### AUDIT OF INFLUENZA AND PNEUMOCOCCAL VACCINATIONS IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS ON BIOLOGICS

S. Selvan. Rheumatology, Basildon and Thurrock NHS Foundation Trust, Essex, UK

**Background:** Rheumatoid arthritis (RA) patients are at increased risk of pneumococcal and influenza disease secondary to a deficient immune system and immunosuppressive medications.<sup>1</sup> Despite the possible reduction in vaccine efficacy in RA, prophylactic vaccination for preventing pneumococcal pneumonia and influenza in RA patients should be routinely advised and practised.<sup>2</sup> EULAR guidelines recommend that influenza and pneumococcal vaccinations should be strongly considered for all patients with RA.<sup>3</sup>

**Objectives:** To study pneumococcal and influenza vaccination rates in a cohort of RA patients on biologic medications.

**Methods:** We undertook a prospective audit of RA patients on biologics attending routine rheumatology clinics in a DGH over a 6 week period. A proforma was given to patients, and data was collected on medications, comorbidities, Disease Activity Score (DAS) and vaccination status for influenza and pneumococcus.

**Results:** Of the 25 patients audited, 17 (68%) were female and 8 (32%) were male. The average age of patients included was 59 years (range 37–75). 18 (72%) patients were seropositive, and 7 (28%) were seronegative. The patients included had the following comorbidities; 14 (56%) none, 6 (24%) thyroid disease, 1 (4%) osteoporosis, 1 (4%) hypertension, 1 (4%) type 2 diabetes, 1 (4%) interstitial lung disease.

On reviewing their medications, 7 (28%) patients were on an Etanercept biosimilar (Benpali), 2 (8%) on Tocilizumab, 2 (8%) on Rituximab, 9 (36%) on Adalimumab, 2 (8%) on an Infliximab biosimilar (Remsima), 2 (8%) on Etanercept, and 1 (4%) on Certolizumab. In addition to their biologic agent, all 25 patients were on Methotrexate. 2 patients (8%) were also on Sulphasalazine, and 2 (8%) were on Hydroxychloroquine additionally. The average DAS CRP score was 2.7.

8 (32%) patients had received both influenza and pneumococcal vaccinations, and 9 (36%) patients had neither. On analysing the vaccination rates individually, 16 (64%) patients were up to date with influenza and 7 (28%) were up to date with pneumococcal. Of the 9 patients that had neither vaccination, 5 (20%) patients were unaware of their requirement, and 3 (12%) felt they were too unwell to receive them. 1 (4%) patient was unsure whether they could have the vaccinations as they had been recruited into a research trial.

**Conclusions:** Only 32% patients had received both influenza and pneumococcal vaccinations. The uptake rate for influenza vaccination was reasonable at 64%, however the rate for pneumococcal vaccination was only 28%. Vaccination assessment should be performed routinely for all RA patients in clinic, and in particular those on biologic medications to reduce the risk of developing these infections in this high risk cohort.

#### AB0400 HIGH PREVALENCE OF COMORBIDITIES IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SOUTH AFRICA

S. Botha-Scheepers, A.G.A. Mohammed, A. Gcelu, B. Hodgkinson. *Medicine/Rheumatology, Groote Schuur Hospital/University of Cape Town, Cape Town, South Africa*

**Background:** Patients with rheumatoid arthritis (RA) are at increased risk to develop comorbidities. Data on the prevalence of comorbidities in RA patients in South-Africa is lacking.<sup>1</sup> Poorly controlled joint inflammation, common use of glucocorticosteroids and nonsteroidal anti-inflammatory drugs, a high prevalence of smoking and obesity, together with a high burden of infectious diseases may be important risk factors for comorbidities in this population.

**Objectives:** To assess the prevalence of comorbidities in RA patients in Cape Town, South-Africa and the association with disease activity and DMARD use using the METEOR (Measurement of Efficacy of Treatment in the 'Era of Outcome' in Rheumatology) database.

**Methods:** This is an ongoing cross-sectional study. Data from 109 RA patients from regular clinic visits at Groote Schuur Hospital in Cape Town, South Africa have been entered in the Meteor database (from December 2016). The Meteor database is a free online tool that was developed to improve the management of RA patients by helping rheumatologists to register, monitor and tightly control disease activity. The tool is currently widely used in other countries, but has it has not yet been described in any African countries. Information on the following parameters were reported: demographics, disease duration, disease activity (CDAI), current DMARDs used and comorbidities.

**Results:** The mean age (SD) was 57.6 (14.7) years, disease duration (SD) 14.1 (14.6) years, female gender 86.7%, RF positive 85.1% and ACPA positive 80.4%. The average (SD) CDAI was 13.1 (9.8) and 49.3% were smokers. Current DMARDs used was Methotrexate (72%), Sulphasalazine (29%), Chloroquine (67%), Low dose corticosteroids (47%), Leflunomide (11%), Etancept (1%), but no other biological agents (0%). At least one comorbidity was present in 69% of the patients, two in 40%, three in 26%, four in 13% and five in 2% of the patients. The most frequently observed comorbid diseases were hypertension (45.5%), tuberculosis (TB) (11.1%), Diabetes Mellitus Type 2 (10.9%) and osteoarthritis (10.9%). Other diseases included hypercholesterolemia (7.1%), gastro-oesophageal reflux disease/peptic ulcer (6.1%), COPD/emphysema (6.1%), HIV (4.0%), hypothyroidism (4.0%), ischaemic heart disease (3.0%), liver disease (3.0%), DVT/pulmonary embolism (3.0%), malignancies (3.0%), asthma (2.0%), discoid lupus erythematosus (2.0%), interstitial lung disease (1.0%), anaemia (1.0%), rheumatic heart disease (1.0%), cerebrovascular accident (1.0%) and depression (1.0%).

**Conclusions:** This study shows a high prevalence of comorbidities among indigent patients with RA in South Africa. In particular, hypertension, TB and osteoarthritis were very common. More patients will be included in this study in the next few months. Furthermore, we will assess the association between comorbidities, disease activity and DMARD use. The METEOR tool offers the unique opportunity to study daily practice care as well as research questions in real life setting in a South African clinic. This study will provide information that is necessary to address the burden of comorbidities in patients with RA in South Africa.

#### AB0401 ECHO-CARDIOGRAPHIC ABNORMALITIES IN RHEUMATOID ARTHRITIS PATIENTS COMPARED TO AGE AND SEX-MATCHED CONTROLS

S. Hannawi<sup>1</sup>, K. Naeem<sup>2</sup>. <sup>1</sup>Rheumatology, Ministry of Health and Prevention of UAE; <sup>2</sup>Cardiology, Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory autoimmune disease of the joints with several extra-articular features. Cardiovascular disease (CVD) mortality accounts for 40%–50% of all deaths in RA. Apart from atherosclerotic heart disease other cardiac abnormalities had been found to be prevalent in RA; including, pericarditis, heart failure, coronary vasculitis and valve disease.

**Objectives:** Due to scarcity of data regarding cardiac disease in the Middle East population, we studied echocardiographic features in RA patients compared to their age, sex, and traditional CVD risk factors matched controls.

**Methods:** In a cross-sectional study, we recruited 39 RA patients meeting the 1987 revised criteria of RA and 37 age, sex and traditional CVD risk factors matched controls. Standard trans-thoracic echocardiography examination was carried out by a specialties cardio-sonographer who was blinded to the status of the participants. Left ventricular dimensions, wall geometry, ejection fraction, diastolic parameters, right ventricular size and function, valve structure and function, pericardium, pulmonary pressures and aortic root dimensions were assessed by echocardiography. t-test and chi-2 test were used to compare the echocardiographic findings between the two groups. P value of <0.05 was considered significant.

**Results:** Thirty-nine RA patients (34 F, 4 M) and 37 controls (32 F, 5 M) were studied. Among RA, 27 (69%) were RF positive. The two groups were similar in terms of age (p=0.86), gender (p=0.71), and traditional cardiovascular risk factors. No significant difference was found between RA and the controls in term of left ventricular ejection fraction, wall geometry, diastolic parameters, right ventricular size and function, valve disease, pulmonary pressures, pericardium and aortic root dimensions. However, left ventricular end-diastolic diameter (43.11±1.14 vs. 39.35±0.84 mm respectively, p=0.01), end-systolic diameter (24.39±0.70 mm vs. 26.96±0.96, respectively, p=0.03) and Left ventricular mass index (79.83±5.11 vs. 63.64±3.15, respectively, p=0.01) were significantly higher in RA patients than in the controls.

**Conclusions:** Patients with rheumatoid arthritis have higher left ventricular end-diastolic and end-systolic dimensions, and greater left ventricular mass index compared to their age, sex and traditional CVD risk factors-matched controls. As the increase in the left ventricular mass index is a predictor of cardiac sudden death, echocardiography might be a simple non-invasive tool for cardiac risk screening in RA.

#### AB0402 RECENT ONSET RHEUMATOID ARTHRITIS HAVE AND INCREASED LEFT ANTERIOR DESCENDING CORONARY ARTERY WALL THICKNESS: EVIDENCE OF SUBCLINICAL CORONARY ARTERY DISEASE

S. Hannawi<sup>1</sup>, I. Al Salmi<sup>2</sup>, H. Hannawi<sup>3</sup>. <sup>1</sup>Rheumatology, Ministry of Health and Prevention of UAE, Dubai, United Arab Emirates; <sup>2</sup>The Royal Hospital, Muscat, Oman; <sup>3</sup>Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

**Background:** Rheumatoid arthritis (RA) is associated with increased cardiovascular disease (CVD). Using different methods, presence of sub-clinical atherosclerosis changes have been reported in RA. As no previous study has measured left anterior descending (LAD) coronary artery thickness in RA

**Objectives:** this study aimed to investigate atherosclerotic changes of coronary artery in early RA of 12 months of symptom onset.

**Methods:** 15 RA patients and 20 control subjects who matched 10 RA participants were included in the study. Demographic details, RA characteristics, and laboratory values of 15 RA patients at first presentation. None of the patients or the control participants had previous CVD/cerebrovascular events or diabetes and matched 10 of the RA group for age and sex. LAD coronary artery wall thickness compared between RA and their matched control. Among early RA patients, Correlation was assessed between LAD coronary artery wall thickness and the demographic features, RA activity features, and cardiovascular risk factors.

**Results:** Within early RA, LAD coronary artery wall thickness was related to Disease Activity Score (p=0.025,  $\beta$ -coefficient 0.066, CI:0.010–0.122) and to the patient global assessment of disease activity at RA onset (p=0.006,  $\beta$ -coefficient 0.003, CI:0.001–0.005), in a positive linear relationship. LAD wall thickness was

thicker among RA patients with rheumatoid factor (RF) positive ( $p=0.015$ , CI:0.53–0.66). LAD coronary artery wall thickness was increased in early RA compare to controls ( $0.61\pm 0.04$  mm (CI:0.52–0.70); and  $0.48\pm 0.08$  mm (CI:0.44–0.51) respectively,  $p=0.001$ .

**Conclusions:** Early RA patients have increased coronary arteries atherosclerotic burden compared to controls matched for age, and sex. Rheumatoid factor positivity, high Disease Activity Score and Patient Global Assessment of disease activity were associated with coronary wall thickness.

**Disclosure of Interest:** None declared

#### AB0403 FACTORS CONTRIBUTE TO THE LEVEL URIC ACID IN RHEUMATOID ARTHRITIS

S. Hannawi<sup>1</sup>, I. Al Salmi<sup>2</sup>, H. Hannawi<sup>3</sup>. <sup>1</sup>Rheumatology, Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates; <sup>2</sup>The Royal Hospital, Muscat, Oman; <sup>3</sup>Ministry of Health and Prevention of United Arab Emirates, Dubai, United Arab Emirates

**Background:** Uric acid (UA) is a strong correlate of renal dysfunction in rheumatoid arthritis (RA), even in the absence of crystal deposition, by causing endothelial dysfunction, intrarenal vascular disease and renal impairment. In hyper or normo-uricaemia RA, UA was the strongest independent predictor of GFR, even after adjustments for most of the potential confounding factors. Additionally, in RA patients UA had been found to be an independent predictor of hypertension and cardiovascular disease (CVD).

**Objectives:** this study aimed to investigate what could be the determinants of the UA level in RA patients.

**Methods:** RA patients with no clinically evident gout, CVD, thyroid disease, liver or renal disease were studied. Serum UA was obtained for all the patients. Renal function parameters, RA disease characteristics, inflammatory markers, and traditional CVD risk factors relation to uric acid level was examined using simple linear regression analysis. To test for the independence association between uric acid and the variables of interest, multiple model was built for the same dependent and independent variables. Statistical significance was accepted at  $p$ -value<0.05.

**Results:** The study recruited 86 consecutive patients meeting the 1987 RA revised ACR criteria, attending routine outpatient clinics at the Department of Rheumatology. Basic demographics and clinical characteristics of were obtained. Of the total 86 patients, 10 (11%) were men and 77 (89%) were women. The mean age of the participants was  $47\pm 14$  years, with mean RA duration of  $68\pm 87$  months. 64 out of 86 participants (74%) had rheumatoid factor positive.

The mean UA value was  $255\pm 86$   $\mu\text{mol/L}$  (NR: 180–340). The mean GFR, calculated using modified MDRD (Modification of Diet in Renal Disease) formula was  $133\pm 52$  ml/min/1.73m<sup>2</sup>.

Using univariate analysis revealed a positive linear relationship between uric acid level and each of the age of the participants ( $p<0.016$ , CI: 0.31, 2.92), age at RA symptoms onset ( $p<0.04$ , CI: 0.025, 0.039), age at RA diagnosis ( $p<0.03$ , CI: 0.101, 2.565), systolic blood pressure ( $p=0.04$ , CI: 0.054, 2.167), diastolic blood pressure (DBP) ( $p=0.02$ , CI: 0.322, 3.777), monocytes absolute count ( $p=0.014$ , CI: 2.510, 4.801), monocytes percentage ( $p=0.005$ , CI: 34.599, 193.595), cholesterol level ( $p=0.008$ , CI: -39.934, -6.286), Triglyceride level ( $p=0.04$ , CI: 0.064, 56.546), urea level ( $p<0.001$ , CI: 9.356, 28.743), creatinine ( $p\leq 0.001$ , CI: 2.345, 3.960), urinary microalbumin ( $p=0.024$ , CI: 0.0296, 0.399), urinary microalbumin/creatinine ratio ( $p=0.006$ , CI: 0.791, 4.616), and ferritin level ( $p=0.025$ , CI: 0.044, 0.633).

As well, univariate analysis revealed a negative linear relationship between UA level and GFR ( $p<0.001$ , CI: -1.127, -0.486)

Building a multiple model, including the entire variable with significant association with the UA in the univariate analysis showed that the UA level in RA is determined by GFR, microalbumin creatinine ratio, cholesterol level, monocytes count and DAS score. The adjusted R2 of the model was 54

**Conclusions:** Whether serum uric acid is merely a marker that reflects the integration of co-morbidities and subclinical renal impairment or a true risk-causative factor for CVD outcome remains as an important question, therefore it is important to know the determinant of UA level and control it.

**Disclosure of Interest:** None declared

#### AB0404 APELIN CONCENTRATIONS ARE ASSOCIATED WITH A REDUCED LEFT ATRIAL VOLUME INDEX AND IMPROVED SYSTOLIC FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Gunter<sup>1</sup>, C. Robinson<sup>1</sup>, L. Tsang<sup>1</sup>, P.H. Dessein<sup>2</sup>, A.M. Millen<sup>1</sup>. <sup>1</sup>Cardiovascular Pathophysiology and Genomics Research Unit, University of Witwatersrand, Johannesburg, South Africa; <sup>2</sup>Free University Brussels, Brussels, Belgium

**Background:** We recently reported that apelin concentrations are associated with reduced atherosclerosis and plaque vulnerability as well as improved aortic function in rheumatoid arthritis (RA)<sup>1,2</sup>. These relations were influenced by RA characteristics<sup>1,2</sup>. Besides protecting against atherosclerosis, apelin is also a vasoactive peptide that improves cardiac contractility. In this regard, patients with RA experience a 2-fold increased risk of developing heart failure<sup>3</sup>. RA patients often demonstrate diastolic dysfunction and heart failure with a preserved ejection fraction (HFpEF). Traditional cardiovascular risk factors do not fully explain the increased heart failure incidence in this population. Metabolic risk factor driven inflammation is highly implicated in HFpEF.

**Objectives:** This study aimed to determine whether apelin can impact left ventricular function in RA and whether disease characteristics can modify this potential effect.

**Methods:** Relationships of apelin concentrations with echocardiographically determined markers of systolic and diastolic function including stroke volume, endocardial fractional shortening, midwall fractional shortening, ejection fraction, relative wall thickness, left ventricular mass, mitral inflow (E/A), filling pressure (E/e') and left atrial volume index (LAVI) were determined in multivariable regression models among 169 patients without established cardiovascular disease.

**Results:** In demographic characteristic adjusted analysis, rheumatoid factor (RF) positivity, joint deformity counts, and CRP were associated with increased apelin concentrations ( $p=0.01$ , 0.02 and 0.05, respectively). Apelin was associated with a reduced LAVI [ $\beta$ (SE)=-4.6 (2.2);  $p=0.04$ ] but not with E/A, lateral e' or E/e' ( $p>0.05$  for all). RA characteristics including disease duration, CRP, erythrocyte sedimentation rate (ESR), RF positivity, and joint deformity counts did not impact apelin concentration-diastolic function marker relationships (interaction  $p$  values>0.05). Apelin levels were associated with increased endocardial fractional shortening [ $\beta$ (SE)=5.99 (2.97);  $p=0.04$ ] and midwall fractional shortening [ $\beta$ (SE)=6.92 (3.0);  $p=0.03$ ]. The ESR and anti-citrullinated peptide antibody (ACPA) status impacted the apelin level-endocardial fractional shortening relationships (interaction  $p=0.05$  and 0.01, respectively). In stratified analysis, apelin concentrations were associated with improved endocardial fractional shortening in those with [ $\beta$ (SE)=14.1 (3.9);  $p=0.001$ ] but not without an ESR >12 mm/hr (median value), and in those with [ $\beta$ (SE)=8.2 (3.7);  $p=0.03$ ] but not without ACPA positivity.

**Conclusions:** In RA, apelin concentrations are associated with a reduced LAVI irrespective of RA activity and severity characteristics. Apelin concentrations are also associated with improved endocardial fractional shortening in patients with RA, particularly in those with high-grade inflammation and ACPA positivity. Whether apelin can improve left ventricular systolic and diastolic function in RA merits further exploration in longitudinal studies.

#### AB0405 CLINICAL FEATURES AND PROBLEMS OF ELDERLY ONSET RHEUMATOID ARTHRITIS IN ULTRA-AGEING SOCIETY –SINGLE CENTRE RETROSPECTIVE COHORT STUDY-

T. Kurasawa, Y. Okada, A. Shibata, S. Saito, K. Chino, A. Okuyama, H. Takei, T. Kondo, K. Amano. Department of rheumatology and clinical Immunology, Saitama Medical Center, Saitama Medical University, Kawagoe, Japan

**Background:** Japan is the ultra-ageing society ahead of any other country in the world, which ageing rate (the ratio of the population aged 65 and older to the total population) was reported to be 27.3% on October 1, 2016. The rate of aged patients, who followed up at the division of rheumatology in Saitama medical centre, had exceeded 40%.

**Objectives:** The aim of our study is to reveal recent clinical features and problems of elderly onset rheumatoid arthritis (EORA) patients for better management.

**Methods:** Patients had a diagnosis by 1987 classification criteria or 2010 ACR/EULAR criteria. We firstly listed up RA patients who were followed up our hospital from April 1 to September 30, and above aged 65 years old as of September 30. Then we retrospectively collected clinical information of EORA patients who onset

above 60 years old, diagnosed and made starts of treatment in our hospital, and observed more than 6 months, from medical records.

**Results:** One hundred eighty eight EORA patients were enrolled in this study. Female were 116 (62.0%). Mean observation period from first visit until September 30, was 68 months. Rheumatoid factor positive rate was 67.0%. Anti-CCP antibody-positive was 68.2% (107/157), and most of them (65.5%, 70/107) had high antibody titer over 100 U/mL. At the time of diagnosis, average CRP was 3.1 mg/dL. Respiratory complications were seen in 26.1% (49 cases), including 28 interstitial lung disease, 10 COPD/emphysema, 7 non-tuberculous mycobacteriosis/obsolete tuberculosis, and 6 bronchiectasis. Other complications were diabetes 16.5% (past 25 cases, new 6), hypertension 38.3% (past 66, new 6), and hyperlipidemia 23.9% (past 33, new 12). Histories of cerebrovascular or cardiovascular events were seen in 10.6% (20 cases), and history of malignancy was seen in 6.9% (13 cases). During observation period, newly developed malignancy was seen in 14 cases (14.1/1000 person-years) including 4 MTX related lymphoproliferative disorders (MTX-LPD), 3 gastrointestinal cancer, 3 gynaecological cancer, 2 lung cancer, and so on. Infectious adverse event were occurred in 35 patients (35.3/1000 person-years). From the point of treatment, corticosteroids were prescribed in 32%, csDMARDs 88%, and biological DMARDs (BIO) 47%. Of 89 EORA patient treated with BIO, average DAS28-ESR was 5.77, and HAQ-DI 1.48 at the baseline. Twenty-nine cases were started to treat with BIO as monotherapy, 13 cases as switching to BIO from csDMARDs, and 47 as addition BIO to csDMARDs. During observation period, reasons of cessation of the first BIO were remission in 21, adverse events in 19 (7 infections, 6 injection-site/infusion reaction, 3 malignancies, and so on), insufficient response in 16, and patient's hope in 2.

**Conclusions:** RF/anti-CCP antibody positive rate was lower than general RA population, but slightly higher than previous reports on EORA.<sup>1)</sup> BIO could be discontinued in 24% of 89 patients who received BIO because of remission. On the other hand, the frequency of infection and malignancy was still higher in EORA patients. So it is necessary to adjust anti-rheumatic therapy for poor prognostic cases, and we should be careful to follow up EORA patients.

#### AB0406 SIGNIFICANT ASSOCIATION BETWEEN RENAL FUNCTION AND AREA OF AMYLOID DEPOSITION IN KIDNEY BIOPSY SPECIMENS IN BOTH AA AMYLOIDOSIS ASSOCIATED WITH RHEUMATOID ARTHRITIS AND AL AMYLOIDOSIS

T. Kuroda<sup>1</sup>, Y. Ito<sup>1</sup>, N. Imai<sup>1</sup>, Y. Nozawa<sup>1</sup>, H. Sato<sup>1</sup>, T. Nakatsue<sup>1</sup>, Y. Wada<sup>1</sup>, M. Ueno<sup>2</sup>, M. Nakano<sup>3</sup>, I.N. Narita<sup>1</sup>. <sup>1</sup>Division of clinical nephrology and rheumatology, Niigata University, Niigata; <sup>2</sup>University Health Center, Joetsu University of Education, Joetsu; <sup>3</sup>Faculty of Medicine, Niigata University, Niigata, Japan

**Background:** The kidney is a major target organ for systemic amyloidosis, which results in proteinuria and an elevated serum creatinine level. The clinical manifestations and precursor proteins of amyloid A (AA) and light-chain (AL) amyloidosis are different, and the renal damage due to amyloid deposition also seems to differ.

**Objectives:** The purpose of this study was to clarify how the difference in clinical features between AA and AL amyloidosis are explained by the difference in the amount and distribution of amyloid deposition in the renal tissues.

**Methods:** A total of 119 patients participated: 58 patients with an established diagnosis of AA amyloidosis (AA group) and 61 with AL amyloidosis (AL group). We retrospectively investigated the correlation between clinical data, pathological manifestations, and the area occupied by amyloid in renal biopsy specimens. In most of the renal specimens the percentage area occupied by amyloid was less than 10%. For statistical analyses, the percentage area of amyloid deposition was transformed to a common logarithmic value (Log10%amyloid).

**Results:** The results of sex-, age-, and Log10%amyloid-adjusted analyses showed that systolic blood pressure (SBP) was higher in the AA group. In terms of

renal function parameters, serum creatinine, creatinine clearance (Ccr) and estimated glomerular filtration rate (eGFR) indicated significant renal impairment in the AA group, whereas urinary protein indicated significant renal impairment in the AL group. Pathological examinations revealed amyloid was predominantly deposited at glomerular basement membrane (GBM) and easily transferred to the mesangial area in the AA group, and it was predominantly deposited at in the AL group. The degree of amyloid deposition in the glomerular capillary was significantly more severe in AL group. The frequency of amyloid deposits in extraglomerular mesangium was not significantly different between the two groups, but in AA group, the degree amyloid deposition was significantly more severe, and the deposition pattern in the glomerulus was nodular. Nodular deposition in extraglomerular mesangium leads to renal impairment in AA group. There are significant differences between AA and AL amyloidosis with regard to the renal function, especially in terms of Ccr, eGFR and urinary protein, even after Log10%amyloid was adjusted; showing that these inter-group differences in renal function would not be depend on the amount of renal amyloid deposits.

**Conclusions:** These differences could be explained by the difference in distribution and morphological pattern of amyloid deposition in the renal tissue.

#### AB0407 THE IMPACT OF DEPRESSION ON SOCIAL CONTACTS OF PATIENTS WITH RHEUMATOID ARTHRITIS

T. Jankovic, J. Zvejk Svorcan. *Rheumatology, Faculty of Medicine, University of Novi Sad Special Hospital for Rheumatic Diseases, Novi Sad, Serbia*

**Background:** Rheumatoid arthritis (RA) affects the psychological and emotional state of the patient, leading to a significant reduction in the quality of life and social contacts.

**Objectives:** Assess the occurrence and degree of depression in RA patients and their impact on quality of life and social contacts.

**Methods:** The study involved 110 patients, 78.4% women and 22.6% men, with RA of median age 58.7. The average disease duration was 13.6 years. 68% of patients were treated with methotrexate monotherapy (MTX), 32% by combination of MTX and other DMARD. The disease activity in patients was determined by the ideax DAS28, the functional status -HAQ-DI questionnaire. The intensity of the pain was determined using a visual analogue scale for VAS pain (0–100 mm). The degree of radiological changes was determined based on the classification by Steinbrocker. Patients completed a questionnaire related to the quality of social relationships. The degree of depression was determined using Bäck scale for depression.

**Results:** The incidence of depression had 65.4% of the patients. A mild degree of depression was observed in 26.4%, moderate 24%, expressed 13% while 2% of the patients had a more severe degree. There was a significant statistic correlation between the degree of depression with age, the duration of the disease, the high degree of DAS28, HAQ-DI, VAS pain and the degree of radiological changes. By analysing the quality of life and social contact, patients in 62% were supported by a close family and a spouse, 28% of their close relatives, 7% of the wider family, while 3% of the patients lived alone.

**Conclusions:** Depression is the most common and most important psychological state that occurs in patients with RA. It is important to recognise and start treatment on time, which should be based on a multidisciplinary approach. In addition to family support, overall social support also takes a significant place.

**Disclosure of Interest:** None declared

### ANALYSIS OF THE CORRELATION OF COMPOSITE INDICATORS OF ACTIVITY OF THE DISEASE AND THE CONCORDANCE BETWEEN THE DIFFERENT STATES OF ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

T. fontana, B. ferreira althoff, C. janson ferreira, Y. alfaró, G. ricardo werner de castro, I. alves pereira. *Rodovia Antonio Luis de Moura Gonzaga, Unisul Pedra Branca, Florianópolis, Brazil*

**Background:** Rheumatoid arthritis (RA) is an inflammatory joint disease of systemic involvement and varied evolution, which uses different disease evaluation scores. It is essential that these instruments be evaluated according to the disease, so that the treatment algorithms can be applied independently.

**Objectives:** To analyse a correlation of disease activity indexes (ICADs) and a concordance between different states of activity in patients with Rheumatoid Arthritis.

**Methods:** Cross-sectional study based on 100 patients of outpatient care from a multicenter prospective cohort study. Approved by CEP UNISUL. Statistical analysis by the SPSS 18.0 program, using the Pearson Correlation Coefficient and McNemar-Bowker Concordance, considering significance level  $p < 0,05$ .

**Results:** Majority female patients (86%), with an average age of 54 years, who were active in their jobs (53%) and had a positive rheumatoid factor in 65%. The average values of the ICADs were DAS-28 (3.6), DAS-28 PCR (3.0), SDAI (13.4), CDAI (12.5) and RADAI (3.5), respectively. Many were classified with moderate disease activity of the disease. The degree of correlation was very strong ( $>0.8$ ) and strong (between 0.8 and 0.6) in most ICADs and a concordance of remission DAS-28PCR ranged from 41.3% to 54.3% with the other ICADs.

**Conclusions:** The ICADs presented a strong correlation with each other, as well as a level of similarities in the classification of the different degrees of activity. These results confirm that in different patients with RA, the ICADs serve to define active disease and to aid in the treatment strategy, so it is not imperative to use only a single evaluation score.

### MISSING THE BIG PICTURE? AN AUDIT OF HAND X-RAYS IN BIOLOGIC TREATED RHEUMATOID ARTHRITIS PATIENTS

U. Habib<sup>1</sup>, A. Sahni<sup>1</sup>, M. Lloyd<sup>1</sup>, B. Barber<sup>2</sup>, J. Cameron<sup>1</sup>, S. Melath<sup>1</sup>, D. Christidis<sup>1</sup>, J. Wajed<sup>1</sup>, A. Mistlin<sup>1</sup>, S. Cooper<sup>1</sup>. <sup>1</sup>*Rheumatology*, <sup>2</sup>*Radiology, Frimley Park Hospital, Frimley, UK*

**Background:** Rheumatoid arthritis (RA) treatment is target driven. The aim is to prevent joint damage and relieve pain and functional loss. X-ray (XR) erosions are an unambiguous sign of disease activity and progression.

**Objectives:** We aimed to review our practice in looking for erosions in our biologic treated patients. We chose this group as they were likely to have the most severe and clearly defined RA.

**Methods:** 100 random biologic treated patients from our biologics database were selected for analysis. We used patient letters and our digital imaging system (PACS) for further information. Our PACS has records running back to 2004.

**Results:** Mean age was 58 years. 77% were female. Mean duration of RA was 10.6 years (range 0.9–44 years). 46 were currently receiving etanercept; 17 tocilizumab; 15 adalimumab; 14 certolizumab; 5 rituximab and 3 abatacept. 61 patients were current prednisolone users. The mean duration of biologic treatment was 4.8 years. 44 patients had received more than one biologic drug; 17 more than two. Mean DAS was 3.4. 72 patients had had previous documented hand XRs; 25 (34%) of these had erosions. The mean duration since the last hand XR was 37 months. 27 patients had had 2 previous hand XRs; 11 had had 3, 4 had had 4 and 2 had had 6 previous XRs. In 19 cases hand erosions appeared to have progressed in the patients who had had more than one XR. 44 patients had had

previous foot XRs; 15 (34%) had erosions. 26 patients had had more than one foot XR. 36 patients had had previous joint ultrasound (US); in 17 (47%) US suggested active synovitis. The mean duration since the last US was 17 months.

**Conclusions:** Our patients had relatively high disease activity despite biologic treatment, over half were also on steroids and significant numbers had had several biologic switches. Despite this only around two thirds of patients had had previous hand XRs documented over an average of 10 years RA duration, and there was a long average time since the last imaging. US rates were lower, but scans were more recent, perhaps suggesting a more modern trend to US over XR. Less than half of patients had had foot XRs. Although there was a lower rate of foot XRs the rate of erosions was similar in hand and foot XRs, suggesting similar patterns of joint damage. Interestingly, despite erosions being a hard end point in most treatment trials, NICE guidance only suggests XR early in RA in 'people with persistent synovitis'<sup>1</sup> and EULAR guidance suggests assessing for 'structural damage' without specifying time intervals.<sup>2</sup> Although newer imaging techniques may be more sensitive, XRs remain cheap, quickly accessible and allow objective assessment, particularly in long term patients being assessed for biologic switches. Our audit suggests that this well established and useful measure of disease burden may currently be relatively neglected.

### DIAGNOSIS OF LUNG DISEASE ASSOCIATED WITH RHEUMATOID ARTHRITIS, A PROSPECTIVE MONOCENTRIC STUDY

V. Huber Somme<sup>1</sup>, S. Hirschi<sup>2</sup>, M. Ohana<sup>3</sup>, R. Felten<sup>1</sup>, E. Chatelus<sup>1</sup>, R.-M. Javier<sup>1</sup>, C. Sordet<sup>1</sup>, L. Arnaud<sup>1</sup>, J. Sibilia<sup>1</sup>, J.-E. Gottenberg<sup>1</sup>, H. Petit<sup>1</sup>. <sup>1</sup>*Rheumatology*; <sup>2</sup>*Pulmonology*; <sup>3</sup>*Radiology, Strasbourg University Hospital, Strasbourg, France*

**Background:** Respiratory involvement in rheumatoid arthritis (RA) is the most common extra-articular localisation, affecting 50% of patients, even though only 5% become symptomatic. Lung pathology as RA related interstitial lung disease is associated with significant morbidity and mortality. Involvement of the respiratory system seems frequent but remains underestimated because of the absence of guidelines about its detection in patients with RA.

**Objectives:** This study aimed at determining the prevalence of respiratory involvement among symptomatic and asymptomatic patients with rheumatoid arthritis managed in a university hospital.

**Methods:** We conducted a prospective observational study from May 2017 to January 2018 at the Strasbourg University Hospital. The patients included were over 18 years of age, had rheumatoid arthritis according to the ACR/EULAR 2010 criteria and signed informed consent. They responded to a self-administered questionnaire about their medical history, cardiorespiratory symptoms and lifestyle. Epidemiological, clinical and radiological data were assessed. All of the patients had a chest computed tomography (CT) and respiratory function tests (RFT). A collection of salivary flow and a test of Shimer were carried out, to investigate the presence of a sicca syndrome. Chest CTs were interpreted by a radiologist specialised in lung area.

**Results:** We included 102 successive patients, 73 women and 29 men. The average disease duration was 34 years. 60 patients were seropositive for rheumatoid factor and 68 for anti-CCP. 59 patients had bone erosions. The average disease activity score (DAS28-CRP) at inclusion was 3.5. 49 patients had associated Sjogren's syndrome. 22 were active smoker. 43 patients were taking long-term corticosteroid therapy. 96 patients were treated with conventional DMARD treatment, 28 with anti-TNF alpha therapy, 16 with Tocilizumab, 12 with Abatacept, 2 with JAK selective inhibitor, and 16 patients were under Rituximab.

Of the 87 RFT performed, 39 were abnormal: 14 reported an obstructive syndrome, 8 a restrictive syndrome, 32 peripheral expiratory braking, suggestive sign of bronchiolitis, and 24 a decrease in the DLCO.

Of the 91 chest CTs, 42 revealed lung nodules (42%), 15 of which were more than 6 mm; 29 interstitial syndrome (29%), among which 5 were non-specific interstitial pneumonitis (PINS), 3 common interstitial pneumonitis (PIC), and the other were non specific interstitial syndrome. 2 chest CT showed pleural effusion and 1 pericarditis. 44 patients had coronary calcifications, among whom 32 had no lipid-lowering therapy.

**Conclusions:** Pulmonary systemic assessment of RA patients show high prevalence of respiratory involvement: 42% of patients had lung nodules and 29% had an interstitial syndrome. Detection of interstitial lung disease may raise questions about RA treatment such as anti-TNF alpha therapy. Rheumatologist should be more aware of respiratory involvement in RA patients and RFT, a non-invasive test, might be useful at diagnosis and follow-up.

**AB0411 RISK OF REACTIVATION OF HEPATITIS B VIRUS IN RHEUMATOID ARTHRITIS PATIENTS WHO RECEIVED LONG-TERM LOW DOSE CORTICOSTEROID THERAPY**

W. Jeong<sup>1</sup>, J. Kim<sup>1</sup>, E.-J. Park<sup>2</sup>, B.-C. Song<sup>3</sup>. <sup>1</sup>Rheumatology, Jeju National University Hospital, Jeju-Si; <sup>2</sup>Rheumatology, National medical center, seoul; <sup>3</sup>Hepatology, Jeju National University Hospital, Jeju-Si, Korea, Republic of Ireland

**Background:** It is well known that the use of corticosteroids results in increased viral replication and elevated ALT in patients with hepatitis B virus. The use of high dose corticosteroids for more than 4 weeks usually results in hepatitis worsening after cessation of steroids. However, few studies have investigated the effect of low dose corticosteroids on hepatitis B virus (HBV) reactivation.

**Objectives:** The aim of this study is to investigate the reactivity of HBV in rheumatoid arthritis (RA) patients treated with long term low dose corticosteroids and its risk factor.

**Methods:** Patients with HBsAg positive who were diagnosed with RA and who received prednisolone of less than 10 mg/day over four weeks and immunosuppressive agent were selected at four university hospitals in South Korea between June 1996 and March 2017. Medical records and laboratory data were retrospectively analysed and multivariate analysis was performed.

**Results:** One hundred forty five patients were included in the study and 26 (17.9%) patients were reactivated with HBV. Mean age at diagnosis of RA was 50.7 years and 41 (28.3%) patients were male. Baseline characteristics including sex, age and laboratory findings at diagnosis of rheumatoid arthritis were not significantly different in patients with HBV reactivation compared to those without HBV reactivation. The average daily dose of prednisolone was 3.65±2.77 mg and the mean duration of prednisolone was 5.11±5.05 years and the average cumulative dose of prednisolone was 5821.6±7021.3 mg. Eleven (42.3%) of 26 HBV reactivated patients were reactivated within one year after prednisolone administration and the period from the start of prednisolone administration to the reactivation was 4.08±5.77 years on average. The duration of prednisolone administration, mean daily dose of prednisolone, and cumulative prednisolone dose and administration of methotrexate, tacrolimus, tumour necrosis factor inhibitor and hydroxychloroquine did not significantly affect HBV reactivation in both univariate and multivariate analyses. However, the administration of leflunomide showed a significant difference in the reactivation of HBV (adjusted odd ratio 3.76; p=0.04)

**Conclusions:** The hepatitis B virus can be exacerbated by spontaneous viral reactivation, so it is difficult to conclude that hepatitis is caused by the administration of steroids. In this study, the administration of low-dose steroids did not affect the reactivation of HBV. However, leflunomide increased the risk of HBV reactivation when the effects of other disease modifying antirheumatic drug (DMARD) were corrected. Therefore, a prospective study is needed to evaluate the effect of DMARDs on HBV reactivation in the long – term administration of low – dose corticosteroids in RA patients.

**AB0412 DYNAMICS OF QUANTITATIVE BODY COMPOSITION INDICES BY THE METHOD OF DUAL-ENERGY X-RAY ABSORPTIOMETRY (DRA) IN PATIENTS WITH EARLY RA DEPENDING ON THE ACHIEVED ACTIVITY OF THE DISEASE**

Y. Gorbunova, T. Popkova, L. Kondratyeva, A. Smirnov, E. Nasonov. *Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation*

**Background:** Adipose tissue an active endocrine organ. In pts with RA the redistribution of body fat mass. Using BMI and WC do not allow to distinguish between

fat and lean (muscle) mass. Performing dual-energy X-ray absorptiometry allows to specify the quantitative composition of the body(mass of adipose tissue and muscle) in pts with early RA.

**Objectives:** to compare the indicators of the quantitative composition of the body in groups of RApts with different disease activity before and after the appointment of therapy.

**Methods:** included 37pts with early RA(ACR/EULAR2010), 57 [46.5, 62] yrs, duration of disease 6 [5.5,15.5]mths, IgMRF seropositive antiCCP, with high RA activity(DAS285.5 [5.1,6], SDAI 32.4 [22.4, 42], CDAI 29 [19.7, 39.5]). After inclusion in the study, all pts started receiving MTX 10 [10–15 mg/week], after 12 weeks, with ineffective MTX, ADA 40 mg/2 weeks was prescribed. The quantitative composition of the body was determined initially and after 6mths by means of DXA using the apparatus HOLOGIC,analysing the following parameters:the total, of fat and lean mass.

**Results:** By the 24th week of therapy, 13 (35%)pts with earlyRA received combined therapy(ADA, MTX), 24 (65%) pts with RA monotherapy MTX. Depending on the activity of RA(DAS28)by the 24th week of therapy, pts are divided into 2groups: I(n=18) pts with remission/low activity, II(n=19)with moderate/high RA activity (table 1). Initially, the groups differed in fat mass:this index was higher in the group of pts with moderate/high activity persisting, compared with the group of pts with remission/low activity of RA:30.2 kg versus 19.4 kg. In the I group of pts before the treatment and after 6mths of therapy,a statistically significant decrease in muscle mass was observed:from 45.2 kg to 41.6 kg. A decrease in the mass of adipose tissue after 24 weeks of therapy was noted in the IIgroup of pts with RA: from 30.2 kg to 28.2 kg. The difference in the indices between the groups by the 6 month of therapy was noted for the mass of adipose tissue. This composition of the body score was also higher in pts with moderate and high RA activity, compared to the group of pts with remission/low RA activity: 28.2 kg versus 18.9 kg (p<0.05 in all cases).

**Abstract AB0412 – Table 1**

	Group I(n=18)Remission/low activity			GroupII(n=19)Medium/high activity		
	0	24 weeks	Δ, %	0	24 weeks	Δ, %
Fat mass, kg	19,4	18,9	-3	30,2	28,2	-7
	[15,8;25,9]**	[16,4;24,3]***		[20,7;37,6]	[22,7;40,2]*	
Lean mass, kg	45,2	41,6	-8	42,9	44,2	+3
	[38,9;54,4]	[38,6;48,4]*		[38,9;54]	[40,1;55,4]	
Total weight, kg	70	64,9	-7	72,8	74,7	+3
	[58;80,8]	[59,5;81]		[60,;102]	[64;97,9]	
BMI, kg/m <sup>2</sup>	23,4 [21,5;27,5]	23,8	+1	26,8	26,0	-2
	**	[20,2;26,5]		[22,8;34,6]	[23,3;34,3]	

\*p<0,05 reliability of differences in factors before treatment and after 6mth(Wilcoxon);

\*\*p<0,05 differences in baseline values in Groups I and II(Mann-Whitney test);

\*\*\*p<0,05 difference in the indices between the groups by the 6mth of therapy; Δ,% the difference between the indices between the groups by the 6mth of therapy.

**Conclusions:** pts with RA who achieved Igroup after 6 mths of therapy initially had a smaller volume of adipose tissue, compared with pts with moderate and high RA activity. Despite the achievement of remission after 6mths of therapy,a loss of lean mass(probably the development of rheumatoid cachexia) continued in some pts, but these data need confirmation in studies with a large number of pts and a longer period of follow-up.

**Disclosure of Interest:** None declared

**AB0413 NODULAR POLYARTERITIS AS AN UNFORESEEABLE ADVERSE REACTION IN RA PATIENT TREATED WITH TOFACITINIB**

Y. Muraviev<sup>1</sup>, S. Radenska-Lopovok<sup>2</sup>, V. Lebedeva<sup>1</sup>, S. Alamankina<sup>1</sup>. <sup>1</sup>Federal State Budgetary Institution «Research Institute of Rheumatology» under the Russian Academy of Medical Sciences; <sup>2</sup>I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

**Background:** Tofacitinib basic prescribing information and guidelines for medical use do not provide any description of such adverse drug reaction (ADR) as vasculitis, in particular polyarteritis nodosa. We present a clinical case of vasculitis emerging during tofacitinib therapy.

**Objectives:** demonstration of an unexpected reaction to tofacitinib

Demonstration of an unexpected reaction to tofacitinib

**Methods:** A 59 y.o. RA female patient was hospitalised in December 2016 due to eruption of indurated nodules on her hips and legs producing sharp pain, ulceration of nodules on the legs, painful hip and ankle joints, and morning stiffness lasting for about one hour.

**Results:** Seropositive RA was diagnosed in this patient in April 2004 with subsequent DMARD with methotrexate (MT) at 7,5 mg/week. The remission achieved

lasted until November 2005. Gradual dose escalation up to 20 mg/week was required during 2006 in view of RA exacerbations, nevertheless, clinical and lab RA activity persisted. Therefore tofacitinib (Jakvinius) was administered in November 2015 at 10 mg/day, with rapid achievement of minimum RA activity (DAS28=3.0). By the end of May 2016 clinical manifestations of vasculitis emerged, and in June 2016 tofacitinib was discontinued due to increasing lab activity of the disease. Clinical examination: patient's condition is moderately grave. The thinned skin looks dry, showing multiple regenerating ulcers on the anterior leg surface and sharply painful ulcerated indurations on the right inner thigh producing serosanguinous fluid. The RA activity is equal to DAS28=5.72, Hb 125 g/L, WBC  $6.0 \times 10^9/L$ , platelets  $40 \times 10^9/L$ , ESR 22 mm/h, CRP 42 mg/L, RF 413 IU/ml, *antibody to cyclic citrullinated peptide* (ACPA) is 195 U/ml, TNF – 13.9 pg/ml. Wrist and distal foot radiographs show moderate extended osteoporosis, narrowing of some joint spaces, rare bone and articular surface erosions, subluxation of some joints. Histopathology of skin and subcutaneous fat biopsy samples is presented on figure 1a, 1b. Histopathology data suggests the presence of cutaneous and subcutaneous fat productive and destructive vasculitis and acute, predominantly lobular, panniculitis; such structural changes are usually present in cutaneous polyarteritis nodosa and other systemic vasculitis. The casual relationship between this ADR and tofacitinib therapy was assessed as probable using Naranjo scale.

Abstract AB0413 – Figure 1

**Conclusions:** development of vasculitis (polyarteritis nodosa) in RA patient can be caused by tofacitinib.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.4192

#### AB0414 RELATIONSHIP BETWEEN SERUM OXYTOCIN LEVELS AND DEPRESSION IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Miwa<sup>1</sup>, T. Kasama<sup>1</sup>, K. Sanada<sup>2</sup>. <sup>1</sup>Division Of Rheumatology, Department Of Medicine; <sup>2</sup>Department of Psychiatry, SHOWA UNIVERSITY SCHOOL OF MEDICINE, Tokyo, Japan

**Background:** Oxytocin (OXT), also referred to as a happy hormone, has been associated with various psychiatric disorders, including depression. However, the relationship between depression and rheumatoid arthritis (RA) has not yet been clarified.

**Objectives:** The objective of this study was to investigate the relationship between serum oxytocin levels and disease activity, depressive state, activity of daily life (ADL), and quality of life (QOL) in RA.

**Methods:** This study included 119 RA patients. We measured the following variables: baseline characteristics including age, sex, disease duration, smoking history, body mass index, prednisolone dose, and methotrexate (MTX) dose, serum levels of rheumatoid factor, matrix metalloproteinase-3, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) level. The disease activity of RA was assessed using the Simplified Disease Activity Index (SDAI); depression was assessed using the Hamilton Depression Rating Scale (HAM-D); ADL were assessed using the Health Assessment Questionnaire; and QOL was assessed using the 36-Item Short Form Health Survey (SF-36). Serum OXT levels were determined by enzyme-linked immunosorbent assay. The subjects were divided into two groups according to the higher or lower of the serum OXT levels, and a retrospective study was performed.

**Results:** The serum OXT levels were correlated with the disease duration ( $r=0.443$ ,  $p=0.000$ ). Weak correlations of MTX dose ( $r=0.208$ ,  $p=0.030$ ), swollen

joint count (SJC) ( $r=-0.306$ ,  $p=0.001$ ), ESR ( $r=-0.245$ ,  $p=0.010$ ), CRP ( $r=-0.283$ ,  $p=0.003$ ) and the mental component summary (MCS) score ( $r=-0.196$ ,  $p=0.041$ ) of SF-36. The binominal logistic analyses findings were as follows: younger age ( $p=0.0209$ , odd ratio: 0.96, 95% CI: 0.94–0.99) and longer disease duration ( $p=0.0053$ , odd ratio: 1.08, 95% CI: 1.02–1.13). Other items did not correlate to the serum OXT levels included with the HAM-D score.

**Conclusions:** The serum oxytocin levels were correlated with longer disease duration and younger age.

## Rheumatoid arthritis – biological DMARDs

### AB0415 DISEASE FLARES AMONG EARLY RHEUMATOID ARTHRITIS PATIENTS TREATED WITH CONTINUED METHOTREXATE EITHER ALONE OR IN COMBINATION WITH ADALIMUMAB

A. Kavanaugh<sup>1</sup>, R. van Vollenhoven<sup>2</sup>, P. Sunkureddi<sup>3</sup>, Y. Zhang<sup>4</sup>, J. Suboticki<sup>4</sup>, J. Smolen<sup>5</sup>. <sup>1</sup>Division of Rheumatology, Allergy, and Immunology, University of California San Diego, La Jolla, USA; <sup>2</sup>Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands; <sup>3</sup>University of Texas Medical Branch, Galveston; <sup>4</sup>AbbVie Inc., North Chicago, USA; <sup>5</sup>Division of Rheumatology, Department of Medicine, Medical University of Vienna and Hietzing Hospital, Vienna, Austria

**Background:** Some rheumatoid arthritis (RA) patients (pts) may experience flares in their disease even after reaching stable low disease activity (sLDA), but the consequences of even temporary elevations in disease activity are poorly understood.

**Objectives:** The purpose of this analysis was to explore the rates of flares after reaching sLDA in pts treated to target with either methotrexate (MTX) monotherapy or adalimumab combination therapy (ADA+MTX).

**Methods:** This post hoc analysis included pts from the randomised, double-blind, double-period OPTIMA<sup>1</sup> trial achieving sLDA [DAS28(CRP) <3.2 at weeks (wks) 22 and 26] at the end of period 1 (P1). In P1, pts were randomised to receive ADA +MTX or placebo (PBO) +MTX for 26 wks. Pts on ADA +MTX achieving sLDA were randomised to receive PBO +MTX (ADA Withdrawal) or continue on ADA +MTX (ADA Continuation) for an additional 52 wks in period 2 (P2). Pts who achieved sLDA on PBO +MTX in P1 continued their treatment in P2 (MTX Continuation). Pts achieving sLDA in each treatment group were categorised based on whether they experienced a flare [change in DAS28(CRP)  $\geq 0.6$  at consecutive visits and DAS28(CRP)  $\geq 3.2$ ]; the proportion of pts experiencing flares and time to flare were assessed. For each group, mean change from wk 26 to wk 78 in disease activity [DAS28(CRP)], functional (HAQ-DI) and structural (mTSS) measures were analysed.

**Results:** In pts achieving sLDA at the end of P1, flare rates in P2 differed based on initial treatment assignment (ADA Continuation: 11.7% [11/94]; MTX Continuation: 22.4% [22/98]). Interestingly, flare rates in pts randomised to withdraw ADA in P2 (ADA Withdrawal: 25% [22/88]) were numerically similar to the MTX Continuation group. The mean time to flare was 193, 191, and 177 days in the ADA Withdrawal, ADA Continuation, and MTX Continuation groups, respectively. During P2, the mean DAS28(CRP) scores were predictably higher in pts who flared compared with those who did not across treatment groups. In pts experiencing flares in P2, disease activity and functional measures worsened from wk 26 to wk 78 as compared with pts without flares (table 1). Of the individual DAS28(CRP) components, pt global assessment of disease activity (PtGA) showed the greatest worsening. There were small differences in radiographic progression between pts experiencing flares compared with pts without flares.

**Abstract AB0415 – Table 1.** Change from Week 26 in Disease Activity, Functional and Structural Measures Based on Flare Status in Patients Achieving Stable LDA\*

Outcome measure Mean (SD)		Visit Mean at Week 26		Mean Change ( $\Delta$ ) from Week 26 to Week 78	
		Flare	No Flare	Flare	No Flare
DAS28(CRP)	ADA Withdrawal	2.2	2.0	1.0 (1.2)	-0.1 (0.6)
	ADA Continuation	2.1	2.0	0.6 (1.1)	-0.2 (0.7)
	MTX Continuation	2.2	2.1	1.0 (1.2)	-0.1 (0.6)
HAQ-DI	ADA Withdrawal	0.4	0.2	0.3 (0.6)	0.0 (0.3)
	ADA Continuation	0.5	0.3	0.2 (0.5)	-0.1 (0.3)
	MTX Continuation	0.4	0.3	0.2 (0.5)	0.0 (0.4)
mTSS	ADA Withdrawal	8.4	11.5	0.3 (0.7)	0.2 (1.1)
	ADA Continuation	6.9	12.7	0.1 (0.5)	-0.1 (0.7)
	MTX Continuation	10.5	9.2	0.1 (0.6)	0.1 (1.0)

\*Flare was defined as change in DAS28(CRP)  $\geq 0.6$  at consecutive visits and DAS28(CRP)  $\geq 3.2$ .

LDA=low disease activity; DAS28(CRP)=28 joint disease activity score based on C-reactive protein; ADA=adalimumab; MTX=methotrexate; HAQ-DI=health assessment questionnaire disability index; mTSS=modified total Sharp score.

**Conclusions:** In early RA pts achieving sLDA, flares were generally infrequent; however, they were more prevalent in pts receiving PBO+MTX compared with ADA+MTX. Flares were numerically associated with higher disease activity, functional deterioration, and higher PtGA, underscoring its impact on health-related quality of life and the importance of preventing flares as a therapeutic outcome.

#### AB0416 ESTIMATING THE SHORT-TERM COSTS ASSOCIATED WITH NON-MEDICAL SWITCHING IN RHEUMATIC DISEASES

A. Gibofsky<sup>1</sup>, V. Garg<sup>2</sup>, M. Yang<sup>3</sup>, C.Z. Qi<sup>3</sup>, M. Skup<sup>2</sup>. <sup>1</sup>Hospital for Special Surgery-Weill Cornell Medicine, New York; <sup>2</sup>AbbVie, Chicago; <sup>3</sup>Analysis Group, Inc., Boston, USA

**Background:** As biosimilars are approved and commercialised for rheumatic diseases, patients may be switched from originator biologic treatment to biosimilars due to perceived cost savings between the two biologic products. However, in the short term, non-medical switching (NMS) may require additional patient education, office visits, lab/imaging tests, and administrative support which could lead to substantial costs.

**Objectives:** To estimate the short-term costs associated with NMS from originator biologics to biosimilars among stable patients with rheumatic conditions (e.g., rheumatoid arthritis, RA; ankylosing spondylitis, AS; psoriatic arthritis – PsA) from the perspective of a rheumatology medical centre in the United Kingdom.

**Methods:** An economic model was constructed including two components: the administrative burden for NMS program set-up and support, and the provider burden for initiating and managing NMS. Administrative burden was modelled at the center-level and considered staff time for program set-up, patient education, scheduling, documentation, and departmental meetings from pre-NMS planning

to post NMS implementation (<1 year). The provider burden was modelled at the patient-level and considered the expected additional provider time needed and extra laboratory/imaging tests when managing NMS from the time of switching until 3 month post NMS implementation. Model inputs for the administrative burden came from the literature<sup>1</sup> and for provider burden from survey of physicians. Literature was used to inform both the total number of rheumatology patients that underwent NMS, and the unit cost associated with provider/staff time and laboratory/imaging tests.

**Results:** From a rheumatology centre perspective, setting up an NMS program and the subsequent administrative support was estimated to cost £19 617 per centre, attributed to general overhead (40%), pharmacist time (26%), consultant time (21%), and nurse time (13%). After the set-up, provider burden for initiating and managing NMS was estimated to be £113 per switched patient. Assuming 5000 patients with relevant rheumatoid conditions in a centre, 572 stable patients with RA, PsA or AS were estimated to switch to biosimilars. The overall short-term cost associated with NMS was estimated to be £84 174 for the entire centre, with 23% attributed to the NMS program set-up and support, and 77% attributed to extra provider time and monitoring (on average £147 cost per switched patient).

**Conclusions:** Switching stable patients with a rheumatic condition from originator biologics to biosimilars could have considerable short-term costs for a centre. Additional real world studies are needed to better weigh the potential saving vs. cost associated with NMS.

#### AB0417 BIOLOGICAL DRUGS IN THE TREATMENT OF RHEUMATOID ARTHRITIS: REAL LIFE DATA IN A BRAZILIAN MULTICENTRIC STUDY

A. Gómes<sup>1</sup>, G. Pinheiro<sup>2</sup>, A. Santos<sup>2</sup>, C. Albuquerque<sup>3</sup>, R. Giorgi<sup>4</sup>, S. Radominski<sup>5</sup>, I. Pereira<sup>6</sup>, M. Guimarães<sup>7</sup>, M. Bértolo<sup>8</sup>, P.L. Júnior<sup>9</sup>, K. Bonfiglioli<sup>10</sup>, C. Brenol<sup>11</sup>, M. Cunha<sup>12</sup>, L. Mota<sup>3</sup>. <sup>1</sup>Universidade de Brasília, UnB-Brasil, Brasília; <sup>2</sup>1. Universidade do Estado do Rio de Janeiro, Rio de Janeiro; <sup>3</sup>Universidade de Brasília, Brasília; <sup>4</sup>3. Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo; <sup>5</sup>4. Universidade Federal do Paraná, Curitiba; <sup>6</sup>5. Universidade Federal de Santa Catarina, Florianópolis; <sup>7</sup>6. Universidade Federal de Minas Gerais, Belo Horizonte; <sup>8</sup>7. Universidade Estadual de Campinas, Campinas; <sup>9</sup>8. Universidade de São Paulo – Ribeirão Preto, Ribeirão Preto; <sup>10</sup>10. Universidade de São Paulo, São Paulo; <sup>11</sup>11. Universidade Federal do Rio Grande do Sul, Porto Alegre; <sup>12</sup>9. Universidade Federal do Pará, Belém, Brazil

**Background:** Rheumatoid arthritis (RA) is a chronic disease, characterised by inflammatory involvement of the synovial joints. The “treat to target” concept is well established in the rheumatologic community, however, in many patients, especially in developing countries, its implementation is not feasible. Considering the high costs of treatment com of RA and the limited national epidemiological data available on this disease, we sought to describe the profile of use of biological drugs in Brazilian patients with RA to help the decision-making process by public health managers.

**Objectives:** To describe the frequency and time of use of biological drugs in Brazilian patients with rheumatoid arthritis.

**Methods:** The REAL – RA in real life in Brazil – is a multicenter prospective cohort study, with twelve-month follow-up period. To be included in this study, consecutive patients from 11 tertiary rheumatology centres had to meet the 1987 ACR or the 2010 ACR/European League Against Rheumatism (EULAR) criteria. Data were collected during routine clinical care and previous medical records were used as secondary sources. The present study present data taken from the participants’ initial assessment. This research was approved by the Ethics Committees of each centre.

**Results:** A total of 1125 patients were analysed. 89% were women with a mean age of 56.6 years. The main clinic data were: DAS 28 (median)=3.52, HAQ (median)=0.87 and CDAI (median)=9. 1022 (90.84%) used synthetic DMARDs

and 406 (36.09%) biologic therapy. The frequency of use of the biologic therapy was: abatacept (73 patients/6.49%), etanercept (66/5.87%), tocilizumab (60/5.33%), adalimumab (54/4.8%), infliximab (50/4.44%), rituximab (49/4.36%), golimumab (37/3.29%), certolizumab (17, 1.51%). The time of use of the biological drugs is presented in table 1.

**Abstract AB0417 – Table 1.** Time (in years) of use of biological drugs in patients with rheumatoid arthritis

DRUG	MEAN	MAXIMUM
ABATACEPT	1.95	8
ADALIMUMAB	1.70	12
CERTOLIZUMAB	0.63	2.0
ETANERCEPT	1.49	9.0
GOLIMUMAB	0.65	2.0
INFLIXIMAB	1.56	9.0
RITUXIMAB	1.27	6.0
TOCILIZUMABE	2.0	6.0

**Conclusions:** The therapeutic profile of this cohort of Brazilian RA patients shows some interesting results. The relatively high number of patients on biologics, compared to other studies, may be related to fact that the centres involved were reference centres, probably dealing with more difficult cases.

#### AB0418 THE EFFECT OF CONCOMITANT METHOTREXATE ON SERUM TNF INHIBITORS LEVELS AND CLINICAL RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS IS DOSE DEPENDENT AND GREATER THAN OTHER DMARDS

A. Martinez-Feito, C. Plasencia, V. Navarro-Compan, B. Hernández-Breijo, M. A. Gonzalez, I. Monjo, L. Nuño, P. Nozal, D. Pascual-Salcedo, A. Balsa. *Immunology Research Group, University Hospital LA PAZ, Madrid, Spain*

**Background:** Several factors influence on the pharmacokinetics(PK) of TNF inhibitors(TNFi). One of the most relevant influencing factors is the development of antidrug- antibodies(ADA), which is associated with low circulating drug levels and loss of clinical efficacy. Previous studies, mostly about Adalimumab (Ada), have demonstrated a beneficial effect of concomitant use of methotrexate(MTX) in patients(pts) under TNFi therapy by reduction of immunogenicity. There are other csDMARDs(OD) as leflunomide, hydroxychloroquine or sulfasalazine which may have also an effect on PK.

**Objectives:** To investigate the effect of csDMARDs on the presence of serum TNFi levels and on the clinical response during the first year of Ada or Infliximab (Ifx) treatment in RA pts. Secondly, to evaluate if MTX has a dose-dependent effect on these outcomes.

**Methods:** This is an inception cohort including pts with RA starting Ifx or Ada in a tertiary hospital since 1999. At baseline, 6 and 12 months clinical(DAS28, EULAR response and  $\Delta$ DAS28) and serological(drug and ADA levels) parameters were measured. Patients were clustered according to the use of concomitant csDMARDs at baseline in three groups: i)TNFi monotherapy;ii)TNFi +MTX;iii) TNFi +OD. Pts within the TNFi +MTX group were also classified according to the MTX dose:MTX <15 mg/week(TNFi +MTX <15) and MTX  $\geq$ 15 mg/week(TNFi +MTX  $\geq$ 15).

**Results:** A total of 92 RA pts[Ada(n=25) or Ifx(n=67)] under TNFi were included. The number and percentage of pts in each group were as follows:TNFi monotherapy,12 pts(13%);TNFi +MTX, 59 pts(64%);TNFi +OD 21 pts(23%). According to MTX dose, the distribution was:TNFi +MTX <15,18 pts(20%);TNFi +MTX  $\geq$ 15, 41 pts(45%). Considering the overall of pts receiving any dose of MTX, the percentage of them with drug levels after 12 months(71%) was numerically higher than in the other groups(20% in TNFi +OD and 9% in TNFi monotherapy,p=0.1). However, after stratifying pts by MTX dose, we observed that circulating drug levels at 12 months were more frequent in higher dose of MTX(54% of the pts with TNFi +MTX  $\geq$ 15) compared to patients with TNFi +MTX <15 (17%), with TNFi +OD (20%) and with TNFi monotherapy (9%);p=0.002). According to EULAR

response, pts treated with TNFi +MTX(81%) achieved more frequently a good response compared with the other groups (11% on TNFi +OD and 8% on TNFi monotherapy, p=0.6). Moreover, differences on clinical response were observed depending on MTX dose. While 58% with TNFi +MTX  $\geq$ 15 were good EULAR responders, 23% with TNFi +MTX <15 achieved this. Overall, the best effect on clinical response was observed in the group of MTX; p=0.4. Finally, the TNFi median survival time(mst) was significantly higher in pts with TNFi +MTX than in pts with TNFi +OD or on TNFi monotherapy(5 years vs 2 years vs 2.15 years, respectively;p=0.03). Analysing by MTX dose, drug survival was superior for high ( $\geq$ 15) and low MTX doses(<15) (mst 5.2 and 3.3, respectively)compared to OD and/or TNFi monotherapy although the difference was not statistically significant p=0.09.

**Conclusions:** In RA pts under Ifx or Ada treatment, the presence of TNFi in serum, the clinical response and the TNFi survival are influenced by MTX but not by OD. Moreover, a MTX dose-dependent effect is closely associated with these outcomes.

#### AB0419 FREQUENCY OF DISEASE FLARE AND STUDY OF THE CD4+CD25+HIGHCD127LOW/- CELL POPULATIONS AFTER DISCONTINUATION OF ANTI-TNFA THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS IN PERSISTENT REMISSION

A. Lo Monaco<sup>1</sup>, C.A. Scirè<sup>1</sup>, F. Casciano<sup>2</sup>, V. Tisato<sup>2</sup>, P. Secchiero<sup>2</sup>, M. Govoni<sup>1</sup>.  
<sup>1</sup>Department of Medical Sciences-Section of Rheumatology, University of Ferrara and Azienda Ospedaliero-Universitaria Sant'Anna di Cona; <sup>2</sup>Department of Morphology, Surgery and Experimental Medicine and LTTA Centre, University of Ferrara, Ferrara, Italy

**Background:** Rheumatoid arthritis (RA) patients in a prolonged remission status represent a population whose future management has yet to be established. Treg cell function in patients with active RA is assumed to be impaired, a trend that seems to be reversed by TNFalpha antagonist therapy (aTNF). Theoretically a deeper remission may be represented by an immunological resetting of immune system, a condition which could enable to consider the possibility of a drug-free remission.

**Objectives:** To evaluate the incidence of disease flare after cessation of aTNF in pts in remission together with reconstitution of the CD4 +CD25highCD127low/- Tcell subset respect to those patients in the same remission status with persistent low CD4 +CD25highCD127low/-Tcell population, assuming the Treg populations as a markers of deep remission allowing a better selection of those patients at low-risk of flare after aTNF withdrawal.

**Methods:** inclusion criteria: patients with RA (>18 years) fulfilling the 1987 ACR classification criteria treated with aTNF and synthetic DMARDs for at least 12 months, in remission (DAS28 <2.6/DAS44 <1.6)>6 months, without glucocorticosteroid. Exclusion criteria:<18 years, glucocorticosteroids within the three months before; another inflammatory disease other than RA; ongoing infections. Intervention: aTNF drug withdrawal with continuation of DMARDs previously associated (MTX or LFN); a 24 months of follow up was performed. Serial clinical and instrumental evaluation, blood sampling and radiographs have been performed according to the scheduled protocol. Treg population and several cytokines/chemokines/growth factors were analysed (Human Cytokine/Chemokine Panel I, Millipore).

**Results:** 23 patients were included, mean age 53 years (SD 12.3), 68% RF +, 52% ACPA +, DAS28 medium 1.41 (SD 0.48); average duration of illness 9.62 years (SD  $\pm$ 5.73). During the 24 month post-suspension follow-up, for a total of 267 person-months, 11 patients presented a flare, for a flare rate of 3.74/100 person-months (CI95% 1.79–6.88). The average observed exacerbation time from aTNF withdrawal was 14.6 months (SD  $\pm$ 9.32). None statistical predictive value of Treg levels regarding disease outcome after aTNF withdrawal was observed IIR (95% CI) 1.38 (0.82–2.30). None significant correlation among cytokines concentrations and disease status/Treg levels was observed. A correlation was observed between the presence of a synovitis with PD1+\* at the baseline and the loss of remission [HR 7.062 (1.64–30.41, p 0.009);\*higher values were exclusion criteria]. All 3 patients with positive US (PD1) who had flare-up were asymptomatic at baseline.

**Conclusions:** 47.8% of pts maintained aTNF-induced remission at 24 months continuing only sDMARDs therapy (MTX). Only in 1 case reintroduction of Adalimumab did not allow to regain clinical remission, which was obtained using another therapeutic target (anti-CTL4). The presence of a residual synovitis, although mild (PD1), was correlated with the risk of exacerbation. Further results will be discussed.

#### DRUG SURVIVAL ON CERTOLIZUMAB AND PREDICTORS THEREOF IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS, AND AXIAL-SPONDYLOARTHRITIS FROM THE APULIAN BIOPURE REGISTRY

A. Semeraro<sup>1</sup>, G. Carlino<sup>2</sup>, R. Bucci<sup>3</sup>, F. D'Onofrio<sup>4</sup>, P.C. Falappone<sup>5</sup>, S. Lopriore<sup>6</sup>, A. Marsico<sup>1</sup>, N. Maruotti<sup>7</sup>, D. Mazzotta<sup>5</sup>, M. Muratore<sup>8</sup>, L. Quarta<sup>8</sup>, L. Santo<sup>9</sup>, C. Zuccaro<sup>5</sup>, F. Iannone<sup>6</sup>. <sup>1</sup>Rheumatology Unit, ASL Taranto; <sup>2</sup>Rheumatology Service, ASL LE Casarano; <sup>3</sup>Rheumatology Hospital Unit, Foggia; <sup>4</sup>UOC Reumatologia Universitaria, University of Foggia; <sup>5</sup>Rheumatology Outpatients, "A. Perrino" Hospital, Brindisi; <sup>6</sup>DETO – Rheumatology Unit, University of Bari; <sup>7</sup>UOC Reumatologia Universitaria, University of Foggia; <sup>8</sup>O.U. of Rheumatology, "V. Fazzi" Hospital, Lecce; <sup>9</sup>O.U. of Rheumatology, ASL Barletta, Italy

**Background:** In BIO.PU.RE. Registry are collected data from patients being treated with Biologics from rheumatologic centres in Apulia (Southern Italy).

**Methods:** We analysed longitudinal data of consecutive patients, affected with RA, PsA or axial-SpA starting a treatment with certolizumab (CTZ) in the time frame from 1st January 2011 to 30th June 2017. Demographic and disease related characteristics were collected at baseline and at last observation visit. Primary endpoint was the persistence on CTZ, and secondary endpoint was the search of baseline predictors of drug survival and clinical outcomes. Drug survival was evaluated by Kaplan-Meier life table analysis. Estimates hazard ratios (HRs, 95% confidence intervals (CI)) of drug discontinuation or achievement of low-disease/remission in RA, and minimal disease activity (MDA) in PsA at last visit, adjusted for patient's demographics, disease characteristics and prior biologic treatments were computed by Cox-regression stepwise backward models.

**Results:** 345 patients were included in this analysis (table 1). Global median survival time (95% CI) was 30 [23–36] months. Drug survival rate was significantly higher in SpA (63.9%, p=0.009) than in RA (54.0%) or PsA (54.5%). Within each disease, naïve-CTZ patients showed higher survival rates than biologic-experienced patients in RA (63.4% vs 45.7%, p=0.0001), but not in PsA (59.1% vs 52.3%, p=0.60), or SpA (62.5% vs 64.4%, p=0.94). In the whole cohort, the only negative predictor of drug discontinuation was the CTZ-naïve status (HR 0.62, 95 CI 0.40–0.96, p=0.03). This association was even stronger for RA (HR 0.45, 95 CI 0.26–0.77, p=0.004). In SpA, patient's age at baseline was weakly correlated to CTZ stopping (HR 0.96, 95 CI 0.93–0.99, p=0.02), but no predictor of CTZ discontinuation was detected in PsA. No factor did correlate to the achievement of low disease/remission in RA, while co-medication with MTX was significantly associated to the achievement of MDA (HR 3.82, 95 CI 1.26–11.54, p=0.01) in PsA. Globally, the causes of discontinuation were: ineffectiveness (nr 94, 27.2%), adverse event (nr. 40, 11.6%), pregnancy (nr.1, 0.3%), remission (nr. 3, 0.9%), others (nr.13, 3.8%).

Abstract AB0420 – Table 1

	All (nr. 345)	RA (nr. 172)	PsA (nr.88)	Ax- SpA (nr.83)
Age (mean)	46.9±11	48.8±12	44.4 ±10	45.7 ±11
Female	72.9%	86.2%	71.6%	43.3%
BMI (mean)	27.3±5	26.4±4	29.4±5	26.7±5
Dis Durat (mean)	8.8±8	8.7±8	8.6±7	9.2±9
Naive	37.1%	47.1%	25.0%	28.9%
Prior biologics	62.9%	52.9%	75.0%	71.1%
Glucocorticoids	64.6%	79.3%	50.0%	41.0%
Methotrexate	60.3%	73.0%	45.5%	27.3%
Comorbidities	62.3%	58.0%	68.2%	65.1%
DAPSA (mean)			22.8 ±12	
DAS28 (mean)		4.8±1		5.4±2
Extra-articular				21.7%
HLA-B27 (nr.44)				64.8%
RF/ACPA +		72.4%		

**Conclusions:** In our real-life experience CTZ seems to have better drug survival in PsA rather in RA and SpA; in all these polyarthritis was observed CTZ-naïve status as negative predictor of drug discontinuation.

**Disclosure of Interest:** None declared

Grika<sup>1</sup>, P. Vlachoyiannopoulos<sup>1</sup>, G. Evangelatos<sup>6</sup>, A. Iliopoulos<sup>6</sup>, T. Dimitroulas<sup>7</sup>, A. Garyfallos<sup>7</sup>, K. Melissaropoulos<sup>8</sup>, P. Georgiou<sup>8</sup>, M. Areti<sup>9</sup>, C. Georganas<sup>10</sup>, P. Vounotrypidis<sup>11</sup>, G. Kitis<sup>1</sup>, D. Vassilopoulos<sup>1</sup>, on behalf of Greek Rheumatology Society RA Study Group. <sup>1</sup>Joint Rheumatology Program, National and Kapodistrian University of Athens School of Medicine, Athens; <sup>2</sup>Rheumatology Clinic, University of Ioannina, Ioannina; <sup>3</sup>Rheumatology Unit, KAT Hospital; <sup>4</sup>Rheumatology Unit, Sismanoglio Hospital, Athens; <sup>5</sup>Department of Rheumatology, University of Thessaly, Larissa; <sup>6</sup>Rheumatology Unit, NIMTS Hospital, Athens; <sup>7</sup>4th Department of Medicine, Aristotle University, Thessaloniki; <sup>8</sup>Rheumatology Unit, Agios Andreas Hospital, Patras; <sup>9</sup>Private Practice, Livadeia; <sup>10</sup>Private Practice, Athens; <sup>11</sup>Private Practice, Thessaloniki, Greece

**Background:** A number of cross-sectional studies have shown that approximately one quarter of rheumatoid arthritis (RA) patients are being treated with biologic disease modifying anti-rheumatic drugs (bDMARDs) as monotherapy. Data regarding the retention of bDMARD monotherapy in real-life settings are limited.

**Objectives:** To study the survival rate of bDMARD monotherapy in RA patients in daily clinical practice.

**Methods:** Multicenter (11 hospital, 3 private office practices), prospective, RA epidemiological study in Greece. At baseline and after one year of follow-up, demographics, disease characteristics, treatments, co-morbidities and serious events (serious infections, cardiovascular events, neoplasms, osteoporotic fractures) were collected via a web-based platform.

**Results:** 1.323 RA patients with paired evaluations one year apart (mean interval: 13.2±3.7 months) were included. Among 611 bDMARD treated patients, 155 patients (25%) were on bDMARD monotherapy (women: 87%, mean age: 60.4 years, mean disease duration: 15 years, RF and/or anti-CCP positive: 66%, TNFi therapy: 57%). The majority had been previously on and had discontinued their csDMARDs (90%). During follow-up, 15% (n=24) discontinued their bDMARD; most of them stayed off any type of therapy (83%) while the rest continued with synthetic DMARD (csDMARD) monotherapy (17%). From the remaining 131 patients, 96 (73%) remained on bDMARD monotherapy (85%, n=82 on the same biologic) while in 27% (n=35) a csDMARD was added. Serious events occurred in 7.7% of patients (n=12). Overall, at the end of 1st year, approximately half of patients (53%, n=82) remained on their initial bDMARD monotherapy. Factors associated with continuation of the same bDMARD by multivariate analysis were a low HAQ score (OR=0.48, 95% C.I.=0.23–0.99, p=0.047) and corticosteroid use (OR=2.2, 95% C.I.=1.02–5.1, p=0.044) at baseline as well as the absence of a serious event during the 1st year of follow-up (OR=0.14, 95% C.I.=0.016–1.3, p=0.094).

**Conclusions:** In real life settings, only half of patients who are on bDMARD monotherapy continue the same agent one year later. Low HAQ score, corticosteroid use and absence of a serious event during therapy predicted bDMARD monotherapy survival.

#### COST EFFECTIVENESS ANALYSIS OF MODIFIED DOSING REGIMEN OF BIOLOGICAL THERAPY IN CHRONIC INFLAMMATORY DISORDER: AN OBSERVATIONAL STUDY

B.D. Pandey<sup>1</sup>, M. Goyal<sup>2</sup>, M.M. Thabab<sup>3</sup>, A.K. Vishwakarma<sup>4</sup>. <sup>1</sup>Rheumatology, Fortis Hospital, NOIDA, Uttar Pradesh; <sup>2</sup>Rheumatology, Goyal Hospital, Udaipur, Rajasthan; <sup>3</sup>Medicine, JIPMER, Puducherry; <sup>4</sup>Pharmacy, Shri Jagdishprasad Jhabarmal Tibrewala University, Jhunjhunu, Rajasthan, India

**Background:** Cost of biologics in rheumatology is a prime concern in India. Due to lack of reimbursement system, a majority of the patients need to pay from their pocket for the therapy.

**Objectives:** Our objective was to estimate the cost-effectiveness in patients with the chronic inflammatory disorder on biological therapy with modified dosing regimen in patients of a tertiary care clinic.

**Methods:** In this retrospective observational study, data were captured from patients' record in a tertiary care centre located in North India who received biological therapy in rheumatology care practice between 1 January 2013 and 31 December 2017. Modification in the dosing pattern was carried out in the patients and cost of therapy were estimated. These patients, who carried out the therapy, were monitored for any safety outcomes for up to 72 weeks.

**Results:** During the study period, 342 patients received modified dosing of biologicals indicated for rheumatoid arthritis and spondyloarthritis. The cost comparison of biologicals is shown in table 1. Among all, 44 (12.86%) patients got reimbursement/claims from central and state government agencies. There were 73 (21.34%) patients who were followed up to 72 weeks (minimum possible) of the period for safety assessment. These patients achieved remission or low disease activity and after six months, mean DAS28 (mean  $\pm$ SD) was 2.26 $\pm$ 0.83, BASDAI (mean  $\pm$ SD) was 2.32 $\pm$ 0.98 and DAPSA (mean  $\pm$ SD) was 3.11 $\pm$ 1.05. A total 11 (3.21%) cases of known adverse events including hematuria (1.05% patient with etanercept), pneumonia (4.34% patient with tocilizumab), sinusitis (3.63% patient with infliximab), mild fungal infection (1.81% patient with infliximab) and urinary tract infection (5.26% patient with adalimumab) were reported. One patient (1.05% patient with rituximab) diagnosed with tuberculosis and diabetes after 37 months of initiation of rituximab and one case of hospitalisation was seen due to community-acquired pneumonia in the patient receiving infliximab. Two cases of mortality were reported in patients receiving etanercept after 18 months (due to clinical parkinsonism with aspirational pneumonia) and adalimumab after one month (reason unknown). After modified dosing, the patients tend to remain longer on therapy with no new safety signal.

**Abstract AB0422 – Table 1.** Cost Comparison of biologicals in protocolled vs modified dosing

Biologics	Number of Patients (%) n=342	Monthly Cost of Protocol Driven Dosing (euro/month)	Monthly Cost of Modified Dosing (euro/month)	Cost Benefit for the Patient (euro/month)
Etanercept	112 (32.7%)	303.12 €	151.56 €	151.56 €
Rituximab	95 (27.7%)	118.09 €	58.98 €	59.11 €
Adalimumab	57 (16.6%)	290.49 €	145.25 €	145.25 €
Infliximab (3 mg/kg body weight)	55 (16%)	252.60 €	151.56 €	101.04 €
Tocilizumab (8 mg/kg body weight)	23 (6.7%)	353.64 €	176.82 €	176.82 €

**Conclusions:** In developing countries, out of pocket biological cost can be brought down with a lower dose than suggested. In this study, our data show comparable safety and efficacy of biologicals achieved till 72 weeks with modified dosing regimen.

**AB0423 SEVERE INFECTIONS IN RHEUMATOID ARTHRITIS (RA) ARE RELATED TO THE USE OF BIOLOGIC DMARDS. ASSESSMENT OF REAL-LIFE PATIENTS**

C.A. Arce-Salinas<sup>1</sup>, A. Tripp-Aguilar<sup>1</sup>, J.L. Amaya-Estrada<sup>1</sup>, F. Rodríguez-García<sup>2</sup>, F. Espinosa-Ortega<sup>3</sup>. <sup>1</sup>Division of Internal Medicine; <sup>2</sup>Service of Rheumatology, Hospital Central Sur de Pemex, Mexico, Mexico; <sup>3</sup>Rheumatology Unit, Karolinska Institutet, Stockholm, Sweden

**Background:** Current strategies for treatment of RA promotes early use of synthetic (s-)DMARDs, their combination, or biologic (b-)DMARDs to achieve remission or low-disease activity. However, such strategies are related to a wide variety of adverse effects, from mild to life threatening. Infections could be detected more frequently among patients with b-DMARDs, although comorbidities, steroid use, chronic accumulated damage, or disease activity could bias such conclusions.

**Objectives:** To investigate the frequency and severity of infections comparing RA patients users of s-DMARDs or b-DMARDs in a long-term period.

**Methods:** Patients were selected from our RA Clinic. Those with at least 5 years using b-DMARD were compared with patients on s-DMARD, each one matched by disease duration, age, and comorbidities in a 1:1 ratio. Demographic features, disease characteristics, number and nature of infections during the follow-up, as well as disease activity, and treatment were recorded. Infections were considered as severe when it required hospitalisation or intravenous antibiotics. Comparison between groups was made with X<sup>2</sup> or t-test as required.

**Results:** A total of 200 patients were prospectively assessed, 100 per group, mean age was 63.5 $\pm$ 12.03 year-old, 91% were female, 78% were RF or ACPA positive, 20% had diabetes mellitus, and 3% other relevant comorbidities. When patients starting the use of b-DMARD, they had more active disease than those in the s-DMARD group (DAS28=4.99 $\pm$ 1.5 vs. 3.91 $\pm$ 1.2; p=0.01). Throughout 5 years of follow-up, there were 18 episodes of severe infections in the b-DMARDs group, and 2 episodes in the s-DMARD group (p=0.01); number of non-severe infections was 569 vs. 577 in such period, respectively (p=NS). No association was observed between severe infections and presence of diabetes mellitus, cumulative annual dose of prednisone, or DAS28, which did not differ in any other measure between groups. Sixteen patients in b-DMARD had severe infections: 6 acute pyelonephritis, 4 pneumonia, 4 acute bronchitis, 1 infectious diarrhoea, 1 emphysematous cystitis, 1 septic arthritis, and 1 haemorrhagic dengue compared with two severe infections in the s-DMARDs group: 1 pneumonia and 1 infectious diarrhoea. Median of hospitalisation days was 4.5, and no deaths were recorded. Infectious agents isolated were *E. coli*, *C. albicans*, *Salmonella* sp., and *P. aeruginosa*. The most frequent non-severe infections were upper respiratory disease, urinary tract infection, herpes zoster, acute diarrhoea, and bacterial vaginosis. Notoriously, 11 episodes of severe infection occurred in the first 2 years of b-DMARD use (7 in first, and 4 in second year), the other 7 in remaining 3 years. b-DMARDs more frequently used were etanercept, rituximab, adalimumab, certolizumab pegol, and tocilizumab, without association between severe infections and any biologic agent.

Item	b-DMARD group	s-DMARD group	p value
Gender MF (n%)	6/94 (6%/94%)	12/88 (12%/88%)	NS
Age years (mean $\pm$ SD)	62.64 $\pm$ 10.14	64.43 $\pm$ 13.63	NS
BMI Kg/m <sup>2</sup> (mean $\pm$ SD)	27.23 $\pm$ 4.61	26.95 $\pm$ 4.81	NS
Disease duration months (median)	156	156	NS
Initial DAS28 (mean $\pm$ SD)	5.14 $\pm$ 1.37	3.99 $\pm$ 1.26	0.001
Average cumulative annual prednisone dose	386.12	378.77	NS
Diabetes mellitus yes/no (n%)	22	21	NS
Other comorbidities yes no (n%)	5	2	NS
Severe infections yes/no (n%)	18	2	.003
Average patient's annual non-severe infections	1.154	1.138	NS

**Abstract AB0423 – Figure 1**

**Conclusions:** b-DMARDs use in our setting, combined with low dose methotrexate, reach higher frequency of severe infections than s-DMARDs, irrespective of comorbidities, steroid use or disease characteristics including disease activity.

**Disclosure of Interest:** None declared

**AB0424 IL-6 RECEPTOR BLOCKADE INDUCED A DIFFERENT IMMUNE RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS WITH AND WITHOUT REMISSION**

C. Diaz-Torne<sup>1</sup>, P. Estrada<sup>1</sup>, M.A. Ortiz<sup>2</sup>, P. Moya<sup>1</sup>, C. Moragues<sup>1</sup>, D. de la Fuente<sup>1</sup>, V. Torrente<sup>1</sup>, J. Ramirez<sup>1</sup>, D. Reina<sup>1</sup>, M. Moreno<sup>1</sup>, E. Casado<sup>1</sup>, N. Busquets<sup>1</sup>, M. Pujol<sup>1</sup>, M.V. Hernandez<sup>1</sup>, P. Santo<sup>1</sup>, S. Ros<sup>1</sup>, E. Garcia-Casares<sup>1</sup>, H. Corominas<sup>1</sup>, S. Vidal<sup>2</sup>, J. de Agustín<sup>1</sup>. <sup>1</sup>Bio-eco group from ECOCAT, Societat Catalana de Reumatologia; <sup>2</sup>Immunologia., Institut de Recerca Sant Pau, Barcelona, Spain

**Background:** Tocilizumab (TCZ) is a humanised antibody that blocks IL-6 receptor. Despite its effectiveness in rheumatoid arthritis (RA), there are patients that do not respond to the IL-6R blockade. The immune characteristics that would explain this lack of response are not known.

**Objectives:** Our aim was to determine the tocilizumab-induced changes in CD4 +T cells of patients that achieve, or not, remission at 12 m.

**Methods:** Prospective, multicenter study in 47 RA patients treated with TCZ during one year following standard clinical practice. Demographic, disease and treatment characteristics were collected at each visit. Ultrasound (US) grey scale and power doppler were assessed for joints and tendons using a semiquantitative scale from 0–3 points. Phenotyping of T lymphocytes was determined by flow cytometry and the plasma cytokine concentration was quantified by ELISA.

**Results:** Forty seven patients were treated with a mean age of 54 $\pm$ 11 y and 85% were women. Years of disease were 13 $\pm$ 8. We segregated patients according to the DAS28-remission. 44% achieved remission at month 12. We observed that absolute counts of neutrophils and CD4 +T lymphocytes decreased significantly in the remission group but not in the other one. Both memory and naïve CD4 +T

cells decreased in the remission group. The analysis of T cells classified according to chemokine receptors showed that memory ( $29.1 \pm 4.0$  vs  $22.7 \pm 2.7 \times 10^4$  cells/mL;  $p=0.06$ ) and naïve ( $22.6 \pm 4.1$  vs  $17.2 \pm 2.8$ ;  $p=0.04$ ) CD4 +with CXCR3 +and with CCR4 +were the subsets that decreased significantly in the remission group but not in the non-remission group. Since the expression of chemokine receptors defines the different Th subpopulations, we analysed them in the two groups of patients. Th1 tended to decrease in the remission group ( $3.5 \pm 0.7$  vs  $2.5 \pm 0.4$ ;  $p=0.06$ ) and Th9 decreased significantly in both groups ( $R: 5.0 \pm 0.8$  vs  $2.5 \pm 0.3$ ;  $p=0.006$  and Non R  $5.5 \pm 0.8$  vs  $3.1 \pm 0.4$ ;  $p=0.001$ ). In regard to the cytokines produced by CD4 +T lymphocytes, IL-17 ( $2.1 \pm 1.1$  vs  $1.2 \pm 0.5$  ng/ml;  $p=0.04$ ) and VEGF ( $0.5 \pm 0.2$  vs  $0.3 \pm 0.1$  ng/ml;  $p=0.05$ ) but not IL-6 and IL-22 changed significantly in the remission group. Interestingly, IL-17 and VEGF correlated with US findings before the initiation of the treatment (grey scale  $R=0.378$ ,  $p=0.01$  and  $R=0.322$ ,  $p=0.03$ ; power Doppler  $R=0.415$ ,  $p=0.004$  and  $R=0.320$ ,  $p=0.03$  respectively).

**Conclusions:** Tocilizumab induced changes in specific subsets of CD4 +T cells and their inflammatory associated cytokines in the remission group.

**AB0425 PREVALENCE AND RISK FACTORS OF SERIOUS INFECTIONS IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING THE BIOLOGIC/TARGETED SYNTHETIC DMARDs: A PROPENSITY SCORE ANALYSIS FROM THE HONG KONG BIOLOGICS REGISTRY**

C.C. Mok, R. Wan, B. Fong, on behalf of The Hong Kong Society of Rheumatology. *Medicine, Tuen Mun Hospital, HK, Hong Kong*

**Objectives:** To study the prevalence and risk factors for serious infections in rheumatoid arthritis (RA) patients receiving the biologic/target synthetic (b/ts) DMARDs.

**Methods:** Patients who fulfilled the EULAR/ACR criteria for RA and were ever treated with b/tsDMARDs were included. Withdrawal of b/tsDMARDs due to serious adverse events (SAEs) and serious infections (SIs) was analysed. Demographic data, medical comorbidities and concomitant use of glucocorticoids and csDMARDs were retrieved and their contribution to SIs was evaluated by logistic regression. The propensity score for SIs was calculated and patients were stratified into 5 quintiles. The hazard ratios (HRs) of SIs with respect to individual b/tsDMARDs in each quintile were studied by Cox regression.

**Results:** Up to December 2017, 2355 courses of b/tsDMARDs were used in 1355 RA patients (83% women; age  $54.0 \pm 12.7$  years). The usage of various b/tsDMARDs was: adalimumab(12%), etanercept(24%), infliximab(17%), golimumab(9.4%), certolizumab(0.9%), tocilizumab(19%), rituximab(6.6%), abatacept(7.7%) and tofacitinib(2.7%). After a follow-up of 5056 patient-years, 1433 courses of b/tsDMARDs were discontinued, with major reasons being inefficacy (50%), SAEs (22.4%) and cost (8.4%). Among those b/tsDMARD courses terminated because of SAEs, 32% were due to SIs (103 episodes). The rate of SIs was 1.17/100 patient-years. The commonest causes of SIs were pulmonary tuberculosis (TB) (41%), severe pneumonia (33%), soft tissue infection (6.8%), atypical TB (2.9%), urogenital sepsis (2.9%), septic arthritis (2.9%), hepatobiliary/gastrointestinal sepsis (2.9%), central nervous infection (1%), severe viral infections including herpes zoster (5.8%), and opportunistic infections (2.9%). A logistic regression model showed that increasing age (OR1.02 [1.001–1.04 per year]), male sex (OR1.88 [1.08–3.26]) and concomitant chronic obstructive pulmonary disease/asthma (OR2.55 [1.05–6.23]) were risk factors significantly associated with SIs. The rate of TB infection was highest in users of infliximab (2.32/100 patient-years), followed by tofacitinib (1.47), adalimumab (1.27), etanercept (0.62) and tocilizumab (0.36). Non-TB SIs occurred most frequently with infliximab (2.32/100 patient-years), tofacitinib (1.47) and abatacept (1.15). In the quintile of patients with the highest propensity score for SIs, infliximab had the highest withdrawal rate due to SIs (18%), followed by tofacitinib (10%), etanercept (8%), adalimumab (6%), abatacept (2.8%) and tocilizumab (2.6%). Cox regression revealed the following HRs for SIs with reference to adalimumab: infliximab (2.81 [0.80–9.88]), tofacitinib (HR 2.12 [0.19–23.4]), etanercept (HR 0.82 [0.22–3.11]), abatacept (HR 0.41 [0.04–3.98]) and tocilizumab (HR 0.38 [0.06–2.26]). Concomitant low-dose glucocorticoid was associated with an insignificantly increased risk of SIs only in the three quintiles of patients with lower propensity to SIs.

**Conclusions:** SIs causing withdrawal of b/tsDMARDs in patients with RA account for one-third of all SAEs. Increasing age, male sex and concomitant chronic chest conditions were independent risk factors for SIs. Infliximab was associated with the highest rates of serious TB and non-TB infection, and this observation was consistent in all quintiles of patients with different propensity to SIs.

**AB0426 EFFICACY OF MONOTHERAPY OF THE BIOLOGIC DMARDs IN PATIENTS WITH RHEUMATOID ARTHRITIS: REAL LIFE DATA FROM THE HONG KONG BIOLOGICS REGISTRY**

C.C. Mok, R. Wan, B. Fong, on behalf of The Hong Kong Society of Rheumatology. *Medicine, Tuen Mun Hospital, HK, Hong Kong*

**Objectives:** To report the prevalence and efficacy of biologic DMARD (bDMARD) monotherapy in real life treatment of rheumatoid arthritis (RA).

**Methods:** RA patients registered in the Hong Kong Biologics Registry who were receiving bDMARD monotherapy (without concomitant conventional synthetic DMARDs [csDMARDs] except low dose prednisolone) were identified. The efficacy (clinical response and drug retention rate) of bDMARD monotherapy was compared with bDMARD combination therapy (with csDMARDs) using statistical tests.

**Results:** From December 2007 to April 2017, 2123 courses of bDMARDs/tsDMARDs were used in 1250 RA patients (83% women, mean age at therapy  $53.8 \pm 12.7$  years). Among 1881 courses of therapies with complete data, 164 (8.7%) was monotherapy at baseline. Low dose prednisolone (<10 mg/day) was used in 56% of these courses. In the combination group, the commonest csDMARDs used in combination with bDMARDs were methotrexate (79%), sulphasalazine (27%), hydroxychloroquine (25%) and leflunomide (21%). The bDMARDs/tsDMARDs most frequently used as monotherapy were tofacitinib (14.3%), tocilizumab (11.6%) and abatacept (11.2%). Overall, the non-TNF was more commonly used as monotherapy (11.2%) than the anti-TNF bDMARDs (7.4%). At 6 months of bDMARD/tsDMARD therapy, the DAS remission rate was non-significantly higher in the combination than monotherapy group (11% vs 5%;  $p=0.42$ ). The change in DAS28 score was also non-significantly greater in the combination group ( $-1.95 \pm 1.26$  vs  $-1.68 \pm 1.56$ ;  $p=0.30$ ). The difference in 6 month efficacy between the combination and monotherapy groups was greater in anti-TNF users. The overall cumulative withdrawal rate of the bDMARDs/tsDMARDs due to either inefficacy or serious adverse events (SAEs) was 0.55 at 3 years and 0.47 at 5 years. The anti-TNF biologics had a significantly higher withdrawal rate than the non-TNF biologics (hazard ratio [HR] 1.83 [1.56–3.14];  $p<0.001$ ). In Cox regression models, monotherapy of the bDMARDs was not significantly associated with drug withdrawal due to inefficacy (HR 0.95 [0.53–1.71];  $p=0.87$ ) or SAEs (HR 1.27 [0.51–3.19];  $p=0.61$ ) after adjustment for age, sex, anti-TNF (vs non-TNF) biologic use, previous use of bDMARDs (vs first time use) and DAS28 at baseline. Separate analyses of the anti-TNF and non-TNF biologics again did not reveal a significant relationship between monotherapy of the biologics with the drug withdrawal due to inefficacy or SAEs after adjustment for age, sex, previous use of bDMARDs and disease activity at baseline (HR 1.002 [0.56–1.80];  $p=0.99$  for anti-TNF and HR 1.20 [0.47–3.08];  $p=0.70$  for non-TNF biologics, respectively).

**Conclusions:** Monotherapy of bDMARD/tsDMARD was used in 8.7% of our RA patients in real life practice, probably due to intolerance, inefficacy or non-compliance to the csDMARDs. Short-term efficacy tended to be better with bDMARDs/csDMARDs combination, especially in the anti-TNF biologics, but the long-term drug retention rate was similar between bDMARD monotherapy and combination therapy with the csDMARDs.

**AB0427 COMPARATIVE SAFETY OF ABATACEPT VS TOFACITINIB IN ADULTS WITH MODERATE-TO-SEVERE RA: A SYSTEMATIC LITERATURE REVIEW AND NETWORK META-ANALYSIS**

D. Paul<sup>1</sup>, R. Diekemper<sup>2</sup>, M. Fazeli<sup>2</sup>, F. Husain<sup>2</sup>, A. Marshall<sup>1</sup>, Y. Kuang<sup>2</sup>, T. Curtice<sup>1</sup>. <sup>1</sup>Bristol-Myers Squibb, Princeton; <sup>2</sup>Doctor Evidence, Santa Monica, USA

**Background:** While targeted (biologic or synthetic) DMARDs are overall highly effective in improving symptoms and function in RA patients (pts), their comparative safety relative to each other remains inconclusive.

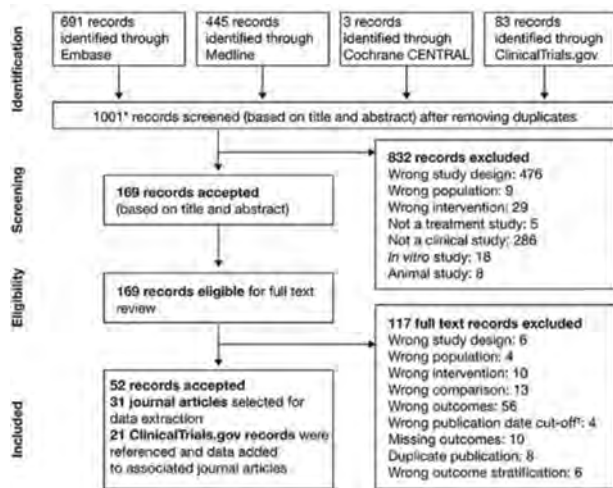

**Objectives:** Compare the safety of abatacept (ABA) and tofacitinib (TOF) through a systematic literature review (SLR) and network meta-analyses (NMA).

**Methods:** A comprehensive search of randomised and non-randomised clinical trials was conducted across MEDLINE, Embase and Cochrane CENTRAL databases from inception to June 2017. The PICO framework (population=moderate to severe RA pts; intervention=ABA and TOF; comparison=placebo and other RA therapies; outcome=AEs, treatment-related AEs [TrAEs], serious infections and treatment-related deaths) was used to design searches and define the eligibility of studies for inclusion. Additional searches were performed on relevant conference proceedings and the US clinical trials registry from the past 2 years (figure 1). Data configuration was performed by expert methodologists using DOC Data 2.0 (Doctor Evidence, Santa Monica, CA). NMAs using the random-effects model were used to examine the risk of AEs, TrAEs and serious infections in

conventional DMARD-experienced ABA- and TOF-treated pts. Treatment-related death was not analysed in an NMA due to insufficient data.

**Results:** Thirty-one randomised controlled trials (n=13,978) were included for data extraction. Of these, ABA and TOF were examined in 16 and 15 trials, respectively. There were no head-to-head comparisons of ABA vs TOF. Most of the trial population were Caucasian (48%–98% across trials), had an average age ranging from 40 to 60 years and were predominantly female (60%–90%). Of the trials, 26 included a US population and 5 a non-US population. Out of 11 studies reporting treatment-related mortality, one study reported four deaths for pts on TOF 5 mg (n=321) within a 1 year follow-up. No such deaths were reported for ABA pts. The NMAs showed no significant differences in the risk of TrAEs for pts on TOF 5 or 10 mg compared with ABA with/without MTX (TOF 5 mg +MTX vs ABA+MTX: risk ratio [RR] 1.1, 95% CI: 0.77, 1.5; TOF 10 mg vs ABA: RR 1.1, 95% CI: 0.78, 1.6). These findings remained consistent for the risk of total AEs and serious infections.

Abstract AB0427 – Figure 1. PRISMA Diagram Showing Study Selection

\*One reference identified manually from a ClinicalTrials.gov record

<sup>†</sup>Wrong publication date cut-off: meeting abstract published before 2015

**Conclusions:** Without head-to-head trials, the data available to make comparisons between abatacept and TOF are limited. Even after conducting an SLR and NMAs, precision is lacking in estimating differences. Additional studies, such as real-world observational analyses with larger patient samples and higher incidence of measured outcomes, are needed to further examine the safety differences of abatacept vs TOF.

#### AB0428 PREFERENCES IN THE USE OF BIOLOGIC DRUGS AND ADVERSE EVENTS IN PATIENTS WITH RHEUMATIC DISEASE FROM A NATIONAL BIOLOGICS REGISTRY IN MÉXICO

D. Xibillé<sup>1</sup>, S. Carrillo<sup>2</sup>, S. Sicsik<sup>3</sup>, F. Irazoqui<sup>4</sup>, A. Ramos<sup>5</sup>, S. Durán<sup>6</sup>, M. Saavedra<sup>7</sup>, L. Barile<sup>8</sup>, G. Olvera<sup>8</sup>. <sup>1</sup>SSM, Cuernavaca; <sup>2</sup>Hospital 1 Oct, ISSSTE, México; <sup>3</sup>UMAE 71 IMSS, Torreón; <sup>4</sup>CMN 20 Nov, ISSSTE, México; <sup>5</sup>CMN NE 25 IMSS, Monterrey; <sup>6</sup>CIRO SC, Guadalajara; <sup>7</sup>HE CMN La Raza, IMSS; <sup>8</sup>Colegio Mexicano de Reumatología, México, Mexico

**Background:** National registries of biologic drugs have proven to be valuable tools in following patients with rheumatic disease and some outcomes in real-life situations.

**Objectives:** The objective of this study was to describe Mexican Rheumatologists' preferences when treating patients with biologic drugs and to analyse factors associated to the use of this therapy.

**Methods:** Data from patients undergoing biologic treatment in México is gathered into the BIOBADAMEX online database, which is part of the BIOBADAMERICA

initiative and based on the BIOBADASER Phase 3 platform. Phase 3 in México started gathering patient data in April 2016 and to date has information on 216 patients. The database collects information such as gender, age, diagnosis, disease duration, biologic treatment, DMARD treatment, concomitant therapy, motives for discontinuation of biologics, comorbidities, adverse event (AE) severity, infection site and germ involved. Descriptive statistics were applied on the data collected from April 2016 to January 2018.

**Results:** We analysed data on the use of 267 biologic treatments in 216 patients. Most of them receive biologic therapy through socialised medical insurance programs which may have led to bias. 89.1% of patients were female, mean age 49 ±15.2 (4–85) years, 42.5% belonging to the <50 group. 69.9% of patients in the registry have RA, 12.5% AS and 5.5% PsA. Mean disease duration is 11±8.9 (0–58) years. The most commonly used biologic overall is Abatacept (15.3%), followed by Adalimumab (13.8%), Tocilizumab (11.2%), Certolizumab (10.1%), Golimumab (8.6%), Rituximab (8.2%), Etanercept biosimilar (7.4%), Etanercept (6.3%), Infliximab (4.1%) and Benlystia (1.1%). All others, including JAK inhibitors, are used in <1% of patients. The preference for first biologic drug was Etanercept (32.4%), followed by Adalimumab (12%), Infliximab (8.3%), Rituximab and Tocilizumab (5.5% each) and Abatacept (2.7%). Most treatments were stopped due to lack of efficacy (60.4%), disease remission (7.4%), other causes (20.1%), AE (4.4%), with the rest of the causes each affecting <5% of patients. The most commonly used DMARD were Methotrexate (49.8%), steroids (33.3%) and leflunomide (23.2%). Comorbidities were present in 87 patients (40%), the most common being Hypertension (13.4%), Diabetes (7.8%) and Dyslipidemia (6.9%). Non-lymphoma neoplasms were reported in 1.3%. 25% of AE were considered serious but most (70%) were mild. Only 6 patients reported infections with the most common sites being the skin (33.3%), urinary tract (16.6%) and middle-ear (16.6%). The causal germ was often undetermined (60%).

**Conclusions:** When using biologic drugs, TNF inhibitors are the most commonly used initial mechanism of action for the treatment of rheumatic diseases in the BIOBADAMEX registry. Upon treatment failure, patients undergo a switch to another mechanism of action, mainly using Abatacept. Adverse events and infections related to the use of biologics are infrequent, but 40% of patients present chronic comorbidities.

#### AB0429 NO DIFFERENCE IN EFFECTIVENESS WITH EITHER ETANERCEPT ORIGINATOR OR BIOSIMILAR AS FIRST LINE BIOLOGIC TREATMENT FOR RHEUMATOID ARTHRITIS

D. De Cock<sup>1</sup>, R. Davies<sup>1</sup>, L. Kearsley-Fleet<sup>1</sup>, K. Watson<sup>1</sup>, K. Hyrich<sup>1,2</sup>, on behalf of the BSRBR-RA contributor group. <sup>1</sup>Arthritis Research UK Centre for Epidemiology, Manchester University; <sup>2</sup>Manchester Academic Health Science Centre, Central Manchester NHS Foundation Trust, Manchester, UK

**Background:** Biosimilars and their reference agents have been shown to be equivalent in clinical trials. In the United Kingdom, etanercept biosimilars (ETA-B) are, since 2016, a first-line treatment option for the management of severe rheumatoid arthritis (RA) defined as no response to 2 or more csDMARDs. However, real world data, including how it compares to the etanercept originator (ETA-O) are lacking.

**Objectives:** This study aims to compare the short-term effectiveness of etanercept originator with its biosimilar in patients with RA when used as a first biologic following csDMARDs.

**Methods:** This study included patients with RA registered with the British Society for Rheumatology Biologics Registers for RA (BSRBR-RA) at the point of starting either ETA-O or an ETA-B since 2011 as their first biologic. Baseline information is collected at drug start and includes demographic and clinical data. Follow-up (FU) data are captured every 6 months and include details on therapy changes, current disease activity, and development of any adverse events. The primary outcome of this study is effectiveness as calculated by change in the 28 joint count disease activity score (DAS28). Only patients with a complete DAS28 at baseline and their 1st FU were included in the final analysis of this study. Hazard ratios (HR) comparing drug survival and risk of first serious adverse event (SAE) between ETA-O and ETA-B patients were calculated using Cox regression.

**Results:** Between January 2010 and 11 December 2017, 1217 and 412 patients starting ETA-O or ETA-B respectively were recruited and had ≥1 FU available. Complete DAS28 data at baseline and 1st FU were available for 740 ETA-O patients and 177 ETA-B patients. Patient characteristics were similar between the 2 cohorts (Table). After adjusting for baseline differences, no difference between groups was seen in DAS28 (p=0.1) or remission status (p=0.1) at 1st FU.

Nine (5%) and 48 (6%) of ETA-B and ETA-O patients had stopped their respective treatments by the 1st FU. The adjusted hazard ratio for stopping ETA-O versus ETA-B over this time period was similar (HR=0.8 (0.4-1.6); p=0.5). Risk of SAEs over the first 6 months was also similar between groups (HR (ETA-B versus ETA-O)=0.6 (0.3-1.1); p=0.1), with 10 (6%) and 73 (10%) SAEs reported in ETA-B and ETA-O patients respectively until 1st FU.

Abstract AB0429 – Table 1

Patients who are	Biological naive	Switched from a non-originator	Switched from originator
<b>Number</b>	36	17	5
<b>Biosimilar</b>			
Infliximab biosimilar	28 (77%)	17 (100%)	3 (60%)
etanercept biosimilar	8 (22%)	0 (0%)	2 (40%)
<b>ILAR class</b>			
Persistent Oligoarthritis	4 (11%)	4 (24%)	0 (0%)
Extended Oligoarthritis	8 (22%)	5 (29%)	1 (20%)
RF Negative Polyarthritis	13 (36%)	4 (24%)	1 (20%)
RF Positive Polyarthritis	0 (0%)	0 (0%)	0 (0%)
Psoriatic Arthritis	2 (6%)	3 (18%)	3 (60%)
Enthesitis Related Arthritis	8 (22%)	1 (6%)	0 (0%)
Unknown	1 (3%)	0 (0%)	0 (0%)
<b>Active uveitis at start of therapy</b>	4 (11%)	7 (41%)	2 (40%)
<b>Female</b>	22 (61%)	12 (71%)	2 (40%)
<b>Age (years)</b>	13 (9-15)	14 (11-15)	13 (12-16)
<b>Disease duration (years)</b>	2 (1-5)	6 (3-10)	7 (6-13)
<b>Active Joints (71 joints)</b>	2 (1-4)	0 (0-2)	0 (0-0)
<b>Limited Joints (71 joints)</b>	2 (1-4)	2 (0-4)	0 (0-1)
<b>Physician Global (0-10cm)</b>	2 (2-4)	1 (0-2)	0 (0-0)
<b>Patient Global (0-10cm)</b>	5 (1-7)	2 (0-4)	2 (0-4)
<b>Pain VAS (0-10cm)</b>	4 (1-7)	4 (2-5)	1 (0-1)
<b>CHAQ (0-3)</b>	1 (0-3)	0 (0-2)	0 (0-1)

All data presented are number (percentages) or median (interquartile range). International League of Associations for Rheumatology (ILAR), Rheumatoid Factor (RF), Visual Analog Scale (VAS), Childhood Health Assessment Questionnaire (CHAQ).

**Conclusions:** In the UK, etanercept biosimilars are now frequently used as first-line biologics in RA patients. These short-term follow-up data demonstrate in routine clinical care that ETA-B appears to be equivalent to ETA-O in terms of short term effectiveness, drug survival and safety.

#### AB0430 SUBJECTIVE ASSESSMENTS OF PATIENTS WITH RHEUMATOID ARTHRITIS REPORTED THAT BIO-HOLIDAY THERAPY BROUGHT THEM FINANCIAL AND PSYCHOLOGICAL IMPROVEMENTS

E. Torikai<sup>1</sup>, D. Suzuki<sup>1</sup>, M. Suzuki<sup>2</sup>, Y. Matsuyama<sup>2</sup>. <sup>1</sup>Department of Rheumatology, Iwata city hospital, Iwata; <sup>2</sup>Department of Orthopaedic surgery, Hamamatsu university school of medicine, Hamamatsu, Japan

**Background:** At EULAR 2016 and 2017 we reported that it is possible to maintain disease activity, radiographic progression, physical function, and bone metabolism status in rheumatoid arthritis (RA) patients with clinical disease activity index (CDAI) remission using the biologic agents (Bio)-holiday therapy. Currently, in RA therapy, subjective assessment of patients as well as objective assessment of doctors is becoming more important<sup>(1)</sup>. How does the patient think about Bio-holiday therapy?

**Objectives:** We conducted questionnaire survey in RA patients with CDAI remission who underwent Bio-holiday therapy or Bio-continue therapy to evaluate the benefits of their therapies and to clarify the number of patients concerned about flare-up.

**Methods:** The first and second survey comprised 9 and 11 questions, respectively; each provided predefined answers. In the first survey, we questioned 85 RA patients in CDAI remission: those treated with any DMARDs. We asked them about the expected elements of RA treatment. In the second survey, we questioned two groups of patients with CDAI remission; those treated with Bio-continue after achieved CDAI remission (BC group: n=26) and those treated with Bio-holiday therapy after achieved CDAI remission (BH group: n=28). We asked them by a questionnaire what was expected from the treatment effect and how much they felt anxiety about the activity of daily life (ADL) deterioration, RA flare-up and treatment costs.

For Bio-holiday therapy, patients with CDAI remission were treated with golimumab or tocilizumab. Bio was discontinued if they achieved CDAI remission. Patients were treated with Bio within 3 months after falling out of CDAI remission. They could be taken off Bio again when they reached CDAI remission.

**Results:** In the first survey (figure 1), pain improvement and inexpensive treatment were the most and the second expected treatment effect, respectively. In the second survey (Figure 2), for questions regarding expectation from RA treatment effect, the patients reported that the most beneficial points was pain improvement and the second one was the active daily living without difficulty. Patients in both groups equally recognised reduction in pain and recovery of activities of daily

living, which are important for patients with CDAI remission. Interestingly, improvement of emotional depression is the higher in BH group than in BC group. For question regarding anxiety, the high medical expense was the most anxious point. Anxiety regarding high medical expenses in BH group was lower than that in BC group. Anxiety regarding flare-up was equal to that in BC group as patients were assured of retreatment with Bio in case of a flare-up.

Abstract AB0430 – Figure 1. Questionnaire results of all RA patients with CDAI remission

Abstract AB0430 – Figure 2. Questionnaire results of RA patients with CDAI remission who underwent Bio-holiday therapy or Bio-continue therapy

**Conclusions:** Patients in both groups were equally satisfied with the improvement of their disease activity and progression of ADL. Reduction of the anxiety regarding treatment costs and flare-up in Bio-holiday therapy also helped to improve psychological aspects. Therefore, we recommended Bio-holiday therapy for RA patients with CDAI remission.

#### AB0431 EARLIER AGE AT THERAPY INITIATION IS ASSOCIATED WITH BETTER RESPONSE TO TOCILIZUMAB THERAPY IN PATIENTS WITH JUVENILE IDIOPATHIC POLYARTHRITIS

E. Alexeeva<sup>1,2</sup>, T. Dvoryakovskaya<sup>1,2</sup>, M. Soloshenko<sup>1</sup>, R. Denisova<sup>1</sup>, K. Isaeva<sup>1</sup>, A. Mamutova<sup>1</sup>, V. Gladkikh<sup>3,4</sup>, A. Moskalev<sup>3,4</sup>. <sup>1</sup>National Medical Research Center for Children's Health; <sup>2</sup>Sechenov First Moscow State Medical University (Sechenov University), Moscow; <sup>3</sup>EOL Labs Ltd, Department of Biostatistics; <sup>4</sup>Institute of Computational Mathematics and Mathematical Geophysics SB RAS, Novosibirsk, Russian Federation

**Background:** The use of therapy with anti-cytokine biologics in routine practice has significantly increased the percentage of children showing good response to therapy and reduced the time to achieve pharmacological remission. Nevertheless, the problem related to selecting the optimal drug for a certain patient still remains to be solved.

**Objectives:** This study was aimed at identifying clinical and laboratory parameters associated with response to tocilizumab (TOC) treatment in patients with RF-negative polyarticular JIA.

**Methods:** The prospective study to assess TOC efficacy involved 55 patients with RF-negative polyarticular JIA aged 9.42 years (IQR 5.96–13.42), with females (85.5%) predominating was conducted at the National Medical Research Centre of Children's Health (Moscow). Treatment efficacy was evaluated using the ACRPed criteria; Wallace's criteria were used to assess whether a patient had reached inactive disease or remission. The potential baseline characteristics associated with treatment response were identified using univariate and multivariate logistic regression analyses. Baseline factors included the clinical, laboratory, and anamnestic data.

**Results:** TOC therapy showed high efficacy in children with RF-negative polyarticular JIA: 81.8/67.3/47.3/23.6% of patients reached the ACR30/50/70/90 criteria for the end of follow-up, respectively. The median time of achieving at least 30% improvement from baseline (ACR30) was 1 month (IQR 1:3).

Univariate analysis showed that earlier age at initiation of Tocilizumab therapy, higher physician's global assessment score using the 100-point Visual Analogue Scale, and longer morning stiffness were the factors associated with reaching ACR90. Younger age at therapy initiation, greater number of swollen joints and joints with limited range of motion, and history of using fewer biologicals are the factors associated with reaching inactive disease and remission. However, multi-factorial analysis showed that only earlier age at initiation of TOC therapy was a statistically significant factor associated with reaching the best response to therapy in all the models.

**Conclusions:** Earlier initiation of TOC therapy is associated with higher chances for reaching ACR90 and pharmacological remission in patients with RF-negative polyarticular JIA. Further studies in larger cohorts are needed to identify the optimal age at therapy initiation.

#### AB0432 BIOLOGIC DMARDS TREATMENT RETENTION IN PATIENTS WITH RHEUMATOID ARTHRITIS ACCORDING TO THE MOSCOW ARTHRITIS REGISTRY (MERA)

E. Koltsova<sup>1</sup>, E. Zhilyaev<sup>2</sup>, G. Lukina<sup>3</sup>, E. Shmidt<sup>4</sup>. <sup>1</sup>Research Institute of the Organization of health and healthcare management; <sup>2</sup>CJSC «European Medical Center»; <sup>3</sup>Moscow Clinical Scientific Center; <sup>4</sup>City Clinical Hospital 1 named after N.I. Pirogov, Moscow, Russian Federation

**Background:** Retention on treatment is a good index of efficacy and safety of treatment used in the real clinical practice. These data may be useful to planning the treatment among some years.<sup>1,2</sup>

**Objectives:** To compare the drug survival of biological therapies.

**Methods:** We followed rheumatoid arthritis patients treated with biologics DMARD and registered in MERA 2012–January 2018. All patients had more than one visit in the registry.

**Results:** We analysed 799 patients (mean age 57.3±13, mean diseases duration 15.6±10.3 years). The average time until a change of treatment for infliximab was 399 days – the shortest treatment duration. Abatacept (median survival – 2922 days) demonstrated significant superiority over adalimumab (1339 days) ( $p<0.001$ ), infliximab (399 days) ( $p<0.001$ ), rituximab (2557 days) ( $p=0.004$ ) and etanercept (1492 days) ( $p=0.035$ ) when they were used as the first biologic drug. Among second-line therapy, the longest treatment survival has etanercept (3435 days), the shortest – infliximab (212 days).

Abstract AB0432 – Figure 1

**Conclusions:** The results of the trial show the differences in treatment survival of some biologics. It can be reasonable to take these significant differences into consideration by the long-term planning of the biologic treatment of rheumatoid arthritis patients.

#### AB0433 TNF-INHIBITORS AND ANTI-B-CELL TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS. REAL-WORLD DATA FROM THE RUSSIAN NORTH-WESTERN BIOLOGICAL TREATMENT COHORT

E. Vasilenko, R.R. Samigullina, V.I. Mazurov, E.A. Trofimov, I.Z. Gaydukova.

North-Western State Medical University named after I.I. Mechnikov, Sankt-Peterburg, Russian Federation

**Background:** Biologics are drugs that improved the status of rheumatoid arthritis (RA). At the same time real-world data (RWD) from large cohorts can give some additional information about efficacy and safety of the biological agents.

**Objectives:** The aim of the study was to analyse the efficacy and safety of biological treatment in large prospective cohort during 102 weeks of treatment.

**Methods:** The data from 1 400 patients on biological treatment from North-Western State Medical University Biological Treatment Cohort Study (St. Petersburg, Russia) were analysed. In final analysis data from 758 patients with RA/EULAR 2010 criteria, were included. Following drugs were used: adalimumab (n=22), certolizumab pegol (n=62), etanercept (n=64), golimumab (n=21) and infliximab (n=69), rituximab (n=520). The disease activity index (DAS28) and high-sensitive C-reactive protein (C-RP) were evaluated as markers of RA activity. Side effects were registered during the study.

**Results:** RA activity, demographic characteristics, and concomitant treatment (including methotrexate, glucocorticoids, NSAIDs, analgesics) at baseline were similar in all the treatment groups ( $p\geq 0.05$  for all the parameters). The faster response was found in golimumab and certolizumab pegol patients ( $p$  and  $It$ ; 0.01 for difference of DAS28 in golimumab, certolizumab pegol treatment and other treatment groups at week 6), figure 1. After week 12 the similar efficacy of all the TNF $\alpha$ -blockers (figure 1).

RA activity, demographic characteristics, and concomitant treatment (including methotrexate, glucocorticoids, NSAIDs, analgesics) at baseline were similar in all the treatment groups ( $p\geq 0.05$  for all the parameters). The faster response was found in golimumab and certolizumab pegol patients ( $p<0.01$  for difference of DAS28 in golimumab, certolizumab pegol treatment and other treatment groups at week 6), figure 1. After week 12 the similar efficacy of all the TNF $\alpha$ -blockers (figure 1). C-RP levels were similar in all the treatment groups in all time-points ( $p\geq 0.05$ ). DAS28 (mean  $\pm$ SD) in RA patients, treated with rituximab, at baseline, and at weeks 24, 54, and 102 was 6.6 $\pm$ 2.4, 3.7 $\pm$ 1.7, 3.62 $\pm$ 2.1 and 3.2 $\pm$ 2.05, respectively;  $p\geq 0.05$  for the differences with all another treatment groups at the same time-points.

The most frequent side-effects were opportunistic infections, OR=1.8 [95% CI 1.4–2.1]. Risk of infections was higher in patients, receiving monoclonal antibodies to TNF $\alpha$ , as compared to other TNF $\alpha$  inhibitors ( $p<0.01$  for differences between infliximab/adalimumab/golimumab and etanercept, and  $p<0.05$  for differences between infliximab/adalimumab/golimumab and certolizumab pegol).

The risk of cancer in RA patients on biological treatment and in total Russian population (including lymphomas and skin cancer) was comparable: for all the tumours OR=0.98 [95% CI 0.76–1.26], for lymphomas OR=1.23 [95% CI 0.92–1.41], for skin cancer OR=1.11 [0.88–0.36].

Abstract AB0433 – Figure 1. The dynamics of the disease activity index DAS28 in patients with RA receiving different TNF $\alpha$  blockers

**Conclusions:** According to the RWD from the North-Western Biological Treatment Cohort, the efficacy of all the TNF $\alpha$ -inhibitors and rituximab in RA treatment

after week 12 is the same. Infections, but not tumours, are the most frequent side-effects of biological treatment in RA patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6211

AB0434

#### THE INFLUENCE OF BODY MASS INDEX ON THE EFFICACY OF TUMOUR NECROSIS FACTOR BLOCKING THERAPY AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

E.N. Mole<sup>1</sup>, K. Zoupidou<sup>1</sup>, A. Alexoudis<sup>1</sup>, E. Koutsantoni<sup>1</sup>, C. Sfontouris<sup>2</sup>, S. Gazi<sup>1</sup>.

<sup>1</sup>Department of Rheumatology, General Hospital of Attica "KAT", Kifisia;

<sup>2</sup>Department of Rheumatology, General Hospital of Athens "Evangelismos", Athens, Greece

**Background:** The impact of Body Mass Index (BMI) on efficacy of TNF blocking therapy in Rheumatoid Arthritis (RA) patients and therefore on control of the disease is an important question.

**Objectives:** The aim of this study is to determine the influence of BMI on the efficacy of TNF blocking therapy in terms of disease activity in patients with RA.

**Methods:** A retrospective, observational study of 168 consecutive RA patients who received subcutaneously (SC) TNF blocking treatment (adalimumab, etanercept, golimumab and certolizumab pegol). Their follow-up data, for at least 26 weeks, and their baseline BMIs were available. The WHO definition for normal weight, overweight and obesity was applied, whereas clinical response was compared by BMI subgroups.

**Results:** The average BMI was 26.83±4.34 kg/m<sup>2</sup> and the baseline Disease Activity Score in 28 joints (DAS28 [ESR]) was high at 5.72±0.84. Mean age was 63.47±12.58 years and 135 (80.36%) were female. The median disease duration was 13.01±8.57 years. Overall, patients with normal weight responded better to treatment regimen, followed by overweight and obese subgroups. After a follow-up period of 26 weeks, the obese group had significantly higher DAS28 (ESR) and Health Assessment Questionnaire (HAQ) than either normal or overweight subgroups (3.26±0.84 vs 2.72±0.78 vs 2.81±0.82, p<0.001, 0.423±0.002 vs 0.076±0.01 vs 0.178±0.01, p<0.001 respectively). Furthermore, obesity was significantly associated with a decreased tendency of achieving week 26 remission, based on DAS28 (<2.6) p:0.002 and normal HAQ (≤0.5) p: 0.003.

**Abstract AB0434 – Table 1.** Summary of responses to TNF-blocking therapy (SC) by BMI category at week 26 in subjects with RA

Variable		% (n/N)			p value [95% CI]
		BMI <25 kg/m <sup>2</sup>	BMI 25-30 kg/m <sup>2</sup>	BMI >30 kg/m <sup>2</sup>	
DAS28 HAQ	Remission (<2.6)	58.18 (22/55)	35.8 (29/81)	0 (0/32)	0.002 [15–16.5]
	LDA (>2.6 – <3.2)	9.09 (5/55)	40.74 (33/81)	37.5 (12/32)	0.001 [16.6–16.7]
	MDA (>3.2 – <5.1)	30.91 (17/55)	23.46 (19/81)	62.5 (20/32)	0.001 [15.2–16.9]
	HDA (>5.1)	1.82 (1/55)	0 (0/81)	0 (0/32)	ns
	<0.5	61.81 (34/55)	58.02 (47/81)	46.88 (15/32)	0.003 [8.9–16.6]

LDA: low disease activity, MDA: moderate disease activity, HDA: high disease activity

**Conclusions:** Patients with RA and higher BMIs demonstrated a diminished clinical response after 26 weeks of SC-administered TNF-blocking treatment compared with their counterparts with lower BMIs.

#### THE TREATMENT PATTERN OF TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS IN CHINA: A MULTICENTER OBSERVATIONAL STUDY

F. Zhang, on behalf of Lijun Wu, Lingli. Dong, Yasong. Li, Changhong. Xiao, Xiaofei. Shi, Yan. Zhang, Qin. Li, Yi. Liu, Bin. Zhou. *Peking Union Medical College Hospital, Beijing, China*

**Background:** Tocilizumab (TCZ) is a humanised monoclonal antibody targeting interleukin-6 receptor. Since TCZ Label for RA has been issued in many countries, administration patterns and dose modifications for managing adverse events (AEs) seems differ depending on clinical opinion. Few data are available from real world practice in China.

**Objectives:** To observe in routine clinical practice the treatment patterns of TCZ in RA patients with regard to persistence on drug and adherence to the licensed label recommendations.

**Methods:** This a 6 month non-interventional, multi-centre study enrolled patients with moderate to severe RA diagnosed per revised 1987 ACR criteria (age ≥18 years) and being treated with TCZ. Data was recorded during routine visit. The primary variable was the proportion of patients on TCZ treatment after 6 months.

**Results:** Of 407 patients from 23 centres in China, 396 were eligible, including 330 (83.3%) women. The mean age was 49.1±13.44 years. The mean RA diagnosis course was 5.4±6.24 years. Among 396 patients, 250 (63.1%) were RF positive, 235 (59.3%) were anti-CCP positive and 123 (31.1%) had anaemia (Hb <90 g/L). Of eligible patients, 293 (74.0%) completed the study. The primary reason of premature termination was treatment costs (n=49, 12.4%). There were 37 (9.3%) patients received anti-TNF biologics previously and 330 (83.3%) received concomitant DMARDs, of which 84 (21.2%), 149 (37.7%) and 97 (24.5%) received single, 2 or ≥3 types of DMARDs, respectively. Methotrexate (n=255, 64.4%) and Leflunomide (n=184, 46.5%) were the most commonly used DMARDs. A total of 126 and 197 patients received corticosteroids or nonsteroidal anti-inflammatory drugs (NSAIDs), respectively. During 6 months observation, 21.0% and 67.7% had TCZ dose modification or discontinuation, respectively. At month 3 and month 6, 161 (40.7%) and 102 (25.8%) kept TCZ treatment, respectively. The mean frequency of TCZ usage was 3.7±1.62. Effectiveness of TCZ was analysed in patients who were still using TCZ at month 6. The mean score of total TJC (28-joint count) at baseline and at month 6 was 11.2±8.0 (n=63) and 2.3±4.12 (n=77), respectively; mean change from baseline was -9.5±8.02 (n=53). The mean score of total SJC (28-joint count) at baseline and at month 6 was 8.0±6.81 (n=63) and 1.7±2.35 (n=77), respectively; mean change from baseline was -6.5±7.2 (n=53). The mean score of DAS28 at baseline and at month 6 was 6.13±1.33 (n=56) and 2.79±1.39 (n=66); mean change from baseline was -3.45±1.48 (n=46). Patients in low disease activity (DAS28 <3.2) or remission (DAS28 <2.6) in those who still using TCZ at month 6 was 63.6% and 51.5%. The mean change from baseline in SDAI and CDAI was -28.03±16.75 (n=41) and -24.25±16.94 (n=51), respectively. Of 396 patients, 90 (22.7%) and 8 (2.0%) experienced at least one treatment-emergent AE and SAE, respectively. One patient died of severe pneumonia.

**Conclusions:** This was the first real-world study in RA patients treated with TCZ in China. The results show that Chinese RA patients have long disease history. TCZ was frequently used in combination with DMARDs, especially with ≥2 types of DMARDs. Compared with the dose recommendations, shorter treatment duration and longer dose interval of TCZ were found in China. TCZ demonstrated effectiveness in treatment of Chinese RA patients in real-life clinical practice with manageable safety profile.

#### CONSOLIDATED LONG-TERM SAFETY OF INFlixIMAB IN INFLAMMATORY ARTHRITIS FROM A PROSPECTIVE, OBSERVATIONAL REGISTRY

D. Choquette<sup>1</sup>, P. Rahman<sup>2</sup>, A. Chow<sup>3</sup>, R. Faraawi<sup>4</sup>, W. Olszynski<sup>5</sup>, E. Rampakakis<sup>6</sup>, O. Asin-Milan<sup>7</sup>, B. Osborne<sup>7</sup>, A.J. Lehman<sup>8</sup>, N. Nantel<sup>7</sup>, <sup>1</sup>Institut de Rhumatologie de Montreal, Montreal, QC; <sup>2</sup>Memorial University, St-Johns; <sup>3</sup>Credit valley Rheumatology, Mississauga; <sup>4</sup>McMaster University, Hamilton; <sup>5</sup>Polmed Research Inc., Saskatoon; <sup>6</sup>JSS Medical Research, Montreal; <sup>7</sup>Janssen INC., Toronto, Canada

**Background:** The Biologic Trial Registry Across Canada (BioTRAC) was a multi-centre, prospective, longitudinal, observational program that gathered and analysed data on inflammatory arthritis patients treated with infliximab (IFX), golimumab and ustekinumab. Patients specifically treated with IFX were recruited from July 2002 to June 2015 and followed up to June 2017.

**Objectives:** The objective of this abstract is to document the final consolidated safety data from the BioTRAC IFX cohort.

**Methods:** Treatment was prescribed by the physician per actual clinical practice or standard of care for rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA); there was no randomised assignments to treatment. There were no restrictions on the use of concomitant medications. At enrolment (baseline) and approximately every 6 months thereafter, information was collected to assess safety, clinical outcomes, quality of life, comorbidities, pharmacoeconomics and treatment regimens.

**Results:** A total of 1390 patients were enrolled and used for this analysis. The proportion of patients by indication was 59.2% for RA (n=890), 25.9% for AS (n=389) and 7.4% for PsA (n=111). The mean (SD) exposure was 3.10 (3.26) years for a sum of 4290.25 patient-years. Treatment with IFX was generally safe, with AEs and SAEs being reported for 64.3% and 19.5% of patients, respectively. The incidence rate of AEs and SAEs was 116.0 and 11.2 events per 100 pt-years, respectively. More specifically, 338 SAEs were reported by 189 (21.2%) RA patients [SAEs/100 pt-yrs: 11.7], 130 SAEs were reported by 60 (15.4%) AS patients [SAEs/100 pt-yrs: 10.5] and 28 SAEs were reported by 22 (19.8%) PsA patients [SAEs/100 pt-yrs: 8.82]. The most commonly reported AE identified was arthralgia, viral upper respiratory tract infection, upper respiratory tract infection and nausea. For SAEs, the most commonly reported SOC ( $\geq 3\%$  of patients) was "Infections and infestations" [5.3% (n=73); 2.16 SAEs/100 pt-yrs] and "Neoplasms benign, malignant and unspecified" [3.5% (n=49); 1.24 SAEs/100 pt-yrs] which occurred at similar rates to the general RA patient population<sup>1</sup> and included two lymphomas [0.1%; 0.05/100 pt-yrs]. Across 3 closely monitored categories of AEs, a total of 302 closely monitored AEs were reported by 293 (21.1%) patients, including cancer (3.7%), lack of efficacy (17.1%) and tuberculosis (0.2%). A total of 21 deaths were reported during the study in 18 RA, 1 AS and 2 PsA patients. Cause of death included MACE (x5), lung cancer (x2), pulmonary fibrosis (x2), pneumonia (x2), respiratory failure, bronchitis, intestinal cancer, throat cancer, intestinal gangrene, disseminated TB, septic shock, procedural complication and drowning. The cause of death was not known for one patient.

**Conclusions:** The results of this longitudinal observational study showed that treatment with IFX was well tolerated in people living with AS, PsA and RA over a 15 year period in a real-world setting.

#### AB0437 ADALIMUMAB THERAPY RESULTS IN SUSTAINED RESPONSE IN RHEUMATOID ARTHRITIS PATIENTS OVER 5 YEARS: THE GERMAN NONINTERVENTIONAL AGIL STUDY

F. Behrens<sup>1</sup>, M. Schmalzing<sup>2</sup>, M. Koehm<sup>1</sup>, E.C. Schwaneck<sup>2</sup>, G. Greger<sup>3</sup>, T. Mosch<sup>3</sup>, H. Burkhardt<sup>1</sup>, H.-P. Tony<sup>2</sup>. <sup>1</sup>Rheumatology, Goethe-University Frankfurt, Frankfurt am Main; <sup>2</sup>Rheumatology/Immunology, Universitätsklinikum Würzburg, Würzburg; <sup>3</sup>AbbVie Deutschland, Wiesbaden, Germany

**Background:** Observational studies provide important insights into therapeutic response during daily clinical practice, including data on the effects of long-term treatment.

**Objectives:** To evaluate treatment responses in rheumatoid arthritis (RA) patients during 5 years of adalimumab (ADA) therapy.

**Methods:** We analysed data from a large German multicenter observational study of patients with active RA who initiated ADA therapy during routine clinical care (the AGIL study). Outcomes of interest included Disease Activity Score-28 joints (DAS28), DAS28 therapeutic response as assessed by the statistical critical difference (dcrit.),<sup>1</sup> Health Assessment Questionnaire-Disability Index (HAQ-DI), and patient-reported global health and pain.

**Results:** A total of 4283 patients had data available for analysis at baseline. The mean age was 55.2 years, 74% of patients were female, the mean disease duration was 9.3 years, and 26% had received previous treatment with one or more biologic drugs. At month 60, 726 patients (17%) of patients remained in the study. During the 5 year study, 41.3% of patients were lost to follow-up, 22.3% discontinued due to lack of effectiveness (about half within the first 6 months), and 4.0% discontinued due to

adverse events. Mean values in patients treated with ADA showed a rapid response to treatment by both objective and patient-reported measures. Responses were maintained over 5 years in patients remaining on therapy (table 1). ADA was well tolerated and no unexpected safety signals were observed.

**Abstract AB0437 – Table 1.** Therapeutic response to ADA in the AGIL study. Values are presented as mean (standard deviation) unless otherwise indicated

<sup>1</sup>Measured on a scale ranging from 0 (best) to 10 (worst)

**Conclusions:** The AGIL study is one of the largest observational cohorts to provide long-term data on ADA therapy. Both objective and subjective measures support the effectiveness and safety of ADA in patients with RA during 5 years of therapy. Approximately 43% of patients experienced a therapeutic response to treatment at 6 months as assessed by statistical methods (DAS28-dcrit),<sup>1</sup> and this level of response increased to 60% at 5 years in patients remaining on therapy. About one-third of patients recovered full functional ability (HAQ-DI remission) at the 6 month and subsequent visits. Our data indicate that ADA is an effective and safe long-term therapy in RA patients who continue on treatment.

#### AB0438 SAFETY OF TNF BLOCKERS IN CASE OF NON-ALCOHOLIC FATTY LIVER DISEASE AND CIRRHOSIS SYSTEMATIC REVIEW

F. Verhoeven<sup>1,2</sup>, D. Weil-Verhoeven<sup>3,4</sup>, T. Thevenot<sup>3,4</sup>, C. Prati<sup>1,2</sup>, V. Di Martino<sup>3,4</sup>, D. Wendling<sup>1,4</sup>. <sup>1</sup>Rhumatologie, CHRU de Besançon; <sup>2</sup>EA 4267 PEPITE, Université de Bourgogne Franche Comté; <sup>3</sup>Hepatology, CHRU de Besançon; <sup>4</sup>EA 4266 EPILAB, Université de Bourgogne Franche Comté, Besançon, France

**Background:** The management of inflammatory rheumatism and psoriasis has largely evolved over the last 15 years with the emergence of biotherapies whose main adverse effect is the increased infection risk. The prevalence of metabolic syndrome is increasing and has been estimated at 30% in patients with rheumatoid arthritis with an excess of 45% compared to healthy subjects. One of the major complications of the metabolic syndrome is the Non Alcoholic Fatty Liver Disease (NAFLD), which prevalence is 25% in the global population, and 30% in a cohort of patients with rheumatoid arthritis. The main complication of NAFLD is

the development of cirrhosis, known to increase infectious risk. Surprisingly, there are no data on the safety of TNF antagonists in patients with chronic inflammatory disease and NAFLD or cirrhosis.

**Objectives:** To assess infectious and liver safety of the main TNF blockers used in chronic inflammatory diseases in patients with cirrhosis or NAFLD.

**Methods:** A systematic review of the literature, following the Prisma recommendations, was conducted on the Pubmed and Embase databases with the following keywords: "adalimumab", "infliximab", "etanercept", "certolizumab", "golimumab" "TNF -blockers "AND" liver cirrhosis "," non alcoholic fatty liver disease ". We selected only studies including patients treated with TNF blockers and with cirrhosis or ultrasonically characterised NAFLD. We excluded animal models and non-English articles.

**Results:** We identified 39 articles and only 11 fulfilled the inclusion criteria. 9 Case Reports have reported the tolerance of TNF-blockers in patients with cirrhosis and one controlled study (44 patients) assessed the safety of etanercept in case of NAFLD. One study (7 patients) investigated the impact of infliximab in refractory autoimmune hepatitis. The cause of cirrhosis was primary biliary cholangitis (5 cases), alpha1 antitrypsin deficiency (4 cases) and post hepatitis B cirrhosis (2 cases). All cirrhosis were compensated. Inflammatory diseases requiring the introduction of TNF blocker were rheumatoid arthritis (n=5), psoriatic arthritis (n=4), ulcerative colitis (n=2) and psoriasis (n=44). The TNF-blockers prescribed were adalimumab in 2 patients, infliximab in 11 patients and etanercept in 49 patients. The duration of treatment ranged from 6 to 24 months. For the 9 cirrhotic patients with an inflammatory disorder, no infection was reported and two of them (2 cases of primary biliary cholangitis) even had an improvement in liver function secondary to the introduction of biotherapy. For the 7 patients receiving infliximab to treat auto-immune hepatitis, 5 patients presented recurrent infections. For patients with NAFLD, no infectious event was reported and an improvement of the hepatic biological parameters was observed, suggesting an improvement in liver function.

**Conclusions:** The results of this review suggest that in case of compensated cirrhosis, TNF-blockers were not deleterious for the liver and did not increase the infectious risk. In case of auto-immune cirrhosis, TNF-blockers increased the infectious risk. In case of NAFLD, TNF-blockers might improve liver function and prevent fibrosis.

AB0439

#### TRAVELLING WITH ARTHRITIS: A CROSS-SECTIONAL ANALYSIS OF DANISH ARTHRITIS PATIENTS TREATED WITH BIOLOGICS

F. Szabados<sup>1</sup>, C. Rasmussen<sup>1</sup>, A. Linauskas<sup>1,2</sup>, P. Leutscher<sup>3</sup>, J. Kragh<sup>1</sup>.

<sup>1</sup>Department of Rheumatology, North Denmark Regional Hospital, Hjørring;

<sup>2</sup>Department of Rheumatology, Aarhus University Hospital, Aarhus; <sup>3</sup>Centre for Clinical Research, North Denmark Regional Hospital, Hjørring, Denmark

**Background:** The development and introduction of biologics has rapidly revolutionised the therapeutic approach of chronic inflammatory diseases. Well-treated patients have high physical activity levels and long life expectancy. They travel widely for holiday, business or family visits. Biological drugs are administered either intravenously or subcutaneous and have to be kept cool.

**Objectives:** To describe the travel patterns, the extent of pre-travel advice, travel insurance, vaccinations, adherence to biological treatment, and self-reported health related problems encountered by rheumatology patients in biologic treatment during their travel.

**Methods:** A cross-sectional study was conducted in an out-patient clinic at the Department of Rheumatology, North Denmark Regional Hospital. During 2017 a questionnaire with focus on travel history was distributed to 300 consecutive arthritis patients treated with biologics.

**Results:** A total of 273 (91%) completed the questionnaire. Median age was 67 years, and 53% were females. Overall 64% of them were receiving subcutaneous (sc) and 28% intravenous (iv) treatment, while in 8% administration route were not stated. Overall 15% of patients reported reduced travel activity after having started biologics and 21% reported that biological treatment or disease have directly influenced their decision about travelling. A total of 74% of patients have travelled outside of Denmark and 45% of these have travelled outside of Europe while treated with biologics. Pre-travel advice was sought by 26% and travel insurance was taken out by 86% of the travellers. However, 59% did not inform the insurance company about their disease or biologics. Only 6% of the travellers have experienced minor health problems which were not related to arthritis, while three patients were hospitalised. Overall 10% of patients were given additional travel vaccination. Patients, receiving sc biologics travelled significantly more than those, receiving iv treatment: 68% versus 21% (p<0.05). Overall 42% of the travellers in sc treatment group continued to take biologics during their travel, 21% had stopped the treatment before and 5% during the travel. A large proportion (72%) of travellers, who discontinued

sc treatment prior to travelling, stopped the medication due to concerns about carrying biologics in general.

**Conclusions:** Biological treated patients with rheumatic diseases travel frequently. Neither health-related problems nor treatments were reported to be major problems. The main problems were failure to seek pre-travel advice, worry for carrying biologics and the lack of disclosure regarding biologic treatment while seeking travel insurance. Patients receiving subcutaneous biological treatment travelled significantly more often than patients treated with intravenous biologics.

#### ETHNIC MINORITIES EXPERIENCE INFREQUENT BIOLOGIC SWITCH DESPITE ACTIVE RHEUMATOID ARTHRITIS DISEASE

G. Kerr<sup>1</sup>, on behalf of EMRAC, C. Swearingen<sup>2</sup>, S. Hochberg<sup>1</sup>, J. Ude<sup>1</sup>, Y. Yazici<sup>2</sup>, on behalf of Ethnic Minority Rheumatoid Arthritis Consortium. <sup>1</sup>VAMC/HUH, Washington; <sup>2</sup>New York University, New York, USA

**Background:** The expanded therapeutic modalities in rheumatoid arthritis (RA) provide options to achieve low disease activity or remission. Yet, in routine care, the frequency and choice of switching of biologic DMARD (bDMARD) amongst ethnic subsets when there is inefficacy, is unknown.

**Objectives:** To evaluate frequency and choice of biologic switch in ethnic RA subsets

**Methods:** Patients enrolled in the Ethnic Minority RA Consortium (EMRAC), with at least one followup visit were analysed. Data included clinical outcomes as assessed by RAPID3 tender/swollen joint counts; medication use (prednisone, methotrexate, other DMARD), and bDMARD (Tumour Necrosis factor inhibitors (TNFi) and non-TNFi). Minimally clinical improvement (MCI) in RAPID3 was defined as a decrease of  $\geq 3.2$  points during followup. Differences between medication usage, biologic switch, and RAPID3 improvement between race and ethnicity groups while on biologics, was investigated.

**Abstract AB0440 – Table 1.** Demographic and clinical features of EMRAC cohort by race group

	White	African-American	Hispanic	Other	Total
<b>N</b>	366	252	158	264	1040
<b>Age (years)</b>	55.4 (15.8)	56.5 (14.5)	54.4 (13.5)	53.9 (16.3)	55.1 (15.3)
<b>Education (years)</b>	15.1 (3.2)	13.4 (3.2)	12.6 (4.5)	15.2 (3.5)	14.2 (3.6)
<b>Female [N(%)]</b>	286 (78%)	208 (83%)	126 (80%)	218 (86%)	838 (81%)
<b>Followup (weeks)</b>	57.0 (53.0)	92.8 (87.6)	48.7 (45.0)	52.2 (50.5)	63.2 (63.9)
<b>RAPID3 [0–30]</b>	11.3 (7.2)	12.9 (7.1)	12.6 (7.7)	10.8 (7.5)	11.9 (7.3)
<b>Tender Joints [0–28]</b>	1.0 (3.6)	2.5 (5.0)	2.4 (4.9)	0.5 (2.4)	1.5 (4.1)
<b>Swollen Joints [0–28]</b>	0.5 (2.0)	2.0 (3.8)	1.7 (3.9)	0.3 (1.8)	1.0 (2.9)
<b>Prednisone Use [N(%)]</b>	130 (36%)	89 (35%)	66 (42%)	78 (30%)	363 (35%)
<b>Methotrexate Use [N (%)]</b>	207 (57%)	130 (52%)	92 (58%)	160 (61%)	589 (57%)
<b>Other DMARD Use [N (%)]</b>	102 (28%)	74 (29%)	60 (38%)	101 (38%)	337 (32%)
<b>Any Biologic Use [N (%)]</b>	198 (54%)	84 (33%)	56 (35%)	105 (40%)	443 (43%)
<b>TNF Use [N(%)]</b>	160 (44%)	71 (28%)	41 (26%)	90 (34%)	362 (35%)
<b>Non-TNF Use [N(%)]</b>	54 (15%)	16 (6%)	16 (10%)	25 (9%)	111 (11%)

**TNF:** adalimumab, certolizumab, etanercept, golimumab, infliximab

**Non-TNF:** abatacept, anakinra, tocilizumab, tofacitinib, rituximab

**Results:** 1040 subjects with 3719 follow-up visits spanning an average of 63.2 weeks were analysed. African Americans and Hispanics comprised 24% and 15%, respectively. Compared to Whites, African Americans and Hispanics had significantly less education ( $p < 0.001$  for both), significantly less biologic use ( $p < 0.001$  for both) and significantly less TNF use ( $p < 0.001$  for both). African Americans had significantly higher RAPID3 scores at enrollment than Whites as well ( $p = 0.018$ ).

Switching between TNFi and non-TNFi was recorded in only 9 subjects, with 7 subjects switching from TNFi to non-TNFi. There was no statistical difference between race/ethnic groups in frequency of bDMARD switching, nor within bDMARD class (TNFi class,  $p = cc$ ; non-TNFi class,  $p = bb$ ). bDMARD treatment led to MCI in RAPID3 in 101 (38%) subjects and in more African Americans (29 [48%]) and Hispanics (12 [41%]) than in Whites (49 [37%]) (but not statistically significant).

**Conclusions:** In our cohort, disparity was seen in bDMARD use between race and ethnic groups but had similar and infrequent biologic switch. Based upon these data, efforts to eliminate biologic use disparity remains paramount and supersedes concerns regarding disparity in biologic switching.

AB0441

#### DRUG SURVIVAL AND REASON FOR DROP-OUT IN RHEUMATOID ARTHRITIS PATIENTS WITH A NON-MEDICAL SWITCH FROM ORIGINATOR TO BIOSIMILAR ETANERCEPT – PRELIMINARY DATA FROM A NORWEGIAN MULTICENTER STUDY

G. Haugeberg<sup>1,2</sup>, G. Bakland<sup>3</sup>, E. Rødevand<sup>4</sup>, B.T. Fevang<sup>5</sup>, I.J.W. Hansen<sup>6</sup>, A. Diamantopoulos<sup>2</sup>. <sup>1</sup>Research Unit, Hospital of Southern Norway Trust, Kristiansand.S; <sup>2</sup>Rheumatology, MARTINA HANSENS HOSPITAL, Bærum; <sup>3</sup>Rheumatology, UNN, Tromsø; <sup>4</sup>Rheumatology, St. Olavs Hospital, Trondheim; <sup>5</sup>Rheumatology, Haukeland University Hospital, Bergen; <sup>6</sup>Rheumatology, Hospital of Southern Norway Trust, Kristiansand.S, Norway

**Background:** Norwegian rheumatologists are encouraged to prescribe the lowest-priced biologic DMARDs according to the national tender system. Thus, non-medical switch from the originator drug to its biosimilar is extensively performed. There is a need for more real life data to clarify the clinical outcomes, dropout rates and reasons for these dropouts after a non-medical switch from the originator to biosimilar ETN.

**Objectives:** To explore drug survival and clinical outcomes in rheumatoid arthritis (RA) patients after a non-medical switch from the originator to biosimilar ETN (SB4) in ordinary outpatient clinics across Norway.

**Methods:** Herein we present preliminary data collected at one participating centre. Patients were monitored and data were collected by the use of a hospital clinical computer system GoTreatIT Rheuma. The computer system is also used for data collection for the Norwegian national arthritis registry, NorArtritt. Demographic, clinical and treatment data were retrieved (21st of January 2018) from the computer system for the time point of non-medical switch of ETN and the last follow up. Wilcoxon matched-pair signed rank test was used for comparison between the two-time points.

**Results:** Since April 2016 191 RA patients (mean age 60.8 years, 67% females) underwent a non-medical switch from originator to biosimilar ETN. Mean (SD) observation time for the 163 patients (85.3%) still on biosimilar ETN was 1.23 (0.46) yrs. 28 patients (14.7%) stopped treatment. Among them mean (SD) observation time for the 7 patients (3.7%) in remission was 0.53 (0.33) yrs, for the 10 patients (5.2%) reporting adverse events 0.44 (0.32) yrs and for the 11 patients (5.8%) reporting lack or loss of efficacy 0.44 (0.35) yrs. The adverse events reported was: 1 chest pain, 1 neuropathy, 1 GI reaction, 1 visual impairment, 1 infection, 2 joint stiffness (1 patient went back on ETN SB4) and 3 skin reactions. For all 191 patients no significant change (median [IQR]) from baseline to last observation was seen for DAS28 (2.1 [1.5–2.8] vs 1.9 [1.5–2.5],  $p = 0.33$ ), MHAQ (0.3 [0.0–0.7] vs 0.4 [0.1–0.6],  $p = 0.62$ ) and patient VAS global (20.0 [10.0–43.0] vs 25.0 [10.0–43.3] mm,  $p = 0.73$ ), whereas CRP improved significantly during follow up (2.0 [1.0–5.0] vs 1.0 [1.0–5.5] mg/dl,  $p = 0.02$ ). For the subgroup of RA patients who stopped treatment because of lack of efficacy a minor non-significant impairment was observed for DAS28 (2.0 [1.4–2.5] vs 2.6 [1.2–4.0],  $p = 0.32$ ), CRP (0.0 [0.0–6.0] vs 3.5 [0.8–13.3] mg/dl,  $p = 0.66$ ), MHAQ (0.1 [0.0–0.1] vs 0.5 [0.3–0.5],  $p = 0.66$ ) and patient VAS global (20.0 [10.0–30.0] vs 29.0 [17.0–58.5] mm,  $p = 0.66$ ).

**Conclusions:** Our preliminary data indicate that for the majority of patients, a non-medical switch from originator to biosimilar ETN (SB4) was well tolerated with no impairment in disease measures. Whether the reported adverse events were associated to the switch needs to be further studied. In patients who stopped the biosimilar because of lack of effect only a minor numerically increase in disease

measures was seen. Our promising preliminary results need to be confirmed in a large scale study.

AB0442

#### LONG-TERM SAFETY AND EFFICACY OF BIOSIMILAR INFLIXIMAB (CT-P13) AFTER SWITCHING FROM ORIGINATOR INFLIXIMAB: RESULTS FROM THE 26-WEEK OPEN LABEL EXTENSION OF A NORWEGIAN RANDOMISED TRIAL

G.L. Goll<sup>1</sup>, K.K. Jørgensen<sup>2</sup>, J. Sexton<sup>1</sup>, I.C. Olsen<sup>1</sup>, N. Bolstad<sup>3</sup>, M. Lorentzen<sup>4</sup>, E. A. Haavardsholm<sup>1</sup>, C. Mørk<sup>5</sup>, J. Jahnsen<sup>2</sup>, T.K. Kvien<sup>1</sup>, on behalf of The NOR-SWITCH study group. <sup>1</sup>Dept of Rheumatology, Diakonhjemmet Hospital, Oslo; <sup>2</sup>Department of Gastroenterology, Akershus University Hospital, Lørenskog; <sup>3</sup>Dept of Medical Biochemistry, OUS-Radiumhospitalet; <sup>4</sup>Department of Dermatology, Rikshospitalet, Oslo; <sup>5</sup>Department of Cancer and Molecular Medicine, Norwegian University of Science and Technology, Trondheim, Norway

**Background:** The NOR-SWITCH study was funded by the Norwegian government to investigate if switching from originator infliximab (INX) to biosimilar CT-P13 is safe in rheumatoid arthritis (RA), spondyloarthritis (SpA), psoriatic arthritis (PsA), Crohn's disease (CD), ulcerative colitis (UC), and chronic plaque psoriasis (Ps).

**Objectives:** Assessing efficacy, safety, immunogenicity at week 78 in patients on CT-P13 for 78 weeks (maintenance group) vs CT-P13 for 26 weeks (switch group).

**Methods:** 481 adult patients on stable originator infliximab were randomised 1:1 to continued INX or switch to CT-P13 treatment in the main study<sup>1</sup>. All extension participants received CT-P13. The primary endpoint was disease worsening, analysed with logistic regression, adjusted for diagnosis and treatment duration.

Abstract AB0442 – Table 1

Demographic and baseline characteristics (52 w) Number of patients (FAS)	Maintenance group 197	Switch group 183	Data are n (%) or mean (SD)
Age (years)	48.8 (14.9)	48 (14.3)	
Duration of ongoing infliximab treatment (years)	7.7 (3.8)	7.4 (3.5)	
Concomitant immunosuppressive therapy	97 (49%)	75 (41%)	
Rheumatoid arthritis	27 (14%)	28 (15%)	
Spondyloarthritis	38 (19%)	29 (16%)	
Psoriatic arthritis	9 (5%)	11 (6%)	
Crohn's disease	65 (33%)	62 (34%)	
Ulcerative colitis	42 (21%)	38 (21%)	
Psoriasis	16 (8%)	15 (8%)	
<b>Disease characteristics</b>			
DAS 28 RA	2.4 (0.9)	2.8 (0.9)	
DAS 28 PsA	2.1 (1.1)	2.9 (1.8)	
ASDAS (SpA)	1.9 (0.8)	1.7 (0.7)	
<b>Disease worsening</b>			
<b>Number of patients (PPS)</b>	<b>190</b>	<b>173</b>	<b>Risk difference (95% CI)</b>
All	32 (16.8%)	20 (11.6%)	-5.9% (-12.9–1.1)
Rheumatoid arthritis	9 (34.6%)	6 (22.2%)	-10.5% (-34.6–13.6)
Spondyloarthritis	3 (7.9%)	2 (7.1%)	-0.6% (-13.5–12.2)
Psoriatic arthritis	1 (12.5%)	3 (33.3%)	20.8% (-17.6–59.1)

ASDAS, Ankylosing Spondylitis Disease Activity Score. DAS28, Disease Activity Score in 28 joints.

**Results:** 380 patients entered the extension trial. Demographic and baseline (52 w) characteristics of the extension study population are shown (table 1). Disease worsening in the study arms (Per Protocol Set, PPS) and in each diagnosis (explorative analyses) are shown (table 1). Generic disease variables, disease specific composite measures, trough drug levels, anti-drug antibodies and reported adverse events were comparable between groups (data not shown).

**Conclusions:** We found no difference between patients switched from INX to CT-P13 vs those on maintained CT-P13

#### AB0443 THE EFFECTS OF DENOSUMAB FOR RHEUMATOID ARTHRITIS PATIENT

I. Yoshii. *Rheumatology and Musculoskeletal Medicine, YOSHII HOSPITAL, Shimanto City, Japan*

**Background:** Denosumab (dMAB), an anti-receptor activator of nuclear factor kappa-B ligand (RANKL) monoclonal antibody, is now popular anti bone absorption suppressant for osteoporosis. Recently, this drug has indicated for rheumatoid arthritis (RA) treatment, for expectance for suppressant in joint destruction. However, except of the effect on joint deformation, anti inflammation effect is not evident in randomised control trial (RCT), although rich case series for OP in RA patient is already collected in clinical practice.

**Objectives:** Aim of this study is to investigate effects of dMAB on RA, and evaluate other effects but joint destruction suppression.

**Methods:** In 352 patients who have been treated with dMAB, RA patients who have been treated with dMAB consecutively for more than 1 year, were picked up for this study. Patient who have had experience of biologic disease modifying anti rheumatic drug (bdMARD) or targeted synthetic DMARD, had been eliminated. In whom bone mineral density (BMD) in lumbar spine (LS), femoral neck (FN), and greater trochanter (GT), and tartrate-resistant acid phosphatase 5b (TRACP5b), 28-joints disease activity score with C-reactive protein (DAS28-CRP), Health Assessment Questionnaire Disease Index (HAQ-DI), yearly progression of Sharp/van der Heijde score (dSHS), joint space narrowing score (dJSN) and bone erosion score (dBE), and pain score with visual analogue scale (PS-VAS) were measured, and their mean values were compared between 6 months before start (BEF) and 6 months after start (AFT) statistically with paired T-test. Statistically significant level was set less than 1%.

**Results:** One hundred and three patients, in whom 100 were female and three were male, were donated in this study. All of them had been supplemented with Denotas Chewable Combination Tablets (Daiichi Sankyo Co., Ltd; Tokyo, Japan), which is medical compound with calcium and natural vitamin D<sub>3</sub>. Average age at start was 71.17 years old, and disease duration of RA at start was 7.42 years. Glucocorticoid was administered in 45 patients (44.7%), and methotrexate was administered in 72 patients (69.9%). BMD demonstrated from 74.03 (%YAM) to 77.32 in LS, whereas from 69.79 to 69.63 in FN, and from 71.99 to 74.27 in GT, from BEF to AFT, respectively. BMD of LS and GT at AFT demonstrated significant increase, while FN demonstrated no significant difference. TRACP5b demonstrated significant less value than at BEF. Disease activity, namely DAS28-CRP, tenderness joint count (TJC), swollen joint count (SJC), patient's global assessment (PGA), evaluator's global assessment (EGA), CRP, pain score with visual analogue scale (PS-VAS), HAQ-DI, SHS, JSN, and BE from BEF to AFT demonstrated 2.12 to 1.86, 1.32 to 0.89, 2.13 to 0.97, 2.23 to 2.01, 1.27 to 0.68, 0.80 to 0.70, 0.537 to 0.590, 81.76 to 80.98, 36.16 to 37.08, 46.96 to 44.27, respectively. DAS28-CRP, and all of its components, and EGA demonstrated significant decrease, although PS-VAS showed decrease yet demonstrated no significance, while HAQ-DI showed increase with no statistical significance. dSHS and dBE demonstrated significant less at AFT than at BEF, while no significance for dJSN yet slightly increased in the AFT, even no significant difference demonstrated for absolute values (table 1).

**Abstract AB0443 – Table 1.** Change of each parameters and statistical significance. BMD, bone mineral density; % YAM, percentage of young adult mean value; BEF, before administration of denosumab; AFT, first value after denosumab was administered; S.S., statistical significance; LS, average value of lumbar spine from L1 to L4; FN, femoral neck; GT, greater trochanter; DAS28-CRP, 28-joints disease activity score with C-reactive protein; TJC, tenderness joint count; SJC, swollen joint count; PGA, patient's global assessment; CRP, C-reactive protein; EGA, evaluator's global assessment; PS-VAS, pain score with visual analogue scale; HAQ-DI, Health Assessment Questionnaire Disability Index; SHS, Sharp/van der Heijde Score; JSN, joint space narrowing score; BE, bone erosion score; n. s., not significant; \*, AFT is statistically significantly smaller than BEF within 1%; §, BEF is statistically significantly larger than AFT within 1%.

BMD (%YAM)	BEF	AFT	S.S.
LS	74.03±15.74	77.32±15.79	*
FN	69.79±11.65	69.63±11.93	n.s.
GT	71.99±13.82	74.27±13.28	*
TRACP-5b	489.3±214.4	255.3±133.6	§
DAS28-CRP	2.12±0.91	1.86±0.72	*
TJC	1.32±2.20	0.89±1.99	*
SJC	2.13±3.54	0.97±1.85	*
PGA	2.23±2.30	2.01±1.88	*
CRP	0.80±1.55	0.70±1.36	n.s.
EGA	1.27±1.64	0.68±1.07	*
PS-VAS	28.34±23.32	27.07±21.65	n.s.
HAQ-DI	0.537±0.611	0.590±0.648	§
SHS	81.76±89.36	80.98±89.65	n.s.
JSN	36.16±37.76	37.08±38.57	§
BE	45.96±53.08	44.27±52.18	*

**Conclusions:** The effect of dMAB on RA is suggested suppression of dBE, BMD increase in LS and GT, improvement of DAS28-CRP, and may have decrease of PS-VAS.

**Disclosure of Interest:** None declared

#### AB0444 DESCRIPTION IN REAL-WORLD OF THE EFFICACY AFTER SWITCHING FROM INTRAVENOUS TO SUBCUTANEOUS ADMINISTRATION OF TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS. THE ROSWITCH STUDY

J. Darloy<sup>1</sup>, N. Segaud<sup>2</sup>, J.-H. Salmon<sup>3</sup>, V. Goeb<sup>4</sup>, M.-H. Guyot<sup>5</sup>, L. Marguerie<sup>6</sup>, C. Chopin<sup>7</sup>, S. Gally<sup>8</sup>, I. Idier<sup>9</sup>, G. Baudens<sup>10</sup>, R.-M. Flipo<sup>11</sup>. <sup>1</sup>Rheumatology, University Hospital, Lille; <sup>2</sup>Rheumatology, General Hospital, Armentières; <sup>3</sup>Rheumatology, University Hospital, Reims; <sup>4</sup>Rheumatology, University Hospital, Amiens; <sup>5</sup>Rheumatology, General Hospital Victor Provo, Roubaix; <sup>6</sup>Rheumatology, Institut Francois Calot, Berck-sur-Mer; <sup>7</sup>Rheumatology, University Hospital Maison Blanche, Reims; <sup>8</sup>Clinical Operations, Roche SAS, Boulogne Billancourt; <sup>9</sup>Medical, Chugai Pharma France, Paris La Defense; <sup>10</sup>Rheumatology, Private Practice, Valenciennes; <sup>11</sup>Rheumatology, University Hospital Roger Salengro, Lille, France

**Background:** It has been proven, in a pivotal RCT, that SC tocilizumab (TCZ) was non-inferior to IV TCZ.<sup>1</sup> However the switch from IV to SC TCZ has not been evaluated to date in a large real-world study.

**Objectives:** The main objective was to assess the maintenance of efficacy of SC TCZ 6 months (M6) after switching from IV to SC formulation in patients (pts) with rheumatoid arthritis (RA) in real-world. Secondary objectives were: characteristics of pts and RA, efficacy of TCZ at M12, TCZ retention rates at M6 and M12 for Switch (IV-SC) and No-Switch pts (IV-IV), predictive factors of switching.

**Methods:** We analysed all RA pts of the shared medical file "RIC Nord de France" with ≥1 DAS 3 months before inclusion, treated with TCZ, switching or not from IV to SC TCZ, between April 30 2015 and January 15 2016. The primary efficacy endpoint was the % of pts remaining in their DAS28-ESR category remission/LDA or moving to an inferior DAS category at M6. Various sensibility analyses were realised on the primary criterion of which a propensity score (IPTW).

**Results:** From the 314 included pts, 30% switched from IV to SC TCZ. At baseline, 77.7% were females, mean BMI was 27.5±6.4, mean RA duration was 14.9 ±9.2 years. Mean IV TCZ duration before inclusion was 35.0±23.1 months in Switch and 26.8±22.1 months in No-Switch pts. Mean DAS28 were 2.1±1.1 in Switch and 2.9±1.6 in No-Switch pts. 81.9% and 59.5% of the pts were in DAS28 remission/LDA, 18.1% and 28.6% in MDA, 0% and 11.8% in HAD in Switch and

No-Switch pts respectively. The improvement of initial DAS28-ESR category or maintenance in remission/LDA was comparable in both groups at M6 and M12 (table 1).

**Abstract AB0444 – Table 1.** DAS28-ESR improvement or maintenance in remission/LDA category

% of pts*, 95% CI	Switch, n=94	No Switch, n=220
M6, n/N	66/90	137/195
	73.3% [63.0–82.1]	70.3% [63.3–76.6]
M12, n/N	63/91	118/204
	69.2% [58.7–78.5]	57.8% [50.8–64.7]

\* Permanent discontinuation of TCZ considered as failure.

Using the IPTW for balancing on baseline characteristics between groups, similar proportions were observed at both M6 and M12. TCZ retention rates at M12 were 78% (95% CI<sup>68–85</sup>) and 80% (95% CI: 74–85 p=0.555 for Switch and No-Switch groups respectively. In the 208 pts with a DAS28 ≤3.2 at inclusion, multivariate analysis showed no parameters associated to the switch. Conversely in the 106 pts with a DAS28 >3.2 at inclusion, rheumatoid nodules (OR=4.78, 95% CI [1.23–18.55], p=0.024) and duration of IV TCZ before inclusion (OR=1.37, 95% CI [1.08–1.73], p=0.009) were significantly associated to the switch.

**Conclusions:** The RoSwitch study showed the maintenance of efficacy at 6 and 12 months in RA pts switching from IV to SC TCZ. Similar efficacy and therapeutic retention rates were observed for No-Switch pts. No factor was associated with the switch in pts in remission/LDA at inclusion suggesting that patient's personal appreciation was preponderant in the choice of the switch.

Flipo<sup>3</sup>. <sup>1</sup>Rheumatology, Maison Blanche Hospital, Reims University Hospitals; <sup>2</sup>University of Reims Champagne-Ardenne, Faculty of Medicine, EA 3797, Reims; <sup>3</sup>Rheumatology, CHRU Lille, Lille; <sup>4</sup>Rheumatology, CH Bethune, Bethune; <sup>5</sup>Rheumatology, CHU Amiens, Amiens; <sup>6</sup>Rheumatology, CH Roubaix, Roubaix; <sup>7</sup>Rheumatology, Hôpital Saint Philibert, Lomme; <sup>8</sup>Rheumatology, Cabinet médical, Saint Quentin; <sup>9</sup>Rheumatology, Cabinet médical, Liévin; <sup>10</sup>Rheumatology, Institut Francois Calot, Berck-sur-Mer; <sup>11</sup>Rheumatology, CH Valenciennes; <sup>12</sup>Rheumatology, Cabinet médical, Valenciennes; <sup>13</sup>Rheumatology, CHU Poitiers, Poitiers, France

**Objectives:** Study the therapeutic maintenance, associated factor with maintenance at 12 months and reasons for abatacept (ABA) stop in daily practice.

**Methods:** Retrospective multicentric study, from the RIC Nord de France network, of patients treated for rheumatoid arthritis who received at least one ABA treatment between January 2008 and July 2016. We studied the therapeutic maintenance at 12 months, according to the number of previous bDMARDs and according to the date of initiation (group 1: from 2008 until 31/07/2010 (ABA authorised in anti-TNFfailure) and group 2 from 01/08/2010 (ABA authorised in the first line)). Therapeutic maintenance was evaluated using the Kaplan-Meier method.

