of them (10.5%) presented respiratory symptoms associated with restriction pattern at PFTs. Skin score returned to baseline in 80% of the patients after resuming therapy.

Conclusions: Recurrent skin progression occurs in up to 26.3% of patients with rp-dcSSc after discontinuation of 2 years of MMF, requiring longer term immuno-suppression. In this group, all patients presented active skin disease recurrence within 6 months of treatment discontinuation. Ergo, slow decrease of MMF dose over time and very close follow up is recommended in patients with rp-dcSSc discontinuing MMF even after a prolonged period of time. In addition, these findings support the therapeutic effect of MMF in rp-dcSSc.

MDA 5 DERMATOMYOSITIS AND RESPONSE TO RITUXIMAB IN A SMALL COHORT AT OUR INSTITUTION
F. Berlingu, V.J. Maya, B. Wang, MAYO CLINIC, Jacksonville, USA

Background: Treatment for anti-melanoma differentiation-associated gene 5 antibody (MDA 5) Dermatomyositis is posing challenging to clinician and there is currently no consensus on therapy. The MDA5 was recently classified as a myositis-specific antibody (MSA) and has been associated with rapidly progressive interstitial lung disease (ILD), amyopathic dermatomyositis (aDM), mechanic’s hands, ulcers, inflammatory arthritis, and increased mortality.

Objectives: This study sought to characterised response to Rituximab in a small cohort of patients with MDA 5 DM at our institution.

Methods: A retrospective chart review was done to identify all MDA5 positive patients who were evaluated at our centre from 2015 to 2017 with suspected myositis and had myositis-associated autoantibodies tested using a commercial panel (MyoMarker Panel 3). For all patients who were positive for MDA5, we collected clinical information on the presence of myopathy, skin involvement and ILD, data on the autoantibody profile, PFTs and high resolution CT pattern along with therapy response.

Results: 11 were positive for MDA5. 7 were females and 4 were males, with mean age 56.6 years. Eight patients were treated with Rituximab from which seven had ILD at presentation: 4 NSIP, 2 with organising pneumonia, one had UIP and one had fatal acute interstitial pneumonitis 2 months after onset of mechanics’ hands and inflammatory arthritis. Three patients without ILD were treated with other DMARDs. All had responded well to Rituximab with improvement in skin ulceration, inflammatory arthritis and mechanic’s hands and most patients had stable ILD except for one patient with fulminant interstitial pneumonitis for which Cytoxan was added without any additional benefit.

Conclusions: Rituximab is a good management option for all manifestation of MDA 5 DM. Further studies are needed to elucidate the association of MSA and the clinical manifestations and response to treatment response of patients with inflammatory myopathies.

EVALUATION OF NAILFOLD VIDEO CAPILLAROSCOPY IN 296 PATIENTS WITH CONNECTIVE TISSUE DISEASES
G. Kumanyovics, G. Nagy, L. Czirjak. Rheumatology and Immunology, University of Pécs, Medical School, Pécs, Hungary

Background: The influence of the presence of Raynaud’s phenomenon (RP) on microangiopathy is not well characterised in connective tissue diseases (CTDs).

Methods: To characterise capillary density and capillary morphology by nailfold video capillaroscopy (NVC) in different CTDs with a special focus on the presence/absence of Raynaud’s phenomenon (RP) and overlap syndromes.

Results: 296 patients with systemic sclerosis (SSc), systemic lupus erythematosus (SLE), idiopathic inflammatory myopathies (IIM), Sjogren’s syndrome (SS), antiphospholipid syndrome (APS), rheumatoid arthritis (RA), systemic vasculitis and undifferentiated connective tissue disease (UCTD) were investigated by NVC. Control groups consisted of 25 healthy controls (HC) and 22 primary RP (PRP) cases.

Conclusions: The mean capillary density was significantly decreased in SSc, SLE, SS, IIM and APS either compared to HC or PRP cases. Mean microangiopathy evolution score (MES) was higher in SSc, SLE, SS, IIM and APS compared to both HC and PRP cases. SSc, SLE, SS patients had a significantly higher giant capillary number compared to either HC or primary RP control cases. Average haemorrhage score was significantly higher in SSc and SS but not in SLE, RA, IIM and APS compared to HC. Average dilatation point was higher in all investigated CTDs compared to HC. Except RA, all investigated CTDs showed significantly higher capillary loss score compared to either PRP controls or HC. RA cases showed such a difference only compared to HC. Average disorganisation score was significantly higher in all CTDs compared to HC but not compared to PRP cases. Ramification score was significantly elevated in SSc and IIM compared to PRP and HC, but no difference was observed in SLE, SS, APS and RA. The mean capillary density was decreased, and MES was higher in RP associated cases compared to patients without RP in cases with SLE, IIM, and RA. Conversely, the presence of RP did not influence these particular parameters in cases with APS and SS. Except SSc, the impact of overlap features was not remarkable on major capillaroscopic findings. SSc capillary pattern was present in 75.3% of all SSc cases, most commonly SSc late pattern was observed (58.43%). SSc pattern was present in other CTD cases too (15.4%–40.7%). SSc patients with a DLCO<70% had significantly more giant capillaries, avascularity, late SSc pattern, increased MES, and lower capillary density compared to cases with DLCO>70%, but in the other CTDs decreased DLCO was not associated with similar pronounced capillary damage.

Conclusions: Microangiopathy with decreased capillary density and increased MES were present in all CTDs compared to controls. RP caused the most pronounced impairment in SLE, IIM and RA compared to non-RP patients, but had no major effect on SS, and APS. Except SSc, the presence of overlap syndrome did not show a remarkable influence on the microvascular abnormalities compared to pure idiopathic cases. SSc late pattern was most frequently observed in CTDs other than SSc, and it may appear even in patients without RP. Previous associations shown by other authors of decreased DLCO and capillary damage in SSc was confirmed. Capillaroscopy is useful not only in IIM and SSc patients but also in all SLE cases and RP associated SS and RA patients. Capillary density and MES are the most valuable parameters.

AB0757
PERSTANT CRS ELEVATION IS ASSOCIATED WITH HIGH MORBIDITY IN SYSTEMIC SCLEROSIS
A. Mitev, D. Feldmann, A-M. Kanne, T. Hugel, P.M. Voller, R.E. Voll, S. Finzel, P. Kollar, 1Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany; 2Service de Pneumologie, CHUV, Lausanne; 3Rheumatology, Immunology and Allergology, University Hospital Bern Inseelklinik, Beme, Switzerland

Background: Elevated levels of C-reactive protein (CRP) in systemic sclerosis (SSc) have been linked to early inflammatory stages of the disease. Objectives: This study has been set to investigate CRP levels in a longitudinal cohort of SSc patients and to correlate these findings to comorbidities and disease characteristics.

Methods: In this retrospective study patients with SSc were recruited from the outpatient clinic of the Department of Rheumatology and Clinical Immunology, University Medical Centre Freiburg. Only patients with at least three consecutive visits at our centre over at least one year were included in this study. CRP serum levels were measured at every visit and categorised as positive if CRP concentrations were ≥5 mg/L. Subjects with elevated CRP levels at more than 80% of visits were defined as being persistently positive. The longitudinal CRP profile was correlated to comorbidities and disease characteristics.

Results: A total of 1852 consecutive visits of 131 SSc patients were analysed. Over the observed time span (91136–56 months) 19% (n=25) of patients had continuously elevated CRP levels, whereas in 29% (n=38) CRP levels were always in the normal range. There was no association between disease duration and CRP levels at first visit (p>0.5). Persistent CRP elevation was associated (p<0.05) with anti-topoisomerase-I antibodies, diffuse cutaneous SSc (dcSSc), modified Rodnan skin score (mRSS), pulmonary fibrosis, and cardiac arrhythmia, whereas no associations with arthritis or malignancy were found (p>0.1). In a patient with dcSSc and persistently elevated CRP even cyclophosphamide and autologous stem cell transplantation did not alter CRP levels.

Conclusions: Persistently elevated CRP levels characterise a more severe fibrotic phenotype and a higher prevalence of cardiac arrhythmias.

Disclosure of Interest: None declared
Background: Gastrointestinal (GI) symptoms are seen in majority of patients with Systemic Sclerosis (SSc) and are a common presenting feature of disease. Severe GI involvement may lead to malabsorption which represents a poor prognostic factor. Accordingly, a regular monitoring of gastrointestinal tract involvement and nutritional status appears crucial in SSc patients. Previous studies reported low values of bone mass density (BMD) in SSc patients. While no specific relationship has emerged between the two conditions, it’s likely that disease-related GI involvement may contribute to the alterations in BMD.

Objectives: To determine if GI-related clinical status was associated to low bone density in our cohort of SSc patients.

Methods: Two-hundred-and-ten unselected SSc patients have been enrolled. The 7-items UCLA SCTG GIT 2.0 questionnaire and Malnutrition Universal Screening Tool (MUST) were administered to each patient. A comprehensive medical history was collected. A blood panel for nutritional status was also performed. T-scores and Z-scores at lumbar spine, femoral neck, Ward’s and total hip measured by dual-energy X-ray absorptiometry (GE Lunar Prodigy) were measured.

Results: In our cohort, 86.7% of patients reported some GI symptoms. The mean UCLA GIT total score was 0.34±0.50 and 51 patients (24.3%) were at risk of malnutrition according to MUST (score <1). 53.7% patients had BMD values <1, and 12.5% had BMD values <2.5. At the end of the observed periods, patients with reduced BMD (<1) showed similar levels of selected nutritional blood markers compared to subjects with normal BMD, including vitamin D and albumin.

Patients with spine T-score <1 had lower BMI (23.2±3.9 vs 25.2±4.8; p=0.011) and reported higher UCLA GIT reflux (0.68±0.53 vs 0.42±0.48; p=0.016), distension (0.80±0.72 vs 0.53±0.56; p=0.15) and total score (0.42±0.37 vs 0.27±0.30; p=0.006) compared to patients with normal BMD. Similar significant differences were observed in the same domains for patients with total hip T-score values <1. Femoral neck T-score <2.5 was associated with higher UCLA GIT reflux (0.88 ±0.78 vs 0.48±0.50; p=0.022), sooilage (0.50±0.78 vs 0.14±0.52; p=0.041) and total score (0.50±0.37 vs 0.31±0.33; p=0.012).

On the other hand, the comparison of patients with severe, moderate and mild symptoms according to UCLA GIT total score showed an association between progressively lower values of spine and total hip T-score and increasing severity of GI symptoms (ANOVA for spine T-score: p<0.015; for total hip T-score: p=0.048).

Patients at risk of malnutrition (MUST score >1) presented significant lower T-score for all the considered sections (spine and hip) and significant lower total hip Z-score.

Conclusions: In our SSc cohort gastrointestinal symptoms were frequent and were associated with low BMD. Considering the heterogeneity of GI involvement, UCLA SCTG GIT 2.0 emerged as a useful and feasible tool to assess GI involvement and other associated comorbidities. In particular, SSc patients who report remarkable GI symptoms and are at risk of malnutrition according to MUST may benefit from a stricter control of BMD to promptly detect osteopenia and osteoporosis.

the other capillary parameters (capillary ramification, microhemorrhages) between the two groups of patients.

Conclusions: In a limited cohort of MCTD patients with an average disease duration of 6.4 years and a follow-up of three years, the nailfold microangiopathy does not seem to be significantly progressive. Patients with MCTD seem to show less enlarged/giant capillaries, and larger absolute number of total and normal capillaries than SSc patients. Still difficult to identify a defined NVC pattern in MCTD patients.

RELATIONSHIP OF THE SIX MINUTE WALKING TEST AND QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS

G. Cuomo, K. Gjeloshi, F. Masini, F. Danzo, C. Romano, L. E. Adinolfi. UOC Medicina Interna, UNIVERSITA DEGLI STUDI DELLA CAMPANIA, NAPOLI, Italy

Background: The six minute walking test (6MWT) is a standardised measure of submaximal exercise capacity. It is a surrogate measure of heart and lung involvement. There are no studies on relationship between 6MW and quality of life evaluated by Short form 36.

Objectives: To evaluate the relationships between the 6 min walking distance (6MWD) and each items of SF36

Methods: Fifty consecutive SSc patients were investigated. They underwent 6MW and complete the SF-36 (assessed the 8 domains of the questionnaire as well as the physical component score-PCS and mental component score-MCS).

Results: 6MWD ranged from 253 to 582 (median 420); we listed the correlations of 6MWD and only the statistically significant features of SSc and the items of SF36

Age: median 48 (range 20–72); Rho –0.51; p<0.00001
EScSSG Index: median 0.5 (range 0–5); Rho –0.33; p=0.009
HAG-DI: median 0.375 (range 0–2.725); Rho –0.26; p=0.048
mRSS: median 2 (range 0–17); Rho–0.35; p=0.007
Pulmonary hypertension (echocardiography): median 30 (range 13–80); Rho –0.26; p=0.048
SF36: PCS: median 43 (range 20–65); Rho 0.41; p=0.0016
PF: median 75 (Range 0–100); Rho 0.40; p=0.002
GH: median 50 (range 10–92); Rho 0.43; p=0.0007

Conclusions: Our study first demonstrates that 6MWT is correlated to some aspects of quality of life as measured by SF36 in the SSc patients. This results must be considered when assessing 6MWT in Ssc.

COMPARISON OF DISEASE CHARACTERISTICS IN PATIENTS WITH JUVENILE-ONSET AND ADULT-ONSET PROGRESSIVE SYSTEMIC SCLEROSIS

G. Karatemi1, A. Androvic2, S.N. Estatoglu1, S. Sahin1, K. Barut1, G. Haterini2, V. Hamuryudan2, O. Kasapcopur1, E. Seyahi1, 1Rheumatology, Istanbul University of Cerrahpasa Medical Faculty, Istanbul, Turkey

Background: Progressive systemic sclerosis (PSSc) has been known to affect mainly adults of 30–50 years of age. Juvenile–onset has been reported to be rare and studies comparing clinical differences between juvenile-onset and adult-onset form have been limited. These studies were coming from European and North American countries. As would be there would be also effects of ethnic differences, we aimed to clinical differences the two forms of pSSc of paediatric and adult rheumatology centres of a tertiary centre, in Turkey.

Methods: Adult onset patients were defined as those who were registered and followed ‘sclerosis’ at the departments of adult and paediatric rheumatology at Cerrahpasa Medical Faculty, Istanbul, between 2005 and 2017. Only those with at least 2 follow-up visits were included. Patients’s charts were re-evaluated retrospectively.

AB0765 DEVELOPMENT AND ASSESSMENT OF A STRUCTURED TRAINING PROGRAM FOR PATIENTS WITH SYSTEMIC SCLEROSIS

H. Ahrens1, E. Siegert2, M. Kraft1, K. Loewe2, M. Worm1. 1Department of Dermatology, Venerology and Allergology, Charité University Medicine; 2Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany

Background: Structured patient education programs are a key element of patient care in many chronic diseases. They are often based on the Stanford University chronic disease self-management program and aim to empower patients and to improve compliance and coping abilities. However, it is unclear if this is feasible in every condition self-management education programs yield the expected benefit.

Objectives: To develop a structured patient education program for SSc patients and to prove training-specific effects on patients’ quality of life and disability.

Methods: We developed a structured patient education program. The content of the program was created by a team of rheumatologists and dermatologists. The program consists of three modules focusing on general knowledge about the disease, gastrointestinal involvement, digital ulcers (DU), skin and wound care and a patient diary on disease symptoms. Patients were either included in the intervention or in the control group. Disease symptoms and severity as well as clinical parameters were assessed at baseline (intervention and control), at the follow-up visit at month 3 (intervention only) and at the final follow-up visit at month 6. In the intervention group satisfaction with the education program was analysed.

Primary outcome measures were SHAQ, SF-12, BFI, SHAQ-DU. Secondary outcome measures was the satisfaction survey. For comparisons between different times analysis of variance for repeated measures was used. For description of cohorts Mann-Whitney Wilcoxon test was used.

Results: 58 SSc patients were included, 27 received the educational program (intervention group) and 31 patients served as a control group. Both groups were matched regarding demographics and disease subtype. Incidence of DUs was significantly higher in patients from intervention group resulting in a more frequent administration of vasoactive therapies. SHAQ, SF-12, BFI, SHAQ-DU were significantly more common in the juvenile group than in the adult onset group. Whereas joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group while the use of vasodilators was more frequent among adults.

Conclusions: Our results are online with previous reports: juvenile onset patients seem to have a milder form of disease. Major organ involvement as defined interstitial lung disease and pulmonary artery hypertension, and serum ANA positivity were significantly more common in the adult onset group. Whereas joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group while the use of vasodilators was more frequent among adults.

AB0766 INITIAL CHARACTERISATION OF WOMEN WITH BREAST IMPLANTS IN A GROUP OF PATIENTS WITH SYSTEMIC SCLEROSIS REFERRED FOR AUTOLOGOUS HSCT

H. Khoun1, R. Burt2, 1Sainte Justine Hospital, Montreal, Canada; 2Immunotherapy and Autoimmune Diseases, Northwestern University, Chicago, USA

Background: The causal relationship between breast implants (BI) and systemic sclerosis (SSc) is still controversially debated.

Objectives: To add further input to this medical controversy, we studied the initial clinical characteristics of patients with breast implants and systemic sclerosis that are referred to our centre for autologous hematopoietic stem cell transplant.

Methods: From 163 patients, with the diagnosis of systemic sclerosis (SSc), limited SSc, CREST, Morphea or scleroderma sine scleroderma, referred to our centre for autologous hematopoietic stem cell transplantation, 132 were found to be females. To identify those with breast implants (BI) or have a history of breast implants, we performed a systemic chart review for all patients. Once the patients with actual breast implant devices or have history of breast implants were identified, alive patients were contacted to check the type of their breast implants (silicone vs saline), the year of insertion, the local complications, whether they were removed or replaced and the year of removal and replacement, and the type of replacement if applicable. Clinical and biological data were collected for all patients and were compared between those who have breast implants or history if breast implants and those who do not have.

Results: From 132 patients with SSc or SSc variants, thirteen had history of BI (9.8%). In 12, the breast augmentation therapy preceded the development of SSc, with median time between BI insertion and the emergence of initial symptoms of SSc of 12 years (range 7-29). The remaining patient showed acceleration of her disease after BI surgery. Surprisingly, in all 12 patients for whom we could know the type of initial implants, the prostheses were saline. When we compared the clinical characteristics of those with BI and those without. Patients with BI appeared to have higher age (mean 49.95 vs 44.42 years, p=0.012, shorter time from initial symptoms to diagnosis (mean 4.76 vs 12.24 months, p=0.001), more frequently positive ANA (13/13 vs 89/114, p=0.06) and more frequently positive anti RNA polymerase III (7/10 vs 20/78, p=0.004).

Conclusions: Our data may support the hypothesis of a possible association between BI and SSc. Furthermore, these results raise questions regarding the safety of saline breast prosthesis. Finally, our finding may indicate a possible difference in the initial characterization of SSc patients with BI and those without.

AB0767 EFFICACY OF SUBCUTANEOUS TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC SCLEROSIS OVERLAP SYNDROME

H. Wakabayashi1, S. Kino1, M. Hasegawa1, A. Sudo1. 1Orthopaedic Surgery, MIE University Graduate School of Medicine, Tsu; 2Orthopaedic Surgery, Kino Orthopedic Clinic, Nabari, Japan

Background: Systemic sclerosis (SSc) is a connective tissue disease that develops sclerotic changes in the skin and visceral organs. SSc is a disease of uncertain etiology, caused by hyperactivation of fibroblasts, cytokine, cardiac, gastrointestinal, and renal complications contribute to patient morbidity and decreased survival1. And patients present with stiffness of the limbs because of joint and swelling in the skin and periarthritis connective tissue structures. Interleukin-6 (IL-6) is a pleiotropic factor that plays a major role in inflammation; furthermore, IL-6 overexpression and pathogenicity in SSc have been demonstrated2. IL-6 expression is reportedly high in both the skin and serum of SSc patients3, more, IL-6 overexpression and pathogenicity in SSc have been demonstrated2. And patients present with stiffness of the limbs because of joint and swelling in the skin and periarthritis connective tissue structures. Interleukin-6 (IL-6) is a pleiotropic factor that plays a major role in inflammation; furthermore, IL-6 overexpression and pathogenicity in SSc have been demonstrated2.

Methods: Two RA with refractory SSc patients were administered tocilizumab at 162 mg/kg twice a month for 12 months. RA disease activity is evaluated by DAS28-ESR and CDAI. Skin condition of SSc is evaluated by pinching the skin for 10s. Skinfold of SSc are measured by skinfold calipers and digital ulcers, Raynaud phenomenon, arrhythmia/heart failure and gastrointestinal involvement were similar between two groups (table 1). The frequency of interstitial lung disease, pulmonary artery hypertension, and serum ANA positivity were significantly more common in the adult onset group. Whereas joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group while the use of vasodilators was more frequent among adults.

Conclusions: Our results are online with previous reports: juvenile onset patients seem to have a milder form of disease. Major organ involvement as defined interstitial lung disease and pulmonary artery hypertension, and serum ANA positivity were significantly more common in the adult onset group. Whereas joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group while the use of vasodilators was more frequent among adults.

and 25 (49%) paediatric patients had localised scleroderma (p<0.001). We studied the remaining patients (adults: n=137, juvenile: n=28) who had systemic pattern. Male/female ratio, median follow-up duration, familial history of chronic inflammatory diseases and the frequency of sclerodactyly, digital ulcers, Raynaud phenomenon, arrhythmia/heart failure and gastrointestinal involvement were similar between two groups (table 1). The frequency of interstitial lung disease, pulmonary artery hypertension, and serum ANA positivity were significantly more common in the adult onset group. Whereas joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group while the use of vasodilators was more frequent among adults.

Conclusions: Our results are online with previous reports: juvenile onset patients seem to have a milder form of disease. Major organ involvement as defined interstitial lung disease and pulmonary artery hypertension, and serum ANA positivity were significantly more common in the adult onset group. Whereas joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group while the use of vasodilators was more frequent among adults.

Disclosure of Interest: None declared

patient 2. CDASI decreased from 31.8 to 7.4 in 12 months in patient 1 and 34.6 to 10.7 in patient 2. Skin thickness evaluated with the 17 site modified Rodnan skin score improved in patient 1 (from 22 to 2) and patient 2 (from 15 to 8) in 12 months.

Adverse reactions were observed cellulitis in right foot planter at 6 week treatment in patient 2. She did withdrawal tocilizumab for 4 week. After cure cellulitis, she continued tocilizumab treatment.

Conclusions: In the two cases of RA with SSc that we report here, softening of the skin was observed during the treatment with tocilizumab. Tocilizumab may be effective against RA and SSc for which conventional treatment is inadequate.

OSTEOMYELITIS COMPLICATING DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

I. Chiapparino1, F. Locatelli1, P. Orsolini1, R. Caporal1, C. Montecucco1, V. Codol1,11, I.RCCS Policlinico San Matteo Foundation, Pavia, Italy; 12Rheumatology Unit, I.RCCS Policlinico San Matteo Foundation; 13Department of Infectious Diseases; 14Rheumatology Unit, University of Pavia, Pavia, Italy

Background: Skin ulcers are a frequent manifestation of systemic sclerosis (SSc).

Skin ulcers are painful, represent a cause of disability and heavily affect patients’ quality of life. The presence of local infection may be responsible for osteomyelitis (OM) of the underlying bone. If gangrene develops, surgical amputation may be required. At the moment is not clear if there are predisposing factors to osteomyelitis development.

Objectives: To describe a population of SSc patients affected by cutaneous ulcers and osteomyelitis

Methods: We collected data of SSc patients satisfying the 2013 ACR criteria for SSc referring to our outpatient clinic from January 1st 2016 to December 31st 2017. The patient’s data were evaluated on the basis of individual clinical records, including demographic, clinical and serological findings. Cutaneous ulcers were defined as epithelial loss and loss of dermis; post-traumatic skin lesions were excluded. In cases suspected of infection, microbiological investigations were carried out. We have diagnosed OM by clinical, radiological and laboratory means, in particular the presence of pain, swelling, fever, erythema, purulent secretions, blood chemistry alterations and typical radiological characteristics at either plain X ray and/or MRI. Statistical analysis was performed using STATA software for descriptive analysis and groups comparisons. Given the low number of events only univariate analysis was conducted.

Results: A total of 189 patients were enrolled in the study. Of them, 21 (11.1%) were males, mean age was 64.39±12.5 years and median disease duration 11.59 (5.6–19.3) years. A diffuse cutaneous (dcSSc) involvement was present in 50 (26.5%), limited cutaneous (lcSSc) in 131 (69.3%) and a limited disease in 8 patients (ISSc) (4.2%). Digital ulcers (DU) were present in 29 patients (15.3%) and in 5 cases (2.6%) was complicated by the occurrence of OM. The pathogens responsible of the infections were isolated in 3/5 (60%) cases and were represented by: Methicillin-sensitive Staphilococcus Aureus (2 cases) and P. Aeruginosa, also multisensitive. OM affected the third finger of right hand in 2 (40%) patients, the second finger of right hand in 1 (20%) patient and the third finger of left hand in 2 patients (40%). In 2 cases (40%) surgical amputation had to be performed. Patients with OM were significantly younger (54.9±16.07 vs 64.65 ±12.34, p=0.0432) and had higher CRP levels than the rest of the patients (1.27 ±0.59 vs 0.42±0.74, p=0.0061). In patients with DU, the only predictive factor for the development of OM was the total number of ulcers in the single patient (OR 2.27, 1.39–3.71, p<0.001) while no significant influence was found for other demographical or disease specific parameter.

Conclusions: OM is a severe complication of DU in SSc. In most cases the aetiological agents are community-acquired pathogens. SSc patients with OM were younger but did not show any other obvious distinguishing feature. The number of ulcers in the single patients were predictive of OM development. Further and larger studies are needed to address this aspect of the microvascular involvement of SSc.

SCLERODERMA MIMICS IN COHORT FROM AN EUSTAR CENTRE

I.R. Dobretz1, L. Damian1, A. Petcu1, I. Felea2, I. Filipescu2, S.P. Simon1,2, S. Rednic1,1 Rheumatology, Emergency County Hospital, I.Rheumatology, Iuliu Hatageanu University of Medicine and Pharmacy, Cluj Napoca, Romania

Background: The differential diagnosis of systemic sclerosis (SSc) can be sometimes challenging, especially when you have symmetrical skin thickening, Raynaud’s phenomenon (RP) or acroosteolysis. When symptoms and signs are unclear, patients should be referred to a specialist centre for assessment to differentiate between scleroderma and its mimics.

Objectives: Assessing the types of scleroderma mimics presenting in a tertiary care centre and underlining the diagnosis difficulties.

Methods: We evaluated a cohort of 140 patient admitted in our clinic with the suspicion of SSc from January 2007 until December 2017. 130 of them are with SSc and 10 patients with scleroderma mimics. The patients were evaluated for quality and distribution of skin involvement, the presence of systemic complications, the presence of scleroderma specific antibodies and the capillaroscopic pattern. If they haven’t met any criteria for SSc, they underwent further specific investigations.

Results: From the 140 patients evaluated, 10 (7.14%) were with scleroderma mimics. All those 10 patients were admitted in our clinic with the suspicion of SSc. 3 of them had severe RP, one had acroosteolysis and 6 had symmetrical skin thickening. There were 4 males and 6 females. All the patients had no organ involvement (pulmonary arterial hypertension or pulmonary fibrosis), normal capillaroscopic pattern and negative antinuclear antibodies and negativespecific scleroderma antibodies. The patients with RP had no skin sclerosis or other clinical or laboratory changes and the diagnostic was primary RP. The patient with acroosteolysis had no skin sclerosis or RP and after genetic testing a diagnosis of Hajdu-Cheney syndrome was made. The 6 patients with skin thickening had no RP. There were 2 patient with solvent induced scleroderma, 2 with scleroderma adultorum, 1 with scleromixedema, 1 with eosinophilic fasciitis. The 2 patients with solvent induced scleroderma had sclerodactyly and one of them the “prayer sign” and they had a complete resolution of skin sclerosis after eliminating the solvent exposure after a few years of follow up. The 2 patients with sclerodema adultorum had no underlying gammapathy or infections. The patient with eosinophilic fasciitis had extended skin thickening with eosinophila ant typical aspect on MRI, with partial clinical resolution after immunosupression. The patient with scleromixedema had associated hypothyrodisim. The period from first symptoms to diagnosis was variable from months to years.

Conclusions: Even though are rare, scleroderma mimics can be a challenging diagnostic even in tertiary care centre and sometimes diagnostic can be delayed. A correct diagnostic is necessary to avoid unnecessary immunosupression.

18 FDG PET/CT PREDICTS DECLINE IN FUNCTIONAL RESPIRATORY TESTS IN SYSTEMIC SCLEROSIS PATIENTS BUT NOT IN RHEUMATOID ARTHRITIS PATIENTS

I. Jordán1, M. Martínez1, J.L. Laloizaba2, M. Garijo3, J.J. Alegre3, S. Herrero6, I. Chalmeta1, I. González2, R. Negueruelos2, R. Aicardi2, K.R. Arevalo1, I. Canovas1, C. Feced1, J.J. Fragio1, R. González2, E. Grau1, E. Labrador3, I. Martínez3, C. Najera1, J.E. Olfer2, F.M. Ortiz3, E. Vicens1, M. De la Rubia1, D. Hervas1, J.A. Roman1,1 Rheumatology Department, 2Pneumology Department, 3Nuclear Medicine Department, HUP La Fe, Valencia; 4Rheumatology Unit, H Leon; 5Rheumatology Department, H Peso; 6Biostatistical Unit, IIS La Fe, Valencia, Spain

Background: Intestinal lung diseases (ILD) is a frequent complication in connective tissue diseases (CTD) such as rheumatoid arthritis (RA) or systemic sclerosis (SS), but the lung is the only affected organ in the idiopathic pulmonary fibrosis (IPF). Nonspecific interstitial pneumonia (NSIP) is the more frequent form in SS while usual interstitial pneumonia (UIP) predominates in RA patients and in the IPF form. Some studies suggested that 18-FDG-PET/CT could help to detect zones of activity in lung tissue in IPF and this in turn could predict the disease
progress, but results are inconclusive. Moreover, little is known about the value of 18-FDG PET uptake in ILD associated to RA or SS.

Objectives: The purpose of this study is to evaluate the predictive value of 18-FDG PET/CT scan images in functional pulmonary progression of ILD associated to RA or SS.

Methods: We conducted a 12 month prospective observational study on patients diagnosed with ILD associated to SS or RA between January 2015 and May 2017. ILD diagnosis was based on clinical assessment, pulmonary function tests (PFTs) and expert HRCT evaluation. We performed three visits: basal, 6 month and 12 month. On all visits a general exploration, forced vital capacity (FVC) and diffusion capacity of the lungs for carbon monoxide (DLCO) were carried out. On basal and 6 month visit a 18-FDG-PET/TC was performed within a period of three months from the PFTs. Patients continued with their treatment (corticosteroids, DMARDs or immunosuppressants). The nuclear medicine physician identified the maximum and mean standardised uptake value (SUVMax and SUVmean) in the three areas with the most FDG uptake, and adenopathies uptake. PET/CT images were reviewed by 2 combined radiologist/nuclear medicine physicians in consensus.

Results: We included 17 patients, 10 had UIP associated with RA and 7 NSIP related to SS. It appeared that RA patients had longer lung illness evolution and worse FVC than SS patients (table 1), in spite of not having found statistical differences. We detected significant statistical relation between the highest SUVMax and FVC (p=0.009) or DLCO progression (p=0.006) in SS patients, independently of the basal FVC and DLCO, and duration of lung illness in a multivariable linear mixed model. We didn’t find any relation between SUVMax and FVC or DLCO progression in RA patients.

Conclusions: In our cohort of patients with SS, 18 FDG PET/TAC can aid in predicting the progression of ILD associated disease, which does not occur in RA patients.

Disclosure of Interest: None declared

ABNORMAL CAPILLAROSCOPY AND PULMONARY HYPERTENSION IN PATIENTS WITH SYSTEMIC SCLEROSIS

J. Reyes-Rueda1, S.R. Gutierrez-Ureña1, V. Gonzalez-Díaz1, G. Martinez-Bonilla1, K.M. Garcia-Osuna1, D. Cardona-Muller2, E.Q. Cardona-Muñoz2, A. Maclas-Chumacera2, S. Cerpa-Cruz1, R. Rheumatology, Antiguo Hospital Civil “Fray Antonio Alcalde” 2Departamento de investigación de Mecánica Vascular, 3Departamento de investigación de Mecánica Vascular, Centro Universitario de la Salud, Guadalajara, Jalisco, Mexico

Background: Systemic sclerosis (SS) is an autoimmune disease characterised by microvascular damage with clinical manifestations such as Raynaud Phenomenon, digital ulcers, abnormal capillaroscopy and pulmonary hypertension. Systemic sclerosis is a major risk factor for the development of pulmonary arterial hypertension. Positive capillaroscopy has been associated with involvement of pulmonary vasculature.

Objectives: To determine if there is association between abnormal capillaroscopy and pulmonary hypertension in patients with systemic sclerosis.

Methods: Cross-sectional study with a study group of 48 patients with SS according to ACR/EULAR 2013 criteria; we included a control group with Rheumatoid Arthritis and healthy subjects. The peripheral microangiopathy was studied by nailfold capillaroscopy and pulmonary involvement with transthoracic echocardiography. Descriptive statistics with mean and standard deviation were done. We did a chi-square test of homogeneity for groups comparison. Pearson’s test was done for correlation analysis. We used SPSS software for statistics.

Results: 48 patients with SS were included, 24 with RA and 24 subjects. 96% were women mean age 48 ±13.6. More frequent co-morbidities were systemic hypertension 17% in SS vs 25% in RA. The most frequent clinical finding was Raynaud phenomenon in 81% and dysphagia in 67%. 64% of the patients with SS were positive to anti-centromere antibody. Abnormal capillaroscopy was found in 77% of the SS patients with the following patterns: early 42%, active 33% and late 23%, also we found abnormal capillaroscopy in 8% of the AR and healthy controls. We found 6% of pulmonary hypertension in SS 4% was mild and 2% severe. Positive Correlations were Abnormal capillaroscopy and Lung interstitial disease r=0.36 (p=0.009), active pattern r=0.385 (p=0.006), dilated capillaries r=0.457 (p=0.001). The Modified Rodnan score was correlated with: active pattern r=0.525 (p=0.000), dilated capillaries r=0.444 (p=0.001) and avascular areas r=0.495 (p=0.000). We did not find association between abnormal capillaroscopy and pulmonary hypertension r=0.106 (p=0.300).

Conclusions: We found positive association between abnormal capillaroscopy and interstitial lung disease and no correlation with pulmonary hypertension

PROSPECTIVE STUDY OF CARDIOVASCULAR RISK ASSESSMENT IN SYSTEMIC SCLEROSIS

J.J. Gonzalez Martín1, M. Novella-Navañaro, J.L. Cabrera Alarcón2, O. Carrión3, A. Abdelkader1, E. Calvo1, P. Arocibio1, F. Aramburu1, F. García de la Peña1, on behalf of HM Sanchinarro. 1Rheumatology, Hospital HM Universitario Sanchinarro; 2Centro de Biología Molecular Severo Ochoa; 3Angiology and Vascular Surgery, Hospital HM Sanchinarro; 4Angiology and Vascular Surgery, Hospital HM Universitario Sanchinarro; 5Rheumatology; 6Angiology and Vascular Surgery, Hospital HM Universitario Madrid, Madrid, Spain

Objectives: Evaluate evolution of cardiovascular risk (CVR) in a cohort of systemic sclerosis (SSc) in one year of follow-up.

Methods: Prospective longitudinal study of a cohort of 45 patients with SSc during a period of one year. Sociodemographic and analytical variables were analysed at the time of inclusion in the study (baseline) and after 12 months of follow-up. The vascular protocol with carotid ultrasound was performed, including the determination of carotid intima-media thickness (IMT) and the evaluation of atheromatous plaques; in addition to the performance of the ankle-brachial index (ABI) and the determination of endothelial dysfunction (ED) through the measurement of flow-mediated vasodilation (FMVD), all at baseline and at one year.

Results: 45 patients were included, 94% of them female, with a mean age of 52.2 ±11.5 years and mean evolution time of 4.6±5.1 years. The distribution by subgroups was 44.4% limited SSc, 35.5% diffuse SSc, 4.4% pre-scleroderma, 4.4% sine scleroderma SSc, 6.6% MCTD, and 4.4% overlap syndrome. Classical CVR variables were collected as smoking habit, DM, HTN, obesity, DLP, hyperhomocysteinemia, and clinical variables of the SSc were added such as modified Rodnan Skin Score (mRSS), pulmonary arterial hypertension (PAH), interstitial lung disease (ILD), capillaroscopic pattern, SSc specific antibodies and previous treatments. A bivariate analysis was performed using binomial logistic regression, both at baseline and at one year. Pathological IMT (>0.9 mm) was significantly associated with hyperhomocysteinemia (p=0.024, OR=3.03, CI 1.33–9.58). The presence of atheromatous plaque was associated with corticosteroid treatment (p=0.048, OR=5.8, CI 0.28–9.79). Pathological ITB (<0.9) was significantly associated with the 25-OH-vitamin D deficit (p=0.031, OR=0.25, CI 0.06–0.77). ED did not show a statistically significant association with the parameters studied.

To evaluate the effect of time, a binomial model was adjusted by linear regression of mixed effects for the variables of CV affection considered (see table 1). Time proved to be a risk factor to present pathological ITB values, since it was evidenced at baseline in 4.4% of the sample compared to 20% in the one-year study. Consequently, a multivariate analysis was performed showing pathological ABI was significantly associated to time (p<0.001, OR=5.97, CI 59.64–59.75) and mRSS, although with little effect (p<0.001, OR=0.042, IC 0.036–0.047). Time was not a risk factor for the appearance of pathological IMT, ED or plaques.

Disclosure of Interest: None declared

DOI: 10.1136/annrheumdis-2018-eular.6133
Conclusions: In our study, we observed the significant variation in ABI in one year, this may be due to the fact that this measurement has a high sensitivity for the detection of early peripheral arterial disease, in those patients who have not manifest signs and symptoms of arterial disease due to more evolved time of evolution.

**INTERVENTIONS FOR MORPHEA: A COCHRANE SYSTEMATIC REVIEW**

**J V. de Albuquerque**, 1 B.N.G, Andriolo2, M.RA, Vasconcellos3, V.T. Civile2, A. Lydall4, V.FM. Trevisani5, 1 Cochrane Brazil, Centro de Estudos de Saúde Baseada em Evidências e Avaliação Tecnológica em Saúde, 2Universidade Federal de São Paulo, São Paulo, Brazil; 3Cochrane Skin Group, The University of Nottingham, Nottingham, UK

**Background:** Morphea is a chronic inflammatory and fibrosing disorder usually limited to the skin and underlying tissues. It is an immune-mediated disease in which excess synthesis and deposition of collagen in the skin and connective tissues results in hardened cutaneous areas.

**Objectives:** To assess the effectiveness and safety of treatments for individuals with any form of morphea.

**Methods:** We searched the following databases up to March 2017: the Cochrane Skin Specialised Register, CENTRAL, MEDLINE, Embase, LILACS, and five trials registry databases. We checked the reference lists of included studies for further references to relevant randomised controlled trials.

We included randomised controlled trials assessing the effects of topical, intralesional, or systemic medications, and five investigated systemic medications.

**Results:** We included 13 trials, totalling 426 participants. There were both juvenile and adult participants (mostly women). The majority had limited morphea, followed by linear morphea. The studies evaluated heterogenous therapies for morphea, covering a wide range of comparisons. Thus, we could not pool data from the studies in a meta-analysis. Six studies investigated topical medications, two evaluated intralesional medications, and five investigated systemic medications.

Regarding our primary outcome global improvement of disease activity or damage:

- The number of juvenile participants with a significant clinical response was higher with oral methotrexate plus oral prednisone than with placebo plus oral prednisone (RR 2.31, 95% CI 1.20 to 4.45, after the 12 month treatment; NNT 3; low-certainty evidence);
- We are uncertain whether fractional carbon dioxide laser therapy and the combination of acupuncature, hot herbal compress and moxibustion plus Centella triterpenes tablets and vitamin E may reduce this outcome, as the certainty of the evidence was very low;
- We found no differences in the MSS score between the following comparisons (very low-certainty evidence): oral hydroxychloroquine plus topical corticosteroid versus oral methotrexate plus folic acid and topical corticosteroid; and medium-dose ultraviolet A-1 (50 J/cm²) versus low-dose ultraviolet A-1 (20 J/cm²) phototherapy versus narrowband UVB.

We are uncertain regarding adverse effects of interventions as the certainty of the evidence was very low. However, participants reported marked pain and pruritus during fractional carbon dioxide laser therapy, and had mild tanning after ultraviolet A-1 phototherapy.

**Conclusions:** There is a lack of high-certainty evidence for the treatment of morphea, and the effectiveness and safety of the interventions are unclear. Low-certainty evidence supports the effectiveness of oral methotrexate plus oral prednisone for treating juvenile morphea. More studies are necessary to assess the effectiveness and safety of interventions for morphea.

**Acknowledgements:** This abstract is based on a draft and pre-peer review version of a Cochrane Review. Upon completion and approval, the final version is expected to be published in the Cochrane Database of Systematic Reviews (www.cochranelibrary.com).

**Disclosure of Interest:** None declared

**IMPACT OF STANDARDISED EDUCATION PROGRAM ON THE ACCURACY OF MODIFIED RODNAN SKIN SCORING IN PATIENTS WITH SYSTEMIC SCLEROSIS**

**J W. Park1, J-B. Jun2, L. Czirják3, Y. Allanore4, M. Matucci-Cerinic5, E.B. Lee6.**

1 Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine; 2 Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of Ireland; 3 Department of Rheumatology and Immunology of Medical Centre, University of Pécs, Hungary; 4Paris Descartes University and Cochin Hospital, AP-HP, Paris, France; 5Department of Experimental and Clinical Medicine, University of Bologna, Florence, Italy; 6Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of Ireland

**Background:** Modified Rodnan skin score (mRSS) has been used as not only a primary outcome in many clinical trials, but also as an important surrogate marker of disease activity in patients with systemic sclerosis (SSc). Therefore, establishment of well-organised training program of mRSS is essential for the proper management of patients. Recently, Scleroderma Clinical Trials Consortium and the World Scleroderma Foundation published the recommendation for 2-phase mRSS training and emphasised assessing scoring accuracy after the training.

**Objectives:** To investigate the effect of modified Rodnan skin scoring (mRSS) education on improving its accuracy

**Methods:** Ten rheumatologists (6 professors and 4 fellows) received an education program composed of video education and live demonstration by master instructor (Marco Matucci-Cerinic) at (Seoul in June, 2017). Physicians measured mRSS of 8 patients with SSc 1) before the education, 2) after the video education and 3) after live demonstration without any clinical information of the patients. Accuracy of skin scoring was estimated by the difference from the pre-defined gold-standard score measured by master instructor. Change in accuracy of mRSS during the education course was analysed using linear mixed model. Intra-observer reliability of the mRSS and its change was assessed by intraclass correlation coefficient (ICC).

**Results:** The number of SSc patients ever experienced by each physician was significantly higher in the professors than fellows but the number of mRSS ever performed was comparable between the two groups. Median (IQR) skin score
measured by master instructor was 10.5 (9.0). Mean (SD) difference between skin scores by physicians and master instructor was 7.7 (9.5) units. In the univariable analysis, video education significantly reduced the difference from the gold-standard score (1.96, 95% CI –3.83 to –0.10) whereas live demonstration did not show additional enhancement in scoring skill. Effect of education program was significantly different according to the physician’s status and patient’s disease type (diffuse vs. limited). In addition, male patient, shorter disease duration and higher gold-standard skin score was associated with more accurate skin scoring irrespective of the education. In the multivariable analysis where above clinical factors were adjusted, video education also led to significantly accurate skin scoring (table 1). When the educational effect was stratified by individual site of examination, face and distal extremities showed greater enhancement of scoring accuracy whereas difference from gold-standard score in proximal extremities was rather increased. ICC of physician’s skin scores was acceptable over all scoring times (0.63 to 0.88) but was not significantly changed after the education.

Conclusions: The mRSS education program can significantly enhance the accuracy of mRSS, which is mainly achieved by video education.

CHARACTERISTICS OF PATIENTS WITH SCLERODERMA (SSC) TREATED WITH VARIOUS DRUGS IN THE CLINICAL ASSESSMENT AND TGF B AND IL13 CONCENTRATION IN COMPARISON TO THE HEALTHY GROUP

1Department of General and Experimental Pathology, CEPT laboratory, Medical University of Warsaw; 2Department and Polyclinic of Systemic Connective Tissue Diseases; 3Department of Molecular Biology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland

Background: Scleroderma (SSc) is a rare multisystem chronic disease the treatment of which is still challenging. Until now, there is no effective therapy that can modify the overall disease course. However, the main aim of SSc treatment is directed toward managing organs involvement and providing symptomatic relief. Effective drug therapy should inhibit three components of the disease: fibroproliferative, inflammatory, limited, and normal-like. It was shown that various subsets could have different profile of specific cytokines: TGFβ – associated with fibroproliferative and inflammatory type of disease and IL13 – mediator of fibrotic and vascular pathology.

Objectives: The aim of the study was to assess the level of TGFβ and IL-13 in SSc pts with various treatment regimen comparing to healthy control.

Methods: Five patients (71% were women) with SSc diagnosed according to EULAR/ACR 2013 criteria were divided into 5 treatment groups: 1st group – 6 pts treated with methotrexate (MTX), 2–3 pts with mycophenolate mofetil (MMF), 3–5 pts with cyclophosphamide (CYC), 4th group- 7 pts with azathioprine (AZA), 5th group- 22 pts without immunosuppressive treatment. All patients have been treated effective drug therapy should inhibit three components of the disease: tissue fibrosis, vascular abnormalities and autoimmunity. Moreover, potential drug needs to be considered in the context of specific four subsets of the disease: fibroproliferative, inflammatory, limited, and normal-like. It was shown that various subsets could have different profile of specific cytokines: TGFβ – associated with fibroproliferative and inflammatory type of disease and IL13 – mediator of fibrotic and vascular pathology.

Results: In 82% pts positive antinuclear antibodies have been revealed: in 16% positive results for CENPB were obtained and in 44% for Sc170. Capillaroscopy showed in 23% of pts early pattern, in 38% – active pattern, and in 27% – late pattern. 32% of SSc pts had confirmed pulmonary fibrosis, while 90% – Raynaud’s syndrome. The median of mRSS in CENPB (+) pts was 5.4 ± 2.4 in Sc170 (+) pts – 12.7 ± 2.8. Statistically significant differences were found between IL13 and TGFβ levels in patients with immunosuppressants and healthy subjects. There was no correlation between IL13 or TGFβ with lung fibrosis progression or skin involvement.

Abstract AB0775 – Table 1. Comparison of serum level of IL 13 and TGF β in SSc pts

Conclusions: In conclusion, our findings indicate that IL 13 and TGFβ are characteristic cytokines in scleroderma, but these parameters did not correlate with severely progressive course of SSc.

MUSCLE ULTRASONOGRAPHY: A POTENTIAL NEW DIAGNOSTIC TOOL FOR INFLAMMATORY MYOPATHIES

K. Bhansing1, C. Saris2, J. Fransen1, F. van den Hoogen1, A. Verrips2, R. Cooper2, P. van Riel2, B. van Engelen2, S. Pillen2, M. Vork1. 1Rheumatology, Radboud University Medical Center; 2Neurology, Canisius Wilhelmina Hospital, Nijmegen, Netherlands; 3Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK; 4Scientific Institute for Quality of Healthcare, Radboud University Medical Center, Nijmegen; 5Child Development and Exercise Center, University Medical Center Utrecht, Utrecht, Netherlands

Background: Quantitative muscle ultrasound (QUMS) imaging has proven to be a useful, non-invasive technique to visualise normal and pathological skeletal muscle tissue.1 Electromyography (EMG) findings are not always disease specific in patients suspected of dopatic inflammatory myopathies (IIM).

Objectives: To assess diagnostic value of QUMS in patients suspected for an IIM and to compare results with EMG.

Methods: In 57 patients, suspected for IIM, panel diagnosis blinded for QUMS was used as reference standard. QUMS results were used to classify patients according an ultrasound neuromuscular disorder (NMD) algorithm (normal/borderline/abnormal). The predictive value of QUMS and EMG was assessed in a two by two table and a multivariate logistic regression model.

Results: Twenty-two patients (39%) were diagnosed with IIM; 8 polymyositis, 4 dermatomysitis, 4 necrotizing myopathy, 3 inclusion body myositis and 3 non-specific myositis. Sixteen patients were classified with other NMD. We found an increased echointensity of the sternocleidomastoid, biceps, forearm flexor and flexor and biceps anterior in the IIM group. Sensitivity, specificity, positive and negative predicative values (PPV/PPV) were 82%, 51%, 51%, 82% for ultrasound NMD algorithm and 63%, 64%, 75% and 84%, respectively for EMG. Multivariate analyses showed area under the curve (AUC) (0.81) (0.69–0.92) for ultrasound NMD algorithm, EMG (0.79) (0.67–0.92) and ultrasound NMD algorithm plus EMG (0.82) (0.70–0.93).

Predictor | Model A | Model B | Model C
--- | --- | --- | ---
Age ≥ 65 | 2.92 (0.65–13.59) | 2.88 (0.62–13.28) | 2.95 (0.62–14.21)
Serum CK | ≥ 2 x upper limit | 8.76 (1.55–49.55) | 7.35 (1.22–44.21)
Muscle ultrasound Total echointensity of proximal muscles/ measured muscle Total number of affected proximal muscles Distal muscles affected (yes/no) NMD algorithm:

Cox and Snell R Square 0.28 0.26 0.28
Nagelkerke R square 0.38 0.35 0.38
Hosmer Lemeshow Test 0.91 0.94 0.69
AUC (95% CI) 0.81 (0.69–0.79) 0.67 (0.67–0.82) 0.70 (0.92–0.93)
Conclusions: QMUS with NMD algorithm provides a fair diagnostic value for patients suspected for an IIM and is similar to EMG results. A sizeable NPV indicates a lower risk of false negative QMUS results. In addition to the relevant help for the presence for NMD, QMUS could serve as a potential screening tool for clinicians to detect possible myopathies and to rule out the presence of IIM.

AB0777  INFLAMMATORY MYOSITIS ASSOCIATED WITH MYASTHENIA GRAVIS WITH AND WITHOUT THYMIC PATHOLOGY: CASE SERIES AND LITERATURE REVIEW

K. Huang1, M. Meez2, K. Shojania1, K. Chapman1, N. Amir1, N. Dehghan1.
1Rheumatology, 2Neurology, University of British Columbia, Vancouver, Canada

Background: Inflammatory myopathies (IM) and Myasthenia gravis (MG) are two well-recognised and distinctive neuromuscular diseases. The association of myasthenia gravis (MG) and inflammatory myositis (IM) is rare and often only one of the diseases is diagnosed. The coexistence of MG and IM might be associated with thymoma. Even less common is the association of IM (polymyositis or dermatomyositis) and myasthenia gravis in the absence of thymoma.

Objectives: Here, we report a case series of 6 patients with concurrent MG and IM who were followed at the Neuromuscular Disease Unit (NMDU) at a tertiary referral centre in Vancouver, British Columbia. We also conducted literature review on clinical characteristics, diagnostic challenge and management of this condition.

Methods: In this study, we retrospectively examined patients seen at NMDU from 2004 to 2017 who had diagnosis of concurrent MG and IM. We reviewed medical records to assess their clinical presentations, laboratory findings, imaging studies and electrophysiological features. The data is presented descriptively.

Results: We identified 6 patients with MG-IM overlap. Three patients had simultaneous onset of MG and IM, 2 of whom presented with myasthenia crisis and fulminant myositis. In the other 3 patients, MG was the initial presentation and IM occurred 3–11 years after MG.

Diagnosis of MG was confirmed with clinical features, electromyography and/or serology. All had symptoms of MG with predominant ocular or bulbar weakness. Among these 6 patients, 3 had underlying thymic pathology including two benign thymoma and one stage IV thymoma; all 3 patients had Acetylcholine Receptor Antibody. Of the 3 patients with no thymic pathology by computed tomography (CT) or thymectomy, 1 had high positive AChR antibody and 2 were negative.

Four patients had biopsies confirming the diagnosis of dermatomyositis or polymyositis. The other 2 patients declined biopsy; however, their MRI and EMG findings were consistent with IM. Only one patient had typical dermatomyositis rash. Among the 3 patients with underlying thymic pathology, thymoma were resected; all 3 were treated with high dose glucocorticoid, IVIG, and methotrexate with complete remission after 2 years. Of the 3 patients with no thymic pathology identified, one patient (ACHR+) was in remission on mycophenolate and passed away from pancreatic cancer; two patients (ACHR−) had refractory MG and IM, and both responded to rituximab.

Conclusions: In summary, this is one of the largest case series with MG-IM overlap with or without thymic pathology. It is very important to recognise such association and the different pattern of muscle involvement because therapies may be adjusted to treat both conditions. In patients with thymic pathology, conventional disease modifying agents, IVIG and glucocorticoid in addition to thymoma resection appear to be effective. In patients with refractory MG and myositis who were ACR-negative, rituximab may be effective.

AB0779  LONG TERM FOLLOW-UP OF A SYSTEMIC SCLEROSIS GROUP TREATED WITH BOSENTAN

L. Grosescu1,2, F. Berghesi3,2, V. Bojinca1,2, A. Balanescu3,2, A. Borangiu1,2, D. Mazlu1,2, S. Dais-liescas2,2, D. Opris-Belinski2,1, I. Saulescu1,2, C. Constantinescu2,3, M. Ababuli2,3, R. Ionescu2,3.
1Internal Medicine and Rheumatology, St Maria Clinical Hospital; 2Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

Background: Prospective studies with Bosentan have shown short term efficacy, while it is not clear whether long-term treatment may be effective or whether ulcers may recur once treatment is discontinued.

Objectives: Our objective was to evaluate the long term efficacy and tolerability of bosentan in patients with systemic sclerosis (SSc) who develop digital ulcers (DU).

Methods: In the present prospective, observational, non-controlled study, we followed 36 SSc patients treated with Bosentan from Sept 2014 to Dec 2017 Number of DU, semiqualitative capillaroscopic scoring, VAS (visual analogue scale) for Raynaud, VAS for DU and HAQ were evaluated every 6 month. Results are presented as mean±SD. The difference between efficacy measures at follow-up visits was tested with the Wilcoxon’s signed-rank test.

Results: The group included 26 patients, 16 females, 11 diffuse subsets, age was 48.08 (9.8) years, disease duration was 84.35 (76.04) months, number of DU was 4.27 (3.71), most of them had a late scleroderma pattern pattern (16/26).
Microangiopathy evolution score was 5.19 (2.04), VAS for DU was 75.52 (16.17), VAS for Raynaud was 67.43 (14.16), HAQ was 1.62 (0.55). 5 patients received Bosentan less than 16 months, so they were excluded from the statistical analysis. 6 month evaluation revealed significant decrease in the number of DU (p<0.01), the VAS for DU (p<0.01), the VAS for Raynaud (p=0.03) and the HAQ (p=0.04), but not of the microangiopathy evolution score. No significant difference was noticed of the above mentioned parameters at the next follow-up evaluations. Regarding Bosentan safety: 6 patients died during the follow up (3 cases of severe pulmonary arterial hypertension, 1 scleroderma renal crisis, 1 heart failure, 1 post vascular surgery), Bosentan was stopped due to lack of efficacy in 2 case and due to side effects in 3 cases: 2 elevated liver enzymes, 1 severe thrombocytopenia and 1 dyspnea aggravation.

12 patients had a follow up after a 6 months Bosentan stop. We did not notice any significant increase in the number of DU, the VAS for DU or Raynaud, the capillaroscopy and extent of calcinosis in SSc patients. Rheumatology (Oxford). 2008;47(4):464–6.

PROLONGED PROTON PUMP INHIBITOR EXPOSURE IS ASSOCIATED WITH DEVELOPMENT OF CALCINOSIS IN SYSTEMIC SCLEROSIS

Background: Long-term use of proton pump inhibitors (PPI) has been associated with some safety concerns, including potential vascular calcification. In a previous retrospective analysis, we noted a possible association between PPI use and the presence and extent of calcinosis in SSc patients.

Objectives: To investigate the association between PPI use and calcinosis in scleroderma (SSc).

Methods: Data from prospectively recruited patients were collected by patient survey, physician assessment and medical records. Calcinosis was graded; size (+ =<1 cm, ++ =<1.5 cm, +++=>3 cm) and number of sites involved (NSI) (I=1 body site, II=2–3, III=10). A total daily PPI equivalent dose (TDED) was calculated for each patient. We calculated PPI exposure score (PFE) by multiplying the total duration of use by TDED. For analysis, PPE was categorised into four groups; 0=no exposure, 1=up to 5 years, 2=6–10 years, 3=10 years. Fisher’s exact test was used to assess categorical variables. Logistic regression assessed association between calcinosis and independent variables.

Results: 216 patients were recruited, 81.5% females, mean age 57.46 (SD 13.5) years, 56.5% had hypertension, 31.5% diffuse SSc, 9.7% had overlap features and 2.3% other CTD. Mean disease duration was 10 years (SD 9). ANA subtypes were defined: ACA positive (31.5%), ATA (25.5%), ARA (12.0%), ANA +ENA (11.6%), USRNFP (5.1%), ANA - ENA (4.2%), PmScl (3.7%) and 6.5% other antibodies. Gastroesophageal reflux symptoms occurred in 83.3% of patients, most were on PPI (81%) and 14.8% had previously been on PPI. Current calcinosis (CC) was present in 30.1% patients, 9.7% reported past calcinosis. 39.6% had calcinosis at any time (CAT). 60.2% of patients never had calcinosis. Of those with CC, 47.7% had >1 site involved. The most frequent sites affected were: finger (70.8%), elbow (35.4%) and knee (18.5%).

Univariable analysis found an association between disease duration and calcinosis, with odds of CAT increased by 7% per year (OR 1.07, CI 1.04–1.11, p=0.001). Similarly, every year of PPE increased odds of CAT by 3% (OR 1.03, CI 1.01–1.05, p=0.001) and the odds associated with CAT (odds increasing by 2% per annum, p=0.043). Exposure to a standard dose of PPI for over 10 years increased the odds of calcinosis by 4 times (OR 4.07, CI 1.68–9.85, p=0.002) compared to no exposure. PPE category associated with NSI (p=0.04). 73.3% of patients with large volume calcinosis (>3 cm) had a PPE for >10 years and all with calcinosis >3 cm had exposure to PPI.

Multivariable logistic regression found that disease duration (OR 1.07, CI 1.03–1.11, p=0.001) and antibody specificity strongly associated with calcinosis. Presence of ATA (OR 0.32, CI 0.14–0.75 p=0.008), ANA- (OR 0.13, CI 0.02–0.79, p=0.026), and ANA+ENA- (OR 0.17, CI 0.05–0.52, p=0.002) reduced odds of calcinosis. Although the effect of PPIs on calcinosis was attenuated after adjusting for disease duration and antibodies, higher exposure to PPIs remained a significant predictor of calcinosis, with PPI category (>10) increasing risk of CAT (OR 5.34, CI 1.16–24.17, p=0.025).

Conclusions: Our data support a novel association of PPI exposure with calcinosis and confirm association of disease duration and antibody profile. Given the clinical impact of calcinosis, a potentially modifiable risk factor of PPI exposure warrants further study.

GLUCOCORTICOID DOSE AND CARDIAC INVOLVEMENT MIGHT BE POTENTIAL RISK FACTORS FOR SCLERODERM Renal CRISIS

X.-N. Wei, D.-H. Zheng, J.-J. Liang, L. Dai. Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China

Background: Scleroderma renal crisis (SRC) is a rare but life-threatening complication of systemic sclerosis (SSc). SRC remains a major risk factor for mortality in SSc. It is important to identify potential risk factors for SRC, and avoid developing overt SRC.

Objectives: To perform a retrospective case series analysis of the characteristics, management and outcomes of SRC in Chinese SSc patients.

Methods: SSc patients hospitalised at Sun Yat-Sen Memorial Hospital from January 1992 to December 2017 were recruited. Clinical data were collected. SRC was defined as new onset, with blood pressure (BP) >140/90 mmHg or >30 mmHg rise in BP from baseline, rising serum creatinine (Scr) levels and/or oligoanuria. Data were showed as mean ±standard deviation.

Results: There were 749 SSc patients recruited and 16 patients (2.1%) of them were hospitalised for SRC. Among these 16 patients, 56% were females, age was 54.6±13.6 years, mean duration from SSc onset to SRC occurred was 4 years.

SRC developed in 14 patients (87.5%) with diffuse cutaneous SSc (dcSSc), and in 2 patients (12.5%) with limited cutaneous SSc (lcSSc). Eleven patients (68.8%) were under glucocorticoid treatment before SRC onset: 4 patients received >30 mg/d of prednisone, 6 patients received >7.5 mg/d prednisone and 1 patient received <7.5 mg/d prednisone. No patient was treated with angiotensin-converting enzyme (ACE) inhibitors before SRC.

All 16 patients manifested progressive renal failure, with Cr levels increase to 220±256 µmol/L. Ten patients manifested new onset hypertension, with systolic BP 175±21 mmHg and diastolic BP108±13 mmHg. Five patients who had a history of well-controlled hypertension manifested accelerated increase in BP 171±108±7 mmHg. One patient was normotensive, but manifested rapidly progressive oliguric renal failure with Scr increase to 969 µmol/L, massive proteinuria and hemolytic anemia.

Twelve patients (75%) had pulmonary fibrosis, 11 patients (88.8%) had cardiac involvement, 6 patients had pulmonary arterial hypertension (PAH) and 6 patients had gastrointestinal dysfunction. Cardiac involvement was common, manifested pericarditis, myocardial damage and heart failure (n=7, 43.8%, respectively). All 5 dead patients were accompanied by cardiac involvement.

Eleven patients had Raynaud’s phenomenon, 8 patients had digital ulcers, 5 patients had arthralgia and 2 patients had oliguria. Thirteen patients (81%) managed anemia, 8 patients (50%) manifested thrombocytopenia, and 8 patients (50%) manifested microangiopathic haemolytic anaemia (MAHA).

Eleven patients (68.8%) received ACE inhibitor treatment. Fifteen patients were treated with glitocorticoid and 12 patients with immunosuppressant (Cyclophosphamide n=10, Azathiprine n=2). After treatment, renal recovered in 4 patients (25%), kidney function improved and developed to chronic kidney disease (CKD) without dialysis in 5 patients (31%), 2 patients required permanent dialysis (13%). Five patients (31%) died.

MYOCARDIAL FIBROSIS DETECTED BY MAGNETIC RESONANCE IMAGING IN SYSTEMIC SCLEROSIS—PATHOPHYSIOLOGICAL SIGNIFICANCE

M. Funachi, K. Kishimoto, Y. Nozaki. Hematology and Rheumatology, Kitaidai University Faculty of Medicine, Osaka, Japan

Background: Systemic sclerosis (SSc) is characterised by chronic fibrosis in various organs such as skin, lung and heart leading to poor prognosis. Myocardial fibrosis is one of factors of pulmonary hypertension (PH) as well as pulmonary arterial hypertension or interstitial lung disease (ILD). Detection of cardiac lesions has progressed much using imaging techniques such as echocardiography (UCG) in combination with measurement of various biomarkers such as BNP. Recently, cardiac magnetic resonance imaging (CMR) has been shown to be sensitive to detect even subclinical cardiac lesions. However, it is unclear what subset of SSc is prone to myocardial fibrosis, when it manifests in the clinical course, or what fibrosis occurs in the different types of SSc simultaneously in various organs.

Objectives: To clarify the pathophysiological significance of myocardial fibrosis in SSc, CMR was performed in the patients with limited (lc) and diffuse (dc) cutaneous SSc with or without PH.

Methods: Twelve patients (male 2, female 10) who fulfilled ACR/EULAR criteria (2013) for SSc were enrolled. Eight patients were diagnosed as having lcSSc and 4 dcSSc. In addition to CMR, chest CT scan, UCG and laboratory tests including serum autoantibodies specific for SSc, blood brain natriuretic peptide (BNP) and pulmonary function test (%FVC,%DLCO) were performed in all patients. Right heart catheterization was performed in patients whose systolic right ventricular pressure estimated by UCG was higher than 30 mmHg. Positivity of late gadolinium enhancement (LGE) was compared with clinical findings and these parameters. Difference between the patient groups were tested using Student’s t-test.

Results: LGE was positive in 6 out of 12 patients. Patient composition of dc/lc in LGE (+) and LGE (-) group was 1/5 and 3/3, respectively. Complication of ILD was present in 3 among LGE (+) patients, while esophageal involvement in 3 among LGE (+) patients. The mean age of LGE (+) group tended to be higher than that of LGE (-) group (73.8±5.8 vs 68±6.4), duration of disease (year) tended to be shorter in LGE (+) group than those of LGE (-) group (1.8±3.0 vs 7.7±5.5), and BNP level (170.6±150.1 vs 90.1±69.9 pg/ml) and RVP (33.5±8.1 vs 29.7 ±8.1 mmHg) tended to be higher in LGE (+) than in LGE (-) group, although difference was not statistically significant. There was no tendency of positivity of autoantibodies and pulmonary function test, while patients with low%DLCO (<70) and without ILD were more sensitive to LGE. LGE tended to be positive in the patients whose E/e’ ratio determined by UCG or pulmonary capillary wedge pressure by RHC was elevated.

Conclusions: Since myocardial fibrosis was found rather in the cases without ILD, there might be difference in the progression of fibrosis depending on the organ, although it accelerates by ageing. If LGE is seen, PH, especially that asso- ciated with left heart disease, might occur in future. This study suggests that CMR might be useful to detect cardiac lesions from early period of clinical course, as well as in the cases with some abnormalities in biomarkers such as BNP or DLCO regardless of existence of ILD, although further study is needed to clarify the indi- cation of CMR using more cases of SSc.

Disclosure of Interest: None declared

ROLE OF CALCIUM ANTAGONISTS IN THE CANCER OF SYSTEMIC SCLEROSIS, AN ASSOCIATION UNDER DISCUSSION

Background: The use of calcium channel blockers (CCB) is widespread in systemic sclerosis (SSc) for the treatment of Raynaud’s phenomenon, present in 95% of patients. CCB can alter apoptosis, a mechanism for the destruction of cancer cells. In SSc the risk of cancer is increased, but the role that CCB can play is not clear, with contradictory data obtained so far.1,2

Objectives: To analyse the role of CCB in the appearance of cancer in a cohort of patients with systemic sclerosis.

Methods: Encoded patients under the diagnosis of SSc in our hospital from 1985 until December of 2017 were collected. Medical records were reviewed, recording clinico-epidemiological data and treatments used.

Results: 120 patients have been diagnosed of SSc (103 females, 17 males), 22 of whom (18.3%) have developed cancer. The type of cancer were (in order of frequency): breast (10 patients, 57%), gastrointestinal (4 patients, 33%), one hypernephroma, one endometrial carcinoma, one lymphoma, one skin cancer and one epidermoid of tongue. Adenocarcinoma was the most frequently histologic pattern found (16 patients, 76%). Interestingly, the diagnosis of SSc was made at an older age in those patients diagnosed of cancer (66.4±11.7 vs 54.8±17.3 years old, p=0.019); An age older than 55 years old conferred a relative risk (RR) of cáncer of 8.99 in the female group (76.9% vs 41.7% in the male group; p=0.001; 95% CI 2.39–32.4). An advanced stage of cancer was more common in the female group (46% vs 10% in the male group; p=0.009). An age older than 55 years old conferred a relative risk (RR) of cáncer of 1.69 (95% CI 1.18–2.43) in the female group compared with the men. The association of the use of calcium channel blockers in the population under study did not reach statistical significance.

Conclusions: CCB increase in our series the risk of cancer in women over 55 years old. CCB could be implicated in the patogenesis of cáncer in SSc. Due to the broad use of this in the SSc population, it may be required to study in a large number of patients in order to explore this association.

RED CELL DISTRIBUTION WIDTH IS A PROMISING MARKER OF PULMONARY ARTERIAL HYPERTENSION IN SCLERODERMA-RELATED DISORDERS

M. Bellari1,2, M. Squazzotti2, P. Piccinni2, A. Gubertoni2, J. Zanaboni2, A. Dimagi2, M. Gravellona2, P. Marini2, M. Piris2, P.P. Sainati2,1. Division of Internal Medicine, Sant’Andrea Hospital, Vercelli; 2Translational Medicine, Universita del Piemonte Orientale; 1Division of Cardiology; 2Division of Internal Medicine, Maggiore della Carita Hospital, Novara, Italy

Background: The early identification of those Systemic Sclerosis (SSc) patients harboring Pulmonary Arterial Hypertension (PAH) is a mainstay in the management of SSc. Novel biomarkers might improve the specificity of screening algo- rithms currently available.

Objectives: In this study we aimed to test the potential diagnostic value of Red cell distribution width (RDW), which has been previously described as a potential prognostic marker in thromboembolic and idiopathic PAH.

Methods: We prospectively recruited 118 patients affected by Scleroderma related disorders (Mixed connective tissue disease N. 7, 5.9%; SSc N. 93, 78.8%; Scleroderma overlap syndromes N. 11, 9.3%), undifferentiated connective tissue diseases N. 7, 5.9%) in a PAH outpatient clinic of a University Hospital. All patients underwent an extensive clinical and laboratory evaluation and an echocardiographic examination; a right heart catheterization was performed in 13 patients according to clinical indication.

Results: According to echocardiography and right heart catheterization, 14/118 patients were diagnosed with PAH. Patients affected by PAH had a higher RDW (15 [13.4–18.9] vs. 13.9 [12.1–19.1]; p=0.005), despite similar haemoglobin levels between groups. Patients affected by PAH also showed a higher BNP plasma concentration (245.6 [81.6–494.3] vs. 60.3 [50.3–77.4]; p=0.001) and lower pla- telets count (206.188–243 × 103/μl vs 240 [189–298] × 103/μl; p=0.04). RDW was also directly related to ultrasound-assessed Pulmonary Artery Pressure (PAPs) (r=0.20; p=0.03) and DLCO corrected for haemoglobin (r=–0.30; p=0.001); finally, RDW was related to the mean PAP measured by right heart catheterization (r=0.65; p=0.015).

Conclusions: RDW is an inexpensive, potentially useful marker in the detection of SSc-related PAH; its inclusion in screening algorithms could be considered to further improve their diagnostic performance.

THE EULAR SYSTEMIC SCLEROSIS IMPACT OF DISEASE (SCLEROID) SCORE – A NEW PATIENT-REPORTED OUTCOME MEASURE FOR PATIENTS WITH SYSTEMIC SCLEROSIS

ABSTRACT

The EULAR Scleroderma Impact of Disease Score (ScleroID) is a promising, novel PRO tool designed for use in clinical practice and clinical trials to display the disease impact of SSc, showing good performance in this pre-final analysis. Importantly, Raynaud’s phenomenon, impaired hand function, pain and fatigue were the main patient reported drivers of disease impact. To date the recruitment has reached more than 80% of the targeted number, the study is ongoing.

OSTEOARTICULAR INVOLVEMENTS IN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Touporti, T. Ben Salem, I. Ben Ghobel, M. Lamlaoui, M.H. Hounam

ABSTRACT

Background: Osteoarticular involvements are common in systemic sclerosis (SS) and are considered as an important cause of disability.

Objectives: The aim of this study was to assess clinical, radiological and immunological characteristics of patients with systemic sclerosis and who present with osteoarticular involvements at any time of the disease course. Patients with arthralgia and/or arthritis and/or imaging abnormalities were included.

Methods: A retrospective descriptive and comparative study was performed in an internal medicine department. One hundred thirty one patients who fulfilled 2013 ACR/EULAR criteria for SS were studied.

Results: We identified 101 patients with osteoarticular involvements (77.1%); 92 women and 9 men. Mean age at SS diagnosis was 47.6±12.4 years. Disease was revealed by joint manifestations in 10.7% of cases. Arthralgia and arthritis were observed in 61.8% and 21.4% of cases respectively. Flexion deformities with disability were noted in 26 cases. X-Ray investigations revealed distal phalanges resorption (n=24), dystrophic calcifications (n=10) and joint space narrowing (n=9). Tendonitis was observed in one patient. Patients with osteoarticular manifestations developed more frequently digital ulcers (100% vs 78.3%; p<0.001). Osteoarticular involvements were associated to diffuse cutaneous sclerosis (37.7% vs 12.5%; p=0.002) and to telangiectasia (91.3% vs 70%; p=0.027), gastrointestinal manifestations (90.1% vs 54.5%; p<0.001) and interstitial lung disease (92.7% vs 67.9%; p=0.001). SS was associated to sJGSD syndrome (n=20), to systemic lupus erythematosus (n=15) and to rheumatoid arthritis (n=2). Patients received non-steroidal anti-inflammatory drug (n=26), corticosteroids (n=8) and methotrexate (n=8).

Conclusions: Osteoarticular involvement in systemic sclerosis has heterogeneous aspects. Its frequency ranges from 40% to more than 85% of cases in some studies. Early screening and treatment associated with physiotherapy session are essential to avoid complication and loss of function.

Disclosure of Interest: None declared

HOW DOES THE DURATION OF THE DISEASE INFLUENCE THE QUALITY OF LIFE?

N. Lochtin-Czepol, S. Vetlia, L. Mazur-Nicorici, V. Salaru, M. Mazur. "Internal Medicine, "Family Medicine, SUMPh Nicolae Testemitanu, Chisinau, Moldova, Republic of

Background: It is noticed that over the last decades the prognosis in patients with Idiopathic Inflammatory Myopathies (IIM) – a group of autoimmune disease characterised by muscle involvement, has improved along with increase of disease duration and thus affects the quality of life.

Objectives: To assess the patient's quality of life related to the duration of the disease.

Methods: We performed a cross-sectional study from December 2015 to December 2017, the patients included fulfilled the Bohan and Peter criteria for IIM. Demographic and clinical data were collected using a special questionnaire. Consistent with the objective the study group was divided in two subgroups by disease duration 1-less than 24 months and second subgroup more than 2 years. In order to estimate the quality of life (QoL) was applied Short Form-8 with 8 items for 8 domains and two components: mental and physical. Statistical data was analysed using MedCalc software version 12.

Results: There were 67 patients enrolled in the study, including 51 females and 16 males with a F:M ratio of 3:2:1, mean age 53±12.5 (range 25-78). The mean disease duration was 8.3±5.3 (range 0.5–12) years, there were 16 patients in the subgroup with the disease duration less than 2 years. The mean physical component was 36.48±0.05 and the mental component – 41.69±0.62 points, determined as reduced quality of life. Regarding the QoL of patients from subgroup 1, we found the physical component – 38.15±8.83 and the mental component 40.56±22 points. In the second subgroup we appreciated the physical and the mental component – 35.77±9.14 and 42.0±1.86 points, respectively. It was identified moderate correlation (r=0.49 p<0.005) between the both domains of the QoL and disease duration till 2 years, for the duration of more than 2 years we found moderate correlation (r=0.51 p<0.005) with mental component and a weak one for physical domain (r=0.24 p<0.005).

Conclusions: Patients with idiopathic inflammatory myopathies had reduced quality of life by both domains. Disease duration in patients with early idiopathic inflammatory myopathies – less than 2 years, has a greater impact on patient's quality of life.

Disclosure of Interest: None declared

FREQUENCY OF OSTEOPOREOSIS IN POSTMENOPAUSAL WOMEN WITH SYSTEMIC SCLEROSIS

O. Dobrovolskaya, N. Demin, A. Smirnov, O. Koneva, N. Toroptsova.

Background: The prevalence of low bone mass or osteoporosis in patients with systemic sclerosis (SSc) varies significantly between studies performed in different countries and vary from 3% to 51% (Omar MA et al. 2013).

Objectives: To determine the frequency of osteoporosis (OP) in postmenopausal women with SSC in comparison with healthy control.

Methods: 163 postmenopausal women were enrolled in the study: 83 with SSc (mean age 58.5±8.1 years, mean disease duration 9.7±6.8 years) and 80 healthy control (mean age 59.2±6.6 years). Demographic characteristics and risk factors for OP in OP study groups are summarised in table 1. BMD was measured at lumbar spine, femoral neck and total hip by dual energy X-ray absorptiometry (DXA, Hologic 4500A). BMD decreasing grade was determined in according to WHO criteria.

Results: BMD in women with SSc was significantly lower than in control group at any site: lumbar spine – 0.83±0.09 vs 0.86±0.08 g/sm² (p=0.031); femoral neck – 0.63±0.08 vs 0.73±0.11 g/sm² (p<0.001), and total hip – 0.75 ±0.16 vs 0.83±0.11 g/sm² (p<0.001). Frequency of OP in SSC group was 32%, in control group – 13% (p=0.002). Mean age at menopause was less in SSc women than in control (p=0.05).

OP was significantly more often in SSc patients taking oral glucocorticoids compared to those without glucocorticoid treatment (39% and 20%, respectively, p=0.05). Low BMD was associated with age and interstitial lung disease in SSc women (p<0.05). At the same time no associations were found out among low BMD and disease duration, daily and cumulative doses of glucocorticoids, 23 (28%) of patients had osteoporotic fracture, among them 8 (10%) of women had two or more fractures in the anamnesis. The most frequent localizations of the fractures were distal forearm and vertebral: 7 (32%) and 5 (23%) patients, respectively.

SPECIFIC FEATURES OF SKIN INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS AND ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

N. Yudkina1, A. Volkov2, T. Martynyuk2, E. Nasonov1, 1VA. Nasonova Scientific Research Institute of Rheumatology, 2Cardiology Scientific Medical Research Center, Moscow, Russian Federation

Background: Pulmonary arterial hypertension, associated with systemic sclerosis (SSc-PAH), is a severe irreversible manifestation of the disease, potentially fatal in its’ late stage. It was shown that survival in SSc-PAH pts is much worse than in pts with idiopathic pulmonary arterial hypertension (IPAH). Unfavourable outcomes due to late recognition can be explained by predominance of subtle, clinically poor manifest SSc types, especially in terms of cutaneous and vascular syndromes.

Objectives: To assess the clinical features and survival rates in pts with systemic sclerosis sine scleroderma (ssSSc), associated with PAH.

Methods: 14 pts with ssSSc-PAH were analysed in comparison with 54 pts with clinically manifest skin involvement SSc-PAH (3 pts with diffuse (dcSSc-PAH) and 51 pts with limited cutaneous involvement (lCSSc-PAH), and 48 pts with IPAH.

Results: Pts with IPAH were younger than both type SSc-PAH – 37 (28; 44), 48 (37; 56) and 54 (48; 62) y, respectively. In SSc-PAH pts with skin involvement and the diagnosis of PAH was established earlier (within 18 (10; 44) mo) than in pts with ssSSc-PAH (23 (15; 45) mo), although differences are not statistically significant. The PAH functional class was slightly higher in ssSSc-PAH, than in IPAH and SSc-PAH, the differences are not significant. Raynaud’s phenomenon (RP) was present in all SSc-PAH pts, although in cutaneous SSc pts clinical ischaemic lesions were more frequent (51% vs 14%, p=0.03), as well as contractures (53% vs 7%, p=0.008). There were no other differences in clinical features between the groups. Anticentromere antibodies (ACA) were present in 7 (50%) pts with ssSSc-PAH and in 36 (65%) pts with cutaneous SSc. Antitopoisomerase-I antibodies (anti-Scl-70) were found only in 2 pts with lCSSc. More than 1 type of autoantibodies was detected in the majority of Ssc pts. A wide range of antinuclear Abs was found in pts with ssSSc-PAH with prevailing ACA (in 7 pts), as well as anti-Sm, anti-La Abs, anti-nucleosome Abs (in one case), anti-Ro Abs (in 5 pts), anti-RNP-70 Abs – in 4 pts, anti-dsDNA Abs – in 2 pts, RF – in 3pts. SSc diagnosis was established according to ACR-EULAR 2013 classification criteria. The following diagnostic criteria were present in ssSSc-PAH pts: RP (in all pts), ulcers (3), scars (2), telangiectasia (10), PAH (14), SSc-associated Abs (7), capillaroscopic lesions (12). The mean total score was 11 (9;12) while ≥ 9 scores are required for SSc diagnosis, 100% pts with ssSSc-PAH met ACR-EULAR 2013 criteria, thus, justifying the SSc confirmation in this group of pts. There were significant differences in survival rates between IPAH pts and pts with various types of SSc-PAH (log-rank test, p=0.06). 5 year survival in ssSSc-PAH was somewhat lower, than in SSc-PAH – 50.6% vs 64.3%, respectively; IPAH pts had the best survival rates of 82.5%, and these differences are close to significant.

Conclusions: Clinical features and survival ssSSc-PAH are very similar to those in pts with cutaneous SSc-PAH with the exception of skin involvement and associated symptoms (digital ischaemic lesions and contractures). Rheumatologists
AUTOIMMUNE AND INFLAMMATORY DISTURBANCES IN PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SYSTEMIC SCLEROSIS

N. Yudkina1, A. Volkov1, T. Martynyuk2, E. Nikolaeva1, E. Nasonov2, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; 2Cardiology Scientific Medical Research Center, Moscow, Russian Federation

Background: The prognosis of patients with pulmonary arterial hypertension associated with systemic sclerosis (SSc-PAH) is significantly worse, than other forms of PAH, and mechanisms of this phenomenon are unknown. Therefore, the isolation of autoimmune disorders is of great importance for early diagnosis and differential diagnosis, as well as the search for new therapeutic targets.

Objectives: To identify the autoimmune disorders in patients with SSc-PAH.

Methods: The study includes 52 pts with idiopathic pulmonary arterial hypertension (IPAH), 51 pts with SSc-PAH, 65 pts with SSc without PAH. Serum concentrations of the C-reactive protein (CRP), antinuclear antibodies (ANA) and antibodies to topoisomerase-I (anti-Scl-70) were routinely measured. The control group consists of 146 volunteers. Statistical analysis includes univariable logistic regression, ROC analysis and Kaplan-Mayer method.

Results: The average age of patients with IPAH was 37.9±10.5 years, SSc-PAH – 52.3±12.7 years, SSc without PAH – 51.2±13.2. Patients did not differ in functional class (FC), which was the main criterion of comparability. Mean values of FC in groups with SSc-PAH and IPAH also did not differ (2.7±0.8 and 2.6±0.7, respectively). ACA was associated with a 15.2-fold increased odds of developing PAH in SSc (OR 15.2, 95% CI 5.4–43.0), on the contrary, presence of anti-Scl-70 associated with low risk of PAH (OR 0.5, 95% CI 0.01 to 0.21). The level of CRP in the serum was significantly higher in patients with PAH than in the control group: 4.1 (1.9, 10.0) and 0.61 (0.25, 1.9), p<0.00001, and also in comparison with patients without PAH (1.9 (0.8, 6.4), p=0.02). In pts with PAH, the level of CRP correlated with FC and right atrium pressure and 6 min walk test distance. The level of CRP was significantly higher in patients with FC III-IV compared with FC I-II and in non-surviving patients. The Kaplan-Mayer analysis showed that pts with CRP level more than 4.75 mg/L at the time of diagnosis of PAH had a significantly lower survival rate (median 48 months) than pts with normal values (median 91 months) (p<0.005), with 67% sensitivity and 61% specificity.

Conclusions: SSc-PAH is a unique phenotype combining the manifestations of SSc and PAH, the pathogenetic mechanisms of which modify the course of these states. It is based on a feature of autoimmunity with the predominance of ACA and a low occurrence of anti-Scl-70. An increase in the concentration of CRP, as well as the effect of its baseline level on survival, attests to the significant role of autoimmunity and inflammation in the pathogenesis of this fatal SSc complication.

DESCRIPTIVE ANALYSIS OF A COHORT OF PATIENTS DIAGNOSED WITH INFLAMMATORY MYOSITIS IN A TERTIARY HOSPITAL

O. Ibarraenresita1, E. Ruiz1, M.L. García1, S. Kapetanovic2, O. Fernández1, I. Torre1, A.R. Incharoob, C. Pérez1, J.M. Blanco1, I. Calvo1, E. Guerrero1, D. Montero1, E. Gailndez1, 1Rheumatology; 2Neurology, Basurto University Hospital, Bilbao, Spain

Background: Inflammatory myopathies are a group of rare systemic diseases characterised by muscle weakness and inflammation. Clinical manifestations, course and prognosis of these pathologies are very heterogeneous.

Objectives: The aim is to describe the main characteristics of patients diagnosed with inflammatory myositis fulfilling Bohan and Peter criteria.

Methods: Descriptive analysis of a cohort of 34 patients from the same hospital with follow-up between January 2010 and December 2017. We recorded demographic characteristics, clinical manifestations, treatment, comorbidity and mortality.

Results: 34 patients (73% female) were recruited with an average age at diagnosis of 56.3 years (range 14–90) among adults and 10 years (range 1–18) among children. Most of them were Caucasian (94%), 18% were smokers and 15% previous smokers. The most frequent type was dermatomyositis (DM) (40%) followed by antisynthetase syndrome (ASS) (15%), necrotizing myopathy (12%), inclusion body myopathy (12%), overlap myositis (9%) and polymyositis (9%), 2 patients (out of 4) with necrotizing myopathy were treated with statins.

Clinical manifestation included muscle weakness (84%) and skin manifestations (48%) mainly among DM patients. 8 patients (24%) showed interstitial lung disease (4 non-specific interstitial pneumonia, 3 usual interstitial pneumonia and 1 cryptogenic organising pneumonia), especially among patients with overlap syndrome (n=3). DM (n=2) and ASS (n=2). Pulmonary hypertension occurred in 7 patients (21%), 30% among patients with overlap myositis associated to systemic sclerosis. The rest of extramuscular manifestations are expressed in the table 1. Muscle biopsy was performed in 57% of patients (77% compatible with myopathy). MRI was carried out in 45% (100% with active myositis). EMG was performed in 94% of patients with myopathic findings in 67% of them. 20 patients (60%) presented positive antinuclear antibodies, being the most frequent anti-PML-SCL (18%), anti-Jo1 (18%), anti-Ro (12%) and anti-MDA5 (9%). All patients were treated with corticosteroids. Only 2 responded to corticosteroids in monotherapy. More than 90% needed additional immunosuppressive treatment and 65% received 2 or more immunosuppressants. The most commonly used drugs were methotrexate (72%), rituximab (28%), azathioprine (25%), immunoglobulins (21%) and cyclophosphamide (21%). Only in 12% treatment could be stopped because of sustained remission. 3 cases of cancer (9%) were reported: myelodysplastic syndrome, lung neoplasm (in the case of paraneoplastic myositis) and lymphoma. During the follow-up period 4 deaths were registered (12%) due to infections and cancer. 38% of patients required a multidisciplinary approach.