**Results:** Of the 517 patients (74% women) who were included, the mean age was 61.4±13.3 years. There were 76% positive anti-CCP. ABA was used as monotherapy in 176 patients (34%) and 22% of patients were naïve to bDMARDs. The mean DAS 28-VS at initiation of ABA was 4.7±1.3.

Therapeutic maintenance at 12 months was 68%. Among the 166 patients (32%) stopped ABA, the reason for discontinuation was primary ineffectiveness (n=54, 32.5%), loss of efficacy (n=40, 24%), adverse events (n=43, 26%) and other (n=29, 17.5%). On multivariate analysis CRP <10 mg/L was associated with better maintenance at 12 months.

No significant difference in therapeutic maintenance was found at 12 months according to the date of initiation and according to the number of previous bDMARDs.

**Abstract AB0445 – Figure 1.** Therapeutic maintenance of Abatacept at 12 months

**Conclusions:** Therapeutic maintenance at 12 months was 68%, this rate is similar to Pan-European Registry. The rate of CRP at initiation seems to have an impact on the maintenance of ABA at 12 months.

#### AB0446 PHYSICIAN-REPORTED BEHAVIOURS AND TREATMENT TRENDS OF TUMOUR NECROSIS FACTOR INHIBITOR USE: CYCLING VERSUS SWITCHING IN FIVE EUROPEAN COUNTRIES: FRANCE, GERMANY, ITALY, SPAIN AND THE UK

J.R. Curtis<sup>1</sup>, E. Sullivan<sup>2</sup>, J. Kershaw<sup>2</sup>, S. Blackburn<sup>2</sup>, P. Mahajan<sup>3</sup>, S. Boklage<sup>4</sup>. <sup>1</sup>University of Alabama at Birmingham, Birmingham, USA; <sup>2</sup>Adelphi Real World, Manchester, UK; <sup>3</sup>Sanofi, Bridgewater, <sup>4</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, USA

**Background:** Previously, most biologics prescribed for treating rheumatoid arthritis (RA) were tumour necrosis factor inhibitors (TNFi) and it was common practice to prescribe a second TNFi after failure of the first. Biologics with different mechanisms of action (MOA) have become available and 2016 European League Against Rheumatism guidelines recommend cycling to another TNFi or switching to a biologic with a new MOA following failure of the first TNFi.

**Objectives:** Describe the proportion of patients in 5 EU countries who, after failure of a first TNFi, cycle to a second TNFi ('TNFi cycling') vs switch to a treatment with a different MOA ('Switch'), and identify patient characteristics and physician attitudes associated with TNFi cycling vs switching.

**Methods:** Data were from the Adelphi Disease Specific Programme (DSP), a cross-sectional survey conducted in 2017 in France, Germany, Italy, Spain and the UK. Rheumatologists prospectively completed records about the next 10 patients with RA who consulted them during the study period; records captured treatment history and clinical details. Patients were included in the analysis if they had been prescribed at least 2 different biologics, their first was a TNFi and their second was known. Patients were assigned to 2 cohorts: 'TNFi cycling' patients received a TNFi at first- and a different TNFi at second-line; 'Switch' patients received a TNFi at first-line and a non-TNFi at second-line. Bi-variate comparisons of groups were conducted using nonparametric tests as appropriate.

**Results:** All physicians in the DSP sample (n=301) were questioned on their beliefs around TNFis; 86.4% believed that there is a class effect with TNFis regarding efficacy and/or safety (table 1). Data from 359 patients were included in the analysis (75.8% female; mean [SD] age 56.5 [12.7]), of whom 167 (46.5%) were TNFi cycling, and 192 (53.5%) were Switch patients (female: 70.7% vs 80.2%, respectively; p=0.04; age: 55.8 [13.1] vs 57.1 [12.4], respectively; p=0.42). The most common reasons for discontinuing first-line therapy among the TNFi cycling and Switch cohorts were worsening condition (36.3% vs 45.3%,

respectively;  $p=0.13$ ) and loss of efficacy (48.9% vs 48.3%, respectively;  $p=1.0$ ). Prior to the second biologic, patients in the TNFi cycling cohort spent a numerically longer amount of time on first-line therapy vs the Switch cohort (2.0 [2.2] years vs 1.7 [1.9] years;  $p=0.35$ ), and had a longer disease duration at the time of initiation of second-line non-TNFi (7.3 [6.6] years vs 6.6 [7.8] years;  $p=0.15$ ).

**Abstract AB0446 – Table 1.** Physician beliefs around tumour necrosis factor inhibitors

	n, %
<b>Do you believe that there is a class effect with the TNFis?</b>	
Yes, with regards to efficacy	81 (26.9)
Yes, with regards to safety	30 (10.0)
Yes, with regards to both efficacy and safety	149 (49.5)
No	41 (13.6)
<b>When do you believe there is a benefit in prescribing another TNFi?</b>	
After primary lack of efficacy (non-response) to a first TNFi	127 (42.2)
After secondary lack of efficacy (response decreasing over time) to a first TNFi	160 (53.2)
After poor tolerability with a first TNFi	127 (42.2)
After primary lack of efficacy (non-response) to a second TNFi	28 (9.3)
After secondary lack of efficacy (response decreasing over time) to a second TNFi	47 (15.6)
After poor tolerability with a second TNFi	31 (10.3)
None of the above	25 (8.3)
<b>How do you believe the practice of TNFi cycling is changing?</b>	
Decreasing	188 (62.5)
Not changing	93 (30.9)
Increasing	20 (6.6)
<b>Assuming no restrictions, which biologics would you prefer to use first for RA?</b>	
Non-TNFi	50 (16.6)
TNFi	251 (83.4)
<b>Assuming no restrictions, which biologics would you prefer to use second for RA?</b>	
Non-TNFi	123 (40.9)
TNFi	178 (59.1)
<b>Assuming no restrictions, which biologics would you prefer to use third for RA?</b>	
Non-TNFi	190 (63.1)
TNFi	111 (36.9)

**Conclusions:** Despite evidence from literature suggesting that RA patients have a better treatment response switching to a non-TNFi after initial TNFi inadequate response<sup>1</sup> and despite the majority of physicians in our study believing that there is a class effect with TNFis, regarding efficacy and safety, 46.5% of patients still cycled to a second TNFi rather than switched to a non-TNFi as second-line therapy.

#### AB0447 AUDIT OF THE CLINICAL EFFICACY AND SAFETY OF ETANERCEPT BIOSIMILAR TO ITS REFERENCE PRODUCT IN PATIENTS WITH INFLAMMATORY ARTHRITIS: EXPERIENCE FROM A DISTRICT GENERAL HOSPITAL IN THE UNITED KINGDOM

J. Ma, S. Petford, L. Jones, K. Douglas, H. John. *Rheumatology, Russells Hall Hospital, Dudley, UK*

**Background:** Etanercept has been widely used in rheumatology practice since NICE approval in 2000. Biologics have been pivotal treatments for inflammatory arthritis but are associated with a considerable economic burden. The expiry of patent protection has led to the introduction of biosimilar drugs at competitive prices. SB4 was the first biosimilar of etanercept approved by the European Medicine Agency. SB4 was launched in February 2016 in the UK for use in all adult indications for which reference etanercept is approved. The rheumatology team at the Dudley Group of Hospitals (DGH) negotiated with commissioners to share the cost savings of switching the cohort of patients who were on reference etanercept to SB4.

**Objectives:** This audit aimed to compare the clinical efficacy and safety profile of etanercept biosimilar SB4i (post switch) with its reference etanercept (pre switch).

**Methods:** The first 50 patients switched were sampled and followed up for 6 months. Data was collected from hospital databases and patient records (demographic; disease activity scores 6 months pre and post switch; adverse events (AE)). Inclusion criteria: all patients established on reference etanercept for more than 12 months. Exclusion criteria: patients attempting to conceive, pregnant or breast feeding women, patients on 25mg of reference etanercept or with JIA.

**Results:** Of the 194 patients on reference etanercept in the Dudley area, 160 (83%) were successfully switched at the time of audit. Of the first 50 patients who switched, 32 (64%) patients had rheumatoid arthritis (RA), 15 (30%) ankylosing spondylitis (AS), and 3 (6%) psoriatic arthritis (PsA). The mean age was 60 years (range 29-83 years) with equal gender distribution. Mean years on reference etanercept was 6 years (range 1-13 years). In the RA cohort: 23(72%) patients were female with mean change of DAS28: +0.1(SD:0.87). In the AS cohort, 14(93%) patients were male with mean change of BASDAI: -0.6 (SD:1.34). PsA: 2 patients' symptoms were unchanged, 1 patient's tender and swollen joint count decreased. At 6 months post switch, 84% patients continued etanercept biosimilar SB4. Reasons for discontinuation included: AE (n=4), inefficacy (n=3) and new contraindication (cancer n=1).

**Conclusions:** Following switching to etanercept biosimilar SB4, no clinically significant change in DAS28 or BASDAI were observed during the audit period. Switching from reference etanercept to SB4 has resulted in a potential yearly saving of £660,000, from which the rheumatology department has secured funding to employ an additional clinical nurse specialist and secretary. Our audit found SB4 to be as safe and effective as its reference etanercept and has demonstrated a positive experience with biosimilar switching. This is relevant given the expiry of their biologic drugs' patent protections and further biosimilar drugs becoming available.

**Disclosure of Interest:** None declared

#### AB0448 PATIENT-REPORTED OUTCOMES FOLLOWING DISCONTINUATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB: RESULTS FROM A RANDOMISED CONTROLLED TRIAL

J. Kremer<sup>1</sup>, W. Rigby<sup>2</sup>, N. Singer<sup>3</sup>, C. Birchwood<sup>4</sup>, D. Gill<sup>4</sup>, W. Reiss<sup>4</sup>, J. Best<sup>4</sup>, J. Pei<sup>4</sup>, M. Michalska<sup>4</sup>. <sup>1</sup>Albany Medical College and The Center for Rheumatology, Albany; <sup>2</sup>Geisel School of Medicine, Dartmouth College, Lebanon; <sup>3</sup>Case Western Reserve University and the MetroHealth System, Cleveland; <sup>4</sup>Genentech, Inc., South San Francisco, USA

**Background:** Patients with rheumatoid arthritis (RA) often receive methotrexate (MTX) in combination with biologics; however, MTX may be discontinued due to intolerance or to reduce the medication burden once disease control is achieved. Whereas previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO) for the treatment of RA,<sup>1,2</sup> patient-reported outcomes (PROs) after MTX withdrawal in patients achieving good clinical response to TCZ +MTX have not been evaluated. PROs are important measures when determining response to therapy in patients with RA with respect to health-related quality of life (HRQOL).<sup>3,4</sup>

**Objectives:** This study evaluated PROs between patients with RA who achieved low disease activity with TCZ +MTX and then continued or discontinued MTX in the COMP-ACT trial (NCT01855789).

**Methods:** US patients with RA who were inadequate responders to MTX were enrolled; initial combination therapy included MTX ( $\geq 15$  mg/week orally) plus TCZ 162 mg subcutaneous either weekly (qw) or every 2 weeks (q2w). Patients who achieved DAS28-ESR $\leq 3.2$  at Week 24 were randomised 1:1 to receive TCZ-MONO or continue TCZ +MTX until week 52 (double-blind). Changes in PRO scores were measured between Week 24 and Weeks 40 and 52, and included patient global assessment of disease activity (PtGA; visual analogue score [VAS], 0–100 mm), pain (VAS), Health Assessment Questionnaire Disability Index (HAQ-DI, 0–3) and Functional Assessment of Chronic Illness Therapy (FACIT)-Fatigue.

**Results:** Of the 296 randomised patients (TCZ +MTX, n=148; TCZ-MONO, n=148), 74.8% were women, mean age was 55.5 years, mean RA duration was 6.8 years and mean DAS28-ESR was 6.3 at baseline. At Week 24 (randomization), PRO scores were similar between the randomised treatment groups. The mean changes in PtGA, pain, HAQ-DI and FACIT-fatigue scores from Week 24 to Weeks 40 were similar between the TCZ +MTX and TCZ-MONO groups (table 1). The proportion of patients with HAQ-DI  $< 0.5$  was similar between the groups at Week 24 (randomization), and remained similar at Weeks 40 and 52.

**Abstract AB0448 – Table 1.** Changes in Patient-Reported Outcomes from Week 24 (Randomization) to Week 40 and Week 52

PRO Measure*	TCZ + MTX n = 147	TCZ-MONO n = 147	Difference (95% CI) (TCZ-MONO minus TCZ + MTX)†
<b>Δ PtGA, mean (SEM)</b>			
Week 24 to week 40	1.72 (1.79)	5.95 (1.75)	4.78 (-0.00, 9.56)
Week 24 to week 52	-0.33 (1.77)	3.58 (1.83)	4.14 (-0.56, 8.84)
<b>Δ Pain, mean (SEM)</b>			
Week 24 to week 40	1.64 (1.74)	5.32 (1.61)	4.19 (-0.23, 8.61)
Week 24 to week 52	-0.05 (1.84)	4.26 (1.69)	4.69 (0.14, 9.24)
<b>Δ HAQ-DI, mean (SEM)</b>			
Week 24 to week 40	0.01 (0.030)	0.04 (0.034)	0.03 (-0.05, 0.12)
Week 24 to week 52	0.01 (0.028)	0.02 (0.038)	0.01 (-0.08, 0.10)
<b>Δ FACIT-Fatigue, mean (SEM)</b>			
Week 24 to week 40	1.57 (0.67)	-0.68 (0.64)	-1.68 (-3.39, 0.02)
Week 24 to week 52	1.30 (0.67)	-1.12 (0.75)	-1.82 (-3.69, 0.06)
<b>HAQ-DI &lt; 0.5, n (%)</b>			
Week 24	64 (43.5)	56 (38.1)	-5.4 (-16.7, 5.8)
Week 40	60 (43.8)	54 (40.6)	-3.2 (-15.9, 8.6)
Week 52	60 (46.9)	53 (41.7)	-5.1 (-17.3, 7.0)

FACIT, Functional Assessment of Chronic Illness Therapy; HAQ-DI, Health Assessment Questionnaire Disability Index; MONO, monotherapy; MTX, methotrexate; PtGA, patient global assessment; SEM, standard error of the mean; TCZ, tocilizumab.

\* A negative change in score represents an improvement in the respective PRO except for Fatigue.

† Estimated means from ANCOVA model includes Week 24 value as a covariate, treatment group, and the randomization stratification factors: DAS28 remission status at Week 24 (<2.6, ≥2.6 to <3.2), baseline weight-by-dosing group (<80 kg every 2 weeks [q2w], <80 kg weekly [qw], 80 to <100 kg q2w, 80 to <100 kg qw, ≥100 kg qw), patient anti-TNF exposure (Yes or No).

**Conclusions:** Patients receiving TCZ who discontinue MTX appear to have similar PROs across multiple measures compared with patients continuing TCZ +MTX. Differences observed in clinical parameters between TCZ-MONO and TCZ +MTX did not appear to achieve a threshold that would be considered clinically meaningful. Similarities in PROs on both treatments were consistent with the clinical efficacy measures previously reported from COMP-ACT.

#### AB0449 SDAI REDUCTION AT WEEK 2 PREDICT THE SDAI REMISSION AT WEEK 24 WHEN CERTOLIZUMAB PEGOL (CZP) WAS ADMINISTERED TO PATIENTS WITH RHEUMATOID ARTHRITIS

K. Oryoji, S.-I. Mizuki. *Matsuyama Red Cross Hospital, Japan, Matsuyama-Shi, Japan*

**Background:** Certolizumab pegol (CZP) is approved for treatment of rheumatoid arthritis.

**Objectives:** To explore the predictor of efficacy of certolizumab pegol (CZP) for MTX-IR patients with rheumatoid arthritis in our retrospective study.

**Methods:** 50 patients who received CZP for rheumatoid arthritis of MTX-IR after 2013 were examined by logistic regression analysis using Age, sex, duration of disease, HAQ, TJC, SJC, gVAS, eVAS, CRP, SDAI, DAS 28-CRP, previous use of biologics, prednisolone use, ACPA, RF, the reduction rate of SDAI at week 2 to assess the predicting factor for SDAI remission at week 24.

**Results:** As a factor capable of achieving SDAI remission at 24 weeks after CZP administration, SDAI reduction rate of 50% or more (n=28, p<0.001), females (p=0.01), the number of swollen joints (p=0.02) were extracted as significant factors. The odds ratio at which SDAI remission can be obtained at 24 weeks point is 15.4 (95% CI: 3.1–109.6) when the SDAI reduction rate at 2 weeks after the start of administration is 50% or more. SDAI remission rate at week 24 were 67% in

SDAI reduction ≥50% at week 2 group and 22% in another. The continuation rate at week 24 in SDAI reduction ≥50% at week 2 is 93%.

**Conclusions:** When SDAI decreased by 50% or more at 2 weeks after initiation of CZP administration SDAI remission was easy to obtain after 24 weeks, and continuation rate was also good.

#### AB0450 IMPACT OF THERAPEUTIC PATIENT EDUCATION ON SAFETY SKILLS AND INFECTIOUS EVENTS OF PATIENTS TREATED BY BIOLOGICAL DMARDs IN RHEUMATOLOGY: A BI-CENTRIC STUDY

L. Frantzen<sup>1</sup>, M. Ardzzone<sup>1</sup>, L. Sparsa<sup>1</sup>, D. Oréface<sup>1</sup>, N. Afif<sup>1</sup>, L. Arnaud<sup>2</sup>, J.-E. Gottenberg<sup>2</sup>, J. Sibilia<sup>2</sup>, C. Sordet<sup>2</sup>. <sup>1</sup>Service de Rhumatologie, GHR Mulhouse Sud Alsace, Mulhouse; <sup>2</sup>Service de Rhumatologie, Hôpitaux Universitaires de Strasbourg, Strasbourg, France

**Background:** Patients treated with biologic DMARDs have to be aware of the specific adverse events and have to be able to manage their treatments in case of infectious disease. Therapeutic Patient Education aims to enable patient to acquire these safety skills.

**Objectives:** To assess the impact of Therapeutic Patient Education on safety skills and management of infectious events in patients treated with biologic DMARDs in rheumatology.

**Methods:** Bi-centric analytical study comparing safety skills and infectious events between two cohorts of patients (TPE and TPE-naïve). Safety skills were assessed by an auto-assessment called "Biosecure", rated on a scale from 0 to 100. This assessment explores several dimensions of treatment management and was validated for assessment of safety skills in patients treated with biologic DMARDs in rheumatology in a preliminary study. Infectious events and their management were self-reported by patients. A cluster analysis aimed to separate patients into working group based on their shortcomings (on the basis of their answers to the Biosecure Assessment).

**Results:** 414 patients answered the assessment. The median Biosecure Score was 70.98/100 (Q1Q3: 60.97–84.63)

47% attended Therapeutic Patient Education. The median Biosecure Score was significantly higher in the TPE group than in the TPE-naïve group (74.88 versus 67.20/100; p<0.05). Regarding the observance to treatment, activity scores, vaccination rates on incidence of infectious events, there were no significant difference between the groups TPE and TPE-naïve. Nevertheless, there were more treatment interruption for infectious events in the TPE group, suggesting that TPE could lead to better management of treatment during infectious events.

Cluster analysis based on Biosecure assessment separated patients into 3 level groups but failed to identify specific patient profiles.

**Conclusions:** Therapeutic Patient Education could provide better safety skills and better treatment management in patients treated with biologic DMARDs in rheumatology. Prospective studies may confirm the impact of TPE on treatment management during infectious events. Further studies may assess the impact of TPE on incidence of serious infectious events.

#### AB0451 INCIDENCE OF OPPORTUNISTIC INFECTIONS DURING RITUXIMAB, ABATACEPT OR TOCILIZUMAB TREATMENTS FOR RHEUMATOID ARTHRITIS IN CLINICAL PRACTICE

L. Leon<sup>1,2</sup>, M. Peñuelas<sup>3</sup>, F.J. Candel<sup>3</sup>, D. Freitas<sup>1</sup>, L. Rodriguez<sup>1</sup>, J.A. Jover<sup>4</sup>, L. Abasolo<sup>1</sup>. <sup>1</sup>Rheumatology and IDISSC, Hospital Clinico San Carlos; <sup>2</sup>Health Sciences, Camilo Jose Cela University; <sup>3</sup>Microbiology; <sup>4</sup>Rheumatology, Hospital Clinico San Carlos, Madrid, Spain

**Background:** With the expanding use of biologic disease-modifying anti-rheumatic drugs (bDMARDs), opportunistic infections (OI) are a major concern in Rheumatology.

**Objectives:** Our purposes were to describe and compare the incidence of OI in RA treated by non-TNF-targeted biologics.

**Methods:** We performed a retrospective longitudinal observational study from 2007 to 2017. We included subjects followed in our outpatient clinic, diagnosed with RA according to ACR criteria, whom started treatment with a bDMARD [rituximab (RTX), abatacept (ABA), or tocilizumab (TCZ)]. According to the microbiologist criteria, we consider OI when there was a positive culture (for Virus, Fungus, bacterial or parasitary) or compatible symptoms that responded to specific treatment. Severe IO was considered if required hospitalisation. We also collected secondary variables: sociodemographic, clinical and other treatments. We used survival techniques to estimate the incidence of OI, expressed per 1000 patient-year [CI 95%]. Exposure time was defined from the start date of each bDMARDs until the development of an OI, discontinuation, loss of follow up or end of study (01/02/2017).

**Results:** We analysed a total of 164 patients with 219 different courses of bDMARDs treatment. Of these, 76% were women with a mean age at first bDMARD of 61.4±15 years. Rheumatoid factor was positive in 73.6%. Main comorbidities were: Hypercholesterolemia (53.3%), Hypertension (53.2%), Depression (25%), Diabetes (15%), and Ischaemic Heart Disease (9.8%). VSG mean was 38±28, and the mean WBC count was 7.8±2.7. The median time from onset of RA until onset of bDMARD was 2.8 years [0.8–6.2]. Of these, 132 were on RTX, 47 were on ABA and 40 were on TCZ. There were 12 OI (9 with RTX, 2 with ABA and 1 with TCZ). RTX have 2 Fungus (*Candida krusei* and *Klebsiella*), and 7 Virus (4 Herpes Zoster, 1 virus B reactivation, 1 virus C reactivation). OI for ABA was 2 Virus (1 Herpes Zoster, 1 virus B reactivation), while we found one virus OI with TCZ Fungus (*Herpes Zoster*). There were no bacterial or parasitary OI. Global incidence rate of OI was 30.49 [17.3–53.6]. The incidence of OI was 38.92 [20.2–74.8] for RTX, followed by ABA with 21.61 [5.4–86.4], and TCZ with 14.3 [2–101.6]. We found 3 severe OI (2 fungus infections, 1 virus B reactivation). The incidence of severe OI was 7.62 [2.4–23.6], all of them requiring hospitalisation with no deaths. Severe OI have a higher incidence for men 21.1 [5.2–84.2] than women 3.3 [0.4–23.7]. All patients with severe OI were taking corticosteroids, and at least one synthetic DMARD. TCZ did not have any severe OI, and the incidence of severe OI was 10.8 [1.5–76.7] for ABA, followed by RTX with 8.6 [2.1–34.5].

**Conclusions:** The incidence of OI in three non-TNF-targeted biologics in real life conditions is described. Incidence found was near 31 cases per 1000 patients - year. Virus and fungus are the OI more frequent in these bDMARDs. Doctors using bDMARDs should be concerned about this problem and be aware for the detection and management of OI.

**Disclosure of Interest:** None declared

#### AB0452 BIOLOGICAL THERAPY ADVERSE EVENTS IN BIOBADAGUAY REGISTRY

M. Franco<sup>1</sup>, Z. Morel<sup>1</sup>, M.G. Avila-Pedretti<sup>1</sup>, S. Cabrera-Villalba<sup>1</sup>, I. Acosta Colman<sup>2</sup>, P. Babak<sup>1</sup>, P. Melgarejo<sup>1</sup>, G. Elizaur<sup>1</sup>, P. Delgadillo<sup>1</sup>, D. Cordovilla Montero<sup>3</sup>, J. Losanto<sup>2</sup>, G. Babak<sup>1</sup>, L. Román<sup>2</sup>, E. Paredes<sup>1</sup>, J. Mazzoleni<sup>1</sup>, P. de Abreu<sup>4</sup>, on behalf of BIOBADAGUAY. <sup>1</sup>Rheumatology, Hospital Central del Instituto de Previsión Social; <sup>2</sup>Rheumatology, Hospital de Clínicas, Asunción, Paraguay; <sup>3</sup>Rheumatology, Instituto Nacional de Reumatología, Montevideo, Uruguay; <sup>4</sup>Rheumatology, Sociedad Paraguaya de Reumatología, Asunción, Paraguay

**Background:** BIOBADAGUAY is the Paraguayan/Uruguayan registry of adverse events (AE) in patients with inflammatory rheumatic conditions under biologic therapy (BT)

**Objectives:** To determine the frequency and severity of AE in patients under BT from the BIOBADAGUAY registry

**Methods:** Prospective, observational study of undetermined length to verify the efficacy, safety and survival of the BT. The methodology applied is available at <https://biobadaguay.ser.es>. For the present study epidemiological and clinical variables, BT, type and severity of AE were analysed. The incidence rate (IR) was calculated as the total number of adverse events per 1000 patients/year and the incidence rate ratio (IRR) was analysed using the Poisson regression model.

**Results:** 778 BT were analysed (56.6% adalimumab, 23.7% etanercept, 9.6% tocilizumab, 5.7% rituximab, 3.5% infliximab, 0.5% golimumab, 0.38% infliximab biosimilar, 0.13% abatacept). In these, 330 AE were observed, 256 (77.6%) mild and 74 (24.4%) severe. The global IR of AE was 143.9 (95% CI, 128.8–160.8) and 32.6 (95% CI, 25.3–40.5), 111.6 (95% CI, 98.4–126.2) for severe and mild respectively. Infection was the most frequent AE in 175 (53.0%) and 39 (22.3%) of them were severe. Infection's IR was 76.3 (95% CI, 65.4–88.5), 59.3 (95% CI, 49.76–70.2) and 17.0 (95% CI, 12.1–23.3) for global, severe and mild respectively. Out of the 39 severe AE, respiratory infections were the most frequent in 43.6% of the cases. 5 tuberculosis, 6 malignancies and 6 deaths were observed.

When analysing the IR according to diagnosis, Idiopathic Juvenile Arthritis (JIA) was associated with a higher IR of global AE when comparing to the other diagnosis (IRR=2.3 [95% CI, 1.6–3.4] p=4.27 × 10<sup>-6</sup>). RA diagnosis was significantly associated with a higher risk of severe AE (IRR=2.20 [95% CI, 1.2–4.1] p=1.17 × 10<sup>-2</sup>). tocilizumab was significantly associated with a higher incidence of global AE, (IRR=2.69 [95% CI, 1.90–3.82] p=3.13 × 10<sup>-8</sup>) and severe ones (IRR=3.34 [95% CI, 1.81–6.1] p=1.10 × 10<sup>-4</sup>). Adalimumab was significantly associated with a lower rate of global AE (IRR=0.6 [95% CI, 0.4–0.8] p=1.86 × 10<sup>-4</sup>).

**Abstract AB0452 – Table 1.** Incidence rate and incidence rate ratio of adverse events according to diagnosis and biological therapy

Variable	IR	IRR	P value
Psoriatic Arthritis	88 [52,2–139,1]	0,59 [0,33–1,04]	7,03e-02
Ankylosis Spondylitis	102,3 [68,0–147,8]	0,68 [0,40–1,17]	1,63e-01
Rheumatoid Arthritis	134,2 [115,6–155,0]	0,85 [0,62–1,15]	2,81e-01
Idiopathic Juvenile Arthritis	286,4 [229,4–353,2]	2,34 [1,63–3,37]	4,27e-06
Adalimumab	113,5 [96,9–132,1]	0,57 [0,43–0,77]	1,86e-04
Etanercept	190,4 [152,7–234,6]	1,44 [1,03–2,02]	3,30e-02
Rituximab	66,9 [26,9–137,8]	0,45 [0,18–1,13]	8,93e-02
Infliximab	75,0 [24,3–175,0]	0,51 [0,21–1,23]	1,35e-01
Tocilizumab	340,0 [261,8–434,2]	2,69 [1,90–3,82]	3,13e-08

IR: incidence, IRR: incidence ratio (per 1000 patients year)

**Conclusions:** AE were mild in general and infections were the most frequent. In the present study, it was found that JIA and treatment with tocilizumab presented a higher IRR of AE while RA presented a higher rate of severe AE.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6725

#### AB0453 BIOLOGICAL THERAPIES RETENTION RATE IN TWO SUDAMERICAN COUNTRIES. DATA FROM BIOBADAGUAY REGISTRY

M.G. Avila-Pedretti<sup>1</sup>, P. Melgarejo<sup>1</sup>, M. Franco<sup>1</sup>, Z. Morel<sup>1</sup>, J.G. Elizaur<sup>1</sup>, P. Delgadillo<sup>1</sup>, I. Acosta-Colman<sup>2</sup>, S. Cabrera<sup>1</sup>, D. Cordovilla Montero<sup>3</sup>, J. Losanto<sup>2</sup>, L. Román<sup>2</sup>, E. Paredes<sup>1</sup>, J. Mazzoleni<sup>1</sup>, P. de Abreu<sup>4</sup>, on behalf of BIOBADAGUAY. <sup>1</sup>Rheumatology, Hospital Central del Instituto de Previsión Social; <sup>2</sup>Rheumatology, Hospital de Clínicas, Asunción, Paraguay; <sup>3</sup>Rheumatology, Instituto Nacional de Reumatología, Montevideo, Uruguay; <sup>4</sup>Rheumatology, Sociedad Paraguaya de Reumatología, Asunción, Paraguay

**Background:** The retention rates (RR) of biological therapies (BT) have been extensively studied in European countries and the United States, but there is a lack of information about them in emerging populations.

**Objectives:** To analyse BT retention rates and variables associated to them at the BIOBADAGUAY registry

**Methods:** Patients with a chronic inflammatory arthritis enrolled in the Paraguayan-Uruguayan biological register (BIOBADAGUAY) between 2015 and 2017 where included in the study. Phase I of the study was focused in the global RR analysis and association with clinical and epidemiological variables. In phase II we analysed BT retention rate according to different discontinuation motives and association with clinical and epidemiological variables. Survival analysis was performed using Kaplan-Meier estimators and proportional hazard regression models

**Results:** A total of 778 BTs were included in the study (etanercept n=184, adalimumab n=440, rituximab n=44, infliximab n=27, tocilizumab n=75, and others n=8). The underlying diagnosis associated to these BTs were rheumatoid arthritis (RA; 58.2%), juvenile arthritis (JIA; 14.2%), ankylosing spondylitis (SA; 12.5%) and psoriatic arthritis (PA; 8.0%).

In phase I we found that mean survival times were 322 (±17.9), 315 (±22.32), 289 (±8.52) and 233 (±16.69) weeks for AS, PA, RA and JIA respectively. The survival association analysis has shown that JIA diagnosis (p=2.26 × 10<sup>-4</sup>, HR=1.80 [95%CI, 1.32–2.46]), corticosteroids (p=1.54 × 10<sup>-2</sup>, HR=1.38 [95% CI, 1.06–1.79]), and previous BT (p=3.32 × 10<sup>-2</sup>, HR=1.43 [95% CI, 1.03–1.98]) were variables significantly associated with a lower BT retention.

In phase II, we stratified the survival analysis by cause of discontinuation. We found that corticoids (p=9.48 × 10<sup>-4</sup> HR=2.02 [95% CI, 1.33–3.06]), female gender (p=4.36 × 10<sup>-2</sup>, HR=1.66 [95% CI, 1.01–2.72]) and previous BT (p=2.56 × 10<sup>-2</sup>, HR=1.72 [95% CI, 1.07–2.78]) were associated with lower BT retention due to inefficacy. When we analysed withdrawn according to adverse events, we found that RA (p=02.80 × 10<sup>-2</sup>, HR=1.83 [95% CI, 1.07–3.15]), previous BT (p=4.83 × 10<sup>-2</sup>, HR=1.76 [95% CI, 1.00–3.09]) and age (p=7.14 × 10<sup>-5</sup>, HR=1.05 [95% CI, 1.02–1.05]) were significantly associated with therapy discontinuation. In the group of treatments with discontinuation due to remission, we found that JIA diagnosis (p=7.93 × 10<sup>-8</sup>, HR=30.58 [95% CI, 8.77–106.71]), age (p=7.83 × 10<sup>-6</sup>,

HR 0,83[IC 95% 0,76–0,90]) and gender ( $p=4,36 \times 10^{-2}$ , HR 1,66[IC 95% 1,01–2,72]) were associated to discontinuation due to remission.

**Conclusions:** Our results show that different sets of clinical and demographical variables are significantly associated to biological therapy survival depending on the discontinuation cause.

**Disclosure of Interest:** None declared

#### AB0454 BIOLOGICAL THERAPIES SURVIVAL IN ADULTS AND JUVENILE ONSET ARTHRITIS. DATA FROM BIOBADAGUAY REGISTRY

M.G. Avila-Pedretti<sup>1</sup>, Z. Morel<sup>1</sup>, N. Cabrera<sup>2</sup>, S. Cabrera-Villalba<sup>1</sup>, I. Acosta Colman<sup>1</sup>, P. Babak<sup>1</sup>, P. Melgarejo<sup>1</sup>, G. Elizaur<sup>1</sup>, M. Franco<sup>1</sup>, P. Delgadillo<sup>1</sup>, D. Cordovilla Montero<sup>3</sup>, J. Losanto<sup>4</sup>, L. Roman<sup>4</sup>, E. Paredes<sup>1</sup>, J. Mazzoleni<sup>1</sup>, P. de Abreu<sup>2</sup>, on behalf of BIOBADAGUAY. <sup>1</sup>Rheumatology, Hospital Central del Instituto de Previsión Social; <sup>2</sup>Rheumatology, Sociedad Paraguaya de Reumatología, Asunción, Paraguay; <sup>3</sup>Rheumatology, Instituto Nacional de Reumatología, Montevideo, Uruguay; <sup>4</sup>Rheumatology, Hospital de Clínicas, Asunción, Paraguay

**Background:** Survival of biological therapies (BT) may be considered as an indicator of efficacy and safety of the drug. BT survival have been studied mainly in adult's patients, whereas only few studies have been focused on paediatric population to date.

**Objectives:** To analyse and compare BT survival in adults and juvenile onset arthritis patients from BIOBADAGUAY registry.

**Methods:** Patients with a chronic inflammatory arthritis enrolled in the Paraguayan-Uruguayan biological register (BIOBADAGUAY) between 2015 and 2017 where included. For this study, patients were divided in two groups: 1. Adults with an chronic inflammatory arthritis and 2. Patients with juvenile idiopathic arthritis (JIA). To compare the groups according to BT, only the first bioterapy was considered.

Survival analysis was performed using Kaplan-Meier estimators and proportional hazard regression model. First we analysed global BT survival in both groups; secondly we compare BT survival between groups.

**Results:** From 778 BTs(etanercept n=184, adalimumab n=440, rituximab n=44, infliximab n=27, tocilizumab n=75, and others n=8), 556 where identify as first line BTs. Of these, only adalimumab and etanercept were included in the study due to sufficient number prescriptions in both groups for the analysis.

We found a mean survival times for adults of 289 ( $\pm 20.7$  SD) weeks for etanercept and 287 ( $\pm 8.6$  SD) weeks for adalimumab. In JIA patients the mean survival were 243 ( $\pm 26.0$  SD) and 216 ( $\pm 24.0$  SD) weeks for etanercept and adalimumab respectively

When comparing survival between groups, we found that JIA presented more discontinuation of BT when compare with adult patients ( $p=4.4 \times 10^{-4}$ , HR=0.51 [95%CI, 0.35–0.73]). Similar results were observed when analysing only etanercept ( $p=3.92 \times 10^{-2}$ ; HR=0.50 [95% CI, 0.26–0.97]) or adalimumab ( $p=1.20 \times 10^{-3}$ ; HR=0.48 [95% CI, 0.30–0.75]) treatments. Then we analysed withdrawn motive in JIA patients, and found that remission was the principal reason of discontinuation in this group of patients.

Finally, we stratified survival analysis by discontinuation according to adverse events, and found that JIA group presented a lower risk of discontinuation due to adverse events than adults ( $p=1.96 \times 10^{-1}$ ; HR=2.18 [95% CI, 0.67–7.07]).

**Conclusions:** In our study we have analysed mean BT survival between adults and JIA at the BIOBADAGUAY registry. When we compared both groups of patients it was observed that JIA patients presented more BT discontinuation but due to remission.

#### AB0455 IMPACT OF ONE-YEAR TREATMENT WITH BIOTECHNOLOGIC DRUGS ON WORK DISABILITY AND ACTIVITY IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. Manara<sup>1</sup>, R. Caporali<sup>2</sup>, R. Gorla<sup>3</sup>, E. Fusaro<sup>4</sup>, R. Pellerito<sup>5</sup>, P.A. Rocchetta<sup>6</sup>, P. Sarzi Puttini<sup>7</sup>, S. Capri<sup>8</sup>, L. Sinigaglia<sup>1</sup>. <sup>1</sup>Gaetano Pini Institute, Milan; <sup>2</sup>University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; <sup>3</sup>Spedali Civili, Brescia; <sup>4</sup>Città della Salute e della Scienza; <sup>5</sup>Ospedale Mauriziano, Torino; <sup>6</sup>ASO SS. Antonio e Biagio e C. Arrigo, Alessandria; <sup>7</sup>L. Sacco Hospital, Milan; <sup>8</sup>School of Economics and Management, LIUC University, Castellanza, Italy

**Background:** Disease activity significantly impacts on work ability of patients with Rheumatoid Arthritis (RA). Biologic agents can control disease activity, but their effects on productivity outcomes were not adequately investigated in Italian population.

**Objectives:** Aim of the study was to evaluate the impact of biologic therapy on work productivity outcomes in a cohort of biologic-naïve patients with active RA from northern Italy.

**Methods:** This is a multicentre prospective study on patients with active RA in working age (18–65 years), scheduled to undergo their first biologic treatment. Demographics and clinical data were collected at baseline and at 6 and 12 months, together with productivity outcomes assessed with the RA-specific work productivity survey (WPS-RA)<sup>1</sup> and the Health and Labour Questionnaire (HLQ)<sup>2</sup>. Primary outcome was the productivity loss or gain after 1 year of treatment.

**Results:** We included 100 patients from 7 rheumatology centres in northern Italy with active RA [mean DAS28: 5,1 (SD 0,9), median SDAI: 25,2 (IQR 18,7–33,2)]. Most of them were females (85%), with a mean age of 49,1 (SD: 10,3) years and a median disease duration of 7 (IQR: 3–14) years. Patients were treated with TNF-inhibitors (68%), Abatacept (24%) or Tocilizumab (8%). At baseline 39 patients were unemployed. After 1 year of treatment, 85 patients were still on follow-up, with an improvement in all indexes of disease activity [mean DAS28: 2,8 (SD 1,3), median SDAI: 5,1 (IQR 1,9–12,9)]. A significant reduction in number of days of work missed (absenteeism) and of reduced productivity (presenteeism) was observed in employed subjects, as well as a significant decrease in number of days missed of household work and social activities in all the study population (table 1).

Abstract AB0455 – Table 1

	Baseline [mean (SD)]	12 months [mean (SD)]	p (t-test for paired data)
Number of days of work missed (absenteeism)	2.5 (3.6)	0.5 (1.3)	0.003
Number of days of reduced productivity (presenteeism)	6.7 (7.9)	0.7 (1.6)	0.000
Rate of arthritis interference with work productivity (0–10 points scale)	3.8 (3.6)	1.3 (2.1)	0.014
Number of days of household work missed	7.5 (8.9)	3.2 (6.2)	0.000
Number of days of reduced productivity in household work	8.9 (9.6)	2.9 (5.3)	0.000
Number of days with social activities missed	6.8 (9.3)	1.9 (4.8)	0.000
Number of days with need for outside help	5.5 (8.2)	1.5 (4.6)	0.000
Rate of arthritis interference with household work productivity (0–10 points scale)	6.1 (2.8)	3.1 (3)	0.000

**Conclusions:** One year of treatment with biological drugs was associated with a significant improvement in outcomes related to productivity both within and outside home in a cohort of patients with RA.

#### AB0456 EFFICACY AND SAFETY OF SWITCHING FROM ETANERCEPT REFERENCE PRODUCT TO LBEC0101 (ETANERCEPT BIOSIMILAR) COMPARED WITH CONTINUING LBEC0101 IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y.W. Song<sup>1</sup>, H. Matsuno<sup>2,3</sup>, M.-C. Park<sup>4</sup>, M. Tomomitsu<sup>5</sup>, S. Shin<sup>6</sup>, J. Lee<sup>6</sup>, on behalf of LBEC0101 Research Group. <sup>1</sup>Seoul National University Hospital, Seoul, Korea, Republic of Ireland; <sup>2</sup>Tokyo Medical University, Tokyo; <sup>3</sup>Matsuno Clinic for Rheumatic Diseases, Toyama, Japan; <sup>4</sup>Division of Rheumatology, Yonsei University College of Medicine, Seoul, Korea, Republic of Ireland; <sup>5</sup>Mochida Pharmaceutical Co., Ltd, Tokyo, Japan; <sup>6</sup>LG CHEM, Seoul, Korea, Republic of Ireland

**Background:** LBEC0101 is a newly developed biosimilar of etanercept (ETN). As rheumatoid arthritis (RA) treatment is a long-standing process in the clinical practice, the long-term safety and efficacy of anti-TNF inhibitors have been studied and reported.<sup>1</sup> Clinical studies have been conducted to evaluate the efficacy and safety of biosimilar after switching from their originator drug.<sup>2</sup>

**Objectives:** To evaluate the long-term efficacy, safety, and immunogenicity of switching from the ETN reference product (RP) to LBEC0101 or continuing LBEC0101 in patients with RA.

**Methods:** This multicenter, single-arm, open-label extension study enrolled patients with RA who had completed the 52 week treatment period of the

randomised, double-blind, parallel-group, Phase III study for LBEC0101 (NCT02357069). Patients who were deemed requiring continuous treatment for RA upon the investigator's discretion and agreed to participate in this study were allowed for participation. All patients received LBEC0101 50 mg/ml once a week for 48 weeks with the stable dose of methotrexate regardless of the randomization group in the Phase III study. Efficacy, safety and immunogenicity were assessed up to Week 100. Data were analysed for patients who continued to receive LBEC0101 for 100 weeks (maintenance group) and for those who had received ETN-RP for 52 weeks and then switched to LBEC0101 for 48 weeks (switch group).

**Results:** A total of 148 patients were enrolled in this study; 70 patients continued to receive LBEC0101 and 78 patients switched to receive LBEC0101 from ETN-RP. DAS28-ESR score in the full analysis set were maintained in both groups from week 52 through week 100 (from 3.068 to 3.103 in maintenance group vs. from 3.161 to 3.079 in switch group). Response rates at week 100 for maintenance and switch groups, respectively, were 79.7% vs. 83.3% for ACR20, 65.2% vs. 66.7% for ACR50% and 44.9% vs. 42.3% for ACR70. The incidences of adverse events were comparable between the groups (70.0% for maintenance group and 70.5% for switch group, respectively). The proportion of patients who newly developed antidrug antibodies was similar between the groups (1.4% for maintenance group and 1.3% for switch group, respectively).

**Conclusions:** The efficacy and safety of LBEC0101 were comparable in both maintenance and switch groups. The efficacy of LBEC0101 was well sustained over 100 weeks.

AB0457

#### CLINICAL EQUIVALENCE IN EFFICACY BETWEEN ABP 501 AND ADALIMUMAB IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS: A TIPPING POINT SENSITIVITY ANALYSIS

N. Zhang, H. Wang, E. Krishnan. *Biosimilars Development, Amgen Inc., Thousand Oaks, USA*

**Background:** ABP 501 is the first approved biosimilar to adalimumab. Patient withdrawals from clinical trials can result in missing data, which may lead to loss of statistical power and bias of the treatment difference estimate. Therefore, it is critical to examine the potential effects of missing data and analyse the sensitivity of the results under various assumptions on the mechanism of missing data.

**Objectives:** To examine and confirm the robustness of the clinical similarity conclusion between ABP 501 and adalimumab reference product (RP) through tipping point sensitivity analyses on ACR20 at week 24, the primary endpoint of the phase 3 study in patients with rheumatoid arthritis.

**Methods:** The primary analysis for this trial has been previously published. The proportions of patients achieving ACR20/50/70 responses with last observation carried forward imputation at weeks 2, 4, 8, 12, 18 and 24, were similar between ABP 501 and the RP over time. Tipping point sensitivity analyses were used to estimate the difference between ABP 501 and the RP with varying assumptions on the outcomes in patients who withdrew from the study early and those who completed the study.

**Results:** The table 1 displays the results of tipping point analyses on the primary endpoint of ACR20 at week 24. There were no scenarios in which the 90% confidence interval (CI) failed to rule out a 12% loss/increase in the ACR20 response.

**Abstract AB0457 – Table 1.** Tipping point analysis results for RD (90% CI) of ACR20 at week 24

Shift between dropouts and completers in ABP 501	Shift between dropouts and completers in adalimumab RP				
	-0.700	-0.525	-0.350	-0.175	0.000
-0.700	0.002	-0.005	-0.014	-0.019	-0.023
	(-0.063, 0.067)	(-0.072, 0.061)	(-0.080, 0.052)	(-0.085, 0.047)	(-0.088, 0.042)
-0.525	0.013	0.005	-0.003	-0.008	-0.012
	(-0.052, 0.078)	(-0.060, 0.071)	(-0.068, 0.063)	(-0.073, 0.057)	(-0.077, 0.053)
-0.350	0.024	0.016	0.008	0.003	-0.001
	(-0.041, 0.088)	(-0.049, 0.081)	(-0.057, 0.072)	(-0.062, 0.067)	(-0.066, 0.063)
-0.175	0.035	0.027	0.019	0.014	0.010
	(-0.030, 0.100)	(-0.038, 0.093)	(-0.046, 0.084)	(-0.051, 0.079)	(-0.055, 0.075)
0.000	0.048	0.040	0.032	0.026	0.023
	(-0.016, 0.111)	(-0.025, 0.105)	(-0.033, 0.096)	(-0.038, 0.090)	(-0.041, 0.086)

The shift represents the assumed difference in week 24 ACR20 response between patients who dropped out prior to week 24 and those who completed week 24. Among completers, the ACR20 response rate was 77.0% and 74.7% for the ABP 501 and adalimumab groups, respectively.

**Conclusions:** The tipping point sensitivity analyses support the findings of the key efficacy analyses in the phase 3 RA study and confirm that the effects of missing data would not change the conclusion of clinical similarity between ABP 501 and the RP.

AB0458

#### EFFICACY AND B-CELL DEPLETION WITH VERY LOW DOSE RITUXIMAB (BIOSIMILAR) IN SERO-POSITIVE DMARD RESISTANT RHEUMATOID ARTHRITIS: A 24 WEEK STUDY

N.S. Jain<sup>1</sup>, S. Pandya<sup>2</sup>, D. Shukla<sup>2</sup>, P. Srivastava<sup>2</sup>. <sup>1</sup>Department of Rheumatology, <sup>2</sup>Department of Rheumatology, VS Hospital Ahmedabad, Ahmedabad, India, India

**Background:** Very Low dose Rituximab (RTX) (100 mg) has been variously used in autoimmune diseases like ITP and rheumatoid arthritis (RA). As cost of treatment is an important issue in resource poor setups, we decided to study efficacy of very low dose RTX in patients with RA.

**Objectives:** 1) To study clinical efficacy of very low dose RTX in DMARD refractory RA. 2) To study B cell depletion with very low dose RTX

**Abstract AB0458 – Table 1.** Demographic profile and response to very low dose Rituximab

Demographic Profile	100 mg × 4 doses				100 mg single dose			
	Baseline	Week 12	Week 24	p	Baseline	Week 12	Week 24	p
Total number of patients	14	14	14	-	13	11	11	-
Male:Female		1:6		-		1:3		-
Mean Age		47±12 years		-		49±10 years		-
Mean duration of illness		6.7±4 years (median 5 years)		-		7.1±3 years (median 4.5 yrs)		-
<b>Disease Activity measures</b>								
DAS28(ESR)	5.5±1.1	3.3±1	3.4 ±0.9	<0.001	5.7±0.7	3.3 ±0.4	3.4 ±0.6	<0.001
RAPID3	5±0.8	2.6 ±1.3	3.3 ±1.5	<0.001	5.1±1.1	2.9 ±1.4	2.8 ±1.6	<0.001
CDAI	26.3±8.5	10±8	8.6±6	<0.001	28.2±7.8	12±6	11±6	<0.001
HAQ	1.7±0.3	0.7 ±0.5	0.5 ±0.4	<0.001	1.9±0.4	0.8 ±0.5	0.7 ±0.5	<0.001
Mean ΔDAS28 (24 weeks)		2.2±1.5		-		2.3±1		-
Mean CD19	152	28	-	-	78	18	-	-
<b>EULAR Response</b>								
EULAR remission	0	3	4	-	0	1	3	-
EULAR low disease activity	0	4	4	-	0	3	4	-
EULAR good response	0	11	11	-	0	9	9	-

**Methods:** Prospective open labelled study. Biologic naïve, conventional DMARD refractory, sero-positive RA patients (ACR 2010 criteria) with high disease activity (DAS 28 ESR) were included after informed consent.

Arm 1: Total 4, weekly 100 mg doses (total dose 400 mg) of a RTX biosimilar were infused.

Arm 2: Single 100 mg RTX infusion.

Efficacy was assessed using standard outcome measures for RA (including RAPID3) at week 24. B cell depletion (CD19 levels in peripheral blood by flow cytometry) was studied at baseline, week 1 and week 12.

**Results:** Total number of patients in Arm 1=14 and in Arm 2=13.

In Arm 1: 28% (4/14) achieved EULAR remission while 78% (11/14) had EULAR good response. In Arm 2: 70% (9/13) had EULAR good response. All patients achieved complete B-cell depletion (defined as <0.01%) at week 1 after just single dose of 100 mg RTX remained so at 6 weeks only to start rising again at week 12. There were no adverse events noted. Steroid doses were reduced in most patients at follow up visits with delta change in steroid dose- 2.2 mg/day. Results comparable with other studies using both low dose and conventional dose of RTX. Limitations of the study includes small sample size and short follow-up.

**Conclusions:** Very Low dose RTX is efficacious in conventional DMARD refractory RA patients. Single dose (100 mg) is as good as 400 mg upto week 24. Complete B cell depletion can be achieved even with 100 mg RTX as early as week 1.

#### AB0459 REMISSION RATE OF TOCILIZUMAB IN CONTROLLED TRIALS AND OBSERVATIONAL STUDIES: SYSTEMATIC REVIEW OF RHEUMATOID ARTHRITIS

Q. Kucuksahin<sup>1</sup>, L. Kılıç<sup>2</sup>, Z. Aşlar<sup>3</sup>, C. Bes<sup>4</sup>, V. Yazısız<sup>5</sup>, A. Yazıcı<sup>6</sup>, D. Solmaz<sup>7</sup>, T. Kaşifoğlu<sup>8</sup>, U. Kalyoncu<sup>2</sup>. <sup>1</sup>Rheumatology, YILDIRIM BEYAZIT UNIVERSITY; <sup>2</sup>Rheumatology, Hacettepe University; <sup>3</sup>Rheumatology, Numune Education and Research Hospital, Ankara; <sup>4</sup>Rheumatology, Medical Science University Bakırköy Sadi Konuk Hospital, İstanbul; <sup>5</sup>Rheumatology, Akdeniz University, Antalya; <sup>6</sup>Rheumatology, Kocaeli University, Kocaeli; <sup>7</sup>Rheumatology, İzmir Katip Çelebi University, İzmir; <sup>8</sup>Rheumatology, Eskişehir Osmangazi University, Eskişehir, Turkey

**Background:** In concept, the state of remission constitutes a clinical condition in which no active disease is present. Target of rheumatoid arthritis (RA) is achieve to remission. Tocilizumab (TOC) is a humanised monoclonal antibody that binds to the interleukin-6 receptor

**Objectives:** The aim of this study was to assess the remission rate of TOC for the treatment of RA patients in randomised controlled trials (RCTs) and longitudinal observational studies (LOS).

**Methods:** In January 2017, a systematic Review (SR) was performed in PUBMED MEDLINE. Publications were identified using the MeSH terms: ("rheumatoid arthritis and Tocilizumab") with a limitation to "humans", "all adults: 19 +years", "English" and "clinical trials". All available studies describing the retention rate of TOC were recruited to SR. Retention rate of TOC were calculated according to route (SC or IV), dosage (4 mg/kg vs 8 mg/kg), monotherapy or combination with methotrexate. Of the 662 publications identified by the literature search, 42 were recruited in the analysis. Retention rates of TOC at 12–16 weeks, 24–32 weeks, 48–52 weeks, 2. Years, 3. Years and 5. years were analysed. Open label extension period of RCTs included to LOS. The causes of withdraw of TOC were recorded as inefficacy, adverse event, and others.

**Results:** Of the 34 studies, 13 (38%) were RCTs and 21 (62%) were LOSs. Totally 12 043 patients (9834 (81%) female) were pooled to analysis that 6190 patients (51%) were from RCTs. The mean age was 53 years and mean disease duration was 9 years. Seropositivity was 73.6% for rheumatoid factor and 72.2% for ACPA. Overall, 5493 (54.6%) of patients were biologic-naïve. TOC was used as monotherapy (2469/6077, 35.4%), or concomitant with methotrexate (8037/11429, 70.3%). Available baseline DAS-28 score, CDAI, SDAI, and HAQ-DI score were 6.2, 32.1, 33.3, and 1.49 respectively. Remission rate of TOC according to study type were shown in table 1.

Abstract AB0459 – Figure 1

**Conclusions:** These systematic literature results show that treatment with of TOC has a high likelihood of inducing a clinically important benefit in terms of different remission criteria. Remission achieved both RCTs and real life results. Moreover, remission rate of TOC in LOSs was comparable with other biologic DMARDs, as well.

#### AB0460 LONG-TERM DRUG SURVIVAL OF ETANERCEPT VS OTHER TNF INHIBITOR THERAPIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Emery<sup>1</sup>, B. Vlahos<sup>2</sup>, P. Szczypa<sup>3</sup>, M. Thakur<sup>4</sup>, H.E. Jones<sup>2</sup>, J. Woolcott<sup>2</sup>, P. V. Santos Estrella<sup>2</sup>, A. Gibofsky<sup>5</sup>, C. Rolland<sup>6</sup>, G. Citera<sup>7</sup>, L. Marshall<sup>2</sup>. <sup>1</sup>Leeds Musculoskeletal Biomedical Research Centre LTH, Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, UK; <sup>2</sup>Pfizer, Collegeville, USA; <sup>3</sup>Pfizer Ltd, Walton Oaks; <sup>4</sup>Pfizer, Sandwich, UK; <sup>5</sup>Weill Medical College, New York, USA; <sup>6</sup>Envision Pharma Group, Horsham, UK; <sup>7</sup>Consultorios Reumatologicos, Buenos Aires, Argentina

**Background:** TNF $\alpha$  inhibitors have profoundly altered outcomes for patients with rheumatoid arthritis (RA) since they were introduced >15 years ago, by reducing disease activity and radiographic progression and improving quality of life. As a chronic disease, RA often requires life-long treatment, understanding drug survival in real-world settings can be beneficial in optimising disease management.

**Objectives:** To compare the long-term drug survival of adalimumab (ADA), certolizumab pegol (CZP), etanercept (ETN), golimumab (GLM), and infliximab (IFX) in patients with RA based on systematic literature review (SLR).

**Methods:** In this SLR, the goal was to identify full-text articles containing registry data or systematic reviews on TNF $\alpha$  inhibitors, following Cochrane dual-reviewer methodology. Searches were conducted in November 2017 with no date restriction, using Embase<sup>®</sup>, MEDLINE<sup>®</sup>, the Cochrane Central Trials Register and Database of Systematic Reviews, other Cochrane Library databases, and PubMed. Outcomes extracted included drug survival data that were analysed and reported using Kaplan-Meier or Cox regression methods.

**Results:** Of 3688 non-duplicated publications initially identified, 3299 were excluded based on titles or abstracts and 344 based on full-text screening, leaving 26 publications published between 2005 and 2017 included in the analysis. The number of studies (range of sample size) for each drug were ADA: 15 (25–2349), ETN: 17 (20–3892), IFX: 21 (26–2898), GLM: 4 (2–88) and CZP: 1 (N/A). Among the analysed studies, the mean disease duration in years (range) was ADA: 10.7 (8.2–15.1); ETN: 15.9 (5.0–18.5); IFX: 14.2 (8.5–19.3); CZP: 10.3 (N/A); GLM: 8.9 (8.1–11.5) and mean baseline DAS28 (range) was ADA: 5.0 (4.2–5.9), ETN: 5.2 (4.3–6.3), IFX: 5.3 (4.1–6.4); CZP: 4.7 (N/A) and GLM: 4.7 (4.1–5.1). Trends for survival rates of first-line ETN were slightly higher than ADA at time points  $\geq$ 36 months; ADA and ETN had higher survival rates than IFX at >48 months (figure 1).

**Abstract AB0460 – Figure 1.** Survival of First-Line Anti-TNF Therapies in Patients with Rheumatoid Arthritis

**Conclusions:** Long-term survival rates for ADA, ETN, and IFX were similar and relatively high for treatment periods up to 36 months. After 36 months, there was a noticeable decline in drug survival for all three TNF $\alpha$  inhibitors. Heterogeneity in study size and design may contribute to the range of survival data for each agent.

Patel<sup>9</sup>, P. Peichl<sup>10</sup>, R. Sanmarti<sup>11</sup>, C. Chauvet<sup>12</sup>, J. Heitzman<sup>13</sup>, C. Rauch<sup>14</sup>, S.E. Connolly<sup>15</sup>. <sup>1</sup>University Medicine Berlin, Berlin, Germany; <sup>2</sup>Université Paris-Sud, Paris, France; <sup>3</sup>University of Leeds, Leeds, UK; <sup>4</sup>University of Pavia, Pavia, Italy; <sup>5</sup>Centre Hospitalier Universitaire de France, Lille, France; <sup>6</sup>Schulthess Klinik, Zürich, Switzerland; <sup>7</sup>University Hospital Geelong, Geelong, Australia; <sup>8</sup>VU University Medical Center and Jan van Breemen Research Institute, Amsterdam, Netherlands; <sup>9</sup>Hull Royal Infirmary, Hull, UK; <sup>10</sup>Evangelical Hospital, Vienna, Austria; <sup>11</sup>Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; <sup>12</sup>DOCS, Nanterre; <sup>13</sup>Excelya, Boulogne-Billancourt, France; <sup>14</sup>Bristol-Myers Squibb, Munich, Germany; <sup>15</sup>Bristol-Myers Squibb, Princeton, USA

**Background:** ASCORE (Abatacept SubCutaneOus in Routine clinical practicE; NCT02090556) is an ongoing, prospective, non-interventional, multicentre study of patients (pts) with RA receiving SC abatacept (ABA). In a similar real-world setting, IV ABA retention was >88% at 6 months (M).<sup>1</sup>

**Objectives:** To present baseline (BL) pt characteristics and 6M interim retention rates and clinical outcomes for SC ABA by biologic (b)DMARD treatment line.

**Methods:** Pts ( $\geq 18$  years) with active, moderate-to-severe RA, naïve to ABA and who initiated SC ABA 125 mg weekly were enrolled across 10 countries (March 2013–January 2017) in 2 cohorts: biologic-naïve pts and pts who had failed  $\geq 1$  prior bDMARD. In some countries, an IV loading dose was administered according to local practice. Pt demographics and disease characteristics at SC ABA initiation were recorded. The retention rate (95% CI) of SC ABA over 6M was estimated by Kaplan–Meier analysis. Good/moderate EULAR response rates based on DAS28 (ESR, otherwise CRP), low disease activity (LDA) or remission according to DAS28 (ESR), CDAI, SDAI and Boolean criteria were assessed at 6M.

**Results:** Of 2943 pts enrolled, 2785 (94.6%) were evaluable: 1155 (41.5%) biologic naïve; 718 (25.8%) had failed 1; and 912 (32.7%) had failed  $\geq 2$  prior biologics. At BL, there was a higher proportion of females and pts with longer disease duration among those who had failed  $\geq 2$  vs 1 or no prior bDMARDs; disease activity was similar across treatment lines; CRP was higher in biologic-naïve vs -failure pts; 402 (48.4%) biologic-naïve pts had erosive disease vs 261 (53.7%) or 390 (63.8%) who had received 1 or  $\geq 2$  prior bDMARDs, respectively. Probability of overall SC ABA retention at 6M was 0.88 (95% CI 0.86, 0.89); retention was higher in pts receiving ABA as a first or second vs later bDMARD (figure 1). At 6M, 335 pts had discontinued ABA, 172 (51.3%) of whom due to inefficacy and 140 (41.8%) due to safety. At 6M, among pts continuing ABA, good/moderate EULAR response rates were 83.5%, 75.1% and 72.0% for biologic-naïve pts and pts with 1 and  $\geq 2$  prior bDMARD failures, respectively. DAS28 (ESR), CDAI or SDAI LDA/remission, or Boolean remission rates were higher with earlier vs later treatment lines. The safety profile was consistent with IV ABA studies.<sup>1,2</sup>

**Abstract AB0461 – Figure 1.** Abatacept Retention (Time to Discontinuation of SC Abatacept) Over 6 Months by Treatment Line

**Conclusions:** In this first observation of SC abatacept in a real-world setting, overall retention of SC abatacept at 6M was high and similar to that observed with IV abatacept.<sup>1</sup> Better retention and response rates were achieved with abatacept as an earlier bDMARD treatment line. Good/moderate EULAR response rates at 6M were consistently >70%, irrespective of treatment line and higher BL radiographic erosion in biologic-failure pts.

### UP TO 5-YEAR RETENTION OF ABATACEPT IN BELGIAN PATIENTS WITH MODERATE-TO-SEVERE RA: PROSPECTIVE DATA FROM THE REAL-WORLD ACTION STUDY

R. Westhovens<sup>1</sup>, S.E. Connolly<sup>2</sup>, J. Margaux<sup>3</sup>, M. Vanden Berghe<sup>4</sup>, M. Maertens<sup>5</sup>, M. Van Den Berghe<sup>6</sup>, Y. Elbez<sup>7</sup>, M. Chartier<sup>8</sup>, F. Baeke<sup>9</sup>, S. Robert<sup>9</sup>, M. Malaise<sup>10</sup>.  
<sup>1</sup>UZ KU Leuven, Leuven, Belgium; <sup>2</sup>Bristol-Myers Squibb, Princeton, USA; <sup>3</sup>Hôpital Erasme, ULB, Brussels; <sup>4</sup>Grand Hôpital de Charleroi, Charleroi; <sup>5</sup>AZ Damiiaan, Oostende; <sup>6</sup>ASZ Aalst, Wetteren, Belgium; <sup>7</sup>Excelya, Boulogne-Billancourt; <sup>8</sup>Bristol-Myers Squibb, Rueil-Malmaison, France; <sup>9</sup>Bristol-Myers Squibb, Braine-L'Alleud; <sup>10</sup>CHU Sart Tilman, Liège, Belgium

**Background:** With its specific mechanism of action, abatacept (ABA) has shown good efficacy, acceptable safety and is well tolerated in patients (pts) with RA in randomised clinical studies.<sup>1,2</sup> In a chronic disease such as RA, the long-term efficacy and safety of treatment are crucial and require validation in a real-world setting.

**Objectives:** To explore long-term safety and retention in pts with RA treated with IV ABA in routine clinical practice in the Belgian cohort of the AbataCepT In rOuTiNe clinical practice (ACTION) study.

**Methods:** ACTION is a noninterventional, multicentre, prospective, longitudinal study of pts (aged >18 years) with established active moderate-to-severe RA, who initiated IV ABA in routine care.<sup>3</sup> In Belgium, reimbursement criteria require failure with 2 conventional synthetic DMARDs and DAS28 (CRP) >3.7. The primary study objective was retention rate estimated using the Kaplan–Meier method.

**Results:** Overall, 135 Belgian pts from 16 sites (6 [4.4%] first-line biological and 129 [95.6%] second or further line) were enrolled between October 2010 and December 2012. Of these, 131 were evaluable for effectiveness analysis. Pts had a mean (SD) disease duration of 10.5 (9.7) yrs and were at high risk of disease progression: 25.4% of the evaluable pts had erosions (n/n=33/130), 71.6% were anti-cyclic citrullinated peptide positive (n/n=63/88) and 76.7% were RF positive (n/n=79/103). Overall, pts showed high disease activity at baseline according to mean (SD) DAS28 (ESR) 5.21 (1.02), DAS28 (CRP) 4.72 (1.09), CDAI 28.5 (11.1), SDAI 29.9 (11.9) and HAQ-DI score 1.23 (0.65). Patient and Physician Global Assessment of disease were mean (SD) 65.3 (20.95) and 58.02 (21.77), respectively. The overall retention rate (95% CI) was 76% (68.8, 82.5), 64% (54.8, 71.5) and 34% (22.6, 45.4) at 12, 24 and 60 mths, respectively. When temporary discontinuations (>84 days, n=24) were not included in the number of events, retention rates were 80% (72.0, 85.9), 73% (64.0, 79.4) and 51% (40.1, 61.0) at 12, 24 and 60 mths, respectively (Fig). Average DAS28 (CRP) before discontinuation and at restart was stable (3.37 [1.30] vs 3.73 [1.78], respectively [n=12]), suggesting that a temporary discontinuation of >2 consecutive ABA infusions does not seem to have a major clinical consequence. Pts who discontinued ABA due to lack of efficacy (n=37) had significantly shorter disease duration, higher CRP, higher number of prior DMARDs at baseline, mean DAS28 (CRP) of 3.61 (1.17) and DAS28 (ESR) of 4.66 (1.35) at discontinuation. Overall, ABA was generally well tolerated and no new safety signals were identified.

**Abstract AB0462 – Figure 1.** Treatment Retention Rate Over Time (Mths) in Study Population Evaluable for Effectiveness.

**Conclusions:** These real-world data demonstrate an acceptable safety profile for abatacept in Belgian pts with a stable retention rate of up to 5 years in a difficult-to-treat population. A temporary discontinuation also seems feasible.

AB0463

### A REVIEW OF THE OUTCOMES OF WOMEN WITH RHEUMATOID ARTHRITIS (RA) TREATED WITH BIOLOGIC AGENTS ATTENDING THE SHEFFIELD COMBINED OBSTETRICS AND RHEUMATOLOGY CLINIC 2002 TO 2013

R. Smith<sup>1</sup>, R. Kilding<sup>1</sup>, K.-P. Kuet<sup>1</sup>, F. Fairlie<sup>2</sup>, R. Jokhi<sup>2</sup>, T. Bonnett<sup>2</sup>, M. Smith<sup>2</sup>, M. Akil<sup>1</sup>. <sup>1</sup>Rheumatology Department, <sup>2</sup>Obstetrics and Gynaecology, Royal Hallamshire Hospital, Sheffield, UK

**Background:** Women with RA have increased risk of complications including preeclampsia, low birth weight babies and Caesarean sections compared with unaffected women.<sup>1</sup> Higher levels of disease activity have a negative influence on birth weight.<sup>2</sup> More women are being treated with biologic agents, and there is growing evidence for their safe use in pregnancy.<sup>3</sup>

**Objectives:** To assess disease activity during pregnancy, and to review foetal and maternal outcomes.

**Methods:** Retrospective review of case notes.

**Results:** Between 2002 and 2013, 17 women with RA treated with biologic agents attended the combined clinic. 13 were treated with Etanercept, 2 Adalimumab, 1 Tocilizumab and 1 Rituximab. 13 were in combination with disease modifying anti-rheumatic agents (DMARDs). There were 17 pregnancies. 2 women stopped their biologic prior to conception; 14 stopped on confirmation of pregnancy. 12 women had active disease during pregnancy. All had some form of steroid treatment, 3 had a DMARD introduced, and 1 restarted Etanercept at 20 weeks.

There were 14 live births and 2 first trimester miscarriages. There was 1 elective Caesarean section, 7 spontaneous deliveries, and 5 inductions, 3 of which proceeded to Caesarean. Data is missing for 2 women. 10 babies were born at term, 3 were pre-term and data is missing for 2. 2 babies weighed less than 2500 g and 2 more than 4500 g. Data is missing for 3 babies. The low birth weight babies were also pre-term, had cardiac abnormalities and required admission to the neonatal unit. Both mothers had stopped Etanercept at confirmation of pregnancy. Both flared during pregnancy.

6 women developed complications: hypertension, diabetes, proteinuria, cervical incompetence, and hypothyroidism. 4 of these had active disease during their pregnancies. 2 babies had intrauterine growth restriction, 2 cardiac abnormalities and 1 macrosomia. All had mothers who flared during pregnancy.

**Conclusions:** Our group of patients is small, but the outcomes are comparable to those of women with RA. There is no discernible increase in adverse events due to biologic use. In 2014 product recommendations were to stop biologics prior to conception.<sup>4</sup> Since 2016 the British Society for Rheumatology has advised that Etanercept and Adalimumab are compatible with use in the first and second trimesters. Tocilizumab and Rituximab should still be stopped prior to conception.<sup>3</sup> Local practice has changed to reflect this guidance, and the next step in this project is to review the data from more recent pregnancies to determine whether more prolonged use of biologics improves disease control and in turn foetal and maternal outcomes.

**AB0464** 'REAL LIFE' BIOLOGIC DRUG TAPERING RESULTS IN FEW FLARES OF DISEASE AND SIGNIFICANT COST SAVINGS

S. Batool<sup>1</sup>, M. Perry<sup>1</sup>, D. Russell<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pharmacist, NHS, Glasgow, UK

**Background:** The treatment of rheumatic diseases has been revolutionised in the biologic era. Remission and low disease activity are realistic targets. Several trials have suggested that dose reduction is achievable without loss of clinical effect. However, 'real life' response data is still lacking.

**Objectives:**

- To increase interval dose of biologic drugs in a standard rheumatology clinic setting
- To assess the clinical response and determine potential cost savings

**Methods:** Patients were identified by database interrogation and hospital prescription record, from a regional population of 4 00 000 over a 2 year period. All rheumatic conditions treated with anti-TNF and IL-6 blockers were potentially accepted for tapering. Those with low disease activity scores (RA and PsA DAS <2.1, AS BASDAI <4.1) for >1 year were screened and invited to consider dose reduction following discussion in a clinic.

**Results:** 154 biologic patients were screened and 97 contacted to consider dose tapering. Of these, 40 patients agreed to participate in biologic dose reduction. Demographics: Mean age 51 years, 18 male patients and 22 females, concomitant MTX use in 49%. Diagnosis: RA-24, PsA -9, AS- 7. Drugs tapered included Adalimumab (28), Etanercept (5), Golimumab (5) and Tocilizumab (2). 8 patients flared during the programme and response was recaptured in 2 patients after increasing dose. 32 patients were successfully maintained on reduced dose with no requirement to date to increase dosing frequency. Biologic drug was completely withdrawn in 1 patient and 2 patients were commenced on reduced dose of DMARD. Prior to dose reduction mean DAS was 1.91 and mean BASDAI was 2.45. Low disease activity scores were recorded (mean DAS 2.1, mean BASDAI 2.6) post dose reduction (although incomplete data capture). Estimated cost savings are between 170,000 EUR and 340000 EUR for the 2 years.

**Conclusions:** Successful tapering of biologic drugs can be achieved and sustained in non-trial settings for patients with low disease activity. Significant cost savings have been confirmed with likelihood of recurrent savings over future years.

**AB0465** SAFETY AND DURATION OF BIOLOGIC TREATMENT IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS

S. Garrote Corral, A. Garcia Fernandez, P. Moran Alvarez, F.J. Bachiller Corral. Rheumatology, Hospital Ramon y Cajal, Madrid, Spain

**Background:** Several differences may be expected between young and elderly patients with rheumatoid arthritis (RA), safety and efficacy results are variable in the different previous studies.<sup>1,2</sup>

**Objectives:** To compare the duration and safety of biological treatment in patients with RA depending on the age of onset of therapy, in a Spanish tertiary centre.

**Methods:** We conducted a retrospective observational study of patients with a diagnosis of RA who were receiving biologic treatment. They were diagnosed between February 1980 and February 2017, on the basis of criteria ACR/EULAR 2010 or 1987 ACR criteria. The information was obtained from review of medical records. We divided the patients in two groups according to age of the onset of treatment: elderly group ( $\geq 65$  years) and young group (<65 years).

**Results:** 140 patients were included. At the beginning of the treatment 89 were under 65 years and 51 older (65–74 years: 28 patients, >75 years: 23). The average duration of the disease from diagnosis until the beginning of the biological treatment was 103 $\pm$ 91 months in young patients and 142,86 $\pm$ 109,5 months in elderly patients (p: 0,023). We detected no differences between both groups at baseline characteristics, except for comorbidities and sex. DAS28PCR prior to biologic therapy was 5.20 $\pm$ 1.44 in young patients and 5.14 $\pm$ 0.813 in elderly (p: 0,37).

Duration of the treatment was similar in both groups. Suspension of biologic treatment occurred in 50 young patients (56%) and 30 elderly patients (58%) (table 1). The causes are detailed in table 2. Adverse effects were more frequent in the elderly but without statistical significance. There were 9 cases of cancer in elderly patients (17.3%) and 4 cases in young patients (4.6%) p: 0.013. The average diagnosis of cancer prior to the introduction of biologic treatment was 5.8 $\pm$ 7.1 years.

**Abstract AB0465 – Table 1**

	Young patients (<65 years) n=89	Elderly patients ( $\geq 65$ years) n=51	p
Age diagnostic AR (years)	42,87 ( $\pm 11.34$ )	62 ( $\pm 10.65$ )	0.42
Age biological treatment (years)	51,39 ( $\pm 10.32$ )	73,8 ( $\pm 5.30$ )	<0.001*
Sex: female	74 (83.1%)	35 (68,65%)	0.04 *
Comorbidities	0	4 (8.3%)	0.006 *
Heart failure	2 (2.2%)	5 (9.8%)	0,048*
Renal failure			
Type biological	16 (18%)	11 (21%)	0,013*
Infliximab	31 (34.8%)	10 (19.6%)	
Adalimumab	27 (30.3%)	10 (19.6%)	
Etanercept	3 (3.4%)	2 (3.9%)	
Certolizumab	4 (4.5%)	2 (3.9%)	
Abatacept	7 (7.9%)	8 (15.7%)	
Tocilizumab	0	6 (11.8%)	
Rituximab			
Duration treatment(months)	39,98 ( $\pm 41,04$ )	46,31 ( $\pm 33,28$ )	0,095
Adverse events	13 (14.6%)	12 (21.56%)	0.7
Serious/recurrentinfection	6 (46%)	6 (54%)	
Active tumour	0	1 (9.1%)	
Cytopenias	1 (7.1%)	1 (9.1%)	
Skin lesions	3 (23%)	0	
Gastrointestinal symptoms	2 (15%)	1 (9.1%)	

**Abstract AB0465 – Table 2**

	Young patients	Elderly patients	p
Lack of efficacy (<6 months)	10 (20%)	0	0.015*
Lack of efficacy (>6 months)	22 (44%)	10 (33%)	0.55
Adverse event	8 (16%)	8 (26.6%)	0.16
Remission	4 (8%)	4 (13.3%)	0.350

**Conclusions:** Our study corroborate that biologic treatment has similar duration and safety in elderly and young patient.<sup>1,2</sup>

**AB0466** SAFETY OF RITUXIMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS. ELEVEN-YEAR FOLLOW-UP OBSERVATIONAL STUDY

S.D.L.C. Rodriguez García, R. Castellanos-Moreira, M.V. Hernandez-Miguel, A. Cuervo, O. Camacho, V. Ruiz-Esquide, J. Ramirez, J.D. Cañete, J. Gomez Puerta, R. Sanmartí. Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain

**Background:** Rituximab (RTX) is a chimeric monoclonal antibody approved for the treatment of active rheumatoid arthritis (RA) in patients who failed to respond to tumour necrosis factor inhibitors (TNFi). Due to its effect on induction of B cell depletion, the administration of multiple cycles can lead to a decrease in immunoglobulins (Ig) which may increase the risk of infection.

**Objectives:** To assess the long-term safety of RTX in patients with RA and to evaluate factors associated with the presence of infections.

**Methods:** A retrospective observational study was conducted including patients with RA treated in a tertiary hospital between June 2006 and May 2017 who had received at least one RTX cycle. At RTX initiation we analysed: age, sex, comorbidities and Charlson score, disease duration, presence of rheumatoid factor (RF)/anti-citrullinated protein antibodies (ACPA), disease activity (DAS28), acute phase reactants (CRP, ESR), previous biological treatments; concomitant treatment (csDMARD/glucocorticoids (GC)). Serum Ig levels before every RTX cycle, the number of RTX cycles and adverse events (AE), including serious and opportunistic infections were also analysed.

**Results:** We included 53 patients (86.8% women, mean age 55.5±13.5 years), 58% with a Charlson score ≥3. Mean disease duration was 16±9.1 years; 84.9% and 92.5% were RF and ACPA positive, respectively.

Before starting RTX, 81% of patients had received other biologic drugs (58.5% ≥ 2), 88% received concomitant csDMARD, (52% methotrexate and 32% leflunomide) and 81% were treated with GC (median dose 10 mg, P<sub>25-75</sub> 5–10 mg). The median number of RTX cycles received per patient was 5 (P<sub>25-75</sub> 2–6).

80 AE were reported: 12 infusion reactions, 8 cases of neutropenia, 51 infections (18 respiratory, 8 urinary, 4 skin and soft tissues, 8 gastrointestinal, 4 cases of non-disseminated *herpes zoster*, 1 bacteremia, 2 septic shock and 6 other) of which 19 were serious, and 5 malignancies (2 melanomas, 2 cervix, and 1 bladder) were also notified. No opportunistic infections were reported.

Ig levels were obtained for 41 subjects: 7, 5 and 1 patients had low levels of IgG, IgM and IgA, respectively.

Patients who developed infections received a greater number of RTX cycles (p<0.0002) and had more frequently low levels of serum IgG during follow-up (p<0.044) than those who did not have infections.

**Conclusions:** Long-term exposure to RTX showed a good safety profile with a low incidence of serious infectious and no opportunistic infections.

Factors associated with the development of infections were the number of cycles received and low serum levels of IgG at any point during follow-up.

#### AB0467 SUSTAINED CLINICAL RESPONSE IN REFRACTORY RHEUMATOID ARTHRITIS PATIENTS WITH A LOW-DOSE RITUXIMAB RETREATMENT REGIMEN

S.D.L.C. Rodríguez García, R. Castellanos-Moreira, M.V. Hernandez-Miguel, A. Cuervo, V. Ruiz-Esquide, J. Ramirez, O. Camacho, J.D. Cañete, J. Gomez Puerta, R. Sanmarti. *Rheumatology, Hospital Clinic de Barcelona, Barcelona, Spain*

**Background:** The standard dose of rituximab (RTX) in rheumatoid arthritis (RA) is two intravenous (iv) 1 g infusions, separated by two weeks. Recently, the efficacy of a low-dose of RTX for retreatment in RA patients has been reported.<sup>1</sup>

**Objectives:** Our aim was to assess the long-term sustained effectiveness of a low-dose of RTX in daily clinical practice.

**Methods:** Observational retrospective study including all RA patients treated on a tertiary hospital who had received at least one cycle of RTX, at the standard dose, between June 2006 and May 2017. We selected those patients who achieved a good or moderate EULAR response and thereafter were down-titrated to a low-dose regimen (1 g). Variables analysed: age, sex, disease duration, presence of ACPA (antiCCP2) and rheumatoid factor (RF), glucocorticoid (GC) and conventional synthetic DMARD (csDMARD) use and dosage before and after RTX treatment, number of biologic DMARD (bDMARD) used prior to initiating RTX. Disease activity was measured using DAS28 index (prior to first RTX infusion, at low-dose regimen initiation and at last follow-up visit).

**Results:** 53 patients received, at least, one cycle of 2 g RTX, 70% achieved a good or moderate EULAR response and were stepped-down to a low dose retreatment regimen. Baseline characteristics of patients receiving low-dose RTX were: mean age 56.4±10.9 years; 13.5% male, mean disease duration 12.7±9.8 years, 91.9% RF + and 97.3% ACPA +; mean DAS28 prior to RTX initiation 5,79 ±1,17.

73% of patients had received other bDMARD before RTX, 48% 2 or more. 92% were on cs-DMARDs, 51.4% methotrexate (MTX) and 37.8% leflunomide (LEF) and 86.5% were receiving concomitant GC (median dose 10 mg, P<sub>25-75</sub> 5–10 mg). 73% of subjects received only one standard cycle before RTX dose reduction.

Mean DAS28 decreased significantly between the first visit on 1 g RTX vs the last follow-up visit (4.08 vs 3.04; p<0.0001). Additionally, 11 patients (8 MTX, 3 LEF) were able to reduce csDMARD dosage, 56.3% of patients receiving GC at the initiation of low-dose retreatment were able to reduce the dose (median 10 mg vs 5 mg; p<0.0001), and 28% discontinued GC therapy.

After a mean follow-up of 3±1.8 years, RTX was withdrawn in 10 patients: 8 due to adverse events (recurrent infections in 4) and 2 cases due to loss of efficacy.

**Conclusions:** A sustained clinical response was observed with the 1 gr retreatment of RTX after a long-term follow-up period.

#### AB0468 CLINICAL AND ULTRASONOGRAPHIC EFFECTIVENESS IN TWO COHORTS OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT: A REAL LIFE STUDY

S. Parisi, M.C. Ditto, M. Scarati, M. Priora, C.L. Peroni, E. Fusaro. *Rheumatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy*

**Background:** Synovitis in Rheumatoid Arthritis (RA) is a phenomenon related to the development of erosions and progressive structural damage; early synovitis improvements are successfully associated with long-term clinical and structural outcomes.

**Objectives:** The aim of this study was to evaluate the efficacy of abatacept in two cohort of patients treated with Abatacept as the first and second or third line of treatment.

**Methods:** We evaluated patients affected by RA (according to ACR 2010 criteria) and were divided into two groups:

**Group A:** patients with moderate or severe active RA, non-responders to Methotrexate (MTX), bDMARDs naïve, treated with Abatacept 125 mg/wk;

**Group B:** patients with moderate or severe active RA, non-MTX and anti-TNF responders, treated with Abatacept 125 mg/wk;

The concomitant treatment with MTX was maintained unchanged in those patients who were taking it at stable doses before the start of the study (10–15 mg/week for ≥28 days); concomitant therapies such as low-dose systemic CS (prednisone ≤7.5 mg/day) and NSAIDs have been maintained for at least 4 weeks if stable. The activity of RA was calculated with the DAS28-CRP according to the clinical practice protocol (week 0,4,12,24). The Ultrasound (US) evaluation of the synovitis was done according to the Omeract criteria (Grey Scale and PDUS score: 0 to 3).

**Results:** We recruited consecutively 34 patients with RA, 16 pts (male n=4; 25,00%) took Abatacept as the first line (Group A), and 18 pts (males n=5; 27,70%) took Abatacept as followed by another anti-TNF drugs (Group B). The mean age was 57.2±10.7 years (median 60, range 45–72); mean of DAS28 at baseline was 4.8±0.9 (median 4.7; range 3.9–5.6); mean duration of the disease was 15.3±5.7 years (median 10; range 3–22). Tab.1

A constant improvement of the DAS28 score is shown in both groups examined until the end of the follow up, resulting respectively -Δ 2.0 for Group A (p<0.05) and -Δ 2.1 (p<0.05) for Group B. The total PDUS score decreased in both groups from week 4, with a mean change (95% CI) compared to baseline of -0.8 (range -1.4/-0.2) and progressive mean significant improvement until follow-up (Gr.A p<0.05; Gr.B p<0.05). No serious adverse events or infections were observed. Patients with ACPA positive showed a greater improvement trend compared to other patients in both groups (p: 0,068). Figure 1.

**Abstract AB0468 – Table 1.** Cohort of patients at baseline

Characteristics	Group A (Abatacept 1 <sup>st</sup> line)	Group B (Abatacept 2 <sup>nd</sup> or 3 <sup>rd</sup> line)
Patients (n <sup>o</sup> )	16	18
Age (mean±SD), yy	44,20 (±8,7)	56,10 (±10,6)
Female (%)	76,00%	77,00%
Disease Duration (mean±SD), yy	7,80 (±5,3)	12,70 (±5,6)
DAS28-CRP (mean±SD)	5,10 (±0,9)	4,90 (±1,1)
PDUS score (mean±SD)	12,30 (±2,5)	12,60 (±3,1)

Abstract AB0468 – Figure 1. PDUS evaluation of two cohorts with ACPA positive

**Conclusions:** The treatment with Abatacept, administered in the first or second or third line, has shown significant efficacy in reducing the synovial inflammation in patients with RA, monitored with clinical and ultrasonographic outcome. Moreover, we have not demonstrate statistically significant differences between two groups into the timing of improvement.

#### AB0469 EFFICACY AND SAFETY OF INTERLEUKIN 6 INHIBITORS IN RHEUMATOID ARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

T. Oton<sup>1</sup>, E. Loza<sup>2</sup>, R. Sanmarti<sup>3</sup>, J. Tornero Molina<sup>4</sup>. <sup>1</sup>Instituto de Salud Musculoesquelética; <sup>2</sup>Instituto de Salud Musculoesquelética, Madrid; <sup>3</sup>Rheumatology, Hospital Universitari Clínic, Barcelona; <sup>4</sup>Rheumatology, Hospital de Guadalajara, Guadalajara, Spain

**Background:** Interleukin 6 (IL-6) inhibitors constitute a therapeutic option for patients with rheumatoid arthritis (RA). Currently, apart from Tocilizumab (TCZ), we have data from other drugs targeting the IL-6 pathway.

**Objectives:** To review published evidence on safety and efficacy of IL-6 inhibitors in RA.

**Methods:** We performed sensitive systematic literature searches in Medline and Cochrane (up to October 2017), screened EULAR and American College of Rheumatology meeting-abstracts. An expert librarian designed the strategies that included Mesh and text word terms. The search was limited to human RA, adults and the English and Spanish language. The inclusion criteria were as follow: 1) RA patients on IL-6 Inhibitors including TCZ, sarilumab (SAR), olokizumab, sirukumab and clazakizumab; 2) Placebo and an active comparator were accepted as comparators; 3) Articles including typical efficacy and safety variables such as DAS-28, radiographic progression or the infections rate; 4) Only meta-analyses, systematic reviews and clinical trials were selected. Two reviewers screened the titles and abstracts of the retrieved articles independently. They also collected the data from the studies included by using ad hoc standard forms. All collection was double by article and independent. Subsequently, a secondary manual search of the bibliography of the articles that were finally included was performed. Evidence tables were produced. The quality was evaluated with the Oxford 2009 scale.

**Results:** We included 64 articles of moderate-high quality, variable duration, between 12 and 108 weeks. These articles analysed more than 8000 patients with RA, most of them with established RA (although there are data on early RA), with high disease activity and severity criteria. More than a half of the studies are of TCZ. IL-6 inhibitors were effective both in the short and long term in terms of clinical remission, RA activity, radiographic progression, function, fatigue, bone metabolism, morning stiffness, pain, quality of life, or anaemia. They also decreased and even normalised CRP values in a rapid and sustained manner. The efficacy of blocking IL-6 has been seen in RA refractory to DMARD or anti-

TNF $\alpha$  and in MTX-naïve patients, as well as in the intravenous and subcutaneous formulations (TCZ). TCZ and SAR are more effective than adalimumab in monotherapy. In general, no statistically significant differences were found between combined therapy and monotherapy. In terms of safety, the rate of adverse events increased over time and with the concomitant use of DMARDs. Infections and hypersensitivity reactions were the most frequent adverse events and infections the most frequent serious adverse events. IL-6 inhibitors were associated with a rapid and subsequently sustainable increase in serum lipid parameters, although this was not associated with a higher prevalence of cardiovascular events and related mortality, nor was it associated with neoplasms. Transaminase elevations were generally mild and without serious disorders. The incidence of gastrointestinal perforations was very low, and it was associated with a previous history of diverticulitis.

**Conclusions:** IL-6 inhibitors are effective to control RA activity and symptoms and to prevent radiographic damage in different disease profiles, with an acceptable safety profile.

#### AB0470 INFLUENCE OF USING ADALIMUMAB IN COMPLEX TREATMENT ON FREQUENCY OF EYES INVOLVEMENT IN PATIENTS WITH JIA

T. Marushko, O. German, J. Golubovska. *National Academy of postgraduate education named after P.L. Shupik, Kyiv, Ukraine*

**Background:** Extra-articular organs involvement in JIA is frequent and mostly includes rheumatoid uveitis in ANA-positive oligoarthritis. In Ukraine almost 10% of children with JIA during systematic ophthalmologic examination have signs of ocular involvement. Early treatment with biological agents can influence inflammation progression in eyes of the JIA patients

**Objectives:** Objective of the study was to investigate the frequency of recurrences of uveitis in patients with JIA and eyes involvement on methotrexate alone and methotrexate with adalimumab.

**Methods:** There were 23 patients with JIA and rheumatoid uveitis involved into the study. Mean age was 9,6 (4–16) years. Among them there were 14 (61%) girls and 9 (39%) boys. Serological characteristic included 17 (74%) patients with positive ANA, and 3 (13%) children with positive HLA-B27. All patients received 15 mg/m<sup>2</sup>/week of SC methotrexate. During onset and recurrence of uveitis all children received glucocorticoids with slowly tapering dosage (from 1 mg/kg/day to 0.2–0.1 mg/kg/day) until uveitis remission. Of 23 patients 11 (47,8%) received adalimumab in standard doses. Study were hold for 5 years during which every child were investigated by ophthalmologist every 3 months irrespectively of clinical status.

**Results:** During 5 year follow up in "methotrexate" group (n=12) there were 15 episodes of uveitis recurrence (0,25 episodes per patient/year). Of them 10 (66,6%) were revealed only by ophthalmological assessment and had no obvious clinical signs (subclinical uveitis). Same time only 2 episodes of uveitis recurrence were registered in "methotrexate +adalimumab" group (0,04 episodes per patient/year) (p<0.05).

**Conclusions:** Adding adalimumab to methotrexate in complex treatment of patients with JIA and eyes involvement allows decreasing frequency of both clinically evident and subclinical recurrences of rheumatoid uveitis.

#### AB0471 BIOSIMILAR MEDICINE IS ACCEPTABLE TO PATIENTS IF RECOMMENDED BY A RHEUMATOLOGIST IN AN AUSTRALIAN TERTIARY RA COHORT

T. Kovitwanichkanont<sup>1,2</sup>, D. Wang<sup>2,3</sup>, S. Raghunath<sup>2,3</sup>, L. Kyi<sup>2</sup>, N. Walpola<sup>3</sup>, S. Pignataro<sup>2</sup>, S. Morton<sup>2</sup>, E. Morand<sup>2,3</sup>, M. Leech<sup>2,3</sup>. <sup>1</sup>University of Sydney, Sydney; <sup>2</sup>Monash Health; <sup>3</sup>Monash University, Melbourne, Australia

**Background:** Advancement in biological disease-modifying antirheumatic drugs (bDMARDs) has greatly improved the prognosis of patients with rheumatoid arthritis. Their high costs, however, pose a significant health-economic challenge. Biosimilars are being adopted in Australia and worldwide to improve affordability and access to treatment. While the predominant focus of current literature has been on physicians' awareness and confidence of biosimilars, an effective introduction of biosimilars requires an understanding of patient acceptance of these products.

**Objectives:** To investigate patient awareness and attitudes to biosimilar medicine in a tertiary hospital RA clinic.

**Methods:** A cross-sectional study of 127 patients with rheumatoid arthritis was performed in Melbourne, Australia. A brief education on biosimilars was provided. Patients rated concerns regarding biosimilar efficacy, side-effect profile, operation

of the medication, and general attitude towards the new medication on a ten-point scale.

**Patients willing to take generic medicines**

**Patients unhappy to take generic medicines**

Abstract AB0471 – Figure 1

**Results:** 45.2% of our cohort have received biological DMARDs. Although only 5.6% have some knowledge of biosimilars, 75.4% would accept biosimilars if their rheumatologist recommends it, with only 5.6% refusing to switch. 19% of patients were unsure. Of those refusing biosimilars, the main concerns related to efficacy and general concerns about change. In our RA cohort, 61.9% took generic medicines regularly and 84.6% of these they would also be comfortable taking biosimilars. In those refusing generic medicines (27%), 61.8% would be still comfortable taking biosimilars. 15.9% and 12.7% of patients had great concerns about the efficacy and safety profile of biosimilars, respectively. 26.2% were significantly worried that their physician may be unaware if they were receiving the biosimilar or reference product.

**Conclusions:** Despite being unfamiliar with biosimilars, most patients in our cohort would be comfortable taking biosimilars if recommended by their rheumatologist, highlighting the role of trust in doctor-patient relationships. Of patients usually refusing generic medicines, nearly two-thirds would still accept biosimilars. Almost a quarter of the patients were unsure about the use of biosimilars and many patients indicated that they would like more information regarding these products. This patient group offered the opportunities to improve the uptake rate of biosimilars by allaying their concerns through information-education strategies. The current legislation in Australia allows pharmacists to substitute biological DMARDs in consultation with the patient without informing the prescriber. This concerns nearly all (89%) prescribers in Australia. The majority of patients in our study were not concerned, whilst approximately one quarter were worried about unrecognised switching. A successful introduction of biological DMARDs is likely to improve patient access to effective biological therapy and to ensure sustainability of the healthcare budgets.

AB0472

**PHARMACODYNAMIC EFFECT AND SAFETY OF SINGLE-DOSE SARILUMAB SC OR TOCILIZUMAB IV OR SC IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA)**

T. Ishii<sup>1</sup>, Y. Sato<sup>2</sup>, Y. Munakata<sup>3</sup>, M. Kajiwara<sup>4</sup>, Y. Takahashi<sup>4</sup>, F. Anwar<sup>5</sup>, A. Paccaly<sup>6</sup>, P. Kovalenko<sup>6</sup>, J. Parrino<sup>6</sup>, A. Boyapati<sup>6</sup>, C. Xu<sup>5</sup>. <sup>1</sup>Tohoku University Hospital, Tohoku, Japan; <sup>2</sup>Sendai Medical Imaging Clinic, Sendai, Japan; <sup>3</sup>Munakata Yasuhiko Clinic, Sendai, Japan; <sup>4</sup>Sanofi K.K., Tokyo, Japan; <sup>5</sup>Sanofi Genzyme, Bridgewater, NJ, USA; <sup>6</sup>Regeneron Pharmaceuticals, Inc, Tarrytown, NY, USA

**Background:** Two studies (PDY14191 [NCT02404558]: randomised, open-label, Japanese patients; 6R88-RA-1309 [NCT02097524]: randomised, open-label, non-Japanese patients) assessed the pharmacodynamic profiles of two monoclonal antibody blockers of IL-6Rα, sarilumab and tocilizumab.

**Objectives:** To evaluate the pharmacodynamics of absolute neutrophil count (ANC), C-reactive protein (CRP), IL-6, soluble IL-6R (sIL-6R), and safety after a single dose of subcutaneous (SC) sarilumab, or intravenous (IV) or SC tocilizumab in patients with RA.

**Methods:** 30 Japanese patients (PDY14191) were randomised 1:1 and received a single injection with SC sarilumab 150 mg or SC tocilizumab 162 mg without background medication. 101 non-Japanese patients (6R88-RA-1309) were randomised 1:1:1:1 and received a single dose of SC sarilumab (150 or 200 mg) +methotrexate (MTX), or IV tocilizumab (4 or 8 mg/kg)+MTX. Pharmacodynamic and safety outcomes were assessed through Week 6.

**Results:** Baseline demographics were comparable between studies except for higher mean body weight in non-Japanese patients (mean 83 vs 57 kg). Although there were numeric differences in baseline pharmacodynamic parameters in the two studies, onset of effects on ANC, CRP, IL-6, and sIL-6R during the first week after a single drug dose were similar regardless of drug, dose, or route of administration in both studies. Within both studies, maximal effects on ANC and CRP nadir and on IL-6 and total sIL6-R peaks were comparable for sarilumab and tocilizumab (table 1). The pharmacodynamic response was more prolonged with IV tocilizumab. Time for pharmacodynamic effects to return to baseline was consistent with the dosing intervals for SC sarilumab (q2w), and IV (q4w) and SC (q2w) tocilizumab. The safety profiles of sarilumab and tocilizumab were generally similar and both drugs were associated with laboratory effects consistent with their mechanism of action (ie, decrease in neutrophil count). There was a dose-dependent effect on ANC<1.0 Giga/L in study 6R88-RA-1309 and numeric differences in ANC<1.0 Giga/L between sarilumab and tocilizumab in PDY14191. The decrease in ANC was not associated with increased risk of infections.

Abstract AB0472 – Table 1. Baseline and change in pharmacodynamic parameters, and safety in studies 6R88-RA-1309 and PDY14191

### IMMUNOGENICITY OF BIOSIMILARS FOR RHEUMATIC DISEASES: AN UPDATED REVIEW FROM REGULATORY DOCUMENTS AND CONFIRMATORY CLINICAL TRIALS

V. Strand<sup>1</sup>, J. Goncalves<sup>2</sup>, T.P. Hickling<sup>3</sup>, H. Jones<sup>4</sup>, L. Marshall<sup>4</sup>, J. Isaacs<sup>5</sup>.  
<sup>1</sup>Stanford University School of Medicine, Palo Alto CA, USA; <sup>2</sup>iMed-Research Institute for Medicines, Faculdade de Farmácia da Universidade de Lisboa, Lisboa, Portugal; <sup>3</sup>Biomedicine Design, Pfizer, Andover, MA; <sup>4</sup>Inflammation and Immunology, Pfizer, Collegetown, PA, USA; <sup>5</sup>NIHR Newcastle Biomedical Research Centre, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle upon Tyne, UK

**Background:** Several biosimilars have been approved for the treatment of rheumatic diseases by the European Medicines Agency (EMA) or the US Food and Drug Administration (FDA).

**Objectives:** To summarise immunogenicity data from regulatory documents or confirmatory trials of biosimilars approved by the EMA or FDA for the treatment of rheumatic diseases.

**Methods:** EMA Public Assessment Reports (EPARs), FDA Clinical Summaries, PubMed records, and EULAR and ACR abstracts were searched for immunogenicity data from confirmatory trials of approved TNF $\alpha$  or CD20 inhibitor biosimilars in patients with rheumatic diseases. Data collected included the proportion (%) of patients positive for anti-drug antibodies (ADABs) among all patients and the proportion (%) of patients with neutralising antibodies (nAbs) among ADAB-positive patients.

**Results:** We identified 10 biosimilars approved by the EMA or FDA: three each for adalimumab (BI 695501, SB5, and ABP 501) and infliximab (SB2, CT-P13, and infliximab-qbtx) and two each for etanercept (GP2015 and SB4) and rituximab (CT-P10 and GP2013). The duration of treatment periods in the 16 identified trials (which varied in design and methodology of ADAB/nAb detection) ranged from 12 weeks to 102 weeks. Across treatment groups in all trials, 0% to 62% of patients were ADAB-positive, of whom 0% to 100% were also nAb-positive. The lowest proportions of ADAB-positive (0%–13%) and nAb-positive patients (0%–3%) were observed in the trials of etanercept and its biosimilars, and the highest in the trials of infliximab and its biosimilars (ADABs: 20%–62%; nAbs: 88%–100%). Consistent with the biosimilar designation, the proportions of ADAB- and nAb-positive patients in individual trials were similar between the originator and biosimilar products. Of note, in a 52 week trial of etanercept and its biosimilar SB4, the incidence of ADAs by Week 52 was significantly lower with SB4 than with etanercept (1% [3/299] vs 13% [39/296],  $p < 0.001$ ). However, as noted in the SB4 EPAR, this difference, which was not reflected in the incidence of nAbs and efficacy or safety of etanercept, may have been due to an ADAB assay bias in samples collected at Weeks 4 and 8, when 37/39 ADABs in the etanercept group and 2/3 in the SB4 group were detected.

**Conclusions:** Immunogenicity of the approved biosimilars is generally similar to that of originator products. For ETN, which has been associated with relatively low

ADAB levels, there was a discrepancy in ADAB incidence compared with its biosimilar SB4, but those differences were transient and did not affect clinical activity or safety.

### THE CLINICAL EFFECTIVENESS AND COST SAVINGS OF TAPERING BIOLOGIC DMARDs IN PATIENTS WITH INFLAMMATORY ARTHRITIS AT A UK DISTRICT GENERAL HOSPITAL

W.P. Lee, R. Manhas, V. Sebbage, S. Kyle. *Rheumatology, North Devon District Hospital, Barnstaple, UK*

**Background:** Biologic DMARDs (bDMARDs) have led to substantial improvement in clinical outcomes for treatment of rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial/peripheral spondyloarthritis (SpA), making remission a realistic target. Current guidelines suggest clinicians should consider tapering after achieving remission in RA.<sup>1</sup> Nevertheless, the optimal approach for tapering bDMARDs remains unknown and un-standardised across conditions.<sup>2</sup>

**Objectives:** To evaluate the tapering strategies on 3 major rheumatological disease entities (RA, PsA, SpA), the number of patients successfully tapered and the total cost saving from successful tapering.

**Methods:** The study was conducted at North Devon District Hospital in Barnstaple, UK and includes all bDMARDs users up until 31st December 2017. The tapering strategy was identified from hospital notes. Patients who are deceased, lost to follow-up or discontinued bDMARDs due to contraindication or adverse effects were excluded. Successful tapering is defined as patient on tapered dose or had their biologics withdrawn and remains at target treatment level (RA: DAS-28 <2.6; PsA: <3 tender joints and <3 swollen joints; SpA: BASDAI <4).

**Results:** There are a total of 298 patients: 174 RA; 59 PsA; 57 SpA; 8 other diagnoses. 94 patients (31.5%) had attempted tapering: 52 RA, 18 PsA, 22 SpA. 60 (20.1%) successfully tapered their bDMARDs: 34 RA (56.7%); 13 PsA (21.7%); 13 SpA (21.7%). Out of 34 RA, 30 seropositive; 4 seronegative; 24 co-prescribed with synthetic DMARDs, 10 on monotherapy. Out of 13 PsA, 8 co-prescribed with synthetic DMARDs; 5 on monotherapy.

59 tapered by increasing interval of subcutaneous treatment. Only 1 RA patient tapered its IV dose of tocilizumab. This patient is excluded from the final analysis. Tapering of subcut bDMARDs therapy by disease and price (table 1). Number rounded to 2 decimal points.

Abstract AB0474 – Table 1

Disease	bDMARDs	No. of patients	Usual dose of interval (days)	Mean tapered dose interval (days)	Mean period of tapering (months)	% saving per unit biologic	Cost per unit biologic (£)	Cost Saving per patient (£)	Total cost saving (£)

#### THE INFLUENCE OF SWITCHING FROM ETANERCEPT ORIGINATOR TO ITS BIOSIMILAR ON EFFECTIVENESS AND THE IMPACT OF SHARED DECISION MAKING ON RETENTION AND WITHDRAWAL RATES

W.D. Müskens<sup>1</sup>, S.A.A. Rongen-van Dartel<sup>1,2</sup>, E. Adang<sup>3</sup>, P.L. van Riel<sup>1,2</sup>. <sup>1</sup>*IQ Healthcare, Radboud UMC, Nijmegen*; <sup>2</sup>*Rheumatology, Bernhoven, Uden*; <sup>3</sup>*Health Evidence, Radboud UMC, Nijmegen, Netherlands*

**Background:** With biological patents expiring, biosimilars are becoming a realistic, less costly alternative to their originator. The data from numerous randomised clinical trials support that it is safe, effective and cost saving to switch to a biosimilar. However, real world data about efficacy, safety, and cost-effectiveness of such a switch are lacking.

Since shared decision making (SDM) is a key factor in the treatment of rheumatic diseases, a non-mandatory open label transitioning from Etanercept originator to its biosimilar was performed at the rheumatology department of Bernhoven.

**Objectives:** The first goal of this study was to investigate the effect of switching from Etanercept originator to its biosimilar on the effectiveness of treatment. The second aim was to analyse the effect of SDM on the 1 year retention rates and reasons for withdrawal in daily clinical practice.

**Methods:** All patients with rheumatoid arthritis (RA), axial spondyloarthritis (SpA) and psoriatic arthritis (PsA) that were using Etanercept originator between 01–06–2016 and 23–10–2017 were informed by letter of the possibility to switch to its biosimilar. During the next outpatient visit with their rheumatologist the possibility to switch was discussed. Patients had the opportunity to ask questions regarding biosimilars and the switch to a biosimilar. If patients agreed the switch was made, with the reservation that they could switch back to the originator if they encountered difficulties with the biosimilar.

Using the registry of the rheumatology department at Bernhoven data were collected on disease activity (DA), medication use and adverse events from the moment of switch till 23–10–2017. As measure for DA the DAS28 was used for RA and PsA, the ASDAS was used for SpA. Stop reasons for biosimilars were verified using the health record system of the hospital. Reasons for change in disease activity and discontinuation of biosimilar treatment were assessed.

**Results:** Between 01–06–2016 and 23–10–2017 80% (69 patients) of the Etanercept originator users switched to its biosimilar. These patients switched to biosimilar after a median time of 5.1 (IQR 2.8–8.3) years. By 23–10–2017, median follow-up of 307 (IQR 196–357) days, the mean DA did not significantly differ from the DA at baseline, 3.1 (95%>CI 2.5–3.7) vs. 2.8 (95%>CI 2.5–3.1). At end of follow-up 25% of the patients had discontinued their treatment and either switched back to originator (18%), switched to another biological (3%) or stopped treatment with biologics (4%).

Reasons for switching back to originator were adverse events (58%), lack of effect (17%) and “adverse event and lack of effect” (25%). Only one serious adverse event was reported. This was a drug hypersensitivity reaction. After the patient was recovered, the originator was restarted without any difficulties.

**Conclusions:** An open label non-mandatory switch from Etanercept originator to its biosimilar showed that around 80% of the patients is willing to perform this switch. Switching did not affect effectiveness of treatment during one year follow-up. 75% of the patients were able to continue biosimilar therapy. In the 69 patients that switched only one serious adverse effect occurred.

AB0476

#### THE EFFICACY OF IMMUNOADSORPTION WITH INFlixIMAB THERAPY ON THE MODULATION OF DISEASE ACTIVITY IN PATIENTS WITH SEVERE RHEUMATOID ARTHRITIS

X. Kong, Y. Xing, C. Liu, M. Zhao. *the Second Affiliated Hospital of Dalian Medical University, Dalian, China*

**Background:** Active refractory rheumatoid arthritis (RA) is common in real-world. Patients with active refractory RA usually have poor prognosis. And they respond poorly to a variety of therapies. The arrival of remission or low disease activity

(LDA) as soon as possible is an important way to improve their prognosis. We investigated the effectiveness of immunoadsorption therapy, a novel blood purification treatment, as a rapid and sustained disease-modifying therapy for active refractory RA.

**Objectives:** To evaluate the efficacy of additional immunoadsorption therapy (2 times) besides infliximab (IFX) on disease remission in patients with active refractory RA.

**Methods:** 90 patients with severe RA were included in this study. 43 patients were treated with basic IFX 3 mg/kg+methotrexate (MTX) therapy, and other different 47 patients, besides of basic therapy, were previous given 2 times additional immunoadsorption therapy. IFX 3 mg/kg was infused at weeks 0, 2, 6, 14, 22 and 30. Age, sex ration, mean disease duration and core index of disease activity in two treatment groups were collected at weeks 0, 2, 6 and 30 weeks to compare the efficacy and safety of combined immunosorbent therapy in the treatment of severe RA.

**Results:** The baseline age, sex ration and core indexes of disease activity were comparable between the two treatment groups ( $p > 0.05$ ). After treatment, the core indexes of disease activity of all patients decreased significantly compared with their baseline levels ( $p < 0.05$ ). The degree of reduction in the combined therapy group was significantly better than that in the basic treatment group ( $p < 0.05$ ), and the proportion of ACR remission patients in the combined treatment group was higher than that in the basic treatment group at different stages after treatment.

**Conclusions:** Additional immunoadsorption therapy can rapid relive the disease activity of severe RA patients, and the remission rate of 30 W was significantly higher than only IFX treatment. However, due to the limited sample size of this study, the efficacy of additional immunoadsorption needs further observations.

#### INHIBITION OF LARGE JOINT DESTRUCTION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB

Y. Hirano, K. Hattori, R. Yamada. *Rheumatology, Toyohashi Municipal Hospital, Toyohashi, Japan*

**Background:** Rheumatoid arthritis (RA) causes not only inflammation of small joints, such as hands and feet, but also inflammation of large joints. Destruction of large joints is correlated with impairments of physical activity in RA patients more than destruction of small joints is<sup>(1)</sup>. We experience strong inhibitory effect of inflammation in synovial joints, not only small joints but also large joints, by treatment with tocilizumab (TCZ), an antibody to IL-6 receptor in RA patients in daily clinical practice. Although inhibitory effects of small joint destruction by TCZ is well known, inhibitory effects of large joint destruction is unknown.

**Objectives:** This retrospective study investigated inhibitory effect of large joint destruction by TCZ treatment in RA patients.

**Methods:** Toyohashi RA database (TRAD) was used. TCZ was initiated in 65 RA patients in our institute. 31 cases (23 female and 8 male) who continued TCZ over 2 years were utilised in this study. Baseline characteristics and time course of disease activity were investigated. Delta-modified Sharp score ( $\Delta$ mTSS) per year was used to evaluate small joint destruction. ARASHI score<sup>(2)</sup> was used to evaluate large joints destruction. Shoulders, elbows, hips, knees and ankles were evaluated using ARASHI score.

**Results:** Treatment continuation rate of TCZ was 86.3% at one year and 77.7% at two years in whole 65 cases (Kaplan-Meier methods). Baseline characteristics of 31 cases was as followed. Average age: 56 years old. Average RA duration: 6.6 years. Concomitant rate of MTX: 74.2%. Concomitant rate of prednisolone:

64.5%. Order of TCZ: 1st biologics in 9 cases, 2nd biologics in 9 cases, 3rd biologics in 13 cases. Rates of symptomatic joints (pain or swelling): 45.1% in shoulders, 44.6% in elbows, 0.0% in hips, 51.9% in knees and 37.7% in ankles. Average CDAI was 23.3 at baseline, 6.8 at one year and 5.0 at two years. Average  $\Delta$ mTSS was 8.1 at baseline, 2.7 from baseline to one year and 1.1 from one year to two years. Evaluation using ARASHI change score from baseline to two years was as followed [worsened, not changed, improved (%)]. Shoulders (51 joints) [9.8, 86.3, 3.9]. Elbows (56 joints) [12.5, 73.2, 14.3]. Hips (53 joints) [0, 94.3, 5.7]. Knees (52 joints) [9.6, 65.4, 25.0]. Ankles (53 joints) [3.8, 91.6, 5.7]. Joint surgery was not performed in evaluated joints during study periods. Influence of symptoms at baseline on large joint destruction: There was a significant difference between ARASHI change score in symptomatic knee joints and that in non-symptomatic joints (-0.5 vs. 0.1,  $p < 0.01$ ).

**Abstract AB0477 – Figure 1.** Evaluation of large joint destruction using ARASHI score during two-year tocilizumab treatment

**Conclusions:** Over 90% of large joints was not destructed during two-year TCZ treatment. Improvement was frequently observed in knees and elbows. Major reasons of improvement of joint destruction were stabilisation of joints by osteophyte formation and repair of bone erosions.

## Rheumatoid arthritis – non biologic treatment and small molecules

### AB0478 MILD AND MODERATE HEPATIC IMPAIRMENT HAVE NO CLINICALLY RELEVANT IMPACT ON UPADACITINIB PHARMACOKINETICS: RESULTS FROM A DEDICATED PHASE 1 STUDY

M.-E.F. Mohamed, S. Coppola, T. Feng, A.P. Lacerda, A.A. Othman. *AbbVie, North Chicago, USA*

**Background:** Upadacitinib is a selective Janus kinase 1 (JAK1) inhibitor being developed for the treatment of several inflammatory diseases, including rheumatoid arthritis (RA). Upadacitinib efficacy was demonstrated in Phase 2 studies in RA, Crohn's disease, atopic dermatitis, in addition to three completed Phase 3 trials in RA. Upadacitinib is a non-sensitive substrate for hepatic metabolism by cytochrome P450 3A; however, 38% and 24% of upadacitinib immediate-release dose are eliminated unchanged in faeces and urine, respectively. Since, there is a potential for upadacitinib use in some patients with hepatic impairment, evaluation of impact of hepatic impairment on upadacitinib exposure is of key clinical relevance. Doses of 15 mg and 30 mg once daily (QD) using upadacitinib extended-release formulation have been evaluated in Phase 3 trials in RA.

**Objectives:** To evaluate the effect of mild and moderate hepatic impairment on the pharmacokinetics of upadacitinib.

**Methods:** This was a Phase 1, open-label study in subjects with mild (n=6) or moderate (n=6) hepatic impairment, according to the Child-Pugh classification, and demographically-matched healthy subjects (n=6). Subjects received a single 15 mg dose of upadacitinib extended-release formulation under fasting conditions. Blood samples for upadacitinib assay were collected over 120 hours after administration. Upadacitinib maximum observed plasma concentration ( $C_{max}$ ), area under the plasma concentration curve (AUC), and terminal phase elimination half-life ( $t_{1/2}$ ) were calculated using non-compartmental analyses. Analyses of covariance were conducted to estimate upadacitinib exposure in subjects with hepatic impairment relative to subjects with normal hepatic function.

**Results:** There was no statistically significant difference in upadacitinib  $C_{max}$  or AUC in subjects with mild and moderate hepatic impairment compared to subjects with normal hepatic function. One subject with moderate hepatic impairment showed significantly lower upadacitinib exposures than subjects with normal hepatic functions and was excluded as an outlier to ensure a conservative estimate for effect of hepatic impairment on exposure. Upadacitinib exposure ratio central values [and 90% confidence intervals] in subjects with mild and moderate hepatic impairment were 1.28 [0.91–1.79] and 1.24 [0.87–1.76] for AUC and 1.04 [0.77–1.39] and 1.43 [1.05–1.95] for  $C_{max}$ , respectively, compared to subjects with normal hepatic function. Upadacitinib terminal elimination half-life (harmonic mean  $\pm$  pseudo standard deviation) was 7.99 $\pm$ 4.60 and 4.14 $\pm$ 1.46 in subjects with mild and moderate hepatic impairment relative to 8.93 $\pm$ 4.87 in subjects with normal hepatic function. Upadacitinib was generally well tolerated by the subjects in the study.

**Conclusions:** Mild and moderate hepatic impairment result in only a very limited effect on upadacitinib plasma exposures (<30% increase in upadacitinib AUC). Therefore, in clinical trials, dose adjustments in subjects with mild or moderate hepatic impairment are not warranted.

### AB0479 CHARACTERISATION OF THE EFFECT OF RENAL IMPAIRMENT ON UPADACITINIB PHARMACOKINETICS

M.-E.F. Mohamed, S. Coppola, T. Feng, J. Anderson, A.A. Othman. *AbbVie, North Chicago, USA*

**Background:** Upadacitinib is a selective inhibitor of Janus kinase 1 (JAK1) which is currently being evaluated for the treatment of several autoimmune disorders, including rheumatoid arthritis (RA). Although renal elimination plays a minor role in upadacitinib clearance (<20% of upadacitinib dose is eliminated unchanged in urine), a considerable number of RA patients have renal dysfunction. As such, characterisation of the effect of different degrees of renal impairment on upadacitinib plasma exposures is important for this patient population.

**Objectives:** The objective of this study was to assess the pharmacokinetics of upadacitinib in subjects with mild, moderate, and severe renal impairment compared to subjects with normal renal function.

**Methods:** This Phase 1 study was conducted in 24 adult subjects, who were assigned to one of four groups (six subjects per group) according to the estimated glomerular filtration rate (eGFR) as calculated by the Modification of Diet in Renal Disease (MDRD) equation: normal renal function (eGFR of  $\geq 90$  mL/min/1.73 m<sup>2</sup>), mild renal impairment (60–89 mL/min/1.73 m<sup>2</sup>), moderate renal impairment (30–59 mL/min/1.73 m<sup>2</sup>), and severe renal impairment (15–29 mL/min/1.73 m<sup>2</sup>). Subjects received a single 15 mg dose of upadacitinib extended-release formulation under fasting conditions. Blood samples for pharmacokinetic assessments were collected for 120 hours after dosing. The effect of renal impairment on upadacitinib plasma exposures was assessed through regression analysis as well as analysis of covariance across the renal impairment categories.

**Results:** The point estimates for upadacitinib plasma exposure ratios [90% confidence interval] in subjects with mild, moderate, and severe renal impairment were 1.18 [1.06–1.32], 1.33 [1.11–1.59], and 1.44 [1.14–1.82] for AUC and 1.06 [0.92–1.23], 1.11 [0.88–1.40], and 1.14 [0.84–1.56] for  $C_{max}$ , respectively, relative to subjects with normal renal function. In this analysis, one subject with moderate renal function showed exposures significantly lower than subjects with normal

renal function. This subject was excluded to ensure a conservative estimate of the impact of renal impairment on upadacitinib exposure. Results from the categorical analysis were consistent with the results from the primary regression analysis.

**Conclusions:** Renal impairment has only a limited effect on upadacitinib pharmacokinetics. Upadacitinib mean plasma exposures (AUC) in subjects with severe renal impairment are within 44% of mean exposures in subjects with normal renal function. This is in agreement with the known limited role of urinary excretion in upadacitinib elimination.

#### AB0480 FOLIC ACID SUPPLEMENTATION DELAYS CLINICAL IMPROVEMENT IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH METHOTREXATE

A. Sulli, C. Pizzorni, S. Paolino, V. Tomatis, M. Ghio, B. Ruaro, M. Cutolo.  
Research Laboratory and Academic Division of Clinical Rheumatology,  
Department of Internal Medicine, University of Genova, San Martino Polyclinic  
Hospital, Genoa, Italy

**Background:** Methotrexate (MTX) is the disease-modifying anti-rheumatic drug (DMARD) most commonly used in the treatment of rheumatoid arthritis (RA), and folic acid (FA) supplementation is usually employed to prevent MTX-related adverse effects.<sup>1</sup> However, the need of FA supplementation remains controversial, as it might influence the efficacy of MTX therapy.<sup>2</sup>

**Objectives:** The aim of this retrospective study was to evaluate the effects of FA supplementation on both efficacy and safety of low-dose MTX in the treatment of RA patients.

**Methods:** 120 RA patients (mean disease duration 11±30 months, mean age 61±13 SD years), according to ACR criteria,<sup>3</sup> who started low-dose MTX treatment were retrospectively evaluated. Patients were not complaining of serious diseases other than RA. Two groups of patients were selected: patients supplemented with FA (#58) and patients not-supplemented with FA (#62). MTX dose, prednisone dose, disease activity (DAS28), and adverse event (AE) were recorded at 3, 6, 9, 12, 24, 36, and 48 months. At baseline, MTX mean dose was 8.3±1.9 and 8.1±1.4 mg/weekly, prednisone mean dose was 7.4±3.1 and 5.3±3.2 mg/daily, and mean DAS28 was 5.1±1.2 and 4.8±1.1, respectively for both groups. The patients were followed-up until MTX discontinuation, new DMARD/BiologicDMARD addition, need for FA supplementation, or after 48 months of therapy (mean follow-up 40±20 months). The maximum MTX dose administered during the follow-up was 15 mg/weekly. Statistical analysis was performed by non parametric tests.

**Results:** DAS28 decreased in both groups during the study. However, DAS28 was found significantly lower (p<0.04) in patients without FA supplementation, when compared with patients taking FA supplementation, at months 3, 6, 9, and 12. Patients without FA supplementation required significantly lower (p<0.01) doses of both prednisone and MTX during the follow-up. AEs were observed in 26% of patients with FA supplementation, as well as in 43% of patients without FA supplementation. The difference was statistically significant (p=0.049). No difference in AE type was observed between the groups (mainly, transaminase or mean red blood cell volume elevation, oral mucositis, urinary tract infections). AEs have been successfully managed in the majority of cases by either discontinuing MTX for two weeks or adding FA if required.

**Conclusions:** In RA patients taking low-dose MTX, FA supplementation decreases the efficacy of the treatment, delaying the clinical responsiveness. The lack of administration of FA increases the risk of AEs; however, by considering the benign type of AEs usually observed in this subset of patients, the treatment with low doses of MTX might be started without FA supplementation, and the FA administration deferred until AE appearance.

#### AB0481 TRANSCUTANEOUS VAGUS NERVE STIMULATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Mohr Drewes<sup>1</sup>, C. Brock<sup>1,2</sup>, S.E. Rasmussen<sup>1</sup>, M. Pfeiffer Jensen<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Aarhus University Hospital, Aarhus; <sup>2</sup>Mech-Sense, Department of Medical Gastroenterology, Aalborg University Hospital, Aalborg, Denmark

**Background:** Rheumatoid Arthritis is a prevalent, autoimmune disease causing joint destruction and severe physical disability. In various studies the vagal nerve has been postulated to play a role in modulation of systemic inflammation.

**Objectives:** Our aim was to investigate the effect of transcutaneous stimulation of the vagal nerve (t-VNS) in patients with rheumatoid arthritis. We hypothesised that stimulation of the vagal nerve and thereby enhanced parasympathetic tone would increase the activity of the vagal nerve and improve experienced clinical pain.

**Methods:** Sixteen patients with rheumatoid arthritis and flare (DAS28-CRP>3.2) and twenty without flare were recruited. Three bilateral electrical stimulations of the vagal nerve were done with a handheld device for 4 days. Cardiac vagal tone (CVT) was assessed with linear vagal scale (LVS) and DAS28-CRP were collected on the 1st, 2nd and 5th day.

**Results:** Cardiac vagal tone was significantly lower in patients with flare in comparison to patients without flare (3.2 vs. 4.9 LVS, p=0.03). t-VNS did not alter CVT in patients with flare, however decreased CVT in patients without flare (baseline: 4.9, 2nd day: 3.8 LVS, p=0.03). A decrease in DAS28-CRP in patients with flare was seen in response to t-VNS (baseline: 4.2, 5th day: 3.9, p=0.03), due to decrease in CRP (baseline: 8.2, 5th day: 6.0 mg/L, p=0.02) and number of swollen joints (baseline: 5.4, 5th day: 4.4, p=0.01) and tender joints (baseline: 3.7, 5th day: 2.8, p=0.02) in RA patients with flare. A negative association between baseline CVT and baseline DAS28-CRP was found in all RA patients, showing that lower CVT was associated to higher disease activity.

**Conclusions:** Baseline CVT was lower in RA patients with flare, possibly due to higher level of inflammation, and the observed decrease in DAS28-CRP was not associated to CVT modulation.

**Background:** The aim of this study was to investigate the drug survival, its efficacy and safety in patients with RA based on the database from the Turkish TURKBIO registry

**Methods:** A total of 180 patients were treated with TOFA for RA. Drug survival was assessed. In 118 patients with available data, treatment response was evaluated using the number of sensitive and swollen joints, VAS values, DAS28, HAQ and CRP at weeks 12, 24, 48 and 60

**Results:** At baseline, RA patients had a median(Q1-Q3) disease duration of 14 years. 75 patients had used ≥1 biologics previously. The other demographic and clinical features of the patients were shown in table 1. Median(Q1-Q3) followup period was 137 weeks. After 48 and 137 weeks, 75% and 48% of the patients respectively, maintained TOFA (figure 1). The most common reason for drug discontinuation was ineffectiveness of treatment (63%), followed by adverse events (23%). After 12 weeks, all disease activity parameters were reduced significantly compared to the baseline and most of them continued to be reduced until week 60. No difference was observed in disease activity parameters between the groups

#### AB0483 PHYSICIANS' AWARENESS ON THE USE OF METHOTREXATE BY RHEUMATOID ARTHRITIS PATIENTS

B.N. Coskun<sup>1</sup>, B. Yagiz<sup>2</sup>, Y. Pehlivan<sup>2</sup>, E. Dalkilic<sup>2</sup>. <sup>1</sup>Rheumatology, Ilker Celikcan Physical Therapy and Rehabilitation; <sup>2</sup>Rheumatology, Uludag University, Bursa, Turkey

**Background:** Methotrexate (MTX) is an anchor drug used in the treatment of rheumatoid arthritis (RA). It is notable that although MTX has severe potential side effects, most of these side effects could be prevented. Patients should be informed very well regarding MTX and prescriptions should be prepared carefully.

**Objectives:** In this research, we sought to investigate patients with RA and also physicians, awareness regarding use of MTX, which is under-researched.

**Methods:** Following Fayet et al., the data were collected from rheumatoid arthritis patients (n=98) and physicians (n=82) through a questionnaire that included questions regarding the effects of MTX, MTX administration, drug interaction, side effects, the frequency of patient follow-up and changes regarding daily life. The questionnaire was filled by the patients in the hospital and physicians filled the on-line questionnaire.

**Results:** 23% patients responded correctly about that MTX is drug modifying anti-rheumatic drugs (DMARD). 88% of the patients stated that they used MTX weekly, only 16% of the patients were able to explain the reason why they used folic acid was reducing the toxicity of MTX and only 5% reported that folic acid did not increase the efficacy of MTX. 95% did not know that trimethoprim should not be combined with MTX. 11% were familiar with haematologic risks. 7% were aware of hypersensitivity pneumonitis. 42% had information regarding laboratory tests. 20% were conscious concerning the need for contraception. 33% noted that alcohol consumption must be limited. The striking findings physicians responded wrongly was that according to 51% physicians, MTX leads to cancer. Surprisingly, approximately 30% physicians responded wrongly concerning surgery protocol.

Abstract AB0483 – Table 1

	Right answer (%)		Wrong answer (%)		Unknown (%)	
	Patient	Physician	Patient	Physician	Patient	Physician
<b>Mechanism of action</b>						
Methotrexate is a disease-modifying drug	23	93	17	7	60	0
Time when MTX becomes effective	12	83	20	12	68	5
Should not be stopped on the disappearance of symptoms	13	98	16	0	71	2
Dosage should not be adjusted to the pain	40	76	15	19	45	5
Maximum dosage allowed	12	82	7	13	81	5
Once weekly administration	88	100	4	0	8	0
Folic acid reduces toxicity of MTX	16	94	5	5	79	1
Decreases efficacy at high doses	3	61	11	28	86	11
Does not increase efficacy of MTX	5	93	10	6	85	1
Should not be combined with trimethoprim	5	71	4	11	91	18
Nonapplicable interactions with analgesics	23	94	16	5	61	1
NSAIDs	22	93	13	3	65	4
Corticosteroids	23	98	13	2	64	0
DMARDs	23	94	12	6	65	0
Nonapplicable interactions with antibiotics	11	88	11	5	78	7

**Conclusions:** The findings showed that patients with RA, who used MTX frequently, had insufficient information regarding MTX. Notably, patients are lack of information about the side effects of MTX, drug interactions and the need for contraception. Hence, we recommend that patients' knowledge should be increased regarding MTX. Physicians should be provided with training to raise awareness proper use of MTX.

AB0484

### MONOTHERAPY WITH FILGOTINIB, A JAK1-SELECTIVE INHIBITOR, REDUCES DISEASE SEVERITY AND ALTERS IMMUNE CELL SUBSETS IN THE NZB/W F1 MURINE MODEL OF LUPUS

C. Pohlmeier, Z.-H. Cui, P. Han, A.S. Clarke, R.M. Jones, N. Mollova, I. Mikaelian, S. Zaboli, A. Shauf, J.A. Di Paolo. *Gilead Sciences, Inc, Foster City, USA*

**Background:** Systemic lupus erythematosus (SLE) is a heterogeneous autoimmune disease characterised by immune system hyperactivation leading to the production of autoantibodies and immune attack on multiple organs including the skin and kidneys. High levels of type I interferons (IFN $\alpha$ /b) alter the activation state of immune cell populations and have been identified as a risk factor for SLE. Antibody blockade of the interferon alpha receptor (IFNAR) has demonstrated clinical efficacy in a Phase 2b study in SLE, and validates targeting this pathway in SLE<sup>1</sup>. Janus kinase 1 (JAK1) is critical for mediating downstream signalling of type I IFNs. Inhibition of JAK1, therefore, is anticipated to reduce IFN signalling, activation of immune cell subsets, and SLE disease activity. The JAK1 selective inhibitor filgotinib (FIL) is currently being evaluated in three proof-of-concept Phase 2 studies in SLE-like diseases.

**Objectives:** To characterise the efficacy and mechanism-of-action of FIL in the NZB/W F1 spontaneous mouse model of lupus in a therapeutic setting.

**Methods:** FIL was tested in the NZB/W F1 model of lupus at two concentrations (0.05% and 0.1%) formulated in chow and administered *ad libitum* from weeks 28–40. Cyclophosphamide (CP) was used as a positive control at 5 mg/kg, once daily, i.p. Efficacy was determined by changes in proteinuria, renal histopathology, and survival. Splenic cell populations were analysed by flow cytometry at study termination at week 40 to measure changes in immune cell subsets in diseased versus non-diseased mice and following FIL treatment. An *in vitro* murine whole blood pSTAT1 assay and PK exposure data were used to assess target coverage in the model.

**Results:** In the NZB/W model, FIL showed a dose-dependent decrease in proteinuria with a concomitant reduction in BUN levels, renal inflammation, improved glomerular morphology, and increased survival (table 1). Diseased mouse spleens had decreased frequencies of naive T cells, increased frequencies of CD11<sup>+</sup>dendritic cells (DCs), and an increased ratio of memory:naive T cells versus non-diseased mice. FIL treatment showed a dose-responsive reversal of these populations toward non-diseased levels. FIL inhibited *in vitro* IFN $\alpha$ -stimulated pSTAT1 signalling in T cells. Calculated JAK target coverage of pSTAT1 inhibition was similar to that observed in human studies at clinical doses.

**Abstract AB0484 – Table 1.** Efficacy scores in the NZB/W F1 model

	Placebo	FIL (0.05%)	FIL (0.1%)	CP (5 mg/kg)
Proteinuria <sup>a</sup>	30.72	29.03 (-5%)	23.40 (-24%)*	17.47* (-43%)
Survival	55%	73%	93%*	100%*
Glomerular diameter	3.66	2.10 (-43%)	0.83 (-77%)*	0.75*
Summed renal histology <sup>b</sup>	14.71	6.81 (-54%)	3.20 (-78%)*	0.37 (-90%)*
Glomerular myeloperoxidase	3%	2% (-52%)	1.1% (-101%)*	1.6% (-73%)*

<sup>a</sup>Urine score AUC (week 28–40)

<sup>b</sup>Includes: glomerular diameter, protein casts, interstitial inflammation, and vasculitis p-values comparing % changes between treatment and placebo groups: \*p<0.05

**Conclusions:** FIL demonstrated efficacy in the NZB/W F1 murine model of lupus with an alteration of splenic immune cell subsets affected by type I IFNs toward non-diseased levels. This data provides the basis for the evaluation of FIL as monotherapy in the currently ongoing Phase 2 studies in lupus-related diseases.

AB0485

### COMPARATIVE EFFICACY OF TOFACITINIB AND BIOLOGIC DMARDS IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH INSUFFICIENT RESPONSE TO SUBCUTANEOUS METHOTREXATE IN CLINICAL PRACTICE

E.L. Luchikhina<sup>1</sup>, D. Karateev<sup>1</sup>, G. Loukina<sup>2</sup>, M. Borisova<sup>3</sup>, N. Demidova<sup>3</sup>, E. Nasonov<sup>3</sup>. <sup>1</sup>1st Department of internal medicine, Moscow Regional Research and Clinical Institute (MONIKI); <sup>2</sup>Department of rheumatology, Moscow Clinical scientific center; <sup>3</sup>V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Tofacitinib (TOFA) – the first registered member of the group of Janus-kinase inhibitors – actively entered into practice. Some clinical trials show efficacy similar to biological DMARDs, but we still do not have enough data from the practice of post-marketing use.

**Objectives:** To evaluate the comparative effectiveness of TOFA and biological DMARDs in clinical practice.

**Methods:** Patients with RA (according to the ACR/EULAR 2010 criteria) having active disease despite treatment by subcutaneous (SC) methotrexate (MTX) were included in post-marketing observational study (REMARCA trial). The patients received a combination of MTX and biologics or TOFA. The follow-up period was 12 months. Patients received biologics in clinical practice according to national standards of care. We used SDAI as a main parameter of disease activity.

**Results:** In total 163 patients were included (81,6% females, 80,4% anti-CCP positive, 79,8 RF-positive, 74,9% with erosive disease, mean age 50,65±12,54, disease duration 30,45±41,9, BMI 27,1±5,78). All patients received SC MTX in the mean dose 22,17±3,92 mg per week, but the most of them had high activity at baseline (SDAI=32,42±14,59). After switching to a combination treatment regimen 88 patients received TNF inhibitors (70 patients – adalimumab, 18 patients – certolizumab pegol), 34 patients – abatacept (ABA), 41 patients – TOFA. Patients in the groups were comparable according to age and the main characteristics of disease severity. We found significant decrease of disease activity in every group (see table 1). In the group receiving TOFA results at 12 months were comparable with patients on anti-TNFs and significantly better than in patients on ABA. Remission (SDAI <3,3) has been achieved in 35,7% of patients on TOFA, in 28,4% – on anti-TNFs and in 14,7% on ABA (p=0055 in comparison with TOFA). No significant differences in safety parameters were found.

**Abstract AB0485 – Table 1.** Changes in disease activity in RA patients during follow-up period.

Group	SDAI at baseline	SDAI at 12 months
Biologics (total), n=122	33,22±15,18	11,05±9,94
Anti-TNFs, n=88	33,98±14,49	9,79±9,22
Abatacept, n=34	31,11±17,05	14,32±11,09*
Tofacitinib, n=41	30,20±12,24	7,59±8,37*

\*) p<0,05 between the groups

**Conclusions:** Tofacitinib demonstrated similar efficacy in comparison to TNF inhibitors and was slightly better than abatacept in clinical practice in RA patients who did not respond to SC methotrexate.

**AB0486** SUBCUTANEOUS METHOTREXATE DISCONTINUATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. Gridneva, Y. Muraviev. Federal State Budgetary Institution «Research Institute of Rheumatology» under the Russian Academy of Medical Sciences, Moscow, Russian Federation

**Background:** Safety of methotrexate (MT) therapy remains the most important issue of early rheumatoid arthritis (RA) therapy.

**Objectives:** A prospective evaluation of most common causes of MT discontinuation in RA patients with disease duration <3 years.

**Methods:** An open 1 year study included 106 patients with active RA meeting ACR/EULAR 2010 or ACR 1987 (DAS28 >3.2) criteria, naïve to subcutaneous (SC) MT. All pts were administered SC MT, starting with 10–15 mg/week dose, and following 5 mg up-titration each 1–2 weeks (to max 30 mg/week) until achieving the target (remission or minimum disease activity) or emergence of adverse reactions (AR). Pts' monthly monitoring procedures included physical examination, blood analysis and biochemistry panel. T. Woodworth et al. inventory was used to assess the severity of ARs, and Naranjo scale was used to assess casual relationship of MT with an AR.

**Results:** Totally 12 (11%) MT discontinuations for the period of >3 weeks were analysed. Permanent discontinuation occurred in 9 pts (8%), and temporary (from 4 weeks to 4 months)—in 3 (3%). 83% of all cases of withdrawal took place during the first 3 months. In 3 patients MT was discontinued because of an AR and inefficiency. Combination of drug failure with AR was the reason for permanent SC MT discontinuation in 3 pts.

The causes led to SC MT discontinuation were: skin reactions in 3 pts (25%), "after-dose reactions"—in 2 (17%), allergic rash—in 2 (17%), diarrhoea—in 2 (17%), elevated liver enzymes—in 3 (25%), leukopenia—in 1 (8%), breast abscess—in 1 (8%). Some patients manifested multiple ARs. Two ARs (17%) were serious (grade 4 severity). Grade 3 ARs were documented in 4 cases (30%), Grade 2 ARs—in 4, and Grade 1 (mild) ARs—in 2 (17%) pts.

Skin lesions became the underlying cause for SC MT discontinuation, such as active dermatitis (n=1) and lichenoid skin reaction (n=1).

Totally 12 (11%) MT discontinuations for the period of >3 weeks were analysed. Permanent discontinuation occurred in 9 pts (8%), and temporary (from 4 weeks to 4 months)—in 3 (3%). 83% of all cases of withdrawal took place during the first 3 months. In 3 patients MT was discontinued because of an AR and inefficiency. Combination of drug failure with AR was the reason for permanent SC MT discontinuation in 3 pts. The causes led to SC MT discontinuation were: skin reactions in 3 pts (25%), "after-dose reactions"—in 2 (17%), allergic rash—in 2 (17%), diarrhoea—in 2 (17%), elevated liver enzymes—in 3 (25%), leukopenia—in 1 (8%), breast abscess—in 1 (8%). Some patients manifested multiple ARs. Two ARs (17%) were serious (grade 4 severity). Grade 3 ARs were documented in 4 cases (30%), Grade 2 ARs—in 4, and Grade 1 (mild) ARs—in 2 (17%) pts. Skin lesions became the underlying cause for SC MT discontinuation, such as active dermatitis (n=1) and lichenoid skin reaction (n=1).

**Conclusions:** Skin reactions were the most common cause for SC MT discontinuation. Therapeutic failure as the leading cause for drug discontinuation was not documented in a single patient.

**AB0487** MULTICENTER 24-WEEK STUDY TO ASSESS THE EFFICACY AND SAFETY OF TACROLIMUS IN ACTIVE RHEUMATOID ARTHRITIS PATIENTS

J. Hur<sup>1</sup>, S. Hong<sup>2</sup>, S. Kim<sup>3</sup>, G. Kim<sup>4</sup>, S. Choi<sup>5</sup>. <sup>1</sup>Internal medicine, Eulji university college of medicine; <sup>2</sup>Internal medicine, Kyunghee university school of medicine, Seoul; <sup>3</sup>Internal medicine, Ulsan university college of medicine, Ulsan; <sup>4</sup>Internal medicine, Kosin university college of medicine, Busan; <sup>5</sup>Internal medicine, Korea university college of medicine, Ansan, Korea, Republic of Ireland

**Background:** Rheumatoid arthritis (RA) is characterised by persistent synovitis and structural joint damage with T cell-driven inflammation. Tacrolimus suppress activation of T cells through the inhibition of calcineurin.

**Objectives:** We evaluated the efficacy and safety of tacrolimus in Korean active RA patient who had inadequate response to disease-modifying anti-rheumatic drugs (DMARDs) including Methotrexate (MTX).

**Methods:** During the study period from Aug. 2012 to Jan. 2016 in this open labelled, multicenter study, 115 patients were enrolled with DAS28 ≥3.2. Patients received tacrolimus during 24 weeks. The initial dose was 1 mg once daily and was increased to 3 mg by every 4 weeks. The disease activity and safety was assessed.

**Results:** Data from 97 patients were evaluated in full set analysis. At week-24, EULAR response rate were 83.5% (81 of 97) with improvements from week-16 in 74.2% (72 of 97). Mean DAS28-ESR was continuously decreased of 5.64 at baseline, 4.14 (±1.22, p<0.001) at week-16 and 3.66 (±1.39, p<0.001) at week-24. Efficacy rates according to SDAI were 89.7% (87 of 97) and KHAQ-20 score decreased -2.42 (±4.37, p<0.001) from baseline 7.27 (±4.59) at week-24. Mean ESR was decreased -10.97 (±24.16, p<0.001) at week-16, -14.77 (±24.57, p<0.001) at week-24 from baseline 46.05 (±23.22). Mean CRP was decreased from 2.86 (±7.85, p=0.0578) at baseline to 1.34 (±3.02, p=0.0367) at week-24. In serious adverse events (6 of 108, 5.56%), two cases (pneumonia, high glucose level) were related with tacrolimus and recovered with treatment.

**Conclusions:** This study demonstrated the efficacy of add on tacrolimus therapy to MTX in patients with active RA patients.

**Disclosure of Interest:** None declared

**AB0488** DISEASE ACTIVITY AT ONE YEAR AFTER ADDITION OF IGRATIMOD OR SULFASALAZINE TO METHOTREXATE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS: PROPENSITY SCORE ANALYSIS

K. Tokunaga<sup>1</sup>, A. Shiraiishi<sup>2</sup>, H. Oshikawa<sup>1</sup>, N. Hagino<sup>3</sup>, S. Tohma<sup>4</sup>. <sup>1</sup>Department of Rheumatology, JAPANESE RED CROSS KUMAMOTO HOSPITAL, Kumamoto-City Higashi-ku; <sup>2</sup>Emergency Department, Kameda Medical Center; <sup>3</sup>Department of Rheumatology, Teikyo University Chiba Medical Center, Chiba; <sup>4</sup>Department of Rheumatology, Tokyo National Hospital, National Health Organization, Tokyo, Japan

**Background:** Igratimod (IGU) is a small-molecule disease-modifying anti-rheumatic drug (DMARD) that has been shown to suppress inflammation via the inhibition of nuclear factor-kappa B activation *in vitro*. The efficacy of combination therapy with IGU and methotrexate (MTX) has been demonstrated in comparison with that of placebo in rheumatoid arthritis (RA). However, its efficacy in comparison with other DMARDs such as sulfasalazine (SSZ) has not been elucidated.

**Objectives:** To assess the disease activity at one year after addition of IGU in comparison with SSZ to MTX in typical clinical practice.

**Methods:** We analysed data from 16,988 RA patients registered in a large database (NinJa: National Database of Rheumatic Diseases by iR-net in Japan) from April 2012 to March 2017.<sup>1</sup> In this study, we compared the two groups who received IGU or SSZ in addition to methotrexate in the earlier year. We excluded patients who started receiving biologic DMARDs, and IGU or SSZ the year prior to the study period, and those whose regimens were changed to other DMARDs such as tacrolimus and bucillamine.

Baseline characteristics were compared using the *t* test, Wilcoxon test, or chi-square test. Fisher analysis was conducted for both outcomes. The predicted probability of IGU treatment was calculated by fitting a logistic regression model using all clinically relevant variables as presented in table 1. Moreover, to reduce the effect of treatment-selection bias and potential confounding in this observational study, we performed rigorous adjustment for significant differences in the baseline characteristics of patients with propensity-score matching using the following algorithm: 1:1 optimal match with a ±0.2 calliper and no replacement. We used the standardised difference to measure covariate balance, whereby a standardised mean difference of >0.1 represents meaningful imbalance. The outcome was remission rate with disease activity score 28 CRP (DAS28-CRP) in the year after initiation of IGU or SSZ therapy.

**Results:** The group that received IGU in addition to MTX included 113 patients; the other group that received SSZ in addition to MTX included 244 patients. Table 1 shows the results of the pre- and post-propensity score matching of patients' characteristics.

One hundred and nine patients were compared in each group after score matching. The remission rates of DAS28-CRP in the following year was 45.0% (49/109 patients) and 54.1% (59/109 patients; p=0.22), and drug retention rate was 79.8% (87/109 patients) and 78.9% (86/109 patients; p=1.00), in the IGU and SSZ groups, respectively.

**Abstract AB0488 – Table 1.** Patients' Characteristics in Full and Propensity Score-Matched Cohorts according to Initiation of Igaratimod or Sulfasalazine

Characteristic	Full Cohort			Propensity Score-Matched Cohort		
	IGU (n=113)	SSZ (n=244)	SMD	IGU (n=109)	SSZ (n=109)	SMD
Sex, male (%)	17 (15.0)	45 (18.4)	0.091	17 (15.6)	18 (16.5)	0.025
Age (mean [SD])	60.23 (12.07)	60.16 (13.13)	0.004	60.48 (11.98)	60.39 (13.31)	0.007
CRP mg/dl (mean [SD])	0.64 (0.92)	0.74 (1.26)	0.082	0.66 (0.93)	0.74 (1.05)	0.087
MTX mg/wk (mean [SD])	9.00 (3.00)	9.12 (3.14)	0.037	8.93 (2.96)	8.70 (3.35)	0.074
PSL mg/d (mean [SD])	1.91 (2.88)	1.47 (2.53)	0.170	1.78 (2.56)	2.02 (3.01)	0.065
SJC (mean [SD])	3.04 (4.02)	2.15 (2.94)	0.253	2.76 (3.46)	3.04 (3.32)	0.081
TJCS (mean [SD])	3.42 (6.59)	2.66 (4.27)	0.136	3.13 (6.52)	3.29 (5.00)	0.011
Disease duration yr (mean [SD])	11.10 (9.18)	9.41 (9.85)	0.180	11.11 (9.24)	10.40 (10.33)	0.073
PGA 0-10 (mean [SD])	3.11 (2.31)	2.91 (2.33)	0.085	3.02 (2.23)	2.99 (2.47)	0.016
mHAQ (mean [SD])	0.38 (0.51)	0.26 (0.41)	0.266	0.37 (0.51)	0.38 (0.49)	0.032

CRP: C reactive protein; IGU: iguratimod; mHAQ: The modified Health assessment questionnaire; MTX: methotrexate; PGA: patient's global assessment; PSL: prednisolone; SD: standard deviation; SJC: swollen joint count; SSZ: sulfasalazine; TJC tender joint count

**Conclusions:** Combination therapy with IGU or SSZ and methotrexate for rheumatoid arthritis did not show a significant difference in disease activity. Further studies are needed.

#### AB0489 TOFACITINIB IMPROVES LEFT VENTRICULAR MASS AND CARDIAC OUTPUT IN RHEUMATOID ARTHRITIS PATIENTS WITH CHRONIC HEART FAILURE

K. Kume<sup>1</sup>, K. Amano<sup>1</sup>, S. Yamada<sup>1</sup>, T. Kanazawa<sup>1</sup>, K. Hatta<sup>1</sup>, N. Kuwaba<sup>2</sup>.  
<sup>1</sup>Rheumatology, Hiroshima Clinic, Hiroshima; <sup>2</sup>Medical Research, EP Sogo, Nagoya, Japan

**Background:** Rheumatologists need to develop primary and secondary prevention strategies for cardiovascular disease (CVD) in rheumatoid arthritis (RA) patients. We reported tofacitinib (Tofa) improved left ventricular mass index (LVMI) in patients with rheumatoid arthritis<sup>1</sup>. We have experienced RA patient with chronic heart failure (CHF). We couldn't use some TNF blockers in RA patients with CHF<sup>2</sup>. There is no evidence that Tofa effects on left ventricular (LV) morphology and function in RA patients with CHF.

**Objectives:** To study the effect of Tofa on LV morphology and function in conventional synthetic (cs) DMARDs resistant active RA patients with CHF, in a cohort study design.

**Methods:** RA patients with CHF were eligible if they had active disease despite treatment with cs DMARDs. Consecutive 24 patients with moderate to severe active RA patients (DAS28 >3.2) despite cs DMARDs were received Tofa plus cs DMARDs. LV morphology and function was assessed with cardio-MRI at baseline and 24 weeks follow-up. Cardiovascular risk factors and clinical data were collected at regular visits.

**Results:** 21 patients completed 24 weeks. New York heart association functional classification (NYHA) class 1 is 12 cases, class 2 is 7 cases, and class 3 is 2 cases respectively. Left ventricular mass index (LVMI) was attenuated significantly by Tofa (week 0 week24,  $-9.02 \pm 5.8$  g/m<sup>2</sup>; p=0.02). Cardiac output (CO) was attenuated significantly by Tofa (week 0 week24,  $-0.42 \pm 1.2$  l/min). DAS28 and CRP improved significantly by Tofa (week 0 week24; DAS28:  $-2.16 \pm 0.95$ ; CRP:  $15.1 \pm 5.7$  mg/L) (p<0.05). Surprisingly, the change of disease activity (DAS

28 and CRP) is no correlation with the change of LVMI or CO in this study. Observationally, 2 cases significantly improved right ventricular mass as well as left ventricular mass (10% improved right ventricular mass index from baseline).

**Conclusions:** Tofa improved LVMI and CO in active RA despite cs DMARDs with CHF. Tofa improves LVMI and CO independently of its effects on disease activity. Tofa might be improved right ventricular mass. JAK-STAT pathway might be an important role of LV hypertrophy. Tofa, JAK-STAT pathway blocking, may prevent cardiovascular morbidity and mortality in RA with CHF.

#### AB0490 EVALUATION OF INHIBITORY FACTOR OF RADIOGRAPHIC PROGRESSION BY IGURATIMOD ADD-ON THERAPY IN RHEUMATOID ARTHRITIS PATIENTS WITH INADEQUATE RESPONSES TO DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS

K. Katayama<sup>1</sup>, Y. Kon<sup>2</sup>, T. Okubo<sup>3</sup>, R. Fukai<sup>4</sup>, Y. Makino<sup>5</sup>, H. Ito<sup>6</sup>.  
<sup>1</sup>Orthopedic Surgery, Katayama Orthopedic Rheumatology Clinic, Asahikawa; <sup>2</sup>Rheumatology, Sapporo Rheumatology and Immunology Clinic, Sapporo; <sup>3</sup>Radiology, Katayama Orthopedic Rheumatology Clinic; <sup>4</sup>Pharmacology, Seien Pharmacy; <sup>5</sup>Medicine, Asahikawa Medical University; <sup>6</sup>Orthopedic Surgery, Asahikawa Medical University, Asahikawa, Japan

**Background:** Igaratimod (IGU) is one of csDMARDs (Conventional synthetic Disease modified anti-rheumatoid arthritis drug) for RA patients in Japan. It was reported to suppress the production of inflammatory cytokines by inhibiting NFκB pass-way. IGU add-on therapy was efficient in patients with RA who were previously designated MTX-monotherapy inadequate responders (MTX-IR). The efficacy of IGU add-on therapy in bDMARDs (Biological DMARD)-IR patients was also reported. In this study, we showed disease activity and safety, and showed also radiographic evaluation for the first time by adding IGU.

**Objectives:** To obtain DAS28-ESR and adverse event data about adding IGU on RA patients with poor response to csDMARDs and/or bDMARDs in single-centre, open label and retrospective study. Furthermore, to show the radiological evaluation after one year.

**Methods:** Clinical and radiographic efficacy was assessed by disease activity score of 28 joints (DAS28) ESR (n=68) and the modified total Sharp score (mTSS) (n=44), respectively. We evaluated which factors are important in determining a prognosis of clinical response and mTSS. For safety, adverse events (AE) were investigated on all patients (n=89).

**Abstract AB0490 – Table 1**

	Non Response		p		Non Response		p
	Response	Response			Response	Response	
SEX	76%	74%	ns	CRP	0.92±0.20	2.38±0.59	<0.05*
AGE	60.19±1.64	61.58±2.44	ns	ESR	24.48±2.96	35.61±3.98	<0.05*
DUR	86.67±10.11	101.03 ±15.76	ns	TJC	3.52±0.54	5.03±0.62	ns
a-CCP-Ab	180.11 ±50.79	153.25 ±40.11	ns	SJC	3.67±0.42	5.32±0.60	<0.05*
RF	133.10 ±28.67	161.39 ±47.20	ns	VAS	32.74±3.34	47.19±4.43	<0.05*
DAS28-CRP	3.85±0.15	4.83 ±0.15	<0.05*	MMP-3	149.33 ±27.60		
CDAI	13.63±0.94	20.06±1.28	<0.05*	PreTSS	5.72±1.07	5.26±0.82	ns
mHAQ	0.34±0.07	0.54±0.11	ns				

**Results:** 89 RA patients were recruited, and male was 28% (n=25). Mean age was 61.5 years old and mean of disease duration was 87 months. Main csDMARDs were MTX (72%). The mean dose of MTX was 7 mg/week (The average dose in Japan). Observational period was 13 months (range, 1 to 30). DAS28-ESR changed from 4.3±1.1 to 3.6±1.2 after adding IGU for 6 months (p<0.0001). The relation with the predictive factors before treatment and the response by using Igaratimod. CRP, ESR, swelling joint, DAS28-ESR, CDAI and

VAS at the baseline were all significantly high in Response (good response+ moderate response) group than No-response group (table 1). Yearly mTSS was 0.60 and rate of structural remission (mTSS  $\leq 0.5$ ) was 87%. Rapid radiological progression was not seen even if yearly mTSS at the baseline was 5.52. The relation between yearly mTSS and disease duration was shown in Figure ( $r=0.33$ ,  $p=0.029$ ). Adverse AE were observed such as transaminase elevation, stomatitis and dizziness. All AE was not serious. DAS28-ESR, CRP, ESR and swelling joint were prognostic factors of the group of good and moderate response against no response group.

Abstract AB0490 – Figure 1

**Conclusions:** Adding IGU to csDMARDs with poor response in RA patients is effective, but AE should be considered. Radiographic progression by Igaratimod might be inhibited in early phase of RA.

**Disclosure of Interest:** None declared

**AB0491 POSSIBLE LINKAGE BETWEEN INTESTINAL BACTERIA COMPOSITION CHANGES AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH NATURAL MILK ANTIBODIES AGAINST ENTERIC BACTERIA AND THEIR TOXINS**

K. Katayama. Orthopedic Surgery, Katayama Orthopedic Rheumatology Clinic, Asahikawa, Japan

**Background:** A growing body of research has indicated potential association between dysbiosis or imbalance of intestinal bacterial flora and RA. Previously, we demonstrated the natural milk antibody preparation containing high levels antibodies against pathogenic enteromicrobes and their toxins seems to be effective in a certain RA subset in an open labelled pilot study.<sup>1</sup>

**Objectives:** To investigate the effects of natural milk antibodies (Ab) on intestinal bacteria composition, and consequent therapeutic effect on disease activity of RA by multicenter randomised double blind clinical trial (UMIN CTR: 000009492).

**Methods:** Eighty-seven patients with RA with disease activity score of 28 joints with ESR (DAS 28-ESR) values above 3.2 were divided into 3 groups (29 patients each), and treated with 600 mg of Ab, 300 mg of Ab plus 10 g of skim milk (prebiotics), and 20 g of skim milk alone, respectively, for 12 weeks. The therapeutic effects of milk antibody treatment were determined by DAS28-ESR, swollen joint count (SJC), tender joint count (TJC), and visual analogue score (VAS). The biological effects of milk antibodies were examined by serum and faecal LPS concentration, and faecal bacterial composition changes before and after the treatment. Bacteria composition changes was determined by quantitative PCR of bacterial 16S rRNA.

**Results:** A significant reduction in DAS28-ESR values from 4.6 to 4.1 was observed at 4th week in Ab 300 mg plus skim milk group (figure 1). Importantly, this effect was lasted through until 12th week ( $p<0.01$ ), but DAS28-ESR values gradually returned to original levels after discontinuation of the treatment. On the other hand, neither high dose of milk antibody (600 mg) nor 20 g of skim milk had little effect on DAS28-ESR. Characteristic effect of milk antibody treatment observed in the Ab 300 mg plus skim milk group was the improvement of SJC, TJC, and Pain VAS. No severe adverse events have been observed. Enteric microbe analysis before the treatment indicated lower *Bacteroides fragilis* (less than 1/100 compared to healthy adults) and higher *Staphylococcus aureus* population (1000x higher) in patients with RA, indicating a dysbiosis in RA. The DAS28-ESR value reduction in the Ab 300 mg group was associated with an increase in the *Lactobacillus* population. In contrast, the improvement of Pain VAS was associated with an increase in the *B. fragilis* population. Possible improvement in the intestinal barrier function was assumed by the reduction of serum and faecal LPS concentration ratio in the Ab 300 mg groups.

\* :  $p<0.05$ , \*\* :  $p<0.01$  (Paired t-test), Data: mean  $\pm$  SE

Abstract AB0491 – Figure 1. Therapeutic effect of natural milk antibodies on rheumatoid arthritis

**Conclusions:** Natural milk antibody treatment modulates the intestinal bacterial composition, and consequently may contribute to improving disease activity of RA.

**AB0492 JAK-INHIBITION WITH PEFICITINIB AND FILGOTINIB IN FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS**

M. Diller<sup>1</sup>, M.-L. Hülser<sup>1</sup>, R. Hasseli<sup>1</sup>, S. Rehart<sup>2</sup>, U. Müller-Ladner<sup>1</sup>, E. Neumann<sup>1</sup>.  
<sup>1</sup>Dept. of Rheumatology and Clinical Immunology, Campus Kerckhoff, Justus-Liebig-University, Gießen; <sup>2</sup>Dept. of Orthopaedics and Trauma Surgery, Agaplesion Markus Hospital, Frankfurt, Germany

**Background:** With the approval of the Janus kinase inhibitors (JAKi) Tofacitinib and Baricitinib for the treatment of rheumatoid arthritis (RA) in the European Union (EU), the opportunities for a successful therapy were extended by a new substance class. Other JAKi like Peficitinib and Filgotinib are currently examined in clinical trials. Peficitinib is a pan-JAKi, whereas the other substances differ clearly in the capability to block the four members of the Janus kinase family. It is unclear, if the new substances offer an additional benefit in RA treatment in comparison to the approved JAKi.

**Objectives:** This study characterised the effect of the different JAKi on inflammatory response of activated fibroblast-like synoviocytes from patients with RA (RA-FLS).

**Methods:** RA-FLS were isolated from synovial tissue of patients with RA undergoing joint replacement surgery. The cells were pretreated for 2 hour with different concentrations of JAKi or vehicle control and then stimulated with IL-1 $\beta$  (10 or 20 ng/ml) or Oncostatin M (OSM, 100 ng/ml). After the indicated time (17–24 hour), the supernatants were collected and the concentrations of IL-6 and MMP-3 were measured by ELISA. An assay combining the measurement of cell viability, cytotoxicity and apoptosis was performed to exclude effects of JAKi caused by cell toxicity.

**Results:** To detect the most effective JAKi in blocking the inflammatory response induced by IL1- $\beta$ , RA-FLS were first pretreated with different JAKi for 2 hour with concentrations of 1  $\mu$ M and 10  $\mu$ M and then additionally stimulated with IL1- $\beta$  (20 ng/ml) for 18 hour. Even at the highest concentration of 10  $\mu$ M Tofacitinib and Baricitinib did not change the IL-6 levels, whereas Peficitinib and Filgotinib reduced the IL-6 release at 10  $\mu$ M. Tofacitinib and Baricitinib reduced the cytokine release if the RA-FLS were stimulated with OSM, a factor directly inducing the JAK-dependent IL-6-pathway (n=3).

To obtain a dose-response curve for the clinically relevant range of concentrations between 0.01  $\mu$ M and 5  $\mu$ M, RA-FLS were pretreated with Filgotinib and Peficitinib for 2 hour and then stimulated with IL1- $\beta$  (10 ng/ml) for 17 hour. In contrast to Filgotinib, Peficitinib at 5  $\mu$ M caused a reduction of IL-6 levels of 66% compared to control with IL1- $\beta$  (p<0.01, n=5). The MMP-3 release was decreased by both substances at 5  $\mu$ M: In comparison to the control with IL1- $\beta$ , Peficitinib caused a reduction of 92% (p<0.0001, n=5) whereas Filgotinib only reduced the levels by 43% (p<0.05, n=3). Furthermore, Peficitinib at 1  $\mu$ M decreased the MMP-3 release by 46% (p<0.01).

The treatment with Peficitinib did not affect the viability, cytotoxicity or apoptosis of RA-FLS (n=3). Therefore, the effects of Peficitinib on the inflammatory response were not caused by cell death.

**Conclusions:** Peficitinib reduced the release of proinflammatory cytokines and of matrix metalloproteinases after activation of RA-FLS with IL1- $\beta$  and appeared to be superior to Tofacitinib and Baricitinib in targeting the pro-inflammatory and matrix destructive properties of RA-FLS.

#### AB0493 EFFECTIVENESS OF SUBCUTANEOUS PRESENTATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Villarreal<sup>1</sup>, M. Rivero<sup>2</sup>, D. Buitrago-Garcia<sup>3</sup>, M. Cabrera<sup>1</sup>, P. Santos-Moreno<sup>4</sup>.

<sup>1</sup>Health Services; <sup>2</sup>Pharmaceutical Chemist; <sup>3</sup>Epidemiology; <sup>4</sup>Rheumatology, Biomab, Center For Rheumatoid Arthritis, Bogota, Bogota, Colombia

**Background:** Methotrexate (MTX) is one of the most used drugs for the treatment of rheumatoid arthritis (RA) and has become the gold standard of therapy. It can be given via oral, intramuscular or subcutaneous (SC). MTX is a highly effective therapy for patients with RA; however, oral MTX has been associated with gastrointestinal intolerance diminishing the adherence of patients to treatment and increasing the switching to biological therapy. Thus, the use of SC methotrexate can improve its efficacy compared to oral MTX.

**Objectives:** The aim was to determine the effectiveness and safety of SC MTX in patients with rheumatoid arthritis.

**Methods:** We performed a retrospective descriptive analysis; our main goal was to provide real-life data regarding effectiveness of SC MTX in patients with RA. We excluded patients who were in remission. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28  $\geq$ 3.1 and  $\leq$ 5.1), and every 11–13 weeks (DAS28 <3.1). Tender joint count (TJC), swollen joint count (SJC) and DAS28 were measured on each visit. Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it; regarding the effectiveness of SC MTX we calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We performed a bivariate analysis using Pearson's  $\chi^2$

**Abstract AB0493 – Table 1.** DAS28 and CDAI in patients with RA receiving SC MTX

DAS 28	BASELINE		12 MONTHS	
	n	%	n	%
Remission			44	33
LDA	36	28	29	22
MDA	84	63	50	38
SDA	12	9	9	7
CDAI	n	%	n	%
Remission			38	29
Low	87	66	62	47
Moderate	34	26	25	19
High	11	8	7	5

**Results:** A total of 132 patients meet our inclusion criteria, 88% were female and 12% male. Mean age was 61 years $\pm$ 9. Mean DAS28 at baseline was 3.8 $\pm$ 0.83, while at 12 months mean DAS28 was 3.28 $\pm$ 1.12. Clinical disease activity CDAI at baseline had a mean of 9.6 $\pm$ 7.2 and at 12 months 7.8 $\pm$ 7.5. We achieved

remission in 33% of patients according to DAS28 and 29% according to CDAI, also it was a significant decrease in patients with moderate disease activity see table 1. Finally, there was a statistical significance between disease activity at baseline compared to disease activity at 12 months (p<0.005). It was not observed major complaints with SC MTX, only 5% of the patients reported some mild and transient discomfort at the local application site.

**Conclusions:** Subcutaneous MXT is an effective and safe alternative for the treatment in patients with RA and intolerance to oral MTX, and could be a good option to prevent a premature switching to biological therapy.

**Disclosure of Interest:** None declared

#### AB0494 USABILITY OF A PRE-FILLED PEN FOR SELF-ADMINISTRATION OF SUBCUTANEOUS METHOTREXATE

M. Hattesoeh, M. Tribanek, K. Gescher. MEDAC GMBH, Wedel, Germany

**Background:** Methotrexate (MTX) is the first-line DMARD for the treatment of rheumatoid arthritis (RA).<sup>1</sup> It is also of high significance in the treatment of psoriasis arthritis (PsA) and psoriasis vulgaris (PsV).<sup>2,3</sup> Studies in RA patients found that there are advantages in terms of bioavailability and efficacy when MTX is administered subcutaneously (SC) as compared to orally.<sup>4,5</sup>

Since the introduction of MTX pre-filled syringes, patients are principally enabled to self-administer methotrexate subcutaneously, however not all patients are able to use syringes easily. Auto-injection using a pre-filled pen can facilitate administration by the patient. Results of a comparative crossover study showed that SC self-injection with a pre-filled pen is mainly preferred to a pre-filled syringe with regard to use, acceptability, and satisfaction<sup>6</sup>. Usability of the pre-filled pen was proven in an actual-use study<sup>7</sup>, however no comprehensive data from routine clinical use is available so far.

**Objectives:** The aim of this practice documentation was the evaluation of the usability of a MTX pre-filled pen under everyday clinical conditions.

**Methods:** This multicentric non-interventional practice documentation, which took place from 2013 to 2015 in Germany, was open to naïve patients and to those who had already been treated with the pre-filled pen in accordance with the approved indications. Usability was evaluated by the patient and the physician through assessment of the individual steps of two self-injections in an interval of approximately 12 weeks (V1, V2) and through a final overall assessment using ordinal scales. Data analysis was carried out descriptively by means of standard statistical methods. Calculation of a total usability score allowed for comparison of V1 and V2.

**Results:** The 478 participating patients had a mean age of 56.2 $\pm$ 13.7 years, 57.1% were female; 39.3% suffered from RA, 34.7% from PsV, 23.4% had PsA, and 12.6% were diagnosed with other conditions. 87.7% received treatment with the pre-filled pen for the first time, and 61.5% had previously received MTX. The individual steps of self-injection, removing of a protective cap, placing the device onto the skin, pressing the injection button, removing the pen, and ergonomics of the pen, were rated as "very good" and "good" by more than 90% of patients as well as of physicians in both visits. Comparing V1 and V2, usability was assessed to be even better at the second visit (p<0.0001 in the total score). Injections were carried out accurately by more than 93% of the patients.

**Conclusions:** Autoinjection with a pre-filled pen enables patients to self-administer subcutaneous MTX easily and comfortably in routine clinical practice.

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Efficacy and safety of tofacitinib have been shown in patients (pts) with RA in global Phase (P)2, P3 and a long-term extension (LTE) study and in 2 P2 and 1 LTE study in Japanese pts.

**Objectives:** To evaluate safety of tofacitinib following drug approval in Japanese pts with RA using all-case post-marketing surveillance (PMS) data.

**Methods:** An interim analysis (IA) of safety data from an ongoing 3 year PMS study was conducted (5 Nov 2017 data-cut). All Japanese RA pts receiving tofacitinib were prospectively registered in the PMS study. All adverse events (AEs) were collected during tofacitinib treatment. Follow-up surveillance after discontinuation was conducted for serious infection events (SIEs; 1 year), malignancy and death (3 years). For all AEs and serious AEs, 6 month IA data was used. For AEs of special interest, all-period data (up to 36 months) was used to calculate cumulative incidence rates (IRs: pts with events/100 pt-years [yrs]) over time for herpes zoster (HZ) and SIEs during treatment +28 days and for malignancies during the full observation period.

**Results:** Overall, 3929 tofacitinib-treated pts with 1704.1 pt-yrs of exposure were included in the 6 month IA of safety: 80.5% were female, mean age was 62.7 years, with 32.6% of pts ≥70 years. Of these, 892 pts (22.7%) discontinued treatment, mainly due to AEs (351 pts; 8.9%) or lack of effectiveness (335 pts; 8.5%). At least one AE was observed in 1313 pts (33.4%); infections were observed in 493 pts (12.5%). The most frequent AEs were HZ (145 pts; 3.7%) and abnormal hepatic function (72 pts; 1.8%). SAEs occurred in 287 pts (7.3%); the most frequent SAEs were HZ (24 pts; 0.6%) and pneumonia/bacterial pneumonia (33 pts; 0.8%). SIEs occurred in 130 pts (3.3%). Malignancy (all causality) was reported in 25 pts (0.6%); lymphoma/lymphoproliferative disorder occurred in 5 pts (0.1%) and breast cancer in 3 pts (0.08%). There were 21 deaths (0.5%) during the 6 month period. The most common causes of death (including pts with multiple causes listed) were infection (6 cases) and malignancy (5 cases). For AEs of special interest from all-period data the IR of HZ (serious and non-serious) was 6.81 (264 pts; 3876 pt-yrs), the IR of SIEs was 5.38 (212 pts; 3941 pt-yrs) and the IR of malignancy was 1.25 (61 pts; 4874 pt-yrs).

**Conclusions:** This IA of tofacitinib PMS in Japan did not reveal any new or unexpected safety signals vs the tofacitinib RA clinical trials. IRs for HZ and malignancy were similar to IRs in clinical trials of tofacitinib in Japanese RA pts and the SIE IR was within the range reported in PMS of biologic treatments. Continuous monitoring of SAEs is required until the final PMS results.

**T2T WITH SUBCUTANEOUS METHOTREXATE IN VERY EARLY RHEUMATOID ARTHRITIS (RA)**

N. Chichasova<sup>1,2</sup>, G. Imametdinova<sup>1</sup>, E. Nasonov<sup>1,2</sup>. <sup>1</sup> *Nasonova State Institute of Rheumatology*; <sup>2</sup> *Federal State Autonomous Educational of Institution of Higher Education I.M. Sechenov First Moscow State Medical University of the Ministry of Health of the Russian Federation, Moscow, Russian Federation*

**Objectives:** Adherence to foundations T2T and education of patients (pts) according to T2T Connect program increase possibility of favourable outcome of RA

**Methods:** In open prospective 36 months study of efficacy and safety of subcutaneous methotrexate (MT) 74 pts with definite very early RA (ACR/EULAR 2010) were included: mean age was 45.2±15.9, mean duration of RA – 5.2±3.48 months, mean DAS28 – 5.66±1.99 (max 7.06, min 4.44), RF positivity 73% and ACCP positivity 77% of pts. 3 pts had joint erosions. FK II had 43% and III- 53% of pts. Education conducted by program T2T Connect. Initial dose of MT was 15 mg/week, all pts used 5–10 mg/week folic acid and NSAIDs in therapeutically dose according to comorbidities, systemic glucocorticoids (GK) were not prescribed. 72 pts completed 12 months of treatment, 54–24 months, 29–36 months.

**Results:** In 88% of pts improvement was observed in first 4–5 weeks. After 3 months low disease activity (LDA) was registered in 18 pts, in over pts therapy wasn't corrected in view with clear tendency to decrease of RA activity, intraarticular injection of GK was performed in 3pts. Changes of DAS28 are in the table 1. After 6 months moderate disease activity was in 49% of pts, LDA – in 51%. After 12 months of study in all pts target of treatment was achieved: LDA in 81% of pts and remission (ACR/EULAR 2010) in 19%; after 24 months 57% and 43% respectively, after 36 months – 36% and 64% respectively (18 pts without treatment). The minimal radiographic progression was observed in 18 pts (24%, mean erosion's score 1.63±1.02), that wasn't cause of firm decrease of functional ability in pts. 3 women with remission after 18 and 20 months of treatment with MT became pregnant and gave birth to normal newborns. Withdraw MT because of AE was in 2 pts (flu-syndrome).

In 88% of pts improvement was observed in first 4–5 weeks. After 3 months low disease activity (LDA) was registered in 18 pts, in over pts therapy wasn't corrected in view with clear tendency to decrease of RA activity, intraarticular injection of GK was performed in 3pts. Changes of DAS28 are in the table 1. After 6 months moderate disease activity was in 49% of pts, LDA – in 51%. After 12 months of study in all pts target of treatment was achieved: LDA in 81% of pts and remission (ACR/EULAR 2010) in 19%; after 24 months 57% and 43% respectively, after 36 months – 36% and 64% respectively (18 pts without treatment). The minimal radiographic progression was observed in 18 pts (24%, mean erosion's score 1.63±1.02), that wasn't cause of firm decrease of functional ability in pts. 3 women with remission after 18 and 20 months of treatment with MT became pregnant and gave birth to normal newborns. Withdraw MT because of AE was in 2 pts (flu-syndrome).

Abstract AB0496 – Table 1

Months	0	3	6	12	24	36
Mean DAS28±SD	5.66±1.77	4.41±2.09	3.25±1.63	2.72±1.10	2.81±1.75	2.69±1.14

**Conclusions:** Peculiarity of our group of pts was the beginning of the treatment by MT, in most cases, at the first 6 months of RA onset. It is possible in this case to achieve remission more, than in half of pts without GK treatment. Thus, the subcutaneous form of MT is effective as regards activity and progression in early RA, safety for the long time in case of the using principles of controlled treatment allows achieve target after 6–12 month of therapy in most of pts with RA.

### EFFECTIVENESS, TOLERABILITY, AND SAFETY OF TOFACITINIB IN RHEUMATOID ARTHRITIS: A RETROSPECTIVE ANALYSIS OF REAL-WORLD DATA FROM THE ST. GALLEN AND AARAU COHORT

R. Mueller<sup>1</sup>, F. Popp<sup>1</sup>, F. Mattow<sup>1</sup>, M. Durmisi<sup>2</sup>, A. Souza<sup>3</sup>, H. Schulze-Koops<sup>4</sup>, P. Hasler<sup>2</sup>, J. von Kempis<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen; <sup>2</sup>Division of Rheumatology, Kantonsspital Aarau, Aarau; <sup>3</sup>Iterata AG, Gränichen, Switzerland; <sup>4</sup>Rheumainheit, University of Munich, München, Germany

**Background:** Tofacitinib is an oral JAK inhibitor indicated for the treatment of RA. Efficacy and safety of tofacitinib have been shown in several randomised clinical studies.

**Objectives:** The study presented here aimed to assess the clinical tolerability and effectiveness of tofacitinib among patients with RA in real life.

**Methods:** Consecutive patients between June 2013 and April 2017 with RA who fulfilled the American College of Rheumatology/EULAR 2010 criteria were analysed in a prospectively designed analysis of retrospective data. Patients were initiated on tofacitinib 5 mg bid. The primary objective was to analyse safety of tofacitinib in a real life cohort. Safety was assessed by the reasons to stop tofacitinib during follow up and changes of liver enzymes, haemoglobin, and creatinine. The secondary outcome was to analyse the frequency of and time to achieve low disease activity (LDA) and remission as defined by DAS28.

**Results:** Overall, 144 patients were treated with tofacitinib. 84.9% of the patients were pre-exposed to at least one biological agent. The average DAS 28 at initiation of tofacitinib was 4.43. 50.0% were rheumatoid factor and 49.0% ACPA positive. The mean follow up was 1.22 years (range 10d – 3.7a) after initiation of tofacitinib treatment. 94 (64.4%) patients remained on tofacitinib during follow up. The average time to stop tofacitinib was 190.0 days. Reasons to stop tofacitinib were: insufficient response (n=23), gastrointestinal symptoms (n=18), infection (n=5), myalgia (n=2), remission (n=2), headache,<sup>2</sup> cough, blue toe syndrome, intolerance, heart burn, psoriasis, and increased liver enzymes (all n=1). Increased ALAT or ASAT >2 x ULN were detected in 3.3% and 4.4%, respectively. These elevated transaminase levels were transient in 50% and 60% of the cases, respectively. Haemoglobin decrease of >10% was detected in 15.1% of the patients and decreased lymphocytes<500/ $\mu$ l in 3.4%. An increase of creatinine >20% was detected in 9.4%.

62.9% and 50.0% of the patients achieved LDA or remission after a median 260 and 616 days, respectively. These rates were significantly higher in patients naïve to biologic agents as compared to patients pre-exposed to biologics (LDA: naïve 100% after median 100d, pre-exposed 57.0% after 359d; remission: naïve 86.7% after 132d, pre-exposed 44.1% after 720)

**Conclusions:** Tofacitinib is a safe and effective treatment option for patients with RA. Tofacitinib may induce high rates of LDA and remission in patients with active disease, even after use of one or more biologics, though the rate is significantly higher in patients naïve to biologics. Tofacitinib may be a valuable option in a treat to target approach. Our data justify an early use of tofacitinib in the therapeutic strategy.

### OPTIMISATION OF METHOTREXATE DOSE INDUCED SUCCESSFUL REDUCTION OF GLUCOCORTICOID WITHOUT IMPAIRED DISEASE CONTROL IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Hirata<sup>1</sup>, T. Kondo<sup>1</sup>, K. Yukawa<sup>1</sup>, T. Tokunaga<sup>1</sup>, T. Kuranobu<sup>1</sup>, K. Oi<sup>1</sup>, Y. Yoshida<sup>1</sup>, M. Funaki<sup>1,2</sup>, K. Oda<sup>1,3</sup>, T. Nojima<sup>1,4</sup>, E. Sugiyama<sup>1</sup>. <sup>1</sup>Department of Clinical Immunology and Rheumatology, Hiroshima University Hospital; <sup>2</sup>Department of Rheumatology, JR Hiroshima Hospital; <sup>3</sup>Hiroshima Clinic; <sup>4</sup>Nojima Internal Medicine Clinic, Hiroshima, Japan

**Background:** Use of short-term glucocorticoids (GCs) along with methotrexate (MTX) have been recommended for newly onset patients with rheumatoid arthritis (RA) in EULAR recommendation 2016. However, it is not always easy to reduce or withdraw GCs due to patients' fear of relapsed pain or fatigue. As well, some patients are negative to increase MTX dose for fear of adverse events.

**Objectives:** To clarify whether GCs could be reduced without impaired disease control by optimising MTX dose in RA patients with stable medication in real-world clinical practice setting.

**Methods:** 70 patients with RA who regularly visit our outpatient clinic for  $\geq 1$  year were enrolled. Clinical characters, disease activity, and medications at present and 1 year before were retrospectively collected. Therapeutic strategy was to increase MTX with reducing prednisolone (PSL) based on patient's consent. Initiating bDMARDs was allowed in case of uncontrollable disease. Wilcoxon test and chi-square test were used for statistics.

**Results:** Clinical characters (median [IQR]) were; age 62<sup>51, 68</sup> yrs; female 69%; disease duration 6.8 [3.4, 13.7] yrs. Rate of MTX was elevated from 57% to 62%,

and dose (mean  $\pm$ SD) was increased from 9.8 $\pm$ 3.2 to 11.6 $\pm$ 3.7 mg/w ( $p < 0.0001$ ) for uses only, whereas PSL was suppressed from 56% to 26%, and decreased from 2.0 $\pm$ 3.1 to 0.8 $\pm$ 1.8 mg/d ( $p = 0.0004$ ) for all patients. bDMARDs were used for 16 patients, and newly initiated for 2 patients. Although not significant, median CDAI, SDAI, and DAS28 were suppressed from 5.7 to 3.8, 6.2 to 3.9, and 2.92 to 2.77, and remission rate were increased from 24% to 39%, 27% to 41%, and 36% to 41%, respectively.

Abstract AB0498 – Table 1

	Baseline	1 Year	p-value
%MTX	57%	67%	0.2226
MTX[mg/w] for users	9.8 $\pm$ 3.2	11.6 $\pm$ 3.7	<0.0001
%PSL	56%	26%	0.0003
PSL[mg/d] for all patients	2.0 $\pm$ 3.1	0.8 $\pm$ 1.8	0.0004
CDAI remission	24%	39%	0.0687
SDAI remission	27%	41%	0.075
DAS28 remission	36%	41%	0.4874

**Conclusions:** GCs could be reduced or withdrawn without deterioration with appropriately increased MTX. Moreover, disease control rather showed improved tendency.

### EVALUATION OF THE EFFECTIVENESS OF METAXODINE IN THE HEPATIC TOXICITY DUE TO METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Parisi, M.C. Ditto, M. Scarati, M. Priora, F. Enrico. *Rheumatology Unit, AOU Città della Salute e della Scienza di Torino, Turin, Italy*

**Background:** Methotrexate inhibits the metabolism of purines resulting in the accumulation of adenosine; it also inhibits the activation of T cells and suppresses the expression of intercellular adhesion molecules for T cells. Side effects may show up during the treatment and among them there is hepatic toxicity, characterised by an increase of AST and ALT; such increase is usually asymptomatic but it may lead to a suspension of the treatment. Metadoxine (MTDX) is a drug which is used in order to treat both acute and chronic alcohol intoxication; it also prevents the inactivation of ATP from acetaldehyde and pyroglutamic acid. MTDX also showed to improve hepatic function markers and to decrease oxidative stress leading to a protective effect against radicals.

**Objectives:** The aim of this preliminary study was to evaluate the possible effect of MTDX on hepatic function in patients affected by RA in therapy with MTX.

**Methods:** The study involved the recruitment of patients affected by RA in treatment with MTX; a following random selection of a subgroup of patients who took MTDX (500 mg twice a day for 28 days, from the 5th to the 8th week of therapy with MTX) was performed. All the patients underwent a 12-week-follow up in which these parameters were evaluated: demographics, blood tests required for MTX in accordance with datasheets (especially AST and ALT), CRP, ESR, ACPA, numbers of swollen and tender joints, concomitant medications (NSAIDs and steroids) and the degree of disability (HAQ, table 1).

**Results:** 24 patients affected by RA (20 women), with a mean age of 51.3 years ( $\pm 14.1$ ) and mean MTX dose of 12.3 $\pm$ 2.6, were recruited. 70.3% took GC with a medium dosage (3.72 $\pm$ 2.71). Among these 24, 13 patients were under MTDX 500 mg twice a day from the 5th to the 8th week. Patients treated with MTDX+MTX showed a significant decrease of hepatic markers (AST  $\Delta$  -18.38  $p = 0.004$  – ALT  $\Delta$  -19.23  $p = 0.004$ ) compare with patients with MTX only (AST  $\Delta$  -4.27  $p = 0.110$  – ALT  $\Delta$  -6.09  $p = 0.045$ ) after a 12-week-monitoring, with no statistically significant difference concerning disease activity (table 2).

**Abstract AB0499 – Table 1.** Variables at baseline

VARIABLES	MTX	MTX+MTDX	p-value
Disease duration (yy), m±SD	4.91±1.70	4.69±1.80	ns
AST (U/l), m±SD	13.18±3.19	18.46±7.15	ns

AST: aspartate amino transferase; ALT: alanine amino transferase; MTX: Methotrexate; MTDX: Metadoxine;

**Conclusions:** This study showed the possible effect of MTDX in increasing the tolerance to the MTX without affecting its effectiveness. Its role may indeed have useful implications in patients who start the therapy with MTX or in those who develop hepatic toxicity during the treatment.

### AB0500 EFFICACY AND SAFETY OF TOFACITINIB (TOF) IN PATIENTS WITH RHEUMATOID ARTHRITIS AT 52 WEEKS IN CLINICAL PRACTICE

T. Aramaki<sup>1</sup>, K. Kojima<sup>1</sup>, S. Kurushima<sup>1</sup>, Y. Tsuji<sup>1</sup>, N. Kawachi<sup>1</sup>, N. Iwamoto<sup>2</sup>, K. Ichinose<sup>2</sup>, K. Terada<sup>1</sup>, K. Eguchi<sup>3</sup>, Y. Ueki<sup>1</sup>, A. Kawakami<sup>2</sup>. <sup>1</sup>Rheumatic Disease Center, Sasebo Chuo Hospital, Sasebo; <sup>2</sup>Unit of Translational Medicine, Department of Immunology and Rheumatology, Nagasaki Graduate School of Biomedical Sciences, Nagasaki; <sup>3</sup>Sasebo Chuo Hospital, Sasebo, Japan

**Objectives:** There are few long-term experience of TOF for Rheumatoid arthritis (RA) patients in clinical use. We evaluated 52 and 104 weeks efficacy and safety of TOF in patients with rheumatoid arthritis in clinical practice.

**Methods:** We enrolled 77 RA patients started to treat with TOF between December 2013 and November 2016 in our hospital. All patients received 5 mg of TOF twice daily. We evaluated clinical disease activity in composite measures (including Disease Activity Score 28(DAS28) -Erythrocyte (-ESR), -C-reactive protein (-CRP), Simple Disease activity Index (SDAI) and Clinical Disease Activity Index (CDAI)) every three months and adverse events (AEs) during 52 and 104 weeks after treatment with TOF. We estimated the drug survival rate with Kaplan-Meier survival analysis.

**Results:** The mean age of patients was 66.3 years and the duration of disease was 15.4 years. Fifty-four (74.0%) patients have positive rheumatoid factor (RF) and 59 (78.7%) patients have positive anti-citrullinated protein antibodies (ACPA). Twenty-three patients were biologic-naïve and fifty-four patients have ever been treated with biologic DMARDs of whose mean number is 2.6 prior to TOF. Regarding the last biologic DMARDs: 14 patients have treat with TNF inhibitor (Infliximab, etanercept, adalimumab, golimumab, certolizumab-pegol), 30 patients with tocilizumab and 10 patients with abatacept. Twenty-three (29.9%) patients were treated with TOF without methotrexate (MTX). Disease activity at TOF start with measured with DAS28-ESR, DAS28-CRP, SDAI and CDAI were 5.15, 4.07, 23.3 and 21.5 respectively. The Drug survival rate at 24 weeks is 84.4% and that at 52 weeks is 73.8%. Twenty-seven patients have been treated with tofacitinib over 104 weeks. Twelve patients was stopped to treat within initial 24 week, including due to adverse events (n=5) and lack of efficacy (n=7). Analysed by last observation continued forward (LOCF) method, the mean of DAS-ESR decreased to 3.52 at 24 week and 3.59 at 52 week. CDAI decreased from 21.5 to 7.94 at 24 week and

7.93 at 52 week. Sixteen (20.8%) patients were remission as which defined less than 2.6 in DAS-ESR and 13 (16.9%) were low disease activity (LDA) as which defined less than 3.2 in DAS-ESR. In 23 patients without MTX, 6 (26.0%) and 5 (21.7%) have achieved remission and LDA at 52 W respectively. The adverse events due to which the patients had to be stopped to treat with TOF occurred in 20.6% of patients in initial 52 weeks. Infection was the most frequent AE to TOF, especially herpes zoster (7 patients). Six patients experienced herpes zoster within 6 month after treat with TOF. All of them could restart to treatment of TOF. Two solid tumours were discovered within 6 months after treatment, both of them had been removed by surgery and has not recurred.

**Conclusions:** Our study shows that TOF can be much effective clinically and have longer-lasting effectiveness. In our patients, herpes zoster was almost as frequent as reported in the phase III trials in Japan and we could retreat almost of them with TOF.

### AB0501 ADVERSE EVENTS WITH TREATMENT REGIMENS OF RHEUMATOID ARTHRITIS (RA) REPORTED BY PATIENTS APPLYING SMART SYSTEM OF DISEASE MANAGEMENT (SSDM) MOBILE TOOLS: A COHORT STUDY OF RA PATIENTS IN CHINA

Y. Wang<sup>1</sup>, J. Yang<sup>2</sup>, H. Wei<sup>3</sup>, C. Li<sup>4</sup>, R. Mu<sup>4</sup>, B. Wu<sup>5</sup>, H. Wang<sup>6</sup>, Y. Wang<sup>7</sup>, X. Wang<sup>8</sup>, H. Guo<sup>9</sup>, J. Xue<sup>10</sup>, J. Ru<sup>11</sup>, X. Xin<sup>12</sup>, F. Zhang<sup>13</sup>, L. Kang<sup>1</sup>, H. Liu<sup>2</sup>, J. YuHua<sup>14</sup>, Y. Liu<sup>14</sup>, F. Xiao<sup>15</sup>, J. Huang<sup>16</sup>. <sup>1</sup>The First Affiliated Hospital of BaoTou Medical College, Bao Tou; <sup>2</sup>Central Hospital of MianYang, Sichuan, MianYang; <sup>3</sup>Northern Jiangsu People's Hospital, Yang Zhou; <sup>4</sup>People's Hospital, Beijing University Medical School, Beijing; <sup>5</sup>Chongqing Traditional Chinese Medicine Hospital, Chongqing; <sup>6</sup>JiaXing First Hospital, Zhejiang, JiaXing; <sup>7</sup>Southwest Hospital, Chongqing; <sup>8</sup>Anyang District Hospital, Puyang; <sup>9</sup>The Second Hospital of Hebei Medical University, Shijiazhuang; <sup>10</sup>The Second Affiliate Hospital of Zhejiang University School of Medicine, Hangzhou; <sup>11</sup>The 264th Hospital of the PLA, Taiyuan; <sup>12</sup>NingBo First Hospital, Zhejiang, Ningbo; <sup>13</sup>Hebei General Hospital, Shijiazhuang; <sup>14</sup>Shanghai Gothic Internet Technology Co., Ltd; <sup>15</sup>Suzhou antiinflammatory research institute, Shanghai; <sup>16</sup>The sixth Affiliated Hospital of Sun Yat-sen University, Guang Zhou, China

**Background:** Hepatic, hematologic and other adverse events (AE) during treatment in RA patients are unavoidable. And monitoring AE in long-term treatment is quite necessary as a part of chronic disease management. SSDM is a smart mobile tool to help patients upload their therapeutic regimens, lab test records and report AEs. Our previous study showed that patients in China can master the application of SSDM after training.

**Objectives:** To determine and compare the incidence of adverse events during treatment of RA with different therapeutic regimens, focusing on mono and combination therapy.

**Methods:** The SSDM includes interfaces of both physicians' and patients' application. Patients were educated to enter the data of lab test records and treatment regimens once a month, all data can be synchronised automatically to the authorised physicians' mobile tool, which formed a large patient reported database. The rheumatologists can also adjust treatment regimens base on patients' profile.

**Results:** From Aug 2014 to Jan 2018, a total of 7048 RA patients from 480 centres in China were entered in the cohort study. These patients contributed more than 12 600 patient-years (PY) of total followup. The mean age was 48.98 ±16.08 (18 to 99) years and the median disease duration was 23.27 months. The treatment regimens include mono or combination of leflunomide(LEF), MTX, hydroxychloroquine (HCQ), sulfasalazine(SSZ), glucocorticoid(GC), biologic DMARD, Tripterygium wilfordii, meloxicam, celecoxib, iguratimod, etc. In this database the five most common treatment regimens is LEF monotherapy (3801 PY), MTX monotherapy (1321 PY), LEF +MTX (1086 PY), HCQ monotherapy (715 PY), LEF +HCQ (576 PY). The incidence rate of hepatic events was lower for LEF monotherapy (35 events/1000 PY) than MTX (52 events/1000 PY) and LEF +MTX combination therapy (115 events/1000 PY) (p<0.01). The incidence rate of leukopenia was lower for LEF monotherapy (42 events/1000 PY) and MTX monotherapy (39 events/1000 PY) than LEF +MTX combination therapy (84 events/1000 PY) (p<0.01).

**Conclusions:** The findings show that mono or combination of csDMARDs are the most commonly used drugs in Chinese RA patients. And AEs may be well described in this patient report database because of the large sample sizes and empowering patient themselves. RA patients can get better safety in the long-term treatment via SSDM.

**AB0502 DRUG SURVIVAL ANALYSIS OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS**

Y. Karakoc<sup>1</sup>, I. Ercan<sup>2</sup>. <sup>1</sup>Rheumatology Clinic, Biyofiz Medical Centre, <sup>2</sup>BioStatistics, Uludag University Medical Faculty, Bursa, Turkey

**Background:** The drug survival rate of tofacitinib in patients with Rheumatoid Arthritis (RA) has not been reported so far.

**Objectives:** To determine the tofacitinib drug survival rate and the factors that may affect it in patients with RA from a single rheumatology clinic.

**Methods:** We have retrospectively analysed the track records of RA patients to whom tofacitinib was prescribed between June 2014 to December 2017. Descriptive analysis includes sex, duration of disease, autoantibody association, smoking, major trauma exposure, initiation in DMARD/Anti-TNF resistant patients, monotherapy/use in combination with DMARD. According to the duration of the disease, the patients were grouped as early (0–4 year), established (5–10 year), and late RA (>10 year).

Drug survival was estimated using Kaplan-Meier survival analysis, and the independent variables that may affect the discontinuation were investigated by log-rank test and modelled by Backward Stepwise Cox regression analysis.

Tofacitinib was prescribed to patients who were resistant to at least three different types of csDMARDs. Low-dose Steroid (below 10 mg) and NSAID drugs were used as needed.

**Results:** During the study period, 192 (163 F, 85%) patients were prescribed tofacitinib in our clinic. Median age was 56<sup>21–81</sup> years, the median age at onset was 45<sup>6–72</sup> years, and median disease duration was 10<sup>1–40</sup> years. In this study, the ratio of RF and anti-CCP positivity were 63% and 60%, respectively. 33% of patients were seronegative. The patients with a smoking history were 26%, and exposure to major trauma was 16%. 15% of patients were early, 31% established, and 54% late Ra.

Tofacitinib was prescribed in 92 (48%) bio-naïve and 100 (52%) bio-experienced patients. It was used as monotherapy in 112 (58%) and in combination with csDMARDs 80 (42%).

The drug survival rates in Kaplan Meier analysis were 77% at 3rd, 69% at 6th, 62% at 12th, 54% at 18th and 49% at 24th, 49% at 30th months. Tofacitinib was discontinued in 51 (27%) patients due to no response and in 22 (11%) patients due to side effects. None of the independent variables in regression analysis showed a relationship to tofacitinib discontinuation ( $p > 0.05$ ). During the follow-up period, one patient had breast cancer, and one had recurrent pneumonia. There were no tuberculosis or shingles cases reported. Two patients died from pulmonary thromboembolism.

**Conclusions:** We found that drug survival rates of tofacitinib in RA patients were 77% at 3rd month, 69% at 6th month, 62% at 12th month, 54% at 18th month and 49% at 24th month, 49% at 30th months. The main cause of discontinuation of the drug was inefficiency and the loss of efficiency. We could not find any link between the predetermined independent variables and the drug discontinuation. This result raises questions about why the drug loses its efficacy in some patients in time, and how this could be preventable.

**Acknowledgements:** One of the theories of autoimmunity is that Damage-Associated Molecular Patterns (DAMPs) may give rise to autoimmune inflammation. We were curious about how many of patients suffered from major trauma, which was defined as accidents terminated with fractures and dislocations or falls from a height of at least three metres.

Bertias<sup>13</sup>, M. Govoni<sup>1</sup>. <sup>1</sup>University of Ferrara, Cona (Ferrara), Italy; <sup>2</sup>Attikon University Hospital, Athens, Greece; <sup>3</sup>State University of Campinas, Campinas, Brazil; <sup>4</sup>University of Pisa, Pisa; <sup>5</sup>Epidemiology Unit, Italian Society of Rheumatology, Milan; <sup>6</sup>Sapienza University of Rome, Rome; <sup>7</sup>University of Udine, Udine; <sup>8</sup>University of Padova, Padova; <sup>9</sup>University of Brescia, Brescia, Italy; <sup>10</sup>Dalhousie University, Halifax, Nova Scotia, Canada; <sup>11</sup>University of Cagliari, Cagliari; <sup>12</sup>AOU Ospedali Riuniti di Trieste, Trieste, Italy; <sup>13</sup>University of Crete, Heraklion, Greece

**Background:** The treatment of neuropsychiatric systemic lupus erythematosus (NPSLE) is extremely challenging and only a few clinical trials have been performed to establish optimal management.

**Objectives:** To describe the therapeutic approach and the short-term outcome of a multi-centre cohort of patients with NPSLE, enrolled at the time of the first NP event.

**Methods:** This is a retrospective cohort study. All NP events were defined according to American College of Rheumatology (ACR) case definition and divided into 3 clusters: central/diffuse (C/D), central/focal (C/F) and peripheral (P). A validated attribution algorithm was used to determine the attribution of all NP events. Demographic variables, global SLE disease activity<sup>Index 2000</sup> (SLEDAI-2K), cumulative organ damage (SLICC/ACR Damage Index (SDI)) and treatment adopted for NP manifestations were collected. The clinical outcome of all NP events was determined by a physician-completed seven-point Likert scale (1=patient demise, 2=much worse, 3=worse, 4=no change, 5=improved, 6=much improved, 7=resolved). The relationship between the variables of interest and the outcome was analysed by crude and adjusted logistic models and reported as Odds Ratio (OR) and 95% confidence intervals (95% CI).

**Results:** 461 SLE patients with at least one NP event were included. 91.8% of patients were female, mean (SD) age 35.4 (13.6) years. 19.7% (91) of events were observed at diagnosis of SLE, 13.4% (62) before and 66.8% (308) after the diagnosis. 111 events (24.1%) were C/F, 286 (62%) C/D and 64 (13.9%) P. 198 (42.95%) of all NP events were attributed to SLE. The overall probability of immunosuppressive therapy was 28.4% (95% CI 24.3–32.8), 38.7% (95% CI 29.6–48.5) in C/F, 21.3% (95% CI 16.7–26.5) in C/D and 42.2% (95% CI 16.7–26.5) in P manifestations. The probability of immunosuppressive therapy was 47.9% (95% CI 40.8–55.2) in attributed events. The one-year outcome was available in 355 patients. Physician assessment indicated resolution (76 patients) or improvement (150 patients) in 49% (226/461) of cases. The crude and adjusted OR of attributed NP events and immunosuppressants on a favourable outcome is illustrated in Figure 1. The multivariable logistic regression analysis was done adjusting for age at diagnosis of SLE [OR 0.96, 0.94–0.98]  $p = 0.001$ , female gender [OR 0.97, 0.33–2.7]  $p = 0.959$ , SDI [0.85, 0.68–1.08]  $p = 0.202$ , SLEDAI-2K [1.06, 1.01–1.11]  $p = 0.008$  and type of event [F/C [REF], C/D [0.37, 0.16–0.83]  $p = 0.016$ , P [0.54, 0.21–1.42]  $p = 0.215$ ].

**Abstract AB0503 – Figure 1.** Crude and adjusted OR of attributed NP events and induction immunosuppression (IS, Figure 1A) or start/increase IS (Figure 1B) on a favourable outcome

**Conclusions:** In our study, the therapeutic immunosuppressive approach was mostly used in attributed, C/F and P manifestations. In patients treated with immunosuppressants, the favourable outcome was lower in C/D phenotype.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6854

**AB0504 EFFICACY OF PROLONGED MAINTENANCE MONOTHERAPY WITH RITUXIMAB IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME: THREE-YEAR FOLLOW-UP**

A. Torgashina<sup>1</sup>, E. Rodionova<sup>1</sup>, T. Safonova<sup>2</sup>, V. Vasiliev<sup>1</sup>. <sup>1</sup>Nasonova Research Institute of Rheumatology, <sup>2</sup>Research Institute of Ophthalmic Diseases, Moscow, Russian Federation

**Background:** There are currently no effective systemic therapies of primary Sjögren's syndrome (pSS); however, open label series have suggested that rituximab may be beneficial for systemic and glandular manifestations.

**Objectives:** To estimate clinical efficacy and safety of prolonged maintenance B-cell targeted monotherapy for pSS.

**Methods:** 25 with pSS ACR-EULAR criteria, 2016 were included in this research. Indications for treatment were significant immunological activity (high titres of rheumatoid factor (RF) and anti-nuclear antibodies) and/or hypergammaglobulinemia in 20 patients, parotid enlargement (lymphoma was excluded) – 5, arthritis – 3, lymphadenopathy – 3, severe keratoconjunctivitis sicca in 7, of them corneal

ulceration – 3, leukopenia – 4 patients. Patients were treated initially with 2 infusions of rituximab (1000 mg) given once every two weeks with premedication (methylprednisolone (250 mg) and chlorpyramine). Then all patients received maintenance therapy with rituximab 500 mg every 6 months. Duration of treatment and follow-up was at least 3 years. Median follow-up was 45 months (36–90). Patients were evaluated, using immunologic, subjective parameters, salivary/lacrimal function at baseline and in 24 weeks and then every year during the follow-up. Patients were not concomitantly treated with another immunosuppressant agent or glucocorticoids daily.

**Results:** All patients were women with a mean age at diagnosis of 49 years [29–70] and median duration of disease was 6 years (1–20). The average cumulative dose of rituximab was 10000 mg (7000–12000 mg). The median European Sjögren's Syndrome disease activity index (ESSDAI) decreased from 2.5 (2–3) to 0 (0–1) ( $p=0.01$ ) by the end of the study. The increase in salivation and lacrimation according to Schirmer test and tear film break-up time was insufficient, however, in all patients the size of the salivary glands normalised and the recurrent parotitis stopped. Furthermore, 7 patients with severe keratoconjunctivitis sicca improved the course of the disease. The healing of corneal ulceration in all patients was observed one year after the initiation of therapy. A significant decrease in the RF level (from 198 IU/ml (51–442) to 71 IU/ml,<sup>30–73</sup>  $p=0,002$ ) and gammaglobulins (from 28%±5% to 19,3%±3,5%,  $p=0,001$ ) was observed one year after this study beginning. Unreliable decrease of immunoglobulins was noted in 23% of patients by the end of the follow-up, that did not increase the risk of secondary infections. We observed good tolerability of therapy, only 4 patients had mild infusion reactions.

**Conclusions:** Rituximab therapy is highly effective, well tolerated and helps to avoid long-term use of glucocorticoids/cytotoxic agents in pSS.

**Disclosure of Interest:** None declared

AB0505

**EARLY AND SUSTAINED REMISSION IN SLE CAN BE ACHIEVED BY USING PULSE METHYL-PREDNISOLONE, HYDROXYCHLOROQUINE AND LOW-MEDIUM DOSE-PREDNISONE**

B.R. Ruiz Estévez<sup>1</sup>, G.R. Irastorza<sup>1</sup>, E. Lázaro<sup>2</sup>, I. Ruiz Arruza<sup>3</sup>, P. Duffau<sup>4</sup>, P. Blanco<sup>4</sup>, on behalf of Systemic Autoimmune Diseases Unit of Cruces Hospital. <sup>1</sup>Systemic Autoimmune Diseases Unit, Cruces Hospital, Bilbao; <sup>2</sup>Internal Medicine, Bordeaux Hospital, Bordeaux; <sup>3</sup>Autoimmunity Diseases Unit, Cruces Hospital, Bilbao, Spain; <sup>4</sup>Internal Medicine, Bordeaux Hospital, Bordeaux, France

**Objectives:** To compare the different therapeutic schemes used in two longitudinal cohorts of patients with Systemic Lupus Erythematosus (SLE): the Systemic Autoimmune Diseases Unit of Cruces University Hospital, Barakaldo, Spain (cohort C), using a low-medium dose prednisone scheme; and the Internal Medicine Department of Bordeaux, France (cohort B) which follows the standard treatment guidelines.

**Methods:** We included patients from both cohorts diagnosed with (SLE from year 2000), with a follow-up from the time of diagnosis (inception cohorts) and for at least 5 years. We analysed the different use of glucocorticoids (prednisone and pulse methylprednisolone), hydroxychloroquine (HCQ) and immunosuppressive drugs in both cohorts. To compare the efficacy of both therapeutic schemes, we analysed the rate of clinical remission and clinical remission on treatment, according to the DORIS definitions, during the 5 years of follow-up

**Results:** 173 patients were studied: Bordeaux (B): 81 and Cruces (C): 92. Baseline clinical variables were similar between both groups, including demographics, autoimmunity and organ involvement. The baseline SLEDAI was: 8 (B) vs. 7 (C),  $p=0.06$ . The proportion of patients in treatment with prednisone was similar from year 1: 79% (B) vs. 72% (C),  $p=0.269$ , to year 5: 63% (B) vs. 55% (C),  $p=0.315$ . However, patients in cohort B received higher doses of prednisone: mean maximum dose at year 1: 38 mg/d (B) vs. 14 mg/d (C),  $p<0.05$ ; at year 5: 8 mg/d (B) vs. 3 mg/d (C),  $p<0.05$ ; average dose of prednisone at year 1: 15.8 mg/d (B) vs. 4.4 mg/d (C),  $p<0.05$ ; at year 5: 6.6 mg/d (B) vs. 3.2 mg/d (C),  $p<0.05$ . Methyl-prednisolone pulses were ever used in 26% (B) vs. 42% (C),  $p<0.05$ ; the mean total pulses per patient was 3 (B) vs. 7 (C),  $p<0.05$ ; however, the mean total dose of methyl-prednisolone per patient was similar 1725 mg (B) vs. 1635 mg (C),  $p=0.835$ , revealing a lower dose per pulse in patients from cohort C. The proportion of patients in treatment with HCQ was lower in cohort B at year 1: 80% (B) vs. 97% (C),  $p<0.05$  and at year 5: 73% (B) vs. 99% (C),  $p<0.05$ . Methotrexate was used more frequently in cohort C ( $p<0.05$ ) with no differences in cyclophosphamide, azathioprine and mycophenolate use.

Clinical remission in both cohorts was as follows: year 1: 25% (B) vs. 40% (C),  $p<0.05$ ; year 2: 29% (B) vs. 42% (C),  $p=0.07$ ; year 3: 37% (B) vs. 42% (C),  $p=0.54$ ; year 4: 37% (B) vs. 48% (C),  $p=0.15$ ; year 5: 36% (B) vs. 49% (C),  $p=0.08$ .

Clinical remission on treatment: year 1: 43% (B) vs. 84% (C),  $p<0.05$ ; year 2: 70% (B) vs. 87% (C),  $p<0.05$ ; year 3: 73% (B) vs. 88% (C),  $p<0.05$ ; year 4: 73% (B) vs. 93% (C),  $p<0.05$ ; year 5: 73% (B) vs. 93% (C),  $p<0.05$ .

**Conclusions:**

- The more frequent use of hydroxychloroquine, pulse methylprednisolone and methotrexate in the Cruces cohort resulted in reduced doses of oral prednisone.
- Patients from the Cruces cohort achieved clinical remission earlier and in a more sustained way during the follow-up.

AB0506

**HYDROXYCHLOROQUINE HAS NO PROTECTIVE EFFECT ON THE DEVELOPMENT OF SYSTEMIC LUPUS ERYTHEMATOSUS IN 7004 PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME: A NATIONWIDE POPULATION-BASED STUDY**

B.-C. Hsu, K.-T. Tang. Department of Allergy, Immunology, and Rheumatology, Taichung Veterans General Hospital, Taichung, Taiwan, Province of China

**Background:** Hydroxychloroquine (HCQ) has been proposed to be associated with later onset of systemic lupus erythematosus (SLE)<sup>1</sup> and is widely used in patients with primary Sjögren's syndrome (pSS) which may evolve to SLE.<sup>2</sup> We want to explore the potentially protective role of HCQ in the development of SLE among patients with pSS.

**Objectives:** This study was conducted to assess whether exposure to HCQ in pSS patients is associated with a reduction in the development of SLE.

**Methods:** This retrospective cohort used claims data from the National Health Insurance Registry Database (NHIRD) in Taiwan. Patients with incident Sjögren's syndrome (SS) from 2000 to 2010 in the Registry of Catastrophic Illness Database (RCIPD) of the NHIRD, which was certified by two rheumatologists, were identified. The date when SS was diagnosed in the RCIPD was defined as the index date. Those who were diagnosed as having SLE, rheumatoid arthritis, polymyositis, dermatomyositis, or systemic sclerosis in the RCIPD before the index date were excluded. Other exclusion criteria included<sup>1</sup> patients who were diagnosed as having SLE in the RCIPD within one year after the index date,<sup>2</sup> patients who withdrew from the NHIRD within one year after the index date, and<sup>3</sup> patients who used oral, intramuscular, or intravenous corticosteroids, methotrexate, azathioprine, leflunomide, sulfasalazine, cyclosporine, tacrolimus, mycophenolate, mercaptopurine, or cyclophosphamide for more than or equal to 90 days within one year before or after the index date. The included SS patients who used HCQ for more than or equal to 90 days within one year after the index date were eligible to HCQ group. The study endpoint was defined as newly-diagnosed SLE in RCIPD or withdraw from NHIRD during the 14 year follow-up period (January 1st, 2000 to December 31st, 2013).

**Results:** A total of 7004 pSS patients were identified. The mean follow-up time was 6.9 years in the HCQ group ( $n=4282$ ) and 7.0 years in the non-HCQ group ( $n=2722$ ). There were 22 newly-diagnosed SLE (0.5%) in the HCQ group and 16 (0.6%) in the non-HCQ group. The overall event rate of SLE was 8.78/10,000 person-years in the HCQ group and 9.83/10,000 person-years in the non-HCQ group (adjusted hazard ratio 0.97, 95% confidence interval 0.50–1.88, in a Cox proportional hazard model).

**Conclusions:** There is no protective effect of HCQ on the development of SLE in patients with pSS.

**BELIMUMAB IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: OUTCOMES IN ROUTINE CLINICAL PRACTICE**

C. Moriano<sup>1</sup>, M. Garijo<sup>1</sup>, C. Iñiguez<sup>1</sup>, E. Díez<sup>1</sup>, C. Díez<sup>2</sup>, L. Gómez-Lechón<sup>3</sup>, J. Martín<sup>4</sup>, M. Corteguera<sup>5</sup>, O. Martínez<sup>3</sup>, J. Cabezas<sup>6</sup>, T. Pérez<sup>1</sup>. <sup>1</sup>Hospital León, León; <sup>2</sup>Hospital El Bierzo, Ponferrada; <sup>3</sup>Hospital Salamanca, Salamanca; <sup>4</sup>Hospital Río Hortega, Valladolid; <sup>5</sup>Hospital Ávila, Ávila; <sup>6</sup>Hospital Zamora, Zamora, Spain

**Background:** Systemic lupus erythematosus (SLE) is a systemic autoimmune disease with a wide range of clinical manifestations. The persistence of activity of the disease and the prolonged use of corticosteroids are amongst the main predictors of accumulated organ damage in patients with SLE. Therefore, we need new strategies to induce long-lasting remission and minimise the adverse effects of standard medications.

**Objectives:** to assess the effectiveness and safety of Belimumab in actual clinical practice during the first year of treatment in patients with SLE.

**Methods:** retrospective observational study of patients treated with Belimumab. This study involves 6 hospitals in Castilla y León (Spain). It collects clinical and analytical data before the start of Belimumab, and 6 and 12 months after the initiation of the therapy. The data collected include the daily dose of prednisone received at different time points and the activity of the disease was classified as mild, moderate and severe based on SELENA-SLEDAI index. A reduction from baseline of 3 points on the SELENA-SLEDAI indicates meaningful symptomatic improvement.

**Results:** Among the twenty-five patients were included, with a mean age of 43.7 +12.2 years, 72% were female and 96% caucasian. The average time from diagnosis of SLE to Belimumab infusion was 9.5+7.1 years; 32% were diagnosed with SLE <5 years ago. Up to 56% of the patients had moderate disease activity and only 8% patients had very high activity of the disease. All but one of the patients had previously received an immunosuppressant (azathioprine in 50% of the cases) and 16% of the sample had not responded to rituximab. The most frequent reasons for initiating Belimumab were an ineffective previous treatment regimen (60%), the intend to decrease steroid use (56%), and worsening patient condition (52%); whereas the most frequent manifestation of SLE in these patients were arthritis (44%), followed by mucocutaneous (20%) and immunologic findings (20%). As for immunologic markers of activity, DNA was elevated by 40% and 68% of the patients showed hypocomplementemia, that dropped to 24% in both cases at 12 months. The mean score of the SELENA-SLEDAI index decreased from 9.5 to 6 in the first 6 months and to 5.2 in the 12 months of follow-up. A reduction in the initial mean steroid dose was also observed from 20 mg/day to 8.9 mg/day and 6.4 mg/day at 6 and 12 months respectively. Hence, the dose of steroid was reduced by 68% during the first year (p=0,06). This reduction was clinically significant, but it did not reach statistical significance in our study. Two patients (8%) had discontinued Belimumab within the first 6 months of therapy (1 pregnancy and 1 worsening proteinuria); 34.7% had discontinued it within the first 12 months, mostly due to ineffectiveness (62.5%). Two patients with severe renal involvement (>1 gr proteinuria/24 hour) were treated with Belimumab, allowing to reduce the steroids to a low dosis (<7.5 mg/day) at 12 months.

**Conclusions:** Belimumab appears to be effective, reducing disease activity as measured by the SELENA-SLEDAI Index and, also, the mean dose of steroids needed, mainly after 12 months of treatment. No significant adverse effects were reported as previous studies have shown.

**FIXED, LOW-DOSE HYDROXYCHLOROQUINE VERSUS WEIGHT-ADJUSTED DOSE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS WITH LOW ACTIVITY**

J.L. Callejas-Rubio<sup>1</sup>, D. Sanchez-Cano<sup>1</sup>, R. Ríos-Fernández<sup>1</sup>, M. Moreno-Higueras<sup>2</sup>, G. Fatoul del Pino<sup>1</sup>, S. Velasco-Fuentes<sup>1</sup>, M. Trigo-Rodríguez<sup>1</sup>, N. Faro-Minguez<sup>1</sup>. <sup>1</sup>Unidad de Enfermedades Autoinmunes Sistémicas; <sup>2</sup>Servicio de Medicina Interna, Hospital Campus de la Salud, Granada, Spain

**Background:** Optimal hydroxychloroquine (HCQ) dose to reduce ocular toxicity risk is 5 mg/kg or actual weight daily, according to new recommendations. In systemic lupus erythematosus patients (SLE) with low or no disease activity, fixed low-dose HCQ might be equally effective in relapse prevention weight-adjusted doses, thus resulting in lower cumulative dose.

**Objectives:** Our aim was to compare a fixed dose of HCQ 200 mg daily with a weight-adjusted dose (5 mg/kg of actual weight daily) in SLE patients with low activity.

**Methods:** SLE activity was assessed using the SLE Disease Activity Index (SLEDAI-2K), the Safety of Oestrogen in Lupus Erythematosus National Assessment (SELENA)-SLEDAI and the Physician Global Assessment (PGA, 0–3 scale) in each visit. Low-activity SLE (LLDAS) was defined according to Franklyn et al: 1) a SLEDAI-2K score ≤4, 2) no new SLE-related activity events compared with the previous visit, 3) a PGA score ≤1, 4) prednisone dose ≤7.5 mg daily and 5) stable

doses of maintenance immunosuppressant therapy. LLDAS was evaluated at baseline and months 3 and 6. In order to adjust doses to weight, and given the impossibility of fractionating HCQ tablets, the adjusted dose was calculated for every week. For example, for 62 kg patient, the calculated dose would be 5 mgx52 kg=260 mg daily, which would mean 1820 mg weekly. Therefore, the patient would receive 400 mg daily for 2 days and 200 mg daily for 5 days every week. A relapse was defined as an increase of SLEDAI scores ≥3, according to current recommendations

**Results:** A total of 50 LLDAS patients were compared, 25 with a fixed dose and 25 with a weight-adjusted dose. No significant differences regarding body weight between groups were observed: 52 kg (41–58.5 kg) vs. 51 kg (44–55 kg). Baseline activity scale scores were not significantly different. No patient relapsed on follow-up in either of both groups. Finally, the mean HCQ cumulative dose at 6 months was reduced by approximately 9.6 grams.

**Conclusions:** In LLDAS patients, a fixed HCQ dose of 200 mg daily may be as effective as the weight-adjusted dose in preventing disease relapses, thus resulting in a decrease in the HCQ cumulative dose and, therefore, a reduction of the risk of ocular toxicity.

**KZR-616, A SELECTIVE INHIBITOR OF THE IMMUNOPROTEASOME, SHOWS A PROMISING SAFETY AND TARGET INHIBITION PROFILE IN A PHASE I, DOUBLE-BLIND, SINGLE (SAD) AND MULTIPLE ASCENDING DOSE (MAD) STUDY IN HEALTHY VOLUNTEERS**

J. Lickliter<sup>1</sup>, D. Bomba<sup>2</sup>, J. Anderl<sup>2</sup>, A. Fan<sup>2</sup>, C.J. Kirk<sup>2</sup>, J. Wang<sup>2</sup>. <sup>1</sup>Nucleus Network, Melbourne, Victoria, Australia; <sup>2</sup>Kezar Life Sciences, South San Francisco, California, USA

**Background:** Proteasome inhibition is a standard of care for plasma cell malignancies. Bortezomib targets the constitutive proteasome and immunoproteasome, and is effective in the treatment of Systemic Lupus Erythematosus (SLE) and lupus nephritis (LN), but is associated with hematologic (e.g. thrombocytopenia) and constitutional (e.g. peripheral neuropathy) adverse events (AEs).

**Objectives:** We report the safety, pharmacokinetics (PK), pharmacodynamics (PD) and immunomodulatory effects of KZR-616, a first-in-class selective inhibitor of the immunoproteasome, in healthy volunteers (HV) following single and repeat subcutaneous (SC) administration.

**Methods:** Cohorts (6 drug:2 placebo) received single or 4 weekly SC doses. Safety assessments, PK and PD were measured to Day 7 (SAD) or Day 28 (MAD). SAD cohorts included 7.5, 15, 30 and 60 mg (SC). MAD cohorts included 30, 45, 60 mg, and 2 intrasubject escalation cohorts with 1 dose at 30 mg and 3 doses at 45 mg. PK was measured by LC/MS<sup>2</sup>. PD was measured using enzymatic and active site binding assays. Inflammatory cytokine release was measured following *ex vivo* stimulation of whole blood in HV receiving placebo or 45 mg KZR-616.

**Results:** 32 HV (24:8) were enrolled in 4 SAD cohorts. The most common AEs were injection site reactions (ISRs), which were generally mild and transient. No clinically-significant (CS) laboratory or ECG abnormalities and no dose limiting toxicities were observed in the SAD subjects. Following SC administration, drug exposure increased dose proportionally and was characterised by rapid absorption (T<sub>max</sub>15–30 min) and clearance (T<sub>1/2</sub> ~2 hours). Inhibition of the immunoproteasome exceeded 80% at ≥30 mg with significant recovery noted over 7 days. Constitutive proteasome inhibition was <37% in all cohorts.

40 HV (30:10) were enrolled in 5 SC MAD cohorts. In the initial cohort of 60 mg, a systemic drug reaction (chills, elevated heart rate, nausea) occurred ~8 hours after the first dose in 4 subjects. Dosing for this cohort was stopped. Subsequent cohorts (initiated at 30 mg) received prophylactic treatment with antihistamines ±prednisone 1 hour prior to the first and second dose. No similar AEs occurred with repeat dosing of 45 mg. No CS laboratory or ECG abnormalities were seen in the remaining MAD cohorts. ISRs did not appear to increase in severity or frequency with repeat dosing. There were no AEs of peripheral neuropathy, and 45 mg was well tolerated across 3 cohorts.

Consistent PK was noted following repeat administration and no drug accumulation was observed. At 45 mg, inhibition of 2 key subunits of the immunoproteasome, LMP7 and LMP2, was ~95% and ~70%, respectively. Reduced *ex vivo* stimulated production of multiple cytokines (IL-23, IL-6, TNF-α, IL-17) was noted in subjects receiving repeat administration of 45 mg KZR-616.

**Conclusions:** KZR-616 up to 45 mg was well tolerated in HV and demonstrated consistent PK and PD. Selective immunoproteasome inhibition did not induce hematologic or constitutional toxicities associated with bortezomib. Candidate dose levels were identified to explore safety, tolerability and efficacy in patients with SLE and LN in an ongoing Phase 1b/2 study.

#### IMPROVING KNOWLEDGE OF SLE DISEASE FLARES AND TREATMENT OPTIONS AMONG RHEUMATOLOGISTS AND PRIMARY CARE PROVIDERS: EFFECT OF AN ONLINE EDUCATIONAL INTERVENTION

E. Jackson, D. Blatherwick, K. Badal. *Medscape Education, New York, USA*

**Background:** With a significantly higher mortality in patients affected by systemic lupus erythematosus (SLE) developing chronic damage, prevention is a major goal in management.<sup>1</sup> Flares are a common feature throughout the course of SLE and can result in organ damage.<sup>2</sup> As a result, clinician knowledge on how to prevent, recognise, and treat flares is crucial.

**Objectives:** Determine whether an online educational intervention could effectively address a knowledge gap and an underlying educational need in the areas of SLE disease management among rheumatologists and primary care providers (PCPs).

**Methods:** An online educational intervention focusing on SLE disease management was made available online, intended for rheumatologists and PCPs who treat patients with SLE. The intervention consisted of a 30 min video presentation by a recognised expert in the treatment of SLE. Synchronised slides supported the presentation. The educational impact was assessed by comparing participants' responses to 3 repeated-pair, multiple-choice pre- and post-intervention questions. The impact on self-reported confidence was also assessed through a separate, 5-point Likert-scale question. Data were collected from 9/28/2017 through 11/29/2017. Statistical analysis included a paired 2-tailed t-test comparing mean pre-intervention and post-intervention scores, McNemar's  $\chi^2$  statistic for measuring changes in responses to individual questions, and Cramer's *V* to determine the overall impact of the intervention.

**Results:** Analysis of pre- versus post-intervention responses demonstrated a significant ( $p < 0.05$ ) improvement in overall knowledge in both rheumatologists (79% to 87%,  $n = 118$ ) and PCPs (61% to 73%,  $n = 253$ ). The overall impact of the intervention was similar in both groups ( $V = 0.106$  for rheumatologists and  $V = 0.123$  for PCPs). This intervention resulted in increased knowledge surrounding several specific areas of SLE, such as pathophysiology, relationship between disease activity and organ damage, and selection of SLE therapies (see table 1).

Abstract AB0510 – Table 1

Topic area	Rheumatologists (n=118)	PCPs (n=253)
Pathophysiology	9% (75% to 84%, $p = 0.106$ )	23% (40% to 63%, $p < 0.05$ )
Relationship between disease activity and organ damage	8% (84% to 92%, $p < 0.05$ )	5% (70% to 75%, $p = 0.197$ )
Treatment selection	7% (79% to 86%, $p = 0.173$ )	6% (74% to 80%, $p = 0.093$ )

The intervention resulted in a +4% shift in self-reported confidence in addressing flare symptoms among rheumatologists, and a +26% shift among PCPs.

**Conclusions:** Participation in an online video educational intervention with synchronised slides was associated with significant overall improvement in knowledge levels of rheumatologists and PCPs in several important aspects of SLE management. Based on assessment of residual gaps, future directions for education should be tailored to specific learner groups including case-based reinforcement of knowledge and competence among rheumatologists, and additional foundational education for PCPs in the areas of pathophysiology and disease progression.

#### THE EFFECT OF MILNACIPRAN ON FATIGUE IN A CLINICALLY STABLE LUPUS COHORT

E.P. Katsaros<sup>1</sup>, F. Dong<sup>2</sup>, I. Moldovan<sup>3</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Graduate College of Biomedical Sciences, Western University of Health Sciences, Pomona; <sup>3</sup>Internal Medicine, Loma Linda University, Loma Linda, USA

**Background:** Systemic lupus erythematosus (SLE) is a chronic multi-system autoimmune disease impacting the physical wellbeing and health related quality of life (HRQOL) of patients<sup>1</sup>. Fatigue occurs in up to 90% of SLE patients and affects their HRQOL<sup>2</sup>. The purpose of this pilot study is to determine the effect of milnacipran, a norepinephrine and serotonin reuptake inhibitor used to treat fibromyalgia, on fatigue in clinically stable SLE patients with widespread pain (WSP). To date, no clinical trials have demonstrated efficacy for the primary treatment of fatigue and WSP in adult SLE patients.

**Objectives:** The objective is to determine the effect of milnacipran on fatigue in a clinically stable lupus cohort.

**Methods:** SLE patients, 18 years and older, with fatigue, WSP and on more than 4 weeks of stable therapy were recruited for a 15 week prospective, double-blind, placebo-controlled study. Patients were randomised at a 1:1 ratio to receive 14 weeks of milnacipran 50–100 mg twice a day or placebo. Disease activity was measured by the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI). Measurements of fatigue, pain and a patient's general impression of change from baseline were assessed at baseline and week 14 using the Fatigue Severity Scale (FSS), the Short-Form McGill Pain Questionnaire (SF-MPQ)<sup>3</sup>, and the Patient's Global Impression of Change (PGIC) respectively.

**Results:** A total of 14 patients were included in the final analysis with seven patients in each group. Upon entry and throughout this study, both groups had low disease activity (mean SLEDAI  $< 3.5$  at week 0 and week 14). Fatigue as measured by FSS in the intervention group improved from 5.70 at week 0 to 5.14 at week 14 and improved in the placebo group from 5.90 to 5.59 respectively ( $\Delta = 0.56$ , 0.31 for the intervention and placebo group, respectively,  $p = 0.70$ ). Pain as measured by the SF-MPQ changed in the treatment group from 20.80 at week 0 to 18.80 at week 14, and in the placebo group from 15.40 to 13.2 respectively ( $\Delta = 2.00$ , 2.20 for the intervention and placebo group, respectively,  $p = 0.97$ ). The patient's Global impression of change was greater in the intervention group than the placebo group (0.67, 0.49,  $p = 0.21$ ).

**Conclusions:** Although results were not significantly different in this pilot study, improvement in fatigue and the patient's impression of global change appeared to be greater in the intervention group than the placebo group even though lupus activity remained low in both groups and the difference in pain between the two groups were nearly identical. Therefore, milnacipran may improve fatigue independently of disease activity and pain in lupus patients. Future randomised controlled trials of the drug's effect with larger cohorts are needed to confirm these findings.

#### OCCURRENCE AND CONSEQUENCES OF ANTI-DRUG ANTIBODIES TO RITUXIMAB IN SYSTEMIC LUPUS ERYTHEMATOSUS

E. Faustini<sup>1</sup>, I. Parodis<sup>1</sup>, N. Dunn<sup>2</sup>, M. Ryner<sup>2</sup>, A. Fogdell-Hahn<sup>2</sup>, I. Gunnarsson<sup>1</sup>. <sup>1</sup>Medicine, Unit of Rheumatology; <sup>2</sup>Clinical Neuroscience, Center for Molecular Medicine, Karolinska Institutet, Karolinska University Hospital, Stockholm, Sweden

**Background:** Anti-drug antibodies (ADA) to rituximab (RTX) have been reported to a limited extent in rheumatoid arthritis (RA, 4%–11%) and in multiple sclerosis (MS, 26%–37%), in the latter being associated with incomplete B-cell depletion.<sup>1</sup> In SLE, data on the clinical significance of ADA are lacking.

**Objectives:** To define the frequency and consequences of ADA to RTX in a SLE population by setting a disease specific threshold using a sensitive ADA method.

**Methods:** SLE patients fulfilling the 1982 ACR classification criteria who received RTX treatment at the Karolinska University Hospital during the years 2001–2015 were included. Stored serum samples obtained prior to and after six months from initiation of treatment were analysed for the detection of ADA using a GSK-developed and validated electrochemiluminescence assay. Disease specific screening and confirmation cut-point for SLE samples (1.44 AU and 29% respectively) were used. Clinical and laboratory data were retrieved from electronic medical charts. SLE activity was measured using SLE disease activity index 2000 (SLEDAI-2K). We defined treatment response according to the SLE responder index (SRI).<sup>2</sup>

**Results:** Thirty-eight patients (89.5% females, median age 35.0 years; IQR: 27.7–55.0) were included in this retrospective analysis. The median disease duration was 6.2 years (IQR: 2.1–11.6) and the baseline median SLEDAI-2K was 6.9 (IQR: 7.0–16.5). The indications for RTX were active lupus nephritis (65.8%), CNS involvement (10.5%), arthritis (13.2%), haematological manifestations (7.9%), or mucocutaneous involvement (2.6%). Twenty-six patients (68.4%) received RTX according to the lymphoma regimen (375 mg/m<sup>2</sup> at day 1, 7, 14, 28) while 12 (31.6%) according to the arthritis regimen (2 infusions at a dose of 1 g, 14 days apart). Intravenous corticosteroids and cyclophosphamide were given in 65.8% and 63.2% of the patients, respectively.

ADA were detected in 18 patient samples (47.4%) at follow-up and stratified into reactive samples (confirmed positive but with a titer <2 AU/mL; n=3), low positive (2–10 AU/mL; n=6), medium positive (11–50 AU/mL; n=4), and high positive (>51 AU/mL; n=5).

We found no association between the occurrence of ADA and either SRI response (p=0.26, Fisher exact test) nor the concomitant use of high dose IV 6-methylprednisolone (p=0.56,  $\chi^2$  test) or IV cyclophosphamide (p=0.11,  $\chi^2$  test). At follow-up, patients positive for ADA had higher levels of CD19 +B cells (median:  $0.03 \times 10^9$  cells/L; IQR: 0.01–0.13) compared to negative patients (median:  $0.01 \times 10^9$  cells/L; IQR: 0.005–0.01; p=0.007, Mann-Whitney test).

**Conclusions:** ADA to RTX in SLE are more frequent than in RA and MS and occur irrespective of treatment response and cotreatments, but are associated with higher counts of CD19 +B cells at follow-up. Such finding could reflect either incomplete B-cell depletion in ADA positive patients, or earlier repopulation. Further studies should address the relation between ADA titers and clinical outcomes as well as immunological consequences.

### AB0513 B AND T LYMPHOCYTES MODIFICATIONS AFTER BELIMUMAB TREATMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

F. Regola<sup>1</sup>, S. Piantoni<sup>1,2</sup>, R. Reggia<sup>1</sup>, R. Kumar<sup>1</sup>, L. Andreoli<sup>1</sup>, F. Franceschini<sup>1</sup>, A. Tincani<sup>1</sup>, P. Airo<sup>1</sup>. <sup>1</sup>*Rheumatology and Clinical Immunology, Spedali Civili and University of Brescia*; <sup>2</sup>*Molecular and Translational Medicine, University of Brescia, Brescia, Italy*

**Background:** B- and T-cell hyper-activation is one of the pathogenic mechanisms of systemic lupus erythematosus (SLE). SLE patients have a severe defect in the B cell tolerance check, resulting in high numbers of autoreactive mature naïve B-cells (CD19 +CD27-IgD+) and of peripheral transitional B-cells (CD19 +38high24high). On the other hand, in patients with active SLE a reduced thymic output with a decreased number of recent thymic emigrants T-cells (RTE; CD4 +CD31+) was demonstrated, whereas repeated antigenic stimulation drives modifications in T-cells subpopulations, with enhanced differentiation into effector memory cells (CCR7-CD45RA-).<sup>1</sup>

Belimumab is a monoclonal antibody against soluble BLYS used in the treatment of severe SLE. Although B cells are the main target of this treatment, a BLYS-dependent T-cell activation pathway has also been demonstrated.<sup>2</sup> However, few data are available on the effects of belimumab on circulating B- and T-cell subsets.

**Objectives:** The aim of this study was to characterise B and T-cell phenotype in a cohort of patients with SLE, and to analyse their modifications during belimumab therapy.

**Methods:** Phenotypic analysis of peripheral blood B and T lymphocyte subsets was made by flow-cytometry in 14 SLE patients before the first infusion of belimumab, and after 12 months of treatment. SLEDAI 2K-score was used to determine disease activity: a score  $\geq 6$  indicated high disease activity. Sex and age-matched healthy controls were enrolled for the comparisons.

**Results:** At baseline, SLE patients had lower numbers of B- (82 vs 153 cell/ $\mu$ l; p=0.05), T- CD4+ (365 vs 1131 cell/ $\mu$ l; p<0.01), T- CD8+ (340 vs 516 cell/ $\mu$ l; p=0.01), and RTE (95 vs 240 cell/ $\mu$ l; p=0.03) than healthy donors.

After treatment there was a decrease of total B lymphocytes (82 vs 19 cell/ $\mu$ l; p<0.01), and particularly of naïve (45 vs 19% of CD19+; p<0.01) and transitional cells (1 vs 0.2 cell/ $\mu$ l; p=0.03). The absolute number of unswitched memory B cells decreased (2.2 vs 1.4 cell/ $\mu$ l; p=0.05), whereas the percentage of switched memory B cells increased (16 vs 44% of CD19+; p<0.01). The absolute number of CD8 +effector memory cells was also reduced (61 vs 53 cell/ $\mu$ l; p=0.05), as well as percentages of RTE (20 vs 10% of CD4+; p=0.01).

After 1 year therapy in the only 2 patients with persistent high disease activity the percentages of transitional B cells and unswitched memory cells were higher than in 7 patients in which an initially high disease activity decreased below SLEDAI=6 (9% vs 1%; p=0.03; and 29% vs 6%; p=0.04, respectively).

**Conclusions:** The effects of belimumab on B cell subpopulations are likely to be directly explained by the blockage of soluble BLYS. On the other hand, the effects on the phenotype of T cells are modest and it cannot be excluded that they are indirectly explained by the reduction of disease activity obtained through the therapy. The number of certain circulating B cell subsets might be a marker of response to treatment.

### AB0514 THE EFFECT OF HYDROXYCHLOROQUINE ON REDUCING PROTEINURIA IN STABLE SLE PATIENTS

H. Takahashi, Y. Nasa, E. Takamasu, S. Sugii, N. Yokogawa. *Rheumatology, Tokyo Metropolitan Tama Medical Hospital, Fucyu Tokyo, Japan*

**Background:** It is thought that hydroxychloroquine (HCQ) reduces proteinuria by preventing endothelial dysfunction in mouse models, but the effects in systemic lupus erythematosus (SLE) patients are not known.

**Objectives:** To investigate the effects of HCQ on proteinuria in stable SLE patients.

**Methods:** This was a single-centre, retrospective cohort study. We included stable SLE patients who met the updated or revised American College of Rheumatology 1997 criteria for SLE or the 2012 Systemic Lupus International Collaborating Clinics criteria, and had no active organ dysfunction that needed an increase in immunosuppressive therapy. The subjects (HCQ group) were SLE patients with proteinuria >0.2 g/gCr who started HCQ between 11/1/2015 and 8/1/2017. The controls (non-HCQ group) were SLE patients with proteinuria >0.2 g/gCr seen between 5/1/2016 and 10/31/2016. The reduction in proteinuria over 6 months in the HCQ and non-HCQ groups was compared. The following patients were excluded from the analysis: those who had proteinuria of other aetiologies (diabetic nephropathy, etc.), those who increased the prednisolone (PSL) dose or started immunosuppressive agents, angiotensin converting enzyme inhibitors, or angiotensin II receptor blockers beginning 1 month before the observation period started until its end. Improvement was defined as a reduction in proteinuria  $\geq 0.1$  g/gCr. The statistical analysis was performed with the *t*-test and chi-square test.

**Results:** There were no significant differences in disease duration, sex, Systemic Lupus Erythematosus Disease Activity Index, or the use of immunosuppressants at baseline between the HCQ (n=16) and non-HCQ (n=14) groups. The respective mean PSL dose at baseline was  $5.9 \pm 2.8$  and  $3.3 \pm 3.8$  mg in the HCQ and non-HCQ groups (p=0.042). Patients in the HCQ group were younger (mean  $47 \pm 12$  vs.  $63 \pm 14$  years, p=0.005). The kidney pathology of the HCQ group was 6.25, 25, 6.25, 6.25, and 6.25% class I to V, respectively, compared with 7.14% class IV, 14.2% class V, and 14.2% class IV+V in the non-HCQ group. The other patients were diagnosed with lupus nephritis clinically.

Proteinuria was significantly lower in the HCQ group than in the non-HCQ group ( $-0.170 \pm 0.343$  g/gCr vs.  $+0.129 \pm 0.401$  g/gCr, p=0.036). The mean proteinuria at baseline and 6 months later was  $0.501 \pm 0.276$  and  $0.331 \pm 0.274$  g/gCr, respectively, in the HCQ group, and  $0.587 \pm 0.409$  and  $0.717 \pm 0.720$  g/gCr in the non-HCQ group. The proportion of patients who improved in the HCQ and non-HCQ groups was 68.7% (11/16) and 28.5% (4/14), respectively (p=0.028).

**Conclusions:** HCQ may reduce proteinuria in SLE patients. This suggests that HCQ administration protects the kidneys of SLE patients.

AB0515

**SPANISH SOCIETY OF RHEUMATOLOGY (SER) RECOMMENDATIONS ON PRIMARY ANTIPHOSPHOLIPID SYNDROME (APS). IN A PATIENT WITH OBSTETRIC APS, WHICH TREATMENTS ARE MORE EFFECTIVE? SYSTEMATIC REVIEW**

H. Sánchez Pérez<sup>1</sup>, M. Nishishinya Aquino<sup>2</sup>, C. Pereda<sup>3</sup>, P. Díaz del Campo Fontecha<sup>4</sup>, M. Martínez Zamora<sup>5</sup>. <sup>1</sup>Rheumatology, Hospital Universitario de Canarias, La Laguna; <sup>2</sup>Programa de doctorado en Ciencias de la Educación y el Deporte de la Facultad de Psicología, Ciències de l'Educació i de l'Esport Blanquerna, Institut Traumatològic Quirón, Barcelona; <sup>3</sup>Rheumatology, Hospital Mediterráneo, Almería; <sup>4</sup>Unidad de Investigación, Sociedad Española de Reumatología, Madrid; <sup>5</sup>Servicio de Obstetricia y Ginecología, Hospital Clínic, Barcelona, Spain

**Background:** Pregnancy complications and poor obstetric prognosis are part of the manifestations of APS. The obstetric APS (O-APS) includes 3 or more early miscarriages, 1 or more intrauterine foetal deaths, prematurity secondary to preeclampsia or placental insufficiency, intrauterine growth retardation and HELLP syndrome among others. There is disagreement among different published studies regarding the need of preconceptual or primary thromboprophylaxis (treating with anticoagulant/antiaggregant drugs in the presence of specific autoantibodies but without previous clinical events) and the most effective and safest drug to use, as well as which treatment should be chosen in the case of secondary thromboprophylaxis (treating in the presence of autoantibodies and recurrent miscarriages or previous obstetric complications).

**Objectives:** To evaluate the available scientific evidence on which treatments are the most effective and safest in O-APS.

**Methods:** A systematic review (SR) was performed to evaluate the efficacy and safety of different interventions (Aspirin (ASA), Heparin, Antimalarials, Immunglobulin IV (IVIg), others) in pregnant women with O-APS. We included SR, randomised clinical trials (RCTs) and comparative cohort studies. Result measures on morbidity (prematurity, low birth weight, need for intensive care, impaired cognitive development, preeclampsia, eclampsia, HELLP, abruptio placentae) and mortality included both the newborn and the pregnant woman. A peer review selection and analysis of the studies was carried out (SP,H; NA, MB).

**Results:** 788 citations were identified (Medline, EMBASE, CENTRAL, May 2017). We included 17 studies: 5 SR, 5 RCTs and 7 cohort studies. Results are shown on the table 1 below:

Abstract AB0515 – Table 1

Drugs	Efficacy	Level of evidence
ASA vs placebo	Inconclusive	1+
ASA + Heparin	The combination is more effective than ASA on its own in order to achieve better obstetric results in women with O-APS One SR and one RCT did not found added benefits with the combination compared to ASA monotherapy	1+, 1+, 1-,2+ 1+, 2+
IVIg	Inconclusive, but: Comparing IVIg with ASA+heparin is favourable to this combination: it is easier to use and has a lower cost IVIg compared with prednisone could be a better option to decrease maternal complications in patients with O-APS	1+, 1-,2+ 2-
Corticoids	There is not enough evidence available.	1+, 2-
Statins	There is not enough evidence available.	2+

**Conclusions:** In women with O-APS:

- **Secondary thromboprophylaxis:** The combination of ASA +Heparin is more effective than ASA monotherapy.

With regards to the use of IVIg, corticosteroids and statins: NO representative conclusions can be drawn from published studies

- **Pre-conceptual thromboprophylaxis, primary thromboprophylaxis:** NO representative conclusions can be drawn from published studies.

**Acknowledgements:** This review is part of the preparation of SER Recommendations on Primary APS treatment.

AB0516

**THERAPEUTIC STRATEGIES AND PROGNOSIS IN CHINESE PATIENTS WITH SEROLOGICALLY ACTIVE CLINICALLY QUIESCENT SYSTEMIC LUPUS ERYTHEMATOSUS**

H. Huang<sup>1,2</sup>, L. Mou<sup>1</sup>, Y. Hao<sup>1</sup>, Z. Zhang<sup>1</sup>, W. Zhou<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology Department, Peking University First Hospital; <sup>2</sup>Rheumatology and Clinical Immunology Department, First Hospital of Tsinghua University, Beijing, China

**Background:** SACQ patients with SLE appears to account for 6%–12% of all patients with SLE, but there is disagreement about whether such patients are indeed clinically stable, especially in Chinese patients. And there is no conclusion as to what kind of treatment should be taken for such patients.

**Objectives:** The aim of our study was to identify the frequency and outcome of SACQ patients with SLE. And we tried to find out potential predictors of flare.

**Methods:** 682 patients with systemic lupus erythematosus who were followed up for more than 6 months at Peking University First Hospital from January 2007 to December 2015 were summarised. SACQ was defined as an at least a 6 month period with persistent serologic activity and without clinical activity and could be taking a daily dose of prednisone or equivalent less than 7.5 mg. Serologically quiescent clinically quiescent (SQCQ) patients and serologically active clinically active (SACA) patients served as control groups. Data including demographics, initial symptoms, duration to SACQ, treatments before and after SACQ, and characteristics of the flare group were analysed.

**Results:** Of the 682 patients, 170 were SACQ patients (24.9%), 187 were SQCQ patients, and 325 were SACA patients (47.7%). SQCQ patients (38.61±15.08 years old) were older at study start than did SACQ patients (38.61±15.08 years vs. 32.09±14.35 years, p=0.000), but there was no significant difference between that of SACQ and SACA patients. 56 of the 170 SACQ patients (32.9%) experienced flare. Corticosteroids (OR 1.323, 95% CI 1.135 to 1.542; p=0.000) was an independent risk factor for flare, while antimalarials (OR 0.040, 95% CI 0.004 to 0.418; p=0.007) and immunosuppressants (OR 0.321, 95% CI 0.153 to 0.673; p=0.003) were protective factors.

**Conclusions:** SLE patients with SACQ remained relatively stable, with 32.9% of patients relapsed. The group of flare patients took greater use of corticosteroids than non-flare ones, whereas antimalarials and immunosuppressants agents were protective factors.

**INVASIVE ASPERGILLOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY FOCUS ON CLINICAL CHARACTERISTICS AND RISK FACTORS OF IN-HOSPITAL MORTALITY**

H. Mingli<sup>1</sup>, C.-Y. Tsai<sup>2</sup>. <sup>1</sup>Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital; <sup>2</sup>Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital, Taipei, Taiwan, Province of China

**Objectives:** To analyse the clinical features and outcomes of patients with invasive aspergillosis (IA), the mortality risk factors and all-cause mortality in patients with systemic lupus erythematosus (SLE) in single centre of Taiwan.

**Methods:** A retrospective study was performed to identify the mortality risk factors associated with IA in patients with systemic lupus erythematosus (SLE). We reviewed the medical records of patients with SLE who were diagnosed with invasive aspergillosis between Jan. 2006 and Jun. 2017 from Taipei Veterans General Hospital in Taiwan. Clinical and laboratory parameters as well as treatment outcomes were analysed.

**Results:** Twenty-one patients diagnosed with proven (n=4; 19.04%) and probable (n=17; 80.95%) invasive aspergillosis according to revised definition by European Organisation for Research and Treatment of Cancer/Invasive Fungal Infections Cooperative Group and the National Institute of Allergy and Infectious Diseases Mycoses Study Group (EORTC/MSG) Consensus Group were enrolled in the study and separated into survivors (n=7; 33.33%) and non-survivors (n=14;

66.67%) groups. All patients in invasive aspergillosis demonstrated significantly high incidence of pneumonia (n=19; 90.47%), concurrent infections (n=17; 80.95%), and high mortality (n=14; 66.67%). The coinfections with bacteremia (n=8; 38.10%), cytomegalovirus (n=9; 42.86%), and candida (n=6; 28.57%) were common in patients with invasive aspergillosis. Gram-negative bacilli (38 isolates; 69.09%), of which the most common isolates were carbapenem-resistant *Acinetobacter baumannii* (8 isolates; 21.05%). The most common Gram-positive isolates were methicillin-resistant *Staphylococcus aureus* (6 isolates; 35.29%), followed by Vancomycin-resistant *Enterococcus* (4 isolates; 23.52%). The daily glucocorticoid dose  $\geq 20$  mg (p=0.007, HR 2.000, 95% CI 1.185–3.377), rates of recent pulse glucocorticoid therapy (p=0.022, HR 2.800, 95% CI 1.387–5.654), rates of azathioprine use (p=0.022, HR 2.000, 95% CI 1.185–3.377), rates of rituximab within six months (p=0.022, HR 2.000, 95% CI 1.185–3.377), plasmapheresis during hospital course (p=0.022, HR 2.000, 95% CI 1.185–3.377), and acute respiratory distress syndrome (p=0.022, HR 2.000, 95% CI 1.185–3.377) among non-survivor group were statistically higher than the survivor group. Non-survivors had significantly higher rate of concurrent infections (p=0.002, HR 5.667, 95% CI 2.029–15.824) and cytomegalovirus (CMV) viremia (p=0.040, HR 1.750, 95% CI 1.112–2.775) than survivors. The sensitivity of Galactomannan assay was not good to exclude the diagnosis of invasive aspergillosis. Septic shock (n=7, 50% of non-survivor group) is the most common cause of in-hospital mortality in patients with invasive aspergillosis.

**Conclusions:** The daily glucocorticoid dose  $\geq 20$  mg, recent pulse glucocorticoid therapy, azathioprine, rituximab within six months, concurrent infections, and CMV viremia are risk factors of in-hospital mortality in invasive aspergillosis patients with Systemic Lupus Erythematosus.

within six months, concurrent infections, and CMV viremia are risk factors of in-hospital mortality in invasive aspergillosis patients with Systemic Lupus Erythematosus. within six months, concurrent infections, and CMV viremia are risk factors of in-hospital mortality in invasive aspergillosis patients with Systemic Lupus Erythematosus.

#### AB0518 EFFICACY OF BELIMUMAB FOR PRIMARY SJÖGREN SYNDROME: RESULTS OF A SYSTEMATIC REVIEW OF THE LITERATURE

H.S. Park<sup>1</sup>, N. Alvarez-Rivas<sup>2</sup>, P. Diaz del Campo<sup>3</sup>, M. Fernandez-Castro<sup>4</sup>, H. Corominas<sup>1</sup>, J.L. Andreu<sup>5</sup>, V. Navarro-Compán<sup>6</sup>. <sup>1</sup>Rheumatology, H.U. Sant Pau, Barcelona; <sup>2</sup>Rheumatology, H.U. Lucus Augusti, Lugo; <sup>3</sup>Research Unit, SER; <sup>4</sup>Rheumatology, H.U. Infanta Sofía; <sup>5</sup>Rheumatology, H.U. Puerta del Hierro Majadahonda; <sup>6</sup>Rheumatology, H.U. La Paz. IDIPAZ, Madrid, Spain

**Background:** Belimumab is a human monoclonal antibody that inhibits B-cell activating factor shown to be efficacious in systemic lupus erythematosus. In other B cell mediated autoimmune disease such as primary Sjögren's syndrome (pSS) the efficacy is unclear.

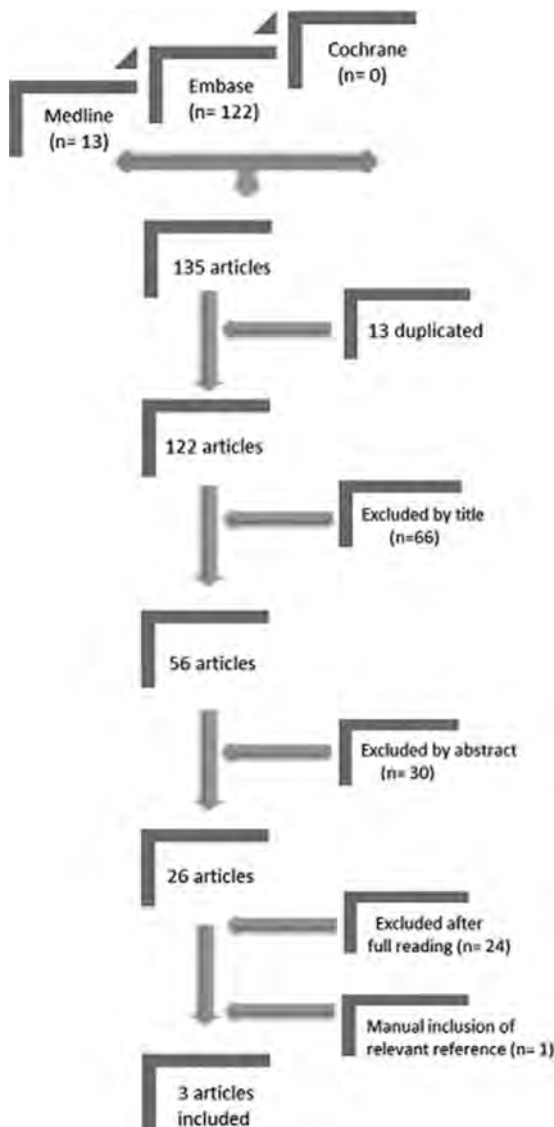

**Objectives:** To evaluate the efficacy of belimumab in patients with pSS.

**Methods:** A systematic literature review was performed (EMBASE, MEDLINE and Cochrane) as part of the Spanish Rheumatology Society's Recommendations for the Use of Biological Therapies in Primary Sjögren's Syndrome. Inclusion criteria was defined as: Population: patients with pSS according to American-European Consensus Criteria 2002 Intervention: belimumab; Control: synthetic or biologic DMARDs, corticosteroids, ursodesoxicolic acid or placebo; Outcome: efficacy in dryness, glandular and extraglandular manifestations. Studies with <10 patients or <3 months of follow up were excluded. Two reviewers independently selected the articles and evaluated the quality of the evidence following SIGN guidelines.

**Results:** 3 articles were included out of 135. All of them published results from the same study<sup>1</sup> at different timepoints. The study design was experimental but with a small sample size and no control group or randomization.

The article of Mariette et al 2015<sup>1</sup> evaluated the efficacy and safety of belimumab in 30 patients with systemic activity or early disease until week 28 (W28). There was a significant decrease in mean ESSDAI (8.8 to 6.3 p=0.02), ESSPRI (6.4 to 5.6 p=0.02) and VAS for dryness (7.8 to 6.2 p=0.02). Physician's VAS for disease systemic activity also decreased in 43% as well as parotid inflammation in 76.9% of patients. Also, B cell biomarkers decreased: IgG (21.2 to 18.2 g/L, p=0.02), IgA (3.7 to 3.3 g/L, p=0.04), IgM (1.6 to 1.3 g/L, p<0.001), RF (146.2 to 106.7 UI p<0.001) and number of B cells (187.2 a 65.1/mm, p<0.001).

The study of De Vita et al 2015<sup>2</sup> compared results at week 52 (W52) and W28 in 19 patients, of whom 15 had previously responded to treatment. Of these 15 patients 13 maintained response and 3 out of the 4 patients that did not respond achieved primary outcome. The improvement at W52 continued for ESSDAI, glandular inflammation, lymphadenopathy and joints. B cell biomarkers remained stable. Overall items contributing to ESSDAI decreased but only physician's VAS for disease systemic activity was statistically significant (3.2 W28 vs 2.5 W52; p=0.04).

**Abstract AB0518 – Figure 1**

The study of Quartuccio et al.<sup>3</sup> compared clinical and lab variables of W52 with 12 months of follow up after interrupting belimumab. A significant decrease in ESSDAI in 9 out of 13 patients (3.5±3.7 vs 7.0±5.7; p<0.01) was observed as well as in RF (52 vs 69UI; p<0.01), IgM (131.9 vs 165 mg/dl; p=0.04) and BLYS (1304 vs 2882 pg/ml; p=0.01).

**Conclusions:** Published evidence to determine the efficacy of belimumab in primary Sjögren is limited and poor. Belimumab seems to be effective to reduce systemic activity, parotid enlargement, dryness, lymphadenopathies, articular manifestation, fatigue and B cell biomarkers.

**AB0519** **IMPACT OF HIGHER BODY MASS INDEX (BMI) IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

I. Saulescu, D. Opris Belinski, A. Borangiu, L. Groseanu, S. Daia-Iliescu, D. Mazilu, M. Negru, V. Stoian, V. Bojinca, A. Balanescu, C. Constantinescu, R. Ionescu.  
*Internal Medicine and Rheumatology, UMF Carol Davila, Sf. Maria Hospital, Bucharest, Bucharest, Romania*

**Background:** Systemic lupus erythematosus (SLE) patients may have nutritional changes triggered by disease itself or by treatment with possible implication for patients prognosis.

**Objectives:** The main focus of the study was to evaluate nutritional status and its impact in a SLE cohort with disease duration of at least 1 year.

**Methods:** 105 SLE patients admitted in Sf. Maria Clinical Hospital in 2017 were enrolled. Inclusion criteria were represented by disease evolution of at least 1 year. All patients agreed to participate in this observational study. Data about demographic, clinical or serological characteristics, but also activity (SLEDAI), damage accrual (SLICC damage index SDI) and treatment or complications (osteoporosis, cataract, glaucoma, etc) were collected. Nutritional status was evaluated by calculating Body Mass Index (BMI) for each patient. A descriptive and analytical statistics was performed with SPSS.

**Results:** 99 females and 6 males were enrolled. Mean age at SLE diagnosis was 34.39, SD 11.34. BMI was calculated as ratio of body weight to squared height (kg/m<sup>2</sup>). According to BMI, 5% of patients were underweight (BMI <18.5), 56% had normal weight (BMI 18.5–25), 25% were overweight (BMI 25–30) and 14% were obese (BMI >30). Increased BMI was correlated with longer disease duration (p 0.0001, r 0.30) and older age (p 0.0001, r 0.35), but these correlation loose the strength for patients older than 40 years (p 0.04, r 0.15), suggesting a more pronounced weight gain at the beginning of the disease. Quality of sleep was significantly altered in patients with abnormal BMI (p 0.005, r 0.35). As expected, overweight and obese patients had a sedentary life style (p<0.01). Higher BMI was correlated also with higher SDI score (p 0.026, r 0.35) and higher number of complications related to chorticotherapy per patient (p 0.0001, r 0.45).

**Conclusions:** SLE patients have an increased risk for higher BMI, especially patients younger than 40 years, in the first years after diagnosis. Optimising weight in our SLE patients should be in our focus in order to limit number of complications, damage accrual and lifestyle patterns that negatively impact their life.

**AB0520** **ASSESSMENT OF ANTI-MÜLLERIAN HORMONE LEVELS IN SYSTEMIC LUPUS ERYTHEMATOSUS TREATED WITH IMMUNOSUPPRESSOR**

J. Yu. *Rheumatology, Distinct Healthcare, Shenzhen, China*

**Background:** Systemic lupus erythematosus (SLE) is a chronic immune-mediated inflammatory disease that affects predominantly females during childbearing age. Fertility in SLE patients is considered to be normal but several factors, such as disease activity, renal involvement and treatment with immunosuppressor may negatively influence fertility.

**Objectives:** To investigate the ovarian reserve of patients with SLE by measuring anti-müllerian hormone (AMH) levels, and compare the AMH levels before and after treatment with immunosuppressor.

**Methods:** This was a self-control study performed on newly diagnosed premenopausal female SLE patients fulfilled the 1997 American College of Rheumatology (ACR) criteria. Serum concentrations of AMH in peripheral venous blood were measured using a human AMH ELISA kit (MSKIBIO, Wuhan, China) before and after treatment with 6 month immunosuppressor.

**Results:** 45 patients were recruited. AMH serum levels reduced after treatment in the cyclophosphamide (CTX) group (n=6) and leflunomide (LEF) group (n=7), P<0.05. AMH serum levels did not differ before and after treatment in the mycophenolate (MMF) group (n=11), tacrolimus group (n=8) and methotrexate (MTX) combined with cyclosporin A (CsA) group (n=13), p≥0.05.

**Conclusions:** In this self-control study, the AMH serum levels reduced after 6 month treatment of CTX or LEF, indicating CTX and LEF might negatively influence ovarian reserve function. AMH serum levels did not differ after 6 month treatment of MMF, tacrolimus or combined use of MTX and CsA, indicating these immunosuppressor might be relatively safe for ovarian reserve function.

**AB0521** **SAFETY, PHARMACOKINETICS, AND PHARMACODYNAMICS OF SINGLE DOSES OF A BISPECIFIC ICOSL AND BAFF INHIBITOR, AMG 570, IN HEALTHY SUBJECTS**

L.E. Cheng<sup>1</sup>, M. Kankam<sup>2</sup>, N. Siebers<sup>3</sup>, R. Stoltz<sup>3</sup>, L. Abuqayyas<sup>4</sup>, B. Ertik<sup>4</sup>, B. A. Sullivan<sup>4</sup>, L. Zhou<sup>4</sup>, D. Mitragotri<sup>4</sup>, J.R. Parnes<sup>4</sup>. <sup>1</sup>Amgen Inc., South San Francisco; <sup>2</sup>Vince and Associates Clinical Research, Overland; <sup>3</sup>Covance Inc., Princeton; <sup>4</sup>Amgen Inc., Thousand Oaks, USA

**Background:** Autoimmune diseases, including systemic lupus erythematosus (SLE), are associated with dysregulation in both T cell and B cell responses. Targeting the activity of both cell types simultaneously holds promise as a treatment for autoimmune disease. AMG 570 is a bispecific molecule targeting both T cell and B cell activity through neutralisation of the inducible costimulator ligand (ICOSL) and the B cell activating factor (BAFF).

**Objectives:** To investigate the safety, tolerability, pharmacokinetics, and pharmacodynamics of AMG 570 in healthy subjects after single subcutaneous doses.

**Methods:** This ongoing, double-blind, randomised, placebo-controlled trial has enrolled healthy subjects (age ≥18 years) into escalating single-dose cohorts. Eight participants were enrolled into each cohort and were randomised 3:1 to receive either AMG 570 or placebo across six cohorts of increased dose level. The primary endpoint of the study was treatment-emergent adverse events (AEs). Secondary endpoints included pharmacokinetics and pharmacodynamics (eg, receptor occupancy of ICOSL, changes in B cell subpopulations, and serum immunoglobulin levels).

**Results:** As of an ad hoc interim analysis on October 5, 2017, 48 participants were enrolled and received one dose of investigational product (either AMG 570 or placebo). 73 AEs were reported; all were mild (n=56) to moderate (n=14) in severity (3 injury AEs had no grade reported). Upper respiratory tract infection and injection site erythema were the most commonly reported AEs. No drug-related serious adverse events were reported. No severe, life-threatening, or fatal AEs were reported. AMG 570 demonstrated nonlinear pharmacokinetics consistent with cell surface target (ICOSL) interaction. In the highest dose tested, AMG 570 achieved greater than 90% mean ICOSL receptor occupancy on circulating B cells 8 days after dosing, and high levels (>85% mean ICOSL receptor occupancy) were observed 29 days after dosing. AMG 570 led to a reduction in circulating naïve B cells and an increase in circulating memory B cells. No apparent changes were observed in serum IgM or IgG.

**Conclusions:** Overall, AMG 570 was safe and well tolerated by healthy subjects. AMG 570 demonstrated pharmacodynamic activity consistent with ICOSL and BAFF neutralisation.

### TACROLIMUS IN REFRACTORY LUPUS NEPHRITIS: A PROSPECTIVE MULTICENTRIC STUDY CARRIED OUT IN CLINICAL PRACTICE SETTING

M. Larosa<sup>1</sup>, M. Zen<sup>1</sup>, L. Iaccarino<sup>1</sup>, A. Tincani<sup>2</sup>, L. Andreoli<sup>2</sup>, F. Conti<sup>3</sup>, F. R. Spinelli<sup>3</sup>, G. De Marchi<sup>4</sup>, S. De Vita<sup>4</sup>, A. Doria<sup>1</sup>. <sup>1</sup>Rheumatology Unit, Department of Medicine-DIMED, University of Padova, Padova; <sup>2</sup>Rheumatology and Clinical Immunology Unit, Ospedale Civile, Brescia, Brescia; <sup>3</sup>Department of Internal Medicine and Medical Specialties, Sapienza University of Rome, Rome; <sup>4</sup>Clinic of Rheumatology, Department of Medical and Biological Sciences, University Hospital "Santa Maria della Misericordia", Udine, Italy

**Background:** The efficacy of tacrolimus (TAC) in lupus nephritis (LN) has been recently demonstrated in several randomised controlled trials in asian cohorts.<sup>1</sup> Nevertheless, data on real-life experience and long-term safety of TAC are still lacking.

**Objectives:** To assess efficacy and safety of TAC in SLE patients with refractory LN in a multi-centric prospective cohort.

**Methods:** Adult SLE patients with refractory LN from 4 Italian centres were prospectively followed for at least 12 months. Clinical and serological variables and previous/concomitant medications were collected at baseline, 3, 6, 12 months after starting TAC. Renal response was assessed by using EULAR/ERA-EDTA definitions.<sup>2</sup> Adverse events (AEs) included non-infectious and infectious AEs; they were defined severe (SAE) when hospitalisation and/or death and/or life-threatening manifestations occurred. Data were analysed using SPSS (v.24.0).

**Results:** Thirteen SLE patients (8 females, 5 males, mean age 33.7±10.2, mean disease duration 11.9±5.9) were enrolled (table 1). Concomitant medications included: prednisone (100%), mycophenolate mofetil (92.3%), hydroxychloroquine (53.8%), azathioprine (7.7%), belimumab (7.7%) and cyclosporine (7.7%). The average number of previous immunosuppressants taken by each patient was 3.15±1.90. Six-months renal response was achieved by 5/13 patients (38.5%): complete renal response (CRR) in 3 (60.0%) and partial renal response (PRR) in 2 patients (40.0%). Twelve-months renal response occurred in 4/13 patients (30.8%): CRR in 2/13 (50.0%) and PRR in 2/13 (50.0%). One patient achieved CRR at 6 and 12 months; one patient achieved PRR at 6 months and CRR at 12 months. Six patients (46.1%) discontinued TAC after an average follow up period of 10.2±7.8 months. Causes of discontinuation were: 3 non-infectious non-SAEs, 1 flare, 1 non-infectious SAE, and 1 non-response. Concerning AEs, no severe infections or deaths occurred.

**Abstract AB0522 – Table 1.** Demographic, clinical and serological features at baseline, 3, 6, 12 months after starting TAC (mean±SD)

	Baseline	3 months	6 months	12 months
Prednisone daily dosage (mg/day)	17.1 ±11.3	12.7±9.5	12.8±13.1	9.6±5.6
Tacrolimus daily dosage (mg/day)	4.1±1.3	3.5±1.9	4.2±1.8	4.0±0.8
Creatinine (mg/dL)	0.8±0.5	0.8±0.3	0.7±0.3	0.9±0.5
24 hour proteinuria (g/day)	3.8±2.2	1.4±1.2	1.5±1.6	2.0±1.6
SLEDAI-2k	8.8±2.4	7.2±4.5	7.5±4.3	7.4±4.4
SLICC-DI	1.3±1.4	/	1.6±1.5	1.4±1.1

SLEDAI-2k: Systemic Lupus Erythematosus Disease Activity Index 2000; SLICC-DI: Systemic Lupus International Collaborating Clinics Damage Index.

**Conclusions:** Our preliminary data from clinical practice setting suggest that TAC could be a therapeutic rescue strategy for refractory LN. Further studies are needed to prove TAC efficacy in the long term.

### METFORMIN COMBINED WITH CONVENTIONAL THERAPY INCREASES ABSOLUTE NUMBER OF REGULATORY T CELLS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Hao<sup>1</sup>, Z. Liang<sup>1</sup>, X. Jing<sup>1</sup>, X.Q. Liu<sup>1</sup>, C. gao<sup>2</sup>, X. li<sup>1</sup>, J. chen<sup>1</sup>. <sup>1</sup>The Second Hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Brigham and Women's Hospital, Harvard Medical School, Boston, USA

**Background:** Systemic lupus erythematosus (SLE) is multisystem and multiorgan autoimmune diseases and the main treatment is hormone combined with immunosuppressant and biological agents. Since the conventional treatment regimens have not achieved expected effects, it is of great practical value to search for good efficacy, lower side-effects, and low-cost drugs. Recently, we have found that the absolute number of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> regulatory T (CD4<sup>+</sup> Treg) cells reduced in SLE. Metformin, a basic hypoglycemic drug, has been shown to increase the number of Treg cells and decrease the number of Th17 cells.<sup>1,2,3</sup>

**Objectives:** To observe the clinical efficacy of metformin on the treatment of SLE and levels of CD4<sup>+</sup>Treg and Th17 cells.

**Methods:** Twenty-three patients with SLE were enrolled in this study. They fulfilled the ACR<sup>1997</sup> standard, their average age was 32.22±8.18 years, and duration was 51.41±15.52 months. These patients were administered metformin (250 mg Bid) combined with conventional therapy for 6 weeks. At week 0 and week 6, the absolute numbers of Th17 cells and Treg, the symptoms, and laboratory indicators were collected.

**Results:** After metformin treatment combined with conventional therapy, average absolute number of Treg cells in 23 patients increased significantly from 20.2 (20.28) (week 0) to 25.76 (25.1) (week 6) (p=0.073) while that of Th17 cells increased slightly from 5.29 (6.43) (week 0) to 5.57 (6.05) (week 6) (p=0.956), which led to reduce average ratio of Th17/Treg from 0.25 (0.31) (0 week) to 0.19 (0.23) (6 weeks) (p=0.147). The treatment attenuated the symptoms of the patients and meantime, the dose of prednisone was decreased. At week 6, metformin combined with interleukin-2, the dosage of prednisone in SLE patients were decreased from 23.70±19.41 mg/d(0 week) to 20.44±17.03 mg/d(6 weeks) (p=0.548).

**Abstract AB0523 – Figure 1**

**Conclusions:** Our findings suggest metformin can effectively up-regulate Treg cells as well as increase Th17 to a certain extent, which restores the balance of Th17/Treg cells in SLE, metformin combined with conventional therapy can reduce the dosage of glucocorticoid, but the long-term effect needs further investigation.

### HOW DO WE TREAT DRYNESS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME? A NATIONWIDE STUDY IN SPAIN FROM THE SJÖGRENSER REGISTRY

M. Fernandez Castro<sup>1</sup>, C. Sanchez-Piedra<sup>2</sup>, J.L. Andreu<sup>3</sup>, V. Martinez Taboada<sup>4</sup>, A. Olive<sup>5</sup>, J. Rosas<sup>6</sup>, on behalf of SJÖGRENSER project (GEEAS-SER).  
<sup>1</sup>Rheumatology, Hospital Infanta Sofía, Madrid; <sup>2</sup>Research Unit of the Spanish Society of Rheumatology; <sup>3</sup>Rheumatology, Hospital Puerta de Hierro Majadahonda, Madrid; <sup>4</sup>Rheumatology, Hospital Marques de Valdecilla, Santander; <sup>5</sup>Rheumatology, Hospital Germans Trias i Pujol, Barcelona; <sup>6</sup>Rheumatology, Hospital Marina Baixa, Alicante, Spain

**Background:** Primary Sjögren syndrome (pSS) is a systemic autoimmune disease whose main characteristic is the involvement of the exocrine glandular system. Thus, its most common clinical manifestation is eye and mouth dryness. No therapy has been demonstrated to significantly modify disease course and, currently, evidence-based therapy for pSS is mainly limited to symptomatic drugs for dryness.

**Objectives:** To describe the dryness treatment in a cohort of primary Sjögren Syndrome patients.

**Methods:** SJÖGRENSER registry is a multicentre descriptive cross-sectional study of pSS patients, fulfilling European/American criteria, from 33 Spanish rheumatology departments. Data were collected by reviewing clinical records and interviewing the patients. Informed consent was obtained and local ethics committees approved the study. Variables were analysed by descriptive statistics using means, medians and ranges. Chi square test was used to compare categorical variables. A  $p < 0.05$  was considered significant.

**Results:** Four hundred and thirty seven patients were included (female 95%; median age 58 years). Ninety four per cent of the patients complained of daily, persistent, troublesome dry eyes for more than 3 months, 92% had sensation of sand in the eyes, 16% developed corneal ulcer. Ninety four per cent of the patients complained of dry mouth for more than 3 months and 27% had dental loss. The most frequent ocular dryness treatments were tear substitutes (96%), followed by lubricating ophthalmological ointments (46%), autologous sera solutions (14%), topical corticosteroids (13%), topical cyclosporine (6%). Comparing patients with and without ocular dryness, only pilocarpine and lubricating eye ointment were used significantly with more frequency in symptomatic patients ( $p < 0.05$ ); tear substitutes was used significantly with more frequency in symptomatic patients only in the subgroup of patients that used tear substitutes more than 3 times a day. The most frequent oral dryness treatments were chewing gums or candies without sugar (65%), followed by pilocarpine (56%), special toothpaste (22%), mucolytic agents (20%), saliva substitutes (19%), lubricating oral gel (13%) xylitol (11%) and fluoride (11%). Comparing patients with and without oral dryness, chewing gums or candies without sugar, xylitol and fluoride were not used significantly more frequently in symptomatic patients. In contrast, saliva substitutes, lubricating oral gel, pilocarpine, mucolytic agents and specific toothpaste were used significantly more frequently in symptomatic patients ( $p < 0.05$ ). The median in ESSPRI (Eular Sjögren's Syndrome Patient Reported Index) in SJÖGRENSER cohort was 5.3 (p25-p75, 3.67-7). Only topical corticosteroids and pilocarpine were used significantly more frequently in patients with a dryness VAS<sub>≥5</sub> in ESSPRI index.

**Conclusions:** Despite the high number of symptomatic patients, the use of dryness treatments is limited in pSS patients. Chewing gums or candies without sugar, xylitol and fluoride remain underutilised in this cohort. Despite the dryness VAS score, patients do not seem to use all the symptomatic therapeutic options available.

### IDENTIFICATION OF EFFECTIVE PARAMETERS INFORMING THE SELECTION OF INTRAVENOUS CYCLOPHOSPHAMIDE VERSUS MYCOPHENOLATE MOFETIL FOR INDUCTION THERAPY FOR LUPUS NEPHRITIS

N. Mino, H. Yamashita, K. Motomura, M. Nakahara, K. Suga, A. Yashima, Y. Takahashi, H. Kaneko. *Rheumatology, National Center for Global Health and Medicine, Tokyo, Japan*

**Background:** The 2012 EULAR recommendations gave equal weight to intravenous cyclophosphamide (IVCY) and mycophenolate mofetil (MMF) as the induction therapy for class III/IV lupus nephritis (LN). However, there are no effective parameters that could inform the choice the induction therapy (IVCY or MMF) in individual cases.

**Objectives:** This study examined the patient characteristics that determine the most appropriate treatment for LN: IVCY or MMF.

**Methods:** We retrospectively examined 29 patients with LN who received induction therapy with IVCY (n=16) or MMF (n=13) between January 1994 and December 2015. Their baseline characteristics and the complete response (CR) rate at

week 24 were analysed. CR was defined as a urine protein:creatinine ratio  $< 0.5$  g/gCr with normal urine sediment.

**Results:** At baseline, the time since diagnosis of systemic lupus erythematosus (SLE) was longer in the IVCY group than the MMF group (4.8±6.4 vs. 1.3±2.5 years,  $p=0.06$ ) and the IVCY group had more frequent flares (1.9±2.4 vs. 0.7±1.1 times,  $p=0.08$ ); however, the differences were not significant. Moreover, there was no difference in age, sex, complement levels, anti-dsDNA antibody titers, anti-Sm/RNP antibody positivity rates, proteinuria, or rate of abnormality in urine sediment at baseline between the two groups. CR was achieved at week 24 in 11/16 patients (69%) in the IVCY group and 9/13 patients (69%) in the MMF group. Considering the 20 patients who achieved CR at week 24, univariate analyses revealed that in addition to a longer time since diagnosis of SLE (4.5±6.6 vs. 1.0±1.7 years,  $p=0.12$ ) and more frequent flares (1.9±2.8 vs. 0.6±1.0 times,  $p=0.16$ ), the anti-RNP antibody positivity rate was higher (OR 8.15;  $p=0.07$ ) in the IVCY group. Furthermore, the positivity rate of anti-RNP antibody differed significantly (OR 12.9;  $p=0.03$ ) in the multivariate analysis.

**Abstract AB0525 – Table 1.** Univariate analyses of patients with CR at week 24

	IVCY (n=11)	MMF (n=9)	p value
age (years)	31.2±10.9	39.6±18.8	0.23
sex (male,%)	9.1	22.2	0.57, OR=2.11
time since diagnosis of SLE (years)	4.5±6.6	1.0±1.7	0.12
flares (times)	1.9±2.8	0.6±1.0	0.16
complement C3 level (mg/dL)	48.3±29.3	47.6±21.5	0.95
anti-dsDNA antibody (IU/mL)	161.2±187.4	128.8±154.2	0.68
anti-Sm antibody (%)	63.6	33.3	0.37, OR=3.27
anti-RNP antibody (%)	72.7	22.2	0.07, OR=8.15

**Abstract AB0525 – Table 2.** Multivariate analyses of patients with CR at week 24

	Model 1		Model 2	
	OR (95% CI)	p value	OR (95% CI)	p value
age	–	–	0.9 (0.8–1.0)	0.15
sex (female)	–	–	1.2 (0.04–38.8)	0.92
time since diagnosis of SLE	1.1 (0.7–1.7)	0.77	1.0 (0.6–1.6)	0.91
flares	1.5 (0.5–4.2)	0.44	1.7 (0.6–4.4)	0.30
anti-RNP antibody	12.9 (1.3–132.3)	0.03*	31.8 (1.1–892.9)	0.04*

Model 1 was adjusted by all of the characteristics which showed  $p < 0.20$  in the univariate analysis; model 2 was adjusted by age and sex in addition to model 1.

dsDNA, double strand DNA; anti-Sm antibody, anti-smith antibody; anti-RNP antibody, anti-ribonucleoprotein antibody; OR, odds ratio; CI, confidence interval. (\* $p < 0.05$ )

**Conclusions:** Although IVCY and MMF are equivalent treatment options for LN, IVCY might be more effective for patients with anti-RNP antibody.

### IMBALANCE IN ELASTIN-ELASTASE SYTEM LEADING TO CLINICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS

O. Emelyanova<sup>1</sup>, O. Rusanova<sup>1</sup>, I. Gontar<sup>1</sup>, L. Maslakov<sup>1</sup>, N. Emelianov<sup>2</sup>.

<sup>1</sup>Federal State Budgetary Institution «Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy»; <sup>2</sup>Federal State Medical Budgetary Institution of Higher Education «Volgograd State Medical University» of the Ministry of Healthcare of the Russian Federation, Volgograd, Russian Federation

**Background:** It is believed that in systemic lupus erythematosus antibodies induce a disturbance in the elastin-elastase metabolism, which yields altered soluble isoforms followed by triggering of autoimmunity mechanisms, which damage the elastin-containing tissues.

**Objectives:** Studying antibody formation in the elastin-elastase system in patients with systemic lupus erythematosus (SLE) using magnetocontrollable adsorbents with an immobilised form of corresponding antigen.

**Methods:** Sera from 30 donors and 65 SLE patients were studied. Antibodies to elastin and elastase were determined using ELISA test and magnetocontrollable adsorbents with an immobilised form of corresponding antigen.

**Results:** We analysed changes in the content of antibodies to elastin and elastase in patients with SLE of varying severity assessed using SLAM, SLEDAI scale, and criteria by V.A. Nasonova.

The greatest elastin antibody titer was noted in patients with SLE grade III (57.1%, 4 people), with grade II – in 42.5% (17 people), and with grade I – in 33.3% (6 people).

The elastin antibody titer in SLE patients being admitted to hospital was reliably higher than in donors ( $p < 0.001$ ).

An analysis of the findings showed that patients with vascular lesions demonstrated a significant elevation of elastin antibodies ( $p < 0.05$ ).

Besides studying elastin antibodies, we analysed elastase antibodies. Elevated elastase antibodies were revealed in 72.2% of SLE patients with grade I of the condition; in 80.0% with grade II, and in 85.7% of patients with grade III. The titer of elastase antibodies in SLE patients admitted to hospital was reliably higher than in the control group ( $p < 0.01$ ). The highest elastase antibody titer was noted when the skin and joints are affected, and vasculopathy is present.

**Conclusions:** The regularities revealed by pathogenetic method can be accounted for by considerable B-clonal expansion in SLE patients as the condition progresses. From the point of view of immunology, hyperproduction of elastin and elastase autoantibodies is noted, which results in autoimmune lesion of the ligamentous apparatus, joints, skin and vessels where this protein is naturally present.

### S100A8 AND S100A9 PROTEINS ARE NOVEL BIOMARKERS FOR THE EFFICACY OF HCQ TREATMENT TO SKIN LESION IN SYSTEMIC LUPUS ERYTHEMATOSUS

R. Wakiya, K. Ueeda, T. Kameda, S. Nakashima, M. Izumikawa, H. Shimada, A. Kondo, M. Kato, T. Miyagi, N. Kadowaki, H. Dobashi. *Department of internal medicine, Division of hematology, rheumatology and respiratory medicine, Kagawa University, Kagawa, Japan*

**Background:** Systemic lupus erythematosus (SLE) is deeply associated with not only acquired immunity but also innate immunity throughout toll like receptors (TLRs) signalling. Among many TLRs, TLR7 and TLR9 were reported to be closely associated with IFN- $\alpha$  production which contributed the pathogenesis of SLE. On the other hand, several reports demonstrated that S100A8 and S100A9 proteins which was known as one of damage-associated molecular patterns (DAMPs), were associated with disease activity of lupus nephritis. These proteins were also shown to reflect the treatment response by immunosuppressive therapy for SLE.<sup>1,2</sup> However, there is no report about the effect of hydroxychloroquine (HCQ) on S100A8 and S100A9 proteins expression.

**Objectives:** To find a new biomarker of treatment with HCQ, we focused on expression of S100A8 and S100A9 proteins in SLE.

**Methods:** We enrolled all SLE patients treated with HCQ in the absence of additional immunosuppressive therapy more than 3 months in our institute from Jan 2016 to Dec 2017. Serum levels of S100A8 and S100A9 proteins were measured by ELISA (CircuLex ELISA Kit, MBL) at the screening, 3 months and 6 months after HCQ administration. Disease activity of SLE was measured using the SLENA-SLEDAI 2011. Cutaneous disease activity was evaluated by Cutaneous Lupus Erythematosus Disease Area and Severity Index (CLASI). Immunological activity was examined by the levels of complement (C3, C4, CH50), anti-dsDNA anti-body and counting blood cell.

**Results:** 61 patients were enrolled in this study. HCQ was administered 48 cases with usual dose (based on ideal weight), 15 cases with low dose than usual dose (table 1).

Abstract AB0527 – Table 1

HCQ dose	Usual dose (n=46)	Low dose (n=15)	P
Age, years, mean $\pm$ SD	40 $\pm$ 12	46 $\pm$ 9	0.07
Female, no. (%)	43 (93)	13 (87)	0.40
Disease duration, years	13 $\pm$ 10	11 $\pm$ 8	0.61
skin lesion	40 (87)	14 (93)	0.48
renal lesion	19 (41)	0 (0)	<0.001
SLEDAI score	3.9 $\pm$ 2.2	2.7 $\pm$ 1.8	0.06
anti-dsDNA, IU/ml	15 $\pm$ 17	9.9 $\pm$ 3.1	0.91
C3, mg/dl	79 $\pm$ 24	87 $\pm$ 26	0.32
C4, mg/dl	16.1 $\pm$ 7.6	19.2 $\pm$ 9.2	0.30
CH50, U/ml	33.6 $\pm$ 9.6	37.3 $\pm$ 7.4	0.30
CLASI activity	3.6 $\pm$ 3.2	2.6 $\pm$ 2.8	0.11
Prednisone	41 (89)	15 (100)	0.11
Dose, mg/day	5.6 $\pm$ 3.1	8.1 $\pm$ 5.1	

CLASI was improved by the treatment with HCQ independent of HCQ dose. However, the effect of HCQ on SLENA-SLEDAI and immunological biomarker was shown in the patients treated with usual dose HCQ, not shown in those treated

with low dose HCQ. On the other hand, serum levels of S100A8 and S100A9 proteins were significantly elevated in SLE patients with renal lesion ( $p = 0.02$ ). These proteins were significantly decreased by the treatment with HCQ regardless of the HCQ dose ( $p < 0.0001$ ). The changes of serum S100A8 and S100A9 proteins during HCQ treatment (for 3 months) were significantly associated with changes of CLASI (figure 1).

**Abstract AB0527 – Figure 1.** S100A8 and S100A9 proteins associated with CLASI score. Compared with SLE patients of 50% and less rate of change of CLASI activity, those of more than 50% rate of change of CLASI activity significantly decreased serum levels of S100A8 and S100A9 proteins after administration of HCQ. There were no SLE patients whose skin lesion got worse during HCQ treatment in this study.

**Conclusions:** HCQ reduced the expression of serum S100A8 and S100A9 proteins, which reflected SLE disease activity especially in skin lesion. The measurement of S100A8 and S100A9 proteins is novel predictive biomarker for the efficacy of HCQ treatment on skin lesion in SLE patients.

### CONCOMITANT MEDICATION IN SYSTEMIC LUPUS ERYTHEMATOUS (SLE) PATIENTS TREATED WITH BELIMUMAB IN CLINICAL PRACTICE SETTINGS: RESULTS FROM THE OBSERVE STUDY IN SWITZERLAND

J. von Kempis<sup>1</sup>, S. Dütsch<sup>2</sup>, N. Reuschling<sup>1,3</sup>, D. Schaer<sup>4</sup>, F. Vallelan<sup>4</sup>, R. Villiger<sup>5</sup>, P.M. Villiger<sup>5</sup>, R.B. Mueller<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Kantonsspital St. Gallen, St. Gallen; <sup>2</sup>GlaxoSmithKline AG, Münchenbuchsee; <sup>3</sup>Division of Rheumatology, Hirslanden, Basel; <sup>4</sup>Universität Hospital Zürich, Zürich; <sup>5</sup>Department of Rheumatology, Inselspital Bern, Bern, Switzerland

**Background:** Systemic lupus erythematosus (SLE) is a complex and potentially severe autoimmune disease. Belimumab is the latest drug, and the first biologic compound, that was registered for treatment of SLE. There is limited information on safety and effectiveness of belimumab and its effects on the use of concomitant medication outside of randomised controlled trials.

**Objectives:** To describe the overall patterns of SLE care, outcomes and concomitant medication among belimumab users in Switzerland.

**Methods:** OBSERVE Switzerland (GSK 201232) was a retrospective, multi-centre observational cohort study collecting data on the use of belimumab therapy in routine care of SLE Patients in Switzerland. SLE patients were included who had started therapy with 10 mg/kg belimumab/4 weeks at least six months before documentation. All patients were included regardless of treatment discontinuation during the study period. All statistical analyses were descriptive for both categorical and quantitative data.

**Results:** 53 SLE patients with belimumab as part of their routine treatment were analysed for this study. 81% of the patients were female, the mean age was 46.7 years and the mean BMI was 25.4 kg/m<sup>2</sup>. The reasons to initiate belimumab were ineffective previous treatment (66.0%), worsening of patient condition (28.3%), and/or the intent to decrease glucocorticosteroid (GC) dose (47.2%).

During treatment, 58% of patients (n=53) showed an improvement of  $\geq 20\%$  and 23% of  $\geq 50\%$ , based on physicians' evaluation of disease activity. This was consistent with an improvement of SELENA-SLEDAI (mean) from 8.0 at therapy start to 3.6 after six months on the basis of all available data (n=27).

Similar outcomes were observed for arthritis, fatigue, rash, dsDNA antibody and complement levels.

Among the 42 patients treated with GC at time of belimumab initiation, GC dose was reduced by 5.7 mg/day (mean) during treatment with belimumab ( $11.6 \geq 5.9$  mg/day at six months). During the six months before initiation of belimumab, GC dose was stable or had to be increased in the majority of patients; however, during the six months therapy with belimumab, GC dose could be reduced in the majority of patients and GCs was discontinued in two patients. The percentages of patients receiving SLE co-medication other than GC were stable over the first six months of belimumab therapy. Within the first six months of treatment, no included patient had discontinued therapy with belimumab.

**Conclusions:** Treatment with belimumab over six months after initiation led to clinical improvement in a significant number of patients in real life settings and had an overall steroid-sparing effect. Belimumab was well-tolerated; no included patient discontinued the treatment within the first six months.

#### AB0529 AN AUDIT FOR SCREENING OF OSTEOPOROSIS AND ITS MANAGEMENT IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S.A. Syed, K. Sunmboye, S. Shaffu. *Rheumatology, University Hospitals of Leicester, NHS Trust, Leicester, UK*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune, multi-system, chronic inflammatory condition. It is managed with long-term immunosuppressive therapy which includes steroid use. SLE is therefore considered an independent risk factor for osteoporosis.

**Objectives:** This clinical audit was undertaken to evaluate the screening of osteoporosis in patients diagnosed with SLE and assess adherence to national guidelines for the management of patients with low bone mineral density (BMD) on prolonged steroid therapy.

**Methods:** We studied 64 SLE patients seen at the Leicester Royal Infirmary. Demographic and clinical data was collected from the clinic letters. Steroid use for a cumulative period of over 4 weeks per year was considered significant and use of bisphosphonates or calcium and vitamin D supplements alone were taken into account for bone protection. BMD measurements by dual X-ray absorptiometry were performed. Osteoporosis was defined as a T score less than  $-2.5$  SD in at least 1 region of measurement.

**Results:** Of the 64 patients studied, 54 (84.4%) were female and 10 (15.6%) male with an age range of 23 to 86 years and mean age of 47.45 years. Steroids were used in 46 (71.9%) patients while 18 (28.1%) patients did not receive any steroids. Twenty-one (32.8%) patients had DEXA scans and whilst 43 (67.2%) had not. Of those who had received steroids, 20 (43.4%) patients underwent DEXA scans and 26 (56.5%) did not. Osteoporosis was diagnosed in 3 (14.3%) patients out of the 21 scanned. The therapies used are summarised in figure 1.

Abstract AB0529 – Figure 1. Bone protection (n=64)

**Conclusions:** Studies have shown that SLE is an independent risk factor for low BMD and use of corticosteroids is already a well-recognised risk for osteoporosis. Our study has shown that a large section of patients (43.8%) did not receive any form of bone protection although, a significant proportion (71.9%) were on oral steroids. Although a small section of those scanned demonstrated osteoporosis (14.3%), many patients were already initiated on bisphosphonates without a DEXA. There was also no exclusion criteria set for young patients (age <45 years) or those who were newly diagnosed. Despite this, our study demonstrates the need for robust guidelines for the screening and management of bone health in patients with SLE in order to improve morbidity and mortality rates in this patient cohort.

#### AB0530 TREATMENT OUTCOME IN LUPUS NEPHRITIS PATIENTS TREATED WITH MYCOPHENOLATE MOFETIL: FROM REAL-WORLD CLINICAL PRACTICE

S.M. Jung<sup>1</sup>, D. Kim<sup>1</sup>, H.W. Kim<sup>2</sup>, S.-W. Lee<sup>1</sup>, J.J. Song<sup>1</sup>, Y.-B. Park<sup>1</sup>. <sup>1</sup>Internal Medicine, Yonsei University College of Medicine; <sup>2</sup>Internal Medicine, Seoul National University Bundang Hospital, Seoul, Korea, Republic of Ireland

**Background:** Systemic lupus erythematosus (SLE) is a systemic autoimmune disease often characterised by the development of glomerulonephritis.<sup>1</sup> There is a growing interest in the use of mycophenolate mofetil (MMF) as induction therapy and maintenance therapy for lupus nephritis.<sup>2,3</sup>

**Objectives:** This study aimed to evaluate the therapeutic outcome of MMF in lupus nephritis from real-world clinical practice, and identify the predictors for failure of remission after MMF treatment.

**Methods:** Korean patients with pathologically proven lupus nephritis class III, IV, and V were recruited from rheumatology clinic in Severance Hospital, Yonsei University College of Medicine between Nov 2011 and Aug 2017 Patients who treated with MMF for at least 3 months were included in the analysis. The probability of remission after MMF therapy, and the difference between patients who achieved remission or failed to achieve remission were analysed using Kaplan-Meier analysis and Cox proportional hazards model.

**Results:** Of 153 patients with lupus nephritis, 116 patients were included in this study. Seventy two patients continued MMF until the last follow-up. The mean age of patients was 34.2 years, and the median duration of SLE was 5.7 months. Anti-dsDNA antibody was positive in 82.8% of patients, and 9.5% of patients showed a histological class with pure V pathology. Mean protein/creatinine ratio in spot urine was 4.6, and active urinary sediment was found in 82.8% of patients. During median follow-up period of 5 years, 80% of patients achieved clinical remission of lupus nephritis. Median time to remission was 4.2 months (IQR 0.9–9.1). Risk factors for failure of remission were nephrotic-range proteinuria and seronegativity of anti-dsDNA antibodies.

**Conclusions:** This study shows the real-world data on MMF treatment in patients with lupus nephritis. Patients with risk factors for failure to remission may require more intensive treatment and management.

#### AB0531 DECISION TO INITIATE IMMUNOSUPPRESSION IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME

S. Daia-Iliescu, C. Buzatu, T. Gudu, D. Zaharia, C. Purice, A. Borangiu, I. Saulescu, L. Groseanu, C. Constantinescu, M.M. Negru, V. Vlad, V. Bojinca, F. Berghea, A. Balanescu, D. Predeteanu, R. Ionescu, D. Opris-Belinski. *Internal Medicine and Rheumatology, SF. Maria Clinical Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

**Background:** There is limited data available (case series, small clinical trials and expert opinion) regarding the need to initiate immunosuppressive therapy in patients with primary Sjogren syndrome (pSS).

**Objectives:** The aim of this study is to determine the factors that correlate with physician's decision to start immunosuppressive therapy in pSS patients.

**Methods:** Subjects with pSS diagnosed according to the classification criteria in use at the time of their first presentation, were included in a monocentric cohort. A retrospective analysis was performed. The EULAR Sjogren's Syndrome Disease Activity Index (ESSDAI) at onset and Sjogren Syndrome Damage Index (SSDI) at the last evaluation were calculated. Treatment was given according to the physician's decision. Laboratory tests and Ultrasonography (US) of major salivary glands were performed in all cases. The data was analysed using Windows Excel/SPSS20.0.

**Results:** Corticotherapy was prescribed in 26/30 cases (86.6%), mean duration 50.65 months. Immunomodulatory treatment with hydroxychloroquine was given in 26/30 cases (86.6%). Immunosuppressive treatment was required in 10/30 patients (33.3%) - azathioprine 7 (23.3%) cases, methotrexate 3 (10%) cases. The mean ESSDAI score was 6.83±SD 1.8. In 19 (63.3%) cases disease activity was moderate or high (ESSDAI >5). The mean damage score value (SSDI) was 3.1±SD 1.2. There was a moderate correlation between the activity score ESSDAI and the damage score SSDI ( $r=0.41$ ,  $p<0.05$ ). The physician's decision to start immunosuppression correlated significantly with the presence of hypergammaglobulinemia ( $r=0.4$ ,  $p<0.05$ ). The duration of immunosuppressive treatment correlated moderately with specific Sjogren's US pattern of salivary glands ( $r=0.40$ ,  $p<0.05$ ). In contrast, immunosuppressive treatment duration did not correlate with the activity and damage scores (ESSDAI and SSDI).

**Conclusions:** An important number of patients received corticotherapy, immunomodulatory agents and immunosuppressive therapy. The decision to initiate and maintain immunosuppressive therapy correlated with hypergammaglobulinemia and specific Sjogren's US changes. The damage score (SSDI) does not correlate with immunosuppressive therapy duration.

#### AB0532 THE EFFECTIVENESS OF EXERCISE THERAPY IN PATIENTS WITH SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW

S.I.E. Liem<sup>1</sup>, T.P.M. Vliet-Vlieland<sup>2</sup>, J.W. Schoones<sup>3</sup>, J.K. de Vries-Bouwstra<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Orthopaedics, <sup>3</sup>Walaeus Medical Library, Leiden University Medical Centre, Leiden, Netherlands

**Background:** Exercise therapy is an important and relatively often used nonpharmacological intervention<sup>1</sup>, yet its effectiveness based on studies where exercise therapy is evaluated as single intervention (and not part of a comprehensive program<sup>2</sup>) has not been determined.

**Objectives:** To evaluate the effectiveness of exercise therapy in SSc patients by means of a systematic review of the literature.

**Methods:** A systematic literature search was performed in February 2017 in ten databases including Pubmed and Embase from 1990 to February 2017. We included clinical studies with an observational or experimental design as long as the study population concerned  $\geq 3$  SSc patients, the intervention consisted only of exercise therapy (categorised into hand exercises, mouth opening exercises, and aerobic exercises either or not combined with other exercises) and its clinical outcome according to at least one assessment of effectiveness done before and after the intervention was reported. Studies where exercise therapy was part of a multidisciplinary intervention were excluded. The selection of studies, data extraction and assessment of methodological quality was done by two of the researchers independently.

**Results:** The search strategy yielded 636 titles and abstracts, with eventually six studies being included (2 randomised controlled trials (RCTs), 3 observational designs (ODs) and 1 single subject experimental design (SSED)). The total number of patients included per study ranged from 4 to 48, patients' mean age from 44.0 to 66.5 years and mean disease duration from 3.5 to 12.6 years. One study concerned hand exercises (an RCT comparing strengthening and mobility exercises using a telemedicine intervention consisting of a portable device guiding patients during workout and sending data to health professionals to no-telemedicine), two studies on mouth stretching and oral-augmentation exercises (an OD and a RCT), and three studies on aerobic exercise (two ODs and one SSED; one program with only aerobic training and two programs combining aerobic and resistance training, lasting 30–60 min, 2–3 days/week for 8–12 weeks). The study on hand exercises reported a greater improvement of hand function using the telemedicine intervention. The RCT on mouth exercises showed a statistically significant effect on maximum mouth opening in the exercise group compared to no exercise at 3 months but not at 6 months follow-up, whereas the OD showed improvement of mouth opening directly after the mouth exercise program. The three studies on aerobic exercise indicate effectiveness and no dropouts were observed. The program of solely aerobic exercise on a treadmill improved patient's exercise tolerance and aerobic capacity. The two programs combining aerobic and resistance exercise showed improvements of strength and muscle function in the OD and improvements of muscular endurance and aerobic capacity in the SSED.

**Conclusions:** The literature on the effect of exercise therapy in SSc patients is scanty. Collaborative efforts to conduct methodologically sound intervention studies with adequate reporting is needed.<sup>3</sup>

#### AB0533 PATTERN OF DRUG USE IN SYSTEMIC LUPUS ERYTHEMATOSUS IN REAL WORLD CLINICAL PRACTICE

T. Costa<sup>1</sup>, M. Eusébio<sup>2</sup>, S. Falcão<sup>1</sup>, F. Araújo<sup>3</sup>, P. Nero<sup>4</sup>, L. Inês<sup>5</sup>, M. Rodrigues<sup>5</sup>, D. Jesus<sup>5</sup>, S. Barreira<sup>6</sup>, C. Macieira<sup>6</sup>, M. Cabral<sup>7</sup>, G. Sequeira<sup>8</sup>, J. Branco<sup>1</sup>, M. Santos<sup>9</sup>.  
<sup>1</sup>Hospital Egas Moniz; <sup>2</sup>Sociedade Portuguesa Reumatologia; <sup>3</sup>Hospital Sant'Ana; <sup>4</sup>Hospital CUF Descobertas, Lisboa; <sup>5</sup>Centro Hospitalar Universitário, Coimbra; <sup>6</sup>Centro Hospitalar Lisboa Norte, Hospital de Santa Maria, Centro Académico de Medicina, Lisboa; <sup>7</sup>Hospital Fernando Fonseca, Amadora; <sup>8</sup>Centro Hospitalar Universitário do Algarve, Faro; <sup>9</sup>Hospital Garcia de Orta, Almada, Portugal

**Background:** Pharmacological treatment for systemic lupus erythematosus (SLE) is aimed at reducing disease activity, preventing flares and minimising the damage. The use of medication varies widely and therapeutic strategies are well defined only for certain organ manifestations. Hydroxychloroquine is the standard treatment for most SLE patients during the entire disease course, while immunosuppressants are recommended for those with severe organ involvement. Belimumab is the only biological currently licensed for SLE, although others are used off-label in clinical practice.

**Objectives:** To describe the real-world patterns of drug use in SLE patients, and their relationship with disease phenotype.

**Methods:** Observational study of adult SLE patients registered in the Rheumatic Diseases Portuguese Registry, who have clinical diagnosis of SLE, followed for at least 1 year and with available data on medication, which was retrieved. Sociodemographic and clinical characteristics were compared among treatment groups defined as: group 1 antimalarials and/or glucocorticoids; group 2 immunosuppressants (azathioprine (AZA)/mycophenolate mofetil (MM)/methotrexate (MTX)) ±antimalarials and/or glucocorticoids; group 3 biologics±immunosuppressants and/or antimalarials and/or glucocorticoids. To assess possible differences

between the groups, univariate regression analyses were made. In all analyses significance level was set at 0.05.

**Abstract AB0533 – Table 1.** Sociodemographic and clinical characteristics according to treatment groups

Characteristic	Group 1 (N=498)	Group 2 (N=272)	Group 3 (N=52)	Global p-value
Female, N (%)	377 (92.2%)	249 (91.5%)	49 (92.3%)	<0.001

Organ damage (SLICC) (mean±SD)	0.5±1.1	0.7±1.5	1.0±1.4	<0.001
SLICC, 0-10 (N (%))	119 (30.7%)	180 (78.1%)	24 (88.9%)	<0.001
Acute cutaneous lupus, N (%)	107 (37.9%)	154 (60.9%)	25 (74.5%)	<0.001
Chronic cutaneous lupus, N (%)	73 (23.5%)	89 (32.9%)	10 (32.7%)	<0.001
Low or stable vitreous, N (%)	91 (23.5%)	80 (30.7%)	25 (52.1%)	<0.001
Non-erosive arthritis, N (%)	59 (15.9%)	87 (32.8%)	10 (20.0%)	<0.001
Arthritis, N (%)	115 (38.4%)	143 (57.8%)	45 (90.0%)	<0.001
Serositis, N (%)	77 (24.8%)	62 (25.7%)	12 (28.1%)	<0.001
Renal involvement, N (%)	76 (20.4%)	134 (53.0%)	19 (63.2%)	<0.001
Neurologic involvement, N (%)	11 (3.7%)	24 (9.4%)	8 (28.2%)	<0.001
Hematologic involvement, N (%)	149 (45.4%)	194 (74.9%)	39 (81.2%)	<0.001
Immunologic anemia, N (%)	29 (9.4%)	41 (15.7%)	7 (18.9%)	<0.001
Thrombopenia, N (%)	179 (57.9%)	142 (58.9%)	43 (79.2%)	<0.001
Leukocytopenia, N (%)	79 (24.9%)	71 (28.4%)	13 (28.9%)	<0.001
Glucocorticoids, N (%)	145 (65.9%)	213 (77.9%)	45 (81.2%)	<0.001
Antimalarials, N (%)	409 (100%)	252 (77.2%)	57 (89.4%)	<0.001
Immunosuppressants, N (%)	117 (50.4%)	117 (50.4%)	11 (20.0%)	<0.001
Anti-Ro/SSA antibodies, N (%)	142 (38.1%)	117 (50.4%)	11 (20.0%)	<0.001

**Results:** A total of 824 SLE patients were included, mean age of 47.3±14.4 years, 92.3% female. The mean age at first symptoms was 31.6±14.1 and at SLE diagnosis of 34.1±14.3 years. On their last assessment, 678 (82.3%) were being treated with antimalarials, 463 (56.2%) glucocorticoids, 343 (41.6%) immunosuppressants (149 AZA, 99 MM, 67 MTX, 14 cyclosporine, 11 cyclophosphamide, 3 leflunomide), 53 (6.4%) biologics (32 rituximab, 21 belimumab) and 26 (3.2%) were off medication. The sociodemographic and clinical characteristics according to treatment groups are shown in table 1. Gender distribution was similar across groups. A high prevalence of women, Caucasians, non-smokers, acute cutaneous lupus and arthritis was found in all groups. Patients in group 1 had lower disease activity measured by SLEDAI, less organ damage measured by SLICC and lower physician's global assessment. In group 2 patients were younger and had higher prevalence of renal involvement. Patients in group 3 had higher SLEDAI score and damage, higher prevalence of mucocutaneous, articular, neurologic and hematologic involvement and more use of glucocorticoids.

**Conclusions:** Almost all SLE patient with established disease were chronically medicated, most with antimalarials and/or glucocorticoids. As expected, group 1 had less severe disease. Patients under immunosuppressants had a higher frequency of renal involvement, which denotes a targeted therapeutic strategy. In routine clinical settings biologics are rarely used, being restricted to patients with very active SLE and multiple clinical manifestations.

**AB0534** PROPORTION OF SJÖGREN'S SYNDROME PATIENTS REFERRED TO ORAL SPECIALISTS AT A RHEUMATOLOGY TERTIARY CENTRE AND FACTORS ASSOCIATED WITH THEIR REFERRAL

G. Levinson<sup>1</sup>, U. Ahmed<sup>1</sup>, C. Ciurtin<sup>1,2</sup>. <sup>1</sup>UCL; <sup>2</sup>Department of Rheumatology, UCLH, London, UK

**Background:** Ideally all patients with Sjögren's Syndrome (SS) and symptoms of mouth dryness should be assessed by an oral specialist (OS) team at 3–6 monthly intervals for optimisation of their treatment for xerostomia and minimisation of the risk of dental loss<sup>1</sup>. However, in reality specialist input is not always offered.

**Objectives:** To determine the proportion of SS patients at a rheumatology tertiary centre who were referred to OS and evaluate if any factors were associated with referral.

**Methods:** We retrospectively collected data about 105 patients with primary or secondary SS who attended outpatient clinics in October – November 2016, including duration of symptoms and years since diagnosis, presence of SS associated symptoms, medications trialled to date, and serological, imaging and histological patient features. We have also assessed proportion of patients referred to OS, as well as the medication recommended by the OS. p<0.05 was considered significant.

**Results:** In our cohort, 58.1% of SS patients were referred to an OS. We compared patient demographics and various disease features (table 1) in SS patients who were referred to OS and those who were not.

**Abstract AB0534 – Table 1**

	SS patients seen by oral specialists n=61	SS patients never referred to oral specialists n=44	P value
Gender F (%)	93	98	0.17
Age (years) mean±SD	60.1±16.7	50.1±15.3	<b>0.023</b>
Disease duration (years) mean±SD	9.7±7.9	7.4±5/2	0.57
Symptoms duration (years) mean±SD	11.0±8.47	10.0±5.80	0.2
<i>Medication</i>			
Oral prednisolone N (%)	13.1	27.3	0.069
Hydroxychloroquine/Chloroquine N (%)	65.6	68.2	0.78
Azathioprine N (%)	12.5	15.4	0.75
Methotrexate N (%)	8.82	24	0.12
Saliva substitutes N (%)	59.5	32	<b>0.034</b>
<i>Associated Symptoms</i>			
Oral dryness (VAS>5/10) N (%)	95.1	72.7	<b>0.0012</b>
Glandular enlargement N (%)	27.9	13.6	0.082
Maximum ESSDAI score (Median (interquartile range))	7 (4–12)	6 (4–10.75)	0.36
<i>Serology, Histology and Imaging</i>			
Anti Ro antibodies N (%)	79.2	78.4	0.92
Anti La antibodies N (%)	61.4	58.1	0.77
Positive salivary gland biopsy N (%)	100	83.3	0.20
Ultrasound scan of salivary glands showing definite features of SS N (%)	86.4	66.7	0.38

The parameters that correlated with the referral to OS were oral dryness (VAS>5/10) (p=0.0012) and the use of saliva substitutes (p=0.034).

The most common OS treatment recommendations were for use of Duraphat 5000 ppm (50.8%), Salivix pastilles (44.3%), mouth wash (41%) and Glandosane (36%), apart from frequent sips of water recommended in all patients.

**Conclusions:** 58.1% of SS patients at a tertiary rheumatology centre were referred to OS. The factors that correlated with onward referral to the OS from the Rheumatologist in SS patients were oral dryness and treatment with saliva substitutes. This suggests that Rheumatologists adequately treat xerostomia and refer to OS appropriately when patients remain symptomatic. Further research is needed to assess whether there is a difference in outcome for patients referred to an OS versus those who are not.

AB0535

**EFFECT OF METFORMIN ON THE ABSOLUTE NUMBER OF CD4+ T CELL SUBSETS IN PATIENTS WITH PRIMARY SJOGREN'S SYNDROME**

X. Sun<sup>1</sup>, H. Yao<sup>1</sup>, J. He<sup>1</sup>, G. Chai<sup>1</sup>, L. Wei<sup>1</sup>, J. Xie<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>, J. Li<sup>1</sup>.  
<sup>1</sup>Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, Shanxi, China; <sup>2</sup>Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, USA

**Background:** Primary Sjogren's syndrome is a chronic inflammatory autoimmune disease characterised by the infiltration of lymphocytes into exocrine glands such as the salivary gland and lacrimal gland. Although its etiology and pathogenesis is unclear at present, we consider immune dysfunction plays a significant role in the process. A lot of studies have confirmed that the formation of Treg and Th17 cells interact between each other, and their balance can affect the immune response results, notably reflected in various autoimmune and inflammatory diseases, including primary Sjogren's syndrome. However, there are few studies on the absolute number of CD4 +T cells in peripheral blood of patients with primary Sjogren's syndrome. In addition, metformin can affect the balance of Th17/Treg cells through the AMPK-mTOR pathway.

**Objectives:** To explore whether metformin can affect the balance of Th17/Treg cells in peripheral blood of patients with primary Sjogren's syndrome, and then be applied in the treatment of pSS patients.

**Methods:** The number of Treg cells(28.74 (21.22,38.68) vs 34.05 (30.14,42.31), P=0.023)significantly increased after the treatment. At the same time, there was a significantly decrease in the ratio of h17/Treg cells(0.25 (0.08,0.44) vs 0.18 (0.04,0.32),P=0.014). Besides, after the treatment the absolute number of Th17 cells were increased, but it was not statistically significant(4.5 (3.64,14.23) vs 7.87 (2.37,19.89),P=0.835). In addition, the clinical symptoms of the metformin group were obviously improved, while the dosage of prednisone, leflunomide or hydroxychloroquine reduced significantly.

**Results:** The number of Treg cells(28.74 (21.22,38.68) vs 34.05 (30.14,42.31), P=0.023)significantly increased after the treatment. At the same time, there was a significantly decrease in the ratio of h17/Treg cells(0.25 (0.08,0.44) vs 0.18 (0.04,0.32),P=0.014). Besides, after the treatment the absolute number of Th17 cells were increased, but it was not statistically significant(4.5 (3.64,14.23) vs 7.87 (2.37,19.89),P=0.835). In addition, the clinical symptoms of the metformin group were obviously improved, while the dosage of prednisone, leflunomide or hydroxychloroquine reduced significantly.

Abstract AB0535 – Figure 1

**Conclusions:** Metformin can increase the absolute number of Treg cells and decrease the ratio of Th17/Treg cells in the peripheral blood of patients with pSS, while reducing the use of hormones and DMARDs drugs. And it may be one of the mechanisms adopted in the treatment for pSS.

**RAPAMYCIN ATTENUATES SYMPTOM AND RESTORES THE BALANCE OF TH17/TREG IN REFRACTORY PRIMARY SJOGREN'S SYNDROME**

Z. Hao<sup>1</sup>, M. Miao<sup>1</sup>, Y. Guo<sup>1</sup>, X. Zhang<sup>1</sup>, X. Li<sup>1</sup>, C. Gao<sup>2</sup>, X. Wang<sup>1</sup>. <sup>1</sup>The Second Hospital of Shanxi Medical University, TaiYuan, China; <sup>2</sup>Harvard Medical School, Boston, USA

**Background:** Primary Sjögren's syndrome (pSS) is one of the more common rheumatological diseases. Despite continued advances, the use of conventional drugs or biologic agents in patients with pSS did not provide expected efficacy and a targeted treatment of pSS is not available at present. We have shown that absolute number of peripheral CD4<sup>+</sup>CD25<sup>+</sup>FOP3<sup>+</sup>regulatory T cells (Tregs) decreased in pSS patients. And rapamycin is an inhibitor of mTOR that can decrease Th17 cells but increase regulatory T cells (Treg cells).

**Objectives:** To observe the effect of rapamycin on Th17/Treg cell balance in patients with refractory pSS.

**Methods:** Twenty-eight refractory SS patients (26 women and 2 men) and 93 health controls were enrolled, with a mean duration of 76.64±49.66 months and mean age of 52.39±10.62 years. They fulfilled the 2002 PSS international classification criteria and were treated with glucocorticoid and immunosuppressant for more than one year, but had not yet reached the disease relief. After the eligible patients are given rapamycin in combination with conventional therapy at 0, 12, 24 weeks, we respectively collect the clinical symptoms, blood routine, urine routine, ESR, the absolute number of Th17 and Treg cells, the ratio of Th17/Treg, and the dosage of corticosteroids and immunosuppressant. Alleviation criteria: no clinical symptoms, inflammation normal range, no organ damage.

**Results:** The absolute number of Treg cells decreased significantly in peripheral blood of pSS patients compared with that of healthy controls. By rapamycin combined with conventional therapy, flow cytometry showed the absolute number of Treg cells in refractory SS patients was increased from 25.51 cells/μl (at week 0) to 27.88 cells/μl (at 12 weeks) and 29.6 cells/μl (at 24 weeks) (P>0.05) respectively. The ratio of Th17/Treg decreased from 0.38 (at week 0) to 0.21 (at 12 weeks) and 0.22 (at 24 weeks) (P>0.05). There was no significant difference in the usage of prednisone, whereas 5 patients gradually stopped using CTX at 24 weeks. Also, the dose of hydroxychloroquine and leflunomide were markedly diminished.

**Conclusions:** Our results suggest that rapamycin combined with the conventional treatment greatly alleviated symptoms of patients with pSS, and gradually reduced the use of DMARDs. The absolute number of peripheral Tregs decreased in pSS patients and restored by this combined therapy. It still needs to be further confirmed by large sample studies.

**SLE, Sjögren's and APS – clinical aspects (other than treatment)**

AB0538

**INCREASED BODY MASS INDEX MAY NOT BE A RISK FACTOR FOR THE DEVELOPMENT OF LUPUS NEPHRITIS**

Y.P. Chock<sup>1</sup>, A. Danve<sup>1</sup>, on behalf of Yale University School of Medicine, M. Petri<sup>2</sup>, W. Fu<sup>2</sup>. <sup>1</sup>Yale University School of Medicine, Connecticut; <sup>2</sup>Johns Hopkins University, Baltimore, USA

**Background:** Studies have indicated that elevated body mass index (BMI) increases risk of Chronic Kidney Disease (CKD). Obesity is a low grade inflammatory state which leads to CKD by glomerulosclerosis. Systemic Lupus Erythematosus (SLE) is associated with high leptin levels and dyslipidemia. We hypothesised that obese SLE patients may be at increased risk of nephritis.

**Objectives:** We studied BMI as possible predictor for development of lupus nephritis (LN) in SLE.

**Methods:** We performed a retrospective cross sectional study on a longitudinal lupus cohort. Patients were enrolled from year 1987 to 2015. We compared demographics, clinical information, labs between patients with and without LN (table 1) and between patients with SLE with and without obesity. Mean and standard

deviations were reported for continuous variables. Number and percentages were shown for categorical variables and chi-square test was utilised for comparison. T-test was used to compare patients between the groups.

**Results:** Total of 1362 patients with SLE fulfilling revised ACR criteria were included; 60.9% were Caucasian and 32.8% African American. 596 had biopsy-proven LN however 524 patients were excluded because they had proteinuria before or at cohort entry. Only first available BMI were analysed: 32.7% were obese (BMI >30 kg/m<sup>2</sup>), 27.2% overweight (BMI: 25–29.9 kg/m<sup>2</sup>), 37.5% normal (BMI: 18.5–24.9 kg/m<sup>2</sup>) and 2.6% underweight (BMI <18.5 kg/m<sup>2</sup>). 39.4% (537) patients were on steroids at first BMI measurement. Results are described in table 1. BMI measured as continuous (p=0.51) and categorical variables (overweight p=0.64, obese p=0.67) were not associated with LN after adjusting for age, sex and ethnicity. SLE patients with obesity were found to have lower disease activity (SLEDAI), proteinuria, dsDNA titers and higher complement levels.

**Abstract AB0538 – Table 1.** SLE Patients with vs without Lupus Nephritis (P<0.05 in bold)

	Lupus Nephritis (n=72) Mean (SD) /N (%)	SLE without Lupus Nephritis (n=1290) Mean (SD) /N (%)	P Value
Age when BMI are measured	32.07 (8.4)	42.53 (13.48)	<0.0001
Kidney Biopsy Age	35.14 (10.9)	–	
Ethnicity	20 (27.78%)	811 (62.87%)	<0.0001
Caucasian			
Asian	5 (6.94%)	36 (2.79%)	
African American	42 (58.33%)	404 (31.32%)	
Others	5 (6.94%)	39 (3.02%)	
Male	6 (8.33%)	76 (5.89%)	0.4387
Age when SLE was diagnosed	27.39 (8.47)	35.46 (12.85)	<0.0001
BMI (continuous)	26.93 (6.72)	28.02 (7.32)	0.1855
BMI (Categorical)	32 (44.44%)	475 (36.82%)	0.6242
Underweight			
Normal Weight	2 (2.78%)	38 (2.95%)	
Overweight	19 (26.39%)	372 (28.84%)	
Obesity	19 (26.39%)	405 (31.4%)	
SLEDAI (continuous score)	5.04 (4.03)	2.13 (2.8)	<0.0001
SLEDAI (≥2)	65 (90.28%)	690 (53.61%)	<0.0001
Anti dsDNA (≥10)	40 (59.7%)	252 (20.31%)	<0.0001
Low C3 (<79)	37 (53.62%)	178 (14.19%)	<0.0001
Low C4 (<12)	27 (39.13%)	146 (11.67%)	<0.0001
ESR (>20)	47 (70.15%)	576 (47.56%)	0.0004

**Conclusions:** Obesity was not associated with the development of lupus nephritis. Obese patients with SLE had lower disease activity as measured by SLEDAI, dsDNA titers and complement levels.

**Disclosure of Interest:** None declared

#### AB0539 CORRELATION BETWEEN MORPHOLOGICAL AND FUNCTIONAL MICROVASCULAR DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

A. Sulli<sup>1</sup>, B. Ruaro<sup>1</sup>, C. Pizzorni<sup>1</sup>, V. Smith<sup>2</sup>, S. Paolino<sup>1</sup>, M. Pendolino<sup>1</sup>, L. Verni<sup>1</sup>, M. Cutolo<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; <sup>2</sup>Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium

**Background:** Numerous articles have investigated peripheral microcirculation in primary Raynaud's phenomenon (PRP).<sup>1–3</sup> However, reports that analyse peripheral microcirculation in systemic lupus erythematosus (SLE) are scanty.<sup>4,5</sup>

**Objectives:** The aim of this study was to investigate possible correlations between morphological and functional aspects of microcirculation in different skin areas of the hands and face in SLE patients and to compare the results with PRP patients and healthy subjects (HS).

**Methods:** A total of 14 SLE patients without RP (ACR criteria)<sup>6</sup> (mean age 53 ±14 SD years, mean disease duration 7±4 years), 14 PRP patients (LeRoy and ACR/EULAR 2013 criteria)<sup>7,8</sup> (mean age 53±17 years, mean RP duration 6±5 years) and 14 HS (mean age 50±17 years) were enrolled during the winter period. Nailfold videocapillaroscopy (NVC) and laser speckle contrast analysis (LASCA) were performed in the three groups of patients. The absolute nailfold capillary number (CN) per linear millimetre at first distal row was assessed by NVC. Blood perfusion (BP) was detected by LASCA at the level of fingertips, periungual areas, dorsum and palm of both hands and face. The average BP was calculated as perfusion units (PU).<sup>2</sup> Patients were not taking vasodilator drugs since at least one month. Statistical analysis was performed by non parametric tests.

**Results:** SLE patients showed a positive correlation between BP and nailfold CN in all areas of hands (p<0.0001), but no statistically significant correlation was observed between BP and nailfold CN at the level of face (p=0.10). In both PRP and HS no statistically significant correlation was observed between BP and nailfold CN in all examined areas (p=0.70 and p=0.20, respectively). SLE patients showed a statistically significant lower nailfold CN than both PRP and HS (median 9.1 vs 10.3 vs 11.0, respectively, p<0.0005). Conversely, no statistically significant difference of nailfold CN was observed between PRP and HS. PRP patients showed a statistically significant lower BP than both SLE and HS at the level of fingertip (median 90, 114, 187 PU, respectively; p<0.0001), periungual (median 74, 100, 141 PU, respectively, p<0.0001), dorsal (median 61, 72, 128 PU, respectively, p<0.0001), and palm areas (median 76, 96, 124 PU, respectively, p<0.0001). Conversely, PRP, SLE and HS patients showed similar BP values at the level of face (median 141, 139, 137 PU, respectively, p=0.30).

**Conclusions:** This study demonstrates a correlation between morphological and functional microvascular features in SLE patients. SLE patients without RP have a subclinical microangiopathy, showing lower nailfold CN and BP than HS. Conversely, PRP patients show only a functional dysfunction, having a lower peripheral skin BP than both SLE patients and HS. The clinical value of this new finding is undergoing further analysis.

#### AB0540 USEFULNESS OF CARDIAC SCREENING IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTI-RO POSITIVE ANTIBODIES

A. Olivé<sup>1</sup>, M. Martínez-Morillo<sup>1</sup>, R. Villuendas<sup>2</sup>, A. Teniente-Serra<sup>3</sup>, A. Riveros-Frutos<sup>1</sup>, S. Heredia<sup>1</sup>, Á. Prior-Español<sup>1</sup>, S. Hologado<sup>1</sup>, L. Mateo<sup>1</sup>, M. Aparicio<sup>1</sup>, L. Gilfré<sup>1</sup>, G. Juncà<sup>2</sup>, E. Martínez-Cáceres<sup>3</sup>, A. Bayes-Genis<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Cardiology; <sup>3</sup>Immunology, Hospital Universitari Germans Trias i Pujol, Badalona, Spain, Badalona, Spain

**Background:** Cardiac block in neonatal lupus is associated with placental transfer of anti-Ro antibodies. The effect of these antibodies on cardiac conduction disorders in adult patients is controversial. The association between anti-Ro antibodies and heart rhythm disorders have been described in isolated cases. However, there are just a few studies that analyse the relationship between auto-immune diseases and electrocardiographic disturbances.

**Objectives:** To determine if there are differences in cardiac conduction of SLE patients in presence of anti-Ro antibodies.

**Methods:** All patients included fulfilled the SLE criteria, SLICC 2012 and they were followed up in a single centre. The inclusion was consecutive and voluntary. Patients who took drugs that altered the conduction (except antimalarial drugs), and those who had heart or thyroid disease were discarded. All patients were assessed blindly by a cardiologist who performed an interrogation and physical examination, an electrocardiogram, an echocardiogram and a 24 hour Holter study. Besides, a rheumatologist performed a clinical and analytical assessment including a qualitative analysis by immunoblotting of anti-Ro Ab and a quantification by chemiluminescence of the anti-Ro52 and Ro60 Ab. The presence of other SLE specific Ab (ANA, DNA, antiphospholipids), was also analysed. Clinical, analytical and, activity and damage indexes, were collected (SLEDAI and SLICC). The data were compared by Student's t test, Fisher's test and Chi square using 21 SPSS version. The level of significance was established at 5%.

**Results:** 145 patients were included: 91.7% women, average age 45±12, average disease duration 11 years. The patients were undergoing the following treatments: antimalarial 91%, mycophenolate 20%, azathioprine 12%, biological treatment 5% and glucocorticoids 70%. The clinical characteristics are summarised in table 1.

There were no significant differences between the group of positive and negative anti-Ro Ab in terms of gender, age, clinical characteristics or cardiovascular risk factors. None of the patients was affected by an atrio-ventricular block and the rest of the electrocardiographic alterations had no clinical significance and did not predominate in the positive Ro Ab group. Additionally, no differences in heart rate, ventricular extrasystoles or PR, QT or QRS intervals were detected between both groups. The echocardiogram's findings were not relevant and there were no differences between groups.

Since the majority of patients with SLE are double positive, differences between the two subspecificities of Ro (52 and 60) could not be analysed. On the other hand, no differences were found in cardiac conduction regarding the treatments received, the activity or damage indexes, or the analytical or clinical characteristics of the patients.

Cumulative clinical manifestations (%)	
Articular	80
Cutaneous	63
Leuco-lymphopenia	42
Renal	24
Serositis	30
Neurologic	9
Secondary antiphospholipid syndrome	10
Secondary Sjögren syndrome	10
Activity and damage indexes	
SLICC	0,32 ± 0,7
SLEDAI in diagnosis	7,97 ± 4,2
SLEDAI in inclusion	1,82 ± 2,48
Analytical parameters	
Increased DNA	51 %
Average DNA	207,86 ± 357 (UI/L)
Hypocomplementemia	39 %
Anti-Ro positive antibodies	31 %

Abstract AB0540 – Figure 1

**Conclusions:** The study results show that there are no differences in cardiac conduction according to the presence of anti-Ro antibodies in SLE patients. Thus, the cardiac screening in SLE patients with anti-Ro positive antibodies seems not helpful in clinical practice.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5179

#### AB0541 HEPICIDIN AND INTERFERON-A IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

D. Archimandriti<sup>1</sup>, A.T. Tzallas<sup>2</sup>, T.-E. Memi<sup>1</sup>, P. Spyrou<sup>1</sup>, A.A. Drosos<sup>1</sup>, P. V. Voulgaris<sup>1</sup>. <sup>1</sup>Rheumatology Clinic, Department Of Internal Medicine, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA; <sup>2</sup>Department of Computer Engineering, School of Applied Technology, Technological Educational Institute (TEI) of Epirus, Kostakioi, 47100, Arta, Greece, Ioannina, Greece

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease where interferon (IFN)  $\alpha$ , is considered to play a central role in its pathogenesis. Anaemia of chronic disease (ACD) in SLE is common. Hepcidin may contribute to anaemia by limiting iron availability for erythropoiesis.

**Objectives:** The aim of the study was to evaluate INF- $\alpha$  and hepcidin levels in sera of anaemic and non-anaemic SLE patients.

**Methods:** This was a pilot study of SLE patients with established disease. Patients were divided as anaemic and non-anaemic according to the haemoglobin (Hb) levels: Hb value <13.5 gm% for men and <11.5 gm% for females. ACD was defined according the levels of iron and ferritin. Serum hepcidin (the active 25 amino acid form) was measured using ELISA (Peninsula Laboratories International). IFN alpha was also measured using ELISA (eBioscience, affymetric). The inter-assay coefficient of variation was <20% for both assays. All analyses were performed with IBMSPSS Statistics for Windows (version 21). Data are expressed as the mean  $\pm$  standard deviation (SD). Statistical analysis was performed using

Student's t-test for independent samples. The relationships between hepcidin level and all variables were analysed using two-tailed Pearson's correlation test. P values less than 0.05 were considered significant.

**Results:** Forty SLE patients (36 women and 4 men) were studied. Demographic parameters were as follows: age 46.78 $\pm$ 16.04 years, disease duration 10.55 $\pm$ 6.58 years. Levels of Hb were 12.49 $\pm$ 1.28 g/dl. Levels of INF- $\alpha$  were 0.16 $\pm$ 0.47 pgr/ml while hepcidin levels were 2.54 $\pm$ 2.63 ngr/ml. When the patients were divided into anaemic (20 patients) and non-anaemic (20 patients) groups (Hb:11.41 $\pm$ 0.56 vs. 13.57 $\pm$ 0.77 g/dl,  $p<0.001$ ), patients with anaemia had lower disease duration (9.75 $\pm$ 6.16 vs. 11.35 $\pm$ 7.03 years,  $p=0.45$ ), lower levels of INF- $\alpha$  (0.13 $\pm$ 0.035 vs. 0.19 $\pm$ 0.036 pgr/ml  $p<0.001$ ) and higher hepcidin levels (2.92 $\pm$ 2.9 vs. 2.17 $\pm$ 2.35 ngr/ml,  $p=0.37$ ) than the patients without anaemia. No correlation was observed between levels of hepcidin with all variables. There was also no correlation between hepcidin and INF- $\alpha$  levels.

**Conclusions:** INF- $\alpha$  does not seem to contribute in ACD pathogenesis in SLE patients and does not correlate with hepcidin levels in SLE patients. Further studies will clarify the role of INF- $\alpha$  in anaemia in SLE.

**Disclosure of Interest:** None declared

#### AB0542 MULTIPLE SCLEROSIS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

E. Kallonoudis<sup>1</sup>, E. Pelechas<sup>1</sup>, S. Konitsiotis<sup>2</sup>, P.V. Voulgaris<sup>1</sup>, A.A. Drosos<sup>1</sup>. <sup>1</sup>Rheumatology Clinic, Department Of Internal Medicine; <sup>2</sup>Neurology Clinic, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, Ioannina, Greece

**Background:** Imaging and histopathologic studies in patients with primary Sjögren's Syndrome (pSS) have demonstrated white matter lesions which are indistinguishable from those observed in multiple sclerosis (MS).

**Objectives:** The purpose of this study was to evaluate the frequency of MS in a cohort of patients with pSS.

**Methods:** One hundred and twenty-one patients with pSS had been evaluated and followed up in the outpatient Rheumatology Clinic at predefined times since 1994. All patients were classified according to the 2016 ACR-EULAR criteria for SS. During follow-up the clinical, laboratory and imaging findings were all recorded. In addition, Magnetic Resonance Imaging and electrophysiological studies as well as spinal fluid analysis were performed when indicated. The diagnosis of MS was based on the 2010 revised McDonald criteria.

**Results:** Seven patients were diagnosed as having MS. All patients with MS were female. Mean age at the time of MS diagnosis was 65.5 $\pm$ 3.6 years, while pSS has been diagnosed at the mean age of 54.4 $\pm$ 3.2 years. Mean time of MS development was approximately 10 years after the pSS diagnosis. pSS patients who developed MS had severe sicca symptoms without other extraglandular manifestations and had positive Ro (SSA) antibodies and a positive minor salivary gland biopsy. pSS patients with MS development were treated appropriately in the Neurology department with biological medications with some improvement of the sicca symptoms.

**Conclusions:** We found that 5.8% of pSS patients as having MS. This percentage of patients clearly indicates the possibility for the coexistence of a second autoimmune disease with similar if not common pathogenetic mechanisms. Thus patients with pSS should be evaluated carefully and screened appropriately for MS when indicated.

#### AB0543 CORRELATION BETWEEN SYSTEMIC LUPUS ERYTHEMATOSUS DISEASE ACTIVITY AND OCULAR SIGNS IN OPHTHALMOLOGICALLY ASYMPTOMATIC PATIENTS

S.A. Fouad<sup>1</sup>, S.M. Esmat Mahmoud Ali<sup>2</sup>, A.R.L. Rezk Alnaggar<sup>1</sup>, S. Mahfouz<sup>1</sup>, M. Essam<sup>1</sup>, H. El-Gendy<sup>1</sup>. <sup>1</sup>Internal Medicine Department; <sup>2</sup>Ophthalmology, Kasr Al Einy hospital, Cairo University, Giza, Egypt

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease involving different organs and systems. Ocular manifestations of lupus may manifest as a presenting feature of the disease or as a complication that can be sight threatening. Almost any part of the eye and visual pathway can be affected by inflammatory or thrombotic processes yet ophthalmological assessment in those patients may be delayed.

**Objectives:** Detection of various ocular pathologies in ophthalmologically asymptomatic SLE patients using Optical Coherence Tomography (OCT), Fundus Fluorescein angiography (FFA), and fundus examination, in addition to studying the

relation of between detected ocular changes and SLE disease activity assessed by SLEDAI score.

**Methods:** 26 ophthalmologically asymptomatic SLE patients recruited from Kasr Alainy hospital, Cairo University, and were subjected to comprehensive ocular assessment in the form of the measurement of visual acuity, fundus examination, FFA, and OCT. Hypertensive, diabetic and renal impairment patients were excluded.

**Results:** SLE patients were 25 females and 1 male, age mean of 25.15 ( $\pm 8.6$ ) years, SLEDAI mean 14 ( $\pm 8.3$ ), duration of illness mean 27 ( $\pm 42.3$ ) months. FFA showed that 38 out of 52 eyes (73%) had signs of pathological changes in the form of splinter haemorrhages, venular occlusion, diffuse mottling and optic nerve leakage and also degenerative changes which indicate chronicity, in the form of hyperfluorescence areas outside the arcades and pre-papillary areas and capillary dropouts. Besides; OCT detected changes in 67.3% of the examined eyes with 26.9% revealing degenerative thinning. There was significant correlation between disease activity and changes detected by FFA (p value 0.017), but neither the fundus findings nor the OCT pathological changes had correlation with disease activity. On the other hand, there was significant correlation between OCT changes and prolonged use of hydroxychloroquine more than 5 years (p value 0.032) and steroid intake for more than 3 month (p value 0.039). There was no correlation between FFA or OCT changes and proteinuria or anti-phospholipid antibodies.

**Abstract AB0543 – Table 1.** Relation between disease activity and FFA changes

SLEDAI	Negative FFA changes	Positive FFA changes	p-value
Inactive	2 (0.03%)	0	0.017
Active	12 (23%)	38 (73%)	

**Abstract AB0543 – Table 2.** Relation between Hydroxychloroquine (HXQ) and OCT changes

	Negative OCT changes	Positive OCT changes	p-value
HXQ<5 years	17 (32.6%)	27 (51.9%)	0.032
HXQ≥5 years	0.0%	8 (15.3%)	

**Abstract AB0543 – Figure 1.** Revealing discrepancy between fundus and FFA changes (left), Correlation between SLEDAI score and FFA changes (right)

**Conclusions:** FFA is can detect early retinopathy changes in patients of SLE which cannot be detected by fundus examination. FFA changes are correlating with disease activity. On the other hand, there was no correlation between OCT changes and disease activity. OCT is more sensitive to detect changes from hydroxychloroquine and steroids intake.

#### AB0544 ROLE OF ANTI-NEURONAL ANTIBODIES (A-NA) IN EPILEPSY LUPUS PATIENTS

C. Mazzuca<sup>1</sup>, A. Rigon<sup>1</sup>, F. Basta<sup>1</sup>, A. Taccone<sup>2</sup>, M. Tombini<sup>3</sup>, R. Iorio<sup>4</sup>, M. Infantino<sup>5</sup>, A. Afeltra<sup>1</sup>. <sup>1</sup>Clinical Immunology and Rheumatology; <sup>2</sup>Internal Medicine; <sup>3</sup>Clinical Neurology, Campus Bio-Medico University of Rome; <sup>4</sup>Institute of Neurology, Università Cattolica del Sacro Cuore, Rome; <sup>5</sup>Immunology, Immunology and Allergy Laboratory, Florence, Italy

**Background:** Epilepsy may occur before, during or after SLE diagnosis, with a prevalence of 6.7%–14%. Recent works showed that a significant proportion of patients with not responding to antiepileptic drugs (AED)-resistant epilepsy harbour neural-specific autoantibodies. The detection of these antibodies may predict a favourable response to immunotherapy (75% of patients).<sup>1</sup> A small number of recent studies have described the existence of antibodies directed against a-NA in neuropsychiatric SLE (NPSLE), and data are contrasting.<sup>2</sup>

**Objectives:** Evaluate the clinical features of epilepsy in patients with SLE. Evaluate any clinical-instrumental differences in epilepsy in patients diagnosed with epilepsy prior to many years of SLE. Evaluate antibodies associated with neurological phenotypes.

**Methods:** We retrospectively evaluated a SLE cohort for epileptic seizures. We single out 11 epileptic SLE patients (about 10%). A control group of 10 SLE patients with no NPSLE was matched for sex and age. Sera patients were tested for: ANA, a-ds-DNA, a-ENA, LAC, anticardiolipin IgG and IgM, anti- $\beta 2$ -glycoprotein IgG and IgM, a-nucleosomes, a-ribosomal.

All sera were evaluated for the presence of autoantibodies directed to neural antigens by indirect immunofluorescence on frozen sections of mouse brain, cell-based assays (a-NA, a-NMDA).

**Results:** In our cohort of SLE patients with epilepsy we confirm the association between SLE and epilepsy of the mesial temporal lobe (MTLE). Six patients had epilepsy at least 5 years prior to SLE diagnosis (average 11.6 years), the presence of minor symptoms suggestive of SLE (eg arthralgia, rash,) was reported many years before immunological diagnosis. Moreover seizure frequency was achieved when they started immunosuppressive drugs. Anti-NA antibodies were present in 6/11 (54%) of patients with SLE/epilepsy compared with 2/10 (20%) of the control group (p=0.05). We obtained specificity 0.80 (95% CI 0.44–0.97), and sensitivity 0.54 (95% CI 0.23–0.82). Among the other antibodies studied, we have not found any statistically significant difference between the two groups.

**Abstract AB0544 – Figure 1**

**Conclusions:** Anti-NA antibodies could be a useful biomarker of NPSLE, allowing a more precocious diagnosis and therefore a more early therapeutic intervention with improvement of long-term prognosis and quality of life.

### AB0545 IS LUPUS MORE PREVALENT IN WORLD'S MOST STRESSED COUNTRIES?

A. Almathkouri, D. Pyne, A. Pakozdi, R. Rajkariar, A. Cove-smith, M. Lewis, on behalf of Barts Lupus Center. *BARTS NHS TRUST, London, UK*

**Background:** A number of studies have implicated psychological stress as a trigger for autoimmune diseases. In a questionnaire study involving 120 lupus patients emotional stress was selected in over 75% cases as a trigger for their disease<sup>1</sup>. The role of stress as a trigger in lupus however is controversial. Here we study whether there is an association between the prevalence of lupus in various countries and their reported stress measures.

**Methods:** We undertook a literature review of the reported prevalence of lupus in various countries across the world. We then recorded the reported stress index in those countries from Bloomberg's study<sup>2</sup>, which utilised seven equally weighted variables: homicide rates, GDP per capita income inequality, corruption perception, unemployment, urban air pollution and life expectancy to rank 74 countries according to stress levels. Pearson's correlation was used to measure association between national stress indices and lupus prevalence

**Results:** Results are presented in graph 1. Prevalence data was only available in the literature for limited countries. Of the countries studied no correlation was found between national stress indices and lupus prevalence ( $r = -0.028$  (p-value 0.449))

Abstract AB0545 – Figure 1

**Conclusions:** We found no association between a country's prevalence of lupus and the measured stressfulness of its living environment.