Disclosure of Interest: None declared

AB0794

MYOSITIS DAMAGE INDEX IN A MIOSITIS POPULATION COHORT

O. Enriquez, A. Lilia, I. Fedra, on behalf of Hospital Centro Medico Nacional 20 de Noviembre. Reumatologia, Hospital Centro Medico Nacional 20 de Noviembre, Ciudad de Mexico, Mexico

Background: Idiopathic inflammatory myopathies (IM) are a heterogeneous and uncommon group of diseases characterised by muscular involvement and many systemic manifestations. They usually have a chronic course, and despite treatment they often develop functional impairment. MDI-MYODAM a score to assess damage has been recently developed. Few publications in this regard have reported a prevalence of 92%. There are no studies in Mexican-mestizo population describing the extent of damage and its main determinants.

Objectives: To investigate the prevalence of damage measured with the MDI-MYODAM tool in patients with IM and its relationship with characteristics of the disease and treatment.

Methods: A cross-sectional study was conducted in an IM cohort from a national reference hospital. MDI questionnaire was applied to all patients. Demographic, disease characteristics, IM subgroup (dermatomyositis, polymyositis and overlap), comorbidities (Charlson index), medical treatment were collected. Descriptive statistics were applied. Bivariate Pearson correlation test was conducted to
analyse associations between MDI score and clinical characteristics. P value<0.05 was considered as a statistically significant.

Results: Fifty subjects participated, 75% were women, mean age at diagnosis was 40.7 years (SD±) and mean duration of the disease was 11.8±8.3 years. Thirty-one percent of patients had polymyositis, 31% dermatomyositis, 12% juvenile dermatomyositis, 10% overlap vasculitis (mainly systemic lupus erythematosus, scleroderma and rheumatoid arthritis). The mean Charlson index was 2.7±2.4. Eighty-one percent had a score greater than 0 for at least one category; majority within the endocrinological systems (55%), skeletal (51%), gastrointestinal (35%). The mean total damage score (MDI) was 3.6±2.9. The mean score for the total damage according to the MYODAM score was 6.9±5.1. A moderate correlation between the MDI score and the use of glucocorticoids (r 0.3, CI 95% 0.1–0.6, p<0.01). No associations between damage and activity of the disease or ILM subgroup were observed.

Conclusions: Most patients with IIM develop some kind of damage, with greater impact on the endocrinological, skeletal and gastrointestinal systems. There increases with the time of evolution and the use of steroids in a non-linear way. Therefore, these results should be taken into account in the decision-making process in long-term treatment.

AB0795
LONG-TERM EFFICACY AND SAFETY OF RITUXIMAB IN SYSTEMIC SCLEROSIS REFRACTORY TO CONVENTIONAL IMMUNOSUPPRESSANTS

P. Polli, E. Zanatta, M. Favaro, M. Felicetti, F. Oliviero, E. Pigatto, F. Cozzi, A. Donà. Rheumatology Unit, Department of Medicine – DIMED, Padova University, Padova, Italy

Background: Recent studies have shown that B-cells are involved in the pathogenesis of systemic sclerosis (SSc) suggesting that B-cell depletion might have a role in the treatment of the disease.

Objectives: To describe the long-term efficacy and safety profile of Rituximab (RTX) in SSc patients who failed previous conventional immunosuppressive drugs.

Methods: We retrospectively analysed medical records of all SSc patients treated with Rituximab in our Rheumatology Unit from July 2011 to December 2017. Disease manifestations, particularly skin, pulmonary and articular involvement, were evaluated at baseline (T0), at 8±2 months (T1) and at the last follow-up visit (T2).

Results: Thirteen patients, 11 females and 2 males, were treated with 32 RTX cycles (median per patient 2.5, range 1–4). Eleven patients had diffuse and 2 limited cutaneous form; all had positive ANA, 9 anti-Topol, 2 anti-RNA polIII, and 1 anti-SSA.

The mean age at first RTX infusion was 49.3±13.6 years and the mean disease duration was 6.5±3.3 years. The main indications to RTX were: interstitial lung disease (11/13), worsening of skin involvement (6/13) and arthritis (5/13), refractory to at least one previous immunosuppressive drug (median 2, range 1–3). Twelve patients were treated with mycophenolate mofetille, 5 with cyclophosphamide, 4 with methotrexate and 2 with azathioprine. All patients were treated with RTX (1000 mg twice, two weeks apart). Twelve patients received more than one cycle; the interval between cycles was 12.7±5.4 months. The mean follow-up period was 41.4±21.9 months. Five patients had arthritis and we observed complete remission of arthritis in all of them. 8 months after the first RTX administration arthritis relapsed in 4 patients who were successfully retreated.

We did not observe a significant decrease in modified Rodnan Skin Score over time (T0: 15.6±9.6, T1: 14.8±7.8, and T2: 13.1±8.3; p=n.s.). Lung involvement, detected in 11/13 patients, remained radiologically stable in 8 patients and worsened in 3. No significant changes in the pulmonary function tests were observed from T0 to T2.

Five patients had a follow-up longer than 33 months after the last RTX cycle: 3 patients had a stable disease, 1 developed severe PAH and 1 lung neoplasia. CD19 cell depletion (<2%) was observed after each RTX cycle, without significant changes in immunoglobulin levels. No infusion reactions were observed. We registered only one severe side effect: hand cellulitis in a patient with digital ulcer, requiring hospitalisation.

Conclusions: Our experience suggests that RTX is well tolerated and could be effective in the management of severe and refractory SSc manifestations.

AB0796
SHORT TERM TREATMENT RESPONSE TO INTRAVENOUS PULSE CYCLOPHOSPHAMIDE TREATMENT IN CONNECTIVE TISSUE RELATED INTERSTITIAL LUNG DISEASE

P.T. Antony, clinical Immunology and rheumatology, AMALA institute of medical sciences, Thrissur, India

Background: Interstitial lung disease (ILD) is a major cause for morbidity and mortality in patients suffering from connective tissue diseases. Early detection and prompt recognition of symptoms with appropriate treatment is necessary for effective control of the disease and for better prognosis and long-term survival. Various treatments have been approved based on observational studies. We have very few studies as regards ILD treatment from the Indian subcontinent. In a resource constrained country like India, we mainly rely on cheap drugs like cyclophosphamide. We have done a study to assess the short-term treatment response of connective tissue related interstitial lung disease to cyclophosphamide in a tertiary centre in India.

Objectives: 1. To assess short treatment outcome for Connective tissue disease related interstitial lung disease treated with intravenous pulses of cyclophosphamide (CYP) based on improvement in lung function 2) Forced vital capacity (FVC)% predicted, forced expiratory volume in first second (FEV1)% predicted 2) Dyspnoea Borg scale 3) Cough visual analogue score.

2. To determine the factors affecting treatment outcome like age, sex, duration of the connective tissue disease, type of connective tissue disease, HRCT type and presence of PAH.

Methods: A cohort study was conducted in the Department of General Medicine, Rheumatology and Pulmonology in Amala Institute of Medical Sciences, Thrissur, Kerala from November 2015 to June 2017, that evaluated 74 patients who were having connective tissue disease related ILD. Detailed history and a thorough clinical examination was done. Treatment with 6 intravenous pulses of cyclophosphamide was done and response was assessed after 6 months. Response to treatment and associations were analysed using SPSS software (version 15).

Method used for statistical analysis was Chi–Square test and paired t test.

Results:
There was no association between treatment response and age, sex or type of connective tissue disease. Following treatment there was a definite improvement in the clinical aspects of the patient which was assessed by dyspnoea Borg score and cough visual analogue score. Following treatment there was a definite improvement in PFT (FVC, FEVI) as well as 6 min walk test which was also statistically significant. CT pattern of Non specific interstitial pneumonitis also had a better outcome.

Conclusions: Our study proves that there is definite clinical and FVC improvement in CTD-ILD patients after giving treatment with cyclophosphamide. Determinants that can predict treatment outcome are duration of disease, HRCT type, (NSIP), presence of Pulmonary artery hypertension(PAH). Poor treatment response should be anticipated in those with longer duration of disease and UIP type in HRCT, presence of PAH.

R A RANDOMISED DOUBLE BLIND PLACEBO CONTROLLED TRIAL TO COMPARE THE EFFICACY OF INITIAL COMBINATION THERAPY VS MONOTHERAPY FOR PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS

P. Dwivedi1, S.K. Sharma1, V. Dixit2, M.K. Rohit1, D. Behera3, S. Jain1. "Internal Medicine, "Cardiology, "Pulmonary Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, India

Background: Pulmonary Arterial Hypertension(PAH) is one of the leading cause of death in Systemic Sclerosis(SSc) population. Trials that have studied the efficacy of initial oral combination therapy versus monotherapy for the treatment of PAH in SSc are limited.

Objectives: To study the efficacy and safety of monotherapy (sildenafil) versus initial combination therapy (sildenafil and bosentan) for treatment of SSc related PAH.

Methods: In a single centre, double blind, prospective, randomised, placebo controlled trial, 34 patients of SSc related PAH defined as Pulmonary Artery Systolic Pressures(PASP)=35 mmHg as measured by echocardiography, New York heart Association(NYHA) functional class II and III with forced vital capacity >60% were randomised in 1:1 ratio to sildenafil (20 mg thrice a day) and matched placebo of bosentan to one study arm or to the combination of sildenafil(20 mg thrice a day) and bosentan (62.5 mg twice daily for 4 weeks maximum up to 125 mg twice daily) to the other arm for 24 weeks. The primary end point of the study was to assess the change in pulmonary artery pressures measured by echocardiography at 4 weeks from baseline. The secondary efficacy end points was to compare the change in 6 min Walk Distance (6MWD). Time To Clinical Worsening(TCW) and adverse events at 24 weeks. Intention to treat analysis was carried for the primary and secondary outcomes. p<0.05 was considered significant. Kaplan Meier survival analysis was done to estimate the time to PAH worsening and hazard ratio was calculated.

Results: The mean change in Pulmonary Artery Systolic Pressures in the monotherapy arm was −1.0 mmHg versus +2.1 mmHg in the combination arm (p=0.56). TTCW is prolonged in the combination arm. The mean survival time in the initial combination arm was 23.76±5.59 weeks and 23.28±0.23 weeks in the monotherapy arm. The hazard ratio was 0.73(95% CI 0.04–11.7) (p=0.87). The mean change in the 6 min walk distance in the monotherapy arm was 15.88±31.83 m and 25.88±38.25 m in the combination arm (p=0.38). The satisfactory clinical response in the combination arm was 82.3% versus 70% in the monotherapy arm (OR=1.9,[CI 0.38–9.88] p=0.44). The upfront combination of sildenafil and bosentan was well tolerated with similar rates of adverse events in both group.

Conclusions: In this study we could not demonstrate any significant difference in the efficacy of initial combination therapy of sildenafil and bosentan over sildenafil monotherapy. The patients of systemic sclerosis tolerated the initial combination of sildenafil and bosentan well and the treatment prevented further deterioration. Larger studies with more number of subjects may be required to confirm the results.

AB0798 CLINICAL ASSOCIATIONS OF VASCULAR ENDOTHELIAL GROWTH FACTOR AND ITS RECEPTOR 2 TYPE IN SYSTEMIC SCLEROSIS

R. Alekperov1,2, E. Alexandrova3, A. Novikov2, L. Ananyeva1. 1Moscow Regional Research and Clinical Institute (MONKI); 2NASCOVA RESEARCH INSTITUTE OF RHEUMATOLOGY, MOSCOW, RUSSIA, Moscow, Russian Federation

Background: Systemic sclerosis (SSc) is characterised by impaired angiogenesis and peripheral microvasculopathy. A major role in the regulation of angiogenesis is attributed to vascular endothelial growth factor, which performs its functions through interaction with its receptor 2 type (VEGFR2).

Objectives: The aim of our study was to assess the levels of VEGF in serum and its associations with clinical manifestations in patients with SSc.

Methods: We studied 46 patients with SSc who underwent clinical examination, pulmonary function tests and echocardiography. Serum VEGF-A and VEGFR2 levels were determined by ELISA in 46 SSc patients and 20 healthy controls.

Results: Mean VEGF levels were increased in SSc patients compared to controls (212.35±253.93 and 97.74±71.46 pg/ml, respectively; p=0.032). Patients with limited cutaneous SSc (n=23) had higher levels of serum VEGF than those with diffuse cutaneous SSc (n=23) (267.11±268.74 vs 120.40±141.09 pg/ml; p=0.012). Patients with fingertip ulcers (n=18) were found to have higher levels of VEGF than pts without fingertip ulcers. (n=27) (214.25±265.93 vs 162.88±198.97) but this difference wasn’t significant. Serum VEGF levels were higher in SSc patients with sPAP >30 mmHg than in those with sPAP ≤30 mmHg (286.51±287.42 vs 92.88±108.06 pg/ml; p=0.0042) and correlated with sPAP values (R=0.40; p=0.007). Mean VEGF levels in patients with DLCO ≤50% (n=14) were significantly higher than those with DLCO >50% (n=30): 364.20±381.95 vs 128.55±142.70 pg/ml, respectively (p=0.034). There weren’t significant differences in VEGF levels between patients with FVC <80% (n=11) and those with FVC >80% (219.15±252.57 vs 154.26±206.91 pg/ml, respectively).

Mean VEGFR2 levels were also increased in SSc pts compared to controls (5784.6±4773.8 and 1552.6±272.8 pg/ml, respectively; p<0.0001). There weren’t any differences between pts with diffuse or limited SSc. In pts with digital ulcers, or normal levels of sPAP, or DLCO >50% mean VEGFR2 levels didn’t differ from those without digital ulcers, or sPAP >30 mm Hg, or DLCO <50%, respectively. Serum VEGF levels directly correlated with sPAP (R=0.40; p=0.007).

Conclusions: Our findings show significantly higher circulating levels of VEGF and VEGFR2 in SSc patients. Associations of VEGF with some clinical signs indicate its role in pathology of SSc.

Disclosure of Interest: None declared

AB0799 ALTERATIONS OF BODY COMPOSITION IN SCLERODERMA PATIENTS ARE ASSOCIATED WITH DISEASE ACTIVITY AND PHYSICAL ACTIVITY BUT NOT WITH LUNG INVOLVEMENT

S. Oreska1, M. Spiritovic1,2, P. Cesak1, M. Cesak1, H. Storkanova1, H. Smucrova1, B. Hermankova1,2, O. Ruzikova1, H. Manfil1, K. Pavelka1, L. Senoil1, J. Vencovsky1, R. Becvar1, M. Tomcik1. 1Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology, 2Department of Physiotherapy, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

Background: Systemic sclerosis (SSc) is characterised by fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal and lung involvement, which limit mobility/self-sufficiency of patients and can have a negative impact on body composition and physical activity.

Objectives: To assess body composition and physical activity of SSc patients and healthy controls (HC).

Methods: 59 patients with SSc [50 females; mean age 52.5; disease duration 6.7 years; limited cutaneous (lcSSc, 34]/diffuse cutaneous (dcSSc, 25) and 59 age-/ sex-matched HC (50 females, mean age 52.5) without rheumatic diseases were
included. SSc patients fulfilled ACR/EULAR 2013 criteria. Anthropometric parameters and body composition were assessed (by densitometry: IDXA Lunar, and by bioelectric impedance: BIA). Body mass index (BMI) was calculated. Relative skeletal muscle mass index (RSMI) <5.5 Kg/m² for women and <7.26 Kg/m² for men. The aim of the study was to evaluate the associations between sarcopenia and other clinical factors in SSc patients.

Methods: 20 female patients fulfilling the ACR 2013 criteria for SSc (mean age 61.7±13.6 years, disease duration 86.2±67.1 months) were enrolled. The RSMI (Kg/m²) was evaluated by dual-energy X-ray absorptiometry scan (Lunar Prodigy). Nail fold videocapillaroscopic (NVC) patterns (early, active, late) were analysed. Serum 25(OH)D concentration was tested by immunofluorescence. Non-parametric statistical tests were used.

Results: Patients showed a modified Rodnan skin score (mRSS) 12.2±7.7. RSM 6.01±9.7 Kg/m², serum vitamin D (25(OH)D) 22.01±13.1 ng/dL and CPK 70.16±31.8 U/L. In this cohort 23% of SSc patients were found affected by sarcopenia, and almost 42% showed the most advanced level of microvascular damage, as characterised by the NVC late pattern. However, no statistically relevant correlations was observed between RSmi, BMI, age, disease duration, CPk, mRSS, 25(OH)D and active or late NVC patterns. Comparing age, disease duration, CPk and mRSS in both sarcopenic and non sarcopenic SSc patients there was no difference between the groups, however sarcopenic patients showed statistically significant lower BMI (p=0.02), lower RSMi (p=0.0008 and higher 25 (OH)D serum concentrations (p<0.01). Particularly, RSmi showed a strong negative correlation with age (p=0.01). No statistical differences were found when grouping the patients according to the positivity for serum anti-topoisomerase I Abs or according to cutaneous diffuse (dcSSc) or limited (lcSSc) systemic sclerosis. Conclusions: This pilot study suggests that sarcopenia seems present in almost 25% of the SSc patients, particularly in a condition of advanced microcirculation damage (late NVC pattern), however does not seem to correlate with skin fibrosis or disease duration. The study had some limitations due to absence of control group and to the small patient sample analysed. Further larger studies would be necessary to better investigate the role of sarcopenia in SSc.

REFERENCE:
about the association between systemic sclerosis (SSc) and osteoporosis (OP) are controversial and scarce about the risk factors of OP in SSc.1,2

Objectives: The aim of the study was to determine the OP frequency in SSc and assess its risk factors.

Methods: In a prospective cohort of SSc patients, usual risk factors of OP were assessed, as well as SSc organ involvements: pulmonary, cardiac, skin and renal involvements and SSc treatments. All patients underwent dual energy X-ray absorptiometry: bone mineral density (BMD) was measured at the lumbar spine (LS), femoral neck (FN) and total hip (TH). Osteoporosis was defined as having a T-score inferior to −2.5.

Results: Forty-eight patients were included with a median age of 60 years,7–81 women (85.4%), with a diffuse cutaneous subtype in 13 cases (27.1%) and illness duration of 12.6 years (0.3–41). Average BMD was 0.98±0.21 in LS, 0.84 ±0.13 in FN and 0.86±0.15 in TH. OP was found in 19 patients (40%). Among patients with OP, an associated autoimmune disorder was found in 13 patients (68.4%) versus 10 (34.5%) in the non-OP group (p=0.04), digestive sub-occlusion in 4 patients (21% versus 0 patients, p=0.02), and chronic liver disease in 6 patients (31.6%) versus 2 (6.9%, p=0.04). Respiratory explorations found a DLCO in 4 patients (21% versus 0 patients, p=0.02); with a higher frequency of hand X-ray erosions (6 OP patients (31.6%) versus 2 (6.9%, p=0.04). No difference was found in Rodnan score, SSc subtype, ILD pattern and all who worsened had UIP. Though there were numerical differences in the mean values of FEV1 and FVC between two groups (NSIP and UIP), it was not statistically significant (paired ‘t’ test, p>0.05). There was no significant difference in FEV1 and FVC values with treatment between the three groups (one way ANOVA test).

Conclusions: Osteoporosis was associated with SSc-related factors such as: articular, digestive and respiratory involvements, and associated auto-immune diseases. Usual OP risk factors where not significantly different between osteoporotic SSc patients and non-osteoporotic patients.

A REAL LIFE EXPERIENCE ON THE EFFICACY AND SAFETY OF MYCOPHENOLATE MOFETIL IN CONNECTIVE TISSUE DISORDER ASSOCIATED INTERSTITIAL LUNG DISEASE – A RETROSPECTIVE STUDY

S. Santhanam1, V. Rahulan2, 1Rheumatology; 2Pulmonology, Gleneagles global hospital, chennai, India

Background: Interstitial lung disease (ILD) is one of the common extra articular manifestations of various connective tissue disorders (CTD). We don’t have enough evidence on the drugs used, except for ILD in systemic sclerosis and the results of the same has been extrapolated to other diseases. Mycophenolate mofetil (MMF) has antiproliferative and anti-fibrotic action in addition to anti-inflammatory property and hence we wanted to study the efficacy and safety of MMF in our diverse cohort of CTD-ILD.

Objectives: To study the efficacy and safety of mycophenolate mofetil (MMF) in a diverse cohort of patients with connective tissue disease (CTD) associated interstitial lung disease (ILD).

Methods: This is a retrospective observational study with records of outpatients with CTD associated ILD were screened from Oct 2014 to Dec 2017. Among them, patients with imaging (HRCT chest) documented ILD were included. All patients underwent detailed clinical assessment, serological investigations (baseline blood test, erythrocyte sedimentation rate, C-reactive protein, rheumatoid factor, ACPA Ab, antinuclear antibody, ANA profile, complements), urine routine, pulmonary function test (PFT), HRCT chest and echocardiogram. The response of ILD to treatment (follow up of 2 years) was assessed clinically, radiologically and by PFT.

Results: 54 patients were identified with CTD-ILD of which 33 patients were on MMF. 13 patients were diagnosed with MCTD, 12 with RA, 3 with diffuse cutaneous systemic sclerosis, 2 with SSc/myositis overlap, 1 with primary sjögren’s syndrome, 1 with SLE/Sjögren’s overlap and 1 with lung dominant CTD (Scl 70+ve). The cohort was divided into 3 groups – MCTD, RA and others (SSc predominant). Among patients with CTD-ILD, 10 had NSIP pattern of ILD, 3 UIP. In RA, 7 had NSIP and 5 UIP and among others 7 NSIP and 1 UIP. The mean FEV1 and FVC values over 2 years and the treatment response has been discussed in table 1 and Figure 1.

FEV1 and FVC had high positive correlations (Pearson correlation, p<0.05) with treatment for all groups of diseases. The values go together in the positive direction with treatment. Among the groups, all patients who improved had NSIP pattern and all who worsened had UIP. Though there were numerical differences in the mean values of FEV1 and FVC between two groups (NSIP and UIP), it was not statistically significant (paired ‘t’ test, p>0.05). There was no significant difference in FEV1 and FVC values with treatment between the three groups (one way ANOVA test).

Abstract AB0803 – Figure 1

Conclusions: Treatment with MMF over a median duration of 24 months stabilised the ILD in majority, MMF appears to be efficacious, safe and well tolerated in our diverse cohort of CTD-ILD and needs to be evaluated further in prospective studies with a bigger sample size.

Abstract AB0803 – Table 1
THE RELATIONSHIP BETWEEN AUTOANTIBODIES AND CLINICAL FEATURES AND OUTCOME IN THE IMPACT OF DYSPHAGIA IN IDIOPATHIC LUNG DISEASE (ILD) AND HAD A HIGHER KL-6 VALUE AT ONSET (P < 0.05). IN MULTIVARIATE ANALYSIS, FACTORS RELATED TO MORTALITY IN SRC WERE OLDER AGE AT ONSET, MALE GENDER, TREATMENT WITH CYCLOSPORINE, dCSc SUBSET, INTERSTITIAL LUNG DISEASE, PULMONARY ARTERIAL HYPERTENSION, HEART INVOLVEMENT, AND THE MODE OF ONSET WITH NON-RAYNAUD’S PHENOMENON, ESPECIALLY IN THE FORM OF PULMONARY INVOLVEMENT. THE MODE OF ONSET SHOULD BE CONSIDERED AN INDEPENDENT PROGNOSTIC FACTOR IN SRC. THE SURVEY OF SRC RELIES ON AGGRESSIVE BLOOD PRESSURE CONTROL WITH AN ACEI, COMBINED WITH ANTI-HYPERTENSIVE DRUGS IF NEEDED.

THE IMPACT OF DYSPHAGIA IN IDIOPATHIC INFLAMMATORY MYOSITIS: AN ONLINE SURVEY OF HIGHLY-SPECIALISED CENTRES

S. Barsotti1, 2, C. Cavazzana1, R. Neir2, L. Cavagna1, F. Iannone3, C. Montecucco4, A. Tincani3, F. Franceschini5, M. Mosca6, 1Division of Medical Biotechnologies, University of Siena, Siena, 2Rheumatology Unit, University of Pisa, Pisa, 3Rheumatology Unit and Chair, ASST Spedali Civili and University of Brescia, Brescia, 4Rheumatology University and IRCCS, Policlinico S. Matteo Foundation, Pavia, 5Rheumatology Unit – DETO, University of Bari, Bari, Italy

Background: Dysphagia represents a frequent and disabling symptom in patients with idiopathic inflammatory myopathies (IM). Despite this, there are not widely accepted diagnostic and therapeutic guidelines for dysphagia in IM.

Objectives: This study is aimed at surveying the approach to dysphagia in IM patients in European and worldwide highly-specialised centres.

Methods: An anonymous on-line survey was designed and clinicians from European Union (EU) countries, and countries from North and Central America and South Korea were invited via email to participate. The questionnaire included 11 items about the characteristics of the hospital of the responder, the evaluation of the impact of dysphagia on disease severity, the diagnostic and therapeutic approach to dysphagia.

Results: Between December 2017 and January 2018, 52 clinicians from different centres working in 21 different countries (18 EU countries, 3 non-EU countries) completed the survey. The total number of patients followed in the participating centres was 581 with an average number of patients followed in each centre of 75 (±83). The majority of centres followed only adult patients, 26% only paediatric patients (<18 years) and 5 both. The impact of dysphagia on disease severity was considered severe by all the participants with a mean VAS score of 7.3. All but one centre routinely ask the patients for the presence of dysphagia during the clinical examination. The assessment of dysphagia is performed using validated PRO questionnaires in only 7 centres (SWAL-QOL 2 centres, EAT-10 2 centres, MDADI 2 centres). 2 centres evaluate dysphagia using a graduate dysphagia scale by means a 10 cm VAS, and 2 routinely screen patients by a functional test (time necessary to drink a glass of water).

Conclusions: This study suggests that the approach to dysphagia is variable, but dysphagia has an impact on IM patients and influences the therapeutic approach.

AB0807 PLATELET INDICES AS MARKERS OF INFLAMMATION IN SYSTEMIC SCLEROSIS

S. Eldessouki Ibrahim1, C. Morad2. 1Ain shams University, Cairo, Egypt; 2Internal medicine, Ain shams University, Cairo, Egypt

Background: Systemic sclerosis (SSc) is a connective tissue disease involving multiple organs with an unknown etiology. Platelet function may be associated with endothelial dysfunction and immune regulatory mechanisms. Recently, an increased tendency to platelet aggregation and enhanced platelet activation have been described in SSc patients, suggesting a role for platelets in the disease itself.1 2

Objectives: To evaluate platelet indices in systemic sclerosis (SSc) patients and identify their clinical significance as novel inflammatory biomarkers in correlation to markers of endothelial dysfunction: vascular endothelial growth factor (VEGF) and flow mediated dilatation (FMD).

Methods: Thirty-five SSc patients were enrolled in addition to thirty-five age and sex matched healthy volunteers as controls. All patients and controls underwent full medical history taking, thorough clinical examination, assessment of severity extent of skin sclerosis using the modified Rodnan skin score, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), complete blood count with special consideration to mean platelet volume (MPV), platelet distribution width and platelets count, assay for serum VEGF concentration, and brachial FMD assessment by colour duplex sonography.

Results: There was a highly significant decrease in the mean MPV in SSc patients compared to the controls (8.65±0.6 fl vs. 9.5±0.52 fl). There was a significant increase in the mean platelet count in SSc patients compared to controls (331.6±56.4×10^3/µl vs. 297.8±64.48×10^3/µl). In SSc patients, a significant negative correlation was found between the mean MPV and each of ESR, CRP and VEGF (r=-0.42–0.368 and –0.55 respectively, p<0.05); and a significant positive correlation was found between the mean MPV and mean FMD (r=0.378, p=0.05). Linear regression test, showed an association between mean MPV and each of ESR and CRP (r=-3.312–2.92 respectively, p<0.05).

Conclusions: MPV levels could be an easily measurable parameter to reflect the inflammatory condition and disease activity in systemic sclerosis patients.

AB0808 MULTICENTRIC STUDY OF SYSTEMIC SCLERODERMA IN TUNISIA

S. Hamman1, S. Bouzamara2, O. Beniche3, A. Barhoumi4, on behalf of The Study Group for Scleroderma, STMI. 1Department of Internal Medicine, CHU F Bourguiba Monastir, Monastir; 2Internal Medicine, military hospital Gabes, Gabes; 3Department of Internal Medicine, CHU T Star Mahdia, Mahdia; 4CHU F Bourguiba, University of Monastir, Monastir, Tunisia

Background: Scleroderma is an autoimmune connective tissue disorder which is characterised by fibrosis of visceral organs, skin and blood vessels. This condition can be localised or systemic. Its estimated prevalence is 250 cases in a million population.

Objectives: The aim of this retrospective multicenter study was to combine clinical characteristics and imaging methods to a composite predictive score.

Methods: Seventy-nine SSc patients received clinical examination and their history was taken. Furthermore, we performed nailfold capillaroscopy (NC), colour Doppler ultrasonography (CDUS) and fluorescence optical imaging (FOI) of the hands at baseline. Newly developed digital ulcers over a period of approximately 12 months were registered. We used criteria with significant (p<0.5) OR values above 3.5 in regard to the development of these new DU to create the score (CIP-DUS, clinical features, imaging, patient history – digital ulcer score)

Results: Twenty-nine percent of the patients developed new DU during follow-up (48.1% diffuse SSc, 18.4% limited SSc). The following criteria were used: SSc diffuse subtype (OR 4.127, p=0.0087), modified Rodnan skin score >8 (OR 9.429 [95% CI: 3.0–29.2], p<0.0001), pulmonary arterial hypertension (OR 6.854 [95% CI: 1.6–29.5], p=0.0088), present digital ulcers or pitting scars at baseline (OR 15.71 [95% CI: 3.3–74.3], p<0.0001), history of digital ulcer or pitting scars (OR 36.15 [95% CI: 2.1–626.9], p<0.0001), NC pattern (OR 18.8 [95% CI: 1.1–326.4], p=0.0035), reduced capillary density (n<7/mm) in digit III of the right hand in NC (OR 9.0 [95% CI: 1.1–73.6], p=0.026), missing initial enhancement in FOI in digit III of the right hand (OR 3.857 [95% CI: 1.2–12.8], p=0.0323), percentage of pathologic (i.e. narrowed or occluded) vessels>35% in CDUS (OR 4.286 [95% CI: 1.5–12.4], p=0.0099). Criteria with greater OR should impact the score to a higher degree so we appointed three points to dichotomous criteria with OR >10, two points for criteria with OR between 5–10, and one point for criteria with OR <5. According to the NC pattern, 3 points were given to patients with late pattern, 2 points for active and 1 point for early pattern.

Best results were found for a cut-off of >10 points with obtained sensitivity levels of 95% and specificity levels of 74% in regard to new DU (AUC=0.8687, p<0.0001). In the absence of CDUS and FOI data, specificity levels dropped slightly to 72% with unchanged sensitivity values of 95%.
Conclusions: A new score was introduced with the aim to predict digital ulcers. If applied correctly and with the new imaging techniques proposed, 95% of patients at risk of digital ulcers throughout about 12 months could be identified.

AB0810

A COMPARISON OF CLINICAL PRESENTATION AND INCIDENCE RATE OF CARDIOPULMONARY INVOLVEMENT BETWEEN MALE AND FEMALE PATIENTS WITH EARLY SYSTEMIC SCLEROSIS

S. Wangkawis, S. Jungteerabunditki, V. Sawanguard, N. Prasertwittaki, J. Euathrongchit, V. Sawanguard, N. Prasertwittaki, J. Euathrongchit, V. Sawanguard, N. Prasertwittaki

Background: Data regarding the incidence rate (IR) of cardiopulmonary involvement in comparison between male and female patients with early systemic sclerosis (SSc) are limited.

Objectives: To compare the prevalence of clinical manifestations and the IR of cardiopulmonary involvement comparing between male and female patients with early SSc.

Methods: An inception cohort of early SSc patients (disease duration ≤3 years from the first non-Raynaud’s phenomenon) seen at the Rheumatology clinic, Maharaj Nakorn Chiang Mai Hospital, Thailand, between January 2010 and June 2016, was used. All patients were assessed for clinical manifestations and underwent ECG, echocardiography, and HRCT at the study entry and every 12 months thereafter. In the last visit, the cumulative clinical manifestations were recorded. Patients who continue to follow up at least 12 months were included for analysis.

Results: One hundred and fifteen patients (89 dcSSc) with a mean (SD) disease duration of 11.6 (8.8) months at cohort entry were enrolled during a mean (SD) observation period of 3.8 (1.6) years. There were 46 male patients (40%). Tests for anti-topoisomerase I and anti-centromere antibodies were positive in 91 (79.1%) and 7 (6.1%) patients, respectively. The male group had higher prevalence of dcSSc subtype (93.1% vs. 69.5%, p=0.006) and positive test for anti-topoisomerase I antibody (89.1% vs. 72.5%, p=0.031) compared with the female group. At enrollment, the male group had higher prevalence of hypo-hyperpigmentation (84.8% vs. 65.2%, p=0.021), suspected myositis (26.1% vs. 10.1%, p=0.024), and right ventricular dysfunction (8.7% vs. 0%, p=0.024) compared with the female group. In the last visit, the male group had higher cumulative prevalence of digital ulcer (47.8% vs. 27.5%, p=0.06), telangiectasia (93.5% vs. 69.8%, p=0.002), joint contracture (69.6% vs. 43.5%, p=0.006), tendinosis (50 mmHg vs. 39.19 per 100 person-years, p=0.022) compared to the female group. The male group had significant higher IR of right ventricular dysfunction (8.21 vs. 69.6%, p=0.002), joint contracture (69.6% vs. 43.5%, p=0.006), tendon friction rub (34.8% vs. 27.5%, p=0.026), telangiectasia (93.5% vs. 72.7%, p=0.001) compared with the female group. The male group had significant higher IR of right ventricular dysfunction (8.21 vs. 69.6%, p=0.002), joint contracture (69.6% vs. 43.5%, p=0.006), tendon friction rub (34.8% vs. 27.5%, p=0.026), telangiectasia (93.5% vs. 72.7%, p=0.001) compared with the female group. The male group had significant higher IR of right ventricular dysfunction (8.21 vs. 69.6%, p=0.002), joint contracture (69.6% vs. 43.5%, p=0.006), tendon friction rub (34.8% vs. 27.5%, p=0.026), telangiectasia (93.5% vs. 72.7%, p=0.001) compared with the female group. The male group had significant higher IR of right ventricular dysfunction (8.21 vs. 69.6%, p=0.002), joint contracture (69.6% vs. 43.5%, p=0.006), tendon friction rub (34.8% vs. 27.5%, p=0.026), telangiectasia (93.5% vs. 72.7%, p=0.001) compared with the female group. The male group had significant higher IR of right ventricular dysfunction (8.21 vs. 69.6%, p=0.002), joint contracture (69.6% vs. 43.5%, p=0.006), tendon friction rub (34.8% vs. 27.5%, p=0.026), telangiectasia (93.5% vs. 72.7%, p=0.001) compared with the female group.

Conclusions: The male group had significant higher IR of right ventricular dysfunction (8.21 vs. 69.6%, p=0.002), joint contracture (69.6% vs. 43.5%, p=0.006), tendon friction rub (34.8% vs. 27.5%, p=0.026), telangiectasia (93.5% vs. 72.7%, p=0.001) compared with the female group.

AB0812

ULTRASONOGRAPHY FOR THE ASSESSMENT OF SKIN IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW

T. Santiago1,2, M. Santiago2, B. Ruardy1, M. Cutedoil, J.A. Pereira da Silva1, R. Rheumatology Department, Centro Hospitalar e Universitario de Coimbra, Portugal, 2Faculty of Medicine, University of Coimbra, 3Centro Hospitalar e Universitario de Coimbra, Portugal, Coimbra, Portugal, 4Research Laboratories and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic, Genova, Italy

Background: Skin involvement is the clinical hallmark of systemic sclerosis (SSc). A palpation-based semi-quantitative tool, the modified Rodnan skin score, is the current gold standard for the assessment of skin involvement. However, this method has significant limitations, with emphasis on low sensitivity to change and a high inter-observer variability. Ultrasonography has been explored, in the past decades, as a basis for more objective, sensitivity and reproducible measure of skin involvement.

Objectives: To identify and synthesise the best available evidence on the use of ultrasonography as a source of skin outcome measures in patients with SSc.

Methods: Two independent reviewers systematically searched PubMed MEDLINE and Embase (up to December 2017). A study was eligible if it included at least one defined group of patients with SSc, and reported a structured evaluation of the skin with ultrasound and/or ultrasound elastography. This search was augmented by review of bibliographic references from the included studies. The same two reviewers independently extracted the data and classified the quality of evidence of the included studies by the Effective Public Health Practice Project system.

Results: A total of 30 studies (21 observational cross-sectional and 9 longitudinal) were included. They enrolled a total of 1171 SSc patients, mostly middle-aged, female and with a limited form of SSc (59%). The most common ultrasound outcome measure used was skin thickness (in 28 studies), although the definition of this parameter was a highly heterogeneous. Other outcome measures were echogenicity (in 7), and/or stiffness (in 6) and/or vascularity (in 1). There was a substantial discordance in the number and exact location of skin sites examined. The main comparator was global and site specific mRSS. There was a lack of construct and criterion validity (only 1 study assessed the correspondence between ultrasound measures and histological findings). Few studies reported information about intra- and inter-rater reproducibility, but when reported, it showed excellent results. Data regarding evidence for responsiveness to change and feasability were also scarce.

Conclusions: This systematic review highlights the remarkable literature heterogeneity and limited quality of most reported studies. This hinders the evidence currently supporting the use of skin ultrasound evaluation in clinical practice, but the very promising data (e.g good reliability and early detection of skin involvement) support its use in clinical research. Further well-designed and dimensioned studies are needed to support the role of skin ultrasound assessment in the early diagnosis and monitoring SSc patients. These may be crucial to improve our
understanding the disease process and to foster the development of much-needed new intervention strategies.

SEVENTEEN MYOSITIS AUTOANTIBODIES: SEROLOGICAL PROFILE OF HISPANIC PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

Rheumatology and Immunology UANL, UANL, MEDICAL UNIVERSITY, Monterrey, Mexico

Background: The idiopathic inflammatory myopathies (IIM) are a heterogeneous group of subacute, chronic, or acute acquired diseases of skeletal muscle, they can be classified into the following clinical pathologic groups: dermatomyositis (DM), polymyositis (PM), and inclusion body myositis (IBM) which differ in clinical presentation, season of onset, genetics, and prognosis.1 Furthermore, the seropositivity of antibodies in these diseases can help to predict the evolution of the disease, and influence therapeutic strategies.2 3 Anti-Mi-2 is a classic marker for DM and its associated with good response for steroid treatment and good prognosis. Anti-SRP is specific for PM and its associated with treatment-resistant myopathy, histologically characterised as necrotizing myopathy. Several new myositis specific antibodies (MSA), autoantibodies with strong clinical significance have been described in IIM manifestations.2 The literature about this topic is limited in Hispanic population. This study represents an effort for a better understanding of this group of diseases.

Objectives: To determine the prevalence of myositis specific and myositis associated antibodies in a cohort of patients with idiopathic inflammatory myopathies, who were treated from January 2016 to January 2018 in a Rheumatology Service from a University (Hospital Jose E. Gonzalez) from UANL and a centre for arthritis at north of Mexico.

Methods: Cross-sectional, retrospective descriptive study cohort of 95 patients who attended the rheumatologic clinic in the period from January 2016 to January 2018 who met Bohan and Peter’s classification criteria. The determination of antibodies was performed by the Immunoblot technique with Euroimmun kit. The following serotypes were included: OJ, Ro 52, Mi2α, MDA-5, TIF 1 gamma, PM/Scl 100, Ku, Jo1, EJ, chN1A, NXP2, SAE 1. Statistical analysis was performed with univariate, for the categorical variables, absolute frequencies and percentages were analysed and for the numerical means and standard deviation with the SPSS V22 (Armonk, NY: IBM Corp.)

Results: From a cohort of 95 patients, 68.42% were women and 31.57% were men. The average age was 47±15.42. A prevalence of seropositive antibodies were observed for Mi2α of 29 (30.52%), 14 (14.73%) in TIF 1gamma and 12 (12.63%) has positive Mda 5.

*SD: Standard Deviation

Conclusions: The systematic and standardised evaluation of the determination of antibodies in patients with inflammatory myopathies play an important role in the predictive evaluation. Knowledge of the prevalence and clinical scenarios in various cohorts increase the standardisation and prompt use of antibodies in the classification of inflammatory myopathies

SODIUM THIOSULFATE 10% INTRALESIONAL TO TREAT CALCINOSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS AND DERMATOMYOSITIS: CASE SERIES

A.F. Tonial1, M.P.M. Cathcart1, T.A.F. G. Santos1, P.M. Azevedo1, T.L. Skare1, P. Martín1,2, Departamento de Reumatología, Hospital Universitario Evangélico de Curitiba; 1Escola de Medicina, Pontificia Universidad Católica do Paraná, Curitiba, Brazil

Background: Calcinosis is a frequent complication of systemic sclerosis and dermatomyositis, causing local pain, joint mobility reduction, ulcers, secondary infections and disability. Currently, there is no effective treatment to calcinosis, but the use of topical dressing or intralesional sodium thiosulfate (STS) has showed promising results.

Objectives: To evaluate efficacy of intralesional STS 10% in calcinosis of patients with dermatomyositis and systemic sclerosis.

Methods: Prospective and open-labeled study including dermatomyositis and systemic sclerosis patients with calcinosis. The primary endpoints were: pain relief evaluated through visual analogue scale (VAS) and reduction of major diameters of calcinosis in x-ray. The secondary endpoints were: improvement in the quality of life and function evaluated by SF12 and HAQ respectively.

Results: A total of 10 calcinosis from 7 patients, one with dermatomyositis and 6 with systemic sclerosis were treated. The average dosage of STS per application was 9.27 mg at intervals ranging between 15 and 30 days (mean=17.85) between each injection. The number of injections per each calcinosis ranged between 3 and 8 (mean 3.3). All patients reported improvements in pain, however the results were not statistically significant (table 1). There were no reductions in calcinosis diameters, nor improvement of quality of life and function.

Conclusions: Low doses of sodium thiosulfate applied through intralesional injections, in a restrict number of applications and long intervals were not effective to treat calcinosis.

Abstract AB0815

HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS TREATED WITH TWO DIFFERENT INTRAVENOUS ILOPROST REGIMENS

T. Schioppo1, L. Scalone2,3, P. Cozzolino2, L. Mantovani2,3, G. Cesana2, O. De Lucia3, A. Murgo3,1, F. Ingegnoli1,4. 1Rheumatology, Pini, Milan; 2CESP, University of Milan Bicocca, Monza; 3Fondazione CHARTA; 4University of Milan, Milan, Italy

Background: In systemic sclerosis (SSc), Raynaud’s phenomenon (RP) and digital ulcers (DU) can decrease health related quality of life (HRQoL). Intravenous (IV) iloprost (ILO) is administered for RP, after oral therapy failure, and DU healing. HRQoL is considered fundamental to assess the impact of the disease and therapy on patients: EQ-5D-5L has been satisfactorily used to assess the general HRQoL in SSc.

Objectives: Aim of our study was to estimate HRQoL in SSc patients treated with two different IV ILO regimens and in patients not requiring IV ILO.

Methods: This was a monocentric, prospective, pragmatic and non-randomised study. Enrolled SSc patients were divided into 3 groups: no IV ILO (group A), IV ILO once monthly (B) or IV ILO for 5 consecutive days every 3 months (C). HRQoL was assessed using EQ-5D-5L through a telephone interview. Group A patients were evaluated at baseline and after 3 months; group B 2 days before each infusion and 2 weeks after each infusion; group C 2 days before each therapy cycle, and after 2 and 6 weeks after the first cycle of therapy. The EQ-5D-5L describes HRQoL, measures the overall health state with a 0-100 visual analogue scale (VAS) and values health with a utility index. Multiple regression analyses was performed to calculate VAS and mean utility index in each group (confounders: age, sex, treatment group, baseline utility or VAS score, average outdoor temperature the week before the evaluation at patient’s place of residence, RP VAS, disease duration and modified Rodnan skin score).

Results: 96 patients were enrolled: 52 in group A, 24 in B, and 20 in C. Of these 35, 21 and 16 completed the study respectively. Utility and VAS score at the end of the three months, as adjusted for the possible confounders, were not statistically different in the three groups.

Conclusions: Utility and VAS, at 3 months follow-up, were not different in the 3 groups as if IV ILO was able to make patients requiring IV ILO as similar as patients not requiring IV ILO. Moreover, in this model there was no difference between the two ILO regimens (1 days monthly vs 5 every 3 months). These results suggest that our therapeutic approach, based on various criteria such as demographic, clinical characteristics, logistic aspects and patients’ preferences, allows to reach or to maintain HRQoL at comparable levels between the three groups considered.

Abstract AB0817

PROLIFERATIVE NAILFOLD CAPILLARY AVASCULAR AREA PREDICTS MALIGNANCY IN PROGRESSIVE SYSTEMIC SCLEROSIS

W.-N. Huang1,2, Y.-M. Chen1,2,3, W.-T. Hung1, C.-W. Hsieh1, C.-T. Lin1, Y.-H. Chen1,2, 1Allergy, Immunology And Rheumatology, Taichung Veterans General Hospital, Taichung; 2Faculty of Medicine, National Yang Ming University, Taipei; 3Institute of Biomedical Science, National Chung Hsing University, Taichung, Taiwan, Province of China

Background: Systemic sclerosis (SSc) is an autoimmune disease characterised with proximal scleroderma and internal organ involvement. Observational studies demonstrated increased incidences of cancer in SSc patients. Nailfold capillaroscopy is useful for the diagnosis and disease activity assessment of SSc.

THE COMPARATIVE STUDY OF SYSTEMIC SCLEROSIS AND SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

Y. Feng, J. Wang, Y. Lei, X. Zhang, Department of Rheumatology, Guangdong Academy of Medical Sciences/Guangdong General Hospital, Guangzhou, China

Background: Systemic Sclerosis (SSc) is the main cause of Connective Tissue Disease-associated pulmonary arterial hypertension (CTD-PAH) in western countries, while Systemic Lupus Erythematosus (SLE) is the first cause in Asian. Systemic Sclerosis (SSc) is the main cause of Connective Tissue Disease-associated pulmonary arterial hypertension (CTD-PAH) in western countries, while Systemic Lupus Erythematosus (SLE) is the first cause in Asian.

Objectives: This study aimed to identify the clinical difference between SSc-PAH and SLE-PAH. This study aimed to identify the clinical difference between SSc-PAH and SLE-PAH.

Methods: SSc and SLE patients with pulmonary arterial hypertension who visited Guangdong General Hospital in China from 2009 to 2017 were recruited. PAH was diagnosed by transthoracic echocardiography or right heart catheterization and clinical data of patients was collected. Comparative study between SSc-PAH and SLE-PAH was conducted to identify the difference.

SSc and SLE patients with pulmonary arterial hypertension who visited Guangdong General Hospital in China from 2009 to 2017 were recruited. PAH was diagnosed by transthoracic echocardiography or right heart catheterization and clinical data of patients was collected. Comparative study between SSc-PAH and SLE-PAH was conducted to identify the difference.

Results: Twenty-nine SSc-PAH and 55 SLE-PAH patients were enrolled. The baseline characteristics of two groups was shown in Table 1. In comparative study:

<table>

</tbody>
</table>

Conclusions: Rheumatologists should be aware of malignancy in SSc patients, especially those with diffuse type and within the 1st year of symptoms onset. SSc patients with malignancy tend to present atypical capillaroscopic pattern of prominent avascular area without loop dilatation, microhemorrhage and angiogenesis.

AB0819 TFH CELLS CONTRIBUTE TO ABNORMAL B CELL PROFILES IN DERMATOMYOSITIS

X. Zhang, X. Ma, H. Wang, Z. Chen, L. Sun, Department of Rheumatology And Immunology, THE AFFILIATED DRUM TOWER HOSPITAL, NANJING UNIVERSITY MEDICAL SCHOOL, NANJING, CHINA., Nanjing, China

Background: CD4+CXCR5+PD-1+T follicular helper (Tfh) cells assist B cells in their proliferation, differentiation and antibody class switch. Several studies indicate that Tfh cells play important roles in autoimmune diseases such as SLE, RA and pSS, which are characterised by the production of multiple antibodies.

The frequency of Tfh cells in the peripheral blood from patients with dermatomyositis (DM) and whether they participate in the development of DM remain to be elucidated.

Objectives: To investigate the frequencies of Tfh cells and B cell profiles in DM patients. To further determine the association of Tfh cells and B cells in DM patients and clarify the possible mechanism.

Methods: Peripheral blood mononuclear cells (PBMCs) were isolated from DM patients and age, gender-matched healthy controls (HCs), respectively. The frequency of Tfh cells (CD4+CXCR5+PD-1+) and B cells (CD19+) were examined by flow cytometry. The serum levels of IL-21, IgG, IgM, IgE and IgA were tested by enzyme linked immunosorbent assay (ELISA).

Tfh: transthoracic echocardiography; PASP: pulmonary arterial systolic pressure; RA: right atrium; RV: right ventricle; LVEF: left ventricle ejection fraction; RHC: right heart catheterization; PAH: pulmonary arterial pressure; PVR: pulmonary vascular resistance; CI: cardiac index.

Disclosure of Interest: None declared
Results: The percentages of circulating Tfh cells are significantly higher in DM patients than HCs (p<0.0001). Compared to HCs, the absolute numbers of circulating Tfh cells also upregulate markedly in DM patients (p<0.0001). The mRNA expression levels of Bls-6, a typical transcription factor of Tfh cells, increase appa- rently in PBMC from DM patients (p<0.05). Serum levels of IL-21, a Tfh-specific cytokine, are obviously higher in DM patients (p<0.01). The percentages of total B cells (p<0.01) and Naive B cells (p<0.01) upregulate significantly in DM patients, while Memory B cells (p<0.05) downregulate markedly when compared with HCs. The absolute numbers of plasmablasts (p<0.05) and Naive B cells (p<0.05) increase notably while memory B cells decreased obviously (p<0.01). Serum lev- els of IgG (p<0.01), IgG (p<0.0001), IgG (p<0.01) and IgG (p<0.05) are obviously higher in DM patients (p<0.05). The frequencies of Tfh cells are positively corre- lated with total B cells (r=0.633, p<0.001) and Naive B cells (r=0.643, p<0.01).

Conclusions: Tfh cells may contribute to abnormal B cell profiles and antibodies production in DM and participate in the pathogenesis of DM. Tfh cell-targeted ther- apy might be a potential strategy for DM.

AB0821 EARLY DETECTION OF THE CHANGES IN PULMONARY ARTERIAL PRESSURE AND VASCULAR FUNCTIONS IN SYSTEMIC SCLEROSIS: EXPLORING NON-INVASIVE CLINICAL TEST METHODS AND UNDERLING GENE EXPRESSIONS

Y. Koyama1, S. Fuke2, T. Ohno3, Y. Sato4, T. Higuchi. 1. Center for Autoimmune Diseases, Division Of Rheumatology, 2Department of Cardiology, 3Department of Dermatology, Japanese Red Cross Okayama Hospital, Okayama, 4DNA Chip Research Inc, Tokyo, Japan

Background: Pulmonary arterial hypertension (PAH) is prominent as a vascular involvement in systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. Although recent studies focused on early diag-nosis of established PAH, it is known that more than a half of the pulmonary circu-lation is impaired before early PAH is detected. However, there is little study about the changes of vascular functions or the underlying gene expressions during its subclinical stage.

Objectives: I. To detect the pathological changes in pulmonary arterial pressure (PAP) and vascular functions before PAH is manifested. II. To explore the changes in its underlying gene expressions of peripheral blood.

Methods: Total of 103 cases without PAH symptoms (NYHA I) with either Ray- naud phenomenon (RP: n=87), skin sclerosis (n=65) or SSc-related autoantibody (n=68) were enrolled. To detect the pathological change of PAP, exercise Doppler echocardiography was carried out, and exercise induced pulmonary hypertension (exPH) group was segregated from normal response group (exN) with using the definition described in R. Naeije et al.1 Vascular function was evaluated with ther- mometry after 0°C-stress and determination of ankle-brachial index (ABI) and cardio-ankle vascular index (CAVI). Furthermore, reactive hyperemic index (RHI), augmentation index (AI) and second derivative of photoplethysmogram ageing index (SDPTGAI) were assessed with using EndoPAT. Micro-vascular changes were also recorded with nailfold videocapillaroscopy. Meanwhile, genome-wide gene expression analysis was performed with using whole peripheral blood. The genes correlated with each vascular function tests were analysed by weighted gene co-expression network analysis (WGCNA) and pathway enrichment analy- sis (PathVisio).

Results: There were significant differences between exPH and exN group in the result of thermography after 0°C-stress test, CAVI and AI normalised to heart rate of 75bpm (AI@75bpm). As the CAVI and AI are known to correlate positively with age, careful interpretation was necessary because the mean age of exPH group was higher as compare with exN group (69.05±11.04 vs. 60.23±14.73). However, the fact that recovery of blood-flow from RP was significantly delayed in exPH group suggested the additional pathological changes of vascular and endothelial functions. Gene expression analysis revealed that several mutual pathways such as “type2 interferon signalling”, “oxidative damage” and “fatty acid omega oxida- tion” were revealed to underlie some vascular changes.

Conclusions: The results of vascular function tests including thermography after 0°C-stress, CAVI and AI@75bpm were significantly different between exPH and exN group. On the other hand, gene expression analysis showed that many factors such as ageing, arteriosclerotic and immunological mechanisms were involved in the changes of these vascular functions. Although further prospective study is required to select appropriate set of the tests, it is possible that evaluation of these vascular functions may be useful as a non-invasive test to assess the pul- monary vascular disease before PAH is manifested.

AB0822 A MEASUREMENT OF ANTI-ARS ANTIBODIES, ANTI-MI-2 ANTIBODY, ANTI-TIF1 GAMMA ANTIBODY AND ANTI-MDA5 ANTIBODY BY ENZYME-LINKED IMMUNOSORBENT ASSAY AS A DIAGNOSTIC TOOL OF IDIOPATHIC INFLAMMATORY MYOPATHY AND RHEUMATOLOGY DAILY PRACTICE

Y. Miyoshi1,2, T. Kise1, N. Yokogawa1, K. Shimada1, S. Sugii1, 1Department of rheumatic diseases, Metropolitan Tama Medical Center, Fuchu, Tokyo; 2Department of rheumatic diseases, Tama-Hokubu medical center, Higashimurayam, Tokyo, Japan

Background: Enzyme-linked immunosorbent assay (ELISA) tests of anti-ARS antibodies, anti-Mi-2 antibody, anti-TIF1γ antibody and anti-MDA5 antibody
became available at daily clinical practice on Oct. 2016 in Japan. Diagnostic accuracy study of myositis-specific autoantibodies (MSAs) except for anti-Jo-1 antibody in daily clinical practice was recorded.

Objectives: This study investigated the diagnostic utility of newly available myositis-specific autoantibodies (ELISA in idiopathic inflammatory myopathy (IIM) suspected patients at a rheumatology clinic with muscle and skin biopsy as a reference standard.

Methods: This study is a retrospective, cross-sectional study. The electrical medical records of patients who visited the department of rheumatic diseases at Tokyo Metropolitan Tama Medical Centre between Nov. 2016 and Aug. 2017 were retrospectively searched for clinical variables and laboratory data. Patients with serum creatine phosphokinase (CK) greater than two-fold of normal upper limit (over 300 IU/ml) or suspected dermatomyositis skin rash were included. Anti-ARS antibodies, anti-Mi-2 antibody, anti-TIF1γ antibody and anti-MDA5 antibody were measured by ELISA. Two muscle pathologists interpreted muscle biopsy. The skin biopsies with interface-dermatitis were considered positive. The biopsy results of patients who did not have biopsy procedure but whose symptoms and signs improved without immunosuppressive therapy were assumed negative. IIM diagnosis was based on 2017 EULAR/ACR classification criteria. We calculated likelihood ratio of MSAs for biopsy results and IIM diagnosis.

Results: Eight hundred and eighty-six new patients visited an outpatient clinic of rheumatic disease department and 38 patients met inclusion criteria. 14 patients were excluded because of apparent causes (1 each for sepsis, rhabdomyolysis, macro CK, serotonin syndrome, motor neuron disease, statin myopathy, SSc, idiopathic IP, seborrhoeic dermatitis, 3 for symptoms not compatible with IIMs.) and were excluded because of apparent causes (1 each for sepsis, rhabdomyolysis, macro CK, serotonin syndrome, motor neuron disease, statin myopathy, SSc, idiopathic IP, seborrhoeic dermatitis, 3 for symptoms not compatible with IIMs.).

Patients with connective tissue diseases had more anxiety (30.5%) than average duration was 3.78±5.07 years. Mean SAS scores were 43.44±18.51, and mean SDS scores were 46.66±12.43. 35 (22%) of the patients had anxiety, while 6 (3.9%) had moderate anxiety, 50 (32.7%) patients suffered from depression, of which 5 (3.3%) had severe depression, and 13 (8.5%) had moderate depression. Patients with connective tissue diseases had more anxiety (30.5%) than average score (p<0.05), especially in patients with lupus. SDS (B=1.073, p<0.001), educational scale (B=−2.147, p<0.05) contributed to SAS scores.

Conclusions: Psychological disorders could concur with rheumatic diseases, especially in connective tissue diseases. Physicians should be aware of psychological status in these patients.

Disclosure of Interest: None.

AB0824 EVALUATION OF THE DETECTION OF MYOSITIS-SPECIFIC ANTIBODIES BY LINEBLOT AS A TOOL FOR THE CHARACTERISATION OF A PROSPECTIVE MULTICENTER COHORT

Y. Piette,1,2 C. Bonroy,1 J. Dehoorne1, J. De Bleeker1, M. De Stover2, W. Van de Vyver,2 P. Jacques3, S. Vandendriessche1, M. Versese3, F. De Keyster1, V. Smith4, Rheumatology, AZ St.-Jan, Brugge;2Rheumatology, Laboratory Medicine;3Pediatric Rheumatology,4Neurology, Ghent University Hospital, Gent; Praktijk 10A, Maldegem;5Internal Medicine, Ghent University, Gent, Belgium

Background: Traditionally, the diagnosis of idiopathic inflammatory myopathies (IIM) is based on clinical findings, muscle enzyme levels, electromyography and biopsy. Newer approaches include the detection of myositis-specific autoantibodies (MSA), with MSA identified in about 50% of patients.

Methods: A total of 225 samples (118 consecutive routine samples for which MSAs were requested and 107 controls [50 systemic sclerosis (SSc), 28 systemic lupus erythematosus (SLE) and 28 rheumatoid arthritis patients (RA)] was analysed on indirect immunofluorescence (HeP-2000, Immunocconcepts) and lineblot (MYO12 blot, D-Tek). All consecutive samples were retrospectively categorised by the treating medical specialist as definite IIM (n=16), probable IIM (n=10), immune mediated inflammatory disease (IMD) – myositis overlap not excluded (n=28), myopathic features without IIM (n=11), IIM excluded (n=44), and lost from follow-up data available (n=19). Data to calculate the EULAR/ACR probability score were also collected.

Results: MSA were detected in 12% of the 225 samples, showing no multiple reactivities. A sensitivity of 50% in the IIM patients (definite and probable n=13/26 – based on judgement of the clinician) was observed, with the lowest frequencies observed for anti-HMGCR (15%, n=4), anti-Mi2 (12%, n=3) and anti-Jo1 (12%, n=3). Less frequent antibodies were anti-EJ (n=1), anti-MDA5 (n=1) and anti-NXP2 (n=1). All these patients had a MSA-compatible clinical IIM subtype. The median minimal EULAR/ACR probability score was 97% (range 6%–100%, no biopsy data entry), with the lowest score observed in the anti-EJ patient. In contrast, MSA were also observed in 8 patients with no convincing clinical diagnosis of IIM or myositis overlap syndrome (anti-TIF1γ in 4 [5 SSc and 1 SLE]; anti-SSP in 1 [1 RA]; anti-SAE in 3 [1 SSc, 1 RA and 1 IIM excluded], mostly showing low anti-body titres (n=6/8) and no compatible immunofluorescence pattern on HEp-2000 (n=7/8). For 2 other positive samples the results were not conclusive (anti-PL7 in patient with myopathic features and anti-SSP in an unspecified IMID patient).

Conclusions: The detection of MSA by lineblot will be useful for the prospective serological characterisation of patients with clinical suspicion of IIM. Nevertheless, careful interpretation in correlation with the clinical findings and other technical examinations is necessary in case of low titres and absence of a compatible immunofluorescence pattern.

Disclosure of Interest: None.

Managing Systemic Sclerosis: Assessing the Educational Needs of Rheumatologists

Z. Ahmad, S. Johnson. Toronto Scleroderma Program, Division of Rheumatology, Department of Medicine, Sinai Health System, University Health Network, University of Toronto, Toronto, Canada

Background: Systemic sclerosis (SSc) is an uncommon, complex and heterogeneous condition, making it challenging to manage. Individual rheumatologists see relatively few cases and patient surveys identify numerous gaps in clinical care. There are no published data on the educational needs of rheumatologists caring for patients with SSc. We aimed to determine rheumatologists’ self-rated knowledge and learning needs.

Methods: Survey questions were adapted from the EULAR Recommendations for the Treatment of SSc with reference to patient-identified care gaps. The survey was conducted on paper and on SurveyMonkey (a cloud-based online survey development software program). The target audience was Ontario rheumatologists, serving a population of 13.6 million. We sought to explore self-reported knowledge, experience, attitudes and perceived barriers in caring for SSc patients. Physician demographics and preferred educational methods were also collected. Gaps between perceived and desired knowledge were calculated to identify the greatest unmet learning needs.

Results: One hundred and sixteen responses were received with a response rate of 54%. The greatest unmet learning needs were seen in the management of sexual dysfunction (average gap of 1.4 on a 5-point scale), pulmonary hypertension (1.1), interstitial lung disease (1.0) and gastrointestinal manifestations of the disease (1.0). The smallest learning gap concerning screening recommendations (0.7). 19% of rheumatologists agreed with the statement “Scleroderma is an untreatable disease.” Agreement with this statement was high (53%) among rheumatologists who treat relatively small numbers of SSc patients.

Conclusions: We have identified several unmet learning needs regarding the management of SSc among rheumatologists. These can be used to inform future educational resources and programs for rheumatologists regarding SSc and to direct further research into their needs.

Disclosure of Interest: None declared

Profile of Myositis-Specific Antibodies in Patients with Polymyositis/Dermatomyositis and Association with Clinical Manifestations and Outcome: Experience from a Tertiary Referral Centre

Z. Chen, X.-P. Li, X.-M. Li. Rheumatology and Immunology, The First Affiliated Hospital of University of Science and Technology of China, Hefei, China

Background: Myositis-specific antibodies (MSAs) have been found to be associated with distinct clinical phenotype and prognosis in patients with Idiopathic Inflammatory Myopathies (IIM). Our objectives were to assess the profile of MSAs in Chinese patients with polymyositis (PM) or dermomyositis (DM) and explore association of antibody profile with clinical characteristics, laboratory findings and prognosis.

Methods: 90 patients with PM/DM were enrolled. 12 MSAs (mi-2, TIF1γ, MDA5, NXP2, SAE1, Jo-1, SRP, PL-7, PL-12, EJ, OJ) were measured by immunoblotting. Associations between antibody profile and clinical manifestations, laboratory data and outcome were determined.

Results: The study population comprised 20 patients with PM and 70 patients with DM, in which 17 DM patients were identified as clinically amyopathic dermatomyositis (CADM). Overall, the most common MSA was anti-ARS (Jo-1/PL-7/PL-12/OJ) (41.1%), followed by anti-MDA5 (33.3%), anti-SRP (15.6%), anti-NXP2/anti-SAE1 (13.3%), anti-TIF1γ (12.2%) and anti-mi-2/anti-mi-2 (5.6%). Anti-MDA5 antibody was exclusively seen in DM and CADM patients and the prevalence was higher in CADM than in conventional DM (82.4% vs 30.2%, p<0.001). Compared with those who were anti-MDA5 negative, patients with positive anti-MDA5 had more rapidly progressive interstitial lung disease (ILD) and Gottron’s sign (93.3% vs 61.7%, p<0.05; 93.3% vs 38.3% (p<0.001) as well as anti-MDA5-negative disease (70.0% vs 992.5 IU/L, p<0.001). Anti-Jo-1 antibody was more prevalent in PM (55.0% vs 20.8%, p<0.05) and patients with positive anti-Jo-1 demonstrated higher prevalence of mechanic’s hand (18.2% vs 1.5%, p<0.05). Anti-SRP positive patients had higher creatine kinase levels than those with negative, although there is no statistical significance (1649.5 vs 199.0 IU/L, p=0.056). Moreover, high TIF1γ antibody was associated with more frequent tumour (18.2% vs 0.0%, p<0.01). In logistic regression analysis, anti-MDA5 OR=9.601, 95% CI (1.940, 47.515), p<0.01 was an independent risk factor for ILD. During the follow-up period (median 8 months), 13 patients died, among which 9 were anti-MDA5 positive. The survival time of anti-MDA5 positive patients was significantly less than those who were negative (3.0 vs 11.0 months, p<0.01).

Conclusions: Anti-ARS antibodies are the most common MSAs in Chinese PM/DM patients. Anti-MDA5 is predominantly seen in patients with CADM and closely associated with rapidly progressive ILD and high mortality thus serve as a marker of poor prognosis. Anti-TIF1γ positive patients routinely screened for tumours will be of clinical significance.

Spondyloarthropathy – Treatment

AB0827

HPP ARTHRITIS REMAIN FREE FROM RADIOGRAPHIC PROGRESSION FOR 24 MONTHS FOLLOWING TREATMENT OF ANKYLOSING SPONDYLOARTHRITIS WITH TNF-A INHIBITORS: A PROSPECTIVE STUDY

Background: HSP involvement is the most frequent extra-skeletal arthritic manifestation of ankylosing spondyloarthritis (AS). It can be severe and may worsen outcomes for patients. There is a large body of high quality evidence for clinical efficacy of TNF-α inhibitors at treating this condition. However, their structural hip benefit remains unknown.

Objectives: In this prospective study undertaken in Algeria, we aimed to evaluate clinical and structural efficacy of TNF-α inhibitor therapies on non-synostosante hip involvement in AS, for a 24 months period.

Methods: This study pursued a follow-up of patients SA using modified New York criteria or ASSAS criteria. Patients were TNF-α inhibitors naïf diagnosed with SA, with hip involvement (identified using clinical and/or radiological findings). Patients were treated with one of the following: adalimumab, infliximab or etanercept.

Exclusion criteria were: history of tuberculosis, serious infections, hepatitis, neoplasms, other inflammatory conditions, and hip involvement due to any other causes. The following data were collected: clinical rating of hip involvement using the Harris Hip scoring system, biological characteristics (CRP), and radiological characteristics of hip lesions using Bath Ankylosing Spondylitis Radiology Index of the hip (BASRI hip). Specific disease indexes such as BASDAI and BASFI were also collected. Follow up was undertaken at the following time points in months: 0, 3, 6, 12 and 24. Statistical analysis of findings was performed using SPSS 11.0 software.

Results: The study recruited a total of 30 patients, 22 males and 8 females. Mean age was (24.1±3.1 years), Bilateral and unilateral hip involvement were identified in 67% and 33% of patients, respectively. Mean time for appearance of hip lesions was (3.9±2.1 years), HLAB 27 was present in 30% of this study population. Baseline characteristics of hips examined have shown an altered function (Harris Hip mean score of 56.1±5.1) and a relatively advanced structural score (BASRI hip mean score 2.4±1.1). These scores correlated with high disease activity (BASDAI mean score 5.5±1.2) and a poor mean BASFI score (5.4±2.0). This was accompanied by a mean CRP score of 22.1±8.1. Non-steroidal anti-inflammatory drugs were ineffective. During the 24 months treatment period using TNF-α inhibitors, there was a statistically significant improvement in hip scores from the third month onwards with mean Harris Hip scores of 70.3±21.5 (p<0.001), and 81.3±11.5 (p<0.001) at months 3 and 6, respectively. This was maintained until the end of the study period at 94.2±10.5 (p<0.001). There have also been statistically significant improvements in BASDAI and BASFI scores as well as CRP (all p<0.001). Mean BASRI score, however, remained unchanged after 24 months. Treatment was well tolerated, and no significant complications (e.g. serious infections or tuberculosis) were observed. No prosthesis was indicated for any patient.

Conclusions: Hip involvement is associated with severe and rapidly evolving AS. In this study, we have demonstrated improved outcomes and stability of radiographic lesions of hip arthritis for a period of 24 months, when SA was treated with TNF-α inhibitors.

PERSISTENCE ON GOLIMUMAB AS SECOND LINE BIOLOGICAL THERAPY IN PATIENTS WITH SPONDYLOARTHRITIS (AXIAL SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS). GO-BEYOND, A RETROSPECTIVE STUDY

Methods: GO-BEYOND was a retrospective study undertaken in 20 Spanish rheumatology clinics. Information was collected on all axSpA and PsA patients who initiated golimumab between January 2013 and December 2015 as second anti TNF-alpha (i.e. after discontinuation of a first anti TNF-alpha drug) and continued the first anti TNF-alpha due to loss of efficacy or to other reasons. The probability of persistence was similarly high in patients with axial SpA or PsA, and in patients who discontinued the first anti TNF-alpha due to loss of efficacy vs other reasons. Real life effectiveness of golimumab as second anti TNF-alpha is high and durable in SpA patients.

MRI EVALUATION OF THE EFFECT OF ANKYLOSING SPONDYLITIS TREATMENT ON HIP JOINT INVOLVEMENT

E. Agapova1, T. Dubinina2, A. Dyomina2, O. Rumyantseva3, S. Erdes1, Laboratory-Spondyloarthritides; Laboratory of Scientific Organizational Problems in Rheumatology, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Coxitis is one of the leading causes of early disability in ankylosing spondylitis (AS) patients. There’s no mild course of the disease as soon as hip joints (HJ) are involved, but epidemiological surveys in Russia show that only 7% of AS associated hip damage require total hip replacement.

Objectives: To evaluate case follow-up data in treated AS patients with hip involvement using hip MRI and radiography for dynamic assessment.

Methods: 30 AS patients (mean age of 27.7±1.7 y ) meeting modified 1984 N-Y criteria with MRI signs of HJ inflammation were followed up for 2 years. Patients’ mean age at the onset of the disease was 22.3±18.3 years. 77% of the population were HLA-B27 positive. Median AS duration was 47 (12–144) months, and median BASDAI score was 5.9±3.1.

Results: All patients were grouped into three arms based on therapeutic regimens: Group I was administered non-steroidal anti-inflammatory drugs (NSAIDs), Group II – genetically engineered biological agents (GESA) + NSAIDs, and Group III was treated with a combination of GESA+DMARD (methotrexate or sulfasalazine). In case of baseline regimen failure patients from Group III were switched to NSAIDs+DMARD + GESA combination at Mo 6 after initiation of treatment.

</table>

Conclusions: 1. Long-standing MRI symptoms of HJ synovitis should be viewed as the factor predisposing to radiographic progression of coxitis in AS patients.
2. NSAIDs therapy does not modify the radiographic progression of coxitis.
3. GESA+NSAIDs in combination with DMARDs reduce the risk of further radiographic progression.
4. Future studies are warranted to better understand potential factors contributing to radiographic progression.

AB0831
THE INFLUENCE OF REMISIVE AND ANTI-INFLAMMATORY TREATMENT ON AXIAL MOBILITY IN PATIENTS WITH ANKYLOSING SPONDYLARTHITIS
E. Russu, L. Chisari, R. Larisa, V. Cazac. Rheumatology and Nephrology, SMPU "Nicolae Testemitanu", Chisinau, Moldova, Republic of

Background: In advanced ankylosing spondylarthritis (AS), bone ankylosis or ossification of the involved joints can make the chest practically immobilize, decrease its compliance, or even lead to intercostal muscle atrophy.

Objectives: The purpose of the study was to evaluate chest involvement in AS by measuring toracoabdominal movements during quiet breathing, by dividing the chest and abdominal contribution to the current volume, by inductive plethysmography methods.

Methods: 60 consecutive patients were recruited from the Rheumatology Department of the Republican Clinical Hospital. They were selected based on AS diagnosis, with no existing cardiovascular or neuromuscular diseases that would alter respiratory mechanisms and the absence of severe obesity.

Results: Monotherapy with DMARD was 27 out of 60 patients (45%) (Sulfasalazine 3 g/day) for a period of 1—48 months (mean value=19.4 (15.5) months). There were no differences in the angle of the Ct-Abd curve between patients with DMARD and DMARD-naive treatment (39.2 (14.5)° and 34.7 (19.5)° for sitting position, 49.3 (18.1)° and 47.2 (23.1)° in orthostatism, and 19.1 (15.6)° and 16.1 (14.6)° for clinostatism, p<0.05). In the baseline study, the Ct-abd patient angle was lower than the control group in sitting position (36.3 (17.3)° and 51.5 (8.9)°, p=0.0002) in orthostatism (48.1 (20.8)° and 62.4 (12.5)°, p<0.01) or orthostatism (17.4 (15.0)° and 24.5 (9.8)°, p<0.05). In the entire patient group, the Ct-Abd angle correlated negatively with CRP in all three body positions (r=−0.50, p<0.001 in the sitting position, r=−0.36, p<0.01 in orthostatism, r=−0.47, p<0.001 in clinostatism); did not correlate with BASDAI, BASMI, or the modified Schoeber test in either of the three body positions.

In 15 AS patients who underwent repeated measurements of toracoabdominal movements while receiving their associated DMARD treatment (Methotrexate 15 mg/week and Sulfasalazine 3 g/day) 3 months after treatment, the angle of the Ct-Abd slope was significantly higher than that of the fundamental study, in all body positions.

The Ct-Abd angle continued to increase, with increments less pronounced and decreased from 4.8 (IQR 2.7) to 3.8 (IQR 2.4, p<0.001) at 6 months and 3 (IQR 2.4) at 12 months. Of note, patients with advanced disease (ankylosis of the spine) reported a decrease in pain and morning stiffness, decreased from 4.8 (IQR 2.9) to 3.6 (IQR 1.2, p<0.001) and 3.1 (IQR 1, p<0.001) at 12 months follow up. Median BASFI decreased from 9.0 (IQR 6.5) to 4.27 (IQR 1.2, p<0.001) at 6 months follow up. Median pain VAS showed a downward trend as well, from 6 at baseline (2 IQR) to 4.5 at 6 months (2 IQR) and 4 at 12 months (IQR 1.4). No differences emerged among PaSpA groups. Clinical trials did not assess efficacy of Secukinumab in patients previously treated with biologic agents other than anti-TNF agents, due to exclusion criteria. We performed subgroup analysis to evaluate its efficacy in patients previously treated with biologic agents other than anti-TNF agents, due to exclusion criteria. We achieved a retrospective descriptive and comparative monocentric study, on 49 patients, with PaSpA including ankylosing spondylitis (AS), psoriatic arthritis (PsA), enteropathic arthritis (EA), reactive arthritis (ReA), and NSAIDs. Our data suggest that this measure can be targeted for further evaluation of its usefulness in monitoring chest involvement and its response to treatment in AS patients.

AB0832
THE EFFECTS OF ANTI-TNF BIOLOGICAL AGENTS IN PATIENTS WITH SPONDYLARTHRTIS: A COMPARATIVE STUDY
F. Essati, O. Saidane, I. Mahmoud, A. Ben Tekaya, R. Tekaya, L. Abdelmoula. Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia

Objectives: The aim of the present study was to compare the efficacy of three anti-TNF agents (adalimumab, infliximab and etanercept) in patients with spondyloarthritis (SpA) at 24 weeks.

Methods: We achieved a retrospective descriptive and comparative monocentric study, on 49 patients, with SpA including ankylosing spondylitis (AS), psoriatic arthritis (PsA), enteropathic arthritis (EA), reactive arthritis (ReA) and CRP. To compare mean differences between time points (week 0 versus week 24), a Wilcoxon test was applied. To compare efficacy between the 3 anti-TNF, a Mann-Whitney test was applied.

Results: Twenty three patients (47%) had AS, 13 patients (27%) had PsA and 11 patients (22%) had EA. One patient had an uSpA, and 1 patient had a ReA. The mean age was 42.81 years±11.77. The median age at disease onset was 29.41 years±11.29. The mean disease duration was 10.16 years. Nineteen patients received etanercept (ETN), 18 infliximab (IFX) and 12 adalimumab (ADA). At six months, the 3 anti-TNF showed improvement in the disease activity scores: BASDAI (p<0.0001), ASDAS CRP (p<0.0001), ESR (p<0.0001) and CRP (p<0.0001). Sixty two percent of the patients have reached BASDAI 50 response at 6 months.

AB0833
REAL-WORLD EFFICACY AND SAFETY OF SECUKINUMAB: DATA FROM VERONA’S COHORT
F. Martins, C. Caimmi, A. Carletto, E. Fraccasi, M. Rossini. Rheumatology, AOUI Verona, Verona, Italy

Background: Secukinumab has been approved for the treatment of active ankylosing spondylitis (AS) and psoriatic arthritis (PsA). Its efficacy has been demonstrated in phase III trials where eligibility criteria ensured a homogeneous population. Although this strategy reduces confounding factors, it does not guarantee the same results in the real world, where clinicians deal with advanced disease, comorbidities, adherence and persistence challenges.

Objectives: Aim of this study was to assess efficacy and safety of Secukinumab in real-world clinical practice.

Methods: Patients received Secukinumab (150 or 300 mg) at weeks 0,1,2,3 and 4 as induction therapy and then every 4 weeks as maintenance therapy. Assessment of disease activity was done at months 6 and 12 using DAPSA, ASDAS, BASDAI, BASMI, pain VAS.

Results: Six patients affected by PsA (65% females, 35% males) and 29 affected by AS (70% males, 30% females) were included. 64% of patients reached 12 months follow up. Baseline characteristics of both groups are shown in the tables below.

In the PsA cohort, the median DAPSA at baseline was 19.5 (IQR 9.6), at 6 months 9.05 (IQR 6.5, p<0.001), at 12 months 8.53 (IQR 6.9, p<0.001). Median pain VAS showed a downward trend as well, from 6 at baseline (2 IQR) to 4.5 at 6 months (2 IQR) and 4 at 12 months (IQR 1.4). No differences emerged among PsA groups. Clinical trials did not assess efficacy of Secukinumab in patients previously treated with biologic agents other than anti-TNF agents, due to exclusion criteria. We performed subgroup analysis to evaluate its efficacy in patients previously treated with biologic agents other than anti-TNF agents, due to exclusion criteria. We achieved a retrospective descriptive and comparative monocentric study, on 49 patients, with SpA including ankylosing spondylitis (AS), psoriatic arthritis (PsA), enteropathic arthritis (EA), reactive arthritis (ReA), and NSAIDs. Our data suggest that this measure can be targeted for further evaluation of its usefulness in monitoring chest involvement and its response to treatment in AS patients.

Disclosure of Interest: None declared
Conclusions: In this first real-world cohorts of patients with PsA and AS Secukinumab has proven to be effective, regardless of PsA subtype, radiographic progression in AS and previous exposure to biologic therapy. The safety profile was favourable and similar to previous studies.

Abstract AB0835 COMPARISON OF LONG TERM ANTI-TNF SURVIVAL IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS; DATA FROM TURKBIIO REGISTRY

G. Can1, E. Dalkiliç2, Y. Pehlivan3, S. Senel4, S. Akar5, D. Solma4, S.S. Koca6, N. İnce7, P. Atagunduz8, A. Yazıcı9, A. Çelik10, B. Goke11, B. Zengin12, S. Üstün13, N. Akköc14, F. Önen15, 1Rheumatology, Dokuz Eylül University, İzmir, 2Rheumatology, Uludağ University, Bursa, 3Rheumatology, Erciyes University, Kayseri, 4Rheumatology, Kartal Celebi University, İstanbul, 5Rheumatology, Firet University, Elazığ, 6Rheumatology, Marmara University, İstanbul, 7Rheumatology, Kocaeli University, Kocaeli, 8Radiology, Gazi University, Ankara, 9Rheumatology, Private Doctor, İzmir, Turkey.

Background: Limited data are available on anti-TNF survival in non-radiographic axial spondyloarthritis (nr-axSpA) patients and their long-term survival in ankylosing spondylitis (AS).

Objectives: The aim of the study was to evaluate long term survival of the first anti-TNF drug treatment among patients with AS and nr-axSpA enrolled in the TURKBIIO database and to compare the discontinuation rates for infliximab (INF), etanercept (ETN), and adalimumab (ADA) in each of the two groups.

Methods: All AS and nr-axSpA patients receiving biological therapies registered in the TURKBIIO database between the dates of october 2011 and april 2017 were included in the study. AS diagnosis was made according to modified New York classification criteria and nr-axSpA according to ASAS AxSpA classification criteria. Demographic and clinical data, the date of starting to use biological drug, using frequency and dose of biological drugs, BASFI, BASDAI, BASMI, ASDAS scores, date and reason for discontinuing to use drug were collected. Baseline characteristics and drug survival rates were compared between AS and nr-axSpA patients. Drug survival was calculated by the Kaplan-Meier method and risk for discontinuation among treatment groups compared by Long Rank test.

Results: A total of 924 patients were included in the study (AS, n=871 and nr-axSpA, n=53). More than half of the patients with AS were male (60.7% in AS vs 34.0% in nr-axSpA group, p<0.001). AS patients had longer symptom duration (104.90±79.06 vs 75.11±45.29 months, p<0.036) compared to nr-axSpA. Median levels of CRP and ESR were similar for nr-axSpA (CRP: 48.15±44.46 vs 48.00±10.40, p=0.48). However, ESR levels of nr-axSpA were higher than those of AS (ESR: 34.0% in nr-axSpA group, p<0.001). ASDAS levels of CRP and ESR were similar for nr-axSpA (CRP: 27.03±34.71, ESR: 30.50±25.77) and AS (CRP: 22.32±29.95, ESR: 35.40±22.91). The scores of
Drug Retention Rate of the First TNF Inhibitor: The Effect of Anti-TNF on Renal Function in Patients with Axial Spondyloarthritis (AxSpA) Treated in a Real-Life Setting

Background: M. Galeazzi2, G. Lapadula1, F. Iannone1.

Methods: We retrospectively assessed 221 patients with axSpA, all fulfilling the ASAS criteria, who underwent first line therapy with TNFi from January 1st 2012 to September 30th 2016. Clinical, therapeutic and demographic features as well as radiographic findings on drug survival were assessed in the limit of the classification criteria for nr-axSpA. In addition over-adjustment for alcohol consumption, BMI, disease duration and disease activity was performed. Cumulative survival in patients with nr-axSpA showed no difference with AS patients (INF (at 78 months: 38,1%), ADA (at 77 months: 52,4%), ETN (at 78 months: 39,0%)) (p=0,151) (Figure 2). Cumulative survival rates in AS patients (at 78 months:42,2%) were found to be significantly higher than that (at 71 months:28,2%) in nr-axSpA patients (p<0,001) (Figure 3).

Conclusions: In contrast to the literature that revealed similar short term survival rates for anti-TNF drugs in patients with AS and nr-axSpA, we found higher survival rates in patients with AS compared to patients with nr-axSpA in this long-term observational study. A limitation of the study may be the low number of nr-axSpA patients using anti-TNF, related to the requirements of social insurance system.

Disclosure of Interest: None declared

Drug Retention Rate of the First TNF Inhibitor in Radiographic and Non Radiographic Axial Spondyloarthritis: Data from a Multicenter Study

G. Lesoain1, V. Venetrot1, L. Cantarini2, G. Emmi2, F. Salaffi2, S. Tatur1, F. P. Bianchi1, M. Di Carlo4, S. Gentilescu2, G. D. Scalz1, M. Nivoni1, S. Pemilia1, M. Fornaro1, M.G. Anelli1, F. Cacciapaglia1, C. Scioscia1, C. Fabiani3, M. Galeazz1, G. Lapadula1, F. Iannone1, M. Fornaro1, M.G. Anelli1, F. Cacciapaglia1, C. Scioscia1, C. Fabiani3, M. Galeazz1, G. Lapadula1, F. Iannone1, M. Fornaro1, M.G. Anelli1, F. Cacciapaglia1, C. Scioscia1, C. Fabiani3, M. Galeazz1, G. Lapadula1, F. Iannone1

Background: Good survival rates of TNF inhibitors (TNFi) have been shown in patients affected with axial Spondyloarthritis (axSpA) treated in a real-life setting, irrespective of administered anti-TNF agent. Although the use of these drugs in patients with non radiographic axSpA (nr-axSpA) remains topic of debate, several RCTs support their employment in these patients. The Objectives: To assess the retention rate of the first TNF inhibitor between axSpA and nr-axSpA patients. Additional aims: i) to evaluate any difference in persistence rates between anti-TNF monoclonal antibodies and etanercept (ETN) ii) to assess any impact of clinical, therapeutic and demographic features as well as radiographic findings on drug survival.

Methods: We retrospectively assessed 221 patients with axSpA, all fulfilling the ASAS criteria, who underwent first line therapy with TNFi from January 1st 2012 to September 30th 2016. Clinical, therapeutic and demographic features as well as radiographic findings were recorded at baseline and at the moment of therapy discontinuation. 125/221 patients (57,01%) were treated with Adalimumab, 45/221 with ETN, 22/221 with Infliximab, 20/221 (9,05%) with Golimumab, whereas 8/221 (3,62%) with Certolizumab Pegol. Drug retention rates were analysed using Kaplan-Meier curves; log-rank test was performed to demonstrate differences in the survival function. Cox regression models were used to estimate the inference of several clinical and disease characteristics on drug discontinuation. Goodness of fit of the final model was assessed comparing Cox-Snell residuals to Nelson-Aalen cumulative hazard function.

Results: Drug survival in first line therapy was significantly lower in patients who had nr-axSpA than in those with radiographic sacroiliitis (p<0,005, figure 1) whereas survival rate did not differ significantly between patients treated with ETN and anti-TNFFx monoclonal antibodies (p=0,057). Multivariate Cox model showed that nr-axSpA (HR 1.90), higher BMI (HR 1.16), higher HAQ, (HR 1.82) and higher BASDAI (HR 1.25), were predictors of drug discontinuation. Nelson–Alen hazard function following very closely Cox-Snell residuals for drug persistence in first line therapy showed that the final model fitted well the data, except for large values of time (figure 2).

Conclusions: Effectiveness of TNFi, estimated by drug survival, seems to be lower in patients with nr-axSpA than those affected with axSpA. The reason of these findings remain to be elucidated. However, a possible explanation may be searched in the limit of the classification criteria for nr-axSpA. In addition over-weight and high disease activity negatively impact the persistence on first line anti-TNF therapy in axSpA patients in real life setting.

Disclosure of Interest: None declared

The Effect of Anti-TNF on Renal Function in Patients with Ankylosing Spondylitis: A Prospective Cohort Study

I.A. Swart, M. Heslinga, I.M. Visman, I.E. van der Horst-Bruinsma, C. van Denderen, M.T. Nurmohamed. AMSTERDAM RHEUMATOLOGY AND IMMUNOLOGY CENTER | READE, Amsterdam, Netherlands

Background: Impaired renal function is common in patients with ankylosing spondylitis (AS) and patients also have an increased risk of cardiovascular disease (CVD). Previous studies showed that biologicals, such as anti-Tumour Necrosis Factor (anti-TNF) reduce CVD in patients with inflammatory rheumatic disease. Impaired renal function is a known predictor of CVD (also elevated in AS). We postulated that the favourable cardiovascular effect of anti-TNF might be mediated by improving renal function. However, data about the effect of biologicals on renal function in patients with AS are lacking.