### AB0546 CRYOGLOBULINEMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL AND IMMUNOLOGICAL FEATURES

A. Barrera-Vargas<sup>1</sup>, F.J. Antiga-López<sup>2</sup>, J. Rangel-Patiño<sup>3</sup>, R. Rosado-Canto<sup>4</sup>.  
<sup>1</sup>Immunology and Rheumatology; <sup>2</sup>Internal Medicine; <sup>3</sup>Hematology; <sup>4</sup>Nephrology, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico

**Background:** Systemic lupus erythematosus (SLE), as the prototype of systemic autoimmune diseases, has a wide array of clinical manifestations. An association between cryoglobulinemia and certain clinical and immunological features of SLE has been proposed, and there are various physiopathologic pathways that could be involved in this relationship. Although the presence of cryoglobulinemia in SLE patients may be related to specific disease features and could even have prognostic value, this association has not been addressed thoroughly.

**Objectives:** To describe clinical and immunological characteristics in SLE patients with cryoglobulinemia.

**Methods:** We performed a retrospective, case-control study, in which we included all patients with a cryoglobulin determination between January 2005 and December 2016 in a third level referral centre in Mexico City. Patients with SLE and a positive cryoglobulin test (cryocrit  $\geq 1\%$ ) were included in the case group, whereas SLE patients with a negative cryoglobulin determination were considered controls. We studied demographic, clinical and immunological

characteristics at the time of the positive cryoglobulin result, as well as three months earlier, and 6 and 12 months later.

**Results:** Thirty-six SLE patients had a cryoglobulin determination throughout the study period. Ten patients had cryoglobulin levels  $\geq 1\%$  and were included in the case group, whereas 26 patients with a negative determination were included as controls. Mean age was  $37.7 \pm 18.3$  in cases and  $41.7 \pm 19.3$  in controls. 70% of cases and 88.5% of controls were women.

Among subjects with cryoglobulinemia, the cryocrit was 1% in 9 patients, and 3% in one. Regarding clinical and immunological characteristics, a positive lupus anticoagulant and a history of vasculitis were more frequent in patients with serum cryoglobulins ( $p=0.004$  and  $0.04$ , respectively).

At the time of the cryoglobulin measurement, patients in the case group had lower levels of C3 and C4 ( $p=0.026$  and  $p=0.003$ , respectively), and serum albumin ( $p=0.028$ ). They also had a higher prevalence of serositis ( $p=0.021$ ) and peripheral oedema ( $p=0.034$ ), as well as a higher SLICC Damage Index score ( $p=0.014$ ) than controls.

Regarding follow-up, patients in the case group had a higher SLEDAI score after six and twelve months ( $p=0.009$  and  $0.034$ , respectively). Also, after 12 months they had a higher prevalence of renal activity ( $p=0.004$ ) and lower C4 levels ( $p=0.001$ ). Among patients with renal activity, 20% of cases and 55% of controls had achieved complete remission after 12 months.

**Conclusions:** Serum cryoglobulins in SLE patients were associated with positive lupus anticoagulant and hypocomplementemia. Cryoglobulinemia was also associated with specific disease manifestations, such as serositis and vasculitis, and with damage accrual. At follow-up, patients with cryoglobulinemia had a higher prevalence of renal activity, as well as an increased disease activity overall. Whether cryoglobulins could be used as a biomarker for renal activity or worse renal prognosis remains to be determined, and larger prospective studies will be needed to address this possibility.

### AB0547 LYMPHADENOPATHY IN SYSTEMIC LUPUS ERYTHEMATOSUS: CLINICAL RELEVANCE AND HISTOLOGICAL SUBTYPES

A. Berbel<sup>1</sup>, M. Estevez<sup>2</sup>, M. Freire<sup>3</sup>, E. González<sup>4</sup>, L. González-Vázquez<sup>5</sup>, I. Carballo<sup>6</sup>, B. Sopeña<sup>7</sup>, on behalf of CEAG (Círculo de Estudios en Enfermedades Autoinmunes de Galicia). <sup>1</sup>Medical Student. Faculty of Medicine, University of Santiago de Compostela, Santiago de Compostela (A Coruña); <sup>2</sup>Systemic Diseases Unit; <sup>3</sup>Systemic Diseases Unit, CHUVI, Vigo; <sup>4</sup>Systemic Diseases Unit, CHOU, Ourense; <sup>5</sup>Department of Medicine, POVISA, Vigo; <sup>6</sup>Systemic Diseases Unit; <sup>7</sup>Hospital Clínico Universitario de Santiago de Compostela (CHUS), Santiago de Compostela (A Coruña), Spain

**Background:** Some patients with Systemic Lupus Erythematosus (SLE) have lymphadenopathy (LAP) at diagnosis or at follow-up. The prevalence of LAP in SLE was 59% in the oldest series,<sup>1</sup> 12% in the 1993 EUROLUPUS series<sup>2</sup> and in the last two decades its prevalence was not mentioned. However, the presence of LAP and their histological type may have clinical relevance.<sup>3</sup>

**Objectives:** To study the prevalence and histologic characteristics of LAP in a cohort of patients with definite SLE and evaluate its relationship with clinical manifestations.

**Methods:** All patients diagnosed with SLE according to the 1997-ACR criteria at the Autoimmunity Units of three different hospitals since 2005 were followed looking for lymph node enlargement at every consult. The moment when LAP was detected, the concomitant clinical symptoms, SLE manifestations and laboratory variables were recorded. The group of patients with and without LAP were compared. A tissue sample was obtained when indicated. All patients agree to participate in the study.

**Results:** 103 patients with definite SLE were included in the study. Valuable LAP ( $>10$  mm) was found in 28 patients (27%). The gender and age of SLE patients with and without LAP was similar (80% vs 78% females, and  $34 \pm 15$  vs.  $40 \pm 28$  years respectively). LAP was detected at the time of SLE diagnosis in 54% of patients. Fever was significantly more frequent in patients with LAP (60% vs 5%,  $p < 0.01$ ) like dermatopathy (86% vs. 60%;  $p < 0.05$ ) and serositis (45% vs 16%  $p < 0.01$ ). High titers of anti-dsDNA antibodies (71% vs. 42%;  $p < 0.05$ ) and hypocomplementemia (89% vs. 60%;  $p < 0.05$ ) were also more frequent in patients with LAP. A total of 28 tissue samples were obtained in 17 patients (FNA 6, Ultrasound-guided biopsy 6 and surgical excision in 17). The histopathological study showed: Reactive lymphadenitis 20, histiocytic necrotizing lymphadenitis in 6 and Non-Hodgkin Lymphoma in 2 (B-cell lymphoma on methotrexate treatment, and a Burkitt lymphoma). All 6 patients with SLE and histiocytic necrotizing lymphadenitis have cutaneous involvement but none of them developed lupus nephritis.

**Conclusions:** Patients con SLE and lymphadenopathy had significantly more fever, cutaneous lesions and serositis. High levels of anti-dsDNA antibodies and hypocomplementemia were more frequent in these patients. In some occasions malignancy could be the cause of lymphadenopathy.

AB0548

**ANTIBODY TO PURINNUCLEOSOID PHOSPHILASE CAN BE USED AS AN ADDITIONAL MARKER OF INFECTIOUS COMPLICATIONS WITH SYSTEMIC LUPUS ERYTHROMATOSIS**

A.V. Aleksandrov, E.V. Benedickaya, I.Y. Alekhina, N.V. Aleksandrova. *Research Institute of Clinical and Experimental Rheumatology named after A.B. Zborovskiy, Volgograd, Russian Federation*

**Background:** Purine nucleoside phosphorylase (PNP, EC 2.4.2.1) plays a leading role in the assimilation of nucleosides and nucleotides by the cell, as well as in maintaining the immune status of the organism. Patients with PNP deficiency are highly susceptible to various infections, in view of the fact that the decreased activity of PNP is closely related to the insufficiency of cellular immunity.

**Objectives:** Study of the possibility of using the level antibodies to purine nucleoside phosphorylase as an additional marker of infectious complications in patients with systemic lupus erythematosus (SLE).

**Methods:** The study included 60 patients with SLE (women – 91.7%, mean age 36.32±15.27 years, average duration of the disease 7.96±7.35 years) with different clinical manifestations (SLEDAI activity 8.93±5.74, ECLAM activity 5.30±2.79, damage index SLICC/ACR 1.95±1.71). Antibodies to PNP (anti-PNP) were determined in our indirect ELISA test using the immobilised form of the enzyme as an antigenic matrix.

The presence of infectious complications in SLE patients was assessed by characteristic clinical manifestations and was considered to be confirmed when the causative agent was recognised and/or the serological analyses are positive. Infections were diagnosed in 38.3% of patients, the most frequent localization was the urinary system (n=12; 52.2%) and female genitalia (n=5; 21.7%).

**Results:** In the presence anti-PNP in the blood serum of patients with SLE we have often noted infectious complications ( $p=0.025$ , criterion  $\chi^2$ ) and less often lung damage ( $p=0.17$ ) (when compared with a group of patients with SLE seronegative for the presence of anti-PNP).

Statistically significant differences (Mann-Whitney U-criterion) were detected only for pyuria ( $p<0.0005$ ), C-reactive protein level ( $p=0.048$ ) and the number of ceruloplasmin ( $p=0.008$ ), while comparing the groups of SLE patients with the presence of infectious complications and without it; differences in the level of antibodies to CP ( $p=0.052$ ) did not reach statistical significance. Other clinical and laboratory parameters do not have statistically significant differences between the two sessions. This fact complicates the recognition and differential diagnosis of infectious complications in SLE significantly.

The analysis of the characteristic curve of antibodies to PNP in the diagnosis of infectious pathology in SLE shows limited possibilities for using this parameter. The square under the curve was 0.687 (95% confidence interval 0.523–0.804,  $p=0.008$ ), the separation point was 0.386 U/ml with a sensitivity of 55% and a specificity of 83%.

Taking into account that the typical clinical manifestations of infection with SLE can be erased as a result of the actual activity of SLE, and due to the use of immunosuppressive drugs, timely diagnosis and treatment become especially relevant. This study indicates the possibility of using the level of antibodies to PNP as an additional marker of infection, but the balance between specificity and sensitivity of this test does not allow to recommend it as a single study.

**Conclusions:** A high level of anti-PNP in the serum, especially combined with the C-reactive protein increase and in the absence of other markers of SLE activation allows to suspect the presence of infection and points to the need for in-depth research directed to identify the pathogen.

AB0549

**CAN THE OVERALL THROMBOTIC RISK IN SYSTEMIC LUPUS ERYTHEMATOSUS BE DETERMINED? THE COMBINED ROLE OF CLASSIC CARDIOVASCULAR FACTORS AND ANTIPHOSPHOLIPID ANTIBODIES**

Â. S. Mota, I. Cunha, J. Andrade, C. Eira, S. Machado, J. Tavares, V. Romão, R. Silvério, C. Martins. *Medicina, CENTRO HOSPITALAR TONDELA-UISEU, E.P. E., Viseu, Portugal*

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic inflammatory disorder. Antiphospholipid syndrome (APS) is a thrombotic disorder associated with the presence of antiphospholipid antibodies (APA) and increased cardiovascular risk (CVR). Framingham (FRM) and SCORE (Systematic Coronary Risk Evaluation) scales are available CVR assessment systems. aGAPSS (adjusted Global Antiphospholipid Syndrome Score) combine positive APA and CVR factors, which was suggested to determine the thrombotic risk in persistently positive APA (PPAPA) patients.

**Objectives:** To determine the role of the thrombotic factors in SLE patients, considering CVR factors and APA. To assess the application of different thrombotic risk scales.

**Methods:** A retrospective cohort study of 84 patients with SLE followed in an out-patient setting of a Portuguese central hospital was performed. The study evaluated patient gender, current age, age at diagnosis, duration of illness, presence of another autoimmune disease (AID), CVR factors [obesity (OB), diabetes (DB), arterial hypertension (AH), dyslipidaemia (DL), smoking (SM)], presence of APA, treatment, dose and duration of steroids. The FRM, SCORE and aGAPSS scores were calculated. The data was analysed using SPSS and considered significant if  $p<0.05$ .

**Results:** Table 1 characterises the study population. Male patients had a higher prevalence of AH ( $p=0.022$ ), DL ( $p=0.047$ ), and SM ( $p=0.001$ ), with a risk of 11%–20% in the FRM scale and a risk of 5%–14% in the SCORE ( $p=0.000$ ). Female patients had a higher presence of another AID ( $p=0.014$ ) and treatment with disease-modifying antirheumatic drugs ( $p=0.014$ ). FRM scale reveals a risk of 11%–20% in the presence of AH and >20% in SM ( $p=0.001$ ). The SCORE scale reveals a risk of 5%–9% in the presence of AH ( $p=0.003$ ) and 10%–14% in DL ( $p=0.024$ ). When the risk is 6%–20% in the FRM scale, the risk is lower in SCORE ( $p=0.000$ ). APA does not correlate with an increased CVR. All APA are associated with another AID, APS and PPAPA. The aGAPSS associates a score of 7–12 if another AID is present ( $p=0.000$ ); 4–9 with APS; >7 with PPAPA ( $p=0.000$ ); 4–6 with DB ( $p=0.039$ ), DL ( $p=0.002$ ) and AH ( $p=0.000$ ); >7 with lupus anticoagulant (LA), >7 with anticardiolipin antibodies (aCL) and >12 with anti- $\beta$ -2glycoprotein-I antibody (anti $\beta$ 2GPI) ( $p=0.000$ ).

**Abstract AB0549 – Table 1**

Women	74%
Current age	52.3±16.2 years
Age of diagnosis	44.9±17.4 years
Duration of disease	7.2±7.5 years
Another AID	30% (APS 60%, Sjögren syndrome 36%)
PPAPA	12%
CVR	AH 42.8%, DL 21.4%, OB 11.9%, DB 10.7%, SM 9.5%
APA	LA 19%, aCL 15.5%, anti $\beta$ 2GPI 7.1%
Steroid use	61%
DMARDs	89%

**Conclusions:** This study highlights the existence of thrombotic factors in SLE. Their risk is even more elevated when another AID is present. The FRM and SCORE scales reflects the CVR. In SLE patients both the CVR factors and the presence of APA must be evaluated. Therefore, not only should the FRM scale be calculated, but also the global thrombotic risk, using the aGAPSS, must be accessed.

### CLINICAL-EPIDEMIOLOGICAL FEATURES OF PATIENTS WITH A LATE-ONSET LUPUS IN A TERTIARY CARE HOSPITAL

A. Crespo Golmar, C. Moriano, M. Garjo, C. Iñiguez, I. González, A. López, E. Díez, C. Álvarez, M. Martín, E. Vallejo, T. Pérez. *Rheumatology Department, University Health Care Complex of León, León, Spain*

**Background:** Different frequency of clinical and serological manifestations has been detected according to the age of onset of the patients with Systemic lupus erythematosus (SLE). According to the literature, senile SLE manifests between 6% and 18% of the patients with lupus.

#### Objectives:

1. To identify and analyse the clinical-serological and epidemiological features of senile SLE in our environment.
2. To determine the average survival time and mortality in these patients, identifying its main cause.

**Methods:** Observational retrospective study of 319 patients diagnosed with SLE (according to ACR 1992 and SLICC 2012 criteria) at the Hospital of León between 1997–2017 and with an age of onset  $\geq 65$  years, obtaining a total of 68 patients with senile SLE.

**Results:** The mean age at diagnosis was  $75.4 \pm 12.1$  years, with a female/male ratio of 2.4. The most frequent manifestations were as joint (63.2%) and haematological manifestations in the form of leuco-lymphopenia (55.9%). The hemolytic anaemia only appeared in 2.9% of the cases and the thrombocytopenia in 25%. 36.8% of patients showed photosensitivity and 29% had other cutaneous manifestations, being the malar erythema the most prevalent type (60%), followed by the discoid lupus erythematosus (20%) and the subacute lupus (15%). Alopecia was only observed in 4.4%. Lupus nephritis was detected in the form of proteinuria in 4.4% of the patients, and only one patient had microscopic haematuria. Lung involvement was uncommon (8.8%), taking precedence the UIP (33.3%) over the rest of the pulmonary manifestations. Only 11.1% of the patients with senile SLE had serositis, being in the form of pleuritis in 75% of the cases, pericarditis in the 37.5% and ascites in the 12.5%. Regarding the neurological involvement, 5 patients showed polyneuropathy and 1 had chorea. Likewise, the frequency of Sjögren, Raynaud and secondary antiphospholipid syndrome was of 16.7%, respectively.

The most important serological findings were: 97.3% ANA; 44.1% DNA and 20.6% hypocomplementemia, with 54.4% of the patients having serological activity. Only 5.9% had anti-Sm. Antiphospholipid antibodies were positive in 41.2% of the cases, with 4.4% of them showing triple positivity.

The average survival time was of 13.7 years (SD: 10.9–16.5). Out of the total patients, 14 died (20.59%), mostly due to infectious etiology (35.7%) and 14.28% due to disease activity. Other less common causes were neoplasia or ischaemic heart disease (7.14% respectively).

#### Conclusions:

- The late-onset SLE prevails in our environment, one of every 5 patients diagnosed with SLE in our consulting room is older than 65 years.
- It is found most often in women and it is confirmed a lower male/female ratio than expected.
- Joint and haematology manifestations and cutaneous involvement in the form of malar erythema define the clinical profile of our patients with senile SLE, with the renal involvement or the presence of serositis being uncommon.
- Half of the patients had serological activity at the onset, having hypocomplementemia only in 1 out of 5 cases.
- Infections were the first cause of mortality in our sample with an average survival time of around 13 years.

### OBSTETRICAL MORBIDITY RELATED TO ANTI-SSA ANTIBODIES: DATA FROM A FRENCH MONOCENTRIC RETROSPECTIVE STUDY

L. Plaçais<sup>1</sup>, F. Carrat<sup>2</sup>, L. Carbillon<sup>3</sup>, P. Nicaise<sup>4</sup>, A. Benbara<sup>5</sup>, O. Fain<sup>1</sup>, A. Mekinian<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Epidemiology and Public Health, Saint Antoine Hospital; <sup>3</sup>Obstetrics and Gynecology, Jean Verdier Hospital; <sup>4</sup>Auto-immunity and Hypersensitivity, Bichat Hospital; <sup>5</sup>Obstetrics and Gynaecology, Jean Verdier Hospital, Paris, France

**Background:** Obstetrical morbidity is an issue among autoimmune diseases patients. Anti-SSA positivity is well known for its effect on fetus and risk of

congenital heart block but no evidence has been yet found for its effect on obstetrical morbidity

**Objectives:** To investigate anti-SSA positivity effect among a large monocentric cohort of obstetrical morbidity patients and to evaluate the efficacy of different treatment regimens

**Methods:** All women who were seen from January 2010 to January 2015 in Jean-Verdier University Hospital for obstetrical morbidities were retrospectively included. All patients had been tested for anti-nuclear antibodies and anti-SSA/Ro and anti-SSB/La antibodies.

**Results:** We included 244 women (median age 34 years [interquartile range 21–53]) with 869 pregnancies overall. In 27 (11%) patients with anti-SSA antibodies, the median age at the time of pregnancy was 29.5 (17–40) years, with mean number of 3.66 pregnancies per woman. For these 27 patients, 83/99 pregnancies (84%) had an adverse obstetrical outcome: fetal loss (n=65; at a median of 20 (4–38) weeks' gestation), preeclampsia (n=15), intrauterine growth restriction (n=7), prematurity (n=7), and congenital heart block (n=2). In comparing women with obstetrical antiphospholipid syndrome and unexplained adverse complications, there was no major difference in frequency of recurrent miscarriages, preterm deliveries, preeclampsia or fetal loss. Among factors associated with obstetrical outcome and fetal loss, aspirin and hydroxychloroquine treatments were significantly associated with a favourable obstetrical outcome: odds ratio 0.05 [95% confidence interval 0.01; 0.37] (p=0.003) and 0.15 [0.02; 0.98] (p=0.04).

**Conclusions:** Women with unexplained recurrent obstetrical complications should be screened for anti-SSA antibodies. The benefit of aspirin and hydroxychloroquine treatment to improve the obstetrical outcome should be confirmed in prospective studies.

**Disclosure of Interest:** None declared

### THE CLINICAL AND LABORATORY FEATURES OF ANTIPHOSPHOLIPID ANTIBODY POSITIVE PATIENTS WITH OR WITHOUT SYSTEMIC LUPUS ERYTHEMATOSUS

A. Yazici<sup>1</sup>, A. Omma<sup>2</sup>, S. Yilmaz<sup>3</sup>, S. Yavuz<sup>4</sup>, K. Ayar<sup>5</sup>, E. Kasapoglu<sup>6</sup>, B. Kisacik<sup>7</sup>, A. Cefle<sup>1</sup>, D. Erkan<sup>8</sup>. <sup>1</sup>Rheumatology, Kocaeli University School of Medicine, Kocaeli; <sup>2</sup>Rheumatology, Numune Hospital; <sup>3</sup>Rheumatology, Gulhane Training and Research Hospital, Ankara; <sup>4</sup>Rheumatology, Bilim University School of Medicine, Istanbul; <sup>5</sup>Rheumatology, University of Health Sciences Yüksek İhtisas Training and Research Hospital, Bursa; <sup>6</sup>Rheumatology, Göztepe Training and Research Hospital, Istanbul; <sup>7</sup>Rheumatology, Medicalpark Hospital, Gaziantep, Turkey; <sup>8</sup>Barbara Volcker Center for Women and Rheumatic Diseases, Hospital for Special Surgery, Weill Cornell Medicine, New York, USA

**Background:** A multicenter antiphospholipid antibody (aPL) clinical database was created in 2016 with the participation of six rheumatology centres around the country. The purpose has been to better define aPL-related clinical manifestations and management strategies; and also to establish a resource for future clinical studies.

**Objectives:** In this first analysis, we compared the clinical and laboratory features of aPL-positive patients with and without systemic lupus erythematosus (SLE).

**Methods:** The demographic, clinical, laboratory, treatment characteristics of the aPL-positive patients with/without other systemic autoimmune diseases (SAID) are recorded at enrollment according to a predefined protocol. The inclusion criteria are positive aPL (lupus anticoagulant test [LA], anticardiolipin antibody [aCL], and/or anti  $\beta_2$ -glycoprotein-1 antibody [ $\beta_2$ GPI]) based on the Updated Sapporo Antiphospholipid Syndrome (APS) Classification Criteria at least twice within one year prior to enrolment.<sup>1,2</sup> For the purpose of this analysis, we only included aPL-positive patients without other autoimmune diseases (primary aPL/APS) and aPL-positive SLE patients (SLE aPL/APS).

**Results:** As of January 2018, 105 aPL-positive patients were recruited (mean age:  $42.6 \pm 10.1$  [min-max: 19–70]; 83 [79%] female; and 67 [64%] with another SAID). Ten patients were excluded from the analysis due to their SAID history other than SLE. Of the remaining 95 patients, 38 (40%) had primary aPL/APS; 57 (60%) fulfilled the ACR SLE Classification Criteria; 42 (44%) had thrombotic APS (TAPS) (8 arterial, 24 venous, and 8 both); 21 (22%) had obstetric APS (OAPS); 22 (23%) had both TAPS and OAPS (7 arterial, 14 venous, and 1 both); and 10 (11%) had no TAPS/OAPS. Fifty percent of the patients had history of at least one non-criteria aPL-manifestation. Demographics, clinical and laboratory manifestations, and medications were similar between primary aPL/APS and SLE aPL/APS patients except increased frequency of autoimmune hemolytic anaemia, aCL IgG, and hydroxychloroquine use in SLE aPL/APS patients (table 1).

Abstract AB0552 – Table 1

n (%)	Primary aPL/APS n=38	SLE aPL/APS n=57	p
Mean Age (min-max)	41.7±10.5 (24-65)	42.9±10.0 (19-70)	0.57
Female	28 (74)	47 (83)	0.3
Thrombosis	18 (47)	24 (42)	0.61
Arterial	4 (10)	4 (7)	0.55
Venous	9 (24)	15 (26)	0.77

\*Defined based on the Updated Sappora APS Classification Criteria

**Conclusions:** The analysis of our multicenter aPL database demonstrates that the frequencies of thrombosis and pregnancy morbidity are similar between aPL-positive patients with or without SLE. Half of the patients in both groups had history of at least one "non-criteria" aPL-manifestation; only autoimmune hemolytic anaemia was more frequent in aPL-positive patients with SLE.

#### AB0553 CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHEMATOSUS AMONG VARIOUS AGE GROUPS: COMPARISON BETWEEN JUVENILE ONSET, ADULT ONSET, AND LATE ONSET SYSTEMIC LUPUS PATIENTS FROM A SINGLE TERTIARY CENTRE IN EGYPT

B.M. Medhat, N. Sobhy, B. Eissa. *Rheumatology and Rehabilitation department, Faculty of Medicine-Cairo University, Cairo, Egypt*

**Background:** Systemic lupus erythematosus (SLE) is a complex autoimmune disease with several factors affecting the characteristics of the disease, including age of onset which is one of these major factors.<sup>1</sup>

**Objectives:** To highlight the differences in disease characteristics among various age groups in an Egyptian cohort from a single tertiary centre.

**Methods:** Information in this study was derived from medical records of patients admitted to the Rheumatology department in Cairo University from December 2015 to June 2017. All patients fulfilled the SLICC classification criteria of 2012.<sup>2</sup> Demographic, clinical and serologic characteristics of all patients were recorded. Age of onset was defined as the age at the time of development of manifestations; upon which patients were divided into 3 groups: juvenile onset (JSLE: onset ≤16 years), adult onset (ASLE: onset 17–50), and late onset lupus (LSLE: onset >50) patients.

**Results:** The study included 369 patients, of which 44 (11.96%) were males and 324 (88.04%) were females. The mean age of onset of the cohort was 24.04 ±10.15 (7–63) years, while the mean disease duration was 65.6±58.4 (0.5–408) months. The study included 75/369 (20.3%) JSLE, 283/369 (76.6%) ASLE, and 10/369 (2.7%) LSLE patients. The median age of onset of JSLE patients was 13 (11–15), 23 (20–30) in ASLE patients, and 54 (52–58) years in the LSLE group. The median disease duration in JSLE patients was 78 (36–125), 36 (24–84) in ASLE patients, and 12 (9–38) months in LSLE patients. Apart from arthritis, malar

rash, and nephritis, there were no differences between the three groups. The prevalence of arthritis was highest among ASLE patients and lowest in JSLE (p=0.004) patients, with LSLE patients showing a comparable prevalence of arthritis to ASLE (p=0.5) and JSLE (p=0.3) patients. On the other hand, JSLE patients showed the highest prevalence of malar rash (p=0.006), as opposed to both ASLE (p=0.04) and LSLE (p=0.004) patients; yet ASLE patients showed a substantially high prevalence of malar rash when compared to LSLE patients (p=0.03). Nephritis was most common in JSLE patients (p=0.007) and least common in LSLE patients. Although there was no statistical difference in the prevalence of nephritis between JSLE and ASLE patients (p=0.1), both groups showed a higher prevalence of nephritis than LSLE patients (p=0.002 and p=0.01 respectively).

**Conclusions:** Adult onset SLE patients showed the highest prevalence of arthritis. On the other hand, JSLE patients showed the highest prevalence of nephritis as opposed to LSLE patients with the lowest prevalence, indicating a predilection towards a more severe disease in the former group.

#### AB0554 FACTORS AFFECTING QUALITY OF LIFE IN INDIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

B. Pinto<sup>1</sup>, S. Grover<sup>2</sup>, M. Rathi<sup>3</sup>, A. Dhooria<sup>1</sup>, A. Sharma<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Psychiatry; <sup>3</sup>Nephrology, PGIMER, Chandigarh, India

**Background:** SLE has a profound impact on Quality of Life (QoL). In addition to disease activity and damage, other factors such as fatigue, fibromyalgia and psychiatric comorbidities also influence QoL.<sup>1</sup> However, there is lack of data in the form of comprehensive assessment of all these factors in the same cohort.

**Objectives:** To assess the quality of life and its correlates among patients with SLE.

**Methods:** Using a cross-sectional study design, 144 patients with SLE were assessed for disease activity and damage by using SELENA –SLEDAI and SLICC/ACR damage Index (SDI)), depression (by using Patient Health Questionnaire-9 (PHQ9)), anxiety (by using Generalised Anxiety Disorder 7 (GAD7)), fatigue (by using Fatigue severity scale (FSS)) and fibromyalgia (as per using ACR 2010 criteria). QoL was assessed using a generic QoL scale – Short Form 36 (SF-36).<sup>2</sup> Statistical analysis was done using STATA version 14.

**Results:** The study sample included 140 females and 4 males. Mean age of the participants was 32.48 (SD-7.26) years and the mean duration of illness was 3.92 (SD-3.76) years. The mean SELENA SLEDAI and SDI was 3.42±4.04 and 0.26 ±0.65 respectively. Prevalence of depression (PHQ9 ≥10) and anxiety (GAD7 ≥10) was 25% and 22.9% respectively. Fatigue (FSS ≥4) was present in 51.4%. Physical domains of SF36 were affected more often than the mental domains, 71.5% of the respondents had scores less than 50 in Physical component Summary (PCS) and 61.1% in Mental Component Summary (MCS) of SF36. No correlation was found between disease activity and damage and various domains of SF36. Depression, anxiety and fatigue had a significant negative correlation with all the domains of SF36 (table 1). On multivariate regression only fatigue was an independent predictor of PCS of QoL.

**Abstract AB0554 – Table 1.** Spearman Correlation between various domains of SF36 and other variables

\*p<0.05 \*\*p<0.001

**Conclusions:** Fatigue, depression and anxiety have a greater influence on QoL in SLE than disease activity and damage. Of these, fatigue appears to be the most important variable which influences QoL.

**AB0555 IS HIGHER FITNESS ASSOCIATED WITH BETTER HEALTH-RELATED QUALITY OF LIFE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS?**

B. Gavilán-Carrera<sup>1</sup>, J. Garcia da Silva<sup>2</sup>, J.A. Vargas-Hitos<sup>3</sup>, P. Morillas-de-Laguno<sup>1</sup>, A. Rosales-Castillo<sup>3</sup>, L.M. Sáez-Urán<sup>3</sup>, C. Montalbán-Méndez<sup>3</sup>, A. Soriano-Maldonado<sup>1,4</sup>. <sup>1</sup>Department of Physical Education and Sport, <sup>2</sup>Department of Personality, Evaluation and Psychological Treatment, University of Granada; <sup>3</sup>Systemic Autoimmune Diseases Unit, Department of Internal Medicine, "Virgen de las Nieves" University Hospital, Granada; <sup>4</sup>Department of Education, University of Almería, Almería, Spain

**Background:** Patients with systemic lupus erythematosus (SLE) present reduced health-related quality of life (HRQoL).<sup>1</sup> As an adjunct to traditional medical therapy, higher levels of physical fitness seem to be associated with better symptomatology and HRQoL.<sup>2</sup> However, a comprehensive characterisation of the association of different components of physical fitness with the different dimensions of HRQoL in this population is lacking and would provide valuable information for the design of prospective studies.

**Objectives:** The aim of this study was to investigate the association of different physical fitness components (flexibility, muscle strength and cardiorespiratory fitness (CRF) with the dimensions of HRQoL.

**Methods:** This cross-sectional study included a total of 70 women with SLE (age 42.5; SD 13.9). The back scratch test, 30 s chair stand test and 6 min walk test (n=49) (from the Senior Fitness Test battery) as well as the handgrip strength test were used to assess physical fitness. The median value of each fitness test [flexibility (0.125 cm), upper muscle strength (24.2 kg), lower muscle strength (15 repetitions) and CRF (575 metres)] was used to consider high ( $\geq$ median value) or low ( $<$ median value) fitness. HRQoL was assessed through the 36-item Short-Form Health Survey (SF-36). Partial correlation was used to examine the association of physical fitness components with all dimensions of the SF-36. For those dimensions significantly associated with fitness, analyses of covariance compared the differences in HRQoL between patients with low and high fitness level. All analyses were controlled for age, body mass index, depression and fatigue.

**Results:** Flexibility was correlated with physical function, social functioning and physical component ( $r_{\text{partial}}$  between  $-0.26$  and  $0.28$ ; all,  $p < 0.05$ ). Patients with a high level of flexibility only presented better physical function than those with a low level ( $p = 0.03$ ). Upper and lower muscle strength were correlated with physical function, physical role, bodily pain and physical component ( $r_{\text{partial}}$  between  $0.28$  and  $0.50$ ; all,  $p < 0.05$ ) with differences between groups of low and high muscle strength (upper and lower body) in all those dimensions ( $p < 0.05$ ). CRF was correlated with physical function, bodily pain and physical component ( $r_{\text{partial}}$  between  $0.39$  and  $0.65$ ; all  $p < 0.01$ ), with differences in physical function and physical component between groups of low and high CRF ( $p < 0.05$ ).

**Conclusions:** The main findings of the present study suggest that flexibility, muscular strength and cardiorespiratory fitness are associated with different dimensions of HRQoL, particularly with those related to self-reported physical health, in women with systemic lupus erythematosus. Future prospective research should assess the predictive role of fitness regarding disease activity and function.

**AB0556 THE DIAGNOSTIC AND PREDICTIVE SIGNIFICANCE OF NAILFOLD VIDEO CAPILLAROSCOPY IN CTD PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION**

B. Jiang, X. Xu, K. Zhou, C. Wang, L. Geng. *The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Pulmonary arterial hypertension (PAH) is a serious complication of connective tissue diseases (CTD), defined as an elevation in mean pulmonary artery pressure 25 mmHg at rest. The 1 year, 3 year survival rates of CTD-PAH are only 69% and 30% respectively. Therefore, to early prediction and diagnosis of PAH is very critical for prolonging survival of CTD patients. Nailfold video capillaroscopy (NVC), is an imaging technique for the study of microcirculation. Until now, capillary abnormalities in systemic sclerosis (SSc) are well documented, but rare study focus on the association between the abnormality of capillary with PAH in CTD patients.

**Objectives:** Through estimating the correlation of the abnormality of nailfold capillary with pulmonary arterial hypertension (PAH) and other organs injury to find out its importance on early diagnosis and prediction for PAH in the patients with connective tissue disease (CTD).

**Methods:** Nailfold video capillaroscopy (NVC) was performed using a videocapillaroscope to test the fingers capillaries of 123 hospitalised CTD patients with and without PAH. The parameters of NVC were estimated including: the inter, outer and top loop diameter, loop number, misshaped or giant capillaries, flowing speed, haemorrhage, erythrocyte aggregation, et al. The organ involvement like interstitial lung disease (ILD) and cardiovascular complications were also considered. Mann-Whitney test was used to estimate the difference.

**Results:** 1) The number of capillary loops in patients with SSc was much lower, but morphologic score, liquid score, and total score were all higher than other CTD patients (Tab). 2) The loop number was significantly decreased but abnormal scores of morphology, liquid, diameter, misshaped loop number, flowing speed, erythrocyte aggregation were increased in CTD-PAH patients especially in SLE-PAH compared with non-PAH patients (Fig). 3) ILD relates the abnormality of peripheral circulation such like capillary malformation, decreased loop number, diameter and blood flow, increased haemorrhage, but the influence of PAP may be larger than ILD. 4) Down-regulated loop number, increased morphology, liquid and total score, and abnormal diameter, malformation, erythrocyte aggregation were found in CTD patients with cardiovascular complications, especially in CTD-PAH patients and SLE patients. 5) Age doesn't directly influence the capillaries of CTD patients, but in young and middle age patients, the difference between PAH and non-PAH groups were more evident.

**Abstract AB0556 – Table 1.** Comparison of number of nail fold capillaries in patients with various CTD

disease	SSc	SLE	SS	PM/DM	RA
loop number	4.688 $\pm 1.301$	5.915 $\pm 1.512^{***}$	5.875 $\pm 1.495^{**}$	5.717 $\pm 1.49^{**}$	6.417 $\pm 1.429^{**}$
morphologic score	4.117 $\pm 0.293$	2.389 $\pm 0.342^{**}$	2.378 $\pm 0.376^{***}$	2.293 $\pm 0.346^{***}$	2.5 $\pm 1.253^*$
liquid score	1.942 $\pm 0.402$	0.5277 $\pm 0.101^{***}$	0.6541 $\pm 0.111^{***}$	0.7367 $\pm 0.125^{**}$	0.5333 $\pm 0.217^*$
total score	8.321 $\pm 0.874$	4.628 $\pm 0.612^{***}$	4.297 $\pm 0.569^{***}$	4.54 $\pm 0.572^{***}$	4.633 $\pm 1.972^{***}$

**Abstract AB0556 – Figure 1.** Loop number and other indexes of nail fold capillaries in patients with various CTD and CTD-PAH with non-PAH CTD

**Conclusions:** In all CTD, the capillaries in SSc patients are most severely damaged. The disease of capillaries in CTD patients correlates with PAH, ILD and cardiovascular complications. So, NVC could be a predictive detection method for PAH and cardiopulmonary disease in CTD patients.

#### HAEMATOLOGICAL INVOLVEMENT (CYTOPENIA) AT THE TIME OF THE DIAGNOSIS IS ASSOCIATED WITH LESS SEVERE OCULAR INVOLVEMENT IN PATIENTS WITH PRIMARY SJOGREN SYNDROME

C.G. Buzatu, S. Daia-Iliescu, I. Saulescu, D. Zaharia, C. Purice, T. Gudu, A. Borangiu, L. Groseanu, V. Bojinca, F. Berghea, A. Balanescu, D. Predeteanu, R. Ionescu, D. Opris-Belinski. *Internal Medicine and Rheumatology, "SFANTA MARIA" Clinical Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

**Background:** In patients with primary Sjogren Syndrome (pSS), haematological involvement – autoimmune cytopenia, might be present at the time of the diagnosis or can develop in time after the characteristic glandular involvement. <sup>(1,2)</sup>

**Objectives:** The objective of the study is to evaluate the correlation between glandular involvement (ocular) and presence of cytopenia in patients diagnosed with pSS.

**Methods:** A retrospective analysis was performed on a cohort of patients diagnosed with primary Sjogren Syndrome under surveillance in one Rheumatology Centre between 2009 and 2016. The documented cases have been diagnosed according to the 2002 American-European Consensus group classification criteria, the 2012 ACR criteria or 2016 ACR/EULAR Classification Criteria for pSS. The EULAR Sjogren's Syndrome Disease Activity Index (ESSDAI) was calculated for all patients. Ocular assessment and follow-up were performed in collaboration with the same ophthalmologist. The data was analysed using Windows Excel/SPSS20.0.

**Results:** 30 female patients diagnosed with pSS were included in the study. The mean age at the time of diagnosis was 52.1 years±SD 9.1. The ESSDAI was calculated for all patients at baseline: 5 (17%) patients presented high disease activity (ESSDAI >14), 14 (46%) patients moderate disease activity (5≤ESSDAI≤13) and 11 (37%) patients low disease activity (ESSDAI <5). The domain weight for glandular involvement when calculating ESSDAI is fairly low (2),<sup>1</sup> so in the studied group there wasn't obtained a statistically significant correlation between ocular involvement and disease activity as evaluated by ESSDAI.

In the clinical case series, Spearman's rank correlation coefficient between haematological (autoimmune cytopenia), and biological markers (hypocomplementemia) and ocular involvement were calculated. A strong negative correlation was found between autoimmune cytopenia and glandular manifestations (ocular involvement-xerophthalmia) ( $r=-0,60$ ;  $p<0,05$ ). Another strong negative correlation was obtained between hypocomplementemia and severe ocular involvement (corneal ulceration) ( $r=-0,59$ ,  $p<0,05$ ), respectively.

**Conclusions:** Patients diagnosed with primary Sjogren Syndrome that presented at disease's onset cytopenia and hypocomplementemia had a less severe ocular involvement.

#### ARE REGULATORY T CELL LEVELS DIFFERENT IN ACTIVE AND INACTIVE SLE PATIENTS?

H. Üsküdar Teke<sup>1</sup>, D. Üsküdar Cansu<sup>2</sup>, C. Bal<sup>3</sup>, C. Korkmaz<sup>2</sup>. <sup>1</sup>Internal Medicine, Hematology; <sup>2</sup>Internal Medicine, Rheumatology; <sup>3</sup>Biostatistics, Eskişehir Osmangazi University, Eskişehir, Turkey

**Background:** The subgroups of T helper cells and regulatory T cells (T-reg) are involved in the pathogenesis of systemic lupus erythematosus (SLE). T-reg cells

suppress immune response to autoantigens and prevent autoimmune diseases (AID). Although there are studies suggesting that Treg cells are reduced during the active period of SLE, there are also studies claiming reversal.

**Objectives:** To determine whether there is a difference between T-reg and Th-17 cell levels in active and inactive SLE patients and to demonstrate the effects of these cells on disease course.

**Methods:** 21 SLE patients without active infection were included. Erythrocyte sedimentation rate, CRP, C3, C4, anti-ds-DNA levels, SLEDAI values were recorded in terms of organ and system involvement, hemogram results, disease activation. SLEDAI ≥6 were considered active disease. Concurrent peripheral blood Th17 and T-reg levels were studied. 15 healthy control subjects were included in the study.

**Results:** 19 of the patients were women, the mean age was 37.3±12.9 years and mean duration of the disease was 7.9±1.29 years. Hematologic involvement was present in 15 (71.4%) of the patients, renal involvement in 17 (81%) and joint involvement in 7 (42.9%). Both Treg cells and CD4 +IL17+ cell levels were significantly higher in SLE group than HC group in terms of CD4 +CD25+, CD4 +FOXP3+T reg, CD4 +CD25+FOXP3+T reg ( $p=0.011$ ,  $p=0.001$ ,  $p=0.001$  and  $p=0.040$ , respectively). There was no significant difference between active ( $n=12$ ) and inactive ( $n=9$ ) SLE patients in terms of Th17 and T-reg levels. However, in the inactive period, the levels of CD4 +FOXP3+T reg and CD4 +CD25+FOXP3+Treg cells tended to increase compared to the active period.

**Conclusions:** This study showed the tendency of increasing in Treg cells in the inactive period. This may be related to the modification of immunosuppressive drugs. It may be more appropriate to perform similar studies before and after treatment.

#### THE PREVALENCE OF NON-CRITERIA ANTI-PHOSPHOLIPID ANTIBODIES IN ANTI-PHOSPHOLIPID SYNDROME

C. Li<sup>1</sup>, L. Zhu<sup>1</sup>, Z. Wang<sup>1</sup>, Y. Sun<sup>2</sup>, R. Mu<sup>1</sup>, Z. Li<sup>1</sup>. <sup>1</sup>Peking University People's Hospital, Beijing; <sup>2</sup>266 Hospital of Chinese People's Liberation Army, Chengde, China

**Background:** Antiphospholipid syndrome (APS) is an autoimmune disease characterised mainly by arterial and/or venous thrombosis, recurrent pregnancy morbidity, with the presence of a variety of heterogeneous circulating antiphospholipid antibodies. However, there are a group of APS patients with persistently negative antiphospholipid antibodies. It is necessary to validate new specific antibodies to better recognition of these APS patients.

**Objectives:** To explore the clinical significance of non-criteria anti-phospholipid antibodies in a large cohort of Chinese patients with anti-phospholipid syndrome (APS).

**Methods:** Serum samples were obtained from 214 APS patients, 122 disease control including systemic lupus erythematosus, sjogren syndrome, ankylosing spondylitis, rheumatoid arthritis, osteoarthritis and 50 healthy control. Antiphosphatidylserine(IgA/IgG/IgM) (aPS), anti-phosphatidylethanolamine (IgA/IgG/IgM) (aPE), anti-prothrombin-antibodies (IgA/IgG/IgM) (aPT), anti-annexin V-antibodies (IgA/IgG/IgM) (aAnxV), anti-phospholipid-antibody(IgG/IgM)(aPL), anti-oxLDL antibody(IgG/IgM)(aoxLDL) were tested by ELISA kits(HUMAN Diagnostics Products, Germany) and IgG/IgM APL were tested by ELISA(Louisville APL Diagnostic, USA). The Chi-square ( $\chi^2$ ) test was used to examine the difference of frequencies of antibodies in APS patients and patients with other diseases. Spearman correlation analysis was performed to investigate the relationship between aPS/PT and other clinical/laboratory parameters.

**Results:** The prevalence of aPS IgG, aPS IgM, aPT, aPE, aAnxV, aPL, aoxLDL and IgG APL, IgM APL were 44.8%, 22.4%, 46.3%, 9.8%, 17.8%, 44.4%, 22.4%, 45.3% and 22.9%. The specificity of the antibodies were 82.6%, 95.3%, 96.0%, 99.4%, 95.3%, 92.4%, 87.2%, 95.3% and 94.8%. The highest positive predictive values of these antibodies were aPE, aPE, aPS IgM and APL IgM were associated with thrombotic events and oxLDL, aPE, aPL, aPS IgG, aPS IgM, aPT, aoxLDL, APL IgG and APL IgM were correlated with anti-cardiolipin antibody (ACL). aPL, aPS IgG, aPS IgM, aPT, APL IgG and APL IgM were associated with  $\beta$ 2-GP1 antibody. APL IgG, APL IgM and PS IgG were the highest prevalence in both ACL and lupus anticoagulant (LAC) negative patients. aPT has the highest prevalence in ACL and  $\beta$ 2-GP1 negative patients and APL IgG and aPS IgG were the highest two antibodies in LAC and  $\beta$ 2-GP1 negative patients and aPT has the highest prevalence in seronegative APS patients.

**Conclusions:** Non-criteria aPLs have a good diagnostic value in APS and were associated with thrombotic events.

### AB0560 PATIENTS WITH RHEUMATOID ARTHRITIS AND LUPUS HAVE SIMILAR PREVALENCE OF PERIODONTITIS – A CROSS-SECTIONAL SURVEY

C. Ciurтин<sup>1</sup>, M. Orlandi<sup>2</sup>, J. Bakshi<sup>1</sup>, J. Guinto<sup>1</sup>, B. Bernstein<sup>1</sup>, F. D'Aiuto<sup>1</sup>.

<sup>1</sup>Rheumatology, University College London; <sup>2</sup>Oral Health, Eastman Dental Hospital, London, UK

**Background:** Periodontitis (PD) is a chronic inflammatory disease of the gingival tissues triggered by a dysbiotic microflora and causing the loss of soft and hard tissues surrounding the dentition. Over the last two decades, PD has been linked to a systemic inflammatory response and an increased risk of other comorbidities including cardiovascular diseases and diabetes. Numerous observational studies have confirmed an association between PD and rheumatic diseases. Some evidence suggests an association with rheumatoid arthritis (RA) and a beneficial effect of periodontal treatment on RA outcomes. Scarce evidence instead exists on the association between PD and Systemic Lupus Erythematosus (SLE). The main aim of this study was to evaluate the prevalence of PD in RA and SLE.

**Methods:** We conducted a cross-sectional survey of consecutive eligible outpatients with RA and SLE attending the Rheumatology Department at UCLH. PD diagnosis was estimated administering a validated self-reported questionnaire. Medical histories, cardiometabolic risk factors and assessment of standard biomarkers of inflammation and RA activity were collected as part of the outpatients' visit.

**Results:** 86 patients affected by RA and 122 by SLE and 5 presenting both diseases were recruited and agreed to complete the questionnaire. PD was detected in 100 patients of the overall survey (47%). 38 (44%) patients with RA and 59 (48%) patients with SLE had prevalent PD. There was no statistically significant difference in the prevalence of PD between the two patients' groups ( $p=0.575$ ). PD was associated with diagnosis of diabetes ( $p=0.023$ ), hypertension ( $p=0.004$ ) and hypercholesterolemia ( $p<0.0001$ ). Diagnosis of PD was associated with increased levels of C-reactive protein (CRP) ( $2.8\pm 3.3$  vs  $4.0\pm 4.4$ ,  $p=0.03$ ) in the whole population. In RA patients PD was associated with increased CRP ( $3.2\pm 3.2$  vs  $5.2\pm 4.4$ ,  $p=0.014$ ) and ESR ( $9.8\pm 10.0$  vs  $18.3\pm 16.6$ ,  $p=0.008$ ).

**Conclusions:** Prevalence of PD is similar in both RA and SLE (approximately 45%) and to the UK national estimates (Adult Dental Survey 2009). PD could contribute to an increased inflammatory profile in patients with RA and SLE. Our data highlight the need of assessing oral health needs of patients with rheumatic diseases.

### AB0561 INFECTIONS IN NEWLY DIAGNOSED SPANISH PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: DATA FROM THE RELES COHORT

C. Gonzalez-Echavari<sup>1</sup>, M. Garcia<sup>2</sup>, G. Espinosa<sup>3</sup>, G. Ruiz-Irastorza<sup>1</sup>, on behalf of Autoimmune Diseases Study Group GEAS. <sup>1</sup>Autoimmune Diseases Unit. Internal Medicine Department, BioCruces Health Research Institute. Cruces University Hospital; <sup>2</sup>Autoimmune Diseases Unit. Internal Medicine Department, Cruces University Hospital, BLBAO; <sup>3</sup>Department of Autoimmune Diseases, Hospital Clinic, Barcelona, Spain

**Background:** Infections continue to be an important source of morbidity and mortality in systemic lupus erythematosus (SLE).<sup>1</sup> Susceptibility to infections is thought to be due to a combination of disease related factors and immunosuppression, however differential contributions during disease course has not been yet studied.

**Objectives:** Using data of patients from the longitudinal inception cohort Registro Español de Lupus Eritematoso Sistémico (RELES), we aimed to analyse how predictors of infection change during the course of the disease.<sup>2</sup>

**Methods:** Two hundred and eighty-two patients from the RELES cohort were included. Markers of lupus activity, average prednisone doses and use of immunosuppressive drugs were compared between patients with and without infections within the first and second year of disease. For the analysis, drugs given during

the first month of follow-up were considered for infections during the first year and medications given during the first year were considered for infections during the second.<sup>3</sup>

**Results:** Nineteen patients (6.4%) had a documented episode of infection during the first year of follow-up and 16 patients (8 (5.67%) during the second. The following variables were associated with infections during the first year: hypocomplementemia at diagnosis ( $p=0.01$ ), nephritis at diagnosis ( $p=0.03$ ), SLEDAI score ( $p<0.01$ ), average dose of prednisone higher than 30 mg/day ( $p=0.01$ ), methylprednisolone pulses ( $p=0.05$ ) and mycophenolate use ( $p=0.02$ ). The independent variables in the final model were hypocomplementemia (OR 4.41, 95% CI 0.96–20.2) and average dose of prednisone higher than 30 mg/day (OR 6.60, 95% CI 1.3–32.4). The following variables were predictors of infections during the second year in the univariate analysis: average dose of prednisone higher than 7.5 mg/day ( $p=0.05$ ), methylprednisolone pulses ( $p=0.07$ ), duration of therapy with anti-malarials ( $p=0.09$ ), mycophenolate use ( $p=0.01$ ) and cyclophosphamide use ( $p=0.05$ ). The independent variables in the final model were average dose of prednisone higher than 7.5 mg/day (OR 4.5, 95% CI 0.99–21) and duration of therapy with anti-malarials as a protective factor (OR 0.99, 95% CI 0.99–1.00).

**Conclusions:** Patients with high baseline activity are at a higher risk of infection during the first months but intensive lupus therapy, specifically with medium-high doses of prednisone, is the strongest predictor of infectious events. Continued use of anti-malarials protects from infections.

### AB0562 EXTRAGLANDULAR MANIFESTATIONS IN PATIENTS WITH PRIMARY SJÖGREN SYNDROME IN A TERTIARY HOSPITAL IN MADRID

C.M. Pijoan Moratalla, C. Sobrino-Grande, C. De la Puente-Bujidos. *Rheumatology, Hospital Ramón y Cajal, Madrid, Madrid, Spain*

**Background:** Primary Sjögren syndrome (pSS) is a chronic autoimmune disorder characterised by generalised dryness. In a variable percentage of cases (up to 50%) patients can present extraglandular disease, which frequently determines the prognosis.

**Objectives:** To determine the frequency of both glandular and extraglandular disease in patients with pSS seen in a tertiary hospital in Madrid and to compare them with the frequency observed in the large cohorts (SER and EULAR).

**Methods:** A descriptive, observational cross-sectional study was conducted. We included patients with diagnosis of pSS according to the ACR/EULAR Classification criteria (2016) attended in our Rheumatology Unit from 2012 to 2017. A database was created, including clinical and epidemiological data and a descriptive analysis was carried out comparing the results with those obtained in the Sjögren-SER project and EULAR group.

**Results:** 106 patients with pSS were included. 92.5% were female (98), with a mean age at diagnosis of 45 years (range: 32–58). Frequency of exocrine gland disease is shown in table 1. Dry eye was the most frequent symptom (91%), with nearly half of them presenting ocular complications. 69.8% complained of dry mouth and 18.9% associated complications such as dysphagia and oral candidiasis. 16 patients (15%) suffered from recurrent parotiditis and 13 (12.3%) from salivary gland enlargement. Glandular disease also included xerosis (25%), dyspareunia (11.3%), upper respiratory tract dryness (12.3%) and atrophic chronic gastritis (14%). Frequency of extraglandular disease is shown in table 2. Chronic fatigue was the most frequent symptom, similar to the observed in both cohorts (50.9%), followed by arthralgia which was less frequent than in the Spanish cohort (40.6% vs 34.5%). 35 patients suffered from inflammatory arthritis and 3 cases associated fibromyalgia, less than the expected (2.8% vs 14.6% and 22%–33%). Sixteen patients suffered from interstitial lung disease, this being higher than the observed in both cohorts (15.1% vs 6.64% and 5%). Fewer patients suffered from depression compared with the EULAR group (24.5% vs 40%). Both peripheral neuropathy and renal disease were diagnosed in a percentage of patients similar to the expected (11.3% vs 8.92% y 1.88% vs 1.83% respectively). 7 patients had autoimmune thyroid disease. Finally, 5 patients (4.7%) developed lymphoma, 3 of them being MALT lymphoma of the parotid gland

which is higher than the observed in the Spanish cohort but it is within the EULAR range. The frequency of Raynaud's phenomenon, cutaneous vasculitis, lymphadenopathy, splenomegaly and pericarditis were similar to those observed both in the Spanish national group and EULAR cohort.

Abstract AB0562 – Table 1. Exocrine Gland Disease

EXOCRINE GLAND DISEASE	NO PATIENTS AFFECTED	PERCENTAGE (%)	SJÖGREN-SER PERCENTAGE (%)
Dry eye	96	91	94.51
Keratoconjunctivitis sicca	43	40.6	91.99
Dry mouth	74	69.8	94.05
Recurrent parotiditis	16	15	85.24
Salivary gland enlargement	13	12.3	4.35
Xerosis	27	25	72.31
Atrophic chronic gastritis	15	14	4.81
Upper respiratory tract dryness	14	13.3	15.13
Vaginal dryness / dyspareunia	12	11.3	48.97

Abstract AB0562 – Table 2. Extraglandular Disease

EXTRAGLANDULAR DISEASE	NO PATIENTS AFFECTED	PERCENTAGE (%)	SJÖGREN-SER PERCENTAGE (%)	EULAR PERCENTAGE (%)
Chronic fatigue	54	50.9	43.16	50.75
Asthma	43	40.6	34.56	33
Inflammatory arthritis	35	33	4.97	15.90
Fibromyalgia	3	2.8	14.65	22.98
Depression	26	24.5	-	40
Raynaud's phenomenon	22	20.8	21.05	18.37
Interstitial lung disease (ILD)	16	15.1	6.64	5
Cutaneous vasculitis	15	14.2	9.13	10.15
Peripheral neuropathy	12	11.3	8.92	5.40
Lymphoma	5	4.7	1.18	5.10
Renal disease	2	1.8	1.83	<5

**Conclusions:** Extraglandular disease in SS, although less frequent than sicca symptoms, have a special relevance when it comes to patient management. In our study the frequency of both glandular and extraglandular disease was similar to the observed in Sjögren-SER and EULAR groups although there were some differences. Fibromyalgia was less frequent in our group, whereas interstitial lung disease and peripheral neuropathy were more prevalent.

#### AB0563 METABOLIC SYNDROME PREDICTS NEW DAMAGE IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

C. Reátegui-Sokolova<sup>1</sup>, R.V. Gamboa-Cárdenas<sup>1</sup>, M. Medina<sup>1</sup>, F. Zevallos<sup>1</sup>, C. Elera-Fitzcarrald<sup>1,2</sup>, V.R. Pimentel-Quiroz<sup>1</sup>, J.M. Cucho-Venegas<sup>1</sup>, J.L. Alfaro-Lozano<sup>1</sup>, Z.J. Rodríguez-Bellido<sup>1</sup>, C.A. Pastor-Asurza<sup>1</sup>, R.A. Perich-Campos<sup>1</sup>, G. S. Alarcón<sup>3</sup>, M.F. Ugarte Gil<sup>1,2</sup>. <sup>1</sup>Rheumatology, Hospital Guillermo Almenara Irigoyen; <sup>2</sup>Universidad Científica del Sur, Lima, Peru; <sup>3</sup>School of Medicine, University of Alabama, Alabama, USA

**Background:** The metabolic syndrome (MetS) is a complex of interrelated risk factors for the occurrence of cardiovascular disease and diabetes, and it is now both a public health and a clinical problem.<sup>1</sup> The MetS has also been reported to be associated with new organ damage, vascular events and mortality in Systemic Lupus Erythematosus (SLE) patients.<sup>2</sup>

**Objectives:** To determine whether the MetS predicts damage accrual in SLE patients.

**Methods:** This prospective study was conducted in a cohort of consecutive SLE patients seen since 2012 at one single institution. Patients had a baseline visit and follow-up visits every 6 months. Patients with  $\geq 2$  visits were included. Evaluations included interview, medical records review, physical examination and laboratory tests. Damage accrual was ascertained with the SLICC/ACR damage index (SDI) and disease activity with the SLEDAI. The MetS was defined if the patient fulfilled 3 of 5 criteria according to Alberti et al.<sup>1</sup> Survival univariable and multivariable Cox-regression models were carried out to determine the risk of developing new damage. The multivariable model was adjusted for age at diagnosis, disease duration, socioeconomic status, SLEDAI, baseline SDI, the Charlson Comorbidity Index, baseline use of prednisone (PDN), antimalarials and immunosuppressive drugs.

**Results:** Two hundred and forty-nine patients were evaluated; 232 were females and 17 males. Their mean (SD) age at diagnosis was 35.8 (13.1) years; nearly all patients were mestizo. Disease duration was 7.4 (6.6) years. The SLEDAI was 5.2 (4.3) and the SDI 0.9 (1.3). The average daily dose of PDN was 7.3 (6.4) mg/d and the time of exposure to PDN was 6.9 (6.2) years. One hundred and eight patients (43.4%) had MetS at baseline. During follow-up, 116 (46.6%) patients accrued at least one new point in the SDI damage index. In multivariable analyses, the presence of MetS was a predictor of development of new damage; with a Hazard Ratio (HR) 1.54 (1.05–2.26);  $p < 0.029$ .

**Conclusions:** The presence of MetS predicts the development of new damage in SLE patients, despite of other well-known risk factors for such occurrence.

#### AB0564 DRY SYNDROME IN RA PATIENTS. COMPARISON WITH SJÖGREN'S SYNDROME PATIENTS

D. Peiteado<sup>1</sup>, G. Bonilla<sup>1</sup>, R. Montejano<sup>2</sup>, A. Boto<sup>2</sup>, A. Del Hierro<sup>2</sup>, I. Monjo<sup>1</sup>, C. Plasencia<sup>1</sup>, A. Balsa<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Ophthalmology, Hospital Universitario la Paz, Madrid, Spain

**Objectives:** The aim of the study is to analyse the clinical characteristics of Rheumatoid Arthritis (RA) patients and dry syndrome, and to compare with primary Sjögren's syndrome (PSS) patients.

**Methods:** Patients with RA and dry syndrome derived from Rheumatology Clinic to Cornea Unit were evaluated. According to symptoms and ophthalmological examination, patients were classified as high or low probability of Sjögren Syndrome (SS). Clinical and laboratory assessments included sex, age and smoking habit, DAS28, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), rheumatoid factor (RF), anti-citrullinated peptide antibodies (ACPA), antinuclear antibodies (ANA), anti Ro, anti La and presence of other extraarticular symptoms. In addition, the ophthalmological examination data (Ocular Staining Score [OSS] and Schirmer test), salivary gland scintigraphy (SGS) and salivary gland biopsy (biopsy) were analysed. The percentage of patients who would be classified according to the criteria of the Revised American-European Consensus Group (AECG) 2002, NIH-funded Sjögren's International Collaborative Clinical Alliance (SICCA) 2012 criteria and ACR/EULAR 2016 criteria is evaluated. RA patients with high probability of SS are compared with SSP patients. Statistics analysis was made by mean  $\pm$ SD, and comparison was made by t-Student test (quantitative parameters) and non parametric test (qualitative) ( $p < 0.05$ ).

**Results:** 24 RA with dry syndrome were included. 71% were women and the mean age was 64 $\pm$ 14 years. The disease duration was 17 $\pm$ 12 years. All patients had ocular manifestations, 2/3 oral manifestations, and 17% other extra-articular manifestations. According to DAS28, 33% of the patients were in clinical remission, 33% in high activity, and the others in low-moderate activity. 17 patients (71%), 19 (86%) and 5 (21%) were positive (+) for RF, ACPA and ANA, respectively. One patient had Anti Ro + and another anti La +. The mean OSS was 4.2 ( $\pm 3.1$ ) and the average of Schirmer was 10 ( $\pm 11$ ). In relation to other tests: 7 patients had a biopsy performed (2 positive [29%]), 5 patients had GGS (2 positive [40%]).

17 of the 24 RA patients (71%) were considered "high probability Sjögren's Syndrome" (SS and AR). These patients were compared with the PSS group (see table 1), showing differences in immunological parameters, sex, age and in the% that fulfilled the classification criteria. No significant differences were found in the ophthalmological examinations or the acute phase reactants.

Abstract AB0564 – Table 1

	SS and RA (n 17)	PSS (n 16)
OSS (mean $\pm$ sd)	6 $\pm$ 2	6.4 $\pm$ 2.6
SCHIRMER (mean $\pm$ sd)	6.8 $\pm$ 8.3	4 $\pm$ 4
ANA	4 (23%)	16 (100%)**
Anti RO/ANTI LA	1 (6%)/1 (6%)	15 (94%)/13 (81%)**
ACPA (media $\pm$ DS)	667 $\pm$ 866	0.1 $\pm$ 0.3 **
Gender (♂/♀)	6/11	0/16*
AECG 2002 criteria	4 (23%)	15 (94%) **
N (%)		
ACR 2012 criteria	2 (12%)	15 (94%) **
N (%)		
ACR/EULAR 2016 criteria	3 (18%)	16 (100%) **
N (%)		
Age	66.7 $\pm$ 11.6	56 $\pm$ 17.2*

\* $p < 0.05$ ; \*\* $p < 0.01$

**Conclusions:** Most of this RA patients cohort with dry syndrome were considered as "high probability SS", however only a small percentage (12%–23%) fulfilled the classification criteria. This can be explained by the low rate of specific antibodies (6%), and by the poor performance of some tests included in the criteria.

**Disclosure of Interest:** None declared

### AB0565 CHANGES IN HEALTH RELATED QUALITY OF LIFE IN RENAISSANCE COHORT OF RUSSIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

E. Aseeva<sup>1</sup>, L. Vorobyova<sup>1</sup>, S. Soloviev<sup>1</sup>, G. Koilubaeva<sup>2</sup>, S. Glukhova<sup>1</sup>. <sup>1</sup>Intensive care department, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; <sup>2</sup>rheumatology department, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov, Bishkek, Kyrgyzstan

**Background:** The Lupus Quality of Life (LupusQoL) is recommended to assess health related quality of life (HRQOL) in systemic lupus erythematosus (SLE).

**Objectives:** The aim of the current study was to assess HRQOL in the first year observation in cohort of patients with systemic lupus erythematosus in Russian Federation (RENAISSANCE).

**Methods:** The LupusQoL-Russian was administered to a cohort of 128 Russian patients affected with SLE at baseline and follow up visit (in 12 months). Disease activity was evaluated by the SLE disease activity Index-2000 (SLEDAI-2K), and chronic damage by the Systemic Lupus International Collaborating Clinics Damage Index score (SDI) at baseline and follow up visit.

**Results:** 128 patients (118 (92%) women; aged 33,02±11,04 years, mean disease duration 100,0±84,3 months) were included. At baseline mean SLEDAI 2K was 11,2±8,5; mean SDI – 1,3±1,6, mean daily prednisolone 16,8±10,9 mg/day). For 12 months all patients received standard therapy according SLEDAI 2K and their clinical manifestations (prednisolone 100%, Hydroxychloroquine 72,4%, Mycophenolate mofetil 25%, Cyclophosphamide 17%, Azathioprine 12,5%, Rituximab 27,3%, belimumab 12,5% pts). At follow up visit SLEDAI 2K score significantly improved up to 6,94±6,93 (p<0,000029), SDI significantly worse up to 1,7±1,9 (p<0,04), mean daily prednisolone significantly reduced up to 12,2±7,3 mg/day (p<0,04). All 8 subscales LupusQoL showed improvement in the 12 months versus baseline (table 1). Spearman's correlation with SLEDAI 2K was obtained for Physical health (r=-0,13), Pain (r=-0,16), Planning (r=-0,21), Intimate relationship (r=-0,17) Burden to others (r=-0,16), emotional health (r=-0,13), Body image (r=-0,21).

**Abstract AB0565 – Table 1.** Changes in LupusQoL domains in the first year observation in cohort of patients with systemic lupus erythematosus in Russian Federation (RENAISSANCE)

LupusQoL domains	Baseline, mean ±SD	12 month, mean ±SD	p
Physical health	63,54±24,03	66,77±23,09	0004
Pain	67,42±25,10	73,62±24,27	0002
Planning	61,28±28,70	67,35±27,11	0008
Intimate relationship	64,96±35,60	72,53±29,58	0,01
Burden to others	53,03±27,78	57,35±29,62	0,04
Emotional health	63,16±22,02	67,65±19,99	0,01
Body image	58,32±29,45	69,49±23,01	0,0003
Fatigue	59,88±24,6	65,68±22,95	0006

**Conclusions:** The LupusQoL-Russian is sensitive to change in SLE patients with active SLE. The HRQOL correlated with disease activity, daily prednisolone and biologic.

**Disclosure of Interest:** None declared

### AB0566 ANTI-PHOSPHOLIPID ANTIBODIES SERONEGATIVIZATION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS TREATED WITH BELIMUMAB

E. Rubini, M. Radin, I. Cecchi, D. Roccatello, S. Sciascia. Università Degli Studi di Torino, Turin, Italy

**Background:** Belimumab is a monoclonal antibody that blocks the B lymphocyte stimulator, preventing it to bind its receptor on B-lymphocyte's surface, thus avoiding B cell activation. Despite some benefits showed in murine models of anti phospholipid syndrome (APS),<sup>1</sup> the use of belimumab in this condition needs further investigation.

**Objectives:** To investigate changes in the antiphospholipid antibodies (aPL) profile in Systemic Lupus Erythematosus (SLE) patients treated with belimumab.

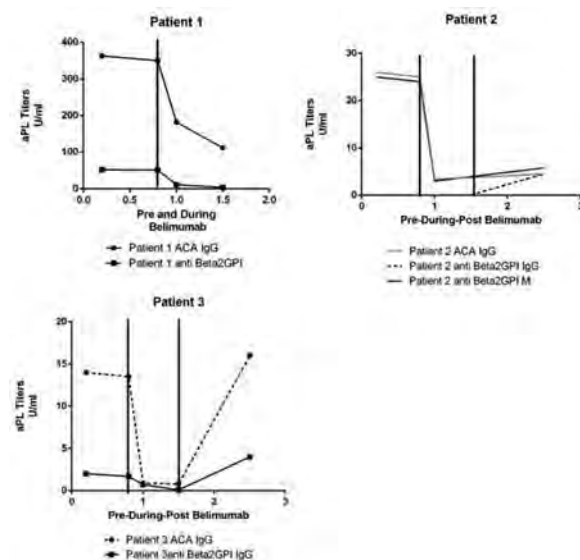

**Methods:** We retrospectively collected data from patients who attended the S. Giovanni Bosco Hospital, Turin, Italy. Inclusion criteria comprised: a) fulfilled ACR criteria for SLE, b) persistent aPL positivity (confirmed ≥3 occasions over a time >24 months before belimumab treatment), c) previous or ongoing belimumab therapy.

**Results:** This retrospective study included 3 patients with diagnosis of SLE [median age 39(range 33–51), male:female 2:1]. Table 1 resumes the characteristics of patients. All 3 patients received belimumab because of SLE flares. Before the treatment, Patient#1, classified as SAPS,<sup>2</sup> presented a persistent triple positivity for lupus anticoagulant (LA), high-titer aCL IgG isotype (>200 GPL) and anti-β2glycoprotein I antibodies (>50 GPL) (anti-β2GPI) IgG isotype. Patient#2 was persistently positive for IgG aCL and IgM anti-β2GPI (both 20–30 GPL and MPL, respectively; cut-off >7U), and had a history of pregnancy morbidity. Patient#3, classified as SAPS, presented positivity of LA and IgG aCL (10–20 GPL).

After 12 months since belimumab was started, a marked reduction of aPL was noticed, as follows. Patient#1 became negative for antiβ2GPI, while his aCL titre significantly decreased. Anti-β2GPI and aCL both turned negative in Patient#2. After being on belimumab for one year, she planned a pregnancy and she stopped the treatment; after 8 months since suspension, IgG antiβ2GPI antibodies were detectable (cut-off >3.5 U). Patient#3 was persistently negative for aCL while being on belimumab. When he discontinued the therapy, IgG aCL antibodies returned positive. Figure 1 illustrates aPL titres of the 3 patients in relationship with belimumab therapy.

**Abstract AB0566 – Table 1.** Characteristics of the patients included in the study

	Sex	Age	Diagnosis	Associated Autoimmune Disease	aPL positivity	Clinical Events
Patient#1	M	51	SAPS	SLE	LA, aCL IgG, anti-β2GPI IgG	Sub-popliteal arteriopathy
Patient#2	F	33	aPL carrier	SLE	aCL IgG, anti-β2GPI IgM	2 miscarriages <10 th week of gestation
Patient#3	M	39	SAPS	SLE	LA, anti-β2GPI IgG	3 episodes of TVP, severe thrombocytopenia

**Abstract AB0566 – Figure 1.** aPL titres of the three patients in relationship with belimumab therapy.

**Conclusions:** Despite its limitations, this pilot study is the first report of aPL negativization after starting therapy with belimumab. The clinical relevance of these findings should be investigated in prospective multicenter studies.

**AB0567** **CLINICAL SIGNIFICANCE OF THE DETECTION OF HLA-DRB1 ALLELES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

E. Belolipetskaia<sup>1</sup>, I. Beliaeva<sup>1</sup>, V. Mazurov<sup>1</sup>, S. Lapin<sup>2</sup>, O. Tkachenko<sup>2</sup>, V. Guseva<sup>2</sup>, O. Inamova<sup>3</sup>. <sup>1</sup>North-Western State Medical University named after I. Mechnikov; <sup>2</sup>St. Petersburg State Medical University named after I.P. Pavlov; <sup>3</sup>Clinical Rheumatological Hospital № 25, Saint-Petersburg, Russian Federation

**Background:** Associations between clinical manifestations of systemic lupus erythematosus (SLE), presence of antiphospholipid antibodies (aPL) and HLA-DRB1 alleles have been established, these associations however need clarification.

**Objectives:** Clarify the associations between clinical features of APS in patients with SLE and the presence of aPL and the HLA-DRB1 alleles.

**Methods:** 79 SLE patients were enrolled in the study (M/F 7/72; mean age 11.0 years, range (18,0;78,0). The main group consisted of 41 aPL carriers (28 of them with antiphospholipid syndrome (APS), a comparison group consisted of 38 aPL-negative SLE patients. The groups were comparable in age, duration and SLE activity.

ELISA was used to test for aPL. Lupus anticoagulant (LA) was evaluated using the DRVV test method. The HLA-DRB1 alleles were identified using HLA-typing.

**Results:** While comparing both groups, HLA-DRB1\*03 allele was found significantly less frequently in aPL-carriers group ( $p=0.04$ ). In APS group HLA-DRB1\*08 allele was present significantly more often ( $p=0.002$ ), both HLA-DRB1\*03 and \*15 alleles were found significantly less often ( $p=0.008$ ) in comparison with the aPL-negative group.

SLE patients with HLA-DRB1\*16 allele were more likely to develop an early pregnancy loss (OR=19,  $p=0.04$ ), patient with HLA-DRB1\*11 allele – more likely to develop a fetal loss (OR=4.9,  $p=0.04$ ) in comparison with other alleles; in patients with HLA-DRB1\*01 allele both early pregnancy loss and fetal loss occurred less often (OR=0.18,  $p=0.04$ ; OR=0.29,  $p=0.04$ ) compared with other alleles. The highest level of anti-double-stranded DNA was found in patients with HLA-DRB1\*13 allele (Me=54, [17.0, 290.0 IU/ml],  $p=0.005$ ), and lowest level – in patients with HLA-DRB1\*04 (Me=0.15, [0.0; 14.2 IU/ml],  $p=0.005$ ).

In the group of aPL carriers significant correlations between the HLA-DRB1\*08 allele and elevated level of anticardiolipin antibodies (aCL) IgM ( $r=-0.42$ ,  $p=0.005$ ) and anti-annexin V antibodies IgG ( $r=0.3$ ,  $p=0.01$ ), between HLA-DRB1\*04 allele and elevated level of aCL IgG ( $r=0.31$ ,  $p=0.008$ ), between the HLA-DRB1\*12 allele and an elevated level of anti-annexin V antibodies IgM ( $r=0.31$ ,  $p=0.01$ ) were found.

Correlations between HLA-DRB1\*16 allele and early pregnancy loss ( $r=0.37$ ,  $p<0.001$ ), between HLA-DRB1\*11 allele and fetal loss ( $r=0.30$ ,  $p<0.001$ ) were observed.

**Conclusions:**

1. HLA-DRB1\*08 allele is a risk factor for the development of APS in SLE patients.
2. HLA-DRB1\*03 and \*15 alleles were more often detected in aPL-negative SLE patients.
3. The presence of HLA-DRB1\*16 and \*11 alleles in SLE patients is a risk factor for the development of obstetric complications.
4. In the group of aPL carriers significant correlations between HLA-DRB1 alleles and elevated levels of aPL were found.
5. SLE patients with HLA-DRB1\*01 were less likely to develop any obstetric complications.

**AB0568** **KNOW YOUR VACCINES – A CLINICAL AUDIT ON THE UPTAKE OF VACCINATIONS IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS**

E.E. Varughese, M. McCartney, K. Sunmboye, S. Shaffu. *Rheumatology, University of Leicester- Leicester Royal Infirmary, Leicester, UK*

**Background:** Systemic Lupus erythematosus (SLE) is a multi-system autoimmune disease with an increased mortality and morbidity rate compared to the controlled population. One of the commonest causes of mortality and morbidity in SLE is infection. This is a result of not only the immunosuppressive effect of the disease process itself but also treatment involving disease modifying anti-rheumatic drugs (DMARDs). In fact, corticosteroids and immunosuppressants increase the risk of opportunistic infection, in addition to the more common pathogens.

Vaccines provide long lasting protective immunity against microbial pathogens and prevent clinically relevant infections. Recommended vaccinations in SLE patients include H. Influenza, Pneumococcal, Hepatitis A and B, and Human Papilloma Virus (HPV). Influenza vaccines are given annually and a Pneumococcal booster dose is given at 5 years following the initial vaccine.

**Objectives:** To assess whether, in routine clinical practise, patients with SLE are immunised against preventable disease according to EULAR recommendations and to assess the level of patient awareness.

**Methods:** A questionnaire was designed to assess the degree of compliance with current recommendations adapted from the EULAR-recommended vaccinations in patients with autoimmune inflammatory rheumatic diseases on DMARD therapy. The questionnaire enquired into the awareness and uptake of the influenza B, pneumococcal and hepatitis B vaccines. They were sent out by postal mail, with an enclosed stamped address envelope, to all SLE patients within the university hospitals of Leicester (UHL) NHS trust identified via the rheumatology patient database. Questions included awareness of the need to have vaccinations whilst on DMARDs. The audit was conducted over a three month period and the results were compiled in Microsoft excel.

**Results:** Of the 396 SLE patients within UHL, 86 responded. Among the patients studied 38% were on DMARD therapy, an equal proportion claimed they were not and 23% were unclear if they were on DMARD therapy. Approximately 60% were unaware of the need for vaccinations and only 27.9% acknowledged awareness for the need of the 3 vaccines mentioned above. Fifty-six (60%) patients had the influenza vaccine yet only 26 (28%) and 15 (21.8%) had the Pneumococcal and Hepatitis vaccines respectively.

**Conclusions:** The increased infection rate in SLE can be reduced through vaccination. This highlights the importance of increasing both physician and patient awareness. Although the sample size was small, the above audit has revealed that current local practice, with regards to ensuring that all SLE patients are appropriately vaccinated, requires improvement. This can be achieved through patient and healthcare worker education, and also creating a checklist that can be added to the clinic notes. Working together with our primary care colleagues will also help bridge the divide between compliance and non-compliance. Such measures will aim to improve mortality and morbidity in SLE patients.

**AB0569** **RELATIONSHIP BETWEEN THE LEVELS OF VITAMIN D AND THE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS IN DOMINICAN REPUBLIC**

E. Tejada-Reyes, I. Mercedes-Núñez, M. Marte-Robles, R. Jiménez-Candelaria, V. Rosario, R. Muñoz-Louis, R. Peña-Blanco, T. Valdez-Lorie, R. Alba-Férez. *Rheumatology, Hospital Docente Padre Billini, Santo Domingo, Dominican Republic*

**Background:** 25 (OH) D is a steroid prohormone that participates in calcium homeostasis and bone health.<sup>1</sup> Nonclassical functions of this vitamin have been described in a variety of cells of the innate and adaptive immune system. Currently, the immunomodulatory role of 25 (OH) D in Systemic Lupus Erythematosus (SLE) continues in debate. In addition, a correlation between non-optimal levels of 25 (OH) D and disease activity has been observed.<sup>2</sup> In the SLE, there is a high prevalence of non-optimal levels of vitamin D. A prevalence of 25 (OH) D insufficiency of 15% to 75% is reported.<sup>3</sup>

**Objectives:** To determine the relationship between vitamin D levels and disease activity in SLE.

**Methods:** It is a prospective, cross-sectional study, in all patients who attended the rheumatology clinic of the Hospital Docente Padre Billini in the period August – October 2017, where the levels of vitamin D and activity of the disease were measured with SELENA-SLEDAI ( $\leq 3$  without activity, 3–12 moderate activity,  $\geq 12$  high activity). Vitamin D deficiency is defined as serum levels of 25 (OH) D  $<10$  ng/ml, insufficiency levels serum levels of 25 (OH) D of  $<30$  ng/ml.<sup>3</sup> Inclusion criteria: all patients with at least 18 years of age who met the SLE SLICC 2012 classification criteria were included with determination of vitamin D and calcium.

**Results:** 45 patients who met criteria SLE SLICC 2012 were included. 97.7% (44) were women. The most frequent age range was 31–45 years. 24.4% (11) had decreased calcium values. The vitamin D values were insufficient in 77.7% (35) of the patients and deficient in 4.4% (2) According to SELENA-SLEDAI, 77.7% (35) had no activity of the disease, 20% (9) had moderate activity and 2.2% (1) had

high activity. Of the patients who reported disease activity, only 13.3%<sup>6</sup> had insufficient vitamin D. There is no significant difference between patients who have vitamin D values greater than or less than 20 ng/ml. In both groups, the majority had SLENA-SLEDAI in low activity.

**Conclusions:** The vitamin D levels were not associated with an increase in disease activity in our study patients. Although our country is an island, the use of sunscreen and avoid sunbathing is something common, it causes to find low levels of vitamin D, not only in patients with SLE, where avoiding sunbathing is a recommendation, but also in other pathologies that come to our service. We believe that vitamin D levels should be measured in the general population, to have a reference range and study their influence on health.

#### AB0570 ASSOCIATION BETWEEN SLEDAI-2K DOMAINS AND ORGAN DAMAGE ACCRUAL

K. Zhang<sup>1</sup>, S. Boyd<sup>2</sup>, F. Petitjean<sup>2</sup>, A. Hoi<sup>3</sup>, R. Koelmeyer<sup>3</sup>, E. Morand<sup>3</sup>, H. Nim<sup>2</sup>.  
<sup>1</sup>Monash University, Melbourne, Australia; <sup>2</sup>Information Technology; <sup>3</sup>Faculty of Medicine Nursing and Health Sciences, Monash University, Melbourne, Australia

**Background:** Prevention of permanent organ damage is a key goal of SLE management<sup>1</sup>. Overall disease activity measured by SLE Disease Activity Index (SLEDAI-2k) is a risk factor for damage<sup>2</sup>, but the contribution of organ-specific activity to damage risk has not been enumerated.

**Objectives:** We sought to determine the degree to which organ domains of SLEDAI-2k are associated with damage accrual.

**Methods:** A dataset of SLE patients (2007 – 2017) at the Australian Lupus Registry was studied. Variables collected at each visit included all domains of SLEDAI-2k, Physician Global Assessment, and medications. Systemic Lupus International Collaborating Clinics/ACR Damage Index (SDI) was recorded annually and each visit was labelled “damage transition” or “non-damage transition” based on whether SDI increased at the subsequent annual measure. The association of risk of SDI increase with SLEDAI-2k domains was assessed using multivariable logistic regression analysis adjusted for confounding by medication use.

**Results:** 5538 visits from 266 patients (86.5% female, 47.4% Caucasian, 66% dsDNA positive) were analysed; at enrolment median (range) SLEDAI-2k was 4 (0–26) and SDI was 0 (0–4). Upon multivariable regression analysis, domains found to be significant were: low complement, proteinuria, haematuria, leukopenia, pyuria, pericarditis, alopecia, rash and arthritis. Upon further adjustment for prednisolone exposure, the effects of some domains were attenuated, but pericarditis (odds ratio (OR)=4.06, 95%CI=1.68–9.83), pyuria (OR=1.94, 1.47–2.56), arthritis (OR=1.71, 1.35–2.16), and rash (OR=1.43, 1.20–1.70), alopecia (OR=1.43, 1.10–1.86) and leukopenia (OR=1.36, 1.03–1.78) remained significant. No other SLEDAI-2k domains showed a significant association, in part due to infrequent occurrence. SLEDAI-2k domains weightings were not congruent with the respective risk of damage accrual.

**Conclusions:** In study, only some SLEDAI-2k domains were significantly associated with organ damage accrual. Re-appraisal of weightings in SLE disease activity scores based on their association with outcome is potentially warranted.

#### AB0571 FACTORS RELATED TO ALEXITHYMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS

F. Basta, D.P.E. Margiotta, G. Dolcini, V. Batani, A. Vernuccio, M. Vadacca, A. Afeltra. *Università Campus Bio-medico di Roma, Rome, Italy*

**Background:** Alexithymia describes the difficulties of people in identifying, differentiating and articulating emotions of others and themselves and in discriminating those from bodily sensations, with a limited fantasy and a concrete, externally oriented cognitive style.<sup>1</sup> A high prevalence of alexithymia has been found in patients with a variety of health conditions, including SLE.<sup>2</sup> Previous authors identified mood states<sup>2</sup> and quality of life<sup>3</sup> as the main factors related to alexithymia in Systemic Lupus Erythematosus (SLE).

**Objectives:** Aim of our study was to assess the impact of clinical, immunological, psycho-social factors on the presence of alexithymia in Systemic Lupus Erythematosus (SLE).

**Methods:** We consecutively enrolled 104 patients in a cross-sectional study. Alexithymia was assessed using the Toronto Alexithymia scale (TAS-20). We also evaluated symptoms of mood disorders using BDI and HAM-H, quality of life using MOS-SF36, sleep disorders with PSQI and physical activity using IPAQ.

**Results:** The mean (standard deviation) TAS-20 score was 49.5 (15.6). The prevalence of alexithymia (TAS-20 ≥61) was 28%. Alexithymic patients (TAS-20 ≥61) were significantly older (p 0.0005), presented more severe depressive and anxiety symptoms (p<0.0001), a higher score of sleep disorders (p<0.0001), a reduced Facit-Fatigue score (p 0.0007), reduced SF-36 mental and physical component summary scores (p 0.0001 and 0.004) and increased daily sedentary time (p 0.002). In the multiple logistic regression analysis the variables associated to the presence of alexithymia were age (OR 1.07, p 0.02) and the score of depressive symptoms (OR 1.15, p 0.02).

**Conclusions:** About a third of SLE patients presented a dysfunctional processing of emotion. It is necessary to carefully consider the symptoms of mood disorders to optimise SLE patient management.

#### AB0572 CORRELATION OF 24 HOURS URINARY PROTEIN QUANTIFICATION WITH RANDOM SPOT URINE PROTEIN/CREATININE RATIO IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS

F. Elbadawi, M. Khamashta, J. Alsaleh. *Rheumatology Department, Dubai Hospital, Dubai, United Arab Emirates*

**Background:** Proteinuria is an important signal of Lupus nephritis. The standard method of proteinuria quantification is 24 hours urine collection. The ongoing practice of using spot urine sample to determine the ratio between protein and creatinine excretion as a convenient, alternative method of proteinuria estimation is not without limitation and criticism questioning its accuracy.

**Objectives:** Given the cumbersome expressed by some patients on collecting 24 hours urine for protein quantification, our aim was to determine the correlation between spot urine protein-to-creatinine ratio (PCR) and 24 hour urinary protein (UP) in patients with active Lupus nephritis.

**Methods:** The active patients included in the analysis was 53 attending Dubai Hospital shared Rheumatology/Nephrology clinic during the period of June 2016 till Dec 2017. All diagnosed to have systemic lupus erythematosus who either had flare with proteinuria or newly diagnosed as Lupus nephritis. Suspicion of active Lupus nephritis was evidenced by active urine sediment and 24 hours UP quantification of more than 0.5 gm or more than 1.0 gm regardless to urine sediment. Paired baseline urine samples were obtained and results included in the final analysis. Most of the patients underwent ultrasound guided kidney biopsy to classify the nephritis according to ISN/RPS 2003 classification, unless contra-indicated or patient refused to give consent. We used Minitab 18.1 software to determine the Spearman’s correlation coefficient (r), and its significance. P-Value <0.05 was considered statistically significant

**Results:** Total of 54 patients evaluated, one patient excluded from the analysis as the patient nephritis was not related to lupus. 93% of the patients were females (49/53) while 7% were males (4/53). 42 patients underwent ultrasound guided kidney biopsy (79%) while 21% of the patients the histopathology class was not defined as no biopsy obtained either due to contra-indication to the procedure (i. e.: single kidney, flared during pregnancy) or the patient refusal to go for biopsy. 15 patients out of 53 (28%) had nephrotic range proteinuria (defined as urinary proteinuria level of more than 3.5 gm per 24 hours), on the other hand 72% (38/53) had sub nephrotic range. Linear regression Analysis revealed positive correlation between the two methods of estimation mainly at lower levels of proteinuria (less than 3.5 gm). We found a positive correlation between PCR and 24 hours UP quantification. The overall corrected correlation coefficient was  $r=0.46$ , with P value  $<0.0001$ .

Abstract AB0572 – Figure 1

**Conclusions:** PCR in spot urine specimens is an accurate and convenient method to estimate the protein excretion in urine only when proteinuria is at sub nephrotic range. Prospective study is required to explore the effect of disease activity, disease duration and co-morbidities on the correlation and predictive power of the model.

#### INFLUENCE OF SMOKING AND OBESITY ON THE RISK OF DEVELOPING PRIMARY SJÖGREN'S SYNDROME: A POPULATION-BASED COHORT STUDY

G. Maciel<sup>1</sup>, L. Servioli<sup>1</sup>, C. Nannini<sup>2</sup>, C. Crowson<sup>3</sup>, E. Matteson<sup>3</sup>, D. Cornec<sup>4</sup>, A. Berti<sup>5</sup>. <sup>1</sup>Maciel Hospital, Montevideo, Uruguay; <sup>2</sup>Department of Rheumatology, Hospital of Prato, Prato, Italy; <sup>3</sup>Mayo Clinic, Rochester MN, USA; <sup>4</sup>Rheumatology Department, Brest Teaching Hospital, Brest, France; <sup>5</sup>Immunology, Rheumatology, Allergy and Rare Diseases Department, San Raffaele Scientific Institute, Milan; and Rheumatology Department, Santa Chiara Hospital, Trento, Italy

**Objectives:** Cigarette smoking and obesity have been identified as risk factors for developing several autoimmune diseases, and may be protective for others. This study explored the role of these risk factors in primary Sjögren's syndrome (pSS).

**Methods:** A cohort of Olmsted County, Minnesota residents diagnosed with pSS between January 1, 2000 and December 31, 2015 was identified based on individual medical record review. Each of the cases was matched to 3 age- and sex-matched comparators without pSS randomly selected from Olmsted County residents, indexed to the date of pSS diagnosis. Smoking status was divided into three categories of current smoker, ex-smoker and never smoker. The body weight and height closest to date of diagnosis/index date ( $\pm 1$  year) were used. Obesity was defined as a body mass index (BMI)  $\geq 30$ /kg/m<sup>2</sup>.

**Results:** 106 incident cases of pSS and 318 controls were identified. The odds ratio (OR) of pSS comparing current smokers with never smokers was 0.34 (95% confidence interval (CI): 0.14, 0.85;  $p<0.05$ ), while the OR for former smokers compared to never smokers was 1.27 (95% CI, 0.80, 2.03). Smoking status was

not associated with antinuclear antibody, anti-SSA, anti-SSB or rheumatoid factor positivity ( $p>0.05$ ). The OR of pSS comparing obese subjects with non-obese subjects was 0.79 (95% CI, 0.48, 1.30), while the OR of pSS for BMI analysed as a continuous variable was 0.97 (95% CI, 0.94, 1.01).

**Conclusions:** In this population-based study, current smokers have a lower risk of developing pSS while BMI does not affect this risk.

**Disclosure of Interest:** None declared

#### RENAL ACTIVITY PATTERNS AND THERAPEUTICS IN LUPUS NEPHRITIS OBSERVATIONS IN 5 MEXICAN RHEUMATOLOGY CENTRES

G. Pickens<sup>1</sup>, D.A. Herrera-van Oostdam<sup>1</sup>, F. Irazoque-Palazuelos<sup>2</sup>, S. Cerpa-Cruz<sup>3</sup>, M.A. Saavedra-Salinas<sup>4</sup>, C. Mendoza-Pinto<sup>5</sup>, C. Abud-Mendoza<sup>1</sup>.

<sup>1</sup>Rheumatology, Hospital Central Dr. Ignacio Morones Prieto, San Luis Potosi;

<sup>2</sup>Rheumatology, Centro Médico Nacional "20 de Noviembre", Ciudad de México;

<sup>3</sup>Rheumatology, Hospital Civil de Guadalajara Fray Antonio Alcalde, Guadalajara;

<sup>4</sup>Rheumatology, Hospital de Especialidades Centro Médico Nacional "La Raza", Ciudad de México;

<sup>5</sup>Rheumatology, Hospital General Regional Numero 36 "San Alejandro", Puebla, Mexico

**Background:** Lupus nephritis (LN) develops in 40%–60% of Systemic Erythematosus (SLE) patients; 45% don't achieve complete response or eventually relapse and 10%–20% progress to end stage renal disease.

**Objectives:** Describe renal activity patterns and therapeutic schemes employed in 5 Mexican Rheumatology Centres.

**Methods:** Retrospective analysis of renal activity in 193 patients with LN with  $\geq 6$  months follow-up. If follow-up was  $\leq 1$  year, response was classified as complete (CR), partial (PR) or no response (NR). If follow up was  $>1$  year, response was classified as one of the following patterns: persistent inactive (PI), relapsing-remitting (RR), chronic active (CA) and mixed.

**Results:** Biopsy was available in 166 subjects (86.01%): class IV (42.77%), III (23.49%), V(10.24%), II(9.03%). The most prevalent schemes were CYC+MMF 46.6%, only CYC 18.13%, only MMF 12.4%, CYC+MMF+ TAC 9.84%. Thirty eight patients had follow-up  $\leq 1$  year with the following response: CR 16 (42.1%), NR 13 (34.21%) y PR 9 (25.7%). One hundred and fifty five patients had  $>1$  year follow-up with the following activity patterns: PI 55 (35.48%), RR 38 (24.51%), CA 31 (20%), mixed 31 (20%).

We then compared patients whose therapeutic schemes were classified as the National Institutes of Health regime (n=109) (as considered by the treating physician) to those with different therapeutic schemes. We observed a higher final GFR ( $100\pm 39.2$  SD VS  $87.1\pm 37.9$  SD,  $p=0.029$ ) and more frequent CYC use ( $106\pm 100$  SD VS  $37\pm 49.3$  SD,  $p<0.0001$ ) in the NIH group. There weren't statistically significant concerning renal response or activity patterns. Although treating physicians stated they had used the NIH regime in 57.9%, 64.03% actually received CYC+MMF and 11.4% CYC+MMF+ TAC. We then compared the group that received CYC monotherapy to the groups that received CYC+MMF and CYC+MMF+ TAC and did not observe any statistically significant differences.

**Conclusions:** The most prevalent renal activity patterns were those that translated intermittent of continuous activity (64.51%). Strict adherence to the original NIH regime is questionable, most subjects actually received CYC+MMF at some point. We did not observe any statistically significant superiority of renal outcomes of combination therapy over CFM monotherapy. Limitations: preliminary initial analysis, heterogeneous information and missing data.

#### CLINICAL ANALYSIS OF 22 CASES OF SYSTEMIC LUPUS ERYTHEMATOSUS COMPLICATED WITH HEMOPHAGOCYTIC LYMPHOHISCYTIOSIS

D. xu, L. zhang, Y. li, D. jiang, Y. guo, J. tang, X. zheng, L. lu, Z. li, Y. li, G. gao. the First Affiliated Hospital of Zhengzhou University, Zhengzhou Henan, China

**Objectives:** To investigate the clinical features of hemophagocytic lymphohiscytosis (HLH) in systemic lupus erythematosus(SLE).

**Methods:** Twenty – two cases of systemic lupus erythematosus complicated with hemophagocytic syndrome were retrospectively analysed. The clinical manifestations, laboratory tests and prognosis were collected.

**Results:** Twenty-two patients with systemic lupus erythematosus complicated with hemophagocytic syndrome developed fever in 22 patients, including 18 with hyperpyrexia, 20 with hyperferritin, 20 with cytopenia, 10 with splenomegaly, 6 with hyperglycemia, 5 cases of hypofibrinogenemia, 14 cases of bone hemoptysis occurred in the bone wear, nk cell activity decreased or absent in 7 cases, 15 cases of lymphadenopathy, mostly bilateral armpit lymph nodes and neck bilateral lymph nodes, liver function Abnormalities/hepatic insufficiency in 11 cases, ultrasound showed 10 cases of cardiac involvement, MRI showed 5 cases of cumulative brain. 22 patients were diagnosed with high-dose glucocorticoid, 9 cases of hormonal impact, 17 cases of human immunoglobulin immunosuppression in 9 cases, 4 cases of ganciclovir, 1 cases of acyclovir, 1 case of relying on Park Glycosides. 21 cases improved, 1 case to persuade invalid to abandon treatment and discharge.

**Conclusions:** SLE and hemophagocytic syndrome have some similarities. The clinical diagnosis is easy to miss. When patients with SLE continue to have high fever, splenomegaly, blood cells decrease, phagocytosis occurs in bone wears, coagulation dysfunction should be combined with vigilance HLH, Improve the relevant inspection. High-dose glucocorticoid combined with immunosuppressive agents, human immunoglobulin therapy can effectively improve the prognosis.

#### AB0576 FEATURES OF NEUROLOGICAL MANIFESTATIONS OF SYSTEMIC LUPUS ERYTHEMATOSUS IN THE KYRGYZ COHORT OF PATIENS

G. Koilubaeva<sup>1</sup>, E. Aseeva<sup>2</sup>, S. Soloviev<sup>2</sup>, T. Reshetnyak<sup>3</sup>. <sup>1</sup>*rheumatology department, National Center of Cardiology and Internal Medicine named after Academician M. Mirrahimov, Bishkek, Kyrgyzstan;* <sup>2</sup>*Intensive care department;* <sup>3</sup>*systemic rheumatic diseases, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The development of a variety of neuropsychiatric symptoms in SLE patients starts with the dysregulation of the immune system. Involvement of the CNS in the pathological process during the onset of the disease can significantly worsen the patient's condition and complicate the prognosis.

**Objectives:** To study the features of neurological manifestations of SLE in the Kyrgyz cohort of patients.

**Methods:** The basis of the study were the results of an initial examination of 460 patients with prospective observation, with a reliable diagnosis of SLE. Out of them, 112 patients were neurological, at the age of 30 (median) [26, 41], predominantly of Kyrgyz nationality (87), with duration of the disease from 6 months to 7 years (median – 2.0) treated in the National Cardiology and Therapy Centre named after M. Mirrahimov (NCTC) from January 2012 to December 2017.

Neurologic manifestations of SLE were diagnosed by clinical examination by a neurologist using some instrumental methods of investigation.

To assess the neuropsychiatric state of patients, the classification criteria by the American College of Rheumatology (1999) were used. Neuropsychiatric disorders were diagnosed through a clinical examination by the psychotherapist using the classification of mental disorders and behavioural disorders according to ICD (International Classification of Diseases) – 10.

**Results:** The damage of the nervous system was observed in 112 (24.305%) Kyrgyz patients from 460, mainly of the central nervous system – in 77 (68.75%), to a lesser extent – the peripheral nervous system (PNS) – in 35 (31.25%) out of 112. In half of the observed patients with CNS lesions, various neuropsychiatric disorders were registered – in 39 (50.65%) out of 77, with psychosis prevalence with visual and auditory hallucinatory syndrome – in 34 (87.18%) out of 39 patients. There were 14 patients with cerebrovascular infection (18.18%) out of 77, mainly with ischaemic stroke in the SMA basin. There was one patient with aseptic meningoencephalitis with manifestations of mild hemiparesis and with the disruption of the function of the pelvic organs in the form of mandatory urges. Symptoms of myelopathy with malfunction of the pelvic organs were registered in 9 (11.69%) patients out of 77.

Five patients had symptoms of combined CNS and PNS lesions. In one of them cases the patient had encephalopolyneuradiculopathy of the Guillain-Barre type with the phenomena of coarse tetraparesis and with disruption of the function of pelvic organs in the form of delay, with a single epicrism.

**Conclusions:** Neurological manifestations of SLE in the majority of Kyrgyz patients were mainly caused by CNS lesions (68.75%), mostly in the form of neuropsychiatric disorders (50.65%), with a predominance of psychosis with visual and auditory hallucinatory syndrome (87.18%).

#### AB0577 CHARACTERISTICS OF VALVULAR HEART DISEASE IN A MONOCENTRIC MALAYSIAN LUPUS COHORT

H.J. Ding, S.G. Ong, S.S. Md Sani. *Medicine, Kuala Lumpur Hospital, Kuala Lumpur, Malaysia*

**Background:** Valvular heart disease (VHD) is one of the commonest cardiovascular manifestations of autoimmune disease, including systemic lupus erythematosus<sup>1</sup>. Its prevalence ranges from 18% to 74%, with predominantly regurgitant lesions and valvular thickening. The cause of such abnormalities is yet unclear. There have been very few such studies performed in Asian patients, and only one in Malaysian patients to date.

**Objectives:** We sought to evaluate the valvular abnormalities of a multiracial cohort of lupus patients and also examine the association of these abnormalities with potentially related factors.

**Methods:** The medical records of all patients with SLE who had attended the Rheumatology Clinic of Kuala Lumpur Hospital between January 2008 and December 2016 were reviewed. All patients fulfilled the 1997 updated ACR criteria for SLE. Transthoracic echocardiographic examinations as part of their standard of care were performed by trained technicians using a standardised protocol. Multivariable logistic regressions were conducted to determine factors associated with valvular abnormalities in these patients.

**Results:** There were 207 patients in this study. VHD was found in 67.1% of patients: they were asymptomatic and did not have murmurs. The main abnormalities were tricuspid regurgitation (TR) (45.4%), mitral regurgitation (MR) (40.6%) and valvular thickening (19.2%). The majority of cases comprised mild TR (37.2%), mild MR (25.1%) and mitral valve thickening (10.6%). There were more patients with moderate to severe MR compared to TR (15.5% vs 8.2%). Median pulmonary artery systolic pressure was 23.0 mmHg (IQR 13.2). Risk of VHD was higher in patients with lower C3 levels (<0.83 g/L) (OR 3.36, 95% CI 1.74–6.66). MR (83.3%) and mitral valve (MV) thickening (58.3%) were the commonest abnormalities in patients with APS. Having APS greatly increased the risk of MR (OR 8.10, 95% CI 1.65–77.95) and mitral valve thickening (OR 16.30, 95% CI 3.93–73.84). Risk of mitral valve thickening was increased by presence of lupus anticoagulant (OR 20.82, 95% CI 3.64–223.08), anticardiolipin antibody (OR 5.24, 95% CI 1.42–17.76), anti-β2GPI antibody (OR 6.35, 95% CI 1.18–37.14) and diabetes (OR 7.85, 95% CI 1.43–40.24). Risk for MR was increased by presence of lupus anticoagulant (OR 3.55, 95% CI 1.10–12.43). Hypertension was associated with an increased risk for developing aortic regurgitation (OR 4.70, 95% CI 1.67–13.44). Anti-histone antibody positivity appeared to protect against development of MR (OR 0.46, 95% CI 0.213–0.968).

**Conclusions:** More than half of our patients had VHD, with regurgitant lesions and valvular thickening being the commonest abnormalities. Our finding of the association of MR and mitral valve thickening with APS and individual antiphospholipid autoantibodies concurs with earlier studies. However, what were unusual about our cohort were that TR was the prevalent abnormality and the association of VHD with low C3. We suggest that all patients with SLE have at least one echocardiogram, especially the patients with APS or antiphospholipid antibodies.

#### AB0578 ANALYSIS OF CLINICAL FEATURES AND RISK FACTORS OF IN-HOSPITAL MORTALITY IN CYTOMEGALOVIRUS (CMV) DISEASES WITH SYSTEMIC LUPUS ERYTHEMATOSUS

H. Mingli<sup>1</sup>, C.-Y. Tsai<sup>2</sup>. <sup>1</sup>*Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital;* <sup>2</sup>*Rheumatology/Immunology/Allergy, Taipei Veterans General Hospital, Taipei, Taiwan, Province of China*

**Background:** Cytomegalovirus (CMV) is known as a major cause for life-threatening complications in immunocompromised hosts, including status post allogeneic bone marrow transplantation, solid organ transplantations, and acquired

immunodeficiency syndrome (AIDS). The reactivation of CMV depends on the immune status of host. Systemic lupus Erythematosus (SLE) often requires steroid and immunosuppressive agents to induce remission and lower disease activity. This study presents the clinical presentations, laboratory characteristics, medical profile (including steroid, immunosuppressive agents, and biological agents) and clinical outcomes in SLE patients with diagnosis of CMV diseases. Further, we attempted to investigate the mortality risk factor in these patients.

**Objectives:** To analyse the clinical features, the mortality risk factors and all-cause mortality of Cytomegalovirus (CMV) diseases in patients with systemic lupus erythematosus (SLE) in single centre of Taiwan.

**Methods:** A retrospective study was performed to investigate the clinical features and identify the mortality risk factors associated with CMV diseases in patients with systemic lupus erythematosus (SLE). We reviewed the medical records in patients with SLE who were diagnosed with CMV diseases between Jan. 2006 and Dec. 2016 from Taipei Veterans General Hospital in Taiwan. Clinical and laboratory parameters as well as treatment outcomes were analysed.

**Results:** Fifty-six patients diagnosed with CMV diseases were enrolled in the study and separated into survivors (n=24) and non-survivors (n=32) groups. All patients in CMV disease demonstrated significantly high incidence of CMV pneumonitis (71.43%). The higher SLEDAI-2000 score (p=0.009, HR1.154, 95% CI 1.037–1.285), percentage of recent pulse therapy (p=0.013, HR 4.569, 95% CI 1.313–15.902), and plasmapheresis during hospital course (p=0.005, HR6.905, 95% CI 1.637–29.122) was more common characteristics in non-survivor group than in survivor group. Non-survivors had significantly higher percentage of pancytopenia (p=0.001, HR9.667, 95% CI 2.307–40.511), CMV-positive PCR of blood and bronchoalveolar (BAL) lavage fluid (Blood: p<0.001, HR 15.000, 95% CI 3.932–57.223, BAL fluid: p=0.021, HR 6.176, 95% CI 1.151–33.151), and presence of concurrent infections (bacteremia: p=0.026, HR 4.833, 95% CI 1.122–20.824, other fungal infections: p<0.001, HR 11.424, 95% CI 2.722–47.952) than survivors. Septic shock (n=10, 41.2% of non-survivor group) is the most common cause of in-hospital mortality in CMV diseases.

**Conclusions:** The recent pulse therapy, pancytopenia, and concurrent infections are risk factors of in-hospital mortality in CMV diseases of patients with Systemic Lupus Erythematosus. The serological data of non-survivor groups showed negative findings of CMV immunoglobulin M (IgM) with detection of CMV DNA by polymerase chain reaction (PCR) was observed in CMV diseases. The pulmonary haemorrhage and acute respiratory distress syndromes (ARDS) were the factors of in-hospital mortality in CMV pneumonitis.

## IMMUNOLOGICAL RESULTS OF SALIVARY GLAND BIOPSY AND THEIR RELATIONSHIP WITH CLINICAL AND SEROLOGICAL PARAMETERS IN PRIMARY SJÖGREN'S SYNDROME

H.S. Park<sup>1</sup>, L. Martinez Martinez<sup>2</sup>, B. Magallares<sup>1</sup>, M. Fernandez Castro<sup>3</sup>, M. A. Martin<sup>4</sup>, F. Sanchez Alonso<sup>4</sup>, I. Castellví<sup>1</sup>, A. Laiz<sup>1</sup>, C. Diaz-Torne<sup>1</sup>, M. Millan Arciniegas<sup>1</sup>, P. Moya Alvarado<sup>1</sup>, L. Lopez Vilaro<sup>5</sup>, M.C. Hernandez Lafuente<sup>2</sup>, E. Molló Lacsota<sup>2</sup>, C. Juarez Rubio<sup>2</sup>, H. Corominas<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Immunology, H.U. Sant Pau, Barcelona; <sup>3</sup>Rheumatology, H.U. Infanta Sofia; <sup>4</sup>Research Unit, Spanish Society of Rheumatology, Madrid; <sup>5</sup>Pathology, H.U. Sant Pau, Barcelona, Spain

**Background:** Positive minor salivary gland biopsy (MSGB) is a major criteria for the diagnosis of primary Sjögren's Syndrome (PSS). In our centre the MSGB analysis is carried out by Immunology and Pathology Department in parallel. The immunological analysis identifies the lymphocytic composition of the inflammatory infiltrate. Their results show: the number of T and B cells, the ratio between CD4 and CD8 T lymphocytes and other non infiltrating lymphocytes.

**Objectives:** The goal of our study was to evaluate whether there is an association between the lymphocytic composition of the MSGB with the clinical and serological findings of PSS patients.

**Methods:** Patients diagnosed of PSS according American-European criteria (2002) underwent . MSGB between February and November of 2017

Demographic (sex and age), clinical (disease duration, xerostomia, keratoconjunctivitis sicca, Schirmer test, systemic disease) data were collected. Present or previous treatment with steroids and/or immunosuppressive therapy, serological studies such as ANA, RF, anti Ro and anti La were also included. MSGB data with the number of infiltrates, quantitative composition of T and B lymphocytes, CD4/CD8 ratio and presence of other non infiltrating lymphocytes were registered. Pathology data concerning Chisholm-Mason scale, presence of fibrosis, atrophy and size of infiltrate (small, moderate and severe) were also registered. A multiple logistic regression for each item of the immunological analysis adjusted for sex and age was made. We also measured the odds ratio and performed correlation test for all variables included.

**Results:** Table 1 and 2 summarise our cohort characteristics. The presence of T lymphocyte was associated with B lymphocyte, OR 99.21 (IC95% 5.12–1921, p=0.002) and with higher CD4/CD8 ratio, OR 17.34 (IC95% 1.45–206.15, p=0.024). CD4/CD8 ratio was also associated with the presence of T lymphocytes OR 10.54 (IC95% 2.16–51.50, p=0.004) and B lymphocytes were associated with the presence of T lymphocytes as well OR 5.38 (CI95% 1.63–17.72, p=0.006). Other non infiltrating lymphocytes were composed of CD8 T cells and were associated with a positive Schirmer test OR 17.47 (IC95% 1.62–188.13, p=0.018) but inversely associated with Chisholm-Mason grade  $\geq 3$  OR 0.09 (IC95% 0.014–0.58, p=0.011). There was no other association observed with clinical or analytical parameters. Colinearity test between pathological and immunological analysis was negative.

**Abstract AB0579 – Table 1.** Immunology, serological and treatment characteristics of patients with PSS

Variable	Absolute number (percent)	Proportion %
Men	26	45.2%
Systemic disease	34	35.2%

Corticosteroids >4mc	15	25.9%

**Abstract AB0579 – Table 2.** Immunological analysis

Variable	Absolute number (patient)	Proportion %
Number of Infiltrates		
0	3	5.2%
1	32	55.2%
2	6	10.3%
3	16	27.6%
Number of T cells		
<50	11	19.0%
50-90	17	29.3%
90-100	11	19.0%
100-120	2	3.4%
120-150	9	15.6%
>150	8	13.8%
CD4/CD8 Ratio		
0	11	19.0%
1/2	2	3.4%
1/1	3	5.2%
2/1	15	25.9%
3/1	19	32.4%
>3/1	4	6.9%
Number of B cells		
<50	17	29.3%
50-90	11	19.0%
90-100	6	10.3%
100-120	4	6.9%
120-150	9	15.6%
>150	7	12.1%
Other infiltrates		
None	38	65.5%
CD8 cells	19	32.8%
CD4+CD8 cells	3	5.2%
Inadequate sample	1	1.7%

**Conclusions:** MSGB in our PSS patients demonstrated an association between T lymphocytes, B lymphocytes and CD4/CD8 ratio. The infiltrate is mostly based on CD4 more than CD8 T cells. Other significant findings were the association between CD8 T lymphocytes and Chisholm-Mason scale grade  $\geq 3$ , regardless of the number of infiltrates. No correlation or colinearity was observed with the number of infiltrates by immunological analysis and the Chisholm-Mason grade reported by the pathology analysis.

### CONGENITAL HEART BLOCK AND MATERNAL POSITIVE ANTI-RO AND ANTI-LA AUTOANTIBODIES: A SINGLE CENTRE-STUDY

I. Añón Oñate, M.Á. Ferrer González, I. Notario Ferreira, L. Pérez Albaladejo, M. Ramírez de la Torre, S. Quirosa Flores, A. García Sánchez, M.C. Ramírez Barberena, J.M. Andreu Ubero, R. Cáliz Cáliz. *Rheumatology, Hospital Universitario Virgen de las Nieves de Granada, Granada, Spain*

**Background:** The fetal Congenital Heart Block (CHB) is thankfully a rare occurrence. It can develop during pregnancy in women with Rheumatic Diseases who have positive autoantibodies anti-Ro/La.

**Objectives:** To evaluate the efficacy of hydroxychloroquine (HCQ) treatment and the monthly control in a multidisciplinary unit of Rheumatic Diseases and pregnancy on the pregnancy outcomes in women with positive anti-Ro/La.

**Methods:** Descriptive, prospective, longitudinal and open study of 28 pregnant patients with positive anti-Ro/La. They were attended in a specialised multidisciplinary unit of Rheumatic Diseases and pregnancy and 46 pregnancies were developed with no complications. The following variables were collected: age, maternal pathology, presence of anti-Ro52, anti-Ro60 y anti-La, prior abortions, prior babies born with CHB, result of fetal echocardiograms, treatment during pregnancy, obstetric outcomes births/abortion, pregnancy length and maternal/fetal complications.

**Results:** 28 pregnant women were included in the study. 64.3% were diagnosed with Systemic Lupus Erythematosus, 21.4% with Sjögren's syndrome, 10.7% with undifferentiated connective tissue and 3.6% with rheumatoid arthritis. Our patients were an average of  $32.24 \pm 5.34$  years old and the 35% were elder than 35 years. 46 pregnancies were developed during the monitoring with an average of  $1.61 \pm 0.74$  pregnancies per patient. Before the inclusion in our unit, the following fetal history was collected: 1 baby with CHB and 11 abortions. Nevertheless, during the multidisciplinary evaluation and treatment there was no baby developing CHB and only 2 abortions occurred during the first trimester. The positivity of anti-Ro52, anti-Ro60 y anti-La was 89.3%, 32% and 29% respectively. Besides, 2 patients had triple positive autoantibodies and 6 patients double positive autoantibodies. 18% of our patients were diagnosed with lupus nephritis and 29% were diagnosed with secondary antiphospholipid syndrome and/or thrombophilia. The immunosuppressive therapy received during the 46 pregnancies is specified in figure 1. Also, 50% pregnant women received treatment with acetylsalicylic acid, 24% with low-molecular-weight heparin and 41% with corticoid. The mean gestational age was 38 weeks and 11% births were caesarean. 11% babies were preterm with an average birth weight of  $2871.6 \pm 494.8$  grams. 87% of our patients did not have complications in the puerperium. All of our patients were monitored with periodic fetal echocardiograms from the 16th week of gestation and none had a baby with CHB or neonatal lupus (100% of the babies were born healthy).

Abstract AB0580 – Figure 1. Immunosuppressive therapy received during the 46 pregnancies (%)

**Conclusions:** Our results demonstrate that both treatment with hydroxychloroquine and close control in a multidisciplinary unit are effective in the prevention of congenital heart block development, in the decrease in the number of abortions and in a reduction of maternal and fetal morbidity and mortality. The multidisciplinary evaluation is essential in women diagnosed with rheumatic diseases with high obstetric risk.

### PREGNANCY OUTCOMES IN WOMEN WITH ANTIPHOSPHOLIPID SYNDROME AND THROMBOPHILIA TREATED IN A MULTIDISCIPLINARY UNIT

I. Añón Oñate, M.Á. Ferrer González, L. Pérez Albaladejo, I. Notario Ferreira, M. Ramírez de la Torre, S. Quirosa Flores, A. García Sánchez, M.C. Ramírez Barberena, J.M. Andreu Ubero, R. Cáliz Cáliz. *Rheumatology, Hospital Universitario Virgen de las Nieves de Granada, Granada, Spain*

**Background:** The Antiphospholipid Syndrome (APS) and Thrombophilia predominantly affect women of fertile age, so their pregnancies should be considered high obstetric risk. These pregnant women need close monitoring in a multidisciplinary unit.

**Objectives:** To evaluate the efficacy of the treatment on the pregnancy outcomes of women with APS and thrombophilia from a Spanish cohort.

**Methods:** Descriptive, prospective, longitudinal and open study of 88 pregnant patients with primary and/or secondary APS and thrombophilia assisted in a specialised multidisciplinary unit of Rheumatic Diseases and pregnancy (integrated by Gynaecologists, Haematologists and Rheumatologists). The following variables were collected: age, maternal pathology, presence of antiphospholipid antibodies, thrombotic episodes and prior abortions, number of childbirths, treatment during pregnancy, obstetric outcomes births/abortion and pregnancy length and maternal/fetal complications.

**Results:** 88 pregnant women were included in the study. 44 patients were diagnosed with thrombophilia (mostly, Heterozygotes for MTHFR gene), 33 with primary or secondary APS and 11 patients were diagnosed with both APS and thrombophilia. 140 pregnancies were developed during the monitoring: 61% of women had a single birth, 30% had two births and 5% had three births. Abortions registered before and during inclusion in our unit are specified in figure 1. Before the inclusion in our unit, 52% patients had 1 or 2 abortions, 25% had 3 abortions and 23% had 4 or more abortions. 10% patients had presented a previous thrombosis. Our patients were an average of  $33.6 \pm 5.5$  years old and the 44.3% were elder than 35 years. Among the 44 patients with APS: 50% presented positivity to Lupus Anticoagulant (LA), 25% had triple positive antiphospholipid antibodies (LA, anticardiolipin antibodies and anti-β2-glycoprotein) and 27% had double positive autoantibodies. As for the treatment received during the 140 pregnancies: 50% pregnant women received treatment with prophylactic doses of low-molecular-weight heparin (LMWH) together with acetylsalicylic acid (ASA), 26% were treated in monotherapy with LMWH and 9% in monotherapy with ASA. 10 patients diagnosed with thrombophilia, with an average of  $5.3 \pm 1.5$  abortions per patient, received treatment with LMWH, ASA and intravenous gammaglobulin. All patients who received LMWH during pregnancy also received LMWH after birth for 6 weeks. The mean gestational age was 38 weeks with an average birth weight of  $3058.5 \pm 595.6$  grams. 13% babies were preterm and 32% births were caesarean. 87% of our patients did not have complications in the puerperium.

Abstract AB0581 – Figure 1

**Conclusions:** The treatment is effective in the prevention of abortions. Our results demonstrate a decrease in the number of abortions and a larger number of term pregnancies since the inclusion of patients with high risk pregnancies in our unit. The multidisciplinary evaluation is essential to prevent complications in women diagnosed with APS and thrombophilia in order to reduce adverse pregnancy outcomes and exacerbations of the mother's pathology.

**AB0582 SOLUBLE TRIGGERING RECEPTOR EXPRESSED ON MYELOID CELLS-1 (STREM-1) AND ADRENOMEDULIN ARE ELEVATED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

L. Jeremic<sup>1</sup>, N. Stojanovic<sup>1</sup>, Z. Stanojevic<sup>2</sup>, B. Jovanovic<sup>3</sup>, J. Tomic<sup>2</sup>, S. Vidicevic<sup>2</sup>, A. Isakovic<sup>2</sup>. <sup>1</sup>Institute of Rheumatology, Belgrade; <sup>2</sup>Institute of Biochemistry, Belgrade; <sup>3</sup>Clinical Centre of Serbia, Belgrade, Serbia

**Background:** Adrenomedulin is a peptide firstly isolated from human pheochromocytoma with vasodilatory effects. Secretion of adrenomedulin is modified by inflammatory cytokines and it may be important as a suppressor of lupus nephritis activity. Triggering receptor expressed on myeloid cells-1 (TREM) is a member of immunoglobulin superfamily clearly elevated in inflammatory conditions. Some subgroups of patients with systemic lupus erythematosus-SLE may have especially elevated levels of s-TREM.

**Objectives:** The aim of this study was to examine adrenomedulin and s-TREM levels in patients with SLE and healthy controls and to assess their relation with SLE disease activity index-SLEDAI

**Methods:** Serum samples from 50 SEL patients and 40 healthy blood donors were analysed. Serum levels of adrenomedulin, s-TREM, complement components C3 and C3, and anti-dsDNA antibodies were measured

**Results:** Patients with SLE had higher adrenomedulin (9.8±4.5 vs. 15.3±7.2 pg/mL, p<0.05) and s-TREM (11.7±4.1 vs. 20.3±13.1 pg/mL) (p<0.05) levels. s-TREM showed correlation with anti-dsDNA antibodies ( $\rho=0.405$ , p<0.05) and SLEDAI score ( $\rho=0.386$ , p<0.001). In multivariate analysis s-TREM did not appear as an independent predictor of SLEDAI score, while only anti-dsDNA antibodies were significant in multivariate analysis.

**Conclusions:** Increased adrenomedulin and s-TREM are found in lupus sera. Despite of correlation with SLEDAI score, s-TREM is not better than anti-dsDNA antibodies as a predictor of SLE disease activity.

Garcia-Garcia<sup>1</sup>, E. Flores-Huerta<sup>1</sup>. <sup>1</sup>Servicio de Reumatología e Inmunología Clínica, Departamento de Medicina Interna, Hospital Universitario "Jose E. Gonzalez", Monterrey; <sup>2</sup>Departamento de Reumatología e Inmunología, Instituto Nacional de Ciencias Médicas y Nutrición "Salvador Zubirán"; <sup>3</sup>Servicio de Reumatología, Juárez de México/Centro Médico ABC, Mexico, Mexico

**Background:** A rheumatic disease may be a casual factor in the pathogenesis of a neoplastic disease, as in other cases, cancer may lead to the development of paraneoplastic rheumatic manifestations that may be the only initial symptoms<sup>1</sup>. Lazarus *et al.* demonstrated in its cohort study with 112 patients that of the 22% of patients who developed some neoplasm during the study, the most prevalent was lymphoma with 44%. according to the same study, patients with pss present a risk 37.5 times more than that of the general population. of generating lymphoma, with another risk 2.6 times of developing another type of cancer<sup>2</sup>. it was also shown that in patients with pss there is an incidence of 320 cases per 100 000 a year of presenting non-hodgkin's lymphoma<sup>3</sup>. In our country there are no epidemiological studies to know the prevalence of cancer in patients with pss, so these numbers are difficult to estimate

**Objectives:** Determine the prevalence of cancer in patients with ss in the mexican population.

**Methods:** Cross-sectional, observational study was conducted in which 393 patients were included, of which 221 (52%) came from the national institute of medical sciences and nutrition "salvador zubiran", 92 (23.4%) from the university hospital "José E González" and 80 (20.6%) of the Juárez Mexico hospital/ABC medical centre whom fulfilled the diagnosis of ssp according to the 2002/2012 criteria of the american college of rheumatology/european league against

rheumatism. Bivariate analysis was performed, normality was demonstrated using the K.S test, the student's T test was used for the numerical variables and the chi2 test for the categorical ones, and no difference was found between the characteristics of patients with or without cancer.

**Results:** We include 393 patients, the majority were women (n=377, 95.9%) with an average age of 56.4 (±13.60), of these 23 (5.85%) had some type of neoplasm regardless of their malignancy. the most prevalent was lymphoma with 9 cases (34.6%), followed by breast cancer with 5 (19.2%), 3 (11.5%) of basal cell cancer and 2 (7.7%) cases of cervical uterine cancer

**Abstract AB0583 – Table 1.** Demographic characteristics in Patients with Primary Sjögren Syndrome (n:393)

	Neoplasia	No neoplasia	P
Age years, mean(SD)	61.57 (15.40)	56.10 (13.44)	0.519
Female gender, n(%)	23 (100%)	354 (95.7%)	0.309
Positive Anti-Ro/SSA, n(%)	15 (71.4%)	238 (64.7%)	0.528
Positive Anti-La/SSB, n(%)	9 (42.9%)	168 (46.3%)	0.760
Positive Schirmer test, n(%)	15 (78.9%)	245 (83.9%)	0.572
Abnormal NSWSF, n(%)	12 (63.2%)	215 (77.1%)	0.169
Positive GSM biopsy, n(%)	18 (81.8%)	276 (77.1%)	0.607
Use of glucocorticoids, n(%)	9 (45%)	131 (36.2%)	0.426
Use of hydroxychloroquine, n(%)	6 (28.6%)	167 (46.1%)	0.116
Use of methotrexate, n(%)	3 (15%)	74 (20.4%)	0.555
Another immunosuppressive agent, n(%)	5 (21.7%)	76 (20.5%)	0.890

NSWSF: non-stimulated whole salivary flow, MSG: Minor salivary gland

**Abstract AB0583 – Figure 1.** Neoplasia prevalence in primary sjögren syndrome in Mexican-Mexitzo patients

**Conclusions:** We confirmed lymphoma as the most prevalent neoplasia in a cohort of non-Caucasian pSS patients. We observed the presence of non-hematological malignancy 60.86% of our patients, whether it risk is increased in pSS population still needs to be addressed.

**PAEDIATRIC VS ADULT ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: THE SIMILARITIES AND DIFFERENCES; A STUDY FROM A TERTIARY CARE CENTRE FROM NORTHERN INDIA** \*;+

J. Patel<sup>1</sup>, M. Agarwal<sup>2</sup>, A. Shivpuri<sup>2</sup>, G.S. Bhandari<sup>1</sup>, N. Jain<sup>3</sup>, S. Sawhney<sup>2</sup>, L. Duggal<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pediatric Rheumatology; <sup>3</sup>Sir Gangaram Hospital, New Delhi, India

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease with myriad of systemic features. While the disease manifestations and therapy remain same for both paediatric onset(cSLE) and adult onset SLE (aSLE), disease manifestation and burden of disease differs in the two populations.

**Objectives:** To study disease profile within 6 months of disease onset and burden of disease by SLEDAI of aSLE and cSLE to understand the similarities and differences and to compare with those from around the world

**Methods:** Retrospective review done of 100 aSLE and cSLE patients, from June 2015 to June 2016, fulfilling SLICC criteria. Demographic data, clinical profile and ds burden at onset(highest of 1st 6 mths of ds onset) by SLEDAI 2K were recorded on a predesigned proforma

**Results:** The incidence of skin involvement (acute and chronic cutaneous lupus, alopecia) serositis more in aSLE. Oral mucositis, neuropsychiatric SLE(NPSLE) and lupus nephritis(LN) more common in cSLE.LN was also higher in cSLE from other centres around the world as compared to aSLE. Of statistical significance were non SLICC features like fatigue, Raynaud phenomenon and fatigue in aSLE. cSLE significantly differed in higher incidence of non SLICC features like fever, vasculitic rash and in laboratory features like leucopenia, low complements, dsDNA positivity and antiphospholipid antibody(APLA) positivity. Although APLA antibodies were frequent in cSLE, thrombotic events were rare. On the other hand, thrombotic events were significantly associated with aSLE. Median SLEDAI at onset was higher in cSLE than aSLE. The higher incidence of LN in CSLE than aSLE was similar from the inception cohort from Toronto.<sup>1</sup>The mean SLEDAI at onset was also similarly higher in cSLE. The spanish SLE registry also reported similar findings.<sup>2</sup>

Abstract AB0584 – Table 1

Data at onset	aSLE(n=100)	cSLE(n=100)	P value	SLICC FEATURES	aSLE(%)	cSLE(%)	p value
Male/ Female	15/85	24/76	0.15	Acute cutaneous lupus	67	55	0.11
Median Age at onset	34 (β - 71)	9.5 (3.4 - 17.4)	-	Chronic cutaneous lupus	07	05	0.77
Median Age at diagnosis(years)	35 (β - 71)	10.25 (3.5 - 19.0)	-	Mouth ulcer	46	55	0.26
Median delay to diagnosis(years)	1 (0 - 15)	0.75 (0 - 5.33)	-	Alopecia	63	57	0.47
Fever	57	82	0.0002 *	Arthritis	47	65	0.015 *
Fatigue	88	57	0.0001 *	Serositis	23	13	0.097
Weight loss	47	33	0.06	Pleural effusion/pericardial effusion	20	11	0.12
RP	39	09	0.0001 *	Lupus nephritis	26	36	0.17
Myalgia	42	52	0.20	NPSLE	13	24	0.068
Vasculitic rash	04	29	0.0001 *	Leukopenia	07	29	0.0008 *
Lymphadenopathy	27	48	0.0034 *	Thrombocytopenia	32	21	0.11
SLEDAI (mean)	12.9	16.59	-	ANA positivity	100	99	1.0
Thrombosis	18	01	0.0001 *	Anti-dsDNA positivity by IF	47	77	0.0001 *
				Anti-5M	24	13	0.068
				Anti-cardiolipin antibody	09	21	0.028 *
				LAC	09	22	0.018 *
				Low complements	41	82	0.0001 *
				DAT positivity	31	33	0.88

**Conclusions:** This study showed significant difference in initial systemic involvement and onset of presentation in aSLE and cSLE.cSLE present with more subtle features and seldom have a classic presentation with malar rash, oral mucositis and alopecia which oft herald aSLE. cSLE and aSLE though being the same disease often have a varied spectrum of presentation and the generalist and the treating teams need to be aware of these for prompt recognition of the disease and optimum therapy

**A LUPUS LOW DISEASE ACTIVITY STATE IS ASSOCIATED WITH REDUCED FLARE, LOWER ORGAN DAMAGE ACCRUAL, AND BETTER QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

J.-H. Kang, K.-E. Lee, D.-J. Park, S.-S. Lee. *Chonnam National University Medical School and Hospital, Gwangju, Korea, Republic of Ireland*

**Objectives:** To identify the potential predictors of a lupus low disease activity state (LLDAS), and the relationship between LLDAS and disease flare, organ damage, and quality of life in Korean patients with systemic lupus erythematosus (SLE).

**Methods:** The study followed 181 SLE patients from a single centre for three years. LLDAS was defined as follows:<sup>1</sup> SLE Disease Activity Index (SLEDAI)–2K≤4, with no activity in major organ systems;<sup>2</sup> no new lupus disease activity compared with the previous assessment;<sup>3</sup> SLEDAI Physician Global Assessment≤1;<sup>4</sup> a current prednisolone (or equivalent) dose ≤7.5 mg daily; and<sup>5</sup> well-tolerated standard maintenance doses of immunosuppressive drugs. We assessed data annually and divided 4 groups according to the number of LLDAS; LLDAS=0, 1, 2, and 3. Univariate and multivariate analyses were performed to identify predictors of LLDAS.

**Results:** Of the 181 patients, 16.0% attained LLDAS on three consecutive years. Each group shows as follows; no LLDAS (n=30), LLDAS=1 (n=60), LLDAS=2 (n=62), and LLDAS=3 (n=29). The patients who had higher number of LLDAS had shorter duration of symptoms, lower anti-histone antibody positivity, lower cumulative prescribed dose of prednisolone at baseline, lower mean PGA, lower mean SLEDAI, lower mean Mental Component Summary in SF-36, lower change in SLICC/ACR damage index, and a lower frequency of flare. In the multivariate analysis, LLDAS was significantly associated with lower mean PGA (OR=0.671, 95% CI: 0.112–0.989, p=0.019) and a reduced risk of flare after adjusting for confounders (OR=0.012, 95% CI: 0.001–0.448, p=0.017).

**Conclusions:** Attaining LLDAS was associated with an improved outcome, as represented by a decreased rate of disease flare, lower organ damage accrual, and better quality of life in Korean patients with SLE.

**CURRENT IMPACT OF ETHNICITY ON RENAL HISTOLOGY AND OUTCOME OF LUPUS NEPHRITIS**

J. Nossent<sup>1,2</sup>, W. Raymond<sup>2</sup>, A. Kang<sup>3</sup>, D. Wong<sup>3</sup>, M. Ognjević<sup>2</sup>, A. Chakera<sup>4,5</sup>. <sup>1</sup>Rheumatology, Sir Charles Gairdner Hospital, Nedlands; <sup>2</sup>Rheumatology, School of Medicine, University of Western Australia, Crawley; <sup>3</sup>Pathology, PathWest Laboratory Medicine, Nedlands; <sup>4</sup>School of Medicine, University of Western Australia, Crawley; <sup>5</sup>Nephrology, Sir Charles Gairdner Hospital, Nedlands, Australia

**Background:** Lupus Nephritis (LN) remains a serious complication of Systemic Lupus Erythematosus (SLE) and continuous worldwide demographic changes as well as new mechanistic insights and treatment options necessitate regular updating of our knowledge of LN.

**Objectives:** To investigate the current relevance of demographic, clinical and histological characteristics as outcome predictors in patients with Lupus Nephritis.

**Methods:** A retrospective single centre cohort study of all SLE patients undergoing a first renal biopsy for LN evaluation between 1997–2017 in a metropolitan hospital in Western Australia with a 750,000 catchment area. Demographic, laboratory and treatment data were collected at baseline and at last follow-up using a predefined form and histological findings (ISN class) were re-evaluated. Kaplan Meier survival estimates for patient and renal survival were tested by log-rank test.

**Results:** The final study cohort included 90 SLE patients (age 31.5 years, 88% female, time since SLE diagnosis 0.3 years.) of Caucasian (n=42), Asian (n=30), Aboriginal (n=11) and other ethnicity (n=7, mainly SubSaharan Africans). The annual LN incidence estimate was 0.6/100,000. There were no significant differences across subgroups regarding renal (overall median 14) and nonrenal SLEDAI (median 4) scores, proteinuria (median PCR 300 mg/mmol), presentation with raised serum creatinine (31% overall), anti-dsDNA Ab (89%) or hypocomplementemia (88%) or presence of proliferative (Class III/IV: 66%) or membranous (Class V:19%) LN. Corticosteroid (86%), immunosuppressive (87% overall) and

antihypertensive drug (69%) use were similar across ethnic subgroups (all  $p > 0.2$ ). After a mean follow-up of 95 months, eight patients (9%) had died, six (7%) received renal replacement therapy and five (6%) had developed CKD. Five and ten years patient survival was similar for Asian and Caucasian patients (95%) and poorest in Aborigines (81% and 70%) ( $p = 0.016$ ) with no impact of gender, ISN class, full house IF findings or PCR  $> 300$ . Renal 5 and 10 year survival (endpoint RRT) was 100% for Asian, 100% and 96% for Caucasian vs 86% and 64% for Aborigines ( $p = 0.02$ ). PCR  $> 350$  predicted worse renal survival ( $p = 0.03$ ), which was not influenced by gender, increased baseline creatinine, ISN class, A/AC/C subclass or presence of full house IF deposits.

**Conclusions:** Asian patients have similar clinical and histological LN findings and experience equally good renal and patient outcomes as Caucasian patients in Western Australia, where the incidence rate of LN is comparable with Europe. Whether the grim outlook for Aboriginal patients relates to intrinsic differences in LN pathophysiology and/or socioeconomic circumstances deserves further study.

#### HAEMATOLOGICAL ALTERATIONS IN COLOMBIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J. Sanchez-Bautista<sup>1</sup>, Y. Santamaria-Alza<sup>2</sup>, A. Coy-Quiroga<sup>2</sup>, M. Alarcon-Gomez<sup>2</sup>, J. Fajardo-Rivero<sup>2</sup>, C. Figueroa-Pineda<sup>2</sup>, on behalf of Internal medicine department, Industrial University of Santander, Colombia. <sup>1</sup>Johns Hopkins University, Baltimore, USA; <sup>2</sup>Internal medicine, Universidad Industrial de Santander, Bucaramanga, Colombia

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disease, with multiple organs and system involvement. The most usual haematological findings are anaemia, leukopenia, and thrombocytopenia. The prevalence of SLE in Colombia was 8.77 per 10 000 persons between 2012 and 2016<sup>1</sup>.

**Objectives:** To evaluate the haematological alterations in a cohort of patients with SLE in Bucaramanga, Colombia.

**Methods:** A retrospective cohort study of 149 patients diagnosed with SLE according to the Systemic Lupus International Collaborating Clinics (SLICC) criteria. Descriptive analysis with frequencies, measures of central tendency and dispersion was done using Stata 12.0 software. The primary outcome was the presence of cytopenia, the secondary outcomes were anaemia, leukopenia, and thrombocytopenia. In the group comparison analysis, a chi-square test was used for qualitative variables and Wilcoxon or T student test for quantitative variables according to their distribution. Bivariate analysis using logistic regression with OR measurement,  $p$ -value, and confidence intervals was performed.

**Results:** 82.5% were women, average age was 36.8 years. The primary outcome was found in the 79.8%, anaemia in the 76.5%, thrombocytopenia in the 22.1% and leukopenia in the 18.7%. In group comparison analysis (cytopenia vs no cytopenia) a statistical difference was found in the variables sex ( $p = 0.023$ ), skin involvement ( $p = 0.003$ ), acute pneumopathy ( $p = 0.050$ ), activity of the disease measured by the ECLAM scale ( $p = 0.037$ ) and anti-DNA antibody titers ( $p = 0.032$ ). In the bivariate analysis, there was an increased risk of cytopenias with statistical significance in male patients (OR: 3.82), ECLAM score greater than 5 (OR: 4.75) and strongly positive anti-DNA antibodies (OR: 3.97). Regarding leukopenia, there was an association with antiphospholipid syndrome (OR: 2.75), ECLAM greater than 5 (OR: 2.51), SLEDAI MEX greater than 10 (OR: 2.35) and strongly positive anti-DNA antibodies (OR: 2.36). Likewise, an increased risk of mortality was found in patients with leukopenia (OR: 3.92). In the case of thrombocytopenia, an association was found with a pericardial alteration (OR: 2.46), ECLAM greater than 5 points (OR: 3.65), SLEDAI MEX greater than 10 points (OR: 2.42). An association with mortality was also observed (OR: 2.97). The risk of presenting anaemia was increased with the variables man (OR: 4.4), ECLAM greater than 5 points (OR: 3.14) and strongly positive anti-DNA antibodies (OR: 3.25).

**Conclusions:** This is the first Colombian study that evaluates haematological alterations in patients with SLE. The most frequent cytopenia was anaemia. It is possible to identify variables that can predict the appearance of cytopenia, such as the increase in the activity of the disease, which is susceptible to intervention. It is noteworthy that both leukopenia and thrombocytopenia are markers of mortality in patients with SLE.

#### IDENTIFICATION OF RISK FACTORS FOR HERPES VIRUS INFECTIONS WITH IMMUNOPHENOTYPING DURING INDUCTION THERAPY IN PATIENTS WITH ACTIVE LUPUS NEPHRITIS

J. Kikuchi<sup>1</sup>, M. Ushikubo<sup>2</sup>, S. Saito<sup>1</sup>, H. Yasuoka<sup>1</sup>, K. Yamaoka<sup>1</sup>, H. Tsujimoto<sup>3</sup>, K. Sugahara<sup>3</sup>, T. Takeuchi<sup>1</sup>. <sup>1</sup>Division Of Rheumatology, Department Of Internal Medicine, Keio University School of Medicine; <sup>2</sup>Department of Connective tissue disease, National Hospital Organization Tokyo Medical Center, Tokyo; <sup>3</sup>Research Unit/Immunology and Inflammation, Mitsubishi Tanabe Pharma Corporation, Kanagawa, Japan

**Background:** Herpes virus infections (HVIs) including cytomegalovirus infections (CMVs) and herpes zoster (HZ) remains as major complications during treatments with immunosuppressant (IS) in patients with autoimmune diseases.<sup>1, 2</sup> Previous reports have suggested the associations between virus infections and characteristics of T cells.<sup>3, 4</sup>

**Objectives:** To elucidate the characteristics of peripheral immune cells associated with risk factors of HVIs during induction therapies in patients with active lupus nephritis (LN).

**Methods:** Standardised peripheral immunophenotyping was performed using flow cytometry in active LN and ANCA-associated vasculitis (AAV) patients starting induction therapy and also with inactive LN patients with maintenance therapy between April 2015 to April 2017. The definition of HVIs was the infection necessary to administer anti-viral agents.

**Results:** Sixty-two LN patients and 11 AAV patients were enrolled. Among 30 active LN patients, 27 were analysed except for 3 patients (2 died and 1 withdrawn consent). Mean age was 41.7 years, 9 patients (33%) had newly-onset, and mean SLE disease activity index (SLEDAI) was 19.3. All active LN patients were treated with prednisolone (PSL) (mean 51.7 mg/day) and 25 were treated with an additional IS (cyclophosphamide [CYC];13, mycophenolate mofetil;8, tacrolimus;3, rituximab [RTX];1). Six (22.2%) patients developed HVIs (5 CMVs and 1 HZ) within 3 months following induction therapy. None of the 32 LN patients in maintenance phase (mean age, 54.8; SLEDAI, 2.5; PSL 2.5 mg/day) developed HVIs during the mean 2.8 years-observational period. Two (18.2%) AAV patients developed HVIs within 3 months following induction therapy. All AAV patients (mean age, 64.3) were treated with PSL (mean 41.8 mg/day) and 10 with IS (CYC;5, RTX;3, azathioprine;1, methotrexate;1).

Among active LN patients, univariate analysis revealed that older age, lower proportions of naïve CD8 +T cells, higher proportions of effector CD8 +T cells and HLA-DR +regulatory T cells (Tregs) at baseline and lower naïve CD8 +T cells at month 3 associated with HVIs ( $p = 0.011$ ,  $p < 0.001$ ,  $p = 0.009$ ,  $p = 0.024$ ,  $p < 0.001$  respectively). Unexpectedly, lymphocyte count, IgG titer, usage of CYC at baseline, renal response and change in SLEDAI at month 3 did not associate with HVIs. Multivariate analysis revealed that low proportions of naïve CD8 +T cells and high proportions of HLA-DR +Tregs at baseline were the only detectable independent risk factor for HVIs ( $p = 0.014$ ).

Among AAV patients, univariate analysis showed that older age, lower proportions of naïve CD8 +T cells, higher proportions of Tregs at baseline associated with HVIs. However, multivariate analysis showed no independent risk factor for HVIs among them.

**Conclusions:** Our results suggest that active LN patients with low proportion of naïve CD8 +T cells and high HLA-DR +Tregs at the time of induction therapy should be closely monitored for HVIs. The different results between LN and AAV implicated the different risks of HVIs by immunophenotyping. Larger prospective study is desired to confirm our results.

### RELEVANCE OF B AND T CELL SUBSETS TO LUPUS FLARE IN KOREAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

J.H. Koh<sup>1</sup>, N. Lee<sup>2</sup>, W.-U. Kim<sup>3</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Pusan National University Hospital, Pusan; <sup>2</sup>Center for Integrative Rheumatoid Transcriptomics and Dynamics, The Catholic University of Korea; <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, Seoul St. Mary's hospital, the Catholic university of Korea, Seoul, Korea, Republic of Ireland

**Background:** Systemic lupus erythematosus (SLE) is a systemic autoimmune disease with heterogeneous clinical manifestations and is characterised with autoreactive T cells and autoantibody overproduction by activated B cells.

**Objectives:** The aims of this study were to characterised T-cell and B-cell subpopulation phenotype in Korean patients with SLE, and to elucidate the association between lymphocyte subpopulation and lupus activity.

**Methods:** We used multicolor flow cytometry to analyse subsets of peripheral blood B-cells (defined by CD19, IgD, CD27, and CD38) and T-cells (CD3, CD4, CD8, CD45RA, CCR7) in 26 patients with SLE and 22 age- and sex-matched healthy subjects. Baseline and 6 month follow-up SLE disease activity index (SLEDAI) was recorded, and SLEDAI score  $\geq 6$  was considered as lupus flare-up. Lymphocyte phenotype was also compared between stable disease and lupus flare-up.

**Results:** The number of B cells and CD8 +T cells were not different between SLE patients and healthy subjects; however, non-switched memory (NSwM) B cells was decreased in SLE patients. Double negative (DN) T cells, CD4 +T cells and its subset [naïve, central memory (CM), effector memory (EM) and terminally differentiated effector memory (TEMRA) cells] were decreased in SLE patients compared to healthy controls. Patients with lupus flare-up showed significantly decreased CD4 +and DN T cells, whereas CD4 +EM T cells were increased in patients with lupus flare up, compared to stable SLE. SLEDAI was correlated with DN T cells ( $\rho = -0.728$ ,  $p < 0.001$ ), CD4 +CM T cells ( $\rho = -0.544$ ,  $p = 0.004$ ), CD4 +EM T cells ( $\rho = -0.697$ ,  $p < 0.001$ ) and CD8 +EM T cells ( $\rho = -0.408$ ,  $p = 0.039$ ). Six (23%) patients experienced lupus flare and a patient presented still high disease activity at 6 month follow-up visit. Interestingly, these patients showed the low number of DN T cells, CD4 +EM and TEMRA cells at baseline when they were stable.

**Conclusions:** Biased differentiation of T-cells was associated with lupus flare and aggravation of SLE 6 months later. Understanding T cell subset enables accurate stratification of lupus flare-up and personalised approach.

### A VALIDATION STUDY OF THE PREGNANCY MORBIDITY QUESTIONNAIRE(PMQ) IN WOMEN WITH ANTIPHOSPHOLIPID ANTIBODIES AND PREGNANCY MORBIDITY

K. Schreiber<sup>1,2</sup>, S. Koder<sup>3</sup>, C. Ay<sup>3</sup>, I. Pabinger<sup>3</sup>, S. Jacobsen<sup>2</sup>. <sup>1</sup>Department of Thrombosis and Haemophilia, Guy's and St Thomas' Hospital, London, UK; <sup>2</sup>Copenhagen Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Copenhagen, Denmark; <sup>3</sup>Clinical Division of Haematology and Haemostaseology, Department of Medicine I, Medical University of Vienna, Vienna, Austria

**Background:** The presence of antiphospholipid antibodies (aPL) are associated with pregnancy complications. There is a lack of validated pregnancy

questionnaires to assess previous pregnancy morbidity reliably in aPL positive patients. We therefore designed the pregnancy morbidity questionnaire (PMQ).

**Objectives:** To validate the pregnancy morbidity questionnaire (PMQ) in the prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS) cohort.

**Methods:** The Vienna Lupus Anticoagulant and Thrombosis Study (LATS) is an ongoing, single-centre, biobank-based, prospective observational cohort study enrolling patients (age >18 years) who are persistently positive for lupus anticoagulant (LA) (two positive tests at least 12 weeks apart) with or without a history of thrombosis or pregnancy complications<sup>1</sup>. The cohort currently consists of 150 patients (mean age: 41.3 years, female gender: n = 122 (81.3%), history of thrombosis or pregnancy complications: n = 111 (74.0%)). Of these 150 women, 15 were approached at their follow up visit and invited to fill out the PMQ. The PMQ consists eight questions outlined in table 2.

**Results:** Twelve women agreed to participate, of whom nine had a previous history of pregnancy and/or pregnancy complications. Patient characteristics are shown in table 2. PMQ results are outlined in table 2.

Abstract AB0590 – Table 1

Patient Characteristics (N=9)	
Age at the time of questionnaire, mean (SD, range)	58 (+/-13.6, 25-86)
Years since last pregnancy, mean (SD, range)	35 (+/- 10, 20-58)
Lupus anticoagulant positive only	5 (25%)
Antiphospholipid syndrome	2 (10%)
Pregnancies (N=20)	
Maternal age at pregnancy, mean (SD, range)	24.5 (+/- 4.3, 18-33)
Live-birth rate	17/20 (85%)
Gestational age, weeks (SD, range)	34.8 (+/- 11, <10-24)
Birthweight, kg (SD, range)	3.2 (+/- 0.5, 2.2-4)
aPL related early pregnancy loss (<10 weeks)	2 (10%)
aPL related preterm delivery (<34 weeks)	1 (5%)
aPL related preterm delivery due to placental insufficiency	1 (5%)
Aspirin taken during pregnancy	0 (0%)
Heparin taken during pregnancy	0 (0%)

Key: SD, standard deviation

Abstract AB0590 – Table 2. Pregnancy questionnaire results

	Correct answer, validated against cohort info	Detailed answer, but not captured on cohort entry	Incorrect answer
Q1: Pregnancy date	20 (100%)	0%	0%
Q2: Live birth	20 (100%)	0%	0%
Q3: Gestational age at delivery	9 (45%)	11 (55%)	0%
Q4: Weight at delivery	1 (5%)	19 (95%)	0%
Q5: aPL related pregnancy complications	18 (90%)	0%	2 (10%)
Q6: Aspirin during pregnancy	20 (100%)	0%	0%
Q7: Heparin during pregnancy	20 (100%)	0%	0%
Q8: Other medications during pregnancy	20 (100%)	0%	0%

**Conclusions:** Our aim was to validate the PMQ in the prospective Vienna Lupus Anticoagulant and Thrombosis Study (LATS) cohort. Patients were able to recall their pregnancy history in great detail over a period of more than three decades. Our PMQ may provide a tool to assess previous pregnancy morbidity in patients with antiphospholipid antibodies.

**AB0591 SLE RES PONDER INDEX (SRI) UNDERESTIMATES CLINICAL RESPONSE IN MUSCULOSKELETAL SYSTEMIC LUPUS ERYTHEMATOSUS**

K. Mahmoud<sup>1,2</sup>, A. Zayat<sup>1,2</sup>, M.Y. Md Yusof<sup>1,2</sup>, E. Hensor<sup>1,2</sup>, P.G. Conaghan<sup>1,2</sup>, P. Emery<sup>1,2</sup>, E. Vital<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, University of Leeds; <sup>2</sup>NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, LEEDS, UK

**Background:** Musculoskeletal (MSK) manifestations are common in SLE. Many recent clinical trials were negative or had small benefits vs. placebo. SRI is a common primary endpoint but has not been independently validated. Ultrasound is an objective measure of synovitis validated in inflammatory arthritis.

**Objectives:** To compare the responsiveness of clinical outcome measures with ultrasound in MSK-SLE.

**Methods:** 20 SLE patients meeting SLICC 2012 criteria with inflammatory MSK symptoms were studied with clinical assessment (BILAG2004, SLEDAI-2K over 30 days, patient and physician VAS, symptomatic, tender and swollen joint counts in 28 joints) and MSK ultrasound (grey scale and power Doppler scores, number of abnormal joints) at 0, 2, and 4 weeks after 120 mg IM depomedrone. Change in each variable was measured using Wilcoxon matched pairs and effect sizes ( $r=Z/\sqrt{2N}$ ) compared using Cohen (1988) criteria. Changes were compared for SRI-4 responders and non-responders.

**Results:** All patients were ANA positive, CCP negative and female. At baseline, 15/20 had clinical synovitis. The others had either ultrasound synovitis (GS in 18/20, PD in 17/20) or >60 min EMS. 19/20 patients scored 4 points on SLEDAI for musculoskeletal involvement, BILAG scores were A in 7/20, B in 8/20, and C in 5/20. MSK-SLEDAI score improved in 9/20 at 4 weeks, MSK-BILAG improved in 16/20. For changes, see table 1.

**Abstract AB0591 – Table 1**

		No. pairs	P	Z	Effect Size r	Cohen Criteria

	GS Score	16	0.002	-3.13	-0.571	Large	
	US Joints	16	0.011	-3.160	-0.559	Large	
	PD Score	16	0.002	-3.099	-0.548	Large	
	SymJC	10	0.047	-1.988	-0.445	Medium	
	Pt VAS	16	0.016	-2.409	-0.426	Medium	
	SJC	16	0.059	-1.889	-0.334	Medium	
	TJC	15	0.274	-1.093	-0.200	Small	
	<b>Week 0 – Week 4</b>	PhysVAS	20	<0.001	-3.388	-0.593	Large
		MSK BILAG	20	0.008	-3.643	-0.576	Large
PD Score		20	<0.001	-3.627	-0.573	Large	
US Joints		20	0.001	-3.627	-0.573	Large	
GS Score		20	<0.001	-3.503	-0.554	Large	
MSK-SLEDAI		20	0.003	-3.000	-0.474	Medium	
TJC		20	0.007	-2.683	-0.424	Medium	
SymJC		14	0.010	-2.576	-0.487	Medium	
SJC		20	0.007	-2.425	-0.383	Medium	
PtVAS		20	0.020	-2.331	-0.369	Medium	

19 patients with MSK-SLEDAI=4 at baseline were grouped into SRI-4 responders (n=9) and non-responders (n=10). There were large effect sizes for improvement in TJC and SJC in responders ( $r=-0.505$  and  $-0.492$  respectively) and medium effect sizes in non-responders ( $-0.365$  and  $-0.331$ ). For ultrasound, large effect sizes for improvements in both grey scale and power Doppler were observed in both responders ( $r=-0.517$  and  $-0.564$ ) and non-responders ( $r=-0.629$  and  $-0.596$ ).

**Conclusions:** In MSK-SLE, ultrasound was the variable most consistently sensitive to change. All commonly used clinical variables significantly improved by week 4 but there was variation in responsiveness between them. BILAG-2004 and physician VAS had similar responsiveness to ultrasound. SRI-4 underestimated response, with substantial objective improvements in synovitis in SRI-4 non-responders. Developing organ-specific outcome measures may improve the ability to measure treatment effects in SLE clinical trials.

**AB0592 IMPAIRMENT IN HAND STRENGTH, DEXTERITY AND ACTIVITIES OF DAILY LIVING PERFORMANCE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF A CROSS-SECTIONAL STUDY**

K. Keramiotou<sup>1</sup>, C. Anagnostou<sup>2</sup>, A. Galanos<sup>3</sup>, P. Sfikakis<sup>1</sup>, M.G. Tektonidou<sup>1</sup>.

<sup>1</sup>First Department of Propaedeutic and Internal Medicine, Medical School, National and Kapodistrian University of Athens; <sup>2</sup>General Hospital of Elefsis 'Thrasio';

<sup>3</sup>Medical School, National and Kapodistrian University of Athens, Athens, Greece

**Background:** Systemic lupus erythematosus (SLE) is a prototypic autoimmune disease affecting multiple systems. To date a small number of studies have assessed the hand function and performance of daily activities in SLE<sup>1</sup>.

**Objectives:** To examine the grip and pinch hand strength, the dexterity, and the performance of Activities of Daily Living (ADL) in SLE patients compared with healthy controls.

**Methods:** 197 SLE patients (48,03±12,76, 88,3% female) and 100 healthy controls (47,87±12,77, 86% female), matched by age and gender, were enrolled in the study. Both groups were assessed by hand grip and pinch grip strength, dexterity and ADL performance tests. Hand grip strength was measured by Jamar dynamometer, and pinch grip strength by pinch gauge, in both hands. Dexterity was measured by purdue pegboard test. Disabilities of the Arm, Shoulder and Hand (DASH) questionnaire and Health Assessment Questionnaire (HAQ) were used in order to determine the difficulties in ADLs.

**Results:** Hand grip strength, both lateral and jaws pinch grip strength, and dexterity, were significantly impaired ( $p<0,001$ ) in both hands of SLE patients compared to healthy subjects (table 1). DASH questionnaire (19.78±20.93 vs 2.43±2.9,  $p<0,001$ ) and Health Assessment Questionnaire score (HAQ) (0.41±0.52 vs 0.03±0.52,  $p<0,001$ ) were also significantly different between SLE patients and healthy controls.

**Abstract AB0592 – Table 1**

	Right Hand			Left Hand		
	Patient group	Control group	P value	Patient group	Control group	P value
Grip Strength	25.59 ±9.12	30.89 ±9.00	<0.001	24.54 ±9.80	29.56 ±9.21	<0.001
Tip to tip Pinch Strength	3.94±2.03	4.25±1.66	0.194	3.45±1.73	4.11±1.55	0.002
Lateral Pinch Strength	6.03±2.12	7.24±1.85	<0.001	5.52±1.98	6.66±1.93	<0.001
Jaws Pinch Strength	4.68±1.99	5.86±1.93	<0.001	4.37±1.94	5.62±1.80	<0.001
Purdue Score	13.09 ±2.58	14.28 ±2.58	<0.001	12.42 ±2.16	13.10 ±2.30	<0.001

All values are presented as mean ±SD

**Conclusions:** These findings demonstrate that SLE patients have lower grip, pinch strength and dexterity and more difficulties in ADL performance. These findings underline the need to develop specific hand therapy programs for SLE patients.

### PREDICTORS OF FATIGUE AND SEVERE FATIGUE IN A LARGE MULTICENTER INTERNATIONAL COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: THE FATILUP STUDY

L. Arnaud<sup>1</sup>, P.-E. Gavand<sup>2</sup>, Z. Amoura<sup>3</sup>, G. Blaison<sup>4</sup>, R. Voll<sup>5</sup>, A. Schwartzing<sup>6</sup>, N. Magy Bertrand<sup>7</sup>, F. Maurier<sup>8</sup>, J.-L. Pennaforte<sup>9</sup>, V. Poindron<sup>2</sup>, P. Kieffer<sup>10</sup>, B. Bonnote<sup>11</sup>, H. Lorenz<sup>12</sup>, C. Fiehn<sup>13</sup>, J. Sibilia<sup>1</sup>, T. Martin<sup>2</sup>, on behalf of LBBR working groupe. <sup>1</sup>Rheumatology, <sup>2</sup>Clinical immunology, CHRU Strasbourg, Strasbourg; <sup>3</sup>Clinical immunology, APHP, Paris; <sup>4</sup>Internal medicine, CH Colmar, Colmar, France; <sup>5</sup>rheumatology, uniklinik, Freiburg; <sup>6</sup>Internal medicine, Acura Rheumatology Center Rhineland Palatinate, Bad Kreuznach, Germany; <sup>7</sup>Internal medicine, CHU Besançon, Besançon; <sup>8</sup>Internal Medicine, CH Metz, Metz; <sup>9</sup>Internal Medicine, CHU Reims, Reims; <sup>10</sup>Internal Medicine, CH Mulhouse, Mulhouse; <sup>11</sup>Internal Medicine, CHU Dijon, Dijon, France; <sup>12</sup>University of Heidelberg, Heidelberg; <sup>13</sup>Unit for Rheumatology and Clinical Immunology, Medical Center Baden-Baden, Baden Baden, Germany

**Background:** Fatigue is an important issue in systemic lupus and has a major impact on quality of life of the patients. Data are controversial about the factors associated with this complex symptom.<sup>1</sup>

**Objectives:** To identify the factors associated with fatigue and severe fatigue in patients with systemic lupus erythematosus (SLE) in a large cohort using a multivariate model to precise the importance of each parameter in this multidimensional symptom.

**Methods:** We used the LBBR data base, a German French data base of SLE patients. All patients fulfilled the 1997 ACR criteria for SLE. The Fatigue Scale for Motor and Cognitive Functions (FSMC) was used to assess fatigue and severe fatigue. The depression and anxiety were measured with Hospital Anxiety and Depression Scale (HADS). Tests were performed at sampling.

**Results:** A total of 570 patients were included (89.1% female). The median age was 42 years (QR25–75: 34–52). The median value of the SELENA-SLEDAI was 2 (QR25–75: 0–4) and 136 patients had a SELENA-SLEDAI score >6. Fatigue was reported by 386 patients (67.7%) including severe fatigue by 209 (36.7%). In univariate analysis among the individual components of the SLEDAI arthritis (p=0.003) and oral ulcers (p=0.002) were associated with severe fatigue.

In multivariate analysis fatigue was strongly associated with anxiety (OR: 4.49 [95%CI: 2.60–7.77], p<0.0001) and depression (OR: 4.72 [95%CI: 1.39–16.05, p=0.01]. It was also associated with age at sampling (OR: 1.01 [95%CI: 1.00–1.03, p=0.03] per 1 year increase), SLEDAI (OR: 1.05 [95%CI: 1.00–1.12, p=0.043] per 1 SLEDAI point increase) and glucocorticoids treatment (OR: 1.54 [95%CI: 1.00–2.38, p=0.04]). It was not associated with physical activity.

Severe fatigue was strongly associated with depression (OR:6.87 [95%CI: 3.12–15.11], p<0.0001) and anxiety (OR: 3.80 [95%CI: 2.46–5.87], p<0.0001) but not with SLEDAI or physical activity.

**Conclusions:** Fatigue is a common symptom in SLE patients and is strongly associated with anxiety and depression. While remission remains an important therapeutic target, these manifestations should also be taken care of with psychological counselling and pharmacological intervention, when needed.

### PREVALENCE OF FRAGILITY FRACTURES IN WOMEN WITH SLE, THEIR CONNEXION WITH THE COURSE OF THE DISEASE AND THE NATURE OF PHARMACOTHERAPY

S. Shevchuk, L. Denyschych, E. Shevchuk. *National Pirogov Memorial Medical University, Vinnytsya, Ukraine*

**Background:** Patients with rheumatic diseases are known to have the risk of osteoporosis and fragility fractures, which is significantly higher than in the healthy population. Recent studies demonstrate that age, sex, postmenopausal status, inactivity, glucocorticoid use, nutrition etc. play an important role in the reduction of bone mineral density (BMD) in systemic lupus erythematosus (SLE) patients. The role of the disease severity and the activity of the inflammatory process in the reduction BMD and the incidence of fractures in SLE patients is discursive.

**Objectives:** The aim of the study was to determine the frequency of osteoporosis and fragility fractures in the Ukrainian SLE patients and to establish their connexion with the course of the disease.

**Methods:** The main study group involved 91 women with a diagnosis of SLE according to the American College of Rheumatology criteria. The disease activity was determined using the SLE Disease Activity Index (SLEDAI), and organ damage was measured using the Systemic Lupus International Collaborating Clinics American College of Rheumatology (SLICC/ACR) Damage Index. In all patients the cumulative dose of glucocorticoids was calculated. Serum CRP and IL-6 levels were determined by immunoassay. BMD at the lumbar spine (L1–L4) and femoral neck were measured using dual-energy X-ray absorptiometry. For premenopausal SLE patients BMD by Z-score <−2.0 SD was defined as «below expected range for age». For postmenopausal women osteoporosis was defined by T-score ≤ −2.5 SD, and osteopenia – between −1.0 and −2.5 SD. To determine fractures female SLE patients were examined with x-ray.

**Results:** In premenopausal SLE patients the abnormal BMD of the lumbar spine was found in 9.8%, at the level of the femoral neck it was in 11.1%, in postmenopausal SLE patients – 18.4 and 13.6%, respectively. In the control group there was any premenopausal woman with low bone mass at both sites, whereas among postmenopausal individuals, these were 12.5 and 6.2%, respectively. Osteoporotic fractures were detected in 13 (14.2%) SLE patients, of which 30.7% had hip fractures and 69.3% had vertebral fractures. The reduction of bone strength and fractures were associated with a high damage index. In particular, in persons with fractures it equaled to 4.85±0.65 points, and in persons without fractures – 3.09±0.22 points. A similar tendency was detected by the disease activity SLEDAI. Glucocorticoid use also had a negative effect on the bone strength in patients with SLE. Thus, in women with fractures, the cumulative dose of glucocorticoids defined 60.9±6.63 g, and was by 37.1% higher than in patients without fractures.

**Conclusions:** In patients with SLE the prevalence of low BMD and fragility fractures is high. Progressive loss of the BMD and the occurrence of osteoporotic fractures are closely associated with the severity of organ damage and glucocorticoid use.

AB0595

### ANTIPHOSPHOLIPID SYNDROME (HUGHES SYNDROME) IS A DISEASE WITH PROTEAN FACES: MULTIDISCIPLINARY APPROACHES ON SERBIAN COHORT OF APS PATIENTS

L. Stojanovich, A. Djokovic, N. Stanisavljevic, G. Bogdanovic, M. Zdravkovic. *Internal medicine department, University Hospital Center Bezanijska Kosa, Belgrade, Serbia*

**Background:** Antiphospholipid syndrome (APS) is a systemic autoimmune disease characterised by thrombophilic state and circulating antiphospholipid antibodies (aPL) including anti beta2-GPI.

**Objectives:** Since than it became one of the most systemic conditions. In the last three and half decades, a variety of clinical manifestations involving almost all organs and tissues (cardiac, pulmonary, neurological, renal, cutaneous, hematologic, gastrointestinal, ocular, skeletal and endocrinology), have been described associated with antiphospholipid antibodies (aPL).

**Methods:** Our study comprises a total of 608 patients: 420 primary APS (PAPS) patients and 188 SLE patients with secondary APS (SAPS). aPL analysis included detection of aCL, aβ2GPI, and LA.

**Results:** Thrombosis was diagnosed in 46.5% patients, with higher prevalence in PAPS compared to SAPS patients: 51.2% and 38.3%, respectively, p=0.045. Pseudo-infective endocarditis was observed in 12.8% secondary APS patients and 3.1% in primary APS patients (p=0.004). 30% of the patients with high levels of aCL IgG antibodies had valve thickening and dysfunction, as compared to 4.1% without valve abnormalities (p=0.002). Presence of β2GPI IgG was significantly related to stroke, and overall β2GPI (IgG and IgM) positivity was significantly related to TIA in SAPS patients. Valvular manifestations were significantly related to TIA in both groups of patients and were independent risk factors for TIA in PAPS (OR 3.790 CI 1.597–8.998 p=0.003: table 2). In PAPS, epilepsy correlated with β2GPI-IgM, migraine with aCL-IgM, thrombocytopenia with aCL-IgM, aCL-IgG, anti β2GPI-IgG and LA. Livedo reticularis was more prominent in PAPS with high levels of aCL-IgG. Skin ulcerations were more prevalent in aCL-IgM positive SAPS patients and epilepsy more frequently had high levels of anti β2GPI-IgG in SAPS.

**Conclusions:** In this cross-section analysis of a large cohort of APS patients we analysed that APS patients can be presented with a wide variety of thrombotic

and nonthrombotic manifestations. The key the success is multidisciplinary approach in all time of patient's life. Antiphospholipid syndrome is really a disease with protean faces.

#### AB0596 THE IMMUNE COMPLEXES OF IGG/IGM BOUND TO B-2-GLYCOPROTEIN I ARE ASSOCIATED WITH LIVEDO RETICULARIS, THROMBOCYTOPENIA AND SICCA IN APS PATIENTS

D. Pérez<sup>1</sup>, L. Stojanovich<sup>2</sup>, L. Naranjo<sup>1</sup>, N. Stanisavljevic<sup>2</sup>, G. Bogdanovic<sup>2</sup>, M. Serrano<sup>1</sup>, A. Serrano<sup>1</sup>. <sup>1</sup>*Immunology, Hospital Universitario 12 de Octubre, Madrid, Spain;* <sup>2</sup>*Internal medicine, Bezanjska Kosa<sup>a</sup>, University Medical Center, Belgrado, Serbia*

**Background:** Several manifestations strongly associated with APS have been excluded as classification criteria.<sup>1,2</sup>

**Objectives:** The aim of this study was to investigate correlation between circulating immune-complexes of IgG or IgM antibodies bound to B2GPI (B2G-CIC and B2M-CIC) and clinical manifestations in Serbian cohort of APS patients.

**Methods:** A total of 57 patients with APS were evaluated: 35 with PAPS and 22 patients with SAPS. Mean age was 47.6±1.6 years; 36 (63.2%) were women. All patients have met the 2006 revised Sydney criteria for APS. Quantification of B2G-CIC and B2M-CIC levels was performed as previously, for detect B2G-CIC was used anti-human IgG HRP-conjugate and for B2M-CIC human IgM HRP-conjugate, both from INOVA (INOVA Diagnostics Inc., San Diego, CA, USA).

**Results:** In our cohort Serbian APS patients the prevalence of CIC was 19.29% (11/57); 8 patients with B2M-CIC and the remain 3 patients with B2G-CIC. Livedo reticularis was diagnosed with higher prevalence in patients with CIC compared with patients without CIC; 63.6% and 23.9%, respectively (OR: 5.57, p=0.01). In patients with CIC, thrombocytopenia and leukopenia were more prominent; 54.4% vs 17.4% (OR: 5.70, p=0.01) and 45.5% vs 13.0% (OR: 5.56, p=0.01), respectively. Ophthalmic sicca was more prevalent in patients with CIC; 54.4% vs 8.7% (OR: 12.6, p<0.001). Although complement consumption was more frequent in patients with CIC (figure 1).