Objectives: To assess the effect of anti-TNF on renal function in patients with AS.

Methods: Biological-naïve consecutive AS patients treated with etanercept or adalimumab were prospectively followed from 2005 to 2014. Renal function was determined by calculation of the estimated Glomerular Filtration Rate (eGFR), which was estimated with the abbreviated Modification of Diet in Renal Disease (MDRD) formula. Patients were divided into two groups: patients with normal renal function at baseline and patients with impaired renal function at baseline, to investigate whether the effect is different for these groups. Normal renal function was defined by eGFR >90 mL/min/1.73 m² at baseline and impaired renal function was defined by eGFR <90 mL/min/1.73 m² at baseline. The effect of anti-TNF on eGFR was analysed using mixed model analysis.

Results: 211 AS patients were followed for a median of 156 (36 – 286) weeks. 153 patients had normal renal function and 58 had impaired renal function at baseline. In patients with normal renal function at baseline eGFR decreased significantly over time (β=−0.041, p<0.001), although this association did not remain significant after adjustment for disease activity (β=−0.015, p=0.212). Patients with impaired renal function at baseline did not have a significant change in eGFR over time (β=0.022, p=0.087) and this association remained not significant after adjustment for alcohol consumption, BMI, disease duration and disease activity (β=0.008, p=0.593). The change in eGFR on average over time after starting anti-TNF in AS patients with normal and impaired kidney function are presented in figure 1.
Abstract AB0837 – Figure 1

Conclusions: This study demonstrates that anti-TNF is not associated with renal function in AS patients, which means that use of anti-TNF is safe concerning renal function in patients with AS. From our results it seems that the effect of anti-TNF on CVD in AS patients is not mediated by an effect on renal function.

Abstract AB0838 – Figure 1. Maximal TBR in PET/CT in sacroiliac joints and aorta are shown before and after treatment with either sulfasalazine (five patients) or adalimumab (nine patients). Each colour depicts one unique patient.

Conclusions: As detected by reduced 18F-FDG uptake, SSZ reduced inflammation in sacroiliac joints. There was also clear trend towards reduction of inflammation in aorta. ADA and SSZ both reduced clinical symptoms, but only ADA reached statistical significance. PET/CT could not show any reduction in FDG uptake in the ADA group. This may be due to the fact that ADA was used as the second line treatment, when the inflammation had already been reduced to the limit detectable by the method.

Abstract AB0839

The Efficacy of Adalimumab and Sulfasalazine in Alleviating Axial and Aortic Inflammation Detected in PET/CT in Patients with Axial Spondyloarthritis

J.-P. Kaijasilta1, A. Kerola2, R. Tuompo2, M. Kauppi2, H. Relas3, A. Loimaala4, H. Koivu2, J. Schildt2, T. Kerola3, K. Eklund4, T. Nieminen5. 1Internal Medicine, Päijät-Häme Central Hospital, Lahti; 2Inflammation Center, Helsinki University Hospital, Helsinki; 3Rheumatology, University of Tampere School of Medicine, Tampere; 4Medical Imaging Center, Helsinki University Hospital, Helsinki; 5Department of Nuclear Medicine, Päijät-Häme Central Hospital, Lahti; 6Heart and Lung Center, Helsinki University Hospital, Helsinki, Finland

Background: Inflammatory pathways are likely the central link from axial spondyloarthritis to the known increased risk of cardiovascular morbidity. Literature on positron emission tomography imaging together with computed tomography (PET/CT) in the context of spondyloarthritis is limited.

Objectives: The aim was to grade the inflammatory signals in the sacroiliac joints and aorta in the PET/CT imaging before and after antirheumatic treatment of clinically active axial spondyloarthritis with either sulfasalazine (SSZ), the first-line anti-rheumatic drug in Finland for axial spondyloarthritis, or adalimumab (ADA).

Methods: Fourteen patients aged 18–75 years with axial spondyloarthritis and radiologic sacroiliitis as detected either by MRI or X-ray and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and visual analogue scale (VAS)>4 have been recruited to the pilot study. DMARD-naïve patients started SSZ for 12 weeks. Those who failed to reach remission (BASDAI and VAS≤4) with SSZ or were known to be resistant to conventional DMARDs before inclusion, adalimumab was started for 16 weeks. The patients were scanned with 18F-fluorodeoxyglucose (FDG) PET/CT after inclusion and after treatment with SSZ and/or ADA.

Results: Aortic maximal TBR in sacroiliac joints declined from 2.44±0.46 to 2.07±0.43 (-15.0%, p=0.23). In the ADA patients, maximal TBR in sacroiliac joints was 1.89±0.37 before and 1.90±0.51 after treatment (-0.3%, p=0.97), and in aorta 2.15±0.54 before and 2.37±0.53 after treatment (+10.4%, p=0.18).
Determinations of serum levels of and anti-asessment of relationship between M. Cinar2, E. Tekgoz2, S. Yilmaz2.

Targeted therapies, such as TNF-alpha inhibitors revolutionised patients treated with anti-TNF-\alpha, etanercept (ETN). Demographic data and parameters measuring disease activity (BASDAI) were also included in the analysis.

Results: A strong negative correlation was found between the concentration of anti-TNF-drug antibodies and drug serum levels (IFX: $R^2=0.833$; ADA: $R^2=0.426$; ETN: $R^2=0.587$). On the other hand, similar correlation could not be demonstrated between serum concentrations of IFX, ADA or ETN and other factors, such as age of the patient (IFX: $R^2=0.050$; ADA: $R^2=0.090$; ETN: $R^2=0.016$), BASDAI (IFX: $R^2=0.099$; ADA: $R^2=0.071$; ETN: $R^2=0.015$), disease duration (IFX: $R^2=0.024$; ADA: $R^2<0.001$; ETN: $R^2=0.182$) and time since the initiation of therapy (IFX: $R^2=0.008$; ADA: $R^2=0.052$; ETN: $R^2=0.062$).

Conclusions: As anti-TNF-alpha antibodies decrease the serum concentration of TNF inhibitors. In our study, drug serum levels and anti-TNF-drug antibody concentrations significantly correlated with each other. However, similarly to some other reports, drug levels did not correlate with treatment efficacy. Therefore, routine assessment of serum drug and anti-TNF-drug antibody levels should not be recommended in the everyday practice in order to determine treatment effectiveness. However, the parallel evaluation of drug and anti-TNF-drug antibody levels may be effectively used in order to determine patient compliance in the case of subcutaneously administered drugs.

Disclosure of Interest: None declared

**Abstract AB0839 – Figure 1**

Conclusions: This study demonstrated a clear association between treatment agents and radiologic parameters in AS. Anti-TNF-\alpha treatment improved lumbar lordosis and slowed thoracic kyphosis progression with improvement of clinical outcomes. Lumbar lordosis was a significant predictor of clinical outcome in AS patients treated with anti-TNF-\alpha.

Determination of serum levels of and anti-drug antibody production against TNF inhibitors in ankylosing spondylitis: testing may be useful for the assessment of compliance but not that of treatment effectiveness

K. Gulyás, A. Medelle, N. Bodnár, Z. Szekanecz, S. Szántó. Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary

Background: Targeted therapies, such as TNF-alpha inhibitors revolutionised the treatment of spondyloarthritides including ankylosing spondylitis (AS).

Objectives: To determine the correlation between serum TNF-alpha inhibitor levels of patients receiving biological therapy and concentration of anti-drug antibodies, disease activity (treatment effectiveness), age of patients and elapsed time since the onset of the diagnosis and from the initiation of the therapy.

Methods: Serum levels of TNF-alpha inhibitors (mg/ml) and concentration of anti-drug antibodies (AU/ml) were measured in 37 AS patients. Altogether 12 patients were treated with infliximab (IFX), 15 received adalimumab (ADA) and 10 received etanercept (ETN).

Results: Mean ESR, CRP, BASDAI, and thoracic kyphosis at baseline were significantly higher in group B. After treatment, group B had significantly higher lumbar lordosis and significantly better clinical outcomes. Correlation analysis revealed significant relationships between radiologic parameters and BASDAI.

Conclusions: As anti-TNF-alpha antibodies decrease the serum concentration of TNF inhibitors. In our study, drug serum levels and anti-TNF-drug antibody concentrations significantly correlated with each other. However, similarly to some other reports, drug levels did not correlate with treatment efficacy. Therefore, routine assessment of serum drug and anti-TNF-drug antibody levels should not be recommended in the everyday practice in order to determine treatment effectiveness. However, the parallel evaluation of drug and anti-TNF-drug antibody levels may be effectively used in order to determine patient compliance in the case of subcutaneously administered drugs.

Assessment of relationship between loneliness, perceived social support, depression and medication adherence in ankylosing spondylitis patients

E. Öksüz1, F.I. Cinar1, M. Cinar1, E. Tekgoz2, S. Yilmaz2.1 University of Health Sciences, Gulhane Faculty of Nursing; 2University of Health Sciences, Gulhane Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

Background: Ankylosing spondylitis (AS) is a chronic, progressive, inflammatory disease which can cause labour loss and deformities and requiring long-term treatment. Loneliness, perceived social support, depression, patients’ beliefs about medicines and treatment may affect their medication adherence and treatment success.

Objectives: In this study, we aimed to investigate the relationship between loneliness, perceived social support, depression and medication adherence in AS patients.

Methods: This cross-sectional study was conducted in a tertiary rheumatology outpatient clinic. One hundred and nineteen AS patients were enrolled to the study. The socio-demographic and clinical features of the patients agreeing to participate were recorded to the “Patient Assessment Form”. The patients’ disease activity and functional status were determined with the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and the Bath Ankylosing Spondylitis Functional Index (BASFI), respectively. The pain and global assessment of the patients were assessed with a numerical visual analogue scale (nVAS; 0–10 cm). The medication adherence of the patients was assessed with the Morisky Greene Levine Scale (MGLS). The UCLA Loneliness Scale, the Multidimensional Scale of Perceived Social Support (MPSS) and the Beck Depression Inventory (BDI) were used to determine loneliness, perceived social support, depression and medication adherence in AS patients.

Results: One hundred five patients (88.2%) were male, the mean age was 35.80 ±9.08 years, and the mean disease duration was 9.88±6.34 years. The mean BASDAI, BASFI and patient global assessment scores were: 4.57±2.63, 3.23 ±2.76, and 4.13±3.23, respectively. According to the MGLS medication adherence groups, patients with low medication adherence had higher BASDAI, spinal pain, spinal pain at night, fatigue and patient global assessment scores and had lower mean ages (p<0.05). Among the MGLS medication adherence groups, patients with low medication adherence had lower MPSS scores, and had higher UCLA Loneliness Scale and Beck Depression Inventory scores (p=0.037, p<0.001, p=0.022, respectively) (table 1).

F: One-way ANOVA. Statistically significant between a and c, and b and c (p<0.05). *It shows the lowest-highest scores that can be taken from the scale and its sub-dimensions.

Conclusions: In this study, it was shown that as the average age and social support scores of patients decreased, and as the BASDAI, spinal pain, spinal pain at night, fatigue, patient global assessment, loneliness and depression scores increased, adherence to treatment were decreased. It is thought that patients should be handled holistically in terms of biopsychosocial aspect in order to improve adherence to medical treatment.

Abstract AB0842

DRUG SURVIVAL AND EFFECTIVENESS OF THE FIRST TNF INHIBITORS IN PATIENT WITH LATE ONSET SPONDYLARTHRITIS: TREASURE REAL-LIFE STUDY

N. Alpay Kanitez1, S. Kiraz1, I. Ertelii2, O. Küçükgün2, E. Dalkeçoğlu3, C. Beş1, T. Kaşköğlu4, H. Emmurdü5, S. S. Koca6, M. Cinár2, S. Yılmaz2, V. Yavuzsar1, B. Keleşoğlu Dinçer1, S. Akar1, O. Geröklü2, A. Ateş1, S. Ertel1, S. Turan6, B. Yağz1, B. Öüz6, S. Yaşar Bilge3, L. Kılıç4, G. K. Yurdımce1, B. N. Coşkun1, U. Kaymuncu2, TRTasure biological registry, İstanbul, TRTasure biological registry, Ankara, TRTasure biological registry, Bursa, TRTasure biological registry, Edirne, TRTasure biological registry, Elazığ, TRTasure biological registry, Antalya, TRTasure biological registry, İzmir, Turkey

Background: Spondylarthritis (SpA) are usually observed in young patients and a clinical onset after 45 years is rare. The average life expectancy is getting longer and the proportion of late onset of SpA in rheumatology practice may become more common. SpA patients with late onset may have a distinctive clinical pattern in terms of functional impairment, extra-articular disease, co-morbidities and treatment status.

Objectives: The aim of this study was to compare the drug survival and effectiveness of tumour necrosis factor (TNF) inhibitors in patients with late onset SpA (LoSpA) compared with early onset SpA (EoSpA).

Methods: TRTasure is a prospective, multicenter biological treatments registry from Turkey since 2016. It includes 15 different rheumatology centres. Patients with SpA fulfilling the ASAS criteria from TRTasure database were divided into two groups as LoSpA (symptom onset >45 years of age) and EoSpA (symptom onset ≤45 years of age). Drug retention rates of first TNF inhibitors were calculated using the time until drug discontinuation independent of the reason that drug interruption. Specific reasons for discontinuing drugs were also assessed.

Results: Of 1382 SpA patients treated with TNF inhibitors, 9.4% (n=130) were included in the LoSpA and 90.6% (n=1252) were included in the EoSpA group. LoSpA had more female, enthesis and psoriasis. The median treatment duration was 53 months in LoSpA and 61 months in EoSpA. The baseline disease activity measures were similar except from ASDAS-ESH which is higher in LoSpA (table 1). The rate of major treatment response (BASDAI50) was lower in LoSpA than EoSpA at the last visit (26.1% vs 46.2%; p=0.009). Regarding the survival rates of TNF inhibitors, there was no significant difference between the patient groups (figure 1). The major cause of discontinuation in both groups was drug ineffectiveness (68.6% in LoSpA and 60% in EoSpA, p=0.05).

<td>3.55 (1.49–5.92)</td>
<td>3.35 (0–7.8)</td>
<td>0.251</td>
</tr>
</tbody>
</table>

Conclusions: LoSpA patients were almost 10% of all biological registry. LoSpA patients were predominantly female, and they had relatively higher baseline disease activity and lower biological treatment response. On the other hand the drug survival rate and discontinuation reasons of TNF inhibitors in the LoSpA group was comparable to that in the younger group.

Abstract AB0843

EFFECT OF TNF INHIBITORS ON BONE MICROARCHITECTURE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A LONGITUDINAL STUDY BASED ON HIGH-RESOLUTION PERIPHERAL QUANTITATIVE BASED HRVQCT

N. Nigil Haroon, E. Szabo, A.M. CHEUNG, R. Inman, Medicine, Northern Ontario School of Medicine, Sudbury; 8Osteoporosis program, UHN; 8Medicine, Univ of Toronto; 8Medicine, unit of Toronto, Toronto, Canada

Background: Ankylosing spondylitis (AS) is associated with high risk of fractures. BMD, bone microarchitecture and strength are negatively affected in AS. TNF inhibitors such as etanercept, adalimumab, golimumab and infliximab are the mainstay of treatment in AS. However no data is available on the effect of TNF inhibitors on bone microarchitecture and strength.

Objectives: This study aimed to assess the effect of TNF inhibitors on bone microarchitecture in patients with AS.

Methods: AS was defined by Modified New York criteria. Areal BMD was measured by DXA. Volumetric BMD (vBMD) and bone microarchitecture were measured using highresolution peripheral quantitative CT (HRpQCT) at the radius and tibia at baseline and after one year of treatment with TNF inhibitors. Intake of calcium and vitamin D were optimised.

Results: There were 31 subjects (58% men). Mean (+SD) age and BASDAI were 40±14 years and 4.1±2.1 respectively. Median duration of disease was 14 (IQR: 6.5–25.5) years. Mean duration of follow-up was 15 months. Areal BMD (n=22) at lumbar spine (1.053±0.235 vs. 1.049±0.202, p=0.89), total hip (0.944±0.152 vs. 0.912±0.164, p=0.5), and femoral neck (0.955±0.151 vs. 0.954±0.191, p=0.2) did not change significantly. HRpQCT (n=31) on follow-up demonstrated that total, trabecular and cortical volumetric BMD were unchanged at both radius and tibia (table 1). Also, HRpQCT based trabecular parameters such as trabecular number, thickness and separation, BV/TV and cortical parameters such as cortical porosity and thickness remained stable (table 1). FEA estimates of bone stiffness and
stress tended to be lower at the radius on follow-up however these parameters were not significantly different at the tibia (table 1).

Abstract AB0843 – Table 1

Conclusions: This is the first study to document the changes in bone strength in AS patients with the use of TNF inhibitors. Treatment with TNF inhibitors might maintain bone microarchitecture at cortical and trabecular sites in patients with AS.

AB0844

EFFECTIVENESS AND RETENTION RATE OF CERTOLIZUMAB PEGOL IN SPONDYLOARTHRITIS. REAL LIFE DATA

dales Consultant for: Celgene, Speakers bureau: UCB, Pfizer, Roche, J. R. Lamua-Riazael: None declared, A. Urruticoechea-Araná: None declared, P. Navarro-Alonso: None declared, J. S. Disclosure of Interest: No significant reduction of BASDAI, BASFI, ASDAS and MASES scores. No differences were observed in the retention rate regardless previous biological treatment.

Conclusions: Real life experience from this nationwide rheumatology study, demonstrated the effectiveness and safety of CZP in patients with axSpA, with a significant reduction of BASDAI, BASFI, ASDAS and MASES scores. No differences were observed in the retention rate regardless previous biological treatment.

AB0845

THE EFFECT OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS PATIENT REPORTED OUTCOMES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW AND A CALL FOR ACTION

S. Rodrigues-Manca1, L. Leite Silva2, A.R. Machado3, C. Coelho4, J. Duarte5, E. Vieira-Sousa6, J. Tavares-Costa7, F.M. Pimentel-Santos8,9, C. Cedovici, E. Moniz1, Centro Hospitalar de Lisboa Ocidental, Lisbon; 2Unidade Local de Saúde do Alto Minho, Ponte de Lima; 3Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre, 4Genetics Laboratory, Instituto of Environmental Health, Lisbon School of Medicine, University of Lisbon; 5Medical Department, Novartis Pharma, Pharmaceutical products, Lisbon, Portugal

Background: Patient reported outcomes (PROs) have gained relevance in the evaluation of several diseases such as axial spondyloarthritis (axSpA). They allow the clinician to have a quantitative measurement of several aspects of the disease, according to the patient perspective.

Objectives: In this review we intended to evaluate the efficacy of different biologic disease-modifying anti-rheumatic drugs (bDMARD) in achieving the minimum clinically important difference (MCID) in several PROs. Data from randomised controlled trials (RCT) conducted in radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-axSpA) patients were included.

Methods: A systematic literature review (SLR) was performed using the MEDLINE database (August 17 2017) with the filters “published in the last 10 years” and “humans”. Abstracts from the EULAR 2017 were also considered. The PICO (P,
Abstract AB0845 – Table 1

| M:F | 30:1 | 7:14 |
| Bio-originator infliximab duration (years), (median, IQR) | 11 (8–15) | 9 (6–14) |
| Concomitant csDMARD, n (%) | 12 (26%) | 17 (81%) |
| MTX, n, (median dose) | 12 (100%, $15 mg/week) | 16 (94%, $10 mg/week) |
| Previous biologic (bDMARD) | 5 (16%) | 5 (24%) |
| Positive ADAs (median, IQR) AU/mL | 12 (37%), 46.5 | 8 (38%), 86.5 |
| Therapeutic range DL | 14 (44%) | 10 (48%) |
| High ADA/very low or undetectable drug (likely drug neutralising) | 1 (3%) | 2 (10%) |
| Drug discontinued (no alternative bDMARD required) | 1 (3%) | 2 (10%) |
| Dose reduced or interval extended | 6 (25%) | 3 (14%) |
| Alternative bDMARD (either TNFi or different mode of action) | 1 (3%) | 3 (14%) |
| Switched to biosimilar | 14 (44%) | 10 (48%) |

Conclusions: These data from a small cohort suggest that measuring ADAs and DLS to characterise treatment response, tailor treatment regime and inform biosimilar switching is a clinically efficacious and cost-effective strategy in infliximab-treated SpA patients. We anticipate further significant savings with our

Five Years of Delay in the Diagnosis of SAPHO Syndrome

A. Erdes1, M. Ecici2, B. Armagan1, A. Sar1, G.K. Yardimo1, L. Klic1, S. Apras Bilgen1, A. Akdogan1, O. Karadag1, S. Kizaz1, I. Ertelini1, U. Kalyoncu1. 1Division of Rheumatology, Department of Internal Medicine; 2Department of Internal Medicine, Hacettepe University, Ankara, Turkey

Background: SAPHO syndrome is a chronic disease with bone, joint and skin involvement characterised by synovitis, acne, pustulosis, hyperostosis and osteitis. It is a rare disease and its diagnosis may depend on detailed clinical examination as well as radiological evaluation.

Objectives: In this study, we aim to present clinical features and diagnostic course of patients with SAPHO syndrome who are followed in our tertiary referral clinic.

Methods: All patients with SAPHO syndrome diagnosed since February 2014 have been registered with a standard form. Patients are prospectively monitored since then. Diagnosis was based on the criteria by Benhamou et al.1 In the questionnaire, demographic data (age, sex, duration of illness), clinical features (skin and joint involvement), laboratory characteristics (acute phase reactants, HLA-B27), radiological imaging (bone scintigraphy (increased activity in the sternum, bilateral sternoclavicular joints and clavicles), MRI) disease activity parameters (BASDAI, BASFI) were questioned. There were 24 patients with SAPHO syndrome. The data of 21 patients were presented because the clinical findings of 3 patients were insufficient.

Results: Data of 21 patients with SAPHO syndrome were available and 11 (52.4%) patients were female. Mean age at diagnosis was 39.9±12.9, mean age of symptom onset was 35.2±12.9, mean follow-up duration was 18.1±25.1 months. The mean delay time of diagnosis SAPHO syndrome was calculated as 49.0±22.5 months. Thirteen patients (61.9%) were followed up with another clinical diagnosis before SAPHO diagnosis. The clinical characteristics of the patients are shown in Figure 1. HLA-B27 was positive in 3 of 13 patients. Mean activity scores of our patients at initial visit were: BASDAI: 4.8±2.8, BASFI: 4.6±2.2, CRP2.3±4.2 mg/dL, and erythrocYTE sedimentation rate 23.8±22.6 mm/h. Scintigraphy findings were positive in 16 (94.1%) of 17 patients. The diagnosis of 2 patients was supported by MRI. The remaining 2 patients were diagnosed with X-ray and clinic findings.

**CORRELATION BETWEEN RAPID3 AND PROMIS10 IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

A. Ogdie1, W.B. Nowell1, R. Reynolds1, K. Gavigan2, S. Venkatachalam2, M. de la Cruz2, E. Flood3, E.J. Schwartz3, B. Romero3, Y. Park4. *Perelman School of Medicine at The University of Pennsylvania, Philadelphia; 2Global Healthy Living Foundation, Upper Nyack; 3ICON, Gaithersburg; 4Novartis Pharmaceuticals Corporation, East Hanover, USA*

**Background:** Patient-reported outcome (PRO) measures are important in managing and improving the quality of care in patients with chronic rheumatic conditions including ankylosing spondylitis (AS). The RAPID3 was developed for use in patients with rheumatoid arthritis, but it has shown good correlation with the BASDAI and ASDAS in patients with AS. The PROMIS10 is a universal (non-disease specific) PRO measure that quantifies physical and mental health; validity of PROMIS10 has not been examined in patients with AS.

**Objectives:** To evaluate the relationship between RAPID3 and PROMIS10 in patients with AS.

**Methods:** US patients aged ≥18 years with a self-reported diagnosis of AS were recruited through CreakyJoints (www.CreakyJoints.org), an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers and via outreach on social media. Respondents completed a web-based survey designed to collect data on socio-demographics and clinical symptoms, RAPID3, and PROMIS10. The RAPID3 score consists of three patient self-reported scores (0–10): functional impairment, pain, and patient global assessment; total scores: 3.0= near remission, 3.1 to 6.0= low disease severity, 6.1 to 12.0= moderate disease severity, and >12.1 = high disease severity. PROMIS10 is a 10-item questionnaire measuring physical, mental, and social domains; physical and mental health domain scores are transformed to T-score distributions normalised to the general population (mean score=50). PROMIS10 physical and mental health T-scores showed a strong correlation in patients with AS.

**Results:** Among 235 respondents, 174 (74%) were female, with a mean (SD) age of 49.8 (10.7) years. The mean (SD) RAPID3 cumulative score was 15.4 (5.4) and PROMIS10 total score and the PROMIS10 physical and mental health T-scores, respectively. Spearman’s correlation coefficient was calculated between the RAPID3 total score and the PROMIS10 physical and mental health T-scores, respectively.

**Conclusions:** Psychological status does not seem to affect response to treatment, disease activity, physical disability and quality of life in patients with Ankylosing Spondylitis (AS).

**Acknowledgements:** This study was sponsored by Novartis Pharmaceuticals Corporation, East Hanover, NJ.

**DO SYMPTOMS OF DEPRESSION AND ANXIETY INFLUENCE TREATMENT RESPONSE AND LONG-TERM PHYSICAL HEALTH OUTCOMES IN ANKYLOSING SPONDYLITIS?**

M. Eus erb io1, C.A. Lopes1,2, M. Bernardes3, P. Pinto4, H. Santos6, J.L. Gomes2,3, J. Tavares-Costa7, J. Dias8, A. Bernardo9, L. Domingues2, C. Crespo9, S. Maia10, F. Martina11, J.C. Branco2,2, F.M. Pimentel-Santos2,3, SPP, Portuguese Rheumatology Society; 2Rheumatology, Hospital Egas Moniz – CHLO; 3CEDOC, NOVA Medical School, NOVA University of Lisbon, Lisbon; 4Rheumatology, Centro Hospitalar São João, Porto; 5Rheumatology, Centro Hospitalar Vila Nova de Gaia/Espinho, Gaia; 6Rheumatology, Instituto Português de Reumatologia, Lisbon; 7Rheumatology, Unidade Local de Saúde de Alto Minho, Ponte de Lima; 8Rheumatology, Centro Hospitalar Médio Tejo, Torres Novas, Portugal

**Background:** Psychological disturbances, frequently observed in inflammatory rheumatic diseases, seem to negatively influence patient’s clinical status and treatment response.

**Objectives:** The aim of this study was to examine the longitudinal impact of depression (D)/anxiety (A) in treatment response, disease activity, physical disability and quality of life in patients with Ankylosing Spondylitis (AS).

**Methods:** Data from patients who fulfilled the modified New York criteria for AS were collected at baseline, weeks 2 and 14 post-treatment with Adalimumab. The Hospital Anxiety and Depression Scale (HADS) was used to evaluate D/A symptoms severity. The primary outcomes were AS disease activity score – C reactive protein (ASDAS-CRP), Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI) and AS Quality of Life (ASQoL) Scale. Secondary outcomes were patient and physician global assessment by Visual Analogue Scale (VAS), erythrocyte sedimentation rate (ESR), CRP and BASDAI question 1 (fatigue). Differences-in-differences estimation took into account the covariates gender, age at baseline and disease duration.

**Results:** Data from 54 patients were included. At baseline, D/A symptoms significantly influenced the mean value of BASFI (p=0.006; p=0.003) and ASQoL (p=0.001; p=0.004). On the other hand, BASDAI (p=0.009), CRP (p=0.017), patient’s VAS (p=0.003) and fatigue (p=0.015) were only influenced in the individuals with A symptoms, while the physician’s VAS (p=0.005) was only influenced in patients with D symptoms. After 14 weeks of treatment, significant differences in ASQoL mean values were found in patients with both D/A symptoms at baseline (p=0.005; p=0.022) and in BASFI (p=0.044) and patient VAS (p=0.006) for the population showing only A symptoms at the baseline. Apart from the physician VAS (p=0.023), D/A baseline symptoms did not affect the treatment’s response.

**Conclusions:** Psychological status does not seem to affect response to treatment with Adalimumab, even if the overall characteristics of the population are different at baseline between patients with/without D/A symptoms.

**Disclosure of Interest:** None declared

AB0851 CLINICAL ASSOCIATIONS OF UVEITIS IN ASAS DEFINED AXIAL SPONDYLOARTHRITIS GROUP AND MODIFIED NEW YORK CRITERIA DEFINED ANKYLosing SPONDYLITIS GROUP
C. Chiu Wai Shirley1, C.S. Lau2, H.H.L. Tsang1, O.M. Wong3, H.Y. Chung3
1Medicine, QUEEN MARY HOSPITAL; 2Medicine, University of Hong Kong; 3Ophthalmology, Hong Kong Eye Hospital, Hong Kong, Hong Kong

Objectives: To identify and compare the associated factors for uveitis in Chinese patients with axial spondyloarthritis (SpA) and ankylosing spondylitis (AS).

Methods: Patients fulfilling the Assessment of SpondyloArthritis (ASAS) axial SpA criteria were recruited consecutively from three rheumatology centres in Hong Kong. Clinical and biochemical parameters were collected. History of uveitis was enquired from both history and medical records. All patients received lumbar-sacral spine x-rays, and whole spine and sacroiliac (SI) joint magnetic resonance imaging (MRI). MRIs were scored according to the Spondyloarthritis Research Consortium of Canada (SPARC) scores. Patients were defined as axial SpA if they fulfilled the ASAS criteria, and AS if they fulfilled the modified New York (mNY) criteria. Clinical and radiological findings were compared between patients with and without uveitis in the two groups. Factors associated with uveitis were identified with univariate analyses and multivariate logistic regression analyses.

Results: Among 253 patients, 67 (26.5%) patients had a history of uveitis. The male to female ratio was 55.7 to 44.3. Disease duration was 12.3±11.7 years. In the axial SpA group, univariate analyses showed that the following factors were associated with uveitis: back pain duration, age, HLA-B27 positivity, history of inflammatory bowel disease (IBD), tender joint count, Ankylosing Spondylitis Disease Activity Index (ASDAS) and SPARC score of spine. Multivariate regression showed that older age (OR 1.05; p=0.01), HLA-B27 positivity (OR 11.79; p=0.01) and history of IBD (OR 1.82; p=0.04) were positively associated with uveitis. In the AS group, univariate analyses showed that the following were associated with uveitis: back pain duration, age, male sex, HLA-B27 positivity, tender joint count, ASDAS, SPARC score of spine and SPARC score of SI joints. Multivariate regression showed that back pain duration (OR 1.65; p=0.01) and male sex (OR 3.46; p=0.03) were associated with uveitis.

Conclusions: Clinical factors associated with uveitis are similar in the axial SpA and AS groups. The former group is associated more with IBD, and the latter with male sex.

AB0852 GENDER DIFFERENCES IN AXIAL AND PERIPHERAL SPONDYLOARTHRITIS: RESULTS FROM THE ESPERANZA COHORT
C. Urrego Laurin1, V. Navarro-Compañí1, P. Zuzita1, T. Ruiz Jimeno1, C. Campos fernandez2, J. Mulero Mendoza2, E. De Miguel Mendeta2, O. behalf of ESPeranza Group. 1Hospital General de Segovia, Segovia; 2Hospital Universitario la Paz, IdiPaz, Madrid, 3Hospital Sierrallana, Torrelavega, Santander, 4Hospital Universitario de Valencia, Valencia; 5Hospital Universitario Puerta de Hierro. Madrid, Spain

Background: In patients with spondyloarthritis (SpA), published data indicate different manifestations and outcomes between genders. Nevertheless, the evidence in patients with early and peripheral disease is lacking.

Objectives: To evaluate differences in the presentation of the disease between genders in patients with early axial and peripheral SpA (axSpA, pSpA).

Methods: This study was carried out within the framework of the ESPeranza program, which was a Spanish multicenter initiative aiming to facilitate early diagnosis and follow-up of patients with SpA between 2008–11. Out of 775 patients referred, 377 patients fulfilled the ASAS classification criteria for SpA 291 (77%) axSpA and 86 (23%) pSpA. Demographic and disease characteristics were compared between genders using Chi-square (for categorical variables) and Student t (for continuous variables) tests.

Results: In total, 241 (64%) patients were males (191 axSpA and 50 pSpA). In the axSpA group, males had more frequently radiographic sacroiliac damage, elevated CRP, HLA-B27 positive and morning stiffness, while females had higher values of ESR and more frequency of peripheral arthritis (table 1). Within the pSpA group, male gender was significantly associated with higher diagnostic delay, psoriasis and elevated CRP while women had higher rates of functional limitation and ESR values.

Conclusions: In patients with SpA, different disease manifestations between genders are observed already from the first stages of the disease. In patients with axSpA, males have worse prognostic factors compared with females. However, in pSpA, females report poorer functionality despite being diagnosed earlier than male patients. This difference in phenotypes may be relevant when therapeutic decision-making.

AB0853 THE ASSOCIATION OF VITAMIN D RECEPTOR LEVELS WITH DISEASE ACTIVITY PARAMETERS IN PATIENTS WITH ANKYLOSING SPONDYLITIS
T. Kultur1, D. Özçelik2, D. Kesik3, G. Kesik2, A. Inal2, H. Kara2. 1PMR, Kırıkkale University, Kırıkkale; 2Public Health, Yıldırım Beyazıt University; 3Immunology, Ankara University, Ankara; 4Immunology, Baskent University, Istanbul; 5Pharmacology, Yıldırım Beyazıt University, Ankara, Turkey

Background: Ankylosing Spondylitis (AS) is a chronic, systemic, inflammatory disease that involves sacroiliac, axial and peripheral joints with an unknown etiology. The role of vitamin D receptor (VDR) in the regulation of multiple pathophysiologic processes, like inflammation, infection and malignancies and systemic disease is not fully understood.

Objectives: The aim of this study was to investigate the relationship between serum VDR levels and disease activity parameters in patients with AS.

Methods: Sixty-two patients with AS and 32 healthy volunteers were included into the study. Demographic features like age, duration of illness, medication, history of uveitis and peripheral involvement of the patients were recorded. Erythrocyte sedimentation rate (ESR), serum C-reactive protein (CRP) levels were recorded. The Bath AS Disease Activity Index (BASDAI) scores were calculated to determine disease activity. Serum Vitamin D receptor (VDR) level was measured by ELISA.

Results: There was no difference in Serum VDR levels between the patient and the control group (p=0.658). In patients with active AS (BASDAI score >4) serum VDR level was significantly high (p=0.00). Also serum VDR levels were statistically significantly high in patients with peripheral joint involvement and enthesis (p=0.00, non-steroidal anti inflammatory drugs (NSAID) compared to patients treated with biological agents (p=0.00). Serum VDR levels were also significantly correlated with BASDAI, CRP and ESR in the patient group (p=0.00, r=0.751, p=0.00, r=0.751 p=0.00, r=0.0860 respectively).

Conclusions: In our study, serum VDR levels are related with disease activity, clinical parameters, peripheral joint involvement and enthesis in patients with AS. Our results suggest that serum VDR level may be used to predict disease activity and prognosis. Further studies in large cohorts are needed to determine the role of Serum VDR level in the pathophysiology of AS.

Dysfunctional Pain Component in Ankylosing Spondylitis Patients

F. Filatova, S. Erdes, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

Background: As a result of chronic inflammation, repetitive activation of primary afferent fibres changes the functional state and activity of Central nervous pathways. On this patients when describing their complaints use neuropathic pain descriptors include numbness, burning, tingling, increased pain response to a stimulus nabulivou etc.

Objectives: The study of chronic pain syndrome in patients with ankylosing spondylitis (AS) to identify dysfunctional component of pain (DCP).

Methods: Was studied 150 patients as 127 men and 23 women. The average age of 35, and 52±10.55, mean disease duration of 7.19±f of 6.31. All the patients were performed clinical and rheumatological examination (indices BASDAI, BASFI), the assessment of pain intensity on visual analogue scale (VAS), to identify DCP were investigated neurological study with the use of questionnaires neuropathic pain DN4 and PainDETECT, and identifying the emotional-affective disorders (HADS questionnaire).

Results: 22 patients (14.7%) on the DN4 questionnaire revealed 4 or more points, but lesions of the somatosensory nervous system in these patients was not detected, hence 14.7% of patients were identified DCP. When comparing patients with the presence of TCS group I (22 people) and no DCP group II (128) it has been found that statistically significantly in patients in group I had higher pain intensity on VAS (6.09±1.85 vs 4.55±2.06, p=0.001, respectively); active disease BASDAI index (7.05±2.16 vs 5.87±2.16, p=0.001, respectively); the expression of functional impairment index BASFI (6.46±2.24 vs 4.05±2.81, p=0.001); the indicators of the questionnaire HADS in group I, consistent with the presence of clinically significant anxiety and lack of it in group II (10.95±2.86 vs 6.17±3.35, p=0.0001). However, duration of disease distinguish authentic in the groups was 46.4%. The most common MRI protocol was the inflammatory spinal protocol (ISP-MRI, 57.2%), with sacroiliac (SIJ) MRI in 17%. 87.4% ISP-MRI and 48.5% MRI SIJ were requested by Rheumatology. GPs requested more ISP-MRI than other sequences (29.7% of their total MRIs). 144 cases had a diagnosis stated on the MRI report: 100 (69.4%) had an existing diagnosis of axSpA, and 20 (13.9%) of a peripheral arthritis. In patients with known AxSpA, the most frequent findings were BMO (70.3%), and erosions (67%). Ankylosis was only seen in 4 patients. Features of axSpA were identified in 26 MRIs requested for mechanical back pain, and in 11 for unrelated medical reasons. 33 cases of BMO and 29 of SIJ erosions were identified in patients who did not have a pre existing diagnosis of AxSpA, and one showed ankylosis. 16 patients went on to have a diagnosis of axSpA.

Conclusions: Through data mining of MRI reports, we have found that appropriate MRI sequences are being requested when features of AxSpA are suspected. The rate of chronic features of AxSpA such as ankylosis was low, suggesting this cohort may have short disease durations. Multiple features of AxSpA were identified in patients without an existing diagnosis prior to imaging. 16 new cases of AxSpA were identified.

AB0855

Identifying Patients with Axial Spondyloarthritis by Data Mining MRI Radiology Reports

F. Reilly, A. Szachowicz, R. Sengupta. Royal National Hospital for Rheumatic Diseases, Bath, UK

Background: Axial Spondyloarthritis (axSpA) encompasses ankylosing spondylitis (AS) and non-radiographic axSpA (nr-axSpA) as part of the ASAS classification criteria2. The role of MRI is now central in identifying patients early in the disease course, but our use of this needs to be standardised to ensure appropriate requesting and correct interpretation of MRI axSpA features.

Objectives: (1) To identify the MRI protocols used to investigate patients with back pain
(2) To describe the prevalence of axSpA associated spinal lesions in patients with known axSpA

Disclosure of Interest: None declared

THE IMPACT OF SYSTEMIC INFLAMMATION AND RADIATIONAL CHANGES ON MOBILITY IN ANCHYLOSING SPONDYLITIS

F. Russo, L. Chisari, R. Larisa, V. Cazac. Rheumatology and Nephrology, SMPU “Nicolae Testemițanu”, Chisinau, Moldova, Republic of

Objectives: The purpose of the study was to investigate the relationship between disease activity, structural lesions and physical function by testing the hypothesis that the level of structural lesions contributes independently to physical impairment.

Methods: For this analysis, the database of Rheumatology Department was used and included 78 consecutive SA patients who have been observed for many years, implying that they have used NSAID’s and DMARD for progression disease, no one has used TNF blocking agents.

Results: BASFI and DFI correlated significantly (r = 0.88). The correlation coefficient for mSASSS and BASFI was 0.508 and for mSASSS and DFI equal to 0.464, suggesting a moderate correlation relationship. The correlation coefficient for the relationship between BASDAI and BASFI was equal to 0.79 and for BASDAI and DFI equal to 0.69 suggesting a moderate to significant correlation. The correlation between mSASSS and BASFI or DFI was dependent on the BASDAI level.

To further investigate the relationship between mSASSS and BASFI/DFI, concurrently adjusting for BASDAI and other covariates, a multivariate analysis was performed using GEE with BASFI or DFI as dependent variables, and mSASSS and BASDAI as covariates, concurrently adjusting for age, sex, duration of illness, HLA-B27 status and hip involvement.

Both BASDAI and mSASSS contributed independently to the BASFI and DFI explanations with significant parameter estimates. Regression coefficients described the independent relationship between the explanatory variables and the dependent variable: in the environment, compared to a patient with mSASSS score 40, a patient with the mSASSS score 50 has a BASFI of 0.57 times greater, independent of BASDAI.

All mSASSS subscores contributed independently to the explanation of BASFI variations (p < 0.001). Compared to the mSASSS model, which had the best result, the model with the total score of the syndesmophyte, the number of the affected vertebral units, the number of vertebral vertebral units, and the model with the non-syndesmophytary summary score, it was deduced that the syndesmophytes are in much but not exclusively responsible for explaining variations in BASFI. A model with the syndesmophyte summary score (p < 0.001) and the non-syndesmophyte (p = 0.002) shows that both components contribute significantly to the explanation of BASFI variations. Results with DFI were similar.

Using mSASSS, the syndesmophyte subservices, the affected vertebral units or vertebral vertebral units, we showed that lumbar and cervical spine involvement contributed independently and almost similarly to explaining variations in BASFI and DFI.

Conclusions: The study conducted by us demonstrates that the patient’s physical function is not only dependent on signs and symptoms reported by the patient (activity of the disease), but also on the degree of structural lesions. Optimal AS treatment should not only include strategies aimed at removing pain, redness and fatigue, but also strategies aimed at preventing the formation and growth of syndesmophyte.

THE BURDEN OF DISEASE IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLARThRITIS IS NOT INFERIOR TO THAT OF ANKYLOSING SPONDYLITIS

THE PROOF STUDY

Background: According to the 2009 ASAS classification criteria, a patient with chronic low back pain (CLBP) may be classified as axial spondyloarthritis (ax-SpA), with or without radiographic evidence of sacroiliitis, if at least one other SpA feature is present in the first case and positive HLA-B27 and at least two SpA features in the second one. There is concern about whether the classification “axial non-radiographic spondyloarthritis” (ax-SpA-nr) includes patients with a mild disease that do not require treatment or special care by rheumatology.

Objectives: To compare disease burden between patients fulfilling criteria for AS and ax-SpA-nr.

Methods: Sub-analysis of Spanish patients from the PROOF study, an international prospective observational longitudinal study conducted in rheumatology clinics. All patients who attended rheumatology clinics due to CLBP (<3 months, start <45 years of age) from Jan 2015 to Feb 2017 not previously diagnosed were consecutively included. The ASAS criteria were applied to all, with centralised image reading. Patients with AS and ax-SpA-nr were compared.

Results: 192 patients with CLBP were included, of whom 151 (79%) met criteria of SpA-axe, 56 (43%) of AS and 74 (57%) of ax-SpA-nr (21 patients had X-ray missing or no central reading had been done so far). The table shows the description of patients with AS and ax-SpA-nr and their comparison.

IMPACT OF APPLICATION OF ASAS CRITERIA FOR AXIAL SPONDYLARThRITIS ON THE DIAGNOSTIC DELAY IN EGYPTIAN PATIENTS

F.J. Abdelrahman, M. Morsada. Rheumatology, ZAGAZIG UNIVERSITY, zagazig, Egypt

Background: Diagnostic delay is a major challenge in axial spondyloarthritis (SpA). The 2009 Assessment of SpondyloArthritis international Society
classification (ASAS) criteria for axial SpA formally recognised the utility of MRI in diagnosis. There are conflicting reports whether there had been any recent improvement in the period of diagnostic delay after application of ASAS criteria.

**Objectives:** To evaluate the period from symptoms onset to diagnosis in Egyptian patients with axial SpA before and after application of ASAS criteria for axial SpA and to examine possible reasons for delayed diagnosis.

**Methods:** The study included all axial SpA patients attending a university tertiary referral centre for regular follow up in the period between May 2016 to November 2017. The patients were divided into 2 groups; group 1 included patients with a diagnosis of axial SpA before the beginning of 2010 (when ASAS criteria became widely available and in use) and group 2 included patients with a diagnosis of axial SpA after the beginning of 2010. A face-to-face interview was applied for both groups to take medical history, and a questionnaire that contains some clinical aspects of disease was used. Diagnosis delay was described as the gap between first SpA symptom and correct diagnosis of axial SpA. Clinical and functional assessment of axial SpA measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI). The direct medical cost during years of delay (including costs of medical consultations, medications, investigations, physiotherapy and surgical treatment) had been estimated.

**Results:** As presented in table 1; more axial SpA cases were in group 2 (diagnosed after the beginning of 2010) with significantly narrower gap of delay, younger age at diagnosis, lesser number of doctor visits, lesser number of unnecessary surgical surgeries, lower total direct estimated costs and better BASDI, BASFI and BASMI.

**Conclusions:** Application of ASAS criteria for axial SpA has resulted in a significant decrease in the diagnostic gap which is reflected in a significant decrease in age at diagnosis and in the costs of unnecessary medications. On the other side, the gap is still large and more sensitive criteria are still needed.

**SIMILARITIES AND DIFFERENCES BETWEEN NON-RADIOGRAPHIC AND RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN PROOF CHINA COHORT**

**Chinese PLA General Hospital, Beijing; 2Renji Hospital of Shanghai Jiao Tong University School of Medicine, Shanghai; 3Southwest Hospital, Third Military Medical University, Chongqing; 4People’s Hospital of Xi’an Jiaotong University, Xi’an, China; 5Zhongshan Hospital affiliated with Fudan University, Shanghai; 6Guanghua Integrative Medicine Hospital, Shanghai; 7First Affiliated Hospital of Anhui Medical University, Hefei; 8Peking Union Medical College Hospital, Beijing; 9Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou; 10China-Japan Union Hospital of Jilin University, Changchun, China; 11AbbVie, Ljubljana, Slovenia; 12Charité Universitätsmedizin Berlin, Berlin, Germany

**Background:** National observational studies, mostly from Europe, have reported some differences between radiographic axial spondyloarthritis (axSpA) and non-radiographic axSpA (nr-axSpA).

**Objectives:** To compare demographic and clinical characteristics of patients (pts) with nr-axSpA and radiographic axSpA (ankylosing spondylitis, AS) in a Chinese subpopulation in the PROOF study.

**Methods:** PROOF is a prospective observational study evaluating clinical and radiographic outcomes in axSpA pts in rheumatology clinical practice in 29 countries over 5 years. Pts diagnosed ≤1 year before study enrollment with axSpA fulfilling ASAS classification criteria were eligible. Investigator confidence with the axSpA diagnosis was ascertained on a numeric rating scale (0–10) at enrolment and end of follow-up. Baseline characteristics, including demographics and clinical features, were compared between nr-axSpA and AS pts included in further analyses; 301 pts (80.9%) were classified as AS and 71 (19.1%) as nr-axSpA. AS pts had longer time since diagnosis, more frequent and higher CRP elevations, and were more often male and treated with TNF inhibitors (table 1). HLA-B27 positivity and prevalence of other SpA features were comparable between the 2 groups. Most disease burden assessments were comparable, but ASDAS-CRP, BASFI, and SF-12v2 physical component score were higher in AS pts (table 1).

**Results:** 464 (21.8%) pts in PROOF were enrolled in China; 307 (66.2%) were classified as AS and 157 (33.8%) as nr-axSpA according to the investigators. Confidence with the axSpA diagnosis was 9.0±1.5. The final classification based on central assessment of sacroiliac radiographs was confirmed in 372 (80%) pts included in further analyses; 301 pts (80.9%) were classified as AS and 71 (19.1%) as nr-axSpA. AS pts had longer time since diagnosis, more frequent and higher CRP elevations, and were more often male and treated with TNF inhibitors (table 1). HLA-B27 positivity and prevalence of other SpA features were comparable between the 2 groups. Most disease burden assessments were comparable, but ASDAS-CRP, BASFI, and SF-12v2 physical component score were higher in AS pts (table 1).

**Conclusions:**

The SIMILARITIES AND DIFFERENCES BETWEEN NON-RADIOGRAPHIC AND RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN PROOF CHINA COHORT study confirms the similarities and differences between non-radiographic and radiographic axSpA in terms of demographic and clinical features. The findings from this study provide important insights into the management and treatment of axial SpA in China, which can be used to improve healthcare practices and patient outcomes.
Problem Total Activity Impairment. *P-values from 2-sided t test for scale variables and Fisher exact test for categorical variables; statistical comparison between nr-axSpA and AS; *p<0.05, **p<0.001.

Conclusions: Clinical features and disease burden were generally similar between nr-axSpA and AS pts in the Chinese PROOF subpopulation. AS pts were more frequently men, had higher inflammatory burden (CRP and ASDAS-CRP), more functional impairment, and were more frequently treated with TNF inhibitors.

Abstract AB0860

ACUTE PHASE REACTANT CHANGE IN ANKYLOSING SPONDYLITIS PATIENTS

F. Demirer Aydemir1, G. Kenar1, B. Zengin1, H. Yarkan Tugsal1, S. Capar2, M. Bitlik1, F. Onen1, N. Akkoç1, G. Can1. ‘Rheumatology, Department of Statistics, Dokuz Eylul University; 2Rheumatology, Private Doctor, Izmir, Turkey

Background: The aim of this study is to investigate the levels of acute phase reactants (APRs) in patients with ankylosing spondylitis (AS) at the time of diagnosis and during follow-up. We also evaluated the associations between APR levels and disease activity.

Methods: The study included 948 patients with AS who were followed-up at Dokuz Eylul University School of Medicine Rheumatology outpatient clinic. The patients’ erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels across all visits were retrospectively reviewed through the Turkbio registry and the hospital’s database. Disease activity and follow-up parameters as BASDAI, ASDAS, BASFI and BASMI were taken from Turkbio visit charts. The correlation between APR and follow-up parameters were evaluated with Spearman correlation coefficient analysis.

Results: There were 948 AS patients (69% male, mean age 46.6±12.1 years) who fulfilled the 1984 modified New York criteria. At first visit, high levels of CRP and ESR were observed in 626 (68.5%) and 578 (64.6%) patients respectively. During follow-up 84.6% of patients had high CRP and 69.5% patients had high ESR at any visit (figure 1). However in 10% of AS patients APRs did not increase at any visits. There was good correlation between ESR and CRP (r=0.666, p<0.001). A better correlation was observed at first visit between CRP and BASDAI (r=0.81, p=0.23) or ASDAS (r=0.468, p=0.001) compared to ESR and BASDAI (r=0.111, p=0.02) or ASDAS (r=0.334, p=0.001) (table 1). Compared to Turkbio visit charts, the correlation between APR and follow-up parameters were evaluated with Spearman correlation coefficient analysis.

Abstract AB0861

HEALTH STATUS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS (AXSPA) AS DETERMINED BY THE ASSESSMENT OF SPONDYLOARTHITIS INTERNATIONAL SOCIETY HEALTH INDEX (ASAS-HI)

R. Burgos-Vargas1, G. Álvarez-Arce2, A. Pérez-Ballesteros2, C. Ramos-Remus3, M. Saavedra Salinas4, F. Enríquez-Sosa5, A. Guisain6, C. Pacheco-Tena7, G. Reyes-Cordero8, O. Muñoz-Monroy9, J. M. Background: The ASAS-HI is a new instrument based in the International Classification of Functioning, Disability and Health to assess the impact of axSpA; ASAS-HI has been validated in Mexican patients.

Objectives: To investigate the status of health in Mexican patients with axSpA using the ASAS-HI.

Methods: This is a multicenter, cross-sectional study of 377/423 patients with axSpA (ASAS criteria) referred by 64 rheumatologists with private or institutional practice across the country in a period of six months. Sociodemographic and clinical data were collected at each site and analyzed centrally.

Results: The ASAS imaging arm were fulfilled 87.5% and the clinical by 61.8%; the ASAS-HI cut off of six identified good health in 46.15% of patients (table 1). The correlation between ASAS-HI and BASDAI, BASMI, and ASDAS was six; values below six meant good health, which corresponded to 203 (53.84%) patients. Univariate analysis disclosed significant differences between groups in variables that were significant in the regression models (see below) and in health care coverage, enthesitis, joint counting, glucocorticoids, HLA-B27, sarcroliitis, BASMI, and ASDAS. In the multivariate analysis, two models were associated ASAS-HI: 1) sex, education, comorbidities, joint surgery, and physician global assessment; 2) BASDAI, BASFI, and EQ-5D.

Abstract AB0860 – Figure 1

Abstract AB0861 – Figure 1. Ven diagram of patients that elevation only ESR/CRP or with both elevation together at any visit

Conclusions: In over 80% patients with AS had elevated levels of CRP, the most frequently used laboratory parameter, during follow-up. CRP is well correlated with ESR, and disease activity parameters as BASDAI, ASDAS, BASFI and BASMI. Compared to BASDAI; ASDAS had better agreement between activity and APRs. Interestingly, in 10% of AS patients APRs did not increase in follow-up.

ANTERIOR THORACIC FATTY CORNER LESIONS ARE USEFUL IN AXIAL Spondyloarthritis (SPA) DIAGNOSIS – DATA FROM A MULTICENTER BACK PAIN-MRI COHORT IN HONG KONG

H.Y. Chung1, S.W.R. Yu1, H.H.L. Tsang2. 1The University of Hong Kong; 2QUEEN MARY HOSPITAL, Hong Kong, Hong Kong

Background: A fatty corner lesion (FCL), as defined by fat infiltration at the vertebral corner in T1 Magnetic Resonance Imaging (MRI) sequence, has been reported to be useful in Spondyloarthritis (SPA) diagnosis.

Objectives: Our objective is to systematically evaluate the diagnostic utility of FCLs in a large, multicenter back pain-MRI cohort in Hong Kong.

Methods: Three hundred and one patients with back pain were recruited from 3 rheumatology centres. Clinical, biochemical and radiological parameters were collected and all patients underwent a whole spine and sacroiliac (SI) joints MRI. FCLs from C4 to L5 levels were scored. Results were compared to expert-diagnosed axial SpA to determine the usefulness of FCLs in disease diagnosis.

Results: Anterior FCLs of whole or thoracic spine were found to be useful in axial SpA diagnosis. (AUC 0.62; p<0.003, AUC 0.64; p<0.001 respectively) Applying FCLs to the Modified New York (MNY) criteria and Assessment of SpondyloArthritis international Society (ASAS) axial SpA criteria, a minimum of 5 FCLs at whole spine level had a sensitivity of 66.4% and 91.6%, specificity of 98.4% and 91.9% respectively. Applying a minimum of 3 FCLs at thoracic spine level to the MNY criteria and ASAS axial SpA criteria yielded a sensitivity of 68.5% and 92.0%, specificity of 95.2% and 93.5% respectively. Three FCLs improves both classification criteria.

Conclusions: FCLs are useful in axial SpA diagnosis. A minimum of 3 FCLs at the thoracic level is useful for the disease diagnosis.

AB0863

ANALYSIS OF THE FREQUENCY OF UVÉITIS IN Spondyloarthritis PATIENTS AND ASSOCIATIONS WITH CLINICAL PARAMETERS OF THE DISEASE

I.M.S. Vale, M.D.S. Mastella, R.B. Trevisol, M.M. Pereira, M.J. do Carmo, I. A. Pereira. Universidade do Sul de Santa Catarina (UNISUL), Florianópolis, Brazil

Background: Acute anterior uveitis is the most common extra-articular manifestation of spondyloarthritis (SpA). The ocular inflammation in SpA is restricted to the uvea, usually unilateral and in some cases may precede the clinical characteristics of SpA.

Objectives: The aim of this study is to analyse if the presence of uveitis is associated with a different clinical manifestation, laboratory, radiological and therapeutic among spondyloarthritis patients.

Methods: This was an observational retrospective study with 153 patients with spondyloarthritis followed in the period from 1997 to 2017 in Florianópolis, Brazil. It was analysed demographical, laboratory, clinical and therapeutic data in spondyloarthritis patients with or without uveitis.

Results: 26.8% of the patients with spondyloarthritis presented uveitis. The presence of complications was rare, with cataract occurring in only four patients and glaucoma in two of them. A higher frequency of acute anterior uveitis in males (p=0.06) was observed in patients with a family history (p=0.19) and HLA-B27 positive (p=0.14). Patients with spondyloarthritis and uveitis more frequently used anti-TNF (p=0.04) and presented sacroiliitis on imaging tests (p=0.02). There was no association between uveitis and cardiovascular (p=0.44), cutaneous (p=0.13) or gastrointestinal involvement (p=0.10).

Conclusions: Uveitis in patients with spondyloarthritis is common, predominantly in males and more frequently, in HLA-B27 positive patients. Ocular manifestation in spondyloarthritis has a low degree of complication when compared to uveitis from other etiologies. The use of immunobiological agents such as anti-TNF is common in patients with uveitis.

AB0864

THE IMPACT OF DISEASE ACTIVITY, STRUCTURAL DAMAGE, AND FATIGUE ON PHYSICAL FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: DIFFERENCES IN EARLY AND LATE DISEASE

J. He1,2, I. Sarí1, R. Inman1, N. Haroon1. 1Rheumatology, Toronto Western Hospital, Toronto; 2Rheumatology, Western University, London, Canada

Background: In patients with ankylosing spondylitis (AS), the physical function impairment caused by the disease is among the biggest concerns for both patients and clinicians. Previous studies have shown that disease activity and structural damage are the main underlying causes for physical function impairment. There is accumulating evidence that suggests fatigue as well contributes to functional limitations. However, the differential impact of these factors on physical function at early and late stage of disease remains unclear.

Objectives: Study the strength of association in AS patients with varying disease duration, between physical function and the three potential determinants of interest: disease activity, structural damage, and fatigue.

Methods: AS patients satisfying the modified New York criteria were followed from 2003 to 2017. Patients completed a standardised annual protocol including demographic and clinical factors, with radiographic data collected biennially. Baseline physical function (BASFI) was analysed for association with factors including disease activity (BASDAI), radiographic changes (mSASSS), and fatigue (FSS). The same analysis was conducted again with patients sub grouped with respect to disease duration (<5 years, 5–9 years, 10–20 years,>20 years), and again with respect to change in BASFI between the first and last patient visit. Multivariable regression analysis was performed to identify independent predictors of physical function at baseline and the change with time.

Results: A total of 611 patients were followed and completed the standard protocol (mean age at initial visit 38.2 years; 74% male; 76.5% HLA-B27+). At baseline BASFI was independently associated (table 1) with BASDAI (p<0.001), CRP (p<0.0001), mSASSS (p<0.0001), and FSS (p<0.0001). In the disease duration subgroup analysis, BASFI was independently associated with BASDAI (p<0.05) and mSASSS (p<0.05) in all disease durations, and with FSS in subgroups with disease duration of 5 years or greater (p<0.05). In the longitudinal analysis, change in BASFI was independently associated with changes in BASFI (p<0.001) and FSS (p<0.05), but not change with mSASSS (p=0.283).

<td>&lt;0.0001</td>
</tr>
</tbody>
</table>

Abstract AB0864 – Table 1
Conclusions: The study demonstrated that disease activity and structural changes consistently contribute to physical function impairment in both early and late stages of disease. Fatigue does not associate with physical function at early stages of the disease, but it increases in contribution to functional impairment as disease duration increases.

DO ASAS, ASDAS AND BASDAI THERAPY RESPONSE EVALUATION TRANSLETE THE SAME INFORMATION?

M. Eusébio1, J.L. Gomes2, M. Bernades3, P. Pinto4, H. Santos5, J. Tavares-Costa1, J. Dias6, S. Pimenta3, L. Domingues7, C. Crespo8, S. Maia9, F. Martins10, J. C. Branco11, F. M. Pimentel-Santos12,13 1SPR, Portuguese Rheumatology Society, 2Rheumatology, HOSPITAL EGAL MONIZ – CHLO, 3CEDOC, NOVA Medical School, NOVA University of Lisbon, Lisbon; 4Rheumatology, Centro Hospitalar São João, Porto; 5Rheumatology, Centro Hospitalar Vila Nova de Gaia/Espinho, Gaia; 6Rheumatology, Instituto Português de Reumatologia, Lisbon; 7Rheumatology, Unidade Local de Saúde do Alto Minho, Ponte de Lima; 8Rheumatology, Centro Hospitalar Médico Tejo, Torres Novas, Portugal

Background: The ASAS-EULAR recommendations for the continuation of biological Disease-Modifying Anti-rheumatic Drugs (DMARD) suggest the evaluation of patients after at least 12 weeks of treatment by either the Ankylosing Spondylitis (AS) Disease Activity Score – C reactive protein (ASDAS-CRP) or by the Bath AS Disease Activity Index (BASDAI). For ASDAS-CRP, a Minimal Clinical Important Difference (MCID) ≥1.1 is necessary, while for the total BASDAI score a 50% reduction or a change of ≥2.0 points is considered clinically relevant. In clinical trials, the Assessment in Ankylosing Spondylitis (ASAS) response criteria – ASAS 20, ASAS 40 and ASAS 70 – are still the most frequent primary outcome measures to evaluate improvement in treatment response. However, in clinical practice the BASDAI is still routinely used.

Objectives: The aim of this work was to assess the concordance/agreement between different therapeutic outcome measures, such as the ASAS response criteria, ASDAS-CRP and BASDAI 50.

Methods: Data from 54 patients who fulfilled the modified New York criteria for AS were collected at baseline, weeks 2 and 14 post-treatment with Adalimumab. Pearson’s correlation (PCCs) and the Cohen’s Kappa coefficients were calculated for the three scores.

Results: A strong correlation was found between the three scores throughout the visits: rho=−0.676 for ASDAS/ASAS, rho=−0.807 for ASAS/BASDAI, and rho=0.786 for BASDAI/ASDAS (all PCCs with p<0.001). Additionally, when the categorization in different disease activity states and response levels was performed, PCCs revealed significant concordance/agreement between the three scores’ cut-offs (see table 1). The individuals categorised as responders, by either BASDAI50 or ASDAS ≥1.1, have shown similar clinical characteristics (Erythrocyte Sedimentation Rate, CRP, AS Quality of Life Scale and Bath AS Functional Index).

Conclusions: This study has been funded by Foreum (Foundation for Research in Rheumatology)

AB0866 ADVANCED METROLOGY IN PATIENTS WITH AXIAL Spondyloarthritis: lumbar or thoracic?

I.C. Aranda-Valera1, L. Garcia-Luque2, S. Alcaraz-Clariana2, J.L. Garrido-Castro3, I. Martinez-Sanchez3, C. Gonzalez3, P. Gardiner4, P.M. Machado5, E. Collantes1, on behalf of iMaxSpA Study Group.

Background: Advanced technologies for measuring human mobility have recently emerged: motion capture, inertial measurement units (IMU) and wearable devices. Some of them are used for mobility assessment of rheumatic patients. Certain devices analyse only lumbar mobility of the patients. Axial Spondyloarthriti-

Methods: 20 patients with axSpA and 20 age, BMI and sex-matched healthy subjects were recruited. An IMU sensor-based system (ViMove®) was used to measure spinal mobility. This system uses two IMU sensors and the angle between both is obtained in real time. Two tests were recorded: one with the recommended anatomical location (pelvis and L1) and another one aimed at combining lumbar+thoracic movement (pelvis and T3). Conventional metrology, radiographic structural damage (axSpA patients) and PROs were also collected.

Results: The table shows the results obtained for measuring only lumbar or lumbar+thoracic mobility, in both groups. The contribution of the thoracic spine to spinal mobility, and if this contribution should be taken into account in the metrological assessment of patients with axSpA.

**AXIAL SPONDYLOARTHRITIS POSTURE ASSESSMENT USING INERTIAL SENSORS**

J.L. Garrido-Castro1, I.C. Concha-Aranda2, P. Gardiner3, P.M. Machado4, J. Williams5, E. Collantes-Estevez2*, on behalf of iMaxSpa Study Group. 1MIBIC; 2HURS, Cordoba, Spain; 3WHSC, London; 4UCL, London; 5BU, Bournemouth, UK

**Background:** Axial Spondyloarthritis (axSpA) often causes spinal deformity in patients, mostly commonly a flexed kyphotic posture. In the early stages a flattening of the lumbar spine or reduced lordosis may become apparent. Kyphosis of the thoracic and cervical spine is also common in severe cases, resulting in an increased ‘tragus to wall distance’ as clinically assessed in the BASMI score. No other measurement related to posture is routinely recorded in clinical practice. Inertial Measurement Units (IMU) is a new technology that can measure angles of anatomical regions where the sensor is located.

**Objectives:** To compare the spinal curvature of axSpA and healthy individuals to analyse if there are any significant differences between them and to correlate these with conventional assessment variables.

**Methods:** 20 axSpA patients and 20 healthy age, BMI and sex matched controls, were recruited. An IMUs system (ViMove©) was used to obtain angles at key points along the spine. Sensors were located at Pelvis, L1, T3 and occiput (figure 1). Calibrated angles for all the participants where obtained with the subject in quiet standing position looking to a point in front of her/him. PRO questionnaires were used for cervical and lumbar spine was also measured using IMUs.

**Results:**

*p<0.05, **p<0.01, ***p<0.001

Results in deg (standard deviation). Pearson correlations: *p<0.05; **p<0.01; ***p<0.001

**Results:** Greater values of posture angles were obtained in healthy controls. Despite this, differences where significant (p<0.05) only for Lordosis and Cervical Posture. Lordosis angle shown a good correlation with mobility measured by Schöber and by IMU system, especially for flexion movements. Pelvis angle correlates better than L1 angle with all mobility variables. For cervical angles, occiput angle appears to be the best indicator for functional assessment. Thoracic angle is very similar between patients and healthy subjects. Figure represents the location of sensors with mean angles obtained by healthy group and the worst patient of axSpA group.

**Conclusions:** IMU based sensors are a useful new tool for the assessment of axSpA patients. This is the first formal evaluation of posture in axSpA and seems to be a promising tool in the functional evaluation of axSpA patients. More studies (reliability, feasibility, sensitivity to change, etc.) are needed for validating these measures.

**LUMBAR MUSCLES STIFFNESS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS IS ALTERED IN COMPARISON WITH HEALTHY SUBJECTS**

I.G. Aranda-Valera1, S. Alcaraz-Carriana2, L. Garcia-Luque2, J.L. Garrido-Castro2, I. Martinez-Sanchez2, C. Gonzalez2, P. Gardiner3, P.M. Machado3, E. Collantes3, on behalf of iMaxSpa Study Group. 1HU Reina Sofia; 2IMIBIC, Cordoba, Spain; 3WHSC, London; 4UCL, London, UK

**Background:** Axial Spondyloarthritis (axSpA) patients have inflammation and/or structural damage in the lumbar spine that reduces their mobility and quality of life. The biomechanical features of axSpA have not been investigated in detail, but could prove to be a very important factor contributing to pain, stiffness and
Conclusions: axSpA increases lumbar muscle stiffness with respect to healthy individuals. Muscle stiffness, as measured by myotonometry, was related to loss of movement and this could be contributing to a loss of function independently of structural damage and inflammation in axSpA. These new outcome measures could be helpful for understanding the evolution of the disease and for the functional assessment.

Conclusions: The results obtained suggests that the follow-up of a cohort of patients with spondyloarthritis in a specialised monographic medical centre allows a control of the symptoms with a low recurrence of extra-axial manifestations. We can conclude from this study that most patients with spondyloarthritis (75%) could have good control of their disease with NSAIDs in the long term.

AB0871 PREDICTIVE VALUES OF INFLAMMATORY LOW BACK PAIN, POSITIVE HLA B 27 ANTEN, INCREASED C-REACTIVE PROTEIN, POSITIVE MAGNETIC RESONANCE AND OTHER FEATURES IN AXIAL SPONDILOARTHRITIS (SPA). A PROSPECTIVE 2 YEARS FOLLOW UP

L. Y. Komsajova, 1 A. Valdivia, P.M. Salinas, 1 Rheumatology, 2Epidemiology and preventive medicine; 3Radiology department, Hospital Marina Salud, Denia, Spain

Background: Diagnosis of Spondyloarthritis remains challenging in the daily practise. Inflammatory back pain might be a good tool for early diagnosis.

Objectives: To analyse sensitivity, specificity and predictive values of inflammatory back pain (IBP), positive HLA B27 antigen, increased C-reactive protein (CRP), positive sacroilitis (SI) magnetic resonance (MRI) imaging, additional features (AF) such as peripheral arthritis, dactylitis, psoriasis, uveitis, inflammatory bowel disease (IBD) and familiar history (FH) and assesse probabilities to develop SPA.

Methods: We prospectively collected and follow up 82 patients referred to our department with suspicion of SPA from September 2014 to December 2016. Data such as IBP, HLA B27, additional features, familiar history of SPA, increased CRP, sacralic v-Rays and sacroilitic MRI imaging was performed for each patient. Each MRI image was separately and independantly evaluated by rheumatologist and radiologist.

Results: The average age in our study was 39.8 years with male/female ratio 0.4/1. 37 (45.1%) patients were diagnosed with axial SPA. Radiographic sacroilitis had only 5 (6.1%) patients. AF had (25%) patients. IBP was found in 36 (43.9%) patients, positive HLA B 27 antigen in 24 (29.3%) and increased CRP in 22 (26.8%). Sacroilitis (SI) MRI images were assessed as clearly positive if patients had more than 2 highly specific for SPA bone marrow oedema (BME) lesions, at least 3 fatty lesions and more than 1 erosion, positive MRI image if patients had at least 2 highly specific BME lesions, and clearly negative MRI images if patients had not got any of those features. We found 83.78% sensitivity and 88.89% specificity for IBP, 37.84% sensitivity and 80.95% specificity for positive HLA B27 antigen, 43.24% sensitivity and 88.1% specificity for increased CRP, AF such as such as peripheral arthritis, dactylitis, psoriasis, uveitis and IBD, evaluated together reached sensitivity 37.84% and specificity 84.44%. Positive FH only contributed to the diagnosis with 13.51% sensitivity, but showed higher specificity (94.44%). Sensitivity for positive SI MRI imaging were poor (51.3%) but reached excellent specificity (100%). Predictive values in our study were as follows: 86.11% predictive positive values (PPV) and 86.96% predictive negative value (PNV) for IBP, 63.64% PPV and 59.65% PNV for HLA B27, 76.19% PPV and 63.79% PNV for increased CRP, 66.67% PPV and 62.30% PNV for AF.

Positive FH contributed to the diagnosis with 66.67% PPV and 62.30% PNV. Positive MRI reached 100% PPV and showed high PNV – 71.43. Multivariate analysis was performed to identify which features were most likely to be diagnostic for SPA if only IBP without AF at the onset of the diagnosis and 94.8% if both IBP and AF were presented.

Conclusions: At the onset, IBP may be a good indicator for SPA with high sensitivity and acceptable specificity. Additional feature such as peripheral arthritis, dactylitis, psoriasis, uveitis and IBD might increase the possibility of SPA. HLA B27 antigen, increased CRP and FH brings low sensitivity for SPA nevertheless, specificity is better. Positive SI MRI imaging is highly specific but lacks sensitivity. Normal SI radiogaphy at the onset does not rule out diagnosis of SPA.
US RHEUMATOLOGISTS HAVE MIXED PERCEPTIONS ABOUT MANAGING PATIENTS WITH NON-RADIOPHAGIC AXIAL SPONDYLOARTHRITIS AND ANKYLOSING SPONDYLITIS

J. Robinson, L. Price. Advanced Analytics Group, Sphero Global Insights, Exton, USA

Background: Non-radiographic axial spondyloarthritis (nrAxSpA) is a relatively new term used to describe patients who clinically appear to have ankylosing spondylitis (AS) but do not exhibit radiographic sacroiliitis. Though several biologics are currently FDA approved for the treatment of AS, there are no agents approved for patients in which there is not radiographic evidence of sacroiliitis. With several agents under investigation with the hopes of gaining a line-extension label for nr-axSpA, it is important to understand how the current treating rheumatologists view these two diseases and their current and future plans for spondyloarthropy management.

Objectives: The study sought to (a) evaluate the differences between AS and nr-axSpA diagnosis and treatment patterns (b) highlight the challenges clinicians face in managing patients with nr-AxSpa and (c) understand rheumatologists’ willingness to use biologic agents to treat nr-AxSpA.

Methods: An independent market analytics firm collaborated with US rheumatologists (n=98) to learn about current and anticipated changes to the management of Ankylosing Spondylitis and Non-radiographic Axial Spondylitis. Participants were administered an online survey, lasting approximately 30 min in length and respondents were compensated for their professional time. Following the fieldwork, data were analysed in SPSS, a statistical software, to determine significant differences.

Results: 87% of the surveyed rheumatologists agree that AS and nr-axSpA are part of a spectrum, and 37% report that they often find it challenging to differentiate between the two conditions. The majority of the respondents report that they treat these conditions in a very similar manner. In fact, 40% agree that distinguishing between the two has no relevance to their treatment decisions. Use of biologics is significantly more pronounced in AS (56% vs. 39%, respectively), largely because there is currently no FDA indicated biologic for nr-axSpA and because many rheumatologists view nr-axSpA simply as a less severe precursor to AS, where aggressive treatment with a biologic is not warranted. In order to gain reimbursement for a biologic in patients with nr-axSpA, rheumatologists frequently classify patients as having AS (as opposed to nr-axSpA). Although adalimumab is the most frequently prescribed biologic in both conditions, rapid adoption of an IL-17 inhibitor (secukinumab) is occurring in the US market.

Conclusions: There is a need to educate both primary care physicians and rheumatologists about the differences between AS and nr-axSpA. The official FDA approval of biologic agents in nr-axSpA is anticipated to lead to more aggressive treatment of these patients earlier in the spectrum.

MENTAL HEALTH DISORDERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: INCREASING OUR UNDERSTANDING OF THE DISEASE. RESULTS FROM THE ATLAS-2017

M. Garrido-Cumbres1,2, V. Navarro-Compan3, D. Gálvez-Ruiz2, C. Delgado-Dominguez1, P. Font Ugalde4, O. Braqe5, P. Zarco5, J. Chacón-García5, P. Plazuelo-Ramos5,1, Universidad de Sevilla, Sevilla, Spain; 2CEADE, 3Rheumatology, Hospital La Paz, IdiPaz, Madrid, Spain; 4Medicina, Universidad de Córdoba, Córdoba; 5Rheumatology, Hospital Fundación Alarcón, Madrid, Spain

Background: Depression and other mental disorders are among the most prevalent comorbidities in patients with axial spondyloarthropathies (axSpA). Objectives: To assess the association between sociodemographic characteristics, disease progression, and mental health comorbidity with risk of mental disorders (RMD).

Methods: In 2016 a sample of 680 axSpA patients was interviewed as part of the Spanish Atlas. To quantify the RMD, GHQ-12 scale was employed. Possible RMD predictors taken into account in the analysis were: sociodemographic characteristics (age, gender, being part of a couple, patient association membership, job status); disease characteristics (BASDAI, spinal stiffness, functional limitation in 18 daily activities; and mental health comorbidities. All clinical variables showed a Cronbach’s alpha coefficient guaranteeing the reliability of the scales used. First, a descriptive analysis was employed to describe the sample and study variables. Second, univariate correlation and homogeneity analyses between each predictor (independent variable) and RMD (GHQ-12) were performed.

Results: All variables except educational level and thoracic stiffness showed significant univariate correlation with RMD. BASDAI, functional limitation and age showed higher coefficient (r=0.543, p<0.001; r=0.378, p<0.001; r=−0.174, p<0.001, respectively). Multiple hierarchical regression analysis showed as sociodemographic variables explained in great detail the RMD (R²=83.2%). By contrast, having established sociodemographic as a control variable, the inclusion of depression and anxiety to the model increased the R² value to just 0.6% (p<0.001), while the inclusion of variables related to the disease characteristics add 5.5% (p<0.001) to the GHQ-12 punctuation variability. The only variables presenting a significant coefficient different from 0 were BASDAI (0.52, p<0.001) and functional limitation (0.14, p<0.01). This suggests that once the sociodemographic and mental comorbidity variables are established, a change in BASDAI levels or functional limitation impacts the GHQ-12 score.

In the stepwise regression analysis, four variables (BASDAI, functional limitation, association membership, cervical stiffness) showed a significant relation to GHQ-12 and explained the majority of RMD variability. BASDAI displayed the highest explanatory degree (R²=0.875, p<0.001).

Conclusions: In axSpA, patients at certain sociodemographic levels are more prone to present a higher BASDAI. Taking these conditions for granted, the degree of disease progression measured by BASDAI is a good indicator of RMD. Therefore, in those patients with higher disease activity, psychiatric evaluation and intervention should be considered within the medical treatment.

QUALITY OF LIFE IMPROVEMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS TREATED WITH NSAIDS AND BIOLOGICAL THERAPY FROM THE PATIENT’S PERSPECTIVE: RESULTS FROM THE ATLAS-2017

M. Garrido-Cumbres1,2, D. Gálvez-Ruiz2, J. Gratacos3,4, C. Blanca-Mur5, V. Navarro-Compan3, Universidad de Sevilla, Sevilla, Spain; 2CEADE, Madrid; 3Rheumatology, Hospital Universitari Parc Tauli, Sabadell; 4GPT, UAB; 5Novartis, Barcelona; 6Rheumatology, Hospital Universitario La Paz, IdiPaz, Madrid, Spain

Background: In patients with axial spondyloarthritides (axSpA), the main long-term outcome is quality of life. Clinical trials and observational studies have shown the efficacy of biological therapy (BT) on improving the signs and symptoms of the disease. However, data assessing the impact of BT on quality of life is scarce and mainly comes from clinical trials.
Objectives: To assess in clinical practice the improvement in quality of life from the patient’s perception as a result of pharmacological treatments in axSpA.

Methods: A sample of 680 patients diagnosed with axSpA was interviewed through an online survey as part of the Spanish Atlas-2017, which aimed to promote early referral, improve healthcare, and the use of effective treatments in patients with axSpA. For this study, self-reported data from patients who had received both NSAIDs and BT were analysed. Patients were asked about the improvement they had experienced on 7 different aspects of quality of life after starting treatment with NSAIDs or BT: independence, leisure and free time, social relations, sport and physical activity, and mood and sexual relations. Improvements were measured on a 0 to 10 Likert Scale and classified as low (<5) and high (≥6). Non-parametric (Wilcoxon) tests were used to compare the degree of improvement between patients with biological therapy and those with NSAIDs.

Results: A total of 189 patients who had received both types of drugs were included. The mean (SD) age was 44.03 (±10.11) years, 50.3% were females, 70.8% married and 47.1% belong to a patients’ association. The mean (SD) disease duration was 21.3±10.7 years and 67.7% were HLA-B27+ patients. A higher percent-age of patients perceived a high level of improvement after receiving a BT than after receiving an NSAID, for both overall quality of life assessment (57% vs 22%, respectively) and the different quality of life-related aspects. Additionally, the mean degree of improvement for overall quality of life assessment and the different aspects related to this were reported to be significantly higher after receiving BT than after NSAIDs (overall improvement: 5.46±2.59 vs 3.19±2.45; p<0.001, respectively).

Conclusions: In clinical practice, patients’ self-reported satisfaction overall and related to different aspects of quality of life is substantially greater after being treated with BT than with NSAIDs. However, these results need to be confirmed in a longitudinal study.

AB0877 ANALYSIS OF THE ASSOCIATION OF THE PERIPHERAL INVOLVEMENT OF THE SPONDYLOARTHRITIS WITH THE EXTRA-ARTICULAR MANIFESTATIONS

M.D.S. Mastella, I.M.S. Vale, M.M. Pereira, M.J. Carmo, G.R.W. Castro, I. A. Perera. UNISUL, Florianópolis, Brazil

Objectives: Patients with SpA present peripheral involvement, such as arthritis and enthesitis, or only axial involvement, such as sacroiliitis and spondylodiscitis. The differentiation of the peripheral and axial presentation is important, being able to guide different therapeutic strategies.

Methods: This is a retrospective observational study, conducted in two clinics in Florianópolis. The population was composed of patients with AS and non-radiographic and peripheral axSpA, according to the criteria of modified New York and ASAS group, respectively, served from 1997 to 2017.

Results: 153 patients were analysed, 82 were male (53.59%), 71.29% were HLA B27 positive (77/108 tested), 87.3% had sacroiliitis detected on x-ray, CT or MRI, 104 presented peripheral involvement (67.97%) and 49 (32.02%) purely axial involvement. Arthritis occurred in 86 (56.2%) and enthesitis in 57 (37.3%) patients. The use of synthetic DMARD occurred in 78.4% of the patients, more frequently in the group with peripheral involvement, with methotrexate being used in 74% versus 56.3% of those with purely axial involvement (p<0.05). The use of biological DMARD occurred in 104 (68%), in the majority of the anti-TNF class (96.1%), with the highest frequency of use in patients with axial involvement (77.1% versus 64.4%), but not statistically significant (p=0.05). Extra-articular manifestations were found in 72 (47.1%) of the patients, with uveitis being the most frequent (26.8%). The presence of uveitis occurred in 68.3% of patients with isolated axial involvement versus 31.7% of patients with peripheral involvement (p=0.019). The cutaneous involvement occurred in 18.3% of the patients with peripheral involvement compared to 8.3% of those with an isolated axial condition. Regarding bowel involvement and cardiovascular impairment, there was no significant difference in prevalence between the two groups.

Conclusions: Extra-articular manifestations are frequent in SpA, but are not more frequent in patients with peripheral involvement versus patients with pure axial involvement. Peripheral involvement is associated with greater use of synthetic DMARDs when compared to pure axial involvement.

AB0876 CORRELATION BETWEEN FAECAL CALPROTECTIN LEVELS AND TOBACCO USE IN PATIENTS WITH SPONDYLOARTHRITIS AND WITHOUT PREVIOUS DIAGNOSIS OF INFLAMMATORY BOWEL DISEASE

1Rheumatology; 2Clinical Pharmacology; 3Digestive, H. U. Puerta de Hierro Majadahonda, Madrid, Spain

Background: It is estimated that between 5% and 10% of patients with spondyloarthritis (SpA) are associated with inflammatory bowel disease (IBD). It has also been proven through endoscopic and histological studies that up to 60% of patients with SpA have microscopic inflammatory intestinal lesions, with a subclinical character and of which the true clinical relevance is unknown, although a greater percentage of these are those that will evolve to IBD.

Objectives: To assess whether tobacco use may be associated with higher faecal calprotectin (FC) levels in patients with diagnosis of SpA and without clinical inclusion previous diagnosis of IBD.

Methods: TT is a single centre, cross-sectional, observational study with prospective collecting data. Data were included for consecutive patients from Rheumatology consultation who had been previously diagnosed of SpA, fulfilled ASAS criteria and without digestive symptoms suggestive of IB (chronic diarrhoea, rectal bleeding, perianal disease, chronic abdominal pain – persistent or recurrent). Details about demographic characteristics, clinical and laboratory variables related with SpA (BASDAI, HLA B27, acute phase reactants), treatments and FC were collected. A pathological cut-off point of FC≥50 mg/kg was determined. Patients on NSAID treatment were advised to discontinue its use 2 weeks before collecting stool samples. This study was approved by the Clinical Research Ethics Committee.

Results: 99 patients were included: 53.5% women, with a mean age of 46±11 years. Nonspecific digestive disorders (dyspeptic symptoms, H. pylori y gastroduodenal reflux) were observed in 9% of the patients. Among all, 18% were smokers. Mean BASDAI was 3.7±2.5; 39% of patients were being treated with any concomitant DMARD and 67% were on NSAIDs. 49.5% of the patients showed elevated FC determinations, with an mean level of 276 mg/kg (range 52–3,038). The percentage of patients with high levels of FC was significantly increased in smokers (72.2% vs. 44.4%, p = 0.033), with higher levels of FC in smokers than non-smokers (262 mg/L vs. 121 mg/L, p = 0.126). The remaining analysed variables did not show any significant differences in terms of FC levels.

Conclusions: Microscopic bowel inflammation is described in approximately 50% of patients with SpA and it is related with more severe disease. Tobacco use has been associated with worse prognosis and response to treatment in SpA. A relationship between elevated FC levels (inflammatory activity biomarker) and tobacco use in patients with SpA without previous diagnosis or clinical suspicion of IBD is established in this study.

Abstract AB0880 – The Objective Automated Measurement of Fluorescence-Signal Intensities in Fluorescence-Optical Imaging Technique Discriminates Between Disease Activity and its Response in AntiTNF Treated Psoriatic Arthritis Patients – An Interims Analysis of the XPLOR-study

M. Köhnb,2, S. Ohmdorf2, T. Rossmanithb, A. Foldenauera, U. Henkemierb, G. Schmittaa, J. Bergerb, H. Burkhardtb,2, F. Behrensb,2, on behalf of The XPLOR Study Group. 1Rheumatology, Goethe-University Frankfurt/Main; 2Clinical Research, Fraunhofer IME TMP, Frankfurt/Main; 3Rheumatology and Immunology, Universitätmedizin Charité, Berlin; 4CIRI, Goethe-University Frankfurt/Main; 5Rheumatology and Immunology, Universitätmedizin Charité, Frankfurt/Main; 6Xiralite GmbH, Berlin, Germany

Background: Psoriatic arthritis (PsA) is a chronic inflammatory disorder combining joint and musculoskeletal inflammation. AntiTNF-therapy is induced after failure of NSAID and DMARD treatment. Up to 30%–40% of the patients are primary non-responders adequately to the induced biological therapy. In daily practice response is calculated by improvement of disease activity measured by clinical examination and calculated using composite indices. Feasible and robust biomarkers for prediction of response are missing.

Methods: Fluorescence optical imaging (FOI) is used as method for detection of changes in microvascularisation of the hands as potential marker for inflammation. ICG is injected as fluorescence agent, that is than stimulated by light and recorded by a specific camera system. An automated computer-based reading of the disease activity (DACT) is used as an objective method to display overall fluorescence-signals and their intensities. In a prospective multicentre study, the value of FOI in measurement of disease activity and its predictive value to discriminate responders in newly treated PsA patients is currently investigated in the XPLOR-study. This interim analysis investigates the value of baseline (BL) DACT to discriminate between responders (at least low disease activity (LDA) with DAS28 ≤3.2) and non-responders compared to standard clinical disease measurements (SJC, TJC, DAS28) over the 52 weeks observational period.

Disclosure of Interest: None declared

Results: Data from 23 patients were analysed during the 52 weeks observational period. Mean age was 54.7 years, 80% of the patients were female. Mean DAS28 score at baseline was 4.26, mean BSA 9%, whereas mean values for SJ were 5.9 and TJC 11.4 using 66/90 joint count. All patients were negative for ACPA and rheumatoid factor.