Figure 1. Mean levels of C3 (A) and C4 (B) complement in groups. Mean levels of C3 (115.6±9.2 mg/dL and 140.9±4.3 mg/dL, group-1 and group-2 respectively) and mean levels of C4 (140.9±4.3 mg/dL and 30.8±1.6 mg/dL, group-1 and group-2, respectively).

**Conclusions:** B2G-CIC and B2M-CIC are strongly associated with clinical manifestations related to APS. Widening the APS spectrum is indispensable to better understand this syndrome.

#### CHANGES IN THE THYROID HORMONES IN PATIENTS WITH SJOGREN'S SYNDROME IN DOMINICAN REPUBLIC

M. Marte-Robles, R. Jimenez-Candelaria, I. Mercedes-Núñez, E. Tejada-Reyes, R. Muñoz-Louis, V. Rosario, R. Peña-Blanco, T. Valdez-Lorie, R. Alba-Férez. *Rheumatology, Hospital Docente Padre Billini, Santo Domingo, Dominican Republic*

**Background:** Sjogren's syndrome (SS) is an autoimmune chronic where there is a B-cell activation and lymphocytic infiltration of exocrine glands, this can be primary or secondary and characterised by xerostomia, xerophthalmia and extraglandular manifestations<sup>1</sup>. Thyroid involvement is frequent in patients with SS sharing histological and antigenic characteristics<sup>2</sup>. 10–24% of patients with SS have thyroid involvement, the most common are Hashimoto's thyroiditis or Grave's disease are the most frequent autoimmune syndromes. Some reports indicated that Hashimoto's Thyroiditis and Grave's disease has an incidence of 4.2% and 3.4% in the patients with SS respectively. A study showed that in patients with SS 45% had changes in the values of thyroid hormones and 24% autoimmune thyroiditis.<sup>3-5</sup>

**Objectives:** Determine the changes in the thyroid hormones in patients with Sjogren's syndrome.

**Methods:** A cross-sectional study. The information was collected from the digital records of Hospital Docente Padre Billini Rheumatology department during the period October 2017-January 2018. Inclusion criteria: age ≥18 years old, patients with Sjogren's syndrome according to ACR/EULAR 2016 criteria. Excluded patients who did not thyroid test during the study and patients who have a thyroid disorder under treatment. The data was analysed using SPSS V23 Windows 10.

**Results:** 79 cases were reviewed, of which 51 met the inclusion criteria. 98% were women, average age of 45 years, 9.8% had hypothyroidism and 3.9% hyperthyroidism by laboratory tests. 82.3% were euthyroid. 82.3% had anti Ro and anti La, 96% Schirmer test + and 37.2% positive biopsy report for SS.

**Conclusions:** In our study, we found that 9.8% of patients with Sjogren's syndrome could be associated with subclinical hypothyroidism and 3.9% with hyperthyroidism what can mask the clinical manifestations at the time of diagnosis. The screening in high-risk patients such as patients with autoimmune disorders remains important.

#### SIGNIFICANCE OF NON CRITERIA ANTI-PHOSPHOLIPID ANTIBODIES IN THE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS ASSOCIATED WITH ANTIPHOSPHOLIPID SYNDROME

M. Dryglewska<sup>1</sup>, A. Majdan<sup>2</sup>, M. Majdan<sup>1</sup>. <sup>1</sup>*Department of Rheumatology and Connective Tissue Diseases;* <sup>2</sup>*Chair of Oncology, Medical University, Lublin, Poland*

**Background:** Systemic Lupus Erythematosus (SLE) is a chronic inflammatory autoimmune disease in which the uncontrolled activation of the immune system leads to overproduction of autoantibodies (Ab) with different mechanisms of action. Coexistence of anti-phospholipid antibodies (aPL) significantly increases the risk of thromboembolic complications and worsens the clinical course and prognosis of SLE.

**Objectives:** The aim of study was to determine the relationship between the presence of non-criteria aPLs in SLE patients with criteria and non-criteria clinical symptoms of APS.

**Methods:** The study involved 70 (52-female and 18-male) patients treated in the Department of Rheumatology and Connective Tissue Diseases. All patients fulfilled the SLICC classification criteria of SLE. 46/70 pts fulfilled clinical and laboratory criteria of Antiphospholipid Syndrome (I group SLE/APS-46pts) and 24/70 pts (II group SLE/aPL (+) -24) -they had criteria antibodies but did not display clinical criteria symptoms of APS. In the whole study group the mean age was: 38,5±12,9 years (range 18–71), the duration of the disease was 8,3±6,5 years (range 0–37). The presence of Ab was detected in patients' serum using the commercially available tests: aPL-immunodot assay Anti-Phospholipid 10 Dot, for the qualitative detection of IgG or IgM antibodies. Statistical data analysis was performed using Statistica v13.0

**Results:** In the study group of 70 patients we detected the presence of the following aPLs: a-cardiolipin IgM -33,7%, IgG -50%; a-phosphatidic acid IgM -17,5%, IgG -11,2%; a-phosphatidylcholine IgM and IgG -0; a-phosphatidylethanolamine IgM and IgG -0; a-phosphatidylglycerol IgM -4,4%, IgG -10%; a-phosphatidylinositol IgM-11,2%, IgG-10%; a-phosphatidylserine IgM-31,2%, IgG-48,7%; a-annexin V IgM -20%, IgG -10%; a-b2-GP I IgM-33,7%, IgG-30%; a-prothrombin IgM -51,4%, IgG-30%.

The following non-criteria clinical symptoms of APS were present: nephropathy in 27,1%, hypertension-41,1%, livedo reticularis 11,4%, convulsions/chorea-5,7%, thrombocytopenia- 20% of the study group.

No statistically significant differences in the frequency of occurrence of individual non-criteria aPLs, as well as non-criteria clinical symptoms of APS have been found in the examined subgroups of SLE/SAPS and SLE/aPL (+) patients.

**Conclusions:** The prevalence of non-criteria aPLs in SLE and APS pts is similar to pts with SLE with criteria- aPL. Non-criteria clinical symptoms of APS occurred with the same frequency in pts with SLE and APS and in SLE with criteria aPL.

#### AB0599 RELATION BETWEEN THE DEFICIT/DEFICIENCY OF VITAMIN D AND THE DEPRESSION/ANXIETY IN PATIENTS WITH LUPUS IN THE DEPARTMENT OF RHEUMATOLOGY OF THE HOSPITAL OF CLINICS

M.A. Vazquez<sup>1</sup>, N. Ortiz<sup>1</sup>, V. Martínez<sup>1</sup>, L. Roman<sup>1</sup>, K. Bauman<sup>1</sup>, M. Melo<sup>1</sup>, E. Acosta<sup>2</sup>, M. Duarte<sup>1</sup>, I. Acosta Colman<sup>1</sup>. <sup>1</sup>Central, Hospital de Clínicas San Lorenzo; <sup>2</sup>Central, Instituto de Investigación en Ciencias de la Salud San Lorenzo, Asunción, Paraguay

**Background:** It has been postulated that low concentrations of 25-hydroxivitamin D serum [25 (OH) D] is associated with a greater prevalence of depression. People with deficient levels of vitamin D are more likely to experience mood disorders such as depression and anxiety. The vitamin D plays a role in the release of neurotransmitters such as serotonin and dopamine which is why is interesting the study of this in patients with systemic lupus erythematosus, who are discouraged from sun exposure.

**Objectives:** Determine the association between the deficit/insufficiency of vitamin D and the anxiety/depression in patients with SLE of the Department of Rheumatology of the Hospital de Clínicas

**Methods:** Observational study of longitudinal court based in a questionnaire according to the scale HADS (*Hospital anxiety and Depression Scale*) and the dosages of vitamin D performed on patients who entered the LUPUS PY cohort with prior informed consent. The dosage of vitamin D realised by chemiluminescence. Data and samples were taken in week 0 and week 24 and the prevalence of depression and anxiety and its association with vitamin D deficiency and insufficiency were identified. Patients with vitamin D deficiency or insufficiency were supplemented with vitamin D. For the descriptive analysis of the quantitative variables, average and SD were used, for the qualitative frequencies and percentages. For the analysis of association the test  $\chi^2$  was used. The value of the p considered statistically significant was less than 0,05.

**Results:** In relation to the characteristics of the studied cohort, we can see that 90.5% were female, with an average age of 33±10.2 years. At week 0 the average value of vitamin D concentration was 31.8±10.2 ng/ml. It is found that 4,48% of patients had depression and 33,69% of patients have anxiety. In the week 24 the value of the average of vitamin D was of 31,1±13,6 ng/ml. It was observed in this week that 6% of patients presented depression and 12% of patients anxiety. In the analysis of association there was no association between vitamin D deficits and the presence of depression or anxiety of these patients both at the week 0 as a week 24 post vitamin D supplementation such, and as seen in table 1.

**Abstract AB0599 – Table 1.** Deficit and insufficiency of vitamin D associated with the depression and anxiety in patients with SLE.

	Deficit/insufficiency of Vit D	Depression	P value
Week 0	35(47,29%)	3 (4,48%)	0,287
Week 24	33(44,59%)	4 (6%)	0,092
	Deficit/insufficiency of Vit D	Anxiety	P value
Week 0	35(47,29%)	14 (33,69%)	0,287
Week 24	33(44,59%)	8(12%)	0,092

**Conclusions:** A significant percentage of patients with deficient or insufficient vitamin D were found, as well as a considerable percentage had depression or anxiety, although no association was found between the state of this vitamin and the alterations of the studied mood. More studies are required that include more patients in order to obtain more conclusive results.

#### AB0600 RELEVANCE OF OPHTHALMOSCOPIC EVALUATION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: UNDERESTIMATION OF INTRAOCULAR PRESSURE VALUES

M.C.D.F. Salgado<sup>1</sup>, A.D.C. M. Paiva<sup>1</sup>, Y.D.F. B. Chagas<sup>1</sup>, J.L.P. Vaz<sup>1</sup>, F.C. Freire<sup>1</sup>, L.M. Arêas<sup>2</sup>, F.C. Freire<sup>1</sup>, V. Vigneron<sup>1</sup>, Y.D.F. B. Chagas<sup>1</sup>, J.L.P. Vaz<sup>1</sup>, A. Vaz<sup>1</sup>, V. Vigneron<sup>1</sup>. <sup>1</sup>General Medicine; <sup>2</sup>ophthalmology, Federal University of Rio de Janeiro State, Rio De Janeiro, Brazil

**Background:** The evaluation of the size of the optic nerve papilla in ophthalmoscopy is an important tool for the diagnosis of glaucoma in individuals who do not present elevated intraocular pressure (IOP) levels. The calibration of the IOP is performed through Goldmann's tonometry, which consists of flattening the central cornea with a tonometer. Patients with Systemic Lupus Erythematosus (SLE) have circulating autoantibodies and immunocomplexes that alter corneal biomechanics, resulting in underestimated IOP values.

**Objectives:** To evaluate the IOP values and the presence of increased excavation in patients with SLE, reinforcing the importance of ophthalmoscopy in this population.

**Methods:** Descriptive study. Analysis of IOP measurement and papillary excavation of 50 SLE patients.

**Results:** All patients had IOP values within the normal range (8–21 mmHg). In a total of 100 eyes evaluated, four (4%) had increased papillary excavation.

**Conclusions:** Type I collagen is essential for the maintenance of biomechanical parameters and resistance of the cornea. At the corneal level, the activation of the complement system results in the lysis of type I collagen fibres, reducing corneal thickness and resistance. Therefore, IOP values for tonometry will be reduced and underestimated. Comparing the IOP values of SLE patients and healthy volunteers, there are lower results ( $p < 0.001$ ) in lupus patients. In the present study, no patient had IOP changes. However, 4% of the eyes revealed increased excavation. These findings reflect the results of Yazici et al, and reinforce the importance of ophthalmoscopy in the screening of glaucoma in SLE patients.

**AB0601**    **ENTHESES ULTRASONOGRAPHY IN TUNISIAN PRIMARY SJÖGREN'S SYNDROME PATIENTS**

K. Ben Abdelghani, M. Chammakhi, A. Faza, K. Ouenniche, S. Kassab, S. Chekili, A. Lataar. *rheumatology, Mongi Slim Hospital, La Marsa, Tunisia*

**Background:** Primary Sjögren's Syndrome is an auto-immune disease characterised by dryness of the eyes and the oral cavity. Musculoskeletal manifestations are common. However, the underlying mechanism remains often unknown.

**Objectives:** The aim of the current study was to describe subclinical enthesal involvement in patients with Primary Sjögren's Syndrome via ultrasound, to calculate a modified Madrid sonography enthesitis index and to compare it with a group of healthy controls.

**Methods:** The study was conducted in the rheumatology department of Mongi Slim hospital in Tunisia, between June 2015 and December 2017, including 25 patients with Primary Sjögren's Syndrome and 25 healthy sex- and age-matched controls. Cases were defined according to the American-European Consensus Criteria for Sjögren's Syndrome. All the included subjects underwent an enthesal ultrasound exploration (EsaoteMyLab 60 machine and a 13–18 MHz linear array transducer) by a rheumatologist experienced in ultrasound. Five enthesal locations bilaterally (distal Achilles tendon, distal and proximal patellar ligaments, distal quadriceps, and brachial triceps tendons) in each patient were explored. The following elemental lesions of enthesal were evaluated: thickening, presence of calcifications, erosions, enthesophyte, loss of fibrillar pattern and power Doppler signal. The calculated index was compared by Mann-Whitney U test between cases and controls. The significance level was set at 5%.

**Results:** In our study population, the median age was 53.2±11.3 years and the median body mass index was 29.±6.4 kg/m<sup>2</sup>. All included subjects were female. The ultrasound abnormalities in the Primary Sjögren's Syndrome were as follows: erosions in 19.2% of cases, enthesophytes in 16.4% of cases, calcifications in 6% of cases, hypoechogenicity in 2.8% of cases, thickening in 2.4% of cases, power Doppler signal in 1.6% of cases and loss of fibrillar pattern in 1.2% of cases. The total enthesitis index was 4,96±2,59 among cases and 5,72±2,92 among healthy control subjects with no statistically significant difference. Considering each affected enthesal, cases had no significantly higher scores than controls.

**Conclusions:** Our study did not find a significant enthesal involvement among patients with Primary Sjögren's Syndrome that could explain the chronic indefinable pain. The diagnosis of an associated fibromyalgia should be kept in mind.

**Disclosure of Interest:** None declared

**AB0602**    **ANTIPHOSPHOLIPID SYNDROME COMPONENTS IN PATIENTS WITH CORONARY HEART DISEASE**

M. Nazarova<sup>1</sup>, M. Stanislavchuk<sup>2</sup>, L. Burdeina<sup>3</sup>. <sup>1</sup>PhD-student of the internal medicine chair #1; <sup>2</sup>Professor, the head of the internal medicine chair #1; <sup>3</sup>PhD of the internal medicine chair #1, National Pirogov Memorial Medical University, Vinnytsa, Ukraine

**Background:** Antiphospholipid antibodies (aPL), such as anticardiolipin antibodies (aCL), are the immunological markers of the antiphospholipid syndrome (APS).<sup>1</sup> The aPL are found in association with venous and/or arterial thrombosis. Myocardial infarction (MI) is usually related to atherosclerosis and thrombosis of coronary arteries.<sup>2</sup> The clinical significance of aPL in MI, however, has not yet been well established.

**Objectives:** To evaluate the presence and levels of aPL in patients with history MI.

**Methods:** 50 patients (100% male) with average age 49.5±6.09 (M±SD) years with history of MI were examined. Serum IgG aPL (anti-cardiolipin, -phosphatidylserine, phosphatidylinositol, -phosphatidylacetate) were determined by enzyme-linked immunosorbent assay (ELSSA).

**Results:** IgG isotype aPL were detected in 26 (52%) patients with the history of MI and 24 patients were negative.

The average age (M±SD) of aPL positive patients was 44.1±5.00 years and of aPL negative patients was 47.7±4.83 years (p<0.01). The difference comprises more than 3,5 years.

Patients with recurrent MI (two and more) had higher level of IgG aPL, then patients with one MI (18,0±7,53 v.s. 11,5±4,21 GPL-U/ml). The difference is significant (p<0.05).

**Conclusions:** Determined younger age of the first MI in aPL positive patients and higher level of IgG aPL in patients with recurrent MI indicate the possible involvement of the autoimmune factor in the pathogenesis of MI. This proves the necessity for further research in this direction.

**AB0603**    **FRAGMENTED QRS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RELATION TO THE DISEASE ACTIVITY: A CROSS-SECTIONAL STUDY**

M. Hosonuma, N. Yajima. *Division of Rheumatology, Department of Medicine, Showa University School of Medicine, Tokyo, Japan*

**Background:** Cardiovascular disease is an important contributor to mortality in Systemic Lupus Erythematosus (SLE)<sup>1</sup>. Fragmented QRS (fQRS) is an easily evaluated non-invasive electrocardiographic parameter defined as additional spikes within the QRS complex<sup>2</sup>. fQRS can represent conduction disturbance and a predictor of cardiac events<sup>3</sup>. Even in a patient with SLE, it has reported that the prevalence of fQRS appears to be higher than in controls<sup>4</sup>. However, no clinical studies have investigated the prevalence at the time of diagnosis. In addition, there is no report that examined the association of disease activity of SLE and fQRS.

**Objectives:** This study aimed to assess the relationship between disease activity of SLE and fQRS in Japanese SLE patients at the time of diagnosis. We hypothesised that the frequency of fQRS on ECGs would be greater in SLE patients with high disease activity.

**Methods:** The study design was a cross-sectional study. The participants were SLE patients who diagnosed at Showa University Hospital and Showa University Koto Toyosu Hospital from January 2010 to December 2017. The participants who satisfied American College of Rheumatology (ACR) criteria were included. The patients with already treatment at the time of an ECG measurement, cardiovascular disease, history of arrhythmia, cardiomyopathy, rheumatoid arthritis, systemic sclerosis were excluded. The exposure was the appearance of fQRS. The primary outcome was Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2K). The secondary outcomes were the complement level, the ds-DNA antibody level and the organ involvement. In the main analysis, a multiple regression analysis was conducted to assess the association between fQRS and SLE activity adjusted for age, sex and period from the estimated date of onset to the date of diagnosis. In the secondary analysis, a multiple regression analysis was conducted to analysis the association between fQRS and the serological activity of SLE (the complement level, the ds-DNA antibody level) and the organ involvement under the same conditions as above.

**Results:** In total, 45 participants were enrolled. The mean age was 42.3 years, and 37 (82%) were female. The median SLEDAI-2K was 14 [IQR, 10 to 20]. The median period from the estimated date of onset to the date of diagnosis was 3 months [IQR, 2 to 14.5]. 25 patients (56%) had fQRS. In the main analysis, the regression coefficients [95% CI] of fQRS for SLEDAI were 2.99 [ 1.15 to 4.84, p=0.002 ] with reference to non-fQRS. In the secondary analysis, there were no significant associations between fQRS and the blood test or the organ involvement.

**Abstract AB0603 – Figure 1**

**Conclusions:** Our results demonstrated that the frequency of fQRS on ECGs would be greater in SLE patients with high disease activity.

#### INITIAL CLINICAL AND IMMUNOLOGICAL FACTORS ASSOCIATED WITH MANIFESTATIONS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME: A SINGLE CENTRE RETROSPECTIVE STUDY

M. Tsukamoto<sup>1,2</sup>, K. Suzuki<sup>1</sup>, T. Takeuchi<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; <sup>2</sup>Department of Rheumatology, National Tokyo Medical Center, Tokyo, Japan

**Background:** Primary Sjögren's syndrome (pSS) is a prototypical systemic autoimmune disease that manifests various signs and symptoms. Although a few studies have focused on these manifestations over the long term,<sup>1,2</sup> the association of initial clinical and immunological factors with subsequent longer-term manifestations has not been fully elucidated.

**Objectives:** To identify initial clinical and immunological factors associated with manifestations in patients with pSS.

**Methods:** A retrospective review was performed on pSS patients followed over a 10 year period at our department. Clinical and immunological data, including levels of serum immunoglobulin (Ig) and autoantibodies, were collected and statistically analysed.

**Results:** A total of 224 patients diagnosed with pSS who had met the classification criteria<sup>3</sup> were enrolled. Among them, 201 patients were diagnosed with pSS at our hospital. Of these, we followed the 91 patients who continued to visit our hospital over 10 years. Of the other 110 patients, 69 suddenly interrupted treatment, 20 visited different hospitals, and 13 interrupted treatment at our department and visited dentistry or ophthalmology departments. During observation, 7 patients were newly diagnosed with rheumatoid arthritis in addition to SS and one patient died.

We then analysed the 91 patients who continued to visit. Of these, 88 were female and 3 were males. Average age was 52 years. 72 and 33 patients had anti-SS-A antibody and rheumatoid factor (RF). 82, 68 and 7 patients had neutropenia, anaemia and thrombocytopenia, respectively. 15% of patients used corticosteroid and/or immunosuppressant treatment. 10% of patients took traditional Chinese medicine. On follow-up for 10 years, titers of IgG, A and M were significantly decreased, whereas complement levels were elevated. The proportion of patients with extraglandular involvement decreased from 90% to 73%, whereas 14% of patients had new extraglandular organ involvement. The frequency of extraglandular involvement at 10 years was high in patients with hyper IgG at the initial test (39% vs 85%,  $p < 0.01$ ). The frequency of extraglandular organ involvement at 10 years was high in patients who were RF-positive at diagnosis (3% vs 15%,  $p < 0.05$ ). 9% of patients developed malignancies. 29% of patients without RF at the initial test had RF during the 10 years observation. The presence of dry eyes or mouth findings did not change during follow-up in pSS patients.

We then created a multivariate model of predictors for malignancies, extraglandular involvement and extraglandular organ involvement with possible variables at diagnosis. Age, anti-centromere antibody, hyper IgG and anaemia were identified to be significant variables associated with malignancies. Extraglandular involvement was associated with the presence of hyper IgG ( $p < 0.01$ ), and extraglandular organ involvement was associated with RF positivity ( $p < 0.05$ ).

**Conclusions:** Our study newly identified initial clinical and immunological factors associated with manifestations in patients with pSS over a long period. pSS patients with RF and hyper IgG at diagnosis were candidates for the development of extraglandular involvements in the future.

#### PROCALCITONIN MIGHT BE USED FOR DISCRIMINATING INFECTIONS FROM INCREASED DISEASE ACTIVITY IN PRIMARY SJÖGREN SYNDROME

B. Arican Tarim<sup>1</sup>, M.E. Tezcan<sup>2</sup>, A. Orcun<sup>3</sup>, O. Keskin<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Rheumatology; <sup>3</sup>Biochemistry, University of Health Sciences, Kartal Training and Research Hospital, Istanbul, Turkey

**Background:** Procalcitonin is a polypeptide which is secreted as a response to bacterial stimulus and accepted as an early and sensitive marker of infection. In healthy subjects procalcitonin should be  $< 0.1$  ng/mL. In case of infection it may rise over 0.5 ng/mL. Its level in inflammatory diseases usually does not reach to such high levels as in infections. Differentiating infection and disease activation may be confusing in autoimmune diseases. For this purpose, there were several studies that evaluated the role of procalcitonin for excluding infection on suspicion of increased autoimmune disease activity.<sup>2</sup>

**Objectives:** As far as we know, there is no study in literature that evaluated procalcitonin levels in patients with primary Sjögren's syndrome (pSS). Our aim is to evaluate procalcitonin levels in pSS and determine whether we can use it as a marker to differentiate infection from disease activation.

**Methods:** The following two groups of patients were included in the study: Forty-eight patients with pSS, who met ACR<sup>2012</sup> Classification Criteria for Sjögren's Syndrome; and fifty-three subjects as control group who have no chronic diseases. Patients with possible infection were excluded according to their clinical evaluation and laboratory data. Then, serum procalcitonin levels were compared between the groups. Finally, we evaluated the correlation between disease activity, measured by Sjögren's syndrome disease activity index (SSDAI) and procalcitonin levels.

**Results:** Procalcitonin levels in pSS group were found statistically higher than control group, whereas it was still in normal ranges ( $p < 0.01$ ). Furthermore, no correlation was found between disease activation and the procalcitonin levels ( $p = 0.63$ ).

**Abstract AB0605 – Table 1.** Demographic properties and Laboratory results of the subjects

	Sjögren (n=48)	Control (n=53)	p
Gender(M/F)	3/45	2/51	0.66
Age	53,50 (48,50–58,75)	50,00 (43,50–55,00)	0.04
Sedimentation (mm)	22,00 (12,00–31,75)	18,00 (11,00–27,00)	0.13
CRP (mg/dl)	3,27 (3,27–3,27)	3,27 (3,16–3,27)	0,16
SSDAI score	1,00 (1,00–2,00)	N/A	
Procalcitonin(ng/ml)	0,036 (0,031–0,044)	0,020 (0,020–0,020)	<b>&lt;0,01</b>
Haemoglobin (gr/dl)	12,50 (11,65–13,50)	12,80 (11,95–13,50)	0,82
Thrombocyte( $10^3$ / $uL$ )	231,00 (189,50–278,00)	265,00 (226,5–304,50)	<b>0,02</b>
WBC (/uL)	6000,00 (5400,00–7200,00)	6700,00 (5450,00–8000,00)	0,15
Creatinine (mg/dl)	0,66 (0,59–0,76)	0,57 (0,52–0,62)	<b>&lt;0,01</b>
ALT (U/L)	18,5 (13,25–25,00)	18,00 (13,50–25,00)	0,74
AST(U/L)	22,50 (19,00–25,00)	21,00 (17,50–25,50)	0,30

Statistically significant P values were shown bold. Numerical variables were summarised by median [interquartile range]

**Conclusions:** Procalcitonin levels were found higher in pSS patients. But, none of the patients had clinically significant increase in procalcitonin. We thought that with careful clinical evaluation, procalcitonin would be an indicator for differentiating infection from disease activation in pSS patients.

**AB0606 NEUROPSYCHIATRIC LUPUS IN A SAMPLE OF EGYPTIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: PREVALENCE AND CLINICAL CHARACTERISTICS**

M. Eissa, B.M. Medhat, A. Moghazy. *Department of rheumatology and rehabilitation, Cairo University, Cairo, Egypt*

**Background:** Neuropsychiatric (NP) lupus is common among patient with systemic lupus erythematosus (SLE). It occurs in about 30%–56% of all SLE patients. However, the diagnosis of neuropsychiatric SLE (NPSLE) remains difficult. Neuropsychiatric lupus (NPL) can present with a wide variety of clinical manifestations.

**Objectives:** The aim is to determine prevalence of NPSLE among a sample of Egyptian SLE patients from a single centre and to describe its features and characteristics.

**Methods:** The study included 301 adult SLE patients from Cairo University Hospital. The patients are classified according to the Systemic Lupus International Collaborative Clinics (SLICC) criteria for SLE. Neuropsychiatric manifestations were recorded using the ACR NPSLE nomenclature and case definitions (1999) Global disease activity was quantified by the SLE Disease Activity Index 2000 (SLEDAI-2K) at first and at last visit of the patient. Systemic Lupus International Collaborative Clinics/ACR Damage Index (SLICC/ACR-DI) was used to measure damage. The period of data collection took 4 months. The collected data included demographic, clinical, serologic data and medications.

**Results:** 301 SLE patients (87.4%) females and (12.6%) males with mean age 30.7±9.2 years and disease duration 72 months (2–288) were included. 101 (33.5%) were diagnosed as having NPSLE. The highest NP manifestation in frequency is headache (55.4%) followed by psychosis (33.7%) then seizures (21.8%). NP manifestation is the onset of the disease in 42.6% of all NPSLE patients. Compared to non-NPSLE group, NPSLE group is significantly older at onset of disease and have longer disease duration ( $p<0.05$ ). They are significantly more active at the onset of the disease than non-NPSLE and have significantly more disease damage ( $p<0.05$ ). Regarding clinical manifestations of lupus; NPSLE are significantly higher in frequency of discoid rash, cutaneous vasculitis, serositis, secondary anti-phospholipid syndrome (APS), associated avascular necrosis of the joints and osteoporosis ( $p<0.05$ ). Anti-cardiolipin IgM antibodies are significantly more frequent in NPSLE group ( $p<0.05$ ). Notably, frequency of psychosis, superior sagittal thrombosis and cerebrovascular disease were significantly higher in NPSLE with positive APS than those with negative APS ( $p<0.05$ ).

**Conclusions:** NPL is common in SLE, its prevalence is about 30% in Egyptian SLE patients. NPSLE patients may present diverse clinical manifestations most commonly headache, psychosis and seizures. NPL is different from non-NPL and presence of APS has an impact on clinical presentation of NP involvement in the patients.

**Disclosure of Interest:** None declared

**AB0607 CLINICAL PROFILE OF FILIPINO PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

A.-T.M. Santiago<sup>1</sup>, M. Tee<sup>1</sup>, C. Tee<sup>2</sup>. <sup>1</sup>*IM-Rheumatology*, <sup>2</sup>*Pediatric Rheumatology, University of the Philippines Philippine General Hospital, Manila, Philippines*

**Objectives:** To determine the clinical profile of Filipino SLE patients as determined using the 2012 Systemic Lupus Collaborating Clinics (SLICC) criteria.

**Methods:** We checked which among the SLICC criteria were fulfilled by Filipino SLE patient when we examined them and their case records, as part of a nationwide genetic study on SLE conducted from October 2015 to March 2017.

**Results:** Two hundred twenty-five patients who were diagnosed to have SLE after 18 years of age were evaluated. The mean age of the population at the time of evaluation was 37.76 years.

Females comprised 98% of our population. Mean age of onset was 30.68-year-old, while the mean age at diagnosis was 31.52-year-old. Acute cutaneous rash was found in 82%; arthritis

80%; non-scarring alopecia 65%; oral ulcers 52%; renal disorder 41%; chronic cutaneous rash in

28%; leukopenia 23%; hemolytic anaemia 17%; thrombocytopenia 16%; serositis 13%; and neurologic disorder 6%. Anti-nuclear antibody was present in 88%; low complement 33%; antidsDNA in 29%; direct Coombs' 4%; antiphospholipid antibody 2%; and anti-Smith antibody in

2%. Kidney biopsy was performed in only 6% (15/225) of patients, 33% of whom had Class IV histopathologic results.

**Conclusions:** Filipino SLE patients typically present with acute cutaneous rash, arthritis, non-scarring alopecia and oral sores. Renal disorder, hematologic and

neurologic manifestations are found to be less common among them. Finally, it was noted that renal biopsy is not commonly performed among these patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrhumdis-2018-eular.6108

**AB0608 CLINICAL PROFILE OF FILIPINO PAEDIATRIC PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

A.-T.M. Santiago<sup>1</sup>, M. Tee<sup>1</sup>, C. Tee<sup>2</sup>. <sup>1</sup>*IM-Rheumatology*, <sup>2</sup>*Pediatric Rheumatology, University of the Philippines Philippine General Hospital, Manila, Philippines*

**Background:** The clinical profile of paediatric SLE patients may present differently from that of adults.

**Objectives:** To determine the clinical profile of Filipino paediatric SLE patients as determined using the 2012 Systemic Lupus Collaborating Clinics (SLICC) criteria.

**Methods:** We checked which among the SLICC criteria were fulfilled by Filipino paediatric SLE patient when we examined them and their case records, as part of a nationwide genetic study on SLE conducted from October 2015 to March 2017.

**Results:** Ninety-eight who were diagnosed to have SLE before 18 years of age were evaluated.

The mean age of the population at the time of evaluation was 19.77 years. Females comprised

94% of our population. Mean age of onset was 14.42-year-old, while the mean age of diagnosis was at 14.58-year-old. Acute cutaneous rash was found in 87%; oral ulcers 65%; renal disorder

65%; non-scarring alopecia 61%; arthritis 58%; chronic cutaneous rash in 37%; leukopenia 36%; hemolytic anaemia 34%; serositis 24%; thrombocytopenia 22% and neurologic disorder 8%.

Anti-nuclear antibody was present in 88%; low complement 33%; anti-dsDNA in 28%; direct

Coombs' 16%; antiphospholipid antibody 3%; and anti-Smith antibody in 1%. Kidney biopsy was performed in only 14% (15/104) of patients, of whom 27% had class III histopathologic characteristic.

**Conclusions:** Filipino paediatric SLE patients typically present with cutaneous, mucocutaneous renal and musculoskeletal involvement. Hematologic and neurologic manifestations are found to be less common among them. Finally, it was noted that renal biopsy is not commonly performed among these patients.

**AB0609 CORRELATION BETWEEN PLASMA LIPOPROTEIN PHOSPHOLIPASE A2 (LP-PLA2) AND ANTI PHOSPHOLIPID ANTIBODY (APL-AB) IN PATIENTS WITH CONNECTIVE TISSUE DISEASES**

M. Yang, Z. Lin, X. Zhang, Q. Lv, Y. Zhang, Y. Jiang, Z. Liao, J. Gu. *Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** Plasma Lp-PLA2 has both anti-inflammatory and pro-inflammatory activity in vascular-related pathologies and is an independent risk predictor for coronary heart disease and stroke because of its important role in atherosclerosis and thrombosis. However, vasculitis is a common pathological feature of connective tissue disease.

**Objectives:** Therefore, the aim of this study was to investigate the association of plasma Lp-PLA2 level with antinuclear antibody (ANA) titer, karyotype, anti-cardiolipid antibody (ACA) and anti-β2GP1 antibody and lupus anticoagulant (LA, including PT-IgG and PT-IgM).

**Methods:** Outpatient and inpatient with connective tissue diseases from Department of Rheumatology of the Third Affiliated Hospital of Sun Yat-sen University from 2015 to 2016 were randomly selected. Venous blood was collected, plasma Lp-PLA2 level was measured by Elisa method. ANA titer and karyotype were detected by indirect immunofluorescence assay. ACA, anti-β2GP1 antibody, PT-IgG and PT-IgM were detected by Elisa method. SPSS23.0 statistical software was used for statistical analysis.

**Results:** A total of 176 patients with connective tissue disease including 38 males (21.59%) and 138 females (78.41%) were enrolled in this study, and the average age was 42.22±17.31 years. The mean plasma level of Lp-PLA2 was (363.96±203.19 ng/ml). There was no significant difference in Lp-PLA2 level between different genders ( $p=0.072$ ), and LP-PLA2 level have no correlation with age ( $p=0.098$ ). The ANA titers were classified as negative (35.80%), weakly positive 1: 100 (11.93%), positive 1: 100 (18.75%), positive 1: 320 (12.50%), positive 1: 1000 and positive 1: 3200 (9.66%). There was no significant difference in plasma Lp-PLA2 level between different titers of ANA ( $p=0.088$ ). ANA karyotypes

included nucleolus type (0.88%), centromere type (3.54%), cytoplasm type (7.96%), homogeneity (29.20%) and granularity (58.41%). Also, there was no significant difference in plasma Lp-PLA2 level between different karyotypes ( $p=0.153$ ). The average level of ACA was  $12.88\pm 23.87$  RU/ml and there was no significant correlation between plasma Lp-PLA2 level and ACA level ( $p=0.839$ ). Anti- $\beta$ 2GP1 antibodies were classified as negative ( $<20$  U/ml, 91.48%) and positive ( $\geq 20$  U/ml, 8.52%). Plasma Lp-PLA2 level did not differ significantly between anti- $\beta$ 2GP1 antibody negative and positive patients ( $p=0.449$ ). Lupus anticoagulant PT-IgG and PT-IgM were classified as negative ( $<18$  U/ml) and positive ( $>18$  U/ml). PT-IgM were all negative and there was no significant difference in plasma Lp-PLA2 level between PT-IgG negative (96.59%) and positive (3.41%) patients ( $p=0.279$ ).

**Conclusions:** Plasma Lp-PLA2 level in patients with connective tissue disease have no significant correlation with age, gender, ANA titer, karyotype, ACA, anti- $\beta$ 2GP1 antibody and LA. The role of plasma Lp-PLA2 in connective tissue disease may be different from APL-Ab.

AB0610

#### CORRELATION BETWEEN TRADITIONAL CARDIOVASCULAR RISK INDEXES AND ARTERIAL STIFFNESS IN PATIENTS WITH GENERALISED LUPUS ERYTHEMATOSUS

M. Vázquez-Del Mercado<sup>1,2</sup>, A. Llamas García<sup>1</sup>, A. Coldivar-Gabriel<sup>2</sup>, E. Gomez-Bañuelos<sup>1</sup>, D.A. Victoria-Ríos<sup>1</sup>, J.I. Lopez-Blasi<sup>1</sup>, K.I. Arrona-Ríos<sup>1</sup>, F.D.J. Perez-Vazquez<sup>2</sup>, G. Diaz-Rubio<sup>2</sup>, F. Grover-Páez<sup>3</sup>. <sup>1</sup>Servicio de Reumatología 004086 PNPC CONACYT, Hospital Civil de Guadalajara Dr. Juan I. Menchaca; <sup>2</sup>Instituto de Investigación en Reumatología y del Sistema Músculo Esquelético; <sup>3</sup>Instituto de Terapéutica Experimental y Clínica, Universidad de Guadalajara, Guadalajara, Mexico

**Background:** Cardiovascular disease (CVD) is the leading cause of late death in patients with systemic lupus erythematosus (SLE). SLE is related with up to 50 fold risk of CVD. SLE is recognised as an independent cardiovascular risk factor (CVR). However, traditional scales underestimates the CVR in SLE.

**Objectives:** Determine the correlation between traditional CVR scores (Framingham, systematic coronary risk evaluation (SCORE), arteriosclerotic cardiovascular disease (ASCVD) and arterial stiffness (AS) in an open population of SLE, assessing AS by pulse wave velocity (PWV), vascular damage through cardio-ankle vascular index (CAVI), ankle-brachial index (ABI), quality intima media thickness (qIMT) and SLE disease activity using the systemic lupus erythematosus disease activity index (SLEDAI) and systemic lupus international collaborating clinics (SLICC).

**Methods:** Patients with SLE of 18 years old and older, diagnosed according to SLICC 2012 criteria. Informed written consent. AS was determined by PWV, CAVI, ABI, and qIMT. Disease activity was recorded by SLEDAI and SLICC. Comparison between qualitative variables will be done through the X2 test or the Fisher exact test. For comparison of the quantitative variables with normal distribution Student's T and ANOVA tests were done. The correlation coefficient (r) of Pearson was calculated. Variables with a  $p\leq 0.2$  value were included in a multiple linear regression model to evaluate the influence of the disease variables on CVR. SPSS v.22 software (IBM, inc) and the Graphpad V software were used.

**Results:** The total of SLE patient were 44 (100%), with a mean age of  $34\pm 12$  years old. Thirty six women (82%). The mean evolution time was  $6\pm 5$  years. Smoke was registered in 16% (7 cases). Systolic blood pressure  $110\pm 14$ , diastolic blood pressure  $73\pm 11$  mmHg. Body mass index  $28.4\pm 9.1$ , total cholesterol  $186\pm 47$ , triglycerides  $143\pm 67$ , cHDL  $42.9\pm 5.1$ , cLDL  $57\pm 27$  mg/dL. Erythrocyte sedimentation rate of  $17\pm 14$  mm/hr, cReactive protein  $7.1\pm 4.8$  mg/L. Anti-dsDNA antibodies were present in 47.7% of the cases.<sup>21</sup> Secondary antiphospholipid syndrome in 13.6%.<sup>6</sup> Mean SLEDAI 8 (range 0–32), mean SLICC 1 (range 0–6). C3 levels  $83.6\pm 21.4$ , C4  $19.5\pm 18.8$  mg/dL. The most important correlations found were with qIMT and age 0.651 ( $<0.001$ ), BMI 0.513 ( $p 0.001$ ), cRp 0.351 (0.033), cLDL 0.400 (0.01). Framingham score was able to predict CVR up to 44.8% the measurement of PWV, ASCVD in 30% and SCORE up to 22%.

**Conclusions:** Traditional scores (Framingham, SCORE, ASCVD) underestimate cardiovascular risk in patients with SLE. The most important finding is that qIMT was able to correlate more than age, to BMI and cLDL in SLE patients.

AB0611

#### DISEASE ACTIVITY AND ORGAN DAMAGE IN PATIENT WITH CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS, FROM CHILDHOOD TO ADULTHOOD: A RETROSPECTIVE STUDY OVER THE LAST 25 YEARS

E. Hosticka<sup>1</sup>, M. Novoselec<sup>1</sup>, M. Sestan<sup>1</sup>, N. Cekada<sup>1</sup>, M. Frkovic<sup>1</sup>, I. Padjen<sup>2</sup>, M. Sentic<sup>2</sup>, B. Anic<sup>2</sup>, M. Jelusic<sup>1</sup>. <sup>1</sup>Department of Paediatrics; <sup>2</sup>Department of Internal Medicine, University Hospital Centre Zagreb, University of Zagreb School of Medicine, Zagreb, Croatia

**Background:** Although clinical symptoms and immunological findings are common in both children and adults with systemic lupus erythematosus (SLE), children generally have a more severe clinical presentation at the time of diagnosis with a larger number of affected organs, a much more aggressive clinical course and greater chance of developing organ damage over time.

**Objectives:** To compare the SLEDAI-2K disease activity index in patients with SLE at the time of diagnosis with SLEDAI-2K in the same patients in adulthood and to compare of the SLICC/ACR damage index (SDI) in patients with cSLE at the last follow up in childhood with SLICC/ACR of the same patients in adulthood.

**Methods:** This retrospective study included children who were diagnosed with cSLE, according to the ACR 1997 and SLICC 2012 criteria, in the period from 1991–2016 at the Referral Centre for Paediatric and Adolescent Rheumatology Republic of Croatia, Department of Paediatrics, University Hospital Centre Zagreb and who by the end of March 2017 reached the age of majority at 18 and continued their treatment at the Department of Internal Medicine, University Hospital Centre Zagreb.

**Results:** Out of 95 children with cSLE, 48 patients (42 females and 6 males) who attained the age of majority, were included in the study. Mean age at the time of diagnosis was 13.5 years (range 6–18), and the mean disease duration was 11 years. Mean SLEDAI-2K was 19,25 (range 0–42) in childhood and 7125 (range 0–30) in adulthood. In adulthood, thirty-two patients (66.67%) showed improvement, three (6.25%) disease progression, six (12.5%) had the same disease activity and seven patients (14.58%) were in remission. 13 children (27%) had organ damage at the last follow up with mean SDI 0.43 (0–6) and 20 patients in adulthood (41.67%) had organ damage with SDI 0.75 (0–6). Cataract, erosive arthritis and avascular necrosis were the most common organ damage in both groups. The most common presenting symptoms in childhood were musculoskeletal (predominantly arthritis) occurring in 34 children (70.83%), mucocutaneous (rash) noted in 31 (64.58%) and fever in 21 patients (43.75%). Of different laboratory tests the most common were positive antinuclear antibodies (ANA) screen (95.83%) and hypocomplementaemia (75%). Proteinuria was noticed in 26 children (54.17%). Similarly, in adulthood the most common symptoms were arthritis in 10 (20.83%) and rash in 8 patients (16.67%). Alopecia, headaches and visual disturbances were represented with 12.5% each. ANA screen was positive in 27 patients (56.25%) and hypocomplementaemia present in 22 patients (45.83%).

**Conclusions:** At the time of diagnosis in childhood, disease activity is very high while in adulthood there is a significant decrease in disease activity. Higher disease activity in childhood is related to the development of the organ damage in adulthood.

### INFRINGEMENT OF THE BLOOD LIPID SPECTRUM IN CHILDREN AND ADOLESCENTS WITH SLE AND THEIR PREDICTIVE VALUE FOR THE FURTHER COURSE OF THE DISEASE

N.S. Shevchenko<sup>1,2</sup>, L.F. Bogmat<sup>2,3</sup>, I.M. Bessonova<sup>2,3</sup>, V.V. Nikonova<sup>2</sup>.

<sup>1</sup>department of pediatrics No2, V. N. Karazin Kharkiv National University,

<sup>2</sup>department of cardiorheumatology, Institute of Children and Adolescents Health Care; <sup>3</sup>department of pediatrics, V. N. Karazin Kharkiv National University, Kharkiv, Ukraine

**Background:** Infringements of the lipid blood spectrum, or so-called dyslipidemia, are common in adults suffering from SLE and ranges from 36% to 60%.<sup>1</sup> Many researchers confirmed the accelerated development of atherosclerosis among patients and high risk of epy cardiovascular complications with deterioration of life expectancy. However, the role of prolonged storage of dyslipidemia and subclinical signs of hypercoagulability on the course of the disease is unspecified.

**Objectives:** The aim of the study was to clarify the prognostic importance of the role of storage of metabolic shifts in children with SLE on the background of treatment for the course of the disease.

**Methods:** A total of 35 people aged 7–18 years with SLE who were ill for more than one year and received complex therapy with glucocorticoids and immunosuppressive drugs were examined. The average age of the patients was 173.56 ± 4.17 months; the total duration of the disease was 48.45 ± 3.18 months. General clinical trials included the complex included autoantibodies, disease activity, drugs. Total cholesterol (TCh), triglycerides (TG), high density lipoprotein cholesterol, low-density lipoprotein cholesterol, apolipoprotein B, ApoA-I and lipoprotein- $\alpha$  were evaluated. The state of the blood coagulation system was also studied: fibrinogen of the blood, prothrombin index, thrombin time, active partial thrombin time, d-dimer, international normalised ratio.

**Results:** The presence of atherogenic dislipoproteinemia in 60.0% of ill children and adolescents on SLE in children and adolescents, disorders in the system of hemostasis in 25.0% was established.

The data on the presence of interconnection of blood triglycerides with glomerular filtration rate ( $r = -0.892$ ;  $p < 0.05$ ) and activity of transaminases (alanine transaminase) ( $r = 0.848$ ;  $p < 0.05$ ).

As a result of multiple regression analysis with step-by-step exclusion of minor variables, serum creatinine serum levels in patients with SLE depend on the level of TG of blood with high predictive accuracy: blood creatinine = 0.0672684 + 0.0127034 \* TG;  $R = 69.79\%$ ;  $R^2 = 62.34\%$ ;  $p < 0.05$ .

A multivariable regression analysis also proved that the level of circulating immune complexes in patients with SFV significantly depends on the level of total cholesterol, complement and TG by the formula:  $CIC = 1.44278 + 0.188976 * TCh - 1.51503 * complement + 0.35538 * TG$ ;  $R = 94.25\%$ ;  $R^2 = 90.02\%$ ;  $p < 0.01$ .

The mean indices of state of the blood coagulation system indices for children and adolescents with SLE and signs of dyslipidemia were within the norm except for fibrinogen (2.76 ± 0.29 g/L in the presence of dyslipidemia against 3.72 ± 0.46 g/L in patients with dyslipidemia,  $p < 0.05$ ). Its increase persisted in 27.78% of patients.

**Conclusions:** Thus, violations in the lipid spectrum of blood are often formed in children and adolescents on the background of SLE with the duration of the disease for more than one year. They are not only a risk factor for atherosclerotic lesions; they are also a factor in maintaining the activity of the disease and the development of sustained kidney damage.

### CLINICAL AND SEROLOGICAL CHARACTERISTICS OF LUPUS ENTERITIS AND ITS PROGNOSTIC FACTORS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

N. Kajio, Y. Kaneko, R. Anan, J. Kikuchi, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Lupus enteritis, known as mesenteric vasculitis including multiple ulcers or ischaemic colitis, and protein-losing enteropathy, is a potentially life-threatening complication of systemic lupus erythematosus (SLE). Although glucocorticoid therapy is usually effective, some patients experience recurrences or severe complications in that surgical treatment or intensive immunosuppressive therapy is required. Little evidence, however, is available with characteristics and prognostic factors of lupus enteritis.

**Objectives:** The aim of this study is to clarify clinical characteristics and associated factors for the prognosis with lupus enteritis.

**Methods:** Consecutive SLE patients in our hospital between 2009 and 2017 were retrospectively reviewed. Patients who developed lupus enteritis which were associated with mesenteric vasculitis or protein losing enteropathy were enrolled. The diagnosis was made by physical examination, contrast enhanced computed tomography and <sup>99m</sup>Tc Albumin scintigraphy. Poor prognosis was defined as any surgical treatment or recurrence.

**Results:** Among 591 SLE patients who fulfilled the 1997 American College of Rheumatology classification criteria, 23 (3.9%) were identified as developing lupus enteritis, and enrolled. Eighteen (78%) were mesenteric vasculitis and 5 (22%) were protein-losing enteropathy. Eighteen (78%) were female, the mean age at SLE onset was 31.5 years, and the mean duration between the onset of SLE and lupus enteritis was 10.6 years. The mean SLE disease activity index at the onset of lupus enteritis was 9.6. All patients were treated with glucocorticoid (mean initial prednisolone dose was 40.4 mg/day), and 4 patients (17%) were in combination with cyclophosphamide. Among the mesenteric vasculitis patients, 4 patients required surgical treatment and 4 patients experienced recurrence. Comparison between patients with poor prognosis and those without revealed that patients in the poor prognosis group had a higher ratio of multiple ulcer type than ischaemic colitis type (43% vs. 0%,  $p = 0.043$ ), colon lesions (71% vs. 9.1%,  $p = 0.012$ ), higher serum IgA (391 mg/dl vs. 247 mg/dl,  $p = 0.008$ ), and lower serum total cholesterol (152 mg/dl vs. 191 mg/dl,  $p = 0.012$ ). No difference was found in abdominal symptoms, SLE disease activity index score at lupus enteritis onset, anti-dsDNA antibodies and complement levels, initial prednisolone dose, and the concomitant cyclophosphamide use between the two groups. No recurrence was seen in patients with protein-losing enteropathy.

**Conclusions:** The higher level of serum IgA and lower level of serum total cholesterol are associated with surgical treatment or recurrence and are potential predictive biomarkers for poor prognosis.

### THE LUPUS STUDIES: THE EUROPEAN AND SPANISH POINT OF VIEW

N. Bahamontes-Rosa<sup>1</sup>, A. Muñoz Jiménez<sup>2</sup>, F.J. Hidalgo<sup>1</sup>, M.V. Pardo<sup>1</sup>, J.I. Diago Cabezedo<sup>1</sup>. <sup>1</sup>GSK, Madrid; <sup>2</sup>Hospital Virgen del Rocío, Sevilla, Spain

**Background:** Improving systemic lupus erythematosus patient care comes from the advances performed first in basic science that improved our understanding of the mechanism underlying the pathogenesis and finding effective and safe medications that led to treatment improvement. Furthermore, clinical trials play a key role in advancing both our medical knowledge of the disease and novel treatments.

**Objectives:** This work aims to offer an overview of the type and characteristics of lupus studies and to analyse the contribution that Europe and Spain have made in supporting those investigations.

**Methods:** A systematic review of the public registry database of publicly and privately supported clinical studies (CS), ClinicalTrials.gov, was done considering “lupus” as a search criteria (database generated with all CS registered on the 19th September 2017). Data collected included: CT code, title, sponsor, countries participating, study phase, condition and intervention.

**Results:** *Study distribution.* By 19th September 2017 there were a total of 256127 CS registered in the world, from which 611 (0.24%) are associated with lupus studies. From those, 27.2% are carried out in Europe. Spain is the third country in Europe in number of lupus CS after France and Germany.

*Type and distribution of the studies.* In the generated clinicaltrials.gov data base, the studies are associated to a type of study. The distribution varies depending on the geographical area. In general, the main type of lupus studies conducted in the world are related to the discovery and development of new treatments (n=406) but there are also behavioural, devices investigation, diagnostic test, dietary supplementation, genetic and radiation studies. In Spain, 94.6% of the studies registered are related to new treatment development.

The distribution of the lupus studies are as follows:

*Financial support.* 58.6% of all studies are funded by sources other than industry and 34.8% are supported by it. In a detailed analysis, 12.5% of the studies are under the economic support of the National Institutes of Health (NIH) or the partnership of NIH+other partners. The scenario is different in Europe where industry supported 54.8% of the studies and in Spain where industry supported 87.3% of the studies.

Moreover, the funding profile in Spain showed that 92.3% of the studies associated with new treatments are supported by industry and 7.7% of them are supported by other sources. On the other hand, 100% of the studies not related with

new treatments development are supported by funding source other than industry.

Abstract AB0614 – Table 1

Phase	Worldwide (n)	%	EU (n)	%	Spain (n)	%
Early Phase 1	7	1.1	2	1.2	0	0.0
Phase 1	76	12.4	17	10.2	3	5.5
Phase 1/2	24	3.9	4	2.4	0	0.0
Phase 2	143	23.4	57	34.3	23	41.8
Phase 2/3	15	2.5	5	3.0	1	1.8
Phase 3	76	12.4	34	20.5	21	38.2

No data	223	36.5	40	24.1	4	7.3

\* The percentages have been rounding

**Conclusions:** Europe participate in more than a quarter of Lupus clinical studies and Spain is the third European country participating in those clinical studies.

New treatment development studies are the main CT performed worldwide and the percentage is even higher in Spain. Regarding the study phase, the distribution of CT in Europe and Spain are similar although phase I studies in Spain are less frequent.

From all studies registered, the majority are non-industry sponsored studies. In Europe and in Spain the situation is the opposite, as 87.3% of the studies are pharma-sponsored studies.

#### AB0615 CHANGES IN SOMATOSENSORY EVOKED POTENTIALS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

E. Dziadkowiak<sup>1</sup>, A. Sebastian<sup>2</sup>, M. Wieczorek<sup>3</sup>, E. Kusińska<sup>1</sup>, M. Waliszewska-Proszó<sup>1</sup>, P. Wiland<sup>2</sup>, M. Ejma<sup>1</sup>. <sup>1</sup>Department of Neurology; <sup>2</sup>Department of Rheumatology and Internal Medicine, Wrocław Medical University; <sup>3</sup>Department of Geoinformatics and Cartography, Institute of Geography and Regional Development, Wrocław, Poland

**Background:** Primary Sjogren's syndrome (pSS) is a chronic autoimmune disease, which, in addition to impaired function of exocrine glands, can affect other organs including nervous system.

**Objectives:** The aim of the study was to establish whether in patients with pSS without central nervous system (CNS) involvement, the function of the central portion of the sensory pathway can be challenged.

**Methods:** In 33 patients diagnosed with pSS without clinical features of CNS damage and normal head CT scan, somatosensory evoked potentials (SEP) were studied. The results were compared to other clinical parameters of the disease, particularly to immunological status. The control group consisted of 20 healthy volunteers selected with respect to age and sex.

**Results:** Mean latency of all components of SEP were considerably prolonged in patients compared to the control group. Mean interpeak latency N20-N13 (duration of central conduction TT) did not differ significantly between the groups. However, in the study group, mean amplitude of N20P22 and N13P16 was significantly higher compared to healthy individuals. In patients with PSS, significant differences in SEP parameters depending on duration of the disease, duration of arthralgia and presence of SSA and SSB antibodies were noted. No significant differences in mean SEP parameters were observed with respect to skin lesions, xerophthalmia, current joint pain and swelling, focus score, levels of C3 and C4 complement components, ESR, CRP and presence of Ro52 antibodies.

**Conclusions:** The authors confirmed central nervous system involvement often observed in patients with pSS. They also showed dysfunction of the central sensory neuron as a difference in amplitude of cortical response, which indicates sub-clinical damage to the CNS.

**Disclosure of Interest:** None declared

#### AB0616 THE CORRELATION BETWEEN FOCUS SCORE AND ULTRASONOGRAPHY OF MAJOR SALIVARY GLANDS IN PRIMARY SJÖGREN SYNDROME

A. Sebastian<sup>1</sup>, J. Silicki<sup>2</sup>, A. Haloń<sup>3</sup>, P. Wiland<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Internal Medicine; <sup>2</sup>Department of General and Paediatric Radiology; <sup>3</sup>Division of Pathomorphology and Clinical Cytology, Department of Pathomorphology, Wrocław Medical University, Wrocław, Poland

**Background:** Currently, the role of salivary gland ultrasonography (SGUS) in the diagnosis of primary Sjogren's syndrome (pSS) is being determined. So far, in none of the proposed classification criteria for pSS SGUS is taken into consideration. The most recent analyses of patients show that SGUS can prove to be useful in the identification of even early forms of pSS.

**Objectives:** We analyzed the SGUS changes in patients with pSS and its correlations with focus score (FS) of minor salivary glands and immunological and laboratory profile.

**Methods:** We included 68 patients with pSS in the mean age of 51, based on the classification criteria from 2002.

**Results:** In 33 (48%) patients were abnormal findings in major salivary glands detected (table 1). Scattered hypoechoic changes of different size were the most common observed changes in SGUS, mainly in parotid glands.

Abstract AB0616 – Table 1. Abnormal images in salivary and mandibular glands in patients with pSS.

Number of patients – 33	Parotid and submandibular glands
Changes in SGUS	Parotid glands 23 patients (70% of changes) Submandibular glands 10 patients (30% of changes)
SGUS changes:	
- gland enlargement	48% of changes
- scattered hypoechoic changes of different size	85% of changes
- fibrosis	6% of changes
- lymph glands	15% of changes
- gland atrophy	12% of changes
- ducts enlargement	3% of changes

The FS was significantly higher in patients with changes in SGUS compare to the patients with normal images of major salivary glands (2.6 SD 1.3 vs 1.8 SD 1.2; p=0.02).

In patients with SGUS abnormalities the hypergammaglobulinemia was most often observed (1.7 g/dl vs 1.2 g/dl; p=0.02). There was not the correlation between changes in major salivary glands and age (p=0.5), CRP value (p=0.1), ESR value (p=0.1), with blood cell count (p=0.1), rheumatoid factor (p=0.1), dry eye (p=0.1), oral dryness (p=0.2), anti-SSA antibodies (p=0.5), anti-SSB antibodies (p=0.2), anti-Ro52 antibodies (p=0.4) observed.

**Conclusions:** SGUS is a useful tool in patients with pSS. The abnormal images in SGUS of major salivary glands correlated with focus score of minor salivary glands and hypergammaglobulinemia but not with specific antibodies.

**Disclosure of Interest:** None declared

#### AB0617 ACROSS-SECTIONAL STUDY OF NAILFOLD MICROVASCULAR CHANGES IN INDIAN PATIENTS WITH RNP+ LUPUS AND MCTD USING NAILFOLD VIDEOCAPILLAROSCOPY

P.P. Chebbi<sup>1</sup>, R. goel<sup>1</sup>, R. aithal<sup>1</sup>, G. mahasampath<sup>2</sup>, D. danda<sup>1</sup>. <sup>1</sup>Clinical Immunology and Rheumatology; <sup>2</sup>Biostatistics, Christian Medical college, Vellore, India

**Background:** Nailfold Capillary (NFC) changes represent degree of microvascular involvement in autoimmune connective tissue diseases. Anti U1-RNP is associated with specific internal organ involvement in SLE. Nailfold capillaroscopy may objectively predict the systemic microvascular abnormalities in SLE patients with positive Anti U1-RNP antibody.

**Objectives:** To study nailfold microvascular changes (NFVC) in SLE patients with RNP +and compare them with NFVC changes observed in patients with RNP negative SLE and Mixed connective tissue disease (MCTD).

**Methods:** Nailfold videocapillaroscopic (NFVC) examination (Optilamediscope, 200X) was performed in consecutive patients satisfying classification criteria of

SLE with or without Anti-U1 RNP positivity. Patients satisfying criteria for MCTD were recruited as disease controls. Individual NFC parameters were analysed by a blinded assessor. Changes in three groups were compared using non-parametric tests. Ordinal logistic or linear regression were used wherever applicable to assess any independent association of NFC changes with disease groups.

**Results:** Total of 81 patients were studied, of which 28 had SLE with RNP+ (age 30.0±10.37; 26 females), 26 had SLE without RNP positivity (age 29.42±9.20; 25 females) and 26 had MCTD (age 37.0±9.86; 25 females). Capillary density was significantly reduced in MCTD as compared to RNP+SLE patients (5.11±1.69/mm vs 7.25±1.38/mm, p=0.0001), as well as in RNP+SLE as compared to RNP negative SLE patients (7.25±1.38/mm vs 8.92±1.13/mm, p=0.0001). Conversely, patients with RNP+SLE had more frequent giant capillaries, enlarged capillaries and ramified/branched capillaries as compared to RNP negative SLE patients (p=0.047, 0.001 and 0.029 respectively). However, there was no statistical difference in number of haemorrhages among these groups. These changes were more severe in patients with MCTD as compared to RNP+SLE. Ordinal logistic regression showed more severe reduction in capillary density in patients with RNP+SLE as compared to RNP negative SLE (OR=9.5, p=0.007) independent of the presence of Raynaud's, ILD and disease duration.

**Conclusions:** Presence of anti-U1RNP antibody is associated with micro-vascular abnormalities in SLE as detected by NFVC. Patients with MCTD have more profound abnormalities as compared to RNP+SLE patients.

**Disclosure of Interest:** None declared

**PREVALENCE OF HYPOVITAMINOSIS D IN ADULTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND THE RELATIONSHIP WITH SLEDAI 2K IN PATIENTS TREATED IN TWO RHEUMATOLOGY SERVICES, BOGOTA 2017**

R.A. Guzman Moreno, L.G. Piñeros, J. Garcia, L.M. Pombo, A. Teheran, J. Bustillo, K.A. Guzman Moreno, V. Cadavid, M.C. Mejía. *Immuno Reumatología and Internal Medicine, IDEARG. Fundación Universitaria Juan N Corpas, Bogota, Colombia*

**Background:** Vitamin D is a steroid hormone with pleiotropic effects on physiological processes. Among others, immune system regulation and their analogues prevent symptom development of autoimmune diseases such as SLE. A previous research in a colombian clinic found a prevalence of hypovitaminosis D of 87% in healthy population, but hypovitaminosis D is higher in SLE patients than healthy controls.

**Objectives:** To establish the prevalence of hypovitaminosis D in patients with SLE and relationship with SLEDAI-2K.

**Methods:** A cross sectional study was carried out. 80 medical records with a diagnosis of SLE o CIE-10 M30-M36 were identified and we included patients >18 years of age who meet at least 4 of the 11 criteria to diagnoses of SLE for medical record. The analysis included means, DS and Kruskal Wallis with p-value < 0.05.

**Results:** The majority of patients are women (94%), with an average age of 39.9 years, married (41%), with secondary education (56.7%) and different occupations. It was found that the patients with higher activity, had lower vitamin D levels. Additionally, if the patient had lupus nephritis, vitamin D levels decreased even more.

Abstract AB0618 – Figure 1

**Conclusions:** Patients with active systemic lupus Erythematosus, (SLE) have hypovitaminosis D more frequently and we noticed that patients with renal involvement have the lowest levels of vitamin D, which justifies a later analysis.

**MANY PERIPHERAL FRACTURES DESPITE NORMAL BONE MINERAL DENSITY IN CAUCASIAN SLE PATIENTS**

R. Biesen, E. Wiebe, D. Freier, K. Zeiner, U. Schneider, T. Alexander, F. Hiepe, F. Buttgerit. *Rheumatology, Charité, Berlin, Germany*

**Background:** Clinical outcome has improved in systemic lupus erythematosus (SLE) and thus, early management of comorbidities like cardiovascular disease and osteoporosis has become highly important. In this disease, osteoporotic risk factors such as female gender, early onset of disease leading to long disease duration, high degree of systemic inflammation, high frequencies of glucocorticoid usage often at higher doses, and chronic fatigue or pain compromising physical activities are often present in combination.<sup>1</sup> Rh-GIOP (NCT02719314) is an ongoing prospective study monitoring glucocorticoid (GC)-induced osteoporosis of rheumatic patients, established in 2015 at the Charité University Hospital. To date, the database comprises clinical data and bone mineral density data measured by dual x-ray absorptiometry (DXA) of 592 patients with inflammatory rheumatic diseases.

**Objectives:** To quantify bone mineral density and fractures in SLE patients.

**Methods:** Bone mineral density (BMD) data of SLE patients as measured by dual x-ray absorptiometry (DXA) were analysed with regard to their relation to detailed clinical data.

**Results:** 43 female and 6 male SLE patients aged between 20 and 77 years (mean: 46.31 years) were assessed by DXA (all of Caucasian ethnicity, mean disease duration: 15.49 years; 61% denied any physical activity). SLE medication included glucocorticoids (93.9%; mean cumulative dose: 25.5 g), antimalarials (67.3%), azathioprine (30.6%), mycophenolate-mofetil acid (22.4%), belimumab (16.3%), cyclophosphamide (10.2%) and methotrexate (8.1%).

In 26 (60.5%) of all studied SLE patients, 36 (92.3%) peripheral and 3 (7.7%) vertebral fractures were recorded. Notably, 6 of these patients with fractures were younger than 30 and only 4 older than 60 years. 10 of all 39 fractures (25.6%) were low-trauma fractures. Of note, 11/26 patients (42.3%) with fractures had a normal BMD, 9/26 (34.6%) osteopenia and 6/26 (23.7%) osteoporosis, while only 4 (15.4%) of them initially received anti-osteoporotic medication.

**Conclusions:** There is a high occurrence of peripheral fractures in SLE. Moreover, 4 out of 10 SLE patients developed fractures despite a normal BMD, stressing that this parameter is of limited value for correctly identifying the fracture risk in SLE. The analysis of a larger number of patients and in-depth analyses are necessary to improve management of osteoporosis and to better prevent fractures in SLE patients.

### HIGH RISK OF MISTAKEN CLASSIFICATION OF PRIMARY ANTIPHOSPHOLIPID SYNDROME AS SYSTEMIC LUPUS ERYTHEMATOSUS ACCORDING TO THE SLICC CRITERIA: ANALYSIS OF A COHORT OF 214 ANTIPHOSPHOLIPID PATIENTS

R. Paule, N. Costedoat-Chalumeau, N. MOREL, V. LE GUERN, M. Fredi, L. Coutte, M. Belhocine, L. Mouthon, C. Le Jeunne, A. Chauvin, J.-C. Piette. APHP, PARIS, France

**Background:** The diagnosis of systemic lupus erythematosus (SLE) is based on the association of clinical and biological manifestations and on clinical experience. In 2012, a major revision by the Systemic Lupus International Collaborating Clinics (SLICC) group sought to improve their sensitivity and specificity. In replications, the SLICC classification produced fewer errors than the previous version; its higher sensitivity but lower specificity meant that some patients could be classified with SLE although they had another disease. In fact, the distinction between PAPS, APS associated with SLE, and isolated SLE may be difficult in some cases because the two diseases share some clinical and biological manifestations.

**Objectives:** To assess the limitations of the SLICC (Systemic Lupus International Collaborating Clinics) classification criteria for systemic lupus erythematosus (SLE), in patients with primary antiphospholipid syndrome (PAPS).

**Methods:** Retrospective study of a cohort of APS patients (Sydney criteria). We successively excluded patients with<sup>1</sup> at least one "SLE-specific" manifestation (biopsy-proven SLE nephropathy, arthritis, cutaneous, or neurologic SLE manifestations, pericarditis, autoimmune haemolytic anaemia, oral and nasal ulcers, non-scarring alopecia, anti-dsDNA, and anti-Sm antibodies),<sup>2</sup> any other autoimmune connective tissue disease, and/or<sup>3</sup> antinuclear antibodies >1/320. Careful file review confirmed PAPS among the remaining patients. We then assessed the number of SLICC criteria each patient met.

**Results:** Among these 214 APS patients, we excluded 85 with at least one SLE-specific manifestation, 8 with another connective tissue disease, and 21 with antinuclear antibodies >1/320, leaving 100 patients with primary APS. Among them, 28% met at least 4 SLICC classification criteria including one clinical and one immunological criterion (antiphospholipid antibodies, aPL, by definition) and could thus theoretically be classified with SLE. Fourteen had an arterial phenotype (50%), 9 a history of catastrophic APS (32%), and 18 a triple-positive profile for aPL (64%). None had developed SLE during a median follow-up of 12 [6.5–17] years.

**Conclusions:** Because 28% of our patients with longstanding and strictly defined PAPS could be mistakenly classified as SLE, they were at risk of deleterious therapeutic management. We therefore suggest that any future classification for SLE should specifically require at least one SLE-specific criterion for patients with aPL.

### EPIDEMIOLOGY, CLINICAL CHARACTERISTICS AND THERAPY APPROACHES OF A RETROSPECTIVE COHORT OF PAEDIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS IN A TERTIARY CENTRE

R.M. Alcobendas, S.M. Loza, A.R. Camba, C.U. Gascon. *Pediatric Rheumatology, university hospital La Paz, Madrid, Spain*

**Background:** Systemic lupus erythematosus (SLE) is a chronic autoimmune disease, potentially severe, with broad clinical spectrum, which can affect multiple organs and systems.

**Objectives:** To analyse the initial manifestations, laboratory examinations and therapeutic approaches of patients diagnosed with childhood onset systemic lupus erythematosus (c-SLE) followed in a tertiary hospital in the last 14 years.

**Methods:** Retrospective chart review. Inclusion criteria were: children under 18 years diagnosed with c-SLE between January 2003 and January 2017.

**Results:** During the study period, 38 patients were identified (ratio female/male: 3/1). The mean age at the onset of disease was 11.5 years (range 6–17). All had caucasian origin, except 5 coming from South America, 2 from India and 1 from Africa. Onset of the disease took place in spring in 22 (58%) patients, while in 10 (26%) patients onset was in summer, 5 (13%) in autumn and only one (3%) in winter season.

The most frequently clinical manifestations found at the debut were cutaneous involvement (66%, predominantly in the form of a malar rash), renal (65%) and joint (60%, 48% arthralgia and 52% polyarthritis). Other manifestations were fever (50%), cytopenias (39%), asthenia (36%), serositis and neurological clinic (both 26%) and oral aphthosis (23%). Among the neurological manifestations, 4 patients showed bradypsychia, 3 headache, 2 seizures and 1 manifested a paralysis of the sixth cranial nerve. Only 1 patient presented macrophage activation syndrome after primoinfection by *Ebstein Barr Virus*. During the study period, no deaths occurred.

Ten patients also had some other associated autoimmune disease: 6 hypothyroidisms, 2 IgA deficiency, 1 vitiligo and 1 celiac disease. No case of diabetes mellitus was identified.

Regarding immunology, in all cases, positive antinuclear antibodies (ANA) were detected, although with variable titers (1/80 – 1/5120). Of the 25 patients who presented renal disease at the onset, 19 associated Anti-dsDNA antibodies positive at the initial time of the determination. Although antibodies related to antiphospholipid syndrome (APS) (anticardiolipin, anti-2glycoprotein and lupus anticoagulant) were detected in 12 patients (32%), only two developed associated clinical manifestations (both deep vein thrombosis in the lower limbs).

Regarding treatment, all patients required corticosteroids. Therapy with acetylsalicylic acid was indicated in all patients with APS-associated immunology. Only 6 patients received treatment with corticosteroids and hydroxychloroquine exclusively. Nineteen (50%) patients initially received azathioprine therapy, being necessary to switch to mycophenolate mofetil for lack of response in eleven, receiving the last treatment 20 patients finally (52%). Eighteen patients (47%) received cyclophosphamide therapy, 16 of them as a consequence of their renal involvement. In addition, biologic therapy (rituximab and belimumab, respectively) was used in two multirefractory patients.

**Conclusions:** As widely already reported, SLE is a disease that affects predominantly women. Moreover, as it has been previously described in the literature the most frequently initial manifestations found in c-SLE are cutaneous, renal and articular. However, a large variability of onset symptoms exists, thus c-SLE should be ruled out in patients with multisystemic involvement

### CHARACTERISTICS OF SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS IN MALTA; A POPULATION BASED CROSS-SECTIONAL COHORT STUDY

R. Magro, A.A. Borg. *Rheumatology, Mater Dei Hospital, Msida, Malta*

**Background:** Systemic Lupus Erythematosus (SLE) is an autoimmune disorder that involves multiple systems including the skin, musculoskeletal, renal, neurological, haematologic, cardiovascular and respiratory systems.

**Objectives:** The aim of this study was to characterise the patients with systemic lupus erythematosus living in Malta, in terms of age of disease onset, BMI, comorbidities, drug history, disease activity, damage and other factors including fatigue, sleep quality, depression, anxiety and vitamin D level.

**Methods:** The study consisted of a cross-sectional cohort study of all known SLE patients, over the age of 18, living in Malta. 92 patients who fulfilled the SLICC classification criteria for SLE, gave informed consent and an interview was carried out. Fatigue, anxiety, depression, sleep quality and disability were assessed respectively by filling in the following questionnaires: Fatigue Severity Scale (FSS), Hospital Anxiety and Depression Scale (HADS), Pittsburgh Sleep Quality Index (PSQI) and modified Health Assessment Questionnaire (mHAQ).

**Results:** 92.4% of SLE patients studied were female. Table 1 summarises the characteristics of the SLE patients.

23.9% of SLE patients were in remission (SLEDAI-2K 0), while 52.2% had a low disease activity (SLEDAI-2K 1–5) at the time of the interview. 20.7% and 3.3% had a moderate (SLEDAI-2K 6–10) and high (SLEDAI-2K 11–19) disease activity respectively. A significant positive correlation was noted between function measured by mHAQ and SLEDAI (R=0.417, p=0.000). 56.5% were noted to have an abnormally high level of fatigue (FSS >3.7). 6.5% were noted to have depression (HADS D>10) and 35.9% had anxiety (HADS A>10). 55.4% were noted to have poor sleep quality (PSQI >5) and 26.1% had an abnormal level of function (mHAQ >0.3). 15.2% were found to have vitamin D deficiency and 27.2% were vitamin D insufficient.

**Abstract AB0622 – Table 1.** Clinical characteristics of the cohort

Characteristics	Values
Age, mean (S.D.) years	46.9 (13.9)
Caucasian race, n/N (%)	90/92 (97.8)
Disease duration, median (range) years	13 (0–35)
Age of SLE onset, mean (S.D.) years	33.8 (12.8)
BMI, median (range) kg/m <sup>2</sup>	26.5 (17.7–53.5)
Current smoker, n/N (%)	14/92 (15.2)
Family history of SLE in first degree relative, n/N (%)	3/92 (3.3)
Osteopaenia/osteoporosis, n/N (%)	30/92 (32.6)
Hypertension, n/N (%)	22/92 (23.9)
Diabetes mellitus, n/N (%)	7/92 (7.6)
Fibromyalgia, n/N (%)	9/92 (9.8)
Anti-phospholipid syndrome, n/N (%)	7/92 (7.6)
Sjogren's syndrome, n/N (%)	4/92 (4.3)
Rheumatoid arthritis, n/N (%)	3/92 (3.3)
Current prednisolone, n/N (%)	41/92 (44.6)
Current hydroxychloroquine, n/N (%)	55/92 (59.8)
Current azathioprine, n/N (%)	20/92 (21.7)
Current methotrexate, n/N (%)	10/92 (10.9)
Current mycophenolate, n/N (%)	6/92 (6.5)

**Conclusions:** This is the first population based study on SLE to be carried out in Malta. The prevalence of SLE in Malta is estimated to be 25.5 patients per 1 00 000 and the estimated incidence is 1.05 patients per 1 00 000 per year. A high frequency of obesity and vitamin D deficiency and insufficiency were noted in SLE patients. Other unmet needs include an uncontrolled disease activity, fatigue, poor sleep quality and anxiety.

**Disclosure of Interest:** None declared

#### AB0623 PREGNANCY OUTCOME IN SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE STUDY

R. Dumitriu<sup>1</sup>, C. Vasiliu<sup>2</sup>. <sup>1</sup>*Infertility and gonadal pathology, National Institute of Endocrinology „C.I. Parhon“;* <sup>2</sup>*Obstetrics and Gynecology, Bucharest Emergency University Hospital, Bucharest, Romania*

**Background:** Pregnancy represents a challenge for patients with systemic lupus erythematosus. One of the major risk is the occurrence of a flare during pregnancy. The influences are mutual, and the risk of complications depend mostly on the disease activity in the last 6–12 months before pregnancy. Therefore, these patients need a multidisciplinary approach, the obstetrician should collaborate with the rheumatologist and nephrologist.

**Objectives:** To determinate the associations between disease activity and pregnancy outcomes, and the risk factors that predict pregnancy complications and flare.

**Methods:** We present a retrospective study conducted between January 2010 and December 2015. We enrolled 35 pregnant patients, diagnosed with SLE with ages between 21 and 46 years old. All patients were followed up since the beginning of the pregnancy until delivery. We tested the correlations between different biomarkers and clinical manifestations of disease activity and pregnancy outcomes.

**Results:** Maternal complications occurred in 71.24% of the cases. The most common complications were: miscarriages, hematologic abnormalities (anemias, thrombocytopenia), premature birth and preeclampsia. The prematurity rate was 11% and most common delivery mode was the caesarian section. Also, the planning of the pregnancy was a predictor of a good fetal outcome ( $p=0.01$ ). The presence of the lupus anticoagulant was associated with prematurity ( $p=0.046$ ) at univariate analysis. Antiphospholipid syndrome was associated in 12% of the cases. Univariate analysis did not show a correlation between the presence of the syndrome and any pregnancy outcome.

**Abstract AB0623 – Table 1.** Risk Estimate preeclampsia in patients with APS

	Value	95% Confidence Interval	
		Lower	Upper
Odds Ratio for Preeclampsia	6667	.607	73 195
For cohort APS=yes	2417	1104	5292
For cohort APS=no	.363	.065	2014
N of Valid Cases	33		

**Conclusions:** Pregnancy should be planned when the disease is in remission. Lupus nephritis, is an important risk factor for preeclampsia. Also, the presence of lupus anticoagulant is a risk factor for preeclampsia, and hematologic determinations during pregnancy. The risk factors for pregnancy complications were; secondary antiphospholipid syndrome, presence of lupus nephropathy,

thrombocytopenia. our study shows that the exacerbations depend on the disease activity in the moment of conception.

#### AB0624 DYSLIPIDEMIA IN SYSTEMIC LUPUS ERYTHEMATOSUS: CORRELATION WITH DISEASE SEVERITY AND CYTOKINES

S. Huang<sup>1</sup>, Z. Zhang<sup>1</sup>, on behalf of Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, S. Wu<sup>1</sup>, J. Qi<sup>1</sup>, D. Wang<sup>1</sup>, G. Yao<sup>1</sup>, L. Sun<sup>1</sup>.

<sup>1</sup>Department of Rheumatology and Immunology, Drum Tower Clinical Medical College of Nanjing Medical University, Nanjing, China

**Objectives:** The patients with systemic lupus erythematosus (SLE) are obviously at high risk of cardiovascular disease (CVD) and the relationships between disturbed lipid metabolism and lupus activity remain to be elucidated. We evaluated dyslipidemia in association with disease severity, organ involvement and cytokines in patients with SLE.

**Methods:** Outpatients with SLE (n=105) and healthy controls (n=75) were recruited in this study. The concentrations of plasma tumour necrosis factor receptors A (sTNFR1), tumour necrosis factor receptors B (sTNFR2) and adipokine angiopoietin-like 4 (ANGPTL4) were measured by ELISA. The clinic and laboratory data were collected from patient records using electronic data processing. The data collected included serum lipid (TG, TC, HDL, LDL, ApoA1, ApoB), renal function (proteinuria, albuminuria, creatinine, blood urea nitrogen, uric acid), liver function (Alanine transaminase [ALT], glutamic oxalacetic transaminase [AST], total protein, albumin, globulin), blood system (lymphocyte, white blood cell [WBC], platelet [PLT], haemoglobin [HB]).

**Results:** Compared with the healthy controls, the level of serum TG, TC, LDL, ApoB were significantly increased, while HDL and ApoA1 were decreased. The serum levels of LDL and ApoB were positively correlated to SLEDAI, while HDL and ApoA1 were negatively correlated to SLEDAI. The patients with lupus nephritis had more severe dyslipidemia. The blood TG, TC, LDL, ApoB levels were positively correlated to 24 hour proteinuria and serum creatinine, urea nitrogen, uric acid. The blood levels of TG, TC, LDL, ApoB were positively correlated to serum total protein, albumin, globulin. The serum level of ANGPTL4 was positively correlated to HDL and ApoA1 as well as sTNFR1 and sTNFR2 with TG

**Conclusions:** Dyslipidemia in SLE was significantly correlated with SLEDAI and kidney involvement. The circulated levels of sTNFR1, sTNFR2 and ANGPTL4 were associated with dyslipidemia in SLE.

**Disclosure of Interest:** None declared

#### AB0625 SYSTEMIC LUPUS ERYTHEMATOSUS IN EGYPTIAN COHORT OF PATIENTS: A MULTICENTER STUDY

S.A. Elbakry<sup>1</sup>, N. Afifi<sup>1</sup>, S.A. Hussein<sup>1</sup>, N. Mohannaq<sup>2</sup>, I.H. Bassyouni<sup>3</sup>, N.F. Abou elezz<sup>4</sup>. <sup>1</sup>*Department of internal Medicine-Rheumatology Division, Ain Shams University-Cairo-Egypt, Cairo;* <sup>2</sup>*Department of internal Medicine-Rheumatology Division, Alexandria University Hospitals-Alexandria, Alexandria;* <sup>3</sup>*Rheumatology and Rehabilitation Department, Faculty of Medicine, Cairo University;* <sup>4</sup>*Community and Public Health Department Faculty of Medicine, Ain Shams University-Cairo-Egypt, Cairo, Egypt*

**Background:** Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease that mainly affects females in the reproductive age.<sup>1</sup> The disease presents with a diverse spectrum of clinical and immunological manifestations which has been studied in many countries and ethnic groups. Data from North Africa especially Egypt are minimal.

**Objectives:** To study the clinical and immunological characteristics of an Egyptian cohort with SLE and compare it with data from MENA region and international data.

**Methods:** In this retrospective study, data of 569 SLE patients who fulfilled the modified American College of Rheumatology (ACR) criteria for the diagnosis of SLE<sup>2</sup> were collected from three tertiary care centres in Cairo and Alexandria from the period of January 2014 to December 2017. Disease activity was assessed by using the SLE disease activity index (SLEDAI).<sup>3</sup>

**Results:** Of 569 patients 92.6% were females and 4.7% males with mean age at presentation 26.3±8.8 years and median disease duration four years (min 0.08-max 30 years). The main presenting symptom was musculoskeletal (arthritis/arthralgia) in 44.1% followed by fever in 39.4% and nephritis in 14.2%. Renal affection was present in 374 patients (65.7%) and renal biopsy was done in 268 patients with the most common is class III and IV lupus nephritis (18.3% and 14.1% respectively) (table 1). Antinuclear antibodies (ANA) was positive in all patients and immunofluorescence pattern was done in 256 patients; homogenous

pattern was the most common followed by speckled (29.9% and 13.4% respectively). Anticardiolipin antibodies was positive in 71.2% while lupus anticoagulant was detected in 50.8% (table 2). Mean SLEDAI was 13.38±9.75 with proteinuria in 58.9%, increased binding to DNA in 54.9% and low complement in 45.5%.

**Abstract AB0625 – Table 1.** Renal biopsy of 268 Egyptian SLE patients

Renal Biopsy	Frequency	Percent
Not done	301	52.9
Class I LN	23	4.0
Class II LN	34	6.0
Class III LN	104	18.3
Class IV LN	80	14.1
Class V LN	20	3.5
Class VI LN	7	1.2

**Abstract AB0625 – Table 2.** Immunological pattern of 569 Egyptian SLE patients

	Number	Percent
ANA pattern	313	55
- Not done	170	29.9
- Homogenous	76	13.4
- Speckled	10	1.8
- Rim		
Anti.ds DNA	488	85.8
Anticardiolipin antibodies	405	71.2
Lupus anticoagulant	289	50.8
Anti-Ro antibodies	16	2.8
Anti-La antibodies	12	2.1

**Abstract AB0625 – Figure 1**

**Conclusions:** These data are similar to that reported from MENA region; however, with little difference from international data as regard presenting symptom and immunological pattern. Differences observed among ethnic groups probably reflect the genetic component of ethnicity.

#### AB0626 CLINICAL FEATURES OF SYSTEMIC LUPUS ERYTHEMATOSUS IN MALES

S. Sayhi, T. Ben Achour, N. Boussetta, B. Arfaoui, N.E.H. Gueddich, F. Ajili, B. Louzir, on behalf of research unit UR 17DN02. *internal medicine, Military hospital, Tunis, Tunisia*

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease that primarily affects the adult woman. Male involvement is rare.

We report a series of men with systemic lupus in order to specify the particularities of the different manifestations of SLE in men.

**Objectives:** we aim to describe the clinical feature of male tunisien patients presenting SLE

**Methods:** This is a retrospective study of male lupus patients hospitalised in internal medicine for a period of 9 years. All patients are Tunisian and meet the lupus criteria established by the ACR.

**Results:** Twenty-one patients with male lupus were enrolled in a total of 97 systemic lupus (gender-to-sex ratio 3.6). The mean age at diagnosis was 34 years (range: 14 to 84 years). A family 1 lupus in one case. The clinical manifestations are dominated by joint damage (95%) with non-erosive arthritis in 9 cases and arthralgia in 12 cases, followed by cutaneous manifestations (erythema vespertilio=71%, photosensitivity=41%), Raynaud (25%). Pericarditis was found in 37.5% and pleurisy in 23%. Venous thrombosis was only observed in 4 cases associated with anti-cardiolipin antibodies in one case, and complicated by pulmonary embolism in one case. Sixteen patients had progressive nephropathy (permanent proteinuria >0.5 g/24 hours with mean proteinuria of 3.2 g/24 hours and extremes of 0.7 and 8 g/24 hours) of which 9 underwent kidney biopsy puncture. Membranoproliferative glomerulonephritis was observed in 4 cases, segmental and focal in 3 cases, mesangial and extramembranous, each in one case. Two patients had progressed to end-stage renal disease requiring hemodialysis. Concerning haematological involvement, anaemia, observed in 50% of cases, was haemolytic in 12.5% of cases. Leukopenia and lymphopenia were each scored in 46% of cases. Sixteen patients 16 were put on chloroquine, all patients were placed on high dose corticosteroids for an average of 25 months with boli in 7 cases, combined with cyclophosphamide (700 mg/month IV) in 4 patients cases in patients with proliferative glomerulonephritis. The evolution was enlabeled with flares in 11 cases, 2 of which had progressed to end-stage renal failure. Aseptic osteonecrosis of the femoral head was observed in one patient after 1 year of corticosteroid therapy. Complete remission was observed in 3 patients with a follow-up of 14, 24, and 144 months and one patient died as a result of peritonitis.

**Conclusions:** Systemic lupus is a disease essentially of adult women and rarely affects humans. The prevalence of the disease in the female gender suggests the intervention of a hormonal factor. In favour of the deleterious role of estrogens, lupus relapses are triggered by pregnancy, the peri and postpartum, as well as the oostroprogestative pill. The most common manifestations in humans in our study were renal impairment including membranoproliferative glomerulonephritis and segmental and focal glomerulonephritis complicated by renal failure in two patients. These data join those of the literature. The same is true for hemolytic anaemia.

LES is rare in men, nevertheless it correlates with a higher mortality in front of the association most frequent with the renal involvement which imposes a better knowledge of these clinical and laboratory particularities.

#### AB0627 PHYSICAL ACTIVITY BY SELF-REPORTED PHYSICAL ACTIVITY AND LUPUS NEPHRITIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S.-K. Kim, J.-Y. Choe, S.-H. Park, H. Lee. *Catholic University of Daegu School of Medicine, Daegu, Korea, Republic of Ireland*

**Background:** Physical activity is found to be associated with clinical status such as disease activity, organ damage, disability, fatigue, and quality of life in systemic lupus erythematosus (SLE).

**Objectives:** The aim of this study was to identify the association between physical activity and disease activity and organ damage in patients with SLE.

**Methods:** A total of 415 patients with SLE were consecutively enrolled from KOREan lupus Network (KORNET) registry. This registry assessed clinical features, disease activity Systemic Lupus Erythematosus Disease Activity Index 2000 [SLEDAI-2K]), and disease damage (Systemic Lupus International Collaborating Clinics/American College of Rheumatology [SLICC/ACR] damage index [SDI]) at the enrollment of study. Self-reported physical activity was measured by International Physical Activity Questionnaire (IPAQ). Statistical analyses were used by Mann-Whitney U test and multivariate logistic regression analysis.

**Results:** There is significant difference of vigour activity between patients with lupus nephritis (n=93) and without lupus nephritis (n=322) (p=0.012), but not moderate and walking activities. In contrast, the differences of each physical activity,

walking, moderate, and vigorous intensity, according to SLEDAI-2K and SDI were not found. In addition to high PCS of SF-36 ( $p=0.006$ ) and SLEDAI-2K ( $p=0.038$ ), less vigorous physical activity were related with lupus nephritis ( $p=0.033$ ). However, the risk of CVD was not associated with physical activity of SLE.

**Conclusions:** This study showed that patients with lupus nephritis had less vigorous physical activity. It implicates that SLE-related organ damage might be associated with levels of physical activity.

#### INFECTIONS IN HOSPITALISED PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS- A PROSPECTIVE OBSERVATIONAL STUDY FROM A TERTIARY CARE CENTRE IN SOUTHERN INDIA

S. Alur<sup>1</sup>, M.M. Thabah<sup>1</sup>, V.S. Negi<sup>2</sup>, S. Sista<sup>3</sup>. <sup>1</sup>Medicine; <sup>2</sup>Clinical Immunology; <sup>3</sup>Microbiology, Jawaharlal Institute of Post Graduate Medical Education and Research, Puducherry, India

**Background:** Infections are one of the main causes of morbidity and mortality in SLE.<sup>1</sup> The high prevalence of infection is attributed to use of immunosuppressive agents and disease activity. There is paucity of literature from India on infections, types of infections, predictors and outcome.

**Objectives:** To determine the frequency, types and determinants of major infections in hospitalised patients with SLE.

**Methods:** Patients with SLE (2012 SLICC-ACR criteria) aged  $\geq 13$  years, admitted to Clinical Immunology and Medicine wards were included. Clinical evaluation for major organ involvement of SLE, disease activity was assessed by SLEDAI-2K. Whenever there was a suspicion of infection appropriate work up to find the etiology of infections was done. Major infection was defined as presence of either one of the following a) sepsis b) pneumonia, or pyelonephritis, or endocarditis, or meningitis. c) skin or soft tissue infection requiring hospital admission for treatment d) Infection requiring IV antibiotic therapy. The diagnosis of infection was made by compatible clinical, microbiological and imaging criteria.

**Results:** From December 2016 till January 2018, 63 (55 women and 8 men) were included; Mean age was  $28.8 \pm 9.8$  years; mean SLEDAI-2K was  $14.6 \pm 7.03$ . Median duration of hospital stay was 14 days; range 2–64 days. Disease manifestation (including present and ever present) were arthralgia/arthritis in 51 (81%), oral ulcers 56 (88.9%), myositis 10 (15.9%), lupus nephritis 35 (55.6%), CNS lupus 14 (22.2%), serositis 14 (22.2%), cardiac involvement 13 (20.6%), APS 3 (4.8%). At the time of enrollment thrombocytopenia was present in 13 (20.6%), and leukopenia 11 (17.5%).

Twenty-three of 63 (36.5%) had infections (table 1), 14/23 (60.8) were microbiologically proven, remaining (39.2%) were confirmed by compatible clinical features and imaging.

Seven of 63 (11.1%) died; 5 (21.7%) in the infection group versus 2 (5%) in no infection group,  $p=0.08$  OR 5.58 [CI 0.98–31.7]. Thirty-four of 63 (54%) had fever on admission; 17/23 (74%) patients with infection had fever compared to 17/40 (42.5%) in no infection group,  $p=0.02$  [OR=3.8, CI 1.2–11.7]. There was no association of lupus nephritis, CNS lupus, leukopenia, receipt of cyclophosphamide, rituximab, methylprednisolone pulse therapy with occurrence of infection.

**Abstract AB0628 – Table 1.** Infections in SLE patients

Type of Infections	n=23 (%)
Bacterial Pneumonia	3 (13.7)
Fungal Pneumonia	2 (8.7)
(Invasive Aspergillosis)	
Pulmonary tuberculosis	2 (8.7)
Disseminated tuberculosis	2 (8.7)
Urinary tract infection	4 (17.4)
Skin and soft tissue infection	4 (17.4)
Blood stream infections	3 (13)
Suspected brain abscess	1 (4.3)
Pyogenic meningitis	1 (4.3)
Disseminated Varicella	1 (4.3)
Viral bronchiolitis	1 (4.3)

**Conclusions:** Almost 36% of SLE patients in hospital have infections. There appeared to be an increase in number of deaths among patients with infections. There was no association of infections with the dose of prednisolone or previous immunosuppression with cyclophosphamide.

#### PREVALENCE OF ASYMPTOMATIC VERTEBRAL FRACTURES IN POSTMENOPAUSAL WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

S. Shkireeva<sup>1,2</sup>, O.M. Lesnyak<sup>1</sup>, E.G. Zotkin<sup>2</sup>. <sup>1</sup>North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg; <sup>2</sup>Research Institute of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation

**Objectives:** To investigate the prevalence of vertebral fractures and to identify risk factors associated with vertebral fractures in postmenopausal women with systemic lupus erythematosus (SLE).

**Methods:** 86 consecutive postmenopausal women with SLE were included in this study. Bone mineral density (BMD) measurements of the hip and spine were performed using the dual energy X-ray absorptiometry (DEXA). Vertebral fracture assessment (VFA) was done for detection vertebral fractures using a method described by Genant. Accumulated damage was scored using the SLICC/ACR damage index (SDI).

**Results:** Vertebral fractures were defined in 42 (48.8%) postmenopausal women with SLE. Half of all patients with SLE ( $n=22$ , 25.6%) had asymptomatic vertebral fractures which were diagnosed only in this study. Every patient had 1.7 vertebral fractures on average (from 0 to 4). Distribution of vertebral fractures along the spine showed one peak at Th7. Univariate analyses of variables associated with fractures were longer duration of postmenopausal status in women with SLE, longer glucocorticoids intake, higher cumulative dose of glucocorticoids, higher SDI, lower BMD of the spine. Multivariate analysis showed longer duration of postmenopausal status in women with SLE (odds ratio 4.05,  $p=0.007$ ), cumulative dose of glucocorticoids  $\geq 60000$  mg of prednisone (odds ratio 3.68,  $p=0.009$ ),  $SDI \geq 7$  (odds ratio 2.94,  $p=0.028$ ) and low BMD ( $T \leq -2.0$ ) of the spine (odds ratio 2.48,  $p=0.015$ ) were significantly associated with vertebral fractures in the thoracic and/or lumbar spine.

**Conclusions:** Vertebral fractures were occurred in 48.8% of postmenopausal women with SLE and half of them were asymptomatic. The current method using DEXA to predict the presence of vertebral fracture has limited value and there is a need for assessment of bone quality. Vertebral morphometry in patients with SLE is recommended and early therapeutic intervention is necessary to prevent vertebral fractures in postmenopausal women with SLE.

AB0630

#### EXPRESSION OF TNF-A AND IL-6 IN SYSTEMIC LUPUS ERYTHEMATOSUS: RELATIONSHIP WITH DISEASE ACTIVITY

T.A. Panafidina, T.V. Popkova, A.A. Novikov, E.L. Nasonov. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Cytokines play an important role in the pathogenesis of SLE. TNF- $\alpha$ , IL-6 are the cytokines with suggested proinflammatory and immunoregulatory actions in the pathogenesis of SLE with differential effects on B or T cells, as well as on programmed cell death. Fas/APO-1 and Fas ligand (FasL) are involved in the apoptosis. FasL is a marker of apoptosis, it induces cell apoptosis when binds to Fas/APO-1. Both are expressed in membrane-associated and soluble forms (sFas/APO-1 and sFasL). sFas/APO-1 is known to inhibit the apoptosis via blocking the binding of Fas/APO-1 to FasL/sFasL.

**Objectives:** We evaluated the levels of IL-6 and TNF- $\alpha$  and their possible association with disease activity, apoptosis markers.

**Methods:** The study included 52pts (89% female, age 30,0 [26,5–44,5 years] (median [interquartile range 25% >75%])) with SLE ACR, 1997 and 20 controls (100% female without any rheumatic and infectious diseases, age 30,0 [25,0–39,5 years]). SLE-related factors, including disease duration, clinical features, SLE Disease Activity Index (SLEDAI 2K) and Systemic Lupus International Collaborating Clinics (SLICC) damage index were evaluated in parallel with relevant laboratory findings, autoantibodies. Serum levels of IL-6 and TNF- $\alpha$  (pg/ml), sFas/

APO-1 (pg/ml) and sFasL (ng/ml) were measured by ELISA (Bender MedSystem GmbH, Austria).

**Results:** Median SLE duration was 5 [1–11] years, SLEDAI 2K–9.5 [4.0–16.0], SLICC-0 [0–1], current prednisone dose–5.0 [0–11.9] mg/day, 44% of pts received hydroxychloroquine, 17% >cyclophosphamide, 10% >azathioprine, 4% >mycophenolate mofetil, 8% >biologics. SLEpts had higher level of IL-6 vs control (2.9 [1.5–9.7] vs 1.4 [0.7–2.1] pg/ml,  $p<0.01$ ) and lower level of TNF- $\alpha$  (1.9 [0.5–3.2] vs 4.5 [3.5–6.4] pg/ml,  $p<0.0001$ ), lower levels of sFas/APO-1 vs control (657.5 [483.2–791.4] vs 1456.9 [426.5–2060.8] pg/ml,  $p>0.05$ ) and lower levels of sFasL vs control (0.01 [0.01–0.03] vs 0.07 [0.05–0.10] ng/ml,  $p<0.0001$ ). In SLE pts serum level IL-6 correlated with IgM ( $r=0.69$ ,  $p<0.01$ ), K<sup>+</sup> ( $r=0.43$ ,  $p<0.01$ ), TNF- $\alpha$  ( $r=0.50$ ,  $p<0.001$ ), APRIL ( $r=0.39$ ,  $p<0.01$ ) and sFas/APO-1 levels ( $r=0.29$ ,  $p<0.05$ ); TNF- $\alpha$  level correlated with SLICC ( $r=0.32$ ,  $p<0.05$ ), APRIL ( $r=0.42$ ,  $p<0.01$ ), IL-6 ( $r=0.50$ ,  $p<0.001$ ), haemoglobin concentration ( $r=0.39$ ,  $p<0.01$ ), sFasL ( $r=0.44$ ,  $p<0.01$ ) and total cyclophosphamide dose ( $r=0.28$ ,  $p<0.05$ ). We divided SLEpts on two groups: the 1st-pts ( $n=31$ ) with high activity (SLEDAI 2K $\geq$ 8), the 2nd-pts ( $n=21$ ) with low (SLEDAI 2K $<$ 8). The pts in the 1st group had lower level of TNF- $\alpha$  compared to 2nd (1.6 [0.3–2.2] vs 2.8 [1.3–4.5] pg/ml,  $p<0.05$ ), with no difference in IL-6 level.

**Conclusions:** SLEpts demonstrated higher IL-6 and lower TNF- $\alpha$  levels as compared to healthy controls. Pts with high activity of SLE had decreased level of TNF- $\alpha$ . There is no correlation between disease activity and IL-6 level, as well as between elevated IL-6 and acute phase indicators. We suggest an immunoregulatory not proinflammatory role of IL-6 in SLE and probable protective role of TNF- $\alpha$  in SLE pathogenesis (it's deficiency can lead to the development and high activity of SLE). There was no correlation between IL-6, TNF- $\alpha$  levels and any SLE features. The correlation of IL-6 with sFas/APO-1 level (apoptosis inhibitor that blocks binding of sFas/APO-1 to sFasL) and TNF- $\alpha$  with sFasL concentration (a marker of apoptosis) suggests their different roles in the mechanisms of apoptosis.

#### IS HYPERHOMOCYSTEINEMIA (HHC) ADDITIONAL RISK FACTORS OF THROMBOSES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND ANTIPHOSPHOLIPID SYNDROME

T.M. Reshetnyak<sup>1,2</sup>, N.V. Seredavkina<sup>1</sup>, E.L. Nasonov<sup>1</sup>, L.I. Patrushev<sup>3</sup>. <sup>1</sup>Vascular Rheumatology, V.A. Nasonova Research Institute of Rheumatology; <sup>2</sup>Russian Medical Academy of Postgraduate Education; <sup>3</sup>Shemyakin-Ovchinnikov Institute of Biorganic Chemistry of RAS, Moscow, Russian Federation

**Background:** HHC may be additional factor of thrombosis in SLE patients

**Objectives:** To assess the role of HHC as additional risk factors in development of vascular complications in SLE and antiphospholipid syndrome (APS).

**Methods:** A total of 125 patients (24 M and 101 F, mean age 38 $\pm$ 13 years and the disease duration 14 $\pm$ 11 years) were divided into three groups: group 1 – SLE patients ( $n=51$ ); group 2 – SLE +APS patients ( $n=49$ ); group 3 – primary APS patients ( $n=25$ ). Homocystein (HC) was assayed by high performance liquid chromatography. DNA diagnostics by the method of polymerase chain reaction was used to determine gene mutation C677T methylenetetrahydrofolate (MTHFR) reductase in 93 out of 125 patients.

**Results:** HHC (HC >15 mcg/L) was diagnosed in 82 of 125 (66%) patients: in 59% patients of group 1, 67% – of group 2 and 76% – of group 3. There was a relationship between HHC and digital necrosis (DN): 80% of patients with DN had HHC while HHC was in 57% patients without DN ( $\chi^2=4.76$ ,  $p=0.03$ ). Elevated level of HC was registered in 43 of 55 (78%) APS patients with thromboses vs. 9 of 19 (47%) aPL-positive SLE patients without thromboses ( $p=0.03$ ). HHC occurred significantly more frequently in patients with arterial thromboses (in all 14 patients) than in patients with venous thromboses – in 16 of 23 (69.9%) pts ( $p=0.03$ ) and in the absence of thromboses ( $p=0.04$ ). HHC was associated with thromboses of cerebral (in 90%), peripheral arteries (in 84%) and myocardial infarction (in 79%) vs. 47% of patients without thromboses ( $p=0.005$ ;  $p=0.04$ ,  $p=0.04$  respectively), (79 vs. 47%). Mutation of C677T MTHFR was revealed in 33.3% of SLE patients, in 57.7% – of SLE +APS and in 63.2% – PAPS. Mutation C677T in the gene MTHFR was detected in 57% of examined patients, 20% of them had homozygous variant and 80% are heterozygous. Patients with a homozygous C677T MTHFR gene was observed the tendency to develop arterial thrombosis

**Conclusions:** More than 50% APS pts had elevated level of HC as additional thromboses factors. Correlation between HHC and thromboses, primarily arterial, in APS patients gives grounds for the role of HHC in development of vascular complications in SLE and APS pts.

Hueber<sup>4</sup>, A.M. Wright<sup>3</sup>. <sup>1</sup>Charité Hospital, Berlin, Germany; <sup>2</sup>Rheumatology Research Group, University of Birmingham, Birmingham, UK; <sup>3</sup>Novartis Institutes for BioMedical Research; <sup>4</sup>Novartis Pharma, Basle, Switzerland

**Background:** According to international consensus, disease activity in primary Sjögren's syndrome (pSS) patients shall be scored across 12 different domains according to the European Sjögren Syndrome Disease Activity Index (ESSDAI<sup>1</sup>). Two separate phase 2 proof-of-concept (PoC) studies using either BAFF receptor inhibitor (VAY736; ionalumab) or CD40 inhibitor (CFZ533) have recently been completed in comparable pSS cohorts with ESSDAI as the primary endpoint.

**Objectives:** To evaluate contribution of individual domains to composite ESSDAI scores at baseline and after interventional treatment with either VAY736 or CFZ533, or placebo. Aggregate efficacy and safety results were presented at previous meetings.<sup>2,3</sup>

**Methods:** Key inclusion criteria for both studies were fulfilling revised European US consensus criteria for pSS,<sup>4</sup> autoantibody positivity, exclusion of secondary SS and ESSDAI  $\geq$ 6. Permitted background medications in both trials included stable doses of hydroxychloroquine, methotrexate and prednisone  $\leq$ 10 mg/d and also azathioprine in the CFZ533 trial. The primary endpoint was change in ESSDAI at week 12. Descriptive and principal component analysis were done with the goal to identify distinct subgroups of patients based on ESSDAI involvement at baseline (BL), and the relative importance of single domain contribution to overall ESSDAI responses were explored.

**Results:** 27 patients received single i.v. dose VAY736 10 mg/kg ( $n=12$ ) or 3 mg/kg ( $n=6$ ) or placebo, and 44 patients received multiple doses of CFZ533 10 mg/kg i.v. ( $n=21$ ) or 3 mg/kg s.c. ( $n=8$ ) or placebo. ESSDAI breakdown at BL showed a predominance of the articular, glandular, biological, constitutional and lymphadenopathy domains in both trials. Activity in more than 3 domains was recorded for 12/27 (44%) and 12/44 (27%) of patients in the VAY736 and CFZ533 studies, respectively. Principal component analysis identified the articular domain as the key component describing the difference between patients in their ESSDAI domains at BL. Two other domains that explained the variability between patients were the biological and glandular domains. Treatment effects in domains with low BL scores were more difficult to assess using ESSDAI. The majority of ESSDAI domains were not amenable to quantitative analysis, due to absence or low incidence at baseline.

**Conclusions:** The most frequently observed ESSDAI domain was articular involvement. Our results provide insights into ESSDAI domain frequency and distribution in the randomised controlled trial setting that may have implication for future trial design in pSS.

**AB0633 MEASURING WHAT MATTERS TO LUPUS PATIENTS: TRANSLATING PATIENT VIEWS INTO NOVEL PATIENT-REPORTED OUTCOMES**

S. Cleanthous<sup>1</sup>, A. Regnault<sup>2</sup>, M. Schneider<sup>3</sup>, C. Gordon<sup>4</sup>, S. Bartlett<sup>5</sup>, S. Cano<sup>1</sup>, T. Morel<sup>6</sup>. <sup>1</sup>Modus Outcomes, Cambridge, UK; <sup>2</sup>Modus Outcomes, Lyon, France; <sup>3</sup>Policlinic and Hiller Research Unit of Rheumatology, UKD, Heinrich-Heine-University, Düsseldorf, Germany; <sup>4</sup>University of Birmingham, Birmingham, UK; <sup>5</sup>McGill University, Montreal, Canada; <sup>6</sup>UCB Pharma, Brussels, Belgium

**Background:** The 2010 U.S. FDA guidance<sup>1</sup> on systemic lupus erythematosus (SLE) acknowledged that ‘improvements in clinical outcome measures in patients with SLE may not always translate to improvements in how patients feel or function’ and encourages the use of patient-reported outcome instruments (PROs) to assess changes in outcomes that matter most to patients. Fatigue, identified by patients as their chief complaint during the Lupus Patient-Focused Drug Development (PFDD) meeting<sup>2</sup>, is not optimally measured by existing PROs<sup>1</sup>. There is a need for new patient-centred outcome measures as they are pivotal to PFDD. To address this, UCB has been conducting a multi-faceted, patient-centric, mixed methods research programme including evidence generated from >2100 SLE patients.

**Objectives:** There were three main objectives of the programme: 1) identify what concepts are most important to measure for SLE patients when evaluating treatment benefit; 2) critically evaluate the extent to which these concepts are captured by existing PROs; and 3) explore the opportunity to develop and evaluate new conceptually-based PROs in SLE.

**Methods:** There were three stages: 1) development of a preliminary treatment benefit conceptual model related to SLE including disease symptoms and impacts (generated from literature review, and patient and clinician input); 2) formal comparison of i) the conceptual model and the content validity (qualitative review) of existing SLE PROs and ii) psychometric properties (ie. SF-36, FACIT-F, and LupusQoL in the discontinued EMBODY Phase 3 studies for epratuzumab); 3) development of new conceptually-based PROs in SLE (figure 1).

Abstract AB0633 – Figure 1

**Results:** A preliminary treatment benefit conceptual model in SLE was developed. Among the many symptoms and disease impacts reported by SLE patients, physical fatigue, mental fatigue (‘brain fog’), sudden fatigability, joint/muscle stiffness and pain, skin symptoms and mobility difficulties featured as most troublesome. The content validity of 10 widely used PROs was found to be limited when compared to this conceptual model. Psychometric analysis (based on Rasch Measurement Theory) confirmed the limitations of the SLE PROs used in the EMBODY studies and suggested post-hoc reconceptualisation would improve the ability of the scales to detect clinical change. This led to the development of five new conceptually-based SLE PROs (ie. fatigue, pain, mobility, symptom severity, and emotional state), which are currently being explored in >500 SLE patients in a Phase 2b dapirolizumab pegol study (NCT02804763) and two cross-sectional, non-interventional, observational studies. Data on the new PROs are currently being assessed at several sites in the USA, Latin America, UK and Germany and will be available in the coming months.

**Conclusions:** New, well-defined and reliable PROs to better capture the patient perceptions of the symptoms and impact of SLE are needed. UCB has developed

five new PROs which offer the promise of improved patient-centred outcome measurements in SLE and other autoimmune diseases.

**AB0634 CHARACTERISATION OF SLE PATIENTS WHO UNDERWENT CARDIOVASCULAR SURGERY**

T. Kawamoto<sup>1</sup>, S. Matsushita<sup>2</sup>, H. Amano<sup>1</sup>, K. Minowa<sup>1</sup>, Y. Asai<sup>1</sup>, K. Yamaji<sup>1</sup>, A. Amano<sup>2</sup>, N. Tamura<sup>1</sup>. <sup>1</sup>Internal medicine and rheumatology; <sup>2</sup>Cardiovascular Surgery, Juntendo University School of Medicine, Tokyo, Japan

**Background:** SLE is characterised by alternate occurrences of flares and remissions throughout its course. During these flares, immune complexes are excessively produced and deposited in affected tissues. Previous reports suggest that immune complexes deposited in the blood vessels, atrioventricular valves, and other associated components of the heart cause disorders in these tissues. Although, the characteristics of patients in whom tissue injuries progress and ultimately require surgery have not been clarified.<sup>1</sup>

**Objectives:** Heart diseases are categorised into valvular disease, ischaemic heart disease, and aortic aneurysm. This study was conducted to determine whether there was a correlation between the activity of SLE and the progress and aggravation of heart disease in each category.

**Methods:** Of the 2707 patients who were diagnosed with SLE at Juntendo University Hospital from 2012–2017, 35 underwent cardiac surgery. Six patients met the exclusion criteria, and thus, 29 patients were included. Patients with infectious endocarditis and those in whom SLE had not been diagnosed prior to surgery were excluded. Indices for SLE activity were anti-DNA Ab and CH50. Peak and bottom values of these indices before surgery were recorded, and the values obtained during the pre-surgery 180 day period were compared with those that had been determined prior to this period.

**Results:** The mean disease duration at the time of cardiac surgery was 24.2 years. The cardiac diseases were heart valve disease (V) in 10, ischaemic heart disease (I) in 7, and aortic aneurysm (A) in 12 patients. The integrated values obtained by the activity indices, anti-DNA Ab, and disease duration were 14 020 for V, 32 966 for I, and 29 444 for A. Thus, there was a tendency for values to be slightly lower in the heart valve disease category. The peak/bottom values for CH50 and anti-DNA Ab in the pre-surgery 180 day period were no different from those obtained prior to this period. Investigation of anti-phospholipid antibodies indicated that the rates of positive result for either CLβ<sub>2</sub>GPI, anti-CL antibodies, or LA were 60% for V, 28% for I, and 33% for A, and thus, higher in the heart valve disease category. All patients were treated with steroids, and five patients (17.2%) of the 29 used immunosuppressants. This rate tended to be lower than the previous frequency of the combined use of immunosuppressive drugs at our hospital (onset:18.4%, first flare 33.3%).<sup>2</sup>

**Conclusions:** There is a possibility that the long-term duration of SLE may lead to cardiac disease requiring surgery. The integrated value for DNA Ab was lower in the heart valve disease category; therefore, the presence of anti-phospholipid antibodies may be a risk factor for valvular disease. The low frequency of combined use of immunosuppressants in SLE patients with cardiovascular manifestations requiring surgery, suggest the possibility that treatment with a single steroid may require heart surgery.

### ANTI-PHOSPHOLIPID ANTIBODIES IN LUPUS MYOCARDITIS

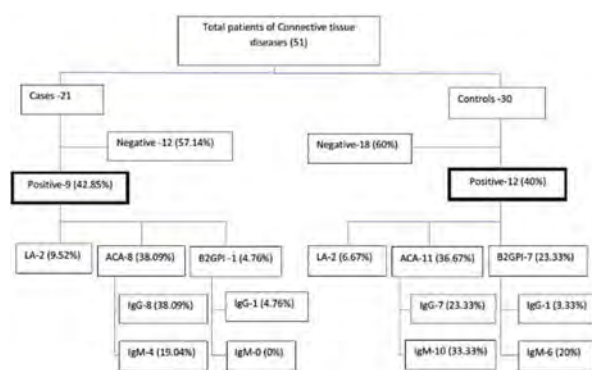

V. Dhir<sup>1</sup>, A. Gawalkar<sup>1</sup>, J. Ahluwalia<sup>2</sup>, A. Bahl<sup>3</sup>, S. Sharma<sup>1</sup>, A. Sharma<sup>1</sup>, S. Jain<sup>1</sup>.  
<sup>1</sup>Internal Medicine (Rheumatology Unit); <sup>2</sup>Hematology; <sup>3</sup>Cardiology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

**Background:** Myocarditis in lupus is an uncommon clinical manifestation, with unknown pathogenesis.<sup>(1)</sup> Suggested etiologies includes Immune-complexes, cell mediated damage and anti-phospholipid antibodies. The latter may affect the myocardial function microthrombi in cardiac vessels or direct cytotoxicity.<sup>(2)</sup> Previously, small studies have suggested an association between antiphospholipid tests as myocarditis.

**Objectives:** To evaluate whether myocarditis in SLE is associated with antiphospholipid positivity.

**Methods:** This was a cross-sectional study in which patients fulfilling SLICC criteria 2012 for SLE or Alarcon Segovia criteria for MCTD were included after consent. Patients were recruited as 'Cases' if they had myocarditis/cardiomyopathy defined by poor generalised contractility and/or dilation of all chambers nad/or reduced ejection fraction on echocardiography without any obvious cause. Those with regional wall motion abnormalities or pulmonary artery hypertension (moderate or severe) were excluded. Controls were age ( $\pm 2.5$  years) and disease duration ( $\pm 25\%$ ) matched patients of SLE without any abnormality on echocardiography. Serum titers of anticardiolipin antibodies and b2 GP1 (both IgG and IgM) were measured by commercial ELISA kit. Lupus anticoagulant was detected by Dilute Russell Viper Venom Test (dRVVT) with both screening (prolonged) and confirmation steps (shortening on higher phospholipid content, ratio  $>1.2$ ) on doubly centrifuged, platelet poor plasma. Proportions were compared using chi-square test (or Fischers exact test) and continuous variables by Mann-Whitney U test.

**Results:** A total of 51 patients were recruited in this study that included 21 cases and 30 controls. All had SLE, except 1 case was of MCTD (among cases). There was no difference in mean ( $\pm$ SD) age ( $33.3 \pm 14.7$ ,  $32.8 \pm 12.4$  years,  $p=0.9$ ) or median (interquartile range) disease duration ( $30^{8-38}$  25 (13.5–45) months,  $p=0.6$ ) between groups. Mean ejection fraction of Cases was 31.7% ( $\pm 9.3\%$ ) while that of Controls was 55.7% ( $\pm 1.7\%$ ) ( $p<0.001$ ). There were no significant differences between proportion of Cases (42.9%) and Controls (40%) with positive antiphospholipid tests ( $p=0.7$ ). The majority had positive anticardiolipin antibodies, followed by b2 GP1, and lupus anticoagulant was positive in only two in each group (figure 1). Among 9 Cases positive at baseline, 6 patients could be re-tested (2 expired and 1 was lost), out of which 3 had persistent positivity. Out of 12 Controls positive once, 8 could be retested (1 expired and 3 were lost), with 1 being persistently positive. There was no significant difference in persistent positivity between groups. ( $p=0.3$ ).

Abstract AB0635 – Figure 1

**Conclusions:** This study did not find any significant association between antiphospholipid antibodies (single time or persistent) with cases of lupus myocarditis.

### DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS NOT RELATED TO SUSTAINED HYPOCOMPLEMENTEMIA

W.D. Raymond<sup>1</sup>, L. Tyack<sup>1</sup>, G. Ø. Eilertsen<sup>2</sup>, J. Nossent<sup>1</sup>. <sup>1</sup>School of Medicine and Pharmacology, University of Western Australia, Perth, Australia; <sup>2</sup>Molecular Inflammation Research Group, Department of Clinical Medicine, Arctic University, Tromsø, Norway

**Background:** Hypocomplementemia (HC) represents a significant clinical finding in Systemic Lupus Erythematosus (SLE) as it suggests complement activation by immune-complexes, which can initiate inflammation. As disease activity contributes to damage accrual in SLE patients, we investigated the role of HC as a predictor of subsequent organ damage.

**Objectives:** Investigate the relationship between HC, disease flares and organ damage accrual in SLE patients.

**Methods:** Longitudinal cohort study of 102 SLE patients with HC defined as a C3 and/or C4 levels below cut-off during median follow-up of 13.8 years (IQR 7.0, 23.1). Disease activity was scored by time averaged SLEDAI-2K without the serological components (cWAS), flares by SELENA-SLEDAI and damage accrual by SLICC-DI. Analysis included comparisons between normocomplementemic (NC) and hypocomplementemic (HC) patients, and multivariate logistic and Cox regression modelling determined the predictive value of HC on organ damage.

**Results:** HC occurred in 2/3 of patients overall and was more often due to low C3 (97%) than low C4 (54%). HC patients had a higher prevalence of anti-dsDNA Ab (72% vs 36%,  $p<0.01$ ) and aPL (74% vs 40%,  $p<0.01$ ), but HC concurred with anti-dsDNA presence in only 36% of cases. HC patients had higher maximum cSLEDAI scores, but the time adjusted cWAS scores (1.9 vs 1.2,  $p=0.9$ ) and the frequency and risk of overall damage accrual ( $SDI>0$ ,  $n=60$ ) associated with HC was similar as for NC patients (OR 1.08,  $p>0.20$ ).

**Conclusions:** Low complement levels occur in 2/3 of SLE patients but have negligible impact on time averaged disease activity and damage accrual in SLE. Discrepancies between low C3, low C4 and anti-dsDNA Ab occurrence indicate that in SLE alternative complement activation occurs frequently and requires further translational study.

AB0637

### HAEMATOLOGICAL INVOLVEMENT OF PRIMARY SJOGREN'S SYNDROME PATIENTS IN A SINGLE CENTRE STUDY OF 232 CHINESE CASES

X. Wang, Z. Wu, Y. Liang, F. Cheng, R. Feng, X. Fang, S. Yang, B. Gong, J. Tang. Department of Rheumatology, Tongji Hospital, Tongji University School of Medicine, Shanghai, China

**Background:** Primary Sjögren's syndrome (pSS) is a common systemic autoimmune disease, characterised by lymphocytic infiltration of the secretory glands and different extraglandular manifestations. Besides haematological disorders are prevalent but not well recognised in patients with pSS.

**Objectives:** Our aim is to determine the existence of cytopenia at diagnosis or during follow-up of our pSS patients as well as the associated factors.

**Methods:** A cohort of pSS patients that had been followed-up in the Department of Rheumatology, Tongji hospital of Tongji University, from 2011 to 2017 was retrospectively assessed. Clinical and laboratory findings about the patients were recorded.

**Results:** Out of 232 pSS patients composing the cohort, cytopenia was already present in 55.60% ( $n=129$ ) at the time of diagnosis. Anaemia was detected in 30.17% ( $n=70$ ), leukopenia in 37.5% ( $n=87$ ), neutropenia in 22.41% ( $n=52$ ), and thrombocytopenia in 26.72% ( $n=62$ ) of patients. The proportion of patients with cumulative cytopenia was 6.47% ( $n=15$ ). Cumulative cytopenia was disease-related in 5.60% ( $n=13$ ) and medication-related in 0.86% ( $n=2$ ) of the patients. In patients with cytopenia at the time of diagnosis, erythrocyte sedimentation rates (ESR) were higher ( $p<0.001$ ), C3 and C4 hypocomplementemia was more prevalent ( $p<0.001$ ,  $p=0.060$ ), and they were positive for anti-SSB at a greater proportion ( $p=0.058$ ). Hyperglobulinemia, C3 hypocomplementemia, positive anti-SSA and anti-SSB might increase the incidence of anaemia in pSS, with OR of 2.700, 2.042, 1.537 and 1.901, respectively. In addition, logistic regression analysis suggest C3 hypocomplementemia might be associated with different types Leukopenia ( $p<0.01$ ), while abnormal Transaminase and C4 hypocomplementemia are independent risk factors for thrombocytopenia with a OR of 4.171 (1.516–11.480) and 5.697 (1.662–19.523). Cytopenia in pSS patients not either at diagnosis or during follow-up, was always easy to be ameliorated, but several cases led to unfavourable outcome.

**Conclusions:** The most common haematological disorders in pSS patients are leukopenia, and cytopenia in pSS patients might be related to disease activity.

#### AB0638 CLINICAL SIGNIFICANCE OF ESR IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Xu, X. Feng, L. Sunon behalf of Jiangsu Lupus Collaborative Group. *The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** During the process of systemic lupus erythematosus (SLE), disease flare and infection are often accompanied by each other and always pose a major challenge to clinical treatments. Although erythrocyte sedimentation rate (ESR) has been tested in SLE patients for many years, there is still a lack of consensus on its value.

**Objectives:** To validate the value of ESR in Chinese SLE patients at the time of their first admission and to determine whether it is related to a poor outcome.

**Methods:** Clinical data of patients with ESR tested on their first admission were extracted from our SLE database; (Feng et al. *PLoS ONE* 2016;11(12): e0168619) and analysed for the relation with disease activity (SLEDAI), infection status, organ involvements and survival situation. To determine the risk of ESR for long-term mortality, cumulative survival was illustrated with the Kaplan-Meier plot and factors were compared using the Log-rank test.

**Results:** Totally 1225 patients were included in this study, of which 92.2% were female and the median age at admission was 34.3 years. The most often seen organ involvements were mucocutaneous (66.4%), musculoskeletal (55.0%), renal (51.7%) and hematologic (45.2%) respectively. ESR levels were correlated with SLEDAI scores ( $r=0.145$ ,  $p=0.000$ ), but not elevated in patients with infections. Patients with cardiopulmonary, renal or hematologic impairments had higher ESR levels (all  $p<0.05$ ). Subgroup analysis showed that serositis, renal insufficiency and anaemia might be responsible for the respective organ involvement. The ten year survival rates for patients with elevated ESR was 80.57%, lower than that of 88.62% for patients with normal ESR ( $p<0.01$ ) (figure 1).

**Abstract AB0638 – Figure 1.** Cumulative survival rates for patients with elevated or normal ESR at first admission

**Conclusions:** High ESR levels in SLE patients are associated with active disease and specific organ involvements, and may predict a poor prognosis. It should be checked routinely for the monitoring of SLE patients.

**Disclosure of Interest:** None declared

#### AB0639 RISK OF MORTALITY IN SJOGREN'S SYNDROME AFTER 1ST ADMISSION

Y.-C. Chen. *Rheumatology, Kaohsiung Chang Gung Memorial Hospital, Kaohsiung, Taiwan, Province of China*

**Background:** The long-term prognosis of patients with SS is unclear. Population-based studies have shown conflicting evidence regarding relative mortality in SS.

**Objectives:** There is conflicting evidence regarding prognosis in patients with SS (pSS). The aim of this study was to estimate the risk factors of mortality in patients with SS through a in hospital review.

**Methods:** Through a review of databases through October 2002 till 2016, we identified cohort studies reporting relative risk (compared with standardised population), risk factors and causes of mortality in patients with SS.

**Results:** We identified 695 (83.2% females) with SS, of whom 88 patients died over a median average follow-up of 13 years. Leading causes of mortality were infections; Risk factors associated with increased mortality were advanced age at diagnosis [HR 1.045 (95% CI 1.024, 1.067)], male sex [RR 2.18 (95% CI 1.45, 3.27)], associated with SLE [HR 2.448 (95% CI 1.108, 5.406)], diabetes [HR 1.986 (95% CI 1.125, 3.505)]

#### Abstract AB0639 – Table 1

	Regression coefficient	P value	HR	95.0% CI for HR	
				Lower	Upper
Gender	0.173	0.568	1.189	0.657	2.152
Age	0.044	0.000	1.045	1.024	1.067
BMI	-0.051	0.075	0.950	0.898	1.005
RA	0.245	0.576	1.277	0.541	3.017
SLE	0.895	0.027	2.448	1.108	5.406
Diabetes	0.686	0.018	1.986	1.125	3.505

**Conclusions:** After first admission, the risk factor for mortality include old age, associated with SLE and diabetes. These require close follow-up.

#### AB0640 IMPLAUSIBLE ANTI-SMITH ANTIBODY IS NOT IMPLAUSIBLE TO AUTOIMMUNE DISEASE IN CHINESE POPULATION USING THE EUROIMMUN LINE IMMUNOASSAYS

Y. Wu, Y. Meng. *Department of Laboratory Medicine, West China Hospital, Sichuan University, Chengdu, China*

**Background:** Anti-Sm antibody is important test for lupus. In China, many labs detected anti-Sm using Euroimmun line immunoassays (LIA) kit, which mixture with purified Sm and RNP antigens as target antigens in Sm/RNP band and purified Sm antigens in Sm band. On the instruction, anti-Sm results should be determined according to the 2 bands. That is divided as true anti-Sm positive cases (having positive Sm and Sm/RNP bands) and implausible cases (having Sm band without Sm/RNP band), the value of implausible anti-Sm is not very clear now.

**Objectives:** We aimed at investigating the clinical value of the implausible anti-Sm in Chinese population.

**Methods:** Total of 39 766 patients were analysed for anti-Sm antibody using the EURO lineimmuno assay skit, of which 1208 cases are positive for anti-Sm. All cases with positive anti-Sm were divided into true anti-Sm group and implausible group according to the result of Sm/RNP band. The proportion of clinical diagnosis including autoimmune diseases (AIDs) and non-immune diseases (NAIDs) and the level of some clinical serum indexes were retrospectively analysed for the implausible anti-Sm cases.

**Results:** Implausible anti-Sm were evidenced in 271/1208 (22.42) of all positive anti-Sm cases. Among patients with positive anti-Sm, 177 cases have definitive diagnoses (65.31%, 177/271), with autoimmune diseases accounting for 68.36% (121/177), of whom 96 had systemic lupus erythematosus (SLE) (79.34%). In addition, there are 5 implausible cases with rheumatoid arthritis (RA), 3 with Sjogren syndrome (SS) and 10 with mixed connective tissue diseases (MCTDs). The titer of antinuclear antibodies (ANA) in patients with implausible anti-Sm is lower than ones with true anti-Sm. Impausible group have the same gender ratio, mean onset age and frequency of autoantibodies with true group. The prevalence of one of NAIDs, kidney disease, was significantly lower in implausible group than in true group ( $X^2=3.841$ ,  $p=0.05$ ).

**Conclusions:** Implausible anti-Sm have great diagnostic value in AIDs just as true anti-Sm. Patients with implausible anti-Sm have less incidence of evolving to autoimmune injury and kidney injury. Patients with implausible anti-Sm but without autoimmune diseases may be potential autoimmune disease victims.

#### AB0641 CORRELATION BETWEEN PHYSICIANS AND PATIENTS IN THE ASSESSMENT OF DISEASE ACTIVITY IN SYSTEMIC LUPUS ERYTHEMATOSUS

Y. Nasa<sup>1,2</sup>, N. Yokokawa<sup>2</sup>, H. Takahashi<sup>2</sup>, E. Takamasu<sup>2</sup>, S. Sugii<sup>2</sup>. <sup>1</sup>First Department of Internal Medicine, Kansai Medical University, Osaka; <sup>2</sup>Department of Rheumatic Diseases, Tokyo Tama Medical Metropolitan Hospital, Tokyo, Japan

**Background:** In the assessment of systemic lupus erythematosus (SLE), laboratory data and clinical findings have been more focused than patient-reported outcomes which reflect quality of Life. Previous studies showed discrepancy between patients and physicians in assessments of disease activity in SLE.<sup>1</sup> The Systemic Lupus Activity Questionnaire (SLAQ), a lupus disease activity index which consisted of only patient reported outcomes, and SLE Disease Activity Index 2000 (SLEDAI-2K) were poorly correlated.<sup>2</sup>

**Objectives:** We aimed to investigate the correlation between SLAQ and SLEDAI-2K scores in those who had discordance between patients' VAS and physicians' VAS or not.

**Methods:** Both SLEDAI-2K and SLAQ were routinely measured at every outpatient visit in all SLE patients. We analysed the data between 9/12/2017 and 12/31/2017. Patients were divided into concordance (|patients' VAS-physicians' VAS| <25) or discordance group (|patients' VAS-physicians' VAS| ≥25).<sup>3</sup> We measured correlation between SLAQ score vs SLEDAI-2K or SLEDAI-2K-nolab scores by Spearman's correlation in the concordance group and the discordance group. Comparison between the concordance group and the discordance group were performed using chi-squared test for categorical variables and Student t-test, Welch's t-test or Mann-Whitney U test for continuous variables.

**Results:** Total 130 patients were analysed; 91% of female, a mean age (SD) of 44<sup>15</sup> years, steroid use of 91%, immunosuppressant use of 54%, HCQ use of 70%. Median SLAQ, SLEDAI-2K and SLEDAI-2K-nolab scores were 4 [IQR: 2–7], 4 [IQR: 2–4] and 0 [IQR: 0–2], respectively. Among them, 86 (66%) were classified in the concordance group. The SLAQ scores were weakly correlated with the SLEDAI-2K scores ( $\rho=0.228$ ,  $p=0.009$ ), and with SLEDAI-2K-nolab scores ( $\rho=0.352$ ,  $p<0.001$ ). In the concordance group, the SLAQ scores correlated with SLEDAI-2K scores ( $\rho=0.327$ ,  $p=0.002$ ) and SLEDAI-2K-nolab scores ( $\rho=0.523$ ,  $p<0.001$ ). The pain VAS and RAPID3 in the discordance group were significantly higher than those in the concordance group (30.77±26.54 vs 10.71±14.31,  $p<0.001$ , 8.11±5.87 vs 2.97±3.23,  $p<0.001$ , respectively). In the discordance group, the SLAQ scores were not correlated with SLEDAI-2K scores ( $\rho=-0.029$ ,  $p=0.849$ ) and with SLEDAI-2K-nolab scores ( $\rho=-0.083$ ,  $p=0.957$ ).

**Abstract AB0641 – Table 1.** LLDAS: Lupus low Disease Activity State \*Student t-test \*\*Welch's t-test †Mann-Whitney U test

	concordance group(n=85)	discordance group(n=44)	p value
Age (mean, SD)	41.74 (14.74)	49.00 (15.83)	0.010*
Sex (female) (%)	76 (90.7)	40 (90.9)	1.000
Disease duration (year, mean, SD)	10.78 (9.47)	12.18 (10.75)	0.447*
Antimalarial (%)	81 (70.9)	30 (68.2)	0.903
Immunosuppressant (%)	47 (54.7)	23 (52.3)	0.943
PSL doses (mean, SD) (mg)	5.13 (4.48)	5.59 (5.95)	0.929†
LLDAS (%)	48 (55.9)	22 (50.0)	0.858
MDHAQ (mean, SD)	0.20 (0.55)	0.33 (0.46)	0.015†
Pain (100mm VAS) (mean, SD)	10.71 (14.31)	30.77 (26.54)	<0.001**
Patient's global (100mm VAS) (mean, SD)	14.43 (15.72)	29.57 (23.25)	<0.001**
Physician's global assessment (100mm VAS) (mean, SD)	15.94 (13.64)	15.07 (15.38)	0.829†
RAPID3 (mean, SD)	2.97 (3.23)	8.11 (5.87)	<0.001**
SLAQ score (mean, SD)	4.83 (3.83)	8.16 (4.88)	0.056*
SLEDAI-2K (mean, SD)	3.50 (3.14)	3.82 (2.90)	0.575*
SLEDAI-2K-nolab (mean, SD)	0.92 (2.22)	1.73 (2.68)	0.030†

LLDAS: Lupus low Disease Activity State \*Student t-test \*\*Welch's t-test †Mann-Whitney U test

**Conclusions:** The correlation between SLAQ vs SLEDAI-2K or SLEDAI-2K-nolab scores was exhibited in the concordance group. Musculoskeletal pain may be associated with the discordance between patients' and physicians' assessment.

#### AB0642 GLUCOCORTICOID INTAKE, HYPERGLYCEMIA AND OSTEOPOROSIS IN PATIENTS WITH AUTOIMMUNE DISEASES

Y. Jiang, G. Du, X. Wu, Y. Xie, M. Zhao, Z. Liao, J. Gu. *Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** Autoimmune diseases (AID) are often treated with glucocorticoids. Glucocorticoids have a number of substantial side effects in human body, including hyperglycemia and osteoporosis.

**Objectives:** Our study was to investigate the use of glucocorticoid in patients with autoimmune diseases and its negative influence on blood glucose and osteoporosis in the patients who receiving glucocorticoid treatment.

**Methods:** Patients with autoimmune diseases were enrolled from July to December in 2017 in rheumatology department of the Third Affiliated Hospital of Sun Yat-sen University. Demographic information, family history, past medical history, and clinical information were collected by two rheumatologists, including years of having glucocorticoids for treatment, largest dose of methylprednisolone, current dose of glucocorticoids. Blood glucose, glycosylated haemoglobin, and bone mineral density was required. The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis.

**Results:** Of all the 75 patients, 15 (20%) were male patients. 14.7% had primary education, while 26.6% received education in university. Numbers of the patients were stated as follows. Lupus, 29; rheumatoid arthritis, 4; Sjogren's syndrome, 10; systemic sclerosis, 10; myositis, 4; mixed connective tissue disease, 1; autoimmune hepatitis, 1; vasculitis, 5; other diseases, 11. Mean age was 40.29±14.64 years. Mean disease duration was 4.74±6.62 years. 3 (4%) patients had family history of diabetes. 3 (4%) patients had past medical history of diabetes. Mean duration of taking glucocorticoids was 3.30±4.40 years. 13 (17.3%) of the patients underwent high dose of glucocorticoid intravenous pulse (120 mg to 1000 mg of methylprednisolone). Current dose of glucocorticoids was 5.30±3.96 tablets of methylprednisolone. Mean blood glucose was 4.61±0.92 mmol/L. Mean glycosylated haemoglobin was 5.46±0.84. 2 patients were found to have diabetes in this study. 5 other patients were found to have higher blood sugar than normal range (3.9–6.1 mmol/L, according to our laboratory). 14 (18.7%) of the patients had osteoporosis according to BMD scores. In 17 patients who had receiving glucocorticoids for more than five years, 3 (17.6%) patients were found to have higher

blood sugar than normal range and 5 (29.4%) patients were found to have osteoporosis.

**Conclusions:** Glucocorticoids have substantial side effects in hyperglycemia and osteoporosis in the patient receiving glucocorticoid treatment. More years of taking glucocorticoids could lead to more hyperglycemia and osteoporosis. We should evaluate side effects of glucocorticoids in the patients with AIDs.

AB0643

### FT3 STRONGLY CORRELATES WITH LIPID PROFILES AND DISEASE ACTIVITY IN SLE PATIENTS

Z. Chen<sup>1</sup>, X. Zhang<sup>1</sup>, L. Liu<sup>1,2</sup>, S. Huang<sup>1</sup>, H. Wang<sup>1</sup>, L. Sun<sup>1</sup>. <sup>1</sup>Department of Rheumatology And Immunology, The Affiliated Drum Tower Hospital, Nanjing University Medical School, Nanjing, China, Nanjing; <sup>2</sup>Department of Rheumatology And Immunology, Changshu People's hospital, Changshu, China

**Background:** Dyslipidemia is prevalent in Systemic Lupus Erythematosus (SLE) patients and associated with lupus nephritis. Non-thyroidal illness syndrome (NTIS) frequently occurs in some autoimmune diseases. The incidence of dyslipidemia and NTIS in SLE patients vary in different studies and the association of NTIS and dyslipidemia in SLE patients has not yet elucidated.

**Objectives:** To investigate the frequency of dyslipidemia and NTIS in SLE patients and their association with laboratory parameters and SLE disease activity index (SLEDAI). To further explore the association between FT3 and blood lipid profiles in SLE patients.

**Methods:** This cross-sectional and prospective study included 271 patients fulfilled the ACR criteria for SLE. Forty-one patients who had a history of thyroid disease and/or familial hyperlipidemia and/or other rheumatologic diseases, and those took lipid-lowering agents or thyroid medications are excluded. Detailed laboratory parameters were collected and SLEDAI were assessed by qualified specialists of Rheumatology.

**Results:** Frequencies of dyslipidemia and NTIS in SLE patients are 61.8% and 57.2%, respectively. Laboratory indexes such as BUN ( $p<0.05$ ), urine acid ( $p<0.01$ ), CRP ( $p<0.001$ ), ESR ( $p<0.001$ ) and SLEDAI ( $p<0.05$ ) are significantly increased in SLE patients with dyslipidemia than non-dyslipidemia. Compared to euthyroid SLE patients, SLE patients with NTIS showed substantially elevated 24 hour urine protein ( $p<0.001$ ), fasting blood glucose ( $p<0.001$ ), BUN ( $p<0.001$ ), serum creatinine ( $p<0.01$ ), uric acid ( $p<0.05$ ), CRP ( $p<0.05$ ), ESR ( $p<0.001$ ) and SLEDAI ( $p<0.01$ ). Moreover, triglyceride ( $p<0.01$ ), total cholesterol ( $p<0.01$ ), LDL ( $p<0.01$ ) and ApoB ( $p<0.001$ ) levels are markedly higher in SLE patients with NTIS than euthyroid ones, while HDL levels obviously decreased in the former group ( $p<0.01$ ). More notably, the lower FT3 patients showed more severe lipid profiles and significantly higher 24 hour urine protein ( $p<0.001$ ), BUN ( $p<0.001$ ), serum creatinine ( $p<0.001$ ), uric acid ( $p<0.05$ ), and SLEDAI ( $p<0.05$ ) than patients with normal FT3. FT3 levels are negatively correlated with triglyceride ( $r=-0.263$ ,  $p<0.0001$ ), total cholesterol ( $r=-0.295$ ,  $p<0.0001$ ), LDL ( $r=-0.273$ ,  $p<0.0001$ ) and positively correlated with HDL ( $r=0.180$ ,  $p<0.01$ ).

**Conclusions:** Dyslipidemia and NTIS are prevalent in SLE patients and strongly correlates with disease activity. SLE patients with NTIS are more likely to combine with dyslipidemia, FT3 levels significantly correlates with lipid profiles and FT3 may plays a protective role in dyslipidemia.

### PREGNANCY OUTCOMES OF PLANNED PREGNANCY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE MULTICENTER STUDY

Z. Zhan<sup>1</sup>, D. Chen<sup>1</sup>, M. Lao<sup>2</sup>, X. Cai<sup>3</sup>, J. Zhang<sup>4</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Rheumatology and Department of Geriatrics, The First Affiliated Hospital of Sun Yat-sen University; <sup>3</sup>Department of Rheumatology, Guangzhou First People's Hospital, The Second Affiliated Hospital of South China University of Technology; <sup>4</sup>Department of Rheumatology, The Third Affiliated Hospital of Guangzhou Medical University, Guangzhou, China

**Background:** Compared with the general population, patients with SLE are still at high risk of adverse pregnancy outcomes (APOs). A number of studies have shown that patients with SLE are more likely to develop fetal complications, including fetal loss, preterm birth and IUGR, compared to healthy women.

**Objectives:** To investigate the fetal and maternal outcomes, as well as predictors for APOs in women with SLE who conceived when disease was stable, the so called "planned pregnancy".

**Methods:** A retrospective multicenter study of 243 patients with SLE who underwent planned pregnancy was performed. APOs in fetus and mothers were recorded.

**Results:** The average age at conception was 28.9±3.9 years. Duration of SLE prior to pregnancy was 4.4±4.3 years. Fetal APOs occurred in 86 (86/243, 35.4%) patients. Preterm births, intrauterine growth retardation (IUGR), fetal distress, and fetal loss accounted for 22.2%, 14.8%, 11.1%, and 4.9%, respectively. Forty-two preterm infants (42/54, 77.8%) were delivered after the 34th week of gestation. All the preterm infants were viable. Fifty-two patients (52/243, 21.4%) had disease flares, among which 45 (45/52, 86.5%) cases were mild, 6 (6/52, 11.5%) were moderate and 1 (1/52, 1.9%) was severe. Fifty-two disease flares (21.4%) occurred, among which 8 disease flares occurred during the first-trimester, 15 during the second-trimester, and 29 during the third-trimester. Disease activity was mild in 45 (45/52, 86.5%) patients, moderate in 6 (6/52, 11.5%), and high in 1 (1/52, 1.9%). Disease flares were mainly presented as active lupus nephritis (41/52, 78.8%), thrombocytopenia (10/52, 19.2%), and skin/mucosa lesions (9/52, 17.3%). Pregnancy-induced hypertension (PIH) occurred in 29 patients, among which 3 were gestational hypertension and 26 were preeclampsia. Multiple analysis showed that disease flares (OR 8.1, 95% CI 3.8–17.2,  $p<0.001$ ) and anticardiolipin antibodies positivity (OR 7.4, 95% CI 2.5–21.8,  $p<0.001$ ) were associated with composite fetal APOs.

**Conclusions:** Planned pregnancy improved fetal and maternal outcomes, presenting as lower rate of fetal loss, more favourable outcomes for preterm infants as well as less severe disease flares during pregnancy. Our research reinforced the importance of planned pregnancy, which allowed women with SLE to conceive in a proper time monitored by multidisciplinary experts.

## Vasculitis

AB0645

### ANCA VASCULITIS: THE EXPERIENCE AND TRENDS IN PATIENT CARE FROM A SINGLE CENTRE

A. Bankole<sup>1</sup>, K. McCoy<sup>1</sup>, B. Yeary<sup>1</sup>, G. Verma, Gita<sup>2</sup>. <sup>1</sup>Medicine, Virginia Tech Carilion School of Medicine, Roanoke; <sup>2</sup>Medicine, Centra Medical Group Bedford LI, Bedford, USA

**Background:** ANCA-associated vasculitis [AAV] is a small-medium vessel vasculitis that presents in a multi-systemic fashion, and is associated with significant mortality. Outcomes have improved with the introduction of immunosuppressive medications [ISM], the evidence supporting the initial choice ISM is limited, and may be influenced by health disparities related to social factors.

**Objectives:** The objective of this study was to compare various factors known to influence management and outcomes in AAV. Factors including, patient demographics, socioeconomic, clinical presentations, and medication choices were reviewed in relation to outcomes within the cohort.

**Methods:** This was a retrospective, single centre, hospital-affiliated cohort study. A list of all patients seen by the Rheumatology service between 2011 and 2016 with a diagnosis of AAV was generated. A review of the 3000 charts confirmed 77 patients that met the 1990 American College of Rheumatology criteria for AAV. General demographic data including age, gender, zip code, and median household income as well as disease related data including serology, disease manifestation, and treatment were obtained through a chart review and recorded in the database. Supplemental socioeconomic information for each patient zip code was obtained from the United States Government Census website.

**Results:** In our cohort the anti-proteinase 3 [PR3] antibody was the most common positive antibody. There was a relationship between PR3 antibody positivity rate

and body mass index [table 1]. Given the low number of non-Caucasians we were unable to comment on the relationship between antibody and race. Medication choice and mortality were independent of mean household income. Rituximab was the most commonly prescribed ISM [44%]. The median age of rituximab exposure patients was 65 years and 60 years for unexposed patients. There was no significant relationship between age and medication choice. Rituximab was prescribed 60% of the time in renal AAV [ $p < 0.01$ ] and 53% of the time in pulmonary AAV [ $p < 0.01$ ]. Other commonly prescribed medications in the cohort included Mycophenolate [20%], Methotrexate [24%] and Cyclophosphamide [28%].

The overall mortality rate was 17% [13/75] [figure 1]. There was no significant difference in the mortality rate of patients 65 years and older [23%, 9/39] compared to patients 64 and younger [11%, 4/36;  $p = 0.17$ ]. The mortality rate was also independent of median household income.

Abstract AB0645 – Table 1

	PR3 antibody		MPO antibody	
	Negative	Positive	Negative	Positive
BMI<29.9	69%	31%	71%	29%
BMI 30–39.9	35%	65%	75%	25%
BMI>40	20%	80%	100%	N/A
p-value	<0.01		0.38	

BMI: body mass index, PR3: proteinase 3, MPO: Myeloperoxidase

Abstract AB0645 – Figure 1

**Conclusions:** There was no relationship between age, sex, income, immunosuppressive therapy, and mortality in our AAV cohort. The mortality rate was higher in more severe disease and rituximab was more commonly used in such cases as well as in older patients. The limitations of the study include this being a hospital based cohort, where social demographics may have less of an impact. There was a lack of racial diversity, though the cohort did reflect the general demographics in southwest Virginia.

#### AB0646 IDENTIFICATION OF RISK FACTORS FOR RECURRENCE IN POLYMYALGIA RHEUMATICA

A. Ueno, M. Hirata, Y. Yamamura, K. Fujita, N. Shibutou, M. Yamamura. *Center for Rheumatology, Okayama Saiseikai General Hospital, Okayama, Japan*

**Background:** Glucocorticoids (GCs) are effective for polymyalgia rheumatica (PMR); however, some patients relapse during GC tapering and develop adverse events of GCs.

**Objectives:** To identify risk factors for recurrence in patients with polymyalgia Rheumatica (PMR).

**Methods:** Cox proportional hazards regression analyses was performed 78 patients with PMR who had been treated by 2015 EULAR/ACR recommendations between January 2015 and December 2017 in our centre. The following data at baseline were collected retrospectively: age, sex, time of diagnosis, location of arthralgia/myalgia, maximum dose of prednisolone, US findings of shoulder, laboratory data before the initial treatment.

**Results:** Seventy-eight patients had been diagnosed with the 2012 EULAR/ACR provisional classification criteria for PMR, and had been treated first with GCs. They were at the age of  $71.7 \pm 9.5$ , including 34 males and 44 females. Duration of symptoms before therapy was  $2.0 \pm 2.0$  months and the PMR duration was  $21.2 \pm 15.5$  months. Twenty-seven patients had arthralgia/myalgia other than shoulders and hips. The maximum dose of prednisolone was  $15.9 \pm 4.4$  mg/day. US findings

of shoulder were positive in 65 patients. Relapses occurred in 37 patients (47%), when the dose of prednisolone was reduced to  $5.6 \pm 5.5$  mg/day at  $8.9 \pm 6.4$  months. MTX ( $8.6 \pm 3.1$  mg/wk) was added in 29 patients or the dose of prednisolone was increased in 8 patients, similarly to the 2015 EULAR/ACR recommendations for the management of PMR. Additional MTX was ineffective in 16 patients, followed by adding tocilizumab in 8 patients. Forty patients discontinued GCs at  $17.6 \pm 10.6$  months.

On univariate analysis, 4 variables were identified as significant risk factors affecting PMR recurrence: increased platelets ( $p = 0.00192$ ), low IgA ( $p = 0.00149$ ), arthralgia/myalgia limited to shoulders and hips ( $p = 0.02$ ), and the maximum dose of prednisolone used ( $p = 0.0062$ ). These 4 variables were introduced into the multivariate analysis, and the following 3 variables were retained as independent significant risk factors: the maximum dose of prednisolone ( $p < 0.005$ ), limitation of arthralgia/myalgia to shoulders and hips ( $p < 0.05$ ) and low IgA ( $p < 0.005$ ).

**Conclusions:** These results indicate that the maximum dose of prednisolone, the absence of peripheral joint pains and low IgA may be associated with the recurrence in PMR patients

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.7128

#### AB0647 TAKAYASU'S ARTERITIS IN ITALY: CLINICAL PRESENTATION, DIAGNOSTIC DELAY AND VASCULAR PATTERN

A. Tomelleri, C. Campochiaro, S. Sartorelli, C. Sembenini, S. Franchini, F. Motta, D. Vanni, G. Cavalli, E. Baldissera, L. Dagna. *Unit of Rheumatology, Immunology, Allergy and Rare Diseases (UnIRAR), San Raffaele Scientific Institute, Milan, Italy*

**Background:** Takayasu arteritis (TA) is a large vessel vasculitis<sup>1</sup>. At disease presentation TA patients may present with inflammatory symptoms, sometimes associated with vascular pain. As arterial lesions ensue, more characteristic features may be found, such as limb claudication, decreased or absent pulses, vascular bruits, discrepancies in blood pressure<sup>2</sup>. Since initial symptoms are often non-specific, early detection of TA is challenging and patients at diagnosis frequently have established damage<sup>3</sup>

**Objectives:** To describe symptoms presentation and vascular involvement in a large cohort of Italian TA patients. To assess the diagnostic delay associated with symptoms and arteries involved at presentation

**Methods:** Data from 114 TA patients diagnosed according to ACR classification criteria at our tertiary centre were retrospectively collected. Signs and symptoms subsequently attributed to TA, age at first symptom onset, and age at diagnosis were analysed. The diagnostic delay was calculated. Arteries involved before the diagnosis were identified. Non-parametric statistic tests were used

**Results:** The cohort included mostly female patients (104;91.2%). Mean age at first symptom subsequently attributed to TA was 30.5 years ( $\pm 13.1$ ). Age at presentation of first TA related symptom was 18–40 years in 68 (59.6%), <18 years in 20 (17.5%), >40 years in 26 (22.8%) patients. Mean age at diagnosis was 36 years ( $\pm 12.7$ ). Mean diagnostic delay was 65.6 months ( $\pm 85.3$ ). Diagnostic delay was >1 year in 75 patients (65.8%). The most frequent finding before diagnosis was raised inflammatory markers (82.4%), the least common pulmonary hypertension (2.8%). The features significantly associated with a diagnostic delay >1 year were arthralgias, hypertension, previous vascular surgery. The mean diagnostic delay (in months) was significantly higher in patients with raised inflammatory markers ( $8.4 \pm 4.9$  vs  $100.5 \pm 121.8$ ,  $p = 0.005$ ), carotidynia ( $5.8 \pm 5.7$  vs  $34.2 \pm 32.9$ ,  $p = 0.034$ ) and in patients who had upper limb claudication ( $11.0 \pm 13.2$  vs  $65.44 \pm 77.01$ ,  $p = 0.002$ ). Data about arteries involved before diagnosis were available for 86 patients (75.4%). They were: subclavian in 43 (50%), carotid in 38 (44.2%), renal in 19 (22.1%), abdominal aorta in 18 (20.9%), ascending aorta in 15 (17.4%), axillary in 12 (14%), vertebral in 11 (12.8%), superior mesenteric in 10 (11.6%), thoracic aorta in 10 (11.6%), aortic arch in 9 (10.5%), celiac tripod in 9 (10.5%), brachiocephalic in 8 (9.3%), iliac in 8 (9.3%), coronary in 6 (7%), femoral in 6 (7%), pulmonary in 5 (5.8%), brachial in 3 (3.5%), popliteal in 2 (2.3%) patients. There was no significant difference in the arteries involved between patients diagnosed <1 year and >1 year from symptoms onset. Mean diagnostic delay was not significantly different according to the arteries involved

**Conclusions:** In Italy TA diagnosis is burdened with an important diagnostic delay. In our cohort it seems that the presence of both specific and non-specific symptoms is associated with delayed recognition of TA. Moreover, the need for vascular surgery in young women should rise the concern about TA

#### AB0648 CORRELATES OF FATIGUE IN ANCA-ASSOCIATED VASCULITIS

A. Masiak<sup>1</sup>, K. Nowicka-Sauer<sup>2</sup>, A. Hajduk<sup>1</sup>, B. Grygiel-Górniak<sup>3</sup>, M. Komorniczak<sup>4</sup>, Z. Zdrojewski<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Connective Tissue Diseases and Geriatrics; <sup>2</sup>Department of Family Medicine, Medical University of Gdansk, Gdansk; <sup>3</sup>Department of Rheumatology and Internal Medicine, Medical University of Karol Marcinkowski, Poznan; <sup>4</sup>Department of Nephrology, Transplantology and Internal Diseases, Medical University of Gdansk, Gdansk, Poland

**Background:** Fatigue is a common symptom among patients with ANCA-associated vasculitis (AAV) identified as the greatest burden of their disease.<sup>1,2</sup> Research revealed associations between fatigue and bio-psychosocial factors but not with clinical factors.

**Objectives:** To assess fatigue and its correlates among patients with granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA).

**Methods:** 37 patients (44% women; mean age 52.3 years; range 18–85) with GPA (27 patients) and MPA (10 patients) hospitalised in 3 clinical centres completed Multidimensional Fatigue Inventory-20 (MFI-20).<sup>3</sup> Anxiety and depression were assessed by the Hospital Anxiety and Depression Scale (HADS). Socio-demographic data including age, sex, education, marital and occupational status were recorded. Disease characteristics included its' duration, severity, activity, organ involvement and laboratory data.

**Results:** The mean age was 52.3 years (range 18–85 years), and the mean disease duration was 43.1 months (range 1–248). 4 patients had limited type of the disease, 13 – early systemic, 16 – systemic and 4 – severe type of the disease. 75% of patients had active disease as defined by Birmingham Vasculitis Activity Score, BVASv3 (mean BVASv3 in active patients 12.2). 8% of patients were not taking steroids. 40.5% of patients had CRP >5 mg/l, 43% had anaemia, 10% – thrombocytosis and 43% had renal insufficiency. Mean score of MFI-20 was 57 points (range 31–100). There were no differences in MFI-20 overall score between groups according to sex, education, marital and occupational status. No significant associations between fatigue and disease-related factors as well as steroid dose were observed. Depression ( $r=0.79$ ,  $p<0.00000$ ) and anxiety ( $r=0.63$ ,  $p<0.00002$ ) were strongly correlated with MFI-20 overall score.

**Abstract AB0648 – Table 1.** Socio-demographic characteristics of the study sample.

Variable	n (%)
<b>Education</b>	
primary	6 (16)
occupational	3 (8)
secondary	12 (32)
higher	16 (43)
<b>Marital status</b>	
married	29 (78)
divorced	3 (8)
free state	4 (11)
widower	1 (3)
<b>Occupational status</b>	
employed	18 (49)
unemployed	3 (8)
pensioner	8 (22)
annuitant	5 (13)
student	3 (8)

**Conclusions:** Since fatigue was not related to clinical characteristics, tiredness declared by the patient should not be interpreted as a symptom of active disease. There were no connexions between fatigue and socio-demographic variables. The strong association between fatigue and depression and anxiety levels indicates the necessity to supplement the standard drug therapy and/or cognitive-behavioural therapy aimed at reducing anxiety and improving mood.

Koca<sup>6</sup>, S. Akar<sup>7</sup>, N. Akkoç<sup>8</sup>, F. Onen<sup>9</sup>. <sup>1</sup>Rheumatology, Kocaeli University School of Medicine, Kocaeli; <sup>2</sup>Rheumatology, Uludag University School of Medicine, Bursa; <sup>3</sup>Rheumatology, Dokuz Eylül University School of Medicine, Izmir; <sup>4</sup>Rheumatology, Gazi University School of Medicine, Ankara; <sup>5</sup>Rheumatology, Kayseri University School of Medicine, Kayseri; <sup>6</sup>Rheumatology, Firat University School of Medicine, Elazig; <sup>7</sup>Rheumatology, Katip Celebi University School of Medicine; <sup>8</sup>Rheumatology, Private Practice; <sup>9</sup>Rheumatology, Dokuz Eylül University School of Medicine, Izmir, Turkey

**Background:** Untreated, The systemic vasculitides can be devastating, with high rates of morbidity and mortality. Recently, most of biological agents have evaluated in clinical trials, and management of systemic vasculitis has been revolutionised over the last decade.<sup>1,2</sup>

**Objectives:** Here, we report the frequency of using and switching rate of biological agents in different types of primary vasculitis patients.

**Methods:** TURKBIO registry is the Turkish version of Danish DANBIO rheumatological database which has been established in 2011. All patients with primary vasculitis who received biological agents registered in TURKBIO registry between dates of October 2011 and January 2018 were included in this study. The demographic data, the date of starting to use of biological drug, frequency of using and switching biological agents were collected.

**Results:** As of January 2018, 108 primary vasculitis patients were recruited (mean age: 38.4±10.9 [min-max: 19–67]; female 48%); 48 patients (44%) of them had Behçet's disease (BH), 35 (32%) had Takayasu arteritis (TA), 24 (22%) had granulomatosis polyangiitis, and one of them had microscopic polyangiitis. The most commonly used biological agents in current treatment were as follows: 75% of patients received infliximab (INF) and 15% received adalimumab (ADA) in BD patients; 48.6% received tocilizumab (TCZ), 23% received INF and 20% received ADA in TA patients; all patients with granulomatosis with polyangiitis (GPA) were treated with rituximab. The switching rate was 54% in TA patients, 27% in BD patients, and 4% in GPA patients. The most frequent switching was found at INF (28/78) and ADA (9/23) which was the most commonly used agent in TA and BD. The lowest switching rate was TCZ (2/17) in TA patients (table 1).

**Abstract AB0649 – Table 1.** Demographical features and managements of patients with primary vasculitis

Etanercept	4	3	1	0

**Conclusions:** This is the first evaluation of primary vasculitis patients who used biological agents from TURKBIO registry. According our data, there was high switching rate with anti-TNF agents in TA patients. The limitation of this study was the low number of the patients with primary vasculitis who used biological agents.

**AB0650 THROMBOTIC MICROANGIOPATHY ASSOCIATED TO ANCA-POSITIVES VASCULITIS: A FRENCH RETROSPECTIVE CASE CONTROL STUDY AND LITERATURE REVIEW**

A. Della, on behalf of Francine Barclay M.D, Jean Jacques. Boffa, Eric. Rondeau, Pierre Yves. Hatron, Christophe. Deligny, Stephane. Bally, Olivier. Fain, Paul. Coppo, Arsène. Mekinian, Saint-Antoine, Paris, 2 rheumatology, Montfermeil,3. HOPITAL MONTFERMEIL, MONTFERMEIL, France

**Objectives:** In this large nationwide French case-control study, we describe the features of TTP and ANCA-positive vasculitis; compare to vasculitis without associated TTP; describe the outcome and treatments.

**Methods:** We collected all cases with TTP and associated vasculitis. We conducted a literature review using PubMed, Web of Science, congress posters from January 2005 to August 2017 of PTT and ANCA-positive vasculitis.

A control group of MPA without TTP during all the disease follow-up was extracted from the Saint Antoine and Montfermeil Hospital patients with vasculitis. Firstly we compared our PTT cases and the literature review cases and secondary with a control group ANCA vasculitis without MAT.

**Results:** 8 patients with MAT secondary to ANCA associated vasculitides were included in our French series 75% of Women with a median age 45 years, 21–76 positive ANCA in 50% and 37.5% is MPO, BVSA score at 16, FFS at 1. In 10 literature cases 90% Women, a median age 60 years [17–77], positive ANCA in 100% and 30% is MPO, BVSA score at 39, FFS at 1.

The clinical features at the diagnosis of vasculitis were fever (n=5; 62%), ENT involvement (25%), kidney crescent glomerular involvement (n=6; 75%) with kidney failure in joint involvement (n=2; 25%) polyarthralgia type, with gastrointestinal involvement type mesenteric ischemia and pericarditis and lung involvement (nodules and alveolar haemorrhage) (n=1; 12.5%), in one case each Median C-reactive protein levels were at 49 mg/L [1–204], with creatinemia at 170 mg/dl [80–588]. ANCA were present in 4 patients (50%), MPO in 3 cases (37.5%). The time between the diagnosis of vasculitis and TTP was 9 months [0–51].

TTP features were: Hb at 7.8 g/dl [4.8–10], LDH 1658 [777–3110], platelets 33000 [3000–1 25 000], haptoglobin at 0 [0–0.05], creatinine at 205 [80–757]. ADAMTS 13 levels were at 10 [1–138], and x patients have normal ADAMTS13 levels, with anti ADAMTS 13 antibodies in 1 case. Plasma exchanges were done in all patients with median of 10 exchanges [4–23], 37.5% are dialyzed.

**Conclusions:** In comparison to our cases, the literature patients have similar organs involvement, but median creatinemia levels and BVAS levels were higher in the literature cases. Considering TTP features, our cases have less frequent active vasculitis, less important creatinine levels and thus less recurs to kidney dialysis.

In vasculitis associated with TTP, there was no significant differences in organ involvements, BVAS and FFS scales values, laboratory data and ANCA levels. Only creatinemia as expected was higher in vasculitis associated with TTP (225 Mmol vs 150 Mmol, p=0.0044).

**AB0651 FREQUENCY OF PULMONARY HYPERTENSION IN BEHÇET'S DISEASE**

B. Armagan<sup>1</sup>, M. Oksul<sup>2</sup>, Y.Z. Sener<sup>2</sup>, A. Sari<sup>1</sup>, A. Erden<sup>1</sup>, G.K. Yardimci<sup>1</sup>, L. Kilic<sup>1</sup>, U. Kalyoncu<sup>1</sup>, O. Karadag<sup>1</sup>, S. Apras Bilgen<sup>1</sup>, S. Kiraz<sup>1</sup>, I. Ertenli<sup>1</sup>, A. Akdoğan<sup>1</sup>.

<sup>1</sup>Hacettepe University Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology; <sup>2</sup>Hacettepe University Faculty of Medicine, Department of Cardiology, Ankara, Turkey

**Background:** Behçet's disease (BD) is a systemic vasculitis that involvement of pulmonary arteries can be seen.

**Objectives:** The aim of this study was to determine the frequency and the causes of pulmonary hypertension (PH) in patients with BD.

**Methods:** We studied consecutively 154 BD patients who were fulfilled the International Study Group criteria for diagnosis of BD. All patients were evaluated with transthoracic echocardiography (TTE) for the presence of PH. BD patients were categorised according to the involved organs in 5 groups: group 1 mucocutaneous and articular, group 2 ocular, group 3 vascular, group 4 gastrointestinal and group 5 neurologic involvements. The presence of PH was defined as estimated sPAB  $\geq 40$  mmHg, by TTE. Every subject evaluated by a detailed medical history and

physical examination was performed. Additional laboratory results were obtained from hospital file records.

**Results:** The mean age (SD) and the median (min-max) months disease duration of the patients were 41.8 $\pm$ 12.6 years and 126 (6–540) months respectively. PH was detected in 17 (11%) BD patients. Only 9 (52%) patients were symptomatic (NYHA FC >1). Left sided heart disease (Group II: 9 (52%) patients) was the leading cause of PH. Four (23%) patients had group IV PH and 75% (3/4) were symptomatic. Diastolic dysfunction (DD) was found in 32 (20.8%) patients and only 1 patient had systolic dysfunction. The number of patients with DD was significantly higher in patients with PH as compare to patients without PH (8 (47.1%) vs 24 (17.6%), p=0.005). There were no difference in demographic and clinical features of patients with and without PH. Only acneiform lesion was more frequently in patients without PH as compare to patients with PH, p=0.047 (table 1). There were no differences in frequency of PH in BD groups (table 2).

**Abstract AB0651 – Table 2.** Behçet disease group distribution in the pulmonary hypertension patients

Behçet disease (n)	Mucocutaneous and articular (39)	Ocular (75)	Vascular (48)	Gastrointestinal (12)	Neurologic (18)	p
sPAP $\geq 40$ , n (%)	2 (5.1)	9 (12)	9 (18.8)	1 (8.3)	2 (11.1)	0.413

sPAP: Systolic pulmonary artery pressure

**Conclusions:** The most frequent cause of PH in BD patients was group II PH. There were also significant number of patients with group IV PH. Pulmonary endarterectomy may be an option of treatment in inactive patients with group IV PH.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6672

**AB0652 PET/MR IN LARGE-VESSEL VASCULITIS: CLINICAL VALUE FOR THE DIAGNOSIS AND ASSESSMENT OF DISEASE ACTIVITY**

C. Laurent<sup>1</sup>, L. Ricard<sup>1</sup>, I. Buvač<sup>2</sup>, O. Fain<sup>1</sup>, A. Mekinian<sup>1</sup>, M. Soussan<sup>2</sup>, on behalf of French «PET –inflammation» Network. <sup>1</sup>Internal Medicine, Hôpital Saint-Antoine; <sup>2</sup>Nuclear Medicine, Hôpital Avicenne, Paris, France

**Background:** The diagnosis and the activity determination could be challenging in large-vessel vasculitis (LVV).

**Objectives:** The aim of this study was to analyze the value of hybrid PET/MR in LVV.

**Methods:** All consecutive patients with LVV who underwent PET/MR were included. PET/MR patterns were defined as inflammatory in the case of positive PET (grade=3) and abnormal MR (stenosis and/or wall thickening) and fibrous in the case of negative PET (grade 1 or 2) and abnormal MR.

**Results:** Thirteen patients with median age at 67 years (23–87 years) and 10 (77%) females were included, and underwent 18 PET/MR scans. Eleven PET/MR performed at diagnosis (n=4) or relapse (n=7) and 7 in patients in remission. 8/18 (44%) had PET/MR inflammatory pattern and 3/18 (17%) had fibrous pattern. PET/MR were normal in 2/10 (20%) cases of TA versus 5/8 (62%) cases of GCA

( $p=0.3$ ). The median SUVmax was 3.0 [1.8–8.6] without significant difference between GCA and TA: 3.4 (2.1–8.6) versus 2.6 (1.8–7.1) ( $p=0.4$ ), respectively. Eleven PET (61%) were performed under treatment, which consisted of steroids with a median dose at 30 mg/day [3–240]. Among 11 patients with active disease, 8 had inflammatory patterns and 3 had normal PET/MR, i.e. a sensibility of 73%, and the sensibility increased to 100% in patients with active TA disease. Median SUVmax were 4.7 [2.1–8.6] in patients with active disease versus 2 [1.8–2.6] in patients with remission ( $p=0.003$ ).

**Conclusions:** PET/MR is a new hybrid modality of imaging which is interesting for the diagnosis and the follow-up of large-vessel vasculitis.