ROC analysis revealed that a DACT cut-off of 4.55 at baseline, indicating moderate expression of fluorescence intensities in context of disease activity, shows a predictive quality to LDA achievement at W52 with 80% specificity, 78% sensitivity and likelihood ratio of 3.89 (LR+) and 0.28 (LR-). The corresponding AUC value is 0.717 (95% CI:0.333, 1.00). Compared to clinical disease measures such as baseline DAS28, TJC or SJC, the DACT at BL is more discriminative to identify patients who attain LDA at W52.

Conclusions: This interim analysis of the XPLOR study shows promising data for the use of FOI as possible imaging biomarker for disease activity measure and prediction of response in PsA-patients newly treated with antiTNF-therapy: Baseline values evaluated using the automated computer-based reading of the fluorescence intensities with a cut-off of 4.55 are predictive for later achievement of DAS28 low-disease activity or remission within the treatment course. Data will be verified in a larger cohort of the XPLOR study.

ASSOCIATION OF RS12218 POLYMORPHISM IN SAA1GENE WITH LUMBAR SPINE SYNDROMES IN RUSSIAN ANKYLOGONITIC SPONDYLOPSYTOPISPOPULATION. A PILOT STUDY

M. Krivoy1, S. Erdes1, A. Starkova, E. Samarkina, I. Guseva, N. Konovalov, D. Varlamov

1V.A. Nasonova Research Institute of Rheumatology; 2All-Russian Research Institute of Agricultural Biotechnology, Moscow, Russian Federation

Background: Ankylosing spondylitis (AS) is a chronic inflammatory disease from the group of spondyloarthritis (SpA). Earlier studies showed a correlation between SAA1 gene polymorphism, encoding serum amyloid A, and the development of secondary AA-amyloidosis in familial Mediterranean fever and rheumatoid arthritis in Caucasian and Asian populations. The Morishige et al (2005) study showed that the −13 T/C polymorphism in the gene 5-flanking region (rs12218) is a better marker of AA-amyloidosis than mapping of polymorphisms in SAA1 exon 3 (SAA1.1 and SAA1 1.3). Data on rs12218 polymorphism contribution into predisposition to AS and its clinical phenotypes are very scarce. One of the clinical phenotypes, determining the severity of spine damage, is associated with presence of syndromes (SM) in the lumbar (SMA), thoracic (SMT) and cervical (SMC) spine, confirmed by x-ray data.

Objectives: To study potential associations of rs12218 polymorphism in SAA1 gene with AS and phenotypes of radiographic progression, with the presence of SMA, SMT and SMC, and correlation with BASDAI, BASFI and ASAS indices.

Methods: rs12218 polymorphism was studied in 112 subjects: 47 AS patients (37 males and 10 females, mean age 40y, mean disease duration 213 weeks, mean age at onset 22y, positive for HLA-B27), and 65 healthy volunteers (controls). Genotyping was performed using allele-specific polymerase chain reaction in real-time (PCR-RT).

Results: The Pearson Correlation analysis showed negative correlation between rs12218 polymorphism and presence of SM, as well as BASDAI, BASFI scores (r=-0.39, r=-0.35 and r=-0.36, p<0.006, p=0.017, p=0.014, respectively). There were no correlations between rs12218 and pts' age, AS duration and pts' age at AS onset. There were similar rs12218 allele distribution rates between AS patients and the controls. rs12218C allele rates were significantly higher in SM group (n=23) compared to subjects without SM (n=24) [50.0% vs. 15.2%, p=0.001]. No association was established between C allele and presence of SM in other parts of the spine. A correlation between BASDAI and BASFI scores and SAA1 gene rs12218 polymorphism was established. Mean BASDAI score was significantly higher in carriers of TC and CC genotypes compared to carriers of TT genotype (5.6±1.3 vs. 3.9±2.3, p<0.004). The mean BASFI scores in carriers of the respective genotypes were (6.1±2.3 vs 4.1±2.8, p=0.012). No significant correlation was found between rs12218 genotypes and mean ASAS scores variable.

Conclusions: Therefore, this pilot study is the first to show the possible participation of rs12218 polymorphism in SAA1 gene in AS pathogenesis in Russian population. We suggest that C allele may be a marker for predicting predisposing to SM [OR 5.14 95% CI(1.75–16.17), p=0.001]. The data obtained on a limited sample of patients require further verification on larger samples of patients involving different population groups.

ACHILLES ENETHESIS IN THE PATIENTS WITH SPONDYLOARTHRITIS: RELATIONSHIP WITH MUSCLE STRENGTH, ACTIVITIES OF DAILY LIVING AND QUALITY OF LIFE

Ö. Kuru, B. Farsığülcan, G. Alayi, A. Bilgici, D. Durmuş, Physical Medicine and Rehabilitation, Ondokuz Mayıs University Medical Faculty, Samsun, Turkey

Background: Enthesitis is a central feature of spondyloarthritis (SpA). In SpA, muscles of the lower extremities are more commonly involved than those of the upper limbs, and the heel is the most frequent site. Investigation of peripheral enthesitis in SpA is based on clinical findings and/or imaging findings. The involvement of Achilles tendon may lead to pain, movement restrictions, decrease in muscle strength, and eventually a diminished quality of life (QoL).

Objectives: In the present study, we aimed to evaluate clinical enthesopathy and relationship with ankle muscle strength, activities of daily living (ADLS) and foot and ankle related QoL in the patients with SpA.

Methods: Sixty SpA patients fulfilling the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for SpA (M/F=39/21) (35.6±18.95 years) and 50 healthy controls (M/F=32/18) (35.40±10.62 years) were enrolled in the study. Clinical enthesopathy was defined by the presence of at least one of the spontaneous pain, tenderness elicited by pressure, mobilization and contraction against resistance of the corresponding tendons and local swelling of the enthesis. Pain by visual analogue scale (VAS), disease activity by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional capacity by Bath Ankylosing Spondylitis Functional Index (BASFI), enthesis severity by SPARCC index was assessed in the patients. Isokinetic measurements of ankle dorsiflexion and plantarflexion were performed by the isokinetic dynamometer. Five patients were tested at 30° and 120°/sec angular velocities. Pain, other symptoms (stiffness, swelling, range of motion), ADLS, sport and recreational activities, and foot and ankle-related QoL were evaluated by the Foot and Ankle Outcome Score (FAOS) in which higher scores indicate less problems and/or functional limitations.

Results: There was no significant difference between the patients and controls regarding age, sex, and body mass index. Clinical enthesopathy was detected in 36.7% of the SpA patients. Although ankle plantarflexion and dorsiflexion muscle strength in all angular velocities were lower in the SpA patients, the difference did not reach statistical significance (p>0.05). All of the FAOS subscales were found to be significantly lower in the patients with SpA than in the controls (p<0.001). When the SpA patients were divided into two groups as with clinical enthesopathy (n=22) and without clinical enthesisopathy (n=38), there were significant differences between the groups regarding VAS pain, BASDAI, BASFI and SPARCC scores whereas there was no significant difference in muscle strength. Also, all FAOS subscale scores were significantly lower in the patients in clinical enthesopathy. Additionally, in the patients with SpA, while there were negative correlations between VAS pain, BASDAI, BASFI, SPARCC and FAOS subscale scores, there was a positive correlation between ankle muscle strength and FAOS scores (p=0.05).

Conclusions: We found that all the FAOS subscale scores were lower in the SpA patients and they were correlated with clinical findings. The results of our study indicate that even though there was not a significant decrease in the muscle strength, ADLs, sport and recreational activities, foot-related QoL are poorly affected in the SpA patients with Achil enthesis.

ASSESSMENT OF EARLY MYOCARDIAL DYSFUNCTION USING SPECKLE TRACKING ECHOCARDIOGRAPHY IN PATIENTS WITH RADIOPHAGIC AND NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

V. Emren1, Q. Cansar2, E. Ozdemir1, D. Solmaz1, S. Gucennaz2, N. Ere2, M. Tokac1, G. Kabadiyå1, S. Akar2, 1Cardiology; 2Rheumatology, Izmir Katip Celebi University School of Medicine, Izmir, Turkey

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly affects axial skeleton. Although some differences like sex and objective signs of inflammation were described between these two subgroups, overall disease burden was found to be similar in radiographic (r-) and non-radiographic (nr-) axSpA patients. The association of chronic inflammation with cardiac dys-function was well documented in many inflammatory rheumatic diseases. However, it was not assessed in the subgroups of axSpA patients. Advanced two-dimensional (2D) speckle tracking echocardiographic analysis is more sensitive and accurate method of early detection of myocardial dysfunction than the conventional 2D transthoracic echocardiography (TTE).

Objectives: To evaluate the left ventricular function by using speckle tracking echocardiography in patients with both r- and nr-axSpA.

Methods: In total 64 patients with r-axSpA (70% male) and age- and sex-matched 27 patients with nr-axSpA (63% male) and 30 healthy control subjects

(83% male) were included in the analysis. Patients with hypertension, diabetes and known cardiac disease were excluded. All patients underwent detailed echo-
cardiographic examination including M-mode, pulsed-wave Doppler imaging, pulsed-wave tissue Doppler imaging and 2D speckle tracking.

Results: Age and sex distribution were not different between groups. Some dem-
ographic and disease related characteristics were shown in the table. BASDAI, 
BASFI, global assessment of disease activity and ASAS-HI scores were found to be 
similar between r-axSpA and control groups however GLS was significantly low in 
r-axSpA patients. In univariate analysis GLS was correlated with age (p=0.025), 
 EF (p<0.001), peripheral arthritis (p=0.047), and smoking (p=0.019). However in 
regression only peripheral arthritis (p=0.032) and EF (p=0.019) were found as the 
independent predictors of GLS.

Abstract AB0883 – Table 1. The demographic and disease related characteristics of study 
groups.

SERUM FIBROBLAST GROWTH FACTOR-23 LEVELS WERE HIGHER IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS AND MAY BE ASSOCIATED WITH DISEASE ACTIVITY

O. Gercik1, E. Coban2, B. Ozbek Ipecte, 3, G. Arcioglu3, D. Solmaz3, 2, O. Bayindir3, 2, O. Kabadayi3, 2, D. Koçaoz3, S. Akar3, 2, Rheumatology, 1Celbi Celebi University School of Medicine, 2Izmir Katip Celebi University School of Medicine, 3Izmir, 4Medical Biochemistry, Ankara Yukim Beyaz University School of Medicine, Ankara, Turkey

Background: Axial spondyloarthritis (axSpA) is a chronic inflammatory disease 
that mainly affects axial skeleton. The disease is characterised by new bone for-
mation; it usually starts with the bony fusion of sacroiliac joints (SJJs) and also 
causes syndesmophyte formation in the intervertebral space, enthesopathies in 
the tendon and ligament insertion sites. Underlying mechanisms of new bone for-
mation in axSpA patients is not completely understood and low levels of sclerostin 
may be associated with the development of syndesmophyte in patients with anky-
losing spondylitis (AS). Beside sclerostin another osteocyte factor is fibroblast 
growth factor 23 (FGF-23) and it has been first described as a phosphaturic hor-
more. It was also shown that FGF-23 may inhibit osteoblast differentiation and 
matrix mineralization.

Objectives: To evaluate serum FGF-23 and sclerostin levels in patients with 
axSpA and to compare them with those of healthy control subjects. We also 
assessed relationship between the serum FGF-23, sclerostin levels and disease 
related variables in particular the presence of structural changes.

Methods: In total 109 axSpA patients according to ASAS classification criteria 
and age- and sex-matched 57 healthy control subjects were included in the analy-
sis. Subjects with renal failure and significant comorbid conditions and axial SpA 
patients who were using anti-TNF agents were excluded. Demographic and dis-
 ease related characteristics were collected by using a standard questionnaire.

Results: Serum levels of FGF-23 and sclerostin were measured using commer-
cially available enzyme-linked immunosorbent assay (ELISA) kits in accordance with 
the supplier’s instructions.

Results: In the present study there were 56 patients with non-radiographic axSpA and 53 patients with AS. Serum levels of FGF-23 levels were significantly higher 
in axSpA patients than healthy subjects. Although there was a trend towards a 
lower sclerostin levels in axSpA patients this difference did not show statistical 
significance (table 1). In axSpA patients serum FGF-23 levels were found to be 
correlated with erythrocyte sedimentation rate (ESR) (r=0.006 and r=-0.265), C-
reactive protein (CRP) (p=0.017 and r=0.229) and patients’ height (p=0.027 and 
r=–0.221). There was no relationship between FGF-23 and mSASSS score or the 
presence of syndesmophyte. Subgroup analysis revealed that the duration of dis-
 ease (p=0.005), ESR (p=0.007), CRP (p<0.001) and mSASSS (p=0.008) scores 
were significantly higher in AS patients than nr-axSpA patients. However serum 
sclerostin levels were significantly higher in nr-axSpA patients (1464.4±728.1 vs 
1150.8±754.3 pg/mL and p=0.029).

Abstract AB0884 – Table 1. Demographic characteristics and serum FGF-23 and sclerostin 
levels in study groups

AB0885

CHARACTERISTICS OF JUVENILE ONSET HIP ARTHRITIS IN PATIENTS WITH SPONDYLOARTHRITIS

W. Hamdi, R. Ben Saad, H. Riahi, K. Maatallah, D. Kaffel, T. Bouazziz, L. Ledia, M. Kchir. 1institut national de Mohamed el Kassab, tunis, Tunisia

Background: Axial spondyloarthropathy (AS) is a chronic inflammatory rheumatic 
disease that affects the axial skeleton. It typically occurs in the late teens or early 
twenty years and rarely in childhood, defining the juvenile onset (JoAS).

The adult-onset AS (AoAS) and Juvenile-onset (JoAS) may share many common 
features including hip involvement. But their impact on function and quality of life 
may differ.

Objectives: To compare demographic, clinical and functional outcome of patients 
with hip involvement in JoAS, with that of patients with AoAS.

Methods: Cross-sectional study including patients with AS according to the 
ASAS criteria of 2009 with hip involvement. The juvenile onset of coxitis was defined 
as onset before 16 years of age. An analysis of demographic and clinical compar-
sions between the two groups was performed including HLA B27 status. Mobility 
spine outcomes were assessed by the Bath AS Metrology Index (BASMI) and 
radiographic disease severity by the Bath AS Radiology Index (BASRI).

Results: There were 100 AS aged on average 36.4±12.2 years old (16–59). The sex 
ratio was 4.6. The mean duration of progression of AS was 10.9±3.9 years 
(0.5–24). It was a JoAS in 15 cases. All patients had a hip involvement. The 
juvenile onset of hip arthritis was associated with male gender (p=0.042), younger age 
of patient with AS at the time of recruitment (p=0.007), less severe clinical spinal 
involvement assessed by schober index (p=0.029) and more frequent and severe 
entheses assessed by MASES (p=0.024). Extra-articular manifestations were 
significantly more frequent in patients with juvenile onset of hip arthritis (p=0.008).

Otherwise the comparison of the two groups showed no difference in the pres-
ence of uveitis (p=0.407) and pulmonary involvement (p=0.097). HLAB27 antigen 
was significantly more common in JoAS (p=0.037). BASRI and BASMI as well as 
ESR and CRP, were comparable between the two groups (p=0.976, p=0.626, 
p=1.000, respectively).

Conclusions: Hip involvement is common in the AS, particularly in JoAS. Our 
study showed that juvenile onset hip arthritis was associated with male gender, 
less severe spine involvement, enthesitis and the presence of HLA B27. This 
would help physicians to identify patients at higher risk of developing hip involve-
ment, to enable early diagnosis.

AB0886  
**DOES RADIO-ANATOMIC FEATURE OF HIP ARTHRITIS IN SPONDYLOARTHRITIS PREDICT FUNCTIONAL IMPAIRMENT?**

W. Hamdi, P. Ben Saad, H. Riahi, K. Maatallah, D. Kaffel, T. Bouaziz, L. Ledab, M. Kchir. institut national de Mohamed El Kassabt, Tunis, Tunisia

**Background:** Axial spondyloarthritis (AS) is a chronic inflammatory disease that primarily affects the axial skeleton. Hip involvement is common in AS patients. The prevalence of clinical hip involvement in AS ranges from 24% to 36%, and the prevalence of radiographic hip arthritis ranges from 9% to 22%. 

**Objectives:** To assess for an association between the radio-anatomic feature of hip arthritis and its clinical impact in patients with AS.

**Methods:** Cross-sectional study including patients with AS according to the ASAS criteria of 2010. All patients had pelvic X-rays. This one allowed to distribute patients according to four radio-anatomic feature of the hip arthritis: destructive, protrusive, ankylosing, and early hip arthritis. To evaluate the functional impairment, two clinical indices were calculated: Lequesne index and Intermalleolar distance between the two medial malleoli in centimetre. The comparison of qualitative variables was performed with the Chi square test and the comparison of qualitative variable and quantitative ones was performed with the Student’s test. The significance level was set at 0.05.

**Results:** One hundred patients were included with 176 hips arthritis. The delay between onset of AS and hip arthritis was on average 5.6 years [0–34]. The distribution of coxitis according to the radio-anatomic feature was as following: destructive (110 cases), protrusive (10 cases), mimicking osteoarthritis (29 cases), ankylosing (7 cases) and early hip arthritis (20 cases). According to the Larsen classification for destructive hip arthritis: a grade 4 was found in 41 cases, a grade 2 in 33 cases, a grade 3 in 33 cases and a grade 1 in 3 cases.

The destructive form had the most important functional impairment with the highest Lequesne index in comparison with other forms (13.05 vs 9.7, p=0.000) and the smallest Intermalleolar distance (74.40 vs 87.29, p=0.010).

The early hip arthritis and protrusive forms had the least important functional impact in with the following scores: Lequesne index (8.83 vs 12.29, p=0.015) and (10.78 vs 11.96, p=0.000) and the Intermalleolar distance (76.36 vs 65.00 p=0.015) and (105.56 vs 70.22, p=0.002) respectively.

Scores were comparables for osteoarthritis and ankylosing forms.

**Conclusions:** Our study showed that radio-anatomic feature of hip arthritis could influence functional impairment. Distinguishing these forms may allow the rheumatologist to select the hip arthritis that deserves more attention because of the highest risk of functional impairment.

AB0887  
**JIA PATIENTS WITH HIGH DISEASE ACTIVITY HAVE INCREASED ACTIVITY OF BOTH THE IDO AND GTP-CH1 PATHWAY, BUT DECREASED BH4 EFFICACY: CONSEQUENCES FOR FATIGUE AND WELL-BEING**

S. Korte, E. Albers, W. van den Bogaard, G. Korte-Bouws, S. de Roock, S. Vasten. 1 Dep of Pharmacology, ’Onderwijscentrum Farmacie, Utrecht University, 2 Paediatric Rheumatology, Wilhelmina Children’s Hospital, University Medical Center, UTRECHT, Netherlands

**Background:** Juvenile idiopathic arthritis (JIA) patients suffer from an inflammatory condition, resulting in painful joints. In addition, JIA patients often report symptoms of sickness behaviour, including depressive symptoms and fatigue. Recent animal studies suggest that proinflammatory cytokines produce sickness behaviour by increasing the activity of indoleamine-2,3-dioxigenase (IDO) and guanosine/adenosine-cyclohydrolase-1 (GTP-CH1). Here it is hypothesised that inflammation in JIA patients affects the enzymatic activity of IDO and GTP-CH1 and the co-factor BH4. These compounds play a crucial role in the metabolism of the neurotransmitters serotonin and dopamine.

**Objectives:** The aim of our study was to reveal whether inflammation affects BH4, IDO and GTP-CH1 (enzymatic) activity in JIA patients.

**Methods:** Serum samples were collected of twenty-four JIA patients. In these samples, the concentrations of tryptophan, kynurenine, tyrosine, neopterin and phenylalanine were measured. An HPLC method with electrochemical detection was developed to quantify tryptophan, kynurenine and tyrosine. Neopterin and phenylalanine were quantified by ELISA. Kyn/trp ratio was measured as an index of IDO activity, while Phen/Tyr ratio was measured as an index of BH4 activity. Neopterin concentrations were used as an indirect measure of GTP-CH1 activity.

**Results:** JIA patients with high disease activity showed higher levels of both neopterin and kynurenine, and a higher ratio of both Kyn/Trip and Phen/Tyr and lower tryptophan levels than clinically inactive patients.

**Conclusions:** Altogether, these data support our hypothesis that inflammation increases the enzymatic activity of both IDO and GTP-CH1 and decreases the efficacy of the co-factor BH4. Further animal studies are needed to investigate whether inflammation-induced changes in these enzymatic pathways and co-factor lowers the levels of the brain neurotransmitters dopamine and serotonin, and consequently produce sickness behaviour and fatigue.

**Acknowledgements:** This study was financially supported by the focus area ‘Future Food Utrecht’ of Utrecht University, The Netherlands.

AB0888  
**PLATELET COUNT IN ANKYLOSING SPONDYLITIS: CAN IT SHOW THE DISEASE ACTIVITY ?**

S. Rahmouni, M. Slouma, R. Dhriri, L. Metoui, N. Boussetta, N. Guedidiche, F. Laajli, I. Ghansallah, B. Louzir. Internal Medicine, Military hospital of instruction of Tunis, TUNIS, Tunisia

**Background:** C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are the main inflammatory biomarkers used in assessment of disease activity in numerous inflammatory diseases such as ankylosing spondylitis (SA). In recent years, it has been shown that Platelet count (PC) provided additional information on inflammatory status.

**Objectives:** The present study aimed to investigate the correlation between PC and clinical activity indices assessed by Bath ankylosing spondylitis disease activity index (BASDAI).

**Methods:** The study included 68 patients who fulfilled Assessment of Spondyloarthritis International Society Criteria. A cell blood count, including platelet count, ESR (mm/h), CRP (mg/L) and albumin (g/L), was obtained for each patient. Disease activity measures at the time of blood sampling were obtained using the BASDAI. Statistical Package for Social Sciences (SPSS) was used for analysis.

**Results:** Of the 68 patients, 73.5% were male (Sex Ratio: 2.7). The mean age was 36±12.9 years. The mean disease duration was 40 months [0–192]. The average age of the onset of the disease was 36±11.9 years. No patient had ongoing infection at time of study. The mean BASDAI score was 5.1 [1.55–9.2]. Forty-one% of our patients (n=28) had active AS (BASDAI >4).

The mean ESR, CRP, albumin and PC were 39.4 (mm/h), 34.1(mg/dL), 39,32 g/L and 311 (103/mL), respectively.

There was a positive correlation between platelet count and following biomarkers: ESR (r: 0.481; p: 0.000), CRP (r: 0.417; p: 0.000) and albumin levels (r: −0.556; p: 0.000). A negative correlation between and Haemoglobin (Hg) was noted (r: −0.643; p: 0.000).

There was no significant difference in laboratory parameters (ESR, CRP, albumin, PC, Hg) between patients with active AS (BASDAI >4) and those with inactive AS (BASDI<4) patients.

**Conclusions:** Although acute phase reactant such as ESR, CRP and PC mirror disease activity in AS, their values were not associated with disease activity assessed by BASDAI in our study. However, new prospective studies including larger study groups are required to verify the findings of the present study.

Clinical Characteristics of 88 Patients with Pustulotic Arthro-Osteitis (PAO) in Japan

S. Teu1, Y. Ishihara2, H. Nishikawa3, Y. Taniguchi4, M. Kishimoto5. 1Department of Rheumatology and Allergology, National Hospital Organization, Osaka Minami Medical Center, Kawashinagano City, Osaka; 2Department of Orthopaedic Surgery, Kasumigaseki Urban Clinic, Tokyo; 3Department of Nephrology and Rheumatology, Kochi Medical School Hospital, Kochi; 4Immuno-Rheumatology Center, St. Luke’s International Hospital, Tokyo, Japan

Background: The prevalence rate of PPP in Japan is somewhat as 0.13%,1) accounting for 61% of cutaneous manifestations diseases associated with SAPHO syndrome2). SAPHO syndrome3) is not a new disease concept in which the cause of the disease has been clarified but is a name that classified diseased groups by collecting known diseases. On the other hand, PAO is a concept of disease that is a ‘proper subset’ of SAPHO syndrome and is the smallest unit disease concept. Therefore, detailed information on PAO was sought.

Objectives: To examine the clinical features and treatment of PAO

Methods: We conducted a multicenter, non-intervention retrospective study of 88 PAO patients who were able to visit directly in 4 hospitals in Japan from January to June 2017. the criteria of Sonozaki et al. 1981 4) was used for PAO diagnosis. Evaluation items were clinical features, image/blood biochemical examination, treatment methods.

Results: The average age at the time of visit was 55.4 years old, palmoplaantal pustulosis/PAO onset age was 44.4 years old, 49.3 years old, the onset pattern was skin leading type/simultaneous onset/joint advanced type (66.7/25.6/7.7%). The clinical features were pain joints of 33.0% of the thoracic joints, 22.7% of the shoulder joints and 10.2% of the joints of the ankle joints, and the adhesion flame was the most abundant in the Achilles tendon at 21.4%. ASDAS-CRP was 1.4 ±0.8 on average, breakdown was inactive disease 52.3%, moderate 22.7%, severe 22.7%, very high disease activity 2.3%, and insufficient disease activity remained in 25% of cases. Radiographic change showed in 81.8% of the sternum/the sternocostoclavicular joint, 33.0% of the spine, 31.0% of the sacroiliac joint (NY I/II more), and 9.8% of the peripheral joint. MRI findings showed changes in intraosseous luminance in 76.9% around the sternum, 52.2% in the spine and 65.2% in the sacroiliac joint. Bone scintigraphy showed abnormal findings in the anterior chest 96.4%, spine 23.6% and sacrum 30.9%. Blood biochemical examination showed CRP 0.35±0.52 mg/dl, RF positive rate 9.4%, ACPA positive rate 5.1%. First-line drugs (NSAIDs, biotin, anti-bacterial drugs) and second-line drugs (Iguratimod sulfasalazine MTX) were selected as therapeutic agents. For other treatments, 64.8% of topical therapy, 12.5% of phototherapy ond-line drugs (Iguratimod sulfasalazine MTX) were selected as therapeutic agents. For other treatments, 64.8% of topical therapy, 12.5% of phototherapy

Conclusions: In this study, we reported the clinical features, radiological findings and treatments in 88 Japanese patients with PAO in Japan. The treatment outcome for PAO in Japan is not sufficient, and it is necessary to try to elucidate further disease condition.

Disclosure of Interest: None declared

Efficiciency of 8-Year Educational Programs for Primary Contact Physicians in Diagnosis and Treatment of Axial Spondiloarthritis in Kazan

S. Lapshina1, L. Myasoutova2, R. Mukhina3. 149 Butlerov street, Kazan State Medical University; 2Clinical Hospital # 7, Kazan, Russian Federation

Background: In recent years, there have been cardinal changes in terminology, understanding of pathogenesis of axial spondylitis (AxSpA) and ankylosing spondylitis (AS), early diagnosis has improved. An important role is played by the level of awareness of primary care physicians in the early diagnosis of AxSpA and AS.

Objectives: To evaluate the effectiveness of educational activities for primary contact physicians in AxSpA (including AS) diagnostics for a long time.

Methods: From 2010 to the present time, educational activities are conducted for primary care physicians in diagnostics and tactics of managing patients with AS with discussion of the criteria for inflammatory back pain, options for onset and the algorithm for diagnosis and examination of patients with AxSpA for primary contact physicians in Kazan. Since 2014, educational modules have been integrated into the system of continuing education of doctors. Assessment of the results of educational schools was carried out according to the analysis of reports of outpatient admission to rheumatologist of the City Rheumatological Centre in Kazan (Clinical Hospital # 7) and the analysis of medical records of patients sent to a rheumatologist in 2009 (base year) in comparison with 2010–2017 in the process of schools.

Results: In the process of conducting schools (2010–2017) the number of patients with AxSpA and AS significantly increased for the first time this year. In 2010–2011, the number of patients almost doubled (575 pts in 2010, 683 pts in 2011) compared to 2009 (378 pts). The second sharp increase in the number of patients was observed in 2016 (1178 pts) and in 2017 (1298 pts).

Primary care physicians were more likely to refer patients with suspected AxSpA or diagnosed AS, the percentage of discrepancies between diagnoses (referral and rheumatology) decreased from 78% in 2009 to 18.1% in 2011, 8.9% in 2013, 2.1% in 2015 and 3.3% in 2017.

The number of patients coming from the primary contact physician to rheumatologist with the required volume of examination (description of back pain, laboratory tests, HLAB27 determination, radiographs and/or MRI) increased significantly from 23.7% in 2009 to 87% in 2017, which allows to verify diagnosis without repeated consultations.

Conclusions: Educational programs for primary care physicians (lectures, schools, remote programs) have great importance for the timely diagnosis of AxSpA, reducing the number of consultations before the diagnosis and with the subsequent appointment of adequate therapy.

Disease Activity Predicts Functional Impairment and Spinal Mobility in Axial Spondyloarthritis

T. Williams1, A. Wedeley2, C. Cavill3, M. Freeth4, J. Hole5, R. Sengupta1. 1Rheumatology, Royal National Hospital for Rheumatic Diseases; 2College of Liberal Arts, Bath Spa University, Bath, UK

Background: Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease, mainly affecting the spine and sacroiliac joints. This results in progressive spinal immobility and can result in a level of disability comparable to Rheumatoid Arthritis1. The natural history of axSpA and relationships between active inflammation,
structural damage and functional impairment remain poorly understood. Previous studies have hypothesised that functional impairment and spinal mobility in axSpA are independently influenced by disease activity and radiographic damage.1,2

Objectives: To define the relationship between disease activity, spinal mobility and radiographic damage with other patient-reported outcome measures in axSpA.

Methods: We performed a cross-sectional analysis of axSpA patients attending the Royal National Hospital for Rheumatic Diseases, Bath. The most recent outcome measures for each patient were compared. Spinal mobility was assessed using the BASMI; structural radiographic damage by the mSASSS; disease activity by the BASDAI; functional impairment by the BASFI; fatigue by the FACIT score; work disability by the WPAI-overall; quality of life by the ASQOL; overall health by the EQ5D. We analysed the correlation between these variables, separately for patients with Ankylosing Spondylitis (AS) and non-radiographic axSpA (nr-axSpA).

Results: 721 axSpA patients were included for analysis (548 AS; 42 nr-axSpA; 39 inflammatory bowel disease-related SpA; 47 juvenile-onset SpA; 24 psoriatic SpA; 3 reactive SpA; 18 undifferentiated SpA). Results are summarised in table 1:

**Correlation is significant at the 0.01 level (2-tailed); *Correlation is significant at the 0.05 level (2-tailed)

Conclusions: Spinal mobility and disease activity are both correlated with functional impairment, along with other measures of disability and poor health in axSpA, with BASDAI the strongest predictor of BASFI. Consistent with other studies, BASDAI was more predictive of spinal mobility in nr-axSpA than AS patients (p=0.002, 1-tailed). Structural radiographic damage is the strongest predictor of spinal mobility in AS. BASMI scores merit further investigation to ascertain their potential as a surrogate for radiographic disease burden in axSpA.

AB0893 INFLUENCE OF INFLAMMATION AND STRUCTURAL DAMAGE ON GLOBAL FUNCTIONING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS – USING THE ASAS HEALTH INDEX IN ROUTINE CARE

U. Kitz, T. Wiart, X. Baraliakos, J. Braun. Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany

Background: Global functioning of patients with spondyloarthritis (SpA) can be influenced by many different factors. ASAS Health Index (ASAS HI) has aims to measure global functioning in patients with SpA. So far, its association with inflammatory spinal changes and structural damage has not been examined.

Objectives: To investigate the relationship between spinal mobility and self-report global functioning as assessed by the ASAS HI, and to study the influence of structural and inflammatory spinal changes on global functioning.

Methods: Patients from the outpatient clinic of our hospital suffering from axial or peripheral SpA completed questionnaires assessing disease activity and functioning (ASAS HI, pain, BASDAI, ASASD, BASFI). Axial inflammation as detected by magnetic resonance imaging (MRI) was assessed by the Berlin score, structural damage by the modified Stokes ankylosing spondylitis (AS) Spine Score (mSASSS) and spinal mobility by the Bath AS Metrology Index (BASMI). Imaging were scored by two independent readers. Correlations between the ASAS HI and other health outcomes were analysed by Spearman’s test. Logistic regression analyses were performed to investigate the association between functioning and other clinical characteristics.

Results: A total of 203 patients (76 non-radiographic (nr)-axSpA, 115 AS patients, and 12 with peripheral SpA (pSpA) were included: 63.5% male, mean (SD) age 46.6 (14.1), symptom duration 18.8 (12.8) years, and 76.4% HLA-B27 positive. The mean values of clinical assessments were ASAS HI 7.9 (3.8), BASDAI 5.0 (2.2), ASASD 2.8 (1.1), BASMI 3.3 (1.8), pain 6.0 (2.6), and BASFI 5.0 (2.6). Elevated CRP levels were found in 37.4% of the patients, while 59.1% of the AS patients had syndesmophytes and 11.3% a bamboo spine. The median (IQR)
mSASSS value was 3.8 (IQR 1.0–22.1) in AS and 0.0 (IQR 0.0–1.4) in nr-axSpA patients. The mean Berlin AS Spine Score for patients with axSpA was 5.3 (SD 7.1). Patients received a treatment with NSAIDs (62.7%), DMARDs (20.9%) and/or biologics (49.4%). A significant correlation of the ASAS HI was found for BASMIs (r=0.5), BASDAI (r=0.7), ASDAS (r=0.5), BASFI (r=0.8), BMI (r=0.3) and Berlin Score (r=0.3). ASAS HI did not correlate with radiographic damage (mSASSS ≥0.2, presence of bamboo spine ≥0.2) and CRP (r=0.07). Stratifying patients by symptom duration (cut-off 3 years) did not affect these results. Logistic regression showed influence of obesity but not of inflammation or structural damage on global functioning (table 1).

Conclusions: The influence of obesity on functioning is remarkable in patients with SpA. In contrast, the influence of structural damage and spinal inflammation on functioning was limited in this study, probably due to the relatively low mSASSS and MRI scores. Further studies with inclusion of more severely affected patients are needed to study the association of functioning, spinal mobility, obesity and radiographic damage over a broader range of affected patients.

AB0894

A COMPARISON OF CLINICAL FEATURES IN PATIENTS WITH SPONDYLOARTHRITIS AND UNILATERAL OR BILATERAL HIP ARTHRITIS

W. Hamdi1, S. Zrida1, H. Riahi1, K. Maatallah1, D. Kaffel1, M. Chelli Bouazizi2, M. F. Ladeb2, M.M. Khichir1, 1Rheumatology, Institute Mohamed Kassab, Ksar Said, Manouba, Tunisia

Background: Axial spondyloarthritis (AS) is a frequent chronic and progressive disease that affects mainly young adults and is characterised by inflammation of the axial skeleton, but peripheral joints such as hips may also be involved. The incidence of hip involvement in AS is around 30%. Nevertheless, data concerning clinical features in patients with spondyloarthritis comparing unilateral and bilateral hip arthritides are lacking.

Objectives: To compare clinical, functional and radiologic outcomes in patients with AS with unilateral or bilateral hip arthritides.

Methods: Cross-sectional study on 100 patients with AS according to the ASAS criteria of 2009 who had unilateral and bilateral hip joint lesions defined by hip pain, limited joint motion and radiographic hip abnormalities. Demographic and clinical outcomes were performed including HLAB27 status. Spinal mobility outcomes were assessed by Schöber index and Bath Ankylosing Spondylitis Metrology Index (BASMI). Radiographic measurements were performed and included Bath Ankylosing Spondylitis Radiology Index (BASRI) and modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS).

Results: Bilateral hip joint lesion was reported in 76% of patients which 14 women and mean age was 37.14 years. Bilateral hip involvement was associated with less height (p=0.002), more long disease duration (p=0.015), more several clinical spinal involvements with more spinal stiffness (p=0.000) and less spinal mobility (p=0.004). Extra-articular manifestations were comparable in patients with unilateral and bilateral hip arthritides (p=0.55), however HLAB27 antigen was significantly more common (p=0.003) in patients with bilateral hip arthritides. BASRI hip (p=0.042) and mSASSS (p=0.009) scores were used to assess structural damage on plain radiographs and were significantly more important in bilateral involvement. Nevertheless, provocative form was more frequent in patient with unilateral hip involvement (p=0.05).

Conclusions: Bilateral hip arthritis seems to be more frequent and more severe than unilateral involvement in patients with AS.

AB0895

ARE LATERAL SPINE BONE MINERAL DENSITY MEASUREMENTS USEFUL IN AXIAL SPONDYLOARTHRITIS?

W. Hamdi1, D. Ben Nessib2, H. Riahi1, A. Kasraoui1, K. Maatallah1, M.D. Kaffel1, M. Bouazizi2, M.F. Ladeb2, M.M. Khichir1, 1Rheumatology, 2Radiology, Kassab Hospital, Tunis, Tunisia

Background: Bone loss leading to osteoporosis (OP) is a well-known feature of axial spondyloarthritis (AS) although this disease is characterised by calcification in extra osseous tissues and new bone formation. In fact, dual-energy X-ray absorptiometry (DEXA) is the most common imaging method used to measure the bone mineral density (BMD). However, many studies have shown an inferiority of the postero-anterior (PA) spine measurements in reflecting the bone loss compared to lateral spine measurements because of the bridging syndesmophytes which may overestimate the BMD.

Objectives: Our aim is to evaluate the Lateral spine BMD (L-BMD) in AS and to assess its association with the disease features.

Methods: Seventy-five patients who met the Modified New York Classification criteria for AS were enrolled in this cross-sectional study. BMD was measured using DEXA at PA lumbar, lateral lumbar and hip regions.

Results: Sixty-two men and 13 women were enrolled with an average age of 36.8 ±11.8 years. Bone loss (osteopenia or OP) was noted in 65% of the patients (n=46) in PA lumbar and in 63% in lateral lumbar (n=45). In L-BMD, BMD was correlated with early menopause and vitamin D level (p=0.01 and p=0.04 respectively). T-score in lateral spine was correlated with coffee consumption (p=0.02), physical inactivity (p=0.037), sexual hormones disorders (p=0.02), hip arthritides (p=0.017), BASMI (p=0.001), BASFI (p=0.03) and ASDAS (p=0.03) scores, ESR (p=0.003) and CRP (p=0.03) levels, and hip (p=0.004) and spine (p=0.007) and total (p=0.001) BASRI.

Conclusions: L-BMD seems to be a reliable measurement in AS, and may avoid the overestimation of the BMD values and allows consequently to detect spinal osteoporosis and prevent fractures in AS.

AB0896

ASSOCIATION OF IGA ANTIBODIES AGAINST CD74 WITH PRODUCTION OF IL17A BUT NOT OF TNFALPHA IN PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS

X. Barajalaks1, K. Kniesch2, N. Baerleckenh2, J. Braun1, T. Witte3, 1Rheumazentrum Ruhrgebiet, Herne; 2Medizinische Hochschule Hannover, Hannover, Germany

Background: Axial spondyloarthritis (axSpA) is strongly associated with HLA-B27. Recently, Iga antibodies (Abs) against CD74 (Iga-anti-Cd74) and T-cells carrying CD-74-specific T-cell receptors were also found to be associated with axSpA, especially in patients with ankylosing spondylitis, the radiographic form of axSpA. Tumour necrosis alpha (TNF-α) inhibitors and IL-17 antagonists are efficacious in patients with active axSpA.

Objectives: To investigate whether Iga-anti-CD74 Abs are associated with pro-inflammatory cytokines in the sera of patients with HLA-B27-positive and -negative patients with active axSpA.

Methods: Blood samples of 62 HLA-B27-positive and 58 HLA-B27-negative patients with axSpA (44% AS) prior to starting a biologic therapy were collected. A cytometric bead-array (CBA Flex Set) was used to measure serum levels of interleukin (IL) -17A, -17L, -1L-1α, TNF-α, and interferon (IFN)-γ. Iga-anti-CD74 Abs were measured by ELISA, using the predefined cut-off of 15 U/ml. Their mean concentrations were compared between groups using T-tests. The patients who were positive or negative for Iga-anti CD74 Abs were compared using chi-square test.

Results: Iga-anti-CD74 Abs were detected in 54/120 axSpA patients (45%). There were no differences in the baseline demographics and clinical assessments in patients with or without Iga-anti CD74 Abs. The presence of Iga-anti-CD74 Abs
was associated with higher serum concentrations of IL-17A (p<0.01), irrespective of the presence of HLA-B27, CRP and IL-6 (both p<0.05) but not TNFα (p=0.2).

Conclusions: In a cross-sectional study, the presence of IgA Abs against CD74 was associated with serum levels of pro-inflammatory biomarkers such as CRP (and IL-6) and IL-17 but not TNFα irrespective of HLA-B27 status. Longitudinal prospective studies are needed to show that the measurement of IgA anti-CD74 Abs and/or serum cytokines can help to guide treatment decisions.

AB0897

THE RELATIONSHIP BETWEEN DISEASE-SPECIFIC INDICES AND BALANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Y. Acac1, N. Için2, B. Gürpınar1, G. Can3, F. Ören2. 1Physical Therapy and Rehabilitation; 2Rheumatology, Dokuz Eylül University, izmir, Turkey

Background: Axial and peripheral joint stiffness, impaired joint mobility and postural deformities may affect balance in AS. However factors affecting balance in AS patients are still unclear. There is limited literature investigating balance-related factors in patients with AS and the results are contradictory.

Objectives: The aim of the study was to investigate relationship between disease-specific indices and balance in patients with AS.

Methods: 72 patients (46 male, 26 female) with AS were included in the study. The demographic and anthropometric features (age, weight, height, body mass index (BMI)) of patients were recorded. Disease-specific indices used in the study were Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Mobility Index (BASMI). BASDAI for disease activity, BASFI for functional capacity, BASMI for spinal mobility were used. Static and dynamic balance was evaluated with Biodex Balance System SD. Limits of stability and bilateral stance (stable platform) postural stability test results were recorded. Overall stability (OA) indices were used. A high score in the OA index indicates poor balance. Spearman correlation test used for statistical analysing. Correlation analyses were performed between BASDAI, BASFI, BASMI scores and Biodex test results

Results: The mean age of patients was 39,95±8,84 years and mean BMI was 26,55±5,82 kg/m². BASDAI, BASFI and BASMI scores of patients are shown in table 1.

Abstract AB0897 – Table 1. BASDAI, BASFI and BASMI scores

</tr>
</tbody>
</table>

Comparison of improvement rates in I and III trimesters, p=0,05.

Worsening of underlying disease was associated with exacerbation of back pain in 44 (51%), emergence and/or recurrence of arthritis in 15 (17,4%), or uveitis in 9 (10,4%), and other symptoms in 11 (12,8%) patients.

Conclusions: Therefore, the majority of participants reported the diverse fluctuations in AS course during pregnancy, although 50% of responders reported the improvement in the course of the disease at least during one trimester (more often in the first). Nevertheless, almost 70% of respondents reported AS worsening with exacerbations rates increasing in parallel with increasing gestation age. 50% of participants noticed worsening back pain, although special attention should be given to correct evaluation of AS activity in these patients keeping in mind the increased physiological load on the backbone during the second half of pregnancy.

AB0901 VASPIN AND LIPOCALIN2 LEVELS IN PSORIATIC ARTHRITIS

S. Colak1, A. Omma1, S. Can Sandikci2, C. Yuce1, T. Turhan3, R. Rheumatology, Ankara Numune Training and Research Hospital, 2Rheumatology, Diskapi Yildirim Beyazit Training and Research Hospital, 3Biotechnology, Ankara Numune Training and Research Hospital, Ankara, Turkey

Background: Psoriatic arthritis (PsA) is a type of spondiloarthropathies which is affiliated with psoriasis. Metabolic syndrome, diabetes mellitus and cardiovascular diseases are comorbid conditions associated with psoriatic arthritis. Adipokines are suggested to be playing proinflammatory or antiinflammatory roles in the proceeding of inflammatory situations.

Objectives: The aim of this study is to investigate the recently interested adipokines vaspin and lipocalin2 levels and their association with disease activity of patients diagnosed with psoriatic arthritis.

Methods: The study was conducted between October 2017 and January 2018 at the Rheumatology Clinic of Ankara Numune Training and Research Hospital, Turkey. The vaspin and lipocalin2 levels of 50 PsA patients, diagnosed according to the Classification Criteria for Psoriatic Arthritis (CASPAR), and 36 age and sex-matched healthy subjects were analysed in current study. The disease activity was assessed by using Psoriasis Area Severity Index, Bath Ankylosing Spondylitis Functional Index, Bath Ankylosing Spondylitis Disease Activity Index and Disease Activity Index for Psoriatic Arthritis. Indexes were applied to the patients in order to evaluate the disease activity.

Results: No significant difference was found between groups with respect to age, sex and body mass index. There was significant difference between vaspin (p=0.001) and lipocalin2 (p=0.014) levels among the PsA patients and control groups. There was no significant difference between the groups in terms of disease activity (p>0.05).

Abstract AB0901 – Table 1. The clinical and laboratory parameters in two groups.

AB0902

EFFICACY OF TOFACITINIB BY BACKGROUND METHOTREXATE DOSE IN PATIENTS WITH PSORIATIC ARTHRITIS: A POST-HOC ANALYSIS OF POOLED DATA FROM 2 PHASE 3 TRIALS

1Department of Rheumatology, Altonna Center for Clinical Research, Dunescvillne, PA, USA; 2Department of Rheumatology, St Vincent's University Hospital, Dublin, Ireland; 3Department of Medicine, University of Queensland, St Lucia, Brisbane, Australia; 4St. Jude Medical Center, Fullerton, CA, USA; 5Universidade Federal do Paraná, Curitiba, Brazil; 6Pfizer Inc, Groton, CT; 7Pfizer Inc, Collegeville, PA, USA

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). The efficacy of tofacitinib has been evaluated in 2 Phase 3 studies in patients (pts) with PsA.

Objectives: To describe the efficacy of tofacitinib by background methotrexate (MTX) dose in pts with PsA.

Methods: This post-hoc analysis utilised efficacy data pooled from 2 Phase 3, randomised, double-blind, placebo-controlled studies (OPAL Broaden [12 months; NCT01877668] and OPAL Beyond [6 months; NCT01882439]) in pts with a diagnosis (>6 months) of active PsA (>3 swollen and >3 tender joints). Pts in OPAL Broaden were tumour necrosis factor inhibitor (TNF)-naive and had at least 2 continuous responses (TNFr) in >1 conventional synthetic disease-modifying anti-rheumatic drug (cDMARD). Pts in OPAL Beyond had an IR to >1 TNF. Pts were randomised to tofacitinib 5 or 10 mg twice daily (BID), placebo or adalimumab 40 mg subcutaneous every 2 weeks (OPAL Broaden; adalimumab data not shown). All pts received a stable dose of 1 cDMARD (eg MTX, leflunomide or sulphasalazine) as background therapy. The maximum dose of MTX allowed per protocol was 20 mg/week. Efficacy outcomes for tofacitinib at Month 3 were compared to placebo and adalimumab in patient subgroups with different background MTX dose (≤15 mg/week vs >15 mg/week). Pts with irAEs were removed from the analysis.

Results: In total, data from 556 pts who received tofacitinib plus MTX only or placebo with PsA were included. Mean (±SD) dose of MTX was 19.8 (0.8) mg/week. Efficacy analyses were based on the full analysis set for pts receiving MTX on Day 1; pts with missing data were considered as having a non-response for binary endpoints. No statistical testing was performed.

Conclusions: The results of this pooled analysis suggest that the efficacy of tofacitinib in pts with PsA was greater than placebo and does not differ when evaluated by background MTX dose (<15 vs >15 mg/week), although small pt numbers in some groups may limit the conclusions that can be made. These results are consistent with findings from similar analyses of tofacitinib in pts with rheumatoid arthritis.

AB0903

EFFECTIVENESS OF TILDRIKAZUMAB IN ETANERCEPT PARTIAL OR NONRESPONDERS

J. Crowley1, K.A. Papp2, C.-H. Hong3, J. Parano4, A.M. Mendelsohn5, O. Li7, N. Cichanowitz8, C. La Rosa9, 1Bakersfield Dermatology, Bakersfield, CA, USA; 2Probity Medical Research, Waterloo, ON, Canada; 3Department of Dermatology and Skin Science, University of British Columbia and Probody Medical Research, Surrey, BC, Canada; 4Sun Pharmaceutical Industries, Inc., Princeton, NJ; 5Merck and Co., Inc., Kenilworth, NJ, USA

Background: Entanercept (ETN) is an anti–tumor necrosis factor (TNF) medication that was among the first biologics approved for psoriasis. Additional medications have been developed or are in development for psoriasis, and patients who do not adequately respond to ETN may benefit from these more recent biologics.

Objectives: Here we report the efficacy of tildrakizumab (TIL), a humanised anti–IL-23p19 monoclonal antibody, as evaluated in patients with moderate to severe chronic plaque psoriasis who were partial (Psoriasis Area and Severity Index [PASI]) 50–<75) or nonresponders (PASI <50) to ETN and subsequently rerandomized to TIL in the phase 3 resURFACE 2 trial (NCT01729754).

Methods: Patients with psoriasis (>10% body surface area, Physician’s Global Assessment [PGA], and PASI >12) participated in resURFACE 2, a 3-part, 52 week, randomised controlled trial. In Part 1 (Weeks 0–12), patients were randomised to subcutaneous TIL 200 mg, TIL 100 mg, or placebo (PBO) administered at Weeks 0 and 4, or ETN 50 mg administered twice weekly. In Part 2 (Weeks 12–28), TIL and ETN patients remained on the same treatment (TIL administered at Week 16; ETN once weekly), whereas PBO patients were rerandomized to TIL 100 or 200 mg. In Part 3 (Weeks 28–52), ETN responders (PASI >75) were discontinued, and partial and nonresponders were switched to TIL 200 mg (administered at Weeks 32, 36, and 48). For this post hoc analysis, the proportion of partial responders (PASI50 [PASI50–<75]) with PGA response (score of 0 [clear] or 1 [minimal] with at least a 2-grade score reduction from baseline) were determined at Week 52. Primary results from the trial have been previously reported.

Results: In total, 1090 patients were randomised. Of the 313 patients randomised to ETN, by Week 28 there were 83 partial responders and 39 nonresponders. At Week 52 (after 20 weeks of TIL treatment) for ETN partial responders, 75%±5%, 54%±5%, 15%±4%, and 58%±5% had achieved PASI 75, 90, 100, and PGA response of 0/1, respectively, with TIL 200 mg treatment. At Week 52 for ETN nonresponders, 54%±6%, 31%±5%, 10%±3%, and 56%±5% had achieved PASI 75, 90, 100, and PGA response of 0/1, respectively, with TIL 200 mg treatment. Adverse events were similar in patients switched from ETN to TIL at Week 28, compared with the patients who were maintained on TIL through Week 52.

*Among pts with baseline HAQ-DI score ≥0.35

The maximum permitted dose of MTX was 20 mg/week. The analyses included all pts who received MTX as background therapy only on Day 1 before FAS ACR, American College of Rheumatology; BID, twice daily; CRP, C-reactive protein; FAS, full analysis set; HAQ-DI, Health Assessment Questionnaire-Disability Index; LSM, least squares mean; MTX, methotrexate; n, number of pts with response; N, number of pts included in the analysis; N1, number of pts included in the HAQ-DI response analysis; N2, number of pts evaluable for change from baseline in HAQ-DI at Month 3; pts, patients; SD, standard deviation; SE, standard error

1Department of Rheumatology, Kenilworth, NJ, USA

Scientific Abstracts

1575
Conclusions: A substantial portion of patients with moderate to severe chronic plaque psoriasis who were partial or nonresponders to ETN may respond after switching to treatment with TIL 200 mg. TIL may be a reasonable option for those who do not achieve adequate response to ETN.

CORRELATION OF RAPID3 AND PROMIS10 IN PATIENTS WITH PSORIATIC ARTHRITIS

A. Ogdie1, W. B. Nowell1, E. Applegate2, K. Gavigan3, S. Venkatachalam4, M. de la Cruz5, E. Flood3, E. J. Schwartz6, B. Romero7, P. Hur1, J. Ferelman School of Medicine at the University of Pennsylvania, Philadelphia; 2Global Healthy Living Foundation, Upper Nyack; 3ICON, Gaithersburg; 4Novartis Pharmaceuticals Corporation, East Hanover, USA

Background: In addition to clinician assessment and laboratory tests, patient-reported outcomes (PROs) are important for managing and improving the quality of care in patients with psoriatic arthritis (PsA). The RAPID3 was originally developed for use in patients with rheumatoid arthritis, but it may be used in clinical practice to assess disease activity in patients with PsA.1 The PROMIS10 is a general (nondisease-specific) PRO instrument that measures physical, mental, and social health.2 Developed for the general population, PROMIS10 has not yet been specifically validated in PsA.

Objectives: To evaluate the relationship between RAPID3 and PROMIS10 in patients with PsA.

Methods: US adults with a self-reported diagnosis of PsA were recruited through CreakyJoints (www.CreakyJoints.org), an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers. Respondents completed an online survey that was designed to collect data on socio-demographics and clinical symptoms and included the RAPID3 and PROMIS10 to evaluate disease activity and health-related quality of life (HRQoL), respectively. The RAPID3 is a general, disease-specific PRO instrument that measures physical, mental, and social health.2 Developed for the general population, PROMIS10 has not yet been specifically validated in PsA.

RESULTS: Of the 203 respondents, the mean (SD) age was 51.6 (10.8) years and 173 (84.7%) were female. The mean (SD) cumulative RAPID3 score was 14.7 (5.8) with mean (SD) functional impairment, pain tolerance, and patient’s global estimate scores of 3.3 (1.8), 6.0 (2.3), and 5.4 (2.5), respectively. Patients’ mean (SD) PROMIS10 global physical and mental health T-scores were 36.4 (7.3) and 40.2 (9.3), respectively. The mean individual domain scores and global T-scores worsened with increasing RAPID3 disease severity levels (all p<0.001) (table 1). PROMIS10 physical and mental health T-scores showed a strong (rs=0.84) and moderate correlation (rs=0.57) with RAPID3, respectively.

AB0905

LONG-TERM (5-YEAR) EFFICACY AND SAFETY OF APREMILAST MONOTHERAPY IN DMARD-NAÏVE SUBJECTS WITH ACTIVE PSORIATIC ARTHRITIS

A.F. Wells1, C.J. Edwards2, A.J. Kiwitz3, P. Bird3, B. Guerette3, N. Deliev3, M. Parise4, L. Teng5, J.A. Aelion6,7, Rheumatology and Immunotherapy Center, Franklin, USA; 2University Hospital Southampton, Southampton, UK; 3Altotna Center for Clinical Research, Dunsansville, USA; 4Combined Rheumatology Practice, Kogarah, Australia; 5Celgene Corporation, Summit; 6West Tennessee Research Institute, Jackson, USA

Background: Apremilast (APR) is an oral phosphodiesterase 4 inhibitor that helps regulate the immune responses that cause joint inflammation and other manifestations of psoriatic arthritis (PsA), including skin disease.

REFERENCES:
Objectives: To describe the long-term (5 year) efficacy and safety of APR mono-
therapy in DMARD-naïve subjects with active PsA from the phase 3 PALACE 4 study.

Methods: Subjects were randomised (1:1:1) to receive placebo, APR 30 mg BID
(APR30), or APR 20 mg BID (APR20). At Week 16, subjects were eligible for early
escape; placebo subjects were re-randomised to APR treatment, and APR sub-
jects remained on their assigned dose. At Week 24, all subjects remaining on pla-
cebo were re-randomised to APR. Double-blind treatment continued to Week 52,
with open-label APR treatment for up to 4 additional years.

Results: A total of 527 subjects were randomised and received ≥1 dose of pla-
cebo (n=176), APR30 (n=176), or APR20 (n=175). Among subjects randomised to
APR30 at baseline, 45.5% (80/176) completed the Week 260 visit. At Week 52,
modified ACR20, ACR50, and ACR70 responses were achieved by 58.0%,
29.8%, and 15.5% of subjects receiving APR30, respectively, regardless of when
APR was started (baseline, Week 16, or Week 24). Rates of improvement in PsA
symptoms and physical function were sustained up to Week 260 with continued
APR30 treatment, including reduction rates in SJC of 84.8% and in TJC of
76.4% (table 1). At Week 260, 65.8%, 39.0%, and 20.3% of subjects achieved a
modified ACR20, ACR50, and ACR70 response, respectively, and 71.2% of
PSA30 subjects with baseline enthesitis achieved a MASES of 0; 95.1% with
baseline PsA polyarthritis achieved a dactylitis count of 0. At Week 260, 52.9% of subjects
achieved a HAQ-DI MCID >0.35, 60.3% achieved a PASI-50 response, and
47.6% achieved a PASI-75 response (table 1). No new safety concerns were
identified with APR up to 260 weeks. During Weeks>208 to 260, the most com-
mon adverse event (AEs) among APR30-exposed subjects was nasopharyngitis
(6.9%). Serious AEs occurred in 5% of subjects; serious infections were
reported in 2 APR30 subjects (pelvic abscess and bacterial uterine tract infection),
and no opportunistic infections were reported during Weeks>208 to 260.

Abstract AB0905 – Table 1

Conclusions: APR monotherapy demonstrated sustained response or improve-
ment in PsARiatric Disease Activity (PSARTDAD), dactylitis, physical function,
and psoriasis in the population of subjects continuing treatment over 260 weeks. APR continued to demonstrate a favourable safety profile and was generally well tolerated.

AB0906 IXEKIZUMAB IMPROVES FATIGUE IN A SUBSET OF PATIENTS WITH PSORIATIC ARTHRITIS

A.-M. Orbai1, D.D. Gladman2, H. Goto3, J. Birt4, C.-Y. Lin5, T.K. Kvien6, 7Johns
Hopkins University School of Medicine, Baltimore, USA; 2University of Toronto,
Toronto, Ontario, Canada; 3Osaka City General Hospital, Osaka, Japan; 4Eli Lilly
and Company, Indianapolis, USA; 5Universitetet i Oslo Medisinske Fakultet, Oslo,
Norway

Background: Psoriatic arthritis (PsA) is a chronic, systemic, inflammatory dis-
ease with both articular and extra-articular symptoms including joint pain, enthes-
tis, dactylitis, and fatigue. Fatigue is increasingly recognised as a priority
symptom to patients and has been added to the PsA core set of outcomes for cli-
nical trials. 8The best instrument to assess fatigue has not yet been defined.

Objectives: To assess fatigue improvement following treatment with ixekizumab
(IXE), an anti-interleukin (IL)–17A monoclonal antibody, relative to placebo
(PBO) in PsA patients.

Methods: In two phase 3 randomised controlled trials, patients naïve to and ex-
perienced with biologic disease-modifying antirheumatic drugs (SPIRIT-P1; SPIRIT-
P2, respectively) received subcutaneous PBO, ADA 40 mg every 2 weeks (SPI-
RIT-P1 only; reference arm), or IXE 80 mg every 2 weeks (Q2W) or every 4 weeks
(Q4W) after a 160 mg starting dose for up to 24 weeks. At Week 16, all patients
considered inadequate responders (IR) received rescue therapy. PBO and ADA
patients were randomised (1:1) to Q2W or Q4W at Week 16 (IR) or Week 24;
ADA patients underwent a washout prior to IXE treatment. Patients rated their
worst level of fatigue during the past 24 hours at baseline, Week 4, 12, 16, 24, 32,
and 52 on the 11-point Fatigue Severity Numeric Rating Scale (Fatigue NRS; not
yet validated) where 0=no fatigue and 10=as bad as you can imagine. The mini-
mally clinically important difference (MCID) was defined as an improvement ≥3 on
the Fatigue NRS.

Results: At Week 24 significantly more patients in both studies achieved fatigue
improvements ≥3 on the Fatigue NRS with both IXE doses versus PBO (table 1;
SPIRIT-P2 study only (table 1; MMRM). For patients who continued IXE treatment beyond
Week 24, mean improvements on the Fatigue NRS persisted through Week 52
(table 1; MII).

*aMixed models repeated measures (MMRM) analysis was used to calculate change from baseline.

*bAnalysis of patients with Fatigue NRS ≥3 at baseline, SPIRIT-P1: PBO, n=93; ADA, n=85; Q4W, n=95; Q2W, n=84. SPIRIT-P2: PBO, n=108; Q4W, n=107; Q2W, n=107.

*cNonresponder imputation (NRI) was used to impute missing data based on logis-
tic model.

*dMultiple imputation (MI) was used to impute missing data.

*p<0.05 vs PBO; **p<0.01 vs PBO.

Conclusions: In a subset of PsA patients, clinically meaningful improvements in
fatigue level were observed following IXE treatment. Fatigue improvement per-
sisted with up to 1 year of IXE treatment.

TREATMENT PATTERNS IN PSORIATIC ARTHRITIS IN US AND EUROPE: RESULTS FROM A REAL-WORLD INTERNATIONAL SURVEY

A.-M. Orbai1, L. Gossec2, S. Lobosco3, R. Moon3, O. Massey3, J. Piery3, J. C. Cappelleri4, L. Fallon4, P. Young4, A.B. Romero4, M.A. Hsu4, 1John Hopkins University, Baltimore, MD, USA; 2Sorbonne Universités, Paris, France; 3Adelphi Real World, Bollington, UK; 4Pfizer, Groton, CT, USA

Background: With the availability of a greater range of Psoriatic Arthritis (PsA) treatment options, it is increasingly necessary to understand their use and impact on disease control in real-world practice.

Objectives: To assess treatment patterns and their impact on clinical outcomes among PsA patients currently receiving conventional/targeted synthetic disease-modifying anti-rheumatic drugs (cs/tsDMARD) or biologic DMARD (bDMARD).

Methods: A point in time survey was conducted in 2015 across the US, France, Germany, Italy, Spain and UK. Patients had physician-confirmed PsA and had to have been receiving their current cs/tsDMARD (bio naive) or bDMARD (1st or 2nd line) for > 6 months. Physicians provided information on demographics, treatment history, disease severity, clinical measures included body surface area (BSA), joint count, flare/remission status. Student t-tests, Pearson’s chi-squared and Fisher’s exact tests were used to compare physician-reported patient profile variables, clinical status and treatment outcomes.

Results: 519 physicians (331 rheums, 188 derms) provided data for 2467 PsA patients, 1463 of whom met the inclusion criteria (1136 EU, 327 US). No significant differences were observed between EU and US patients in demographics (male 52.6%, mean age 49.0 years), disease duration 6.3 years; disease severity 29.1% moderate to severe). In the EU, 32.3% patients were on cs/tsDMARDs, 55.4% 1st-line bDMARD, 12.3% 2nd-line bDMARD vs 21.7%, 58.4%, 19.9% respectively in the US. Time in months (mo) from diagnosis to first cs/tsDMARD was similar in the EU and US (EU mean 4.7 mo; US 8.1 mo, p=0.24), from 1st cs/tsDMARD to 1st bio (EU 37.4 mo; US 29.4 mo, p=0.15). Patients in the EU received more cs/tsDMARDs prior to bDMARD initiation than US patients (mean 1.4 v 0.8; p<0.001). US patients were more likely to have bDMARD without combination cs/tsDMARDs (US 65.1% vs EU 52.3%; p=0.004). Patients receiving cs/tsDMARDs had a worse clinical profile than those on 1st-line bDMARD in all areas other than joint count. Patients on 2nd-line bDMARD had more symptoms, more affected joints and more likely to flare vs 1st-line bDMARD.

Patients receiving cs/tsDMARDs had a worse clinical profile than those on 1st-line bDMARD in all areas other than joint count. Patients on 2nd-line bDMARD had more symptoms, more affected joints and more likely to flare vs 1st-line bDMARD. These findings were directionally similar in the EU and US (table 1). BSA was higher for cs/tsDMARD patients than for any bDMARD patients.

<table>
<thead>

<td>7.8%</td>
<td>&lt;0.001</td>
<td>8.6%</td>
</tr>
</tbody>
</table>

Conclusions: Only 39%–60% of patients were considered by physicians as in remission, revealing a considerable unmet need in both the EU and US in patients treated with cs/tsDMARDs and bDMARDs. Further research is needed to identify patients on cs/tsDMARDs who may be a candidate for advanced therapy and to recognise patients who might fail on bDMARD who therefore may benefit from a different therapeutic alternative.

AB0908 ABILITY OF THE REDUCTIVE X-RAY SCORE FOR PSORIATIC ARTHRITIS (REXSPA) TO DETECT CHANGE IN AN OBSERVATIONAL COHORT OF PATIENTS WITH PSA

A. Antony1, A. Allard1, G. Shadick2, D. Jadon3, C. Cavil1,4, E. Korendowich1, N. McHugh1,4, W. Tilliet1,4, 1Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath; 2Mathematical Sciences, University of Exeter, Exeter; 3Rheumatology, Cambridge University Hospitals, Cambridge, 4Pharmacy and Pharmacology, University of Bath, Bath, UK

Background: The measurement of radiographic joint damage is important in characterising disease severity, progression, and prognosis in psoriatic arthritis (PsA). Existing radiographic measures are time-consuming to perform, leading to limited data collection from existing longitudinal observational studies.

Objectives: We have previously proposed a Reductive X-ray Score for Psoriatic Arthritis (ReXSPA) as more feasible method, and in this study set out to examine the sensitivity of ReXSPA in a new cohort of patients.

Methods: A retrospective sample of 28 patients who had hand and feet radiographs at 3 time points (5 years before [T0], at the time of [T1], and 5 years post [T2] commencement of anti-TNF treatment) were taken from the Bath longitudinal PsA cohort. Radiographs were scored for erosion, joint space narrowing and proliferation to calculate the Sharp-van der Heijde modified method (VDH) and ReXSPA scores. A sample of 9 radiographs were scored by all assessors (WT, AA and AA) to determine inter- and intra-rater reliability using intra-class correlation coefficients (ICC). Sensitivity to change was determined from timepoint T0 to T2 using the Standardised Response Mean (SRM) and Smallest Detectable Change (SDC).

Results: The patients’ mean age (SD) at T0 was 61 years (13.4), the mean disease duration was 11.2 years (11.14). Patients were followed up for a mean (SD) of 10.2 years (2.76). Overall inter- and intra-rater reliability for ReXSPA and VDH were 0.80 and >0.92 and 0.91 and >0.90 respectively. The median (IQR) of ReXSPA score was 8.5 (1–14), 12.5 (5–20) and 14.5 (8–36) at T0, T1, and T2 respectively. The percentage SDC was 0.91 for the ReXSPA method and 0.77 for the VDH method, and the SRMs were 0.92 and 0.87 respectively (table 1), demonstrating the sensitivity of both methods in detecting change. There was a trend towards slowing in radiographic progression following the initiation of TNF-inhibitors, but ReXSPA was less sensitive compared to the VDH and was not able to detect a significant change in the rate of progression post-TNF inhibition (p=0.08) (Graphical 1).

CERTOLIZUMAB PEGOL’S EFFECTIVENESS, RETENTION RATE AND SAFETY IN PSORIATIC ARTHRITIS. ROUTINE CLINICAL PRACTICE DATA

1Rheumatology, Hospital Clinico Universitario, Valencia; 2Rheumatology, Hospital Universitario de Guadalajara, Guadalajara; 3Rheumatology, Hospital Comarcal de Laredo, Laredo; 4Rheumatology, Hospital Universitario Puerta de Hierro, Madrid; 5Rheumatology, Hospital Universitario Germans Trias i Pujol, Badalona; 6Rheumatology, Hospital del Henares, Alcala de Henares; 7Rheumatology, Hospital de Fuenlabrada, Fuenlabrada; 8Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain

Background: Certolizumab pegol (CZP) is the only antiTNF pegylated without Fc available for patients with psoriatic arthritis (PsA). The efficacy and safety of CZP in clinical trials is known, but there are few published data on the effectiveness of CZP in a setting of usual clinical practice.

Objectives: To evaluate the effectiveness and safety of Certolizumab Pegol (CZP) in a real in PsA patients.

Methods: Multicentric cohort of PsA patients treated with CZP according routine clinical practice. Study approved by local Ethics Committee. Maximum time of observation was 12 months. Effectiveness variables: SJC, TJC, PtGA (Patient Global Assessment) and DAS28-CRP. Safety variables: discontinuation rate.

Results: 262 patients with PsA were included: 43.5% male, mean (SD) age 49.9 (11.9) years, mean (Q1-Q3) disease duration 6.9 (1.9–9.3) years, 14.9% of patients HLAB27 positive, mean (SD) IMC (kg/m²) 26.9 (4.7), never smokers 70.3%. Extra-articular manifestations ever: Psoriasis (90%); PASI>10 40.9%, enthesitis (44.4%), dactylitis (41.9%), nail disease (32%), inflammatory bowel diseases (4.9%). 37.3% of the PsA patients had bone erosions and 3% arthritis mutilans. 48.9 patients received 1 prior csDMARD and 52.1% at least 2 csDMARD. Prior bDMARD: 28.4% none; 38.1% 1, 33.5%>2. 29.6% of PsA patients received CZP in monotherapy. Mean time on treatment with CZP 10 months.

Conclusions: In this study of routine clinical practice CZP was effective in patients with PsA, with a significant decrease in DAS28-CRP and the percentage of patients with enthesitis and dactylitis. The retention rate of certolizumab pegol was not affected by the number of previous biological treatments.

Abstract AB0908 – Figure 1. Cumulative probability plot demonstrating RexSPA progression pre- and post- TNF inhibition

Abstract AB0909 – Figure 1. CZP retention rate and biologics exposure (n° of previous biologics)

Statistically significant differences in SJC, TJC and DAS28-CRP were observed at the last visit comparing with baseline (Table 1). Percentage of patients with enthesitis at baseline (25.4%) decrease to 9.5% at the last visit; 73.2% of the patients had a resolution of the enthesitis (MASES=0). The percentage of patients with dactylitis at baseline (29.1%) decrease to 8.6% in the last visit; 82.5% of these patients had a resolution of the dactylitis. Statistically significant reduction of patients with nail disease was observed from 30.6% to 16.4%. According to Kaplan-Meier analysis, the drug survival of CZP was 78.2%, and no differences were observed in patients who received CZP as first/second biologic or after more than 1 failure to other biologicals agents (Figure1).

262 patients were included in the safety analysis, 21.8% withdrawn treatment: 12.6% due to lack of effectiveness, 5.3% due to intolerance and 3.8% other reasons.

Abstract AB0909 – Figure 1. Cumulative probability plot demonstrating ReXSPA progression pre- and post- TNF inhibition
LONG-TERM GOLIMUMAB RETENTION RATE IN PATIENTS WITH PSORIATIC ARTHRITIS. IS CONCOMITANT DMARD IMPORTANT?

B. Serrans-Benítez1,2, C.M. González-Fernández1,2, L. Valor1, I. Janta1, R. D. González-Benítez1, C. Sáenz Tenorio1, J.C. Nieto-González1, J.G. Ovalls-Bonilla1, J. Martínez-Barrio1, M. Corretero Plaza1, L. García-Montoya1, F.J. López-Longo1, I. Monteagudo Saez1. 1Rheumatology, Hospital General Universitario Gregorio Marañón, 2Faculty of Medicine, Universidad Complutense de Madrid, Madrid, Spain

Background: The efficacy of Golimumab treatment in psoriatic arthritis (PsA) patients has been widely documented.

Objectives: The aim of this study was to analyse the long-term retention rate of golimumab and to identify independent predictors of drug retention in patients with PsA including concomitant synthetic disease-modifying antirheumatic drugs (sDMARD)

Methods: Prospective monocentric cohort of PsA patients treated with golimumab according to clinical practice. Study was approved by local Ethics Committee. Demographic and clinical variables were analysed with Cox proportional hazard regression model.

Results: 48 patients were included, 20/48 (41.7%) oligoarticular, 19/48 (39.6%) polyarticular and 9/48 (18.7%) with peripheral and axial PsA. The baseline characteristics of the patients are shown in table 1.

Follow-up time was 89.25 patients-year. Mean survival time was 40.3 months (95% CI: 32.0–48.5). Age, mean evolution time and previous biological use were significant in the univariate analysis. Concomitant sDMARD had no influence on golimumab retention rate (HR: 1.3; 95% CI: 0.5–3; p: 0.6). Figure 1. When golimumab was used as first or second biologic treatment, it had a better retention rate than when it was used as third or fourth, but did not reach statistical significance (HR: 2.3; IC 95%: 0.8–6.2; p: 0.1). 18/48 patients (37.5%) withdrew golimumab treatment. 13/18 (72.2%) due to lack of efficacy, 1/18 (0.6%) due to adverse events and 4/18 (22.2%) due to other reasons.

Conclusions: Real-world Golimumab retention rate in patients with PsA was good and did not depend on concomitant treatment with sDMARD. When used as first or second biologic, Golimumab retention rate tended to be better.

THE RELATIONSHIP BETWEEN NEUROPATHIC PAIN AND DISEASE ACTIVITY, SLEEP, FATIGUE, QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS

C. Ural1, F. Ultrutu2, M.T. Duruaz2. 1PMR Department, Rheumatology Division, Marmara University School of Medicine, Istanbul, Turkey

Background: Neuropathic pain (NP) is composed of several abnormal sensations, including burning, pricking hyperalgesia and allodynia. NP is a common problem in rheumatic diseases such as rheumatoid arthritis and ankylosing spondylitis due to inflammatory processes. Previous studies showed that NP in other rheumatic diseases had a negative influence on sleep and quality of life.1, 2

Objectives: To examine the relationship of neuropathic pain symptoms in Psoriatic Arthritis (PsA) with demographic, clinical and functional parameters.

Methods: PsA patients according to CASPAR criteria were recruited into the study. Demographic and clinical parameters were noted. PainDETECT measurement tool was used for evaluation of NP. Physical examination such as manual muscle testing and sensory examination for hyperalgesia and allodynia was performed (pinprick and light touch test). Disease Activity Score-28 (DAS-28) was noted for disease activity. Associations of NP with quality of life, sleep and fatigue were analysed by filling out Psoriatic Quality of Life (PsAQoL), Pittsburgh Sleep Quality Index (PSQI), Multidimensional Assessment of Fatigue (MAF). PainDETECT scores were categorised as no NP (<12 points), ambiguous NP (13–18 points), probable NP (>19 points). Group analysis was performed with Independent-Samples Kruskal-Wallis test. Spearman correlation coefficient (rho) was used for correlations between functional parameters. p<0.05 was accepted as significant.

Results: Forty eight PsA patients (31 female, 17 male) with a mean age 50.4 years (SD:10.0) and mean disease duration 92.2 months (SD: 90.2) were recruited into the study. The number of patients with ambiguous NP was 6 patients (4 female, 2 male) and probable NP was 12 patients (10 female, 2 male). The mean scores of PSQI, PsAQoL and MAF were significantly higher in patients with NP (p<0.05). There was no difference in mean scores of DAS-28 and disease duration among groups. The correlations between PainDETECT and other functional parameters were found moderate-strong as PSQI (rho=0.43, p=0.002), MAF (rho=0.44, p=0.002), PsAQoL (rho=0.66, p=0.0005). Also, the probability of NP existence increased with the age (rho=0.40, p<0.01). There was no significant correlation between and clinical parameters such as disease duration and DAS-28 (p>0.05).

Conclusions: These findings suggest that a substantial number of PsA patients suffering from NP. The neuropathic pain symptoms are found to be associated with worse self-reported quality of life and sleep disturbances. It is important to consider the existence of NP in the assessment and treatment process of PsA.

TWO-YEAR EFFICACY AND SAFETY OF GUSELKUMAB FOR TREATMENT OF MODERATE-TO-SEVERE PSORIASIS: PHASE 3 VOYAGE 1 TRIAL

C.E. Griffiths1, K.A. Papp2, A.B. Kimbal3, B. Randazzo4, Y. Wash4, S. Lü1, Y. K. Shen4, A. Blauvelt1. 1U of Manchester, Manchester, UK; 2K. Papp Clinical Research and Probitly Research Inc, Waterloo, Canada; 3Harvard Medical Faculty Physicians at Beth Israel Deaconess Medical Center, d, Boston; 4Janssen Research and Development, LLC, Spring House; 5Oregon Medical Research Center, Portland, USA

Background: Gusekumab (GUS) is an interleukin-23 inhibitor recently approved in the US for treatment of moderate-to-severe psoriasis.

Objectives: Efficacy and safety data for up to 100 wks of GUS treatment are reported.

Methods: In the VOYAGE 1 Phase 3, randomised, double-blind, placebo/active comparator-controlled trial, 837 patients were randomised at baseline to placebo (PBO) at wks0/4/12 then GUS 100 mg at wks16/20 and q8w (n=174); GUS at wks0/4/12, and q8w (n=329); or adalimumab (ADA) 80 mg at wk 0, 40 mg at wk1, and q2w through wk47 then GUS at wk52 and q8w (n=334). Efficacy was assessed using nonresponder imputation through wk48 and treatment failure rules from wks52–100.

Results: Among patients randomised to GUS, or PBO—GUS at wk16, efficacy (PASI, Psoriasis Area and Severity Index; IGA, Investigator’s Global Assessment) was maintained from wks52–100 with continuous GUS treatment. Among those
randomised to ADA (−GUS at wk52), efficacy improved from wks52−100. Similar findings were observed for patient-reported outcomes (PSSD, Psoriasis Symptom and Signs Diary; DLQI, Dermatology Life Quality Index; table 1). Through wk100, there were no disproportionate increases in rates of Adverse Events (AEs) compared with rates through wk48. Serious AE rates were low and remained stable; no TB, opportunistic infections, or serious hypersensitivity reactions were reported.

Conclusions: Efficacy among GUS patients was maintained through 2 years of continuous treatment. Efficacy among ADA−GUS patients improved from wk52−100. GUS was well-tolerated, with a similar safety profile as previously reported.

AB0913
TO DETERMINE THE ASSOCIATION BETWEEN PLAQUE AND NON PLAQUE PSORIASIS WITH THEIR JOINT MANIFESTATION IN PSORIATIC ARTHRITIS PATIENT – A SINGLE CENTRE EXPERIENCE IN MALAYSIA

C.R. Ng1, L. Selvarajah2, Y.L. Loh3, HOSPITAL SULTAN ISMAIL, JOHOR BAHRU, MALAYSIA, Johor Bahru, Malaysia; 1Internal medicine, HOSPITAL SULTAN ISMAIL, JOHOR BAHRU, MALAYSIA, Johor Bahru, Malaysia.

Background: Psoriatic arthritis (PsA) which is a member of the spondyloarthritides includes axial and peripheral joint involvement. It affects women and men equally. The clinical patterns of PsA were classified into 5 groups according to Moll and Wright. 1 Psoriatic arthritis is a common chronic inflammatory skin disease and chronic plaque psoriasis is the commonest form.

Objectives: To study the relationship between plaque and non-plaque psoriasis with their joint manifestation and to describe the demographic characteristics of PsA patients.

Methods: This was a retrospective study. The electronic medical records of all PsA patients under rheumatology clinic Hospital Sultan Ismail followed up from 1/1/2009 to 31/12/2017 were reviewed. Data on demographic, type of skin disease, joint manifestation, past medical history, fasting serum lipid and body mass index were obtained and analysed.

Results: We identified 163 patients, 84 were male patients with male to female ratio of 1.06. The Malays (84/163) were the majority being affected, followed by the Chinese (46/163), Indians (30/163) and others (3/163). The patients were divided into plaque psoriasis (140/163) and non-plaque psoriasis (23/163). The commonest joint involvement in the study was peripheral joint involvement (121/163), axial involvement (22/163) and both axial and peripheral joint involvement (20/163). The peripheral joint involvement was categorised as polyarthritides (67/121), followed by oligoarthrailgeal arthritides (47/121) and distal interphalangeal arthritides (41/121) and arthritis mutilans (3/121). In the study, we divided the patients into plaque psoriasis [peripheral joint involvement (102/121); axial involvement (16/121); both (18/140)] and non-plaque psoriasis [peripheral joint involvement (15/23); axial involvement (6/23); both (2/23)] and analysed the results by using the SPSS logistic regression. It showed no significant association between type of skin psoriasis with its joint manifestation. (p>0.05).

Amongst the 163 patients, 68/163 (42%) had hypertension, 50/163 (31%) had diabetes mellitus, 32/163 (20%) had hypercholesterolemia, 12/163 have ischaemic heart disease, 1 patient had congestive heart disease, 3 had breast cancer, 1 had hepatocellular carcinoma and 2 have chronic kidney disease and cerebral vascular disease respectively.

There was no association between types of skin psoriasis with their joint manifestation. There was a significant number of patients who had deranged fasting serum lipid and majority of them have BMI in the overweight and obese group.

AB0914
COMPARISON OF 25-HYDROXYVITAMIN D3 SERUM LEVELS IN PATIENTS WITH PSORIATIC ARTHRITIS WITH OR WITHOUT PSORIASIS SKIN INVOLVEMENT

C. Picon-Montaltia, J.R. Quiliones-Torres, M. Vázquez-Díaz. Rheumatology, HOSPITAL RAMON Y CAJAL, MADRID, Madrid, Spain

Objectives: To determine 25-hydroxyvitamin D3 (25OH-D3) serum levels in patients with psoriatic arthritis (PA) and to assess differences according to the presence or absence of psoriasis skin involvement. To evaluate the response to vitamin D supplements in case of deficiency in both groups.

Methods: We conducted an observational retrospective study including patients with diagnosis of PA according to the CASPAR classification criteria who had at least one serum determination of 25OH-D3 in the last 36 months. Clinical and epidemiological data were collected, including arthritis distribution, age of diagnosis, presence of psoriasis skin involvement, treatment received and serum 25OH-D3 levels at baseline and within the subsequent 3 months if treatment with oral supplements had been initiated. Patients already receiving oral vitamin D supplements at baseline were excluded.

Results: Sixty patients met the inclusion criteria and were analysed. 42 were female (70%), with a mean age of 47.6 years (range: 30–82). Psoriasis skin involvement was present in 40 patients and preceded onset of arthritis in 80% of them (20% with psoriatic nail dystrophy). Regarding 25OH-D3 levels, mean value was 17.99±13.23 ng/dL. In the global analysis, 7 patients (11.6%) had levels between 0–10 ng/dL, 22 patients (36.6%) between 10–20 ng/dL, 23 patients (38.3%) between 20–30 ng/dL, 6 patients (10%) between 30–40 ng/dL and 2 patients >40 ng/dL. In our sample, 58.53% of patients with psoriasis skin involvement had 25OH-D3 levels higher than 20 ng/dL, in contrast to the group without skin involvement, who reached sufficiency levels only in 37.5% of the cases. In the comparative analysis, patients with psoriasis skin involvement had a mean 25OH-D3 serum level of 20.88 ng/dL whereas patients without skin involvement had lower levels (mean value 19.42 ng/dL). Similarly, patients with skin psoriasis had more frequently 25OH-D3 levels between 20–30 ng/dL (insufficiency) compared to those without, who presented lower levels (44% vs 16%) but without statistically significant difference. Results are shown in Figure 1. Finally, all patients presenting 25OH-D3 deficiency at baseline (<20 ng/dL) were treated with oral supplements (calcitriol 0.266 mg every two weeks). Of them, 23 patients had a second determination of 25OH-D3 within the subsequent 3 months, with only 13 patients reaching sufficient levels (56%), whereas the rest did not respond to the dose administered. No statistically significant differences were found in the response depending on the presence or absence of cutaneous psoriasis.
Conclusions: In patients with PA, the presence of psoriasis skin involvement correlates with higher 25OH-D3 serum levels. This finding could be explained by the treatment received in these patients for moderate-severe skin involvement, which includes topical vitamin D analogues and phototherapy that could increase 25OH-D3 serum levels. After oral supplements, there was no statistically significant difference in the percentage of patients that reached sufficiency levels in both groups.

Disclosure of Interest: None declared

Abstract AB0915 – Figure 1. 25-Hydroxyvitamin D3 levels in patients with Psoriatic arthritis with and without psoriasis skin involvement (ng/dL).

Background: Reports on the prevalence of osteoporosis, osteoporotic fractures and risk factors for osteoporosis in patients with Psoriasis or Psoriaticarthritis are scarce, and the published results on this are, at least in part, contradictory. Additionally, there is no firm understanding of the impact of potential risk factors such as smoking and low vitamin D (Vit D) levels have on the occurrence of osteoporotic fractures in this patient group.

Objectives: RH-GIOP is an ongoing prospective study monitoring glucocorticoid (GC)-induced osteoporosis of rheumatic patients, established in 2015 at the Charité University Hospital. To date, the database comprises clinical data and bone mineral density data measured by dual x-ray absorptiometry (DXA) of 592 patients with inflammatory rheumatic diseases. (ClinicalTrials.gov Identifier NCT02719314) The objective of this cross-sectional analysis was to evaluate the prevalence of osteoporosis and frequency of fractures in patients with Psoriasis (PsO) or Psoriaticarthritis (PsA). Additionally, smoking and Vit D status were investigated as possible risk factors for low BMD.

Methods: We evaluated the initial visit of 55 patients with PSO (80% female) or PsA (60% female). Descriptive analyses were performed, and values are displayed as means and standard deviations. For subgroup analyses non-parametric tests were used.

Results: Overall, mean age was 60 years (+12 years), and 69% of the patients were female. The mean disease duration was 16±13 years and patients generally showed a good functional status as quantified by the Health Assessment Questionnaire (HAQ mean: 1.0±0.8). While osteoporosis and osteopenia were present in 16% and 38%, respectively, osteoporotic fractures were found in 33% of all patients. However, the family history for osteoporosis was positive in 20% of the patients. Smoking and low Vit D levels showed a good functional status as quantified by the Health Assessment Questionnaire (HAQ mean: 1.0±0.8). While osteoporosis and osteopenia were present in 16% and 38%, respectively, osteoporotic fractures were found in 33% of all patients. However, the family history for osteoporosis was positive in 20% of the patients. Smoking and low Vit D levels have on the occurrence of osteoporotic fractures in this patient group.

Efficacy and Predictive Factors of Clinical Response to TNF Inhibitors in Patients with Axial and Peripheral Psoriatic Arthritis

AB0916

Background: Patients with psoriatic arthritis (PsA) may have predominant axial (axPsA) or peripheral (pPsA) manifestations. The development of TNF inhibitors (TNFi) has changed the course of PsA. However, most published data is focused on pPsA but almost no data is available for TNFi response in axPsA.

Objectives: To analyse the efficacy and the predictive factors of clinical response in patients with axPsA and pPsA starting treatment with TNFi in clinical practice.

Methods: An observational study analysing data from a prospective cohort including 93 patients (pts) with axPsA or pPsA treated with TNFi from 2002–2018 was conducted. Demographic information, disease activity indexes (ASDAS for axPsA and DAS28 for pPsA) and laboratory tests were collected before starting TNFi (baseline visit) and 6 months later (6 m visit). At 6 m, the percentage of pts achieving inactive disease (ASDAS <1.3 or DAS28 <2.6) were determined. Baseline predictor factors of inactive disease/remission and clinical improvement at 6 m were identified using a univariable and multivariable binary regression models adjusted for confounder factors.

Results: Out of 93 included pts, 45 pts had predominant axPsA and 48 pPsA. Administered TNFi was etanercept for most pts (42%), infliximab in 29%, adalimumab in 22% and golimumab in 7%. Baseline characteristics are shown in table 1. Male sex was more frequent in axPsA vs pPsA (62% vs 42%; p=0.04, respectively). In axPsA, 55% clinically improved and 32% pts achieved inactive disease. After multivariable analysis, male gender (OR 25.8, p=0.01) and higher baseline ASDAS (OR 6.3, p=0.01) were associated as independent predictors of clinical improvement at 6 m. Also, male gender (OR 15.7, p=0.03) and lower BMI (OR
0.7, p=0.03) were associated as independent predictor factors for achieving inactive disease. In pPsA, 45% pts clinically improved and 33% pts were on remission at 6 m. The percentage of pts on remission tended to be higher in males than females (47% vs 20%; p=0.08, respectively). However, after running the regression analyses, none of the baseline predictor factors was significantly associated neither with clinical improvement nor with remission in patients with pPsA.

</table>

**Conclusions:** In clinical practice, 1 out of 3 pts with PsA is on remission 6 m after initiating a TNFI, and 1 out of 2 clinically improve; both proportions are similar for axPsA and pPsA. Male gender, higher baseline disease activity and lower BMI are associated with more probability to achieve inactive disease or an important clinical improvement in axPsA.

**AB0917**

**CLINICAL AND RADIOLOGICAL CHARACTERISATION OF AXIAL PSORIATIC ARTHRITIS**

**Background:** Defining axial involvement in psoriatic arthritis (PsA) is a challenge; thus, according to which criteria used, the differences in prevalence of axial PsA range from 20% to 70%. Two different phenotypes have been suggested in axial PsA. One of them remind us typical Ankylosing Spondylitis (AS) with bilateral sacroiliitis according to the New York modified criteria (mNY) and a strong association with HLA-B27 and another phenotype with more indolent course, with unilateral and asymmetric sacroiliitis and a lower association to HLA B27

**Objectives:** To define clinical and radiological characteristics of a cohort of patients with axial PsA with associated sacroiliitis in a third level hospital in southern Spain.

**Methods:** Cross-sectional study of an axial PsA cohort with sacroiliitis from a third level hospital. Demographic, clinical and radiological variables were collected. Sacroiliitis was defined as: sacroiliitis according to mNY, or unilateral sacroiliitis grade II in X-ray, and/or according to ASAS criteria of positive MRI. We excluded those patients with axial PsA without sacroiliitis according to definition. The statistical package SPSS v21 was used. The qualitative variables were analysed by the Chi2 and Fisher tests, as required. The quantitative variables were analysed by Student’s T Test/Mann-Whitney U Test. Statistical significance was considered, values of p<0.05

**Results:** Of 209 patients with axial SpA with sacroiliitis according to the definition found, 39 patients with diagnosis of PsA were analysed. The main characteristics of the patients are shown in image 1. Of the 39 patients, 62% did not meet mNY criteria. Regarding the patients who met mNY criteria, those who did not comply them had the following differences (specifying the significance). The initial diagnosis was different from PsA more frequently (40% Vs. 17%, p 0.124). They presented a lower evolution of the disease (7 Vs. 13 years, p 0.052). They presented as initial symptomatology a greater frequency of peripheral arthritis (71% Vs 27%, p 0.03); and consequently, a greater presence of mixed forms (92% Vs 53%, p 0.015). They presented a lower frequency of positive HLAB27 (21 V. 80, p 0.042).

**Conclusions:** Patients with axial PsA with sacroiliitis according to ASAS criteria of positive MRI/unilateral grade II X-ray sacroiliitis presented more peripheral joint involvement, and less association with HLA B27 compared to patients who did meet mNY criteria. A smaller proportion of patients with axial PsA that meet the mNY criteria suggests a less aggressive structural sacroiliac involvement.

**PATIENT-REPORTED OUTCOMES IMPROVEMENT IN THE RUSSIAN COHORT OF EARLY PERIPHERAL PSORIATIC ARTHRITIS PATIENTS TREATED ACCORDING TO TREAT-TO-TARGET STRATEGY (OPEN-LABEL REMARCA STUDY)**

**Background:** Psoriatic arthritis (PsA) has a significant impact on patients’ mood and quality of life. Patient reported outcome (PRO) measures are an important component to assessing disease impact and therapy response in PsA pts. There is limited data concerning the influence of T2T strategy on PROs.

**Objectives:** To assess the effect of tight control T2T strategy on the PROs dynamics over 1 year (yr) period.

**Methods:** 78 pts (M/F8/39) with early PsA according to CASPAR criteria were included; mean age 36.5±10.7 years, disease duration 12.2±10.3 mo. Disease activity indexes (DAS)=4.0±1.4, DAS28=4.2±1.1. Pts underwent standard clinical examination of PsA activity. At baseline all pts were treated with MTX (sc). The dose of MTX was escalated by 5 mg eow from 10 mg/wk to 20–25 mg/wk. If the patient did not achieve minimal disease activity (MDA) or remission after 3 mo of treatment, the T2T strategy was initiated (Fig. 3). The clinical variables were assessed at 6 mo, then every 3 mo. The PROs were measured by the SF-36, the HAQ-DI, the VAS pain, the VAS global health, and the CDAI. The PROs were measured at 6 mo, then every 3 mo. The PROs were measured by the SF-36, the HAQ-DI, the VAS pain, the VAS global health, and the CDAI.

**Conclusions:** No significant differences were found in reference to the presence of extra-articular involvement (dactylitis, uveitis, psoriasis, onychopathy), nor in reference to the presence of related family history (spondyloarthritis, psoriasis, uveitis).

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.1583
MTX mono-therapy, combination therapy with MT + adalimumab 40 mg s/c every other week was started. At baseline and after 1 year of therapy the following PROs were ana-lysed: trends in fatigue according to FACIT-F and PGA, TJC, SJC, PGA, EDA and DAS/DASI in 78 pts, trends in patient’s global disease activity (PGA) and in patient’s pain VAS were studied in 78 pts, trends in levels of anxiety and depression (HADS) were studied in 49 pts. The data acquired was analysed with the use of Spearman’s correlation. **Results:** After 1 year of therapy, there was a significant improvement in the fol-lowing scores: anxiety changed from 5.7±3.1 to 4.3±3.2 (p<0.003), fatigue from 35.3±9.6 to 41.3±9.9 (p<0.001), RAPID3 from 13.4±5.1 to 6.2±5.2 (p<0.001), PGA from 56.0±17.8 to 18.9±17.1 (p<0.001), pain from 53.7±18.6 to 16.9±16.6 (p<0.001). Depression scores had also changed though not significantly: from 3.8 ±3.0 to 3.2±3.1 (p=0.235). The dynamics of anxiety and depression indexes correlated with the dynamics of fatigue (r=0.64 and r=0.39, accordingly), as well as dynamics of FACIT and RAPID3 indexes (r=0.36). Correlation of the dynamics of RAPID3 indexes with DAS (r=0.45) and DAS28 (r=0.41) activity reduction was found. Association of RAPID3 dynamics with the achievement of remission according to DAS (p<0.001) and DAS28 (p<0.001) was detected. Intereation between RAPID3 dynamics and the achievement of MDA (p<0.001) was found. Correlation between dynamics of anxiety and depression indexes and the reduc-tion of tender joint count (TJC) (r=0.38 and r=0.36, accordingly) was found. There is correlation between the dynamics of fatigue indexes and TJC, swollen joint count (SJC) and PGA (r=0.30, r=0.25 and r=0.35, accordingly). Dynamics of RAPID3 correlated with TJC and SJC dynamics (r=0.33, r=0.25), as well as with PGA and pain dynamics (r=0.49 and r=0.58). PGA and pain dynamics correlated with TJC and SJC dynamics (r=0.34 and r=0.26, r=0.43 and r=0.39, accordingly). **Conclusions:** The T2T strategy in the Russian cohort of peripheral early PsA pts demonstrated the improvement of PROs indexes and decrease in PsA activity. Interrelation between the improvement of psychological status according to PROs (anxiety, depression and fatigue) and improvement in joint status (TJC and SJC) was found. RAPID3 is a reliable tool for evaluating patient’s status: RAPID3 indexes correlate with the achievement of MDA and DAS/DAS28 remission. **Disclosure of Interest:** None declared **DOI:** 10.1136/annrheumdis-2018-eular.6250

**Abstract AB0919 – Figure 1**

**Conclusions:** Two serum proteomic biomarkers, previously identified in a cohort of monozygotic twins discordant for psoriatic arthritis, can discriminate psoriatic arthritis, thus representing potential biomarkers of disease and possibly playing a pathogenetic role in disease.

**Rheumatology and Clinical Immunology; 2Dermatology Unit, Humanitas Research Hospital; 3Dermatology, Milan, Italy**

**Background:** Skin psoriasis affects 3% of the general population and as much as 20%-40% of patients will develop psoriatic arthritis (PsA), with the two conditions representing a clinical and immunological continuum within a prototype for chronic inflammation. Different from most rheumatic diseases, no serum autoantibody is associated with PsA, and there are currently no biomarkers for an early diagnosis and prediction of PsA onset in psoriasis, frequently causing a delayed diagnosis. Monozygotic twins discordant for psoriasis/PsA represent a unique setting to investigate the influence of environmental and stochastic factors on disease phe-notypic. Through a high-throughput proteomic analysis (SomaLogic) we have pre-viously identified a set of 13 proteins differentially expressed in the serum of monozygotic twins discordant for psoriatic disease.

**Objectives:** To validate serum proteomic biomarkers of psoriatic disease using commercially available ELISA in monozygotic twins and in unrelated patients with psoriasis/PsA.

**Methods:** Our study included sera from our cohort of monozygotic twins previ-ously described and from 70 unrelated patients with psoriatic disease (psoriasis without PsA 34%-49%, PsA with/without psoriasis 36%-51%; women 46%, median age 52 years, interquartile range 41–59) followed at Humanitas Research Hospital, and 25 healthy subjects (52% women, median age 52 years, IQR 44– 62). Candidate serum proteomic biomarkers obtained by SomaLogic analysis were validated using commercially available ELISA kits and proteins are herein anonymized due to a pending patent request.

**Results:** We found a significant correlation between SomaLogic results in monozygotic twins and ELISA results in unrelated psoriatic cases in the serum levels of 2 proteins (figure 1), which are involved in inflammatory and immune response, and one has been previously reported in psoriatic plaques. Four proteins showed a significantly different expression between psoriasis and PsA versus controls, in particular two proteins have a potential role in disease pathogenesis, as protein #1 acts as cell-surface receptor and regulates differentiation, proliferation and sur-vival of dendritic cells, while protein #2 is involved in regulation of UV radiation-induced apoptosis and protein folding.

**AB0920 TUMOUR NECROSIS FACTOR INHIBITORS PERSISTENCE IN PSORIATIC ARTHRITIS PATIENTS**

E. Vieira-Sousa1, M. Eusébio2, P. Ávila-Ribeiro1, N. Kholmelniklini3, A.R. Machado1, T. Martins Rocha4, M. Bernardes1, D. Santos-Faria5, J. Leite Silva1, H. Santos1, C. Miguel6, P. Carvalho6, T. Costa6, L. Teixeira6, T. Mesinhos6, P. Nero1,2, M. J. Santos6, E. Rhenumatologia and Metabolic Bone Diseases Department, Hospital of Santa Maria, CHLN and Rheumatology Research Unit, Instituto of Medicina Molecular, Faculty of Medicine, University of Lisbon, Lisbon Academic Medical Centre; 2Portuguese Society of Reumatology, Lisbon; 3Rheumatology Department, Centro Hospitalar São João do Porto and Faculdade de Medicina da Universidade do Porto, Porto; 4Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima; 5Instituto Português de Reumatologia, Lisbon; 6Rheumatology Department, Hospital Universitários de Coimbra, Coimbra; 7Rheumatology Department, Hospital de Évora, Évora, Portugal; 8Rheumatology Department, Hospital Garcia de Orta, Almada; 9Rheumatology Department, Centro Hospitalar do Baixo Vouga, Aveiro, Portugal

**Background:** Tumour necrosis factor inhibitors (TNFi) lead to a dramatic improvement in the management of psoriatic arthritis (PsA). Nevertheless, a sig-nificant proportion of patients still do not respond and/or are intolerant to TNFis, requiring treatment switch for an adequate control of disease activity.

**Objectives:** To assess TNFis drug retention and the main reasons for TNFi dis-continuation in PsA patients.

**Methods:** This was a non-interventional study of PsA patients registered at the Rheumatology Departments Portuguese Registry (Reuma.pt), with at least one TNFi pre-scription. Drug retention for a first, second and third line TNFi was assessed by Kaplan-Meier survival analysis. The reasons for discontinuation were described as frequencies.

**Results:** 750 PsA patients were included, with a mean age of 47.6 years (±11.6); 50.3% (n=377) female. 200 patients (26.7%) treated with adalimumab, 335 (44.7%) with etanercept, 114 (12.2%) with golimumab and 101 (13.5%) with inflixi-mab, as first line TNFi. The majority (67.6%) were receiving concomitantly conv-entional synthetic drug modifying anti-rheumatic drugs (62.3% MTX) and 33.9% corticosteroids. The mean duration of TNFi retention was of 48.5±40.1 months, when treated with a 1st TNFi, decreasing to 35.5±33 months for the 2nd TNFi, and to 22.7±22.9 months for the 3rd TNFi (figure 1). After being treated with a 1st TNFi, the majority of discontinuers (35.9%) of the total population), withdrew due to lack of effectiveness (53.9%) and due to adverse events (24.4%). The rates of discontinuation for the 2nd and 3rd TNFi were of 39% and 54%, respectively. Lack of loss of effectiveness and adverse events were maintained the two main reasons of withdrawal for the 2nd (62.3%; 21.6%) and 3rd TNFi (63%; 22.2%).

Conclusions: PsA patients registered at Reuma.pt treated with a 1st TNFi had an overall drug retention of 49 months. We observed a decrease in the average retention of TNFi therapy of 13.0 months in PsA patients who switched to a 2nd TNFi or a 3rd TNFi. Lack or loss of response were the main reason for TNFi discontinuation, independently of TNFi position, responsible for more than half of the discontinuations. The observed short survival of TNFis in PsA, and the inability to regain drug expectancy when switching to another TNFi, highlights the limitations from recycling between TNFIs when aiming at long-term disease remission.

**IMPACT OF BASELINE DEMOGRAPHICS, DISEASE ACTIVITY AND CONCOMITANT MEDICATION ON AMERICAN COLLEGE OF RHEUMATOLOGY 20 RESPONSE RATE AND HEALTH ASSESSMENT QUESTIONNAIRE-DISABILITY INDEX SCORE WITH TOFACITINIB IN ACTIVE PSORIATIC ARTHRITIS: A POOLED SUBGROUP ANALYSIS OF 2 PHASE 3 STUDIES**

F. Behrens1, J. Gomez-Reino2, P. Nash3, D.D. Gladman4, O. FitzGerald6, C. Ritchin5, E. Kudlace7, J. Wu8, C. Wang9, A.B. Romero10, 1CIRI/Rheumatology and Fraunhofer Institute IME, Translational Medicine and Pharmacology, Goethe University, Frankfurt, Germany; 2Hospital Clinico Universitario, Santiago de Compostela, Spain; 3University of Queensland, St Lucia, Brisbane, Australia; 4University of Toronto, Toronto Western Hospital, Toronto, ON, Canada; 5St Vincent’s University Hospital, Dublin, Ireland; 6University of Rochester Medical Center, Rochester, NY; 7Pfizer Inc, Groton, CT, USA; 8Pfizer Inc, Barcelona, Spain

Background: Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). In a pooled analysis of data from 2 Phase 3 trials in patients (pts) with active PsA, tofacitinib 5 and 10 mg twice daily (BID) significantly improved American College of Rheumatology (ACR) 20 response rates vs placebo (PBO) (50.0, 53.0 vs 28.0%, respectively; p<0.001) and least squares mean (LSM) change from baseline (BL) in Health Assessment Questionnaire-Disability Index (HAQ-DI) score vs PBO (-0.38, -0.38 vs -0.16, respectively; p<0.001) at Month 3.1

Objectives: To compare the efficacy of tofacitinib 5 and 10 mg BID vs PBO in predefined pt subgroups based on differences in BL demographics, disease activity and concomitant medication.

Methods: This was an analysis of pooled efficacy data from 2 Phase 3, randomised, double-blind, PBO-controlled studies (OPAL Broaden [12 months; NCT01877668] and OPAL Beyond [6 months; NCT01882439]) in pts with active PsA (defined as ≥3 swollen and ≥3 tender joints). Pts in OPAL Broaden were tumour necrosis factor inhibitor (TNFi)-naïve with an inadequate response (IR) to ≥1 conventional synthetic disease-modifying anti-rheumatic drug (csDMARD). Pts in OPAL Beyond had an IR to ≥1 TNFi. Pts were randomised to receive tofacitinib 5 or 10 mg BID, subcutaneous adalimumab 40 mg every 2 weeks (OPAL Broaden; data not included) or PBO. Pts continued to receive a stable dose of a single csDMARD. ACR20 response rates and LSM change from BL in HAQ-DI at Month 3 (primary endpoint data) were evaluated by subgroup category (demographic and disease characteristics at BL or at screening).

Results: In total, 238, 236 and 236 pts received tofacitinib 5 mg BID, 10 mg BID, or PBO, respectively. Across all subgroups analysed, tofacitinib 5 and 10 mg BID were generally associated with greater improvements at Month 3 in ACR20 and change from BL in HAQ-DI score than PBO (table 1). In pts classified as current smokers, slightly lower ACR20 response rates and similar changes from BL in HAQ-DI score to corresponding PBO at Month 3 were observed relative to never- or ex-smokers; however, the sample size was small.

Disclosure of Interest: None declared

*Analysis was not conducted due to small sample size; \(^{\text{a}}\)At screening; \(^{\text{b}}\)In pts with baseline PASI ≥0 and baseline BSA ≥3%

Statistical methods: ACR20 response was defined as achieving a ≥20% improvement in ACR criteria components Missing ACR20 response was considered a non-response to treatment

LSMs were calculated based on a mixed model for repeated measures without imputation for missing values

ACR, American College of Rheumatology; BID, twice daily; BMI, body mass index; BSA, body surface area; CRP, C-reactive protein; csDMARD, conventional synthetic disease-modifying anti-rheumatic drug; DSS, Dactylitis Severity Score; HAQ-DI, Health Assessment Questionnaire-Disability Index; LEI, Leeds Enthesitis Index; LSM, least squares mean; MTX, methotrexate; N, number of patients in full analysis set (randomised and received ≥1 treatment dose); n, number of responders; N1, number of patients in the full analysis set by category of subgroup and treatment; N2, number of patients included in the repeated measures model by category of subgroup and treatment; NC, analysis not conducted; PASDAS, Psoriatic Arthritis Disease Activity Score; PASI, Psoriasis Area and Severity Index; PsA, psoriatic arthritis; pts, patients; ROW, rest of world (Brazil, Mexico and Taiwan); SPARCC, Spondyloarthritis Research Consortium of Canada (enthesitis index)

Conclusions: In this analysis of pooled data from 2 Phase 3 studies in pts with active PsA, tofacitinib 5 and 10 mg BID consistently improved efficacy at Month 3 compared with PBO across all pre-defined subgroups evaluated, with the exception of current smoking; however, this was not a pre-specified analysis and some subgroups (including smoking status) were small, interpretation should be made with caution.
**METABOLIC SYNDROME IS ASSOCIATED WITH ACTIVE DISEASE IN PSORIATIC ARTHRITIS AND MAY CONTRIBUTE TO DEVELOPMENT OF SYNDENISMOPHYES**

P. Sanci1, G. Kenar1, B. Zengin2, S. Uslu1, A. Koken1, H. Yarkani3, H. Ellidokuz2, G. Can2, M. Birlik2, F. Oner1. 1Internal Medicine, Dokuz Eylul University School of Medicine, Izmir, Turkey

**Background:** An increased prevalence of metabolic syndrome (MetS) has been reported in psoriatic arthritis (PsA) suggesting an association between the inflammation and MetS.

**Objectives:** The aim of this study is to investigate its relationship with disease activity in patients with PsA. We also evaluated whether an association exists between MetS and axial involvement in PsA.

**Methods:** This study included patients with PsA followed in the Rheumatology outpatient clinic at Dokuz Eylul University. Age-matched patients with Takayasu arteritis (TA), an inflammatory systemic disease, were enrolled as diseased controls. The NCEP-ACC III criteria were used to identify subjects with MetS. Disease activity was assessed in patients with PsA by using several parameters including BASDAI, ASDAS, VAS patients' and physician's global, tender and swollen joint assessment (28/66), DAS28, DAPSA, CPDAI and SPARC Enthesis Index. ESR and serum CRP levels were measured. BASFI and BASMI were used to evaluate functional status and HAQ, ASQOL and DLOI to evaluate health and quality of life. BASMI and BASFI were used to evaluate functional status and HAQ, ASQOL and DLOI to evaluate health and quality of life.

**Results:** There were 104 PsA patients (63.5% F; mean age: 50.9±13.0 years) who fulfilled the CASPAR criteria and 28 TA patients (89% F, mean age: 46.3±9.1) who fulfilled the ACR 1990 criteria. The prevalence of MetS was found to be 37.5% (21.4% compared to those without MetS (p<0.001). In the comparison of PsA patients with and without MetS, no differences were found regarding treatment frequencies of NSAIDs, glucocorticoids, DMARDs and anti-TNFs and also mean glucocorticoid dosages. PsA patients with MetS had higher BASDAI, BASMI, VAS, ASQoL, CPDAI, ASDAS and HAQ scores compared to PsA patients without MetS (table 1). More patients with syndenosophytes were found among PsA patients with MetS compared to those without MetS (p=0.027). There were no differences in indexes related predominantly peripheral involvement, such as tender and swollen joint counts, enthesis score and presence of dactylitis. In multivariable regression analysis, presence of syndenosophytes had no relationship with MetS, but still related with ESR and BASMI.

**Conclusions:** The study demonstrates a higher prevalence of MetS in PsA patients compared to TA. It also suggests that MetS might be associated with high disease activity and more severe disease especially in patients with axial involvement.

AB0924  Efficacy of subcutaneous Ustekinumab Therapy in Patients with Psoriatic Arthritis: A Single Centre-Study

Background: Ustekinumab is a monoclonal antibody that inhibits IL-12 and IL-23 and has demonstrated efficacy and safety for the treatment of patients with psoriatic arthritis, plaque psoriasis, and Crohn’s disease.

Methods: Descriptive, prospective, longitudinal and open study of 66 patients diagnosed with psoriatic arthritis: 63 patients received subcutaneous USTE and 3 patients received USTE at 90 mg every 12 weeks, both groups received a first dose of induction according to technical specifications. The following variables were collected: age, sex, years of evolution, previous treatment with Synthetic Disease Modifying Anti-Rheumatic Drugs (DMARDs) and/or biologic DMARD, counting of painful and swollen joints, determination of C-reactive protein, presence of dactylitis, onychopathy and cutaneous psoriasis. Clinical efficacy was evaluated with EULAR response criteria and Disease Activity Score 28 joints (DAS28) according to low activity criteria (DAS28 > 2.6 – 3.2) and remission clinical response. The dose of Ustekinumab 90 mg may improve the response to treatment in some patients, but we would need a greater number of studies in clinical practice.

Results: 66 patients were included, 51.5% were female. The mean age was 47.2 ±11.3 years and the mean disease duration was 6 ±7.76 years. USTE was prescribed in 44% as a first line therapy and was administered in combination with DMARDs in 51.5% of the patients (mostly, methotrexate). In our cohort, 74.2% of patients had exclusively peripheral involvement, 10.6% had axial involvement and 15.2% had mixed involvement. 21% of our patients had dactylitis and 36% enthesitis, as well as cutaneous psoriasis (74%) and onychopathy (42%). At 6 and 12 months of treatment, we observed a statistically significant decrease in the count of painful and swollen joints, in the DAS28 index and in the MASES index.

Conclusions: Ustekinumab is effective for the treatment of psoriatic arthritis and constitutes an alternative to treatment with anti-TNFα. The dose of Ustekinumab 90 mg may improve the response to treatment in some patients, but we would need a greater number of studies in clinical practice.

Abstract AB0925 – Figure 1. EULAR response rates (%) at 6 (p=0.027) and 12 months
Conclusions: DAPSA correlates well with MDA in patients with mild skin disease and can be used in these patients instead of MDA. In patients who fail to respond to therapy according to MDA there can be a substantial proportion of patients with mild joint disease, due to more severe skin disease and/or presence of enthesis-dies, which are nevertheless vaguely defined.

Abstract AB0926 – Figure 1

EFFECTIVENESS OF CERTOLIZUMAB PEGOL IN PSORIATIC ARTHRITIS. RELATIONSHIP WITH SMOKING STATUS AND BMI

Background: Previous literature have investigated that tobacco and weight in PsA patients. The relationship of smoking and BMI has been investigated in PsA patients.

Methods: Multicentric cohort of PsA patients treated with CZP according to routine clinical practice. This study was approved by local Ethics Committee. Maximum observation time was 12 months. Effectiveness variables: DAS28 (CRP).

Results: 262 patients with PsA were included: 43.5% male, mean (SD) age 49.9 (11.9) years, mean (Q1-Q3) disease duration 6.9 (1.9–9.3) years, and 14.9% of patients were HLAB27 positive. Among these, 229 (87.4%) had known smoking status (29.7% smokers and 70.3% never smokers) and 85 (32%) had known BMI (median 26.9 kg/m², SD 4.7). Statistically significant differences in DAS28 were observed at last visit comparing to baseline in both groups according to BMI and smoking status (table 1).

CZP retention rate was 78.5% in non-smokers and 76.7% in smokers. In patients with BMI <25 kg/m² CZP retention rate was 78.6% compared to 78.9% in patients with BMI ≥25 kg/m² (figure 1). No statistical differences were observed in both sub-groups.

Abstract AB0928 – USTEKINUMAB AND TNF INHIBITORS IN PSORIATIC ARTHRITIS: FIRST FOLLOW-UP DATA FROM A ROUTINE CARE STUDY IN 8 EUROPEAN COUNTRIES (PSABIO)

J.S. Smolen1, P. Bergman2, I. Bondareva3, K. de Vlam4, E. Gromese5, B. Joven-Ibáñez6, T.V. Kortoeva7, M.T. Nurmohamed8, P.P. Silksakis9, S. Siebert10, P. Smirović11, E. Theander12, V. D’Abrasca13, L. Gossec14, D. Medical University of Vienna, Vienna, Austria; 2Janssen-Cilag B.V., Breda, Netherlands; 3Kemerovo Regional Clinical Hospital, Ministry of Health of Russia, Kemerovo, Russian Federation; 4University Hospitals Leuven, Leuven, Belgium; 5Fondazione Polifarno Gemelli-Catholic University of the Sacred Heart, Rome, Italy; 6University Hospital 12 de Octubre, Madrid, Spain; 7V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; 8Amsterdam Rheumatology and Immunology Center, VU University Medical Centre and Reade, Amsterdam, Netherlands; 9University of Athens Medical School, Athens, Greece; 10University of Glasgow, UK; 11Janssen Pharmaceutica NV, Moscow, Russian Federation; 12Janssen EMEA, Issy-les-Moulineaux, France; 13Università della Campania “Luigi Vanvitelli”, Naples, Italy; 14Sorbonne Université, Paris, France

Background: The purpose of PsABio (ClinicalTrials.gov id: NCT02627768) is to evaluate the efficacy, tolerability and persistence of TNF inhibitors (TNFi) and ustekinumab (UST) for patients with psoriatic arthritis (PsA) starting 1st, 2nd or 3rd line biologic disease-modifying antirheumatic drugs (bDMARDs) in real-world routine care.

Objectives: Here we present the first interim follow-up data on joint-related outcomes.

Methods: Of 278 UST- and 285 TNFi-treated patients consecutively enrolled between Dec 2015 and Aug 2017, 152 and 151, respectively, had data available at 6 months for their initial line of treatment. Joint-related outcomes, as observed data, were compared between baseline and 6 months within the treatment cohorts.

Results: Among all enrolled patients, 7.6% of UST- and 10.2% of TNFi-treated patients stopped or switched to another bDMARD before the 6 month timepoint. For those with 6 month data for their initial bDMARD, UST was used as the first-line bDMARD in 40.1%, as 2nd in 35.3%, and as 3rd in 24.3% of patients; these numbers were 64.2%, 28.5%, and 7.3%, respectively, for TNFi. DAS28 scores improved significantly at 6 months from mean baseline values of 4.3 (SD 1.2) and 4.3 (SD 1.2) for UST and TNFi, respectively, by means of −1.3 (95% CI: −1.6, −1.0) and −1.3 (95% CI: −1.6, −1.0). Significant improvements were seen for both cohorts across all treatment lines (table 1) and subtypes of PsA (data not shown). Minimal disease activity (MDA) was achieved at 6 months for 28.8% of UST- and 29.7% of TNFi-treated patients. CDAI results similarly and significantly improved. For the DAPSA, equally, statistically significant improvements were seen: mean −18.4 (95% CI: −22.2, −14.5) and −19.5 (95% CI: −22.5, −16.5) for UST and TNFi, respectively, with 12.2% and 15.7% reaching DAPSA remission and 37.8% and 37.1% reaching low disease activity, cDAPSA showed similar improvement. For details on components of the DAS28 and of the DAPSA, see table 1. Axial joint involvement was significantly improved with reductions in BASDAI and ASDAS.

Conclusions: Both UST- and TNFi-treated patients showed statistically significant and considerable improvements in joint-related measures after 6 months in a real-world setting, irrespective of whether first or further line of treatment.

Abstract AB0928 – Table 1. Baseline and follow-up data for joint-related outcomes for patients having reached 6 months on their initial bDMARD. Values are mean (SD) or mean (95% CI) if not otherwise indicated. na, not applicable.

AB0929 BURDEN OF SKIN AND JOINT SYMPTOMS OF PSORIATIC DISEASE: RESULTS OF A MULTI-NATIONAL PATIENT SURVEY

Background: Psoriatic Arthritis (PsA) and Psoriasis (PsO), have a significant impact on health-related quality of life and work productivity loss. In patients with both PsA and PsO, the full extent of the physical and emotional burden due to either joint related or skin related symptoms is not well understood from the perspective of the patient.

Objectives: To evaluate the patients’ perspective on the overall burden of skin and joint related symptoms of PsA in a cross-sectional online survey.

Methods: A 20 min web based survey was developed based on analysis of 1-on-1 interviews with 30 PsA patients from the US, France and Germany. The final survey contained validated instruments including the PASI Quality of Life (PASOQL) and Work Productivity and Activity Impairment (WPAI) questionnaires as well as custom questions designed to capture emotional burden of PsA and its impact on daily activities/situations. Additional data collected included demographics, severity of PsO by patient-reported body surface area involvement (BSA), severity of PsA by RAPID3, impact of PsO and PsA by a Patient Global Assessment scale with focus on skin or joint symptoms. In total, 439 psoriatic arthritis (PsA) patients from the US (68%), Germany (20%) and France (12%) were recruited to complete the survey.

Results: Among all participants, 30% had mild and 70% had mod-severe PsA based on RAPID3-3 cutoffs, while 51% had mild and 48% had mod-severe PsO based on BSA cutoffs. According to multiple regression analyses, severity of joint symptoms and skin symptoms were significantly associated with lower PsAQL (p<0.0001) as was age (p<0.0001). In patients with mild joint severity, impact of skin symptoms was significantly associated with PsAQL (p<0.0001) as well as age and gender (p<0.05). Joint severity and impact of joint symptoms were the strongest contributors to the WPAI scores (p<0.05). When asked to select the 2 emotions most associated with the impact of their joint symptoms, patients most often chose fatigue (36%), worry/concern (19%) and depression (17%), and with respect to their skin symptoms, patients most often chose embarrassment (24%), fatigue (23%), worry/concern (14%) and depression (12%). When asked to rate the impact of their disease in certain scenarios or situations, more than 25% of patients reported that skin symptoms had a severe impact (a choice of 8, 9 or 10 on a 10-point scale with 0=no impact and 10=severe) on fatigue (32%) and embarrassment (24%), while more than 25% of patients reported that their skin symptoms had a severe impact on fatigue (28%) and embarrassment (24%) (28%).

Conclusions: In this survey of patients with PsA, we evaluated the patient’s perspective on the burden of both skin-related and joint-related symptoms with the PsAQoL, and WPAI as well as with a set of novel questions. Both skin and joint symptoms have a broad and meaningful impact on patient QoL, work productivity and patients reported a range of emotions as well as a variety of impacts on their daily activities with respect to skin and joint symptoms. This data highlights that there is a unique impact of PsA for each patient.

AB0930 REAL-WORLD EFFECTIVENESS AND SAFETY OF APREMILAST IN GERMAN PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSIS OF AN ONGOING MULTICENTRE, PROSPECTIVE, NON-INTERVENTIONAL STUDY

J. Wollenhaup1, T. Klopsch2, H. Strohmyer3, S. Morys4, C. Bach5, N. Nunez-Gomez6, J. Birt1

1Schoen Klinik Hamburg Eilbek, Klinik für Rheumatologie, Hamburg; 2Praxis Dr. med. Thilo Klopsch, Neubrandenburg; 3Rheumatologische Gemeinschaftspraxis Düsseldorf, Düsseldorf; 4Celgene GmbH, München, Germany

Background: Apremilast (APR) has been studied extensively in phase III randomised, controlled trials. However, there is a lack of real-world evidence of effectiveness and safety in a broad population of pts with psoriatic arthritis (PsA).

Objectives: To assess effectiveness and safety of APR in pts with active PsA from routine clinical practice settings in Germany.

Methods: In this multicentre, prospective, non-interventional study, the primary endpoint was the proportion of pts reaching ≥1 point (≥20%) improvement from baseline (BL) in the Physician’s Global Assessment of Disease Activity (PhGA) score. Other endpoints included effects on tender and swollen joint counts, psoriasis-affect ed body surface area (BSA), enthesis, dactylitis, Patient’s Global Assessment of Disease Activity score (PtGA), Psoriatic Arthritis Impact of Disease tool (PsAID), pain and pruritus. The current analysis is based on observed data.

Results: The first 202 of a planned 500 German pts receiving APR for ≥4 months (≥1 month [V1]; ≥4 month [V2]) and 127 pts receiving APR for ≥7 months (V3) were evaluated. Mean age was 54 years, mean BMI was 29 kg/m² and 61% were female. The mean duration of psoriasis was 25 years and of PsA was 18 years; 64% of pts were biologic-naïve and the mean duration since diagnosis of PsA was 5.6 years, at BL. After V1, 60% of pts achieved ≥1 point improvement in PhGA, which increased to 76% (V2) and 87% (V3). Mean (SD) PhGA decreased to 1.7 (0.69) 1.4 (0.73) and 1.1 (0.74) at V1, V2, and V3 respectively. Achievement of a PhGA of 0–1 improved from 0% at BL to 36.8% (V1), 65.0% (V2) and 77.2% (V3). Median improvements in tender and swollen joint counts from BL to V3 were 51% and 60%, respectively. BSA improved from 11.4% at BL to 8.3%, 5.1% and 3.5% at V1, V2 and V3, respectively. At BL, 48.4% of pts had enthesis involvement, on Leeds Enthesitis Index; 46% reached a score of 0 by V1, 57% by V2 and 60% by V3. At BL, 27.3% of pts had dactylitis; a score of 0 was achieved by 40.0%, 66.7% and 71.9% of pts by V1, V2, and V3 respectively. BL mean PsAID score (5.33; max-10.00) decreased to 4.40 (V1), 3.85 (V2) and 3.36 (V3). Improvements were also seen in PtGA, overall pain and pruritus. A sub-analysis suggests that APR was associated with greater benefits in biologic-naïve pts compared with pts who previously received biologic therapies. The observed safety and tolerability after V3 was consistent with the known overall safety profile of APR. Common AEs in clinical trials were similar, with a lower incidence: diarrhoea (10.4%), nausea (5.6%), headache (4.0%) and respiratory tract infection (1.2%).

Conclusions: The first results from this real-world PsA study reinforce findings from previous clinical trials of APR. In pts with >4 and >7 months of follow-up, APR was associated with improvements in both physician-assessed and patient-reported outcomes, with possibly a greater benefit in biologic-naïve compared with biologic-experienced pts. Safety and tolerability were similar to the known profile of APR.

PERSISTENCE WITH SUBCUTANEOUS ADMINISTERED BIOLOGICS AMONG PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSES FROM A US CLAIMS DATABASE

1Rheumatic Disease Center, Glendale, WI; 2Novartis Pharmaceuticals Corporation, East Hanover, NJ; 3Shores Rheumatology, St. Clair Shores, MI, 4Truven Health Analytics, an IBM Company, Cambridge, MA, USA

Background: Persistence with biologic therapies among patients with psoriatic arthritis (PsA) provides insight into the real-world effectiveness of biologics in routine clinical practice. With different dosage schedules and durations of action of currently available biologics, measuring persistence using varying treatment gap cutoffs may better guide physicians in their treatment decisions.

Objectives: To evaluate the persistence of subcutaneously (SC) administered biologics in patients with PsA.

Methods: Patients with ≥1 pharmacy claim for an FDA-approved SC biologic (adalimumab, certolizumab pegol, etanercept, golimumab, and secukinumab) for the treatment of PsA between 01/15/2016 and 07/31/2017 were identified in the Truven Health Analytics MarketScan Commercial and Medicare Supplemental Databases. Eligible patients were aged ≥18 years at the time of biologic initiation (index date) and continuously enrolled with medical and pharmacy claims ≥12 months prior to (baseline period) and ≥12 months after the index date. Patients had ≥1 PsA diagnosis (ICD-9-CM 716.0 or ICD-10-CM L40.5x) and no pharmacy claims for the index biologic during the baseline period. Persistence over 12 months was measured as the discontinuation rate and number of days persistent on the index biologic from the index date to reported treatment gaps of ≥45, ≥90, and ≥180 days based on clinical expert opinion, or the end of follow-up if no gap was observed. The median time to discontinuation of the index biologic over 12 months was assessed by Kaplan-Meier analysis for each treatment gap cutoff.

Results: A total of 1558 patients with PsA enrolled in the analysis initiated SC biologics, including adalimumab (n=720), certolizumab pegol (n=93), etanercept (n=426), golimumab (n=64), and secukinumab (n=255). Overall, 680 patients (43.6%) discontinued their index biologic therapy during 12 month follow-up. The 12 month discontinuation rate for each treatment gap cutoff was lowest with secukinumab compared with other SC biologics (51.8%, 36.5%, and 21.6% for patients discontinued within 45, 90, and 180 days, respectively) and etanercept (270.7 days for ≥90 days or ≥180 days, respectively) and the lowest with certolizumab pegol (216 days ± 155 to 274 days) days and lowest with certolizumab pegol (216 days ± 155 to 274 days) days and lowest with certolizumab pegol (216 days ± 155 to 274 days) days. Median time to discontinuation could not be calculated for patients with treatment gaps ≥90 days or ≥180 days due to low event rates and limited follow-up.

Disclosure of Interest: This study was sponsored by Novartis Pharmaceuticals Corporation, East Hanover, NJ. This study was supported by Novartis Pharmaceuticals Corporation, East Hanover, NJ. None declared.

HELCOBACTER PYLORI ANTIGEN SPECIFIC ANTIBODIES IN PSORIATIC ARTHRITIS

E. Patrício1, C. Lisboa1, E. Zafiriou2, G. Efthymiou1, T. Scheper3, W. Meyer4, A. Roussakis-Schultz2, L. Sakkas3, D.P. Bogdanos1, R. Cáliz Cáliz4, 1Rheumatology and Clinical Immunology, 2Dermatology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece, 3Institute of Immunology, EUROMMUN, Lübeck, Germany

Background: The role of Helicobacter pylori (Hp) infection in the aetopathogenesis of psoriatic arthritis (PsA) and psoriasis (Ps) is currently inconclusive, as studies reported increased, decreased or comparable to controls frequency of anti-Hp antibodies.

Objectives: To test antigen-specific Hp antibodies in a well-defined cohort of PsA patients and demographically matched Ps patients and healthy controls (HCs).

Methods: A total of 140 serum samples (48 PsA, 37 Ps and 55 HCs) were tested for anti-Hp antibodies by a western blot immunoassay using whole Hp extract as antigenic source.

Results: Overall, anti-Hp seropositivity was similar in PsA (19/48, 39.6%) and Ps (15/37, 40.5%) patients (p=0.79) but significantly lower compared to HCs (35/55, 65%, PsA vs HC, p<0.05). Overall, IgG anti-CagA and VacA, the most diagnostically relevant anti-Hp antibodies, were present in 26/48 (54.2%) and 5/48 (10.4%) PsA patients, respectively, compared to 15/37 (40.5%) (p=ns) and 1/37 (2.7%) (p=ns) Ps respectively, as well as in 39/55 (70.9%) (p=0.079) and 45/57 (25.2%) (p=ns) HCs, respectively. Compared to HCs, patients with PsA had higher reactivity to n29 (Urea) (31/48, 64.6% vs 24/55, 45.5%, p=0.033) and to p54 (24/48, 50% vs 15/55, 27.2%, p=0.017) and tended to have higher positivity against p75 antigen (9/48, 18.9% vs 3/55, 5.4%, p=0.062). Reactivity to p50 (15/48, 31.3% vs 50.9%, p=0.042) and p33 antigen (3/48, 6.3% vs 10/55, 18.2%, p=0.061) was lower in PsA than in HCs. No differences on anti-Hp antigen specific antibodies was found between PsA and Ps.

Conclusions: Although overall reactivity to Hp in PsA and Ps is lower than HCs, Hp infection cannot safely be considered a protecting microbial agent for these diseases, as reactivities to some Hp antigens are more frequently recognised to these diseases than in HCs.

AB0932

SURVIVAL AT 6 AND 12 MONTHS OF USTEKINUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS IN CONDITIONS OF CLINICAL PRACTICE

L. Pérez Albaidejo1, I. Notario Ferreira, I. Añón Oñate, M. Á. Ferrer González, M. J. Soto Pino, S. Quirosa Flores, A. García Sánchez, M.C. Ramírez Barberena, M. Ramírez de la Torre, J.M. Andreu Ubaro, R. Cáliz Cáliz. HOSPITAL UNIVERSITARIO VIRGEN DE LAS NIEVES, Granada, Spain

Introduction: Psoriatic arthritis (PsA) is a chronic inflammatory disease associated with skin psoriasis. Ustekinumab is a monoclonal antibody which inhibits IL-12/23 and has proven efficacy and safety in the treatment of patients with PsA.

Objectives: To determine the survival rate and the reasons for Ustekinumab dis-continuation in a patient cohort with PsA in conditions of clinical practice.

Methods: Descriptive, prospective, longitudinal and open study including 66 patients diagnosed with PsA and treated with Ustekinumab at dosis according to the data sheet (45 mg in the 0, 4 and every 12 weeks), except for 3 patients who were administered a 90 mg dose with the aforementioned regimen. The patients were monitored at 6 and 12 months. The following variables were collected: age, sex, years of evolution, previous treatment with Synthetic Disease Modifying Anti-Rheumatic Drugs (DMARDs) and/or biologic DMARD. All the adverse events (AE) which caused the discontinuation of the drug in patients who had received at least one dose of Ustekinumab were also collected. The Kaplan-Meier method was used to analyse the survival rate. The survival rate in naïve patients with bio-logic DMARD was compared with those who had received at least one biologic DMARD treatment before; and patients treated with Ustekinumab in monotherapy with those who were in a combined therapy with DMARDs. The Log-Rank Test was used for the comparative analysis of both subgroups.

Results: Out of the 66 patients of our cohort, 34 (51.5%) were women, whose mean age was 47.2±11.3 years. 49 presented only peripheral affection (74.2%), mainly in polyarticular form, and 10 had mixed affection. The rest presented axial affection exclusively. Our patients had been suffering from this disease for...
an average of 6.7 ± 7 years, and had received an average of 1.26 ± 1.45 previous biologic DMARD. 51.5% were receiving Ustekinumab in a combined therapy with DMARD (most of them Methotrexate) and 48.5% were in monotherapy. The survivor rates at 6 and 12 months were 85% and 74.6% respectively. Comparing the subgroups, the naïve patients with biologic DMARDs presented higher survivor rates at 6 (91.6% vs 80.7%) and at 12 months (85.1% vs 66.7%), a statistically significant difference with the group that received previous biologic DMARD (p=0.036). The patients in combined therapy with DMARDs presented higher rates of survival than the patients in monotherapy with Ustekinumab (80% vs 80%; 78% vs 71.1% at 6 and 12 months respectively), although the differences were not statistically significant. The main reason for discontinuation was the decrease of efficacy (14 patients; 21.2%), mostly in patients who had received previous treatment with biologic DMARD. 5 patients (7.6%) did not continue due to AE (2 due to relapsing herpetic zoster; 1 patient deceased, with a personal history of neoplasms and a previous treatment with anti-TNF; and 2 had reactions at the injection site).

Conclusions: Ustekinumab is a safe drug, presenting high rates of drug retention, especially in patients who have not received any previous biologic therapy.

Disclosure of Interest: None declared

AB0934

OBESITY IN PATIENTS WITH PSORIATIC ARTHRITIS IN OUR AREA

1Rheumatology, Hospital Dr Peseet, 2Rheumatology, Foundation for the Promotion of Health and Biomedical Research of Valencia (FISABIO), Valencia, Spain

Background: Obesity is a comorbid condition in patients with psoriasis which tends to be less common in patients with psoriatic arthritis (PsA). In the general population, obesity is associated with increased inflammatory load and vascular risk, and with hypovitaminosis D.

Objectives: To explore the relationship between obesity and disease activity, vascular damage, serum concentrations of vitamin D (25(OH)D) and bone mineral density (BMD) in patients with PsA.

Methods: Descriptive cross-sectional study. Patients with PsA patients and peripheral joint involvement were consecutively included. Demographic (age, sex), clinical [duration of the disease, BMI (body mass index), DAS28] and analytical [25OHD, CRP, ESR] variables were collected. Patients with a BMI > 30 kg/m²; were considered obese, and we considered vitamin D deficiency when 25OHD < 20 ng/ml. Within 25 ng/ml - 30 ng/ml range we considered vitamin D insufficiency when 25OHD 20-30 ng/ml. Withing a period of 3 months, atheroma plaque and intima media thickness (IMT) measurement was performed by ultrasonography of the carotid arterial tree using an Esaote MyLab70XVG with a 7–12 MHz linear transducer and an automated program measuring IMT through radiofrequency (Quality intima media thickness in real time, QIMT). Pulse wave velocity (PWV) was obtained by analysis of brachial pulse waves with an automated and validated system (Mobil O Graph). IMT>900 μm and PWV >10 m/s were considered pathological. Measurement of BMD was performed using a HOLOGIC densitometer. Statistical analysis was performed with the SPSS 17.0 program.

Results: We included 188 patients, 60% women, with a mean age of 55.6 (SD 12.6) years and a mean duration of PsA of 19.5 (SD 28) years. The mean BMI was 27(DE 5.4) kg/m²; 35% of the patients being obese. The mean CRP, ESR and DAS28 were 6.6 (DE 4.5) mg/l, 10.7 (DE 11) mm/h and 2.32 (DE 0.8), respectively, 28% of patients had 25OHD deficiency and 32% had 25OHD insufficiency. The mean values of the IMT and PWV were 715 (SD 149μm) and PWV 8 (SD 1.8) m/s, respectively. 12% of patients had osteoporosis, and up to 39% had osteopenia. Obesity was associated with a higher PsA activity measured by CRP (8.5 vs 5.7 mg/l, p=0.001) and ESR (38.6 vs 8.7 mm/h, p=0.04), although DAS28 was not different between groups. We also observed differences between obese and non-obese regarding the mean values of IMT (770 vs 709 μm, p=0.046) and PWV (8.9 vs 8 μm, p=0.021), the presence of atheroma plaque nearly reaching statistical significance (39% vs 30%, p=0.07). No association was observed between obesity and 25OHD levels, BMD and DAS28.

Conclusions: obesity is linked to an increased inflammatory load and more vascular damage in our PsA patients. A strategy of tight control of obesity and other vascular risk factors should be implemented when monitoring PsA patients.

CANADIAN ADALIMUMAB POST-MARKETING OBSERVATIONAL EPIDEMIOLOGICAL STUDY ASSESSING THE EFFECTIVENESS OF ADALIMUMAB VS NON-BIOLOGIC DMARDS IN PSORIATIC ARTHRITIS (COMPLETE-PSA): 12-MONTH EFFECTIVENESS DATA

M. Khrashi1, L. Bessette2, A. Chow2, B. Harauqui3, V. Pavlova2, J. Stewart2, V. Remple1.

1Memorial University of Newfoundland, St. John’s; 2Laval University, Centre Hospitalier de l’Université Laval, Quebec; 3University of Toronto, Toronto; 4Centre Hospitalier de l’Université de Montréal, Montreal; 5McMaster University, Hamilton; 6University of British Columbia, Penticton; 7AbbVie Corporation, Montreal, Canada

Background: To date, observational studies comparing the effectiveness of adalimumab (ADA) to non-biologic DMARDs (nbDMARD) in psoriatic arthropathies (PsA) are scarce. This analysis was performed on a real-world cohort of PsA patients initiating prior treatment with biologic DMARD. 51.5% were receiving Ustekinumab in a combined therapy with nbDMARD and 48.5% were in monotherapy. The survivor rates at 6 and 12 months were 85% and 74.6% respectively. Comparing the subgroups, the naïve patients with biologic DMARDs presented higher survivor rates at 6 (91.6% vs 80.7%) and at 12 months (85.1% vs 66.7%), a statistically significant difference with the group that received previous biologic DMARD (p=0.036). The patients in combined therapy with DMARDs presented higher rates of survival than the patients in monotherapy with Ustekinumab (80% vs 80%; 78% vs 71.1% at 6 and 12 months respectively), although the differences were not statistically significant. The main reason for discontinuation was the decrease of efficacy (14 patients; 21.2%), mostly in patients who had received previous treatment with biologic DMARD. 5 patients (7.6%) did not continue due to AE (2 due to relapsing herpetic zoster; 1 patient deceased, with a personal history of neoplasms and a previous treatment with anti-TNF; and 2 had reactions at the injection site).

Conclusions: Ustekinumab is a safe drug, presenting high rates of drug retention, especially in patients who have not received any previous biologic therapy.

Additionally, the percentage of patients with severe psoriatic symptoms decreased from 11.8% (BL) to 1.8% (M12) to 0.4% (M24), and the percentage of patient without any symptom increased from 8.8% (BL) to 31.8 (M12) to 36.2% (M24). An increase in any of the prospessed concomitant diseases was not observed. No new safety signals were detected.

Conclusions: GLM SC once-monthly, administered to PsA patients according to routine clinical practice in Germany, showed remarkable improvements in Physician’s Global Assessment of patient’s health status, decrease in the number of concomitant diseases and concomitant glucocorticoids use, inflammatory markers (CRP/ESR) and skin symptoms over 24 months of treatment.

EFFICACY OF NEW TREATMENTS ON DACTYLITIS OF PSORIATIC ARTHRITIS: UPDATE OF SYSTEMATIC LITERATURE REVIEW

M. Sondag, F. Verhoeven, X. Guillot, C. Prati, D. Wending, Rheumatology, Hopital Jean Minjoz, Besançon, France

Background: Dactylitis is a frequent disabling feature of psoriatic arthritis (PsA). Therapeutic strategy on dactylitis is not really codified.

Objectives: The objective of the study was to evaluate efficacy on dactylitis of different treatments actually available in PsA.

Methods: We performed a literature review from June 2014 to October 2017 based on Pubmed, using the search terms “psoriatic arthritis” and “treatment” with only clinical trials. 89 articles were identified (English-language reports only). Thus, we selected only randomised, double-blind placebo-controlled trials in which analysis of dactylitis was exposed: 11 articles were selected for full review.

Results: Significant improvement of dactylitis (p<0.05) compared to placebo was observed with the use of golimumab in GO-VIBRANT, ustekinumab in PSUMMIT-1/PSUMMIT-2 trial, with apremilast 30 mg only in PALACE 3, with ixekizumab and adalimumab in SPIRIT-P1 (post hoc analysis).

For secukinumab, results are different: McInnes et al. (FUTURE 2) found no significant efficacy with 47% of dactylitis resolution at 24 weeks for secukinumab vs 11% for placebo (p=0.9195). At the opposite, Kavanaugh et al. (FUTURE 2) demonstrated secukinumab efficacy on anti-TNF-naive (300 mg and 150 mg dosages) and anti-TNF-exposed patients (only 300 mg).

For Mc Innes et al., clazakizumab permitted great decreases in the mean number of dactylitis from baseline to weeks 16 and 24 but no statistical data are available in the report. Similarly, in a recent publication, promising results were found for tofacitinib and abatacept, but no statistical data are available.

At the opposite, no significant efficacy was demonstrated in a randomised controlled trial with brodalumab.

Calculating of effect size was possible and available only in one study: secukinumab in patients TNF exposed (figure 1). Ratio (with of residual dactylitis between treatment and placebo groups was possible on part of studies with significant results for clazakizumab (200 mg dosing) and secukinumab in patients TNF exposed (figure 1).

Conclusions: Dactylitis was always used as secondary outcome criteria with heterogeneous results. So conclusions need to be cautious. This invalidating clinical manifestation need to be evaluated as a primary outcome in the future.

TREATMENT PATTERNS IN EARLY PSORIATIC ARTHRITIS ACCORDING TO THE AGE OF ONSET

M. Cilio1,2, G. Tramontano1, U. Bottini3, A. Padula1, S. D’Angelo1,1. 1Rheumatology Institute of Lucania (ReIL), the Rheumatology Department of Lucania, San Carlo Hospital of Potenza, Potenza; 2PhD Scholarship in Life Sciences, Department of Health Sciences, University of Catanzano “Magna Graecia”; 3Department of Health Sciences, University of Catanzano “Magna Graecia”, Catanazzo, Italy

Background: The initial treatment of Psoriatic Arthritis (PsA) is largely based on the extent of musculoskeletal involvement and disease severity according to the stepwise approach of EULAR and GRAPPA recommendations for PsA management, but without regard to the age of onset.

Objectives: This prospective observational study aimed1 to describe treatment prescribing patterns in PsA over the first 2 years of follow-up and2 to determine if the treatment patterns are conditioned by the age of onset.

Methods: Patients with at least 2 years of follow-up within the PsAReT (Psoriatic arthritis Age-related Treatment patterns) study were included. Patients with a diagnosis of early (symptom duration <52 weeks) PsA, made by rheumatologists with long-standing expertise in PsA, were consecutively recruited and divided into Adult-Onset (AOPsA) (age <60 years) and Late-Onset (LOPsA) (onset age >60 years) PsA according to the age at the onset of musculoskeletal manifestations.

For the aim of this study, patient’s data were collected at the enrolment (baseline) (T0), at 12 months (T12) and at 24 months (T24). Clinical, laboratory features and treatment patterns, over 2 years were described according to the age stratification.

Results: 46 PsA patients (22 M, 24 F; age 49±16, range 16–90 years) with a disease duration of 20±15 weeks (range 1–22) were enrolled. Compared to the 31 patients with AOPsA, the 15 patients with LOPsA had a significant shorter disease duration (17±15 vs. 21±15 weeks, p<0.05) and showed more frequently increased levels of ESR (75% vs. 43%, p<0.05) and CRP (87% vs. 52%, p<0.01). In addition, patients with LOPsA developed more frequently inflammatory extremity swelling with pitting oedema (IESPE) over the dorsum of hands and/or of the feet (56% vs. 13%, p<0.01). There were no other significant differences between the 2 groups even though more males were observed in the LOPsA group (56% vs. 42%, p=0.05).

The sensitivity of the CASPAR criteria was similar in AOPsA (78%) and LOPsA (75%). Of 46 patients during the first year 80.4% received non steroidal anti-inflammatory drugs, 32.6% received oral corticosteroids, 13.0% received local corticosteroids, 19.5% received systemic disease-modifying anti-rheumatic drugs (sDMARDs) and 6.5% received biologics (bDMARDs: IFX, ADA, GOL, ETN). During the second year of follow up 73.9% received non steroidal anti-inflammatory drugs, 30.4% received oral corticosteroids, 50% received systemic disease-modifying anti-rheumatic drugs (sDMARD), 15.2% received biologics (IFX, ADA, GOL, ETN) and received 30.4% local corticosteroids. (see figure)

About the drug intake, the only statistical significant difference between the two groups was the rate of patients using NSAIDs in LOPsA group during the first year (100% vs. 70.9%, p value 0.02). There were no other significant differences in drug intake, therapy changes, discontinuation, add-on therapy according to the age of PsA onset.

Conclusions: During the two years of follow up period a high proportion of patient received NSAIDs in LOPsA group during the first year. The main limit of our study is the low number of patients, therefore a greater number could help to understand whether the age of onset may affect the use of specific type of drugs.

OFF-LABEL SECUKINUMAB DOSE ESCALATION IN THE TREATMENT OF MODERATE-TO-SEVERE PSORIASIS: A MULTICENTER, RETROSPECTIVE STUDY

M. Phung1, A. Ighani2, J.R. Georgakopoulos3, R. Vender4, L. Giroux5, P. Lansarg3, J. Yeung4.1Department of Pharmacology and Toxicology, 2Faculty of Medicine, University of Toronto, Toronto; 3Schulich School of Medicine and Dentistry, Western University, London; 4Division of Dermatology, Department of Medicine, McMaster University, Hamilton; 5Division of Dermatology, Sunnybrook Health Sciences Centre, 6Division of Dermatology, Faculty of Medicine, University of Toronto, Toronto; 7Probity Medical Inc., Waterloo, Canada

Background: There have been significant advancements in the development of biologics over the past decade that revolutionised treatment for psoriasis and psoriatic arthritis. Interleukin (IL) –17A is a pro-inflammatory cytokine that plays a pivotal role in the pathogenesis of psoriatic disease, and is therefore a target for biologic drug development. Secukinumab is an IL-17A antagonist approved in 2015 for the treatment of psoriatic arthritis and moderate-to-severe psoriasis in adults. Its current approved dosing schedule for psoriasis patients is 300 mg subcutaneous weekly for 5 weeks, followed by monthly maintenance dosing. Some psoriasis patients in clinical practice exhibit a suboptimal response to secukinumab or experience relapse with the approved dosing schedule. In these cases, clinicians may use off-label secukinumab dose escalation regimens, which involve increasing the maintenance dosing frequency to every 2 or 3 weeks, or increasing the monthly dose to 450 mg. No guidelines currently exist for high dose secukinumab regimens.

Objectives: The objective of this study was to assess the efficacy and safety of off-label high dose secukinumab regimens in adults with moderate-to-severe psoriasis.

Methods: We performed a retrospective chart review for adult patients diagnosed with moderate-to-severe psoriasis treated with an off-label secukinumab up-dose regimen. Efficacy was measured using Psoriasis Area and Severity Index (PASI) –75 or a Physician Global Assessment (PGA) score of 0 or 1 after dose escalation. To assess safety, adverse events (AEs) were recorded.

Results: Twenty-five patients were included in this study, 13 (52%) of which also had psoriatic arthritis. The mean treatment time with secukinumab prior to dose escalation was 44.5 weeks. Twelve patients had PASI recorded prior to dose escalation, with a mean score of 5.7. Of the remaining 13 patients, 1 had no documentation of disease severity and 12 had PGA scores of 0 (n=2), 1 (n=1), 2 (n=5), 3 (n=2), and 4 (n=2). These patients then increased their dose to 300 mg secukinumab every 3 weeks (n=10), 300 mg every 2 weeks (n=9), or 450 mg monthly (n=6). Mean follow-up time was 15.9 weeks after dose escalation, where 4 patients achieved PASI-75 and 10 achieved PGA 0 or 1. Therefore, 14 out of 25 (56%) patients had effective outcomes from secukinumab dose escalation based on our study endpoints. AEs included one case of the common cold and an upper respiratory tract infection after dose escalation.

Conclusions: This study provides evidence of safety and moderate efficiency for high dose secukinumab regimens in psoriasis patients who display an inadequate response to the approved regimen. Increased dosing did not result in more AEs compared to secukinumab phase 3 clinical trials that used the approved regimen. As such, there may be a role for increased dosing in psoriatic arthritis patients.

HEALTH SERVICES RESEARCH PROJECT FOR THE EARLY DIAGNOSIS OF PSORIATIC ARTHRITIS: MONOCENTRIC QUESTIONNAIRE-BASED STUDY TO IDENTIFY PATIENTS WITH ARTHRITIS AND DETECT SIGNS OF DEPRESSION IN 150 PATIENTS

N. Fredi1, F. Schauer2, C. Schemp2, S. Finzeli3, F. Räuber3, R. Vol1, J. Thiel2, N. Venhoff1.1Department of Rheumatology and Clinical Immunology, 2Department of Dermatology, Medical Center – University of Freiburg, Freiburg, Germany

Background: Psoriatic arthritis (PsA) is an inflammatory rheumatic disease affecting approximately 30% of psoriasis (PsO) patients. Despite increased awareness there is still a considerable delay in diagnosis. Untreated PsA may lead to irreversible joint destruction associated with a high rate of disability and depression. A timely diagnosis and initiation of treatment are therefore essential.
PATIENT AND PHYSICIAN GLOBAL ASSESSMENTS CONCORDANCE BETWEEN FATIGUE, PAIN AND DISEASE ACTIVITY IN INDIVIDUAL PATIENTS WITH PsORIATIC ARTHRITIS

O. Rintek Madsen. Center for Rheumatology and Spine Diseases and the DANBIO Registry, Copenhagen University Hospital Rigshospitalet/Gentofte, Hellerup, Denmark

Background: Associations between fatigue (FTG), pain and patient global assessment (PaGl) have been examined on the group level in patients with psoriatic arthritis (PsA), but studies focusing on the concordance between these patient-reported outcome measures (PROMs) in individual patients are missing. A better understanding of how tight the measures are bounded in individuals may improve our ability to deal with them in the daily clinic. To examine associations on the group level and concordance on the individual patient level between FTG, pain and PaGl as scored on 0–100 visual analogue scales (VAS) in the daily clinic by patients with PsA. The influence of other clinical disease activity measures on these measures was also examined.

Methods: Data on 132 outclinic PsA patients treated with biological agents were extracted from the Danish registry for biological treatment in rheumatology (DANBIO). Data comprised VAS FTG, pain, PaGl and physician global assessment (PhGl), and HAQ-DI, swollen and tender joint counts (66/88), CRP, DAS28-CRP and age. Simple linear regression analyses were used to assess the association between FTG, pain and PaGl. Independent predictors of FTG, pain and PaGl were identified using stepwise multiple regression analysis. Degrees of association were expressed by coefficients of correlation, beta-values and standard errors of estimation (SEE).

Results: Mean age was 54±13 years, mean DAS28 3.7±1.5 and mean PaGl 56.5±28. FTG, pain and PaGl were strongly inter-associated but errors of estimation were substantial (r-range 0.80–0.94, p<0.0001, SEE-range 11.5–16.9), FTG, pain and PaGl were only poorly correlated with objective measures of disease activity for example, r-range for swollen joint count 0.19–0.25, p<0.05). FTG was independently predicted (beta, p-value) by PaGl (0.51, <0.001) and pain (0.31, <0.05) (R²=0.66, p<0.05, SEE=16.7), pain by PaGl (0.82, <0.0001) and HAQ-DI (0.15, <0.005) (R²=0.88, p<0.005, SEE=10.5) and PaGl by pain (0.80, <0.0001) and fatigue (0.17, <0.001) (R²=0.89, p<0.001, SEE=12.4). Swollen and tender joint count, CRP and PhGl did not add to the explanation of the patient-reported VAS scores. The bias [LLoA; ULoA] for FTG versus pain was 8.5±19.1 (p<0.0001) [–29.1; 45.9], for FTG versus PaGl 4.1±19.4 (p<0.05) [–34.0; 42.2] and for PaGl versus pain 4.4±11.5 (p<0.0001) [–18.1; 26.9]. Thus biases were small but limits of agreement were pronounced.

Conclusions: In patients with PsA, VAS FTG, pain and PaGl were nearly identically scored and were strongly inter-associated on the group level with no explanatory influence of more objective measures. However, on the individual patient level substantial discrepancies between the VAS scores were observed. The findings emphasise the complexity of understanding and dealing with PROMs in the daily clinic.

PATIENT AND PHYSICIAN GLOBAL ASSESSMENTS REFLECT STRONGLY DIVERGING ATTITUDES BETWEEN PATIENTS WITH PSORIATIC ARTHRITIS AND THEIR RHEUMATOLOGISTS TO SEVERITY OF DISEASE AND TO THE RELATIVE IMPORTANCE OF DIFFERENT OUTCOME MEASURES

O. Rintek Madsen. Center for Rheumatology and Spine Diseases and the DANBIO Registry, Copenhagen University Hospital Rigshospitalet/Gentofte, Hellerup, Denmark

Background: Assessment of disease activity is important in the evaluation and monitoring of patients with psoriatic arthritis (PsA) in clinical care and research. As there is no single ‘gold standard’ variable for assessment of disease activity several markers of disease activity are used, among these ‘global assessment’ by the patient (PaGl) and by the physician (PhGl). The agreement and interplay between PaGl and PhGl are not well clarified in patients with PsA, however.

Objectives: The study aimed to examine associations on the group level and agreements on the individual patient level between PaGl and PhGl as scored on visual analogue scales (VAS) in the daily clinic by patients with active PsA and by their rheumatologists.

Methods: Traditional disease activity data on 76 PsA patients with active disease planned to initiate biological treatment were extracted from the Danish DANBIO registry for biological treatment in rheumatology. Data comprised PaGl, PhGl and pain (0–100 VAS), 28 swollen joint count (SJC), 28 tender joint count (TJC), CRP, HAQ-DI and DAS28-CRP (4); Analyses were performed using parametric statistics. The association between PaGl and PhGl was examined by simple linear regression analysis. The predictability of PaGl and PhGl, respectively, by all other disease markers mentioned and by age and sex was examined using stepwise multiple regression analysis. Agreement between the VAS scores was expressed as the bias (mean difference between intra-individual scores) and the 95% lower and upper limits of agreement (LLoA;UloA) according to the Bland-Altman method.

Results: Mean age was 52±11.1 years and mean DAS28 4.7±11.1, 59.2% of the women were women. Mean PaGl was 63.7±23.2 and mean PhGl 39.9±19.8 (p<0.0001). Thus the difference between PaGl and PhGl was substantial on the group level. Differences between PaGl and PhGl were even more pronounced on the individual level, however. The average difference was 23.8 (bias) but differences on the individual level ranged from −21.9 (LloA) to +69.5 (UloA). The corresponding of PaGl vs. PhGl was 4.9 (bias), −17.1 (LloA) and 22.0 (UloA), and for pain vs. PhGl 18.9 (bias), −23.0 (LloA) and 60.8 (UloA). PaGl was significantly but weakly correlated with PhGl (R=0.42, p<0.0001) with a high standard error of estimation (SEE)=21.2. PaGl was independently predicted by pain (beta=0.76, p<0.0001) and HAQ-DI (beta=0.19, p<0.01) and was not predicted by PhGl (p=0.61) (R=0.78, SEE=10.5, p=0.0001). PhGl was independently predicted by SJC (beta=0.43, p<0.0001) followed by pain (beta=0.41, p<0.0001) and CRP (beta=0.20, p<0.05) (R=0.70, SEE=14.4, p<0.0001) with no significantly contribution by PaGl (p=0.49).

Conclusions: In patients with active PsA initiating biological treatment, PaGl was in general scored considerably higher than PhGl. On the individual patient level, differences between PaGl and PhGl varied substantially. PaGl was best explained by pain, and PhGl by SJC. The findings reflect strongly diverging attitudes between PsA patients and their rheumatologists to severity of disease and to the relative importance of different outcome measures.

AB0942
SUSTAINED IMPROVEMENTS WITH UP TO 104 WEEKS OF APREMLAST MONOTHERAPY IN BIOLOGIC-NAÏVE SUBJECTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM A PHASE 3B, RANDOMISED, CONTROLLED TRIAL

1University of Queensland, Brisbane, Australia; 2University of Newfoundland, St. John’s, Newfoundland, Canada; 3University of Utah School of Medicine, Salt Lake City; 4Celgene Corporation, Summit, USA; 5Hospital Clinico Universitario, Santiago, Spain; 6West Tennessee Research Institute, Jackson, USA

Background: ACTIVe is the first apremilast (APR) study to demonstrate onset of response to APR starting at Week 2 in biologic-naïve subjects with psoriatic arthritis (PsA) who may have had exposure to 1 prior conventional disease-modifying anti-rheumatic drug.

Objectives: To determine the efficacy and safety of APR through Week 104 in the ACTIVE study.

Methods: Subjects were randomised (1:1) to receive APR 30 mg BID or placebo (PBO) for 24 weeks; thereafter, all subjects received active treatment with APR. The long-term durability of APR treatment on various PsA manifestations was evaluated. Along with safety data, adverse events (AEs) of diarrhea were further characterised.

Results: A total of 219 subjects were randomised (APR: n=110; PBO: n=109); 89% (142/160) of subjects entering year 2 of the study completed the Week 104 visit, and 64.8% (142/219) of randomised subjects completed the Week 104 visit, including 60.9% (67/110) of subjects randomised to APR at baseline. Early onset of response to APR was observed for ACR20 response and improvements in DAS-28 (CRP), HAQ-DI, enthesitis (in subjects with enthesitis at baseline), and morning stiffness severity. With continued APR exposure, the Week 104 ACR20 response rate was 62.9%; ACR50 and ACR70 response rates were 33.3% and 20.1%, respectively. Mean percent change in swollen joint count was –75.9%, and mean percent change in tender joint count was –68.3%. In all, 65.7% of APR subjects with baseline enthesitis reached a Gladman Enthesitis Index score of 0 (table 1). More than half of the APR subjects had improvements in morning stiffness severity. Sustained improvements in physical function were also observed, with a mean change of 5.9 in the SF-36v2 Physical Functioning score and a mean change of 0.37 at Week 104. Safety findings for the APR-exposure period were consistent with previous reports. The most commonly reported AEs (>5% of subjects) during the APR-exposure period were bronchitis (5.3%), headache (6.3%), hypertension (6.3%), nasopharyngitis (8.3%), upper respiratory tract infection (8.3%), nausea (8.7%), and diarrhoea (16.5%). New incidences of patients who experienced serious AEs (including serious infections), or discontinuations due to AEs were warranted. In SPIRIT-P2, TNFi-experienced patients with active PsA were treated with ixekizumab (IXE), a high-affinity monoclonal antibody that selectively targets IL-17A.

Objectives: We conducted post-hoc analyses of SPIRIT-P2 data to investigate the efficacy and safety of IXE relative to placebo (PBO) when used alone or in combination with background MTX or cDMARDs in patients with PsA.

Methods: SPIRIT-P2 (NCT02349295) is a phase 3, multi-centre, randomised, double-blind, placebo-controlled trial of IXE in adults with active PsA and prior TNFi-inadequate response or intolerance. Patients were randomised 1:1:1 to receive PBO, 80 mg IXE every 4 weeks (Q4W) or every 2 weeks (Q2W), after receiving a 160 mg initial IXE dose. Eligible established background cDMARD therapy was allowed in the double-blind treatment period (Week 0–24), but no changes were allowed unless for safety reasons or due to inadequate response at week 16. Efficacy and safety were assessed at week 24. Efficacy outcome measurements included ACR 20/50 responses, achievement of minimal disease activity (MDA), 28-joint disease activity score using CRP (DAS28-CRP), disease activity in psoriatic arthritis (DAPSA), and HAQ-DI. All comparisons were made relative to PBO by Fisher’s exact test for categorical end points and analysis of covariance models for continuous end points.

Results: At baseline, 185 (51%) patients received background cDMARDs. Of these patients, 149 received background MTX. ACR20, ACR50, and MDA response rates were significantly higher in patients treated with IXE versus PBO regardless of background cDMARD use (table 1). Disease activity improved significantly with IXE versus PBO in each subgroup, as measured by DAS28-CRP and DAPSA. Likewise, physical function improved with IXE versus PBO as indicated by significantly more profound decreases in HAQ-DI with IXE-Q4W with or without background cDMARDs, and with IXE-Q2W monotherapy. HAQ-DI improvements were significantly more profound versus PBO in patients treated with IXE-Q4W with or without background cDMARDs, and with IXE-Q2W monotherapy. Among IXE treated patients, higher proportions of patients achieved HAQ-DI MCID in all subgroups versus PBO, but these were only significantly higher in patients treated with IXE-Q4W or IXE-Q2W monotherapy. Regardless of background cDMARD use, efficacy outcomes were significantly improved with both IXE groups versus PBO, except for HAQ-DI for IXE-Q2W in combination with cDMARDs and HAQ-DI MCID in all background cDMARD subgroups. The proportions of patients who experienced >1 treatment emergent adverse events (AE), serious AEs (including serious infections), or discontinuations due to AEs were comparable to the overall trial population.
Abstract AB0945 – Figure 1

Conclusions: Secukinumab provided improvements in the signs and symptoms of active PsA regardless of previous anti-TNF therapy or concomitant MTX use. Higher response rates were generally observed in anti–TNF-naïve pts compared to anti–TNF-IR pts. Secukinumab 300 mg was associated with higher responses compared to 150 mg particularly in anti–TNF-IR pts and in pts with no concomitant MTX use.

SECUKINUMAB EFFICACY IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: POOLED ANALYSIS OF FOUR PHASE 3 TRIALS BY PRIOR ANTI-TNF THERAPY AND CONCOMITANT METHOTREXATE USE

B. Kirkham1, P. J. Mease2, P. Nash3, A. Balda3, B. Combe4, J. Rech5, R. Martin6, G. Ligozio7, K. Abrams7, L. Pricop7, on behalf of the FUTURE 2, 3, 4 and 5 study groups.

1Guy’s and St Thomas’ NHS Foundation Trust, London, UK; 2Swedish Medical Centre and University of Washington, Seattle, USA; 3University of Queensland, Brisbane, Australia; 4Instituto de Investigación Sanitaria del Hospital Universitario La Paz, Madrid, Spain; 5Hôpital Lapeyronie, Université Montpellier 1, Montpellier, France; 6Friedrich-Alexander-Universität Erlangen-Nürnberg (FAU), Monash University, Erlangen, Germany; 7Novartis Pharmaceuticals Corporation, East Hanover, USA

Background: Secukinumab has demonstrated rapid, significant and sustained improvement in the signs and symptoms of psoriatic arthritis (PsA) in multiple Phase 3 studies.1-3 Objectives: To report pooled efficacy results for secukinumab versus placebo at Week (Wk) 16 in PsA patients (pts) by previous anti-TNF therapy and with or without concomitant methotrexate (MTX) use from four Phase 3 studies: FUTURE 2, FUTURE 3, FUTURE 4 and FUTURE 5. Methods: Overall, 397, 414, 341, and 396 pts with active PsA were randomised in FUTURE 2, FUTURE 3, FUTURE 4 and FUTURE 5, respectively. Secukinumab doses included subcutaneous (s.c.) 300 mg and 150 mg administered at baseline (BL) with loading doses at Wks 1, 2, and 3, followed by maintenance dose every 4 wks (q4w) starting at Wk 4 and s.c. secukinumab 150 mg administered at BL without loading dose, followed by q4w starting at Wk 4. Data collected up to Wk 16 were pooled. Assessments included ACR20/50/70, DAS-28 CRP, PASI 75/90, SF-36 PCS, HAQ-DI, and resolution of dactylitis, and enthesis.

Pooled analyses examined the effect of prior anti-TNF use (naïve/inadequate response or intolerance to these agents, -IR) and with/without MTX use on clinical endpoints and are reported after application of non-responder imputation for binary variables and a mixed-effects model for repeated measures for continuous variables.

RESULTS: A total of 2049 pts were included in the analysis, of which 461, 572, 335, and 681 pts received secukinumab 300 mg, 150 mg, 150 mg without load and placebo, respectively. Improvements were observed with secukinumab vs placebo for all endpoints at Wk 16 in both anti–TNF-naïve and anti–TNF-IR pts and in pts with and without concomitant MTX use. Higher ACR and PASI responses and greater improvement of disease activity were observed in anti–TNF-naïve pts compared to anti–TNF-IR pts. Secukinumab 300 mg provided numerically higher ACR and PASI responses compared to the 150 mg dose particularly for anti–TNF-IR pts in pts with no concomitant MTX use. Earlier responses were observed with secukinumab with load compared to without load primarily across ACR, DAS28-CRP and PASI endpoints.
AB0946

IMPROVEMENTS IN WORK PRODUCTIVITY WITH UP TO 104 WEEKS OF APERIMLAST MONOTHERAPY: RESULTS FROM A PHASE 3B, RANDOMISED, CONTROLLED STUDY IN BIOLOGIC-NAIVE SUBJECTS WITH ACTIVE PSORIATIC ARTHRITIS

1Swedish Medical Center and University of Washington School of Medicine, Seattle, USA; 2Krembil Research Institute, Toronto Western Hospital, Toronto, Canada; 3RTI Health Solutions, Research Triangle Park; 4Cellgene Corporation, Summit, USA; 5University of Queensland, Brisbane, Australia

Background: Psoriatic arthritis (PsA) patients may experience disease manifestations across multiple domains and impaired functioning in daily activities at home and work. The phase 3b ACTIVE study is evaluating the efficacy of apremiast (APR) monotherapy in biologic-naive subjects with active PsA who may have had exposure to 1 prior conventional DMARD.

Objectives: To assess work productivity through Week 104.

Methods: Subjects were randomised (1:1) to receive APR 30 mg BID or placebo (PBO). Subjects who did not improve by ≥10% in swollen and tender joint counts at Week 16 were eligible for early escape. At Week 24, all remaining PBO subjects were switched to APR. Work productivity and activity impairment were assessed at baseline (BL) and Week 16 using the 6-item, self-administered Work Productivity and Activity Impairment Questionnaire: Psoriatic Arthritis (WPAI:PsA). WPAI:PsA includes 4 subscale scores (Absenteeism, Presenteeism, Work Productivity Loss, and Activity Impairment), each ranging from 0% to 100%; higher scores indicate greater impairment. Work-related subcales were evaluated only among employed subjects, while activity impairment was evaluated among all subjects, regardless of employment. Correlations were examined at Week 16 between WPAI:PsA subscale scores and the SF-36v2 domain scores for Physical Functioning (PF), Bodily Pain (Pain), and Vitality (VIT), as well as associations with ACR20 response. Improvement in work productivity was assessed through Week 104.

Results: BL characteristics were similar between APR and PBO subjects with WPAI:PsA scores included in this analysis. At Week 16, APR significantly improved work productivity and the ability to carry out daily activities vs PBO, with significantly greater mean improvements observed in the overall Work Productivity Loss (p<0.001) and Activity Impairment (p<0.001) scores (table 1). Estimated mean change in the Absenteeism score was similar with APR vs PBO (p=0.079). By contrast, the Presenteeism score showed significant improvement with APR vs worsening with PBO (–10.8% vs 4.1%; p=0.002). At Week 16, statistically significant correlations were observed between WPAI:PsA subscale scores (except Absenteeism) and the SF-36v2 domain scores for PF, Pain, and VIT, as were associations with ACR20 response. Among subjects randomised to APR at BL, improvements in Week 16 WPAI:PsA subscale score were generally maintained through Week 104 in those continuing APR.

Conclusions: In biologic-naive subjects with PsA, APR monotherapy contributed to an overall improvement in work productivity at Week 16, which correlated with SF-36v2 PF, Pain, and VIT scores and was associated with ACR20 response; improvements in WPAI:PsA subscale scores were generally maintained to Week 104.

AB0947

IMPACT OF CLINICAL SPECIALTY SETTING ON DISEASE MANAGEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM A CROSS-SECTIONAL OBSERVATIONAL STUDY IN THE UNITED STATES

Background: Early diagnosis and effective treatment has been shown to decrease functional disability and structural progression in patients (pts) with psoriatic arthritis (PsA).1 However, factors that influence treatment management decisions are poorly understood.

Objectives: To evaluate the impact of clinical specialty setting on the management of US pts with PsA.

Methods: LOOP was a multi-centre, cross-sectional observational study conducted across 44 sites in US. Adult pts with a suspected or an established diagnosis of PsA who were routinely visiting a rheumatologist (rheum) or a dermatologist (derm) were eligible to participate in this study. Each enrolled pt was assessed by both rheum and derm. The association between enrolling or diagnosing clinical specialty setting and time from symptom onset to PsA diagnosis and to different disease management steps were examined.

1598

Scientific Abstracts
RESULTS: Of 681 pts enrolled, 513 pts with a confirmed diagnosis of PsA were included in this analysis. PsA diagnosis was established prior to study entry in 404 pts (established pts), while diagnosis was confirmed during the study in 109 pts (suspected pts). In established pts, PsA was first diagnosed in 352 (87.1%) pts by a rheum and 40 (9.9%) pts by a derm. Among suspected pts, 87 (79.8%) and 15 (13.8%) pts were being managed by derm and rheum setting, respectively. Pt demographics and disease characteristics were comparable between PsA pts enrolled by rheum and derm setting. Current disease activity and disease burden were also mostly similar between rheum and derm setting (table 1); though pts enrolled by derm setting had higher scores on skin measures and enthesis. The median (95% CI) time from symptom onset to PsA diagnosis was 1.0 (0.5, 1.1) and 2.6 (1.7, 4.1) years (y) in pts enrolled in rheum and derm setting, respectively (p<0.001). However, the median time to PsA diagnosis was 0.9 (0.5, 1.0) and 1.0 (0.0, 2.0) y in pts diagnosed by rheums and derms, respectively. After PsA diagnosis, the median time to first csDMARD and to first bDMARD was 1.0 and 2.4 y, respectively. Overall, 282 (55.0%) and 354 (69.0%) pts received csDMARDs and bDMARDs, respectively. Treatment with first csDMARD occurred in 106 (20.7%) pts before PsA diagnosis and 176 (34.3%) pts after diagnosis; for first bDMARD, it was 121 (23.6%) and 233 (45.4%) pts, respectively.

CONCLUSIONS: The duration from symptom onset to PsA diagnosis was longer in pts enrolled by derms and was similar in pts diagnosed by both rheums and derms. The median time was longer for treatment with first csDMARD compared with first csDMARD. Current disease activity and disease burden highlight the delay in PsA diagnosis and the need for appropriate management of PsA pts, irrespective of clinical specialty setting.

AB0948 TUMOUR NECROSIS FACTOR INHIBITORS AND THEIR IMPACT ON DIABETES MELLITUS AMONG PATIENTS WITH PSORIASIC ARTHRITIS

S. Mantravadi1,2, M. George2, A. Ogdie2, 1Thomas Jefferson University, 2University of Pennsylvania, Philadelphia, USA

Background: Tumour necrosis factor is a key inflammatory cytokine in the pathogenesis of psoriatic arthritis (PsA) and diabetes mellitus (DM). 1,2 Tumor necrosis factor inhibitors (TNFi) have been shown to be associated with a decreased incidence of DM, but it is unknown whether treatment of PsA with TNFi has off-target therapy benefits for patients with DM. 3

Objectives: To determine whether initiation of a TNFi, compared to initiation of methotrexate (MTX) or metformin, results in a decrease in Haemoglobin A1c (HbA1c) in patients with PsA and DM, and elevated HbA1c.

Methods: A retrospective cohort study was conducted in OptumInsight, a de-identified administrative claims database that includes laboratory values for entire DM population for one year line period of 12 months prior to the index date was required to capture potential confounders. All patients were required to have one HbA1c in the six months prior to and one HbA1c in the 6 months after drug initiation. We evaluated median HbA1c change in each group and then assessed statistical differences using the Wilcoxon Rank Sum test (unadjusted). We then used linear regression models to determine the relative differences in HbA1c change using MTX as the reference and adjusted for age, sex, baseline A1c, DM medications, and comorbidities in the baseline period, with clustering to account for multiple new drug initiations per patient.

Results: Among 914 drug initiations in 756 patients with PsA and available HbA1c values, HbA1c was >7 before 125 (44%) of TNFi initiations, 90 (43%) of MTX initiations, and 233 (55%) of metformin initiations. The average time between baseline and follow-up HbA1c values was 231 days. Median HbA1c change was −0.50 (IQR −1.30, 0.30) after TNFi initiation, −0.40 (IQR −1.50, 0.10) after MTX initiation, and −0.90 (IQR −1.80, 0.00) after metformin initiation (figure 1). In adjusted analyses, TNFi initiators had a similar decrease in HbA1c compared to MTX initiators, β 0.02 (95%CI: −0.29, 0.33). Metformin initiators had a significantly greater change in HbA1c than MTX patients, β −0.43 (95%CI: −0.72, −0.13).

CONCLUSIONS: TNFi and MTX initiation lead to a decline in HbA1c by half as much as metformin. Changes in HbA1c were not different among patients initiating TNFi versus MTX.

AB0949 SERUM 25-HYDROXYVITAMIN D STATUS IN PATIENT WITH PSORIASIC ARTHRITIS

S. Tsuji1, J. Hashimoto1, T. Noguchi2, S. Aoki2, K. Yachi2, S. Ohshima3, Y. Saeki4, M. Higashiyama4, 1Department of Rheumatology and Allergology, 2Department of Orthopaedic Surgery, 3Department of Clinical Research, NATIONAL HOSPITAL ORGANIZATION, OSAKA MINAMI MEDICAL CENTER, Kawachinagano City, Osaka; 4Department of Dermatology, Nissay Hospital, Osaka city, Japan

Background: Vitamin D has been recognised not only in calcium metabolism and bone metabolism but also in the physiological activities of a wide variety of cells, and its deficiency is caused by fractures/falls, osteoporosis and other various disease risks have been reported.

Objectives: To clarify vitamin D satisfaction status of patients with PsA, which is one of spondyloarthritids, by measuring serum 25OH D concentration.

Methods: 180 patients with PsA satisfying CASPARI criteria during the visit to our hospital between August 2015 and June 2017, 125 males, averaging age 54.1 y.o., BMI average 24.2, mean disease duration of PsA and psoriasis were 8.1 years, 19.3 years, respectively. The type of psoriatic arthritis was 79 spondylitis type and 101 peripheral type. MTX was 51.7% as an agent for treating PsA, and the average dose was 3.35±1.1 mg/week. The number of biologics use was 37.2%. There were 9 cases of osteoporosis and 21 cases of osteopenia, 20 patients who were undergoing treatment for osteoporosis, and all patients were treated with activated VD3. 110 patients (61.1%) had active type VD3 paint applied to psoriasis eruption. The ACA positive rate was 7.4%, the rheumatoid factor positive was 17.7%, and

Abstract AB0949 – Figure 1

Conclusions: TNFi and MTX initiation lead to a decline in HbA1c by half as much as metformin. Changes in HbA1c were not different among patients initiating TNFi versus MTX.
average CRP was 0.25±0.36 mg/dL. The test method for the serum 25OHD concentration was measured with the CLIA antibody method (SRL, Inc.). Regarding the judgment criteria of deficiency, although various discussions are in progress, "the index of serum 25OHD deficiency less than 20 ng/ml" prepared by the institute of medicine (IOM) in 2011 was used. As a study item, firstly, the degree of satisfaction of vitamin D using serum 25OHD concentration was determined. Second, it divided into VD deficient group and non-deficient group age, sex, disease duration, psoriatic arthritis type, blood biochemical test, presence of active VD administration, presence or absence of active type VD coating for skin, presence or absence of enthesitis.