#### AB0653 PREDICTION OF RELAPSES IN AUTOIMMUNE LARGE-VESSEL VASCULITIS – TOWARDS PERSONALISED IMMUNOSUPPRESSIVE TREATMENT STEWARDSHIP

P.S. Fuchs<sup>1</sup>, M.B. Bigler<sup>2</sup>, C. Küng<sup>2</sup>, T. Manigold<sup>3</sup>, M. Aschwanden<sup>4</sup>, D. Staub<sup>4</sup>, D. Kyburz<sup>3</sup>, V. Greiff<sup>3</sup>, T. Daikeler<sup>3</sup>, C.T. Berger<sup>1</sup>. <sup>1</sup>Clinical and Translational Immunology; <sup>2</sup>Translational Immunology; <sup>3</sup>Rheumatology; <sup>4</sup>Angiology, University Hospital Basel, Basel, Switzerland; <sup>5</sup>Computational and Systems Immunology, University of Oslo, Oslo, Norway

**Background:** Giant cell arteritis (GCA) is an autoimmune disease of the large arteries. Treatment consists in long-term immunosuppression with glucocorticoids (GC). About half of the patients have disease flares ('relapses') despite standard therapy. Tocilizumab (TCZ) – an anti-IL6 receptor antibody – is highly effective in reducing relapses, but has high costs.

**Objectives:** Here, we tested whether the initial clinical presentation and/or immunological findings might predict a GCA patient subset with poor response to GC. These might benefit from early TCZ therapy.

**Methods:** We performed a chart review on 113 patients from our prospective GCA cohort over the first two years after diagnosis. All had a follow-up of at least three months (median follow-up 24 months, IQR 12.6–24). Clinical findings at diagnosis, routine labs (at 0, 1, 3, 6, and 12 months) and therapy information (drug and dose) were extracted from the electronic database.

Relapses were defined as the presence of GCA-related symptoms (ischaemic pain, polymyalgia (PMR)) and/or elevated systemic inflammation parameters (CRP, ESR) that responded to an increase in GC-dose. GC receptor (GCR) expression levels in T cells were assessed using flow cytometry. Patients were genotyped for two polymorphisms in the Glucocorticoid receptor gene (NR3C1) that have been associated with steroid-responsiveness in other autoimmune disease (Systemic lupus, Pemphigus...).

**Results:** Over the first 12 months, 50,6% experienced at least one relapse. The majority of relapses occurred after three months of treatment (median time to relapse 102 days, range 19–312). This is when the GC dose is tapered below 20 mg/d. 'Relapsers' had an average of 1.66 (range 1–4) relapses in the first year. Patients with fever at initial presentation had a 2.2-fold (CI 1.1–5.05) higher risk to experience relapses ( $p=0.02$ ). Other clinical findings were not associated with subsequent relapses. Low lymphocytes after the first month of therapy was the only lab value associated with relapse free follow up (698/ul vs 1021/ul,  $p=0.02$ ). This was independent of the cumulative GC dose that 'non-relapsers' and

'relapsers' received in this period (1747 mg vs. 1710 mg mg,  $p=0.4$ ). Relapsers had lower GCR expression levels, as assessed by flow cytometry.

**Conclusions:** Fever, lack of lymphocytopenia after one month of therapy and low GCR expression are risk factors for relapses in GCA. Low GCR expression combined with absence of lymphocytopenia during high dose GC therapy points at a constitutional steroid-resistance in relapsers. Whether patient stratification based on these parameters allows to safely adapt ('personalise') the intensity and/or duration of GCA treatment needs to be tested in a prospective clinical trial.

#### AB0654 CLINICAL PROFILE AND RISK FACTORS OF INFECTIONS IN PATIENTS WITH ANCA-ASSOCIATED VASCULITIS (AAV) – 18-YEAR DATA FROM A SINGLE TERTIARY CENTRE

C.-H. Ho. Department of Medicine, Queen Elizabeth Hospital, Kowloon, Hong Kong

**Background:** Despite advances in the treatment of AAV, there are still considerable morbidities related to treatment-related complications. Infection is one of the most commonly encountered problems in patients on immunosuppressive therapy.

**Objectives:** This single centre, retrospective study reviewed the clinical features and investigated the risk factors for infections among patients with AAV.

**Methods:** 104 patients with AAV diagnosed between January 2000 and December 2017 in a tertiary hospital were included. Demographic data and clinical parameters were reviewed. Logistic regression was performed to identify factors predicting infections.

**Results:** Around two-thirds of the 104 patients included were female (63.5%  $n=66$ ). Mean age at diagnosis was 64.4-year-old. The majority (65.4%,  $n=68$ ) had microscopic polyangiitis (MPA), 19.2% ( $n=20$ ) had granulomatosis with polyangiitis (GPA) and 15.4% ( $n=16$ ) had eosinophilic granulomatosis with polyangiitis (EGPA).

More than half of the patients (58%,  $n=61$ ) experienced at least one episode of infection and 22% ( $n=23$ ) had recurrent sepsis during their disease course. Infection was the leading cause of mortality of the 56 deceased patients in this series. Infections were less frequent in EGPA patients compared to their counterparts with MPA and GPA (37.5% vs 61.8%–65%).

Most infections were bacterial and multiple-drug resistant organisms were the causative agents in 8 patients. Two had neutropenic sepsis. Three had M. tuberculosis and five had herpes zoster. One had concomitant VZV and pneumocystis jiroveci pneumonitis.

Abstract AB0654 – Table 1.

Factors predicting infection	Odds Ratio ( $p<0.05$ )
– · Age	1.034
– · Renal insufficiency (serum creatinine $\geq 140$ umol/L) at diagnosis	5.452
– · Disease-related organ failure	3.006
– · Dialysis support	6.504
– · Use of cyclophosphamide as induction agent	2.956

**Conclusions:** Infections were common and often led to significant morbidities and mortalities among AAV patients. Risk factors included age, renal insufficiency (serum creatinine  $>140$  umol/L) on presentation, disease-related organ failure, need for renal supportive therapy, and the use of cyclophosphamide as induction agent.

**Disclosure of Interest:** None declared

#### AB0655 AGREEMENT BETWEEN 18-FDG PET/CT AND CLINIMETRIC TAKAYASU ACTIVITY SCORES

D. Hernandez-Lopez<sup>1</sup>, L.A. Martinez-Martinez<sup>1</sup>, D. Jimenez-Arenas<sup>2</sup>, B. Rivera-Bravo<sup>2</sup>, E. Hernandez-Lemus<sup>3</sup>, J.A. Barragan-Garfias<sup>4</sup>, V. Guamer-Lans<sup>1</sup>, M. E. Soto-Lopez<sup>1</sup>. <sup>1</sup>Instituto Nacional de Cardiología Ignacio Chavez; <sup>2</sup>PET/CT Unit, School of Medicine at National Autonomous University of Mexico; <sup>3</sup>Instituto Nacional de Medicina Genómica; <sup>4</sup>Instituto Mexicano del Seguro Social, Ciudad de Mexico, Mexico

**Background:** The 18-FDG PET/CT is an objective tool employed for the diagnosis of Takayasu arteritis and also is used for the assessment of disease activity of this vasculitis.<sup>1</sup> There are few clinimetric scores developed for Takayasu clinical activity assessment such as the Indian Takayasu Clinical Activity Score (ITAS2010/ITAS.A),<sup>2</sup> the National Institutes of Health criteria (NIH score) from USA<sup>3</sup> and the Mexican effort by Dabague-Reyes (DR score).<sup>4</sup> The validity and

utility of 18-FDG PET/CT to measure the disease activity by studying wall enhancement compared to the clinimetric assessment has been slightly studied.

**Objectives:** To explore the agreement between 18-FDG PET/CT and the clinimetric tools for the estimation of Takayasu activity in one national reference centre.

**Methods:** The clinical records of patients that had performed an 18-FDG PET/CT were consecutively included. The required information to fulfil the ITAS2010, ITAS.A, NIH and DR were gathered from clinical charts. The cut-off points we used are the following: SUVmax  $\geq 2.1$  for 18-FDG PET/CT, for ITAS2010  $\geq 2$  points, for ITAS.A  $\geq 4$  points, for NIH  $\geq 2$  points and for DR  $\geq 5$  points. Kappa index was calculated, comparing SUVmax with all the clinimetric measures. As an exploratory exercise, ROC curves were performed. A p value less than 0.05 was considered statistically significant.

**Results:** Thirty six clinical records were reviewed. There was enough information to score ITAS2010 in 31 patients, ITAS.A in 28 patients, NIH and DR in 35 patients each. In our patients, moderate agreement was observed between 18-FDG PET/CT and DR score (Kappa=0.542, p=0.001). A tendency of weak agreement was observed with the NIH score (Kappa=0.215, p=0.086) and ITAS.A (kappa=0.351, p=0.063). There was no agreement with ITAS2010 (Kappa=0.107, p=0.519). Significant AUC were observed with DR (AUC=0.817, p=0.005) and NIH (AUC=0.756, p=0.025); however, this results were not obtained with ITAS2010 (AUC=0.675, p=0.124) and ITAS.A (AUC=0.697, p=0.083).

**Conclusions:** There was no strong agreement between 18-FDG PET/CT and any of these activity indices. On the other hand, these data suggest that the best disease activity tool in Mexican patients were DR and the NIH scores. Comparative studies in other populations are warranted.

#### AB0656 CRYOGLOBULIN EVALUATION: ANALYSIS OF INTRA-LABORATORY AND INTER-LABORATORY VARIABILITY

D. Campioli<sup>1</sup>, P. Natali<sup>1</sup>, D. Debbia<sup>1</sup>, A. Spinella<sup>2</sup>, G. Sandri<sup>2</sup>, C. Cerami<sup>3</sup>, L. Scichilone<sup>3</sup>, F. Fontana<sup>3</sup>, M.T. Mascia<sup>2</sup>. <sup>1</sup>Department of Laboratory Medicine; <sup>2</sup>Chair and Rheumatology Unit, University of Modena and Reggio Emilia, Policlinico of Modena; <sup>3</sup>Chair and Nephrology Unit, University of Modena and Reggio Emilia, Policlinico of Modena, Modena, Italy

**Background:** Cryoglobulins (CRG) are immunoglobulins that precipitate in serum at temperatures below 37°C and resolubilize upon warming. The main reasons of interest of a clinical pathologist in the study of cryoglobulinemia are: 1) lack of standardisation in the preanalytical, analytical and postanalytical phases of the process (classification and reporting); 2) peculiarities of physiopathological mechanism 3) important clinical consequences. Vermeersch et al. studied these issues in 2008. To assess current practice in the detection, analysis, and reporting of cryoglobulins, a questionnaire was sent to 140 laboratories. They showed that only 36% of laboratories used standard procedures of analysis. Consequently, they concluded that standardisation was needed for cryoglobulin detection to avoid missed diagnoses and improve the comparability of results. Sargur et al. in 2010 reviewed the classification and clinical features of cryoglobulins and suggested “best practice” guidelines for laboratory detection and identification of cryoglobulins. They particularly highlighted the relevance of preanalytical and analytical phases: maintenance of the sample at a stable temperature of 37°C, especially throughout the initial steps (collection and transportation); centrifugation and separation methods; cryoprecipitate quantification; cryoprecipitate washing techniques; immunocharacterization of cryoprecipitates especially through immunofixation techniques (considered the “gold standard”).

**Objectives:** To verify and assess the variability of laboratory processes of CRG. **Methods:** We checked laboratory databases of Hospital and University (Lab A and B) of Modena with long tradition in the cryoglobulin analysis (more than 6000 tests from 2002 to 2017). Concerning CRG testing, 734 patient samples were studied in both laboratories. We compared our results according to Brouet classification into subgroups: type I, II and III. Therefore, we evaluated intra-laboratory variability, compared to previous or more frequent results. Finally, we studied inter-laboratory variability based on non-concordant laboratory reports.

**Results:** In the following table, we have represented the comparison between labs about the same patient cohort in 734 patient samples:

**Abstract AB0656 – Table 1.**

	I type (n)	II type (n)	III type (n)
Lab A	21	242	108
Lab B	42	270	108
Chi-quadro	p=0.0016	p=0.0004	Ns

Intra-laboratory variability: 14% Lab A, 16% Lab B (ns). Inter-laboratory variability: non-concordance in 25% of cases, considering 133 patients studied in both laboratories (Chi-square test).

**Conclusions:** No data about variability in CRG analysis are reported in literature. National and international guidelines are not explicative enough. Furthermore, many doubts about classifications are established. Our experience is unique but limited in two laboratories. Given the variability of testing conditions used in different laboratories and the lack of test standards and reference values, we confirm the need of further investigations into standardisation of CRG testing. New guidelines are fundamental, in order to optimise all phases of CRG research (pre and post analysis) and to ensure correct diagnosis and adequate treatments of the associated diseases.

#### AB0657 CYCLOPHOSPHAMIDE-SPARING ROLE OF AN INTENSIFIED B-CELL DEPLETION PROTOCOL IN ANCA-ASSOCIATED VASCULITIS: A CASE-CONTROL STUDY

D. Roccatello<sup>1\*</sup>, R. Fenoglio<sup>1</sup>, D. Rossi<sup>1</sup>, M. Radin<sup>1</sup>, I. Cecchi<sup>1</sup>, S. Murgia<sup>1</sup>, S. Baldovino<sup>1</sup>, E. Rubini<sup>1</sup>, S. Sciascia<sup>1</sup>. <sup>1</sup>Center of Immunopathology and Rare Diseases, University of Turin, Turin, Italy

**Background:** The management of ANCA-associated-vasculitis (AAV) requires the use of immunosuppressive drugs with potential toxicity. Recently, two trials demonstrated the efficacy of Rituximab (RTX) for the therapy of AAV.

**Objectives:** this case-control study aims to evaluate the immunosuppressive-sparing effect of a RTX-based protocol compared to the standard CYC treatment.

**Methods:** 26 patients with AAV and extracapillary glomerulonephritis were prospectively enrolled. Thirteen patients received an intensified protocol of B-cell depletion therapy (IBCDT) consisting of 4-weekly infusions of 375 mg/sm RTX followed by 2 infusions after 1 and 2 months, 3 pulses of methylprednisolone followed by prednisone tapered to 5 mg/day in three months and 2 pulses of 10 mg/kg CYC, without further maintenance therapy. Thirteen patients treated with 2 mg/kg/day CYC followed by azathioprine as a maintenance therapy served as controls.

**Results:** A significant improvement (p<0.05) of B-VAS, ESR, CRP and ANCA was observed in the IBCDT-group at 3, 6 and 12 months, with decrease of mean creatinine values from 4.81±6.4 mg/dl to 2.21±3.8 mg/dl.

When compared to controls, no difference was observed in terms of complete and partial response. However, the IBCDT regimen achieved a 1 g/month reduction of CYC cumulative dose (p<0.001).

**Conclusions:** in the treatment of this sample of severe AAV patients, the IBCDT protocol appeared to be noninferior to CYC-based regimen. Notably, the IBCDT regimen allowed a significant reduction of CYC cumulative dose.

#### AB0658 DIFFERENT ORBITAL MANIFESTATIONS OF GRANULOMATOSIS WITH POLYANGIITIS. COMPARATIVE STUDY

D. Ismailova<sup>1</sup>, I. Abramova<sup>1</sup>, P. Novikov<sup>2</sup>. <sup>1</sup>Institute of Eye Diseases of Russian Academy of Medical Sciences; <sup>2</sup>Rheumatology, I.M. Sechenov First Moscow State Medical University, Moscow, Russian Federation

**Background:** Ophthalmic manifestations are typical for granulomatosis with polyangiitis (GPA), and occur in 28.6%–60% of patients. In 8% of cases they lead to permanent visual loss. According to different studies orbital lesion develops in 5%–30.6% of GPA patients and is considered to be the second most prevalent ophthalmic manifestation after conjunctivitis/episcleritis.

**Objectives:** to study clinical features of different orbital manifestations of GPA.

**Methods:** 74 GPA patients with orbital involvement were studied and compared. 3 types of orbital involvement were proposed: orbital mass (45 patients),

dacryoadenitis (26 patients) and myositis (3 patients). Patients with orbital mass (group 1) and dacryoadenitis (group 2) were included into further investigation.

**Results:** Patients in group 1 had systemic disease in 51,1% compared to 7,7% in group 2. Patients with orbital mass presented with more severe clinical manifestations, including significant exophthalmos (82,2%), periorbital oedema (95,5%) and hyperemia (46,7%), strabismus (31,1%), globe movement restriction (71,1%), chemosis (8,9%). Orbital mass was accompanied by necrotizing scleritis in 7 and PUK in 6 patients. Symptoms included orbital pain (88,9%) and binocular diplopia (73,3%). BCVA in this group was 0.67. Clinical outcome was relatively unfavourable: in 24,4% BCVA was less than 0.3, in 5 patients enucleation was performed, in 24,4% strabismus developed and in 73,3% globe movement restriction occurred. Clinical course and outcome were significantly more favourable in patients with dacryoadenitis. Periorbital oedema, exophthalmos and chemosis did not show significant difference in groups, though orbital pain, binocular diplopia, globe movement restriction, strabismus, optic neuropathy, necrotizing scleritis, PUK were observed in group1 significantly more often. Clinical outcome in group 2 was much more favourable with no cases of enucleation and persistent visual loss. They only had moderate exophthalmos 1–3 mm (65,4%), strabismus (7,7%) and mild globe movement restriction (19,2%).

**Conclusions:** Three types of orbital involvement in GPA were proposed: orbital mass, dacryoadenitis and myositis. Patients with orbital mass are characterised more often with systemic disease, more severe clinical course not uncommon associated with other ocular manifestations (necrotizing scleritis, PUK, orbital walls destruction), relatively unfavourable outcome with high level of morbidity (optic nerve atrophy, anophthalmos, strabismus) and higher rate of recurrences.

#### AB0659 PREVALENCE AND CLINICAL FEATURES OF CRANIAL AND EXTRACRANIAL GIANT CELL ARTERITIS

E. Fernández<sup>1</sup>, I. Monjo<sup>1</sup>, L. Coronel<sup>2</sup>, D. Benavent<sup>1</sup>, A. Balsa<sup>1</sup>, E. De Miguel<sup>1</sup>.  
<sup>1</sup>Rheumatology, Hospital Universitario La Paz, Madrid; <sup>2</sup>Rheumatology, Hospital Universitario Nuestra Señora de La Candelaria, Santa Cruz de Tenerife, Spain

**Background:** Giant cell arteritis (GCA) is the most common systemic vasculitis in adults. Although it typically affects the cranial branches derived from the aortic arch, there is increasing evidence of the damage occurring to large vessel extracranial arteries, which is usually misdiagnosed. This subset of large vessel extracranial GCA may have specific clinical features that could hinder the diagnosis, which highlights the need for a different treatment and follow up.

**Objectives:** To analyse the frequency and clinical and analytical features in cranial and extra-cranial GCA.

**Methods:** An observational retrospective descriptive study analysing data from patients with GCA was performed in our hospital. Colour duplex sonography (CDS) studies carried out in the last 29 months were revised. Standardised CDS images from the frontal and parietal branches of the temporal superficial artery (TA) and axillary artery (AXE) with GCA compatible image with intra or extra-cranial involvement (hypochoic, homogeneous and circumferential thickening of the artery wall  $\geq 0.34$  mm in TA, and  $\geq 1$  mm in AXE, respectively). SPSS version 23 were used to analyse a total of 29 variables.

**Results:** Out of the 119 patients that were tested in our fast track GCA clinic, with standardised CDS of TA and AXE, 22 had GCA. All GCA patients was halo sign in CDS. From them, 7 had large vessel involvement (31.8%), from whom 6 were mixed and 1 had exclusively extra-cranial involvement. Mean age at diagnosis was 76 $\pm$ 9.7 SD in the extracranial GCA arteritis and 79 $\pm$ 5.7 SD in the cranial GCA. The extracranial subset had a greater number of men than the cranial (28.6% and 26.6%, respectively) and suffered usually more fever (28.5%>6.6%, respectively), constitutional syndrome (85.7%>40%, respectively) or polymyalgia rheumatica (42.8%>40%, respectively). However, they suffered with more frequency from headache (85.7% vs 93.3%) and jaw claudication (28.5% vs 33.3%). None of them suffered from visual impairment or central nervous system involvement; both do appeared in the cranial GCA group in 13.3% and 6.6%. In the blood tests, mean  $\pm$ standard deviation was: ESR 87.6 $\pm$ 36 mm/h in cranial GCA and 89.5 $\pm$ 19.5 SD mm/h in extracranial GCA, CRP 65 $\pm$ 57.6 and 82.6 $\pm$ 48.4 mg/L and Hb 11.4 $\pm$ 1.3 and 12.1 $\pm$ 1.3 g/dl, respectively. Patients with large vessel involvement met ACR criteria in 80% opposite 92.8% from these with solely cranial GCA. AT biopsy was performed in 7 patients in the cranial subset and 2 in the extra-cranial, testing positive for GCA in 5 (71.4%) in the first group, and none in the second one. CT-PET was performed in 2 patients with cranial GCA with negative results, and in 4 with large vessel involvement, testing positive in 50%. Despite the large differences, the statistical analysis didn't reach statistical significance due to the small sample size.

**Conclusions:** One third of the patients in our study had large vessel involvement, making axillary vessel CDS an important tool for the clinical exam of this disease. These patients tend to be younger and start more often with fever or general

syndrome and less with GCA typical symptoms like headache, jaw claudication or visual loss.

#### AB0660 THE ROLE OF ANTI-NEUTROPHIL CYTOPLASMIC AUTOANTIBODY SPECIFICITY FOR MPO OR PR3 IN PHENOTYPE OF ANCA ASSOCIATED VASCULITIS: KNOWING THE AUTOIMMUNITY IN LATIN AMERICA

E. Calle<sup>1</sup>, M. Calle<sup>2</sup>, H.B. Cabrera<sup>3</sup>, D. Jaramillo-Arroyave<sup>1,4,5</sup>, A.L. Vanegas-García<sup>6,7</sup>, G. Vásquez-Duque<sup>1</sup>, M. Restrepo-Escobar<sup>1</sup>, L.A. González-Naranjo<sup>1</sup>, J. Hernández-Zapata<sup>1</sup>, C.H. Muñoz-Vahos<sup>1,5,7</sup>. <sup>1</sup>Grupo de Reumatología Universidad de Antioquia, Medellín; <sup>2</sup>Universidad CES, Medellín; <sup>3</sup>Medicina Interna, Universidad de Antioquia; <sup>4</sup>Universidad CES; <sup>5</sup>IPS Universitaria Clínica León XIII, Medellín; <sup>6</sup>Grupo de Reumatología Universidad de Antioquia, Medellín; <sup>7</sup>Hospital Universitario San Vicente Fundación, Medellín, Colombia

**Background:** Antineutrophil cytoplasmic antibodies (ANCA) are present in up to 90% granulomatosis with polyangiitis, 80% microscopic polyangiitis and 70% eosinophilic granulomatosis with polyangiitis. MPO-ANCA has been associated with vasculitis limited to the kidney, chronic renal damage and less frequent gastrointestinal or respiratory tract involvement. PR3-ANCA are characterised by destructive lesions of the ears, nose and throat, alveolar haemorrhage, combination of upper and/or lower respiratory tract involvement with renal compromise and increased number of relapses. The frequency of pulmonary involvement is similar in both serotypes, and most ANCA associated vasculitis (AAV) patients are diagnosed between ages 50 and 70 years.

**Objectives:** To describe differences in clinical profiles of patients with AAV regarding ANCA specificity against MPO or PR3 in a Colombian based adult population

**Methods:** All medical records of patients with a diagnosis of AAV in two high complexity hospitals in Medellín, Colombia from January 1, 2014 to December 31, 2016 were reviewed. The clinical and demographic characteristics were abstracted and analysed with descriptive and inferential statistics in SPSS.22

**Results:** Of 59 cases of AAV, 44 were positive for MPO or PR3-ANCA with male predominance (65.5% men vs 34.5% women) and similar age at diagnosis (47 years in MPO-ANCA vs 50 in PR3-ANCA). MPO-ANCA group had more fever and weight loss (34.8% vs 20%), arterial hypertension (34.5% vs 26.7%), hematuria (34.5% vs 26.7%), proteinuria (31% vs 26.7%), creatinin higher than 5.6 mg/dL (20.7 vs 13.3%), myalgias (13.8 vs 0%) pachymeningitis (7% vs 0%) and skin compromise. PR3-ANCA patients had more arthralgias/arthritis (40% vs 31%), escleritis (33% vs 13.8%), episcleritis (13.3% vs 0%) and uveitis (10% vs 7%).

**Conclusions:** In this Latin American population ANCA specificity affected the phenotype of clinical disease. MPO-ANCA patients had more constitutional symptoms, renal and central nervous system compromise while PR3-ANCA patients showed more articular and ocular involvement.

#### AB0661 ASSESSMENT OF DAMAGE AND PROGNOSIS IN PATIENTS WITH ADULT IGA VASCULITIS: RETROSPECTIVE MULTICENTERED COHORT STUDY

E. Alibaz-Oner<sup>1</sup>, A. Omma<sup>2</sup>, A. San<sup>3</sup>, Ü. Gazel<sup>1</sup>, D. Üsküdar Cansu<sup>4</sup>, A. Yazıcı<sup>5</sup>, A. Cefle<sup>5</sup>, C. Bes<sup>6</sup>, Ö. Karadağ<sup>3</sup>, H. Direskeneli<sup>1</sup>. <sup>1</sup>Rheumatology, Marmara University, School of Medicine, Istanbul; <sup>2</sup>Rheumatology, Ankara Numune Research and Training Hospital; <sup>3</sup>Rheumatology, Hacettepe University, School of Medicine, Ankara; <sup>4</sup>Rheumatology, Osmangazi University, School of Medicine, Eskişehir; <sup>5</sup>Rheumatology, Kocaeli University, School of Medicine, Kocaeli; <sup>6</sup>Rheumatology, Bakirköy Sadi Konuk Research and Training Hospital, Istanbul, Turkey

**Objectives:** IgA Vasculitis is a leukocytoclastic vasculitis involving small vessels with depositions of immune complexes containing IgA. IgA Vasculitis is a predominantly paediatric vasculitis. There is limited data for the prognosis of adult IgA Vasculitis, with also no damage assessment. In this study, we aimed to evaluate

the clinical characteristics, treatment, outcome and damage of patients with adult IgA Vasculitis.

**Methods:** We assembled a retrospective cohort of patients with adult IgA Vasculitis from tertiary Rheumatology Centres in Turkey. The demographics, clinical characteristics, treatment and outcomes of patients were abstracted from medical records. Birmingham Vasculitis Activity Score (BVAS), prognostic Five Factor Score (FFS) and vasculitis damage index (VDI) were calculated.

**Results:** The study included 103 (male/female: 67/36) patients with adult IgA Vasculitis. The mean age was 42.6±17 years. Infection history within 6 weeks before presentation was present in 40 (38.8%) patients (32 upper respiratory tract, 3 urinary tract, 2 gastrointestinal, 3 others). Cutaneous manifestations and arthritis/arthralgia were the most common clinical manifestations (table 1). 92 (89.3%) patients were treated with oral glucocorticoids (GC). Pulse GC treatment was also given to 29 (28.1%) patients. As additional immunosuppressive agents, azathioprine was given to 36 (34.9%) and pulse cyclophosphamide to 13 (12.6%) patients. Fifty-nine patients (58.2%) had follow-up of mean 35.6 months. Eleven (18.6%) patients relapsed during follow-up. While 5 relapses were major, six of them were minor relapses. At the last visit, disease status was evaluated as active or treatment failure by the treating physician in 7 (11.8%) patients. The rate of chronic renal failure was 8.3%(n=5). Mortality was 1.6% (n=1) during follow-up, due to pneumonia. The mean VDI score was 0.3 in the last visit. Twelve (20.3%) patients had at least one damage item at the end of follow-up period.

**Abstract AB0661 – Table 1.** Baseline clinical characteristics of patients with adult Henoch Schönlein Purpura

	Adult Henoch Schönlein Purpura (n=103)
<b>Laboratory parameters</b>

### AB0662 SUBGLOTTIC STENOSIS IN GRANULOMATOSIS WITH POLIANGIITIS

C.E. Pena<sup>1</sup>, F. Giordano<sup>2</sup>, L. Garcia<sup>1</sup>, C. Costi<sup>1</sup>, G. Pendon<sup>2</sup>, A. Vulcano<sup>1</sup>, D. Pereira<sup>1</sup>, M. Garcia<sup>1</sup>. <sup>1</sup>Rheumatology, HIGA San Martin La Plata; <sup>2</sup>Rheumatology, Hospital Gutierrez La Plata, La Plata, Argentina

**Background:** The characteristic lesion of laryngotracheal involvement in granulomatosis with polyangiitis (GPA) is subglottic stenosis (SGS), due to active disease or from chronic recurrent inflammation, 8% to 23% during the course of GPA and as initial manifestation in 1% to 6% of cases.

**Objectives:** Describe clinical features and treatment of patients with SGS

**Methods:** We retrospectively reviewed the medical records of 46 patients with SGS due to GPA diagnosed at a Rheumatology department (2000–2017).

We retrospectively reviewed the medical records of 46 patients with SGS due to GPA diagnosed at a Rheumatology department (2000–2017).

**Results:** 6/46 patients with GPA diagnosis presented SGS (13%). 83% women, mean age of 37.8 years (DS ±14.8). Mean time between the presentation of the GPA and the diagnosis of SGS:18 months. Most frequent clinical manifestations of SGS: dyspnea (83%), stridor (83%), dysphonia (50%), cough (33%), bronchospasm (16%). One patient presented SGS as initial manifestation of the disease. Mean BVAS:14. Two patients presented such complication with evidence of systemic manifestations. Re stenosis was observed in one patient.

**Treatment:** IV CYC 83%, oral CYC 16%, methylprednisolone (MP) 83%, oral steroids, plasma exchange (16%) in each one. Endoscopic intervention and balloon dilatation 33%, and intralesional Mitomycin 16%.

**Conclusions:** 13% patients with GPA presented SGS, being in the majority of cases associated with other manifestations of the disease. However, 67% had no signs of systemic involvement (localised disease). Local treatment was necessary in only 33% because there was a good response to IS in 67% of the cases.

### AB0663 18F-FDG-PET/CT DISEASE DISTRIBUTION IN A LARGE VESSEL VASCULITIS COHORT – SUPPORTS VASCULAR ULTRASOUND AS A SCREENING AND DIAGNOSTIC TOOL

F. Coath<sup>1</sup>, F. Laskou<sup>1</sup>, S. Moghul<sup>2</sup>, A. Sidhu<sup>1</sup>, S. Banerjee<sup>1</sup>, T. Aung<sup>1</sup>, S. Jain<sup>2</sup>, J. Mo<sup>2</sup>, B. Dasgupta<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Southend University Hospital, Westcliff-On-Sea, UK

**Background:** Subsets of GCA have extensive vascular involvement, termed Large Vessel GCA (LV-GCA), seen in 12%–37% depending on imaging used. These patients have higher relapse rates and are more often refractory to glucocorticoids (GC), requiring steroid-sparing treatment to minimise GC toxicity and vascular complications. Diagnosis is reliant upon imaging, given the relative inaccessibility of tissue for histological analysis beyond temporal artery biopsy (TAB). If axillary and subclavian arteries are often affected, vascular ultrasound could be an effective screening tool.

**Objectives:** To determine disease distribution in the Southend Large Vessel Vasculitis (LVV) cohort, particularly levels of axillary and subclavian involvement.

**Methods:** The cohort has sixty-five patients (2010–2017), from which sixty <sup>18</sup>F-FDG-PET/CT scans were performed. They were retrospectively examined by two nuclear radiologists. Vascular involvement was determined by consensus opinion at six territories (thoracic-aorta, abdominal-aorta, subclavian, axillary, carotid, vertebral, and iliac and femoral). Six negative scans were excluded from analysis, with LVV confirmed from other evidence (ultrasound, computed tomography). Of these, four were on concurrent GC (7–12 mg prednisolone), raising the possibility of “false negatives”. Nineteen scans were positive despite GC (1–60 mg prednisolone). Higher doses tended to be of short duration, being unable to postpone due to clinical necessity, but exceeded the 3 day limit at which FDG signal starts to attenuate.

**Abstract AB0663 – Figure 1.** Disease distribution via <sup>18</sup>F-FDG-PET/CT

**Results:** 14.8% (n=8) had isolated supra-aortic disease, 14.8% (n=8) had isolated aortic disease, and 29.6% (n=16) had involvement in both (Fig 1). 72.2% of

Abstract AB0662 – Table 1

Case	Sex/Age at diagnosis of SGS	Time from diagnosis (months)	Manifestations of SGS	Manifestations of vasculitis/BVAS	ANCA	Treatment Induction (I) Maintenance (M)	Evolution
1	W/20	12	Stridor Dysphonia Bronchospasm	No systemic manifestations BVAS: 6	MPO	I: IV CYC+IV steroids M: MTX+oral steroids	Resolution

scans had involvement at either or both of the axillary and subclavian territories. Femoral and iliac involvement alone was seen in 1.9% (n=1), and in addition to aortic involvement in 7.4% (n=4). In this latter group, it was limited to the abdominal aorta in half, and included 1 case of Retroperitoneal Fibrosis. 31.5% (n=17) had involvement in all 3 regions. 24.1% (n=13) had no supra-aortic involvement.

**Conclusions:** This cohort demonstrates LVV has a predilection for aortic and supra-aortic regions. High axillary and subclavian involvement supports the use of vascular ultrasound as an effective imaging tool. Further imaging would still be warranted if suspicion remained high despite negative ultrasound, or to assess for vascular complications and alternate pathology. <sup>18</sup>F-FDG-PET/CT is not without limitations. Atherosclerosis and vascular remodelling display increased FDG uptake, so requires cautious interpretation. Further research on GC influence is also needed. As such it has a role in monitoring flaring or non-responsive patients, rather than routine interval scanning. For the latter, ultrasound may be an alternative, especially if there is previously documented intimal-medial thickening at ultrasound accessible sites.

#### LIFE EXPECTANCY IN PATIENT WITH GIANT CELL ARTERITIS (GCA): IMPACT OF VISION LOSS

G.S. Breuer<sup>1,2,3</sup>, V. Poltorak<sup>1,3</sup>, R. Neshar<sup>4</sup>, G. Neshar<sup>1,2,3</sup>. <sup>1</sup>Hebrew University, School of Medicine; <sup>2</sup>Medicine; <sup>3</sup>Rheumatology, Shaare Zedek Medical Center, Jerusalem; <sup>4</sup>Ophthalmology, Meir Medical Center, Kfar Saba, Israel

**Background and purpose:** Several epidemiologic studies reported increased mortality in patients with GCA, while others found that the overall survival was essentially identical to that of the general population. Those studies used different methods to calculate the mortality rates.

**Objectives:** In this retrospective study we evaluated longevity in a group of GCA patients using specific gender and age-matched life expectancy tables.

**Methods:** Medical records of patients diagnosed with GCA in one Medical Centre between 1980–1999 were reviewed for clinical parameters at the time of diagnosis and during the first year of treatment, and for time of death and cause of death. All patients diagnosed as GCA during that time period have already passed away. For each patient the observed survival was compared with the specific age and gender-matched life expectancy in the general population, based on life expectancy tables of the Israel Central Bureau of Statistics.

**Results:** 87 patients (51 females, 36 males) were included, their mean age at the time of GCA diagnosis was 73.9±8.4 and 75±8.1 years, respectively. The calculated mean life expectancy for this group of patients, from the time of diagnosis, was 14.1±6 years for females and 12±5.2 for males. However, the actual survival was significantly shorter, 7.5±6.2 years (p<0.001) in females, and 7.7±7.3 years (p=0.005) in males. Survival was not significantly affected by the intensity of inflammation at the time of diagnosis (based on the presence of fever, anaemia, sedimentation rate above 100 mm/h, thrombocytosis and leukocytosis), by the daily dose of prednisone at 1 year, or by the use of low-dose aspirin during the first year. However, vision loss at the time of presentation (n=13), was associated with further decrease in survival, 4.1±4.4 years compared to 8.3±6.8 years in GCA patients with no vision loss (p=0.035). Causes of death were defined in 54 patients. The leading causes of death were cardiovascular/cerebrovascular diseases, in 43% of the patients, slightly exceeding the respective rate in the age-matched general population (40%, p=0.8), and infectious diseases, in 37% of the patients, significantly exceeding the respective rate in the age-matched general population (22%, p=0.015).

**Conclusion:** Infectious diseases were often the cause of mortality in this group of GCA patients, relative to the background population. Survival following GCA diagnosis was significantly shorter than expected, especially in patients presenting with vision loss.

#### INTERSTITIAL LUNG DISEASE AMONG PATIENTS WITH GIANT CELL ARTERITIS

H. Tamaki<sup>1</sup>, T. Jinta<sup>2</sup>, M. Okada<sup>1</sup>. <sup>1</sup>Immuno-Rheumatology Center, St. Luke's International Hospital; <sup>2</sup>Pulmonary Medicine, St Luke's International Hospital, Tokyo, Japan

**Background:** Lately interstitial lung disease (ILD) has been recognised more and more as a manifestation of primary systemic vasculitis, particularly among patients with microscopic polyangiitis (MPA), which is predominantly a disease of the elderly in Japan. Another primary systemic vasculitis that occurs frequently in

the elderly is Giant Cell Arteritis (GCA) and one of the unusual manifestations of GCA includes non-productive cough that can occur in about 10% of patients. It is speculated that vasculitis in the area of cough receptors results in this manifestation. There have been only anecdotes about the association of GCA with ILD and it is unknown whether ILD is truly prevalent in patients with GCA.

**Objectives:** Here we systematically reviewed chest images of patients with GCA and investigated the prevalence of CT scan abnormality consistent with ILD among patients with GCA.

**Methods:** Single centre retrospective chart review was conducted at St. Luke's International Hospital in Tokyo. The charts of patients with the diagnosis of GCA who were seen from March 2004 till August 2017 were extracted. The clinical data were obtained. Pulmonary images were reviewed by one of the authors, who is a pulmonologist and characteristics of the pulmonary lesions based on computed tomography (CT) of the lung were recorded.

**Results:** Forty-six patients had a diagnosis of Giant Cell Arteritis. Thirty-nine of them had a chest CT scan. The mean age of the patients was 69±17 years and 27 patients (58%) were female. Ten patients (26%) had abnormality in the CT scan. The abnormality included linear infiltrates beneath the posterior aspect of the pleura in the lung bases (n=9), ground glass opacities (n=3), honeycombing (n=3), and reticulonodular infiltrates (n=2). Two patients received prednisolone for ILD, ILD of whom were stable. No patients died during the median follow up of 14.5 months.

**Conclusions:** Chest CT abnormality consistent with mild ILD was prevalent among patients with GCA. The prognosis of these patients appears to be favourable and these patients responded to prednisolone.

AB0666

#### CLINICAL AND SEROLOGICAL OUTCOMES OF PATIENTS WITH GIANT CELL ARTERITIS TREATED WITH TOCILIZUMAB OR ABACEPT AS STEROID-SPARING AGENTS

D. Rossi, L. Cecchi, E. Rubini, M. Radin, S. Sciascia, D. Roccatello. *Università Degli Studi di Torino, Turin, Italy*

**Background:** Giant cell arteritis (GCA) is a common form of systemic vasculitis. The current mainstay of GCA management is glucocorticoid (GC) therapy. Recently, at least 2 biological therapies [tocilizumab (TCZ) and abatacept (ABA)] have been proven to be effective in the management of CGA in randomised controlled trials. Nevertheless, their use as steroid sparing agents might need further investigation.

**Objectives:** We aimed to investigate the steroid-sparing effect of biological therapies, namely TCZ and ABA, in a cohort of GCA patients when compared to standard GC treatment.

**Methods:** We retrospectively collected data from GCA patients who attended the S.G. Bosco Hospital, Turin, Italy, who were treated with TCZ, both intravenous (IV) and subcutaneous (SC), and/or ABA SC (8 mg/kg/month, 162 mg/week, and 125 mg/week respectively). These therapies were prescribed as first line agents or as second line when patients were refractory/intolerant/contraindicated to standard immunosuppressive therapies. Complete response to the treatment was defined as a clinical and serological remission after 12 months of therapy; partial response was defined as clinical or serological remission after 12 months of therapy.

**Results:** This retrospective study included 33 GCA patients [mean age 74 (range 85–57), females 63%, mean follow-up from GCA diagnosis 44.4±33.5 months]. *Table 1* resumes the characteristics of the GCA patients included in the study. Twenty-eight patients out of 33 (85%) received one biologic agent. Five patients (15%) needed a therapeutic switch (one patient from TCZ to ABA, and 4 patients from ABA to TCZ). Patients were treated as follow: 9 with TCZ IV, 11 with TCZ SC, and 18 with ABA.

Among the TCZ IV group, all patients experienced a response (57% complete response, and 43% partial response). Among the TCZ SC group, 83% experienced a response (67% complete response, and 16% partial response). Among the ABA group, 86% experienced a response (36% complete response and 50% partial response). After 12 months of therapy, 100% of patients in TCZ groups, both IV and SC, and 64.2% of ABA group were treated with low doses of oral prednisone (≤7.5 mg/day) as maintenance. We noticed a significant reduction of inflammatory parameters [C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR)] after 12 months of therapy with TCZ [TCZ IV group: mean baseline CRP (mg/dl) 1.9±2.3, mean CRP after 12 months of therapy 0.3±0.2; mean baseline ESR (mm/h) 58.1±25.6, mean ESR after 12 months 9.5±4.2; TCZ SC group: mean baseline CRP 4.5±3.8, mean CRP after 12 months 0.2±0.2; mean baseline ESR 51.9±27, mean ESR after 12 months 6.5±6]. When compared to standard GC regimen,<sup>1</sup> in patients treated with TCZ, both IV and SC, we estimated a median steroid-sparing effect quantifiable in 30 mg/daily in the first month and an overall steroid-sparing effect of 15 mg/daily when assessed in 12 months.

**Abstract AB0666 – Table 1.** Characteristics of GCA patients included in the study

	Total number of patients (33)	%
<b>Demographic characteristics</b>		
Female/Male	21/12	
Age (years) (mean, SD)	73.6 ±8.7	
<b>Clinical characteristics at the onset of GCA</b>		
Fever (n)	12	36.4
Fatigue (n)	18	54.5
Headache (n)	28	84.8
Scalp tenderness (n)	8	24.2
Jaw claudication (n)	15	45.4
Vision loss (n)	16	48.5
PMR (n)	11	33.3
<b>Diagnosis</b>		
Biopsy proven	27/32	84.4
PET positivity	12/29	41.4
Eco-color-doppler positivity	30/31	97
<b>GC therapy</b>		
Previous methylprednisolone pulses (n)	7	21.2
Oral prednisolone (n)	33	100
Dose of oral prednisolone (mg/day) (mean, SD)	49.7 ±15.1	
<b>Previous immunosuppressive therapies</b>		
Methotrexate (n)	11	33.3
Mean dose (mg/week) (mean, SD)	15.6 ±1.7	
Mycophenolate (n)	6	18.1
Mean dose (g/day) (mean, SD)	2.2 ±0.4	

**Conclusions:** This retrospective study confirms the efficacy of biological therapies in the management of CGA. Besides, in our experience TCZ allowed a significant reduction of GCs use, especially in the first month of therapy, when compared to standard GCs-based regimens.

#### PREGNANCY OUTCOMES IN A TERTIARY TAKAYASU ARTERITIS CARE CENTRE

I.E. Szabo<sup>1</sup>, M.M. Tamas<sup>1,2</sup>, L. Damian<sup>1</sup>, I. Filipescu<sup>1,2</sup>, I. Dobrota<sup>1</sup>, S. Rednic<sup>1,2</sup>.  
<sup>1</sup>Department of Rheumatology, Emergency Clinical County Hospital; <sup>2</sup>Department of Rheumatology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj-Napoca, Romania

**Background:** Fertility and pregnancy are concerning issues in women of child-bearing age with Takayasu arteritis (TA). Available data on the management and expected events in TA during pregnancy are sparse and inconsistent among study populations<sup>2,3</sup>. Conflicting reports exist on both favourable pregnancy outcomes as well as increased fetal or maternal complications<sup>1,4</sup>.

**Objectives:** To assess the obstetric and maternal outcomes in a tertiary centre TA cohort.

**Methods:** 15 female patients fulfilling the American College of Rheumatology 1990 criteria for the classification of TA were included in this retrospective study. Data regarding number of pregnancies, disease characteristics and pregnancy related events were gathered from medical records. Disease extent was classified according to Numano classification criteria for TA: type I (4 patients, 26.66%), type III (4 patients, 26.66%), type V (3 patients, 20%), type IV (2 patients, 13.33%), type IIa (1 patient, 6.66%), type IIb (1 patient, 6.66%). The prevalence of obstetric and maternal complications was evaluated in women before or after TA diagnosis. 6 patients were further excluded due to the paucity of information concerning pregnancy outcomes.

**Results:** A total of 15 pregnancies were identified in 9 patients, with 9 (60%) occurring before TA diagnosis – group 1, and 6 (40%) occurring concomitant with or after TA diagnosis – group 2. In the first group the extent of arterial involvement was mostly consistent with type I TA (6 pregnancies, 66.66%). No fetal or maternal complications were observed in this group. Type III TA was most commonly encountered (4 pregnancies, 66.66%) in group 2. Only one patient from the second group had more than 1 pregnancy after TA diagnosis. Active disease (National Institutes of Health/NIH score >1) was reported in 2 (33.33%) pregnancies in the second group. Cardiovascular events occurred exclusively during 2 (33.33%) pregnancies exhibiting active disease. One patient suffered severe aortic regurgitation and gestational hypertension during pregnancy, while the second patient experienced worsening of preexisting hypertension. These required steroid dose increase and addition of antihypertensive drugs. There were no obstetric events in group 2.

**Conclusions:** Most TA pregnancies are uneventful, bearing favourable fetal-maternal outcomes. However, pregnant TA patients with active disease, have higher risk of developing maternal complications, especially cardiovascular events. In this setting, close monitoring and disease remission should be maintained during pregnancy.

### AB0668 TREATMENT OF THROMBOTIC EVENTS IN BEHÇET DISEASE: A SYSTEMATIC LITERATURE REVIEW

J. Janta, R.D. Gonzalez Benitez, B. Serrano Benavente, I. Monteagudo Saez. *Rheumatology, Gregorio Marañón General Hospital, Madrid, Spain*

**Background:** Behçet's disease (BD) is a systemic disease which etiopathogenesis is largely unknown. It is characterised by a wide variety of clinical manifestations. Venous disorder is a serious manifestation being potentially life-threatening. There is little evidence on the management of the venous complications in BD.

**Objectives:** To perform a systematic literature review on the treatment used in venous thrombotic events in BD.

**Methods:** The objective was reformulated according to the PICO approach. Several synonyms for the main components (i.e. Behçet, thrombosis, treatment) were used. Search limits were applied for humans. The literature search was performed in Medline and Embase from databases inception to 1st November 2017. Only articles in English and Latin languages were retained. We excluded abstracts, reviews and letters. From the selected studies, data about the venous involvement and treatments were retired using a predefined data collection form.

**Abstract AB0668 – Table 1**

Treatment	Nº articles (%)
Anticoagulant	22 (78.6)
Antiplatelet	9 (33.3)
Corticosteroids	22 (78.6)
Immunosuppressive	25 (89.3)
Cyclophosphamide	16 (57.1)
Azathioprine	16 (57.1)
Cyclosporine A	5 (17.9)
Mycophenolate mofetil	2 (7.1)
Interferon alpha	2 (7.1)
Methorexate	4 (14.3)
Hydroxychloroquine	1 (3.6)
Anti-TNF alpha	4 (14.3)
Colchicine	11 (39.3)
Thalidomide	1 (3.6)
Dapsona	1 (3.6)
Fibrinolytic	3 (10.7)
Surgery	7 (25.9)

**Results:** The literature search resulted in 1552 articles, of which 632 were captured in Medline and 920 in Embase. Figure 1 shows the study flow-chart for article selection. The main reasons for article exclusion after full-text review were the lack venous involvement and the lack of explanation of venous involvement treatment. 28 articles reporting 1904 patients were included in qualitative analysis. The mean (range; SD) duration time between the disease onset and the vascular onset was evaluated in 15 articles and was 4.9 (1.2–9.3; 2.7) years. Superficial thrombosis was evaluated in 6 (21.4%) articles, profound thrombosis in 19 (67.9%) articles, cerebral in 7 (25%), inferior or superior cava vein in 15 (53.6%) and Budd-Chiari syndrome in 8 (28.6%) articles. Table 1 shows the treatments described in the selected articles. Treatment response was evaluated in 20 (71.4%) articles; in 7 of these treatments response was evaluated in a subjective way. In total, 52 (2.7%) deaths were reported in relation to BD. In 319 (16.7%) patients, partial efficacy or recurrence of thrombosis was reported. Considering the heterogeneity of the reported data and the variability in the measures of treatment response, predictors of mortality risk cannot be analysed. However, in the reviewed articles, a higher mortality rate was observed in patients with hepatic involvement due to Budd-Chiari syndrome. We have also observed a higher risk for the development of venous thrombosis in patients with patergia phenomenon and male sex. Two studies suggested that immunosuppressive treatment

concomitant with anticoagulant treatment is associated with a lower risk of thrombosis relapse compared with anticoagulant treatment alone.

**Abstract AB0668 – Figure 1**

**Conclusions:** There is a great variability in the treatment of venous thrombosis related to Behçet's disease. Budd-Chiari syndrome seems to be related to a worse prognosis of the disease.

**Disclosure of Interest:** None declared

**Background:** Uveitis is the most common ocular manifestation in Behçet's Disease (BD), which can cause irreversible blindness.<sup>1–2</sup>

**Objectives:** To assess efficacy, safety and cost-effectiveness of adalimumab (ADA) therapy optimisation in a series of patients with uveitis due to BD.

**Methods:** Multicenter study of 74 ADA-treated patients with BD uveitis refractory to conventional immunosuppressants. Following remission, optimisation was performed by increasing the ADA dosing interval. Comparison between optimised and non-optimised group was performed.

**Results:** Ocular remission was achieved in 65 (86.6%) patients after a median ADA duration of 6<sup>3–12</sup> months. ADA was optimised in 23 cases. In the remaining 42 ADA was maintained at 40 mg/sc/2 weeks. No baseline differences were found at ADA onset between the optimised and non-optimised groups. Ocular outcomes were similar after a mean  $\pm$ S.D. follow-up of 34.7 $\pm$ 13.3 and 26 $\pm$ 21.3 months in the both groups (table 1). Adverse effects were seen in non-optimised group (lymphoma, pneumonia, local reaction and bacteremia). Mean ADA treatment costs were lower in the optimised vs non-optimised group (6101.25 €/patient/year vs 12339.48).

Abstract AB0669 – Table 1

**Background:** Retinal vasculitis (RV) is a serious complication of uveitis due to Behçet's disease (BD).<sup>1-2</sup>

**Objectives:** We assess the short/long-term efficacy of Infliximab (IFX) in refractory RV of BD.

**Methods:** Multicenter study of patients with RV of BD refractory to corticosteroids and at least 1 conventional immunosuppressant (IS). We compared efficacy of IFX between baseline, 1st week, 1–6 months and 1–6 years.

**Results:** 72 patients/129 affected eyes (40♂/32♀) with mean age of 39.6±9.7 years. HLA-B51 was (+) in 63%. Before IFX onset, patients had received: oral/e.v. glucocorticoids (n=98), CyA (n=56), AZA (n=43), MTX (n=34) and other IS (n=22). IFX was used as monotherapy in 17 patients and combined with conventional IS in the remaining 55.

IFX dose was as follows: 3 mg/kg/4–8 w (n=5), 4 mg/kg/4 w (n=1), 5–5.5 mg/kg/4–8 w (n=66).

Following IFX onset, an improvement in RV was seen, as well as in the other ocular outcomes. This enhancement was maintained (table 1).

After a mean follow-up of 26.5±22.1 months, IFX was discontinued in 44: remission (n=15), primary failure (n=16), preference of another route of administration (n=8), pregnancy (n=1) and adverse effects (n=4).

**AB0671 FIRST DOCUMENTATION OF RS3PE AFFECTING THE HANDS ON 18F-FDG WHOLE BODY PET/CT IN POLYMYALGIA RHEUMATICA**

C.E. Owen<sup>1,2</sup>, A.M. Poon<sup>2,3</sup>, L.P. Yap<sup>4</sup>, J.L. Leung<sup>1,2</sup>, D.F. Liew<sup>1,2</sup>, S.T. Lee<sup>2,3,5</sup>, A.M. Scott<sup>2,3,5</sup>, R.R. Buchanan<sup>1,2</sup>. <sup>1</sup>*Rheumatology, Austin Health, Heidelberg VIC*; <sup>2</sup>*Medicine, University of Melbourne, Parkville VIC*; <sup>3</sup>*Molecular Imaging and Therapy, Austin Health, Heidelberg VIC*; <sup>4</sup>*Olivia Newton-John Cancer Research Institute, Heidelberg VIC, Australia*

**Background:** Remitting seronegative symmetrical synovitis with pitting oedema (RS3PE) syndrome describes a clinical entity characterised by distal synovitis with pitting oedema, the absence of rheumatoid factor (Rf) and an excellent response to glucocorticoid therapy.<sup>[1]</sup> Most frequently associated with polymyalgia rheumatica (PMR), tenosynovial sheath inflammation represents the magnetic resonance imaging (MRI) hallmark of this condition, with concomitant joint synovitis also present in some cases.<sup>[1]</sup> More recently, diffusely increased <sup>18</sup>F-fluorodeoxyglucose (<sup>18</sup>F-FDG) uptake in the soft tissues around the ankles and feet has been described as the correlate of RS3PE on whole body positron emission tomography/computed tomography (PET/CT).<sup>[2]</sup>

**Objectives:** To document the clinical and radiologic appearance of RS3PE syndrome affecting the hands on MRI and whole body PET/CT in PMR patients.

**Methods:** Patients with newly diagnosed PMR were prospectively recruited as part of the Melbourne Predictors of Relapse in PMR (MPR-PMR) study. A standard physical examination was carried out with specific focus upon the presence of peripheral synovitis and pitting oedema. In patients with findings suggestive of RS3PE, clinical photography was undertaken. All study participants underwent a whole body PET/CT scan including dedicated views of the hands using the Philips T/F machine prior to prednisolone commencement. To precisely identify anatomic correlates of abnormal <sup>18</sup>F-FDG uptake in patients with RS3PE, MRI of the wrist and hand was performed using a 1.5 Tesla magnet.

**Results:** 3/35 patients (0.86%) were noted to have distal synovitis and pitting oedema of the hands at enrolment. Mean age was 70.9±10.1 years, two patients were male, and all were Caucasian. Rf and anti-citrullinated peptide autoantibodies were negative in all cases. On whole body PET/CT, intense <sup>18</sup>F-FDG uptake was visualised at the wrist joint and hand in a distinctive volar distribution. MRI of the wrist and hand in two participants (contraindicated in the third)

confirmed flexor tenosynovitis (white arrows) and intercarpal synovitis (yellow arrow) in keeping with RS3PE syndrome.

Abstract AB0671 – Figure 1

**Conclusions:** On whole body PET/CT, RS3PE syndrome is associated with a distinctive volar pattern of abnormal  $^{18}\text{F}$ -FDG uptake at the wrist and hand, which correlates with flexor tenosynovitis and intercarpal synovitis as previously described on MRI.

#### AB0672 18F-FDG WHOLE BODY PET/CT AS A DIAGNOSTIC TEST FOR POLYMYALGIA RHEUMATICA IN PATIENTS WITH NORMAL INFLAMMATORY MARKERS

C.E. Owen<sup>1,2</sup>, E. Martin<sup>1</sup>, A.M. Poon<sup>2,3</sup>, J.L. Leung<sup>1,2</sup>, D.F. Liew<sup>1,2</sup>, S.T. Lee<sup>2,3,4</sup>, A. M. Scott<sup>2,3,4</sup>, R.R. Buchanan<sup>1,2</sup>. <sup>1</sup>Rheumatology, Austin Health, Heidelberg VIC; <sup>2</sup>Medicine, University of Melbourne, Parkville VIC; <sup>3</sup>Molecular Imaging and Therapy, Austin Health; <sup>4</sup>Olivia Newton-John Cancer Research Institute, Heidelberg VIC, Australia

**Background:** Despite abnormal C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) being required in the 2012 EULAR/ACR classification criteria, 7%–20% of polymyalgia rheumatica (PMR) patients possess normal inflammatory markers at diagnosis.<sup>1</sup> A characteristic pattern of  $^{18}\text{F}$ -fluorodeoxyglucose ( $^{18}\text{F}$ -FDG) uptake is seen on whole body positron emission tomography/computed tomography (PET/CT) in PMR, hence this imaging modality may be a useful diagnostic test in this clinical scenario.

**Objectives:** To report the utility of whole body PET/CT for diagnosing PMR in patients with normal inflammatory markers and compare the clinical and radiologic characteristics of this subgroup with patients from the Melbourne Predictors of Relapse in PMR (MPR-PMR) study.

**Methods:** Patients presenting with clinical features of PMR according to the 2012 EULAR/ACR classification criteria but normal CRP and ESR underwent  $^{18}\text{F}$ -FDG PET/CT as part of their diagnostic work-up. A whole body scan from skull vertex to feet (including dedicated hand views) was performed using the Phillips T/F machine prior to prednisolone commencement. Qualitative and semi-quantitative (standardised uptake value maximum [SUV<sub>max</sub>]) scoring of abnormal  $^{18}\text{F}$ -FDG uptake was undertaken. Newly diagnosed and untreated PMR patients who underwent the same  $^{18}\text{F}$ -FDG PET/CT protocol as part of the MPR-PMR study were used as the comparator group. Statistical analysis was conducted using Stata 13.1 (StataCorp, College Station, TX, USA).

**Results:** Three patients with normal inflammatory markers (Median CRP 1 [0.9–2], median ESR 6<sup>1–7</sup>) underwent  $^{18}\text{F}$ -FDG PET/CT. Mean age was 60.15±7.55

years, two patients (66.67%) were male and all were Caucasian. Shoulder and hip pain was present in all cases, but only one patient reported peripheral joint involvement. Median early morning stiffness (EMS) was 30 min.<sup>15–60</sup> On whole body PET/CT, characteristic  $^{18}\text{F}$ -FDG uptake was visualised in each patient at the shoulder capsule, trochanteric bursae and adjacent to the ischial tuberosities, with hip capsule involvement similarly present in 2/3. When compared with 35 patients from the MPR-PMR study, there were no statistically significant differences in the clinical characteristics nor the distribution or intensity of abnormal  $^{18}\text{F}$ -FDG uptake between the two populations.

**Conclusions:** In patients with suggestive clinical features but normal inflammatory markers, whole body PET/CT may be utilised to confirm a diagnosis of PMR.

#### AB0673 ANCA-ASSOCIATED VASCULITIS AND INFECTIONS: RETROSPECTIVE ANALYSIS IN A REFERRAL CENTRE

J. Álvarez Troncoso, Z. Iannaccone, E. Álvaro Valiente, C. Busca Arenzana, L. Ramos Ruperto, G. Daroca Bengoa, J. Vasquez Manau, F. Arnalich Fernández, J.J. Ríos Blanco. *Internal Medicine, Hospital Universitario La Paz, Madrid, Spain*

**Background:** The antineutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) are rare multisystem autoimmune diseases of unknown cause, characterised by inflammatory cell infiltration causing necrosis of blood vessels. The AAV comprise granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA). The AAV are autoimmune diseases with potentially severe systemic involvement that require prolonged immunosuppressive therapy. Infection is a frequent complication in AAV and is associated with increased morbidity and mortality.

**Objectives:** The aim of this study was to define epidemiology, ANCA patterns, treatments, infections and outcomes of a series of 39 patients with AAV.

**Methods:** We retrospectively analysed 39 patients diagnosed with AAV between 1995 and 2017 from the Internal Medicine Department of a Spanish referral centre.

**Results:** A total of 39 patients were reviewed. 23 female (58.9%). Mean age at diagnosis was 55.6 years. Median time delay to diagnosis was 7.6 weeks. Median follow-up was 91.3 months. Most frequent AAV was MPA with 18 patients (46.2%), followed by GPA with 11 (28.2%) and EGPA with 10 (25.6%). 6 patients (15.4%) had a concomitant autoimmune disease: Systemic sclerosis,<sup>2</sup> Antiphospholipid syndrome,<sup>2</sup> Lupus<sup>1</sup> and Sjögren.<sup>1</sup> Only 2 patients (5.1%) had previous infection with hepatitis C virus. Regarding the treatments, all patients received corticoids (bolus 24 patients, 61.5%), 29 (74.4%) cyclophosphamide, 10 (25.6%) rituximab, 19 (48.7%) azathioprine, 4 (10.3%) mycophenolate and 1 (2.6%) methotrexate. 16 patients presented post-treatment lymphopenia, 5 pancytopenia, and 15 hypogammaglobulinemia. 21 patients (53.8%) presented any infection after the diagnosis. The most frequent were bacterial infections (15 patients), presenting 9 patients with sepsis criteria (7 due to gram-negative organisms). 9 opportunistic infections were described: 3 infections by cytomegalovirus, 5 by tuberculosis and 1 by *Mycobacterium avium*. There were no cases of *Pneumocystis jirovecii* despite the fact that only 16 patients (41%) performed primary prophylaxis. The factors associated with increased risk of infections were: lymphopenia, pancytopenia and increased BVAS ( $p < 0.05$ ). 6 patients had died at the time of the study (3 associated with infections, 2 with neoplasms and 1 directly with AAV). The Charlson index performed at the time of the study was the best predictor of mortality ( $p < 0.01$ ).

**Conclusions:** Infections were a frequent complication in patients with AAV and one of the main causes of mortality. Risk factors were lymphopenia, pancytopenia and increased BVAS. Bacterial infections were the most frequent but opportunistic infections must be taken into account.

**AB0674 RISK FACTORS OF ATHEROSCLEROSIS IN PATIENTS WITH TAKAYASU'S ARTERITIS**

J. Du, Beijing Anzhen Hospital, Beijing, China

**Background:** The incidence of atherosclerosis (As) in Takayasu's arteritis (TAK) was significantly higher than that of other people of the same age and gender. The incidence of carotid artery plaque in TAK patients was 27%, while only 2% of the age and sex matched controls were in the control group<sup>1</sup>. Autopsy confirmed that atherosclerotic lesions were found in arterial wall in TAK<sup>2</sup>. Inflammation of the vascular wall may promote As in TAK, which may be related to the disorder of lipid metabolism disorder, which accelerates the development of As. The ratio of low-density lipoprotein cholesterol (LDL-C)/high-density lipoprotein cholesterol (HDL-C) predicted As progression better than LDL-C or HDL-C alone<sup>3</sup>. Higher triglyceride (TG)/HDL-C ratio was found to be associated with presence of endothelial dysfunction and As<sup>4</sup>.

**Objectives:** The aim of this study is to investigate the clinical manifestations, serological and imaging features in TAK with As and non-As, to find the risk factors of As in those patients.

**Methods:** A retrospectively study of 105 patients in TAK were divided into 2 groups according to with or without As. We compared the difference of general information, traditional risk factors, disease activities and imaging features between 2 groups. Logistic model were used to determine the risk factors of As in TAK patients.

**Results:** In this study, 53 patients (50.48%) with TAK were had As. The duration of disease in TAK patients with As significantly longer than non-As group ( $p=0.011$ ). LDL-C/HDL-C ratio in TAK with As significantly higher than non-As ( $p=0.025$ ). Serum level of CRP in TAK with As patients lower than non-As patients. In disease activities, there were no differences in Kerr score and ITAS between 2 groups. The traditional risk factors of As in two groups were compared, hypertension ( $p=0.001$ ) and family history of As ( $p=0.012$ ) were all higher in As group than non-As group. In As group, most common angiographic type was Numano type V, which was higher than that in non-As patients (58.49% vs 38.46%,  $p=0.040$ ). Logistic regression showed the age above 40 years old is 5.196 times higher than the patients who are under 40 ( $p=0.002$ , 95%CI: 1.843–14.648) to develop to As. The incidence of As increased by 2.945 times every 5 years ( $p=0.003$ , 95%CI: 1.431–6.062). History of hypertension has more risk to As ( $p=0.029$ , OR=4.088, 95%CI: 1.153–14.494). More important, the LDL-C/HDL-C ratio was above the predicted cut-off value 3.038, the incidence of As increased by 8.515 times ( $p=0.023$ , 95%CI: 1.343–53.976), the TG/HDL-C ratio was above predicted 0.909 cut-off value, the incidence of As increased by 3.725 times ( $p=0.024$ , 95%CI: 1.185–11.711).

**Abstract AB0674 – Figure 1.** Levels of serum lipids in 2 groups of TA patients. There were no differences in TG, CHO, HDL-C and LDL-C between TA patients with atherosclerosis (As) and non-atherosclerosis (non-As)

**Abstract AB0674 – Figure 2.** Ratios of serum lipids in 2 groups of TA patients. There were no differences in TG/HDL-C ratio and CHO/HDL-C ratio between 2 group. LDL-C/HDL-C

ratio in patients with atherosclerosis (As) were higher than that of non-atherosclerosis (non-As) group ( $2.33\pm 1.09$  vs  $2.00\pm 0.74$ ) ( $p=0.025$ ).

**Conclusions:** Our study showed the duration of disease and LDL-C/HDL-C more higher in TAK patients with As than without As. Age  $\geq 40$  years old, the duration of disease, hypertension, TG/HDL-C and HDL-C/HDL-C ratios were the risk factors of As in TAK patients.

**AB0675 RHEUMATOID FACTOR POSITIVITY IS RELATED TO CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS IN PATIENTS WITH EOSINOPHILIC GRANULOMATOSIS WITH POLYANGIITIS**

J. Inamo, Y. Kaneko, Y. Ohta, T. Takeuchi. Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan

**Background:** Eosinophilic granulomatosis with polyangiitis (EGPA) is a rare anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV), which is characterised by vasculitis with allergic features such as asthma and eosinophilia. Although rheumatoid factor (RF) positivity is known to be as high as 37%–50% in AAV patients<sup>1</sup> the clinical significance of RF-positivity remains unknown.

**Objectives:** To investigate clinical features in patients with RF in EGPA.

**Methods:** Consecutive patients who were diagnosed with EGPA between January 2008 and January 2018 in Keio University Hospital were enrolled. Clinical information were collected from medical records retrospectively. We divided patients into 2 groups according to RF positivity, and compared clinical features.

**Results:** Seventeen patients were enrolled in the study. The mean age was 57.4 years old, and 82% were female. Among them, 11 patients were RF positive (RF positive group) and 6 patients were negative (RF negative group). The female rate tended to be higher in the RF positive group than the negative group (82% vs 50%,  $p=0.087$ ). While the Birmingham Vasculitis Activity Score was comparable between the two groups (21.5 vs 17.3,  $p=0.329$ ), general symptoms (fever and weight loss) and gastrointestinal lesions were more frequent in the RF positive group (55% vs 17%,  $p=0.072$ ; 45% vs 17%,  $p=0.137$ ) and central nervous involvement was less frequent (18% vs 67%,  $p=0.024$ ). No patient with negative RF presented with arthralgia/arthritis. The count of eosinophil and IgA levels at diagnosis were significantly higher in the RF positive group than the RF negative group (15704/ $\mu$ l vs 4751/ $\mu$ l,  $p=0.009$ ; 238 mg/dL vs 162 mg/dL,  $p=0.048$ ). Interestingly, ANCA positivity was negatively correlated with RF positivity. MPO-ANCA was positive in 27% of the RF positive group and in 66% of the RF negative group, and PR3-ANCA was positive in none of the RF positive group and 17% of the RF negative group. Double negative was more frequent in RF positive group (73% vs 33%,  $p=0.060$ ).

**Conclusions:** RF positivity was associated with clinical and serological characteristics in patients with EGPA, suggesting different pathogenesis or immunological disturbances is related.

Kitamura<sup>1</sup>. <sup>1</sup>Third Department of Internal Medicine, University of Yamaguchi, Chuo city, Yamaguchi; <sup>2</sup>Department of Rheumatology, National Hospital Organization, Shimoshizu Hospital; <sup>3</sup>Department of Internal Medicine, Narita Red Cross Hospital; <sup>4</sup>Department of Allergy and Clinical Immunology, Chiba University Hospital, Chiba, Japan

**Background:** Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis presents with various symptoms. ANCA-associated hypertrophic pachymeningitis (HP) is a very rare pathology.

**Objectives:** This study aimed to investigate the efficacy of rituximab (RTX) against patients with ANCA-related HP.

**Methods:** Seven patients were identified by retrospective chart review from local registries at four Hospitals in Japan. All patients met Chapel Hill 2012 Consensus Conference definitions of ANCA-associated vasculitis and were complicated with HP. We assessed the dose of prednisolone, CRP, and MRI findings of HP before and after RTX administration.

**Results:** Three female and 4 male were evaluated. Median age was 66 years-old. Four cases had HP at the onset of vasculitis. Relapse of HP before RTX administration was found in 2 cases. RTX was used as an initial treatment in one patient. Daily dose of prednisolone and CRP were significantly decreased from baseline levels 24 weeks after RTX treatment. Evaluation of HP by contrast MRI showed improvement in six of seven cases. No relapse after RTX treatment was observed during the follow-up period of 24 weeks. Severe adverse effects were not found in any patients.

**Conclusions:** Our case series highlight the efficacy of RTX against patients with difficult-to-treat ANCA-related HP. Future studies in this context in a prospective manner are definitely required to establish the B-cell depletion therapy by RTX as a treatment option for ANCA-related HP.

AB0677

### BONE MINERAL DENSITY AND GLUCOCORTICOID TREATMENT IN PATIENTS WITH GIANT CELL ARTERITIS AND/OR POLYMYALGIA RHEUMATICA

K.N. Zeiner, D. Freier, E. Wiebe, B. Robert, U. Schneider, T. Alexander, F. Buttgerit. *Rheumatology and Clinical Immunology, Charité University Hospital, Berlin, Germany*

**Background:** Glucocorticoids (GC) are widely used in treating giant cell arteritis (GCA) and polymyalgia rheumatica (PMR) because of their strong anti-inflammatory and immunomodulatory effects. However, considerable adverse effects like osteoporosis can occur, especially when GC are used as a long-term treatment and disease relapses are frequent. While additional treatment options with conventional immunosuppressive drugs such MTX showed modest effects, the most recent and promising evidence points towards use of biologic agents like the IL-6-receptor antagonist Tocilizumab (TCZ) as an efficient novel treatment option in GCA.

**Objectives:** Rh-GIOP is an ongoing prospective study monitoring GC induced osteoporosis in patients with inflammatory rheumatic diseases, established in 2015 at the Charité University Hospital (ClinicalTrials.gov Identifier NCT02719314). To date, our database comprises clinical data and bone mineral density (BMD) data measured by dual x-ray absorptiometry (DXA) collected from 592 patients with inflammatory rheumatic diseases. The objective of this cross-sectional analysis was to describe GCA and PMR patients in terms of their clinical characteristics, immunosuppressive therapies and BMD.

**Methods:** We evaluated data from the initial visit of 61 patients (37 female, 24 male), 43 (70.5%) with PMR, and 18 (29.5%) with GCA (with or without PMR symptoms). Statistical analyses were performed for the overall cohort (GCA +PMR) and separately for the subgroups GCA and PMR. For subgroup analyses non-parametric tests were used.

**Results:** The whole group showed a mean age of 70.4 years ( $\pm 9.0$ ), BMI of 27.7 kg/m<sup>2</sup> ( $\pm 4.8$ ), disease duration of 2.9 years ( $\pm 4.0$ ), daily GC dose of 12.5 mg ( $\pm 19.6$ ) and cumulative GC dose (CGCD) of 6.1 g ( $\pm 6.5$ ). While 40 (93%) PMR patients and all 18 GCA patients received GC on a daily base, GCA patients took significantly higher median doses (8.75 mg, interquartile range (IR) 5/27.5 mg) than PMR patients did (5 mg, IR 3.5/10 mg,  $p=0.03$ ). However, no significant difference was seen in the CGCD. Overall, 34 (55.7%) patients demonstrated osteopenia and 5 (8.2%) patients osteoporosis. 27 (44.3%) patients suffered from at least one fracture, while 10 (16.4%) of these cases were confirmed fragility fractures. Methotrexate (MTX) was the most common conventional immunosuppressive drug being used in 12 (27.9%) PMR and in 6 (33.3%) GCA patients. 2 (11.2%) GCA patients and 1 (1.6%) PMR patient were treated with TCZ.

**Conclusions:** No increased prevalence of osteoporosis or fractures was found in our patient cohort compared to a normal German population over 50 years.<sup>1</sup> This might be due to therapeutic approaches, which include optimal disease control, the use of lowest possible GC doses and GC-sparing co-medications, and a rigorous osteoporosis prevention and treatment strategy. Alternatively, the number of patients may be still too small to identify significant differences when comparing with a non-diseased population.

### PERIPHERAL ULCERATIVE KERATITIS ASSOCIATED TO AUTOIMMUNE SYSTEMIC DISEASES: VISUAL PROGNOSIS AND OCCURRENCE WHILE SYSTEMIC DISEASE IN REMISSION

L. Pelegrin<sup>1</sup>, J. Hernández-Rodríguez<sup>2</sup>, J. Torras<sup>3</sup>, G. Espinosa<sup>3</sup>, A. Adán<sup>3</sup>, M. T. Sainz<sup>3</sup>. <sup>1</sup>Uveitis unit; <sup>2</sup>Autoimmune diseases; <sup>3</sup>Hospital Clinic, Barcelona, Spain

**Background:** Background: Peripheral ulcerative keratitis (PUK) is a corneal crescent-shaped inflammatory damage with/without concomitant scleritis. PUK can occur isolated or as part of an underlying systemic disease (SD).

**Objectives:** Objective: To characterise a cohort of PUK patients with a long-term follow-up and to evaluate clinical (ocular and systemic) parameters as predictors of ocular prognosis, in terms of relapses and visual outcomes.

**Methods:** Methods: Retrospective review (1996–2017) of patients with PUK from a multidisciplinary Uveitis Unit (Ophthalmology/Autoimmune Diseases). Data recorded included ophthalmological features, clinical assessment and laboratory markers at disease onset, and therapeutic interventions, ocular relapses and visual outcomes during follow-up.

**Results:** Results: Among 18 PUK patients evaluated, 3 were idiopathic, 3 infectious and 12 (67%) associated with systemic diseases (SD-PUK): 8 rheumatoid arthritis (RA), 2 ANCA-vasculitis, 1 SLE and 1 Takayasu's arteritis. Among SD-PUK patients, sex ratio favoured women (rate 9:3) with a median age of 72 (range 33–85) years. Unilateral/bilateral involvement occurred in 7/5 patients and associated scleritis in 50% (11 eyes). All patients presented with eye pain/redness and visual impairment. Four (33%) patients (5 eyes) suffered ocular perforation and required surgery. All patients received topical glucocorticoids (GC), 75% systemic GC, 33% additional immunosuppressant, and 42% biologic therapy. Mean follow-up were 7.3 (range 0.5–12) years. The annual relapse rate was 0.3. Final visual acuity worsened in 42% (8 eyes). In 10 (83%) patients PUK onset occurred previous to SD diagnosis or with SD in remission, and only 3 (25%) were receiving

treatment for SD. No prognostic factors were found to correlate with PUK relapses and final visual acuity/ocular perforation.

**Conclusions:** RA and ANCA-vasculitis are the SD more frequently associated with PUK. Visual outcomes are poor in less than 50% of patients despite of topical and systemic GC/biologic therapy. SD-PUK may emerge previous to the SD diagnosis or with the associate SD in remission.

#### AB0679 LEVEL OF SERUM 25(OH)D WITH DISEASE ACTIVITY OF A COHORT STUDY

L. Hua. Department of Rheumatology and Immunology, Beijing Anzhen Hospital, Capital Medical University., Beijing, China

**Background:** Takayasu's arteritis (TAK) is a chronic large vessel vasculitis primarily involving the aorta and its major branches. TAK has been considered a rare disease that affected mostly young Asian women<sup>[1]</sup>. Its pathogenesis is still under investigation. However, some studies have demonstrated that immune disorder results in TAK. Especially cellular immunity plays a vital role in TAK. Recently, some studies shown that Vitamin D can regulate immune system in rheumatological diseases, such as SLE, RA and so on<sup>[2]</sup>. The relationship between Vitamin D and disease activity of TAK has not been reported yet. This study focuses on identifying the role of Vitamin D in pathogenesis of TAK through studying the correlation of serum 25(OH)D level and the disease activity of TAK

**Objectives:** To evaluate the level of serum 25-hydroxyvitamin D in patients with Takayasu's Arteritis (TAK)

**Methods:** Totally 57 untreated TA patients (TA group) and 51 healthy people (control group) were enrolled. The level of serum 25(OH)D were measured and compared between groups. The correlations of 25(OH)D level with related indicators were analysed.

**Results:** Lower concentrations of serum 25(OH)D were detected in TAK patients compared with healthy subjects [(11.91±5.26) ng/ml versus (17.64±8.85) ng/ml] (p<0.01). In all patients with TAK, serum 25(OH)D correlated negatively with erythrocyte sedimentation rate (ESR), interleukin (IL)-6 (r=-0.321, p=0.022; r=-0.322, p=0.031). There was no correlation between serum 25(OH)D level and NIH score, ITAS2010 score, ITAS.A score, anti-tumour necrosis factor (TNF)-α antibody. TAK Patients with therapy showed a significantly higher serum level of 25(OH)D compared with that before therapy [(10.74±3.49) ng/ml versus (18.66±8.03) ng/ml] (p<0.01). After therapy, the changes of 25(OH)D level present a positive correlation with the changes of NIH score, ITAS2010 score AND ITAS.A score.

**Conclusions:** We observed a high prevalence of vitamin D deficiency in patients with TAK. The 25(OH)D levels in serum was negatively correlated with ESR and IL-6. Levels of 25(OH)D were improved after therapy. The changes of 25OHD level correlation to Disease Activity of Index.

#### AB0680 NON OPHTHALMOLOGICAL NEUROLOGIC ISCHAEMIC MANIFESTATIONS OF GIANT CELL ARTERITIS

L. Coronel Tarancón<sup>1</sup>, I. Monjo<sup>2</sup>, E. Fernández<sup>2</sup>, A. Balsa<sup>2</sup>, E. De Miguel<sup>2</sup>.

<sup>1</sup>Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de Tenerife;

<sup>2</sup>Hospital Universitario La Paz, Madrid, Spain

**Background:** Giant cell arteritis (GCA) is a very infrequent cause of stroke. It is diagnosed in 0.15% of brain infarctions. On the other hand, in scientific literature there are very little patients with ischaemic brain infarctions that describes stroke as the clinical presentation of GCA. It might suggest that it is a underdiagnosed condition.

**Objectives:** To check the frequency of stroke as presentation symptom of GCA and other findings related with it.

**Methods:** Retrospective observational study of 123 consecutive patients diagnosed of GCA in our hospital. We reviewed the past medical history to obtain sings, symptoms and ultrasound parameters of the first medical evaluation. We searched for: age, sex, hypertension, diabetes, dyslipidemia, anterior ischaemic

optic neuropathy (AION), headache, visual disturbances, Polymyalgia Rheumatica (PMR), jaw claudication, general symptoms, non oftalmological brain ischaemic symptoms, disease outbreak and laboratory test: erythrocyte sedimentation rate (ESR), C reactive protein (CRP), Haemoglobin (Hb). For the analysis we divided the sample into two groups: a). Neurological symptoms b). Other presentations.

For statistical comparisons, we used SPSS version 17.0. Descriptive analysis and comparison was performed of the two groups. X<sup>2</sup> was used for qualitative values and means comparisons for quantitative.

Abstract AB0680 – Table 1

	Non ophthalmic neurologic symptoms	Non neurologic symptoms	p value
Age *	79±5.42	77.86±8.86	0.62
Sex ** (Women)	7 (58,33%)	67 (60,36%)	0.56
ESR* (mm/h)	66,63±32.24	68,18±30,41	0.89
CRP* (mg/L)	53,73±79,43	42,55±45,35	0.60
Hb* (g/dL)	12,56±2.12	13,34±4,71	0.64
Outbreak**	5 (41,66%)	57 (51,35%)	0.52
Headache**	6 (50%)	68 (61,26%)	0.22
Visual disturbances**	1 (8,33%)	24 (21,62%)	0.27
PMR**	0 (0%)	25 (22,52%)	0.06
Jaw claudication**	0 (0%)	14 (12,61%)	0.19
General symptoms**	1 (8,33%)	20 (18,01%)	0.61
<b>Total patients</b>	<b>12</b>	<b>111</b>	

\*Mean ±SD. \*\* n (%).

**Results:** Of our 123 patient's cohort: 37 patients (30.08%) suffered from ischaemic events of the internal carotid artery, 25 patients (20.32%) of AION and 12 patients (9.8%) presented with neurological symptoms different from AION.

Out of the 12 patients with non ocular ischaemic symptoms of the central nervous system: 5 (44.66%) were diagnosed of transitory ischaemic accident (TIA), 4 (33.33%) of stroke, 2 (16.66%) of VI cranial nerve paresis, one the patients that presented with III and VI par paresis suffered also from TIA, at last, one patient presented ischaemic phenomena related with small-vessels vasculitis and one patient with dizziness due to cerebellum affection.

Clinical and analytical data are presented in the table:

No patient was presented with PMR or jaw claudication.

3 (25%) patients died during the follow up in the neurologic symptoms group in comparison with 11 (9.90%) of the non neurological (p 0.11).

**Conclusions:** Stroke is not a rare form of presentation of GCA and should be suspected in all ischaemic brain events that are associated with high acute phase reactants in elderly patients. It is important to identify these patients due to the severity of the disease and the possibility of specific treatment that may avoid new events.

#### AB0681 BIOPSY RESULTS FROM PATIENTS WITH SUSPECTED GRANULOMATOSIS WITH POLYANGIITIS A DECADE (2005–2015). ALEATORISED SAMPLE ANALYSIS OF CLINICOPATHOLOGICAL CORRELATION

L.F. Flores-Suarez<sup>1</sup>, H. Echeagaray<sup>2</sup>, G. Tona-Acedo<sup>2</sup>, R.M. Rivera-Rosales<sup>3</sup>, N. Ruiz<sup>1</sup>, A. Castorena-Maldonado<sup>2</sup>. <sup>1</sup>Primary Systemic Vasculitides Clinic;

<sup>2</sup>Department of Otorhinolaryngology, Head and Neck Surgery, <sup>3</sup>Department of Pathology, Instituto Nacional de Enfermedades Respiratorias, Mexico City, Mexico

**Background:** The diagnostic yield of airway biopsies in granulomatosis with polyangiitis (GPA) is usually less than 50%.

**Objectives:** To review the histologic diagnostic yield of airway biopsies sent with a suspected GPA diagnosis in a single-centre devoted to respiratory diseases by use of previously published criteria. Also, to know the interobserver variability among in-house pathologists, correlate signs and symptoms with GPA positive histologic findings, and with additional paraclinical data, apply the algorithm proposed by the European Medical Agencies (EMA) to know if a higher number of biopsies confidently supported a GPA diagnosis.

**Methods:** From 137 airways biopsies during a decade (2005–2015), fifty were randomly selected for the second review by an expert pathologist. Thereafter, with the incorporation of antineutrophil cytoplasm autoantibodies (ANCA) the EMA algorithm was applied. Demographic data were descriptively analysed, and

results expressed according to their distribution. Categorical data, expressed in percentages, were analysed with  $\chi^2$  test and variance analysis. The associations of independent variables were analysed with one-tail exact Fisher test. Simple logistic regression was used for variable associations. The interobserver correlation was tested with calculation of the kappa coefficient.

**Results:** A poor interobserver correlation was found among pathologists (kappa = 0.19), and no airway sign or symptom was predictive of a positive GPA biopsy. Several pitfalls were noticed: lack of adequate clinical information on files (including endoscopic); incomplete relevant information sent to pathologists and inadequate tissue sampling. Nevertheless, in patients with generalised disease, a 2.6 probability to obtain a diagnostic GPA airway biopsy was found. After expert pathologist's review, and applying Devaney et al and Travis et al proposed criteria, from 16 initial GPA diagnoses, the number increased to 25. It further raised to 35/50 randomised biopsies when ANCA results were incorporated, and the EMA algorithm was applied.

**Conclusions:** Carefully retrieved clinical, endoscopic and serological data, coupled with systematic histopathologic sample review in patients with a GPA suspicion shall be incorporated in an orderly fashion in order to increase the diagnostic yield of this malady, especially in patients with the limited form of the disease.

#### AB0682 RISK FACTORS ASSOCIATED WITH RELAPSE OF ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY-ASSOCIATED VASCULITIS

M. Nakahara, H. Yamashita, Y. Takahashi, K. Araki, N. Mino, K. Suga, A. Yashima, H. Kaneko. *Rheumatology, National Center for Global Health and Medicine, Tokyo, Japan*

**Background:** Several factors increasing the risk of anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis have been reported. These include pulmonary and cardiovascular lesions, PR3-ANCA-positivity in patients with granulomatosis with polyangiitis, and persistent ANCA-positivity or an increase in the titer of such antibodies.

**Objectives:** We aimed to identify potentially novel factors predicting relapse in patients with ANCA-associated vasculitis.

**Methods:** We reviewed data on 73 patients (61 with microscopic polyangiitis [MPA], 12 with granulomatosis with polyangiitis [GPA]; 46 females) treated in our centre from 1998 to 2017 for whom medical histories were available. All achieved at least one remission after induction therapy. Relapse was defined as novel organ involvement or a need for therapy intensification. Follow-up continued to the first relapse or for as long as possible if no relapse was noted.

**Results:** The median age at disease onset (interquartile range) was 74 years (range: 67–80 years). The relapse rate was 42.5% (MPA 41%, GPA 50%), thus not significantly different between the two groups ( $p=0.75$ ). The median follow-up duration was 23 months (range: 11–65 months) and the median time to relapse was 18 months (range: 10.5–54 months). Although pulmonary and cardiac lesions reportedly increase the relapse rate, neither contributed significantly to the rate in this study. Furthermore, ANCA-positivity after remission and increases in ANCA levels prior to relapse did not significantly increase the relapse risk. In terms of medical histories recorded at the time of first onset of disease, the frequency of diabetes, dyslipidemia, coronary artery disease, and cerebral infarction did not differ significantly between patients who did and did not relapse. However, in MPA patients, a history of hypertension was significantly less in those who relapsed ( $p=0.01$ ). In a multiple logistic regression analysis adjusted for sex and age, history of hypertension was a significant predictor of fewer relapse (odds ratio: 0.23; 95% confidence interval 0.07–0.69,  $p=0.009$ ).

**Abstract AB0682 – Table 1.** The clinical characteristics of two groups

	Relapse, n=31	Non-relapse, n=42	p	OR (95% CI)

#### AB0683 TREATMENT WITH STATINS IN PATIENTS STUDIED BY FDG-PET/CT FOR POSSIBLE LARGE VESSEL VASCULITIS IS ASSOCIATED WITH A LOW VASCULAR SCORE

M.A. Cimmino<sup>1</sup>, F. Iannuzzi<sup>1</sup>, D. Camellino<sup>2</sup>, S. Morbelli<sup>3</sup>, C. Pizzorni<sup>1</sup>, M. Cutolo<sup>1</sup>, G. Sambucetti<sup>3</sup>. <sup>1</sup>Department of Internal Medicine; <sup>2</sup>Autoimmunology Laboratory; <sup>3</sup>Division of Nuclear Medicine, University of Genova, Genova, Italy

**Background:** Polymyalgia rheumatica (PMR), giant cell arteritis (GCA), and fever of unknown origin (FUO) may show large vessel vasculitis (LVV) when studied with FDG-PET/CT. Statins, widely used to lower cholesterol concentrations, have shown anti-inflammatory activity in both the atherosclerotic plaque and in rheumatoid arthritis.

**Objectives:** To test the hypothesis that the concomitant treatment with statins induces a low uptake of the vessels in patients with PMR, FUO and GCA.

**Methods:** Consecutive patients with a diagnosis of PMR, GCA or FUO underwent a thorough clinical examination, including drug history, and a PET/CT scan. Arterial uptake of FDG was scored relative to liver uptake as 0=no uptake present, 1=lower than liver uptake, 2=similar to liver uptake, 3=higher than liver uptake. The values of each district were summed to obtain a total vascular score (TVS). A further semi-quantitative analysis of FDG uptake was carried out, drawing regions of interest (ROIs) on the theoretical arterial wall and within the left ventricular chamber (blood-pool, BP). Arterial FDG uptake was quantified by calculating the mean standardised uptake value (SUV) within each ROI and the results expressed as the ratio between mean SUV value of each ROI and BP ROI (SUV/BP).

**Results:** 129 patients were included, 87 women, with median age of 74 years (range 50–92). 95 patients were diagnosed with PMR, 13 with GCA, 16 with both PMR and GCA and 5 patients presented with FUO. 37/129 patients (28.7%) were assuming glucocorticoids (GC) at the time of examination. The mean interval between onset of symptoms and PET/CT was 85 days (range 4–1957 days). LVV was present in 75 patients (58.2%) when a cut-off  $\geq 2$  was used and 32 patients (24.8%) had a score of 3.

Twenty/129 patients (15.5%) were treated with statins for hypercholesterolemia. The median TVS was significantly lower in these patients when compared with those not treated with statins (8 [range 1–27] vs. 12 [range 0–42],  $p=0.02$ ). This difference was present at the ascending aorta ( $p=0.017$ ), the aortic arch ( $p=0.023$ ), and the femoral arteries ( $p=0.025$ ). The analysis of SUV was not

significant ( $p=0.45$ ). As expected, the arterial calcium load, corresponding to the extent of vessel calcification, was higher in patients treated with statins (14 [range 2–35] vs. 8 [range 0–35];  $p=0.012$ ). However, calcium load did not correlate with the TVS, whereas it inversely correlated with SUVs ( $p=0.03$ ). At multiple regression, assumption of statins was not predicted by sex, type of diagnosis, GC treatment or presence of LVV at PET/CT. Only age predicted statin therapy ( $p=0.04$ ), but age was not associated with LVV ( $p=0.23$ ). Among clinical features, only fever was significantly less frequent in patients treated with statins ( $p=0.03$ ).

**Conclusions:** With the limits of an observational retrospective study, our data suggest that treatment with statins may lower arterial uptake in patients studied for LVV. This finding was seen using the theoretically more subjective TVS but not with SUV analysis. We feel that the latter is more easily influenced by the presence of calcific plaques, as suggested by its inverse correlation with arterial calcium load. The role of statins in tempering arterial inflammation deserves further studies.

#### AB0684 A REVIEW OF TEMPORAL ARTERY BIOPSIES AT A DISTRICT GENERAL HOSPITAL

M.A. Yusuf, M. Al-Zaza, T. Walton. Colchester Hospital University NHS Trust, Colchester, UK

**Background:** Giant cell arteritis is the most common vasculitis in the western world in the over 50 population. The morbidity associated with its natural progression and treatment is significant. No single investigation has been identified to accurately confirm or reject its diagnosis, though for some years biopsy of the superficial temporal artery has been carried out to support the diagnostic process. More recently, doppler ultrasound of the artery has gained prominence, though its widespread use is limited.

Temporal artery biopsy (TAB) is a significant use of resources, involving a surgeon and their team, as well as a histopathologist. It is an invasive procedure with the risks that this entails. It behoves the referring doctor to ensure that the probability of a positive result is as high as practicable.

**Objectives:** To determine the factors providing the highest likelihood of a positive TAB result.

**Methods:** The notes of all patients undergoing a TAB during a 3 year period 2013–2016 were requested from the Medical Records department at a district general hospital. The first 100 of these were reviewed by the authors. Each set of notes was examined for the following:

- Demographics (sex, age)
- The first department the patient was referred to (Rheumatology/Ophthalmology/Neurology/direct from the General Practitioner to Vascular Surgery)
- Period of time from symptom onset to biopsy
- Period of time on steroids to biopsy
- Initial dose of steroids prescribed
- Pre-treatment ESR
- Pre-treatment CRP
- Presence of symptoms (headache/jaw claudication/polymyalgia rheumatica)
- Other causes for a raised ESR
- The pre-test probability of a positive TAB result as assessed by the reviewer
- TAB result as reported by local histopathologist
- Evidence of the biopsy result impacting treatment

**Results:** Of the 100 TAB's reviewed, 16 yielded positive results (16%). A breakdown of the notes review for these patients is included in the following table:

**Abstract AB0684 – Table 1**

Positive TAB	16/100	Visual symptoms	6/16
Age (years)	58–88, Mean 73	Jaw claudication	5/16
Female:Male	13:3	Headache	11/16
GP referral direct to Vascular Surgery	5/16	PMR	1/16
Initial referral to Rheumatology	4/16	Other causes of raised ESR	3/16
Initial referral to Ophthalmology	4/16	Pre-test probability of positive result	9/16
Initial referral to Neurology	3/16	Biopsy influencing treatment	6/7
Symptom onset to TAB (days)	14–90, Mean 52		
Steroid duration before TAB	1–28 days		
Steroid starting dose range	30–500 mg		

**Conclusions:** This study has shown that less than a fifth of TAB's conducted during this period at our district general hospital yielded a positive result. There is scope to improve this yield significantly if we identify candidates for TAB better.

There was no positive result for any of the 16 patients less than 58 years of age. The majority had a raised CRP and ESR, though one patient had a CRP of 2. This reflects the need for vigilance before discounting GCA as a diagnosis.

One patient had a positive TAB even after 28 days of prednisolone 40 mg daily. The majority (14/16) had their biopsy within 3 weeks of steroid initiation, indicating that a short delay in biopsy does not rule out a positive result.

This study will help us develop a local pathway including Ophthalmology, Neurology, Vascular Surgery and Primary Care to improve the yield of positive TAB. This will improve patient experience as well as ensure appropriate use of resources.

#### AB0685 THE INCIDENCE OF GIANT CELL ARTERITIS IN SLOVENIA – PROSPECTIVE STUDY

N. Potočnik Pucelj<sup>1</sup>, A. Hocevar<sup>1</sup>, R. Ješe<sup>1</sup>, Ž. Rotar<sup>1</sup>, J. Pižem<sup>2</sup>, M. Hawlina<sup>3</sup>, A. Fakin<sup>3</sup>, M. Tomšič<sup>1</sup>. <sup>1</sup>Dpt. of Rheumatology, University Medical Center Ljubljana; <sup>2</sup>Institute of Pathology, Faculty of Medicine, University of Ljubljana; <sup>3</sup>Department of Ophthalmology, University Medical Center Ljubljana, LJUBLJANA, Slovenia

**Background:** Giant cell arteritis (GCA) represents the most common vasculitis in adults over age of 50 years in Europe. Recently the diagnostic options greatly improved with the implementation of imaging techniques such as colour Doppler ultrasonography (CDS) and positron emission tomography-computed tomography (PET/CT).

**Objectives:** The aim of our single centre prospective study was to determine the incidence of GCA in well-defined Slovenian region, based on the temporal artery (TA) biopsy (TAB) and/or the result of CDS and/or PET/CT.

**Methods:** The study was conducted at University medical centre Ljubljana (UMC Ljubljana), that represents the only secondary/tertiary centre in a region, serving a population of 3 23 297 residents aged 50 years or more (1 76 104 females and 1 47 193 males). Patients with suspected GCA are referred either to the Department of Rheumatology, or in case of severe visual disturbances, to the Department of Ophthalmology. In the analysis we included all GCA cases diagnosed between 1 January 2012 and 31 December 2017. The diagnosis of cranial GCA (c-GCA) was established with the help of American College of Rheumatology (ACR) 1990 classification criteria, positive TAB and/or TA CDS. Cases of extracranial large vessel vasculitis (lv-GCA) were diagnosed using CDS of branches of the aortic arch and/or PET-CT.

**Results:** During the six-year observation we identified 169 new GCA cases (66.3% females), with a median (IQR) age of 75.1 (68.6–80.0) years. Forty-two (24.8%) patients had lv-GCA, and the others had c-GCA. One-hundred and thirty-nine patients (24 lv-GCA and 115 c-GCA) fulfilled ACR 1990 classification criteria. The other patients had positive arterial CDS or PET-CT (18 CDS, 9 CDS and PET-CT, 3 PET-CT). TAB was performed in 119 patients and was positive in 88.2%. Clinical characteristics of our GCA cases are presented in table 1. The estimated annual incidence rate of GCA was 8.7 per 1 00 000 adults aged  $\geq 50$  years (95% CI 7.5–10.1), in c-GCA 6.5 per 100.000 adults aged  $\geq 50$  years (95% CI 5.5–7.8) and in lv-GCA 2.2 per 100.000 aged  $\geq 50$  years (95% CI 1.6–2.9).

**Abstract AB0685 – Table 1.** Characteristics of GCA cohort

Characteristics	all GCA	lv-GCA	c-GCA
No. of cases	169	42	127
Female gender (%)	66.3	76.2	63.0
Age (years) <sup>#</sup>	75.1 (68.6-80.0)	69.5 (64.4-78.1)	75.7 (72.2-81.6)
Disease duration (day) <sup>#</sup>	30 (14-60)	60 (30-97.5)	28 (14-45)
Constitutional symptoms (%)	69.2	71.4	68.5
Headache (%)	71.6	45.2	80.3
PMR (%)	14.2	11.9	15.0
Jaw claudication (%)	45.0	26.2	51.2
Vision disturbances (%)	33.1	19.0	37.8
Clinically abnormal TA <sup>†</sup>	62.1	38.0	69.3
TAB (%)	88.2(105/119)	79.2 (19/24)	85.6 (89/104)
TA CDS (%)	76.9 (130/160)	54.8 (23/42)	92.4 (109/118)
ESR $\geq 50$ (mm/h) (%)	82.8	81.0	85.0
ACR criteria (%)	82.2	57.1	90.5

Legend: GCA giant cell arteritis; lv-GCA extracranial large vessel GCA; c-GCA cranial GCA; PMR polymyalgia rheumatica; TA temporal artery; <sup>‡</sup> TA tenderness or decreased pulse; TAB temporal artery biopsy; CDS colour Doppler sonography; ESR erythrocyte sedimentation rate; ACR American Colleague of Rheumatology; <sup>#</sup> median (interquartile range);

**Conclusions:** GCA is the most common vasculitis in adults aged 50 years or above, with an annual incidence rate of 8.7 per 100.000. c-GCA is nearly 3 times more common than lv-GCA.

**AB0686** **ARTERIAL ANEURYSMS IN BEHÇET'S DISEASE: A RETROSPECTIVE DESCRIPTIVE ANALYSIS AND LONG-TERM OUTCOME**

N.H.A. El Ghobashy, A. EL-Garf, K. EL-Garf. *rheumatology, cairo university, cairo, Egypt*

**Background:** Behçet's Disease (BD) was described in 1937 after Hulusi Behçet; as a triad of recurrent aphthous and genital ulcers together with iridocyclitis.<sup>1,2</sup> Arterial disease is seen in 3%–5% of the patients.<sup>3,4</sup> Thrombosis and/or aneurysmal formation are common sequelae mainly false aneurysms.<sup>5</sup> In spite of the fact that BD is not uncommon in the clinical practice in Egypt; the paucity of data that looked specifically to the arterial aneurysms in the Egyptian patients with BD had prompted the present study.

**Objectives:** Arterial aneurysm in Behçet's disease is a rare manifestation of Behçet's disease. The presence of Arterial aneurysm in Behçet's disease change the course of disease and it is management remains a challenge for rheumatologists

**Methods:** A retrospective revision of files of 160 patients admitted and followed up in the rheumatology department, Cairo University Hospitals between 2004–2017 was done. We looked specifically for the prevalence of arterial aneurysms. Demographic characteristics of patients with aneurysms, clinical presentation, and associated clinical features.

**Results:** Twenty-seven (16.8%) patients had arterial aneurysms. All of them were males and the onset of development of the aneurysm is usually under the age of 40 years, 74% of the patients developed aneurysm 3.2±3.0 years after their disease onset. Apart from the oro-genital ulcerations; deep venous thrombosis was the most common associated manifestation. Pulmonary artery was the most common artery involved in 12 (44.4%) of patients, followed by the abdominal aorta in 4 (14.8%). Surgical intervention was done for 11 (40.7%) patients; all of them received cyclophosphamide pulses before surgery except one. Four (14.8%) patients in this study died.

**Conclusions:** Arterial aneurysms are common in Egyptian patients with BD. The profile of Egyptian BD patient that is susceptible for development of arterial aneurysm is a male patient, under the age of 40 years, smoker with relatively short disease duration.

**AB0687** **DOES ANTI-GLOMERULAR BASEMENT MEMBRANE (ANTI-GBM) ANTIBODY POSITIVITY CORRELATE WITH RELAPSE IN PATIENTS WITH ANTI-GBM DISEASE?**

N. Droz<sup>1</sup>, A. Katz<sup>2</sup>, J. Sedor<sup>3</sup>, R. Hajj-Ali<sup>1</sup>. <sup>1</sup>*Rheumatology*; <sup>2</sup>*Internal Medicine*; <sup>3</sup>*Nephrology, Cleveland Clinic Foundation, Cleveland, USA*

**Background:** Anti-GBM disease is characterised by rapidly progressive glomerular nephritis with or without pulmonary haemorrhage. It is usually monophasic in nature and disease severity correlates with antibody titer. The disease is mediated by pathogenic antibodies directed against the non-collagenous region of the  $\alpha 3$  chain of type IV collagen.

Despite the known pathogenicity of anti-GBM antibodies, and the correlation of disease severity with their titers, there is conflicting reports on whether anti-GBM antibody positivity correlates with disease relapse on long term follow up.

**Objectives:** To assess for correlation of anti-GBM antibody positivity and disease relapse in patients with anti-GBM disease.

**Methods:** Patients seen in one single academic centre between 1997 and 2017 were initially screened for the presence of anti-GBM disease by ICD 9/10 code for anti-GBM disease or Goodpasture's syndrome. 435 patients were identified. Patients were then included in the study if the diagnosis was confirmed by a board certified rheumatologist or nephrologist at our institution and had positive anti-GBM antibodies and/or biopsy results consistent with a diagnosis of anti-GBM

disease. The primary endpoint of this study was anti-GBM antibody positivity at the time of relapse. All charts were reviewed for baseline demographics, clinical manifestations, anti-GBM antibody and anti-neutrophil cytoplasmic antibody (ANCA) positivity at the time of initial presentation; these were compared between those with relapsing and non-relapsing disease. Results were analysed using a two tailed standard t-test. These same characteristics were also examined the relapsing cohort at the time of relapse.

**Results:** 40 patients were confirmed as having anti-GBM disease at our institution. Mean follow up from disease onset to the date of last follow up was 56.2 months. 8 patients had relapsing disease and 32 patients had non-relapsing disease. Baseline characteristics and clinical manifestations were similar between groups (table 1). Patients with relapsing disease had a statistically higher incidence of ANCA co-positivity as compared to non-relapsing patients (62.5% vs. 21.7% respectively p value- 0.03).

In patients with relapsing disease, only 14.7% (1/7 tested patients) had positive anti-GBM antibodies at the time of their relapse.

**Abstract AB0687 – Table 1.** Clinical features and laboratory values at baseline and at the time of relapse of Anti-GBM disease

	Non-relapsing Anti-GBM Disease (n=32)	Relapsing Anti-GBM Disease (n=8)	p-Value
<b>Baseline characteristics</b>			
Length of follow up, mos (range)	62.79 (2-228)	26.29 (3-78)	0.16
Time to diagnosis, days (range)	30 (1-182)	62 (5-243)	0.33
Age, Yr (range)	46.06 (17-78)	41 (14-62)	0.52
Male Gender (%)	53.1	37.5	0.44
Non-Smoking Status (%)	43.8	50.0	0.61
Renal involvement (%)	93.8	100	0.48
Peak creatinine mg/dL (range)	7.24 (0.9-17.6)	5.37 (1.6-13.7)	0.33
Pulmonary hemorrhage (%)	30.0	37.5	0.69
Positive Anti-GBM antibodies (%)	73.9 (17/23)*	37.5 (3/8)	0.07
Positive ANCA (%)	21.7(5/23)*	62.5 (5/8)	<b>0.03</b>
<b>Characteristics at time of relapse</b>			
Time to relapse, weeks (range)		77.14 (6-480)	
Positive Anti-GBM antibodies (%)		14.3 (1/7)*	
Positive ANCA (%)		75 (3/4)*	
Renal involvement (%)		93.3	
Peak creatinine mg/dL (range)		3.42 (2.7-4.85)	
Pulmonary hemorrhage (%)		71.4	

Values are expressed as mean (range) or percent

\*Incomplete data available. Number of positive patients out of total tested represented in parentheses

**Conclusions:** In this study, anti-GBM positivity did not correlate with disease relapse in patients with anti-GBM disease. Patients with relapsing disease had a higher incidence of ANCA positivity, consistent with previous investigations. In patients with newly diagnosed anti-GBM disease, ANCAs should be obtained to assess for the risk of relapse. Larger studies are needed to validate our results.

**AB0688** **PULMONARY AND THORACIC VASCULAR FINDINGS OF BEHÇET'S DISEASE AT COMPUTED TOMOGRAPHY**

N. İşıksalan Özbülül<sup>1</sup>, D. Üsküdar Cansu<sup>2</sup>, C. Korkmaz<sup>2</sup>. <sup>1</sup>*Radiology*; <sup>2</sup>*Internal Medicine, Rheumatology, Eskişehir Osmangazi University, Eskişehir, Turkey*

**Background:** Behçet disease is a multisystemic and chronic inflammatory disorder with unknown etiology. Pulmonary involvement is relatively infrequent.

**Objectives:** To investigate the pulmonary parenchymal changes and thoracic vascular abnormalities due to Behçet's disease at computed tomography.

**Methods:** 21 patients diagnosed with a diagnosis of Behçet's disease between 2004–2017 were evaluated. Clinical, laboratory, and thoracic computed tomography findings were retrospectively evaluated. Also, the immunosuppressive treatments of the patients were documented.

**Results:** 18 of the patients (85.7%) were male. The mean age of the patients was 44.42±11.7 years, onset age of the disease was 32.4±6.4 years, length of follow-up was 8.1±2.3 years. 13 of the patients (61.9%) had hemoptysis at the time of initial diagnosis of Behçet's disease. 14 of the patients (66.6%) showed vascular involvement except pulmonary system. Pulmonary artery aneurysm was observed in 9 patients (42.8%). Pulmonary artery thromboembolism was observed in 15 patients (71.4%). Thoracic computed tomography demonstrated that 5 patients (23.8%) with pulmonary infarct, 4 patients (19%) with pulmonary consolidation, 5 patients (23.8%) with ground-glass opacity in the lung representing pulmonary haemorrhage, 2 patients (9.5%) with pleural effusion, 7 patients (33.3%) with non-specific parenchymal changes, and one patient with focal atelectasis. Also, one of the patients had intracardiac thrombus. Five of the patients were smokers.

**Conclusions:** Aneurysm of the pulmonary artery with or without thrombosis is the most common manifestation of Behçet's disease. Pulmonary vasculitis and thrombosis of pulmonary vessels result in infarction, hemorrhage, focal

atelectasis. Thoracic computed tomography can clearly demonstrate the pulmonary and vascular abnormalities of Behçet's disease.

#### AB0689 EXTRAVASCULAR MANIFESTATIONS OF TAKAYASU ARTERITIS: HISTORICAL COHORT STUDY IN KOREA

O.C. Kwon<sup>1</sup>, S.-W. Lee<sup>2</sup>, Y.-B. Park<sup>2</sup>, W.J. Seo<sup>3</sup>, J.S. Oh<sup>4</sup>, S. Hong<sup>1</sup>, C.-K. Lee<sup>1</sup>, B. Yoo<sup>1</sup>, Y.-G. Kim<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Medicine, University of Ulsan, College of Medicine, Asan Medical Center, <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, <sup>3</sup>Division of Rheumatology, Department of Medicine, Seoul Veterans Hospital, <sup>4</sup>Clinical Research Center, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of Korea

**Background:** Takayasu arteritis (TAK) is systemic disease characterised by large vessel involvement. Although the vascular characteristics of TAK are well characterised, there is no well-organised study demonstrating the extravascular manifestations of TAK.

**Objectives:** To evaluate the characteristics of extravascular manifestations of TAK, and to identify the association between vascular and extravascular manifestations of TAK.

**Methods:** TAK patients from two independent cohorts who fulfilled the 1990 ACR classification and encoded M314 according to ICD-10 code between January 2012 and October 2017 were included in the study. Characteristics of the patients were retrospectively collected from the electronic dataset. A radiologist reviewed CT scans of all included patients to evaluate the pattern of vascular involvement and presence of sacroiliitis. Clinical findings including uveitis, skin lesion, oral ulcer, arthritis, and inflammatory bowel disease (IBD) were reviewed. Logistic regression analysis was performed to evaluate the association between vascular and extravascular manifestation.

**Results:** A total of 268 TAK patients were included. Mean age at diagnosis was 41.2±14.2 years and 236 (88.1%) were female. The most commonly involved vessel was common carotid artery (176 [65.7%]), and the most common type of vascular involvement was type V (120 [44.8%]). Extravascular manifestation of TAK was observed in 51 (19.0%) patients (table 1). The most common extravascular manifestation was arthritis (axial arthritis [sacroiliitis] [7.1%] and/or peripheral arthritis [6.0%]) (11.9%) followed by recurrent aphthous stomatitis (8.6%) and IBD (2.6%). In multivariable logistic regression analysis, the following factors were significantly associated with presence of arthritis (axial and/or peripheral arthritis): type IIB vascular involvement (adjusted OR 2.956, 95% CI 1.337–6.537, p=0.007) and erythrocyte sedimentation rate (ESR) (adjusted OR 1.014 95% CI 1.003–1.025, p=0.012).

**Abstract AB0689 – Table 1.** Extravascular manifestations of Takayasu arteritis

	n=268
Any extravascular manifestation	51 (19.0%)
Arthritis (axial arthritis [sacroiliitis] and/or peripheral arthritis)	32 (11.9%)
Recurrent aphthous stomatitis	23 (8.6%)
Inflammatory bowel disease	7 (2.6%)
Erythema nodosum	4 (1.5%)
Uveitis	2 (0.7%)

**Conclusions:** Extravascular manifestations of TAK are not rare and observed in up to one-fifth of patients. The most common extravascular manifestation was arthritis including sacroiliitis (11.9%). Type IIB vascular involvement pattern and high ESR were significantly associated with arthritis in TAK.

#### AB0690 DIAGNOSTIC VALUES OF ENDOTHELIN-1 IN PATIENTS WITH SYSTEMIC NECROTIZING VASCULITIS

L. Petelytska<sup>1</sup>, O. Iaremko<sup>1</sup>, K. Iaremko<sup>2</sup>. <sup>1</sup>Bogomolets National Medical University, <sup>2</sup>Oleksandrivska City Clinical Hospital, Kyiv, Ukraine

**Background:** Systemic necrotizing vasculitis (SNV) is characterised by destructive and inflammatory changes in the vessels. Binding of autoantibodies and immune complexes on the surface of endothelial cells stimulates the synthesis of endothelin-1 (ET-1), which leads to activation of macrophages and adhesion of neutrophils, remodelling of the vascular wall and its damage.

**Objectives:** To evaluate the serum level of ET-1 in patients with SNV and the possibility of its using for the diagnosis of SNV and involvement of individual organs.

**Methods:** The study included 36 patients with SNV (polyarthritis nodosa – 8, ANCA – associated vasculitis – 28) and healthy controls (n=26). Clinical activities of patients were calculated according to the Birmingham Vasculitis Activity Score (BVAS). All patients had active disease (BVAS >11). The serum levels of ET-1 (pmol/L) were determined by immunoassay analysis using the kits of Biomedica. The outcomes of this study were the differences in marker levels between patients with active SNV and healthy controls, patients with different forms of vasculitis, with varying degrees of BVAS activity, with involvement different organs and systems estimated by analysis of the absolute changes in marker levels and the areas under receiver operating characteristic (ROC) curves (AUC).

**Results:** The level of ET-1 (M±σ) in the general group of patients with SNV was 0.31±0.24 and did not differ significantly from the control group (0.27±0.10, p>0.05). At the same time, in patients who did not receive at screening glucocorticoids and cytotoxic agents (n=9), it was significantly elevated (0.62±0.58, p=0.03). However, ROC analysis indicated the moderate sensitivity (67%) and the low specificity (48%) of ET-1 for diagnosis of SNV. There were no significant differences in the levels of ET-1 between patients with different forms of vasculitis and with varying degrees of BVAS activity. In the analysis of the values of the ET-1 depending on the involvement of different organs and systems, it was found that only in patients with kidney involvement (n=15) its level (0.40±0.33) was significantly higher compared with patients without kidney involvement (0.28±0.22, p=0.04) and control group (p<0.01). ROC analysis showed that the AUC for ET-1 is 0.75±0.10 (p=0.004), which indicates acceptable capacity for ET-1 differentiate groups of patients with kidney involvement and patients without kidney involvement (sensitivity – 80.0%, specificity – 78.3%).

**Conclusions:** The serum levels of ET-1 were elevated in patients with SNV with kidney involvement (48% compared to healthy controls and 43% compared with patients without kidney involvement), which can be used for diagnostic purposes.

#### AB0691 INTERSTITIAL LUNG DISEASE AND MICROSCOPIC POLYANGIITIS IN CHILEAN PATIENTS

P. Wurmman, F. Elgueta, D.E. Vargas, M.L. Molina, K. Vergara, M. Mac-Namara, A. Goecke, H. Gatica, F. Sabugo, S. Saavedra, F. Bozán, J.C. Diaz. *Hospital Clínico de la Universidad de Chile, Santiago, Chile*

**Background:** Microscopic Polyangiitis (MPA) is an ANCA associated vasculitis (AAV), associated with p-ANCA (perinuclear) fluorescence pattern and anti-myeloperoxidase (MPO) specificity. Most frequently involved organs are kidney (80%–100%), peripheral nervous system and skin (30%). There is Pulmonary involvement in 25%–35% of patients, being alveolar haemorrhage frequently described. Interstitial lung disease (ILD) has also been recognised.

**Objectives:** The aim of our study is to report the characteristics of MPA Chilean patients with ILD and to compare it with other series.

**Methods:** Retrospective study. Patient diagnosed between 2007 and 2016 at the Hospital Clínico Universidad de Chile, with ILD, defined as interstitial lung disease on CT scan with Usual Interstitial Pneumonia (UIP) or Non Specific Interstitial Pneumonia (NSIP) pattern, and MPA were included. Demographic, clinical, laboratory and mortality data were plotted. Data from other series were compared with our results. Other causes that could explain the pulmonary involvement were excluded.

**Results:** From 94 patients with AVV, 36,1% were MPA, being 16 patients with ILD. All were Hispanic, median age 65.3 years, <sup>32–84</sup> female 62.5% (table 1). Common manifestations were constitutional symptoms (100%), weight loss (68,7%) and fever (68,7%). All patients had anaemia, high ESR (mean 84 mm/hr. range 33–120) and CRP (8–22 times above upper normal limit). All patients were ANCA-p and MPO positive. In 10 cases ILD was diagnosed concomitantly with MPA and in 6 was 0.5 to 15 years before. 4 patients developed pulmonary haemorrhage. Images patterns were 10 UIP and 5 NSIP. All patients received corticosteroid as induction therapy, 15 also received cyclophosphamide. One patient plasmapheresis, and one received Rituximab after a relapsed. Azathioprine was used as

Maintenance therapy. Four patients died during follow-up. table 2 shows data from other worldwide region compared with our data.

**AB0692 BELIMUMAB IN COMBINATION WITH AZATHIOPRINE FOR REMISSION MAINTENANCE IN GRANULOMATOSIS WITH POLYANGIITIS AND MICROSCOPIC POLYANGIITIS: EFFECT ON BIOMARKERS**

D. Jayne<sup>1</sup>, D. Blockmans<sup>2</sup>, R. Luqmani<sup>3</sup>, B. Ji<sup>4</sup>, Y. Green<sup>4</sup>, L. Hall<sup>5</sup>, D. Roth<sup>6</sup>, R. B. Henderson<sup>7</sup>, P.A. Merkel<sup>7</sup>. <sup>1</sup>University of Cambridge, Cambridge, UK; <sup>2</sup>University Hospital Gasthuisberg, Leuven, Belgium; <sup>3</sup>Botnar Research Centre, University of Oxford, Oxford; <sup>4</sup>GSK, Stockley Park; <sup>5</sup>GSK, Stevenage, UK; <sup>6</sup>GSK, Collegeville, PA; <sup>7</sup>University of Pennsylvania, Philadelphia, PA, USA

**Background:** GPA and MPA (related types of ANCA-associated vasculitis [AAV]) are organ-/life-threatening systemic vasculitides. B cells and increased circulating BLYS (a B cell survival factor) are implicated in AAV pathogenesis, suggesting a role for BLYS in these vasculitides. BEL is an anti-BLYS human immunoglobulin (Ig) G1 $\lambda$  monoclonal antibody.

**Objectives:** Examine the effects of BEL plus azathioprine (AZA), on biomarkers in patients with AAV for remission maintenance following standard induction (IND) with glucocorticoids (GC) and CYC or RTX.

**Methods:** This double-blind, placebo-controlled, multicentre study (BEL115466/NCT01663623) randomised (1:1) patients ( $\geq 18$  years) with new/relapsing AAV following IND (oral or IV CYC or RTX), to AZA 2 mg/kg/day and oral GC, plus IV BEL 10 mg/kg or PBO (Days 0, 14, 28 and every 28 days until completion). Remission was defined as Birmingham Vasculitis Activity Score=0, plus GC  $\leq 10$  mg/day. The study was truncated after initiation (n~300 to~100) due to revised AAV standard of care (SoC) affecting recruitment. Biomarker endpoints (serum Igs, B cells and ANCA [anti-MPO/PR3]) were measured at baseline (BL) and thereafter. Summaries by IR were post hoc; no analyses were performed.

**Results:** At BL, RTX patients had B cell counts  $\leq$  LLQ. CYC patients had notably low BL B cell counts: the lowest were in oral-CYC patients. Circulating memory B cells (CD20+/CD27+) increased rapidly with BEL, then gradually returned to BL (CYC); no major changes occurred with PBO. BEL had no impact on the proportion of naive CD20 +CD27 – B cells vs PBO, post CYC IND. The number of RTX patients with quantifiable data was low; partial reconstitution occurred in a minority of patients (PBO 2/13; BEL 4/14) and did not translate into vasculitis relapses. Overall Ig levels declined more noticeably with BEL vs PBO; suggesting BEL affects antibody-secreting cells. ANCA+patients were similar between groups (PBO 32/50; BEL 30/49). No trends in change in ANCA status over time occurred, regardless of IR. Individual patient data showed no apparent trends between ANCA titres and AAV activity.

**Conclusions:** Choice of IR for active AAV affects B cell dynamics. BEL pharmacodynamic effects occurred in patients with AAV receiving SoC. Given the small sample size and high variability, data must be interpreted with caution.

**AB0693 DEMOGRAPHIC, CLINICAL, LABORATORY AND IMAGING CHARACTERISTICS OF AN INCIDENCE COHORT OF 93 PATIENTS WITH LARGE VESSEL GCA**

P. Macchioni<sup>1,1</sup>, L. Boiardi<sup>1</sup>, G. Restuccia<sup>1</sup>, F. Muratore<sup>1</sup>, P. Mancuso<sup>2</sup>, M. Catanoso<sup>1</sup>, C. Salvarani<sup>1</sup>. <sup>1</sup>OSPEDALE SANTA MARIA NUOVA; <sup>2</sup>Epidemiology, Ausl Reggio Emilia, Reggio Emilia, Italy

**Background:** Few study have evaluated the clinical and imaging data of patients with large vessel GCA (LVGCA)

**Objectives:** To evaluate clinical, demographical and imaging data of an inception cohort of 93 patients with LVGCA recruited in Reggio Emilia (Northern Italy)

**Methods:** All patients with incident large vessel GCA diagnosed between 1 January 2005 and 31 December 2016 and living in the Reggio Emilia area, were identified by capture and re-capture checking of computerised discharge diagnosis codes (ICD10) and using outpatients databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital as well

as by examining the Reggio Emilia district database for rare diseases. To be included in the study, patients must satisfy the following 2 criteria: Age at disease onset  $\geq 50$  years; evidence of large-vessel vasculitis by clinical criteria, angiography, MRA, CTA, PET/CT and/or ultrasonography. Demographic, clinical, laboratory and imaging data collected at first visit were retrieved from patients records.

**Results:** There were 93 incident cases of LV GCA (66 women, 71%) during the 12 year study period; Mean  $\pm$ SD age at diagnosis was 72 $\pm$ 9 years. The three most prevalent signs an symptoms were: systemic in 49 pts (52.7%), GCA cranial symptoms in 39 pts (41.9%) and PMR in 35 pts (37.6%). Peripheral ischaemic symptoms were observed only in 8 pts (8.6%). Forty four pts had temporal artery biopsy and 70.5% resulted positive. At US examination the three most common involved arteries were: common carotid artery (59.2% pts), subclavian artery (53.3% pts) and axillary artery (49.3 pts). At PET/CT scan examination the most common involved arteries were: thoracic aorta (72.1% pts), subclavian artery (61.8% pts) and abdominal aorta (58.8% pts). Celiac trunk and mesenteric artery were involved in 18.4% of pts and renal artery in 10.2% of pts.

**Conclusions:** In an inception cohort of LVGCA systemic manifestations had the highest prevalence among presenting symptoms. Imaging studies demonstrated an high prevalence of aortic and subclavian involvement.

#### AB0694 GIANT CELL ARTERITIS EPIDEMIOLOGY IN LA REUNION: A RETROSPECTIVE CASES SERIES

Q. Richier<sup>1</sup>, T. Deltombe<sup>1</sup>, A. Foucher<sup>2</sup>, C. Roussin<sup>3</sup>, A. Randrianjohany<sup>4</sup>, A. Gerber<sup>1</sup>, P. Poubeau<sup>2</sup>, L. Raffray<sup>1</sup>. <sup>1</sup>Internal Medicine, CHU de La Réunion, Saint Denis; <sup>2</sup>Internal Medicine, CHU de La Réunion, Saint Pierre; <sup>3</sup>Internal Medicine, CH Gabriel Martin, Saint Paul; <sup>4</sup>Internal Medicine, Groupe Hospitalier Est Réunion, Saint Benoît, France

**Background:** Giant Cell Arteritis (GCA) is the most common vasculitis in people over 50 years, with incidence varying according to geographic location. In Europe, the average incidence is 10–30 per 1 00 000 inhabitants over 50 years, whereas in Africa and Asia it is approximately 1.5 per 1 00 000.

**Objectives:** To define GCA epidemiology in La Réunion, a French oversea territory in South West Indian Ocean characterised by several ethnic groups and genetic admixture.

**Methods:** Retrospective study between January 2005 and August 2017 in the 4 main hospitals of La Réunion. Patients were identified through hospital informatics databases and practitioner records. A definite diagnosis of GCA was considered for patients fulfilling ACR criteria and/or by assessment by a trained rheumatologist. Incidence and prevalence calculation was based on French national census data.

**Results:** Sixty patients were included, of which 60% were women. Mean age at diagnosis was 73.7 years, with a mean delay to diagnosis of 6.8 months. Cases met an average of 3.78/5 ACR criteria, and 78% had >2 criteria. The mean annual incidence was 2.33 per 1 00 000 inhabitants older than 50 years (203,000), with 95% confidence interval (IC) of 1.74–2.92. The prevalence at the end of period study was 24 cases per 100,00 (IC: 18–30). There was no seasonal variation regarding disease onset. Clinically, patients complained of asthenia and headache in 75%, fever in 33% and ophthalmologic damage for 32% of the cases, of which 5 had anterior ischaemic optic neuropathy. Polymyalgia rheumatica was associated in 42% of all cases. Total blood cells counts were usually within normal values, whereas mean CRP was 111 mg/L. Anicteric cholestasis was a common finding: mean GGT=78 IU/L (n<42) and alkaline phosphatase=107 IU/L (n<104). Radiological examinations contributed to diagnosis in only 9/31 cases. Temporal artery biopsy was performed in 91% of patients and showed specific histological features of GCA in 55%. Corticosteroid regimen was introduced in 59 patients (1 died the day after the biopsy) and mean treatment duration was 26 months, for a total dose of 10.6 g. Antiplatelet therapy was given in 47% of patients. One patient in three experienced one or more relapses.

**Conclusions:** This is the first study to describe GCA in La Réunion, and more generally in Indian Ocean. It shows an incidence 4–12 times lower than in most European countries with white ancestry background. This discrepancy could be explained by the contribution of the various ethnic groups of La Reunion, especially those coming from parts of the world characterised by a lower GCA incidence (Africa, India, South East Asia). A shorter life expectancy may also account for this observation, assuming that GCA incidence increases with age. Sex ratio and age at diagnosis were similar to European studies, as well as clinico-biological features, response to treatment and side effects. Some limitations of our study should be taken in consideration: inclusions of hospitalised patients only, informatics record limits and retrospective design that did not afford for ethnic background determination.

#### AB0695 PREDICTIVE FACTORS OF LONG-TERM CLINICAL OUTCOME IN BEHCET'S SYNDROME PATIENTS WITH OCULAR INVOLVEMENT: DOES ACTUALLY THE DISEASE TEND TO GROW DIM OVER TIME?

R. Talarico<sup>1</sup>, M. Figus<sup>2</sup>, C. Posarelli<sup>2</sup>, A. d'Ascanio<sup>1</sup>, R. Neri<sup>1</sup>, C. Tani<sup>1</sup>, C. Baldini<sup>1</sup>, M. Mosca<sup>1</sup>. <sup>1</sup>Department of Clinical and Experimental Medicine, University of Pisa, Rheumatology Unit; <sup>2</sup>Department of Surgical, Medical, Molecular Pathology and Emergency, University of Pisa, Pisa, Italy, Ophthalmology Unit, Pisa, Italy

**Background:** Behçet's syndrome (BS) is a multisystemic, chronic relapsing inflammatory disease classified among the vasculitis. Eye involvement represent one of the most serious manifestation of BS and occurs in half of all patients. It seems more frequent and severe among young males and, unluckily, it still represents a significant cause of morbidity.

**Objectives:** The aims of the study were: to study the relapse rate of BS patients with ocular involvement and to identify factors able to predict long-term outcome

**Methods:** Among a cohort of 138 patients with a diagnosis of BS according the ISG criteria, 62 patients (37 males and 25 females; mean age at the onset 38 $\pm$ 5 years) with ocular involvement were prospectively studied. The probability of clinical relapse after remission of the first ocular attack was calculated using the Kaplan-Meier method. Predictors of long-term outcome were identified by univariate analysis using the log-rank test and by multivariate analysis using Cox proportional hazards regression models.

**Results:** The mean time between the first initial symptoms of BS and the onset of eye lesions was 2 $\pm$ 2 years. The number of ocular attacks were the following: 43 posterior uveitis, 27 anterior uveitis, 26 retinal vasculitis, while panuveitis developed in 18 subjects. The cumulative relapse rates at 1 year, 3 years, and 5 years after remission of the first ocular attack were 41%, 31%, and 28%, respectively. On multivariate analysis, a younger age (<30 years) at the onset of ocular involvement, male sex and medical treatments other than biological agents represent independent predictive factors for more early relapses in BS patients with ocular involvement.

**Conclusions:** The relapse rate seems to be more frequent in the first years of diseases, and probably it could be related to the fact the disease tend to grow dim over time. As literature data suggest, younger age and male sex still represent predictive factors of poor long-term clinical outcome.

#### AB0696 CLINICAL CHARACTERISTICS AND OUTCOME OF PATIENTS WITH GRANULOMATOSIS WITH POLYANGIITIS (GPA) ACCORDING TO ANCA POSITIVITY AND SPECIFICITY

R. Solans-Laque<sup>1</sup>, J. Rios<sup>2</sup>, M. Rodriguez-Carballeira<sup>3</sup>, B. Frutos<sup>4</sup>, L. Saez<sup>5</sup>, F. Pasquau<sup>6</sup>, J. Oristell<sup>7</sup>, E. Fonseca<sup>8</sup>, G. Fraile<sup>9</sup>, on behalf of REVAS-GEAS (SEMI). <sup>1</sup>Autoimmune Diseases Unit, Internal Medicine Department, Vall-Hebron Hospital, Barcelona; <sup>2</sup>Internal Medicine, H La-Paz, Madrid; <sup>3</sup>Internal Medicine, H-Mutua, Terrassa; <sup>4</sup>Internal Medicine, H Fuenlabrada, Madrid; <sup>5</sup>Internal Medicine, H Miguel-Servet, Zaragoza; <sup>6</sup>Internal Medicine, H Marina-Baixa, Alicante; <sup>7</sup>Internal Medicine, H Parc-Tauli, Sabadell; <sup>8</sup>Internal Medicine, H Cabueñes, Asturias; <sup>9</sup>Internal Medicine, H Ramon-Cajal, Madrid, Spain

**Background:** GPA is a necrotizing granulomatous vasculitis associated with ANCA that usually involves ENT, lung and kidneys. ANCA are mostly directed against proteinase 3 (PR3), although in few cases are directed against myeloperoxidase (MPO) or negative.

**Objectives:** To analyse the phenotype, clinical course and outcome of patients with GPA according to ANCA positivity and specificity

**Methods:** multicenter retrospective-longitudinal study that included patients diagnosed with AAV between Jan 1995 and Jan 2016 in 21 Hospitals from Spain (REVAS-Study). We analysed the clinical characteristics, treatment and outcome, depending on the ANCA positivity and specificity. Statistical analysis was performed using SPSSv20

**Results:** 221 patients with GPA were included:162 with PR3-ANCA, 36 with MPO-ANCA, and 23 with negative-ANCA. The mean-age at disease onset was higher in patients with MPO-ANCA (59.9 $\square$ 16.5 years) than in patients with PR3-ANCA (50.5 $\square$ 16.5) and negative ANCA (48 $\square$ 14.5), p=0.006. Compared to

patients with PR3-ANCA, patients with MPO-ANCA presented a lower prevalence of toxic syndrome (42.9% vs. 55.6%,  $p=0.021$ ), arthralgias (34.3% vs. 59.9%,  $p=0.008$ ), arthritis (8.6% vs. 26.5%,  $p=0.026$ ), pulmonary involvement (cavitated/infiltrated nodules,  $p=0.007$  and  $p=0.05$ ), and anaemia (57.1% vs. 77.8%,  $p=0.05$ ). Renal disease was less severe in patients with MPO-ANCA (creatinine  $\geq 1.58$  mg/dL 14.3% vs. 30.4%,  $p=0.04$ ). Subglottic stenosis and sensoryneural deafness were more frequent in patients with MPO-ANCA (20% vs. 6.8%,  $p=0.05$  and 34.3% vs. 18%,  $p=0.03$ ). The mean BVAS at baseline was lower in patients with MPO-ANCA (16.3 $\square$ 8.8) and negative ANCA (12.5 $\square$ 6.7) than in patients with PR3-ANCA (19.6 $\square$ 8.9),  $p=0.029$ . Patients with negative ANCA had less frequently toxic syndrome, fever, arthritis, subglottic stenosis, kidney disease, and peripheral neuropathy, and more frequently orbital masses. Disease relapses were less frequent in patients with MPO-ANCA than in patients with PR3-ANCA (37.1% vs. 48.8%,  $p=0.04$ ), but more frequent than in patients with negative ANCA (20.8%),  $p=0.002$ . Patients with MPO-ANCA and negative ANCA received less frequently oral cyclophosphamide. No significant differences were found related to death in patients with MPO-ANCA and PR3-ANCA. Patients with negative ANCA had the lower mortality

**Conclusions:** A small percentage of patients with GPA present MPO-ANCA or negative ANCA. In our series, patients with MPO-ANCA were older at the disease onset, presented limited or less severe organic disease than patients with PR3-ANCA, lower percentage of relapses and lower requirement of aggressive therapies. Patients with negative ANCA had the best prognosis. Our findings are similar to those recently published,<sup>1</sup> although our patients with MPO-ANCA were older. Classification of GPA patients considering ANCA specificity can improve the treatment stratification and reduce adverse events.

#### GIANT CELL ARTERITIS WITH NORMAL INFLAMMATORY MARKERS AT DIAGNOSIS

R. Solans-Laque<sup>1</sup>, E. Fonseca<sup>2</sup>, B. Escalante<sup>3</sup>, A. Martinez-Zapico<sup>4</sup>, G. Fraile<sup>5</sup>, M. Perez-Conesa<sup>6</sup>, M. Abdilla<sup>7</sup>, M. Monteagudo<sup>8</sup>, on behalf of REVAS-Study (GEAS-SEMI). <sup>1</sup>Autoimmune Diseases Unit, Internal Medicine Department, Vall Hebron University Hospital, Barcelona; <sup>2</sup>Internal Medicine, H Cabueñes, Asturias; <sup>3</sup>Internal Medicine, H Lozano-Blesa, Zaragoza; <sup>4</sup>Internal Medicine, H Central, Asturias; <sup>5</sup>Internal Medicine, H Ramon y Cajal, Madrid; <sup>6</sup>Internal Medicine, H Miguel-Servet, Zaragoza; <sup>7</sup>Internal Medicine, H La Ribera, Alzira; <sup>8</sup>Internal Medicine, H Parc-Tauli, Sabadell, Spain

**Background:** GCA is an inflammatory vasculitis affecting medium and large-sized arteries, that can result in arteritic anterior ischaemic optic neuropathy. C-reactive protein (CRP) level and erythrocyte sedimentation rate (ESR) are usually elevated at GCA diagnosis, but inflammatory-marker negative disease does occur.

**Objectives:** To analyse the clinical and histological findings of patients with biopsy-proven GCA and negative inflammatory-markers at diagnosis.

**Methods:** multicenter-longitudinal retrospective study that included patients with biopsy-proven GCA recruited at 10 Hospitals from Spain (REVAS Study). Statistical analysis was performed using SPSS vs. 21.

**Results:** 418 patients: 290 (69.4%) females (ratio F/M: 2.3/1) were included. The mean age at diagnosis was 75.5 $\pm$ 7 (53–92). The most frequent symptoms at diagnosis were recent onset headache (81%), toxic syndrome (47%) and rheumatic polymyalgia (44.5%). Jaw claudication, cranial hyperesthesia and amaurosis fugax were reported by 44.5%, 31.8% and 16.5% of patients, respectively. A total of 84 patients suffered permanent vision loss. Fourteen patients (3.3%) had normal ESR (<40 mm/h) and CRP (<5 mg/L) at diagnosis. No significant differences were found related to age at disease onset in these patients. Most patients (85%) reported headache; 42.9% jaw claudication, 28.6% cranial hyperesthesia and 42% rheumatic polymyalgia. Fever was less frequent in patients with negative inflammatory-markers (7.7% vs. 40.4%,  $p=0.020$ ), as well as toxic syndrome (21.4% vs. 51.5%,  $p=0.031$ ). In contrast, patients with negative inflammatory-markers had more frequently amaurosis fugax (35.7% vs. 16.8%,  $p=0.03$ ) and optic ischaemic neuropathy (50% vs. 18.7%,  $p=0.009$ ). Temporal arteries were abnormal (thickened and/or pulse less) in 78.6% of patients with negative inflammatory-markers vs. 37% of patients with elevated ESR and/or CRP. Anaemia was less common in patients with negative inflammatory-markers (28.6% vs. 81.5%,  $p<0.001$ , mean haemoglobin 12.9 $\pm$ 1.1 g/dL). No significant differences were found related to temporal artery biopsy findings, although patients with normal ESR and CRP showed giant cells in 74.3% of cases vs. 62%.

**Conclusions:** typically patients with GCA present with elevated inflammatory-markers (ESR and CRP) at disease onset. However, a few percentages of patients (4%–5%) have normal ESR and CRP at diagnosis.<sup>1</sup> In our series, 3.3% of patients had negative inflammatory-markers at diagnosis. These patients had fewer constitutional symptoms and more visual symptoms (amaurosis fugax and permanent visual loss) than patients with elevated ESR and/or CRP. Our result are similar to those published in the literature. Abnormal temporal arteries on physical examination may help to diagnosis

#### A COMPARISON OF THE EFFECTIVENESS OF MYCOPHENOLATE MOFETIL OR METHOTREXATE IN COMBINATION WITH PREDNISOLONE VERSUS PREDNISOLONE ALONE IN THE TREATMENT OF LARGE VESSEL VASCULITIS

R. Smith, R. Kilding, K.-P. Kuet, M. Akil, J. Maxwell. *Rheumatology Department, Royal Hallamshire Hospital, Sheffield, UK*

**Background:** The mainstay of treatment for large vessel vasculitis is glucocorticoids. Immuno-suppressants, including mycophenolate mofetil (MMF) and methotrexate (MTX) are used as steroid-sparing agents.<sup>1</sup> A previous study at our centre showed MMF to have a steroid sparing effect in 97% of patients and to reduce C-reactive protein (CRP) in 80%.<sup>2</sup>

**Objectives:** This study was undertaken to compare the efficacy of MMF or MTX combined with prednisolone or prednisolone alone in the treatment of large vessel vasculitis.

**Methods:** Patients with large vessel vasculitis (LVV) confirmed on positron emission tomography (PET) scan and those meeting ACR criteria for a diagnosis of giant cell arteritis (GCA), treated with prednisolone alone, prednisolone with MMF or prednisolone with MTX started within 3 months of prednisolone being commenced and with a minimum follow up of 24 months were included in a retrospective single centre study. CRP and prednisolone doses were recorded at baseline, after 3, 6, 9, 12, 18 and 24 months of treatment and area under the curve (AOC) calculated for CRP and prednisolone doses. Median AOC prednisolone dose for patients treated with MMF or MTX was then compared with that of patients treated with prednisolone alone. A quantile regression model was also constructed to compare prednisolone dose between the 3 treatment groups, adjusted for CRP. StataCorp. 2013. *Stata Statistical Software: Release 13*. College Station, TX: StataCorp LP was used for all statistical calculations.

**Results:** 65 patients were included in the study, 41 with GCA and 24 LVV. 49 were female and 16 male. Mean age at diagnosis was 68; range 21 to 87. 37 patients were treated with prednisolone alone; 35 had GCA and 2 LVV. 20 were treated with MMF and prednisolone; 4 with GCA and 16 LVV. 8 were treated with MTX and prednisolone; 2 had GCA and 6 LVV. The AOC for prednisolone and CRP were not normally distributed across the cohort, and non-parametric methods were therefore used for comparisons. Median AOC prednisolone dose for the prednisolone only group was 68.0, (interquartile range (IQR) 17.7,  $n=37$ ), for the MMF treated group 70.8 (IQR 28.7,  $n=20$ ) and for the MTX treated group 67.8 (IQR 20.4  $n=8$ ). Median AOC CRP was highest in the group treated with prednisolone alone (58.9, IQR 34.5) compared to MMF (43.8, IQR 26.5) and MTX (49.3 IQR 67.5) but there were no statistical differences between median AOC prednisolone dose or CRP in either the unadjusted or regression models.

**Conclusions:** No significant difference was shown between the groups. MMF is as effective as MTX and prednisolone alone in the treatment of LVV. However, there are limitations to the study. The patient group was small. There was no randomisation to treatment group; treatment choice was based on clinician preference. There was potential bias in that patients perceived to be more difficult to treat may have been given MMF or MTX in addition to prednisolone, and there was a higher proportion of patients with LVV compared to GCA in the MMF and MTX treated groups.

**AB0699 BENZATHINE PENICILLIN IN TREATMENT OF ULCERS OF BEHCET'S DISEASE**

S. Benamour. ALMS, Casablanca, Morocco

**Background:** Prednisone therapy, Thalidomide, azathioprine, anti-TNF-alpha inhibitors are presently used in resistant mucocutaneous lesions of Behçet's Disease (BD). In this study, we used only ambulatory Benzathine Penicillin (BP), without being preceded by high doses of penicillin infusion. This Study confirm the value of BP in the treatment of refractory ulcers of BD and point out a probable role of Streptococcus on the pathogenesis of BD

**Objectives:** This open Study confirm the value of BP in refractory oral, genital and skin ulcers of BD. We propose to use BP when ulcers of BD are resistant to colchicine 1.5 mg/day and to add BP in the recommendations of EULAR for the treatment of resistant cases of mucocutaneous involvement.

**Methods:** 15 patients with BD (12 patients fulfilled all criteria for BD) had Giant (mean size of ulcer superior to 1 cm), or Multiple oral, genital, skin ulcers received BP at the dose of 2.4 million units in intramuscular injection; 3 intramuscular injections with an interval of 3 weeks between injection. Colchicine at the dose of 1 mg/day was maintained. Serology of syphilis was negative. Patients had seen 15 days, 3 months and 1 year after the starting treatment.

**Results:** This study started in 2012, in a private office and comprised 15 patients:9 males; 6 females. Arthritis was observed in 11 patients, uveitis in 6 cases. BP was used in 8 patients with oral ulcers(4 Giants and 4 multiples), Genital ulcers in 3 patients (2 multiple and 1 Giant), oral and genital ulcers(2 Multiples) and cutaneous aphthosis in 2 patients 0.2 weeks after the first injection of BP, recovery from ulcers was achieved. BP was administrated a second time with success, in 9 patients who have developed resistant ulcers, after 1 to 3 years of recovery. One patient with panuveitis treated with azathioprine in 2013 and interferon alpha in 2015 and 2017, developed refractory ulcers: Excellent efficacy of BP was observed in this patient.

**Conclusions:** In this study, we confirm the recovery from refractory oral, genital and cutaneous ulcers (Giant, Multiple) in these 15 patients with BP. We recommend using more frequently BP and we propose to add BP in the recommendations of EULAR for the treatment of resistant cases of mucocutaneous involvement because treatment with BP is rather easy in outpatients, it is efficient, it has a low cost and have few side-effects

**AB0700 IS IT FEASIBLE TO WITHDRAW IMMUNOSUPPRESSIVE TREATMENT IN REAL-LIFE PATIENTS WITH ANCA-ASSOCIATED VASCULITIS?**

S. Monti<sup>1,2</sup>, B. Vitolo<sup>1</sup>, S. Balduzzi<sup>1</sup>, M. Felicetti<sup>3</sup>, R. Padoan<sup>3</sup>, A. Berti<sup>4</sup>, M. Bond<sup>5</sup>, L. Quartuccio<sup>5</sup>, G. Paolazzi<sup>4</sup>, F. Schiavon<sup>3</sup>, C. Montecucco<sup>1</sup>, R. Caporali<sup>1</sup>.  
<sup>1</sup>Rheumatology, IRCCS Policlinico S. Matteo Foundation; <sup>2</sup>University of Pavia, PhD in Experimental Medicine, Pavia; <sup>3</sup>Rheumatology, University of Padova, Padova; <sup>4</sup>Rheumatology, Santa Chiara Hospital, Trento; <sup>5</sup>Rheumatology, University Hospital S. Maria della Misericordia, Udine, Italy

**Background:** The optimal duration of remission-maintenance treatment in ANCA-associated vasculitis (AAV) is still unknown,<sup>1</sup> with International recommendations suggesting to maintain it for at least 24 months. Data supporting the correct balance between relapse risk, treatment-related adverse events and damage are highly needed.

**Objectives:** To analyse the frequency and predictors of withdrawal of remission-maintenance immunosuppressive drugs (IS) in a large real-life cohort of AAV patients.

**Methods:** Clinical records of patients with granulomatosis with polyangiitis (GPA) or microscopic polyangiitis (MPA) were retrospectively analysed from a multicentric cohort. We divided the cohort into group A (withdrawal) and group B (ongoing).

**Results:** We included 185 patients. Forty-one patients (22%) had withdrawn IS at the end of follow-up (median 73.5 months, IQR 54–115). Concomitant glucocorticoids were stopped in 33%. There were no significant differences in AAV subtype,

ANCA pattern, age at diagnosis, diagnostic delay or comorbidities rates between group A and group B (table 1). Disease onset with pulmonary involvement was significantly more frequent in patients in whom IS was maintained (69.7% vs 45%; p=0.004). Figure 1. Disease activity at onset, but not during follow-up, was significantly higher in patients from group B (ongoing): median BVAS 18 (12–24) vs 15; (8–20) p=0.02. The type of IS used for remission induction did not differ between the two groups. Maintenance treatment with Rituximab (RTX) was associated with higher probability of discontinuing IS by the end of follow-up (21% vs 7.6%; p=0.02). There was no difference in the number of major relapses between the two groups. Safety profile was equally good in both groups, except for a higher number of infections over the course of disease in patients who withdrew IS (5% vs 0). Vasculitis damage index (VDI) was comparable between the two groups.

**Abstract AB0700 – Table 1.** Clinical characteristics and outcome: comparison between IS withdrawal group (A) and ongoing group (B).

	Group A (withdrawal) n=41	Group B (ongoing) n=144	p
Sex:	18 (43.9%)	67 (46.5%)	0.769
Male, N (%)			
Diagnostic delay, months, median (IQR)	4 (2–11.75)	3.5 (1–8)	0.551
Age at diagnosis (mean±SD)	53.85±16.30	54.41±15.39	0.847
Mean follow up duration months, median (IQR)	73.5 (54–115)	66 (36.5–109.5)	0.315
AAV subtypes N(%)			
GPA	32/41 (78%)	112/144 (77.8%)	0.976
MPA	9/41 (21.9%)	29/144 (20.1%)	0.801
p-ANCA (MPO) N(%)	10/41 (24.4%)	47/143 (32.9%)	0.302
c-ANCA (PR3) N(%)	19/41 (46.3%)	78/143 (54.5%)	0.355
Number of major flares, median (IQR)	0 (0–1)	0 (0–1.25)	0.695
Safety: cancer	6/41 (14.6%)	11/135 (8.1%)	0.220
Safety: infections: >3, N(%)	2/40 (5%)	0/134 (0%)	0.009
Number of hospitalisations, median (IQR)	0 (0–1)	0 (0.1)	0.454
VDI last follow-up	3 (2–4.75)	3 (2–4)	0.773

**Abstract AB0700 – Figure 1**

**Conclusions:** IS withdrawal was observed in a minority of real-life patients with AAV. Drug-free remission was negatively associated with pulmonary involvement and higher BVAS at disease onset. Remission maintenance with RTX was associated with a higher frequency of drug withdrawal at the end of follow-up.

**AB0701** **COMPARISON OF THE NEW ACR/EULAR CLASSIFICATION CRITERIA OF ANCA-ASSOCIATED VASCULITIS WITH THE EMA ALGORITHM IN CLASSIFICATION OF VASCULITIS**

S. Li<sup>1</sup>, Q. Zhang<sup>2</sup>. <sup>1</sup>department of Rheumatology and Immunology, Peking University International Hospital; <sup>2</sup>department of Rheumatology and Immunology, The First affiliated hospital of Chinese PLA general Hospital, Beijing, China

**Objectives:** A new set of classification criteria for ANCA-associated vasculitis (AAV) was presented in 2017's ACR annual scientific meeting. In order to evaluate this new set of classification, we conducted the current study to compare it with the EMA's consensus algorithm for classification of systemic vasculitis proposed by Watt et al. in our centre.

**Methods:** One hundred and twenty-two Chinese patients with clinically diagnosed as AAV in our centre during the past 15 years were retrospectively studied. We compared the new set of ACR/EULAR's classification criteria for AAV, with the EMA's consensus algorithm with surrogate parameters, in the same cohort of patients with primary systemic vasculitis.

**Results:** Applying the EMA's consensus algorithm with surrogate parameters, the diagnoses were EGPA (n.3), GPA (n.55), microscopic polyangiitis (MPA) (n.47), drug related AAV (n.2), and unclassified (n.5). Using the new ACR/EULAR's classification criteria for AAV, the diagnoses were EGPA (n.8), GPA (n.33), MPA (n.65), overlap with EGPA and GPA (n.2), overlap with GPA and MPA (n.8), and unclassified (n.7) (See the below picture).

Abstract AB0701 – Figure 1

**Conclusions:** The new 2017 ACR/EULAR classification criteria for AAV and Watts' algorithm were all useful methods to classify patients with systemic vasculitis. The Watts' algorithm can classify all patients into a single category, with more GPA patients, less unclassified patients and without overlapping diagnosis, in comparison, the new 2017 ACR/EULAR classification criteria classified more MPA patients, more unclassified and more overlapping patients.

**AB0702** **ALKALINE PHOSPHATASE AS A PREDICTOR OF GIANT CELL ARTERITIS – A RETROSPECTIVE ANALYSIS OF CLINICAL FEATURES AND TEMPORAL ARTERY BIOPSY FINDINGS**

S. Varrier, C. Li. Rheumatology, Royal Surrey County Hospital, Surrey, UK

**Background:** Giant cell arteritis (GCA) is the most common large vessel vasculitis in the United Kingdom and Northern Europe. Inadequate treatment and delay in diagnosis can lead to a number of devastating consequences.

**Objectives:** This study looks at whether the presence of a raised alkaline phosphatase (ALP) may aid the diagnosis of GCA, improve the sensitivity of TAB, including in the presence of other proven serum markers and whether it has any correlation with severity of clinical presentation.

**Methods:** Retrospective multicenter cohort study. Information was retrospectively gathered on patients who underwent TABs following a clinical working diagnosis of GCA. Only patients who fulfilled the American College of Rheumatology (ACR) classification criteria and had ALP measured within 4 weeks of undergoing TAB were included in the study. Once patients were identified, further information was extrapolated including the values of other serum markers taken, and presenting clinical features.

**Results:** Our 223 patients sample population who fulfilled the inclusion criteria reflected typical GCA patients: 147 (65.9%) were female and mean age was 73.1 years (SD 10.5). TAB was positive in 54 patients (24.2%). Two patients (3.7%) who had a positive TAB had completely normal serum markers. We were unable

to comment on variables, which could have contributed to this but they likely represented already administered aggressive glucocorticoid treatment at time of serum measurement or atypical presentation of GCA. Raised ALP sensitivity at the current cut off value was very low (14.8%) but with high specificity (90.5%), which was reinforced following ROC curve analysis. Pearson coefficient analysis suggested that there was a weakly associative relationship between raised ALP and degree of clinical suspicion (Correlation 0.346, Sig 0.01)

**Conclusions:** Patients with a higher level of clinical suspicion and TAB positivity were more likely to have a raised ALP. However, the association strength was weak. ALP is suggested to be highly specific for TAB positivity. The association of raised ALP to degree of clinical features and suspicion of GCA is weak and of low significance, likely a reflection of the limitations of this study. Further robust research may further evaluate this observed relationship.

<sup>1</sup>Istanbul University, Cerrahpasa Medical School; <sup>2</sup>Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology, Istanbul, Turkey; <sup>3</sup>Cleveland Clinic, Department of Hematology and Oncology, Taussig Cancer Institute; <sup>4</sup>Cleveland Clinic, Department of Internal Medicine, Cleveland, USA

**Background:** Cyclophosphamide (CYC) remains an important treatment option for Behçet's syndrome (BS) patients with life-threatening conditions such as arterial aneurysms. However, several adverse events may occur with CYC and this has led to increased use of biologic agents such as rituximab in other vasculitides.

**Objectives:** The aim of this study is to delineate the outcome and short and long-term adverse events with CYC use among BS patients.

**Methods:** We conducted a retrospective chart review of all BS patients treated with oral or intravenous CYC between 1976 and 2006. Patients were called and a standard form was used for collecting demographic characteristics, CYC indication, cumulative dose of CYC and short-term serious adverse events necessitating the cessation of therapy and/or requiring hospitalisation and long-term adverse events (malignancy and infertility), and outcome.

**Results:** We identified 198 (M/W: 184/14) BS patients who had received CYC. After a median follow up of 17 (IQR: 9–26) years after the initiation of CYC therapy, 52 (26%) patients had died within a median duration of 4<sup>1–12</sup> years, 33 (17%) were lost after a median follow-up of 9 (3.5–14) years, and 113 (57%) were contacted. CYC was prescribed for vascular involvement in 132 (67%) patients, eye involvement in 52 (26%), central nervous system involvement in 5, both vascular and eye involvement in 7 and both vascular and central nervous system involvement in 2 patients. The median duration of CYC use was 12 (IQR:4–24) months and median cumulative dose was 13.5 (IQR:6–49) gr. Among the 52 patients who died, reasons for death were vascular involvement in 26, malignancies in 7, infections in 5 (5 bacterial infections, 1 additional tuberculosis), neurologic involvement in 2, ischaemic stroke in 1, traffic accident in 1, and secondary amyloidosis in 1, esophageal variceal bleeding in 1, and unknown in 5 patients. Sixteen (8%) patients experienced serious adverse events associated with short-term CYC use and 1 of them died due to infection. Among these adverse events, haemorrhagic cystitis occurred in 7 patients, infections in 4 (1/4 died), leukopenia, acute myocardial

infarction, anaphylactic reaction, azoospermia, liver toxicity, and severe nausea in 1 patient each. Overall, 16 malignancies were observed in 14 (7%) patients after a median follow up of 25 (IQR:15–26) years. The malignancies were bladder carcinoma (n=4), lung adenocarcinoma (n=3), prostate adenocarcinoma (n=2), carcinoma of unknown primary origin, pancreas adenocarcinoma, t-MDS-AML, lymphoma, colon adenocarcinoma, squamous cell carcinoma and thyroid papillary carcinoma. Among the 113 patients, we were able to question regarding infertility, 67 patients (59%) had children, 22 (19.5%) did not wish to have a child and 24 (21.5%) tried to have a child, but was not able to.

**Conclusions:** Short term serious adverse events occurred in 8% of the patients during CYC treatment. During long term follow-up malignancies occurred in 7% and infertility in 21.5% of the patients. These results underline the need for safer and effective alternatives to CYC for serious organ involvement in BS, similar to that in other vasculitides.

#### CLINICAL-ANALYTICAL CHARACTERISATION OF 52 DIAGNOSED PATIENTS OF BEHÇET DISEASE WITH INCLUSION OF PAEDIATRIC CASES IN A SPANISH TERTIARY HOSPITAL

S. Zegarra Mondragon, A. Alia-Jimenez, C. Bouroncle Alaluna, A. Boteanu. *Rheumatology, Hospital Ramon y Cajal (Spain), Madrid, Spain*

**Background:** Behçet's disease (BD) is a chronic and recurrent inflammatory disease of unknown etiology, classified into polygenic autoinflammatory diseases or variable vessel vasculitis. It has a wide spectrum of symptoms with a very variable range of severity, from mucocutaneous involvement to neurological manifestations, systemic vascular or severe ocular manifestations. About 5.4%–7.6% of Behçet's cases have a paediatric debut.

**Objectives:** To evaluate and compare the clinical and laboratory manifestations of a series of 52 patients, adults and children, diagnosed with BD according to the classification criteria of the International Study Group of BD (ISGBD-1990).

**Methods:** Retrospective cross-sectional observational study, which included 43 adult patients and 9 paediatric patients diagnosed with EB in the Rheumatology Department of a Madrid tertiary hospital. The clinical-analytical characteristics of both groups were evaluated, as well as the correlation of HLA-B51 with the described symptomatology.

**Results:** The mean age at diagnosis of BD was 36.9±11.8 years in adults and 11.4±5.1 years in children. 27.3% of adults and 11.1% of children with BD were male, with oral ulcers close to 90% in both groups. Contrary to what was reported in other series, genital ulcers were more frequent in children (77.8% versus 65.9% of adults), as was the presence of uveitis (44.4% in children compared to 22.7% in adults) and neurological manifestations (22.2% in children versus 6.8% in adults). Joint involvement was also more frequent in children (88.9% versus 52.3% in adults), as well as fever (44% in children versus 14% in adults); being these two manifestations the only parameters that were associated in a statistically significant way with their presentation in the paediatric age in BD. In contrast, skin involvement and vascular manifestations were more frequent in adults. The positivity of HLA-B51 did not correlate statistically with any clinical manifestation, but those who had it had a mean age at diagnosis of 26.5 years compared to a mean of 39 years in those who did not present this genetic marker.

**Conclusions:** Behçet's disease presents with a wide spectrum of clinical manifestations, potentially serious, ranging from skin lesions to neurological or vascular manifestations. In our series, patients diagnosed at paediatric age most frequently had systemic manifestations (fever), arthritis or severe clinical manifestations such as neurological involvement or uveitis. **Limitations:** a small number of paediatric cases included in our study.

**Disclosure of Interest:** None declared

#### LONG-TERM OUTCOMES AND PROGNOSTIC FACTORS ASSOCIATED WITH AORTIC VALVE SURGERY IN PATIENTS WITH TAKAYASU ARTERITIS AND AORTIC VALVEREGURGITATION

S.H. Nam<sup>1</sup>, O.C. Kwon<sup>1</sup>, W.J. Seo<sup>2</sup>, Y.-G. Kim<sup>1</sup>, C.-K. Lee<sup>1</sup>, B. Yoo<sup>1</sup>, S. Hong<sup>1</sup>.

<sup>1</sup>Internal medicine, Asan Medical Center, <sup>2</sup>Internal medicine, Veterans Health Service Medical Center, Seoul, Korea, Republic of Ireland

**Background:** Some patients with Takayasu arteritis (TA) have aortic valve (AV) involvement, which can lead to aortic regurgitation (AR). However, data on the long-term outcomes, including survival of TA patients with AR, are lacking. Moreover, previous studies were limited to patients who underwent AV surgery.

**Objectives:** This study aimed to characterise the long-term outcomes and clinical characteristics of TA patients with AR regardless of whether they underwent surgical intervention.

**Methods:** Medical records of patients with TA between January 1995 and December 2015 were retrospectively reviewed. AR was diagnosed using transthoracic echocardiography. Poor outcomes were defined as all-cause death and major adverse cardiac and cerebrovascular events (MACCE). Multivariate analysis was performed to determine the factors affecting poor prognosis in the surgical group.

**Results:** Of the total 105 patients with TA and AR, 41 (39.0%) underwent AV surgery. Among patients who underwent AV surgery, inflammation values (Erythrocyte sedimentation rate, 62.07±31.8 mm/hr vs. 39.16±28.4 mm/hr; C-reactive protein, 3.66±4.1 mg/dL vs. 0.92±1.7 mg/dL), AR degree (3.56±0.7 grade vs. 2.08±1.0 grade), and sinus diameter (37.24±5.7 mm vs. 33.22±4.5 mm) were significantly higher than in those who did not undergo AV surgery. Long-term survival and freedom from MACCE were not significantly different between the groups (10 year survival, 84.3% vs. 79.4%; p=0.827; 10 year event-free survival, 51.8% vs. 71.2%; p=0.29). Twelve of the 41 patients who underwent AV surgery had a poor outcome during follow-up (median, 92.5 months; IQR, 54.5–183.5), and eight of them had a recurrence of AR requiring reoperation. Multivariate Cox analysis revealed that coronary disease [hazard ratio (HR), 4.234; 95% confidence interval (CI), 1.381–12.979; p=0.012], LV dysfunction (HR, 3.387; 95% CI, 1.143–10.042; p=0.028), and impaired renal function (HR, 19.983; 95% CI, 3.480–114.731; p=0.001) were significant risk factors associated with poor outcomes at follow-up (table 1).

**Abstract AB0705 – Table 1.** Multivariate analysis of predictive factors of poor outcomes in patients with Takayasu arteritis who underwent aortic valve surgery.

Variables	HR	95% CI	p-value
Coronary disease*	4.234	1.381–12.979	0.012
LV dysfunction**	3.387	1.143–10.042	0.028
Impaired renal function	19.983	3.480–114.731	0.001

\*coronary disease: severity is more than moderate stenosis

\*\*LV dysfunction: EF <50%

**Conclusions:** In patients with TA with AV involvement, there were no significant differences between long-term survival rate and event-free survival (MACCE) among those who had or had not undergone AV surgery. In the surgical group, the prognosis was poor when coronary artery disease, LV dysfunction, and renal impairment were present at the time of surgery.

#### OCULAR PRESENTATION IN GRANULOMATOSIS WITH POLYANGIITIS (GPA) PATIENTS: RELATION TO AUTOANTIBODIES AND DISEASE ACTIVITY

T.A. Gheita<sup>1</sup>, E.M. Abd El-Latif<sup>2</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Faculty of Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo; <sup>2</sup>Ophthalmology, Faculty of Medicine, Alexandria University, Alexandria, Egypt

**Objectives:** To study the disease characteristics, autoantibodies and activity in granulomatosis with polyangiitis (GPA) patients with ocular manifestations.

**Methods:** 46 GPA patients visiting the ophthalmology clinic were included. Ocular manifestations, clinical and slit lamp examination were performed. The Birmingham Vasculitis Activity Score (BVAS) was recorded. Laboratory investigations were recorded and the antineutrophil cytoplasmic antibody (ANCA) performed.

**Results:** The median age of the patients was 44.5 (32–63) years, 22 males:24 females and disease duration 6.5 (1–16) years. Ocular manifestations were present in all patients; 12 (26.1%) had proptosis, 40 (87%) scleritis/episcleritis with perforation in 3 (6.5%), keratoconjunctivitis in 33 (71.7%) – acute infiltrative stromal keratitis in 11, peripheral ulcerative keratitis in 15 and sclerosing keratitis in 11 patients. Uveitis was present in 11 (23.9%) and retinal changes included vasculitis, exudates and haemorrhage was present in 7 (15.2%). 43 (93.5%) of the patients had blurring of vision and vision loss was present in 2 (4.3%). Glaucoma was present in 4 (8.7%) and hypotony in 2 (4.3%). Involvement was bilateral in 32 (69.6%) patients. Rheumatoid factor was positive in 56.5% and significantly associated with uveitis (p=0.04) while ANA was positive in 45.7% and significantly associated with keratoconjunctivitis (p=0.04). BVAS tended to be higher in those with uveitis (p=0.05).

**Conclusions:** Ocular involvement must be considered in all GPA patients and referral to an experienced ophthalmologist is mandatory for proper management and improved outcome of such a rare systemic disease. ANA and RF positivity may raise suspicion for KC or uveitis respectively. There was a remarkable association between uveitis and disease activity.

**AB0707** **FOUR DISTINCT CLINICAL PHENOTYPES OF VASCULITIS AFFECTING MEDIUM-SIZED ARTERIES**

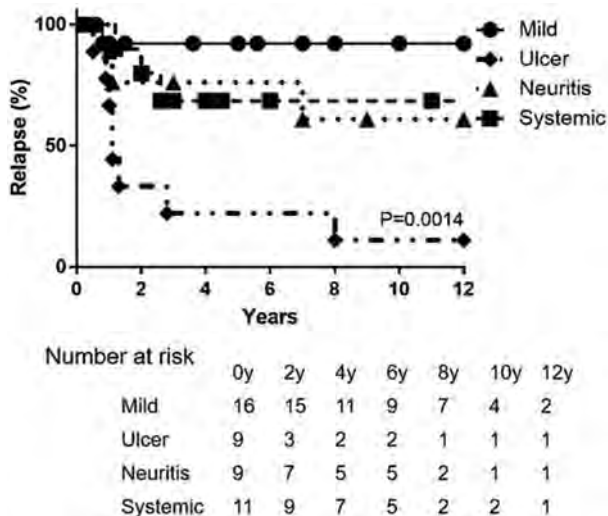

T. Shirai, H. Fujii, Y. Shirota, T. Ishii, H. Harigae. *Hematology and Rheumatology, Tohoku University Graduate School of Medicine, Sendai, Japan*

**Background:** Polyarteritis nodosa (PAN) is a necrotizing arteritis of medium-sized arteries. PAN is divided into systemic and cutaneous PAN (cPAN). cPAN is further classified into mild cPAN or severe cPAN, which presents with ulcer, necrosis, or neuritis. However, it is sometimes difficult to distinguish between severe cPAN and systemic PAN, and their optimal managements are still unclear. The aim of this study is to evaluate clinical characteristics of patients with necrotizing arteritis of medium and small artery.

**Objectives:** To evaluate the clinical characteristics of patients with necrotizing arteritis of medium-sized arteries in order to further clarify the subtypes of PAN.

**Methods:** Forty-nine patients diagnosed with necrotizing arteritis of medium-sized arteries between 2008 and 2017 at our institution were enrolled to this study. Patients with evidence of glomerulonephritis or vasculitis in arterioles, capillaries, or venules, which are hallmarks of small-vessel vasculitis, were excluded. Clinical backgrounds, laboratory findings including inflammatory markers and antineutrophil cytoplasmic antibodies (ANCA), affected organs, treatments, and rates of relapse and death were evaluated.

**Results:** Among 49 patients, 11 patients (22%) presented with systemic vasculitis. Organ involvement was diverse and ranged from central nervous system to cutaneous manifestations. The remaining 38 patients were diagnosed as cPAN and further classified as mild cPAN (16 patients) or severe cPAN (22 patients: ulcer type, 9; neuritis type, 9; both, 4). There was one case of cPAN which resulted in renal damage. The clinical characteristics of mild cPAN included female predominance (87.5%) and younger age (median, 32), and patients tend to have normal inflammatory markers and laboratory findings. Those of systemic PAN included older age (median, 69), higher levels of inflammatory markers, lower levels of serum proteins, and organ damage. Nonspecific elevation of autoantibodies is frequently observed. Particularly, 54.5% of systemic type possessed MPO-ANCA though the titers were significantly lower than those of microscopic polyangiitis, suggesting non-specific elevation of MPO-ANCA in Japanese population. Severe cPAN manifested with intermediate phenotypes, and inflammatory activities were significantly correlated with age ( $p < 0.001$ ). Although the mortality rates were indistinguishable, the relapse rates of cPAN (ulcer type) were significantly higher than those of other types (88.9%, Figure). The mean doses of prednisolone (PSL) used to treat mild cPAN, severe cPAN, and systemic type were 18.5, 38.6, and 39.1 mg/day, respectively. Immunosuppressants were used in 20% of mild cPAN, 90.9% of severe cPAN, and 72.7% of systemic PAN patients. Most patients with cPAN (ulcer type) were initially treated by corticosteroid monotherapy, and immunosuppressive agents were added when they relapsed. Considering its high relapse rate, it might be reasonable to select combination therapy with cyclophosphamide for severe cPAN (ulcer type) as is proposed in nonsystemic vasculitic neuropathy.

Abstract AB0707 – Figure 1

**Conclusions:** The clinical characteristics of mild cPAN, severe cPAN (ulcer type), severe cPAN (neuritis type), and systemic PAN were distinct from each other. Particularly, patients with severe cPAN (ulcer type) had higher relapse rates, thus indicating the importance of combination therapy in this patient cohort.

**AB0708** **THE USE OF TEMPORAL ARTERY BIOPSIES (TAB) IN DIAGNOSIS AND MANAGEMENT OF PATIENTS WITH GIANT CELL ARTERITIS (GCA)- A RE-AUDIT IN RHEUMATOLOGY IN THE BELFAST HEALTH AND SOCIAL CARE TRUST (BHSC)**

U.A. Lavery, E. Banks, M. McHenry. *NHS, Belfast, Ireland*

**Background:** Patients should meet at least 3/5 American College of Rheumatology (ACR) criteria for a diagnosis of GCA. British Society of Rheumatology (BSR) guidelines on the management of GCA from 2010 emphasise the importance of early referral for specialist management. TAB should be considered depending on local experience and availability of other imaging modalities. Biopsy should be at least 10 mm in length and ideally done within 14 days of presentation. TABs performed in BHSC over a three-year period were audited in 2014.