Results: Mean serum 25OHD concentration in patients with PsA was 16.4 ±6.3 ng/ml and serum 25OHD deficiency was observed in 134 cases (74.4%). Factors that showed significant differences between the two groups (VD deficient group/normal group) were age (54.4±9.9 y.o. p=0.032), gender (female rate) 35.0%(11.9%: p=0.040, ACPS negative rate 97.0%/85.2%: p=0.010, serum MMP-3 (69.0/84.6 ng/ml p=0.030), active vitamin D top coating use rate for skin 54.0%/88.9%: p=0.001, Biologics treatment rate 49.3%/11.1%: p<0.001.

Conclusions: 74.4% of patients with PsA had vitamin D deficiency. In the vitamin D-deficient group, low age, high female rate, ACPS negative, low serum MMP-3, VD coating low use rate for skin, biological product high usage rate were significant.

MINIMAL DISEASE ACTIVITY IN REAL LIFE IN PSORIATIC ARTHRITIS

S.B. Ureyen1, D. Solmaz2, N. Al Asosmi3, on behalf of PsArt-ID (Psoriatic Arthritis-International Database), E. Dalikci4, M. Can4, A. Erdener4, C. Ozisler5, M. Cinarc6, L. Kilic4, U. Kalyoncu4, S.Z. Aydin1, on behalf of PsArt-ID (Psoriatic Arthritis-International Database), 1PsArt-ID, Ottawa, Canada; 2PsArt-ID, Buru; 3PsArt-ID, Istanbul; 4PsArt-ID, Ankara, Turkey

Background: Minimal disease activity (MDA) is an important target in patients with psoriatic arthritis (PsA), however it is also criticised for having low threshold for patient reported outcomes (PRO).

Objectives: The aim of the study was to compare the prevalence of MDA components in patients with PsA and to evaluate disease characteristics and patterns in patients with or without MDA.

Methods: PsArt-ID (Psoriatic Arthritis-International Database) is a prospective, multicentre web-based registry (www.trials-network.org). PsA patients who had at least 1 year of disease duration were included for this analysis. Patients were considered in MDA when they met at least 5/7 of the MDA criteria (figure 1).

</table>

Results: In January 2018, 1283 patients from Turkey and 119 patients from Canada were recruited, 317 of whom had full data for MDA and were included in this analysis. The demographics, disease characteristics and patterns in patients with MDA achieved vs not are summarised in the table. There were no differences regarding demographics in both groups. The monoarthritis subtype (RR: 2.01, 95% CI: 1.579-2.559), the absence of enthesitis (RR: 1.570, 95% CI: 1.027–2.398) and the absence of distal interphalangeal joint disease (RR: 1.1, 95% CI: 1.001–1.25) were associated with higher probability of achieving MDA. Across different domains included in MDA, pain VAS±15 and PGA ±20 could less frequently be achieved even when MDA is fulfilled as 44.5% and 26.5% of patients respectively still did not fulfil these domains (figure 1). On the other hand, for patients that did not achieve MDA, the body surface area (51.2%) and swollen joint count (53.5%) domains could be achieved in the majority of the patients and 93.5% of them had no enthesitis using the Leeds enthesitis index. Physician global assessment (>21 vs<20) and BASDAI (>41 vs<40, only for axial disease) had only moderate agreement with MDA (achieved or not) (kappa=0.47, p=0.05 and kappa=0.469, p=0.072 respectively).

All data were given n/total n (percentage (%)) or median (first-third percentiles).

ULTRASONOGRAPHIC ASSESSMENT OF NAIL IN PSORIATIC DISEASE FOUND A LINK BETWEEN NAIL DISORDER AND SOFT TISSUE SWELLING AROUND THE NAIL

T. Okano1, K. Inui1, Y. Yamada2, K. Manda3, K. Mamoto1, Y. Sugikota2, T. Koko2,3, H. Nakamura1, 1Department of Orthopedic surgery; 2Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka; 3Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama, Japan

Background: Although skin lesion is the most typical findings in patients with psoriasis (PsO), nail psoriasis is also one of the clinical manifestation. Moreover, nail disorders in PsO are known as a risk factor for psoriatic arthritis (PsA). However, pathological feature and the relationship with inflammation of the soft tissue around the nail is unknown.

Objectives: The aim of this study was to compare the soft tissue thickness around the nail in patients with PsO, PsA and other rheumatic diseases by using ultrasonography.

Methods: Twenty-five PsO - 35 PsA - 25 rheumatoid arthritis (RA) - 28 ulcerative colitis (UC) and 13 Crohn’s disease (CD) patients performed ultrasonographic assessment in nail were included in this analysis. Ultrasonographic examination was performed by using HI VISION Ascendus (Hitachi Medical Corporation, Japan) with a multifrequency linear transducer (18–6 MHz) and the grey scale (GS) and power Doppler (PD) findings were assessed. The distance between the proximal nail fold on the dorsal side of the nail matrix and the nail bed on the volar side of the nail matrix was measured by electric calliper.

Results: The distance between the proximal nail fold and the nail bed was 2.58 ±0.56 mm in PsA and 2.55±0.58 mm in PsO patients (p=0.603). Among the 60 patients who combined PsO and PsA patients, 41 patients with nail psoriasis and 19 patients without nail psoriasis was compared. The distance was 2.68 ±0.62 mm in patients with nail psoriasis and 2.30±0.41 mm in without nail psoriasis (p=0.001), which was also swelling compared with the RA, UC and CD group.

HIGH PREVALENCE OF INFLAMMATORY AND NON-INFLAMMATORY LIVER AND GASTROINTESTINAL DISEASES IN YOUNG PATIENTS WITH PSORIATIC ARTHRITIS: A HOSPITAL-BASED STUDY

N. Batkaeva1, E. Batkaev2, T. Korotseva3. 1Dermatology, Peoples’ Friendship University of Russia (RUDN University); 2Dermatology, Peoples’ Friendship University of Russia (RUDN University); 3Research Institute of Rheumatology n. a. V. A. Nasonova, Moscow, Russian Federation

Background: Psoriatic arthritis (PsA) is associated with numerous comorbidities, including gastrointestinal (GI) and liver diseases (LD). But there is limited data about the prevalence of these disorders among patients (pts) with PsA and severe PsO. That information should be taken in account during the choice of safety therapy in this group of pts.

Objectives: To evaluate the prevalence of LD and GIT comorbidity in a hospital-based cohort of PsA pts.

Methods: 417 (304 Male (M)/113 Female (F)) PsA pts, according the CASPAR criteria, mean age 38.5±11.3/36±11.0 years (yrs) accordingly, PASI 49.4±0.56, PsA duration 6.6±7.4 years were included. PsA pts with all GIT and LD, including Diseases of esophagus, stomach and duodenum (K20–K31), Disorders of gallbladder, biliary tract and pancreas (K80–K87), Alcoholic and toxic liver disease (K87), Viral hepatitis (B15–B19) and NEC (K55-K63) were found in 75 out of 229 pts (32.75%). LD coding as K70 and GIT coding as K80–K87 were found in 31 out of 159 pts (19.4%) accordingly (p<0.05). NEC coding as K55-K63 was found in M. only 22 (159 pts) (14.6%) and in F. out of 417 pts (54.9%) had LD and GIT disorders.

Results: 229 (159 – M./70 – F.) out of 417 pts (54.9%) had LD and GIT disorders. Gallbladder, biliary tract and pancreas disease coding as K80–K87 was found in significantly more cases in F. compared to M. pts – in 26 out of 70 pts (37.4%) and in 31 out of 159 pts (19.4%) accordingly (p<0.05). NEC coding as K55-K63 was found in M. only – in 1 out of 159 (0.62%) pts. Diseases of esophagus, stomach and duodenum coding as K20–K31 were found in 96 out of 229 pts (42%). All GI of the alcoholic, toxic and viral liver disease were found in 75 out of 229 pts (32.75%), LD coding as K70–K77 were found in 33 out of 75 pts (44%).

Conclusions: Soft tissue thickness around the nail in patients with PsO and PsA was compared with other rheumatic diseases by ultrasonographic assessment. In patients with PsA and PsO with nail psoriasis, soft tissue swelling around nail was observed.

Disclosure of Interest: None declared

PSAID-12 CAN BE USED TO DETERMINE THE ANTI-TNF TREATMENT DECISION IN THE PSORIATIC ARTHRITIS REGISTRY

U. Kalaycu1, S. Kiraz2, S. Agras Bilgen3, O. Karadaag1, A. Akdogan4, L. Kılıç1, A. Erdén1, B. Armagan1, A. Sarı2, I. Ertenli3, Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

Background: Psoriatic Arthritis Impact of Disease (PsAID-12) score has 12 questions and each question has its own weight. PsAID-12 is developed to be used in daily practice. However, in the daily practice, there has been no information on the utilisation of determining the response of the biological DMARD treatment.

Objectives: The assessment of utilisation of PsAID-12 for PsA patients on determination of the efficiency and inefficiency of anti-TNF treatment in a biological registry.

Methods: In this study patients were taken from Hacettepe University biological database (HUR-BIO). Since January 2013 PsAID-12 score was built in HUR-BIO database. PsAID-12 score was known for 116 patients before starting off the first anti-TNF treatment and 88 patients whose PsAID-12 score was 4 and above were included in the enquiry. Overall, 70 PsA patients included to analysis. Demographic data before anti-TNF treatment of PsA patients were noted. The decision of continuation, stopping or switching to another anti-TNF drugs were performed by both clinicians and the patients agreement. According to baseline evaluation, decrease of 20 mm and above on pain-VAS score and PGA, improvement of 0.22 unit and above on HAQ-DI score, or decrease of 1.2 unit and above on DAS-28 score were considered favourable to the anti-TNF treatment. Stopping or switching the anti-TNF treatments due to inefficacy was definitely a negative response.

Results: Seventy (70) pts were analysed, mean age was 45.5 (12.0). Mean follow-up duration was 18.3 (12.6) months, and total of 213 clinical visits were performed, median 3 (4) control visits were done. At baseline, the mean (SD) DAS-28 4.07 (1.22), HAQ-DI 0.86 (0.53), pain-VAS 6.9 (2.1), PGA-VAS 6.4 (1.7), and PsAID-12 6.6 (1.5) was as follows. Anti-TNF treatments were stopped due to inefficacy in 43/210 (20.5%) outpatient visit during the follow-up period. The results of anti-TNF stopped and continuing patients; ΔPsAID-12 were 0.38 (1.71), and 3.12 (2.14), respectively and PsAID-12 baseline/control visits were 0.96 (0.29) vs 0.50 (0.33), respectively. Level of favourable response and achieving to goal according to ΔPsAID-12 and PsAID-12 Baseline/control visit were shown table 1. On the follow up visits, among measured parameters one of the highest SRM was detected in PsAID-12; PsAID-12 (1.10), DAS-28 (1.14), PGA (0.88), Pain (0.85), and HAQ-DI (0.51), respectively.

Conclusions: Having 3.5 unit or 50% decrease in the PsAID-12 score indicates a favourable response to anti-TNF treatment, 4 unit or 70% decrease indicates level as B15–B19 were found in 42 out of 75 pts (56%). No significantly gender differences were found in those group of pts.

A RANDOMISED, DOUBLE-BLIND TRIAL COMPARING THE EFFICACY, SAFETY AND IMMUNOGENICITY OF MSB11022, A PROPOSED BIOSIMILAR OF ADALIMUMAB, VersUS ADALIMUMAB ORIGINATOR IN PATIENTS WITH moderate-TO-SEVERE PLAQUE PSORIASIS

J. Hercogová1, K.A. Papp2, C.J. Edwards3, V. Chyrok4, T. Halady4, M. Ullmann5, P. Vlachos5, C. Charles University, Prague, Czech Republic; 2Probity Medical Research Inc, Waterloo, ON, Canada; 3University of Southampton, Southampton, UK; 4Fresenius Kabi, Aubonne, 5Cytel, Geneva, Switzerland

Background: Adalimumab is a fully human anti-TNF mAb, indicated for the treatment of multiple inflammatory disorders. MSB11022 is a proposed adalimumab biosimilar that has shown analytical similarity [1] and bioequivalence to US-licensed and EU-approved adalimumab originator, as well as comparable safety, tolerability and immunogenicity in a phase I trial [2].

Objectives: The aims of this multicentre, double-blind, parallel-group, 52-week phase III study (AURIEL-Pso, NCT02660580) were to demonstrate equivalence in efficacy (Psoriasis Area and Severity Index [PASI] 75) and to compare the safety and immunogenicity of MSB11022 vs. adalimumab originator in patients with moderate-to-severe chronic plaque psoriasis. This study was designed in line with the biosimilar regulatory framework as part of the totality of evidence to confirm similarity and rationale for extrapolation.

Methods: A total of 443 eligible patients (391 evaluable, including 43 with psoriatic arthritis) from 69 sites in 12 countries were randomised 1:1 and treated with MSB11022 (n=220) or adalimumab originator (n=189) (80 mg subcutaneously [SC] on day 1; 40 mg SC every other week from weeks 2–14). The primary endpoint was PASI 75 at week 16; equivalence was established if the 95% confidence interval (CI) for the treatment difference was within ±18%. Secondary endpoints included % change from baseline in PASI (equivalence confirmed if 95% CI within ±15%), Physician Global Assessment (PGA), quality of life (QoL), immunogenicity and safety. Interim results at week 16 are presented.

Results: Patient baseline characteristics were comparable between MSB11022 and adalimumab originator groups: mean age 44.8 vs. 42.4 years, male 66.8% vs. 68.3%, mean PASI score 20.7 vs. 21.2, respectively. PASI 75 scores were 89.6% for MSB11022 and 91.5% for adalimumab originator (difference –1.9% [95% CI –7.82–4.16]). Mean % change from baseline in PASI was –90.6% for MSB11022 and –91.7% for adalimumab originator (difference –0.1% [95% CI –1.23–2.98]). PGA and QoL scores were comparable between treatment groups. The incidence of treatment-emergent adverse events (TEAEs)/serious TEAEs was 51.3/6% for MSB11022 and 53.2/2.7% for adalimumab originator. Immunogenicity profiles of MSB11022 and adalimumab originator were also similar and consistent.

Conclusions: Week 16 results of this phase III confirmatory study demonstrated equivalent efficacy and similar safety and immunogenicity profiles for MSB11022 vs. adalimumab originator at 16 weeks in patients with moderate-to-severe chronic psoriasis.

LEUCINE-RICH ALPHA-2 GLYCOPROTEIN IS A PREDICTABLE BIOMARKER FOR THERAPEUTIC RESPONSE AND CLINICAL RELAPSE TO BIOLOGICS, BUT NOT TO APREMILAST IN PATIENTS WITH PSORIASIS

1Dermatology; 2Center for Intractable Immune Disease, Kochi Medical School, Kochi; 3Laboratory of Immune Signal, National Institutes of Biomedical Innovation, Health and Nutrition, Osaka, Japan

Background: Leucine-rich alpha-2 glycoprotein (LRG) is a 50 kDa protein produced by hepatocytes, endothelial cells, neutrophils and macrophages, and it was identified as an inflammatory biomarker that correlates with the disease activity of autoimmune diseases such as inflammatory bowel disease and rheumatoid arthritis.

Methods: Antibodies to TNF-alpha, IL-12/IL-23p40, IL-17A and IL-17 receptor A and apremilast were administered in patients with psoriasis vulgaris and psoriatic arthritis (n=15, 6, 14, 4 and 8 respectively). Serum LRG levels were measured by enzyme-linked immunosorbent assay. Serum CRP and ESR, and PASI, DAS-28 and BASDAI were also recorded.

Results: Serum LRG decreased along with the improvement of clinical scores after the administration of biologics, and reflected the change of scores more accurately than CRP and ESR. Furthermore, the LRG levels predicted the changes of clinical symptoms and predicted both primary and secondary treatment failure at the early time point, allowing us to determine if we should increase the doses, discontinue or switch to another drug. In some patients with PASI clear, complete regression of eruption, after biologics, serum LRG rose from the baseline while their PASI scores remained stable; however, they later relapsed. On the other hand, LRG did not reflect the therapeutic effectiveness of apremilast.

Conclusions: Serum LRG in psoriasis patients would be a sensitive biomarker for predicting the effectiveness and treatment failure of biologics, but not of apremilast. Monitoring LRG levels may enable us to decide the timing of bio-attenuation and to detect the relapse after discontinuation of biologics.

AB0957 SEVERITY OF SKIN SYMPTOMS IS NOT ASSOCIATED WITH MUSCULOSKELETAL MANIFESTATIONS IN PATIENTS WITH PSORIASIS

1Department of orthopedics surgery, Yokogawa Christian Hospital; 2Center for Senile Degenerative Disorders (CSDD), OKA CITY UNIVERSITY, Osaka City; 3Shirahama Foundation for Health and Welfare; 4Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama; 5Department of orthopedics surgery, Osaka City General Hospital; 6Department of Dermatology, OKA CITY UNIVERSITY, Osaka City, Japan

Background: Among patients with psoriasis, risk factors for developing musculoskeletal manifestations, known as psoriatic arthritis (PsA), are not recognised well.

Objectives: The aim of this study is to clarify the relationship between severity of skin disease and arthritis.

Methods: Psoriasis patients referred from dermatologists for assessment of musculoskeletal manifestations between June 2013 and July 2017 were enrolled. Their age, comorbidity, disease duration and treatment were collected. Presence of inflammatory back pain, sacroiliac joint tenderness or enthesitis were examined.

Severity of skin symptoms were evaluated by dermatologists in Psoriasis area and severity index (PASI), Psoriatic arthritis screening and evaluation (PASE) and disease activity score (DAS28 ESR) were also evaluated. PsA was diagnosed by The Classification for Psoriatic Arthritis (CASPAR) criteria assisted with musculoskeletal ultrasound examination.

Results: Among 107 patients with psoriasis referred from dermatologists during designated period, 63 patients were diagnosed as PsA. These PsA patients were compared with 44 patients who had no arthritis (PsO). Multiple logistic regression analysis showed neither of age, sex, PASI, disease duration, rheumatoid factor (RF), CRP or Matrix Metalloproteinase-3 (MMP3) had no association with presence of PsA (table 1). Among 63 patients with PsA, those using NSAIDs (p=0.028), those with inflammatory back pain (p=0.002) and male patients (p=0.017) had significantly high PASI. PASI significantly correlated with age (Spearman’s correlation coefficient R= 0.303: p=0.016), body height (R= 0.301: p=0.019) and weight (R= 0.383: p=0.002), but not with DAS28 ESR, MMP3 or disease duration (table 2).

Conclusions: PASI did not associate with presence of arthritis. Furthermore, even DAS28 ESR, reflecting musculoskeletal manifestations, or disease duration did not correlated with PASI among patients with PsA. These indicates severity of skin symptoms is not associated with musculoskeletal manifestations in patients with psoriasis.

KNEE PAIN IN OSTEOARTHRITIS: CORRELATION WITH SONOGRAPHIC FINDINGS

A. Radwan, A. Radwan, M. Khalifa, A.M. Elsaman, Rheumatology and Rehabilitation, Sohag University, Sohag, Egypt

Background: Osteoarthritis (OA) is a common joint disorder, with the knee being one of the most frequently involved sites. Knee OA causes pain and stiffness and can lead to considerable disability and consequently to a reduced quality of life (Wideman et al. 2014). The level of radiographic knee OA is, at most, moderately associated with the level of pain. Therefore, it is unlikely that pain is predominantly caused by only bone and cartilage pathology. Mechanical, structural, inflammatory, bone-related, neurological and psychological factors play a role in the process that results in painful knee OA (Wenger et al. 2013). As OA is a disease of the entire joint that is characterised by cartilage breakdown, subchondral bone alterations and formation of osteophytes, as well as soft tissue abnormalities including meniscal degeneration, bursitis, tendinosis, Baker's cyst and synovial inflammation; information about these soft tissue structures might provide more insight into their potential role in the complex process of pain in knee OA (Cook 2016).

Musculoskeletal ultrasonography (US) is a relatively new imaging tool that is non-invasive, safe and relatively inexpensive and is able to create static as well as dynamic images. In addition, it has been shown to be more sensitive than clinical examination in picking up peri- and intra-articular soft tissue lesions (Bevers et al. 2014).

Objectives: To investigate the cause of pain in Knee OA by comparing sonographic and clinical findings in painful and non-painful osteoarthritic knee.

Methods: A cross-sectional case-control study carried out on fifty patients attending to Sohag University Hospitals rheumatology and rehabilitation outpatient clinic with Knee OA fulfilling ACR clinical criteria. They were divided into two groups. Group A (53) patients with knee pain (VAS 33 mm) during physical activity once at least in the previous 3 days prior to inclusion. Another (42) patients without signs of Gout or CPPD and scoring of the osteophytes and cartilage degeneration, osteophytes, effusion, synovial hypertrophy, bursitis, and overweight respectively, are the leading causes of pain in knee OA. Disclosures: None declared DOI: 10.1136/annrheumdis-2018-eular.3971

CONSUMPTION OF DAIRY PRODUCTS IN RELATION TO PRESENCE OF CLINICAL KNEE OSTEOARTHRITIS: THE MAASTRICHT STUDY

K. Denissen1,2, A. Boonen3,2, J. Nielen1,3,4, A. Feitsma5, E. van den Heuvel6, P. Emans3, S. Sep7,8,9, C. Stehouwer7,10, M. van Dongen1,2, P. Dagnelie1,2,10, S. Eussen7,10, D. Grobbee9, J. Background: Observational studies showed inverse associations between milk consumption and knee osteoarthritis (knee OA). There is lack of information on the role of specific other dairy product categories.

Objectives: To explore the association between dairy consumption and presence of clinical knee OA in individuals aged 40–75 year participating in the Maastricht Study.

Methods: Presence of clinical knee OA was defined according to a slightly modified version of the American College of Rheumatology (ACR) clinical classification criteria. Data on dairy consumption was appraised by a 253-item Food Frequency Questionnaire covering 47 dairy products with categorization on fat content, fermentation or dairy type. Multivariable logistic regression analyses were performed to estimate odds ratios (ORs) and 95% confidence intervals (95% CI), while correcting for relevant factors.

Results: Of the 9010 participants included in this study, 427 individuals (14%) were classified as having clinical knee OA. Significant inverse associations were observed between presence of clinical knee OA and intake of full-fat dairy and Dutch, primarily semi-hard, cheese, with OR for the highest compared to the lowest tertile of intake of 0.85 (95%CI 0.78–0.93) for full-fat dairy, and 0.75 (95%CI 0.66–0.89) for Dutch cheese. No significant associations were found for other dairy product categories.

Conclusions: In this Dutch population, higher intake of full-fat dairy and Dutch cheese, but not milk, was cross-sectionally associated with lower presence of clinical knee OA. Prospective studies need to assess the relationship between dairy consumption, and in particular semi-hard cheeses, with incident knee OA.

POLYMORBIDITY AND COGNITION IN AMBULATORY POSTMENOPAUSAL HIP AND KNEE OSTEOARTHRITIS PATIENTS

A.A. Popov1, N.V. Izmostrova2, N.A. Getmanova2, 1Hospital Therapy Dept, 2Pharmacology and Clinical Pharmacology Dept., Ural State Medical University, Ekaterinburg, Russian Federation

Background: Osteoarthritis (OA) has been reported to be a risk factor of morbidity, disability and premature cardiovascular mortality.

Objectives: to assess the impact of polymorbidity on cognitive function in postmenopausal women with primary OA.
Methods: cross-sectional study included ambulatory 682 postmenopausal women aged 48 to 62 (median 56; 25%–75%: 52.0 – 60.0). Inclusion criteria were: confirmed positive menopausal status and Kellgren stage 2 or 3 OA of the knee and/or hip joints fulfilling ARA criteria. Cognitive impairment (CI) was verified by MMSE scale (Mini Mental State Examination). For all patients expected individual risk of premature death and Charlon index were calculated.

Results: Median Charlon comorbidity index in women with OA was 4 (3 / 4). None of the patient had a comorbidity index of 0. The most frequent comorbidities were chronic heart failure (364 women (53.4%) and type 2 diabetes mellitus (180 women, 26.4%).

Charlon index increase was associated with decline of cognitive function (see table 1) with incline of quantity and severity of CI cases.

IRISIN LEVELS ARE ASSOCIATED WITH EXERCISE, PAIN AND FUNCTION IN PATIENTS WITH KNEE OSTEOARTHRITIS

Rheumatology, Parc Taulí Sabadell Hospital Universitari, Sabadell, Spain

Background: Muscle strengthening and aerobic exercise have been shown to improve joint pain and function in patients with knee osteoarthritis (OA). Irisin is a hormone-like myokine synthesized by skeletal muscle and its secretion appears to be related to physical activity in healthy people.

Objectives: To determine the levels of irisin synovial fluid and plasma and evaluate their association with exercise level and pain and function in patients with symptomatic knee OA.

Methods: Cross-sectional study with systematic inclusion of 108 symptomatic primary knee osteoarthritis patients (VAS>4) with ultrasound-confirmed joint effusion. Age, physical exercise, knee osteoarthritis symptoms duration and different anthropometric measurements were collected. Radiographic severity was evaluated according to Kellgren-Lawrence scale. Physical exercise was categorised as never, occasional (less than 150 min per week) or regular (more than 150 min per week). Pain and disability were assessed by the Lequesne algofunctional questionnaire. Irisin was measured by ELISA in synovial fluid and plasma. Summary of clinical data and laboratory parameters and their association with Lequesne scale were performed using non-parametric methods. Medians and Spearman correlation (r) were used for continuous measures, and Mann-Whitney test was applied to categorical variables. This study was approved by the local ethics committee.

Results: Plasma and synovial irisin levels were strongly related (r=0.7). Plasma and joint irisin levels showed an inversely significant association with the level of exercise in patients with symptomatic knee OA: no exercise 763.3 ng/mL, occasional exercise 631.8 ng/mL and regular exercise 523 ng/mL (p<0.01). Patients with severe pain and disability (Lequesne algofunctional score >11) had higher plasma (791.5 vs 680.4 ng/mL, p<0.05) and synovial (711.4 vs 468.7 ng/mL, p<0.05) irisin levels compared to patients with less disability and pain. No relationship was found between irisin concentration in plasma or synovial fluid and radiographic severity.

Conclusions: Irisin levels were associated with pain and function in patients with knee osteoarthritis. Irisin levels were negatively associated with exercise level in this population.

AB0963

CALPROTECTIN AS A USEFUL MARKER OF INFLAMMATION IN KNEE OSTEOARTHRITIS

Rheumatology, Parc Taulí Sabadell Hospital Universitari, Sabadell, Spain

Background: Low-grade synovial inflammation is known to be present in many patients with knee osteoarthritis and appears to have clinical and prognostic implications. Calprotectin seems to be more sensitive than CRP to detect minimal inflammatory activity in many inflammatory rheumatic diseases and could be a biomarker in osteoarthritis with inflammatory features.

Objectives: To determine the levels of synovial calprotectin in patients with knee osteoarthritis showing inflammatory traits and their relationship with clinical and ultrasonographic features and other proinflammatory markers.

Methods: Cross-sectional study with systematic inclusion of 108 symptomatic primary knee osteoarthritis patients (VAS>4) with ultrasound-confirmed joint

While walking with a speed of 3.5 km/h at a random level of BW, VO2 (p=0.03), RPE (p<0.01) and RER (p<0.01) values were statistically greater than 2.5 km/h. In the post-hoc analysis, all other conditions except comparison of RER values between a speed of 2.5 km/h and a speed of 3.5 km/h under 100% level of BW was statistically significant.

In addition, multiple linear regression analysis was performed to define VO2 as functions of gait speed and fraction of BW under each condition. Based on BW and gait velocity settings of the LBPP treadmill, the equations were VO2=1.46 v +0.008 BW–3.13 (adjusted R2=0.54)
THE ROLE OF MTOR GENE EXPRESSION, APOPTOSIS AND INFLAMMATION IN OBSE Patients with KNEE OSTEOARTHRITIS

E. Strebkova, E. Chetina, L. Alekseeva. NASONOVA RESEARCH INSTITUTE OF RHEUMATOLOGY, Moscow, Russian Federation

Background: Metabolic osteoarthritis (OA) has been identified in rheumatology as a specific phenotype due to the growing rates of obesity and other comorbidities, with meta-inflammation as the key factor in its pathogenesis. On the other hand, OA progression is associated with altered regulation of chondrocytes' metabolism, namely, with up-regulated expression of genes encoding m-TOR, apoptosis, cartilage degeneration and inflammation.

Objectives: To measure the expression levels of genes encoding mTOR, apoptosis (caspase-3), cartilage destruction (cathepsin K), and inflammation (TNF-a) in patients with knee OA (KOA) and obesity.

Methods: 50 female patients (45–65 y.o.) with Kellgren-Lawrence stage II-III KOA and obesity (BMI >30 kg/m²) were randomised into 2 groups. Pts in Group 1 (n=25) were administered orlistat as a specific therapy for obesity for the period of 6 months, and life-style modifications including low caloric diet and physical exercise (n=27) or non-pharmacological methods (n=21). The efficacy of the treatment was assessed according to Kellgren-Lawrence scale. Pain and disability were assessed by WOMAC-pain and WOMAC-function. Calprotectin, TNF-alfa and cell proliferation (m-TOR) was documented in KOA obese pts from Group 1, gaining body weight during the second stage of the study, as compared to the expression values in pts from Group 2 (figure 1). The analysis demonstrated direct positive correlation (p<0.05) between expression of genes encoding inflammation, cartilage destruction and apoptosis and pain intensity in knee joints assessed by VAS and WOMAC scales.

Conclusions: Therefore up-regulation of m-TOR, caspase-3, TNF-a and cathepsin K gene expression is observed in obese pts with KOA following weight gain and worsening of clinical parameters, which is suggestive of aggravated apoptotic, inflammation and cartilage destruction, providing further KOA progression.

Disclosure of Interest: None declared

AB0965 MEDICAMENTAL AND NON-MEDICAMENTAL THERAPY PREGNANT WOMEN WITH HIP OSTEOARTHRITIS

E. Trofimov, V. Mazurov, A. Trofimova, E. Melnikov, I. Gaydukova. North-West II Mechnnikov State Medical University, Saint-Petersburg, Russian Federation

Objectives: The management of patients with severe pain caused by primary or secondary osteoarthritis (OA) of the hip joint (TBS) has not been developed. The aim of the present work was to evaluate the impact of NSAIDs, glucocorticoids (GCS), analgesics and non-drug treatment methods on pregnancy outcomes in patients with primary and secondary OA TBS.

Methods: The study included 99 pregnant women aged 35–49 with an intensive pain (> 4.0 points for VAS) due to primary or secondary OA TBS. Depending on the form of OA, the severity of the pain and the patient’s opinion, the therapy was prescribed – ibuprofen up to 800 mg per day orally (n=31) or paracetamol up to 1000 mg per day orally (n=20) or methylprednisolone up to 12 mg per day orally (n=27) or non-pharmacological methods (n=21). The efficacy of the treatment was evaluated within a month from the start of the therapy, pregnancy outcomes for the mother and fetus and pathology of the child after 12 months after the birth. The factors, associated with low efficacy of treatment, were evaluated.

Results: In 50 (51%) women was established primary OA TBS, in 49 (49%) secondary OA TBS. A decrease of pain in TBS in patients of all treatment groups (p>0.05 for comparison with baseline) was registered. Patients with secondary OA, who received Methylprednisolone, showed a statistically significant (p<0.05) improvement in pain compared to patients in other clinical groups. A correlation was found between the intensity of pain syndrome (VAS) and BMI. 85 (85%) patients had urgent deliveries, 14 (14%) had premature, natural delivery in 82 (82%) women, and a caesarean section was performed in 29 (29%) cases. The cases of ante- and perinatal fetal death were not recorded.

Pathological conditions were absent in 28 (84.85%) of newborns, whose mothers refused medical treatment, in 28 (90.32%) newborns, who received ibuprofen, in 15 (75%) – paracetamol, and in 23 (85.19%), who were on methylprednisolone therapy – differences between groups are unreliable, p>0.05. In 12 months after birth in the group of newborns receiving antenatal ibuprofen, pathological conditions were observed in 3 children, paracetamol – in 5, methylprednisolone – in 4 children who were “without therapy” – in 5 children.

Conclusions:

- The use of non-medicamental and medicamental (non-selective NSAIDs or GCS in small doses or analgesics) treatment in pregnant woman with hip osteoarthritis has equal efficiency and safety for the health of the mother and fetus.
- Children, born to mothers with primary or secondary hip osteoarthritis, treated with NSAIDs or analgesics or GCS by medical treatment in age of 12th month do not differ from children, born to mothers with osteoarthritis of hip joints, receiving non-medicamental therapy.
- An increase of the body mass index of a pregnant woman with osteoarthritis of the hip joints is a predictor of refractoriness to any form of drug and non-drug therapy.

Disclosure of Interest: None declared

Background: Osteoarthritis (OA) is one of the most common type of arthritis and it most frequently involves joints of the hands. Measuring functional ability of hand OA patients is important in terms of assessment of treatment response, patient management and improvement of quality of life. The functional index for hand osteoarthritis (FIHOA) is one of the most frequently utilised questionnaire to assess the physical function of hand OA patients. The FIHOA has been translated into 17 languages, however, no Korean version of FIHOA is yet available.

Methods: The FIHOA was translated into Korean following cross-cultural adaptation guidelines. The K-FIHOA was pretested in 40 hand OA patients (defined by the modified Health Assessment Questionnaire (mHAQ), and visual analogue scale (VAS) for hand pain. The test-retest reliability of each item and total scores were assessed using Spearman’s correlation coefficient and intraclass correlation coefficient (ICC). The internal consistency reliability was evaluated as the Cronbach’s alpha. The external construct validity was assessed using correlation between K-FIHOA and mHAQ and hand pain VAS.

Results:

Values are given as mean ±standard deviation. Abbreviations: K-FIHOA, the Korean version of functional index of hand osteoarthritis; ICC, intraclass-correlation coefficient.

The mean total score of the K-FIHOA was 4.39 [standard deviation (SD)=5.56] in the first assessment and 4.04 (SD=5.22) in the second assessment. The test-retest reliability for the total score was strong (r=0.87 and ICC=0.75). Spearman’s rho for single item correlation ranged from 0.58 to 0.85 and ICC between single items were good or excellent (0.54–0.80). Cronbach’s alpha was high (0.88) suggesting a strong internal coherence in the items of the questionnaire. We identified significant correlations between K-FIHOA and hand pain VAS (r=0.53, p<0.01), mHAQ (r=0.52, p<0.01), and mHAQ hand function score (r=0.57, p<0.01).

Conclusions: The K-FIHOA is a reliable and valid instrument for evaluating functional disability in Korean hand OA patients.

Disclosure of Interest: None declared

EVALUATION OF OSTEOARTHRITIS OF TEMPOROMANDIBULAR JOINT BY COMPUTED TOMOGRAPHY, CLINICAL FEATURES AND CORRELATIONS

M. Salokhiddinov, G. Haydarova. TASHKENT MEDICA ACADEMY, Tashkent, Uzbekistan

Background: Osteoarthritis (OA) of the temporomandibular joint is a unilateral, degenerative disease of the jaw joint. It is characterised by breakdown of the articular cartilage, architectural changes in bone, and degeneration of the synovial tissues causing pain and/or dysfunction in functional movements of the jaw

Objectives: To determine the prevalence and relationship between clinical signs, symptoms and computed tomography (CT) manifestations of temporomandibular joint (TMJ) osteoarthritis

Methods: The study included 56 patients with osteoarthritis of the TMJ, including 25 unilateral and 31 bilateral lesions, a total of 87 joints with degenerative changes. Clinically, there was a significant restriction of the movement of the lower jaw and chewing efficiency and a significant increase in articular sounds and general complaints of pain

Results: CT data of the most frequent bone changes were erosions of the joint surfaces of the condyles (70 joints, 81%), osteophytes (73 joints, 87%), then their smoothing (67 joints, 77%), hypoplasia (24 joints, 27.6%), sclerosis (6 joints, 6.8%) and subchondral cysts (4 joints, 4.6%). Smoothing of the joint elevation and pneumatisation were observed in five joints. Thirty-one patients had bilateral degeneration. In 25-one-sided degeneration. Hypermobility is found in 37 degenerative joints. Chewing efficiency was negatively correlated both with the degree of smoothing of condyles. Sclerosis and the general complaints of pain positively correlated with the smoothing of condyles

Conclusions: Conjunctural erosion, flattening, osteophytes, revealed with CT, along with pain, noise in the joint, restriction of the jaw movement and deterioration of the chewing movement were characteristic signs of the TMJ. A correlation was found between bone changes and the severity of the clinical signs and symptoms of the TMJ. CT is a powerful diagnostic tool for the diagnosis of TMJ osteoarthritis

CONVENTIONAL AND BIOLOGIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS FOR OSTEOARTHRITIS: A META-ANALYSIS OF RANDOMISED CONTROLLED TRIALS

M.S.M. Ponsseur1,2, A. Sarmanova1,2, M. Doherty1,2, W. Zhang1,2, 1Academic Rheumatology, Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, UK

Background: The role of inflammation in osteoarthritis (OA) is controversial. Some perceive OA as a reparative process where modest inflammation is secondary to largely biomechanical insult.1 In contrast, others believe synovial inflammation to be a central driver of OA pain and progression.2 This has encouraged randomised controlled trials (RCTs) of conventional and biologic disease modifying anti-rheumatic drugs (DMARDs) in OA. However, it is unknown whether these treatments that are primarily used for rheumatoid arthritis are effective for OA

Objectives: To examine the efficacy of DMARDs, including biologics, in people with symptomatic OA

Methods: A systematic literature search was conducted (to November 2017) for placebo-controlled RCTs of DMARDs in OA. Data extraction and Cochrane’s risk of bias assessments were conducted independently by two reviewers (MP, AS). Pain relief at treatment peak time-point was combined using a random-effects meta-analysis. All DMARDs were pooled and sensitivity analysis was undertaken for high-quality trials and subgroup analyses for DMARD type, biologic target, joint site, OA subtype, and publication type

Abstract AB0969 – Table 1. Subgroup analysis

<td></td>
</tr>
</tbody>
</table>

Results: Eleven RCTs (n=1205), including six (n=757) for conventional and five (n=448) for biologic DMARDs, were included in the meta-analysis (7 full texts, 4 abstracts). Overall, conventional and biologic DMARDs were marginally superior to placebo. However, statistical superiority was not observed in high-quality studies (table 1) or subgroup analysis for conventional or biologic DMARDs separately (figure 1). Furthermore, no differences were observed between erosive versus non-erosive hand OA, hand versus knee OA, anti-IL1 versus anti-TNF biologics, or full text versus abstract-only publications (table 1).

Conclusions: No significant pain relief was observed from either conventional or biologic DMARDs compared to placebo. Combining all DMARDs gave statistical separation from placebo, but this was below the minimal clinically important difference threshold (0.5 SD) used in the UK.2 Furthermore, the analysis is based on peak point time for the intervention, so even at their most effective timepoints these treatments do very little over placebo. Lack of efficacy of DMARDs supports the perspective that inflammation is not an important driver for OA pain and differs fundamentally from that in rheumatoid arthritis

INVESTIGATION OF THE EFFECTS OF BALANCE TRAINING ON BALANCE AND FUNCTIONAL STATUS IN PATIENTS WITH TOTAL HIP ARTHROPLASTY DUE TO OSTEARTHROSIHIS: A RANDOMISED CONTROLLED PILOT STUDY

N. Elibol1, B. Unver2, V. Karatosun1, 1Physiotherapy and rehabilitation, European of Lefkde University, 2Physiotherapy and rehabilitation, 2Orthopaedics, Dokuz Eylul University, Izmir, Turkey

Background: Osteoarthritis (OA) of the hip is one of the most common disorders in musculoskeletal system. The hip osteoarthritis is painful and this causes disability of various degrees, postural and gait disorders. Total hip arthroplasty (THA) has been to one of the most frequent elective surgical procedures that can effectively reduce pain and improve the function in patient with hip OA.2 It was reported that patients with coxarthrosis and THA have decreased proprioception with motor control and balance disorders, compared to healthy subjects.3 The purpose of current study was to investigate the effects of balance exercises on balance and functional level with objective assessment methods until the 26th week of surgery in patients with THA.

Objectives: The purpose of our study is investigating of the effects of balance training on balance and functional status in patients with THA.

Methods: Sixteen patients with unilateral elective THA were randomised to 2 groups: conventional rehabilitation (CR, n=8) or conventional rehabilitation plus balance training (CR + BT, n=8) groups. The CR group completed typical surgery-specific joint range-of-motion and muscle strengthening exercises, while the CR + BT group completed the CR plus balance exercises during 6 weeks. The patients were evaluated by single leg stance test, Tetrax balance system, Harris hip scoring, lower extremity function scale, 5 times sit to stand test and 50-foot timed walk test preoperatively and 8, 14, and 26 weeks after THA.

Results: While there was significant improvement, in terms of on the right extremity eyes closed single leg stance test in the CR group (p<0,05), there was no significant difference in terms of other assessment parameters between CR and CR + BT groups (p>0,05). There were significant improvement after THA surgery in both groups (p<0,05).

Conclusions: The results of our study indicate that there were similar improvements in the balance and functional parameters in the CR and CR + BT groups. There was no additional benefit of the balance exercises in balance in the 14 and 26 weeks after THP. Significant differences could be found between groups by continuing balance training with more patients for 1–2 years following THA.

THE EFFECTIVENESS OF PHYSICAL ACTIVITY INTERVENTIONS FOR PEOPLE WITH OSTEARTHROSIHIS AND OBESITY: A META-ANALYSIS

S. McKeever1, C. Jinks, E.L. Healey, J.G. Quicke, Primary Care and Health Sciences, Keele University, Keele, UK

Background: Osteoarthritis (OA) is one of the diseases with the highest prevalence and comorbidity. Clinical guidelines recommend physical activity (PA) for people with OA irrespective of comorbidity. Research investigating the effectiveness of PA interventions in OA and comorbidity is needed.

Objectives: To synthesise existing evidence investigating the effectiveness of PA interventions in adults with OA and obesity.

Methods: A systematic review with meta-analysis was conducted (PROSPERO registered as CRD42017060265). Six electronic databases, MEDLINE, EMBASE, AMED, CINAHL, SportDiscus and CENTRAL were searched for studies from their inception to 29.03.17. Inclusion criteria were: randomised controlled trials (RCTs) comparing the effectiveness of any PA intervention to non-PA control group; including adults aged 45 years old and over with clinical or radiographic OA at any site; at least one of the comorbidities of interest (COPD, depression, diabetes, hypertention, obesity, T2DM); and measuring pain, physical function, quality of life, global health post intervention and adverse events. Included study risk of bias (ROB) was assessed using the Cochrane risk of bias tool. Two reviewers screened titles, abstracts and full text articles, checked data extraction, and carried out ROB assessment. Random-effects model meta-analysis pooled outcomes from sufficiently homogeneous studies to calculate effect sizes (Standardised Mean Difference (SMD) with 95% confidence interval (CI)). Meta-analysis findings of the OA and obesity subgroup are reported.

Results: The literature search retrieved 8171 citations of which 14 studies (n=4222 participants) were included in the full review, with 9 (n=1382 participants) analysed in the OA and obesity subgroup. PA interventions included: aquatic, aerobic, strengthening and functional activity; of 1–18 months in duration. Four studies of OA and obesity measuring either Western Ontario Osteoarthritis Index (WOMAC) pain, WOMAC function or Six Minute Walking Test (6MWT) and were included in three meta-analyses. Best estimates showed PA to improve WOMAC pain (n=3 studies; n=547 participants; SMD=−0.09 (95% CI) −0.65, 0.47), improve WOMAC function (n=3 studies, n=415 participants; SMD=−0.35 (95% CI) −0.89, 0.16) and the 6MWT (n=4 studies, n=573 participants; SMD=−0.93 (95% CI) −0.49, 2.35). However, results were not statistically significant. There was substantial between-trial outcome heterogeneity (I²=89.4% (p=0,000); 77.5% (p=0.012); 97.8% (p=0.000)); respectively); results should be interpreted with caution.

ROB domain judgements were generally either low or unclear. A small minority of judgements were at high risk of bias.

Conclusions: Best estimates suggest small beneficial effects of physical activity on WOMAC pain, WOMAC function and the 6MWT. Mixed effectiveness among individual RCTs was likely due to heterogeneous intervention types, intensity and duration.

COMBINATION OF HYALURONATE AND SODIUM SUCINATE IN TREATMENT OF KNEE OSTEARTHROSIHIS

O. Burianov1, L. Khimio2, T. Ormelchenko1, H. Havryluk2. 1Traumatology and Orthopedics, Bogomolets National Medical University; 2Family Medicine, Shupyk National Medical Academy of Postgraduate Education, Kyiv, Ukraine

Background: At present hyaluronic acid (HA) is rather widely used in treatment of patients with osteoarthrosis (OA). HA normalises the properties of the synovial fluid; has a protective effect; promotes the cartilage nutrition and so improves the signs of OA and function of the joints. To the contrary the effects of sodium succinate (the salt of the succinic acid) are not investigated but can be promising in OA treatment due to its known and hypoxic and energetic properties.

Objectives: To investigate the clinical efficacy of combination of hyaluronate and sodium succinate in OA treatment in early stages.

Methods: The study included 126 patients with knee OA (stages I-II, Kelgren and Lawrence), mean age (54.3±2.7) years, among them – 75 women(60%) and 51 men(40%). All enrolled patients had OA exacerbation (without clinically evident synovitis) and received standard OA treatment (NSAIDs, exercises, orthopaedic devices) for 15 days; Gr.1 patients (58) also got 5 intra-articular injections of 1.1% hyaluronic acid, stabilised with sodium succinate (2 ml, once a week); patients of Gr.2 (68) in addition to standard treatment received 5 intra-articular injections of 1.1% solution of non-stabilised HA (2 ml, once a week). Clinical observation and evaluation of the results were performed at the beginning of the treatment, at 6th, 12th and 24th week after the study beginning.

Results: During the treatment period, patients in both groups showed the positive changes in clinical signs and symptoms of OA. The VAS score in both groups indicated a significant pain reduction, but the stability and duration of the clinical effect in the groups was different. In patients of Gr.1, the pain syndrome continued to decrease after 12 weeks till 24th week, whereas in Gr.2 after the treatment course there was no significant changes in further pain regression after 6th week point. The KOOS total and WOMAC index was decreased from (78.3±4.1) in Gr. 1 and (75.4±3.8) in Gr. 2 at the beginning of the study to (27.9±2.6) and (29.8±1.9) accordingly at week 12, p<0,05. The changes in Lisholm score were also significantly better in Gr.1 than in Gr. 2 (before treatment (21.7±4.6) and (22.6±5.3), at week 6 (86.4±5.7) and (71.3±4.8), at week 12 – (87.6±6.2) and (63.8±5.3), respectively, p<0,05.

Conclusions: Combination of the hyaluronic acid and sodium succinate in early stages of knee OA (as intra-articular injections) allows to increase the treatment efficacy. Add of sodium succinate to hyaluronic acid achieve better pain control and longer remission.

THE EFFICACY OF ELECTROMYOGRAPHIC BIOFEEDBACK ON PAIN, FUNCTION AND MAXIMAL THICKNESS OF VASTUS MEDIALIS OBLIQUE MUSCLE IN PATIENTS WITH KNEE OA: A RANDOMISED CLINICAL TRIAL

L. Sedighipour1, S.A. Raeissadat1, S.M. Rayegani2, Z. Bossaghzadeh1, M. Abdollahzadeh1, F. Malayi3, H. Abdollahzadeh1, F. Malai3

Background: Isometric exercises play important role in treatment of Knee OA and are easy to do by the growing elderly population. Electromyographic (EMG) biofeedback devices are designed to enhance patient’s participation in these exercises by giving them feedback signals of visual or auditory nature, so that it can affect the subject’s voluntary activity.

Objectives: The aim of this survey was to study the effect of EMG biofeedback on pain, function, thickness of the vastus medialis oblique muscle and maximal electrical activity of this muscle in isometric contraction, in patients with knee OA.

Methods: In this single-blinded clinical trial, 46 patients aged between 45 to 70, referring to Shohadaye Tajrish and Shahid Modarres hospitals with diagnosis of knee OA, were recruited. Patients were randomly assigned to two groups of case (23 patients), with EMG biofeedback associated exercise, and control (23 patients), with sham biofeedback associated exercise. The exercise program includes 12 sessions of 15 min isometric quadriceps exercise. Data were gathered via VAS score, the Persian version of WOMAC and Lequesne questionnaires, ultrasonography of VMO muscle and surface electromyography of this muscle at baseline and at the end of 2 months period of this study. Variables compared before and after exercises program in each group and between the two groups.

Results: At the end of the study, there were no significant differences between the two groups regarding VAS score, VMO muscle thickness, WOMAC and Lequesne questionnaires scores including overall scores and scores in each subcategories. Although all assessed parameters, except for VMO muscle thickness, were found to be improved significantly in each group, the changes were not more significant in case group except for the VAS score. VMO muscle thickness didn’t change significantly after 12 sessions of exercise in either of the groups.

Conclusions: Isometric exercises accompanied by EMGBF and the same exercises with sham biofeedback for 2 months both lead to significant improvements in pain, and function of patients with knee OA. Real EMG biofeedback was not superior to sham biofeedback. The only parameter found to be improved to a greater extent in the EMGBF group was the subjective measure of VAS score.

THE EFFICACY AND SAFETY OF INTRA-ARTICULAR BOTULINUM TOXIN INJECTION IN KNEE OSTEOARTHRITIS

S.M. Rayegani1, S.A. Raeissadat2, E. Enayati3, S. Rahimi Dehghan1,2,3

Physical Medicine and Rehabilitation, Shohada-e-Tajrish Hospital, Shahid Beheshti University of Medical Sciences, Tehran, Iran;
Physical Medicine and Rehabilitation, Clinical Development Research Center of Shahid Modarres Hospital, Physical Medicine and Rehabilitation Research Center, Shahid Beheshti University of Medical Sciences, Tehran, Iran, Islamic Republic of Ireland

Background: Osteoarthritis (OA) is a common disease that has a great burden through pain and decreased functional capacity. Botulinum toxin A (BTA) injection has been recently proposed for knee OA patients to reduce pain and disability.

Objectives: In this study we evaluate BTA injection efficacy and safety among non-advance knee OA participants in a before-after trial.

Methods: This trial was conducted on knee OA patients presented to our PM and R clinic. Thirty participants aged 40–75 years who had radiographic OA grades of II and III KLS were included. Single intra articular injection of half of a 500/1500 BTA was applied for all participants. Patients were prospectively evaluated as baseline and then at 8 and 24 weeks after injection using the visual analogue scale (VAS) for pain and Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) in three subscales: pain, stiffness and function.

Results: Both main outcome measures of this trial (VAS and WOMAC) significantly improved after 24 weeks follow up. About two-thirds of final VAS improvement was achieved in the first week after injection (from 7.2 to 4.5, MD%-36%, p value<0.008); then at 8 and 24 weeks post injection VAS reached 3.8 and 3.3, respectively. Almost 81%–77% of patients had more than 30% decline in their baseline VAS at 8th and 24th week visits, respectively. Also a similar pattern was observed for WOMAC index of sixth month (from 56.7 to 31.0, Mean Difference−25.7 (MD%−45%), p value<0.005), with more remarkable changes in function subscale (MD%−46%). In this study no major adverse events were noted.

Conclusions: BTA showed promising effects in improving knee pain, ROM and functional status. Therefore this single session method could be considered as an alternative to other intra articular injections in knee OA patients who did not response to preliminary conservative treatments. Further data is necessary to assess long-term effects and cost-benefit analysis of BTA against other similar choices.

AB0976 Efficacy of intra-articular injection of PRP-driven growth factor (PRP without platelet and WBC) versus hyaluronic acid on pain and function of patients with knee osteoarthritis: A single-blinded randomised clinical trial

S.A. Raeissadat, A. gharooee ahangar, S.M. Rayegani, physical medicine and rehabilitation, shahid beheshti university of medical science, tehran, Iran, Islamic Republic of Ireland

Background: Knee osteoarthritis is the most common joint disease.

Objectives: We aimed to compare the efficacy and safety of intra-articular injection of PRP-driven growth factor versus hyaluronic acid (HA) on pain and function of patients with knee osteoarthritis.

Methods: In this single-blinded randomised clinical trial, patients with symptomatic osteoarthritis of knee were assigned to receive 2 intra-articular injections of PRP-driven growth factor in 3 weeks or 3 weekly injections of HA. Our primary outcome was the mean change from baseline until 2 and 6 months post intervention in scores of visual analogue scale, Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC), and Lequesne index.

Results: A total of 69 patients entered final analysis. The mean age of patients was 58.2 ± 7.41 years and 81.2% were women. Total WOMAC index decreased from 42.9 ± 13.51 to 26.8 ± 13.45 and 24.4 ± 16.54 at 2 and 6 months in the PRGF group (within subjects p = 0.001), and from 38.8 ± 12.62 to 27.8 ± 11.01 and 27.4 ± 11.38 at 2 and 6 months in the HA group (within subjects p = 0.001), respectively (between subjects p = 0.631). There was no significant difference between PRP-driven growth factor and HA groups in patients’ satisfaction and minor complications of injection, whereas patients in HA group reported significantly lower injection-induced pain.

Abstract AB0976 – Figure 1

Conclusions: In 6 months follow up, PRP-driven growth factor and HA, both are effective options to decrease pain and improvement of function in patients with mild to moderate knee osteoarthritis.

AB0977 Correlation of the level of C-reactive protein and bone mineral density in patients with gonarthrosis

T. Tarasenko. Polyclinic, Regional Clinical Hospital named after I.I. Mechnikov, Dnipro, Ukraine

Background: The results of recent studies also indicate a link between loss of bone mineral density (BMD) and progressive loss of articular cartilage in patients with knee joint osteoarthritis (OA). The presence of correlation of changes in bone tissue and degradation of cartilage in OA is due to the possible presence of common pathogenesis chains, including activation of proinflammatory mediators.

Objectives: Determine the relationship between the level of C-reactive protein (CRP) and the level of BMD in patients with gonarthrosis.

Methods: We conducted a cross sectional study including confirmed radiographic knee osteoarthritis according to Kellgren-Lawrence scale, with normal and reduced BMD according to the classification of Report of a WHO Study Group. The structural and functional status of bone tissue in patients was

evaluated using the method of ultrasonic densitometry and DEXA at the beginning of treatment and 12 months. The CRP level was determined at the beginning of the observation and after 1, 3, 6, 9 and 12 months. The two groups were compared on the level of BMD, radiological grade, the level of CRP and WOMAC function after adjusting for significant covariates. Multiple regression analysis was used to identify the independent effects to each specific component for level of CRP on knee osteoarthritis parameters.

Results: One hundred forty women were included. The mean age was 55.28 ± 8.90 years. Overweight had 86.42% of patients. The body mass index averaged 30.18±0.43–37.37 kg/m2. According to Kellgren-Lawrence classification, 55% of patients had II and 45% of patients – III radiological stage of gonarthritis. 55.7% of knee OA patients had reduced bone mineral density. Multiple regression analysis showed, after adjusting for significant covariates, that the CRP level was significantly higher (p<0.0001) in patients with reduced BMD compared to normal (6.32 ± 1.67 mg/L and 4.74±0.75 mg/L respectively), an average of 33.3%.

Conclusions: It was found that in patients with gonarthritis with reduced BMD, a higher level of CRP was observed at 33.3%, which was associated with a more severe course of the disease.

AB0978 DECREASED PAIN AND IMPROVED DYNAMIC KNEE INSTABILITY MEDIATE THE BENEFICIAL EFFECT OF WEARING A SOFT KNEE BRACE ON ACTIVITY LIMITATIONS IN PERSONS WITH KNEE OSTEOARTHRITIS

T. Cudejko1, M. van der Esch2, J. van den Noort1, J. Rijnhart1, M. van der Leeden1, L.D. Roorda3, W. Lems1, J. Harlaar1, G. Waddington4, J. Dekker1.
1VU University Medical Center; 2De Boelelaan 1117, Afdeling revalidatiegeneeskunde; 3Amsterdam Rehabilitation Research Center Reade, Amsterdam, Netherlands; 4University of Canberra, Canberra, Australia

Background: We have previously shown that wearing a soft knee brace reduced activity limitations in persons with knee osteoarthritis (OA). Several underlying mechanisms have been proposed via which a soft knee brace reduces activity limitations in persons with knee OA. However, to our knowledge, no study has identified mechanisms explaining this effect.

Objectives: The aim of the study was to identify mechanisms explaining the beneficial effect of wearing a soft knee brace on activity limitations in persons with knee OA.

Methods: This was an exploratory analysis of data from 44 participants with knee OA from Amsterdam Osteoarthritis cohort, who enrolled in a single-session within-subject cross-over design study, comparing a soft brace with no soft brace and comparing a non-tight soft brace with a tight soft brace (GENUTEX A2, Human I). A mediation analysis was performed and the mediation effect was calculated based on the product of coefficients approach. Confidence intervals were calculated with a bootstrap procedure. The outcome measures were activity limitations assessed with the 10-metre walk test and the Get up and Go test. The studied mediators were the changes in: knee joint proprioception, pain, pressure pain threshold (PPT) and objective dynamic knee instability. Knee joint proprioception was assessed by the active movement extent discrimination assessment; pain with the Numeric Rating Scale (NRS); PPT with a hand-held pressure algometer, and dynamic knee instability with the Perturbation Response i.e. a measure reflecting deviation in the mean knee varus-valgus angle after a controlled mechanical perturbation on the treadmill, in respect to level walking.

Results: Both a decrease in pain during walking and a decrease in dynamic knee instability mediated the association between wearing a soft knee brace and reduction in time to complete both 10 m walk test and the GUG test (p<0.05). Changes in proprioception and PPT did not mediate these associations (p>0.05). Magnitudes of the mediation effects were similar for a non-tight and a tight soft knee brace.

Conclusions: The decrease in activity limitations in persons with knee OA who wear a soft knee brace might be explained by a decrease in self-reported pain and a reduction in dynamic knee instability.

FACTORS ASSOCIATED WITH LOSS OF CARTILAGE IN KNEE OSTEOARTHRITIS

V. Vardanyan1, V. Mukuchyan2, A. Kirakosyan2. 1Internal Medicine, Yerevan State Medical University; 2Rheumatology, “Erebouni” Medical Center, Yerevan, Armenia

Background: Osteoarthritis (OA) is one of the leading causes of pain and disability worldwide. The structural changes in knee OA are characterised mainly by the progressive loss of cartilage, which is associated with additional structural changes such as subchondral bone lesions and alterations in the menisci. Unfortunately, these changes cannot be effectively treated conservatively. Further determination of modifiable risk factors of cartilage loss is extremely important for improvement of OA management.

Objectives: The main objective of the study was the determination of factors associated with loss of cartilage in knee OA.

Methods: 294 patients (277 female, 17 male, mean age 55, 09±5.6 years) with newly diagnosed mild to moderate primary knee osteoarthritis were investigated. X-ray and ultrasound examinations of knee joints were performed. The thickness of cartilage and synovial layer, as well as presence of synovitis, tendinitis, osteophytes, Baker’s cysts, tear of meniscus were determined. For determination of factors associated with loss of cartilage both univariate and multivariate analyses were performed. The data is introduced as odds ratios (OR) with 95% confidence interval (CI). The results were considered significant when p <0.05.

Results: Expressed thinning of cartilage (≤2 mm) was observed in 216 (73.5%) patients, abnormal thickening of synovial layer (≥3 mm) – in 76 (25.9%), synovitis – in 88 (29.9%), tendinitis – in 38 (12.9%), osteophytes – in 273 (92.9%), Baker’s cysts – in 93 (31.6%), tears of meniscus – in 93 (31.6%) patients.

Univariate analysis had shown that loss of cartilage (≤2 mm) was significantly (p<0.05) associated with age ≥55 (OR/95% CI=2.0/1.3), osteophytes (OR/95% CI=1.4/1.4), synovitis (OR/95% CI=2.4/1.7), tendinitis (OR/95% CI=2.4/1.7), and osteophytes (OR/95% CI=2.0/1.4). Baker’s cysts (OR/95% CI=2.2/1.4) and synovitis (OR/95% CI=2.2/1.4) were the factors associated with loss of cartilage (≤2 mm) in the multivariate analysis. The odds ratio for synovitis and osteophytes was 2.0/1.3 and 2.4/1.7, respectively.

Conclusions: The identification of modifiable risk factors of cartilage loss is extremely important for improvement of OA managemen.t

PREVALENCE OF OSTEOARTHRITIS IN HIGH ALTITUDE AREA OF TIBET

Y. Liang, Y. Mei, S. Guan, W. Sun, W. Wang, F. Teng, X. Han, Z. Zhang. "The First Affiliated Hospital of Harbin Medical University, Harbin, China"

Background: Osteoarthritis is a degenerative joint disease; the specific etiology and pathogenesis are unclear. The prevalence of osteoarthritis of subtypes of joints is different, whereas the most common osteoarthritis occurs in knees. In China, the prevalence of osteoarthritis is about 15%, the prevalence of the patients over 40 years old is 10%-17%, and 50% over the age of 60, while over 75 years old was as high as 80%. Few data exist regarding the prevalence of OA in plateau in China.

Objectives: To investigate the prevalence of osteoarthritis (OA) in Jiuhu village, which is located about 3.5 kilometres high of Gonggaiy County of Tibet and the associated factors in order to provide the guidance for the prevention and treatment of OA.

Methods: The participants in this analysis were all the resident people aged 50 years and above in Jiuhu village, Gonggaiy County of Tibet. All subjects were invited to completed an questionnaire, physical examination and radiographic examination. The questionnaire included sex, age, body mass index(BMI) and dietary habit.

Results: A total of 136 participants aged 50–86 years were enrolled, including 47 males with mean age of 62.66±11.21 years, and 89 females with mean age of 61.30±9.52 years. Altogether 102 knee OA can be diagnosed, the total prevalence of knee OA was 75.00%. Knee OA occurred in 78.72% of male and 73.03% of female. The prevalence of knee OA combined with hand OA was 19.12%, and 21.28% for male and 17.98% for female. The prevalence of knee OA combined with hand OA increased with age in the female, no such trend was observed in male or in only knee OA patients. No significant difference was found about sex, BMI, drinking between the OA patients and the controls.

Conclusions: The prevalence of osteoarthritis in Jiuhu village, plateau of Tibet was significantly high. The prevalence in male is higher than that in female. The prevalence of knee OA combined with hand OA increased with age in the female.

PRIORITIES FOR OSTEOARTHRITIS RESEARCH SHOULD BE DONE IN CHINA

Y. Mei1, S. Guan1, Y. Shi1, D.J. Hunter2, Z. Zhang1. 1The First Affiliated Hospital of Harbin Medical University, Harbin, China; 2University of Sydney, Sydney, Australia

Background: Osteoarthritis (OA) exacts a tremendous toll on patients and society due to its impact on lifestyle and functional impairment. In China, the prevalence of OA is increasing sharply, especially among the aged, while the prevalence in male or in only knee OA patients. No significant difference was found about sex, BMI, drinking between the OA patients and the controls.

Objectives: The objectives of this study are to investigate key priorities for OA in the next five years to make use of limited funding and resource in China. In addition, it will also help researchers, especially Chinese rheumatologists, to get more support from the government, which will push OA studies faster towards elusive breakthroughs. Therefore, it will improve prognosis and health and quality of life for OA patients.

Methods: The study combined 4 stages, including 1) Identify research priorities for the next five years that match the strengths and expertise of Chinese OA researchers at the OA potential priority-setting summit, 2) Initial ranking of suggested research priorities using 1000Minds software prior to the summit, 3) Discussion and selection of top five thematic priorities from the original list of 10 priorities at the final OA priority-setting summit. 4) Final ranking of five research priorities by all attendees at the summit and design experimental aims and approaches for the priorities. Finally, the top three priorities from five prioritised topics were selected.

Results: 39 Chinese rheumatologists attended stage one and identified 10 priorities in the next five years. There were 313 Chinese rheumatologists invited to participate in stage two, among them, 104 rheumatologists finished the process and identified the initial prioritised rankings of the research topics. 29 Chinese rheumatologists attended the final OA priority-setting summit. Through these multistage processes, three key topics about OA were identified as essential and were prioritised. These three priorities include targeting inflammation should be a focus of research in osteoarthritis, setting biomarkers for osteoarthritis diagnosis and monitoring, research into early OA would be expected to understand OA across disease development and translate to better therapy. Experimental aims included to detect inflammatory in OA pathology, to identify well-established criteria for early OA, to protect and repair chondrocytes and cartilage, and the approaches included longitudinal study, placebo-controlled randomised controlled trial, animal experiments.

Conclusions: Chinese rheumatologists identified OA priorities for the first time, and these key topics would have guiding effect significantly on Chinese OA research in the future.

HYALURONAN DERIVATIVE HYMOVIS® INCREASES CARTILAGE VOLUME AND TYPE II COLLAGEN TURNOVER IN OSTEOARTHRITIC KNEE: DATA FROM MOKHA STUDY

Y. Hevrín1, R. Barunou2, M. Malaise3, K. EA4, C. Confltreveu5, J. Benit6, D. Urban-Choffray7, T. Connozier8, Brasseur9, T. Thomas10, A. Martellino11, N. Giordan12, P. Richette13. 1Bone and Cartilage Research Unit, University of Liège, Liège, Belgium; 2Center for Treatment Comparison and Integrative Analysis, Tufts Medical Center, Boston, USA; 3Service de Rhumatologie, CHU Saint-Tilman, Liège, Belgium; 4Service de Rhumatologie, Hôpital Lariboisière, Paris; 5Department of Rheumatology, Hospices Civils de Lyon, Lyon, France; 6Service de Rhumatologie, CHU Brugmann, Bruxelles; 7Service de Médecine Physique, CHR Citadelle, Liège, Belgium; 8Service de Rhumatologie, Hôpital Nord Franche-Comté, Trévaniens, France; 9Service de Rhumatologie, CHU UCL, Namur, Yvoir, Belgium; 10Service de Rhumatologie, CHR Metz-Thionville, Metz, France; 11Fidia Farmaceutici, S.p.A.; 12Fidia Farmaeutici, S.p.A., Fidia, Abano, Italy; 13Centre Viggio Petersen, Hôpital Lariboisière, Paris, France

Background: Intra-articular injections of hyaluronan represent one of the well-accepted standard of care for treating symptomatic knee osteoarthritis (OA). Until now, not much is known about the structural-modifying effect of this treatment justifying this pilot study.

Objectives: This exploratory non-controlled study aims to study effects of HYMOVIS® on bone mineral density, due to cadmium toxicity.

Methods: Forty six patients with symptomatic knee OA (mean age 61.4 years [min.35-max.80; 67.4% female; Kellgren and Lawrence grade II and III (63% and 37%, respectively); mean BMI 30.6 kg/m²] were enrolled in this open-label, prospective, multicenter, pilot study. Patients received two treatment cycles of 730 kDA hyaluronic acid hexadecylamide) at 6 months interval. Each treatment cycle corresponded to two intra-articular injections one week apart. All patients had MRI of the target knee at baseline and 1 year, and blood samples (D30, D90, D180, D210 and D360) to assess joint biomarkers. The primary outcome was the change in type II collagen-specific biomarkers (Col2–1, Coll2–1N2O2 and CTTX-II) after Hymovis treatment versus baseline. Secondary endpoints included levels of bone turnover markers (effects of both renal and liver functions) of cadmium and lead. This study was designed to evaluate the effects of smoking on bone mineral density and bone metabolism in elderly men: the Fujiwara-kyo Osteoporosis Risk in Men (FORMEN) study. Osteoporos Int 2010, 22 (1):133–141.

PERSISTENCE AND ADVERSE EVENTS IN PATIENTS TREATED WITH DENOSUMAB

Background: Denosumab (DNS) is a human monoclonal antibody directed against RANKL, which blocks the maturation of the osteoclast, inhibiting bone resorption. The binding of DNS to RANKL suppresses bone resorption mediated by osteoclasts and decreases bone turnover.

Disclosure of Interest: None declared
Objectives: To evaluate the survival rate of DNS, adverse events and reasons for the DNS discontinuation.

Methods: This was a retrospective observation study in patients with OP which initiated treatment with DNS between January 2013 and December 2017. Patients included were followed up in the Rheumatology Nurse Clinic every sixth month. Demographics, date, disease features, concomitant disease and treatments, adverse events and reasons for discontinuation were collected.

Results: We included 220 patients (80.5% women) with a mean age (range, SD) of 67.19 (30–89, 12.2) years. In average (range, SD), patients received 3.85 (1–11, 2.2) doses of DNS, with a mean duration of treatment (range, SD) of 23.03 (6–66, 13.3) months. 191 (86.8%) patients received also treatment with calcium and vitamin D supplements. Before the start of the treatment with DNS, 123 (55.9%) patients had received another specific treatment for OP with mean previous treatment duration of 51.6 months. Previous fragility fractures were reported in 150 (68.1%) patients, of whom 91 (41.3%) patients had two or more fractures before starting treatment with DNS. Of all included the patients, 108 (49%) patients had an inflammatory autoimmune disease (IAD) diagnosed. In addition, 100 (45.4%) patients had concomitant biological and/or synthetic treatment and 77 (35%) patients received concomitant treatment with corticosteroids.

During the treatment with DNS, 30 (13.6%) patients had new fractures, 5 (2.3%) patients had 2 fractures. Eleven fractures were vertebral, 3 of femur, one of radius and 21 other locations. There were no differences between patients with and without glucocorticoid treatment (0.234).

The most frequent adverse events (AE) were infections in 88 (40%) patients, muscle pain in 15 (0.6%) patients, fatigue in 7 (0.31%) patients, itching, heat and fever in 2 (0.9%) patients and osteonecrosis of the jaw in 2 (0.9%) patients. The 2 patients with osteonecrosis of the jaw had previous treatment with bisphosphonates for more than 24 months.

At 60 months, 185 (84.1%) patients continued with DNS. In 37 (1.6%) patients, DNS was discontinued; in 4 patients DNS was restarted. The reasons for suspension were hypercalcemia 1 (0.04%), hypocalcemia 1 (0.04%), local hypersensitivity reactions 4 (0.18%), normalisation of BMD 5 (0.2%), dental problems 11 (0.4%) and others 17 (0.7%). The mean (SD, 95% CI) of DNS survival was 51.2 (1.9; 47.3–55.1) months. There are no differences in the survival rates of DNS between patients with and without concomitant biologic therapy (p=0.995).

Conclusions: The majority of patients who started treatment with DNS continue the treatment with good tolerance. The most frequent adverse effects were infections but they have not led to suspension of treatment.

AB0986 MANAGEMENT OF OSTEOPOROSIS AFTER MAJOR FRACTURE IN A COHORT OF WOMEN AGED OVER 50 IN A REAL LIFE SETTING

A. Nauty1, S. Bastide2, F. Flaisier1, C. Gajouj-Viala1, 2 Rheumatology, Nîmes University Hospital, Hôpital de Vers-Pont-du-Gard; 2Biostatistics, Epidemiology, Public Health and Innovation in Methodology (IBESPIM), Nîmes University Hospital, NÎMES, France

Background: Osteoporosis is the most common metabolic bone disease. Fractures constitute a major health concern because prior fractures are associated with an increased risk of subsequent fracture. Moreover, osteoporotic fractures have been associated with increased mortality risk.1 Hence secondary fracture prevention is recommended. Anti-osteoporotic drugs are available, but in the last decade an alarming decrease of anti-osteoporotic therapy use was observed.2

Objectives: The objective of this study was to analyse the management of osteoporosis after major fracture (hip, vertebral and humerus fractures) in women aged over 50 in a real life setting.

Methods: We conducted an observational study on all women over 50 years of age who experienced a major fracture at Nîmes University Hospital in 2015 identified by informatic codes. Only fragility fractures were included. Data collected prospectively in the computerised medical files were extracted: prescription of a post-menopausal osteoporosis therapy; therapy initiation; prescription and completion of generalised bone mineral density testing; and prescription and completion of blood sample tests to look for secondary osteoporosis. We also recorded the department in which the hospitalisations occurred and the fracture localization.

Results: Of 375 women over 50 with a registered fracture in 2015, 264 were included. The exclusion criteria were women with traumatic fracture or minor osteoporotic fracture. The median age was 84 years old. The most common major fractures were hip (52.3%), humerus (20.8%) and spine (18.9%). Forty-five (10.7%) patients had experienced a fracture prior to the 2015 fracture. Only 12 patients (4.5%; IC95% [2.4–7.8]) had an anti-osteoporotic drug prescription at the end of the hospitalisation and only 45 women (17%) had anti-osteoporotic drug prescription planned later. The median period until anticipated prescription was 9 days and the median period until prescription in practice was 18 days.

In surgical department, anti-osteoporotic drug prescription was planned in only 3 women (1.5%) compared with 40 women (56.3%) in medical departments.

Conclusions: A large majority of women with osteoporotic major fracture are not receiving appropriate therapy and recommended management in 2015 in Nîmes University Hospital. The rate is dependent on the department in which patients are hospitalised.

The results of our study highlight the urgent need for optimisation of osteoporotic fracture management, especially in the surgical department.

AB0987 FREQUENCY OF UTILISATION OF THE CENTRAL DXA BONE DENSITOMETRY IN PATIENTS WITH MULTIPLE SCLEROSIS

A.N. Klimo. Specialized hospital of rehabilitation "Banja Kanjiža", Kanjiža, Serbia

Background: Multiple sclerosis patients can have a higher risk from occurrence of osteoporosis. Reduced bone mass density can be related to a cumulative effect of different factors, most common ones being physical inactivity, reduced intake of vitamin D and use of medications such as glucocorticoids.

Objectives: The aim of this research was to explore the level of awareness in patients and physicians on the significance of the utilisation of DXA bone densitometry in patients with multiple sclerosis.

Methods: The observational analytical cross-section study included 366 multiple sclerosis patients on stationary treatment at the Special rehabilitation hospital “Banja Kanjiža” in Kanjiža in the period between 2013 and 2017. The following parameters were observed in patients: sex, age, duration and form of basic disease, the frequency of the low bone mineral density (BMD). Statistical data processing and analysis was conducted in the SPSS ver 20.0 program by IBM corporation.

Results: In the period in question, an average of 128 multiple sclerosis patients were treated, out of those 62.3% (n=228) with relapsing-remitting type of disease, and n=366 first time patients. Within the given period, 36% more women than men were rehabilitated (f=249 vs. m=117). During the five-year long period of observation of said patients, only 8.5% (n=31) of patients with different levels of bone metabolic disorders established underwent central DXA bone densitometry. Pathological fracture on a small trauma was suffered in 6.8% (n=25) patients. Of the abovementioned parameters, only the female sex (χ²=84.492; p<0.001) and age (t=2.200; p=0.036) statistically significantly influenced the occurrence of low bone mineral density.

Conclusions: It is necessary to increase the level of health education of multiple sclerosis patients on the consequences of low bone mineral density. The highest risk of osteoporotic fracture is in older women suffering from multiple sclerosis.

Disclosure of Interest: None declared

Background: Patients affected by Rheumatoid Arthritis (RA) show an increased risk of low bone mass, as a result of multi-systemic disorders including toxic drug, low vitamin D levels, use of glucocorticoids, and physical inactivity. Trabecular Bone Score (TBS), is an index extracted from the dual-energy X-ray absorptiometry (DXA) images, that provides an indirect measure (Score) of bone axial microarchitecture and allows to get information about bone quality. 1,2

Objectives: The aim of this investigation was to evaluate by TBS the bone quality in RA patients (high risk population) receiving vitamin D supplementation from at least 3 months (1000 IU/die).

Methods: 108 female patients (mean age 61±8 years) affected by RA and 60 age-matched controls (CNT) (mean age 64±11 years) were analysed in winter time. Bone Mineral Density (BMD, g/cm²) of the lumbar spine (L1-L4) was analysed using a DXA scan (GE, Lunar Prodigy). Lumbar spine TBS (TBS iNsight Medimaps) was derived for each spine DXA examination. All patients were evaluated for serum 25 hydroxyvitamin D (25(OH)D) serum concentrations.

Results: RA patients showed lower 25(OH)D concentrations (18.4±3.9 ng/ml) than CNT (26.2±0.9 ng/ml; p<0.04) possibly due to low dosage and short treatment. Seventy-eight RA patients (80% of study population) presented a bone loss that was significant when compared to the control group (p<0.001). In particular, BMD was found significantly lower in RA patients compared with matched control group (respectively, Lumbar spine: 0.862±0.194 g/cm² vs 1.240±0.932 g/cm²; Femoral neck: 0.688±0.141 g/cm² vs 0.845±0.164 g/cm²; Ward: 0.486±0.221 g/cm² vs 0.657±0.106 g/cm²; Trochanter: 0.598±0.231 g/cm² vs 0.725±0.143 g/cm²; Total hip: 0.764±0.244 g/cm² vs 1.033±0.161 g/cm², all p<0.001). Likewise, lumbar spine TBS score was found significantly lower in RA patients when compared with control group (1.197±0.148 vs 1.361±0.126, p=0.000).

Conclusions: This study shows in RA patients a reduction of TBS values that seem placed side by side with reduced BMD values and in presence of serum 25 (OH)D insufficiency. A more careful analysis of the clinical status/treatments should let to better identify RA patients at higher risk of bone loss.

**AB0089**

**THE IMPACT OF A LOW-COST DIGITAL AND PRINT AWARENESS CAMPAIGN ON PATIENT BEHAVIOUR IN RELATION TO PERSONAL RISK OF OSTEOPOROSIS AND FRAGILITY FRACTURE**

H. Mace, C. Bovey, H. Arden, T. Jones. National Osteoporosis Society, Bath, UK

Background: The National Osteoporosis Society (NOS) ‘Stop at One’ campaign aims to encourage people who are over 50 and have broken a bone to find out, by taking an online quiz, if they are at risk of osteoporosis and to take action to reduce their risk of further fractures. A low-cost marketing intervention was trialled making printed campaign materials available direct to patients at the point of care (fracture clinic).

Objectives: The analysis sought to establish whether the marketing intervention increased take up of the online quiz, and to what extent taking the quiz influenced people’s behaviour with regard to their bone health.

Methods: Between May and October 2017, the NOS placed Stop at One printed campaign materials encouraging people to take the online bone health quiz at 8 sites across the UK covering 13% (16/124) of UK postcode areas. 7 sites had no enhanced provision for secondary fracture prevention such as a fracture liaison service, 1 had a partial service. People who took the online quiz were sent a follow-up survey one month later.

Results: Up to 1st January 2018 1900 people took the quiz:
- 89% (1699) of these were over 50
- 95% (1814) were female.
- 21% (443) of these lived in postcode areas of the pilot sites.
- 1359 people were sent a follow up survey one month after taking the online quiz, and 10% (142) completed it. 27%20 of these were individuals living in the postcode areas of the pilot sites.

When surveyed, of the 142 respondents:
- 50% (71) of respondents had broken a bone in the previous ten years.
- 73% (104) thought they were at risk of osteoporosis after taking the test.
- 24%24 had either booked or attended an appointment with their GP to discuss their possible risk of osteoporosis.
- A further 10%24 planned to book a GP appointment to discuss their risk.
- 31%45 had made changes to their exercise habits.

Conclusions: Digital activity (patients accessing website) and the electronic patient survey show meaningful changes in patient behaviour to reduce their fracture risk. Visibility of the awareness campaign at the point of care increased uptake of the quiz and subsequent survey.

**AB0090**

**THREE YEARS IMPROVEMENT IN OSTEOPOROSIS TREATMENT ADHERENCE FOLLOWING A THERAPEUTIC PATIENT EDUCATION (TPE) PROGRAM**

D. Poiret1, V. Noirez2, C. Goetz3, C. Wickle4, 1CHR METZ THIONVILLE; 2URPS Grand Est, Metz, France

Background: The management of osteoporosis requires a restrictive drug treatment over several years and lifestyle changes: maintaining a suitable physical activity, a sufficient calcium intake and maintenance of ground balance. Unfortunately, treatment adherence at one year does not exceed 50%. The education of the patient allows to take care of himself in his therapeutic approach but requires a relay to continue the follow-up over several years.

Objectives: To improve the follow-up of the patient, we created a cooperation between the doctor and the pharmacist.

Methods: We suggested to patients treated for osteoporosis by bisphosphonate, denosumab or teriparatide to participate at two half-day TPE sessions, one year apart. It is taught that osteoporosis requires at least 5 years of treatment, and must be associated with the absorption of three daily dairy products, maintaining physical activity and preventing falls.

A follow-up notebook that contains 6 doctor and 6 pharmacist questionnaires is given to each patient participating in a TPE session. The patient sends his book to the doctor, and then to the pharmacist twice a year for three years. The doctor and the pharmacist questionnaire explains the drug intake. The doctor questionnaire evokes lifestyle changes. This one is completed by the patient in the waiting room and is discussed with the doctor during the consultation. Each completed questionnaire provides a financial compensation to the health professional.

The program is funded by the Regional Health Agency of Lorraine and by the Regional Union of Health Professionals (doctors and pharmacists). Inclusions started in January 2013. We studied the results of the 3 year questionnaires for 94 patients included in 2013 and 2014.

Results: Among the 94 patients, only 49 continue their treatment at 3 years. Patients who stopped treatment, 4 died, 1 presented an atypical fracture of the femoral shaft, 6 stopped due to dental treatment, 4 had a contraindication to any anti-osteoporosis treatment, 1 stopped treatment due to multiple sclerosis 11 left the program, 2 had poorly tolerated the infusion and 1 discontinued treatment because of improved bone mineral density (BMD). Among the 49 patients who continue their treatment, 13 returned a doctor and pharmacist questionnaire at 3 years. There are 4 doctors and 2 pharmacists who refused to fill out the questionnaire, 20 patients didn’t agree to respond to our request for news about their health condition and 4 patients lost to follow-up.

The study of 13 questionnaires received shows that at 3 years, 38% of patients continue to consume 3 daily dairy products against 56% at 6 months. Nearly 70% of patients maintained their physical activity, 8% improved and 8% decreased it. It also shows that 46% of patients walk more than 30 min per day. The ground balance is satisfactory for 62% of patients compared to 71% at 6 months. Regarding compliance, at 6 months and 3 years, only 69% of patients never forget their treatment and 15% wanted to stop it. During the 3 years of follow-up, all patients were re-contacted at least once.

Conclusions: 52% of patients included continued the treatment at 3 years, 21% refuse to participate in the program. The doctor/pharmacist collaboration around the patient requires time and understanding. Patients recall and their participation in a research program improves their adherence to treatment and lifestyle changes.

OSTEOPOROSIS AND FRACTURES IN PATIENTS WITH CIRRHOSIS. CAN FRAX BE USEFUL FOR SCREENING?

E. Casado1, M. Arévalo1, J. Protófo2, A. Lira1, L. Del Río1, O. Valero1, M. Larrasa1, J. Sánchez-Delgado3, J. Gratacos1, G. Rheumatology, University Hospital Parc Taulí. 13PT, UAB, Sabadell, Sabadell; 2Gastroenterology and Hepatology, Consorci Hospitalari de Terrassa, Terrassa; 3Gastroenterology and Hepatology, University Hospital Parc Taulí. 13PT, UAB, Sabadell, Sabadell; 8Radiology, CETIR Centre Mèdic, Barcelona; 9Statistics, Unversitat Autònoma Barcelona (UAB), Bellaterra, Spain

Background: Osteoporotic fractures are a serious complication in patients with cirrhosis. In addition to the high morbidity and mortality of the patients who suffer them, fragility fractures represent a high cost for Healthcare systems.

However, there are very few studies that evaluate the prevalence of osteoporosis and fractures in patients with liver cirrhosis different than primary biliary cirrhosis (non-PBC cirrhosis). There are also no clinical guidelines with recommendations for osteoporosis screening in these patients.

Objectives: To assess the prevalence of osteoporosis and fracture in patients with non-PBC cirrhosis in our environment, and the associated risk factors.

To analyse if the FRAX tool can be useful in the diagnostic screening of these patients.

Methods: From November 2015 to September 2017, outpatients older than 40 years diagnosed with non-PBC cirrhosis (any Child stage) were randomly included. Demographic, clinical and analytical data (calcium, phosphorus, 25-hydroxyvitamin D and PTH) were collected from all patients. A bone densitometry, GE, Lunar Prodigy (DXA) and vertebral fracture assessment (VFA) were also performed, for the diagnosis of osteoporosis (T-score <-2.5), and vertebral fracture. The 10-year absolute fracture risk was calculated using FRAX (https://www.sheffield.ac.uk/FRAX/tool.aspx?country=4).

A descriptive statistic of the main variables was carried out, with univariate and multivariate analysis to assess which predictive factors could be related to the presence of osteoporosis and/or fragility fractures.

Results: Ninety-two patients were included (71% male and 29% female). Age 63 ±11 years. The etiology of cirrhosis was: alcohol (52%), hepatitis C virus (27%) and alcohol +hepatitis C virus (9%). Stage: Child A (80.4%), B (17.4%) and C (2.2%). Mean 25-hydroxyvitamin D 18.5±5.8 ng/ml and PTH 51±23.0 pg/ml.

16 patients (17%) had osteoporosis by DXA, 54 patients (59%) osteopenia and 22 (24%) had a normal bone mineral density (BMD). 8 patients (9%) had suffered some fragility fracture (vertebral fracture in 6 cases).

The 10 year absolute risk for major fracture (vertebra, humerus, femur or radius) by FRAX without BMD was 5.7±4.5; and with BMD 4.7±4.9. Age and female sex were associated with the presence of osteoporosis, and a BMI higher than 30 was found to be a protective factor. A BMD in the range of osteoporosis was the only factor associated with fracture.

FRAX for major fracture without BMD higher than 6.6% in this population had a high sensitivity (69%) and specificity (85%) for the diagnosis of osteoporosis, which implies a negative predictive value of 93%. Using this FRAX cut-off for indicating DXA in cirrhotic patients could expect a saving of 76% of DXA scans.

Conclusions: The prevalence of osteoporosis and fractures in patients with non-PBC cirrhosis, even in mild stages, is higher than in the healthy population, being more frequent in women and older patients.

The FRAX tool can be useful in the selection of patients with cirrhosis to be assessed by a bone densitometry.

BONE REMODELLING BIOMARKERS IN HIV INFECTED PATIENTS

F. López1, J. Loarce1, C. Sobrino1, J.L. Casado2, M. Vázquez1. 1Rheumatology Department, 2Infectious Diseases Department, Ramón y Cajal University Hospital, Madrid, Spain

Background: Bone metabolism is an equilibrium of resorption and growth, maintained by many regulating factors. Several molecules have been identified that estimate bone turnover, being P1NP and b-CTX the most commonly used. Many studies have shown a relationship between their levels and metabolic bone disease, and possibly with risk of fracture.

Human Immunodeficiency Virus (HIV) infected patients have lower bone mineral density (BMD), as documented on many studies. An increased incidence of fractures has been noted as well, probably due to predisposing factors related to HIV infection, apart from the traditional risk factors.

Objectives: To assess the relationship between mean values of bone biomarkers P1NP and b-CTX and incidence of vertebral fractures (VF) in a HIV infected population; and compare such values with those of a Spanish healthy population of reference.

Methods: We performed a cross-sectional study with HIV infected patients followed up in the Infectious Diseases Department of our centre from 2014 to 2016. P1NP and b-CTX values were determined and lumbar and thoracic spine radiographs made to assess presence of VF (Genant grading scale). Other clinical and demographic data were collected retrospectively. P1NP and b-CTX values in the presence (VF group) and absence of fractures (non-VF group) were compared.

Mean values were also compared with the Camargo cohort, comprised of 1080 healthy postmenopausal Spanish women, used as reference. Statistical analysis were made with STATA. All patients signed and informed consent, previously approved by the Hospital’s Ethics Committee.

Results: A total of 144 patients were included, 38 were women with a mean age of 56.4 years old45–77 and 106 men with mean age of 56.5 years old45–86 of the patients had at least one VF. No statistically significant differences were found between P1NP mean levels in the VF and the non VF groups, with values of 45.30 ng/ml (±7.19 ng/ml) and 49.48 ng/ml (±32.92 ng/ml) respectively, (p=0.52). Mean levels of b-CTX were 0.38 ng/ml (±0.18 ng/ml) in the VF group and 0.43 ng/ml (±0.22 ng/ml) in the non-VF group, again without significant differences (p=0.35).

Mean general b-CTX values in our population were 0.41 ng/ml (±0.21); 0.46 ng/ml (±0.20) in women and 0.39 ng/ml (±0.20) in men. Higher levels were found in HIV infected women than in the Camargo cohort (0.38±0.19 ng/ml), with statistical significance (p=0.03). Mean general P1NP values were 48.34 ng/ml (±29.47), 58.63 ng/ml (±32.9) in women and 44.95 ng/ml (±27.56) in men, with no statistically significant differences found when HIV infected women were compared with those of the Camargo cohort, (47.7±19.9 ng/ml) (p=0.06), although a trend towards higher levels in HIV infected women was observed.

Conclusions: In the present study no correlation between P1NP and b-CTX levels in HIV infected patients and incidence of vertebral fracture was found. P1NP and b-CTX mean values in HIV infected women in our study are higher than those of healthy postmenopausal Spanish women, which means a higher bone turnover in this population. More studies are needed to clarify the extent and clinical impact of this finding.

PAIN RELIEF MANAGEMENT OF ACUTE OSTEOPOROTIC VERTEBRAL FRACTURE IN A REAL LIFE STUDY

F. Bertoldo1, G. Gandolini2, A. Venturini2, C. Cisari3, R. Lovato3, M. Longhi3, S. Farina4, E. Bertoldo5, R. Nult5, on behalf of Servatius GISMO study group. 1Internal Medicine, University of Verona, Verona; 2Rheumatology, IRCCS Don Gnocchi, Milan; 3Rehabilitation Unit, University of Padua, Padua; 4Orthopedic Unit, University of P O, Novara; 5Internal Medicine, Villa Berea Hospital, Vicenza; 6Orthopedic Unit, Galeazzi Institute, Milan; 7Rheumatology Unit, Crema Hospital, Crema; 8Rheumatology Unit, University of Verona, Verona; 9Internal Medicine, University of Siena, Siena, Italy

Background: Among all osteoporotic fractures the painful vertebral fractures (PFV) are the minority and their management is challenging for the clinician because the evidences about the best approach are conflicting and of low quality. Moreover there are no guidelines or consensus of experts. A real life picture of the management of the PFV is lacking in the literature.

Objectives: The primary end point of the study is to describe the pharmacological and/or non-pharmacological management of PFV through the record of use of individual classes, associations and sequences of drugs or procedures. Secondary end point is the outcome of treatment in term of pain, disabilities and quality of life.

Methods: We present the item analysis results of a multicentric cross-sectional observational study. 400 interviews will be collected consecutively about pain, disability, pharmacological, spinal orthoses and orthopaedic surgery after the diagnosis of PFV in postmenopausal women treated by orthopaedics, endocrinologists, geriatricians, physiatrists, neurosurgeons and E.R. physicians. Pain and disability were quantified by NRS scale and by QUALEFFO 41. Data collected from the first 100 patients have been analyzed.

Results: One hundred postmenopausal women aged 73.1±7.49 y.o (age of menopause 48.6±3.9 years, L1-L4 T-score –2.75±0.92. Total hip T-score –2.35 ±0.98) with a new or first PFV were recorded. About 49% of them had a previous vertebral fracture and 22% a previous non-vertebral fragility fracture, 27% was not on osteoporosis treatment. The interviews were collected 135±114 days from diagnosis of PFV,17±4 days from onset of pain. 92.3%±12% of subjects were treated for pain relief for a mean time of 98±12 days. Only 1.6% of cohort
underwent to percutaneous vertebraloplasty while 84.6±17.1% had spinal ortho-
theses. Pharmacological treatment for pain was prescribed to 98.2±7.1% of subjects:
acacetaminophen (42%), tapentadol (24%), opioids (24%), NSAID (6%) and
codiene with acetaminophen (4%). In 95% of patients with spinal orthoses drugs
for pain were assumed. In about 40% of cases NSAID was switched to acetamino-
phen, in 18% opioid and tapentadol switched to NSAID or acetaminophen. Only
a few titration of opioids/tapentadol were reported. Not adequate pain relief (NRS
scale 6.2±3.1; QUALEFFO-41 pain score 70±14.2) and impairment quality of life
(mean total QUALEFFO-41 score 65.1±20.1) were reported.

Conclusions: With the limits of the study design and low number of cases, pre-
liminary data seem to confirm an inadequate pain relief in PVF. The emerging crit-
ical issues across all categorieys of physicians are the lag of diagnosis, the
inappropriate use of acetaminophen, the missing titration of opioids or tapentadol.
A definition of optimal management of acute vertebral fracture is missing due to
conflicting and scarce evidences in this field predisposing to chronic pain and
disability.

AB0994

IMPACT ON THE ADHERENCE AND PERSISTENCE OF
DENOSUMAB VS WEEKLY BISPHOSPHONATE IN
HEALTH-RELATED QUALITY OF LIFE IN
POSTMENOPAUSAL OSTEOPOROSIS

G. Carlino1, R. Cinzia1, R. Maggio2. 1Rheumatology, ASL LE, Casarano; 2Internal
Medicine, ‘Vena Delli Ponti’ Hospital, Scorrano, Italy

Background: Long term adherence and persistence in patients undergoing treat-
ment for postmenopausal osteoporosis remains poor despite the proven efficacy
of the therapy.

Objectives: In this study, we evaluated whether greater adherence and persis-
tence in treatment can lead to an improvement in the quality of life.

Methods: A cohort of 268 patients, all women, in postmenopausal osteoporosis
divided into two groups was evaluated: ‘DEN Group’ (DEN) in treatment with
denosumab (n=131) and ‘BIS Group’ (BIS) in treatment with bisphosphonates
(n=137). Table 1 shows demographic and clinical data. Patients were followed for
3 years with baseline, 6 month, 18 month, and 36 month evaluation. The evalua-
tion criteria were the persistence in therapy and the self-related treatment compli-
ance, as well as the quality of life assessed with the 41-item Quality of Life
questionnaire for osteoporosis (QUALEFFO-41) performed at baseline, at 18 and
at 36 months.

Results: Table 2 shows the percentage of patients who abandoned treatment at
different times with a statistical significance towards both 18 and 36 months. In the
BIS the main reason for abandonment were the adverse events (gastrointestinal,
dental interventions, etc.), in the DEN the abandonment was due to drop-out. In
BIS, the most frequent reason for non-compliance with therapy was oversight,
and most patients who continued treatment always used the drugs regularly on
the recommended days and dosages. In the period of time considered the major-
ty of patients both BIS and DEN said they were satisfied with the treatment and
wanted to continue it. The QUALEFFO scores (Fig 1) of patients from the baseline
visit were significantly improved in the 36 month visit (BIS 79.6±25.4 vs 65.4
±14.6; DEN 80.2±18.5 vs 55.6*±16.4 (*p<0.001); the difference was not signifi-
cant between BIS and DEN group at both baseline visit and 36 month visit, but in
the DEN group there was significance between baseline and 36 month visit.

Abstract AB0994 – Table 1. Baseline characteristics (Mean±SD)
OC=Osteocalcin, CTX-C terminal telopeptide, PTH=parathyroid hormone.

Abstract AB0994 – Table 2. Percentage of patients who abandoned.

Conclusions: In conclusion, the observation, although numerically limited, notes
that the use of denosumab in patients with postmenopausal osteoporosis leads to
a greater persistence in treatment and a statistically significant adherence to ther-
apy, which allows to obtain the maximum therapeutic effect of the therapy, also
determining in 36 months of treatment an improvement in the quality of life, which
is not achieved in subjects treated with bisphosphonates.

Disclosure of Interest: None declared

AB0995

VERTEBRAL FRACTURES CASCADE: POTENTIAL
ETOLOGIES AND RISK FACTORS

H. Che1, V. Breuil2, B. Cortet3, J. Pacou3, F. Debias4, R.M. Javier6, N. Mehsen Cetre1, S. Loiseau Peres3, T. Thomas3, C. Roux3, K. Broit1,1, CHU
Lapeyronie, Montpellier, 2CHU Nice, Nice, 3CHU Lille, Lille; 4CH du Vire, Vire;
5CHU Poitiers, Poitiers, 6CHU Bordeaux, Bordeaux; 7CHR Orleans, Orleans; 8CHU Saint Etienne, Saint Etienne; 9CHU Cochin, Paris, France

Background: Vertebral fracture (VF) is the most common osteoporotic fracture,
and a strong risk factor of subsequent vertebral fracture. Prospective studies have
shown that a recent VF increases an imminent risk of a subsequent one, and
attention has been paid recently to a possible cascade phenomenon i.e. the
occurrence of multiples VFs in less than one year.

Objectives: This cascade could have severe consequences, and we prompted a
study to identify potential causes of osteoporosis and risk factors.

Methods: Vertebral fractures cascade (VFC) observations were collected retro-
spectively between January 2016 and April 2017. VFC was defined as the occur-
rence of at least 3 vertebral fractures within one year. Patients with other
eoetologies than osteoporosis (i.e. malignant or traumatic VFs) were excluded. The
cause of osteoporosis associated with VFC was the one retained by the physician
at the time of diagnosis.

Results: Ninety-five observations of VFC (80% of women, mean age of 71 years)
were collected in 10 centres (9 tertiary centres and 1 outpatient centre). The median
number of incident VFs over 1 year was 4.2-11 Forty-five patients (45.9%) had a
previous major fracture before the VFC and 65 (70.7%) had densitometric osteoporosis
(T-Score ≤−2.5 SD either at lumbar or femoral site). Eighteen (19%) patients
currently received oral glucocorticoids treatment at the time of VFC, with a mean
daily dose of 20 mg. Thirty-three (35.1%) patients received systemic glu-
corticoids in the past. The main comorbidities were history of cancer (n=19) and
chronic inflammatory diseases (n=21) including asthma (n=7), chronic obstructive
pulmonary disease (n=7) and rheumatoid arthritis (n=7).

A secondary osteoporosis associated with the cascade was diagnosed in 54
patients (54.5%) with the following causes: glucocorticoid-induced osteoporosis
(n=22, 23.7%), benign hemopathies (mastocytosis, MGUS) (n=7, 7.1%), use of
aromatase inhibitors (n=3, 3.1%), anorexia nervosa (n=3, 3.1%), alcoholism (n=3,
3.1%), pregnancy and lactation-associated osteoporosis (n=2, 2.1%), primary
hyperparathyroidism (n=2, 2.1%) and hypercorticism (n=1, 1.1%). In addition, 11
cases (11.3%) were reported following a vertebroplasty procedure. Primary
either postmenopausal or idiopathic osteoporosis was diagnosed in 48
patients (51.6%). A total of 29 (29.6%) patients previously received an anti-oste-
oporotic treatment. In six patients (6.3%), VFC occurred early (in the year) following
discontinuation of an anti-osteoporotic treatment: 5 after denosumab and one 12
months after an infusion of zoledronic acid.

Conclusions: The results of this retrospective study show that almost half of VFC
occurred in patients with secondary osteoporosis. While they suggest that a care-
ful management has to be given to these patients in order to prevent VFC in these
circumstances, prospective studies are needed to further explore the determi-
nants of such a severe complication of osteoporosis.

AB0996

BONE MINERAL DENSITY AT DIFFERENT SITES AS A
PREDICTOR OF RIB FRACTURES: A CASE-CONTROL
STUDY

H.L. Wu, M. Bukhari. Rheumatology, University Hospitals of Morecambe Bay NHS
Foundation Trust, Lancaster, UK

Background: Rib fractures commonly occur as a result of direct trauma, though
pathological causes have also been identified. Literature on the specific risk fac-
tors of rib fractures is scarce. There was an American prospective cohort study
which highlighted the relationship between risk factors of osteoporosis and rib fractures in older men aged 65 or above. It was observed that the incidence of rib fractures was 3.5/1000 years. Only 3% of rib fractures occurred with absence of trauma. Bone mineral density (BMD) is an important measure for predicting various bone fractures. However, prediction of rib fractures using BMD measurement in different body sites is not reported.

Objectives: To determine if reduction in femoral neck and lumbar spine BMD are predictive of rib fractures.

Methods: Patients referred from primary care to a DEXA scanner in the north west of England between January 2006 and December 2016 were used in this study. Patients with a history of rib fractures at first scan were matched with controls who did not have any indication for scanning. Cases and controls were matched for age and gender. Differences in BMD at L1-L4 spine and the femoral neck were analysed using two-sample t test. Logistic regression models were fitted to analyse the association between lumbar spine and femoral neck BMD and rib fracture occurrence. The fit of each model was compared using receiver operating characteristic (ROC) curves.

Results: A total of 1554 patients were included in the study (777 cases of rib fractures and 777 controls). Mean age for both cases and controls were 62.5 years (SD 12.0). 605 patients (77.9%) were female in both the case cohort and the controls. The mean T score in the lumbar spine is 1.00 in cases versus 1.10 in controls (diff 0.100 95% CI, 0.448, 0.142 p<0.001). The mean T score in the femoral neck is 0.812 in cases versus 0.935 in controls (diff 0.123 95% CI, 0.108, 0.137 p<0.001). The odds of lumbar spine BMD and femoral neck BMD were 0.111 (95% CI 0.0640, 0.194, p<0.001) and 0.00209 (95% CI 0.000963, 0.00485, p<0.001) respectively. The areas under ROC curve (AUC) for lumbar spine BMD and femoral neck BMD were 0.623 and 0.733.

Conclusions: This study demonstrated that reduction in BMD at the lumbar spine and femoral neck positively correlated to the risk of rib fractures. Reduction in femoral neck BMD is a stronger predictor of the two. Prediction of rib fractures could be affected by other factors influencing lumbar spine and femoral neck BMD. Further work in different demographic groups should be done for comparison and analysis.

AB0997 CLINICAL CHARACTERISTICS OF NON-RESPONDER TO DENOSUMAB TREATMENT FOR POSTMENOPAUSAL OSTEOPOROSIS IN JAPANESE WOMAN

Yoshi. Orthopaedics, YOSHI HOSPITAL, Shintomo City, Japan

Background: Denosumab (d-mab), an anti-receptor activator of nuclear factor kappa-B ligand (RANKL) monoclonal antibody, is now widely used in postmenopausal osteoporosis (OP) treatment. It can attain reliable increase of bone mineral density (BMD) despite any OP drugs previous used, and that can be predicted in a long period. However, sometimes we observe BMD decrease. Factor that suppresses BMD gain is still unclear.

Objectives: This study investigates non-responder to d-mab, and attempted to evaluate factors that concerns non-responder in clinical practice retrospectively.

Methods: 212 postmenopausal OP patients have been treated with d-mab discontinuously for more than two years under vitamin D supplement and calcium since June 2013. These patients were enrolled, and their clinical background (CBs), such as age at start of d-mab, past history of bone fragility fracture, alcohol habit, current smoking, being treated for rheumatoid arthritis (RA), glucocorticoid steroid thrown, OP drug naive, length of administration (LA), concurrence of lifestyle disease (LD) such as diabetes mellitus, hypertension, and chronic obstructive lung disease (COPD), and number of comorbidity (N.Com), were investigated (table 1a). BMD of lumbar spine (LS), femoral neck (FN), greater trochanter (GT), and whole femur (WF) at the start and every six months thereafter were measured. Tartrate-resistant Acid Phosphatase 5b (TRACP5b) and total dose of type-one pro-collagen-N-propeptide (P1NP) at the same time of BMD measurement, and reduction ratio (RR) of them compared to the first shot were calculated. Patients were divided into two groups whether BMD increased. BMD in each part at final measurement was compared and the result was compared statistically with paired T-test. CBs were statistically evaluated between the two BMD groups (Res and n-Res; Responder and non-Responder) with Mann-Whitney U-test (MWT), and then correlation between the BMD groups and factors of CB that had demonstrated significantly difference, and TRACP5b and P1NP was also evaluated statistically with Binary Logistic Analysis (BLR). Statistical significance was set less than 5%.

Results: For all patients, BMD in LS, WF did not demonstrated significant increase at final measurement than at start (p<0.001), while FN demonstrated no significant increase. However, n-Res counted 30, 89, 46, and 44 for LS, FN, WF, and GT, respectively. LA demonstrated negative significant correlation for being n-Res in all part, while LSD, N.Com, TRACP5b at start and, RR of TRACP5b at second shot and last shot, demonstrated significant positive correlation in LS with MWT. However, with BLR, only RR of TRACP5b at second shot demonstrated significant negative correlation with n-Res in LS (OR:0.0702, 95% CI:0.0058–0.9655) with 0.39 cut-off index (COI), while no other factors but LA demonstrated negative significant correlation with n-Res in WF (OR:0.9669, 95% CI:0.9433–0.9911) and GT (OR:0.9632, 95% CI:0.9391–0.9878) with 26 and 24 months COI, respectively (table 1b).

Table 1a Patient’s background. Age at Start, Length Administered, Number of Chronic Comorbidities, and Bone Mineral Density, show average value and standard deviation. The other parameters show numbers.%YAM.% of young adult mean value. LS: lumbar spine, FN: femoral neck, WF: whole femur, GT: greater trochanter, SERM: selective oestrogen receptor modulator.

Table 1b Parameters that demonstrated significant difference between responder and non-responder to denosumab, and their p-values, and results of these parameters with binary logistic regression analysis. LS: lumbar spine, FN: femoral neck, WF: whole femur, GT: greater trochanter, LSD: concurrence of lifestyle disease, LA: length of administration, N.Com: number of concurrent comorbidities, TRACP5b at start; tartrate-resistant acid phosphatase 5b (TRACP5b) at start of administration, rTRACP5b@1stP: reduction ratio of TRACP5b of second shot compared to the first, rTRACP5b@LT: reduction ratio to TRACP5b of last shot compared to the first, Drug Naive: initial drug as osteoporosis treatment, P1NP: total dose of type-one pro-collagen-N-propeptide.

Conclusions: These results suggest that non-responder to d-mab exists. Length of administration works for BMD to increase in femur, and concurrence of LSD, and N.Com are suggested to be risk factors in LS. Less reduction ratio of TRACP5b at second shot is referred for prediction of non-responder. However, there is no parameter that predicts non-responder before administration.

Disclosure of Interest: None declared

AB0998 OSTEOPOROSIS PREVALENCE IN POST-MENOPAUSAL PATIENTS TREATED WITH AROMATASE INHIBITORS USING BONE MINERAL DENSITY VALUES FROM A SPANISH POPULATION

J. Loarca-Martos1, W.A. Silfuentes-Giraldo1, L.V. Maldonado-Romeró2, M. Anijón-Lana1, C. Velázquez-Arce1, N. Martinez-Jaíres2, M. vazquez-Diaz1, 1Rheumatology, Ramon y Cajal University Hospital, Madrid, Spain; 2Rheumatology, Hospital Trinitat, Barcelona, Spain

Background: The majority of cases of breast cancer (BC) are hormone receptor positive and are sensitive to aromatase therapy. For postmenopausal women, adjuvant hormonal therapy with an aromatase inhibitor (AI) is the standard of care, and is associated with greater prevalence of osteoporosis (OP). Definition of osteoporosis is made depending on the T-Score value, which is calculated according to the bone mass peak obtained from a reference population; in our country, BMD reference values in clinical practice are obtained from the National Health and Nutrition Examination Survey cohort (NHANES III) for femoral neck (FN) and those proportionated by the commercial brand Hologic for lumbar spine (LS), which may not be representative of our population and could be distorting the assessment of OP in our patients.

Disclosure of Interest: None declared
Objectives: To assess the prevalence of OP in Spanish postmenopausal patients diagnosed with BC and treated with AI using BMD values obtained from a local cohort for T-score calculation.

Methods: We performed a cross-sectional study with postmenopausal women diagnosed with BC and treated with AI attended at our hospital between August 2011 and December 2014. We estimated BMD for LS and FN using dual X-Ray absorptiometry. The prevalence of OP in our cohort was assessed using BMD reference values from the Spanish cohort of Diaz-Curiel\(^2\), which included a group of 2442 healthy patients from both genres stratified by age, and compared it with OP prevalence obtained using clinical practice reference values applied in our country (NHANES III/Hologic).

Results: A total of 54 patients were included. The mean age at diagnosis was 61.50±5.00 years. The AI used in both groups was letrozole. For LS we didn’t find statistically significant differences between both groups. For FN we found 13 patients (24%) with OP according to NHANES/Hologic, and 8 patients (14.8%) according to Diaz-Curiel values. These values are summarised in the table.

### Abstract AB0999 – Table 1

<table>
<thead>

<td></td>
</tr>
<tr>
<td>Osteopenia: 16 (29.6%)</td>
<td>Osteopenia: 15 (27.7%)</td>
<td>Mean T-score: −1.77</td>
<td>Mean T-score: −1.57</td>
<td></td>
</tr>
</tbody>
</table>

Conclusions: In our study, we observe statistically significant differences in osteoporosis prevalence for FN, and around 10% of patients could be reclassified using our local BMD values, which highlights the relevance of the use of BMD values obtained from local population for T-score calculation.

**OPPORTUNISTIC SCREENING FOR OSTEOPOROSIS USING THORACO-ABDOMINO-PELVIC COMPUTED TOMOGRAPHY FOR ASSESSMENT OF VERTEBRAL DENSITY IN RHEUMATOID ARTHRITIS PATIENTS**

J. Perier-Comel\(^1\), I. CHARY-VALCKENAERE\(^1\), D. LOEUILLE\(^1\), A.Y. OMOROU\(^2\), \(^1\)Rheumatology; \(^2\)INSERM CIC-1433 Clinical Epidemiology, CHU NANCY, NANCY, France

Background: Screening for osteoporosis is crucial in rheumatoid arthritis (RA) patients. Computed tomography (CT) attenuation assessment has been proved to be of interest in general population for detection of osteoporosis.

Objectives: To assess the value of thoraco-abdomino-pelvic CT-derived bone mineral density (BMD) in L1, compared with dual energy X-ray absorptiometry (DXA) for osteoporosis screening in rheumatoid arthritis patients.

Methods: Consecutive RA patients who underwent a CT-scan and a DXA within a two-year period are retrospectively included. CT sagittal images are evaluated from T4 to L5 for vertebral fractures according to Genant classification. CT attenuation values (in Hounsfield units [HU]) of trabecular bone in L1 are measured on axial images and compared to DXA results.

Results: One hundred and five patients (mean age 61.1 years (±9.5), 78.1% women) were included. Twenty-eight patients (26.7%) have DXA-defined osteoporosis and 32 (30%) have osteoporotic fractures (vertebral and/or non-vertebral). According to CT assessment, mean (SD) vertebral L1 attenuation is 142.2 HU (-18.5). The diagnostic performance for vertebral CT-attenuation measurement was good, with an AUC of 0.67 for predicting osteoporotic fractures and of 0.69 for predicting vertebral fractures. Among 31 patients with osteoporotic fractures, 23 (74%) patients are categorised as osteoporotic with L1 CT-attenuation of 135 HU or less, whereas only 13 patients (42%) with DXA.

Conclusions: This technique offers a combined opportunistic screening for osteoporosis by assessing both vertebral fractures and bone density on routine CT-scans. This seems of particular interest in RA patients who are at high risk for osteoporosis.

**ASSOCIATION OF SERUM URIC ACID LEVEL WITH BONE MINERAL DENSITY AND OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS**

J. H. Ko\(^1\), S.-G. Lee\(^1\), H.-N. Lee\(^1\), E. Kim\(^2\), D. H. Sohn\(^2\), Y. Kim\(^3\), G. T. Kim\(^3\), \(^1\)Internal Medicine, Pusan National University School of Medicine, Pusan National University Hospital, Busan; \(^2\)Microbiology and Immunology, Pusan National University School of Medicine, Yangsan; \(^3\)Internal Medicine, Kosin University College of Medicine, Busan, Korea, Republic of Ireland

Background: Previous studies have reported that higher serum uric acid (SUA) levels are associated with higher bone mineral density (BMD) in men and postmenopausal women, and lower risk of fragility fracture in men. However, whether this association is also present in patients with rheumatoid arthritis (RA) has not yet been investigated.

Objectives: To examine the association of SUA levels with BMD and osteoporosis in postmenopausal women with RA.

Methods: We retrospectively evaluated 447 postmenopausal female RA patients (mean age 61.1 years) who underwent measurement of L1–4, femoral neck, and total hip BMD using dual energy X-ray absorptiometry, in addition to SUA levels at a university rheumatology centre in South Korea between 2004 and 2017. Osteoporosis was defined as a T-score of < −2.5 according to the World Health Organisation classification.

Results: The median (interquartile range) SUV level was 4 (3.3–4.8) mg/dL. The mean (±SD) L1–4, femoral neck, and total hip BMD were 0.93±0.16 g/cm², 0.75±0.12 g/cm², and 0.81±0.12 g/cm², respectively, and the frequencies of osteoporosis in the spine, hip, and either site were 25.6%, 15.9%, and 32.5%, respectively. SUA levels were positively correlated with L1–4 (r=0.102, p=0.032), femoral neck (r=0.123, p=0.01), and total hip BMD values (r=0.146, p=0.002) and body mass index (r=0.231, p<0.001), and negatively correlated with glomerular filtration rate (r=−0.363, p<0.001) in Spearman correlation analysis. In multivariable linear regression models adjusted for confounding factors, SUA levels showed a significant positive association with femoral neck BMD (β=0.0099, p=0.015) and total hip BMD (β=0.0086, p=0.159) as shown in table 1. In addition, multivariable logistic analysis revealed that the third (OR=0.44, p=0.038) and fourth SUA quartiles (OR=0.37, p=0.021) were associated with lower risk of hip osteoporosis, as compared with the first SUA quartile. However, this association was not observed in lumbar spine osteoporosis.

*Estimated using stepwise multivariable linear regression models adjusting for age, BMI, DAS28-ESR, cumulative GCs dose, disease duration and eCOPR.

Conclusions: Higher SUA levels were associated with a reduced risk of low BMD and osteoporosis at hip in postmenopausal women with RA, but no significant association between SUA levels and lumbar spine BMD was found. Our data suggests that uric acid may act as a protective factor against hip bone loss in RA patients.

MANAGEMENT OF GLUCOCORTICOID-INDUCED OSTEOPOROSIS IN RHEUMATOID ARTHRITIS: THE EXAMPLE OF THE "RIC NORD DE FRANCE" COHORT

J. Corli1, G. Baudens2, R.-M. Filipo1, B. Cortel1, on behalf of RIC-Nord-de France.
1 Rheumatology, CHRU Lille, Lille; 2Rheumatology, Va[len]cien[n]es, Va[len]cien[n]es, France

Background: Glucocorticoid-induced osteoporosis (GIOP) is the most common cause of secondary osteoporosis. Patients followed for Rheumatoid Arthritis (RA) are particularly exposed to OP and have a greater risk of fracture, which must be prevented. The newest French guidelines for GIOP management were published in 2014 and it is not known yet how they are applied in real life.

Objectives: The objective of our study was to investigate the treatment of glucocorticoid-induced osteoporosis in the Rhumatismes Inflammatoires Chroniques – Nord de France (formerly known as RIC-NPC) network in 2016 for patients with rheumatoid arthritis.

Methods: In this observational study, the patients studied were followed in the RIC network for RA from 2004 until June 2016, had at least one bone mineral density (BMD) assessment and glucocorticoid therapy during follow-up. Demographic characteristics of patients, BMD results, fractures and treatments implemented were collected from network data completed during consultations by practitioners.

Results: 647 patients were enrolled, including 511 women (79%). The average age of patients was 65.5 years (SD=12) with a mean ASAS28 of 3.91 (SD=1.44), mean dose of steroid of 7.6 mg (SD=6.6) and a mean duration of treatment of 49 months (SD=53.7). The average T-score at the first BMD assessment was –0.99 at the spine and –1.03 at the total hip. 298 patients received an anti-osteoporotic treatment (46%). Treated patients were older (p<0.0001), with lower weight at the spine and 1.5 SD (p<0.0001).

Conclusions: Our study has the advantage of reflecting the management of GIOP in a ‘real life’ cohort. Almost half of our patients followed for RA who received corticosteroids had received treatment. According to French guidelines the number of patients requiring an anti-osteoporotic treatment should be higher.

DIFFERENCES IN BONE METABOLISM BETWEEN INTERMITTENT AND CONTINUOUS TREATMENT WITH LHRH AGONISTS IN PROSTATE CANCER PATIENTS

K.R. Arevalo1,1*, J. Ivorra1, C. Vera1, E. Grau1, I. Chalmeta1, L. Gonzalez2, R. Negueruelas1, C. Alcaliz1, I. Canovas1, C. Feced1, J.J. Frago1, R. Gonzalez1, E. Labrador1, I. Martinez1, C. Najera1, J.E. Oliver1, F.M. Ortiz2, E. Vicenta2, M. de la Rubia3, D. Hervas3, J.A. Roman1.
1Rheumatology Department; 2Urology Department; 3Biostatistical Unit, University of Valencia, Valencia, Spain

Background: Prostate cancer is a hormone dependent neoplasia, therefore androgenic inhibition by LHRH agonists is the mainstay of treatment. There are different treatment regimen options: continuous or intermittent in order to decrease side effects. As for the bone effects, therapy with LHRH agonists increases bone resorption and decreases bone mineral density (BMD) altogether increasing the risk of fracture. The influence of the different treatment regimen in bone metabolism has not been studied enough.

Objectives: To evaluate the effect of the LHRH agonists therapy different regimens on bone metabolism in prostate cancer patients, and whether antiresorptive treatment influences the evolution of BMD according to LHRH agonists treatment.

Methods: We recruited patients from the Prostate Cancer Protocol of Osteoporotic Risk Assessment in our institution. The patients were evaluated in a basal visit (month 0) and 6–12–18–24 months after basal evaluation. Data of bone metabolism biomarkers, BMD values, LHRH agonists regimen and antiresorptive treatment was collected. Biostatistical analysis with software R was performed.

Results: We reviewed 69 patients and 52 prostate cancer patients without bone metastasis with 12 months follow up were selected. The mean age at cancer diagnosis was 68.92 (8.44) years old, with a mean Gleason score of 7.8. 81% of patients had LHRH agonists active treatment, 81% of them were under continuous treatment scheme. 39% of patients initiated antiresorptive therapy, 24% with intermittent LHRH agonists and 76% with continuous LHRH agonists. At the basal evaluation 12% of patients had osteoporosis and the 32% had osteopenia. 43% of patients displayed viD levels under 20 ng/mL.

Antiresorptive treatment influenced lumbar spine, femoral neck and hip BMD values (p<0.001). In patients with antiresorptive treatment, LHRH agonists intermittent scheme did not have an independent effect in any locations of BMD. In patients without antiresorptive therapy intermittent LHRH agonists regimen have a positive effect on BMD in total hip and lumbar spine increasing their values compared to those on continuous LHRH agonists regimen. The effect in lumbar spine depends on the time of the intermittency. LHRH agonist intermittent therapy showed no significant influence on T score values of femoral neck, this effect was independent of antiresorptive therapy. In patients without antiresorptive treatment elevated beta-CTX levels were related to a decrease of BMD values (p<0.017).

No fractures were reported during the follow up period.

Conclusions: In our patients there is a high prevalence of viD deficiency. Antiresorptive therapy had a positive effect in the BMD on both LHRH agonists treatment schemes. Patients without antiresorptive treatment under an intermittent LHRH agonists scheme display a better evolution in BMD values compared to those under a continuous scheme. In patients without antiresorptive treatment the evolution of BMD values was related to beta-CTX levels during follow up.

Disclosure of Interest: None declared.

USEFULNESS OF DOPPLER ULTRASOUND EXAMINATIONS FOR DETECTING DEEP VENOUS THROMBOSIS DURING THE PERIOPERATIVE PERIOD IN PATIENTS WITH OSTEOPOROTIC FRACtURES OF THE PROXIMAL FEMUR

K. Nakaseko, N. Mayumi. Department of Orthopaedic Surgery and Rheumatology, KUWANA CITY MEDICAL CENTER, Kuwana Me, Japan

Background: Deep venous thrombosis (DVT) can lead to a venous thromboembolism and increase the risk of a pulmonary thromboembolism (PE). PE is one of the most common causes of death in hospitalised surgical patients. Although there have been some prospective studies regarding the prevalence of DVT on Doppler ultrasound examinations of the lower extremities, there have not been any prospective studies in which three consecutive Doppler ultrasound examinations were performed to detect DVT during the perioperative period. The purpose of the present study was to prospectively evaluate the occurrence of DVT in patients with osteoporotic fractures of the proximal femur, based on the results of examinations involving three consecutive ultrasound scans. In addition, the usefulness of the d-dimer level as a predictor of DVT was investigated.

Objectives: This study was a single-centre prospective study. One hundred-five patients (18 males and 87 females) between the ages of 46 and 97 years with osteoporotic fractures of the proximal femur were enrolled. All patients were asymptomatic in terms of their clinical DVT findings.

Methods: Three Doppler ultrasound examinations of the lower extremities were conducted in each case: on admission, one day before surgery, and one week after surgery. The period from admission to surgery ranged from 2 to 8 days (mean: 5.4 days). The d-dimer level was measured at one week after surgery and its relationship with the presence/absence of DVT was evaluated by calculating sensitivity, specificity, positive predictive value, and negative predictive value.

Results: DVT was detected in 20 patients (2 patients on admission, 9 patients one day before surgery, and 9 patients one week after surgery). The overall prevalence of DVT in the perioperative period was 19.0% (20/105). As for the characteristics of the patients that did and did not develop DVT, there were no significant differences between the two groups. When the d-dimer cut-off level was set at 4.3 µg/mL, the sensitivity and negative predictive value reached 100%, while the specificity was 16.5%, and the positive predictive value was 22.0%. A receiver operating characteristic (ROC) curve was drawn, and the optimal d-dimer cut-off level was examined. The ROC curve was closest to the upper left corner when the d-dimer cut-off level was 12.2 µg/mL. At that point, the sensitivity, specificity, positive predictive value, and negative predictive value were 55.0%, 69.4%, 28.9%, and 86.8%, respectively.
Conclusions: In this prospective study, DVT was detected in 2 patients on admission, 9 patients one day before surgery, and 9 patients one week after surgery. As DVT can occur at any moment, performing repeated Doppler ultrasound examinations in the perioperative period is useful for quickly detecting DVT, which can cause PE. As for the d-dimer level, its sensitivity and negative predictive value reached 100% at a cut-off level of 4.3 mg/ml. Therefore, d-dimer assays could be a useful screening tool for DVT and might be a suitable substitute for Doppler ultrasound examinations.

AB1004 OSTEOPOROSIS SCREENING IN A TERTIARY RHEUMATOID ARTHRITIS CLINIC. WHO’S SCREENING NOW?

L. Kyi1, T. Kovitwanichkanont1,2, D. Wang3, N. Walpola4, S. Raghunath1,3, S. Pignataro1, S. Morton1, M. Leech1,3, N. Walpola3, S. Raghunath1,3, S. Pignataro1, S. Morton1, M. Leech1,3, N. Walpola3, S. Raghunath1,3, S. Pignataro1, S. Morton1, M. Leech1,3

Background: Osteoporosis is a complication of rheumatoid arthritis (RA) due to inflammatory disease and treatment with glucocorticoids. Screening and management of osteoporosis (OP) is shared amongst General Practitioners (GP) together with subspecialists including rheumatologists.

Objectives: To assess the adequacy of osteoporosis screening in a tertiary RA clinic in Melbourne, and to determine where most screening is occurring.

Methods: A cross-sectional study of patients at a tertiary RA clinic was undertaken. Osteoporosis screening, therapy and related factors were evaluated. This was compared to best practice screening ACR/GIOP guidelines.

Results: 116 RA patients, 66% female (median age 58 years) were included. OP screening occurred in 61.2% of patients with 40.5% and 20.7% performed by their rheumatologist and by the GPs respectively. The remainder 38.8% of patients recalled no recent screening. 36.2% of patients were taking prednisolone, while 74% reported prior exposure. 58.6% of patients had prednisolone for over 3 months. Calcium or vitamin D supplementation was noted in 62% of the population; 21.6% reported a history of minimal trauma fracture and alarmingly only 10% reported currently taking anti-resorptive therapy. 47% of patients had a DEXA scan performed within the last 3 years. Of the 53% that did not have a recent DEXA scan, three quarters had indications for osteoporosis screening based on the 2010 ACR/GIOP guidelines. 35 patients had indications based on age, 11 patients based on glucocorticoid exposure and 1 patient based on history of minimal trauma fracture.

Disclosure of Interest: None declared

AB1005 RELATIONSHIP BETWEEN AUTOIMMUNITY AND OSTEOPOROSIS IN RHEUMATOID ARTHRITIS

M.C. Carnisco Cubero1, S.M. Rojas Herrera2, J. Malave Calzada2, P. Pérez David2, I. Braña Abascal2, E. Chamizo Carmona1, Rheumatology, CHU de Badajoz; 2Rheumatology, Hospital de Mérida, Mérida, Spain

Background: Osteoporosis (OP) is more prevalent in patients with rheumatoid arthritis (RA) than in the general population. Positive anti-citrullinated peptide antibody (ACPAb) has been related with juxta-articular OP, but their relationship with systemic OP in RA is controversial.

Methods: Observational study. We analysed the relationship between RF and/or ACPAb with the DXA BMD values of the femoral neck (FN) and lumbar spine (LS) (GE LUNAR Prodigy). We perform the analysis using logistic regression, bi and multivariate models, and correlation models. The control variables were sex, body mass, age, duration of RA, prednisone and vitamin D.

Results: We included 294 patients with RA who had all the tests, with a mean age of 63.4 (±10.9) years and duration of RA of 9.8 (±7.8) years. There were 229 (77.9%) women, 229 (77.9%) positive-RF, 196 (66.7%) positive-ACPAb, 109 (37.1%) deficient in 25-OH cholecalciferol (<20 ng/ml) and 59 (20.1) smoker patients. They received corticosteroids at low doses 207 (70.4%) and suffered some bone fracture 42 (14.3%) patients. In the BMD, 226 (77.9%) had a T-score <0.5, of whom 86 (27.6%) reached a T-score <-2.5 in LS and/or in FN.

Disclosure of Interest: None declared
Lumbar OP was associated with the female sex (OR=3.6). The FN T-score (and, to a lesser extent, lumbar T-score), showed a correlation with age (r = -0.515, p<0.01). No differences were found in the mean values of BMD, T-score y Z-score of FN and LS between positive or negative patients for FR or ACPA (t-student), neither between their possible combinations (one-way ANOVA). Association between positivity of RF, ACPA or their combinations and T-score < -1 (osteopenia) or T-score < -2.5 (OP) in LS or FN were not found. A negative weak correlation was found between the RF and lumbar BMD values (~0.121, p=0.04) and a positive weak correlation between ACPA and FN (0.136 with BMD, 0.131 with T-score and 0.038 with Z-score; p<0.05 for all).

### SEASONAL VARIATIONS OF 25-HYDROXYVITAMIN D3 LEVELS AND ITS RELATION TO PARATHYROID HORMONE LEVELS

**M.A. Teran Tinedo, P. Cristina, HOSPITAL RAMON Y CAJAL, MADRID, Spain**

**Objectives:** To analyse the relationship between 25-hydroxyvitamin-D3 and parathyroid hormone levels and to determine its variation between the different seasons of the year.

**Methods:** An observational descriptive study was carried out, collecting and analysing 25-hydroxyvitamin-D3 (25OH-D3) and parathyroid hormone (PTH) serum levels of patients from January to December of 2017. The frequencies distribution analysis of both variables was compared and Pearson’s correlation coefficient (PCC) was used to analyse linear relationship between them. The results were classified by date in four seasons: winter, spring, summer, and autumn, assessing the mean seasonal oscillations of each variable and calculating correlation in each case. Different levels of 25OH-D3 were evaluated in order to identify differences in the grade of correlation.

**Results:** Serum samples from 6265 patients were recollected. 59% of the patients had 25OH-D3 levels lower than 25 ng/ml. Pearson’s correlation coefficient between both variables was ~0.15 (p<0.01). The mean values of 25OH-D3 were calculated for each seasonal period, establishing a mean level of 23 ng/ml for winter, 25 ng/ml for spring, 31 ng/ml for summer and 29 ng/ml for autumn. Regarding PTH levels, the mean values for each season were 108 pg/ml, 101 pg/ml, 86 pg/ml and 84 pg/ml from winter to autumn respectively. PTH/Vitamin D correlation was also assessed for each period: Pearson’s correlation coefficient during winter was ~0.06 (p<0.01), for spring ~0.24 (p<0.01), for summer ~0.21 (p<0.01) and for autumn ~0.19 (p<0.01). At last, correlation calculated with deficiency levels of 25OH-D3 (<30 ng/ml) was ~0.18 (p<0.01), and with levels inferior than 10 ng/ml was ~0.12 (p<0.01).

**Abstract AB1007 – Figure 1**

**Conclusions:** Linear correlation between levels of 25OH-D3 and PTH could not be established in our study, not even using levels classified as vitamin D deficiency. 25OH-D3 levels tended to increase from winter to summer whereas PTH levels decreased inversely during these seasons, without any linear correlation.

### COMPARISON OF BONE MINERAL DENSITY BETWEEN RHEUMATOID ARTHRITIS PATIENTS AND HEALTHY INDIVIDUALS OVER SEVEN YEARS FROM THE TOMORROW STUDY

**M. Tada1, K. Inui2, Y. Sugikawa2, T. Okano2, Y. Yamada2, K. Mandai2, K. Mamoto2, T. Koke3, H. Nakamura3.**

**1Orthopaedic Surgery, Osaka City General Hospital;**

**2Orthopaedic Surgery; 3Center of Senile Degenerative Disorders, Osaka City University Graduate School of Medicine, Osaka, Japan**

**Background:** Despite advances in treatment, rheumatoid arthritis (RA) remains a key cause of secondary osteoporosis and is also a risk factor for fragility fracture. We have previously reported that bone mineral density (BMD) was lower in patients with RA than in healthy individuals (HI) and examined changes in BMD over 3 years.

**Objectives:** To observe BMD changes over 7 years and identify factors that affect BMD changes in patients with RA.

**Methods:** We analysed data from the TOMORROW study (UMIN000003876), a prospective cohort for patients with RA and age- and sex-matched HI. BMD was measured at three parts (whole body, lower limb, lumbar spine) using dual-energy X-ray absorptiometry (DXA). We compared the percentage change in BMD (%Δ BMD) at the three parts in RA and HI from 2010 to 2017. Factors affecting %Δ BMD in RA were analysed.

**Disclosure of Interest:** None declared

AB1010  RISK OF INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS TAKING DENOSUMAB CONCURRENT WITH BIOLOGIC THERAPY

M. Zabieyeganeh1, A.M. Mirzade2, S.A. Jaheid2. 1Rheumatology, Bone and Joint
Reconstruction Research Center, Shafa Orthopedic Hospital, Iran University of Medical Sciences; 2Endocrinology, Diabetes Advisory Committee, Gabric Diabetes Education Association, Tehran, Iran, Tehran, Iran, Islamic Republic of Iran

Background: Apart from Denosumab effects on bone, there are some promising data on its inhibitory effect on structural damagies patients with rheumatoid Arthritis (RA). Despite some clinical concerns on its potential harm for increasing risk of infections, Denosumab is officially approved for the treatment of postmenopausal osteoporosis. Still there are even greater debates on its use and predisposing patients to infection in cases receiving immunosuppressive therapy.

Conclusions: Our study proved the good agreement between the VFA and the standard X-ray in the detection of VFs. This shows the sensitivity of this technique which has the advantages of low cost and less irradiation.

Disclosure of Interest: None declared

RESULTS: Participants comprised 172 HI and 119 RA, after excluding those who dropped out (HI, n=21; RA, n=19) or underwent implant surgery (HI, n=12; RA, n=60). Height and weight reduced significantly over 7 years (p=0.001) each in both groups (table 1). The %BMDs of RA were –2.6% (whole body), –3.6% (lower limb), and 1.8% (lumbar spine), compared to –2.0%, –2.7%, and 0.6%, respectively, for HI. No significant differences in BMD for the whole body or lower limb were seen during 7 years, while BMD of the lumbar spine was significantly increased in both groups (p=0.001). No significant differences between groups were identified. In patients with RA, DAS28ESR improved significantly over 7 years (p=0.008; table 1) and %BMD of the lumbar spine correlated significantly with cumulative period of treatment for osteoporosis (r=0.341, p<0.001). The cumulative period of osteoporosis treatment was identified as a regulatory factor for increasing BMD of the lumbar spine (odds ratio: 1.36; p=0.003) adjusted by age and sex (table 2). However, cumulative period of biologics, change of glucocorticoid and DAS28ESR were not detected as factors affecting BMD by logistic regression analysis.

Background: Osteoporosis (OP) is a systemic bone disease characterised by decreased bone mass and deterioration of bone microarchitecture with increased brittleness and fracture risk. This is associated with high rates of morbidity and mortality for patients and has a high impact on health expenditure. Bone marrow stromal mesenchymal stem cells (BM-MSC) give rise to osteoprogenitor cells and osteoblasts and influence bone homeostasis. However after their intravenous (i.v) infusion their osteotropism is limited. Our group has demonstrated that the exofucosylation of the CD44 membrane antigen in MSC improves their homing to bone tissue and that the infusion of these cells is safe in a murine model.

Objectives: To evaluate the safety of i.v infusion of fucosylated BM-MSC in patients with OP, and secondarily assess their ability to improve the course of the disease.

Methods: 10 women between 50 and 75 years old diagnosed with osteoporosis with a low impact fracture will be included and treated i.v with autologous fucosylated BM-MSC. The first 4 patients were treated with a dose of 2 x 10⁶ cells/kg body weight and the other 6 with 5 x 10⁵ cells/kg body weight. A 24 month follow-up will be conducted to evaluate the rate of severe and non-severe adverse events and secondary endpoints (decreased fracture rate, pain scores, functional status and quality of life, biochemical indexes of bone metabolism, quantitative computed tomography for morphometric and mechanical analysis of bone quality, densitometry, and histomorphometry).

Results: Seven patients have been recruited to date. Two left the study for lack of cell proliferation and appearance of a complex form in karyotype during the cell culture, respectively. The first 4 patients were successfully infused, and after a median follow-up of 3 months no related adverse effects have been observed, no new osteoprotective fractures have appeared, and the analogue pain scale score (EVA) shows a tendency to decrease of pain in 3 of the 4 patients.

Conclusions: Our preliminary data indicate that clinical and GMP-grade production of BM-MSC is feasible. We have not observed any short-term adverse effects associated with treatment in infused patients.

PREDICTION OF BONE MINERAL DENSITY CHANGES IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. Tomizawa1, H. Ito1, M. Furui1, M. Hashimoto1, M. Tanaka1, T. Mimori1, S. Matsuda1, 1Orthopedic Surgery; 2Rheumatology and Clinical Immunology, Kyoto University Graduate School of Medicine, Kyoto-City, Japan.

Background: Osteoporosis and its related fractures is one of the most dominant, troublesome complications in rheumatoid arthropathies (RA). Newly-introduced drugs such as methotrexate and biological and targeted synthetic disease modifying anti- rheumatic drugs have decreased disease activity drastically, but the improvement of osteoporosis remains to be investigated.

Objectives: To find useful factors for bone mineral density (BMD) management of RA patients under the current treatment.

Methods: We consecutively recruited 370 RA patients treated at Kyoto University Hospital in 2012. We prospectively collected the BMD values of the lumbar spine and the distal forearm measured by dual-energy X-ray absorptiometry (DXA) blood sampling test, urinalysis including bone metabolic biomarkers and clinical parameters of the RA patients in 2012 and 2014. Multivariate regression analysis was performed after adjustment by age, sex, body mass index (BMI), steroid use, anti-osteoarthritis medication. We set the annualised BMD change as an outcome variable and allotted the other parameters as explanatory variables by a stepwise procedure.

Results: The average values (minimum-maximum value) of age and BMI were 63.3 (32.8–85) years and 22.1 (12.3–30.0), respectively. Female patients and steroid users accounted for 91.1%, and 41.0%, respectively. Coincidentally, anti-osteoporosis drug-user also reached 41.0%. User of biological accounted for 3.8%.

The averages of disease activity score (DAS) 28-erythrocyte sedimentation rate, Health Assessment Questionnaire was 2.6 (0.1–5.9) and 0.8 (0–2.9), respectively. The average of total Sharp score was 122.6 (0–443). Laboratory data showed serum tartrate-resistant acid phosphatase (TRACP) –5b, serum homocysteine, serum undercarboxylated osteocalcin, bone specific alkaline phosphatase, and urinary pentosidine were 320.0 (68–877) μL/dL, 9.7 (3.2–23.9) μL/dL, 4.8 (0–23) μg/L and 50.0 (11.5–561) μg/L, respectively. Next, we describe by the result of multiple regression analysis, the levels of serum homocysteine (β=0.19; 95% CI: 0.24 to 1.75; p=0.01) and anti- osteoporosis drug (β=−0.19; 95% CI: −0.26 to −0.19; p=0.009) were significantly predictive variables of annualised BMD change of the lumbar-spine. On the other hand, serum TRACP-5b (β=−0.28; 95% CI: −0.005 to −0.001; p=0.002) was significant predictive one for the distal forearm.

Conclusions: Anti-osteoporosis medication may be particularly important for lumbar spine BMD for RA patients, regardless of steroid-use. Specific biomarkers would be useful such as homocysteine as lumbar spine BMD and TRACP-5b as

Disclosure of Interest: None declared

DOI: 10.1136/anrheumdis-2018-eular.6625
the forearm BMD. These findings would be helpful for osteoporosis management in RA patients.

EPIDEMIOLOGICAL FEATURES OF PERIPHERAL OSSEOINTEGRATED IMPLANTS FOR LOWER LIMB AMPUTEES: EVALUATION OF BONE MINERAL DENSITY

T. Mokhort1, N. Filiptsova3, A. Naumenka3, V. Vasilkova1, T. Mokhort2, N. Filiptsova3, A. Naumenka3

Objectives: To address stress distribution issues associated with socket prostheses and related problems. All patients received osseointegrated implants press-fitted into the amputated limb. BMD was assessed using DXA in the femoral neck (operative and contralateral) and lumbar spine (L2-L4) regions, and corresponding Z-scores were generated. DXA scans were taken preoperatively as well as one-year and two-years following osseointegration surgery.

Results: Mean BMD and Z-scores of spine, and operative and contralateral sides were generated for all patients. BMD was assessed using DXA in the femoral neck (operative and contralateral) and lumbar spine (L2-L4) regions, and corresponding Z-scores were generated. DXA scans were taken preoperatively as well as one-year and two-years following osseointegration surgery.

Conclusions: These results suggest that osseointegrated implants are effective at encouraging bone growth and restoring BMD levels for amputees within a short period of time post-surgery. Osseointegrated implants therefore have the potential to address stress distribution issues associated with socket prostheses and restore the normal bone loading regime in lower limb amputees.

AB1015

BONE MINERAL DENSITY IN PATIENTS WITH CHRONIC KIDNEY DISEASE

V. Vasilkova1, T. Mokhort2, N. Filiptsova3, A. Naumenka3, 1GOMEL STATE MEDICAL UNIVERSITY, Gomel, 2Belarusian State Medical University, Minsk; 3The Republican Research Center for Radiation Medicine and Human Ecology, Gomel, Belarus

Background: Chronic kidney disease (CKD) is commonly associated with disorders of mineral and bone metabolism. However, the relationship between renal function and bone mineral density (BMD) is controversial.

Objectives: To evaluate the relationship between markers of renal function and BMD in patients with CKD.

Methods: 95 patients both sexes with CKD aged 55.49±10.07 years were studied. Control group included 84 healthy subjects the same age. Standard laboratory analyses were performed in all patients. Renal function was assessed by the estimated glomerular filtration rate (eGFR), which was calculated using an equation based on creatinine (eGFRcreatinine) and cystatin C (eGFRcystatinC). Osteoporosis was defined as a femoral neck BMD T-score below -2.5.

Results: The serum cystatin C level was negatively correlated with BMD and T-score right and left femoral neck (p<0.05), but not with BMD T-score lumbar spine. The level of creatinine was negatively correlated only with BMD and T-score right femoral neck (r=−0.653, p<0.05). Higher cystatin C levels were associated with a higher prevalence of osteoporosis in CKD patients (OR 3.54; 95% CI 1.63–7.85; p<0.002). In logistic regression analysis, after adjusting for age, body mass index, calcium, only cystatin C showed a negative correlation with femoral BMD. In addition, the eGFRcreatinine showed a stronger positive correlation with femoral BMD than the eGFRcreatinine.

Conclusions: Our findings suggest that serum cystatin C level could be a marker for femoral BMD and might help identify patients with osteoporosis who are susceptible to fractures.

OSSEOINTEGRATED IMPLANTS FOR LOWER LIMB AMPUTEES: EVALUATION OF BONE MINERAL DENSITY

S. Thomson1, W. Lu1, M. Al Mudenis2,3, 1The Osseointegration Group of Australia; 2Macquarie University; 3The University of Notre Dame, Sydney, Australia

Background: The use of dual-energy X-ray absorptiometry (DXA) is a standard clinical procedure for the evaluation of bone mineral density (BMD). Amputee patients are known to have decreased BMD and an increased risk of osteoporosis in the affected proximal femur and hip region. The major cause of these issues in these patients is the absence of adequate loading leading to bone resorption in accordance with Wolff’s law.

Objectives: In this paper, we present a prospective study reporting changes in BMD among amputees who received osseointegrated implants to determine if the loading through the Osseointegrated implant can overcome the bone resorption issues.

Methods: This is a prospective study of 33 patients, consisting of 24 males and 9 females, aged 22–77 (mean=51.0±2.0) years with one and two-year follow-up. Selection criteria included age over 18 years, unilateral amputees with socket-related problems. All patients received osseointegrated implants press-fitted into the amputated limb. BMD was assessed using DXA in the femoral neck (operative and contralateral) and lumbar spine (L2-L4) regions, and corresponding Z-scores were generated. DXA scans were taken preoperatively as well as one-year and two-years following osseointegration surgery.

Results: Mean BMD and Z-scores of spine, and operative and contralateral sides were generated for all patients. Dependent t-tests were used to test for significant differences (p<0.05) preoperative, one-year, and two-years for mean changes in BMD and Z-Scores following surgery. Analysis of the BMD and Z-scores indicated that patients showed improvements at one-year post-surgery.

Conclusions: These results suggest that osseointegrated implants are effective at encouraging bone growth and restoring BMD levels for amputees within a short period of time post-surgery. Osseointegrated implants therefore have the potential to address stress distribution issues associated with socket prostheses and restore the normal bone loading regime in lower limb amputees.

AB1017 VERTEBRAL FRACTURES ARE LIKELY TO OCCUR IN LUMBAR VERTEBRA IN PATIENTS WITH OSTEOPOROSIS AND EVEN IN OSTEOPENIA

Background: Osteoporosis is a common disease, which can lead to fracture. New diagnosis includes fracture of the vertebral bodies and hips. T-scores of bone mineral density (BMD) less than 2.5 or osteopenia together with humeral, forearm or the pelvis facture. Vertebral assessment should be considered in some conditions.1

Objectives: Our study was to investigate the condition of osteoporosis in patients who underwent bone mineral density in our hospital and fracture status according to lateral X-ray of cervical, thoracic and lumbar vertebra. Bone mineral density measured by Dual Energy X-ray Absorptiometry was performed based on clinical needs. Patients with osteoporosis or osteopenia were asked to have X-ray scan of cervical, thoracic and lumbar vertebra. The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis.

Results: Of all the 210 patients, 60 (28.6%) were male patients. 59.5% of female patients were in post-menopause stage. Mean age was 57.6±13.17 years. 124 patients were asked to perform BMD by the rheumatologists. 20 patients did the test after they saw an endocrinologist. 40 patients did the test after they saw an orthopedist. 102 patients had T-scores of less than 2.5. 61 patients had osteoporosis according to BMD. 22 patients had fracture according to past history or X-ray scans’ findings. 10 patients had multiple fractures. The most frequent fractures were located in L1 (nine patients) and L2 (four patients). The other parts included L3, L5, C7, T12, T6, T8, and T9. Two patients had ankylos or humeral fractures before because of injury. Vertebral fractures were found in 5 (8.2%) of the patients with T-scores of –2.5 to –1 during this study.

Conclusions: Lateral X-ray scans of the vertebra can detect vertebral fractures in patients with osteoporosis according to BMD scores, even in patients less than 50-year-old. Osteoporosis could be underestimated without measurement of the vertebra. The most frequent vertebral fracture happens in L1.

AB1019 PATIENTS COMPLIANCE TO CHRONIC GOUT THERAPY WHEN ADMINISTERED BY DIFFERENT MEDICAL PROFESSIONALS

A. Sarapulo1, O. Teplyakova1, A. Popov1, T. Popova2, P. Palaubugina1. 1URALS STATE MEDICAL UNIVERSITY, 2City Clinical Hospital 40, Ekaterinburg, Russian Federation

Background: In everyday practice chronic gout patients are frequently consulted by general practitioners, surgeons, and rheumatologists. In general, chronic gout patients have been reported to be quite uncompliant, but it remains unclear whether low compliance depends on the specialty of the prescribing physician.1

Objectives: To compare the clinical course of gout in patients consulted by different specialists and to identify factors of low patients’ compliance in Russia.

Methods: Cross-sectional study included 56 chronic gout patients aged 31 to 82 (median 54 years). Average gout symptoms duration was 6.8 years, average attacks frequency was 6.4 per year. Tofi were present in 21.4% of patients. All subjects were divided into three groups: Group 1 consisted of treatment naive patients at primary rheumatologist visit, Group 2 and Group 3 included patients who had previously been treated. Group 2 subjects were visiting both non-rheumatologists and rheumatologists. Group 3 were managed by rheumatologists strictly according to the EULAR evidence-based recommendations.2

Results: Group 1 primary consulted rheumatologists at the age of 47.3±14.5, Group 2 patients were assessed at the age of 58.4±15.2, and Group 3 were aged 51.2±13.5. Disease symptoms duration was maximal in Group 2 (10.6±10.6 years) while 5 years in Groups 1 and 3. Flares frequency was the lowest in Group 2 (2.2±1.8 per year), while in Group 1 it was extremely high (~10.56 per year). The incidence of tofi and urolithiasis was lowest in the Group 3 whereas every third treatment naive patient had tophi or/and urolithiasis. To relieve gouty arthritis vast majority of patients used NSAIDs, though at 50% strength of the recommended dose. Only 9%~14% of flares were controlled by colchicine in Groups 2 and 3. Colchicine prevention of flares was prescribed only in 45% of cases by rheumatologists. The most frequent urate-lowering therapy (ULT) was allopurinol, it was taken only by 63% of patients of the third group and 35.7% in the second group. While patients in the third group took the drug daily, the other patients did not follow the administration scheme. Serum creatinine level was the lowest (87.5–16.8 µmol/L) in Group 3, being the highest in treatment naive patients (102.7±30.0 µmol/L). Serum uric acid target level was achieved only in the compliant Group 3 patients (343 µmol/L), while Group 2 levels varied between 462–546 µmol/L, being the highest (625 µmol/L) in treatment naive Group 1.

Low compliance risk factors were: age under 45, absence of comorbidity and long-term multiple drugs consumption.

Conclusions: Chronic gout patients’ compliance and quality of patient management can be assessed as alarmingly low. Rheumatologists adhering to EULAR evidence-based approach to gout management can actually achieve recommended treatment targets. Both general practitioners and other specialists are in need of consistent educational program on gout management. Younger and comorbidity-free gout patients should be encouraged to follow attending physician’s recommendations.

AB1018 INTRAVENOUS NERIDONATE IN THE TREATMENT OF BONE MARROW ODEMA SYNDROME: EFFICACY AND SAFETY OF TWO DIFFERENT TREATMENT SCHEDULES

A. Lurati1, A. Laria1, P. Faggio2, M. Marrazza2, D. Mazzocchi2, A. Gilardi2, A. Tamburello2, L. Castelvovo2, K.A. Re1, A. Mazzone2. 1Rheumatology Unit, FORNAROLI HOSPITAL; 2MEDICINA INTERNA, ASSIT OVEST MILANESE – OSPEDALE CIVILE DI LEGNANO E CUGGIONO, LEGNANO, Milan, Italy

Background: Bone Marrow Oedema Syndrome (BMES) is a severely disabling pain syndrome without a definite treatment well established.

Objectives: The aim of this monocentric prospective trial was to test the efficacy and the safety of the amino-bisphosphonate neridronate in patients with BMES administered in two different schedules.

Methods: one hundred seventy-three patients with BMES at various joints were consecutively assigned to I.V. infusion of 100 mg neridronate given four times over 10 days (Group A) or alternatively to I.V. infusion of 100 mg every 21 days over 63 days (Group B). At baseline (T0) and after 90 days from the first infusion we performed a MRI (T2). We assessed a 0–100 mm pain VAS in each patient at T0, at the day of the last infusion (T1: day 10 for group A and day 63 for group B) and at T2. Primary outcome was to evaluate the MRI changes, secondary endpoint was the VAS change.

Results: we observed a significant improvement in MRI with the resolution of bone marrow oedema present at T0 (p<0.01), without a significant difference between Group A and Group B. Visual analogue scale (VAS) score decreased significantly during the study in both groups (p<0.05) without a significant difference between the two treatment groups (p>0.1).

Conclusions: In patients with BMES, the infusions of neridronate 100 mg every 21 days over 3 months or alternatively every 3 days over 10 days are associated with clinically relevant and persistent benefits without significant differences between the two treatment-schedules. These results provide conclusive evidence that the use of bisphosphonates, at appropriate doses, is the treatment of choice BMES

Disclosure of Interest: None declared
AB1020 PILOT ASSESSMENT OF CURRENT CHRONIC GOUT TREATMENT IN RUSSIA

A.A. Popov1, O.V. Teplyakova2, T.A. Popova3, A.V. Sarapulova4, P.A. Palabugina1, 1Hospital Therapy Dept; 2Outpatient Therapy Dept., URALS STATE MEDICAL UNIVERSITY, 1Rheumatology Dept., City Clinical Hospital 40, Ekaterinburg, Russian Federation

Background: In 2016 EULAR evidence based clinical guidelines on Gout treatment have been updated.1 Objectives: to assess current daily practice physicians’ approach to management of chronic gout patients

Methods: a cross-sectional anonymous survey had been offered to hospital and outpatient departments physicians dealing with gout patients resulting in 97 back-feed replies yielded. This publication deals with chronic gout treatment practice.

Results: all survey participants were divided into 3 groups. Group 1 consisted of 18 rheumatologists (professional experience median 19.6 years, range 1 to 43), group 2 included 60 general practitioners (GP, professional experience 27; 4–47), group 3 included other specialists (cardiologists, surgeons etc.) who reported frequent contacts with gout patients (professional experience 16.5; 1–44).

Rheumatologists reported to contact median 15 (range 2–40) gouty subjects per month, while group 2 reported to see 31–18 and group 3 consults 41–15 patients per month. All rheumatologists and 45 GPs reported initiation of allopurinol or febuxostat after gouty arthritis resolution, while 11 general practitioners did not start antihyperuricemic drugs in subjects with kidney and/or cardiovascular comorbidities.

In Group 3 only 6 responders had experience of antihyperuricemic drugs administration, but 3 of them reported allopurinol initiation during gout flare. Only 2 rheumatologists and 2 GPs reported starting allopurinol or febuxostat for maintenance doses over 300 mg was reported only by 7 rheumatologists and 7 GPs. Other specialists did not have any personal experience of allopurinol dose adjustment, but 3 of them reported allopurinol initiation during gout flare. Only 2 rheumatologists and 2 GPs reported starting allopurinol for maintenance doses over 300 mg.

Conclusions: intensive educational intervention is urgently required to change current practice of chronic gout treatment in Russia.

Disclosure of Interest: None declared

AB1021 ANEURYSMAL BONE CYSTS OF THE SPINE: 4 CASE REPORTS AND REVIEW OF LITERATURE

Background: Aneurysmal bone cysts (ABC) are rare, benign, highly vascular pseudotumors of unknown cause. It most often affects individuals during their second decade of life.

Objectives: Our goal was to document the clinical characteristics, diagnostic modalities and treatment results of ABCs.

Methods: We reviewed our institution’s database over a period of 15 years to identify patients diagnosed with aneurysmal bone cysts of the spine. Four patients underwent surgery in our department (2 men and 2 women). For those four patients, we tabulated the clinical characteristics, location, diagnostic modalities and treatment.

Results: The clinical manifestations were gait disturbance in 2 patients and leg pain in the other two. The tumor occurred in the dorsal spine in 2 cases and in the lumbar spine in the other two. All patients underwent surgical resection with total removal in only 2 patients. Postoperatively, clinical signs improved in all patients. Only one case presented tumour recurrence requiring second intervention and instrumentation.

ABCs constitute approximately 1.5% of spinal bone tumours. They usually affect the posterior elements of the spine. MRI is the most useful modality for preoperative planning. It also helps to evaluate the fluidfluid level, which is characteristic for ABC on MRI. The differential diagnosis is mainly with giant cell tumours and osteoblastomas. The primary option for treatment is surgery. Instrumentation is sometimes necessary because of the increased risk of postoperative instability, especially in cervical spine surgery. The recurrence rate is 20% to 30% in case of incomplete resection.

Conclusions: ABCs are benign lesions. Surgical resection en bloc has the lowest recurrence rate. Instrumentation is sometimes necessary because of the increased risk of postoperative instability.

AB1022 EFFICACY AND TOLERANCE OF SODIUM THIOSULFATE INJECTION IN CALCIFIC TENDINOPATHY OF THE ROTATOR CUFF

C. DarrieuFert-Laffitte1, T. Garraud1, A. Bertrand-Vasseur2, B. Le Goif1, 1RHEUMATOLOGY UNIT, 2RADIOLOGY UNIT, HOPITAL HOTEL DIEU/HME, NANTES CEDEX 1, France

Background: Calcific tendinitis of the rotator cuff is one of the most common causes of shoulder pain. Ultrasound-guided percutaneous lavage of calcific tendonitis (UGPL) is indicated when conservative treatments have failed. It has been shown that dense calcifications are associated with a higher risk of treatment failure. Sodium thiosulfate (STS) has recently been used with success in the treatment of tumoral calcinosis. We hypothesised that STS lavage could be of interest in the treatment of dense calcification of the rotator cuff.

Objectives: To evaluate the tolerance and efficacy of sodium thiosulfate lavage in the treatment of calcific tendinosis

Methods: This was a prospective phase II open label study. We included only patients with a type A calcification according to the Molé classification. Patients were treated with a US-guided single needle technic. When backflow of calcific material could be identified in the syringe, lavage of the deposit was performed using STS 25% until the backflow becomes clear followed by the injection of 1 mL (250 mg) of STS inside the calcific deposit. Finally, 1.5 mL of corticovial was injected in the subacromial bursa. All patients had follow-up visits at 1 week, 1 month and 3 months after intervention. At each time point, VAS pain at rest and during activities was recorded and US and X-ray were performed. Our primary outcome was the percentage of patients with more than 50% of decrease of the calcification size at 1 month. Based on our experience and on the literature, we expected than more than 60% of the patients should have more than 50% of decrease in their calcification for the results to be significant.

Results: A total of 17 patients were included. Mean age was 50±11 years. There were 9 female (52.9%). Baseline VAS at rest and during daily activities was a mean 40.2±25.9 and 65.5±21.6 (27–91) respectively. Calcification involved the supraspinatus in 12 cases (70.6%) and the infraspinatus in 5 cases (29.4%). Mean surface on radiography was 80.7 mm2±52.4 and the calcification longest axis was 18.8±7.1 mm. All patients underwent the entire procedure with no adverse event apart of a mild and transient vasovagal reaction. Calcium backflow could be obtained in 15 patients (88.2%) with a small amount of calcium in 8 cases (53.3%) and a large quantity in 7 cases (46.7%). We found that 5 patients (30%) had more than 50% decrease of their calcific deposit at 1 month and 8 (47%) patients at 3 months. VAS pain during activities and at rest decreased significantly from 65±22 and 40.2±26 at baseline to 37.8±31 and 24.1±24 at 3 month respectively (p=0.0004; p<0.001)

Conclusions: Overall, our study is the first to evaluate the tolerance and efficacy of sodium thiosulfate for the treatment of the calcifications of the rotator cuff. We could not demonstrate a significant effect of one STS lavage and injection in patients with dense calcification. This treatment was well tolerated with no side effect occurring during the procedure and the follow-up. New studies using larger volume and repeated injections of STS will be needed to definitely conclude on the interest of this molecule in the treatment of calcific tendinopathies.

ENHANCED RENAL TRANSPORTER ACTIVITIES OF OAT1 AND OAT3 BY KEISHIBUKURYOGAN (K-06) AND IN VIVO URIC ACID MODULATING EFFECT AT POTASSIUM OXONATE-INDUCED MOUSE SETTING

D.-S. Oh1, H.-J. Shin2,3, S.-H. Lee1, S.-M. Oh1. 1The K-herb Research Centre, Korea Institute of Oriental Medicine, Daejeon; 2Department of Pharmacology and Pharmaco Genomics Research Centre, College of Medicine, Inje Univ.; 3DMPK, SPMED, Busan, Korea, Republic of Ireland

Background: Studies on renal solute carrier transporters have made the renal pathophysiology be in progress towards more mechanistic and the knowledge on renal drugs including drug-drug interaction be more evidentiary. Among the evidence, uricosuric phenomenon has been known that rodent experimental model is also useful for predicting human uricosuria.

Objectives: The aim of this study was to assess the substrate uptake at the over-expression of renal transporters, OAT1, OAT3 and URAT1 at kidney proximal tubular cell lines with or without a commercial herbal medicine, Keishibukuryogan (K-06) and to further measure serum and urinary uric acid concentrations in the setting of potassium oxonate (PO)-induced icr mouse model with or without K-06.

Methods: The transporter-expressed HEK293-OAT1 and HEK293-OAT3 cells were seeded on BD poly-d-lysine microplates to uptake the [3H] estrone sulfate for 5 min in absence or presence of K-06. URAT1 was overexpressed using Xenopus oocytes being injected with in vitro-copied RNA of URAT1, and then to measure the uptake of [3H] uric acid with/without K-06. Total radioactivity was measured using a liquid scintillation counter. Serum and urinary uric acid was measured in PO icr mice after three-day intake of K-06. They were assigned by 4 per each group; 1) control group, 2) PO-induced group, 3) PO-induced with allporinol 50 mg/kg/day intake group and 4) PO-induced with allporinol plus K-06 300 mg/kg/day intake group.

Results: To determine the kinetic parameters of concentration-dependent uptake of overexpressed OAT1 and OAT3 transporters in HEK293 cells, the K-06 inhibitory parameters on OAT1 and OAT3 were presented with the IC50 values of 49.3 and 31.5 μg/mL, respectively. The K-06 inhibited URAT1 with IC50 of 59.3 μg/mL. The K-06 (300 mg/kg) reduced serum levels of uric acid approximately 30% compared to that of PO-control group (p=0.039) and K-06 showed the slight elevation of urinary uric acid by 12% compared to that of PO-control group with no statistical significance.

Conclusions: The present findings demonstrated that the K-06 modulated basolateral and apical renal transporters and the K-06 showed the slight increased uric acid excretion and the uric acid lowering effect in experimental mouse setting.

RISK OF DRUG INDUCED LIVER INJURY FROM NSAIDS IN PATIENTS WITH GOUT

E. Mikhailov1, T. Pavlović1, T. Rayeuneva1, E. Mytnik2, E. Leonchik2, V. Tettegah2,3. 1Department Of Internal Medicine, UNIVERSITY OF MEDICINE; 2Department Of Rheumatology, Diagnostic Center; 3Emergency Department, Hospital #5, "UNIVERSITY OF MEDICINE, Minsk, Belarus

Background: Drug Induced Liver Injury (DILI) in patients under nonsteroidal anti-inflammatory drugs (NSAIDs) is more frequently presented by hepatocellular damage when serum alanine aminotransferase (ALT) level exceeds 2 times (or more) the upper limits of norms. 1 The value of minimal hypertransaminasemia (MHTE) (when serum ALT exceeds the upper limit of normal up to twice) is still not clear today.

Objectives: To define the terms of DILI development and the value of MHTE in patients with gouty arthritis (GA) under NSAIDs.

Methods: By 89 patients (25.6% of 378 with GA), 1977 were included in our retrospective study. At the onset of gout attack, all patients had normal basal serum ALT, which elevated after starting NSAIDs therapy. Pre-existing liver impairment was not registered. Patients were divided into 2 groups according to the changes in serum ALT after NSAIDs treatment: patients with MHTE (n=101) and those with DIIL (n=88). The mean age of 55±9–60 years and 54±4–59.5 years as well as the sex distribution (men 90,1% and 93.3%, respectively) were compatible in both the groups (p=0.05). In DIIL group, elevated serum ALT exceeded 2–3 times the upper norms in 81.8% (n=72) of patients; 3–5 times in 14.8% (n=5); more than 5 times in 3.4% (n=3) with the mean serum ALT being of 89±10.5 U/L. In MHTE group, serum ALT exceeded the upper norms by more than 50% in 50.5% (n=51) of cases. After NSAIDs therapy, the mean serum ALT of 51±17±5 U/L was revealed.

Conclusions: The mean duration of NSAIDs therapy in the groups made 8±10 days in MHTE group and 10±14 days in DIIL group. Statistically significant difference (U=3236, p<0.001) was revealed between the groups when comparing the duration of NSAIDs treatment. In addition, in DIIL group, 97.7% of patients received NSAIDs in high doses during less than 11 days (AUC=0,64±0,04, p=0,010, S=47.7, Sp=82.2%, OR=4,21, 95% CI =3,38–5,24).

Results: 25.6% of patients with GA have demonstrated elevated serum ALT after NSAIDs therapy; MHTE developed in 13.7% of cases, DIIL in 11.9%. Our study showed that MHTE developed in the period less than 11 days of high dose NSAIDs treatment with DIIL being likely to occur during more prolonged treatment. MHTE group may be considered as a risk group for DIIL development.

AB1025  MONOSODIUM URATE CRYSTAL FORMATIONS FROM TOPHI IN SYNOVIAL FLUID

E. Pascual1, M. Andrés2,3, F. Sivera4. 1Emeritus Professor, Universidad Miguel Hernández; 2Sección de Reumatología, Hospital General Universitario De Alicante-Isaba1; 3Dpt Medicina Clínica, Universidad Miguel Hernández; 4Sección De Reumatología, Hospital General Universitario de Elda, Alicante, Spain

Background: At the joints MSU crystals form primarily at the cartilage surface; on occasions also tophi form at joint margins. Most often monosodium urate (MSU) crystals at the synovial fluid (SF) are found isolated. In tophi MSU crystals often show as spherulitic formations, fanning away from a central point1 (Figure 1, 200x, polarised light). We have detected in synovial fluid formations of MSU crystals with an organisation indicative that they formed in tophi, draining later to the fluid. The formations also help to understand how crystals formed in tophi.

Methods: Our photographic archive of SF have been reviewed.

Results: Two types of formations are found. A) A spherulitic formation where the crystals fan radially as in the segment of a sphere (Figure, middle, 600x, polarised light), B) Paired crystals bound longitudinally to each other (Figure, right, 600x, phase contrast).

Conclusions: At tophi spherulitic crystal formations are usual (figure 1) in which MSU crystals radiate as in a fan. A) Pieces of these same formations, seen as the segment of a sphere, are occasionally seen in SF (Figure 2), usually containing a large number of crystals and suggesting that they have drained from a tophus. Likely to build these formations, the initial crystals served as a template on which successive crystals formed by epitaxia, -- the crystal formation method of least energy requirement -, explaining the rapid growth that tophi can present. Their unimpeded migration to the joint cavity suggest that they formed freely and uncon- nected to any organic structure within the tophus. B) In SF containing large numbers of crystals, paired crystals – two crystals lying side by side and usually of similar length and width – are also found. Their paired position likely indicates that one served as template to the other, or that they grew together sharing a crystal net – twin crystals. In all, these MSU crystal formations appear to indicate that besides the crystals formed in the surface of joint cartilages, the content of tophi can drain into the joint fluid, also contributing to the presence of crystals in it; the
periaricular tophi frequently seen in ultrasound appear as the likely source for these formations.

CLINICAL CHARACTERISTICS AND RISK FACTORS FOR GOUT ATTACK DURING THE POSTSURGICAL PERIOD

1 Soon Chun Hyang University Hospital, Bucheon; 2 Samsung Medical Center; 3 National Medical Center, Seoul; 4 Bundang Jesaeng Hospital, Seongnam, Korea, Republic of Ireland

Objectives: To evaluate the clinical features and risk factors for gout attack during the post-surgical period in patients with gout.

Methods: Seventy patients who had histories of gout and had been consulted to rheumatologic clinic before surgery under general anaesthesia at a single tertiary hospital were included. Clinical characteristics of patients who developed postsurgical gout attack were compared with patients who did not develop gout attack.

Results: Among 70 patients, 31 (44.3%) patients developed gout attack during postsurgical period. Mean time of gout attack after surgery was 3.7±4.9 days. Most of attacks involved lower extremity joints (83.9%) and tended to monoarticulation (61.3%). Knee joint (26%) and foot (0%) except 1st metatarsophalanagal (MTP) joint (26%) were more frequently involved than 1st MTP joint (13%). Uric acid levels before surgery (OR 1.46, 95% CI 1.13–1.88, p=0.004) and amount of uric acid changes between before and after surgery (OR 1.62, 95% CI 1.21–2.18, p=0.001) were risk factors for postsurgical gout attack. Taking medications for gout including uric acid lowering agents and/or colchicine reduced the risk of postsurgical gout attack (OR 0.11, 95% CI 0.04–0.32, p=0.001). Operation time, amount of blood loss during surgery, amount of fluid administration during surgery, and surgery site were not significantly associated with postsurgical gout attack.

Conclusions: Adequate uric acid control and taking medications for gout could prevent the postsurgical gout attack.

Disclosure of Interest: None declared

THE PREDICTIVE VALUE OF CYSTATINE C FOR GOUTY NEPHROPATHY

D. Rekalov, I DanjuK, G. Medvedchuk. Internal diseases-3, Zaporizhzhia State Medical University, Zaporizhzhia, Ukraine

Background: Gout is the most common cause of an inflammatory arthritis in men older than 30 years, varies up to 1.7% of the total morbidity. One of the most common complications of chronic gout is gouty nephropathy with the morphological signs of kidney damage, even in the early stages. It's well known, that urine albumin and glomerular filtration rate (GFR) are the generally accepted markers of nephropathy. But, recent data has shown, that the informative and obtainable new biomarkers of the kidney function are still needed. Thus, evaluation of the pathogenic role in the renal failure of cystatin C could be a “clue”. The dozen trials have shown that an increasing of ranges cystatin C in serum could be tested at the stage of subclinical reduction of GFR with normal level of creatinine.1-3

Objectives: To determine the serum ranges of cystatin C and creatinine as the markers of nephropathy in patients with gout.

Methods: The main group was the 80 males with primary gout (average age 53.4±8.2 years), with the disease duration from 3 up to 25 years. The second group – 20 healthy men (49.5±4.5). We determined the concentration of serum uric acid, serum cystatin C, creatinine, calculate the GFR using CKD-epi formula. For urine albumin evaluation we used the albumin/creatinine ratio in the morning urine portion.

Results: e determined that the main group identified by more significant violations of renal function. In the main group was found the statistically significant increase of the serum creatinine (97±18 µmol/l) and decrease of GFR (73±50 ml/min/m²). The serum cystatin C concentration in the main group was (1.7±1.4; 1.5; mg/l which was the significantly larger than in the comparison group (0.8 [0.7; 0.92] mg/l, p<0.001). The albumin/creatinine ratio was statistically higher in the main group (26±15; 55) mg/g than in comparison (0.8 [0.7; 0.92] mg/l, p<0.001). Also the patients with gout are characterised by the larger concentration of uric acid in the serum (500±74) µmol/l than healthy men (497±25) µmol/l and negative correlation between uric acid level and GFR (r=0.4, p<0.05) which explain the increase of uric acid concentration in the serum.

We determined the correlation between level of urinary albumin and creatinine concentration (r=0.5, p<0.05) in the main group, but concentration between albuminuria and cystatin C was stronger (r=0.6, p<0.05). We detected that cystatin C level had a greater accuracy for the diagnosis of albuminuria than creatinine according to the ROC-analysis. These facts show that serum concentration of cystatin C more closely connected with the renal function than creatinine.

Conclusions: 1. The increase of serum cystatin C level can be identified before the clinical manifestation of renal dysfunction while the serum creatinine remain relatively normal.
2. Serum ranges of cystatin C more closely correlate with elevation of urine albumin than creatinine.

ACTH VS BETAMETHASONE FOR THE TREATMENT OF ACUTE GOUT IN HOSPITALISED PATIENTS

P. Kordas1, I Antonomopulos2, D. Velissaris3, D. Daoussis2. 1 Internal Medicine; 2 Rheumatology, University of Patras Medical School, Rio, Patras, Greece

Background: The management of gout can be problematic in the hospital setting: hospitalised patients usually have significant comorbidities and receive multiple medications which leads to a high frequency of contraindications to established gout therapies. We have previously shown the ACTH is a safe and fast acting therapeutic option for acute gout in hospitalised patients in a large scale retrospective study.1

Objectives: To directly compare the efficacy of ACTH vs betamethasone for the treatment of acute gout in hospitalised patients in a prospective manner.

Methods: Hospitalised patients with acute gout, fulfilling the ACR criteria, were recruited with an IM injection of either 100 IU of ACTH (Synacthen Depot) or 5 mg of betamethasone (Celestone Chronodose-the most widely used IM steroid formulation in our country) on an alternate 1/1 basis. Clinical efficacy was assessed at 24, 48, 72 hour and 5 days as follows: a) Intensity of pain using a Visual Analogue Scale (VAS 0–10), b) physician global assessment (0–10) and c) swelling, redness and warmth (0–3 scale). Pain VAS was also self reported by the patient at 6 and 12 hour. Comorbidities representing contraindications to established gout therapies were recorded. Primary outcome of the study was the change in pain VAS at 24 and 48 hour. Secondary outcomes were changes in physician global assessment and changes in objective signs of inflammation.

Results: This is a 6 month interim analysis of an ongoing investigator initiated clinical study. Twelve patients (8 male) with a mean ±SD of 66.9±12.3 years were recruited and treated with ACTH or betamethasone on an alternate basis (6 in each treatment group). In most cases (n=11) the attack was monocular. The majority of patients had multiple comorbidities with the commonest being hyper-tension (9/12). Both treatments were effective. ACTH led to a significant decline in pain VAS at 24 hour compared to baseline (mean ±SEM: 2.33±1.21 vs 7.66 ±0.81 respectively, p=0.002) and at 48 hour (1.40±1.14, p=0.011 compared to baseline). Betamethasone was also effective with an improvement in pain VAS at 24 hour compared to baseline (mean ±SEM: 1.83±0.98 vs 5.33±2.16 respectively, p=0.0024) and at 48 hour (0.75±0.95, p=0.02 compared to baseline). However, direct comparison between treatment arms showed that ACTH treated patients exhibited a higher change in pain VAS at 24 hour compared to betamethasone treated patients (mean ±SEM: 5.5±0.5 vs 3.5±0.61 respectively, p=0.03). At the 48 hour time point ACTH treated patients still showed a higher change in pain VAS (mean ±SEM: 6.4±0.6 vs 4.0±0.91 respectively, p=0.056). A trend favouring ACTH was already evident at the 12 hour time point: the change in pain VAS was 4±1.54 vs 3±1.147 for ACTH vs betamethasone, respectively, (p=ns). No changes in physician global assessment and objective signs of
inflammation was found at 24 and 48 hour between treatment groups. Treatment was well tolerated in both groups.

## Conclusion

Both steroids and ACTH are effective in the treatment of gout in hospitalised patients but ACTH is faster acting. ACTH may be an attractive therapeutic choice in patients with multiple comorbidities that cannot receive standard treatment.

**ALLPURINOL AND CARDIOVASCULAR OUTCOMES IN PATIENTS WITH ISCHAEMIC HEART DISEASE (ALL-HEART) STUDY: BASELINE CHARACTERISTICS OF THE RANDOMISED PATIENT POPULATION**

L. Mackenzie1, I. Ford2, C. Hawkey3, A. Begg4, J. Taggar5, A. Struthers6, L. Wei6, A. Avery6, A. Walker7, S. Ducot7, R. Barr7, J. Dumbleton3, T. MacDonald1, on behalf of the ALL-HEART study group.

**Background:**

Allopurinol is licensed for the prevention of gout. In recent years, several studies have suggested that allopurinol may have beneficial effects on cardiovascular parameters. The ALL-HEART study is a large outcome trial designed to investigate whether allopurinol improves cardiovascular outcomes in patients with ischaemic heart disease. It is a multicentre, controlled, prospective, randomised, open-label, blinded endpoint trial of allopurinol (up to 600 mg daily) versus no treatment added to usual care in patients aged 60 and over with ischaemic heart disease. Patients are followed up by electronic record-linkage and annual questionnaires. Patient recruitment to the trial started in 2014 and completed in 2017 and follow-up is ongoing.

**Objectives:** To describe the baseline characteristics of the patients randomised into the ALL-HEART study.

**Methods:**

The primary endpoint of the ALL-HEART study is the composite of non-fatal myocardial infarction, non-fatal stroke or cardiovascular death. Secondary outcomes include all-cause mortality, quality of life and cost-effectiveness of allopurinol. The study will end when 631 adjudicated primary outcomes have been recorded.