**Objectives:** We re-audited the Rheumatology TAB referrals in the BHSC from August 2016 to August 2017 to assess how biopsies influenced the management of patients with GCA in comparison to the previous audit.

**Methods:** Histopathology based LabCentre search detected 36 TABs within the given period. A retrospective audit was carried out with the use of Electronic Care Record and 16 of these patients were Rheumatology based TAB referrals. A proforma was used to aid data collection.

**Results:** Female:Male ratio was 2.2:1, age range was 61–91 with a mean age of 76. 94% of patients presented with headache. Of those patients referred for biopsy, 100% already fulfilled 2 of ACR criteria, compared with only 80% in previous audit. TAB was positive in 25%. In those with a positive biopsy, 75% had an ESR >50. All patients were on steroid treatment at the time of biopsy. In 42% of patients with a negative biopsy, steroids were rapidly reduced. 100% of patients with a positive biopsy continued on steroids. 68% of biopsies were greater than 10 mm compared with 38% in the previous audit. 68% of patients had a TAB within 14 days of commencing on steroids, with 31% having biopsy within 7 days of commencing steroids. 63% of patients developed steroid related complications. In 56% of patients the biopsy result changed patient management.

**Conclusions:** The percentage of appropriate referrals for biopsy (based on the ACR criteria) has improved compared with the previous audit. The length of biopsy improved. 32% of patients were waiting longer than 2 weeks for biopsy but some of these patients presented late to the rheumatology team. Biopsy results changed management in 56% of patients. Areas for consideration include improvement in time to biopsy and biopsy length.

**AB0709** **SWITCHING FROM ORIGINATOR INFILIXIMAB TO BIOSIMILAR INFILIXIMAB: EFFICACY AND SAFETY IN A COHORT OF PATIENTS WITH ESTABLISHED BEHÇET'S DISEASE**

V. Venerito<sup>1</sup>, G. Lopalco<sup>1</sup>, L. Cantarini<sup>2</sup>, C. Fabiani<sup>3</sup>, M. Nivunori<sup>1</sup>, F. Cacciapaglia<sup>1</sup>, M. Galeazzi<sup>2</sup>, G. Lapadula<sup>1</sup>, F. Iannone<sup>1</sup>. <sup>1</sup>Department of Emergency and Organ Transplantations, Rheumatology Unit, University of Bari "Aldo Moro", Bari; <sup>2</sup>Department of Medical Sciences, Surgery and Neurosciences, Rheumatology Unit, Policlinico "Le Scotte", University of Siena, Siena; <sup>3</sup>Department of Ophthalmology, Humanitas Clinical and Research Center, Rozzano, Italy

**Background:** Infliximab (IFX) has been proved to be effective in several organ involvement of Behçet's Disease (BD). A recent report<sup>1</sup> describing rapid loss of efficacy of biosimilar IFX after switching from originator IFX suggests the necessity to exercise caution regarding the automatic substitution of originator IFX with biosimilar IFX in patients achieving remission with originator IFX.

**Objectives:** The purpose of the present study was to describe our experience with biosimilar IFX CT-P13 in patients affected with BD, who were switched from originator IFX.

**Methods:** Retrieved data including demographic characteristics, clinical manifestations and previous treatments were collected. All patients met the ISG and/or ICBD classification criteria for Behçet's Disease. In order to evaluate disease activity, the BD Current Activity Form (BDCAF) has been evaluated before starting biosimilar, at three, six and nine months after switching to CT-P13. The occurrence of adverse events was also recorded. Wilcoxon matched-pairs signed-ranks test was carried out to evaluate differences between BDCAF distributions pre-switch and either at three, at six and at nine months after switching.

**Results:** Thirteen caucasian adult BD patients (mean age 39.77±7.46 years) with a mean disease duration of 12.54±4.21 years, underwent IFX treatment at licensed dosage for a period of 117.66±48.01 months. After 106.92±46.37 months of treatment with originator IFX, all of them were switched to CT-P13 biosimilar IFX. At 3 months after switching, none of them had discontinued CT-P13 biosimilar IFX treatment. No significant difference was noticed between BDCAF mean score assessed at switch and 3 months after switching ( $p=0.15$ ). At 6 months follow up, 2/13 patients (15.38%) discontinued CT-P13 biosimilar IFX treatment, both for recurrence of mucocutaneous involvement. One out of 2 patients who discontinued CT-P13 IFX had previously experienced a disease flare under originator IFX therapy, requiring a modification of ongoing therapy. BDCAF mean score assessed before and 6 months after switching were not significantly different ( $p=0.81$ ). Nine months after switching 2 out of the remaining 11 patients were lost at follow up. Once more, no difference was shown between BDCAF mean score assessed at switch and at 9 months follow up ( $p=0.85$ ). No adverse events occurred during the observed period.

Female n(%)	3 (23.08%)
Age at Onset (mean±SD)	27.15±10.02
Clinical Manifestations n(%)	
Uveitis	10 (76.92)
Oral Aphthosis	9 (69.23)
Genital Aphthosis	7 (53.85)
Cutaneous Involvement	7 (53.85)
Concomitant Treatment n(%)*	
Colchicine	5 (38.46)
csDMARDs	4 (30.77)
Corticosteroids	1 (7.69)

Abstract AB0709 – Figure 1

**Conclusions:** Despite the short follow up period, these data suggest that switching BD patients from originator IFX to CT-P13 seems to be effective and safe; only a small percentage of patients experienced relapse of symptoms, whereas a significant modification of BDCAF pre-switch and post-switch was not noticed. Although encouraging, these results need to be confirmed over a longer follow up period and on larger cohorts of patients.

#### AB0710 INTERFERON A2A FOR THE TREATMENT OF REFRACTORY BEHÇET'S DISEASE UVEITIS

W. Zheng<sup>1</sup>, J. Shi<sup>1</sup>, C. Zhao<sup>2</sup>, J. Liu<sup>1</sup>, J. Zhou<sup>1</sup>, F. Gao<sup>2</sup>, M. Zhang<sup>2</sup>.

<sup>1</sup>Rheumatology and Clinical Immunology, <sup>2</sup>Ophthalmology, Peking Union Medical College Hospital, BEIJING, China

**Background:** Behçet's Disease uveitis(BDU) mostly involved bilateral panuveitis and retinal vasculitis, which are very challenging to treat. Interferon alfa-2a (IFN $\alpha$  2a) has been shown to have comparable effectiveness and tolerance profiles for BDU as tumour necrosis factor (TNF) inhibitors in a number of studies with a much lower cost. IFN $\alpha$ -2a treatment combined with corticosteroids without immunosuppressants was common in previous studies. We herein report a cohort of highly refractory BDU patients who experienced recurrence despite aggressive treatment with multiple immunosuppressants at their therapeutic doses.

**Objectives:** To investigate the efficacy and safety of IFN $\alpha$ 2a treatment in combination with corticosteroids and immunosuppressants in patients with refractory BDU.

**Methods:** Clinical records of refractory BDU patients who underwent IFN $\alpha$ 2a treatment in our centre between 2015 and 2017 were retrospectively reviewed. IFN $\alpha$ 2a was initially given 3.0 million IU (MIU) subcutaneously daily for 4 weeks, on the basis of conventional corticosteroid and immunosuppressive therapy. The dosage was gradually tapered down to 3.0 MIU three times or even once per week for maintenance. Primary outcome measure was success rate and changes in ocular relapse rates before and after initiation of IFN- $\alpha$ 2a treatment. Disease activity, corticosteroid- and immunosuppressive agent-sparing effects and potential side effects were considered to be secondary outcomes.

**Results:** A total of 26 patients (23 males and 3 females) were included, with a median disease course of 41 months (range 5–168) before IFN $\alpha$  2a treatment. No major organ involvement except for ocular inflammation was noted. Concomitant medical conditions include chronic hepatitis B virus infection in 2 patients, pulmonary tuberculosis in 1 patient who was treated with antitubercular agents in the meanwhile. Prior to IFN $\alpha$ 2a therapy, the median minimum dosage of corticosteroids was 20 (range 15–45) mg/day prednisone or equivalent, and 17 patients (65.4%) were treated with at least two immunosuppressive agents. Four received short terms of TNF $\alpha$  inhibitor therapy but stopped due to economic burden. Severe side effects related to previous therapies including femoral head necrosis and secondary hypertension were observed in some patients. Treatment success of IFN $\alpha$ 2a was achieved in the majority of the patients (24/26, 92.3%). During a mean follow-up of IFN $\alpha$ 2a therapy for 13.6±6.0 months, the median rate of uveitis relapse decreased notably from 8 per patient-year (range 2–12) to 0 per patient-year (range 0–6) ( $p=0.000008$ ). Oral corticosteroids were successfully decreased in 20 cases (76.9%) and completely discontinued in 2 patients (7.7%), with the median minimum dosage reduced from 20 mg/day (range 15–45) to 15 mg/day (range 0–50) ( $p=0.006221$ ). Moreover, immunosuppressive agents were cut down on types and dosage in 15 (57.7%) and 23 patients (88.5%), respectively, and were totally quitted in 5 cases (19.2%). Slight elevated liver and renal function parameters were detected in one and two patients, respectively. No other severe adverse events occurred. The serum autoantibodies were all negative during treatment with IFN $\alpha$ 2a.

**Conclusions:** IFN $\alpha$ 2a, in combination with corticosteroids and immunosuppressants, was effective and relatively safe in refractory BDU, with a potential steroid- and immunosuppressive agent-sparing effect.

#### AB0711 TOCILIZUMAB FOR SEVERE/REFRACTORY VASCULAR BEHÇET'S DISEASE

W. Zheng<sup>1</sup>, Y. Ding<sup>2</sup>, J. Liu<sup>1</sup>, J. Shi<sup>1</sup>, C. Li<sup>1</sup>, Y. Zhao<sup>1</sup>, X. Zeng<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Peking Union Medical College Hospital, BEIJING;

<sup>2</sup>Rheumatology, The First Affiliated Hospital of Zhengzhou University, Zheng Zhou, China

**Background:** Vascular Behçet's Disease (BD) is a common yet severe complication of BD. Despite aggressive conventional therapy, vascular BD remains as one of the leading causes of morbidity of BD. Tocilizumab (TCZ), an IL-6 receptor antagonist, is an emerging biological agents for neurologic BD or ocular BD, however, the efficacy of TCZ for vascular BD is unknown.

**Objectives:** To elucidate the efficacy and safety of TCZ for severe/refractory vascular BD.

**Methods:** We retrospectively analysed the clinical data of vascular BD patients treated with TCZ in our centre between 2014 and 2017.

**Results:** Seven patients (6 males and 1 female) were enrolled, with a mean age and median course of 32.9±9.1 years old and 72 months (range 54 to 138), respectively. Multiple arterial lesions were documented in all patients, including arterial aneurysm (n=5), stenosis (n=4), occlusion (n=3), and multiple venous thrombosis were documented in two patients. Recurrent aneurysms together with

graft occlusion or endoleak occurred in two out of 3 aneurysms patients who underwent endovascular stent placements. As for concomitant medical conditions, one patient complicated with hepatitis B infection, and three complicated with latent tuberculosis infection and received anti-tuberculosis prophylaxis. Prior to TCZ therapy, all patients experienced disease progression despite high-dose glucocorticosteroid in combination with multiple immunosuppressants. All patients received TCZ, 8 mg/kg iv every 4 weeks for a median of 7 (range 3 to 15) doses, and baseline medium-to-low dose corticosteroid and immunosuppressants. After a median follow-up of 16 months (range 4 to 29), all patients achieved both clinical and serological improvements. Radiologic improvement of artery stenosis was demonstrated in one patient. The condition of one patient with endoleak after the stent placement remained stable without surgical intervention. No newly-onset arterial lesions or venous thrombosis were observed. The median ESR (18 vs 7 mm/h,  $p < 0.05$ ) and hsCRP level (30.6 vs 2.0 mg/L,  $p < 0.05$ ) were also significantly decreased. Furthermore, corticosteroids dose was tapered from 27.1  $\pm$  6.3 mg to 8.9  $\pm$  1.2 mg ( $p < 0.05$ ), and immunosuppressants were tapered in number and dosage in 3 (42.9%) and 3 patients (42.9%), respectively. No serious adverse event or TB reactivation was observed.

**Conclusions:** TCZ, in combination with corticosteroids and immunosuppressants, was effective and well tolerated in severe/refractory vascular BD, with a favourable steroid- and immunosuppressant-sparing effect.

**Disclosure of Interest:** None declared

AB0712

#### ELIGIBILITY OF PATIENTS WITH GIANT CELL ARTERITIS FOR ENTRY INTO A PROSPECTIVE RANDOMISED CONTROLLED TRIAL: A SINGLE-CENTRE EXPERIENCE

W.A. Schmidt<sup>1</sup>, K. Hofheinz<sup>1</sup>, S. Burger<sup>1</sup>, V.S. Schäfer<sup>1,2</sup>, A. Juche<sup>1</sup>. <sup>1</sup>Medical Center for Rheumatology Berlin-Buch, IMMANUEL KRANKENHAUS BERLIN, Berlin; <sup>2</sup>Medizinische Klinik III, University of Bonn, Bonn, Germany

**Background:** The interest in pharmaceutical trials in giant cell arteritis (GCA) is increasing. Trial recruitment may be more challenging in GCA than in other rheumatic diseases because of a higher proportion of elderly patients who are additionally faced with a new diagnosis when being considered for trial participation.

**Objectives:** To analyse the eligibility of newly diagnosed and flaring GCA patients in one centre for randomization in the SIRRESTA trial (ClinicalTrials.gov Identifier, NCT02531633; sirukumab versus placebo), to list reasons for non-randomization, and to compare eligible with non-eligible patients.

**Methods:** All patients with newly diagnosed or relapsing GCA considered for trial participation between August 2016 until trial termination in October 2017 were included. The trial was prematurely terminated by the sponsor based on the decision to discontinue development of sirukumab in autoimmune diseases. Analysis of variance, two-sided Fisher's exact and Pearson's chi-squared tests were applied for calculating statistical significance.

**Abstract AB0712 – Table 1.** Comparison of eligible and non-eligible GCA patients for trial participation

	Total	Eligible for trial	Not eligible for trial	Significance
N	95	12 (13%)	83 (87%)	
Age (SD)	71.1 (8.3) years	65.3 (8.0) years	71.8 (8.5) years	0.008*
Females	61%	75%	59%	0.356
New diagnosis	81%	58%	84%	0.047*
Cranial GCA only	46%	58%	45%	0.537
Cranial and extracranial GCA	35%	25%	36%	0.533
Extracranial GCA only	19%	17%	19%	1.0
Ischaemic events	14%	0%	16%	0.208
Headache	59%	58%	59%	1.0
Jaw claudication	34%	33%	34%	1.0
PMR	62%	83%	59%	0.125
ESR (SD)	71 (33) mm/h	85 (31) mm/h	69 (34) mm/h	0.125
CRP (SD)	90 (69) mg/l	121 (83) mg/l	85 (65) mg/l	0.095

\* $p < 0.05$ , significant; CRP, C-reactive protein; ESR, erythrocyte sedimentation rate; GCA, giant cell arteritis; PMR, polymyalgia rheumatica; SD, standard deviation

**Results:** Ninety-five patients were pre-screened. Fifteen of these patients were screened and only 12 of the 95 (13%) pre-screened GCA patients were eligible for randomization based on inclusion and exclusion criteria. The other 83 patients were not eligible for one or more of the following reasons: Concomitant diseases (42%) including second autoimmune disease (11%), malignancy (6%), history of diverticulitis (5%), hepatopathy (2%), renal insufficiency (1%) frailty (6%) and dementia (2%), ischaemic disease (2%); 1 myocardial infarction and 1 severe tongue necrosis), abnormal or inconclusive tests for tuberculosis (5%) and

hepatitis (1%); failure to meet inclusion criteria (41%), including symptoms (12%), histology/imaging (1%), exceedance of maximum glucocorticoid dose (7%), too low ESR and CRP (10%), too long treatment duration (11%); declined consent (29%), before (11%) and after receiving the consent form (18%); too long distance to study centre (5%).

Patients eligible for the trial were younger. They had no ischaemic complications (see table 1). A higher proportion of relapsing GCA patients were included. This subgroup of a larger trial represents only data from one centre. It may not be representative for the findings in other centres or the whole study.

**Conclusions:** Many newly diagnosed or relapsing GCA patients were not eligible for a trial due to concomitant diseases, failing inclusion criteria or declined consent. Eligible patients were younger; and more had relapsing disease.

#### INTERFERON-ALPHA FOR THE MANAGEMENT OF LOWER EXTREMITY DEEP VEIN THROMBOSIS IN BEHCET'S SYNDROME: A CASE SERIES

Y. Ozguler, G. Hatemi, F. Cetinkaya, K. Tascilar, S. Ugurlu, E. Seyahi, H. Yazici, M. Melikoglu. Istanbul University Cerrahpasa Medical Faculty, ISTANBUL, Turkey

**Background:** Lower extremity deep vein thrombosis (LEDVT) is a disabling complication of Behçet's syndrome (BS). Relapses are frequent and cause permanent disability due to post-thrombotic syndrome.<sup>1</sup> The management of LEDVT in Behçet's syndrome (BS) constitutes mainly of azathioprine (AZA) and corticosteroids (CS) as first-line agents.<sup>2</sup> Interferon- $\alpha$  (IFN) has been used with good results in the management of eye involvement of BS. However data regarding its efficacy for vascular involvement has been scarce.<sup>3</sup>

**Objectives:** We aimed to evaluate the efficacy and safety of IFN for LEDVT in BS.

**Methods:** All BS pts who had a first episode of acute LEDVT since March 2010 are being prospectively followed with a standard protocol in our dedicated BS centre. Acute LEDVT is confirmed by Doppler ultrasonography (DUS) at initial diagnosis and serial DUS assessment is performed and also repeated in case of clinical suspicion of relapse. Our standard treatment strategy consists of AZA and CSs as first-line treatment in pts with LEDVT. IFN has been used in pts who were refractory or intolerant to this regimen, or who had co-existing eye involvement. Our endpoints for assessing efficacy of IFN have been recanalisation of the index thrombus and prevention of relapses. Presence of recanalisation of thrombosed vein and extension of thrombosis have been assessed at each visit. Recanalisation has been assessed in the transverse plane and defined as the ratio of the vein area at maximum compressibility to the non-compressed vein area. Good recanalisation was defined as a ratio of at least 50%. Adverse events during IFN use were recorded.

**Results:** 33 pts with LEDVT (26 M/7 F) were prospectively followed for a mean of 40.7  $\pm$  13.4 mo. Among these IFN was started in 18/33. In 2 pts IFN was started at the first episode of LEDVT due to co-existing uveitis. Seven pts were treated with IFN due to LEDVT relapses under AZA. In the remaining 9 pts, the reasons for switching from AZA to IFN were adverse events with AZA (n=2), relapse of superficial thrombophlebitis (n=4), leg ulcers due to severe post-thrombotic syndrome (n=2) and eye involvement (n=1). Among 17 pts treated with IFN mainly for vascular involvement during a mean follow-up of 29  $\pm$  20 mo, 3 pts already had good recanalisation when starting IFN. In the remaining 14 pts, 13 (93%) had good recanalisation under IFN. Two pts (11%) experienced relapses. One of the 2 pts who had a relapse had had poor recanalisation despite IFN. In contrast, among the 29 pts treated with AZA, only 13 (45%) had good recanalisation and 13 (45%) pts experienced relapses. Nine of the 13 pts who had relapses under AZA had poor recanalisation. Overall we observed 23 LEDVT relapses in 15 pts. Relapse rates were 29%, 37% and 45% at 6, 12 and 24 months respectively. The only adverse event with interferon-alpha causing drug withdrawal was thyroiditis in 1 patient.

**Conclusions:** Relapse rate for LEDVT in BS is high despite AZA treatment. IFN seems to be a promising agent for preventing LEDVT relapses and achieving good recanalisation, an important predictor of relapse. The small number of pts and the lack of a parallel control group are the limitations of this prospective study.

### MONOCYTES TO LYMPHOCYTES RATIO IS CORRELATED WITH DISEASE ACTIVITY IN BEHÇET'S DISEASE

Y. Huang, S. Zheng, T. Li, F. Feng, W. Deng, Q. Huang, Z. Huang, Z. Huang, X. Pan. *Department of Rheumatology and Immunology, Guangdong Second Provincial General Hospital, Guangzhou, China*

**Background:** Behçet's disease (BD) is a complex, inflammatory multisystem disorder. Since the lack of universally recognised pathognomonic laboratory test, the diagnosis relies heavily on clinical findings. Currently, the Monocytes to lymphocytes ratio (MLR), Neutrophils to Lymphocytes ratio (NLR), Platelets to Lymphocytes ratio (PLR) and Red blood cell Distribution Width(RDW) have been demonstrated as a assessment of disease severity in many rheumatism diseases. Nevertheless, to our knowledge, only a few studies have investigated NLR, PLR, RDW in patients with BD.

**Objectives:** The aim of this study is to determine MLR, NLR, PLR and RDW in BD and to investigate their relationships with disease activity.

**Methods:** A total of 37 patients with BD fulfilling the criteria of the International Study Group for BD and 37 age and gender-matched healthy controls were enrolled in the study retrospectively. MLR, NLR, PLR, RDW, C-reactive protein (CRP) level and Erythrocyte Sedimentation Rate(ESR) level were evaluated. The correlation between the variables were tested with Pearson correlation. Area Under Curve(AUC) value, sensitivity, specificity, and the optimal cut-off values were determined using Receiver Operating characteristic Curves (ROC). According to the optimal cut off value, BD patients were divided into low-value group (<the optimal cut off value) and high value group ( $\geq$ the optimal cut off value). The patient's clinical characteristics between the two group were compared.

**Results:** The MLR, NLR, PLR and RDW were (0.37 $\pm$ 0.24), (2.91 $\pm$ 1.95), (155.09 $\pm$ 55.08) and (13.83 $\pm$ 1.77) in BD group, while (0.18 $\pm$ 0.04), (1.45 $\pm$ 0.46), (115.66 $\pm$ 28.01) and (13.07 $\pm$ 1.19) in control group, the difference was significant (P all<0.05). MLR, NLR and PLR were all correlated positively with ESR(r=0.363, P<0.05; r=0.611, P<0.05; r=0.496, P<0.05) and CRP(r=0.713, P<0.05; r=0.785, P<0.05; r=0.394, P<0.05). RDW was not correlated with ESR and CRP. ROC curve results showed that the AUC of MLR, NLR, PLR and RDW for BD were 0.841(CI95%: 0.748–0.935), 0.815(CI95%: 0.712–0.918), 0.720(CI95%: 0.699–0.840), 0.635(CI95%: 0.505–0.765), MLR yielded a highest AUC. In addition, the optimal cut off value of MLR for BD was 0.23, with the specificity of 73.0% and sensitivity of 83.8%. In 37 BD patients, 14 belong to low MLR group, 23 belong to high MLR value group. The comparison results show that high MLR value group have higher CRP level and higher incidence of genital ulceration(P<0.05).

Abstract AB0714 – Figure 1

**Conclusions:** MLR was elevated in BD patients as compared to control group, having a close relationship with disease activity.

AB0715

### GIANT CELL ARTERITIS IS COMORBID WITH TUBERCULOSIS

Y. Zhang<sup>1</sup>, D. Wang<sup>2</sup>, Y. Yin<sup>1</sup>, X. Zeng<sup>1</sup>. <sup>1</sup>General Internal Medicine, Peking Union Medical College Hospital, Beijing; <sup>2</sup>Neurology, Nanfang Medical College hospital, Guangzhou, China

**Background:** Giant cell arteritis (GCA) is a medium- and large-vessel vasculitis with an onset age after 50 years, whereas Takayasu arteritis (TA) is a rare large-vessel vasculitis with an onset age younger than 40 years. The association between TA and tuberculosis (TB) was suggested. However, the association between GCA and TB was rarely reported.

**Objectives:** To understand the association between TA and TB

**Methods:** Clinical data between November 1998 and October 2017 at PUMCH, Beijing, China, were retrospectively reviewed. Ninety-one patients diagnosed with GCA were included in the study. Precise clinical data were collected and analysed.

**Results:** A total of 20 patients (22.0%) had a history of active tuberculosis and received anti-tuberculosis therapy. On comparing the clinical features of the patients with TB and those without TB, obvious weight loss (p=0.011), lower percentage of dyslipidemia (p=0.042), higher percentage of anti-phospholipid (p=0.010), and lower white blood cells (p=0.006) were noted in the TB group.

Abstract AB0715 – Table 1. Clinical features and comorbid diseases of the patients with TB and without TB

	GCA with TB n=20 (%)	GCA without TB n=71 (%)	P value
Age (year, diagnosis)	65.10 $\pm$ 8.39	65.38 $\pm$ 7.51	0.886
Scalp tenderness or pain	2 (10)	22 (31.0)	0.060
Tenderness and abnormal pulsation of temporal artery	6 (30)	13 (18.3)	0.256
Visual loss	8 (40)	25 (35.2)	0.694
Hearing loss	3 (15)	20 (28.2)	0.231
Jaw claudication	6 (30)	20 (28.2)	0.873
Arthralgia	11 (55)	36 (50.7)	0.734
GI symptoms	1 (5)	11 (15.5)	0.221
Weight loss	16 (80)	34 (47.9)	<b>0.011</b>

**Conclusions:** This study demonstrated that the percentage of TB history in patients with GCA was higher than that in the general population. The definite association between TB and GCA remains unknown. Hence, further studies are required to elucidate the mechanisms underlying TB in the pathogenesis of GCA. Clinicians should recognise the possibility of comorbid TB in patients with obvious weight loss and relatively lower white blood cell count.

## Scleroderma, myositis and related syndromes

### AB0716 AN AUTOPSY CASE OF SYSTEMIC SCLEROSIS WITH SEVERE INTESTINAL INVOLVEMENT AND LITERATURE REVIEW

A. Aoki<sup>1</sup>, H. Hirano<sup>2</sup>, H. Kobayashi<sup>1</sup>, T. Okubo<sup>1</sup>, Y. Umebayashi<sup>3</sup>, H. Oka<sup>1</sup>. <sup>1</sup>Dept. of Rheumatology; <sup>2</sup>Dept. of Pathology; <sup>3</sup>Dept. of Dermatology, Tokyo Medical University Hachioji Medical Center, Tokyo, Japan

**Background:** The gastrointestinal tract (GIT) is the second most common internal organ affected by systemic sclerosis (SSc). The rate of SSc patients who develop severe GIT symptoms is lower than 10%, although various degrees of chronic intestinal pseudo-obstruction (CIPO) may occur in as many as 40% of cases (1,2).

**Objectives:** To report an autopsy case of SSc with severe intestinal involvement and review the associated literature.

**Methods:** We will present the clinical features and autopsy findings of a SSc patient and literature concerning Japanese SSc autopsy cases associated with severe intestinal involvement, found *Igaku-chuo* and *Pub-med* on Internet.

**Results:** A 69-year-old Japanese woman was diagnosed with diffuse cutaneous SSc from skin sclerosis, Raynaud's phenomenon, and mild interstitial pneumonia in January 2013. The antinuclear antibody was positive (1:160, speckled pattern), but the specific antibodies, including the anti-RNP, topoisomerase I, and centromere antibodies, were negative. In August 2015, at the age of 71, she was hospitalised for vomiting and abdominal pain. Plain abdominal radiograph showed dilation of the small bowel with air-fluid levels. Abdominal CT revealed large dilation of the small bowel in the absence of any mechanical obstruction. These findings were consistent with CIPO. Her symptoms soon improved by decompression with a long intestinal tube. But she experienced frequent relapse of CIPO. During the third hospitalisation in May 2016, an abdominal CT showed pneumatosis cystoides intestinalis (PCI) and free air in the peritoneal cavity. Medical management failed to control the CIPO. Her general conditions had gradually worsened with weight loss of 10 kg in 3 years. Home parental nutrition was initiated in January 2017. On May 2017, she developed severe pneumonia after vomiting, and her condition gradually deteriorated. She finally succumbed to her illness and an autopsy was performed. The whole alimentary tract except for the duodenum showed a thinning of the lamina propria and atrophy of the smooth muscular layers. Intimal proliferation and narrowing of arterioles were also noted. There was non-specific interstitial pneumonitis in the both lower lobes and diffuse alveolar damage in the both of upper lobes of the lungs. Vasculopathy was also seen in the lungs and heart.

The cases in the literature are summarised in table 1. Vascular damage and/or smooth muscle atrophy were presented in all cases.

**Abstract AB0716 – Table 1.** Autopsy cases of systemic sclerosis associated with severe gastrointestinal symptoms in Japan

Case No.	Publication year	Age of death (yr) / Sex	Time from onset of 1 <sup>st</sup> to death		Cause of death	Comorbidity / Past history	GIT symptoms	Pathological findings of intestine

5	2002	58/F	3 yr 7mo	2 weeks	Pneumonia	Dermatomyositis, IP	CIPO, PCI	○	○	○
6	2007	71/F	6 mo	2 mo	Septic shock	Renal failure/gastric and lung cancer	CIPO	○		
7	this report	72/F	4 yr	1y 10mo	Pneumonia	IP / breast cancer	CIPO, PCI	○	○	○

M, male; F, female; yr, years; mo, months; GIT, gastrointestinal tract; IP, interstitial pneumonia; CIPO, chronic intestinal pseudo-obstruction; PCI, pneumatosis cystoides intestinalis;

1) Intimal proliferation and narrowing of the small arteries

**Conclusions:** Vasculopathy in SSc involves small vessels, and it precedes fibrosis.<sup>3</sup> The triggering event of vasculopathy is unknown, but the narrowing of intestinal arterioles causing hypoxia might be responsible for dysmotility of GIT.

### AB0717 RISK ASSOCIATION BETWEEN SCLERODERMA DISEASE CHARACTERISTICS, PERIODONTITIS AND TOOTH LOSS

G. Isola<sup>1</sup>, R. Williams<sup>2</sup>, A. Lo Gullo<sup>3</sup>, M. Matarese<sup>4</sup>, L. Ramaglia<sup>5</sup>, G. Matarese<sup>6</sup>. <sup>1</sup>Department of Biomedical Sciences and of Morphological and Functional Images, Policlinico G Martino, Messina, Italy; <sup>2</sup>Department of Periodontology, UNC School of Dentistry, Chapel Hill, USA; <sup>3</sup>Clinical and Experimental Medicine; <sup>4</sup>University of Messina, Messina; <sup>5</sup>Department of Neurosciences, Reproductive and Odontostomatological Sciences, University of Naples "Federico II, Napoli; <sup>6</sup>Department of Biomedical Sciences and of Morphological and Functional Images, University of Messina, Messina, Italy

**Background:** Systemic Sclerosis (SSc) is a multi-system disorder that can have significant adverse effects upon the health of the mouth.

**Objectives:** The aim of this study was to investigate the associations between the disease characteristics of SSc, periodontal disease (PD) and tooth loss.

**Methods:** Fifty-four patients affected by SSc and 55 non-diseased controls were matched for age and gender. SSc was characterised in subtypes and with the mean duration of disease and the Modified Rodnan Skin Score [mRSS]. Patients were surveyed and examined through the evaluation of the periodontal parameters and the number of teeth.

**Results:** A logistic regression analysis showed that patients with SSc presented a higher number of missing teeth (p=0.001) and a significant median increased odds 2.95 (95% CI 1.26 to 6.84) of PD (defined as clinical attachment loss, CAL) compared to non-diseased controls (6.83, 95% CI 1.94 to 24.36). Moreover, the less values of PD was correlated with mRSS in the total SSc group and with the mean duration of disease in patients with limited SSc (p=0.007), even after adjusting this correlation with the presence of the major organs involvement.

**Conclusions:** This study showed that patients with SSc presented an increased odds of PD and tooth loss compared to non-diseased controls. In SSc patients, the magnitude of PD was strongly associated with the mRSS and with the mean duration of the disease. The clinicians should be aware of the potential systemic health problems related to PD.

### AB0718 AUTOLOGOUS HEMATOPOIETIC STEM-CELL TRANSPLANTATION IN SEVERE AND REFRACTORY DIFFUSED SYSTEMIC SCLEROSIS. LONG-TERM STUDY IN A SINGLE REFERENCE CENTRE

A. Ruiz Roman<sup>1</sup>, B. Atienza Mateo<sup>2</sup>, V. Calvo del Rio<sup>2</sup>, M.A. Gonzalez-Gay Mantecón<sup>2</sup>, R. Blanco Alonso<sup>2</sup>. <sup>1</sup>Hospital Universitario Virgen del Rocío, Sevilla; <sup>2</sup>Hospital Marqués de Valdecilla, Santander, Spain

**Background:** Pharmacological therapy does not reverse the natural course of systemic sclerosis (SS). Autologous hematopoietic stem-cell transplantation (AH SCT) has been used in refractory autoimmune diseases, including SS. The autologous hematopoietic stem-cell transplantation is based on the ablation of the immunoreactive system with high doses of chemotherapy and a subsequent regeneration of the immune system.

**Objectives:** Study of the efficacy of autologous hematopoietic stem-cell transplantation in a cohort of patients with SS from a referral centre.

**Methods:** Descriptive study of patients with SS (ACR/EULAR<sup>2013</sup> criteria) treated with autologous hematopoietic stem-cell transplantation in a single reference centre between 2002 and 2017. These clinical variables were reviewed

(Raynaud's phenomenon, pulmonary interstitial involvement, digital ulcers, digestive alterations, presence of sclerodermic renal crisis) and activity index variables (modified Rodnan score, HAQ-DI, SHAQ-VAS).

**Results:** Four patients were included (75% women). The median age at the time of the AHSCT was 36.5 years (range 27–51). In all cases, the initial diagnosis was diffuse cutaneous ES, refractory to corticosteroids and at least one DMARD. Prior to autologous hematopoietic stem-cells transplantation, the clinical manifestations presented were a) severe Raynaud's phenomenon (100%) with significant joint and cutaneous involvement; b) digital ulcers (50%); c) interstitial lung disease (50%) and d) sclerodermal renal crisis (25%). In 3 of the cases (75%) the antitopoisomerase antibodies were positive. The conditioning treatment for the autologous hematopoietic stem-cells transplantation was cyclophosphamide at high doses (50 mg/kg x4 days) and anti-thymocyte globulin. In 3 patients (75%) there were slight post-transplant complications (febrile neutropenia, diarrhoea) after a median follow-up of 6.5 years (range 1–15).

The response to AHSCT is summarised in table 1. All patients showed values <1 in the Health Assessment Questionnaire on the Disability Index (HAQ-DI), in 75% with a modified Rodnan skin score (mRSS) lower than 7.

Abstract AB0718 – Table 1

PATIENT	FOLLOW-UP	MODIFIED RODNAN SKIN SCORE PRE-TRASPLANT	MODIFIED RODNAN SKIN SCORE POST TRASPLANT	HAQ-DI POST TRASPLANT	SHAQ-VAS POST TRASPLANT
Patient 1	15 years	Unknown	1/51	0,25	4/13
Patient 2	8 years	Unknown	7/51	0	3/13
Patient 3	5 years	28/51	6/51	0	0/13
Patient 4	1 year	33/51	20/51	0,50	7/13

**Conclusions:** Autologous hematopoietic stem-cells transplantation can be a therapeutic option in refractory and severe SS. These hopeful data must be ratified in larger studies.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.7007

#### AB0719 CLOSE TEMPORAL ASSOCIATION BETWEEN SILICONE COSMETIC SURGERY AND SYSTEMIC SCLEROSIS ONSET

A. Sulli, S. Paolino, E. Alessandri, B. Ruaro, M. Pendolino, M. Cutolo, C. Pizzorni. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genova, Italy*

**Background:** The pathogenesis of systemic sclerosis (SSc) still remains unclear, however it is increasingly thought to result from interactions between environmental factors and epigenetic features leading to the onset and progression of SSc in genetically susceptible patients.<sup>1</sup> Case reports of women with silicone breast implants who developed SSc have been published, but several case-control series and prospective studies in connective tissue diseases (including SSc) failed to find an increased risk of SSc associated with silicone cosmetic surgery.<sup>2</sup> However, several biases may be recognised in these studies, i.e. heterogeneous cohorts of enrolled patients not selective for SSc, non homogeneous either disease duration or disease stage at study entry. For these reasons the possible effect of silicone implants as immune adjuvants is not clear.<sup>3</sup>

**Objectives:** Retrospective study to find out patients who developed SSc after cosmetic surgery.

**Methods:** The clinical files of 110 female patients with systemic sclerosis were retrospectively evaluated. Among these, four patients showing a history of silicone cosmetic surgery (3.6%) were identified, and clinical data collected.

**Results:** The clinical data of the four patients are below reported. 1. LS 28 year old female who underwent cosmetic breast prosthesis: two years later she complained of Raynaud's phenomenon (RP), and one more year later aggressive diffuse cutaneous SSc, along with anticentromere antibodies (ACA) positivity. 2. PJ 38 year old female who underwent cosmetic breast prosthesis: one year later she experienced RP and one more year later aggressive diffuse cutaneous SSc; antinuclear antibodies were positive with a speckled pattern, but specific SSc-related autoantibodies negative. 3. BS 33 year old female who underwent cosmetic breast prosthesis: two years later she complained of RP and one more year later limited cutaneous SSc with ACA positivity; SSc clinical condition partially improved and its progression stopped after breast prosthesis removal. 4. CM 58 year old female who underwent cosmetic lip silicone application: one year later she complained simultaneous onset of RP and aggressive diffuse cutaneous SSc with anti-Topoisomerase positivity; she died during follow-up.

**Conclusions:** This study reports a prevalence of 3.6% of silicone cosmetic surgery before SSc onset. The close temporal association between silicone implant

and disease development suggests a possible role of silicone in SSc pathogenesis. Specifically addressed clinical studies or big-data studies need to rule out this matter.

#### AB0720 SYSTEMIC SCLEROSIS AND CANCER DEVELOPMENT. A SINGLE-CENTRE EXPERIENCE

E. Pelechas, E. Kaltsonoudis, P.V. Voulgari, A.A. Drosos. *Rheumatology Clinic, Department Of Internal Medicine, MEDICAL SCHOOL, UNIVERSITY OF IOANNINA, Ioannina, Greece*

**Background:** Systemic Sclerosis (SSc) is an autoimmune connective tissue disease with multisystem involvement, and sometimes devastating results. In bibliography there are reports that scleroderma patients present a higher incidence of risk for cancer when compared with the general population. However, different estimates have been reported.

**Objectives:** The purpose of the present study was to evaluate the frequency of cancer development (CD) in a cohort of patients with SSc.

**Methods:** Patients that fulfilled the 2013 American College of Rheumatology/European League Against Rheumatism criteria for SSc and were followed up since 1999, were included. Date of disease onset, disease duration, autoantibodies, age, pulmonary hypertension, comorbidities and the type of CD have all been taken into account, during the period 1991–2016.

**Results:** Seventy-nine SSc patients have been included. 46 with limited (lcSSc) and 33 with diffuse cutaneous Systemic Sclerosis (dcSSc). Six of them, (7.6%) developed different types of cancer. Most of them were adenocarcinomas. More specifically, 2 developed pulmonary adenocarcinoma (1 with lcSSc and 1 with dcSSc), 1 follicular carcinoma of the thyroid gland (lcSSc), 1 colorectal adenocarcinoma (lcSSc), 1 B-cell lymphoma (MALT lymphoma), and 1 prostate adenocarcinoma (dcSSc). Five out of six were female patients. Mean age at the time of cancer diagnosis was 66.8-years-old, while SSc has been diagnosed at the mean age of 49.4 years. Mean time of developing any type of cancer was 15.8 years after SSc diagnosis. The diagnosis of cancer was done the last 20 months. All patients were non-smokers, had gastro-oesophageal reflux disease and pulmonary fibrosis, while 4/6 had also pulmonary hypertension and were under treatment with phosphodiesterase 5 inhibitors and bosentan. Scleroderma patients with CD have been referred to the corresponding oncology clinic for further treatment.

**Conclusions:** The present study on SSc and CDE provides data showing a potential association between the two entities. We found a high frequency of cancer development in patients with SSc (7.6%). Thus, a careful monitoring and screening is required when physicians follow-up scleroderma patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3396

#### AB0721 TRANSFER OF SYSTEMIC SCLEROSIS AFTER ALLOGENEIC BONE MARROW TRANSPLANTATION

A. Silva Riveiro, J.C. Nieto González, J. Martínez Barrio, A. López-Cerón Cofiño, L. A. Torrens Cid, C. Soletto Kharkovskaya, B. Serrano Benavente, R.D. González Benítez, C.M. González Fernández, F.J. López-Longo, I. Monteagudo Sáez. *Rheumatology, HOSPITAL GENERAL UNIVERSITARIO GREGORIO MARAÑÓN, MADRID, Spain*

**Background:** It is accepted that donor-derived immunity is transferred with allogeneic bone marrow transplantation (BMT)<sup>1</sup>.

**Objectives:** To show evidence of the transfer of systemic sclerosis by allogeneic BMT.

**Methods:** In this report we describe a patient with T acute lymphoblastic leukaemia who underwent BMT and developed systemic sclerosis.

**Results:** 34-year-old man in complete remission from a T acute lymphoblastic leukaemia treated with allogeneic BMT from his mother in February of 2012.

First seen in November 2017 for digital ulcers that appeared one year before.

He presented two necrotic ulcers: one on the second finger of the left hand and other on the third finger of the right hand (IMAGE 1). He was admitted to receive intravenous prostaglandins and complete the study.

After the BMT he developed Raynaud's phenomenon and in the examination he only presented facial and corporal telangiectasia, attributed before to chronic graft versus host disease (cGVHD).

The analysis showed ANA 1/640 centromere pattern, anticentromere antibodies, rheumatoid factor (RF) (652 UI/mL) and C3 of 86.4 mg/dL. Previously to the BMT he had negative ANA, but we do not know the rest of the previous autoimmunity. On the videocapillaroscopy we observe an active scleroderma pattern (IMAGE 2–3).

He was diagnosed with systemic sclerosis based on Raynaud’s phenomenon, digital ulcers, anticentromere antibodies and abnormal nailfold capillaries.

He had not familiar background of connective tissue diseases, but his mother presented Raynaud’s phenomenon since she was thirty. So we studied her.

She presented facial telangiectasia, puffy fingers and fingertip pitting scars and the same autoantibodies: ANA 1/320 centromere pattern, anticentromere antibodies, RF (159 UI/mL) and consumption of C3 (74.3 mg/dL) and C4 (7.6). We do not have previous autoimmune studies of her. On the videocapillaroscopy we observed a late scleroderma pattern (IMAGE 4–5).

She was also diagnosed with systemic sclerosis, based on Raynaud’s phenomenon, puffy fingers, fingertip pitting scars and facial telangiectasia, anticentromere antibodies and abnormal nailfold capillaries.

**Conclusions:** Experimental animal studies and human clinical reports have described the transfer of immune-mediated diseases from affected donors to unaffected recipients, because of that the importance of screening these diseases in the donor before a BMT<sup>2</sup>.

To our knowledge, this will be the first described case of transmission of systemic sclerosis by this mechanism. However, other explanations should also be taken into consideration. This include recipient’s own persistent intrathymic lymphocyte population that may produce autoantibodies and autoimmunity in the context of cGVHD. However, this last hypothesis is not supported since there is a familiar background and presence of anticentromere antibodies.

**AB0722 CAPILLAROSCOPY AND PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW**

A. Vanhaecke<sup>1,2</sup>, V. Smith<sup>1,2</sup>, K. Melsens<sup>1,2</sup>, S. Paolino<sup>3</sup>, Y. Piette<sup>2</sup>, A. Sulli<sup>3</sup>, A. C. Trombetta<sup>3</sup>, F. De Keyser<sup>1,2</sup>, E. Vandecasteele<sup>4</sup>, M. Cutolo<sup>3</sup>, on behalf of the EULAR study group on microcirculation in Rheumatic diseases. <sup>1</sup>Department of Internal Medicine, Ghent University; <sup>2</sup>Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; <sup>3</sup>Research Laboratory And Academic Division Of Clinical Rheumatology, Department Of Internal Medicine, IRCCS San Martino Aou, University Of Genoa, Genoa, Italy; <sup>4</sup>Department of Cardiology, Ghent University Hospital, Ghent, Belgium

**Background:** At this very moment, no systematic review evaluating the role of nailfold videocapillaroscopy (NVC), with standardised definitions, in pulmonary arterial hypertension (PAH) has been published.

**Objectives:** To systematically identify and review all available literature evaluating the role of capillaroscopy in PAH in SSc, according to the definitions of the EULAR study group on microcirculation in Rheumatic diseases.

**Methods:** A systematic literature search was performed in Pubmed, EMBASE and Web of Science. All retrieved articles were screened on title, abstract and full-text level. Reference lists and google scholar were additionally searched. Original research papers that documented an association between NVC and PAH (confirmed on right heart catheterization [RHC]) in SSc were included. Subsequently, NVC parameters were subdivided in quantitative (density, dimension, morphology and haemorrhages), semi-quantitative (NVC score) and qualitative assessment (presence of scleroderma pattern, severity of scleroderma pattern and worsening of scleroderma pattern) according to the definitions of the EULAR study group on microcirculation in Rheumatic diseases.

**Results:** The systematic search identified 215 unique search results, of which 171 references were withheld after title screening. Abstract screening resulted in 51 references, only 19 were eligible for full-text review. Finally, 9 references were included in the final analysis after full-text screening (n=7) and bibliographic and google scholar search (n=2) (see table 1).

Regarding cross-sectional studies, density has been evaluated in 5 studies, with no unequivocal results for mean density; avascular score has been unequivocally associated with PAH. Dimension has been evaluated in 4 studies, with no unequivocal results. Morphology has been evaluated in 1 study and has been unequivocally associated with PAH. Haemorrhages and scleroderma pattern has been evaluated in 1 and 2 studies respectively, with no association. Severity of

scleroderma pattern has been evaluated in 3 studies and has been unequivocally associated with PAH.

Regarding longitudinal studies, density (i.e. capillary loss) has been evaluated in 2 studies and has been unequivocally associated with incident PAH. Dimension and haemorrhages have been evaluated in 1 study both, with no association. Morphology has been evaluated in 2 studies, with no unequivocal results. Worsening of scleroderma pattern has been evaluated in 2 studies and has been unequivocally associated with incident PAH.

Capillaroscopic parameter	Significant association	Non-significant association	CONCLUSION
Density	Mean density Numerically correlated with PAH (p<0.0017) (p<0.00022) (p<0.00036) +PAH (p<0.00022)	PAH (p<0.0016)	Regarding cross-sectional studies *Avascular score unequivocally associated with PAH
	Capillary loss Incident PAH (p=0.03) (p=0.00022) (p=0.00022) Worsening PAH (p<0.00022)	N/A	No unequivocal results regarding mean density and PAH
	Avascular score Mean (p<0.0017) +PAH (p=0.00022)	N/A	Regarding longitudinal studies *Capillary loss unequivocally associated with incident PAH
Dimension	Width Mean (p<0.0013)	PAH (p=0.0022), CSR, HA+	Regarding cross-sectional studies *No unequivocal results
	Mean Mean (p<0.0013)	Incident PAH (p=0.03) (p=0.00022) (p=0.00022)	Regarding longitudinal studies *No association
	Morphology Normal N/A	N/A	Regarding cross-sectional studies *Morphology unequivocally associated with PAH
Haemorrhages	Abnormal PAH (p<0.0013) Incident PAH (p<0.00022)	Incident PAH (p=0.03) (p=0.00022) (p=0.00022)	Regarding longitudinal studies *No unequivocal results
	N/A	PAH (p=0.0022) Incident PAH (p=0.03) (p=0.00022) (p=0.00022)	Regarding cross-sectional studies *No association
	N/A	N/A	Regarding longitudinal studies *No association
NVC score	PAH (p<0.0017) +PAH (p=0.00022)	N/A	NVC score unequivocally associated with PAH in cross-sectional studies
	N/A	N/A	NVC score unequivocally associated with PAH in cross-sectional studies
Qualitative assessment	Scleroderma pattern in non-scleroderma patients N/A	PAH (p=0.0022)	No association in cross-sectional studies
	Severity of scleroderma pattern (with/without/none) PAH (p<0.0013) Mean (p<0.0017)	N/A	Severity of scleroderma pattern unequivocally associated with PAH in cross-sectional studies
	Worsening of scleroderma pattern Incident PAH (p<0.03) (p=0.00022) (p=0.00022) Worsening PAH (p=0.03) (p=0.00022) (p=0.00022)	N/A	Worsening of scleroderma pattern unequivocally associated with incident PAH in longitudinal studies

Abstract AB0722 – Figure 1

**Conclusions:** This systematic literature review, on behalf of the EULAR study group on microcirculation in Rheumatic diseases, is the first to investigate unequivocal associations between (incident) PAH and capillaroscopic alterations in a standardised way. Unequivocal associations were found in cross-sectional studies between avascular score, morphology, NVC score and severity of scleroderma pattern and PAH and in longitudinal studies between capillary loss and worsening of scleroderma pattern and incident PAH.

**AB0723 SEROPREVALENCE OF EPSTEIN-BARR VIRUS AND CYTOMEGALOVIRUS IN SYSTEMIC SCLEROSIS PATIENTS: PRELIMINARY RESULTS**

A.C. Trombetta<sup>1</sup>, V. Tomatis<sup>1</sup>, E. Alessandri<sup>1</sup>, S. Paolino<sup>1</sup>, C. Pizzorni<sup>1</sup>, M. Ghio<sup>1</sup>, B. Ruaro<sup>1</sup>, M. Patane<sup>1</sup>, E. Gotelli<sup>1</sup>, F. Goegan<sup>1</sup>, A. Sulli<sup>1</sup>, V. Smith<sup>2</sup>, M. Cutolo<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, IRCCS Polyclinic Hospital San Martino, University of Genoa, Genoa, Italy; <sup>2</sup>Department of Rheumatology, University Hospital of Ghent, Ghent, Belgium

**Background:** Epstein-Barr Virus (EBV) and cytomegalovirus (CMV) are among the most diffused virus in humans, with prevalence of 90% and 80% respectively in adult immunocompetent population<sup>1,2</sup>. Hypothesis for a role of EBV and CMV in systemic sclerosis pathogenesis was reported<sup>3</sup>.

**Objectives:** To evaluate the prevalence of EBV and CMV in a population of patients affected by SSc. As an exploratory aim, correlations with available clinical variables were evaluated.

**Methods:** A total of 49 patients (44 females and 5 males, age 65.6±9 years, 34 with limited cutaneous involvement and 14 with diffused cutaneous involvement) diagnosed according to the 2013 ACR/EULAR criteria<sup>4</sup> were randomly enrolled at their follow-up visit for a further more detailed analysis. After consent, all participants undergone serological testing for VCA-IgM, VCA-IgG and EBNA-IgG and CMV IgM and IgG, to determine prior or actual EBV and/or CMV infection. All SSc patients undergone also to clinical examination and instrumental evaluations according to SSc clinical standard follow up.

**Results:** Results for EBV seroprevalence were: VCA-IgM negative=43 (87%), positive=4 (8,2%), borderline=2 (4,1%) in all SSc patients. VCA-IgG resulted positive in 48 patients (98%) and EBNA-IgG resulted positive in 40 (81,6%) patients, borderline in 4 (8,2%) and negative in 5 (10,2%) patients. Forty-six (93,9%) patients resulted positive for CMV-IgG and 22 (44,9%) showed detectable CMV IgM. Consequently, EBV and CMV seroprevalence was significantly higher (p=0.01 and p=0.032 respectively) than that calculated in general population (90% and 80% respectively). Interestingly, the presence of higher CMV-IgM correlated linearly with higher pulmonary arterial pressure values (p=0.036) and was different in patients with or without sicca syndrome (p=0.012) and arthralgias

( $p=0.04$ ). Finally, higher CMV-IgG correlated with diffused cutaneous SSc form ( $p=0.023$ ) and nephropathy ( $p=0.036$ ).

**Conclusions:** The seroprevalence of EBV and CMV positivity was found significantly higher in the sample of SSc patients. EBV seropositivity (VCA-IgG) was present nearly in the totality of patients (98%). Of relevance, the high presence of CMV-IgG (93%) and CMV-IgM (44.9%) in SSc patients: the last correlated linearly with higher pulmonary arterial pressure values. EBV and CMV infections, among the supposed triggers in several autoimmune diseases, might also play a role in SSc patients, at least with progressive disease.

### AB0724 CARDIO-PULMONARY DISEASE MANAGEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS: CARDIO-RHEUMATOLOGY CLINIC AND PATIENT CARE STANDARDISATION PROPOSAL

A. Spinella<sup>1</sup>, F. Lumetti<sup>1</sup>, A.V. Mattioli<sup>2</sup>, F. Coppi<sup>3</sup>, R. Rosario<sup>3</sup>, E. Cocchiara<sup>1</sup>, M. Colaci<sup>4</sup>, C. Ferni<sup>1</sup>, C. Salvarani<sup>1</sup>, D. Giuggioli<sup>5</sup>. <sup>1</sup>Scleroderma Unit, Chair of Rheumatology; <sup>2</sup>Department of Surgical, Medical and Dental Department of Morphological Sciences related to Transplant, Oncology and Regenerative Medicine; <sup>3</sup>Chair of Cardiology, University of Modena and RE, Modena; <sup>4</sup>Internal Medicine Unit, University of Catania, Catania; <sup>5</sup>Scleroderma Unit, Chair of Rheumatology, University of Modena and RE, Modena, Italy

**Background:** Systemic sclerosis (SSc) is a chronic connective tissue disease characterised by endothelial dysfunction, dysregulation of fibroblasts with excessive fibrosis of the skin and internal organs and autoimmune abnormalities. Cardio-pulmonary manifestations are common in SSc and their detection in the early stage of the disease as well as their careful follow-up are mandatory in order to counteract their impact on the overall disease outcome. Despite the need of establishing a proper methodology, literature provides few reports about this issue.

**Objectives:** To evaluate the activity of our Cardio-Rheumatology Clinic in order to optimise diagnostic management of cardio-pulmonary disease in SSc patients.

**Methods:** We retrospectively analysed data from 350 consecutive SSc patients referred to our University-based Rheumatology Centre and SSc Unit (F/M 308/42; lc/dcSSc 45/305; mean age 50.8±14.7 years; mean disease duration 10.9±7.0 years). All patients underwent general and cardio-pulmonary assessment, in particular they were evaluated in the Cardio-Rheumatology Clinic. The following parameters were considered: physical examination; past and current drugs; blood tests, in particular Erythrocyte sedimentation rate-ESR, C-reactive protein-CRP, CPK enzymes, troponin, NT-pro-BNP, d-dimer, serum autoantibodies, 25-OH-vitamin D; capillaroscopy; pulmonary function tests; high resolution scan of the lungs (HRCT); standard electrocardiogram (ECG) and 24 hour Holter ECG monitoring; Doppler echocardiography; cardiac stress test; coronary angiography and right heart catheterization (RHC); cardiac MRI and CT; vascular ultrasound (intima-media-thickness, carotid-femoral and brachial-ankle pulse-wave-velocity). The clinicians decided to perform these examinations according to clinical picture and current methodologies.

Abstract AB0724 – Figure 1

**Results:** In the last 12 months we assessed 300 patients with 1st-level screening (cardio-rheumatologic evaluation, standard ECG, Doppler echocardiography, pulmonary function tests, thoracic imaging). Among 2nd-level, 30 procedures of 24 hour Holter ECG and 15 RHC tests were performed. Cardiac MRI, coronary CT angiography and vascular ultrasound were assessed, when requested, as 3rd-level examinations (30 procedures). After 1 year we observed a mean time of 10±5 days between request and clinical cardio-rheumatologic evaluation, 20±12 days to perform 1st-level screening, 25±15 days to execute the 2nd-level examinations. Figure-1 shows Cardio-Rheumatology algorithm for the management of SSc cardio-pulmonary disease.

**Conclusions:** The activity of our Cardio-Rheumatology Clinic optimises the cardio-pulmonary SSc assessment, determining an early detection of these harmful complications with reduced waiting times which are critical issues. Screening algorithms are useful to stratify the risk and to establish the most appropriate diagnostic-therapeutic protocols, improving outcome of scleroderma patients. The development of a cardio-pulmonary risk score and the standardisation of a patient care approach, according to international quality indexes, could represent further tools to optimise SSc management.

### AB0725 SEVERE DYSPHAGIA “POOR PROGNOSTIC MARKER” IN IDIOPATHIC INFLAMMATORY MYOPATHIES

A.C. Costi, L. Garcia, C. Pena, A. Testi, P. Sansinanea, R. Aguila, M. Pera, S. Velloso, F. Savy, M. Garcia. *Reumatology, HIGA San Martín, La Plata, Argentina*

**Background:** In Idiopathic Inflammatory Myopathies (MII), 18%–20% of patients have dysphagia.

**Objectives:** To evaluate the frequency of dysphagia in patients with MII, association with other manifestations of the disease, treatment and evolution.

To evaluate clinical characteristics and evolution of severe dysphagia.

To compare clinical characteristics and evolution of mild-moderate versus severe dysphagia.

**Methods:** Retrospective, observational study. Patients with a diagnosis of MII were included according to modified classification criteria of Bohan and Peter. Demographic, clinical and complementary studies were recorded. Serious dysphagia was considered: contraindication of oral feeding. Descriptive statistics were performed. Chi2 test, Student's test or Mann Whitney as appropriate.

**Results:** We included 91 of 106 patients evaluated from 1992 to 2017: 76% female, mean age at diagnosis 48±14 years. 53% presented dysphagia: mild/moderate 62.5% (30/48 pts), severe 37.5% (18/48). Idiopathic dermatomyositis was the most frequent MII in these patients (71%). In patients with dysphagia, proximal muscle weakness was 90%, weakness of neck muscles 45%, weakness of respiratory muscles 27%.

A significant association was found between dysphagia and weakness of respiratory muscles, weak neck muscles, glucocorticoid pulses, gammaglobulin, grave infections and death. (Data not shown in the summary).

In patients with **severe dysphagia**, we observed a significant association with the requirement for mechanical ventilation, hospitalisation in an intensive care unit, serious infections and death (table 1).

When comparing mild-moderate dysphagia vs severe dysphagia, a statistically significant association was found with neck muscles weakness, respiratory muscle weakness, glucocorticoid pulses, gamma globulin use, requirement for mechanical ventilation, hospitalisation in an intensive care unit, severe infections and mortality (table 2).

Abstract AB0725 – Table 1

	Severe dysphagia (SI) 18/91	Severe dysphagia (NO) 72/91	p	OR	IC 95%
Weakness of respiratory muscles	8/18	6/63	0 00 054	7,6	2,1–26,6
Weak neck muscles	8/16	6/63	0 00 129	8	2,5–26
Glucocorticoid pulses	12/18	8/69	<0,0001	15	4,4–51,9
Gammaglobulin	10/18	7/72	<0,0008	11,60	0,8–10
Intensive therapy unit	7/18	8/72	0,0046	5	1,5–16,8
Mechanical respiratory assistance	6/18	5/72	0002	6,70	1,7–25
Grave Infections	10/17	11/66	0,0003	7	2,2–22,8
Death	12/18	9/72	<0,0001	14	4,2–46,6

Abstract AB0725 – Table 2

	Dysphagia (mild-moderate) 30/48	Dysphagia (severe) 18/48	p	OR	IC 95%
Weakness of respiratory muscles	4/30	9/18	0.005	6,5	1,6–26
Weak neck muscles	9/30	13/18	0.004	6	1,6–22
Glucocorticoid pulses	5/28	13/18	0,0002	12	2,9–49
Gammaglobulin	3/30	10/18	0,0005	10	2,4–51
Intensive therapy unit	1/30	7/18	0,0013	18	2–167
Mechanical respiratory assistance	1/30	6/18	0.004	14,50	1,5–133
Grave Infections	5/27	10/18	0.009	5,50	1,4–21
Death	3/30	13/18	<0.001	23,5	4,8–113

**Conclusions:** Fifty-three percent of patients with MII had dysphagia at some point during their evolution. Severe dysphagia was associated with parameters of disease severity, poor prognosis and increased mortality.

#### AB0726 INTERSTITIAL LUNG DISEASE IN SCLERODERMA PATIENTS – A PORTUGUESE PORTRAIT

A.C. Duarte<sup>1</sup>, A. Cordeiro<sup>1</sup>, T. Santiago<sup>2,3</sup>, M.J. Salvador<sup>2,3</sup>, M.J. Santos<sup>1</sup>.  
<sup>1</sup>Rheumatology, Hospital Garcia de Orta, Almada; <sup>2</sup>Rheumatology, Centro Hospitalar e Universitário de Coimbra; <sup>3</sup>Faculty of Medicine, University of Coimbra, Coimbra, Portugal

**Background:** Systemic sclerosis (SSc) is characterised by inflammation and fibrosis of skin and internal organs. Lung involvement, particularly interstitial lung disease (ILD), is a major cause of morbidity and a leading cause of SSc-related mortality.

**Objectives:** To characterise SSc patients (pts) with ILD and identify possible predictors for its development.

**Methods:** A multicenter prospective cohort study using the Rheumatic Diseases Portuguese Register/Scleroderma database was performed. All patients fulfilled ACR/EULAR<sup>2013</sup> classification criteria for SSc. Demographic and clinical data until 15th January 2018 were collected as well as pulmonary function tests (PFTs), including diffusing capacity of carbon monoxide (DLCO). ILD was defined by fibrosis in chest x-ray and/or high-resolution computed tomography (HRCT) scan. Disease progression was defined by an increase from baseline in the area of involved parenchyma and/or development of honeycombing in pts with previous ground glass imaging and/or reduction of more than 15% in DLCO or 10% in forced vital capacity in pts with established ILD. We performed a descriptive analysis of SSc cohort. Logistic regression analysis was used to identify variables independently associated with ILD.

**Results:** A total of 146 pts were included, 88.4% female, with a mean age of 61.5 ± 14.4 years (yrs) and mean disease duration of 14.3 ± 11.3 years. Limited cutaneous SSc (lSSc) was present in 66.4%, diffuse cutaneous SSc (dSSc) in 24%, overlap syndrome in 6.8% and very early diagnosis SSc in 1.4% (information missing in 2pts).

In our cohort, 42 pts (28.8%) presented ILD after 17.5 ± 14.1 years of disease duration, 83.5% of them were female; 45.2% had dSSc and 42.9% lSSc. Anti-Scl70 antibody occurred in 23 pts, anticomere antibody (ACA) in 8, anti-Pm/Scl in 2, anti-RNA polymerase I in 2, anti-RNA polymerase III in 1 and anti-U3RNP in 1. Ten pts had current/previous smoking habits. Nailfold capillaroscopy (NCP) was available in 23 out of 42 pts and 21 had a SSc pattern (5 early, 6 active and 10 late). Table 1 shows differences between pts with and without ILD.

In multivariate analysis, anti-Scl70 (OR:3.7 95% CI 1.3–10.5) and current/previous digital ulcers (OR:2.2 95% CI 1.9–5.3) were associated with ILD development. ACA had a protective effect (OR:0.3 95% CI 0.1–0.8).

Mycophenolate mofetil was used in 11pts, with 5 of them having previous treatment with cyclophosphamide (CYC; 4 as induction drug). Four pts received azathioprine, half of them as maintenance therapy after induction with CYC. Two pts received rituximab and 1 nintedanib.

During follow-up, disease progression occurred in 17 pts (40.1%), 3 of them under immunosuppression.

Death occurred in 7 pts with ILD, 5 of them with direct relation to lung disease, 14.4 years after the diagnosis.

Table 1 Differences between patients with and without ILD (total=146)

**Conclusions:** This was the first multicentre Portuguese study about ILD in SSc. In our cohort, ILD occurred in about 30% of the pts and was associated with a mortality rate of 3.4%.

Our results confirm that some variables are associated with pulmonary disease development, and thus its identification may help the clinician to detect pts with a higher risk of early ILD.

#### AB0727 ANTIBODY PROFILE AND SYSTEMIC SCLEROSIS CLINICAL FEATURES – MYTH OR REALITY?

A.C. Duarte, A. Cordeiro, M.J. Santos, J. Canas da Silva. Rheumatology, Hospital Garcia de Orta, Almada, Portugal

**Background:** Antinuclear antibodies(ANA) occur in 80%–98% of systemic sclerosis(SSc) patients (pts), with different specificities. Anticentromere antibody (ACA), antitopoisomerase I(anti-Scl70) and anti-RNA polymerase III are the commonest and are included in the new SSc ACR/EULAR classification criteria. According to literature, ANA specificities are associated with clinical features of the disease.

**Objectives:** Evaluate the relationship between antibody profile and clinical manifestations in a cohort of SSc pts.

**Methods:** We conducted a retrospective analysis of SSc pts followed in our department. Demographic data, disease duration, ANA specificities and clinical manifestations were collected. Mann-Whitney U test and Chi-square were used for comparisons between pts who tested positive or negative for different ANA specificities.

**Results:** In total, 117 pts were included, 91.5% female with mean age of 60.7 ± 15.2 years and mean disease duration of 11.9 ± 10.7 years. Seventy-five pts (64.1%) had limited cutaneous SSc(lcSSc), 26 (22.2%) diffuse cutaneous SSc (dcSSc), 8 (6.8%) very early diagnosis SSc, 7 (6%) overlap syndromes and 1 (0.9%) SSc sine scleroderma. Most (92.3%) were ANA positive, with 53.8% having ACA, 26.5% anti-Scl70, 3.4% anti-U3 RNP, 2.6% anti-U1 RNP, 1.7% anti-PM/Scl and 0.9% anti-RNA polymerase III and 0.9% anti-Th/To.

Positivity for ACA was significantly associated with female gender (OR: 1.18 95% CI 1.04–1.34) and lcSSc phenotype (OR: 9.43 95% CI 3.86–23.03). ACA was also associated with older age at disease onset (p=0.008). Vascular involvement, defined by current/previous digital ulcers and/or telangiectasias, was also more prevalent in this group (OR: 5.59 95% CI 2.47–12.66). Pulmonary arterial hypertension (group 1 ERS/<sup>ECS 2013</sup> classification) was present in 6.3% of pts with ACA. Oesophageal involvement was the second commonest manifestation and occurred in 57.1% of pts with ACA, although this association was not statistically significant. ACA seemed to have a protective effect for interstitial lung disease (ILD) (OR: 0.027 95% CI 0.004–0.213).

Anti-Scl70 positivity was associated with dcSSc phenotype (OR: 9.29 95% CI 3.26–26.5) and ILD (OR: 10.39 95% CI 3.86–27.92).

From the 4 pts with anti-U3 RNP, 3 had dcSSc subtype. The only patient with renal manifestations was anti-U3 RNP positive and had rapidly progressive cutaneous involvement.

Abstract AB0727 – Table 1. Clinical features according to auto-antibody positivity

Antibody	ACA (n=63)	Anti-Scl70 (n=31)	AntiU3-RNP (n=4)	AntiU1-RNP (n=3)	Anti-PM/Scl (n=2)	Anti-RNA pol 3 (n=1)	Anti-Th/To (n=1)
Onset age mean±SD (years)	57.1±12.9	52±20.3	49.4±9.2	48.7±10.4	42.5±14.8	46	26
Female	98.4%	50.3%	75%	66.7%	50%	0%	100%
lcSSc	95.7%	38.7%	25%	0%	50%	100%	100%
dcSSc	0%	54.8%	75%	33.3%	0%	0%	0%
Overlap	1.6%	6.4%	0%	66.7%	50%	0%	0%
Vascular involvement	79.4%	51.6%	25%	33.3%	0%	0%	100%
PAH	6.3%	3.2%	0%	0%	0%	0%	0%
Lung involvement	1.6%	45.2%	25%	0%	50%	0%	0%
Cardiac involvement	0%	3.2%	0%	0%	0%	0%	0%
Oesophageal involvement	57.1%	45.2%	0%	0%	0%	100%	0
Faecal incontinence	4.8%	0%	25%	0%	0%	0%	0%
Renal involvement	0%	0%	25%	0%	0%	0%	0%
MS involvement	12.7%	12.9%	25%	66.7%	50%	0%	0%

Legend: ACA – anticentromere antibody; anti-Scl70 – antitopoisomerase I; lcSSc – limited cutaneous systemic sclerosis; dcSSc – diffuse cutaneous systemic sclerosis; PAH – pulmonary arterial hypertension; GI – gastro-intestinal; MS – muscle-skeletal

Anti-U1RNP was associated with muscle-skeletal manifestations (OR: 10.7 95% CI 0.92–20.44) and with overlap syndromes (OR: 15.2 95% CI 4.7–29.1). Pts with anti-Th/To and anti-RNA-polymerase III had lcSSc subtype. Vascular manifestations, oesophageal involvement and calcinosis cutis were the main manifestations, respectively. Table 1 shows detailed clinical manifestations and antibody profile.

**Conclusions:** In our cohort, ACA and anti-Scl70 were the commonest antibodies and were associated with lcSSc and dsSSc phenotype, respectively. ACA positivity conferred a higher risk of vascular disease and had a protective effect for ILD, while anti-Scl70 was associated with ILD.

Pts with anti-U1 RNP and anti-PM/ScI had mainly muscle-skeletal manifestations. This study confirms an association between immunological profile and clinical manifestations, reinforcing the importance of antibody profile and raising awareness for possible disease complications. Larger national studies would be desirable, specially for a better understanding of major organ involvement associated with least common antibodies.

**AB0728 NAILFOLD CAPILLAROSCOPY IN SYSTEMIC SCLEROSIS – SIX YEARS IN REVIEW**

A.C. Duarte, A. Cordeiro, M.J. Santos. *Rheumatology, Hospital Garcia de Orta, Almada, Portugal*

**Background:** Microvascular dysfunction is a dynamic process that is crucial in systemic sclerosis (SSc) pathogenesis. Nailfold capillaroscopy (NCP) is a rapid, non-invasive exam that illustrates the early capillary changes in SSc and monitor their evolution. It is extremely useful in clinical practice and has been recognised in 2013 ACR/EULAR classification criteria for SSc.

**Objectives:** Evaluate the prevalence and evolution of NCP scleroderma pattern in SSc patients and analyse possible associations with disease-phenotype.

**Methods:** NCP of SSc patients followed in our centre were reviewed; clinical and demographic features were collected. A descriptive analysis was performed and nonparametric tests compared patients with and without SSc pattern.

**Results:** In total, 70 out of 117 SSc patients had at least 1 NCP available during the last 6 years. Most of these patients (62.9%) had limited cutaneous SSc, 21.4% diffuse cutaneous SSc, 11.4% very early diagnosis SSc and 4.3% overlap syndromes; mean disease duration was 10.7±9.6 years.

At the moment of the first NCP, 46 patients (39.4%) had a scleroderma pattern, 12 (10.3%) had non-specific(NS) NCP abnormalities and 12 had a normal NCP. During the 6 years follow-up, NCP changed in 5 patients as illustrated in figure 1. However, none had concomitant development/worsening of other clinical manifestations.

At the end of the follow-up, 49 (70%) patients had a NCP scleroderma pattern. Early pattern was present in 13 (26.5%) patients, active pattern in 21 (42.9%), active/late pattern in 3 (6.1%) and late pattern in 12 (24.5%).

When comparing patients with and without scleroderma specific patterns (table 1), the presence of scleroderma pattern was associated with the presence of current/previous digital ulcers (OR 1.49 95% CI 1.17–1.92). However, this difference was not confirmed between the different scleroderma patterns.

Regarding, major organ involvement, although there were no statistical differences between both groups, patients with scleroderma pattern had a higher prevalence of oesophageal involvement.

**Abstract AB0728 – Table 1.** Comparison between patients with and without scleroderma pattern

NCP pattern	Non-scleroderma		Scleroderma				p
	Normal (n=10)	Non-specific abnormalities (n=11)	Early (n=13)	Active (n=21)	Active/Late (n=3)	Late (n=12)	
Female	100%	72.7%	100%	85.7%	66.7%	91.7%	0.623

**Abstract AB0728 – Figure 1.** Progression of nailfold capillaroscopy alterations during follow-up

**Conclusions:** This study demonstrates how NCP can illustrate the dynamic vascular damage in SSc. In our data, a NCP scleroderma pattern was significantly associated with a higher number of digital ulcers and these patients had a higher percentage of oesophageal involvement.

In daily clinical practice, NCP is useful not only for corroborating SSc diagnosis, but also for monitoring endothelial injury and potential macrovascular/systemic damage. Although our sample is too small to demonstrate possible associations between specific NCP alterations and internal organ involvement, some studies have already identify NCP patterns as predictive factors for organ damage.

**AB0729 QUALITY OF LIFE ASSESSMENT IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH AUTOLOGOUS STEM CELL TRANSPLANTATION: A LONGITUDINAL STUDY**

A.L.C. Guimaraes<sup>1</sup>, K. Costa-Pereira<sup>2</sup>, J.B. Elias<sup>2</sup>, D.A. Moraes<sup>2</sup>, E.A. Oliveira-Cardoso<sup>1</sup>, J.T. Garcia<sup>1</sup>, M.C. Oliveira<sup>3</sup>, V. Leopoldo<sup>3</sup>, A.F. Zombrilli<sup>2</sup>, T.M. Costa<sup>2</sup>, M. Vasconcelos<sup>2</sup>, M.C. Oliveira<sup>2</sup>. <sup>1</sup>Ribeirao Preto School of Philosophy, Sciences and Literature; <sup>2</sup>Division of Clinical Immunology, Ribeirao Preto Medical School; <sup>3</sup>Ribeirao Preto School of Nursing, University of Sao Paulo, Ribeirao Preto, Brazil

**Background:** Autologous Hematopoietic Stem Cell Transplantation (AHSCT) has been explored as a therapeutic option for patients with systemic sclerosis (SSc) that do not respond to conventional treatment.

**Objectives:** To investigate changes in quality of life of severe and rapidly progressive SSc patients treated with AHSCT.

**Methods:** This is a longitudinal and comparative study. Patients were evaluated before (n=27), and at 6 (n=27) and 12 months (n=21) after AHSCT. The Generic Questionnaire for Evaluation of Quality of Life Medical Outcomes Study 36 Item Short-Form Health Survey (SF-36) was applied individually, face-to-face, under patient written consent. This questionnaire evaluates eight domains: physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), social functioning (SF), vitality (VT), role-emotional (RE) and mental health (MH). Results were transformed into a 0–100 scale, where zero corresponds to a worse health condition and 100 to the best possible score, and submitted to statistical analysis. Significance was defined as p<0.05.

**Results:** Most participants were females (n=24), with mean age of 33 years (standard deviation, SD=10.33) and mean time from diagnosis of 34.4 months (SD=34.89). Before AHSCT, the mostly impaired aspects were: PF (mean=8.33, SD=18.34), and RP (mean=38.52, SD=21.56), while MH (mean=61.63, SD=15.46) and SF (mean=56.87, SD=27.17) were mostly preserved. At 6 and 12 months post-AHSCT, there was significant improvement of the SF-36 scores in the following domains: PF (6 months, p<0.01, 12 months, p<0.01); RP (6 months, p<0.01, 12 months, p<0.01); BP (6 months, p<0.01, 12 months, p<0.01); GH (6 months, p<0.01, 12 months, p=0.02); VT (6 months, p<0.01, 12 months, p<0.01); MH (6 months, p<0.01, 12 months, p<0.01). The SF domain showed significant increase only at 12 months (p=0.02). The only domain in which there was no significant change was RE.

**Conclusions:** Increases in the physical components of quality of life are more evident in the initial periods that follow AHSCT, while improvements in mental state, which are also associated with social aspects, are detected on longer follow-up. These data reinforce the relevance of AHSCT upon patient quality of life, signalling the importance of psychotherapeutic evaluations and follow-up.

**AB0730** **COMPARISON OF A SINGLE-CENTRE IDIOPATHIC INFLAMMATORY MYOPATHY COHORT FROM ARGENTINA WITH THE EUROMYOSITIS INTERNATIONAL REGISTRY**

A.S. Brailard Pocard, R. Gomez, M. Pino, M. Garcia Carrasco, D. Dubinsky. Hospital de Clinicas "Jose de San Martin", Ciudad Autonoma de Buenos Aires, Argentina

**Background:** The idiopathic inflammatory myopathies (IIM) are rare systemic autoimmune diseases that affect the muscle and other organs. Traditionally, IIM encompasses polymyositis (PM) and dermatomyositis (DM), but progressively inclusion body myositis (IBM), Immune-mediated necrotising myopathy (IMNM), the antisynthetase syndrome (ASS) and connective tissue diseases-over myositis (CTD-OM) have been recognised within the IIM spectrum

**Objectives:** To compare the clinical characteristics and treatment in a IIM cohort from an Argentinian university hospital with the international IIM cohort EUROMYOSITIS

**Methods:** Descriptive, retrospective study. IIM patients defined by expert opinion followed in our centre between October 2007 and October 2017 were included. ASS was defined by the presence of arthritis, raynaud's phenomenon, mechanic hands, elevated CK, muscle weakness, interstitial lung disease and/or presence of antisynthetase antibodies and, as in EUROMYOSITIS, patients with IIM with positive antisynthetase antibodies were reclassified as ASS. CTD-OM was defined as patients with IIM fulfilling classification criteria for other CTD. Demographic data, accumulated clinical features, time interval between disease onset and diagnosis, IIM subtype, treatment and presence of neoplasm were evaluated.

Ethnicity was defined using the same classification as in EUROMYOSITIS

**Results:** 58 patients were included: DM 24, PM 4, ASS 10, CTD-OM 20. 89.6% Hispanic, mean age 48.4±15.2 years, median time interval between disease onset and diagnosis 5 months (IQR 2–11 months), been higher in AAS (8.5 months, IQR 1.5–18.2 months). 6.89% (4/58) patients presented associated neoplasm, 3 with DM and 1 with CTD-OM. Table 1 shows the demographic and clinical features of our IIM cohort and EUROMYOSITIS. Table 2 shows treatments received in our cohort and EUROMYOSITIS.

**Abstract AB0730 – Table 1.** Demographic and clinical features

	DM		PM		ASS		CTD-OM

Gender % (M/F)	20 (71)/20 (29)	36 (38)/56 (59)	2 (50)/2 (50)	4 (31)/7 (54)	4 (40)/6 (60)	20 (39)/31 (61)	10 (50)/10 (50)	21 (59)/15 (41)
Mean Age at Onset, years (SD)	48.7 (15.20)	49 (16)	41 (13.36)	49 (15)	48.5 (13.80)	48 (19)	45.8 (15.90)	49 (19)
Mean Age at Diagnosis, years (SD)	46.7 (15.10)	47 (16)	44 (15.20)	52 (19)	43.3 (13.34)	48 (19)	42.3 (15.53)	48 (19)
Median interval between onset and diagnosis, months (IQR)	4 (1-8)	5 (2-11)	5.5 (2-6.5)	9 (3-19)	5.5 (1.5-18.2)	7 (3-17)	6 (2-25)	11 (4-20)
Muscle weakness (%)	79 (33)	72	100	100	100	90	100	84
Raynoud's phenomenon (%)	58 (24)	19	0	0	50	44	40	52
Raynaud's phenomenon (%)	33.3	26	0	25	50	53	60	60
Pericardial effusion (%)	20 (8)	62	0	0	10	19	10	33
Arthritis (%)	25 (10)	28	100	25	60	50	60	43
Antisynthetase (%)	0	0	0	0	20	36	0	16
Calcinosis (%)	20 (8)	7	0	0	0	3	0	13
Interstitial Lung Disease (%)	12.5	13	0	0	10	3	0	18
Cardiac involvement (%)	16.6	21	0	0	20	11	10	22

**Conclusions:** DM was the most frequent IIM subtype in both cohorts. In our group, CTD-OM was second and ASS was third.

Muscle weakness was found less frequently in our DM and AAS than reported in EUROMYOSITIS. However, calcinosis was more frequent. This could be explained by our mostly Hispanic population and/or by frequent Systemic Sclerosis overlap in our patients. It's important to remark that the ethnic variety defined as Hispanic in EUROMYOSITIS has a complex composition in Latin America, due to interbreeding.

No difference was found in terms of most frequent treatments between both cohorts. However, use of IVIg was more frequent in our patients.

To our knowledge, this is the first comparative report of an argentinian single-centre IIM cohort and an international multi-centre cohort

**Disclosure of Interest:** None declared

**AB0731** **TREATMENT ALGORITHMS FOR SYSTEMIC SCLEROSIS ACCORDING TO EXPERTS**

A. Fernández-Codina<sup>1,2</sup>, K.M. Walker<sup>3</sup>, J.E. Pope<sup>1</sup>, on behalf of Scleroderma Algorithm Group. <sup>1</sup>Medicine, Rheumatology Division, University of Western Ontario, London, Canada; <sup>2</sup>Internal Medicine, Systemic Autoimmune Diseases Unit, Hospital Universitari Vall d'Hebron, Universitat Autònoma de Barcelona, Barcelona, Spain; <sup>3</sup>Rheumatology Division, The Ottawa Hospital, University of Ottawa, Ottawa, Canada

**Background:** Treatment for many aspects of systemic sclerosis (SSc) lacks agreement.

**Objectives:** To generate SSc treatment algorithms endorsed by high percentage of SSc experts.

**Methods:** Experts from the Scleroderma Clinical Trials Consortium and the Canadian Scleroderma Research group (n=170) were asked whether they agreed with SSc algorithms (from 2012<sup>1</sup>). A further 2 consensus rounds refined agreement; 62 (36%), 54 and 48 experts completed surveys.

**Results:** For scleroderma renal crisis (SRC), 82% of the experts agreed (1st line ACEi, 2nd and 3rd adding: CCB or ARB). Pulmonary arterial hypertension (PAH) had 81% agreement. For mild PAH, PDE5i, then endothelin receptor antagonists plus PDE5i, then prostanoids; while for severe PAH prostanoids were first-line. Raynaud's phenomenon (RP) had 78% of agreement [mild (1st CCB, 2nd adding PDE5i, 3rd ARB or switching to another CCB, 4th prostanoids), severe (1st CCB, 2nd adding PDE5i, 3rd ERA, 4th prostanoids)]. Digital ulcer (DU) treatment had 69% agreement (1st CCB, 2nd PDE5i). Interstitial lung disease (ILD) had 65% agreement including induction (Mycophenolate mofetil (MMF) then intravenous cyclophosphamide then rituximab) and maintenance (1st line MMF). Skin involvement had 71% agreement. For a modified Rodnan skin score (mRSS) of 24 1st MTX, 2nd MMF; and for mRSS 32 1st MMF, 2nd MTX, 3rd intravenous cyclophosphamide (CYP), 4th hematopoietic stem cell transplantation. For inflammatory arthritis 79% agreed with 1st MTX, 2nd low dose glucocorticoids, 3rd hydroxychloroquine, 4th rituximab or tocilizumab. Cardiac and gastrointestinal algorithms had ≥75% agreement. The evolution of the agreement rates is shown in table 1:

**Abstract AB0731 – Table 1**

Algorithms for SSc treatment	Agreement 2012 <sup>1</sup> (%)	Agreement 2017 (%)
Scleroderma renal crisis	69	82
Pulmonary arterial hypertension	45	81
Raynaud's phenomenon	66	78
Digital ulcers	58	69
Interstitial lung disease	64	65
Gastrointestinal involvement	NA	77
Skin involvement	56, 40, 36 <sup>†</sup>	71
Inflammatory arthritis	45	79
Cardiac involvement	NA	75

Agreement is the% who agreed to the algorithm.

SSc: Systemic Sclerosis; NA: Not applicable; <sup>†</sup>For modified Rodnan skin scores 10, 24 and 32, respectively

**Conclusions:** Total agreement for SSc algorithms was considerable. These SSc algorithms may guide treatment.

**AB0732 EFFICACY AND SAFETY OF RITUXIMAB IN SYSTEMIC SCLEROSIS: FRENCH RETROSPECTIVE STUDY AND LITERATURE REVIEW**

M. Thiébaud<sup>1</sup>, D. Launay<sup>2</sup>, S. Rivière<sup>1</sup>, T. Mahévas<sup>1</sup>, S. Bellakhal<sup>3</sup>, E. Hachulla<sup>2</sup>, O. Fain<sup>1</sup>, A. Mekinian<sup>1</sup>. <sup>1</sup>Médecine Interne, Hôpital Saint-Antoine AP-HP, Paris; <sup>2</sup>Médecine Interne, Hôpital Claude Huriez CHU Lille, Lille, France; <sup>3</sup>Médecine Interne, Hôpital des Forces de Sécurité Intérieure, La Marsa, Tunisia

**Background:** Interstitial lung disease occurs in 42% of diffuse SSc patients and have a major impact on the overall survival.<sup>1</sup> Cyclophosphamide and mycophenolate mofetil can allow the lung disease stabilisation.<sup>2,3</sup> Recently several case-reports and little series reported the efficacy of rituximab in SSc, showing a possible improvement of pulmonary involvements.<sup>4,5,6</sup> Large studies are lacking to determine the factors associated with rituximab response, the maintenance regimen and the long term efficacy of rituximab in SSc.

**Objectives:** To describe safety and efficacy of rituximab in patients with systemic sclerosis.

**Methods:** We included 13 patients with systemic sclerosis treated with rituximab and pooled with 40 additional patients from the literature. SSc rituximab untreated patients were matched to rituximab treated ones.

**Results:** Thirteen patients who received rituximab and 26 rituximab-untreated patients were included. In comparison to 26 patients who did not received rituximab, FVC changes were not significantly different, whereas DLCO improved in 13 patients who received rituximab (0 [-4; 4] vs loss of -7 [-19; 0]; p=0.05). Considering 7 rituximab treated and 14 untreated diffuse SSc, FVC was improved during the 24<sup>12</sup>; 46 months of follow up in dSSc who received rituximab (gain of 12 [7.5;14]%) vs loss of 1.5 [-16.8; 2.5]; (p=0.003). Pooled analysis of 53 patients (40 literature patients and 13 from personal series) showed significant improvement of median mRSS from 18<sup>8</sup>; 32 at baseline to 9<sup>4</sup>; 19 at M6 (p=0.007), 13<sup>8</sup>; 18 at M12 (p=0.008) and 10<sup>4</sup>; 16 at the last follow-up (p=0.0002). FVC increased from 71%<sup>66</sup>; 80 at baseline to 84%<sup>75</sup>; 90 at M12 (p=0.001). DLCO increased from 58%<sup>39</sup>; 65 at M0% to 63%<sup>53</sup>; 78 at M12 (p=0.04).

**Conclusions:** Our personal data and pooled literature analysis suggest the efficacy of rituximab in the subset of diffuse SSc in particular in skin and interstitial disease involvements. The safety of rituximab seems to be reasonable and similar to previous data in other autoimmune diseases.

<sup>1</sup>Department of Rheumatology, Ankara University Faculty of Medicine, Ankara;

<sup>2</sup>Department of Rheumatology, Trakya University Faculty of Medicine, Edirne, Turkey

**Background:** Neutrophil-to-lymphocyte ratio (NLR), monocyte-to-lymphocyte ratio (MLR), eosinophil-to-lymphocyte ratio (ELR), basophil-to-lymphocyte ratio (BLR), and mean platelet volume (MPV) may potentially reflect inflammatory status in systemic autoimmune diseases.

**Objectives:** The aim of this study is to investigate the association of NLR, MLR, ELR, BLR and MPV with disease manifestations, activity and severity in patients with systemic sclerosis (SSc).

**Methods:** 59 patients with SSc and 50 healthy controls were included in the study. All patients were diagnosed according to the 2013 ACR/EULAR systemic sclerosis classification criteria. Adult patients with SSc and healthy controls were compared in terms of NLR, MLR, ELR, BLR and MPV.

**Results:** SSc and control groups had similar ages and genders. Lymphocyte number was lower in SSc group compared to controls (p<0.001). SSc group also have higher NLR and MLR (table 1). There were no significant differences in ELR and BLR ratios between SSc patients and controls. Patients with active disease (2.9 [IQR 2.13], p=0.042), pulmonary hypertension (PHT), digital ulcers, and tendon friction rubs (TFR) had higher NLRs (table 2). MLR was also higher in dcSSc patients (0.28 [IQR 0.73]) compared to lcSSc (0.2 [IQR 0.48] (p=0.045), and there were also significant associations with disease manifestations like digital ulcers, tendon friction rubs (table 2). MLR was positively correlated with mRSS (rho=0.35 p=0.009), Valentini (rho=0.453 p=0.001) and Medsger (rho=0.283 p=0.036) scores. According to capillaroscopy images, patients with late stage findings had higher MLRs compared to patients with normal findings (0.27 [IQR 0.3] vs 0.15 [IQR 0.04], p<0.001). Patients with digital ulcers (p=0.02) and arthritis (p=0.013) had higher ELRs and patients with tendon friction rubs has higher ELRs (p=0.014) and BLRs (0.036) compared to those without. There was no significant relation between MPV and disease manifestations (table 2). There were no relationships between dysmotility and haematological parameters.

**AB0734 SERUM IL-35 LEVELS IN SYSTEMIC SCLEROSIS AND RELATIONSHIP WITH CLINICAL FEATURES**

M.E. Yayla<sup>1</sup>, M. Torçutalp<sup>1</sup>, I.E. Okatan<sup>1</sup>, E. Uslu Yurteri<sup>1</sup>, O. Küçükşahin<sup>2</sup>, A. B. Keleşoğlu Dinçer<sup>1</sup>, E.G. Aydemir Gülöksüz<sup>1</sup>, S. Sezer<sup>1</sup>, E. Us<sup>3</sup>, T.M. Turgay<sup>1</sup>, G. Kınıklı<sup>1</sup>, A. Ateş<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Ankara University Faculty of Medicine; <sup>2</sup>Department of Rheumatology, Yıldırım Beyazıt University Faculty of Medicine; <sup>3</sup>Department of Clinical Microbiology, Ankara University Faculty of Medicine, Ankara, Turkey

**Background:** Interleukin (IL)-35 is a member of the IL-12 family. Studies show that IL-35 is an important anti-inflammatory cytokine and suppresses effector T cell activity. Systemic sclerosis (SSc) is a chronic disease characterised by vascular damage, autoimmunity and fibrosis.

**Objectives:** In this study, we aimed to evaluate serum IL-35 level in SSc patients and its potential relation with disease findings.

**Methods:** Fifty-five SSc patients and 25 healthy controls were included in the study. All patients were diagnosed according to 2013 ACR/EULAR systemic sclerosis classification criteria. Serum IL-35 was measured using a commercial ELISA kit (Cloud-Clone Corp, Wuhan, China).

**Results:** SSc patients and healthy controls had similar ages and genders. The mean of serum IL-35 level was significantly higher in SSc patients (8.2±1.3 pg/ml) than in healthy controls (6.9±0.7 pg/ml) ( $p < 0.001$ ). Serum IL-35 levels were similar in lcSSc (n=44) and dcSSc (n=11) groups (8.3±1.2 and 8±0.1, 6 pg/ml, respectively). There were no significant relationships between serum IL-35 level and digital ulcer, interstitial lung disease, pulmonary hypertension, tendon friction rub, gastrointestinal motility disorder, cardiac involvement and Anti-SCL70, anti-CENP-B positivities (table 1). There was not any correlation between IL-35 level and disease duration, modified Rodnan skin score, Valentini disease activity score, Medsger disease severity score, erythrocyte sedimentation rate and C-reactive protein (CRP) levels. Serum IL-35 levels between patients treated with or not vasodilating agents such as calcium channel blockers, endothelin receptor antagonists and prostaglandin analogues, and also immunosuppressive drugs did not differ significantly.

**Abstract AB0734 – Table 1.** Relationship between clinical and laboratory features and IL-35

		IL-35 (pg/ml)	P
		*	
Digital ulcer	- (n=32) + (n=23)	8.3±1.4 8.1±1	0.5
Gastrointestinal involvement	- (n=43) + (n=12)	8.3±1.2 8±1.5	0.512
Cardiac involvement	- (n=52) + (n=3)	8.1±1.3 9.5±0.8	0.073
Interstitial pulmonary disease	- (n=34) + (n=21)	8.3±1.3 8.1±1.3	0.593
Pulmonary arterial hypertension	- (n=51) + (n=4)	8.2±1.3 7.9±1.2	0.617
Arthritis	- (n=36) + (n=19)	8.4±1.3 7.9±1.2	0.160
Tendon friction rub	- (n=47) + (n=8)	8.2±1.3 8.3±1	0.798
Anti-Scl 70	- (n=34) + (n=20)	8.3±1.3 8.2±1.2	0.793
Anti-CENP B	- (n=33) + (n=21)	8.1±1.3 8.4±1.3	0.442

\*mean ±std, + and – denote presence and absence, respectively.

**Conclusions:** It has been reported that serum IL-35 level is higher SSc patients than healthy volunteers and is associated with interstitial lung disease. In our study, the level of IL-35 was higher SSc patients than healthy controls. There is no relationship between clinical parameters and IL-35 levels, this may be due to small sample size. Our results suggest that IL-35 may have a role on the pathogenesis of SSc. Further investigations are needed in large sample size of SSc patients.

**AB0735 NAILFOLD CAPILLARY COUNTS CORRELATE MOST WITH COMPLICATIONS OF SYSTEMIC SCLERODEMA IN JAPANESE PATIENTS**

A. Kondo<sup>1</sup>, H. Dobashi<sup>1</sup>, T. Kameda<sup>2</sup>, M. Izumikawa<sup>2</sup>, S. Nakashima<sup>2</sup>, H. Shimada<sup>2</sup>, R. Wakiya<sup>2</sup>, M. Kato<sup>2</sup>, N. Kadowaki<sup>2</sup>. <sup>1</sup>Kagawa university, Klta, Japan; <sup>2</sup>Department of Internal Medicine, Division of Hematology, Rheumatology and Respiratory Medicine, Kagawa university, Klta, Japan

**Background:** Connective tissue diseases (CTD) patients have various clinical manifestation including pulmonary hypertension (PH) and digital ulcer (DU). Especially, Raynaud's phenomenon (RP) is one of the common symptoms. On the other hand, "abnormal nailfold capillaries" are important as the findings that suggest RP associated with CTD. They are included in one of the items of classification criteria for Scleroderma (SSc) in 2013 Classification Criteria for Systemic Sclerosis (ACR/EULAR) <sup>1</sup>. Recently, some reports presented the usefulness of nailfold capillaroscopy (NFC) in SSc <sup>2</sup>. NFC findings showed enlarged/giant capillaries, fresh or old haemorrhages, avascular areas, ramified/bushy capillaries. These findings are known as "scleroderma pattern" features. Additionally, there are some reports that nailfold capillary density in SSc related with DU, PH and interstitial pneumonia (IP).

In this study, we clarify the association between nailfold capillary density and clinical manifestation by analysis of the case in our institution.

**Objectives:** To clarify the association between nailfold capillary density and clinical manifestation.

**Methods:** We enrolled Japanese SSc patients from May 2016 to May 2017 in our institution.

We measured total nailfold capillary count per 1 μm from second to fifth finger by NFC "OptiPIX Capillaroscopy Clinic 1.7.x". In addition, we investigated relationship with NFC findings and clinical manifestation such as current and previous DU, PH and IP.

**Results:** We enrolled 42 SSc patients. Total nailfold capillary counts significantly decreased, especially in SSc patients with, previous DU ( $\rho = -0.4122$ ,  $p = 0.0054$ ), and PH ( $\rho = -0.3226$ ,  $p = 0.0023$ ). In addition, there is significant difference between DU and existence of giant capillaries ( $\rho = 0.3019$ ,  $p = 0.0464$ ), existence of avascular areas ( $\rho = 0.4057$ ,  $p = 0.0063$ ). On the other hand, there is no significant difference between IP, PH and other "scleroderma pattern" features.

**Conclusions:** Our study revealed that total nailfold capillary counts were associated with PH and DU in SSc patients. We suggest that nailfold capillary density may most predict complications with SSc patients.

**AB0736 SYSTEMIC SCLEROSIS SINE SCLERODERMA: CHARACTERISTICS OF A SOUTH INDIAN COHORT FROM A TERTIARY CARE CENTRE**

B. Chilukuri<sup>1,2</sup>, S. Chinnadurai<sup>2</sup>, B. Mahendran<sup>3</sup>, R. Ramamoorthy<sup>2</sup>, B. Selvakumar<sup>2</sup>, R. Sankaralingam<sup>4</sup>. <sup>1</sup>Dept of Rheumatology, Parvathy Hospital; <sup>2</sup>Institute of Rheumatology, Madras medical college, Chennai; <sup>3</sup>Dept of Rheumatology, KIMS Hospital, Trivandrum; <sup>4</sup>Dept of Rheumatology, SRMC, Chennai, India

**Background:** Systemic Sclerosis is a complex disorder characterised by autoimmunity, vasculopathy and fibrosis. The hallmark of Systemic Sclerosis is skin thickening. Systemic Sclerosis sine scleroderma is a variant of Systemic sclerosis which shares visceral, serological and vascular manifestations but lacks skin thickening. Systemic Sclerosis sine scleroderma still remains a rarely reported subtype of Systemic Sclerosis unlike commonly reported limited cutaneous and diffuse cutaneous types.

**Objectives:** Aim of this study was to analyse the characteristics of patients with Systemic Sclerosis sine scleroderma from a cohort of Systemic Sclerosis patients.

**Methods:** This study was done at Institute of Rheumatology, Madras Medical College, Chennai, India. It was a retrospective observational study (January 2006 to November 2016). Patients satisfying ACR/<sup>EULAR</sup> 2013 Classification criteria for Systemic Sclerosis were included in this study. Patients with Overlap syndrome, MCTD, UCTD, children and pregnant women were excluded. Poormoghim criteria was used for diagnosis of Systemic Sclerosis sine scleroderma: Absent skin

thickening +Raynaud's Phenomenon or peripheral vascular involvement +Positive ANAs+One visceral organ involvement typical of SSc +Absence of another defined connective tissue disease. Demographic, clinical and laboratory profile of all patients were analysed.

**Results:** Among the 249 patients included in this study, patients with limited cutaneous systemic sclerosis were 59.4% (n=148) and diffuse cutaneous systemic sclerosis were 31.3% (n=78). 9.2% (n=23) of patients satisfied poormoghim criteria for Systemic Sclerosis sine scleroderma. The following characteristics of Systemic Sclerosis sine scleroderma were observed in our cohort. Dyspnoea (82.6%) was the most common presenting complaint and Raynauds (100%) the most common sign observed. Most common internal organ involvement was oesophageal dysfunction (78%) followed by lung involvement in the form of interstitial lung disease (52.1%) and pulmonary hypertension (47.8%). Renal involvement was not observed in any of the patients. Most common autoantibody detected among patients with Systemic Sclerosis sine scleroderma was anti-centromere antibody (78.2%) followed by anti-scl70 antibody (21.8%). Nine patients (39.1%) received pulse cyclophosphamide therapy and 3 patients received rituximab therapy in view of interstitial lung disease.

Abstract AB0736 – Figure 1

**Conclusions:** The most common pattern of Systemic Sclerosis sine scleroderma observed in our cohort was Oesophageal dysfunction +Raynauds Phenomenon +Anti centromere antibody positivity +Interstitial lung disease with or without pulmonary hypertension which are usually the characteristics of limited cutaneous type of Systemic Sclerosis. Hence Systemic Sclerosis sine scleroderma could be a subset of limited cutaneous type without the phenotypic skin involvement.

AB0737

#### AMINAPHTONE INCREASES SKIN BLOOD PERFUSION AND IMPROVES CLINICAL SYMPTOMS IN PATIENTS WITH RAYNAUD'S PHENOMENON INDEPENDENTLY FROM DIFFERENT TREATMENT BACKGROUNDS

B. Ruaro, C. Pizzorni, E. Gotelli, J. Alsheyyab, E. Alessandri, A. Sulli. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy*

**Background:** Aminaphtone is a vasoactive drug that was recently demonstrated to improve both peripheral blood perfusion (BP) and clinical symptoms of Raynaud's phenomenon (RP) in patients with either primary or secondary RP to systemic sclerosis (SSc).<sup>1-2</sup>

**Objectives:** The aim of this study was to evaluate possible interferences of different treatment backgrounds on both skin BP and RP-related clinical symptoms in patients treated with aminaphtone, during a six-month follow-up.

**Methods:** Forty-six patients with active RP were enrolled during routine clinical assessment after informed consent (11 primary RP, mean age 49±19 SD years, mean RP duration 6±3 years; and 35 secondary RP to systemic sclerosis, mean age 61±17 years, mean RP duration 11±9 years). Aminaphtone was orally administered 75 mg twice daily in addition to current treatments, and all patients were on a stable drug regimen for at least two months, which remained unmodified during the follow-up. All patients were taking cardioaspirin. Six groups of treatment backgrounds were identified: 1) no further treatments (12 patients); 2) hydroxychloroquine (2 patients); 3) colchicine (5 patients); 4) methotrexate (3 patients); 5) cyclosporine A (6 patients); 6) mycophenolate (6 patients); 7) proton-pump inhibitors (12 patients). Blood perfusion was measured by Laser Speckle Contrast Analysis (LASCA)<sup>3</sup> at the level of fingertip, periungual areas, dorsum and palm of hands, and face at baseline (T0), after one (T1), four (T4), twelve (T12) and twenty-four (T24) weeks of treatment. Raynaud's condition score (RCS) and both frequency and duration of Raynaud's attacks were assessed at the same time. Statistical analysis was performed by non-parametric tests.

**Results:** During aminaphtone treatment, a progressive statistically significant increase of blood perfusion, as well as an improvement of RP clinical symptoms (decrease of RCS, frequency and duration of RP attacks/day), were observed in all above reported seven groups of RP patients with different treatments backgrounds from T0 to T12 in all skin areas (p<0.01). There were no statistically significant difference between the seven groups of patients concerning skin BP at different times (p=0.60). The results were similar in both primary and secondary (SSc) RP patients (p=0.40). Aminaphtone administration had to be stopped in 2 patients due to headache, and one patient was lost during follow-up.

**Conclusions:** This study demonstrates that the increase of skin blood perfusion and the improvement of RP clinical symptoms is not influenced by different treatment backgrounds in RP patients treated with aminaphtone. These preliminary results should be further confirmed by a randomised blind clinical trial.

#### IMPROVEMENT OF DERMAL THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS TREATED WITH ENDOTHELIN RECEPTOR ANTAGONIST: LONG TERM STUDY BY HIGH FREQUENCY ULTRASOUND

B. Ruaro<sup>1</sup>, A. Sulli<sup>1</sup>, C. Pizzorni<sup>1</sup>, M. Ghio<sup>1</sup>, V. Smith<sup>2</sup>, V. Tomatis<sup>2</sup>, M. Cutolo<sup>1</sup>.

<sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; <sup>2</sup>Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium

**Background:** Systemic sclerosis (SSc) is a connective tissue disorder characterised by skin involvement, which may be evaluated by both modified Rodnan skin score (mRSS) and skin high frequency ultrasound (US).<sup>1-4</sup> Endothelin-1 (ET-1) seems implicated in the development of dermal fibrosis in SSc.<sup>5</sup> Bosentan, a dual ET-1 receptor antagonist seems effective in reducing skin fibrosis in SSc patients.<sup>6,7</sup>

**Objectives:** The aim of this study was to evaluate by US the long-term effects of bosentan on dermal thickness (DT) in SSc patients, in combination with long-term cyclic intravenous iloprost versus iloprost monotherapy.

**Methods:** Thirty-eight SSc patients were enrolled during their standard treatment for digital ischemia. At baseline (T0), 19 patients already receiving cyclic intravenous infusion of iloprost (5 continuous days, average 80 mcg/day, every two

months), continued the treatment for further 4 years (T4) (ILO group). Other 19 patients, although they continued the same cyclic intravenous iloprost treatment as the previous group, also received bosentan 125 mg twice a day for 4 years (ILO +BOS group), due to digital ulcers. DT was yearly evaluated by both US (18 MHz probe, MyLab 25, Esaote, Italy) and mRSS at the level of the usual seventeen skin areas (zygoma, fingers, dorsum of hands, forearms, upper-arms, chest, abdomen, thighs, legs, and feet).<sup>1-4</sup> Non-parametric tests were used for the statistical analysis.

**Results:** A statistically significant decrease of DT, measured by US, was observed in the ILO+BOS group from T0 (median DT 1.135 mm) to T4 (median DT 1.088 mm) ( $p=0.01$ ). No statistical significant variation of mRSS was observed during the follow-up in this group of patients (median mRSS at T0 12/51 and at T4 11/51,  $p=0.70$ ). Conversely, in ILO group, a statistically significant increase of DT was observed after four years, as measured by US (median DT at T0 1.070 and at T4 1.258,  $p<0.0001$ ), as assessed by mRSS (median mRSS at T0 4/51 and at T4 8/51,  $p<0.0001$ ). Transient increase of transaminases was managed by temporary bosentan discontinuation.

**Conclusions:** In this open study, the long-term treatment with ET-1 receptor antagonist in combination with iloprost seems to be associated with a decrease of DT in SSc patients, in contrast to the treatment with iloprost alone. DT evaluated by US over long term seems to be more susceptible to change than by mRSS.

#### LONGITUDINAL ASSESSMENT OF NAILFOLD CAPILLARY NUMBER, PERIPHERAL BLOOD PERFUSION AND DERMAL THICKNESS IN SYSTEMIC SCLEROSIS PATIENTS OVER A PERIOD OF 5 YEARS

B. Ruaro<sup>1</sup>, A. Sulli<sup>1</sup>, C. Pizzorni<sup>1</sup>, V. Smith<sup>2</sup>, E. Gotelli<sup>1</sup>, J. Alsheyab<sup>1</sup>, A. C. Trombetta<sup>1</sup>, M. Cutolo<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; <sup>2</sup>Department of Rheumatology, Ghent University Hospital, Department of Internal Medicine, Ghent University, Ghent, Belgium

**Background:** Several studies demonstrated the relationship between blood perfusion (BP), dermal thickness (DT) and nailfold microangiopathy (“Early”, “Active” and “Late” videocapillaroscopic patterns) in patients with systemic sclerosis (SSc).<sup>1-3</sup>

**Objectives:** The aim of this study was to evaluate the changes of BP and DT, during a follow-up of 5 years, in SSc patients with persistent “Late” NVC pattern at baseline, as well as to confirm the correlations among microvascular damage extent, absolute nailfold capillary number (CN), BP and DT, during the follow-up.

**Methods:** Twenty-three female patients affected by SSc according to the LeRoy criteria<sup>4</sup> (mean age 63±4 SD years, mean disease duration 6±4 years), displaying the most advanced “Late” NVC pattern of microangiopathy at baseline (T0), were enrolled and followed for five years (T5), after informed consent. Laser speckled contrast analysis (LASCA), skin high frequency ultrasound (US), modified Rodnan skin score (mRSS), and nailfold videocapillaroscopy (NVC) were yearly performed. Blood perfusion (BP), assessed by LASCA at the level of fingertips, periungual areas, dorsum and palm of both hands, was calculated as perfusion units (PU).<sup>1-3</sup> Dermal thickness (DT) was assessed by both US and mRSS in the same above reported areas.<sup>5</sup> The microangiopathy evolution score (MES) and the CN per linear millimetre at first distal row were evaluated by NVC.<sup>6,7</sup> Patients were receiving a wide range of drugs, including vasodilators, immunosuppressive agents and endothelin receptor antagonists. Statistical analysis was performed by non parametric tests.

**Results:** A progressive statistically significant decrease of both BP ( $p<0.0001$ ) and nailfold CN ( $p<0.0001$ ) values was observed from T0 to T5 at the level of all areas, as well as a progressive statistically significant increase of DT ( $p<0.0001$ ), mRSS ( $p<0.0001$ ) and MES ( $p=0.01$ ) values. The progressive decrease of BP positively correlated over time with the worsening of nailfold CN ( $p=0.03$ ,  $r=0.62$ ), MES ( $p=0.05$ ,  $r=0.62$ ), mRSS ( $p=0.002$ ,  $r=0.72$ ) and DT ( $p=0.002$ ,  $r=0.64$ ).

**Conclusions:** Microvascular damage with progressive reduction of nailfold capillary number was found, in a five-year follow-up, associated with progressive

functional microvascular damage and DT worsening in the present cohort of SSc patients showing a persistent “Late” NVC pattern.

#### EVALUATION OF HAND DERMAL THICKNESS AND PERIPHERAL BLOOD PERFUSION IN SYSTEMIC SCLEROSIS PATIENTS

B. Ruaro<sup>1</sup>, A. Sulli<sup>1</sup>, T. Santiago<sup>2,3</sup>, J.A. Pereira da Silva<sup>2,3</sup>, C. Pizzorni<sup>1</sup>, V. Tomatis<sup>1</sup>, M. Cutolo<sup>1</sup>. <sup>1</sup>Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, Genoa, Italy; <sup>2</sup>Rheumatology Department, Centro Hospitalar e Universitário de Coimbra; <sup>3</sup>Faculty of Medicine, University of Coimbra, Coimbra, Portugal

**Background:** Systemic sclerosis (SSc) is characterised by progressive skin involvement. The modified Rodnan Skin Score (mRSS) is the gold standard to assess skin damage, but it has significant limitations. Recently, several studies demonstrated the utility of skin high frequency ultrasound (US) as an alternative.

**Objectives:** The aim of this study was to identify possible correlations between peripheral blood perfusion (BP) and ultrasound dermal thickness (US-DT) at level of hand and finger in SSc patients.

**Methods:** Sixty-seven patients, satisfying the 2013 ACR/EULAR SSc criteria (mean age 64±9 SD years, mean disease duration 6±4 SD years) were enrolled. BP was measured as perfusion units (PU) by laser speckle contrast analysis (LASCA) at the level of dorsal region of hands. In a second time, different regions of interest (ROIs) were created at level of dorsum of the middle phalanx of 3rd finger and dorsum of hand bilaterally and the average BP was scored as perfusion units (PU), as previously reported.<sup>1,2</sup> Both skin high frequency US and mRSS were used to evaluate DT at the above mentioned skin sites.<sup>2</sup> The same examinations were performed in 65 healthy subjects.

**Results:** BP was negatively correlated with both US-DT ( $p=0.0005$ ) and mRSS ( $p=0.007$ ) in SSc patients at the finger sites, but not at the level of dorsum of the hands. In healthy subjects, there was no statistically significant correlation between BP and DT as evaluated by both US and mRSS at either skin sites. SSc patients showed a statistically significant lower BP at the finger sites than healthy subjects ( $p<0.0001$ ). No statistically significant difference in BP values was observed between SSc and healthy subjects at the dorsum of hand.

**Conclusions:** This study demonstrates a negative correlation between BP, as evaluated by LASCA and DT, as evaluated by both US and mRSS, in the 3rd finger of SSc patients. Additionally, the results confirm a reduced finger BP in SSc patients when compared to healthy subjects.

#### T-REG AND TH17 LEVELS IN PATIENTS WITH SYSTEMIC SCLERODERMA

D. Üsküdar Cansu<sup>1</sup>, H. Üsküdar Teke<sup>2</sup>, C. Korkmaz<sup>1</sup>. <sup>1</sup>Internal Medicine, Rheumatology; <sup>2</sup>Internal Medicine, Hematology, Eskişehir Osmangazi University, Eskişehir, Turkey

**Background:** Regulatory T-cells (T-reg) may play an inhibitory role in the development of autoimmune diseases (AID) by suppressing the immune response to autoantigens. Impaired or decreased T-reg and/or increased Th17 cells may be responsible for the development of AID. However, studies about the association of T-reg and systemic scleroderma (SSc) are limited and conflicting.

**Objectives:** Our aim is to determine whether there is a relationship between T-reg and Th-17 levels and disease activation in patients with SSc.

**Methods:** 17 patients with <sup>SSc who met 2013</sup> ACR/EULAR SSc criteria were included in the study. Clinical and laboratory parameters, Rodnan skin scores, Valentini disease activity index, were evaluated in detail. Concurrent peripheral blood T-regs (CD4 +CD25+, CD4 +FOXP3+T reg, CD4 +CD25+FOXP3+T reg) and Th17 (IL-17 producing T cells) were studied. Age and sex matched 11 subjects were included as healthy control (HC) in this study.

**Results:** Fifteen of seventeen patients were female, median age was 52.8±9.36 years, median disease duration was 5.41±4.51 years. While skin involvement and Raynaud's phenomenon were determined in all of the patients, esophageal involvement was determined in 13 of the patients (76.5%), digital ulcer in 2 patients (11.7%), and lung involvement in 14 (94.1%) patients. Median ESR level was 31.29±12.7 mm/hour, median CRP level was 0.573±0.474 mg/dl, median Valentini disease activity index was 3.23±1.53. The medications of the patients during the follow up period were as; nifedipine n=15 (88.2%), hydroxychloroquine n=14 (82.4%), corticosteroids n=14 (82.4%), azathioprine n=10 (58.6%), mycophenolate mofetil n=1 (5.9%), cyclophosphamide n=7 (41.2%). In comparison of SSc and HC, all the T-reg cell levels were significantly higher in SSc group than HC (p≤0.0001, p≤0.0001 and p≤0.0001, respectively). Although the levels of CD4 +IL-17 cells in SSc group were high compared to HC, it was not significant (p=0.100). A positive correlation between CD4 +IL-17-cell levels and CRP (r=0.613, p=0.009), a negative correlation between CD4 +CD25+T reg cell levels and dosage of corticosteroid (r=-0.513, p=0.035), a negative correlation between CD4 +CD25+T reg cell levels and platelet levels (r=-0.560, p=0.019) and a negative correlation between CD4 +CD25+FOXP3+T reg cell levels and platelet levels (r=-0.500, p=0.041) were determined.

**Conclusions:** In a cross-sectional study, it is rather difficult to explain the meaning of increased T-reg cell in SSc patients. These results may be due to modification of the cells by immunosuppressive treatment. It might be more meaningful to evaluate T-reg cell before and after the treatment.

#### HAND X-RAY LESIONS ARE FREQUENT IN ANTISYNTHEASE SYNDROME PATIENTS WITH ARTHRALGIA AND INCREASE WITH THE RADIOGRAPHIC FOLLOW-UP, WHATEVER THE EXTRA-ARTICULAR FEATURES AND THE SEROTYPE OF ANTISYNTHEASE SYNDROME

C. Guillochon-Petitcuenot<sup>1</sup>, G. Bierry<sup>2</sup>, F. Maurier<sup>3</sup>, N. Afif<sup>4</sup>, L. Messer<sup>5</sup>, J.-E. Gottenberg<sup>1</sup>, J. Sibilia<sup>1</sup>, A. Meyer<sup>6</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Radiology, Hôpitaux universitaires de Strasbourg, Strasbourg; <sup>3</sup>Internal medicine, Hôpitaux privés de Metz, Metz; <sup>4</sup>Rheumatology, Centre hospitalier de Mulhouse, Mulhouse; <sup>5</sup>Rheumatology, Hôpitaux civils de Colmar, Colmar; <sup>6</sup>Physiology and functional explorations, Hôpitaux universitaires de Strasbourg, Strasbourg, France

**Background:** Arthritis is frequent in antisynthetase syndrome (ASS) but the prevalence, the characteristics and the risk factors of radiographic lesions have been poorly assessed.

**Objectives:** To report prevalence, characteristics and risk factors of radiographic abnormalities in ASS patients with arthralgia.

**Methods:** A mono-centric cohort of 101 patients with ASS and arthralgia was screened for hand X-ray availability. Patients with osteoarthritic lesions were excluded from the analysis. ASS patients with radiographic lesions were compared to ASS patients with normal X-ray.

**Results:** Thirty one patients were included. Thirteen patients (41.9%) had radiographic lesions on hand X-ray, including periarticular calcifications (53.8%), joint pinching (46.1%), erosions (23%), and subluxations (15.3%). Age (54.15±4.5 vs 49.17±3.3 years old, p=0.17) and sex ratio were similar in both groups.

Duration of ASS was two-fold longer at first hand X-ray with radiographic lesion compared to the ASS patient without radiographic lesion at last radiographic

follow-up (10,08±2,4 years vs. 4,83±1,6, p=0,06). However, the cumulative number of immunomodulatory drugs at first hand X-ray with radiographic lesion or last hand X-ray if normal tended to be lower in patients with radiographic lesions (0,818 vs 1,28, p=0,55).

History of extra-articular involvements (including myositis, interstitial lung disease, skin lesions and Raynaud phenomenon) were not different in both groups, although mechanic's hand tended to be less frequent in patients with radiographic lesions (23.1% vs 61.1%, p=0.07).

Patients with radiographic lesions had more frequently anti-EJ (31% vs. 0%, p<0.05). Other anti-tRNA synthetase antibodies were not significantly associated with abnormal hand x-ray which were found in 50% of anti-PL-7 positive patients (2/4), 33,3% of anti-PL-12 positive patients (1/3), 30% of anti-Jo1 positive patients (6/20), and 0/1 anti-OJ positive patient (one patient was positive for anti-Jo1 and anti-PL7). ACPA (27.3% vs 7.1%, p=0.29) and rheumatoid factor (50% vs 14.2%, p=0.09) were more frequently positive in case of radiological abnormality.

**Conclusions:** Hand X-ray lesions are frequent in ASS patients with arthralgia, whatever the extra-articular features and the ASS serotype and was associated is a longer duration of ASS.

**Disclosure of Interest:** None declared

AB0743

#### THE CLINICAL MANIFESTATIONS IN ANTI-RO52 ANTIBODY- POSITIVE PATIENTS WITH SYSTEMIC SCLEROSIS; A RETROSPECTIVE CASE CONTROL STUDY

C. Kawata, S. Miyauchi, M. Kimura, Y. Rikitake, K. Iwao, M. Rikitake, A. Aizawa, T. Kawaguchi, Y. Kariya, M. Matsuda, K. Umekita, K. Takajo, I. Takajo, A. Okayama. Department of Internal Medicine, Rheumatology, Infectious Diseases and Laboratory Medicine, Faculty of Medicine, University of Miyazaki, Miyazaki, Japan

**Background:** Autoantibodies (abs) directed against Ro52/TRIM21 are common in systemic sclerosis (SSc) but their clinical significance remains uncertain. Some reports suggested that anti-Ro52/TRIM21 abs-positive SSc patients present interstitial lung disorders (SSc-ILD). However, it is not clear whether positive for anti-Ro52/TRIM21 related to other clinical manifestations in patients with SSc.

**Objectives:** The aim of this study is to clarify the prevalence of anti-Ro52/TRIM21 abs in patients with SSc. Then, we investigated the clinical manifestations between anti-Ro52/TRIM21 abs-positive and negative patients with SSc.

**Methods:** This study is a retrospective case control study. The medical records of 42 patients who were diagnosed as having SSc admitted to our hospital were reviewed. We evaluated the clinical manifestations at the first-onset of SSc such as Rodnan skin score, digital ulcer, abnormal subcutaneous calcification, esophageal reflux, pulmonary hypertension, myositis and arthralgia. Co-existing rheumatic diseases were also reviewed such as Sjogren syndrome (SjS), rheumatoid arthritis (RA), and polymyositis. All subjects underwent SSc-associated abs testing using EUROLINE immunoblot assay. The autoantibodies include anti-Scl-70, anti-centromere A and B (CENP-A, CENP-B), anti-RNA polymerase III (RP-11, RP-155), anti-fibrillarin (U3RNP), anti-90-kd nucleolar protein (NOR-90), anti-Th/To, anti-PM/Scl-100, anti-PM/Scl-75, anti-Ku, anti-platelet-derived growth factor receptor (PDGFR), and tripartite motif-containing protein 21 (Ro-52). The association between clinical features and autoantibody profile was evaluated. Diagnosis of ILD was evaluated by chest high-resolution CT (HRCT).

**Results:** Thirty-five patients with SSc are female (87%). Twenty-one and nine patients with SSc are positive and negative for anti-Ro52/TRIM21 abs, respectively (47 v.s 52%). There is no difference in population of diffuse type of SSc between anti-Ro52/TRIM21 abs-positive and negative SSc patients. In addition, the prevalence of ILD is not different between two groups (57 v.s 52%, p=0.76). The prevalence of SjS is tended to be higher in anti-Ro52/TRIM21 abs-positive SSc patients than in negative SSc patients (68 v.s 33%, p=0.05). Unexpectedly, 57% of anti-Ro52/TRIM21 abs-negative SSc patients present polyarthralgia at the onset of SSc. In addition, there were not any complications such as osteoarthritis and RA in anti-Ro52/TRIM21 abs-negative SSc patients. The prevalence of arthralgia was higher in anti-Ro52/TRIM21 abs-negative SSc patients than in positive SSc patients (p=0.02).

**Conclusions:** The prevalence of anti-Ro52/TRIM21 abs in SSc patients of this study seems to be high compared to other reports. In addition, there seems to be no difference in the prevalence of ILD regardless of existence of anti-Ro52/TRIM21 abs in SSc patients. Anti-Ro52/TRIM21 abs-negative SSc patients were tended to present polyarthralgia. This musculoskeletal disorder of anti-Ro52/TRIM21 abs-negative SSc patients may be not associated with other rheumatic diseases such as SjS and RA in this study. It is necessary the large number study to clarify whether anti-Ro52/TRIM21 abs involve in the pathogenesis of musculoskeletal disorders in patients with SSc.

**AB0744** A "LOST-TO-FOLLOW-UP" AUTOANTIBODY FOR THE DIAGNOSIS OF AUTOIMMUNE DISEASE: PREVALENCE AND CLINICAL CHARACTERISTICS OF ANTI-NOR90/HUBF POSITIVE PATIENTS

C. Koutsianas<sup>1</sup>, K. Levasseur<sup>2</sup>, M. Rutter<sup>1</sup>, C. Webber<sup>3</sup>, M. Bhole<sup>3</sup>, C. Bell<sup>2</sup>, K. Douglas<sup>1</sup>. <sup>1</sup>Department of Rheumatology, The Dudley Group NHS Foundation Trust, Dudley; <sup>2</sup>Department of Rheumatology, Worcestershire Acute Hospitals NHS Trust, Worcester; <sup>3</sup>Department of Immunology, The Dudley Group NHS Foundation Trust, Dudley, UK

**Background:** Anti-nuclear antibody (ANA) patterns in indirect immunofluorescence testing (IIF) have been valuable in the diagnosis of autoimmune diseases. A pattern of speckling with fluorescent mitotic dots is considered to represent autoantibodies against nucleolar organising regions (NORs). Anti-NOR90 antibodies target the human upstream binding factor (hUBF) which activates RNA polymerase I-activated ribosomal RNA transcription. They have been anecdotally associated with systemic sclerosis (SSc), Sjögren's Syndrome (pSS) and rheumatoid arthritis (RA).

**Objectives:** To analyse the prevalence and clinical characteristics of patients found to be anti-NOR90 positive by immunology at The Dudley Group NHS FT (DGH) which also serves Worcestershire Acute Hospitals NHS Trust (WAH).

**Methods:** Clinical letters and electronic patient records of anti-NOR90 positive patients identified in the DGH immunology laboratory between July 2016 and October 2017 were reviewed. Advice was sought regarding ethical approval and consent; this was deemed unnecessary for this clinical survey. Anonymized patient data was collected on Excel. Anti-NOR90 was tested for when the characteristic ANA pattern was observed and as part of an extended SSc blot (EUROLINE SSc (Nucleoli) profile (IgG) – EUROIMMUN).

**Results:** We identified 11 anti-NOR90 positive patients among 8000 positive ANA results (estimated prevalence 0.0137%). Patient demographics, diagnoses and immunology are illustrated in table 1. Patients were in their vast majority female (10/11, 91%) and had a median age of 63 (IQR:53–74) years. The median anti-NOR90 titer was 111 (IQR:14–139) intensity units. 6/11 (54.5%) had a confirmed diagnosis of rheumatic disease. The most common clinical features were Raynaud's phenomenon (63.6%), sicca symptomatology (36.4%) and polyarthritis (36.4%). Interstitial lung disease (ILD) and oesophageal dysmotility (OD) were predominant clinical features in two cases (SSc, pSS). In general, patients lacked skin involvement (scleroderma, telangiectasias, calcinosis).

**Abstract AB0744 – Table 1.** Demographic, clinical and immunological characteristics of anti-NOR90 positive patients

Patient	Age/ Sex	Diagnosis	Rheumatoid Factor	ANA titre	ANA pattern	anti- NOR90 titre
1	82/F	SSc	-	weak positive	mitotic dots	positive
2	80/ M	pSS	-	1:320	speckled mitotic dots	11
3	35/F	UCTD	-	1:2560	nucleolar with mitotic dots	140
4	63/F	RA	+	weak positive	mitotic dots	positive
5	81/F	Bronchiectasis	-	1:1280	speckled mitotic dots	107
6	18/F	Raynaud's	-	1:1280	mitotic dots	139
7	68/F	Raynaud's	-	1:320	nucleolar with mitotic dots	130
8	56/F	UCTD	+	1:320	mitotic dots	11
9	66/F	Raynaud's	-	negative	negative	14
10	53/F	Raynaud's/ Crohn's disease	-	1:1280	nucleolar +homogenous with mitosis dots	151
11	52/F	Polyarthritis	-	weak positive	mitotic dots	111

**Conclusions:** Literature regarding anti-NOR90 auto-antibodies has been scarce and in the age of automated IIF ANA testing, it is plausible that their specific nucleolar pattern is frequently missed. In our survey, they were observed in the context of several rheumatic diseases and linked to Raynaud's, sicca symptoms and polyarthritis. Studies in larger relevant patient cohorts are needed to further clarify their clinical value.

**AB0745** MECHANICS OF EARLY VENTRICULAR IMPAIRMENT IN SYSTEMIC SCLEROSIS AND THE EFFECTS OF PERIPHERAL VASCULOPATHY

C. Tountas<sup>1,2</sup>, V.-K. Bourmia<sup>1</sup>, S. Panopoulos<sup>1</sup>, A. Goumizakis<sup>2</sup>, D. Beldekos<sup>2</sup>, M. G. Tektonidou<sup>1</sup>, A.D. Protogerou<sup>1</sup>, P.P. Sfikakis<sup>1</sup>. <sup>1</sup>First Department of Propaedeutic and Internal Medicine/Joint Rheumatology Program, "Laikon" Hospital, School of Medicine, National and Kapodistrian University of Athens, Athens; <sup>2</sup>Cardiology Department, Tzaneio Hospital, Piraeus, Greece

**Background:** Multiple mechanisms commonly lead to severe cardiac involvement in systemic sclerosis (SSc), an autoimmune disease characterised by microvascular lesions, systemic inflammation and fibrosis.

**Objectives:** To examine the mechanics of right and left ventricles (RV, LV) at the early stage of possible impairment and test the hypothesis that peripheral arterial hemodynamics are associated with an early LV compromise.

**Methods:** Ninety-five asymptomatic SSc patients free of cardiovascular disease (88% women, 53±14 years) and 54 apparently healthy controls matched for age, gender, arterial hypertension, dyslipidaemia, and diabetes mellitus underwent echocardiography, including multilayer speckle-tracking, and tonometry-based pulse wave analysis of the peripheral arteries; 66 SSc patients were prospectively assessed after 32±7 months. Indices of ventricular and arterial structure and function, as well as LV-arterial coupling, were calculated.

**Results:** At baseline, patients presented RV diastolic/systolic impairment, as well as LV remodelling and diastolic/systolic impairment in terms of reduced deformation parameters versus controls. No association was evident between RV and LV strain within individual patients, whereas by multivariate analysis including age, gender and SSc characteristics we found that the global longitudinal strain of RV free wall was associated only with the presence of diffuse skin involvement (b=2.63, p=0.042) and both global longitudinal and circumferential strain of LV were correlated only with disease duration (b=0.14, p=0.001 and b=0.17, p=0.032, respectively). Both RV and LV abnormalities progressed independently during follow-up. Moreover, in the absence of differences in aortic stiffening and LV-arterial coupling between patients and controls, arterial pressure wave reflections assessing small vessel function and/or microcirculation were abnormal in SSc patients and strongly correlated with impaired indices of LV diastolic function and remodelling.

**Conclusions:** These novel findings show the mechanics of RV early impairment in SSc that develops and progresses independently from the concomitant LV impairment, which, in turn, may be influenced by peripheral microvascular abnormalities in the absence of macrovascular damage.

**AB0746** FREQUENCY AND CLINICAL ASSOCIATION OF RARE ANTIBODIES IN A LARGE CONNECTIVE TISSUE DISEASE COHORT

C. Campochiaro, K. Clark, L. Host, A. Sari, S. Nihtyanova, C. Fonseca, C. Denton, V. Ong. Centre for Rheumatology and Connective Tissue Diseases, The Royal Free Hospital, London, UK

**Background:** Connective tissue diseases (CTDs) are characterised by the presence of specific antibodies (Abs). These are useful in diagnosis and prognostic stratification. Rare Abs have been reported but their clinical significance is currently not as clear.

**Objectives:** to assess the diagnosis, and frequency of clinical features within each rare antibody subgroup in our CTD cohort

**Methods:** The immunology results for 5828 patients obtained over the past 17 years and patients positive for 1 of the rare Abs (Jo-1, PCNA, XR, PL-4, PL-7, PL-12, SRP, Ku, Mi-2, EJ, SL, PmScl, rRNP, Th/To, NuMA-1, OJ and hnRNP) were identified. Diagnosis and frequency of major organ involvement were reported.

**Results:** 758 patients (12.5%) were positive for at >1 rare Abs. Clinical information confirming a diagnosis of a CTD was available for 514 patients. The most frequent rare Ab in our cohort was PmScl (3.10%). The majority of patients had clinical features of overlap syndromes (33.8%), the 2nd most common diagnosis was systemic sclerosis (SSc) (31.10%). Interstitial lung disease (ILD) was more commonly seen in patients with PL-7+ (82.4%), PL-12+ (75%), Jo-1+ (70.8%) and SRP+ (66.7%). ILD was not reported in PCNA+, PL-4+, NuMA-1+ and hnRNP+. Pulmonary arterial hypertension (PAH) was most frequently seen in patients with XR+ (31.8%). Inflammatory myositis (IM) was found in all Jo-1+ and SRP+ patients, and in the majority of PL-7+ (88.2%) patients. Inflammatory arthritis was commonly reported in patients with PCNA+ (57.1%), NuMA-1+ (50.0%) and rRNP+ (40%). Renal involvement was classified as either glomerulonephritis (GMN) or scleroderma renal crisis (SRC). GMN was more common in patients with rRNP+ (60%), PL-4+ (45.4%) and PCNA+ (42.9%) patients. SRC was diagnosed in patients with SL+ (3.2%), PM/Scl+ (5.5%) and Th/To+ (2.5%) (table 1).

**Conclusions:** Our data from a large CTD cohort suggest that rare Abs associate with distinct features in particular ILD and inflammatory myositis. A majority of these patients fulfil the criteria for overlap syndrome and SSc.

### AB0747 INTERSTITIAL LUNG DISEASE IS INDEPENDENTLY ASSOCIATED WITH INCREASED FAECAL CALPROTECTIN LEVELS IN SYSTEMIC SCLEROSIS

C. Caimmi<sup>1</sup>, E. Bertoldo<sup>1</sup>, A. Venturini<sup>1</sup>, P. Caramaschi<sup>1</sup>, L. Frulloni<sup>2</sup>, R. Ciccocioppo<sup>2</sup>, S. Brunelli<sup>2</sup>, L. Idolazzi<sup>1</sup>, D. Gatti<sup>1</sup>, O. Viapiana<sup>1</sup>, M. Rossini<sup>1</sup>.  
<sup>1</sup>Rheumatology Unit, <sup>2</sup>Gastroenterology Unit, University of Verona, Verona, Italy

**Background:** Interstitial lung disease (ILD) is one of the leading cause of death in systemic sclerosis (SSc).

**Objectives:** The aim of this paper was to evaluate the relationship between faecal calprotectin (FC) and ILD.

**Methods:** 129 outpatients with SSc were enrolled. Data about disease characteristics, in particular lung involvement, were collected and FC was measured.

**Results:** Eighty-seven patients (67.4%) had a limited subset with a mean disease duration of 13.3 (7.1) years. Anti-Scl70 antibodies were found in 35 (27.1%) patients. GI tract involvement was severe/end stage in 3 cases (2.4%). ILD affected 35 patients (27.1%). Median levels of FC were 80 µg/g (157 µg/g). FC was found to be higher in patients with a moderate/severe/end stage score for gastrointestinal tract (p=0.046) and on steroids (p=0.015). In addition, it positively correlated with age (p<0.001).

Other than well-known risk factors such as higher mRSS or diffuse subset, patients with ILD had higher values of FC (p<0.001). In multivariate analysis correcting also for factors affecting FC levels (i.e. disease duration, mRSS, Valentini activity score, total Medsger severity score, proton pump inhibitor, anti-Scl-70 antibody, diverticulosis, limited cutaneous subset, faecal calprotectin levels, steroid treatment), diffuse disease subset (p=0.001), higher mRSS (0.04), longer disease duration (0.046), higher severity scores (0.026), higher FC levels (p=0.003) and steroid treatment (0.014) were associated with increased risk of ILD, while diverticulosis was protective. In addition, we ran a second multivariate analysis considering the 110 cases with FC level <275 µg/g, in order to correct for a possible small intestine bacterial overgrowth. Increased FC levels (p=0.019), steroid treatment (p=0.03), higher severity scores (p=0.016) and diffuse disease subset (p=0.002) were confirmed to be associated with ILD.

**Conclusions:** in this paper we have found a possible link between gut inflammation and ILD. Many hypothesis may be done but it is intriguing that these data further support what previously found by other authors (Andreasson et al. 2016), that is a correlation between gut inflammation and dysbiosis and non-gastrointestinal disease manifestation. Our study may support the hypothesis of a role of gut

dysbiosis in triggering a pathologic immune response leading to ILD. It may also be that increased FC simply reflects a more severe disease but this still doesn't explain why only ILD was found to be linked with FC. Is it because lung is a filter of molecule (i.e. antigens, cytokines, metabolites, etc.) produced in the gut? Further studies with longitudinal evaluation are warranted.

**Background:** Systemic sclerosis (SSc) is a disorder with a well-known autoimmune base. There is evidence suggesting a common background with other connective tissue diseases, thus predisposing to the development of other autoimmune disorders in these patients, that is, poliautoimmunity (PAI).

**Objectives:** To assess PAI in a cohort of SSc patients.

**Methods:** A nationwide, cross-sectional study was performed including the 1928 patients enrolled in the Spanish SSc Registry (RESCLE). Ethics Committee approval was obtained by all participating centres.

**Results:** Prevalence of PAI was 45%, with 32% having more than one association. Most of these patients were women (93%, p<0.001), with older age at diagnosis (53.7±14.7 years, p=0.027). Regarding subtypes, PAI was significantly more frequent in limited cutaneous SSc (48%, p=0.004) and pre-SSc (47%, p<0.001). Sjögren's syndrome was by far the most common association (55%), followed by global autoimmune thyroid disorders (31%), autoimmune liver disorders (17%) and inflammatory myopathies (12%). Clinical features are shown on table 1.

**Abstract AB0746 – Table 1.** Diagnosis and clinical features in patients positive for rare antibodies

Abstract AB0748 – Table 1

	TOTAL	ISOLATED SSC	PAI	p
Raynaud's Phenomenon	1826	1005 (55%)	821 (45%)	1.000
Digital ulcers	745	408 (55%)	337 (45%)	0.888
Calcinosis	322	142 (44%)	180 (56%)	<0.001
Arthritis	270	128 (47%)	142 (53%)	0.064
Myositis	172	37 (22%)	135 (78%)	<0.001
Gastrointestinal involvement	1222	632 (52%)	590 (48%)	<0.001
ILD	795	399 (50.2%)	396 (49.8%)	<0.001
PH confirmed by right heart catheterisation	148	66 (45%)	82 (55%)	0.438
Heart involvement	409	196 (48%)	213 (52%)	0.001
Scleroderma renal crisis	43	27 (63%)	16 (37%)	0.353

We found no significant differences concerning capillaroscopy patterns, or causes of death, neither SSc-related nor non-SSc-related.

Finally, a multivariate analysis with logistic regression was performed to evaluate the risk factors for PAI, which are shown on the table 2.

Abstract AB0748 – Table 2

Variables	Multivariate analysis OR (95% I.C.)	p value
Gender	2,72 <sup>1,87-3,98</sup>	<0001
Age at dianosis	1,01 <sup>1,00-1,02</sup>	0012
Calcinosis	1,63 <sup>1,23-2,16</sup>	<0001
ILD	1,37 <sup>1,08-1,73</sup>	<0001
Gastrointestinal involvement	1,32 <sup>1,05-1,66</sup>	0019
Centomere Ab	1,41 <sup>1,12-1,77</sup>	<0001
Ro Ab	1,61 <sup>1,18-2,18</sup>	<0001

**Conclusions:** PAI in SSc is a frequent condition that special attention in these patients. We found a rather higher prevalence compared with those published in the literature, even though the distribution of those associated disorders was similar. In our cohort, there were no remarkable differences between both groups concerning clinical manifestations (although not always statistically significant). Finally, certain circumstances should make us aware of a possible associated condition to SSc.

#### AB0749 DON'T FORGET THE CAREGIVERS OF PATIENTS WITH SYSTEMIC SCLEROSIS

M. Boonstra<sup>1</sup>, D.F. Stoop<sup>1</sup>, T.W. Huizinga<sup>1</sup>, T.P. Vliet Vlieland<sup>2</sup>, J.K. de Vries-Bouwstra<sup>1</sup>. <sup>1</sup>department of Rheumatology; <sup>2</sup>department of Orthopedics, Leiden University Medical Center, Leiden, Netherlands

**Background:** Systemic sclerosis (SSc) is a disease with considerable physical and psychosocial impact. Previous studies among partners of patients with other chronic diseases, such as Parkinson's and stroke, showed that 6%–25% of caregivers experience high levels of stress related to caregiving. To our knowledge, the burden experienced by caregivers of patients with SSc has not been determined so far.

**Objectives:** To evaluate perceived strain, quality of life and health care needs among SSc caregivers.

**Methods:** During a patient information meeting, companions of SSc patients were invited to complete 3 questionnaires: 1. The Caregiver Strain Index questionnaire (CSI), in which a score  $\geq 7$  indicates high care burden, 2. Short Form-36 (SF-36): a measure of self-reported Quality of Life (QoL) and 3. a self-designed questionnaire on the needs and preferences for caregiving support. Caregivers with and without high care burden were compared regarding their general characteristics and QoL.

**Results:** Thirty-six SSc caregiver filled out questionnaires (n=31 completed the CSI questionnaire). Respondents were mostly men (64%), on average 62 years old (SD 14), 35% (n=11) had a paid job, and 50% (n=18) suffered from chronic disease. The majority was in a spousal relationship (75%) with the SSc patient and 56% of patients had been diagnosed with SSc more than 5 years ago. Nineteen percent of patients (n=7) needed daily personal caregiving and 25% (n=9) was

transport-dependent. Median CSI was 2 (range 0 to 5), and 6/31 (19%) perceived high care burden (CSI  $\geq 7$ ). Caregivers with high care burden were significantly more often involved in daily personal caregiving of the patients (3/6 vs. 2/25). Although not statistically significant, all caregivers perceiving a high burden were spouses, while the remaining caregivers had varying relationships with SSc patients. SF-36 summary scale scores were similar in both groups (table 1). Regarding needs and preferences of caregivers, 15% (n=5) reported a need for additional individual information, and 21% (n=7) a need for contact with fellow caregivers of patients, preferably during information meetings.

Abstract AB0749 – Table 1. Characteristics of caregivers of SSc patients with and without high care burden (CSI  $\geq 7$ ).

	Total (n=36)	CSI<7 (n=25)	CSI $\geq 7$ (n=6)	p-value
CSI, median (IQR)	2.0 (0.0–5.0)**	2.0 (0.0–4.0)	8.0 (7.0–8.0)	n.a.
Gender, n (% female)	13 (36)	10 (40)	1 (17)	0.383 <sup>1</sup>
Age (years, median (IQR))	65.5 (53.8–72.0)	66.0 (51.0–73.0)	63.5 (56.8–66.0)	0.448 <sup>2</sup>
Relationship (%)				
Partner	27 (75)	18 (72)	6 (100)	0.293 <sup>1</sup>
Father/mother	2 (6)	2 (8)	0 (0)	
Friend	2 (6)	1 (4)	0 (0)	
Son/daughter	4 (11)	4 (16)	0 (0)	
Involved in daily personal caregiving patient SSc (%)	7 (19)*	2 (8)	3 (50)	0.038 <sup>1</sup>
Transport dependency patient SSc (%)	9 (25)*	5 (20)	2 (33)	0.596 <sup>1</sup>
SF –36 (mean $\pm$ SD)				
Physical component score	50.9 $\pm$ 7.2***	51.2 $\pm$ 7.0****	53.6 $\pm$ 3.4	
Mental component score	43.7 $\pm$ 6.8***	43.4 $\pm$ 7.8****	42.9 $\pm$ 3.8	

<sup>1</sup> Fisher's exact <sup>2</sup> Mann-Whitney U \*n=35, \*\*n=31, \*\*\*n=28, \*\*\*\*n=19

**Conclusions:** Within a small group of SSc caregivers, 19% experienced high care burden. In particular caregivers involved in personal caregiving seem to be at risk for increased strain related to caregiving. The results of the current study can direct clinical practice aiming at support of the caregivers.

**Disclosure of Interest:** None declared

#### AB0750 RHEUMATIC DISEASES WITH LUNG INVOLVMENT AND PSYCHOLOGICAL STATUS

D. Abdulganjeva, N. Shamsutdinova, G. Nurullina, E. Kirillova, E. Makaricheva, A. Krasnov, A. Surikov. *Kazan State Medical University, Kazan, Russian Federation*

**Objectives:** assess the impact of psychological status indicators on lung function in patients with rheumatic diseases with lung lesions

**Methods:** A study of 30 patients with diagnoses of systemic sclerosis (SSD) – 14 patients, systemic vasculitis (CB) – 10, rheumatoid arthritis (RA) – 6 patients.

The average age of the patients was 56.55 $\pm$ 10.59 (from 22 to 77 years). All patients had high activity of the underlying disease and received pathogenetic therapy in the form of pulse therapy for HA – 19 patients, high doses of HA (1 mg/kg) per os – 11 patients; were hospitalised in connexion with the first detected lung lesions or signs of progression of the existing lung injury (increased dyspnea, reduced exercise tolerance). Patients are consulted by a cardiologist to exclude the cardiac genesis of symptoms.

All patients underwent a standard clinical examination, in addition they performed: high-resolution RCT of lung (64-slice CT system Philips Diamond Select Brilliance), a 6 min walk test.

Evaluation of lung function was carried out using spirometry, bodiplotzomography, diffusion "single breath".

The following scales were used to assess the psychological status: State-Trait Anxiety Inventory (STAI) personal and situational anxiety assessment, symptomatic questionnaire SCL-90-R (English Symptom Check List-90-Revised), anxiety and depression, the Toronto Alexitimic Scale (TAS)

**Results:** All patients according to RKT data had manifestations of IZL in the form of nonspecific interstitial pneumonia. Among the patients examined, the group with DV 1st. was 11 patients, DN 2 tbsp. – 14 patients, DN 3 tbsp. – 5 patients. A high level of situational anxiety was present in 11 patients (36.7%), personal – in 13 patients (43.3%). At the same time, the DLCO relationship to the alveolar volume was identified with the level of personal anxiety ( $r=-0.526$ ,  $p<0.05$ ) and situational ( $r=-0.423$ ,  $p<0.05$ ). In addition, the DV index has an average correlation with the level of anxiety ( $r=0.513$ ,  $p<0.05$ ). The symptomatic questionnaire revealed a significant degree of somatization in patients with IBD – in 14 patients

(46.7%), which is the somatic equivalent of depression and anxiety. TAS data indicate the presence of apparent alexithymia in 10 patients (33.3%), the "risk group" for alexithymia is 26.7%.

In addition, saturation after a 6 min walk was correlated with alexithymia ( $r = -0.526$ ,  $p < 0.05$ ).

**Conclusions:** The psychological status of patients with rheumatic diseases with lung involvement in the form of nonspecific interstitial pneumonia is characterised by depression, anxiety, alexithymia.

**Disclosure of Interest:** None declared

#### AB0751 THE EPSTEIN-BARR VIRUS INFECTION IN SYSTEMIC SCLEROSIS

G. Efthymiou<sup>1</sup>, C. Liaskos<sup>1</sup>, E. Marou<sup>1</sup>, E. Dardiotis<sup>2</sup>, V. Tsimourtou<sup>2</sup>, T. Scheper<sup>3</sup>, W. Meyer<sup>3</sup>, D.P. Bogdanos<sup>1</sup>, G. Hadjigeorgiou<sup>2</sup>, L.I. Sakkas<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, <sup>2</sup>Neurology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece; <sup>3</sup>Institute of Immunology, EUROIMMUN, Lübeck, Germany

**Background:** Epstein-Barr virus (EBV) infection has been considered trigger of various autoimmune diseases, including systemic sclerosis (SSc), mainly due to studies investigating cross-reactive responses amongst EBV and disease-specific antigens. Meticulous assessment of antibody reactivities to the most immunodominant EBV antigens in SSc has not been performed.

**Objectives:** To assess ab reactivity against EBV viral capsid antigens (VCA), early antigens (EA) and EBNA-1 in SSc, and investigate their clinical relevance.

**Methods:** Sera from 59 SSc patients, including 31 diffuse SSc (dcSSc) and 28 limited SSc (lcSSc), 43 matched multiple sclerosis (MS) as controls and 32 matched healthy controls (HC) were tested for IgG anti-EBV VCA, EA and EBNA-1 abs by immunoblotting, using EBV whole SDS extract as antigen substrate.

**Results:** Percentages of EA and EBNA-1 reactivities were significantly higher in SSc patients compared to HC (EA: 33.9% vs 3.1%,  $p = 0.001$ ; EBNA-1: 89.8% vs 68.8%,  $p = 0.012$ ), but were comparable between SSc and MS. These differences remained when SSc was divided in dcSSc and lcSSc (EA: 32.3% in dcSSc and 35.7% in lcSSc,  $p_{dcSSc vs HC} = 0.002$ ,  $p_{lcSSc vs HC} = 0.001$ ; EBNA: 92.9% in lcSSc,  $p_{lcSSc vs HC} = 0.020$ ). VCA positivity was comparable between SSc or its two subgroups and MS or HCs. Also, triple positivity for all three antigen categories was observed more frequently in SSc, dcSSc and lcSSc compared to HCs (32.2% in SSc, 29% in dcSSc and 35.7% in lcSSc vs 3.1% in HC,  $p = 0.001$ ,  $p = 0.004$  and  $p = 0.001$ , respectively). Anti- EA was present more frequently in SSc patients with calcinosis compared to those without (75% vs 27.5%,  $p = 0.014$ ) and tended to be more frequent in patients with pulmonary fibrosis compared to those without (47.8% vs 25%,  $p = 0.071$ ).

**Conclusions:** Antibodies against EBV appear to be more frequent in SSc than in healthy controls, and equally prevalent with MS, a disease known to be associated with anti-EBV antibody responses and a known risk factor for MS. Whether an EBV-specific response is also an initiating trigger of SSc remains to be investigated.

#### AB0752 CLINICAL FEATURES OF SYSTEMIC SCLEROSIS ASSOCIATED TO ANTI RNA POLYMERASE III ANTIBODIES IN VALLD'HEBRON HOSPITAL

E.L. Callejas-Moraga<sup>1</sup>, A. Guillén-Del-Castillo<sup>2</sup>, A. Marín-Sánchez<sup>2</sup>, V. Fonollosa-Plá<sup>2</sup>, E. Balada<sup>2</sup>, J. Martín<sup>3</sup>, C.P. Simeón-Aznar<sup>2</sup>. <sup>1</sup>Internal Medicine, Parc Taulí Hospital; <sup>2</sup>Internal Medicine, Hospital Vall d'Hebron, Barcelona; <sup>3</sup>Instituto de Parasitología, Instituto de Parasitología y Biomedicina López Neira, Granada, Spain

**Objectives:** Systemic sclerosis (SSc) is an autoimmune disease whose clinical features are related closely with the specific autoantibody that is expressed. The main objective was to analyse the clinical characteristics of patients with positive anti-RNA polymerase III antibody (anti-RNAP III) and compare them with patients who were negative.

**Methods:** We analysed 221 patients with SSc who visited Vall d'Hebron Hospital from 1980 to 2016. 26 patients who were positive were compared with 195 who were negative. Different epidemiological, clinical, capillaroscopic and immunological variables were analysed.

Data from the Vall d'Hebron Hospital cohort were collected from patients diagnosed with ES since 1980. 24 patients with positive anti-RNAP III antibodies were

selected using the technique of immunoblot on paper or enzyme immunoassay and were compared with 151 who were negatives. Different epidemiological, clinical, capillaroscopic and immunological variables were analysed. Statistical analysis was performed using SPSS 20.0. Statistical significance was considered  $p < 0.05$ .

**Results:** 24 patients (13.7%) showed anti-RNAP III reactivity. Female sex (151, 86.3%) was the most frequent. There were no differences in the age at onset of the disease ( $40.3 \pm 15.9$ ) or in the age at diagnosis ( $46.6 \pm 15.7$ ). Diffuse cutaneous (Dc) subtype was more frequent in the anti-RNAP III group (70% vs 16.6%  $p < 0.001$ ). Patients with positive anti-RNAP III met the ACR/EULAR 2013 diagnostic criteria more frequently (24, 100% vs. 118, 78.1%  $p < 0.01$ ). Regarding the first manifestation, Raynaud's phenomenon was less frequent in the anti-RNAP III group (13, 54.2% vs. 121, 80.1%  $p < 0.01$ ). Regarding to vascular features, there were no differences in digital ulcers (15, 62.5% vs. 66, 43.7%,  $p = 0.08$ ), in the presence of Raynaud's phenomenon (24, 100% vs. 145, 96.7%) or telangiectasias (18, 75% vs. 102, 67.5%). There were no differences with respect to the overall digestive involvement (21, 87.5 vs. 124, 82.1%) No differences were found in cardiac involvement in both groups (9, 37.5% vs. 51, 47%). Scleroderma renal crisis (SRC) was significantly more frequent in patients with anti-RNAP III (3, 12.5% vs. 3, 1.9%  $p = 0.03$ ). There were no differences in prevalence of cancer (4, 16.7% vs. 12, 7.9%  $p = 0.24$ ). There were no differences in mortality (2, 8.3% vs. 16, 10.6%). The slow-type capillary pattern of Maricq was the most frequent in both groups (20, 83.3% vs. 132, 87.4%). Regarding the expression of other auto-antibodies, anti-Ro52 positivity was less frequent in patients with anti-RNAP III (2, 8.2% vs. 14, 9.3%  $p = 0.03$ ).

**Conclusions:** Patients with ES who presented positivity for anti-RNA polymerase III antibodies had more frequent onset manifestations different from the Raynaud's phenomenon, more DcSSc subtype and higher frequency of SRC. Regarding positivity against other antibodies, they expressed less reactivity to anti-Ro 52 than patients without anti-RNA pol III antibodies.

**Disclosure of Interest:** None declared

#### AB0753 COMPARATIVE STUDY OF SYSTEMIC SCLEROSIS WITH OTHER AUTOIMMUNE DISEASES FOR HEALTH-RELATED QUALITY OF LIFE

E.H. Park<sup>1</sup>, V. Strand<sup>2</sup>, Y.J. Oh<sup>1</sup>, H. Kwon<sup>3</sup>, Y.W. Song<sup>1</sup>, E.B. Lee<sup>1</sup>. <sup>1</sup>Seoul National University Hospital, Seoul, Korea, Republic of Ireland; <sup>2</sup>Stanford University, California, USA; <sup>3</sup>Gangnam Sungshim Hospital, Seoul, Korea, Republic of Ireland

**Background:** Systemic sclerosis (SSc) is a rare autoimmune disease characterised by fibrosis of the skin and multiple internal organ involvement. Previous studies reported a poorer health-related quality of life (HRQoL) in patients with SSc compared to the general population. However, very little is known about HRQoL of SSc as compared with other systemic autoimmune diseases, including rheumatoid arthritis (RA), systemic lupus erythematosus (SLE), and Sjogren's syndrome (SJS)

**Objectives:** To compare the HRQoL of patients with SSc and other systemic autoimmune disease and general population.

**Methods:** HRQoL was captured by the Korean short form-36 health survey version 2 (SF-36), short form-6D (SF-6D) and 3 level version of EuroQol five-dimensional (EQ-5D) descriptive system (EQ-5D-3L). Between March and July 2017, consecutive patients with SSc, and randomly chosen patients with RA, SLE and SJS were recruited from the outpatient rheumatology clinics of Seoul National University Hospital, and were asked to answer SF-36 and EQ-5D. Disease activity of RA was evaluated by Disease Activity Score 28-ESR (DAS 28-ESR), SLE by Systemic Lupus Erythematosus Disease Activity Index-2k (SLEDAI-2k), and SJS by EULAR Sjogren's syndrome disease activity index (ESSDAI). For patients with SSc, Korean version of Health Assessment Questionnaire Disability Index (HAQ-DI) and Systemic sclerosis HAQ-DI (SSc HAQ-DI) were also evaluated. Demographic, clinical, laboratory information were obtained through a medical chart review. Data on representative Korean healthy controls were obtained from a study of psychometric properties of the Korean SF-36 v2 for assessing the general population, which was performed on six hundred healthy Koreans.

**Results:** A total of 480 patients with SSc (n=120), RA (n=120), SLE (n=120) and SJS (n=120) and 600 healthy controls were included. The demographic features of patients were similar to the known features of each rheumatic disease group. Patients with rheumatic diseases had significantly lower SF-36 scores ( $p < 0.001$  in all domains), SF-6D scores ( $p < 0.001$ ), EQ-5D-3L index scores and EQ-VAS ( $p < 0.001$ ) than the healthy controls; adjustments for age and sex did not change those results. Patients with SSc showed significantly lower scores in the mental component summary scores compared with patients with RA (age and sex-adjusted scores,  $43.0 \pm 0.9$  vs  $48.9 \pm 0.9$ ;  $p < 0.001$ ). Specifically, domain of mental health was lower in SSc patients than RA patients (age and sex-adjusted scores,  $61.3 \pm 1.8$  vs  $71.7 \pm 1.8$ ,  $p < 0.001$ ). Among the physical domains scores, SSc

patients showed lower score in general health domain than RA patients (age and sex-adjusted scores,  $41.4 \pm 1.8$  vs  $51.3 \pm 1.8$ ,  $p < 0.001$ ). Moreover, SSc patients reported remarkably lower scores of EQ-5D-3L index scores than all comparative rheumatic disease groups (RA, SLE, SJS) ( $p < 0.001$ ). HRQoL of patients with SSc was associated with HAQ-DI and SSc HAQ-DI.

**Abstract AB0753 – Table 1.** Comparisons of the SF-36, SF-6D and EQ-5D-3L, adjusted by age and sex in study subjects.

	Group					Anova <sup>1</sup>
	SSc (N=128)	RA (N=120)	SLE (N=128)	SJS (N=120)	Control (N=600)	
Physical function	70.5 (2.2)	70.3 (2.2)	68.2 (2.2)	73.9 (2.2)	82.4 (1.0)	<0.001
Role-physical	67.8 (2.3)	70.5 (2.3)	65.8 (2.3)	68.6 (2.4)	86.3 (1.1)	<0.001
Bodily pain	61.3 (2.2)	61.4 (2.2)	66.1 (2.2)	63.1 (2.3)	81.4 (1.0)	<0.001
General health	41.4 (1.1) <sup>2</sup>	51.3 (1.1)	44.2 (1.1)	45.8 (1.1)	61.9 (0.8)	<0.001
Vitality	53.2 (1.0)	51.8 (1.0)	49.7 (1.0)	45.8 (1.0)	64.4 (0.9)	<0.001
Social function	72.4 (2.1)	77.8 (2.1)	74.6 (2.1)	71.3 (2.1)	87.1 (1.0)	<0.001
Role-emotional	68.4 (2.3)	77.2 (2.3)	72.7 (2.3)	69.6 (2.4)	87.7 (1.1)	<0.001
Mental health	61.3 (1.1) <sup>2</sup>	71.7 (1.1)	67.2 (1.0)	63.7 (1.1)	75.2 (0.8)	<0.001
Physical component score	44.6 (0.3)	45.3 (0.3)	44.3 (0.3)	46.9 (0.3)	51.9 (0.4)	<0.001
Mental component score	43.0 (0.9) <sup>2</sup>	48.9 (0.9)	46.6 (0.9)	44.2 (0.9)	59.1 (0.5)	<0.001
SF-6D	0.70 (0.01)	0.73 (0.01)	0.72 (0.01)	0.71 (0.01)	0.79 (0.00)	<0.001
EQ-5D-3L index score	0.75 (0.01) <sup>2</sup>	0.81 (0.01)	0.82 (0.01)	0.83 (0.01)	0.90 (0.01)	<0.001
EQ VAS	63.98 (1.55)	69.95 (1.56)	67.49 (1.55)	64.84 (1.56)	77.88 (0.72)	<0.001

**Conclusions:** HRQoL of patients with systemic autoimmune diseases is significantly worse and affects all health domains in comparison to healthy controls. Patients with SSc have poorer HRQoL than patients with other rheumatic diseases. Specifically, SSc patients have more impaired mental health than RA patients, and the perception of an individual's general health is also poor compared to RA.

#### AB0754 LONG-TERM FOLLOW-UP OF 214 PRIMARY RAYNAUD'S PHENOMENON PATIENTS

F.M. Ortiz Sanjuan, C. Alcañiz Escandell, K.R. Arevalo Ruales, I. Chalmeta Verdejo, M. De la Rubia. Navarro, C. Fedec Olmos, J.J. Frago Gil, R. Gonzalez Mazario, L. Gonzalez Puig, E. Labrador Sánchez, I. Martinez Cordellat, R. Negueroles Albuixech, E. Grau Garcia, J. Ivorra Cortés, J.E. Oller Rodriguez, E. Vicens Bernabeu, C. Najera Herranz, I. Canovas Olmos, J.A. Roman Ivorra. *Rheumatology Department, HUP La Fe, Valencia, Spain*

**Background:** Raynaud's phenomenon (RP) is frequently associated with the presence of scleroderma or other connective tissue diseases (CTD). Identify the presence of secondary RP is important to perform an adequate therapeutic management and to achieve the early control of these patients. Nailfold capillaroscopy is safe, economic, and relatively easy to perform and has proven to be useful in identifying patients with secondary RP.

**Objectives:** To assess a long-term follow-up primary RP patient's series.

**Methods:** Retrospective observational study of a wide and unselected series of patients diagnosed as primary RP from a single university hospital from January 2012 to August 2017. Patients were classified as primary RP after the presence of CTD at the onset was excluded.

**Results:** We studied 214 patients (85.98% were female), with a mean age of  $47.6 \pm 16.7$  years (range 15–88). After a mean follow-up period of  $46.4 \pm 23.3$  months, 8 patients were diagnosed of a CTD (2 Scleroderma/Systemic sclerosis, 3 Systemic Lupus Erythematosus, 1 Rheumatoid arthritis and 2 Sjogren's syndrome). The remaining 206 patients continued classified as primary RP.

The main capillaroscopic patterns observed were: Normal ( $n=157$ ), unspecific ( $n=49$ ), scleroderma pattern ( $n=2$ ) and suggestive of other rheumatic diseases pattern ( $n=6$ ).

All patients who developed a CTD during the follow-up, showed changes in successive nailfold capillaroscopic examinations. 20 of 206 patients who remained primary RP showed minor changes at successive nailfold capillaroscopy. The main capillaroscopic changes detected on this group were: presence of capillary tortuosity ( $n=4$ ), presence of a decreased capillary density<sup>2</sup> and the presence of capillary bleeding ( $n=16$ ).

Antinuclear antibodies (ANA) were positive at the onset in 34 patients and after follow-up in 39 patients.

**Conclusions:** After a mean follow-up period next to four years, most of our primary RP patients remained free of CTD. A minority of our patients showed changes at nailfold capillaroscopy exam or positivity of ANA.

**Disclosure of Interest:** None declared

#### AB0755 SKIN SCORE PROGRESSION AFTER DISCONTINUATION OF MYCOPHENOLATE TREATMENT IN SYSTEMIC SCLEROSIS PATIENTS

F.A. Mendoza<sup>1</sup>, C.P. Lee Ching<sup>1</sup>, S.A. Jimenez<sup>2</sup>. <sup>1</sup>Scleroderma Center and Division of Rheumatology; <sup>2</sup>Scleroderma Center and Jefferson Institute of Molecular Medicine, THOMAS JEFFERSON UNIVERSITY, Philadelphia, USA

**Background:** Rapid progressive skin involvement in diffuse Systemic Sclerosis (rp-dcSSc) is associated with higher mortality and internal organ involvement. Treatment with Mycophenolate Mofetil (MMF) has been shown to halt the progression of the disease. However, the optimal duration of therapy is unknown and has not been studied. We follow up a known cohort of rp-dcSSc patients treated with MMF after discontinuation of therapy.

**Objectives:** To describe the progression of skin involvement in rp-dcSSc patients after discontinuation of MMF

**Methods:** Twenty-five previously untreated consecutive patients with recent-onset (<24 mo) rp-dcSSc received MMF as the only disease-modifying therapy. Their Modified Rodnan skin score (mRSS) and Pulmonary function tests were followed after discontinuation of MMF after 2 years of treatment. Patients were followed up every 3–6 months. Therapy was re-initiated if their mRSS increased more than 20% or worsening respiratory symptoms with progression of restrictive lung disease were reported.

**Results:** Six patients lost follow up after terminating the open label trial with MMF. From the 19 patients followed up after MMF discontinuation, 26.3%<sup>5</sup> required to resume MMF. All these patients required to resume MMF within 6 months after discontinuation. All of them presented increase in mRSS. Two of them (10.5%) presented respiratory symptoms associated with restriction pattern at PFTs. Skin score returned to baseline in 80% of the patients after resuming therapy.

**Abstract AB0755 – Figure 1.** mRSS after MMF discontinuation.

**Conclusions:** Recurrent skin progression occurs in up to 26.3% of patients with rp-dcSSc after discontinuation of 2 years of MMF, requiring longer term immunosuppression. In this group, all patients presented active skin disease recurrence within 6 months of treatment discontinuation. Ergo, slow decrease of MMF dose over time and very close follow up is recommended in patients with rp-dcSSc discontinuing MMF even after a prolonged period of time. In addition, these findings support the therapeutic effect of MMF in rp-dcSSc.

**AB0756** **MDA 5 DERMATOMYOSITIS AND RESPONSE TO RITUXIMAB IN A SMALL COHORT AT OUR INSTITUTION**

F. Berianu, V.J. Maya, B. Wang. *MAYO CLINIC, Jacksonville, USA*

**Background:** Treatment for anti-melanoma differentiation-associated gene 5 antibody (MDA 5) Dermatomyositis is posing challenging to clinician and there is currently no consensus on therapy. The MDA5 was recently classified as a myositis-specific antibody (MSA), and has been associated with rapidly progressive interstitial lung disease (ILD), amyopathic dermatomyositis (ADM), mechanic's hands, ulcerations, inflammatory arthritis, and increased mortality.

**Objectives:** This study sought to characterised response to Rituximab in a small cohort of patients with MDA 5 DM at our institution.

**Methods:** A retrospective chart review was done to identify all MDA5 positive patients who were evaluated at our centre from 2015 to 2017 with suspected myositis and had myositis-associated autoantibodies tested using a commercial panel (MyoMarker Panel 3). For all patients who were positive for MDA5, we collected clinical information on the presence of myopathy, skin involvement and ILD, data on the autoantibody profile, PFTs and high resolution CT pattern along with therapy response.

**Results:** 11 were positive for MDA5. 7 were females and 4 were males, with mean age 56.6 years. Eight patients were treated with Rituximab from which seven had ILD at presentation: 4 NSIP, 2 with organising pneumonia, one had UIP and one had fatal acute interstitial pneumonitis 2 months after onset of mechanics' hands and inflammatory arthritis. Three patients without ILD were treated with other DMARDs.

All had responded well to Rituximab with improvement in skin ulceration, inflammatory arthritis and mechanics' hands and most patients had stable ILD except for one patient with fulminant interstitial pneumonitis for with Cytoxan was added without any additional benefit.

**Conclusions:** Rituximab is a good management option for all manifestation of MDA 5 DM. Further studies are needed to elucidate the association of MSA and the clinical manifestations and response to treatment response of patients with inflammatory myopathies.

**AB0757** **PERSISTENT CRP ELEVATION IS ASSOCIATED WITH HIGH MORBIDITY IN SYSTEMIC SCLEROSIS**

A. Mitev<sup>1</sup>, D. Feldmann<sup>1</sup>, A.-M. Kanne<sup>1</sup>, T. Hugel<sup>2</sup>, P.M. Villiger<sup>3</sup>, R.E. Voll<sup>1</sup>, S. Finzel<sup>1</sup>, F. Koller<sup>3</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany; <sup>2</sup>Service de rhumatologie, CHUV, Lausanne; <sup>3</sup>Rheumatology, Immunology and Allergology, University Hospital Bern Inselspital, Berne, Switzerland

**Background:** Elevated levels of C-reactive protein (CRP) in systemic sclerosis (SSc) have been linked to early inflammatory stages of the disease.

**Objectives:** This study has been set to investigate CRP levels in a longitudinal cohort of SSc patients and to correlate these findings to comorbidities and disease characteristics.

**Methods:** In this retrospective study patients with SSc were recruited from the outpatient clinic of the Department of Rheumatology and Clinical Immunology, University Medical Centre Freiburg. Only patients with at least three consecutive visits at our centre over at least one year were included in this study. CRP serum levels were measured at every visit and categorised as positive if CRP concentrations were  $\geq 5$  mg/L. Subjects with elevated CRP levels at more than 80% of visits

were defined as being persistently positive. The longitudinal CRP profile was correlated to comorbidities and disease characteristics.

**Results:** A total of 1852 consecutive visits of 131 SSc patients were analysed. Over the observed time span (91<sup>136–56</sup> months) 19% (n=25) of patients had continuously elevated CRP levels, whereas in 29% (n=38) CRP levels were always in the normal range. There was no association between disease duration and CRP levels at first visit ( $p>0.5$ ). Persistent CRP elevation was associated ( $p<0.05$ ) with anti-topoisomerase I-antibodies, diffuse cutaneous SSc (dcSSc), modified Rodnan skin score (mRSS), pulmonary fibrosis, and cardiac arrhythmia, whereas no associations with arthritis or malignancy were found ( $p>0.1$ ). In a patient with dcSSc and persistent elevated CRP even cyclophosphamide and autologous stem cell transplantation did not alter CRP levels.