**Results:**

5938 patients from the UK have been randomised into the ALL-HEART study. The mean age at randomisation was 72.1±6.8 (SD) years. 75.2% of participants are male. 56.5% are former smokers and 9.4% current smokers. Mean systolic blood pressure was 138±18 mmHg and mean diastolic blood pressure 72±11 mmHg. Mean body mass index was 31.1±5.2 kg/m². 57.6% had a history of hypertension. 3.9% had a history of previous cerebrovascular accident and 4.8% a history of peripheral arterial disease. 22.5% had a history of diabetes mellitus and 4.6% a history of heart failure. 78.0% had a history of high blood pressure. 33.3% had a history of any cardiovascular disease (defined as history of myocardial infarction, cerebrovascular accident, coronary heart disease, renal disease or peripheral arterial disease). The mean baseline urate was 311±52 μmol/L.

**Conclusions:** This large ongoing trial will determine whether allopurinol improves major cardiovascular outcomes in patients with ischaemic heart disease.

Disclose of Interest: None declared

Background: The development of gout is associated with obesity and metabolic syndrome (MS). Obesity is defined by body mass index (BMI). However, BMI has been challenging for the limitation of not distinguishing different comprising tissues of the body. Body composition (BC) has been frequently recommended to assess metabolic status and will eventually replace BMI as a more reliable measure.

Objectives: To investigate the characteristics of BC in gout patients and their significance with disease characteristics.

Methods: BC was assessed in 180 consecutive gout patients and 1,860 control subjects (white-collar employees in Zhejiang InnoPark of Shanghai) by bioelectric impedance analysis. Overfat was defined by body fat percentage (BF%) as \( \geq 25\% \) for men and \( \geq 35\% \) for women. Demographic and clinical data as well as comorbid diseases were collected simultaneously. For the significant differences in the proportion of gender and age between two groups, the age- and gender-matched control subjects were randomly selected with the ratio of 1:1 for further statistics.

Results: (1) Among 180 gout patients recruited, the mean age was 42.5±15.5 years, mean serum uric acid (sUA) was 9.0±2.4 mg/dl and 17.2% of patients presented tophi. The mean BMI was 25.4±3.5 kg/m\(^2\) with 44.4% overweight and 25.6% obesity. The mean BF was 26.2±6.6% with 50.5% overfat. (2) Compared with control subjects, gout patients were characterised by higher BMI (25.4±3.5 kg/m\(^2\) vs. 9.7±0.7 kg/m\(^2\)), fat mass (19.3±6.9 kg vs. 16.5±3.2 kg), trunk fat mass (10.2±5.4 kg vs. 8.4±3.4 kg), BF (26.2±6.6% vs. 22.4±6.2%), proportion of overweight (50.5% vs. 27.2%), but lower lean mass (53.0±7.7 kg vs. 55.6±7.7 kg, all \( p<0.05 \)). (3) Compared with normal fat patients (n=89), gout patients with overfat (n=91) presented higher duration of gout, the count of affected joints, flare times in the past year, family history and presence of tophi (all \( p<0.05 \)). Overfat gout patients also exhibited higher BMI, more obesity, hyper-low density lipoproteinemia, MS and fatty liver (all \( p<0.05 \)). (4) There were 9 (17.3%) overfat gout patients who presented more hypercholesterolemia (55.6% vs. 13.3%), hyper-low density lipoproteinemia (55.6% vs. 17.8%) and fatty liver (77.8% vs. 35.6%) and less skeletal muscle mass index (SMMI, 8.3±0.5 kg/m\(^2\)) vs. 9.7±0.7 kg/m\(^2\)) than those patients with normal fat and weight (all \( p<0.05 \)). Meanwhile, there were 44 (34.9%) gout patients with normal fat with an 126 overweight and obesity patients who had less MS (40.9% vs. 63.4%) and more SMMI (11.1±0.9 kg/m\(^2\) vs. 10.6±1.1 kg/m\(^2\)) than overfat patients (both \( p<0.05 \)). (5) Overfat was a risk factor for MS [OR 3.4 (1.8, 6.4), \( p<0.001 \)] after adjusted by age and gender.

Conclusions: The present study demonstrated that oral intake of fructose induces an increase in plasma urate level within a short time and that a decrease in renal urate clearance could mainly work for that.

Disclosure of Interest: None declared
THE URATE-LOWERING EFFECT OF FEBUXOSTAT 80 MG AND 40 MG (80 MG FILM-COATED TABLETS SPLIT IN HALF) IN GOUT PATIENTS IN DAILY CLINICAL PRACTICE

M. Flensdorff1, B. van den Bermb, V. Huiskesc, M. Hoelnagelc, F. van den Hoogen1.
1Rheumatology; 2Pharmacy, Sint Maartenskliniek, Nijmegen, Netherlands

Background: In Europe, the urate-lowering drug febuxostat for gout is registered in two strengths, 80 mg and 120 mg, but not 40 mg. Starting 40 mg can sometimes be considered desirable, for instance for safety reasons. Splitting an 80 mg film-coated tablet in half is an option, but is off-label and might violate coating function and influence effectiveness and safety.

Objectives: To investigate the urate-lowering effect and safety of starting febuxostat at 40 mg once daily (80 mg film-coated tablet split in half) in gout patients compared to 80 mg once daily.

Methods: Single-centre retrospective study on all gout patients starting febuxostat 80 mg or 40 mg (80 mg film-coated tablets split in half). Patients characteristics were collected, as well as starting dose and starting date of febuxostat, follow-up time, adverse events (AEs), stop date and reason, serum urate (sU) and creatinin (sCreat) over time and relevant comorbidity.

Patient characteristics were compared by Chi-square or T-test. Mean sU, percentage change in sU and percentage of patients reaching targets.

Conclusions: Both daily dosages febuxostat of 80 and 40 mg (80 mg film-coated tablets split in half) result in significant decline in sU levels within 12 weeks. A starting dose of 80 mg febuxostat appears more effective in reducing sU levels.

Disclosure of Interest: None declared

ULTRA-LOW DOSE ANTI-INTERLEUKIN1 IN CHRONIC GOUT: A SAFE AND SUCCESSFUL COMBINATION THERAPY WITH LOW DOSE COLCHICINE AND URATE LOWERING AGENTS

M. Caporossi, F. Galuccio, M. Matucci Cerinic. AOUC Careggi, Reumatologia, Firenze, Italy

Background: Gout is the most common inflammatory arthritis in humans; it is caused by deposition of monosodium urate (MSU) crystals within and around joints. Left untreated, a more chronic course may develop, characterised by persistent inflammation and visible MSU deposits (tophi), bone erosion, irreversible joint damage, and significant disability.1 Management is based on two strategies: treating pain and inflammation with NSAIDs, steroids and colchicine and preventing flares and urate deposition with urate-lowering therapy.2 For many patients, standard treatments are ineffective or contraindicated, mainly due to comorbidities.3 The main mechanism of crystal-induced inflammation is interleukin 1\(\beta\) (IL-1\(\beta\)),4 which strengthens the relevance of targeting IL-1\(\beta\) in patients with crystal-induced arthritis. Selective blockade of IL-1\(\beta\) has shown to drastically reduce pain, inflammation and risk of flares. Three biologic therapies inhibit IL-1\(\beta\) and have been studied for difficult to treat acute gouty arthritis flares: anakinra, rilonacept and canakinumab.5,6

Objectives: Evaluate the efficacy of low dose anti-IL1 inhibitors administer by sublingual route in gout arthritis with remitting course that cannot be completely controlled with standard therapy regimens

Methods: Inclusion criteria was diagnosis of chronic gouty arthritis with remitting course (acute flares in patients with chronic gout and no inter-critical period), high CRP levels and need of chronic assumptions of NSAIDs or steroids, with flare at suspension. 20 patients fulfilled the criteria (exclusion criteria: intolerance to the study drug, poor compliance to therapies or diet, hyperuricemia, end stage renal disease) The study consist of two consecutive parts. An observational part were patients are treated for 6 months with 0.5–1 mg/daily of colchicine and 300 mg/daily of allopurinol. They performed visits at baseline, 3 and 6 months and we collected data about blood tests, VAS score, number of flares, compliance to therapy and adverse events. An experimental part were we added GUNA anti-IL1 (an infuse of MSU crystals within and around joints) and MSU deposits (tophi) that has shown a concentration of 10 mg/mL 20 drops administered SL. Again patients performed visits at baseline (which coincides with the last visit of the observational phase), 3 and 6 months and we collected the same kind of data.

Results: At 6 months after introduction of GUNA anti-IL1 all patients, except 1, responded. Only patient was not able to continue the treatment because of side effects (nausea and fatigue). CRP levels and need of chronic assumptions of NSAIDs or steroids, with flare at suspension. The study was concluded at 12 months.

Conclusions: Ultra-low dose of anti-IL1 agents added to standard therapy is an effective and safe way to achieve disease remission

FEATURES OF KIDNEY FUNCTION AND URODYNAMICS AT PATIENTS WITH CHRONIC GOUT BASED ON COMPLEX RENAL SCINTIGRAPHY DATA

M. Gromova1, O. Klyak1, V. Tsuro1, A. Kashkadayeva2, S. Averinova2, S. Shiryaev2, 1PIROGOV RUSSIAN NATIONAL RESEARCH MEDICAL UNIVERSITY (RNRMU); 2N.N.Blokhin National Medical Research Center, Moscow, Russian Federation

Background: One of the frequent manifestations of gout is the gout nephropathy. For assessment of the urinary system functional reserves and the risk of renal failure routine analyses of urine in combination with a sonography are often not enough. Modern technology of the systemic examination of nephrourological status based on complex renal scintigraphy (SENS-CRS) was developed in the laboratory of radioscintography in "N.N. Blokhin National Medical Research Centre", and realised as an automated workplace. SENS-CRS technology is designed for assessment of the urinary system functional reserves and the risk of renal failure at all macrostructural levels, and allows lowest radiation doses (0.6 mSv for one patient).

Objectives: To define features of kidney function and urodynamics at patients with chronic gout based on the complex renal scintigraphy (CRS) data.

Methods: 59 medical records of patients with gout (2007–2011) were analysed retrospectively. Most of the patients (95%) were men, average age was 54.4±9.5 years. Duration of the disease was 8–11 years. All patients had chronic gouty arthritis, 28% of patients had polyphases. The CRS tests was carried out on a two-detector gamma camera with simultaneous 2 projections recording.99mTc-tec-nephrophere was used, a Russian radiopharmaceutical (RP) from the group of bisphosphonates with hemodynamics of a glomerulotropic product, concentrating mainly in the nephrons via filtration, with partial (10%–15%) involvement of secretion. Working protocol consisted of a base 21 min (1 min angiophase) study with administration of RP and a delayed 21 min study without administration of RP, but after taking 200–300 ml of water and/or an antispasmodic or diuretic drug to identify persistent urodynamic dysfunction. The interpretation of CRS data is based on a concentronal-hydrodynamic model of urinary excretion and SENS-CRS software. The Statistica 10.0 software was used too.

Results: According to CRS tests patients with gout had, on average, the level of blood cleansing from RP reduced slightly with a trend to a moderate level, and buffer retention of RP labelled blood in extrarenal structures increased. The signs of a relative hemostasis were found against the background of fast excretion accelerated by taking hypotensive drugs. Quantitative analysis of CRS data allows to estimate sustainability of relative urine delays in the pyelocolical system (PCS), in 70% of patients residual urostasis in the renal parenchyma and groups of calyx remained relatively stable, and the urostasis signs in the renal pelvis were disappearing. This result means that there could be a latent increased residence time of substances such as uric acid as well as nephrotoxic drugs in the kidney parenchyma. This requires control of correct drugs dosage and when prescribing repeated therapy courses.

Conclusions: The SENS-CRS technology provides the quantitative assessment of kidney blood cleansing from RP and concentrational function of parenchyma as well as unique quantitative indicators of urodynamic delays in all parts of urinary tract. This kind of functional diagnostics allows to monitor parenchyma and urinary tract condition promptly with lowest radiation doses, apply therapeutic measures to prevent more severe kidney dysfunction and refer patients to a specialist consultation.

PHARMACOKINETICS, PHARMACODYNAMICS AND SAFETY OF NC-2500, A NOVEL XANTHINE OXIDASE INHIBITOR, IN HEALTHY JAPANESE MALE SUBJECTS

M. Hirose1, S. Kobayashi2, E. Miyayama2, T. Ohta1, M. Yamamoto2, T. Yamakawa1, 1Discovery Research Laboratories, Nippon Chemiphar Co., Ltd., Misato, Saitama Prefecture; 2Development Planning Department, Nippon Chemiphar Co., Ltd., Tokyo, Japan

Background: Gout flare due to rapid urate reduction after initiating urate-lowering therapy (ULT) is one of the major issues in the therapy, which impairs patients quality of life and adherence. For the prevention of it, the guidelines in the ACR, the EULAR and Japan recommend initiating ULT with a low starting dose followed by adequate titrations, however it is rare in clinical settings. NC-2500 is a novel orally active xanthine oxidase (XOR) inhibitor in development for the treatment of gout/hyperuricemia. Preclinical studies showed that multiple doses increase the plasma concentration and enhance the urate-lowering effect of NC-2500, suggesting that NC-2500 may decrease the risk of gout flare when initiating the treatment.

Objectives: The aim of this study was to evaluate the pharmacokinetics, pharmacodynamics and safety of NC-2500 in healthy Japanese male subjects.

Methods: A Phase 1, randomised, single-blind, placebo-controlled, single and multiple ascending dose study was conducted. Each cohort consisted of 8 subjects, with 6 receiving NC-2500 and 2 receiving placebo orally. A total of 5 cohorts were studied in the single-dose study (10 mg to 160 mg, fasted conditions) and 4 cohorts were studied in the multiple-dose study (10 mg to 80 mg, fed conditions). The levels of NC-2500 and urate in plasma/serum and urine were assayed at predetermined time points. Safety and tolerability were assessed by physical examination, vital signs, electrocardiography, clinical laboratory tests and adverse events (AEs).

Results: Following single oral doses of NC-2500, maximum plasma concentration (Cmax) and area under the plasma concentration-time curve (AUC) increased approximately in a dose-proportional manner except that the increase in the Cmax at 160 mg was less than dose proportional. The time to reach the Cmax (Tmax, median) was 2.0–3.5 hours post dose and food intake delayed the Tmax by 1 hour. In the presence of food, NC-2500 absorption appeared to decrease slightly or not be affected. Plasma NC-2500 concentration increased
with multiple doses and the Cmax and AUC on Day 7 at 80 mg were 1.4–1.5 times higher than those on Day 1. NC-2500 was hardly excreted through the kidneys, which can be a favourable profile for patients with renal impairment, frequently observed in gout.

**Conclusions:** From the results, NC-2500 is expected to have potential to resolve the issues of current ULT by its unique urate-lowering property to decrease acute flare, with no or minimal titrations. As for safety, NC-2500 was considered safe and well-tolerated. Furthermore, NC-2500 was hardly excreted through the kidneys, which can be a favourable profile for patients with renal impairment, frequently observed in gout.

**Conclusions:** We found that diet was the only factor that relate with success of ULT while patients were on pharmacologic ULT. So, clinicians should emphasise the importance of all part of ULT including diet with informing patients about the nature of disease and benefits of ULT during visits.

**Conclusions:** To determine the presence of physical, laboratory and ultrasound (US) signs of inflammation on the affected joints, but also on the joints that in the clinical sense never showed an inflammatory reaction in the intercritical gout period.

**Methods:** This prospective study included 43 patients (pts.) with diagnosis primary gout (20 with and 23 without acute gout attacks). The research included: demography; medical history; laboratory analyses: sedimentation of erythrocytes (ESR), C reactive protein (CRP), and serology; physical: detect tender and swollen joint; and US examination detect synovial fluid and hypertrophy, Power Doppler (PD) signal and “double contour” sign on the wrist, first metatarsal joint (MTP1), tubiarial (TT) joint and knee.

**Results:** A physical examination showed presence of 78% tender and 43% swollen joints in the group pts. with acute gout attack, but also 23% pts. had painful and 10% swollen joints in the group without acute gout attack (p<0.001). In the group with acute gout attacks the mean ESR was 32.80 mm/L, value CRP was 8.20 mg/L and leucocytes (Le) (9.09 x 10 9/L), and in the group without acute gout attacks SE was 21.60 mm/L median CRP was 6.40 mg/L and also a higher average Le (8.39 x 10 9/L). So we found that there was no statistical difference (p=0.05) in the laboratory parameters (ESR, CRP and Le) between the groups. There was also no statistically significant difference in the findings of US signs of “double contour” (p=0.5), synovial fluid and hypertrophy(p=0.05), per group, but the presence of PD signal statistics was more often observed in a group of patients in an acute gout attack (p=0.05), table 1.
Conclusions: Our cohort, about one on six patients treated with FBX suffered from a CV event, some being fatal. The development associated with older age and CV disease background, so it merits a cautious use in this setting, although whether these CV events are directly related to FBX needs further clarification.

PATHOLOGIC MUSCULOSKELETAL ULTRASOUND FINDINGS IN PATIENTS WITH CHRONIC KIDNEY DISEASE ON DIALYSIS- A PILOT CONTROLLED STUDY

R.D. Decius1, M. Bojinc2, C.A. Capusa3, A. Zugrava2, V.C. Bojinc1. Internal Medicine and Rheumatology, St. Maria Clinical Hospital; Internal Medicine and Rheumatology, Dr. I. Cantacuzino Clinical Hospital; Nephrology, Carol Davila Clinical Hospital, Bucharest, Romania

Background: There are numerous studies about the musculoskeletal abnormalities associated with dialysis, but most of them target osteoporosis and the bone metabolism. While this is, in fact, of great importance, we consider that the abarticular abnormalities should also be taken into account: Because of the pain they cause, and the quality of life impairment in patients already affected in this domain, suffering from depression or at its’ edge.

Objectives: We aimed to detect the dialysis associated soft tissue abnormalities, using musculoskeletal ultrasound (MSUS) scanning of patients diagnosed with late-stage chronic kidney disease (CKD) on dialysis. In order to achieve this, we compared the data obtained from this group, to a control group of pre-dialysis late-stage CKD.

Methods: Over the last 8 months, we ran a prospective study including 102 patients. The study group included 52 patients with stage G5 (GFR <15 ml/min/1.73 m2, pre-dialysis), while the control group included 50 patients with stage G5 (GFR <15 ml/min/1.73 m2, pre-dialysis). Each patient had 68 joints scanned with a Samsung HM70A machine, by the same ultrasonographer, in order to avoid the inter-observer variability. Also, each patient completed a visual analogue scale (VAS) for evaluating pain. Sex study group: M: 30 (57.69%) F: 22 (42.3%) Sex control group: M: 28 (56%) F: 22 (44%) Age (years) study group: 62.5 ± 8.2 Age (years) control group: 61.4 ± 3.3

HD/PO study group: HD: 46 (88.46%) PD: 6 (11.53%) Time on dialysis (years) study group: 6.41 (0.5—22)

Results: The findings included median nerve entrapment (71.1% — study group, 18% — control group), tendon calcifications (61.5% — study group, 38% — control group), degenerative abnormalities (57.6% — study group, 50% — control group), synovitis (32.6% — study group, 22% — control group) and tenosynovitis (13.4% — study group, 8% — control group). There were no particular abnormalities found only in the study group, but the percentages of the common findings were significantly higher.

The VAS results were split in three groups: low, moderate and high. Among the patients on dialysis, 46.1% declared a low VAS, 36.5% moderate and 17.3% a high VAS, while in the control group the distribution according to VAS was 46% in the low lot, 34% in the moderate and 20% in the high lot.

Conclusions: We detected soft tissue abnormalities in an important percentage of patients associated with dialysis, but the results were disproportionate to the algo-functional symptoms. We found a higher percentage of low VAS then we were expecting.

Considering the results, we plan to continue our study, aiming to create a rehabilitation programme adapted to the needs of the dialysed patient.

AB1043 THE CLINICAL PROFILE OF GOT SIGNIFICANTLY DIFFERS BETWEEN MALE AND FEMALE

R. te Karne1, C. van Dreurse1, M. Janssen2, A. Boonen2, T. Jansen2

1 Rheumatology, Maastricht University Medical Center, Maastricht; 2 Rheumatology, VieCuri Medical Center, Venlo, Netherlands

Background: Gout, the most common type of inflammatory arthritis, is considered as a predominant male disease. Notwithstanding, there is an increased risk of gout in female after the menopause.

Objectives: Our objective was to assess differences in the clinical features between female and male patients.

Methods: Data of newly diagnosed gout patients attending the rheumatology outpatient clinics of one secondary and one tertiary i.e. university centre in the south of the Netherlands were used. We compared baseline characteristics of males and females regarding to demographics, BMI, presence of tophi, medication use (diuretics, prophylaxis of gout and uric acid lowering drugs), serum and urine concentration of uric acid and creatinine, and comorbidities. Additional, fractional excretion of uric acid (FEUA), calculated as (urinary uric acid x serum creatinine)/ (serum uric acid x urinary creatinine), was compared. FEUs gives the percentage of uric acid renally filtered and thus excreted in the urine (normal range 7%–12%). Independent t-tests and chi square were used to assess differences between males and females statistically.

Results: 66 female (16.6%) and 331 male (83.4%) patients with gout (MSU crystals 60.6 vs 68.6%, respectively) were included. At baseline, females compared to males had a significantly higher age (73±12 vs 63±13 years, p<0.001), BMI (30.1±5.2 vs 28.7±4.7 kg/m², p=0.034) and diuretic use (63.6 vs 27.6%, p<0.001). Females had also a significantly higher percentage of comorbidities, including hypertension (77.3 vs 59.5%, p<0.003), diabetes (48.5 vs 22.7%, p<0.001) and chronic kidney disease (eGFR of 46±24.2 vs 62±22.9, p<0.001). There was no significant difference in serum and urine uric acid concentration, current urate lowering and prophylactic medication, presence of tophi and nephro lithiasis. Also, the FEUs was similar in females vs males (5.1±3.0 vs 4.4±1.7%, p=0.201).

Conclusions: The clinical profile of gout in females significantly differs compared with males: significantly older, more advanced decrease in renal function and higher prevalence of hypertension. As Dutch guidelines recommend starting with a diuretic for the treatment of hypertension in patients aged 70+; this may have a role in explaining the higher numbers of females using diuretics. The start of diuretics has previously been associated with hyperuricemia and increases the risk of gout in the female population. Although diuretic use has proven to be a safe and effective first-line treatment for hypertension, our results suggest that diuretic use in combination with a decreased renal function is associated with an increased risk at developing gout in females, and possibly needs reconsideration. Furthermore, despite the fact that the FEUs was similar distributing between gender females did seem to have a lower urinary uric acid excretion. However, the number of patients with tophi and nephrolithiasis and the serum uric acid level are comparable between the genders. This suggests that the urate burden is similar but that the clinical profile for the development of gout differs due to the uric acid production vs excretion. In depth analysis of our population underlines the differences in female and male gout patients which highlight the need for more research into pathophysiology and management of gout between sexes.

AB1044 THE EDUCATION OF PATIENTS WITH GOUT IMPROVES THE EFFECTS OF TREATMENT

S.J. Yoo, S.W. Kang, S.C. Shim, J. Kim, I.S. Yoo, C.K. Park, Internal Medicine, CHUNGNAM NATIONAL UNIVERSITY SCHOOL OF MEDICINE, Daejeon, Korea, Republic of Ireland

Background: The recent studies about gout demonstrated the correlation between gout and cardiovascular disease (CVD). The urate lowering therapy (ULT) ameliorates the outcomes of CVD. The poor adherence with ULT is the first harbinger of kidney damage. However, predictors of GN have not been established for today.

Objectives: To establish predictors of GN.

Methods: A total of 103 patients with chronic gouty arthritis were examined in rheumatology department of Ternopil University Hospital. All patients had no history of any kidney disease. ELISA method was used to determine microproteins in urine. Subsequently, patients were divided into 2 groups: I (n=58) – patients with subclinical gouty nephropathy, abnormal microproteins level (56.3%), II (n=45) – control group, patients without kidney damage, normal microproteins level (43.7%). Statistical analysis was performed with STATISTICA software.

Results: Patients with subclinical gouty nephropathy had a higher prevalence of arterial hypertension and metabolic syndrome. The prevalence of osteoarthritis, diabetes mellitus and dyslipidemia was the same in both groups. Also, group I patients showed longer duration of the disease, greater radiologic changes, higher levels of hyperuricemia, tophi, work incapacity, greater number of affected joints and more frequent changes in urinalysis than the control group.

Conclusions: Formation of GN is asymptomatic, causing delays in early diagnosis, but can be suspended timely. Gouty nephropathy develops in 56.3% of patients with chronic gouty arthritis, and manifests by microproteinuria in the early subclinical stages. Duration of the disease, obesity, presence of tophi, arterial hypertension, hyperuricemia, increased triglycerids and low-density lipoproteins levels were found to be predictors of gouty nephropathy.

AB1045 MICROPROTEINURIA AS A MARKER OF SUBCLINICAL GOUTY NEPHROPATHY

S. Smiyan, M. Franchuk, R. Komorovsky. Internal Medicine No.2, I. Horbachevsky Ternopil State Medical University, Ternopil, Ukraine

Background: The prevalence of kidney damage in patients with gout ranges from 30% to 70%. Currently the concept of “gouty nephropathy” (GN) comprises all renal pathologies due to gout. There is no clear opinion whether hyperuricemia is a marker of renal dysfunction or risk factor. It is important to identify the early stages of GN as its course is subclinical for a long period of time. Microproteinuria is the first harbinger of kidney damage. However, predictors of GN have not been established for today.

Objectives: To establish predictors of GN.

Methods: A total of 103 patients with chronic gouty arthritis were examined in rheumatology department of Ternopil University Hospital. All patients had no history of any kidney disease. ELISA method was used to determine microproteins in urine. Subsequently, patients were divided into 2 groups: I (n=58) – patients with subclinical gouty nephropathy, abnormal microproteins level (56.3%), II (n=45) – control group, patients without kidney damage, normal microproteins level (43.7%). Statistical analysis was performed with STATISTICA software.

Results: Patients with subclinical gouty nephropathy had a higher prevalence of arterial hypertension and metabolic syndrome. The prevalence of osteoarthritis, diabetes mellitus and dyslipidemia was the same in both groups. Also, group I patients showed longer duration of the disease, greater radiologic changes, higher levels of hyperuricemia, tophi, work incapacity, greater number of affected joints and more frequent changes in urinalysis than the control group.

Conclusions: Formation of GN is asymptomatic, causing delays in early diagnosis, but can be suspended timely. Gouty nephropathy develops in 56.3% of patients with chronic gouty arthritis, and manifests by microproteinuria in the early subclinical stages. Duration of the disease, obesity, presence of tophi, arterial hypertension, hyperuricemia, increased triglycerids and low-density lipoproteins levels were found to be predictors of gouty nephropathy.

REFERENCES:
Objectives: We aim to compare the frequency of achieving target uric acid level in stage 4 chronic kidney disease (GFR < 30 mL/min) and worse. Due to concerns related to adverse effects of allopurinol, we hypothesised that allopurinol use would be less aggressive in terms of achieving target uric acid.

Methods: We reviewed charts of patients in a large private practice who were prescribed Allopurinol. Patients who had at least at least two office visits and had been on Allopurinol at least six months were included in the study. Charts were reviewed of patients for uric acid level, Allopurinol dose, GFR and any major adverse events. Major allopurinol related adverse event was defined as any adverse event leading to hospitalisation or cessation of medication.

Results: Mean Allopurinol dose for patients with GFR of more than 60 was 244 mg/day. There were no major adverse events and 52 out of total 103 patients (50.5%) had achieved goal uric acid.

Conclusions: There was no difference noted in patient with GFR less than 60 or more than 60 in terms of achieving goal uric acid level. No major adverse events were noted in either group.

Disclosure of Interest: None declared

Infection-related rheumatic diseases

CERVICAL POTT'S DISEASE: 5 CASE REPORTS AND REVIEW OF LITERATURE

Background: Spinal tuberculosis (Pott's disease) is the most common as well as one of the most dangerous forms of skeletal tuberculosis and accounts for 50% of all cases of skeletal tuberculosis. Pott's disease is still common in developing countries. Although the thoracolumbar junction seems to be the most common site of the spinal column involvement, cervical localization is rare and accounts for 2% to 5% of spinal tuberculosis. Furthermore, the incidence of neurologic complications in spinal tuberculosis varies from 10% to 43%.

Objectives: The purpose of this study was to perform an updated review and present our experience with 5 cases of tuberculosis of cervical spine, including clinical characteristics, diagnostic modalities and management of spinal tuberculosis.

Methods: A review of 5 cases of cervical Pott's disease collected at the Department of Neurosurgery of National Institute of Neurology of Tunis over a period of 2 years, between 2011 and 2012 and an updated literature review.

Results: The average age of our patients was 35 years old with extremes ranging from 16 to 63 years old. There is a slight male predominance. The diagnostic delay is on average 6 months. The clinical manifestations were dominated by cervical pain (4 cases) and progressive spinal cord compression syndrome (3 cases). The biological inflammatory syndrome is found in only one patient. The intra-dermal reaction to tuberculin is positive in 4 patients. X-ray of the cervical spine, CT scan and magnetic resonance imaging were performed in all patients. All patients underwent a surgical resection. The medical treatment was administered to all our patients. The evolution was favourable, clinically and biologically, under anti-tubercular treatment.

Tuberculous spondylodiscitis remains a major global public health problem in endemic countries that affects mostly young adults in their most productive years. Thoracolumbar junction seems to be the most common site of the spinal column involvement in spinal tuberculosis (85%) and cervical spine is concerned in only 5% of cases. The delayed diagnosis, between 3 and 20 months, explains the frequency of neurological deficits which are found in proportions of 20% to 40%. For the diagnosis of spinal tuberculosis, magnetic resonance imaging is more sensitive, imaging technique than x-ray and more specific than computed tomography. Antitubercular treatment remains the cornerstone of treatment. Surgery may be required in selected cases. With early diagnosis and early treatment, prognosis is generally good.

Conclusions: Cervical Pott’s disease is a rare localization. The diagnosis is easy in front of the cervical signs. The conservative management of cervical spine immobilisation and antitubercular chemotherapy remains a sufficient attitude to healing. Surgery is reserved in case of neurological aggravation or spinal instability.

RHEUMATOLOGICAL MANIFESTATIONS DURING CHRONIC HEPATITIS C

H. Kchi1, H. Kaffel2, H. Dabbabi1, D. Issaoui1, H. Sailhi1, W. Hamdi1, M. Elleuch2, M. Mmoumi1. Gastroenterology, La Rabta Hospital, Tunis; 2Rheumatology, Kassab, Manouba; 3Rheumatology, La Rabta Hospital, 4Gastroenterology, Charles Nicolle Hospital, Tunis, Tunisia

Background: Chronic hepatitis C (CHC) is assimilated to a systemic disease because of his multiple extrahepatic manifestations notably rheumatological.

Objectives: The aim of this study was to determine the frequency and the characteristics of the rheumatological manifestations (RM) associated with CHC.
Methods: A retrospective study including all patients suffering from CHC followed over a period of 11 years (2002–2012). Were excluded all patients co-infected by hepatitis B virus or by human immunodeficiency virus and those having decompen-sated cirrhosis. Different RM were collected and analysed according to the epidemiological, clinico-biological, immunological, virological and histological data of the CHC.

Results: Two hundred and four patients affected by CHC were included, meanly aged by 52 years [22–68 years]. The sex-ratio was 0.46. MR were noted in 76 patients (37.25%), dominated by inflammatory polyarthritis of big joints (88.25%). Non erosive arthritis was observed in a woman and was localised to the proximal interphalangeal articulation of the index. Myalgia were noted in 11 cases (14.47%) among them, 2 appeared under antiviral treatment. Sica Syndrome was observed in 17 cases (22.36%). RM were associated to other extrahaepatic manifestations of CHC in 69.7% of cases, notably to mixed cryoglobulinemia (MC) (60%) and to antinuclear antibodies (21.6%). Anti DNA, anti SSA, anti SSB, rheumatoid factor and anti CCP were absent in all cases. A partial to total amelio-
ration of RM was noted in almost patients under antiviral treatment and sometimes associated to symptomatic measures. In univariate analyse, only female sexe and presence of MC were significantly correlated to the presence of MR.

Conclusions: During CHC, MR are frequent, dominated by arthralgia, myalgia and sicca syndrome. Authentic arthritis are rare and constitute a diagnostic prob-
lem essentially when they inaugurate the disease. MC is the immunological factor the most associated with RM. Treatment of MR still antiviral.

AB1051
BRUCELLOSIS IN RHEUMATOLOGY: A STUDY OF 27 CASES IN TUNISIA
K. Saadaoui1, S. Sahli, S. Rekik, A. Ajlani, M. Mariem, T. Aissaoui, S. Boussaid, E. Cheour, M. Elleuch, on behalf of CHU LARABTA. Rheumatology, CHU LA RABTA, Tunis, Tunisia

Background: Brucellosis is an endemic zoonosis in the Mediterranean basin. The osteo articular localization, although rare, remains redoubtable.

Objectives: The aim of our work is to study the characteristics of osteoarticular brucellosis in Tunisia.

Methods: This is a descriptive retrospective study including 27 cases of osteoarticular brucellosis, collected in a rheumatology department over a period of 12 years (2006–2017).

Results: The Sex Ratio Female/male was 1.07 with an average age of 50.9 years.1–7 Diagnosis delay was 5.9 months [0.3–13]. The diagnosis of spondylo-
discitis was retained in 23 patients (85.2%) and sacrolithiasis in 4 cases (14.8%). Spinal or sacroiliac pain was found in all patients. Fever was present in 22 patients, sweat in 11 patients, loss of weight or appetite were respectively found in 16 and 12 patients. Eleven patient reported fatigue.

Laboratory examination found high erythrocyte sedimentation rate in 23 patients with an average of 69.4 mm.1–7 CRP was elevated in 26 patients with an average of 59.6 mg/L [3.5–237]. The WBC average was 9451 elements/mL [5500–14 000]. Wight serology was positive in all cases, Rose Bengal was positive in 15 cases, and IFI was positive in 3 cases. Bruella melitensis was isolated in blood cultures in 3 cases.

Standard X Rays showed disk involvement in 21 patients, vertebral lesions in 20 cases and sacrolithiasis in 4 patients. Sectional imaging (MRI or CT) was performed for all patients confirming standard X rays data and showing abscess in 13 patients and epiduritis in 7 patients.

The most affected spinal segment was the lumbar one (13 cases), cervical local-
ization was found in 5 cases and thoracic in only 1 case. The spondylitis was multi-
focal in 2 cases.

Spinal disc biopsy was performed in only 4 cases, neither anatomo-pathologic nor bacteriological examination were conclusive.

The treatment was based on the cyclical and rifampicin combination for an aver-
age duration of 4.5 months.3–4 The evolution was favourable in the majority of the cases with a relapse in only 2 cases.

Conclusions: Osteoarticular brucellosis is a focal form of brucellosis, the most frequent location is spinal and whose adequate treatment allows a favourable evolution.

AB1052
COMPARISON OF SEVERAL BIOMARKERS (MMP-2, MMP-9 AND ITS INHIBITOR TIMP-1, CTX-II, CALPROTECTIN AND COMP) IN THE SYNOVIAL FLUID AND SERUM OF PATIENTS WITH AND WITHOUT SEPTIC ARTHRITIS
M. Courier1,2, C. Peyreodé1, B. Pereira3, E. Miot-Noiraux4, S. Mathieu1, M. Soubré1, J.-J. Dubost1,2. 1Rheumatology, CLERMONT FERRAND UNIVERSITARY HOSPITAL; 2Umost, UMR 1340/INSERM/UCA; 3biostatic unit, CLERMONT FERRAND UNIVERSITARY HOSPITAL, Clermont-Ferrand, France

Background: Diagnosing septic arthritis (SA) is an emergency, and for a diagno-
sis to be made a microorganism must be found in the synovial fluid or blood cul-
ture. Besides direct bacteriological examination, which is positive in only 25% to 50% of cases, no laboratory examination can differentiate SA from other forms of arthritis.

Objectives: To assessed the performances of several serum and synovial bio-
markers (matrix metalloproetinase [MMP]-2, MMP-9, the metalloprotease inhibitor [TIMP]-1, cartilage oligomeric matrix protein [COMP], C-terminal telopep-
tide of type II collagen [CTX-II], and calprotecin [CALP]) for discriminating between septic and non-SA in a population of patients with suspected SA.

Methods: Using the ELISA technique, a number of potential biomarkers (MMP-2, MMP-9, TIMP-1, COMP, CTX-II, and CALP) were measured in the synovial fluid and serum of 39 patients with suspected SA (of whom 21 had SA and 18 non-SA). The levels of the various markers were compared on univariate and then multivariate analysis using logistic regression.
Factors associated with tuberculosis in rheumatoid arthritis

O. Saidane, I. Oueslati, R. Tekaya, A. Ben Tekaya, I. Mahmoud, L. Abdelmoula

Background: Rheumatoid arthritis (RA) is associated with infections that are favored by the disease itself or by its treatments. Tuberculosis (TB) is a severe infection that can occur in patients with RA, especially with the use of anti-TNF.

Objectives: This study aimed to estimate the incidence of TB in RA patients and identify factors associated with TB during RA.

Methods: This was a retrospective study of RA patients according to ACRA/EULAR criteria 2010 collected in rheumatology department during the period from April 2010 to April 2015. Diagnosis of latent or patent TB was made as part of the pretreatment screening (biotherapy) or if signs of infection occurred.

Results: During the study period, 150 RA patients (124 women and 26 men) were enrolled. The mean age was 57.09 years. Mean disease duration was 7.52 years. Rheumatoid Factor was positive in 79% of cases. Eighty-eight percent of patients received corticosteroids with a mean dose of 10 mg/day. All patients were treated with at least one conventional synthetic disease-modifying antirheumatic drug (methotrexate, sulfasalazine and leflunomide in respectively 87%, 37% and 7% cases) and only 36% (24%) patients received biotherapy. A history of patent TB treated appropriately and prior to RA was found in 5 patients (3%); 3 pulmonary TB and 2 lymph node forms. The pretreatment test showed 11 cases of latent TB (30%). No relapsed TB was reported on RA treatment. Nine cases (25%) of new active TB were noted during biotherapy: 5 pulmonary TB (under infliximab, adalimumab and tocilizumab), 2 lymph nodes TB (under infliximab) and 2 urogenital TB (under infliximab).

Conclusions: Our study showed that RA patients were exposed to a higher risk of TB, especially when using anti-TNF therapy with increased incidence of extra pulmonary TB. Understanding associated factors with TB may lead to establish a continuous monitoring in order to improve the quality of care.

BRUCELLAR SPONDYLODICTYSIS: DO MRI SIGNS OF SEVERITY INFLUENCE THE DURATION OF THE TREATMENT

O. Saidane, I. Oueslati, R. Tekaya, A. Ben Tekaya, I. Mahmoud, L. Abdelmoula

Background: Brucellar spondylodictisis is rarely associated with neurological involvement. Magnetic resonance imaging has high sensitivity for detecting the paravertebral and epidural extension.

Objectives: The purpose of this study was to determine the influence of the MRI severity signs on the treatment duration.

Methods: A retrospective study of 27 patients with Brucellar spondylodictisis during a period of 17 years (2000–2016) was performed. Diagnosis was made on clinical presentation, laboratory findings, radiographic evidence and Brucellar seroagglutination tests. Three patients underwent CT scans and a spinal MRI was carried out for 24 patients. All of them received antibiotic treatment based on a combination of Rifampicin and Doxycycline of varying duration.

Results: Ten women and 17 men were included. The mean age was 54 years. Twenty-six patients suffered from spinal pain (96.3%) and 12 patients had radiculalgia (44.4%). The lumbar spine was the most frequently involved region (59.3%), followed by the dorsal spine (18.5%) and the cervical spine (11.1%). The

ADVERSE EFFECTS AND THEIR CONSEQUENCES IN PATIENTS WITH CHRONIC INFLAMMATORY ARTHROPATHIES IN TREATMENT WITH BIOLOGICAL THERAPY

N. Martínez-López, D. Castro1,2, A. Martín-Vila, M. Alvarez-Payero, M. Samartín-Ucha, G. Piñeiro-Corrales, J.M. Pego-Reigosa1

1Pharmacy and 2Institute of biomedica investigation of South Galicia, Universitary Hospital of Vigo, Vigo, Spain

Background: The introduction of biological therapies (BT) for the treatment of chronic inflammatory arthropathies (CIA) has improved the prognosis of these diseases and the quality of life of patients. However, the safety of these drugs in the long term continues to be an aspect of interest.

Objectives: The aim of this study is to review the safety of BT in patients with CIA and the consequences of these adverse effects for patients and the health system under daily clinical practice conditions.

Methods: A descriptive, observational and retrospective study was performed. All patients with CIA: rheumatoid arthritis (RA), anklyosing spondylitis (AS) and psoriatic arthritis (PsA) who started BT (adalimumab, etanercept, adalimumab, certolizumab, infliximab, tocilizumab and ustekinumab) from January 2009 to January 2017 in the Rheumatology Department of the Sanitary Area of Vigo (Spain) were included. Demographic variables (age, sex), variables related to CIA and its comorbidities: clinical and analytical data (CRP, ESR, haemoglobin, DAS and BASDAI) and years of disease evolution and variables about BT: concomitant treatment (glucocorticoids, methotrexate and leflunomide), persistence and number of lines were collected. Variables about the adverse effects (AE) of BT: type and clinical consequence, requirement for additional visits to the Rheumatology clinic, visits to the Emergency Department or need for hospital admission was also collected.

Results: Three hundred sixty-two patients and 478 BT lines (250 lines in patients with RA, 119 with AS and 109 with PsA) were analysed (mean ±SD of BT lines: 1.7 ±1.1 per patient). In total, 683 AEs were detected (0.57 AEs per patient and year of treatment). The most frequent types of AEs were: bacterial infection (0.39 events per year of BT), viral infections (0.04 events per year of BT), fungal infections (0.04 events per year of BT), reactions related to the administration of BT (0.03 events per year of BT) and cardiovascular alterations (0.02 events per year of BT). Certolizumab and abatacept were the drugs that were more associated with bacterial infections: 0.82 and 0.69 per year of BT, respectively. Infliximab was the BT that was less associated with bacterial infections: 0.24 per year of BT. There were 7 deaths in probabilistic relation with the AEs (4 bacterial infections, 1 cardiovascular event and 2 solid tumours). The AEs caused 71 hospital admissions (688 days of hospital stay), 113 hospital emergency room visits and 42 urgent visits to the Rheumatology Department. Sixty percent of the AE were managed from Primary Care without hospital admission. The AEs caused 71 hospital admissions (668 days of hospital stay), 113 hospital emergency room visits and 42 urgent visits to the Rheumatology Department. Sixty percent of the AE were managed from Primary Care without hospital admission. The AEs caused a definitive interruption of BT in 51 episodes and a switch to a different BT in 52 episodes.

Conclusions: In our setting, patients with CIA on BT have an incidence of 0.57 AE per patient and year of BT. Infection (particularly bacterial) is the most frequent AE. Although more than 50% of these AEs are managed from Primary Care, they imply a high consumption of hospital resources.

AB1054 FACTORS ASSOCIATED WITH TUBERCULOSIS IN RHEUMATOID ARTHRITIS

O. Saidane, M. Sellami, I. Mahmoud, A. Ben Tekaya, H. Ajlani, R. Tekaya, L. Abdelmoula

Rheumatology, Charles Nicole hospital, Tunis, Tunisia

Background: Rheumatoid arthritis (RA) is associated with infections that are favored by the disease itself or by its treatments. Tuberculosis (TB) is a severe infection that can occur in patients with RA, especially with the use of anti-TNF.

Objectives: We aimed to estimate the incidence of TB in RA patients and identify factors associated with TB during RA.

Methods: This was a retrospective study of RA patients according to ACR/EULAR criteria 2010 collected in rheumatology department during the period from April 2010 to April 2015. Diagnosis of latent or patent TB was made as part of the pretreatment screening (biotherapy) or if signs of infection occurred.

Results: During the study period, 150 RA patients (124 women and 26 men) were enrolled. The mean age was 57.09 years. Mean disease duration was 7.52 years. Rheumatoid Factor was positive in 79% of cases. Eighty-eight percent of patients received corticosteroids with a mean dose of 10 mg/day. All patients were treated with at least one conventional synthetic disease-modifying antirheumatic drug (methotrexate, sulfasalazine and leflunomide in respectively 87%, 37% and 7% cases) and only 36% (24%) patients received biotherapy. A history of patent TB treated appropriately and prior to RA was found in 5 patients (3%); 3 pulmonary TB and 2 lymph node forms. The pretreatment test showed 11 cases of latent TB (30%). No relapsed TB was reported on RA treatment. Nine cases (25%) of new active TB were noted during biotherapy: 5 pulmonary TB (under infliximab, adalimumab and tocilizumab), 2 lymph nodes TB (under infliximab) and 2 urogenital TB (under infliximab). In our study, factors associated to TB infection were an advanced age, high level of C-reactive protein, a history of diabetes, dose of steroids<7.5 mg/day and dose of Infliximab>3 mg/kg (table 1).

AB1055 RHEUMATOID ARTHRITIS
neurological examination showed no abnormalities. Spinal MRI showed paravertebral abscess in 56.5% of cases. Seventeen patients (73.9%) had epiduritis and 9 patients (39.9%) had spinal cord compression on the MRI. An abnormal signal of the spinal cord was observed in 2 cases (8.7%). All patients received a combination of Rifampicin and Doxycycline. The mean duration of the antimicrobial treatment was 8 months. There was no statistically significant association between the occurrence of abscesses, epiduritis, spinal cord compression, abnormal signal of the spinal cord on the MRI and the duration of treatment (p=0.935, p=0.889, p=0.379, p=0.889 respectively).

Conclusions: MRI of the spine frequently revealed signs of severity in brucellar spondylodiscitis patients, although without clinical expression. Despite their severity these signs did not result in a longer period of antibiotic therapy.

Disclosure of Interest: None declared

AB1056
 DIAGNOSIS VALUE OF PERCUTANEOUS SPINAL NEEDLE BIOPSY IN BRUCELLLAR SPONDYLODISCITIS

O. Saidane, I. Oueslati, I. Mahmoud, A. Ben Tekaya, R. Tekaya, L. Abdelmoula.
Rheumatology department, Charles Nicolle hospital, Tunis, Tunisia

Background: Spondylodiscitis is a serious condition with a large variety of infectious etiology. Vertebral biopsy is needed to perform the microbiologic diagnosis when no causative organism is identified. CT-guided percutaneous spinal biopsy (CTSB) may reduce the risk of contamination and complications.

Objectives: The aim of this study is to determine the contribution of CTSB to the diagnosis of Brucellar spondylodiscitis.

Methods: We conducted a retrospective study on 27 patients admitted for Brucellar spondylodiscitis over a 17 years period [2000 to 2016]. The etiological diagnosis was based on Brucella agglutination test which was positive for all patients. Twelve patients had a CTSB with cytobacteriological and histological tests.

Results: Twenty seven patients (17 men and 10 women) with a mean age of 54 years were included. Twenty six patients (96.3%) reported a spinal pain. This pain involved the lumbar spine (59.3%), the dorsal spine (18.5%) and less frequently the cervical spine (11.1%). Eight patients reported lombosacralgia (29.6%). An etiological doubt subsisted in 12 cases and a CTSB was performed. Culture results were negative for 11 biopsy samples and one culture was positive to Staphylococcus aureus. The mean duration of the antimicrobial treatment was 8 months. There was no statistically significant association of Rifampicin and Doxycycline. The mean duration of the antimicrobial therapy was 8 months. There was no statistically significant association of Rifampicin and Doxycycline.

Results: Twenty seven patients (17 men and 10 women) with a mean age of 54 years were included. Twenty six patients (96.3%) reported a spinal pain. This pain involved the lumbar spine (59.3%), the dorsal spine (18.5%) and less frequently the cervical spine (11.1%). Eight patients reported lombosacralgia (29.6%). An etiological doubt subsisted in 12 cases and a CTSB was performed. Culture results were negative for 11 biopsy samples and one culture was positive to Staphylococcus aureus.

Conclusions: Our results suggest that CT-guided spinal biopsy is not useful to diagnose Brucellar spondylodiscitis. However, the absence of tuberculoid granuloma and caseous necrosis helped ruling out the tubercular origin.

Disclosure of Interest: None declared

AB1057
 BRUCELLAR SPONDYLODISCITIS: THE IMAGING FINDINGS

O. Saidane, I. Oueslati, R. Tekaya, A. Ben Tekaya, I. Mahmoud, L. Abdelmouloua.
Rheumatology department, Charles Nicolle hospital, Tunis, Tunisia

Background: Brucellar spondylodiscitis is an important complication of brucellosis that can cause neurologic involvement and spinal deformities if not appropriately treated. Imaging examination is a major key in diagnosis.

Objectives: The aim of this study was to report the imaging findings in brucellar spondylodiscitis.

Methods: We performed a retrospective study including 27 patients with Brucellar spondylodiscitis over a period of 17 years from 2000 to 2016. Diagnosis was made on clinical presentation, laboratory findings, radiographic evidence and Brucella agglutination test. All patients underwent X-rays of the involved spine levels. Spinal computed tomography (CT) was carried out in 13 cases and spinal MRI in 24 cases.

Results: Seventeen men and 10 women aged from 33 to 75 years were included. Plain radiographs showed a disc space narrowing for 26 patients (96.3%) and an irregularity of the vertebral end plate in 16 cases (59.3%). A paravertebral abscess formation was detected for 3 patients. No obvious abnormalities were found in one case. CT scans of most patients revealed signs of spondylodiscitis (92.3%). This examination showed an erosion of the vertebral end plates (69.2%), intervertebral disc space narrowing (61.5%), and bone destruction (38.5%). The severity signs detected on the CTs were the soft tissue thickening (46.2%), abscesses formations (7.4%), epiduritis (30.8%) and one patient had a spinal cord compression. The 24 MRIs realised exhibited a signal abnormality of the vertebral body (95.7%) and the intervertebral disc (47.8%) in addition to disc space narrowing (73.9%) with erosions of the vertebral end plates (56.0%). The contrast enhanced T1-weighted images showed marked enhancement of affected vertebral and disc (78.3%). Thirteen patients had abscesses formations (56.5%), 17 had epiduritis (73.9%) and 9 patients (31.9%) presented a spinal cord compression on the MRI. Brucellar spondylodiscitis involved one spinal level in 23 cases whereas multilevel involvement was found in the 4 others.

Conclusions: Plain radiographs and spinal CT scans lack sensitivity in diagnosing brucellar spondylodiscitis and spinal MRI remains the referential imaging modality to recognise early bone infection, allowing complete lesion topography and identifying the complications.

AB1058
 IS HEPATITIS B SURFACE ANTIGEN (HB S AG) ENOUGH ALONE AS A SCREENING TEST FOR HBV INFECTION IN RHEUMATIC DISEASE PATIENTS BEFORE STARTING IMMUNOSUPPRESSIVE THERAPIES?

R.A. Abdel Noor1, M. Watany2, S. Abd-Elisalami2, W. Elkhalawany3, S. Soliman4, R. Badawi5, 1Internal Medicine and Rheumatology, 2Clinical Pathology, 3Tropical Medicine, Faculty of Medicine, Tanta University, Tanta; *public heathandcommunity medicine, Faculty of Medicine, Menofia university, Menofia, Egypt

Background: Prevalence of hepatitis B virus in patients with rheumatic diseases has been reported differently among studies. The loss of immune control in these patients may result in the reactivation of HBV replication within hepatocytes. Considering the lifelong use of multiple anti-rheumatic drugs, screening for HBV is recommended before starting immunosuppressive or immunomodulatory therapy.

Objectives: The aim of this study was to select the best and simplest test for screening of HBV in rheumatic patients in Egypt.

Methods: This cross sectional study was carried out on 102 patients with different rheumatic diseases. Screening to all patients by hepatitis B surface antigen (HBsAg), hepatitis C virus (HCV) and human immune deficiency virus antibodies (HIV) were done. HBV core antibodies and real time PCR to detect HBV DNA were done.

Results: The mean age of the patients was 37.18±13.27. 3.9% of them were males and 96.1% were females. We found that HBsAg was positive in two patients (2%) and negative in 100 patients (98%). HBeAb was positive in 24 patients (23.5%) and negative in 78 patients. However PCR for hepatitis B DNA was positive in 2 patients (2%) only who were positive for both HBsAg and HBe Ab. HBsAg had 100% Sensitivity, 100% Specificity, 100% PPV, 100% NPV and 99.0% accuracy. While anti HBe had 100% Sensitivity, 78% Specificity, 8% PPV, 100% NPV and 78% accuracy in screening of HBV.

Abstract AB1058 – Figure 1. Receiver operating characteristic (ROC) plot for ‘HBs Ag in relation to PCR in diagnosing HBV’ on the left side & ‘HB c Ab in relation to PCR’ on the right side.
Conclusions: We can conclude that screening for hepatitis B virus is essential for all patients with rheumatic diseases before starting therapies either steroids, immunosuppressive therapies or biologics. For financial issues especially in developing countries screening by HBsAg may be enough as an initial test especially if non biological therapies are used as it is superior to anti HBc for screening for HBV infection.

CONTRIBUTION OF CT-GUIDED DISCOVERTEBRAL BIOPSY DURING INFECTIOUS Spondylodiscitis

S. Lataye1, S. Belgiri1, H. Zaghouani2, S. Sirid1, K. Baccouche1, S. Majdoub2, N. Elame1, F. Bouzayene2, H. Zeglaoui1, D. Bakri2, E. Bouajina1, D. Spiridon1, H. Abdelatif1, M. Sarholz1, V. Korendovych1, J. Schoenherr1, T. Duerdoth1, F. Schumann2, D. Blendea1, S. Lataoui1, S. Belghali1, H. Zaghouani2, S. Sridi2, K. Baccouche1, S. Majdoub2

Background: Infectious spondylodiscitis is an infection involving the vertebral endplates and the intervertebral discs. The diagnosis is based on a combination of clinical symptoms, biological and radiological findings. Identifying the causative germ is sometimes difficult and a CT-guided discovertebral biopsy (DVB) might be of help, with varying success rates.

Objectives: The aim of this study was to assess the contribution of CT-guided DVB in the diagnosis of infectious spondylodiscitis in a rheumatological environment in Tunisia.

Methods: A retrospective study including patients diagnosed with infectious spondylodiscitis in the rheumatology department of Farhat Hached hospital. Sousse, Tunisia, between 1998 and 2017. Only patients who underwent a DVB for etiologic diagnosis of infectious spondylodiscitis were included in this study.

Results: Thirty five patients, with 12 (34.3%) women, were included. The mean age was 57.3±19.14 years [15–83 years]. All patients presented with back pain for 83.06±73.32 days [10–330 days], seven (20%) patients had fever and six (17.1%) patients had abnormal neurological signs on examination. The mean WBC, CRP and ESR levels were respectively 8170.83±3547.94 elements/mm³, 50.22±59.22 mg/L and 86.85±50.74 mmh1. The affected levels were the lumbar in 23 (65.7%) cases and dorsal spine in 9 (25.7%) cases. Three patients (8.6%) had both dorsal and lumbar spondylodiscitis.

First DVB was contributive in 11 (31.4%) cases, isolated germs were staphylococcus aureus in 4 (36.4%) cases, tuberculosis in 3 (27.3%) cases, and brucellosis, coagulase negative staphylococcus, enterobacter cloacae, streptococcus oralis in one case each. Only one patient underwent a second DVB attempt, which was contributive, isolating a staphylococcus aureus. The rest of patients were treated based on base bacteriological findings (2 cases of brucellosis, 2 cases associated with Escherichia coli urinary infection and 1 case with pulmonary tuberculosis), or presumption arguments (6 cases treated as pyogenic infection and 12 cases as tuberculosis).

Conclusions: DVB remains essential for the positive diagnosis of infectious spondylodiscitis. Nevertheless, its bacteriological insufficient contribution should not delay therapeutic management based on presumptive arguments.

WHIPPLE DISEASE WITH INITIAL PRESENTATION AS NON-EROSIve SERONEGATIVE POLYARThRITIS: A CASE REPORT FROM A SINGLE CENTRE

V. Korendovych1, J. Schoenherr1, T. Duerrdh1, F. Schumann2, D. Blendea1, D. Spiridon1, H. Abdelatif1, M. Sarholz1, D. Department of Rheumatology, St. Marien-Hospital Vreden, Academic Educational Hospital of the University Duisburg-Essen, Vreden; 2Rheumatology, Praxis Center Reken, Reken, Germany

Background: Whipple disease (WD) is a rare disease caused by the bacterium Tropheryma whipplei (TW), which manifestations may range from joint and G1tract involvement to severe neurological complications.

Objectives: To present a clinical case of WD with non-erosive seronegative polyarthritis, sacroiliitis, abdominal and CNS involvement, and immune reconstitution inflammatory syndrome after antibiotic therapy.

Methods: Case report. Prospective follow-up of the patient E. with WD, who was diagnosed HLA-B27-negative nonerosive seronegative rheumatoid arthritis in 2013. The disease was partially responsive to glucocorticoids with temporary effect to different DMARDS (MTX, lefunomid, etanercept, abatacept, tocilizumab either as monotherapy or in combination).

Results: A 54 y.o. male patient E. was admitted to the Rheumatological department with complaints of joint swelling, low back pain, weight loss, diarrhea, headache, and low grade fever. Peripheral joint arthritis appeared about 4 years ago with progressive worsening of general condition and development of additional complaints during the past year. From 2013 to 2017 the patient received in-hospital and outpatient treatment because of active seronegative polyarthritis without sufficient effect. On admission: clinical examination and joint ultrasound (US) investigation revealed the signs of polyarthritis. Neurological evaluation showed organic psychiatric disorder with signs of pseudodemodatemia, bradykinesia without focal neurological defects.

Because of both incomplete responsiveness to DMARD-therapy and suspicion of chronic infection or malignant neoplasm, abdominal US and transorhachic echocardiography, gastroscopy, colonoscopy, immunofixation, bone marrow biopsy, chest X-ray and bone scintigraphy, tests for viral hepatitis (B,C), HIV, Lues and QFT-Tb were performed, however without objective evidence of the case. PET-CT was performed as well, showed no signs of malignancy or infection. MRI revealed bifrontal brain atrophy, low-grade bilateral sacroilitis and degenerative changes of the cervical spine.

For differential diagnosis PCR stool investigation for TW was performed and was positive. Upon the suspicion of WD endoscopy with duodenal biopsy were done. Histological examination showed PAS-positive macrophages, typical for WD. Immunohistochemical analysis also supported the diagnosis. PCR investiga-

MULTIFOCAL Spondylodiscitis in Immunocompetent Patients

W. Handi, S. Bouden, H. Riahi, K. Maatallah, M.D. Kaffel, M. Bouaziz, M. Iadeb, M. M. Khrif. Institut Kassab, tunis, Tunisia

Background: The prevalence of infectious spondylodiscitis (ISPD) has decreased recently with the development of effective means of prevention. Multifocal forms are more common in immunocompromised persons, but may be seen in immunocompetent ones. They are severe, and fortunately remain rare.

Objectives: The aim of our study was to report the clinical, biological, radiological and therapeutic features of multifocal ISPD in immunocompetent patients.

Methods: A retrospective study was performed including patients hospitalised in the department of rheumatology between January 2007 and December 2017. Clinical data, laboratory findings and radiologic features were evaluated.

Results: Six patients were included. Their mean age was 53 years. No comorbidities were found in all patients. The interval between the beginning of the symptomatology and the diagnosis was 3 to 6 months. Fever was noticed in 4 cases. All the patients had inflammatory spinal pain. Two patients had neurologic deficit: one spinal compression and one root compression. The localization of the infection was lumbar and thoracic in 3 cases, cervical in 1 case and lumbar in 2 cases. MRI showed epiduritis in 3 cases and paravertebral abscess in 1 case. The infectious agent was identified by blood cultures in 1 case (Staphylococcus Aureus), by disco vertebral biopsy in 3 cases (tuberculosis) and by brucella serology in 2 cases. All patients underwent antibiotic therapy and immobilisation with a spinal cord. Investigation for immunodeficiency was negative in all patients.

Conclusions: Multifocal ISPD in immunocompetent patients remains rare. Its etiology is dominated by tuberculosis. The most frequent localizations are lumbar and thoracic spine.

AB1062  RISK FACTORS FOR MORTALITY AFTER TUBERCULOUS ARTHRITIS
Y.-C. Chen, Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China

Background: Tuberculosis arthritis is an emerging international problem despite advances in the methods of diagnosis and treatment; it is still prevalent in developing countries and on the increase in developed ones.

Objectives: Patients with tuberculous (TB) arthritis increase mortality. This study investigated to search for the risk factors of mortality in TB arthritis.

Methods: We retrospectively reviewed patients with TB arthritis who admitted to Kaohsiung Chang Gung Memorial Hospital January 2001 to December 2015. The long-term outcomes of the patients were analysed.

Results: A total of 281 patients (124 females and 17 males; mean age: 64.86 ±14.51 years) were enrolled. At the end of the study, 229 patients were alive and 52 had died. The mean follow-up period was 8.31±4.52 years. The patients who were old age (p=0.004, HR=1.038, 95% CI 1.012–1.062) were old age and underlying liver and cancer (p<0.05). There was a significant difference between the patient groups in swallowing intervals (p<0.05).

Ultrasonographic measurement results in healthy subjects were higher than patient groups (p<0.05). But ultrasonographic values of patients groups were similar (p>0.05).

Conclusions: Swallowing functions and structures are affected in patients with FMS, even though there are no symptoms of swallowing difficulty. Therefore, the main symptoms such as pain, fatigue, and sleep disturbance are being questioned, and a detailed evaluation including swallowing should be performed.

Fibromyalgia

AB1063  SWALLOWING DIFFICULTY IN FIBROMYALGIA: REAL OR MYTH?
E. Umay, E. Gurcay, O. Karaahmet, A. Hasturk, D. Dulgeroglu Erdogdu, University of Health Sciences Ankara Yildirim Beyazit Education and Research Hospital, Ankara, Turkey

Background: Fibromyalgia Syndrome (FMS) is a chronic disease that the most common disease in medical practice. This syndrome is including some general symptoms such as chronic pain, fatigue, tenderness and sleep disturbance, that can be seen in many disorders. Other than these, there are symptoms such as dysphagia, which are reported less frequently but have serious consequences such as aspiration. Studies in literature have been reported that this may not be a real swallowing difficulty and may be a symptom of somatization or may be due to adverse events such as drug side effects.

Objectives: This study was aimed to reveal the presence of dysphagia with objective diagnostic tests in FMS patients.

Methods: This study was conducted on 165 subjects. Patients (n=83) with FMS regardless of whether the complaint is difficulty swallowing as well as had ages between 18–65 were included in the study. Healthy volunteers (n=82) consisting of hospital staff and relatives of patients and sex, age and body mass index-matched with patients were included as control group.

Demographic and disease characteristics were recorded. Fibromyalgia Impact Questionnaire (FIQ) was used to assess severity of disease, functional disability and specific quality of life of patients. Also, the general quality of life of patients was evaluated with Short Form-36 (SF-36). All subject were evaluated with clinical screen test (10-item eating assessment tool–Eat-10) flexible fiberoptic endoscopic evaluation of swallowing (FEES) and electrophysiologic evaluation (EE) as well as ultrasonography (US).

The patients were divided into two groups according to the presence of complaints of difficulty in swallowing, which was taken with eat-10 as group 1 (with dysphagia) and group 2 (with normal swallowing). Patients ve healthy volunteers (group 3) were compared in terms of swallowing evaluation methods.

Results: Twenty-one (25.3%) of the 83 patients were defined with dysphagia (group 1) as well as 62 (74.7%) patients with normal swallowing (group 2) according to the eat-10 scale. The groups were similar in terms of demographic characteristics (p>0.05).

The mean disease severity of all the patients was between moderate and severe levels as well as there was a mild impact on quality of life. Disease severity and quality of life by using FIQ and SF-36 were significantly worse in patients with dysphagia (group 1) compared with normal swallowing patients (group 2) (p<0.05).

None of the patients had dysphagia with endoscopic evaluation. All subjects could drink 20 ml of water which normal dysphagia limit. Swallowing intervals in patients groups were significantly prolonged compared to healthy volunteers (p<0.05).

There was no significant difference between the patient groups in swallowing intervals (p>0.05).

Conclusions: Swallowing functions and structures are affected in patients with FMS, even though there are no symptoms of swallowing difficulty. Hence, while the main symptoms such as pain, fatigue, and sleep disturbance are being questioned, a detailed evaluation including swallowing should be performed.

EXPLORING CEREBROSPINAL FLUID PROTEOME IN FIBROMYALGIA

E. Ossipova1, P. Emami Khonsarsi2, J. Lengqvist1, E. Kosek1, D. Kadeto3, P.-J. Jakobsson1, K. Kultima1, J. Lampa1,2, Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Fibromyalgia (FM) is a heterogeneous disease of unknown etiology characterised by chronic widespread pain that affects up to 4% of population. Overlapping and heterogeneous symptoms of various chronic pain conditions complicate their diagnosis, emphasising the need for more specific biomarkers to improve the diagnosis and understand the disease mechanisms. Cerebrospinal fluid (CSF) flows in the ventricles within the brain and diffuses over the brain and spinal cord. Due to direct contact of CSF with CNS, content of CSF reflects biochemical changes in CNS making it an excellent source for biomarker discovery.

Objectives: In current study we aim to explore CSF proteome of FM patients utilising quantitative proteomics method based on stable isotope labelling of CSF peptides combined with multivariate data analysis (MVDA) in order to monitor the dynamics of the proteome while comparing to the CSF proteomes in patients with rheumatoid arthritis (RA) and other neurological diseases (OND) and define the potential biomarker candidates in FM. We also investigate, which protein products have been found in human CSF with respect to known "pain" genes, human CSF proteome explored if these proteins represent any clear subgrouping of "pain proteins".

Methods: CSF samples from patients with FM, RA and control OND group were collected by lumbar puncture and equal aliquots were subsequently reduced, alkylated and digested by trypsin. Obtained peptides were labelled by stable isotopes and mixed prior sample fractionation. The degree of sample complexity was reduced by off-line peptide separation using HPLC instrumentation. Obtained 80 peptide fractions were combined into 10 fractions across the gradient area. Fractions were analysed by LC-MS/MS, proteins in acquired data were identified and quantified, and data was analysed using MVDA.

Results: Out of the 1422 proteins identified, 855 proteins were included in the quantitative data analysis. Comparing FM, RA and OND groups to each other using univariate testing we found 53 statistical significant proteins (q-value <0.05). Six out of these have been reported as "pain proteins" (Complement C4-A, Prostaglandin-H2 d-isomerase, Apolipoprotein D, Granulin, Pro-cathepsin H, and BMP) and active membrane-bound inhibitor homolog.

Conclusions: We have employed quantitative proteomics methods combined with extensive bioinformatics data analysis to investigate differences in proteome profiles in CSF obtained from patients with FM, and identified six differentially expressed pain proteins of various functions in CSF of FM patients. The involvement of these proteins in the disease pathogenesis as well as use of the identified proteins as potential biomarkers should be investigated.

PRELIMINARY FINDINGS OF A 2-MONTHS ACUPUNCTURE INTERVENTION ON SYMPTOMATOLOGY AND QUALITY OF LIFE IN PATIENTS WITH FIBROMYALGIA

M. Di Carlo, G. Beci, F. Salaffi. Rheumatological Clinic, Università Politecnica delle Marche, Jesi, Italy

Background: Acupuncture is frequently used in the treatment of different chronic pain conditions. In Fibromyalgia (FM) the evidences are available someway conflicting, and the correct positioning of such kind of therapy has not yet precisely defined. Objectives: To assess the response to a single course of acupuncture in patients with FM non-responsive to the usual pharmacological treatment.

Methods: Consecutive FM patients with unsatisfactory response or intolerance to the pharmacologic treatment (duloxetine and/or pregabalin) were involved in this study. Unsatisfactory response was defined by the presence of a revised Fibromyalgia Impact Questionnaire (FIQ-R) total score ≥40 and of a Patient Health Questionnaire 15 (PHQ15) ≥5 after 3 months of stable pharmacological treatment. Acupuncture treatment consisted in 8 weekly sessions. The acupuncture formula, according to the Traditional Chinese Medicine indications, included the following points: LV3 + LI4 (to move Qi), ST36 + CV6 + CV12 (to tonify Qi and Blood), GV20 (to raise Qi), and EX-HN-3 (Yingxi) (to calm the Shen), with acupuncture needle 0.25 × 25 mm with guide tube (Huanqi). For each session needles were retained for 30 min. At baseline (before the first session) and at the end of the treatment course (after the eighth session) were collected the number of tender points (TP) and patient-reported outcomes (PROs). Differences between baseline and end of the acupuncture treatment were evaluated through the Wilcoxon test, results expressed in median values with 95% confidence interval (CI).

Results: Thirty-four subjects were enrolled in the study. Thirty-two patients (29 women, 3 men, mean age 49 years, range 18–75) completed the acupuncture treatment. In two patients (one woman and one man) the acupuncture therapy was stopped at the second session for poor tolerance to the needles. Eleven patients were in pharmacological therapy with pregabalin, nine with duloxetine, while 12 resulted intolerant both to pregabalin and duloxetine. From baseline, after the 2 months of acupuncture treatment, different parameters showed a significant improvement. Particularly, it has been observed a significant reduction in the TP frequency of fruit and vegetable consumption, physical activity, personal history of high blood glucose, and family history of DM.2 Fast plasma glucose (FPG), oral glucose tolerance test (OGTT) and/or glycated haemoglobin (HbA1C) values were collected from all subjects before and after 2 months of acupuncture treatment. In two patients (one woman and one man) the acupuncture treatment was associated with the pharmacologic treatment. The strongest ameliorations are represented by the reduction in the health status in FM patients refractory/intolerant to the pharmacologic treatment. In two patients (one woman and one man) the acupuncture therapy was considered good and the patient was referred to the rehabilitation center for further treatment.

Conclusions: 2 months acupuncture treatment provides an important global improvement in the health status in FM patients refractory/intolerant to the pharmacologic treatment. The strongest ameliorations are represented by the reduction in the TP frequency and in the somatic symptoms.

PAIN, FATIGUE AND FUNCTIONAL IMPAIRMENT IN FIBROMYALGIA (FM) IN PATIENTS WITH PAINFUL KNEE OA

Background: Fibromyalgia Syndrome (FM) is a persistent and debilitating disorder estimated to impair the quality of life of 2% of the population. FM is an important representative example of central nervous system sensitisation and is an underlying the symptoms of FM patients. Increasing oxygen concentration by hyperbaric oxygen therapy (HBOT) may rectify abnormal brain function underlying the symptoms of FM patients. Increasing oxygen concentration by HBOT may change the brain metabolism and glial function to rectify the FM-associated brain abnormal activity.

Objectives: To evaluate the effect of HBOT on clinical symptoms in FM resistant to the usual pharmacological treatment

Methods: Thirty female patients, aged 21–67 years and diagnosed with FM at least 2 years earlier, and resistant to any pharmacological treatment were assigned to be added on with HBOT. The treated group patients were evaluated at baseline and after 10 and 20 HBOT sessions. Evaluations consisted of physical examination, including tender point count, extensive evaluation of quality of life. Study endpoints included assessments of pain (VAS), the FACIT Fatigue Scale and 18 body regions. Sleep problems (initiating sleep, frequent awakenings, not feeling rested early awakening) were reported by Uppsala Sleep Inventory (four items scored 0–3, best to worst). PPTs were measured in kPa at eight different anatomical sites representing upper, lower, left and right side of the body using the Algomed Computerised Pressure Allogometer FPX (Medoc Ltd. Advanced Medical Systems, Israel). A mean was calculated from all eight points to create a global pressure pain threshold (PPTg).

Results: Out of 146 subjects, 89 (61%) were women. Mean age was 64.6 (SD 12.7) years. This sub-population from the Epipain cohort reported a high prevalence of CWP without significant difference between men and women (33.9% vs 44.9%; p=0.411). Women had lower PPTg than men (345.0 kPa vs. 563.9 kPa; p<0.001). Subjects classified as CWP had lower PPTg than those classified as NCP (362.0 kPa vs. 479.9 kPa; p=0.003). A report of CRP did not affect PPTg in disease activity ranging from 0 to 10. The HBOT protocol comprised 20 sessions, 3 days/week, 90 min, 100% oxygen at 2.5 ATA.

Results: The effect of the hyperbaric oxygen therapy on the clinical symptoms are summarised in table 1. HBOT treatments of treated group led to statistically significant improvements in the mean scores of pain and fatigue (FACIT) after 10 and 20 HBOT sessions (mean change of pain after 20 sessions −1.76±2.5, p<0.001) (mean change of fatigue after 20 sessions 5.9±3.2±10, p<0.001). The FIQ-R score significantly improved following HBOT in the treated group (mean change after 20 sessions −12.8±17.04, p<0.001). The FAS score showed a positive trend after 10 sessions and a significant improvement after 20 sessions (mean change −2.02±3.14, p=0.006).

AB1069 CHRONIC WIDESPREAD PAIN, SLEEP PROBLEMS AND PRESSURE PAIN THRESHOLDS IN A POPULATION SAMPLE

S. Bergman1,2,3, E. Haglund2,4, K. Aili2,5, C. Olsson2, A. Bremander1,2,4
1Department of Clinical Sciences, Section of Rheumatology, Lund University, Lund;
2Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg;
3RandD centre Spenshult;
4School of Business, Technology and Science, Halmstad University, Halmstad;
5Unit of occupational medicine, Institute of Environmental Medicine, Karolinska Institutet, Stockholm, Sweden

Background: Chronic musculoskeletal pain is common in the general population and 11% report chronic widespread pain (CWP). A sensitisation of the nociceptive system has been proposed to be one possible mechanism behind CWP, a prerequisite for fibromyalgia (FM). A reduced pressure pain threshold (PPT) has been reported in subjects with FM, but also as an effect of bad sleep. Objectives: The aim was to study pain thresholds in people with CWP in comparison with those having no chronic pain (NCP) or chronic regional pain (CRP), but also in relation to self-reported sleep problems.

Methods: From a 21 year follow-up of the Swedish population based Epipain cohort (n 1321), 146 subjects, with and without a report of chronic pain, were invited to a clinical assessment including measurement of PPT. Subjects were classified as having NCP, CRP or CWP, according to the definition of CWP in the ACR criteria for FM, with two pain thresholds exceeding 4.5 kg body regions. Sleep problems (initiating sleep, frequent awakenings, not feeling rested, early awakening) were reported by Uppsala Sleep Inventory (four items scored from 1–5, best to worst). PPTs were measured in kPa at eight different anatomical sites representing upper, lower, left and right side of the body using the Algomed Computerised Pressure Allogometer FPX (Medoc Ltd. Advanced Medical Systems, Israel). A mean was calculated from all eight points to create a global pressure pain threshold (PPTg), where a lower PPTg indicated a higher sensitivity to pain. ANCOVA regression analysis was performed to study associations between PPTg and reports of chronic pain and sleep problems, controlled for age and gender.

Results: Out of 146 subjects, 89 (61%) were women. Mean age was 64.6 (SD 12.7) years. This sub-population from the Epipain cohort reported a high prevalence of CWP without significant difference between men and women (33.9% vs 44.9%; p=0.411). Women had lower PPTg than men (345.0 kPa vs. 563.9 kPa; p<0.001). Subjects classified as CWP had lower PPTg than those classified as NCP (362.0 kPa vs. 479.9 kPa; p=0.003). A report of CRP did not affect PPTg in...
AB1070 VARIATIONS IN THE LENGTH OF MUSCULOSKELETAL TEMPORARY WORK DISABILITIES IN PATIENTS INCLUDED IN AN EARLY INTERVENTION PROGRAM

A. Lois Iglesias, C. Bejerano, F.J. de Toro Santos. Hospital Universitario A Coruña, A Coruña, Spain

Background: Musculoskeletal disorders cause in Spain 23% of temporary work disability (TD) and they are the first cause of permanent work disability (PD). A study of early intervention (early assessment and immediate treatment by a rheumatologist) reduced TD days (39%) and evolution to PD (50%).1 Using the “Fit for Work” European coalition led by AbbVie, the program is implemented nationwide.

Objectives: The aim of this study is to analyse the variation in the number of days of sick leave in the patients included in an early intervention program comparing to usual care.

Methods: Observational cross-sectional study of a hospital cohort of outpatients referred during 18 consecutive months. The patients were referred for the first time to the Rheumatology Early Intervention consultation program because of temporary work disabilities due to musculoskeletal disorders. All of them received medical treatment; and underwent ultrasound, joint injections and learned exercises when needed. Patients whose disabilities were due to trauma or surgery were not included in the study.

Results: We evaluated 270 patients with a mean age of 48.9 years. 64% were women. The most frequently reported diseases were lumbar/sciatic pain (28.5%), shoulder pain (20%), neck pain (8%), knee pain (5.6%) and other arthalgias and tendinopathies (20%). All patients received medical treatment, 38.5% underwent ultrasound examination and 19.2% received joint injections.

The pathologies with longest lengths of TD after the first visit to the rheumatologist were lumbar/sciatic pain (mean 40.6 days), neck pain (mean 33 days) and shoulder pain (mean 23.8 days). If we compare this data with the existent control group from Madrid, we can see a decrease of the days in sick leave of 29.5% in lumbar/sciatic pain (from 57.6 to 40.6 days), 11.7% in neck pain (from 37.4 to 33 days) and 36.3% in shoulder pain (from 37.4 to 23.8 days).

Conclusions: Early intervention by rheumatologists in patients with temporary work disability due to musculoskeletal disorders reduces the length of sick leaves. A quick diagnosis and assessment by specialists can improve the patient outcome and saving costs to health system.

AB1071 WHAT FACTORS AFFECT THE EFFECTIVENESS OF NSAIDS FOR ACUTE LOW BACK PAIN?

A. Karateev, E. Pogozheva, A. Lila. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

Background: Nonsteroidal anti-inflammatory drugs (NSAID) are the main instruments for acute LBP (LOW BACK PAIN) treatment. However, up to now, factors that influence the effectiveness of NSAIDs have not been determined fully.

Objectives: To assess effects of some clinical and anamnestic factors on NSAIDs effectiveness in acute LBP.

Methods: The study group comprised 2078 patients (46.3±13.4 years, women 56.6%) with acute LBP treated in real clinical practice. 34.8% had first episode of LBP, 65.2% had second episode (an average of 2.6±1.4 episodes a year). Numerical rating scale (NRS) of 0–10 points estimated the level of pain. Initially, the pain level was 6.69±1.85, 57.0% of patients had severe pain (≥7 NRS). Pain remained at rest in 32.0%, at night in 19.0%, stiffness was noted in 60.7%, radiating leg pain in 28.2%, sciatica at 9.6%. NSAIDs used 70.2% of patients in the history of LBP. 28.0% rated their effectiveness as good, 54.6% as moderate and 17.4% as low. Meloxicam 15 mg once daily was prescribed for a period of up to 2 weeks for all the patients. 86.1% of patients received meloxicam intramuscular injection (im) for 2 days, then per os, 13.9% only per os. 52.3% received muscle relaxants, 17.4% – B vitamins, per os or im. 21.6% of patients received PPI for the prevention of gastrointestinal complications. The study evaluated the frequency of LBP complete relief with NSAIDs for up to 2 weeks.

Results: The complete pain relief was in 75.2% of patients, the average NSAID use duration before pain ceased was 8.6±5.5 days. 83.7% of patients rated the effectiveness of treatment as “good” or “excellent”. Adverse reactions were noted only in 4.6% of patients, there were no serious complications. Female sex and the use of B vitamins did not influence the outcome of the treatment: odds ratio (OR, 95% confidence interval) 0.967 (0.795–1.177), p=0.763 and 0.917 (0.804–1.1201), p=0.452. Age <65 years, the first episode of LBP and a good effect of NSAIDs in a history were associated with the best result of treatment: OR 2.053 (1.592–2.642), p<0.000; 1.415 (1.09–1.836), p<0.009; 1.937 (1.513–2.481), p<0.000. Severe pain (≥7 NRS), pain at rest and at night, radiating leg pain and especially sciatica were associated with worse results: OR 0.599 (0.487–0.737), p<0.000; 0.481 (0.393–0.588), p<0.000; 0.559 (0.441–0.709), p<0.000; 0.511 (0.413–0.631), p<0.000; 0.348 (0.256–0.466), p<0.000. The combination of NSAIDs with muscle relaxants and B vitamins, in comparison with the monotherapy of NSAIDs, was associated with a lower incidence of pain: OR 0.827 (0.594–0.889), p=0.02.

Conclusions: Meloxicam 15 mg/day dosage is effective and safe for treating acute LBP. The sex of patients does not affect the outcome of this treatment. Age <65 years, first episode of LBP and a good “response” to NSAIDs in history are associated with better treatment outcomes. Severe pain, the pain at rest and pain at night, radiating leg pain and sciatica are associated with the worst result. The combination of NSAIDs with muscle relaxants and B vitamins did not improve the outcome of the treatment.

AB1072 THE MEDIUM NERVE CROSS-SECTIONAL AREA MAY BE A PARAMETER OF FOLLOW-UP AFTER TREATMENT IN PATIENTS WITH CARPAL TUNNEL SYNDROME?

B. Mansız-Kaplan1, I. Yagci2, G. Akay2.1 Department of Physical Medicine and Rehabilitation, University of Health Sciences, Ankara Training and Research Hospital, Department of Physical Medicine and Rehabilitation, Ankara, Turkey; 2 Department of Physical Medicine and Rehabilitation, Marmara University School of Medicine, Department of Physical Medicine and Rehabilitation, Istanbul, Turkey

Objectives: Carpal tunnel syndrome (CTS) is the most common extramembranous neuropathy in general population. Diagnosis of CTS depends on clinical symptoms, physical examination and electrophysiological findings. In recent years, diagnostic value of median nerve ultrasonography has increased particularly for the CTS. To aim of this study was to ultrasonographically and electrophysiologically follow up the patients with CTS, whom were diagnosed with mild or moderate CTS, received a fabricated night orthotic which held the wrist in a neutral position during three months. All patients were evaluated clinically, electrophysiologically, and ultrasonographically before treatment and at 3 months by blind physicians. Pain was evaluated using Visual Analogue Scale (VAS) Boston Carpal Tunnel Questionnaire was used to evaluate symptom severity and functional capacity. In electrophysiologic evaluation median nerve conduction studies was recorded. Median nerve cross-sectional areas (M-CSA) were measured by ultrasonography at the level of radio-ulnar joint, pisiform bone, and hook of hamate. After treatment, 68
patients were divided into two groups according to whether there was a ≥50 reduction in VAS.

Results: The study was completed with 68 patients and 114 hands. While in group 1, in which VAS reduction was less than ≥50, there were 38 hands; in group 2, in which VAS reduction was more than ≥50, there were 76 hands. There were no differences improvement of symptom severity, nerve conduction studies parameters, M-CSA at the level of radio-ulnar joint between groups. Improvement of functional capacity and decrease of M-CSA at the level of pisiform bone and hook of hamate were significantly better in group 2 (p<0.05).

Conclusions: After conservative treatment, while M-CSA was consistent with clinical findings, this consistency has not been observed with nerve conduction studies. M-CSA may be used to follow-up after receiving conservative treatment in patient with CTS.

Disclosure of Interest: None declared
evaluation and low vitamin D is often the underlying cause. Both clinical and sub-clinical low level vitamin D is common.3

Objective: To evaluate the relationship between musculoskeletal complaints and vitamin D3 (cholecalciferol) level.

Methods: This prospective cross-sectional descriptive study was conducted during July 2017 to December 2017 in Chittagong, Bangladesh. Patients with common musculoskeletal complaints were enrolled. Each patient was screened to exclude common possibilities. Serum cholecalciferol was measured for each patient. Race, occupation, skin complexion, body mass index, sunlight exposure, covering of body with clothing’s and use of sunscreen were taken under consideration in final analysis. Visual analogue scale (VAS; 1–10) was used to quantify all complaints. Correlation of serum cholecalciferol level with VAS score of individual complaints was analysed.

Results: A total of 110 patients (79 Female and 31 Male) were enrolled after screening 165. All of them were Bangladesh of multi-ethnic Asian origin. Mean age was 46.5±12.8 years. Their skin complexions were pale white to white skin 45.5%, light brown 30%, moderate brown 11.8% and dark brown 12.7%. Most had (90.9%; n=100) inadequate sunlight exposure and 77.2% (n=61) women used Burkha (full covered dress). Mean vitamin D3 level was 25.2±7.3 ng/ml. Vitamin D deficiency was (mean 17.3±2.8 ng/ml) observed in 30 (27.3%), insufficiency (mean 25.1±2.7 ng/ml) in 62 (56.4%) and normal level (mean 34.8±4.4 ng/ml) in 18 (16.4%). After classifying Vitamin D level in relation to symptoms it was found that majority of patients (81.2% to 90.3%; depending on complaints) had insufficient or deficient cholecalciferol level (table 1).

</tbody>
</table>

Significant negative correlation was found between the serum cholecalciferol level and VAS for difficulty in getting up from squatting position (r=0.253, p=0.008) and positive correlation was found for muscle cramps (r=0.220, p=0.021). Correlations with remaining symptoms were not statistically significant.

Conclusions: Vitamin D status directly and indirectly influences musculoskeletal health. Hypovitaminosis D should consider in every patient with muscle cramp.

Complex Regional Pain Syndrome Type 1: Which Treatment?
M. Sohni,1, S. Saliha,2 A. Haj Salah,3, W. Kessomtini1, Z. Ben Salah2

Background: The treatment of Complex Regional Pain Syndrome Type 1 (CRPS-I) is multidisciplinary.1 It aims to minimise symptoms, pain, preserve functional ability and professional activity. Unfortunately, therapeutic possibilities are still very limited and there is no Gold standard.

Objectives: The purpose of our work is to evaluate the efficiency of four therapeutic modalities in the management of CRPS-I.

Methods: Retrospective study of 60 patients (21 men and 39 women) treated for CRPS-I. Four groups were identified according to therapeutic modalities used: rehabilitation alone (16 patients), Calcitonin associated with rehabilitation (15 patients), Bisphosphonates (BP) (Sodium Risedronate, 1 tablet per week, over an average duration of 1 month) associated with rehabilitation (20 patients) and Calcitonin in combination with BP and rehabilitation (9 patients).

Results: The mean age of the patients was 51±16.5 years. The average time of treatment was 2 months and the average duration of follow-ups was 7 months. Traumatic origin was found in 88.3% of cases. Distal radius fractures (DRF) were the most incriminated (40% of cases). The evolution was judged on pain reduction, vasomotor signs and on functional improvement. For all etiologies combined, no statistically significant difference was found between the different groups (p=0.462). For patients with a DRF, a favourable outcome was noted in the BP group associated with rehabilitation in 85.7% of cases while it was only 42.9% for rehabilitation alone. In the Calcitonin group the improvement was 81.2%.

Conclusions: Our study concludes that the different therapeutic modalities evaluated for the treatment of CRPS-I had an efficiency close to each other with a superiority of BP. Oral Sodium Risedronate could therefore be proposed as a treatment for CRPS-I without marketing authorisation (MA).