**Conclusions:** Persistently elevated CRP levels characterise a more severe fibrotic phenotype and a higher prevalence of cardiac arrhythmias.

**AB0758** **EVALUATION OF NAILFOLD VIDEO CAPILLAROSCOPY IN 296 PATIENTS WITH CONNECTIVE TISSUE DISEASES**

G. Kumánovics, G. Nagy, L. Cziráj. *Rheumatology and Immunology, University of Pécs, Medical School, Pécs, Hungary*

**Background:** The influence of the presence of Raynaud's phenomenon (RP) on microangiopathy is not well characterised in connective tissue diseases (CTDs).

**Objectives:** To characterise capillary density and capillary morphology by nailfold video capillaroscopy (NVC) in different CTDs with a special focus on the presence/absence of Raynaud's phenomenon (RP) and overlap syndromes.

**Methods:** 296 patients with systemic sclerosis (SSc), systemic lupus erythematosus (SLE), idiopathic inflammatory myopathies (IIM), Sjogren's syndrome (SS), antiphospholipid syndrome (APS), rheumatoid arthritis (RA), systemic vasculitis and undifferentiated connective tissue disease (UCTD) were investigated by NVC. Control groups consisted of 25 healthy controls (HC) and 22 primary RP (PRP) cases.

**Results:** The mean capillary density was significantly decreased in SSc, SLE, SS, IIM and APS either compared to HC or PRP cases. Mean microangiopathy evolution score (MES) was higher in SSc, SLE, SS, IIM and APS compared to both HC and PRP cases. SSc, SLE, SS patients had a significantly higher giant capillary number compared to either HC or primary RP control cases. Average haemorrhage score was significantly higher in SSc and SS but not in SLE, RA, IIM and APS compared to HC. Average dilatation point was higher in all investigated CTDs compared to HC. Except RA, all investigated CTDs showed significantly higher capillary loss score compared to either PRP controls or HC. RA cases showed such a difference only compared to HC. Average disorganisation score was significantly higher in all CTDs compared to HC but not compared to PRP cases. Ramification score was significantly elevated in SSc and IIM compared to PRP and HC, but no difference was observed in SLE, SS, APS and RA. The mean capillary density was decreased, and MES was higher in RP associated cases compared to patients without RP in cases with SLE, IIM, and RA. Conversely, the presence of RP did not influence these particular parameters in cases with APS and SS. Except SSc, the impact of overlap features was not remarkable on major capillaroscopic findings. SSc capillary pattern was present in 75.3% of all SSc cases, most commonly SSc late pattern was observed (58.43%). SSc pattern was present in other CTD cases too (15.4%–40.7%). SSc patients with a DLCO<70% had significantly more giant capillaries, avascularity, late SSc pattern, increased MES, and lower capillary density compared to cases with DLCO>70%, but in the other CTDs decreased DLCO was not associated with similar pronounced capillary damage.

**Conclusions:** Microangiopathy with decreased capillary density and increased MES were present in all CTDs compared to controls. RP caused most pronounced impairment in SLE, IIM and RA compared to non-RP patients, but had no major effect on SS, and APS. Except SSc, the presence of overlap syndrome did not show a remarkable influence on the microvascular abnormalities compared to pure idiopathic cases. SSc late pattern was most frequently observed in CTDs other than SSc, and it may appear even in patients without RP. Previous associations shown by other authors of decreased DLCO and capillary damage in SSc was confirmed. Capillaroscopy is useful not only in IIM and SSc patients but also in all SLE cases and RP associated SS and RA patients. Capillary density and MES are the most valuable parameters.

### THE ASSESSMENT OF GASTROINTESTINAL TRACT INVOLVEMENT THROUGH UCLA SCTC GIT 2.0 QUESTIONNAIRE IDENTIFIES SCLERODERMA PATIENTS WITH REDUCED BONE MINERAL DENSITY

G. Natalello, E. De Lorenzis, G.B. Canestrari, L. Gigante, L. Verardi, L. Mirone, S. L. Bosello, G. Ferraccioli, E. Gremese. *Rheumatology Unit, Fondazione Policlinico Universitario A. Gemelli – Catholic University of the Sacred Heart, Rome, Italy*

**Background:** Gastrointestinal (GI) symptoms are seen in majority of patients with Systemic Sclerosis (SSc) and are a common presenting feature of disease. Severe GI involvement may lead to malabsorption which represents a poor prognostic factor. Accordingly, a regular monitoring of gastrointestinal tract involvement and nutritional status appears crucial in SSc patients. Previous studies reported low values of bone mass density (BMD) in SSc patients<sup>1</sup>. While no specific relationship has emerged between the two conditions, it's likely that disease related GI involvement may contribute to the alterations in BMD.

**Objectives:** To determine if GI-related clinical status was associated to low bone density in our cohort of SSc patients.

**Methods:** Two-hundred-ten unselected SSc patients have been enrolled. The 7-items UCLA SCTC GIT 2.0 questionnaire and Malnutrition Universal Screening Tool (MUST) were administered to each patient. A comprehensive medical history was collected. A blood panel for nutritional status was also performed. T-scores and Z-scores at lumbar spine, femoral neck, Ward's and total hip measured by dual-energy X-ray absorptiometry (GE Lunar Prodigy) were measured.

**Results:** In our cohort, 86.7% of patients reported some GI symptoms. The mean UCLA GIT total score was 0.345±0.34 and 51 patients (24.3%) were at risk of malnutrition according to MUST (score ≥1). 53.7% patients had BMD values <1, and 12.5% had BMD values ≤-2.5 at any of the considered sections. Patients with reduced BMD (<-1) showed similar levels of selected nutritional blood markers compared to subjects with normal BMD, including vitamin D and albumin. Patients with spine T-score <-1 had lower BMI (23.2±3.9 vs 25.2±4.8; p=0.011) and reported higher UCLA GIT reflux (0.66±0.63 vs 0.42±0.48; p=0.016), distention (0.80±0.72 vs 0.53±0.56; p=0.15) and total score (0.42±0.37 vs 0.27±0.30; p=0.006) compared to patients with normal BMD. Similar significant differences were observed in the same domains for patients with total hip T-score values <-1. Femoral neck T-score <-2.5 was associated with higher UCLA GIT reflux (0.88±0.78 vs 0.48±0.50; p=0.022), soilage (0.50±0.78 vs 0.14±0.52; p=0.041) and total score (0.50±0.37 vs 0.31±0.33; p=0.012).

On the other hand, the comparison of patients with severe, moderate and mild symptoms according to UCLA GIT total score<sup>2</sup> showed an association between progressively lower values of spine and total hip T-score and increasing severity of GI symptoms (ANOVA for spine T-score: p=0.015; for total hip T-score: p=0.048).

Patients at risk of malnutrition (MUST score ≥1) presented significant lower T-score for all the considered sections (spine and hip) and significant lower total hip Z-score.

**Conclusions:** In our SSc cohort gastrointestinal symptoms were frequent and were associated with low BMD. Considering the heterogeneity of GI involvement, UCLA SCTC GIT 2.0 emerged as a useful and feasible tool to assess GI involvement and other associated comorbidities. In particular, SSc patients who report remarkable GI symptoms and are at risk of malnutrition according to MUST may benefit from a stricter control of BMD to promptly detect osteopenia and osteoporosis.

### ADVANCED OXIDATION PROTEIN PRODUCTS IN SERUM OF PATIENTS WITH SYSTEMIC SCLEROSIS: A POSSIBLE INDICATOR OF CLINICAL EVOLUTION

G. Sighinolfi, M. Colaci, A. Spinella, F. Lumetti, E. Artoni, C. Salvarani, D. Giuggioli. *Chair and Rheumatology Unit, University of Modena and Reggio Emilia, Policlinico of Modena, Modena, Italy*

**Background:** Systemic sclerosis (SSc) is a chronic, multisystem connective tissue disease characterised by immune dys-regulation, obliterative microvasculopathy and fibrosis. Endothelial dysfunction, immune system imbalance and fibroblast activation constitute the three major factors of the pathogenetic process. In this context, oxidative stress could play a significant role through direct damage of endothelial cells and the persistent activation of the immune system.<sup>1,2</sup>

**Objectives:** This study investigated the presence of advanced protein oxidation products (AOPP) in serum of patients with SSc and its correlation with disease's features.

**Methods:** 50 patients with SSc (M:F 1:7, mean age 57.3±11.2 SD, mean duration of disease 10±9.1 SD years), were screened for AOPP in the serum, using the AOPP OxiSelect Kit of CELL BIOLABS (San Diego, Ca, USA). Among 50 SSc patients, 39 had limited cutaneous subset, while 11 had the diffuse one. Anamnestic and clinical data were collected for all SSc patients. As a control group 50 consecutive healthy subjects, sex and age matched, were recruited.

**Results:** We found serum levels of AOPP increased in the SSc group compared with the controls (p<0.0001) with mean values of 336.9±167.8 mmol/L and 167.5±59.2 mmol/L, respectively. In addition, higher levels of AOPP directly correlated with the diffuse cutaneous subset (p=0.0242), presence of digital ulcers (p=0.005), esophagopathy (p=0.006) and pulmonary fibrosis (p=0.0128).

**Conclusions:** Serum AOPP levels are significantly higher in patients with SSc than in controls. In addition, the correlations of AOPP with SSc diffuse cutaneous subset, digital ulcers, and pulmonary involvement (indicative of progressive disease and worse prognosis) suggest a possible role of this marker in the identification of the cases with worse clinical evolution. The data of this preliminary study should be confirmed on larger case series and analysed in prospective studies, in order to understand its eventual usefulness during the follow-up of SSc patients.

### FOLLOW-UP OF NAILFOLD MICROVASCULAR DAMAGE IN MIXED CONNECTIVE TISSUE DISEASE VERSUS SYSTEMIC SCLEROSIS PATIENTS

G. Ferrari, A. Sulli, C. Pizzorni, M. Ghio, M. Patané, S. Paolino, A.C. Trombetta, M. Cutolo. *Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic Hospital, GENOA, Italy*

**Background:** Nailfold videocapillaroscopy (NVC) is a non invasive diagnostic technique useful for evaluating microvascular status in patients with connective tissue diseases.<sup>1</sup> In systemic sclerosis (SSc) capillary abnormalities, when evaluated by NVC, evolve in a clearly defined sequence called the "scleroderma patterns" (Early, Active, Late).<sup>2</sup> On the contrary, mixed connective tissue disease (MCTD) doesn't show characteristic either nailfold capillary abnormalities or typical sequence.<sup>1,2</sup> Until today, few studies described the main NVC changes in MCTD.<sup>3</sup>

**Objectives:** To retrospectively study nailfold microangiopathy by NVC in MCTD patients with a follow-up of three years and to compare capillaries abnormalities between patients affected by MCTD and SSc.

**Methods:** Ten patients (mean age 50±19 years) affected by MCTD with Raynaud phenomenon (Kasukawa's criteria)<sup>4</sup> who performed their first NVC were enrolled. Among these, complete capillaroscopic and clinical data at three years were available for 7 patients (disease duration 6.4±4.2 years). Main NVC parameters (absolute number of normal and total capillaries and scores of capillary ramifications, enlarged capillaries, giant capillaries, microhemorrhages, number of capillaries) were evaluated by NVC at baseline (T0, first NVC), and after one (T1) and three years (T3). Possible variations of capillary findings were analysed, along with correlations among capillaroscopic and clinical parameters. Furthermore, we compared main NVC parameters at T0 of ten above-mentioned MCTD patients versus ten random SSc patients with the same disease duration (6.4±4.2 years) and similar age (51±17 years). Statistical analysis was performed by non parametric tests. The patients were receiving different immunosuppressive treatments.

**Results:** No statistically significant variation of the scores as well as of the absolute value of the above reported capillary parameters was observed during the 3 years of follow-up. No statistically significant correlation was observed between capillary parameters and MCTD clinical aspects (Raynaud phenomenon, dysphagia, dyspnoea, sclerodactyly, sicca syndrome, telangiectasies and arthralgia) at first visit and during follow-up. The scores of enlarged capillaries and giant capillaries were found significantly higher (p<0.05) in patients with SSc versus MCTD patients at T0. Moreover, the absolute number of total capillaries and normal capillaries were found significantly lower (p<0.05) in SSc patients versus MCTD patients. On the contrary, no statistically significant difference was observed for

the other capillary parameters (capillary ramification, microhemorrhages) between the two groups of patients.

**Conclusions:** In a limited cohort of MCTD patients with an average disease duration of 6.4 years and a follow-up of three years, the nailfold microangiopathy does not seem to be significantly progressive. Patients with MCTD seem to show less enlarged/giant capillaries, and larger absolute number of total and normal capillaries than SSc patients. Still difficult to identify a defined NVC pattern in MCTD patients.

#### AB0762 RELATIONSHIP OF THE SIX MINUTE WALKING TEST AND QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS

G. Cuomo, K. GJELOSHI, F. Masini, F. Danzo, C. Romano, L.E. Adinolfi. *UOC Medicina Interna, UNIVERSITA DEGLI STUDI DELLA CAMPANIA, NAPOLI, Italy*

**Background:** The six minute walking test (6MWT) is a standardised measure of submaximal exercise capacity. It is a surrogate measure of heart and lung involvement. There are no studies on relationship between 6MWT and quality of life evaluated by Short form 36.

**Objectives:** To evaluate the relationships between of the 6 min walking distance (6MWD) and each items of SF36

**Methods:** Fifty consecutive SSc patients were investigated. They underwent 6MWT and complete the SF-36 (assessed the 8 domains of the questionnaire as well as the physical component score-PCS and mental component score-MCS).

**Results:** 6MWD ranged from 253 to 582 (median 420); we listed the correlations from 6MWT and only the statistically significant features of SSc and the items of SF36

Age: median 48 (range 20–72); Rho  $-0.51$ ;  $p < 0.00001$

EScSG Activity Index: median 0.5 (range 0–5); Rho  $-0.33$ ;  $p 0.009$

HAQ-DI: median 0.375 (range 0–2.275); Rho  $-0.26$ ;  $p 0.048$

mRSS: median 2 (range 0–17); Rho  $-0.35$ ;  $p 0.007$

Pulmonary hypertension (echocardiography): median 30 (range 13–80); Rho  $-0.26$ ;  $p 0.048$

SF36: PCS: median 43 (range 20–65); Rho  $0.41$ ;  $p 0.0016$

PF: median 75 (Range 0–100); Rho  $0.40$ ;  $p 0.002$

GH: median 50 (range 10–92); Rho  $0.43$ ;  $p 0.0007$

**Conclusions:** Our study first demonstrates that 6MWT is correlated to some aspects of quality of life as measured by SF36 in the SSc patients. This results must be considered when assessing 6MWT in SSc.

#### AB0763 BIOELECTRICAL IMPEDANCE ANALYSIS FOR THE ASSESSMENT OF BODY COMPOSITION IN PATIENTS WITH SYSTEMIC SCLEROSIS

G. Cuomo, G. Guarino, F. Danzo, C. Romano, F. Masini, R. Ferrara, S. Gentile, L. E. Adinolfi. *UOC Medicina Interna, UNIVERSITA DEGLI STUDI DELLA CAMPANIA, NAPOLI, Italy*

**Objectives:** The aim of the present study was to evaluate the body composition by bioelectrical impedance analysis (BIA) and to assess the nutritional status by BMI and possible correlations with epidemiological and clinical characteristics in patients with SSc

**Methods:** Malnutrition was defined as BMI  $< 18.5$  kg/m<sup>2</sup> or unintentional weight loss  $> 10\%$  in combination with a fat-free mass index (FFMI)  $< 15$  kg/m<sup>2</sup> for women or  $< 17$  kg/m<sup>2</sup> for men or BMI  $< 20.0$  kg/m<sup>2</sup> (age  $< 70$  years) or  $< 22$  kg/m<sup>2</sup> (age  $> 70$  years). Body composition was assessed in 40 patients (female) (age mean  $\pm$ sd:  $45.2 \pm 12.2$ ) and 20 healthy controls (age mean  $\pm$ sd  $41.5 \pm 5.3$ ) with BIA

(Akern, Italy) and BMI. The manufacturer's equation and the Geneva equation were used to estimate fat mass (FFM).

In addition, correlations with disease activity, gastrointestinal severity, disease subset, autoantibody profile, skin score were evaluated.

**Results:** Malnutrition was found in 10% of patients vs 8% of healthy controls; and low FFMI in 30% of patients vs 10.5% of HC. Bioimpedentiometry showed a Fat Free Mass (FFM) (metabolically active component of fat free mass) reduced in patients compared to controls ( $46.8 \pm 7.6$  vs  $53.6 \pm 6.3$  respectively;  $p = 0.01$ ). Furthermore, with the same instrument a lower basal metabolic rate was found in patients compared to controls:  $1462 \pm 145$  vs  $1720 \pm 169$  calories ( $p = 0.001$ ). The correlations between FFM and basal metabolism with the clinical features of the patients were not statistically significant

**Conclusions:** This study confirms the study of Spanjer MJ et al<sup>1</sup> and shows a relatively low prevalence of malnutrition in comparison with other studies, but a high prevalence of low FFMI, underlining the necessity of measuring body composition in SSc patients with a standardised and validated method. Furthermore, Caporali et al,<sup>2</sup> have shown an alteration of the nutritional status of patients of SSc probably related to a gastro-intestinal commitment. In our patients despite the presence of an apparent good nutritional status the use of bioimpedanceometry revealed a different body composition, a lower share of muscle mass, in patients compared to controls, related, in part, to musculoskeletal involvement by systemic sclerosis (increase in muscle catabolism and/or poor nutrient supply due to malabsorption phenomena). The early detection of such alterations could be useful to insert subjects at risk in physical rehabilitation programs.

#### AB0764 COMPARISON OF DISEASE CHARACTERISTICS IN PATIENTS WITH JUVENILE-ONSET AND ADULT-ONSET PROGRESSIVE SYSTEMIC SCLEROSIS

G. Karatemiz<sup>1</sup>, A. Androvic<sup>2</sup>, S.N. Esatoglu<sup>1</sup>, S. Sahin<sup>2</sup>, K. Barut<sup>2</sup>, G. Hatemi<sup>1</sup>, V. Hamuryudan<sup>1</sup>, O. Kasapcopur<sup>2</sup>, E. Seyahi<sup>1</sup>. <sup>1</sup>*Rheumatology*; <sup>2</sup>*Pediatric Rheumatology, Istanbul University of Cerrahpasa Medical Faculty, Istanbul, Turkey*

**Background:** Progressive systemic sclerosis (PSSc) has been known to affect mainly adults of 30–50 years of age. Juvenile-onset has been reported to be rare and studies comparing clinical differences between juvenile-onset and adult onset form have been limited.<sup>1</sup> These studies were coming from European and North American countries.<sup>1–2</sup> As there would be also effects of ethnic differences, we aimed to assess clinical differences between the two forms of pSSc of paediatric and adult rheumatology centres of a tertiary centre, in Turkey.

**Methods:** Adult onset patients were defined as those who were registered and followed as 'scleroderma' at the departments of adult and paediatric rheumatology at Cerrahpasa Medical Faculty, Istanbul, between 2005 and 2017. Only those with at least 2 follow-up visits were included. Patients's charts were re-evaluated retrospectively.

Abstract AB0764 – Table 1

	Adult onset, n=137	Juvenile onset, n=26	P
Age at disease onset, mean $\pm$ SD	38.6 $\pm$ 13.4	10.1 $\pm$ 4.3	-
Age at diagnosis, mean $\pm$ SD	43.6 $\pm$ 14.0	11.4 $\pm$ 3.2	-
Follow-up duration, med. [IQR], years	5 [2.0–7.0]	4 [2.5–6.0]	NS
Male/Female	20/117	2/24	NS
Familial history of chronic inflammatory diseases, n (%)	20 (14.6)	4 (15.4)	NS
Sclerodactyly, n (%)	128 (93.4)	25 (96.2)	NS
Raynaud phenomenon, n (%)	135 (98.5)	24 (92.3)	NS
Digital ulcers, n (%)	55 (41.4)	14 (54.0)	0.001
Interstitial lung disease, n (%)	71 (52.2)	6 (24.0)	0.009
PAH, n (%)	20 (14.9)	0	0.045
Arrhythmia/heart failure, n (%)	14 (10.4)	1 (4.0)	NS
Joint involvement, n (%)	20 (14.9)	13 (50.0)	<0.001
Skeletal muscle involvement/myopathy n (%)	10 (7.5)	7 (28.0)	0.002
Gastrointestinal system involvement, n (%)	42 (31.8)	8 (32.0)	NS
Arterial hypertension, n (%)	24 (18.2)	0	0.015
ANA positivity, n (%)	119 (93.0)	18 (75.0)	0.007
DMARD use, n (%)	90 (65.7)	25 (96.2)	0.002
Vasodilators, n (%)	113 (82.5)	13 (50.0)	<0.001

**Results:** There were 140 patients with scleroderma in the adult outpatient clinic records and 51 in the paediatric clinic records. Of these patients, 3 (2%) adults

and 25 (49%) paediatric patients had localised scleroderma ( $p < 0.001$ ). We studied the remaining patients (adults:  $n = 137$ , juvenile:  $n = 26$ ) who had systemic pattern. Male/female ratio, median follow-up duration, familial history of chronic inflammatory diseases and the frequency of sclerodactyly, digital ulcers, Raynaud phenomenon, arrhythmia/heart failure and gastrointestinal involvement were similar between two groups (table 1). The frequency of interstitial lung disease, pulmonary artery hypertension, and serum ANA positivity were significantly more common in the adult onset group. Whereas joint and muscle involvements were significantly more common among juvenile onset patients. DMARD use was significantly more common in the juvenile group while the use of vasodilators was more frequent among adults<sup>1</sup>

**Conclusions:** Our results are online with previous reports: juvenile onset patients seem to have a milder form of disease. Major organ involvement as defined interstitial lung disease and pulmonary artery hypertension was more common among adult onset patients. On the other hand, as expected, joint involvement and myopathy were major causes of morbidity in the juvenile group. Contrary to that previously reported, cardiac involvement was not common in the juvenile group.

#### AB0765 DEVELOPMENT AND ASSESSMENT OF A STRUCTURED TRAINING PROGRAM FOR PATIENTS WITH SYSTEMIC SCLEROSIS

H. Ahrens<sup>1</sup>, E. Siegert<sup>2</sup>, M. Kraft<sup>1</sup>, K. Loewy<sup>2</sup>, M. Worm<sup>1</sup>. <sup>1</sup>Department of Dermatology, Venerology and Allergology, Charité University Medicine; <sup>2</sup>Department of Rheumatology and Clinical Immunology, Charité University Medicine, Berlin, Germany

**Background:** Structured patient education programs are a key element of patient care in many chronic diseases. They are often based on the Stanford University chronic disease self-management program and aim to empower patients and to improve compliance and coping abilities. However, not in every condition self-management education programs yield the expected benefit.<sup>1</sup>

**Objectives:** To develop a structured patient education program for SSc patients and to prove training-specific effects on patients' quality of life and disability.

**Methods:** We developed a structured patient education program. The content of the program was created by a team of rheumatologists and dermatologists. The program consists of three modules focusing on general knowledge about the disease, gastrointestinal involvement, digital ulcers (DU), skin and wound care and a patient diary on disease symptoms. Patients were either included in the intervention or in the control group. Disease symptoms and severity as well as clinical parameters were assessed at baseline (intervention and control), at the follow-up visit at month 3 (intervention only) and at the final follow-up visit at month 6. In the intervention group satisfaction with the education program was analysed.

Primary outcome measures were SHAQ, SF-12, BFI, SHAQ\_DU. Secondary outcome measure was the satisfaction survey. For comparisons between different times analysis of variance for repeated measures was used. For description of cohorts Mann-Whitney Wilcoxon test was used.

**Results:** 58 SSc patients were included, 27 received the educational program (intervention group) and 31 patients served as a control group. Both groups were matched regarding demographics and disease subtype. Incidence of DUs was significantly higher in patients from intervention group resulting in a more frequent administration of vasoactive therapies. SHAQ, SF-12, BFI, SHAQ\_DU were comparable between control and intervention group. However, patients in the intervention group rated the training program as helpful and reported an increase in knowledge about their disease afterwards. A positive impact of the training program on SHAQ, SF-12, BFI, SHAQ\_DU was observed in individual patients.

**Conclusions:** Patients who participated in the training were overall satisfied with the program. However, no significant effects on quality of life after the intervention were observed. One reason for this finding might be the disease duration (mean 11.5 years). This needs to be further analysed in a consecutive study considering patients with shorter disease duration.

#### AB0766 INITIAL CHARACTERISATION OF WOMEN WITH BREAST IMPLANTS IN A GROUP OF PATIENTS WITH SYSTEMIC SCLEROSIS REFERRED FOR AUTOLOGOUS HSCT

H. Khoury<sup>1</sup>, R. Burt<sup>2</sup>. <sup>1</sup>Sainte Justine Hospital, Montréal, Canada; <sup>2</sup>Immunotherapy and Autoimmune Diseases, Northwestern University, Chicago, USA

**Background:** The causal relationship between breast implants (BI) and systemic sclerosis (SSc) is still strongly contested.

**Objectives:** To add further input to this medical controversy, we studied the initial clinical characteristics of patients with breast implants and systemic sclerosis that are referred to our centre for autologous hematopoietic stem cell transplant.

**Methods:** From 163 patients, with the diagnosis of systemic sclerosis (SSc), limited SSc, CREST, Morphea or scleroderma sine scleroderma, referred to our centre for autologous hematopoietic stem cell transplantation, 132 were found to be females. To identify those with breast implants (BI) or have a history of breast implants, we performed a systemic chart review for all patients. Once the patients with actual breast implant devices or have history of breast implants were identified, alive patients were contacted to check the type of their breast implants (silicone vs saline), the year of insertion, the local complications, whether they were removed or replaced and the year of removal and replacement, and the type of replacement if applicable. Clinical and biological data were collected for all patients and were compared between those who have breast implants or history of breast implants and those who do not have.

**Results:** From 132 patients with SSc or SSc variants, thirteen had history of BI (9.8%). In 12, the breast augmentation therapy preceded the development of SSc, with median time between BI insertion and the emergence of initial symptoms of SSc of 12 years (range 7–29). The remaining patient showed acceleration of her disease after BI surgery. Surprisingly, in all 12 patients for whom we could know the type of initial implants, the prostheses were saline. When we compared the clinical characteristics of those with BI and those without. Patients with BI appeared to have higher age (mean 49.95 vs 44.42 years,  $p = 0.012$ , shorter time from initial symptoms to diagnosis (mean 4.76 vs 12.24 months,  $p = 0.0001$ ), more frequently positive ANA (13/13 vs 89/114,  $p = 0.06$ ) and more frequently positive anti RNA polymerase III (7/10 vs 20/78,  $p = 0.004$ ).

**Conclusions:** Our data may support the hypothesis of a possible association between BI and SSc. Furthermore, these results raise questions regarding the safety of saline breast prosthesis. Finally, our finding may indicate a possible difference in the initial characteristics of SSc patients with BI and those without.

#### AB0767 EFFICACY OF SUBCUTANEOUS TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND SYSTEMIC SCLEROSIS OVERLAP SYNDROME

H. Wakabayashi<sup>1</sup>, S. Kino<sup>2</sup>, M. Hasegawa<sup>1</sup>, A. Sudo<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, MIE University Graduate School of Medicine, Tsu; <sup>2</sup>Orthopaedic Surgery, Kino Orthopedic Clinic, Nabari, Japan

**Background:** Systemic sclerosis (SSc) is a connective tissue disease that develops sclerotic changes in the skin and visceral organs. SSc is a disease of uncertain etiology, and is characterised by fibrotic changes. Pulmonary, cardiac, gastrointestinal, and renal complications contribute to patient morbidity and decreased survival<sup>1</sup>. And patients present with stiffness of the limbs because of sclerosis and joint swelling in the skin and periarticular connective tissues. Interleukin-6 (IL-6) is a pleiotropic factor that plays a major role in inflammation; furthermore, IL-6 overexpression and pathogenicity in SSc have been demonstrated<sup>2</sup>. IL-6 expression is reportedly high in both the skin and serum of SSc patients<sup>3</sup>, and its elevation depends on the skin score<sup>4</sup>. And it is a candidate factor that can reproduce the pathological conditions of SSc as well as RA.

**Objectives:** We report the cases of rheumatoid arthritis (RA) patients with SSc who was administered anti-interleukin-6 receptor antibody tocilizumab (TCZ).

**Methods:** Two RA with refractory SSc patients were administered tocilizumab at 162 mg/kg twice a month for 12 months. RA disease activity is evaluated by DAS28-ESR and CDAI. Skin condition of SSc is evaluated by pinching the skin according to the modified Rodnan total skin score (mRTSS).

**Results:** They were both female, and age at the time of SSc diagnosis was 74 (patient 1) and 51 (patient 2) years old. The time lapse since SSc diagnosis was at first visit and 14 years, respectively. And it since RA diagnosis was 14 years and 6 years, respectively. Tocilizumab was administered at 162 mg every 2 weeks, which is equal to the dosage used for RA. Administration of prednisolone at 5 mg/day and DMARDs were continued. Overall, TCZ was well tolerated, and both patients experienced a general improvement in coping with normal daily activities. During the 12 month tocilizumab therapy, both RA disease activity and mRTSS decreased. The patient global assessment improved by 70 (75 to 5) and 44 (68 to 24) in patients 1 and 2 in 12 months, respectively. In RA disease activity, DAS28 decreased from 5.66 to 1.73 in 12 months in patient 1 and 7.14 to 4.43 in

patient 2. CDAl decreased from 31.8 to 7.4 in 12 months in patient 1 and 34.6 to 10.7 in patient 2. Skin thickness evaluated with the 17 site modified Rodnan skin score improved in patient 1 (from 23 to 2) and patient 2 (from 15 to 8) in 12 months.

Adverse reactions were observed cellulitis in right foot planter at 6 week treatment in patient 2. She did withdrawal tocilizumab for 4 week. After cure cellulitis, she continued tocilizumab treatment.

**Conclusions:** In the two cases of RA with SSc that we report here, softening of the skin was observed during the treatment with tocilizumab. Tocilizumab may be effective against RA and SSc for which conventional treatment is inadequate.

#### AB0768 OSTEOMYELITIS COMPLICATING DIGITAL ULCERS IN SYSTEMIC SCLEROSIS

L. Chiapparoli<sup>1</sup>, F. Locatelli<sup>2</sup>, P. Orsolini<sup>3</sup>, R. Caporali<sup>4</sup>, C. Montecucco<sup>4</sup>, V. Codullo<sup>2</sup>. <sup>1</sup>IRCCS Policlinico San Matteo Foundation, Pavia, Italy; <sup>2</sup>Rheumatology Unit, IRCCS Policlinico San Matteo Foundation; <sup>3</sup>Department of Infectious Diseases; <sup>4</sup>Rheumatology Unit, University of Pavia, Pavia, Italy

**Background:** Skin ulcers are a frequent manifestation of systemic sclerosis (SSc). Skin ulcers are painful, represent a cause of disability and heavily affect patients' quality of life. The presence of local infection may be responsible for osteomyelitis (OM) of the underlying bone. If gangrene develops, surgical amputation may be required. At the moment is not clear if there are predisposing factors to osteomyelitis development.

**Objectives:** To describe a population of SSc patients affected by cutaneous ulcers and osteomyelitis

**Methods:** We collected data of SSc patients satisfying the 2013 ACR criteria for SSc referring to our outpatient clinic from January 1st 2016 to December 31st 2017. The patient's data were evaluated on the basis of individual clinical records, including demographic, clinical and serological findings. Cutaneous ulcers were defined as epithelial loss and loss of dermis; post-traumatic skin lesions were excluded. In cases suspected of infection, microbiological investigations were carried out. We have diagnosed OM by clinical, radiological and laboratory means, in particular the presence of pain, swelling, fever, erythema, purulent secretions, blood chemistry alterations and typical radiological characteristics at either plain X ray and/or MRI. Statistical analysis was performed using STATA software for descriptive analysis and groups comparisons. Given the low number of events only univariate analysis was conducted.

**Results:** A total of 189 patients were enrolled in the study. Of them, 21 (11.1%) were males, mean age was 64.39±12.5 years and median disease duration 11.59 (5.6–19.3) years. A diffuse cutaneous (dcSSc) involvement was present in 50 (26.5%), limited cutaneous (lcSSc) in 131 (69.3%) and a limited disease in 8 patients (lSSc) (4.2%). Digital ulcers (DU) were present in 29 patients (15.3%) and in 5 cases (2.6%) were complicated by the occurrence of OM. The pathogens responsible of the infections were isolated in 3/5 (60%) cases and were represented by: Methicillin-sensitive Staphylococcus Aereus (2 cases) and P. Aeruginosa, also multisensitive. OM affected the third finger of right hand in 2 (40%) patients, the second finger of right hand in 1 (20%) patient and the third finger of left hand in 2 patients (40%). In 2 cases (40%) surgical amputation had to be performed. Patients with OM were significantly younger (54.9±16.07 vs 64.65 ±12.34, p 0.0432) and had higher CRP levels than the rest of the patients (1.27 ±0.59 vs 0.42±0.74, p 0.0061) In patients with DU, the only predictive factor for the development of OM was the total number of ulcers in the single patient (OR 2.27, 1.39–3.71, p<0.001) while no significant influence was found for other demographic or disease specific parameter.

**Conclusions:** OM is a severe complication of DU in SSc. In most cases the aetiological agents are community-acquired pathogens. SSc patients with OM were younger but did not show any other obvious distinguishing feature. The number of ulcers in the single patients were predictive of OM development. Further and larger studies are needed to address this aspect of the microvascular involvement of SSc.

#### AB0769 SCLERODERMA MIMICS IN COHORT FROM AN EUSTAR CENTRE

I.R. Dobrota<sup>1</sup>, L. Damian<sup>1</sup>, A. Petcu<sup>1</sup>, I. Felea<sup>1</sup>, I. Filipescu<sup>1,2</sup>, S.P. Simon<sup>1,2</sup>, S. Rednic<sup>1,2</sup>. <sup>1</sup>Rheumatology, Emergency County Hospital; <sup>2</sup>Rheumatology, Iuliu Hatieganu University of Medicine and Pharmacy, Cluj Napoca, Romania

**Background:** The differential diagnosis of systemic sclerosis (SSc) can be sometimes challenging, especially when you have symmetrical skin thickening, Raynaud's phenomenon (RP) or acroosteolysis. When symptoms and signs are unclear, patients should be referred to a specialist centre for assessment to differentiate between scleroderma and its mimics.

**Objectives:** Assessing the types of scleroderma mimics presenting in a tertiary care centre and underlining the diagnosis difficulties.

**Methods:** We evaluated a cohort of 140 patient admitted in our clinic with the suspicion of SSc from January 2007 until December 2017. 130 of them are with SSc and 10 patients with scleroderma mimics. The patients were evaluated for quality and distribution of skin involvement, the presence of systemic complications, the presence of scleroderma specific antibodies and the capillaroscopic pattern. If they haven't met any criteria for SSc, they underwent further specific investigations.

**Results:** From the 140 patients evaluated, 10 (7,14%) were with scleroderma mimics. All these 10 patients were admitted in our clinic with the suspicion of SSc. 3 of them had severe RP, one had acroosteolysis and 6 had symmetric skin thickening. There were 4 males and 6 females. All the patients had no organ involvement (pulmonary arterial hypertension or pulmonary fibrosis), normal capillaroscopic pattern and negative antinuclear antibodies and negativespecific scleroderma antibodies. The patients with RP had no skin sclerosis or other clinical or laboratory changes and the diagnostic was primary RP. The patient with acroosteolysis had no skin sclerosis or RP and after genetic testing a diagnosis of Hajdu-Cheney syndrome was made. The 6 patients with skin thickening had no RP. There were 2 patient with solvent induced scleroderma, 2 with scleroedema adutorum, 1 with scleromixedema, 1 with eosinophilic fasciitis. The 2 patients with solvent induced scleroderma had sclerodactily and one of them the "prayer sign" and they had a complete resolution of skin sclerosis after eliminating the solvent exposure after a few years of follow up. The 2 patients with scleroedema adutorum had no underlying gammopathy or infections. The patient with eosinophilic fasciitis had extended skin thickening with eosinophilia ant typical aspect on MRI, with partial clinical resolution after immunosupresion. The patient with scleromixedema had associated hypothyroidism. The period from first symptoms to diagnosis was variable from months to years.

**Conclusions:** Even though are rare, scleroderma mimics can be a challenging diagnostic even in tertiary care centre and sometimes diagnostic can be delayed. A correct diagnostic is necessary to avoid unnecessary immunosupresion.

#### AB0770 18 FDG PET/CT PREDICTS DECLINE IN FUNCTIONAL RESPIRATORY TESTS IN SYSTEMIC SCLEROSIS PATIENTS BUT NOT IN RHEUMATOID ARTHRITIS PATIENTS

J. Ivorra<sup>1</sup>, M. Martinez<sup>2</sup>, J.L. Loaiza<sup>3</sup>, M. Garijo<sup>4</sup>, J.J. Alegre<sup>5</sup>, S. Herrera<sup>6</sup>, I. Chalmeta<sup>1</sup>, L. Gonzalez<sup>1</sup>, R. Negueroles<sup>1</sup>, C. Alcañiz<sup>1</sup>, K.R. Arevalo<sup>1</sup>, I. Canovas<sup>1</sup>, C. Feded<sup>1</sup>, J.J. Frago<sup>1</sup>, R. Gonzalez<sup>1</sup>, E. Grau<sup>1</sup>, E. Labrador<sup>1</sup>, I. Martinez<sup>1</sup>, C. Najera<sup>1</sup>, J.E. Oller<sup>1</sup>, F.M. Ortiz<sup>1</sup>, E. Vicens<sup>1</sup>, M. De la Rubia<sup>1</sup>, D. Hervas<sup>1</sup>, J.A. Roman<sup>1</sup>. <sup>1</sup>Rheumatology Department; <sup>2</sup>Pneumology Department; <sup>3</sup>Nuclear Medicine Department, HUP La Fe, Valencia; <sup>4</sup>Rheumatology Unit, H Leon, Leon; <sup>5</sup>Rheumatology Department; <sup>6</sup>Pneumology Department, H. Peset; <sup>7</sup>Biostatistical Unit, IIS La Fe, Valencia, Spain

**Background:** Interstitial lung diseases (ILD) it's a frequent complication in connective tissue diseases (CTD) such as rheumatoid arthritis (RA) or systemic sclerosis (SS), but the lung is the only affected organ in the idiopathic pulmonary fibrosis (IPF). Nonspecific interstitial pneumonia (NSIP) is the more frequent form in SS while usual interstitial pneumonia (UIP) predominates in RA patients and in the IPF form. Some studies suggested that 18-FDG-PET/CT could help to detect zones of activity in lung tissue in IPF and this in turn could predict the disease

progress, but results are inconclusive. Moreover, little is known about the value of 18-FDG PET uptake in ILD associated to RA or SS.

**Objectives:** The purpose of this study is to evaluate the predictive value of 18 FDG-PET/CT scan images in functional pulmonary progression of ILD associated to RA or SS.

**Methods:** We conducted a 12 month prospective observational study on patients diagnosed with ILD associated to SS or RA between January 2015 and May 2017. ILD diagnosis was based on clinical assessment, pulmonary function tests (PFTs) and expert HRCT evaluation. We performed three visits: basal, 6 month and 12 month. On all visits a general exploration, forced vital capacity (FVC) and diffusing capacity of the lungs for carbon monoxide (DLCO) were carried out. On basal and 6 month visit a 18-FDG-PET/TC was performed within a period of three months from the PFTs. Patients continued with their treatment (corticosteroids, DMARDs or immunosuppressants). The nuclear medicine physician identified the maximum and mean standardised uptake value (SUVmax and SUVmean) in the three areas with the most FDG uptake, and adenopathies uptake. PET/CT images were reviewed by 2 combined radiologist/nuclear medicine physicians in consensus.

**Results:** We included 17 patients, 10 had UIP associated with RA and 7 NSIP related to SS. It appeared that RA patients had longer lung illness evolution and worse FVC than SS patients (table 1), in spite of not having found statistical differences. We detected significant statistical relation between the highest SUVmax and FVC ( $p=0.009$ ) or DLCO progression ( $p=0.006$ ) in SS patients, independently of the basal FVC and DLCO, and duration of lung illness in a multivariable linear mixed model. We didn't find any relation between SUVmax and FVC or DLCO progression in RA patients.

**Conclusions:** In our cohort of patients with SS, 18 FDG PET/TAC can aid in predicting the progression of ILD associated disease, which does not occur in RA patients.

**Disclosure of Interest:** None declared

AB0771

#### ABNORMAL CAPILLAROSCOPY AND PULMONARY HYPERTENSION IN PATIENTS WITH SYSTEMIC SCLEROSIS

J. Reyes-Rueda<sup>1</sup>, S.R. Gutierrez-Ureña<sup>1</sup>, V. Gonzalez-Díaz<sup>1</sup>, G. Martínez-Bonilla<sup>1</sup>, K.M. García-Osuna<sup>1</sup>, D. Cardona-Muller<sup>2</sup>, E.G. Cardona-Muñoz<sup>3</sup>, A. Macías-Chumacera<sup>3</sup>, S. Cerpa-Cruz<sup>1</sup>. <sup>1</sup>Rheumatology, Antiquo Hospital Civil "Fray Antonio Alcalde"; <sup>2</sup>Departamento de investigación de Mecánica Vascular; <sup>3</sup>Departamento de investigación de Mecánica Vascular, Centro Universitario de la Salud, Guadalajara, Jalisco, Mexico

**Background:** Systemic sclerosis (Ss) is an autoimmune disease characterised by microvascular damage with clinical manifestations such as Raynaud Phenomenon, digital ulcers, abnormal capillaroscopy and pulmonary hypertension. Systemic sclerosis is a major risk factor for the development of pulmonary arterial hypertension. Positive capillaroscopy has been associated with involvement of pulmonary vasculature.

**Objectives:** To determine if there is association between abnormal capillaroscopy and pulmonary hypertension in patients with systemic sclerosis.

**Methods:** Cross-sectional study with a study group of 48 patients with Ss according to ACR/EULAR 2013 criteria; we included a control group with Rheumatoid arthritis patients (RA) and healthy subjects. The peripheral microangiopathy was studied by nailfold capillaroscopy and pulmonary involvement with transthoracic echocardiography. Descriptive statistics with mean and standard deviation were done. We did a chi-square test of homogeneity for groups comparison. Pearson's test was done for correlation analysis. We used SPSS software for statistics.

**Results:** 48 patients with Ss were included, 24 with RA and 24 subjects. 96% were women mean age 48 ( $\pm 13.6$ ). More frequent co-morbidities were systemic hypertension 17% in Ss vs 25% in RA. The most frequent clinical finding was Raynaud phenomenon in 81% and dysphagia in 67%. 64% of the patients with Ss were positive to anti-centromere antibody. Abnormal capillaroscopy was found in 77% of the Ss patients with the following patterns: early 42%, active 33% and late 23%, also we found abnormal capillaroscopy in 8% of the AR and healthy controls. We found 6% of pulmonary hypertension in Ss 4% was mild and 2% severe. Positive Correlations were Abnormal capillaroscopy and Lung interstitial disease  $r=0.36$  ( $p=0.009$ ), active pattern  $r=0.385$  ( $p=0.006$ ), dilated capillaries  $r=0.457$

( $p=0.001$ ). The Modified Rodnan score was correlated with: active pattern  $r=0.525$  ( $p=0.000$ ), dilated capillaries  $r=0.444$  ( $p=0.001$ ) and avascular areas  $r=0.495$  ( $p=0.000$ ). We did not find association between abnormal capillaroscopy and pulmonary hypertension  $r=0.106$  ( $p=0.300$ )

**Conclusions:** We found positive association between abnormal capillaroscopy and interstitial lung disease and no correlation with pulmonary hypertension

#### PROSPECTIVE STUDY OF CARDIOVASCULAR RISK ASSESSMENT IN SYSTEMIC SCLEROSIS

J.J. Gonzalez Martin<sup>1</sup>, M. Novella-Navarro<sup>1</sup>, J.L. Cabrera Alarcón<sup>2</sup>, O. Carrión<sup>3</sup>, A. Abdelkader<sup>4</sup>, E. Calvo<sup>5</sup>, P. Alcocer<sup>1</sup>, F. Aramburu<sup>1</sup>, C. Marin<sup>5</sup>, F. Sainz<sup>6</sup>, P. García de la Peña<sup>3</sup>, on behalf of HM Sanchinarro. <sup>1</sup>Rheumatology, Hospital HM Universitario Sanchinarro; <sup>2</sup>Centro de Biología Molecular Severo Ochoa; <sup>3</sup>Angiology and Vascular Surgery, Hospital HM Sanchinarro; <sup>4</sup>Angiology and Vascular Surgery, Hospital HM Universitario Sanchinarro; <sup>5</sup>Rheumatology; <sup>6</sup>Angiology and Vascular Surgery, Hospital HM Universitario Madrid, Madrid, Spain

**Objectives:** Evaluate evolution of cardiovascular risk (CVR) in a cohort of systemic sclerosis (SSc) in one year of follow-up.

**Methods:** Prospective longitudinal study of a cohort of 45 patients with SSc during a period of one year. Sociodemographic and analytical variables were analysed at the time of inclusion in the study (baseline) and after 12 months of follow-up. The vascular protocol with carotid ultrasound was performed, including the determination of carotid intima-media thickness (IMT) and the evaluation of atheromatous plaques; in addition to the performance of the ankle-brachial index (ABI) and the determination of endothelial dysfunction (ED) through the measurement of flow-mediated vasodilation (FMVD), all at baseline and at one year.

**Results:** 45 patients were included, 94% of them female, with a mean age of  $52.2 \pm 11.5$  years and mean evolution time of  $4.6 \pm 5.1$  years. The distribution by subgroups was 44.4% limited SSc, 35.5% diffuse SSc, 4.4% pre-scleroderma, 4.4% sine scleroderma SSc, 6.6% MTCD, and 4.4% overlap syndrome. Classical CVR variables were collected as smoking habit, DM, HTN, obesity, DLP, hyperhomocysteinemia, and clinical variables of the SSc were added such as modified Rodnan Skin Score (mRSS), pulmonary arterial hypertension (PAH), interstitial lung disease (ILD), capillaroscopic pattern, SSc specific antibodies and previous treatments.

A bivariate analysis was performed using binomial logistic regression, both at baseline and at one year. Pathological IMT ( $>0.9$  mm) was significantly associated with hyperhomocysteinemia ( $p=0.024$ , OR=3.03, CI 1.33–9.58). The presence of atheromatous plaque was associated with corticosteroid treatment ( $p=0.048$ , OR=0.58, CI 0.28–0.97). Pathological ITB ( $<0.9$ ) was significantly associated with the 25-OH-vitamin D deficit ( $p=0.031$ , OR=0.25, CI 0.06–0.77). ED did not show a statistically significant association with the parameters studied.

To evaluate the effect of time, a binomial model was adjusted by linear regression of mixed effects for the variables of CV affection considered (see table 1). Time proved to be a risk factor to present pathological ITB values, since it was evidenced at baseline in 4.4% of the sample compared to 20% in the one-year study. Consequently, a multivariate analysis was performed showing pathological ABI was significantly associated to time ( $p<0.001$ , OR=59.7, CI 59.64–59.75) and mRSS, although with little effect ( $p<0.001$ , OR=0.042, IC 0.036–0.047). Time was not a risk factor for the appearance of pathological IMT, ED or plaques.

Abstract AB0772 – Figure 1

**Conclusions:** In our study, we observed the significant variation in ABI in one year, this may be due to the fact that this measurement has a high sensitivity for the detection of early peripheral arterial disease, in those patients who have not manifested signs and symptoms of arterial disease due to more evolved time of evolution.

**AB0773 INTERVENTIONS FOR MORPHEA: A COCHRANE SYSTEMATIC REVIEW**

J.V. de Albuquerque<sup>1</sup>, B.N.G. Andriolo<sup>1</sup>, M.R.A. Vasconcellos<sup>2</sup>, V.T. Civile<sup>1</sup>, A. Lydiatt<sup>3</sup>, V.F.M. Trevisani<sup>1</sup>. <sup>1</sup>Cochrane Brazil, Centro de Estudos de Saúde Baseada em Evidências e Avaliação Tecnológica em Saúde; <sup>2</sup>Universidade Federal de São Paulo, São Paulo, Brazil; <sup>3</sup>Cochrane Skin Group, The University of Nottingham, Nottingham, UK

**Background:** Morphea is a chronic inflammatory and fibrosing disorder usually limited to the skin and underlying tissues. It is an immune-mediated disease in which excess synthesis and deposition of collagen in the skin and connective tissues results in hardened cutaneous areas.

**Objectives:** To assess the effectiveness and safety of treatments for individuals with any form of morphea.

**Methods:** We searched the following databases up to March 2017: the Cochrane Skin Specialised Register, CENTRAL, MEDLINE, Embase, LILACS, and five trials registry databases. We checked the reference lists of included studies for further references to relevant randomised controlled trials.

We included randomised controlled trials assessing the effects of topical, intralesional, or systemic treatments for morphea (isolated or combined).

Two authors independently assessed study eligibility, extracted data, assessed risk of bias and performed analyses. A third author settled any disagreements.

**Results:** We included 13 trials, totalling 426 participants. There were both juvenile and adult participants (mostly women). The majority had limited morphea, followed by linear morphea.

The studies evaluated heterogenous therapies for morphea, covering a wide range of comparisons. Thus, we could not pool data from the studies in a meta-analysis. Six studies investigated topical medications, two evaluated intralesional medications, and five investigated systemic medications.

Regarding our primary outcome global improvement of disease activity or damage:

- The number of juvenile participants with a significant clinical response was higher with oral methotrexate plus oral prednisone than with placebo plus oral prednisone (RR 2.31, 95% CI 1.20 to 4.45, after the 12 month treatment; NNT 3; low-certainty evidence);

- We are uncertain whether fractional carbon dioxide laser and the combination of acupuncture, hot herbal compress and moxibustion plus Centella triterpenes tablets and vitamin E may reduce this outcome, as the certainty of the evidence was very low;

- We found no differences in the MSS score between the following comparisons (very low-certainty evidence): oral hydroxychloroquine plus topical corticosteroid versus oral methotrexate plus folic acid and topical corticosteroid; and medium-

dose ultraviolet A-1 (50 J/cm<sup>2</sup>) versus low-dose ultraviolet A-1 (20 J/cm<sup>2</sup>) phototherapy versus narrowband UVB.

We are uncertain regarding adverse effects of interventions as the certainty of the evidence was very low. However, participants reported marked pain and pruritus during fractional carbon dioxide laser therapy, and had mild tanning after ultraviolet A-1 phototherapy.

**Conclusions:** There is a lack of high-certainty evidence for the treatment of morphea, and the effectiveness and safety of the interventions are unclear. Low-certainty evidence supports the effectiveness of oral methotrexate plus oral prednisone for treating juvenile morphea. More studies are necessary to assess the effectiveness and safety of interventions for morphea.

**AB0774 IMPACT OF STANDARDISED EDUCATION PROGRAM ON THE ACCURACY OF MODIFIED RODNAN SKIN SCORING IN PATIENTS WITH SYSTEMIC SCLEROSIS**

J.W. Park<sup>1</sup>, J.-B. Jun<sup>2</sup>, L. Cziriák<sup>3</sup>, Y. Allanore<sup>4</sup>, M. Matucci-Cerinic<sup>5</sup>, E.B. Lee<sup>6</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine; <sup>2</sup>Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of Ireland; <sup>3</sup>Department of Rheumatology and Immunology of Medical Centre, University of Pécs, Hungary; <sup>4</sup>Paris Descartes University and Cochin Hospital, AP-HP, Paris, France; <sup>5</sup>Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; <sup>6</sup>Division of Rheumatology, Department of Internal Medicine, Seoul National University College of Medicine, Seoul, Korea, Republic of Ireland

**Background:** Modified Rodnan skin score (mRSS) has been used as not only a primary outcome in many clinical trials, but also as an important surrogate marker of disease activity in patients with systemic sclerosis (SSc). Therefore, establishment of well-organised training program of mRSS is essential for the proper management of patients. Recently, Scleroderma Clinical Trials Consortium and the World Scleroderma Foundation published the recommendation for 2-phase mRSS training and emphasised assessing scoring accuracy after the training.

**Objectives:** To investigate the effect of modified Rodnan skin scoring (mRSS) education on improving its accuracy

**Methods:** Ten rheumatologists (6 professors and 4 fellows) received an education program composed of video education and live demonstration by master instructor (Marco Matucci-Cerinic) at (Seoul in June, 2017). Physicians measured mRSS of 8 patients with SSc 1) before the education, 2) after the video education and 3) after live demonstration without any clinical information of the patients. Accuracy of skin scoring was estimated by the difference from the pre-defined gold-standard score measured by master instructor. Change in accuracy of mRSS during the education course was analysed using linear mixed model. Intra-observer reliability of the mRSS and its change was assessed by intraclass correlation coefficient (ICC).

**Abstract AB0774 – Table 1.** Multivariable analysis indicating effect of the education program on the accuracy of modified Rodnan skin scoring

Education	Regression coefficient*	95% CI	P-value
Before education	Reference	NA	NA
After video education (vs. before education)	-0.95	-2.13 to 0.23	0.002
After live demonstration (vs. before education)	-0.44	-0.83 to -0.05	0.000
Education & live demonstration (vs. before education)	-1.59	-2.97 to -0.21	<0.001
Professor vs. before video education	1.79	0.33 to 3.25	0.000
Professor vs. before live demonstration	0.66	0.04 to 1.28	0.000
Professor vs. before education (vs. fellow type vs. limited type)	-0.07	-0.43 to 0.29	0.150
Fellow vs. limited after video education	1.00	-0.00 to 2.00	0.230
Fellow vs. limited after live demonstration	0.05	-0.10 to 0.20	0.500
Doctor/limited	0.52	-0.11 to 1.15	0.140
Gold-standard skin score†	-0.00	-0.00 to -0.00	0.990
Physician's accuracy‡ (vs. no. correct)	-0.47	-0.84 to -0.10	0.010

\*. Dependent variable = (Examiner's skin score – gold-standard skin score). Regression coefficient indicates the difference in dependent variable as compared with reference.

†. This clinical factor consistently influence the dependent variable irrespective of education course.

‡. indicates P value for type 3 fixed effect

§. (Physician's skin score – gold-standard skin score) (95% CI) was estimated as 7.66 (6.03 to 9.29) before the education.

**Results:** The number of SSc patients ever experienced by each physician was significantly higher in the professors than fellows but the number of mRSS ever performed was comparable between the two groups. Median (IQR) skin score

measured by master instructor was 10.5 (9.0). Mean (SD) difference between skin scores by physicians and master instructor was 7.7 (9.5) units. In the univariable analysis, video education significantly reduced the difference from the gold-standard score ( $\beta = -1.96$ , 95% CI  $-3.83$  to  $-0.10$ ) whereas live demonstration did not show additional enhancement in scoring skill. Effect of education program was significantly different according to the physician's status and patient's disease type (diffuse vs. limited). In addition, male patient, shorter disease duration and higher gold-standard skin score was associated with more accurate skin scoring irrespective of the education. In the multivariable analysis where above clinical factors were adjusted, video education also led to significantly accurate skin scoring (table 1). When the educational effect was stratified by individual site of examination, face and distal extremities showed greater enhancement of scoring accuracy whereas difference from gold-standard score in proximal extremities was rather increased. ICC of physicians' skin scores was acceptable over all scoring times (0.63 to 0.88) but was not significantly changed after the education.

**Conclusions:** The mRSS education program can significantly enhance the accuracy of mRSS, which is mainly achieved by video education.

#### AB0775 CHARACTERISTICS OF PATIENTS WITH SCLERODERMA (SSC) TREATED WITH VARIOUS DRUGS IN THE CLINICAL ASSESSMENT AND TGF B AND IL13 CONCENTRATION IN COMPARISON TO THE HEALTHY GROUP

K. Romanowska-Próchnicka<sup>1,2</sup>, A. Wajda<sup>3</sup>, A. Paradowska-Gorycka<sup>3</sup>, M. Walczyk<sup>2</sup>, M. Marecka<sup>2</sup>, J. Trochimiuk<sup>2</sup>, D. Szukiewicz<sup>1</sup>, M. Olesińska<sup>2</sup>.  
<sup>1</sup>Department of General and Experimental Pathology, CEPT laboratory, Medical University of Warsaw; <sup>2</sup>Department and Polyclinic of Systemic Connective Tissue Diseases; <sup>3</sup>Department of Molecular Biology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland

**Background:** Scleroderma (SSc) is a rare multisystem chronic disease the treatment of which is still challenging. Until now, there is no effective therapy that can modify the overall disease course. However, the main aim of SSc treatment is directed toward managing organs involvement and providing symptomatic relief. Effective drug therapy should inhibit three components of the disease: tissue fibrosis, vascular abnormalities and autoimmunity. Moreover, potential drug needs to be considered in the context of specific four subsets of the disease: fibroproliferative, inflammatory, limited, and normal-like. It was shown that various subsets could have different profile of specific cytokines: TGF $\beta$  – associated with fibroproliferative and inflammatory type of disease and IL13 – mediator of fibrotic and vascular pathology.

**Objectives:** The aim of the study was to assess the level of TGF $\beta$  and IL-13 in SSc pts with various treatment regimen comparing to healthy control.

**Methods:** 55 patients (71% were women) with SSc diagnosed according to EULAR/ACR 2013 criteria were divided into 5 treatment groups: 1st group – 8 pts treated with methotrexate (MTX), 2–13 pts with mycophenolate mofetil (MMF), 3–5 pts with cyclophosphamide (CYC), 4th group- 7 pts with azathioprine (AZA), 5th group- 22 pts without immunosuppressive treatment. All patients have been treated based on a scheme required for organs involvement in accordance with the update of EULAR recommendations from 2016. Mean age of patients was 54.56  $\pm$  13.97. The blood and serum samples have been collected for basic examination. TGF $\beta$  and IL13 concentration in serum was quantitated by ELISA. Differences in cytokine concentration were determined using non-parametric Kruskal-Wallis test. The level of statistical significance was set at  $p < 0.05$ . The modified Rodnan Skin Score (mRSS) examination were taken by one assessor at the beginning of the study and six months later. There were measured DLCO, HRCT, echocardiography and capillaroscopy.

**Results:** In 82% pts positive antinuclear antibodies have been revealed: in 16% positive results for CENPB were obtained and in 44% for Scl70. Capillaroscopy shown in 23% of pts early pattern, in 38% – active pattern, and in 27% – late pattern. 32% of SSc pts had confirmed pulmonary fibrosis, while 90% – Raynaud's syndrome. The median of mRSS in CENPB (+) pts was 5,4<sup>-24</sup> in Scl70 (+) pts – 12,2<sup>-30</sup>. Statistically significant differences were found between IL13 and TGF $\beta$  levels in patients treated with immunosuppressants and healthy subjects. There was no correlation between IL13 or TGF $\beta$  with lung fibrosis progression or skin involvement.

**Abstract AB0775 – Table 1.** Comparison of serum level of IL 13 and TGF $\beta$  in SSc pts

	MTX (n=8)	MMF (n=13)	CYC (n=5)	AZA (n=7)	patients without immunosuppressive treatment (n=22)	healthy control (n=6)	p value
<b>TGF<math>\beta</math></b>							$<0.001$
Minimum	170.8	175.4	203.0	96.15	104.4	44	
Maximum	226.6	272.3	273.2	272.3	202.0	150	
Average	414.0	385.3	306.5	306.6	309.9	323	
<b>IL13</b>							$<0.001$
Minimum	0	0	0	0	0	150	
Maximum	88	175.2	0	172.4	178.0	250	
Average	185	191	197	197.3	224.4	309	
<b>IL13</b>							$<0.001$
Minimum	90.14	123.8	75.29	163.7	115	228.7	
Maximum	95.42	85.96	150.3	95.81	96.7	31.53

#### AB0776 MUSCLE ULTRASONOGRAPHY: A POTENTIAL NEW DIAGNOSTIC TOOL FOR INFLAMMATORY MYOPATHIES

K. Bhansing<sup>1</sup>, C. Saris<sup>2</sup>, J. Fransen<sup>1</sup>, F. van den Hoogen<sup>1</sup>, A. Verrips<sup>3</sup>, R. Cooper<sup>4</sup>, P. van Riel<sup>5</sup>, B. van Engelen<sup>6</sup>, S. Pillen<sup>6</sup>, M. Vonk<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Neurology, Radboud University Medical Center; <sup>3</sup>Neurology, Canisius Wilhelmina Hospital, Nijmegen, Netherlands; <sup>4</sup>Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK; <sup>5</sup>Scientific Institute for Quality of Healthcare, Radboud University Medical Center, Nijmegen; <sup>6</sup>Child Development and Exercise Center, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** Quantitative muscle ultrasound (QMUS) imaging has proven to be a useful, non-invasive technique to visualise normal and pathological skeletal muscle tissue. <sup>1</sup>Electromyography (EMG) findings are not always disease specific in patients suspected of idiopathic inflammatory myopathies (IIM).

**Objectives:** To assess diagnostic value of QMUS in patients suspected for an IIM and to compare results with EMG.

**Methods:** In 57 patients, suspected for IIM, panel diagnosis blinded for QMUS was used as reference standard. QMUS results were used to classify patients according an ultrasound neuromuscular disorder (NMD) algorithm (normal/borderline/abnormal). The predictive value of QMUS and EMG was assessed in a two by two table and a multivariate logistic regression model.

**Results:** Twenty-two patients (39%) were diagnosed with IIM; 8 polymyositis, 4 dermatomyositis, 4 necrotizing myopathy, 3 inclusion body myositis and 3 non-specific myositis. Sixteen patients were classified with other NMD. We found an increased echointensity of the sternocleidomastoid, biceps, forearm flexor and tibialis anterior in the IIM group. Sensitivity, specificity, positive and negative predictive values (PPV/NPV) were 82%, 51%, 51%, 82% for ultrasound NMD algorithm and 63%, 64%, 50%, 75% for EMG. Multivariate analyses showed area under the curve (AUC) (0.81) (0.69–0.92) for ultrasound NMD algorithm, EMG (0.79) (0.67–0.92) and ultrasound NMD algorithm plus EMG (0.82) (0.70–0.93).

Predictor	Model A	Model B	Model C
Age $\geq$ 50 year	2.97 (0.65–13.59)	2.88 (0.62–13.28)	2.98 (0.62–14.21)
Serum CK $\geq$ 2 x upper limit	7.52 (1.57–36)	8.76 (1.55–49.55)	7.35 (1.22–44.21)
<i>Muscle ultrasound</i>			
Total echointensity of proximal muscles/ measured muscle			
Total number of affected proximal muscles			
Distal muscles affected (yes/no)			
NMD algorithm:			
- No NMD	Reference:		Reference:
- Borderline presence of NMD (yes/no)	1.61 (0.13–18.87)		1.62 (0.13–19.57)
- Presence of NMD (yes/no)	3.01 (0.44–20.55)		3.01 (0.43–21.09)
<i>EMG qualitative report:</i>			
Negative myopathic results		Reference:	Reference:
Borderline myopathic results		1.00 (0.08–11.67)	0.94 (0.07–12.09)
Positive myopathic results		1.28 (0.23–7.13)	1.03 (0.17–6.04)
Cox and Snell R square	0.28	0.26	0.28
Nagelkerke R square	0.38	0.35	0.38
Hosmer Lemeshow Test	0.91	0.94	0.69
AUC (95% CI)	0.81 (0.69–0.92)	0.79 (0.67–0.92)	0.82 (0.70–0.93)

**Conclusions:** QMUS with NMD algorithm provides a fair diagnostic value for patients suspected for an IIM and is similar to EMG results. A sizeable NPV indicates a low rate of false negative QMUS results. In addition to the relevant PPV for the presence for NMD, QMUS could serve as a potential screening tool for clinicians to detect possible myopathies and to rule out the presence of IIM.

AB0777

#### INFLAMMATORY MYOSITIS ASSOCIATED WITH MYASTHENIA GRAVIS WITH AND WITHOUT THYMIC PATHOLOGY: CASE SERIES AND LITERATURE REVIEW

K. Huang<sup>1</sup>, M. Mezei<sup>2</sup>, K. Shojania<sup>1</sup>, K. Chapman<sup>2</sup>, N. Amin<sup>1</sup>, N. Dehghan<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Neurology, University of British Columbia, Vancouver, Canada

**Background:** Inflammatory myopathies (IM) and Myasthenia gravis (MG) are two well-recognised and distinctive neuromuscular diseases. The association of myasthenia gravis (MG) and inflammatory myositis (IM) is rare and often only one of the diseases is diagnosed. The coexistence of MG and IM might be associated with thymoma. Even less common is the association of IM (polymyositis or dermatomyositis) and myasthenia gravis in the absence of thymoma.

**Objectives:** Here, we report a case series of 6 patients with concurrent MG and IM who were followed at the Neuromuscular Disease Unit (NMDU) at a tertiary referral centre in Vancouver, British Columbia. We also conducted literature review on clinical characteristics, diagnostic challenge and management of this condition.

**Methods:** In this study, we retrospectively examined patients seen at NMDU from 2004 to 2017 who had diagnosis of concurrent MG and IM. We reviewed medical records to assess their clinical presentations, laboratory findings, imaging studies and electrophysiological features. The data is presented descriptively.

**Results:** We identified 6 patients with MG-IM overlap. Three patients had simultaneous onset of MG and IM, 2 of whom presented with myasthenia crisis and fulminant myositis. In the other 3 patients, MG was the initial presentation and IM occurred 3–11 years after MG.

Diagnosis of MG was confirmed with clinical features, electromyography and/or serology. All had symptoms of MG with predominant ocular or bulbar weakness. Among these 6 patients, 3 had underlying thymic pathology including two benign thymoma and one stage IV thymoma; all 3 patients had Acetylcholine Receptor (AChR) Antibody. Of the 3 patients with no thymic pathology by computed tomography (CT) or thymectomy, 1 had high positive AChR antibody and 2 were negative.

Four patients had biopsies confirming the diagnosis of dermatomyositis or polymyositis. The other 2 patients declined biopsy; however, their MRI and EMG findings were consistent with IM. Only one patient had typical dermatomyositis rash.

Among the 3 patients with underlying thymic pathology, thymoma were resected; all 3 were treated with high dose glucocorticoid, IVIG, and methotrexate with complete remission after 2 years. Of the 3 patients with no thymic pathology identified, one patient (AChR+) was in remission on mycophenolate and passed away from pancreatic cancer; two patients (AChR-) had refractory MG and IM, and both responded to rituximab.

**Conclusions:** In summary, this is one of the largest case series with MG-IM overlap with or without thymic pathology. It is very important to recognise such association and the different pattern of muscle involvement because therapies may be adjusted to treat both conditions. In patients with thymic pathology, conventional disease modifying agents, IVIG and glucocorticoid in addition to thymoma resection appear to be effective. In patients with refractory MG and myositis who were AChR negative, rituximab may be effective.

AB0778

#### CLINICAL CHARACTERISTICS AND PROGNOSIS OF POLYMYOSITIS AND DERMATOMYOSITIS ASSOCIATED WITH MALIGNANCY: A 25-YEAR RETROSPECTIVE STUDY

K. Motomura, H. Yamashita, S. Yamada, Y. Takahashi, H. Kaneko. *Division of Rheumatic Diseases, National Center for Global Health and Medicine, Tokyo, Japan*

**Background:** Previous studies indicate that malignancies in polymyositis (PM) or dermatomyositis (DM) patients are associated with high mortality. Hence, it becomes important clinically to identify patients who are at high risk of developing

malignancy. However, previous studies to characterise such risk factors for malignancy in patients with PM and DM were small size or the findings were not conclusive.

**Objectives:** This study investigated factors predictive of malignancy and prognosis in patients with PM and DM.

**Methods:** We conducted a retrospective study of PM and DM patients who were inpatients at our hospital between January 1992 and September 2016. The diagnosis of PM or DM was made according to Bohan and Peter criteria. The collected data included gender, age at onset, laboratory test results at presentation, clinical features and complications in all progress. Past history of hypertension or diabetes mellitus was determined upon diagnosis of myositis. All patients in this study were followed from the baseline visit until loss of follow-up or death or otherwise until censor date 1 September 2017. Fisher exact test and Mann-Whitney U test were used for group comparisons. Univariate and multivariate analysis of the predictors of malignancy associated with PM or DM were performed by logistic regression to identify independent risk factors. Patient survival was analysed by using Kaplan-Meier curve and log-rank test.

**Results:** Among 134 patients, 29 had cancer diagnosed between 2 years prior and 3 years following identification of PM or DM. Esophageal cancer (n=5, 14.7%) and lung cancer (n=5, 14.7%) were the most frequent. Univariate analysis showed that male sex (55.2% vs 23.8%, p=0.003), older age (64.6±11.3 vs 53.4±16.5, p<0.001), past history of diabetes mellitus (28.6% vs 2.9%, p<0.001), dysphagia (41.4% vs 17.3%, p=0.01) and absence of interstitial lung disease (37.9% vs 64.8%, p=0.01), arthralgia (17.2% vs 47.1%, p=0.005) and the Raynaud phenomenon (3.4% vs 23.1%, p=0.02) were associated with increased malignancy. Multivariate analysis showed that independent factors included male sex (OR=3.65, p=0.03), older age (OR=1.05, p=0.02), past history of diabetes mellitus (OR=10.4, p=0.005) and absence of interstitial lung disease (OR=0.25, p=0.03) (table 1). Survival was significantly lower in patients with malignancy than in patients without malignancy (p<0.001).

**Abstract AB0778 – Table 1.** Multivariate analysis of PM/DM with and without cancer

Variables	Adjusted OR	95% CI	P value
Male, n(%)	3.65	1.17–11.30	0.03
Onset age, years, mean±SD	1.05	1.01–1.10	0.02
Interstitial lung disease, n(%)	0.25	0.08–0.84	0.03
Diabetes mellitus	10.4	2.00–54.3	0.005
Arthralgia, n(%)	0.55	0.15–2.04	0.37
Dysphagia, n(%)	2.82	0.82–9.71	0.10
Raynaud phenomenon, n(%)	0.25	0.03–2.29	0.22

Abbreviation: OR, odds ratio; CI, confidence intervals.

**Conclusions:** This study is the first to associate a past history of diabetes mellitus with malignancy; 28.6% of PM or DM patients with malignancy had diabetes mellitus whereas 7.3 percent of cancer patients had diabetes mellitus.

#### LONG TERM FOLLOW-UP OF A SYSTEMIC SCLEROSIS GROUP TREATED WITH BOSENTAN

L. Groseanu<sup>1,2</sup>, F. Berghea<sup>1,2</sup>, V. Bojinca<sup>1,2</sup>, A. Balanescu<sup>1,2</sup>, A. Borangiu<sup>1</sup>, D. Mazilu<sup>1,2</sup>, S. Daia-Iliescu<sup>1,2</sup>, D. Opris-Belinski<sup>1,2</sup>, I. Saulescu<sup>1,2</sup>, C. Constantinescu<sup>1,2</sup>, M. Abobului<sup>1,2</sup>, R. Ionescu<sup>1,2</sup>. <sup>1</sup>Internal Medicine and Rheumatology, *Sf Maria Clinical Hospital*, <sup>2</sup>Carol Davila University of Medicine and Pharmacy, Bucharest, Romania

**Background:** Prospective studies with Bosentan have shown short term efficacy, while it is not clear whether long-term treatment may be effective or whether ulcers may recur once treatment is discontinued.

**Objectives:** Our objective was to evaluate the long term efficacy and tolerability of bosentan in patients with systemic sclerosis (SSc) who develop digital ulcers (DU).

**Methods:** In the present prospective, observational, non-controlled study, we followed 26 SSc patients treated with Bosentan from Sept 2014 to Dec 2017 Number of DU, semiquantitative capillaroscopic scoring, VAS (visual analogue scale) for Raynaud, VAS for DU and HAQ were evaluated every 6 month. Results are presented as mean(sd). The difference between efficacy measures at follow-up visits was tested with the Wilcoxon's signed-rank test.

**Results:** The group included 26 patients, 16 females, 11 diffuse subsets, age was 48.08 (9.8) years, disease duration was 84.35 (76.04) months, number of DU was 4.27 (3.71), most of them had a late scleroderma pattern pattern (16/26).

Microangiopathy evolution score was 5.19 (2.04), VAS for DU was 75.52 (16.17), VAS for Raynaud was 67.43 (14.16), HAQ was 1.62 (0.55). 5 patients received Bosentan less than 6 months, so they were excluded from the statistical analysis. 6 month evaluation revealed significant decrease in the number of DU ( $p<0.01$ ), the VAS for DU ( $p<0.01$ ), the VAS for Raynaud ( $p=0.03$ ) and the HAQ ( $p=0.04$ ), but not of the microangiopathy evolution score. No significant difference was noticed of the above mentioned parameters at the next follow-up evaluations.

Regarding Bosentan safety: 6 patients died during the follow up (3 cases of severe pulmonary arterial hypertension, 1 scleroderma renal crisis, 1 heart failure, 1 post vascular surgery). Bosentan was stopped due to lack of efficacy in 2 cases and due to side effects in 3 cases: 2 elevated liver enzymes, 1 severe thrombocytopenia and 1 dyspnea aggravation.

12 patients had a follow up after 6 months Bosentan stop. We did not notice any significant increase in the number of DU, the VAS for DU or Raynaud, the capillaroscopic semiquantitative scoring or the HAQ.

**Conclusions:** We noted a significant decrease in the number of DU, patients perception of Raynaud and of DU after 6 months of treatment and the effect was maintained in the 3 years follow-up, even 6 months after Bosentan was stopped. In this long-term follow-up no new unidentified adverse reactions were found, except for the unexpected severe thrombocytopenia. The present study is limited due to the small sample size, to the observational nature and should be viewed as descriptive. Questions rise about drug costs (6 months or long term treatment), but it also has to be emphasised that most of these lesions were chronic and non-responsive to previous treatments.

#### AB0780 PROLONGED PROTON PUMP INHIBITOR EXPOSURE IS ASSOCIATED WITH DEVELOPMENT OF CALCINOSIS IN SYSTEMIC SCLEROSIS

L.V. Host, C. Campochiaro, S.I. Nihtyanova, V.H. Ong, C.P. Denton. *Centre for Rheumatology and Connective Tissue Diseases, The Royal Free Hospital, London, UK*

**Background:** Long-term use of proton pump inhibitors (PPI) has been associated with some safety concerns, including potential vascular calcification. In a previous retrospective analysis, we noted a possible association between PPI use and calcinosis in scleroderma (SSc).

**Objectives:** To investigate the association between PPI use and the presence and extent of calcinosis in SSc patients.

**Methods:** Data from prospectively recruited patients were collected by patient survey, physician assessment and medical records. Calcinosis was graded; size ( $=<1$  cm,  $+=1-3$  cm,  $++>=>3$  cm) and number of sites involved (NSI) ( $I=1$  body site,  $II=2-3$ ,  $III\geq 3$ ). A total daily PPI equivalent dose (TDED) was calculated for each patient. We calculated PPI exposure score (PPE) by multiplying the total duration of use by TDED. For analysis, PPE was categorised into four groups; 0=no exposure, 1=up to 5 years, 2=6–10 years, 3> $\geq 10$  years. Fisher's exact test was used to assess categorical variables. Logistic regression assessed association between calcinosis and independent variables.

**Results:** 216 patients were recruited, 81.5% females, mean age 57.46 (SD 13.5) years. 56.5% had limited, 31.5% diffuse SSc, 9.7% had overlap features and 2.3% other CTD. Mean disease duration was 10 years (SD 9). ANA subtypes were defined: ACA positive (31.5%), ATA (25.5%), ARA (12.0%), ANA +ENA- (11.6%), U3RNP (5.1%), ANA- (4.2%), PmSCL (3.7%) and 6.5% other antibodies. Gastroesophageal reflux symptoms occurred in 83.3% of patients, most were on PPI (81%) and 14.8% had previously been on PPI. Current calcinosis (CC) was present in 30.1% patients, 9.7% reported past calcinosis. 39.8% had calcinosis at any time (CAT). 60.2% of patients never had calcinosis. Of those with CC, 47.7% had  $>1$  site involved. The most frequent sites affected were; finger (70.8%), elbow (35.4%) and knee (18.5%).

Univariable analysis found an association between disease duration and calcinosis, with odds of CAT increased by 7% per year (OR 1.07, CI 1.04–1.11,  $p<0.001$ ). Similarly, every year of PPE increased odds of CAT by 3% (OR 1.03, CI 1.01–1.05,  $p=0.003$ ). Increasing age associated with CAT (odds increasing by 2% per annum,  $p=0.043$ ). Exposure to a standard dose of PPI for over 10 years increased the odds of calcinosis by 4 times (OR 4.07, CI 1.68–9.85,  $p=0.002$ ) compared to no exposure. PPE category associated with NSI ( $p=0.04$ ). 73.3% of patients with

large volume calcinosis ( $>3$  cm) had a PPE for  $>10$  years and all with calcinosis  $>3$  cm had exposure to PPI.

Multivariable logistic regression found that disease duration (OR 1.07, CI 1.03–1.11,  $p=0.001$ ) and antibody specificity strongly associated with calcinosis. Presence of ATA (OR 0.32, CI 0.14–0.75  $p=0.008$ ), ANA- (OR 0.13, CI 0.02–0.79,  $p=0.026$ ), and ANA +ENA- (OR 0.17, CI 0.05–0.52,  $p=0.002$ ) reduced odds of calcinosis. Although the effect of PPIs on calcinosis was attenuated after adjusting for disease duration and antibodies, higher exposure to PPIs remained a significant predictor of calcinosis, with PPE category ( $>10$ ) increasing risk of CAT (OR 3.34, CI 1.16–9.17,  $p=0.025$ ).

**Conclusions:** Our data support a novel association of PPI exposure with calcinosis and confirm association of disease duration and antibody profile. Given the clinical impact of calcinosis, a potentially modifiable risk factor of PPI exposure warrants further study.

#### AB0781 GLUCOCORTICOID DOSE AND CARDIAC INVOLVEMENT MIGHT BE POTENTIAL RISK FACTORS FOR SCLERODERMA RENAL CRISIS

X.-N. Wei, D.-H. Zheng, J.-J. Liang, L. Dai. *Rheumatology, Sun Yat-Sen Memorial Hospital, Sun Yat-Sen University, Guangzhou, China*

**Background:** Scleroderma renal crisis (SRC) is a rare but life-threatening complication of systemic sclerosis (SSc). SRC remains a major risk factor for mortality in SSc. It is important to identify potential risk factors for SRC, and avoid developing overt SRC.

**Objectives:** To perform a retrospective case series analysis of the characteristics, management and outcomes of SRC in Chinese SSc patients.

**Methods:** SSc patients hospitalised at Sun Yat-Sen Memorial Hospital from January 1992 to December 2017 were recruited. Clinical data were collected. SRC was defined as new onset, with blood pressure (BP)  $>140/90$  mmHg or  $\geq 30$  mmHg rise in BP from baseline, rising serum creatinine (Scr) levels and/or oliguria. Data were showed as mean  $\pm$  standard deviation.

**Results:** (<sup>1</sup> There were 749 SSc patients recruited and 16 patients (2.1%) of them were hospitalised for SRC. Among these 16 patients, 56% were females, age was  $54.6\pm 13.6$  years, mean duration from SSc onset to SRC occurred was 4 years.

(<sup>2</sup> SRC developed in 14 patients (87.5%) with diffuse cutaneous SSc (dcSSc), and in 2 patients (12.5%) with limited cutaneous SSc (lcSSc). Eleven patients (68.8%) were under glucocorticoid treatment before SRC onset: 4 patients received  $\geq 30$  mg/d of prednisone, 6 patients received  $\geq 7.5$  mg/d prednisone and 1 patient received  $<7.5$  mg/d prednisone. No patient was treated with angiotensin-converting enzyme (ACE) inhibitors before SRC.

(<sup>3</sup> All 16 patients manifested progressive renal failure, with Scr levels increase to  $420\pm 256$   $\mu\text{mol/L}$ . Ten patients manifested new onset hypertension, with systolic BP  $175\pm 21$  mmHg and diastolic BP  $108\pm 13$  mmHg. Five patients who had a history of well-controlled hypertension manifested accelerated increase in BP  $178\pm 17/108\pm 7$  mmHg. One patient was normotensive, but manifested rapidly progressive oliguric renal failure with Scr increase to 969  $\mu\text{mol/L}$ , massive proteinuria and hemolytic anaemia.

(<sup>4</sup> Twelve patients (75%) had pulmonary fibrosis, 11 patients (68.8%) had cardiac involvement, 6 patients had pulmonary arterial hypertension (PAH) and 6 patients had gastrointestinal dysfunction. Cardiac involvement was common, manifested pericarditis, myocardial damage and heart failure ( $n=7$ , 43.8%, respectively). All 5 dead patients were accompanied by cardiac involvement.

(<sup>5</sup> Eleven patients had Raynaud's phenomenon, 8 patients had digital ulcers, 5 patients had arthritis and 2 patients had oliguria. Thirteen patients (81%) manifested anaemia, 8 patients (50%) manifested thrombocytopenia, and 8 patients (50%) manifested microangiopathic haemolytic anaemia (MAHA).

Eleven patients (68.8%) received ACE inhibitor treatment. Fifteen patients were treated with glucocorticoid and 12 patients with immunosuppressant (Cyclophosphamide  $n=10$ , Azathioprine  $n=2$ ). After treatment, renal recovered in 4 patients (25%), kidney function improved and developed to chronic kidney disease (CKD) without dialysis in 5 patients (31%), 2 patients required permanent dialysis (13%). Five patients (31%) died.

**Abstract AB0781 – Table 1.** Characteristics of 16 patients with Scleroderma renal crisis

Pt.No	Age(y)	Sex	SRC diagnosis	Prednisone before SRC	Ssc form	Pulmonary fibrosis	Cardiac involvement	PAH	MAHA	BP (mmHg)	Ser (mmol/L)	ACE inhibitor	Outcome
1	62	F	0.25	10mg/d	dcSSc	-	-	-	-	170/100	206	None	Recovered

15	58	F	1	None	dcSSc	-	-	-	-	150/86	473	None	died
16	46	F	1	35mg/d	dcSSc	-	-	-	-	180/100	392	Captopril	died

SRC: Scleroderma renal crisis, SSc: systemic sclerosis, dcSSc: diffuse cutaneous SSc, lcSSc: limited cutaneous SSc, PAH: pulmonary arterial hypertension, MAHA: microangiopathic haemolytic anaemia, CKD: chronic kidney disease

**Conclusions:** Medium-to-high doses of glucocorticoids (prednisone  $\geq 7.5$  mg/d) were associated with an increased risk of SRC. Cardiac involvement was common and associated with high mortality in SRC patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6559

### AB0782 SYSTEMIC SCLEROSIS PATIENTS WITH CONCOMITANT PSORIASIS: A PROOF-OF-CONCEPT PILOT STUDY

L. Magnani<sup>1</sup>, G. Bajocchi<sup>1</sup>, I. Chiarolanza<sup>1</sup>, A. Caruso<sup>1</sup>, R. Aldigeri<sup>2</sup>, C. Salvarani<sup>1</sup>.  
<sup>1</sup>ASMN Reggio Emilia, Reggio Emilia; <sup>2</sup>Università di Parma, PARMA, Italy

**Background:** Psoriasis and Systemic Sclerosis (SSc) are chronic inflammatory diseases characterised by a systemic immunological response which is mainly driven by activated T helper (Th) Th1/Th17 lymphocytes.<sup>1,2</sup> Further, genome-wide association studies (GWAS) in SSc have demonstrated an association at PSORS1C1, the same gene linked to psoriasis susceptibility<sup>3</sup>

**Objectives:** Evaluate the statistical significance of a clinical correlation between Scleroderma and Psoriasis

**Methods:** From April 2014 to April 2017, we enrolled 180 consecutive patients with a diagnosis of SSc fulfilling 2013 ACR/EULAR classification criteria. Patients with Localised Scleroderma (Morphea) had to have a diagnostic skin biopsy before being included. Patients satisfying VEDOSS criteria<sup>4</sup> were also included. Patients with psoriasis had a dermatologist-proven diagnosis.

**Results:** 11/180 (6.1%, 95% IC:0.03–2.9) with scleroderma had a dermatologist-proven diagnosis of Psoriasis, and 23 patients (12.7%) had a family history of Psoriasis in a first-degree relative. For all the psoriatic patients except one, BMI was calculated; 50% had a BMI of >20 (average: 23.7). A metabolic syndrome was present in 3 out of 11 (27.2%), and in ten patients there were data available to calculate the presence of average moderate cardiovascular (CV) risk (11.5%). Finally, 3/11 patients (27.2%) had Psoriatic Arthritis (CASPAR classification criteria). In all 11 patients, Psoriasis was defined as mild (PASI  $\leq 10$ ).<sup>5</sup> The average value of modified Rodnan Skin Score (mRSS) was curiously low (0.5), [limited cutaneous (lcSSc) 5 patients, Morphea 3 patients, Very Early Systemic Sclerosis (VEDOSS) 2 patients, and diffuse cutaneous disease (dcSSc) 1 patient. Anticentromere antibodies (ACA) were detected in 5/11 patients; antinuclear antibodies, with negative extractable nuclear antigens in 4/11; Anti-topoisomerase I were found in two cases.

**Conclusions:** Psoriasis was significantly associated with SSc ( $p=0.014$ ), with a 2-fold higher frequency than that observed in general population (3%). Psoriasis +SSc, represent a further increased risk of CV disease. Th17 seems to play a crucial role in the pathogenesis of both diseases.

### AB0783 CLINICAL CHARACTERISTICS OF A COHORT OF PATIENTS WITH ANTI-JO1 ANTIBODIES

M.C. Carrasco Cubero<sup>1</sup>, S.M. Rojas Herrera<sup>2</sup>, M.L. Vargas Pérez<sup>3</sup>, M.I. Alcalá Peña<sup>3</sup>, M. Espárrago Rodilla<sup>4</sup>, E. Chamizo Carmona<sup>2</sup>. <sup>1</sup>Rheumatology, CHU Infanta Cristina; <sup>2</sup>Rheumatology, Hospital de Mérida; <sup>3</sup>Immunology, CHU Infanta Cristina; <sup>4</sup>Immunology, Hospital de Mérida, Badajoz, Spain

**Background:** Anti-synthetase syndrome (ASSD) is characterised by myositis associated with anti-synthetase antibodies, fever, arthritis, Raynaud's phenomenon, "mechanic's hands" and diffuse interstitial lung disease (ILD); 80% of patients present incomplete forms. The most frequently detected anti-synthetase antibody is anti-Jo1 (anti-histidyl-tRNA synthetase), which usually leads to a greater lung involvement. In some cases of myositis, the simultaneous presence of anti-Jo1 and anti-Ro52 antibodies has been described, and it is debated whether the presence of both antibodies is accompanied by more severe pulmonary involvement.

**Objectives:** To compare the clinical manifestations of the positive anti-Jo1 patients, with and without associated anti-Ro52 antibodies.

**Methods:** This is a retrospective observational study of anti-Jo1 positive patients confirmed in the Immunology Laboratory, between 2009 and 2018. Two techniques were used to identify the anti-Jo1 and anti-Ro52 antibodies: Western blot (EUROLINE Myositis Profile 3 (IgG)) and Fluoroenzimoinmunoassay (EliA, Thermofisher).

**Results:** In this study, 22 patients with anti-Jo1 antibodies were included, 16 (72.7%) women and 6 (27.2%) males. There was no association with FR or ACPA. The mean age was 57.3 years (SD:14.6) and the mean time of follow-up was 4.01 years (SD: 2.1). Of all patients, 5 had ASSD, the rest expressed the clinical picture of incomplete form. The most frequently clinical manifestations associated with anti-Jo1 were: muscular involvement (n=18, 81.8%), ILD (n=13, 59.1%), arthritis (n=9,40.9%), Raynaud's phenomenon (n=4, 18.2%). No patient developed lesions of mechanic's hands. The majority of patients with muscular involvement (83.3%), had histological confirmation of inflammatory idiopathic myopathy (Dermato or Polymyositis). The most frequently found X-ray pattern (HRCT) in patients with ILD was Non-specific interstitial pneumonia (NSIP) (n=9, 69.2%), followed by 2 Respiratory bronchiolitis interstitial lung disease (RB-ILD) and 2 Idiopathic interstitial pneumonia (IIP). Nine patients presented ILD and Myositis concomitantly (40.9%), more than half had fibrosing pulmonary involvement. 50% (n=11) also had criteria for other autoimmune diseases (2 rheumatoid arthritis, 4 polymyositis, 4 dermatomyositis, and 1 overlap). Half of the patients with anti-Jo1 presented also anti-Ro52, which 27.3% exclusively developed myopathy, 18.2% ILD and both entities 54.5%. Half of the ILD presented a radiological fibrosing radiological pattern. During follow-up, 7 patients (31.8%) died, 2 of metastatic cancer (one renal and one ovarian) and 5 of complications of the ILD, of which 80% were anti-Jo1/anti-Ro52 "doublet" positives.

**Abstract AB0783 – Table 1**

	Age years (SD)	Follow-up years (SD)	Arthritis n(%)	Raynaud n(%)	Myositis n(%)	ILD n (%)	ILD/Myositis n(%)	Exitus n(%)
Anti-Jo1 (n=22)	57,3 (14,6)	4,0 (2,1)	9 (40,9)	4 (18,2)	18 <sup>(81,8)</sup>	13 <sup>(59,1)</sup>	9 (40,9)	7 (31,8)
"Doublet"	59,2 (15,3)	3,8 (2,0)	6 (54,5)	3 (27,3)	9 (81,8)	8 (72,7)	6 (54,5)	4 (36,4)
Anti-Jo1/ Anti-Ro52 (n=11)								

**Conclusions:** The ILD is a frequent manifestation and the main cause of death in the patients with anti-Jo1 of our cohort. The presence of anti-Jo1/anti-Ro52 "doublet" seems to lead to a worse prognosis in these patients.

**Disclosure of Interest:** None declared

**AB0784 MYOCARDIAL FIBROSIS DETECTED BY MAGNETIC RESONANCE IMAGING IN SYSTEMIC SCLEROSIS—PATHOPHYSIOLOGICAL SIGNIFICANCE**

M. Funauchi, K. Kishimoto, Y. Nozaki. *Hematology and Rheumatology, Kindai University Faculty of Medicine, Osakasayama, Japan*

**Background:** Systemic sclerosis (SSc) is characterised by chronic fibrosis in various organs such as skin, lung and heart leading to poor prognosis. Myocardial fibrosis is one of factors of pulmonary hypertension (PH) as well as pulmonary arterial hypertension or interstitial lung disease (ILD). Detection of cardiac lesions has progressed much using imaging techniques such as echocardiography (UCG) in combination with measurement of various biomarkers such as BNP. Recently, cardiac magnetic resonance imaging (CMR) has been shown to be sensitive to detect even subclinical cardiac lesions. However, it is unclear what subtype of SSc is prone to myocardial fibrosis, when it manifests in the clinical course, or whether fibrosis occurs simultaneously in various organs.

**Objectives:** To clarify the pathophysiological significance of myocardial fibrosis in SSc, CMR was performed in the patients with limited (lc) and diffuse (dc) cutaneous SSc with or without PH.

**Methods:** Twelve patients (male 2, female 10) who fulfilled ACR/EULAR criteria (2013) for SSc were enrolled. Eight patients were diagnosed as having lcSSc and 4 dcSSc. In addition to CMR, chest CT scan, UCG and laboratory tests including serum autoantibodies specific for SSc, blood brain natriuretic peptide (BNP) and pulmonary function test (%FVC,%DLCO) were performed in all patients. Right heart catheterization was performed in patients whose systolic right ventricular pressure estimated by UCG was higher than 30 mmHg. Positivity of late gadolinium enhancement (LGE) was compared with clinical findings and these parameters. Difference between the patient groups were tested using Student's t-test.

**Results:** LGE was positive in 6 out of 12 patients. Patient composition of dc/lc in LGE (+) and LGE (-) group was 1/5 and 3/3, respectively. Complication of ILD was present in 3 among LGE (-) patients, while esophageal involvement in 3 among LGE (+) patients. The mean age of LGE (+) group tended to be higher than that of LGE (-) group (73.8±5.8 vs 68±6.4), duration of disease (year) tended to be shorter in LGE (+) group than those of LGE (-) group (1.8±3.0 vs 7.7±5.5), and BNP level (170.6±150.1 vs 90.1±69.0 pg/ml) and RVP (33.5±8.1 vs 29.7±8.1 mmHg) tended to be higher in LGE (+) than in LGE (-) group, although difference was not statistically significant. There was no tendency of positivity of autoantibodies and pulmonary function test, while patients with low%DLCO (<70) and without ILD were positive for LGE. LGE tended to be positive in the patients whose E/e' ratio determined by UCG or pulmonary capillary wedge pressure by RHC was elevated.

**Conclusions:** Since myocardial fibrosis was found rather in the cases without ILD, there might be difference in the progression of fibrosis depending on the organ, although it accelerates by ageing. If LGE is seen, PH, especially that associated with left heart disease, might occur in future. This study suggests that CMR might be useful to detect cardiac lesions from early period of clinical course, as well as in the cases with some abnormalities in biomarkers such as BNP or DLCO regardless of existence of ILD, although further study is needed to clarify the indication of CMR using more cases of SSc.

**AB0785 RED CELL DISTRIBUTION WIDTH IS A PROMISING MARKER OF PULMONARY ARTERIAL HYPERTENSION IN SCLERODERMA-RELATED DISORDERS**

M. Bellan<sup>1,2</sup>, M. Sguazzotti<sup>2</sup>, C. Piccinino<sup>3</sup>, A. Giubertoni<sup>3</sup>, J. Zanaboni<sup>3</sup>, A. Dimagli<sup>3</sup>, M. Gravellona<sup>3</sup>, P. Marino<sup>3</sup>, M. Pirisi<sup>4</sup>, P.P. Sainaghi<sup>4</sup>. <sup>1</sup>Division of Internal Medicine, Sant'Andrea Hospital, Vercelli; <sup>2</sup>Translational Medicine, Università del Piemonte Orientale; <sup>3</sup>Division of Cardiology; <sup>4</sup>Division of Internal Medicine, Maggiore della Carità Hospital, Novara, Italy

**Background:** The early identification of those Systemic Sclerosis (SSc) patients harbouring Pulmonary Arterial Hypertension (PAH) is a mainstay in the management of SSc. Novel biomarkers might improve the specificity of screening algorithms currently available.

**Objectives:** In this study we aimed to test the potential diagnostic value of Red cell distribution width (RDW), which has been previously described as a potential prognostic marker in thromboembolic and idiopathic PAH.

**Methods:** We prospectively recruited 118 patients affected by Scleroderma related disorders (Mixed connective tissue disease N. 7, 5.9%; SSc N. 93, 78.8%; Scleroderma overlap syndromes N. 11, 9.3%, undifferentiated connective tissue

diseases N. 7, 5.9%) in a PAH outpatient clinic of a University Hospital. All patients underwent an extensive clinical and laboratory evaluation and an echocardiographic examination; a right heart catheterization was performed in 13 patients according to clinical indication.

**Results:** According to echocardiography and right heart catheterization, 14/118 patients were diagnosed with PAH. Patients affected by PAH had a higher RDW (15 [13.4–18.9] vs. 13.9 [12.1–19.1]; p=0.005), despite similar haemoglobin levels between groups. Patients affected by PAH also showed a higher BNP plasma concentration (245.6 [81.6–494.3] vs. 60.3 [50.3–77.4]; p=0.0001) and lower platelets count [206 188–243 × 10<sup>3</sup>/μl vs 240 [198–299] × 10<sup>3</sup>/μ; p=0.04]. RDW was also directly related to ultrasound-assessed Pulmonary Artery Pressure (PAPs) (ρ=0.20; p=0.03) and DLCO corrected for haemoglobin (ρ=-0.30; p=0.001); finally, RDW was related to the mean PAP measured by right heart catheterization (ρ=0.65; p=0.015).

**Conclusions:** RDW is an inexpensive, potentially useful marker in the detection of SSc-related PAH; its inclusion in screening algorithms could be considered to further improve their diagnostic performance.

**AB0786 ROLE OF CALCIUM ANTAGONISTS IN THE CANCER OF SYSTEMIC SCLEROSIS, AN ASSOCIATION UNDER DISCUSSION**

M. Freire, A. Cabaleiro, M. Suarez, M. Estevez, L. Rodríguez, J.M. Cacheiro, R. Lorenzo, N. Val, A. Argibay, A. Rivera. *Systemic Autoimmune Diseases and Thrombosis Unit, Complejo Hospitalario Universitario De Vigo, Vigo, Spain*

**Background:** The use of calcium channel blockers (CCB) is widespread in systemic sclerosis (SSc) for the treatment of Raynaud's phenomenon, present in 95% of patients. CCB can alter apoptosis, a mechanism for the destruction of cancer cells. In SSc the risk of cancer is increased, but the role that CCB can play is not clear, with contradictory data obtained so far.<sup>1,2</sup>

**Objectives:** To analyse the role of CCB in the appearance of cancer in a cohort of patients with systemic sclerosis.

**Methods:** Encoded patients under the diagnosis of SSc in our hospital from 1985 until December of 2017 were collected. Medical records were reviewed, recording clinico-epidemiological data and treatments used.

**Results:** 120 patients have been diagnosed of SSc (103 females, 17 males), 22 of whom (18,3%) have developed cancer. The type of cancer were (in order of frequency): breast (12 patients, 57%), gastrointestinal (4 patients, 33%), one hypernephroma, one endometrial carcinoma, one lymphoma, one skin cancer and one epidermoid of tongue. Adenocarcinoma was the most frequently histologic pattern found (16 patients, 76%). Interestingly, the diagnosis of SSc was made at an older age in those patients diagnosed of cancer (66,4±11,7 vs 54,8±17,3 years old, p=0,019); An age older than 55 years old conferred a relative risk (RR) of cancer of 1,69<sup>1,26-2,25</sup> in the global cohort and a RR of 3,26<sup>1,18-8,99</sup> in the female cohort. Although the association cancer and CCB did not reach statistical significance, the association CCB and female patients older than 55 years elevate de RR of cancer to 4,16 (0.96–17,95). All other characteristics (epidemiological, clinical, analytical and another treatments) analyzed did not reach statistical significant differences.

**Conclusions:** CCB increase in our series the risk of cancer in women over 55 years old. CCB could be implicated in the pathogenesis of cancer in SSc. Due to the broad use of this in the SSc population, it may be require to study in a large number of patients in order to explore this association.

Distler<sup>1</sup>. <sup>1</sup>Rheumatology, UNIVERSITY HOSPITAL ZUERICH, Zurich, Switzerland; <sup>2</sup>Royal Free London NHS Foundation Trust, London, UK; <sup>3</sup>Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands; <sup>4</sup>Federation of European Scleroderma Associations, Dublin, Ireland; <sup>5</sup>Rheumatology, University Paris Descartes and Cochin Hospital, Paris, France; <sup>6</sup>Rheumatology, Hospital Universitario 12 de Octubre and Universidad Complutense de Madrid, Madrid, Spain; <sup>7</sup>Immunology and Rheumatology, Faculty of Medicine, University of Pécs, Pécs, Hungary; <sup>8</sup>Rheumatology, Royal Free and University College London Medical School, Royal Free Campus, London, UK; <sup>9</sup>Rheumatology, Lund University, Lund, Sweden; <sup>10</sup>Department of Rheumatology and Internal Medicine, Medical University of Białystok, Białystok, Poland; <sup>11</sup>Rheumatology, University of Florence, Florence, Italy; <sup>12</sup>Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; <sup>13</sup>Rheumatology and Clinical Immunology, Justus-Liebig University Giessen, Kerckhoff-Klinik Bad Nauheim, Bad Nauheim, Germany; <sup>14</sup>Research Support Services CTU, Oslo University Hospital; <sup>15</sup>Health and Social Sciences, Oestfold University College, Oslo, Norway

**Background:** Patient reported outcome measures (PROs) are increasingly important for clinical practice and research. Given the unmet need for a comprehensive PRO for systemic sclerosis (SSc), the ScleroID questionnaire was developed by a joint team of patients with SSc and medical experts in the field. This approach was designed as a brief, specific, patient-derived, disease impact score for research and clinical use in SSc. A preliminary analysis was previously reported. Here, we present the first computation of the ScleroID score and an extended pre-final analysis from the ongoing ScleroID validation study.

**Methods:** This EULAR-endorsed project involves 11 European expert SSc centres. Patients fulfilling the ACR/EULAR 2013 criteria were prospectively included since 05/16 in the ongoing observational cohort study. Patients completed the ScleroID questionnaire (figure 1), as well as the selected comparators mSHAQ, EQ5D, and SF36. Additionally, they weighted the 10 dimensions of the ScleroID by distributing 100 points according to the perceived impact on their health. The final score calculation was based on the ranking of the weights. The study included a reliability arm (follow-up questionnaire 7–10 days from baseline), as well as a longitudinal arm, looking at sensitivity to change at follow-up visits after 6 and 12 months from baseline.

How much have the different aspects of systemic sclerosis affected you during the last week? Please mark your responses on the scale by choosing the appropriate number for each of the following dimensions:

Reynaud's phenomenon:  
Circle the number that best describes the severity of your Reynaud's phenomenon during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Hand function:  
Circle the number that best describes your hand function limitations due to your systemic sclerosis during the last week:  
No limitation 0 1 2 3 4 5 6 7 8 9 10 Extreme limitation

Upper gastrointestinal tract symptoms (e.g. swallowing difficulties, reflux, vomiting):  
Circle the number that best describes the severity of your upper gastrointestinal tract symptoms due to your systemic sclerosis during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Pain:  
Circle the number that best describes the pain you felt due to your systemic sclerosis during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Fatigue:  
Circle the number that best describes the impact of overall fatigue due to your systemic sclerosis during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Lower gastrointestinal tract symptoms (e.g. bloating, diarrhea, constipation, anal incontinence):  
Circle the number that best describes the severity of lower gastrointestinal tract symptoms during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Limitations of life choices and activities (e.g. social life, personal care, work):  
Circle the number that best describes how severe the limitations of life choices and activities due to your systemic sclerosis were during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Body mobility:  
Circle the number that best describes how much your body mobility was affected due to your systemic sclerosis during the last week:  
Not affected 0 1 2 3 4 5 6 7 8 9 10 Extremely affected

Breathlessness:  
Circle the number that best describes how severe your breathlessness due to systemic sclerosis was during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Digital ulcers:  
Circle the number that best describes how much your digital ulcers affected you overall during the last week:  
None 0 1 2 3 4 5 6 7 8 9 10 Extreme

Abstract AB0787 – Figure 1. The EULAR Scleroderma Impact of Disease Score (ScleroID)

**Results:** As of January 2018, the study cohort included 417 patients with valid baseline data, 80 patients also had a reliability visit and 42 patients a follow-up

visit. 84% of patients were female, 62% had limited cutaneous SSc, mean age was 56 years, and median disease duration 10 years. 19% of patients were not able to work. The highest weights by the patients were assigned to Raynaud's phenomenon, fatigue, hand function and pain, in accordance with our previous results. The total ScleroID score showed good Spearman correlation coefficients with the comparators (mSHAQ, 0.59; EQ5D –0.62; Patient's global assessment, VAS 0.75; SF36 physical score –0.62; each p<0.001). The internal consistency was good with a high Cronbach's alpha by 0.86.

**Conclusions:** The EULAR ScleroID score is a promising, novel PRO tool designed for use in clinical practice and clinical trials to display the disease impact of SSc, showing good performance in this pre-final analysis. Importantly, Raynaud's phenomenon, impaired hand function, pain and fatigue were the main patient reported drivers of disease impact. To date the recruitment has reached more than 80% of the targeted number, the study is ongoing.

### OSTEOARTICULAR INVOLVEMENTS IN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Tougorti, T. Ben Salem, I. Ben Ghorbel, M. Lamoum, M.H. Houman. *Internal medicine, RABTA HOSPITAL, Tunis, Tunisia*

**Background:** Osteoarticular involvements are common in systemic sclerosis (SS) and are considered as an important cause of disability.

**Objectives:** The aim of this study was to assess clinical, radiological and immunological characteristics of patients with systemic sclerosis and who present with osteoarticular involvements at any time of the disease course. Patients with arthralgia and/or arthritis and/or imaging abnormalities were included.

**Methods:** A retrospective descriptive and comparative study was performed in an internal medicine department. One hundred thirty one patients who fulfilled 2013 ACR/EULAR criteria for SS were studied.

**Results:** We identified 101 patients with osteoarticular involvements (77.1%); 92 women and 9 men. Mean age at SS diagnosis was 47.6±12.4 years. Disease was revealed by joint manifestations in 10.7% of cases. Arthralgia and arthritis were observed in 61.8% and 21.4% of cases respectively. Flexion deformities with disability were noted in 26 cases. X-Ray investigations revealed distal phalanges resorption (n=24), dystrophic calcifications (n=10) and joint space narrowing (n=9). Tendinitis was observed in one patient. Patients with osteoarticular manifestations developed more frequently digital ulcers (100% vs 78.3%; p<0.001). Osteoarticular involvements was associated to diffuse cutaneous sclerosis (37.7% vs 12.5%; p=0.002) and to telangiectasis (91.3% vs 70%; p=0.027), gastrointestinal manifestations (90.1% vs 54.5%; p=0.001) and interstitial lung disease (92.7% vs 67.9%; p=0.001). SS was associated to sjögren syndrome (n=20), to systemic lupus erythematosus (n=15) and to rheumatoid arthritis (n=2). Patients received non-steroidal anti-inflammatory drug (n=26), corticosteroids (n=8) and methotrexate (n=8).

**Conclusions:** Osteoarticular involvement in systemic sclerosis has heterogeneous aspects. Its frequency ranges from 40% to more than 85% of cases in some studies. Early screening and treatment associated with physiotherapy session are essential to avoid complication and loss of function.

**AB0789** HOW DOES THE DURATION OF THE DISEASE INFLUENCE THE QUALITY OF LIFE?

*N. Loghin-Oprea*<sup>1</sup>, *S. Vetrila*<sup>1</sup>, *L. Mazur-Nicorici*<sup>1</sup>, *V. Salaru*<sup>2</sup>, *M. Mazur*<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Family Medicine, *SUMPh Nicolae Testemitanu, Chisinau, Moldova, Republic of*

**Background:** It is noticed that over the last decades the prognostic in patients with Idiopathic Inflammatory Myopathies (IIM) – a group of autoimmune disease characterised by muscle involvement, has improved along with increase of disease duration and thus affects the quality of life.

**Objectives:** To assess the patient's quality of life related to the duration of the disease.

**Methods:** We performed a cross-sectional study from December 2015 to December 2017, the patients included fulfilled the Bohan and Peter<sup>1</sup> criteria for IIM. Demographic and clinical data were collected using a special questionnaire. Consistent with the objective the study group was divided in two subgroups by disease duration 1-less than 24 months and second subgroup more than 2 years. In order to estimate the quality of life (QoL) was applied Short Form-8 with 8 items for 8 domains and two components: mental and physical. Statistical data was analysed using MedCalc software version 12.

**Results:** There were 67 patients enrolled in the study, including 51 females and 16 males with a F:M ratio of 3.2:1, mean age 53.1±12.5 (range 25–78). The disease mean duration was 8.3±5.3 (range 0.5–12) years, there were 16 patients in the subgroup with the disease duration less than 2 years. The mean physical component was 36.48±9.05 and the mental component – 41.69±9.62 points, determined as reduced quality of life. Regarding the QoL of patients from subgroup 1, we found the physical component – 38.15±8.83 and the mental was 40.95±9.22 points. In the second subgroup we appreciated the physical and the mental component – 35.77±9.14 and 42.01±9.86 points, respectively. It was identified moderate correlation ( $r=0.49$   $p<0.005$ ) between the both domains of the QoL and disease duration till 2 years, for the duration of more than 2 years we found moderate correlation ( $r=0.51$   $p<0.005$ ) with mental component and a weak one for physical domain ( $r=0.24$   $p<0.005$ ).

**Conclusions:** Patients with idiopathic inflammatory myopathies had reduced quality of life by both domains. Disease duration in patients with early idiopathic inflammatory myopathies – less than 2 years, has a greater impact on patient's quality of life.

**AB0790** FREQUENCY OF OSTEOPOROSIS IN POSTMENOPAUSAL WOMEN WITH SYSTEMIC SCLEROSIS

*O. Dobrovolskaya*, *N. Demin*, *A. Smirnov*, *O. Koneva*, *N. Toroptsova*, *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The prevalence of low bone mass or osteoporosis in patients with systemic sclerosis (SSc) varies significantly between studies performed in different countries and vary from 3% to 51% (Omair MA et al. 2013).

**Objectives:** To determine the frequency of osteoporosis (OP) in postmenopausal women with SSc in comparison with healthy control.

**Methods:** 163 postmenopausal women were enrolled in the study: 83 with SSc (mean age 58.5±8.1 years, mean disease duration 9.7±6.8 years) and 80 healthy control (mean age 59.2±6.6 years). Demographic characteristics and risk factors for OP in study groups are summarised in table 1. BMD was measured at lumbar spine, femoral neck and total hip by dual energy X-ray absorptiometry (DXA, Hologic 4500A). BMD decreasing grade was determined in according to WHO criteria.

**Results:** BMD in women with SSc was significantly lower than in control group at any site: lumbar spine – 0.832±0.119 vs 0.867±0.098 g/cm<sup>2</sup> ( $p=0.031$ ); femoral neck – 0.633±0.098 vs 0.739±0.114 g/cm<sup>2</sup> ( $p<0.0001$ ), and total hip – 0.752±0.116 vs 0.839±0.119 g/cm<sup>2</sup> ( $p<0.0001$ ). Frequency of OP in SSc group was 32%, in control group – 13% ( $p<0.002$ ). Mean age at menopause was less in SSc women than in control ( $p<0.05$ ).

OP was significantly more often in SSc patients taking oral glucocorticoids compared to those without glucocorticoid therapy (39% and 20%, respectively,  $p<0.05$ ). Low BMD was associated with age and interstitial lung disease in SSc women ( $p<0.05$ ). At the same time no associations were found out among low BMD and disease duration, daily and cumulative doses of glucocorticoids. 23 (28%) of patients had osteoporotic fracture, among them 8 (10%) of women had two or more fractures in the anamnesis. The most frequent localizations of the fractures were distal forearm and vertebrae: 7 (32%) and 5 (23%) patients, respectively.

**Abstract AB0790 – Table 1.** Demographic characteristics of the study groups and risk factors of osteoporosis

Factor affecting BMD	SSc (n=83) Mean±SD or%	Control (n=80) Mean±SD or%
Age (years)	58.5±8.1	59.2±6.6
Body height (m)	1.61±0.06	1.59±0.06
Body weight (kg)	67.7±14.3	66.5±11.7
Body mass index (kg/m <sup>2</sup> )	26.1±5.2	25.7±5.7
Age at menopause (years)	46.4±5.4*	49.7±3.0
Postmenopause duration (years)	12.2±7.2*	9.5±7.0
Smoking et presence time	3 (3.6%)	5 (6.3%)
Low energy fracture	23 (28%)	16 (20%)

\* $p<0.05$  compared vs control group

**Conclusions:** OP in postmenopausal women with SSc were detected among 1/3 of cases, significantly exceeded its frequency in healthy control. Risk factors for OP were age, oral glucocorticoids and interstitial lung disease.

**AB0791** SPECIFIC FEATURES OF SKIN INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS AND ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

*N. Yudkina*<sup>1</sup>, *A. Volkov*<sup>1</sup>, *T. Martynyuk*<sup>2</sup>, *E. Nasonov*<sup>1</sup>. <sup>1</sup>V.A. Nasonova Scientific Research Institute of Rheumatology; <sup>2</sup>Cardiology Scientific Medical Research Center, Moscow, Russian Federation

**Background:** Pulmonary arterial hypertension, associated with systemic sclerosis (SSc-PAH), is a severe irreversible manifestation of the disease, potentially fatal in its' late stage. It was shown that survival in SSc-PAH pts is much worse than in pts with idiopathic pulmonary arterial hypertension (IPAH). Unfavourable outcomes due to late recognition can be explained by predominance of subtle, clinically poor manifest SSc types, especially in terms of cutaneous and vascular syndromes.

**Objectives:** To assess the clinical features and survival rates in pts with systemic sclerosis sine scleroderma (ssSSc), associated with PAH.

**Methods:** 14 pts with ssSSc-PAH were analysed in comparison with 54 pts with clinically manifest skin involvement SSc-PAH (3 pts with diffuse (dcSSc-PAH) and 51 pts with limited cutaneous involvement (lcSSc-PAH)), and 48 pts with IPAH.

**Results:** Pts with IPAH were younger than both type SSc-PAH – 37 (28; 44), 48 (37; 56) and 54 (48; 62) y, respectively. In SSc-PAH pts with skin involvement and the diagnosis of PAH was established earlier (within 18 (10; 44) mo) than in pts with ssSSc (23 [15; 47] mo), although differences are not statistically significant. The PAH functional class was slightly higher in ssSSc-PAH, than in IPAH and SSc-PAH, the differences are not significant. Raynaud's phenomenon (RP) was present in all SSc-PAH pts, although in cutaneous SSc pts digital ischaemic lesions were more frequent (51% vs 14%,  $p=0.03$ ), as well as contractures (53% vs 7%,  $p=0.006$ ). There were no other differences in clinical features between the groups. Anticentromere antibodies (ACA) were present in 7 (50%) pts with ssSSc-PAH and in 36 (65%) pts with cutaneous SSc. Anti-topoisomerase-I antibodies (anti-Scl-70) were found only in 2 pts with lcSSc. More than 1 type of autoantibodies was detected in the majority of SSc pts. A wide range of antinuclear ABs was found in pts with ssSSc-PAH with prevailing ACA (in 7 pts), as well as anti-Sm, anti-La ABs, anti-nucleosome ABs (in one case), anti-Ro ABs (in 5 pts), anti-RNP-70 ABs – in 4 pts, anti-dsDNA ABs – in 2 pts, RF – in 3pts. SSc diagnosis was established according to ACR-EULAR 2013 classification criteria. The following diagnostic criteria were present in ssSSc-PAH pts: RP (in all pts), ulcers (3), scars (2), telangiectasia (10), PAH (14), SSc-associated ABs (7), capillaroscopic lesions (12). The mean total score was 11 (9;12) while  $\geq 9$  scores are required for SSc diagnosis, 100% pts with ssSSc-PAH met ACR-EULAR 2013 criteria, thus, justifying the SSc confirmation in this group of pts. There were significant differences in survival rates between IPAH pts and pts with various types of SSc-PAH (log-rank test,  $p=0.06$ ). 5 year survival in ssSSc-PAH was somewhat lower, than in SSc-PAH – 50.6% vs 64.9%, respectively; IPAH pts had the best survival rates of 82.5%, and these differences are close to significant.

**Conclusions:** Clinical features and survival ssSSc-PAH are very similar to those in pts with cutaneous SSc-PAH with the exception of skin involvement and associated symptoms (digital ischaemic lesions and contractures). Rheumatologists

should be aware of such specific features as similar survival rates in cutaneous and ssSSc pts, and late recognition of PAH in pts with ssSSc, as well as its similarity with IPAH.

AB0792

### AUTOIMMUNE AND INFLAMMATORY DISTURBANCES IN PATIENTS WITH PULMONARY ARTERIAL HYPERTENSION ASSOCIATED WITH SYSTEMIC SCLEROSIS

N. Yudkina<sup>1</sup>, A. Volkov<sup>1</sup>, T. Martynuk<sup>2</sup>, E. Nikolaeva<sup>1</sup>, E. Nasonov<sup>1</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia; <sup>2</sup>Cardiology Scientific Medical Research Center, Moscow, Russian Federation

**Background:** The prognosis of patients with pulmonary arterial hypertension associated with systemic sclerosis (SSc-PAH) is significantly worse, than other forms of PAH, and mechanisms of this phenomenon are unknown. Therefore, the isolation of autoimmune disorders is of great importance for early diagnosis and differential diagnosis, as well as the search for new therapeutic targets.

**Objectives:** To identify the autoimmune disorders in patients with SSc-PAH.

**Methods:** The study includes 52 pts with idiopathic pulmonary arterial hypertension (IPAH), 51 pts with SSc-PAH, 65 pts with SSc without PAH. Serum concentrations of the C-reactive protein (CRP), anticentromere antibodies (ACA) and antibodies to topoisomerase-I (anti-Scl-70) were routinely measured. The control group consists of 146 volunteers. Statistical analysis includes univariable logistic regression, ROC analysis and Kaplan-Mayer method.

**Results:** The average age of patients with IPAH was 37.9±10.5 years, SSc-PAH – 52.3±12.7 years, SSc without PAH – 51.2±13.2. Patients did not differ in functional class (FC), which was the main criterion of comparability. Mean values of FC in groups with SSc-PAH and IPAH also did not differ (2.7±0.8 and 2.6±0.7, respectively). ACA was associated with a 15.2-fold increased odds of developing PAH in SSc (OR 15.2, 95% CI 5.4–43.0), on the contrary, presence of anti-Scl-70 associated with low risk of PAH (OR 0.5, 95% CI 0.01 to 0.21). The level of CRP in the serum was significantly higher in patients with PAH than in the control group: 4.1 (1.9, 10.0) and 0.61 (0.25, 1.9), p<0.000001, and also in comparison with patients without PAH (1.9 (0.8, 6.4), p=0.02). In pts with PAH, the level of CRP correlated with FC and right atrium pressure and 6 min walk test distance. The level of CRP was significantly higher in patients with FC III-IV compared with FC I-II and in non-surviving patients. The Kaplan-Mayer analysis showed that pts with CRP level more than 4.75 mg/L at the time of diagnosis of PAH had a significantly lower survival rate (median 48 months) than pts with normal values (median 91 months) (p<0.005), with 67% sensitivity and 61% specificity.

**Conclusions:** SSc-PAH is a unique phenotype combining the manifestations of SSc and PAH, the pathogenetic mechanisms of which modify the course of these states. It is based on a feature of autoimmunity with the predominance of ACA and a low occurrence of anti-Scl-70. An increase in the concentration of CRP, as well as the effect of its baseline level on survival, attests to the significant role of autoimmunity and inflammation in the pathogenesis of this fatal SSc complication.

### DESCRIPTIVE ANALYSIS OF A COHORT OF PATIENTS DIAGNOSED WITH INFLAMMATORY MYOSITIS IN A TERTIARY HOSPITAL

O. Ibarquengoitia<sup>1</sup>, E. Ruiz<sup>1</sup>, M.L. García<sup>1</sup>, S. Kapetanovic<sup>2</sup>, O. Fernández<sup>1</sup>, I. Torre<sup>1</sup>, A.R. Inchaurre<sup>1</sup>, C. Pérez<sup>1</sup>, J.M. Blanco<sup>1</sup>, I. Calvo<sup>1</sup>, E. Guerrero<sup>1</sup>, D. Montero<sup>1</sup>, E. Galindez<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Neurology, Basurto University Hospital, Bilbao, Spain

**Background:** Inflammatory myopathies are a group of rare systemic diseases characterised by muscle weakness and inflammation. Clinical manifestations, course and prognosis of these pathologies are very heterogeneous.

**Objectives:** The aim is to describe the main characteristics of patients diagnosed with inflammatory myositis fulfilling Bohan and Peter criteria.

**Methods:** Descriptive analysis of a cohort of 34 patients from the same hospital with follow-up between January 2010 and December 2017. We recorded demographic characteristics, clinical manifestations, treatment, comorbidity and mortality.

**Results:** 34 patients (73% female) were recruited with an average age at diagnosis of 56.3 years<sup>27–83</sup> among adults and 10 years<sup>4–15</sup> among children. Most of them were Caucasian (94%). 18% were smokers and 15% previous smokers. The most frequent type was dermatomyositis (DM) (40%) followed by antisynthetase syndrome (ASS) (15%), necrotizing myopathy (12%), inclusion body myopathy (12%), overlap myositis (9%) and polymyositis (9%). 2 patients (out of 4) with necrotizing myopathy were treated with statins.

Clinical manifestation included muscle weakness (84%) and skin manifestations (48%) mainly among DM patients. 8 patients (24%) showed interstitial lung disease (4 non-specific interstitial pneumonia, 3 usual interstitial pneumonia and 1 cryptogenic organising pneumonia), especially among patients with overlap syndrome (n=3), DM (n=2) and ASS (n=2). Pulmonary hypertension occurred in 7 patients (21%), 30% among patients with overlap myositis associated to systemic sclerosis. The rest of extramuscular manifestations are expressed in the table 1. Muscle biopsy was performed in 57% of patients (77% compatible with myopathy). MRI was carried out in 45% (100% with active myositis). EMG was performed in 94% of patients with myopathic findings in 67% of them. 20 patients (60%) presented positive antinuclear antibodies, being the most frequent antiPML-SCL (18%), antiJo1 (18%), antiRo (12%) and anti-MDA5 (9%).

All patients were treated with corticosteroids. Only 2 responded to corticosteroids in monotherapy. More than 90% needed additional immunosuppressive treatment and 65% received 2 or more immunosuppressants. The most commonly used drugs were methotrexate (72%), rituximab (28%), azathioprine (25%), immunoglobulins (21%) and cyclophosphamide (21%). Only in 12% treatment could be stopped because of sustained remission.

3 cases of cancer (9%) were reported: myelodysplastic syndrome, lung neoplasm (in the case of paraneoplastic myositis) and lymphoma.

During the follow-up period 4 deaths were registered (12%) due to infections and cancer.

38% of patients required a multidisciplinary approach.

	n	%	Dermatomyositis	Polymyositis	Inclusion Body Myopathy	Necrotizing Myopathy	Antisynthetase syndrome	Overlap syndrome
Raynaud	7	21.2%	3	0	0	1	2	2

**Conclusions:** Inflammatory myopathies have frequent multiorganic involvement and represent a heterogeneous group of systemic diseases as shown in our registry and in the literature. Most patients need chronically combined immunosuppressive treatment and few achieve sustained remission. In consequence the collaboration of several specialties is necessary for the diagnosis and management of these pathologies.

### MYOSITIS DAMAGE INDEX IN A MYOSITIS POPULATION COHORT

O. Enríquez, A. Lilia, I. Fedra, on behalf of Hospital Centro Medico Nacional 20 de Noviembre. *Reumatología, Hospital Centro Medico Nacional 20 de Noviembre, Ciudad de Mexico, Mexico*

**Background:** Idiopathic inflammatory myopathies (IIM) are a heterogeneous and uncommon group of diseases characterised by muscular involvement and many systemic manifestations. They usually have a chronic course, and despite treatment they often develop functional impairment. MDI-MYODAM a score to assess damage has been recently developed. Few publications in this regard have reported a prevalence of 92%. There are no studies in Mexican-mestizo population describing the extent of damage and its main determinants.

**Objectives:** To investigate the prevalence of damage measured with the MDI-MYODAM tool in patients with IIM and its relationship with characteristics of the disease and treatment

**Methods:** A cross-sectional study was conducted in an IIM cohort from a national reference hospital. MDI questionnaire was applied to all patients. Demographic, disease characteristics, IIM subgroup (dermatomyositis, polymyositis and overlap), comorbidities (Charlson index), medical treatment were collected. Descriptive statistics were applied. Bivariate Pearson correlation test was conducted to

analyse associations between MDI score and clinical characteristics. P value<0.05 was considered as a statistically significant.

**Results:** Fifty subjects participated, 75% were women, mean age at diagnosis was 40.7 years (SD±) and mean duration of the disease was 11.8±8.3 years. Thirty-one percent of patients had polymyositis, 31% dermatomyositis, 12% juvenile dermatomyositis, 10% overlap myositis (mainly systemic lupus erythematosus, scleroderma and rheumatoid arthritis). The mean Charlson index was 2.7±2.4. Eighty-one percent had a score greater than 0 for at least one category; majority within the endocrinological systems (55%), skeletal (51%), gastrointestinal (35%). The mean total damage score (MDI) was 3.6±2.9. The mean score for the total damage according to the MYODAM score was 6.9±5.1. A moderate correlation between the MDI score and the use of glucocorticoids ( $r$  0.3, CI 95% 0.1–0.6,  $p$ <0.01). No associations between damage and activity of the disease or IIM subgroup were observed.

Abstract AB0794 – Figure 1

**Conclusions:** Most patients with IIM develop some kind of damage, with greater impact on the endocrinological, skeletal and gastrointestinal systems. There increases with the time of evolution and the use of steroids in a non-linear way. Therefore, these results should be taken into account in the decision-making process in long-term treatment.

#### LONG-TERM EFFICACY AND SAFETY OF RITUXIMAB IN SYSTEMIC SCLEROSIS REFRACTORY TO CONVENTIONAL IMMUNOSUPPRESSANTS

P. Polito, E. Zanatta, M. Favaro, M. Felicetti, F. Oliviero, E. Pigatto, F. Cozzi, A. Doria. *Rheumatology Unit, Department of Medicine – DIMED, Padova University, Padova, Italy*

**Background:** Recent studies<sup>1 2</sup> have shown that B-cells are involved in the pathogenesis of systemic sclerosis (SSc) suggesting that B-cell depletion might have a role in the treatment of the disease<sup>3</sup>.

**Objectives:** To describe the long-term efficacy and safety profile of Rituximab (RTX) in SSc patients who failed previous conventional immunosuppressive drugs.

**Methods:** We retrospectively analysed medical records of all SSc patients treated with Rituximab in our Rheumatology Unit from July 2011 to December 2017. Disease manifestations, particularly skin, pulmonary and articular involvement, were evaluated at baseline (T0), at 8±2 months (T1) and at the last follow-up visit (T2).

**Results:** Thirteen patients, 11 females and 2 males, were treated with 32 RTX cycles (median per patient 2.5, range 1–4). Eleven patients had diffuse and 2 limited cutaneous form; all had positive ANA, 9 anti-TopoI, 2 anti-RNA polIII, and 1 anti-SSA.

The mean age at first RTX infusion was 49.3±13.6 years and the mean disease duration was 6.5±3.3 years. The main indications to RTX were: interstitial lung disease (11/13), worsening of skin involvement (6/13) and arthritis (5/13), refractory to at least one previous immunosuppressive drug (median 2, range 1–3). Twelve patients were treated with mycophenolate mofetil, 5 with cyclophosphamide, 4 with methotrexate and 2 with azathioprine.

All patients were treated with RTX (1000 mg twice, two weeks apart). Twelve patients received more than one cycle; the interval between cycles was 12.7±5.4 months. The mean follow-up period was 41.4±21.9 months.

Five patients had arthritis and we observed complete remission of arthritis in all of them. 8 months after the first RTX administration arthritis relapsed in 4 patients who were successfully retreated.

We did not observe a significant decrease in modified Rodnan Skin Score over time (T0: 15.6±6.9, T1: 14.6±7.8, and T2: 13.1±8.3;  $p$ =ns).

Lung involvement, detected in 11/13 patients, remained radiologically stable in 8 patients and worsened in 3. No significant changes in the pulmonary function tests was observed from T0 to T2.

Five patients had a follow-up longer than 33 months after the last RTX cycle: 3 patients had a stable disease, 1 developed severe PAH and 1 lung neoplasia.

CD19 cell depletion (<2%) was observed after each RTX cycle, without significant changes in immunoglobulin levels. No infusion reactions were observed. We registered only one severe side effect: hand cellulitis in a patient with digital ulcer, requiring hospitalisation.

**Conclusions:** Our experience suggests that RTX is well tolerated and could be effective in the management of severe and refractory SSc manifestations.

#### SHORT TERM TREATMENT RESPONSE TO INTRAVENOUS PULSE CYCLOPHOSPHAMIDE TREATMENT IN CONNECTIVE TISSUE RELATED INTERSTITIAL LUNG DISEASE

P.T. Antony. *clinical Immunology and rheumatology, AMALA institute of medical sciences, thrissur, India*

**Background:** Interstitial lung disease (ILD) is a major cause for morbidity and mortality in patients suffering from connective tissue diseases. Early detection and prompt recognition of symptoms with appropriate treatment is necessary for effective control of the disease and for better prognosis and long-term survival. Various treatments have been approved based on observational studies. We have very few studies as regards ILD treatment from the Indian subcontinent. In a resource constrained country like India, we mainly rely on cheap drugs like cyclophosphamide. We have done a study to assess the short-term treatment response of connective tissue related interstitial lung disease to cyclophosphamide in a tertiary centre in India.

**Objectives:** 1. To assess short treatment outcome for Connective tissue disease related interstitial lung disease treated with intravenous pulses of cyclophosphamide (CYP) based on improvement in-

Lung function 1) Forced vital capacity (FVC)% predicted, forced expiratory volume in first second (FEV1)% predicted 2) Dyspnoea Borg scale 3) Cough visual analogue score

2. To determine the factors affecting treatment outcome like age, sex, duration of the connective tissue disease, type of connective tissue disease, HRCT type and presence of PAH.

**Methods:** A cohort study was conducted in the Department of General Medicine, Rheumatology and Pulmonology in Amala Institute of Medical Sciences, Thrissur, Kerala from November 2015 to June 2017, that evaluated 74 patients who were having connective tissue disease related ILD. Detailed history and a thorough clinical examination was done. Treatment with 6 intravenous pulses of cyclophosphamide was done and response was assessed after 6 months. Response to treatment and associations were analysed using SPSS software (version 15). Method used for statistical analysis was Chi-Square test and paired t test.

**Results:**

Abstract AB0796 – Table 1

Count of FEV1	Column Labels				
Row Labels	31–50	51–70	71–90	91–110	Grand Total
31–50	4	4			8
51–70		25	23	4	52
71–90			14		14
<b>Grand Total</b>	<b>4</b>	<b>29</b>	<b>37</b>	<b>4</b>	<b>74</b>

There was no association between treatment response and age, sex or type of connective tissue disease. Following treatment there was a definite improvement in the clinical aspects of the patient which was assessed by dyspnoea Borg score and cough visual analogue score. Following treatment there was a definite improvement in PFT (FVC, FEV1) as well as 6 min walk test which was also statistically significant. CT pattern of Non specific interstitial pneumonitis also had a better outcome.

**Conclusions:** Our study proves that there is definite clinical and FVC improvement in CTD-ILD patients after giving treatment with cyclophosphamide. Determinants that can predict treatment outcome are duration of disease, HRCT type, (NSIP), presence of Pulmonary artery hypertension(PAH). Poor treatment response should be anticipated in those with longer duration of disease and UIP type in HRCT, presence of PAH.

#### A RANDOMISED DOUBLE BLIND PLACEBO CONTROLLED TRIAL TO COMPARE THE EFFICACY OF INITIAL COMBINATION THERAPY VS MONOTHERAPY FOR PULMONARY ARTERIAL HYPERTENSION IN SYSTEMIC SCLEROSIS

P. Dwivedi<sup>1</sup>, S.K. Sharma<sup>1</sup>, V. Dhir<sup>1</sup>, M.K. Rohit<sup>2</sup>, D. Behera<sup>3</sup>, S. Jain<sup>1</sup>. <sup>1</sup>Internal Medicine; <sup>2</sup>Cardiology; <sup>3</sup>Pulmonary Medicine, Postgraduate Institute of Medical Education and Research, Chandigarh, India

**Background:** Pulmonary Arterial Hypertension(PAH) is one of the leading cause of death in Systemic Sclerosis(SSc) population. Trials that have studied the efficacy of initial oral combination therapy versus monotherapy for the treatment of PAH in SSc are limited.

**Objectives:** To study the efficacy and safety of monotherapy (sildenafil) versus initial combination therapy (sildenafil and bosentan) for treatment of SSc related PAH.

**Methods:** In a single centre, double blind, prospective, randomised, placebo controlled trial, 34 patients of SSc related PAH defined as Pulmonary Artery Systolic Pressures(PASP)>35 mmHg as measured by echocardiography, New York heart Association(NYHA) functional class II and III with forced vital capacity >60% were randomised in 1:1 ratio to sildenafil (20 mg thrice a day) and matched placebo or bosentan to one study arm or to the combination of sildenafil(20 mg thrice a day) and bosentan (62.5 mg twice daily for 4 weeks maximum up to 125 mg twice daily) to the other arm for 24 weeks. The primary end point of the study was to assess the change in pulmonary artery pressures measured by echocardiography at 24 weeks from baseline. The secondary efficacy end points was to compare the change in 6 min Walk Distance (6MWD), Time To Clinical Worsening(TTCW) and adverse events at 24 weeks. Intention to treat analysis was carried for the primary and secondary outcomes. p<0.05 was considered significant. Kaplan Meier survival analysis was done to estimate the time to PAH worsening and hazard ratio was calculated.

**Results:** The mean change in Pulmonary Artery Systolic Pressures in the monotherapy arm was -1.0 mmHg versus +2.1 mmHg in the combination arm (p=0.56). TTCW is prolonged in the combination arm. The mean survival time in the initial combination arm was 23.76±0.59 weeks and 23.28±0.23 weeks in the monotherapy arm. The hazard ratio was 0.73[95% C.I 0.04–11.7] (p=0.87). The mean change in the 6 min walk distance in the monotherapy arm was 15.88 ±31.83 m and 25.88±38.25 m in the combination arm (p=0.38). The satisfactory clinical response in the combination arm was 82.3% versus 70% in the

monotherapy arm (O.R=1.9[C.I 0.38–9.88] p=0.44). The upfront combination of sildenafil and bosentan was well tolerated with similar rates of adverse events in both group.

**Conclusions:** In this study we could not demonstrate any significant difference in the efficacy of initial combination therapy of sildenafil and bosentan over sildenafil monotherapy. The patients of systemic sclerosis tolerated the initial combination of sildenafil and bosentan well and the treatment prevented further deterioration. Larger studies with more number of subjects may be required to confirm the results.

#### CLINICAL ASSOCIATIONS OF VASCULAR ENDOTHELIAL GROWTH FACTOR AND ITS RECEPTOR 2 TYPE IN SYSTEMIC SCLEROSIS

R. Alekperov<sup>1,2</sup>, E. Alexandrova<sup>2</sup>, A. Novikov<sup>2</sup>, L. Ananyeva<sup>2</sup>. <sup>1</sup>Moscow Regional Research and Clinical Institute (MONIKI); <sup>2</sup>NASONOVA RESEARCH INSTITUTE OF RHEUMATOLOGY, MOSCOW, RUSSIA, Moscow, Russian Federation

**Background:** Systemic sclerosis (SSc) is characterised by impaired angiogenesis and peripheral microvasculopathy. A major role in the regulation of angiogenesis attributed to vascular endothelial growth factor, which performs its functions through interaction with its receptor 2 type (VEGFR2).

**Objectives:** The aim of our study was to assess the levels of VEGF in serum and its associations with clinical manifestations in patients with SSc.

**Methods:** We studied 46 patients with SSc who underwent clinical examination, pulmonary function tests and echocardiography. Serum VEGF-A and VEGFR2 levels were determined by ELISA in 46 SSc patients and 20 healthy controls

**Results:** Mean VEGF levels were increased in SSc patients compared to controls (212,35±253,93 and 97,74±71,46 pg/ml, respectively; p=0,032). Patients with limited cutaneous SSc (n=23) had higher levels of serum VEGF than those with diffuse cutaneous SSc (n=23) (267,11±268,74 vs 120,40±141,09 pg/ml; p=0,012). Patients with fingertip ulcers (n=19) were found to have higher levels of VEGF than pts without fingertip ulcers.(n=27) (214,25±265,93 vs 162,88±188,97) but this difference wasn't significant. Serum VEGF levels were higher in SSc patients with sPAP >30 mmHg than in those with sPAP ≤30 mmHg (286,51 ±287,42 vs 92,88±108,06 pg/ml; p=0,0042) and correlated with DLCO values (R=0,40; p=0,007). Mean VEGF levels in patients with DLCO <50% (n=14) were significantly higher than those with DLCO ≥50% (n=30): 364,20±381,95 vs 128,55±142,70 pg/ml, respectively (p=0,034). There weren't significant differences in VEGF levels between patients with FVC <80% (n=11) and those with FVC ≥80% (219,15±252,57 vs 154,26±208,91 pg/ml, respectively).

Mean VEGFR2 levels were also increased in SSc pts compared to controls (5784,6±4773,8 and 1552,6±272,8 pg/ml, respectively; p<0,0001). There weren't any differences between pts with diffuse or limited SSc. In pts with digital ulcers, or normal levels of sPAP, or DLco ≥50% mean VEGFR2 levels didn't differ from those without digital ulcers, or sPAP >30 mm Hg, or DLco <50%, respectively. Serum VEGF levels directly correlated with sPAP (R=0,40; p=0,007).

**Conclusions:** Our findings show significantly higher circulating levels of VEGF and VEGFR2 in SSc patients. Associations of VEGF with some clinical signs indicate its role in pathology of SSc.

AB0799

#### ALTERATIONS OF BODY COMPOSITION IN SCLERODERMA PATIENTS ARE ASSOCIATED WITH DISEASE ACTIVITY AND PHYSICAL ACTIVITY BUT NOT WITH LUNG INVOLVEMENT

S. Oreska<sup>1</sup>, M. Spiritovic<sup>1,2</sup>, P. Cesak<sup>2</sup>, M. Cesak<sup>2</sup>, H. Storkanova<sup>1</sup>, H. Smucrova<sup>1</sup>, B. Hermankova<sup>1,2</sup>, O. Ruzikova<sup>1</sup>, H. Mann<sup>1</sup>, K. Pavelka<sup>1</sup>, L. Senolt<sup>1</sup>, J. Vencovsky<sup>1</sup>, R. Becvar<sup>1</sup>, M. Tomcik<sup>1</sup>. <sup>1</sup>Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; <sup>2</sup>Department of Physiotherapy, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

**Background:** Systemic sclerosis (SSc) is characterised by fibrosis of the skin and visceral organs, especially digestive tract, and musculoskeletal and lung involvement, which limit mobility/self-sufficiency of patients and can have a negative impact on body composition and physical activity.

**Objectives:** To assess body composition and physical activity of SSc patients and healthy controls (HC).

**Methods:** 59 patients with SSc [50 females; mean age 52.5; disease duration 6.7 years; limited cutaneous (lcSSc, 34)/diffuse cutaneous (dcSSc, 25)] and 59 age-/sex-matched HC (50 females, mean age 52.5) without rheumatic diseases were

included. SSc patients fulfilled ACR/EULAR 2013 criteria. Anthropometric parameters and body composition were assessed (by densitometry: iDXA Lunar, and by bioelectric impedance: BIA-2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Pulmonary function and diffusing capacity of lung were examined, disease activity was evaluated by ESSG activity index. Data are presented as mean  $\pm$ SD.

**Results:** Compared to HC, patients with SSc had significantly lower body-mass index (BMI: 27.9 $\pm$ 8.3 vs. 22.4 $\pm$ 4.3 kg/m<sup>2</sup>,  $p < 0.0001$ ) and body fat% assessed by both iDXA (BF%: 38.0 $\pm$ 7.6 vs. 32.6 $\pm$ 8.2%,  $p < 0.0001$ ) and BIA (BF%: 31.3 $\pm$ 7.6 vs. 24.3 $\pm$ 7.9%,  $p < 0.0001$ ), and decreased visceral fat weight (1.0 $\pm$ 0.8 vs. 0.5 $\pm$ 0.5 kg,  $p = 0.001$ ). Compared to HC, SSc patients also demonstrated significantly decreased lean body mass assessed by both iDXA (LBM: 51.9 $\pm$ 8.4 vs. 47.8 $\pm$ 7.0 kg,  $p = 0.005$ ) and BIA (LBM: 45.4 $\pm$ 7.3 vs. 40.9 $\pm$ 6.8 kg,  $p = 0.005$ ), significantly lower bone mineral density (BMD: 1.2 $\pm$ 0.1 vs. 1.0 $\pm$ 0.1 g/cm<sup>2</sup>,  $p < 0.0001$ ), and had increased extracellular mass/body cell mass (ECM/BCM) ratio (1.03 $\pm$ 0.1 vs. 1.28 $\pm$ 0.4,  $p < 0.0001$ ), which reflects deteriorated nutritional status and worse muscle predispositions for physical exercise, aerobic fitness/performance. Increased ECM/BCM in SSc patients positively correlated with disease activity (ESSG:  $r = 0.273$ ,  $p = 0.0439$ ), skin score (mRSS:  $r = 0.371$ ,  $p = 0.0045$ ) and inflammation (CRP:  $r = 0.292$ ,  $p = 0.0278$ ; ESR:  $r = 0.302$ ,  $p = 0.0226$ ). Increased ECM/BCM was also associated with worse quality of life (HAQ:  $r = 0.438$ ,  $p = 0.0007$ ; SHAQ:  $r = 0.268$ ,  $p = 0.0436$ ), fatigue (FSS:  $r = 0.366$ ,  $p = 0.0040$ ), and worse ability to perform physical activity (HAP:  $r = -0.644$ ,  $p < 0.0001$ ). Disease activity (ESSG) negatively correlated with BF% by iDXA ( $r = -0.324$ ,  $p = 0.0138$ ). Physical activity (HAP) positively correlated with BMD ( $r = 0.280$ ,  $p = 0.032$ ). There was no significant correlation of lung involvement with alterations of body composition.

**Conclusions:** Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our SSc patients, which are associated with their disease activity and physical activity, and could reflect their nutritional status, and gastrointestinal and musculoskeletal involvement. We found no significant association between lung involvement and changes of body composition.

#### CHANGES OF BODY COMPOSITION IN MYOSITIS PATIENTS ARE ASSOCIATED WITH DISEASE DURATION, INFLAMMATORY STATUS, SKELETAL MUSCLE INVOLVEMENT AND PHYSICAL ACTIVITY

S. Oreska<sup>1</sup>, M. Spiritovic<sup>1,2</sup>, P. Cesak<sup>2</sup>, O. Marecek<sup>2</sup>, H. Storkanova<sup>1</sup>, H. Smucrova<sup>1</sup>, B. Hermankova<sup>1,2</sup>, K. Kubinova<sup>1</sup>, M. Klein<sup>1</sup>, L. Vemerova<sup>1</sup>, O. Ruzikova<sup>1</sup>, R. Becvar<sup>1</sup>, K. Pavelka<sup>1</sup>, L. Senolt<sup>1</sup>, H. Mann<sup>1</sup>, J. Vencovsky<sup>1</sup>, M. Tomcik<sup>1</sup>. <sup>1</sup>Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; <sup>2</sup>Department of Physiotherapy, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

**Background:** Idiopathic inflammatory myopathies (IIM) are characterised by inflammation and atrophy of skeletal muscles, pulmonary and articular involvement, which limit the mobility/self-sufficiency of patients, and can have a negative impact on body composition.

**Objectives:** To assess body composition and physical activity of IIM patients and healthy controls (HC).

**Methods:** 54 patients with IIM (45 females/9 males; mean age 57.7; disease duration 5.8 years; polymyositis (PM, 22)/dermatomyositis (DM, 25)/necrotizing myopathy (IMNM, 7)) and 54 age-/sex-matched HC (45 females/9 males, mean age 57.7) without rheumatic diseases were included. PM/DM patients fulfilled Bohan/Peter criteria for PM/DM. Anthropometric parameters and body composition were assessed (by densitometry: iDXA Lunar, and by bioelectric impedance: BIA2000-M), and physical activity was evaluated using Human Activity Profile (HAP) questionnaire. Routine biochemistry analysis was performed after 8 hours of fasting. Muscle involvement was evaluated by manual muscle test (MMT-8) and functional index 2 (FI2). Data are presented as mean  $\pm$ SD.

**Results:** Compared to HC, patients with IIM had a trend towards significantly increased body fat% as assessed by iDXA (BF%: 39.9 $\pm$ 7.1 vs. 42.4 $\pm$ 7.1%,  $p = 0.077$ ), but significantly decreased lean body mass as assessed both by iDXA (LBM: 45.6 $\pm$ 8.1 vs. 40.6 $\pm$ 7.2 kg,  $p = 0.001$ ) and BIA (LBM: 52.6 $\pm$ 8.8 vs. 48.7 $\pm$ 9.0 kg,  $p = 0.023$ ), and increased extracellular mass/body cell mass (ECM/BCM) ratio (1.06 $\pm$ 0.15 vs. 1.44 $\pm$ 0.42,  $p < 0.0001$ ), which reflects worse muscle predispositions for physical exercise, aerobic fitness/performance, and also deteriorating nutritional status. Compared to HC, IIM patients had significantly lower bone mineral density (BMD: 1.2 $\pm$ 0.1 vs. 1.1 $\pm$ 0.1 g/cm<sup>2</sup>,  $p < 0.001$ ). Disease duration negatively correlated with BMD ( $r = -0.392$ ,  $p = 0.004$ ) and LBM-BIA ( $r = -0.272$ ,  $p = 0.047$ ). CRP was positively associated with BF% assessed both by DEXA ( $r = 0.276$ ,  $p = 0.035$ ) and BIA ( $r = 0.306$ ,  $p = 0.025$ ). Higher BF% $>$ DEXA was associated with worse physical endurance (FI2:  $r = -0.311$ ,  $p = 0.026$ ) and worse ability to

perform physical activity (HAP:  $r = -0.292$ ,  $p = 0.032$ ). MMT-8 score negatively correlated with ECM/BCM ratio ( $r = -0.385$ ,  $p = 0.006$ ).

**Conclusions:** Compared to healthy age-/sex-matched individuals we found significant negative changes in body composition of our IIM patients, which are associated with their disease duration, inflammatory status, skeletal muscle involvement, and physical activity, and could reflect their impaired nutritional status and predispositions for physical exercise, aerobic fitness and performance.

Department of Internal Medicine, Research Laboratory and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, Genoa, Italy, Genoa, Italy

**Background:** Systemic sclerosis (SSc) patients may present muscle involvement in the form of myositis or non-inflammatory myopathy with different degree of weakness and muscle atrophy.<sup>1</sup> Sarcopenia is described as a multifactorial syndrome with muscle mass loss associated to functional impairment; according to the anthropometric equation by Baumgartner et al. sarcopenia was defined as relative skeletal muscle mass index (RSMI)  $< 5.5$  Kg/m<sup>2</sup> for women and  $< 7.26$  Kg/m<sup>2</sup> for men. The relationships between sarcopenia and other clinical aspects in SSc are poorly investigated.

**Objectives:** The aim of the study was to evaluate the associations between sarcopenia and other clinical factors in SSc patients.

**Methods:** 20 female patients fulfilling the ACR 2013 criteria for SSc (mean age 61.7 $\pm$ 13.6 years, disease duration 86.2 $\pm$ 67.1 months) were enrolled. The RSMI (Kg/m<sup>2</sup>) was evaluated by dual-energy X-ray absorptiometry scan (Lunar Prodigy). Nail fold videocapillaroscopic (NVC) patterns (early, active, late) were analysed. Serum 25(OH)<sub>2</sub>D concentration was tested by immunofluorescence. Non parametric statistical tests were used.

**Results:** Patients showed a modified Rodnan skin score (mRSS) 12.2 $\pm$ 7.7, RSMI 6.01 $\pm$ 0.97 Kg/m<sup>2</sup>, serum vitamin D (25(OH)<sub>2</sub>D) 22.01 $\pm$ 13.1 ng/dL and CPK 70.16 $\pm$ 31.8 U/L. In this cohort 23% of SSc patients were found affected by sarcopenia, and almost 42% showed the most advanced level of microvascular damage, as characterised by the NVC late pattern. However, no statistically relevant correlations were observed between RSMI, BMI, age, disease duration, CPK, mRSS, 25(OH)<sub>2</sub>D and active or late NVC patterns. Comparing age, disease duration, CPK and mRSS in both sarcopenic and non sarcopenic SSc patients there was no difference between the groups, however sarcopenic patients showed statistically significant lower BMI ( $p = 0.02$ ), lower RSMI ( $p = 0.0008$ ) and higher 25(OH)<sub>2</sub>D serum concentrations ( $p = 0.01$ ). Particularly, RSMI showed a strong negative correlation with age ( $p = 0.01$ ). No statistical differences were found when grouping the patients according to the positivity for serum anti-topoisomerase I Ab or according to cutaneous diffuse (dcSSc) or limited (lcSSc) systemic sclerosis.

**Conclusions:** This pilot study suggests that sarcopenia seems present in almost 25% of the SSc patients, particularly in a condition of advanced microcirculation failure (late NVC pattern), however does not seem to correlate with skin fibrosis or disease duration. The study had some limitations due to absence of control group and to the small patient sample analysed. Further larger studies would be necessary to better investigate the role of sarcopenia in SSc.

#### OSTEOPOROSIS IN SYSTEMIC SCLEROSIS: CASE-CONTROL STUDY WITH A FRENCH OFELY COHORT AND RISK FACTORS

S. Thietart<sup>1</sup>, M. Gatifosse<sup>1</sup>, E. Sornay-Rendu<sup>2</sup>, L. Lemeunier<sup>3</sup>, P. Delmaire<sup>4</sup>, J. Sellam<sup>3</sup>, F. Berenbaum<sup>3</sup>, O. Fain<sup>1</sup>, R. Chapurlat<sup>2</sup>, A. Mekinian<sup>1</sup>. <sup>1</sup>Internal medicine, Hôpital Saint Antoine, AP-HP, Université Paris 6, 75012 Paris, France., Paris; <sup>2</sup>Unité Inserm UMR 1033, Université de Lyon, Lyon; <sup>3</sup>Rheumatology; <sup>4</sup>Nuclear medicine, Hôpital Saint Antoine, AP-HP, Université Paris 6, 75012 Paris, France., Paris, France

**Background:** Systemic sclerosis (SSc) is a rare autoimmune disorder characterised by a vascular and fibrosing involvement of the skin and internal organs. Data

about the association between systemic sclerosis (SSc) and osteoporosis (OP) are controversial and scarce about the risk factors of OP in SSc.<sup>1,2</sup>

**Objectives:** The aim of the study was to determine the OP frequency in SSc and assess its risk factors.

**Methods:** In a prospective cohort of SSc patients, usual risk factors of OP were assessed, as well as SSc organ involvements: pulmonary, cardiac, skin and renal involvements and SSc treatments. All patients underwent dual energy X-ray absorptiometry: bone mineral density (BMD) was measured at the lumbar spine (LS), femoral neck (FN) and total hip (TH). Osteoporosis was defined as having a T-score inferior to -2.5.

**Results:** Forty-eight patients were included with a median age of 60 years,<sup>27-81</sup> 41 women (85.4%), with a diffuse cutaneous subtype in 13 cases (27.1%) and illness duration of 12.6 years (0.3-41.1). Average BMD was 0.98±0.21 in LS, 0.84±0.13 in FN and 0.86±0.15 in TH. OP was found in 19 patients (40%). Among patients with OP, an associated auto-immune disorder was found in 13 patients (68.4%) versus 10 (34.5%) in the non-OP group (p=0.04), digestive sub-occlusion in 4 patients (21% versus 0 patients, p=0.02), and chronic liver disease in 6 patients (31.6%) versus 2 (6.9%, p=0.04). Respiratory explorations found a DLCO of 12.7 (6.8-17.2) versus 15.6 (9.6-32.2) (p=0.007), a CVF of 2.47 (1.1-4) versus 3 (1.7-5.9) (p=0.03). DAS28-CRP was significantly higher (2.29 (1.53-4.46) in the OP group versus 1.86 (0-3.8) in the non-OP group, p=0.02); with a higher frequency of hand X-ray erosions (6 OP patients (31.6%) versus 2 (6.9%), p=0.04). No difference was found in Rodnan score, SSc subtype, illness duration, malnutrition, treatments (proton pump inhibitors, cyclophosphamide, steroids), autoantibodies profile; nor with the usual OP risk factors: age, smoking, personal or family history of OP fractures, alcohol consumption, weight, BMI, long term steroid treatment, early menopause and thyroid disease. No difference in serum vitamin D, calcium, thyroid hormones and C-reactive protein levels was found between OP and non-OP groups.

**Conclusions:** Osteoporosis was associated with SSc-related factors such as: articular, digestive and respiratory involvements, and associated auto-immune diseases. Usual OP risk factors were not significantly different between osteoporotic SSc patients and non-osteoporotic patients.

**AB0803 A REAL LIFE EXPERIENCE ON THE EFFICACY AND SAFETY OF MYCOPHENOLATE MOFETIL IN CONNECTIVE TISSUE DISORDER ASSOCIATED INTERSTITIAL LUNG DISEASE – A RETROSPECTIVE STUDY**

S. Santhanam<sup>1</sup>, V. Rahulan<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pulmonology, Gleneagles global hospital, Chennai, India

**Background:** Interstitial lung disease(ILD) is one of the common extra articular manifestations of various connective tissue disorders(CTD). We don't have enough evidence on the drugs used, except for ILD in systemic sclerosis and the results of the same has been extrapolated to other diseases. Mycophenolate mofetil(MMF) has antiproliferative and anti fibrotic action in addition to anti inflammatory property and hence we wanted to study the efficacy and safety of MMF in our diverse cohort of CTD-ILD.

**Objectives:** To study the efficacy and safety of mycophenolate mofetil (MMF) in a diverse cohort of patients with connective tissue disease(CTD) associated interstitial lung disease(ILD).

**Methods:** This is a retrospective observational study with records of outpatients with CTD associated ILD were screened from Oct 2014 to Dec 2017. Among them, patients with imaging (HRCT chest) documented ILD were included. All patients underwent detailed clinical assessment, serological investigations (baseline blood test, erythrocyte sedimentation rate, C-reactive protein, rheumatoid factor, ACPA Ab, antinuclear antibody, ANA profile, complements), urine routine, pulmonary function test(PFT), HRCT chest and echocardiogram. The response of ILD to treatment(follow up of 2 years) was assessed clinically, radiologically and by PFT.

**Results:** 54 patients were identified with CTD-ILD of which 33 patients were on MMF. 13 patients were diagnosed with MCTD, 12 with RA, 3 with diffuse cutaneous systemic sclerosis, 2 with SSc/myositis overlap, 1 with primary sjogren's syndrome, 1 with SLE/Sjogren's overlap and 1 with lung dominant CTD(Scl 70+ve). The cohort was divided in to 3 groups – MCTD, RA and others (SSc predominant). Among patients with MCTD, 10 had NSIP pattern of ILD, 3 UIP. In RA, 7 had NSIP and 5 UIP and among others 7 NSIP and 1 UIP. The mean FEV1 and FVC values over 2 years and the treatment response has been discussed in table 1 and Figure 1. FEV1 and FVC had high positive correlations (Pearson correlation, p<0.05) with treatment for all groups of diseases. The values go together in the positive direction with treatment. Among the groups, all patients who improved had NSIP pattern and all who worsened had UIP. Though there were numerical differences in the mean values of FEV1 and FVC between two groups (NSIP and UIP), it was not statistically significant (paired 't' test, p>0.05). There was no significant difference in FEV1 and FVC values with treatment between the three groups (one way ANOVA test).

Abstract AB0803 – Figure 1

**Conclusions:** Treatment with MMF over a median duration of 24 months stabilised the ILD in majority. MMF appears to be efficacious, safe and well tolerated in our diverse cohort of CTD-ILD and needs to be evaluated further in prospective studies with a bigger sample size.

AB0804 **THE RELATIONSHIP BETWEEN AUTOANTIBODIES AND CLINICAL SYMPTOMS IN PATIENTS WITH INFLAMMATORY MYOPATHY**

S. Nakashima<sup>1</sup>, H. Nakaishi<sup>2</sup>, T. Kameda<sup>1</sup>, M. Izumikawa<sup>1</sup>, H. Shimada<sup>1</sup>, R. Wakiya<sup>1</sup>, K. Atsushi<sup>1</sup>, M. Kato<sup>1</sup>, N. Kadowaki<sup>1</sup>, H. Dobashi<sup>1</sup>. <sup>1</sup>Division of Hematology, Rheumatology and Respiratory Medicine, Department of Internal Medicine, Faculty of Medicine; <sup>2</sup>Clinical Laboratory, KAGAWA UNIVERSITY, Kagawa, Japan

**Background:** Myositis-specific autoantibody (MSA) and myositis-associated autoantibody (MAA) are often detected in dermatomyositis (DM) and polymyositis (PM), and are useful diagnostic markers. In addition, autoantibodies are reportedly related to clinical symptoms, including skin findings, muscle symptoms, and interstitial lung disease, and provide information useful for medical treatment. However, the clinical significance of the presence of multiple MSA/MAA and anti-Ro52 autoantibodies has not been determined.

**Objectives:** The purpose of our study was to clarify the clinical significance of multiple MSA/MAA and anti-Ro52 autoantibodies.

**Methods:** We enrolled 58 patients diagnosed with DM and PM at Kagawa University Hospital. PM and DM were diagnosed according to the Bohan and Peter criteria.<sup>1</sup> The patients were analysed for MSA (anti-Mi-2, anti-Jo-1, anti-SRP, anti-PL-7, anti-MDA5, anti-TIF1 $\gamma$ , anti-PL-12, anti-EJ, and anti-OJ) and MAA (anti-RNP, anti-Ku, and anti-PM-Scl) by ELISA (MESACUP anti-ARS, MDA5 and TIF1 $\gamma$  test, MBL, Nagoya, Japan) and Line blot (EUROLINE Myositis Profile 3, EUROIMMUN, Lübeck, Germany). We extracted MSA/MAA(+) and anti-Ro52(+) patients and analysed the association between the presence of multiple MSA/MAA or anti-Ro52 autoantibodies and patients' clinical features (skin findings such as Gottron papule, heliotrope rash and mechanic's hand, interstitial lung disease, malignancy, and arthritis).

**Results:** 53/58 patients were positive for MSA/MAA, followed by anti-Ro52 (n=27), anti-PL7 (n=12), anti-Jo1 (n=8), anti-PM-Scl75 (n=7), anti-Ku (n=6), anti-SRP (n=4), anti-EJ (n=4), anti-TIF1 $\gamma$  (n=4), anti-MDA5 (n=4), anti-Mi2 (n=3), anti-PL12 (n=1), anti-PM-Scl100 (n=1), and five cases were MSA/MAA(-). Five patients had multiple MSA/MAA (anti-PL-7+anti-Jo-1, anti-PL-7+anti-PL-12, anti-PL-7+anti Ku, anti-Ro52 +anti-Jo1+anti-PM-Scl75, and anti-Ro52 +anti-Jo1+anti Ku). In patients with DM/PM, anti-Ro52(+) patients were complicated by interstitial lung disease (ILD) and had a higher KL-6 value at onset (p<0.05). Notably, 17/27 patients with anti-Ro52 autoantibodies were also anti-ARS(+) and all patients with anti-ARS autoantibodies had ILD. In contrast, among the anti-ARS(-) patients (n=35), there was no significant correlation between anti-Ro52(+) and ILD. Therefore, anti-ARS may be a greater risk factor for ILD than anti-Ro52. Furthermore, patients with multiple MSA/MAA had a higher incidence of rapidly progressive ILD (p<0.05). There was no correlation between multiple MSA/MAA or anti-Ro52 autoantibodies and CK or muscle symptoms.

**Conclusions:** We hypothesise that the presence of multiple MSA/MAA may be useful for predicting ILD. However, in this study, anti-Ro52 autoantibodies did not correlate with ILD and myositis.

AB0805 **CLINICAL FEATURES AND OUTCOME IN SCLERODERMA RENAL CRISIS**

S. Monov<sup>1</sup>, D. Monova<sup>2</sup>, E. Miloshova<sup>3</sup>, R. Shumnalieva<sup>1</sup>. <sup>1</sup>Department of Rheumatic Diseases, Medical University; <sup>2</sup>Department of Internal Medicine, Medical University, Medical Institute; <sup>3</sup>Department of Internal Medicine, Medical Institute – Ministry of Interior, Sofia, Bulgaria

**Background:** Systemic sclerosis (SSc) is a chronic, autoimmune disease of the connective tissue that involves skin, subcutaneous tissue, muscles and joints, as well as the internal organs: kidneys, lungs, heart. Depending on the extent it can occur as limited (lcSSc) or diffuse (dcSSc) clinical variant. About half of the patients with renal involvement the clinical manifestation is limited to a moderate increase in serum creatinine, mild proteinuria, and moderate hypertension. The most serious complication remains scleroderma renal crisis (SRC). There was significant heterogeneity in definitions. As a rule for SRC was characterised by new-onset severe hypertension, hypertensive encephalopathy and seizures, acute kidney injury with oliguria, proteinuria and erythrocyturia, and microangiopathic hemolytic anaemia with thrombocytopenia.

**Objectives:** The aim of our study was to analyse the clinical features and outcome of patients with scleroderma renal crisis.

**Methods:** We retrospectively reviewed the medical records of patients with scleroderma renal crisis between January 2002 and December 2016. Conditional logistic regression and multivariate analysis was performed to determine factors independently associated with outcome in patients with SRC.

**Results:** 18 (14 females and 4 males, median age 47.3±14.6 years) patients diagnosed with SRC were included in the study. The mean duration from first symptom of systemic sclerosis (Raynaud's phenomenon, cutaneous sclerosis, arthralgia/arthritis, puffy hands, interstitial lung disease, pulmonary arterial hypertension, digestive hypomotility and etc.) to SRC attack was 4.47±2.9 years. 13 SRC patients belonged to dcSSc, and 5 patients – to lcSSc. Among SRC patients, 9 were negative of anti-centromere antibodies (ACAs). All these 18 patients had hypertension and renal insufficiency, including 4 dialysis dependent after the onset of SRC and 6 with thrombotic microangiopathy. There were 6 patients receiving renal biopsy (the pathological findings were mainly summarised as intimal thickening and stenosis of renal arterioles). Among 16 patients with long-term followed-up, 15 patients received angiotensin converting enzyme inhibitors (ACEI), 8 patients died, 1 patient was dialysis dependent. Survival from first symptom in those patients with Raynaud's phenomenon mode of onset was higher at 5 years and at 10 years than those with onset as non-Raynaud's phenomenon (p < 0,05). In multivariate analysis, factors related to mortality in SRC were older age at onset, male gender, treatment with corticosteroids, dcSSc subset, interstitial lung disease, pulmonary arterial hypertension, heart involvement, and the mode of onset with non-Raynaud's phenomenon, especially in the form of pulmonary involvement. The mode of onset should be considered an independent prognostic factor in SRS. The treatment of SRC relies on aggressive blood pressure control with an ACEI, combined with other antihypertensive drugs if needed.

**Conclusions:** SRC usually occurred at the early course of SSc. dcSSc was more frequent than lcSSc. ACAs were found in 50% of SRC patients. The use of ACEIs was still the cornerstone of SRC treatment.

**Disclosure of Interest:** None declared

AB0806 **THE IMPACT OF DYSPHAGIA IN IDIOPATHIC INFLAMMATORY MYOSITIS: AN ONLINE SURVEY OF HIGHLY-SPECIALISED CENTRES**

S. Barsotti<sup>1,2</sup>, I. Cavazzana<sup>3</sup>, R. Neri<sup>2</sup>, L. Cavagna<sup>4</sup>, F. Iannone<sup>5</sup>, C. Montecucco<sup>4</sup>, A. Tincani<sup>3</sup>, F. Franceschini<sup>3</sup>, M. Mosca<sup>2</sup>. <sup>1</sup>Department of Medical Biotechnologies, University of Siena, Siena; <sup>2</sup>Rheumatology Unit, University of Pisa, Pisa; <sup>3</sup>Rheumatology Unit and Chair, ASST Spedali Civili and University of Brescia, Brescia; <sup>4</sup>Rheumatology University and IRCCS, Policlinico S. Matteo Foundation, Pavia; <sup>5</sup>Rheumatology Unit – DETO, University of Bari, Bari, Italy

**Background:** Dysphagia represents a frequent and disabling symptom in patients with idiopathic inflammatory myopathies (IIM). Despite this, there are not widely accepted diagnostic and therapeutic guidelines for dysphagia in IIM.

**Objectives:** This study is aimed at surveying the approach to dysphagia in IIM patients in European and worldwide referral centres.

**Methods:** An anonym on-line survey was designed and clinicians from European Union (EU) countries, and countries from North and Central America and South Korea were invited via email to participate. The questionnaire included 11 items about the characteristics of the hospital of the responder, the evaluation of the impact of dysphagia on disease severity assessed on a visual analogue scale (10 VAS), the techniques used for the assessment of dysphagia, the use of validated patients reported outcome (PRO) and the therapeutic approach of dysphagia.

**Results:** Between December 2017 and January 2018, 52 clinicians from different centres working in 21 different countries (18 EU countries, 3 non-EU countries) completed the survey. The total numbers of patients followed in the participating centres were 3817 with an average number of patients followed in each centre of 75 (±83). The majority of centres followed only adult patients,<sup>45</sup> 2 only paediatric patients (<18 years) and 5 both. The impact of dysphagia on disease severity was considered severe by all the participants with a mean VAS score of 7.3. All but one centre routinely ask the patients for the presence of dysphagia during the clinical examination. The assessment of dysphagia is performed using validated PRO questionnaires in only 7 centres (SWAL-QOL 2 centres, EAT-10 2 centres, MDADI 2 centres, UCLA-GIT 1 centre); 2 centres evaluate dysphagia using a graduate dysphagia scale by means a 10 cm VAS, and 2 routinely screen patients by a functional test (time necessary to drink a glass of water).

In all the centres an instrumental evaluation of esophageal motility is performed: esophageal manometry in 24 centres, videofluoroscopic swallowing exam in 17, esophageal barium x-rays in 16, and pHmetry and functional endoscopy in 14 each. Esophageal scintigraphy and esophagogastrosopy were respectively performed in 5 and 3 centres. The presence of dysphagia greatly influences the therapeutic approach to IIM in 49 centres leading to an increase of the corticosteroids dosage (11 centres), a change of the immunosuppressive treatment<sup>12</sup> or the initiation of intravenous immunoglobulins (IVlg).<sup>26</sup>

**Conclusions:** This study suggests that the approach to dysphagia is variable, but dysphagia has an impact on IIM patients and influences the therapeutic

decisions of the treating physician. Different therapeutic strategies are adopted regarding the treatment, and in many cases highly expensive drugs as Ivlg are prescribed. Further studies and recommendations are certainly needed for homogenising the patient management for this severe aspect of the disease.

#### AB0807 PLATELET INDICES AS MARKERS OF INFLAMMATION IN SYSTEMIC SCLEROSIS

S. Eldessouki Ibrahim<sup>1</sup>, C. Morad<sup>2</sup>. <sup>1</sup>Ain shams University, Cairo, Egypt; <sup>2</sup>Internal medicine, Ain shams University, Cairo, Egypt

**Background:** Systemic sclerosis (SSc) is a connective tissue disease involving multiple organs with an unknown etiology. Platelet function may be associated with endothelial dysfunction and immune regulatory mechanisms. Recently, an increased tendency to platelet aggregation and enhanced platelet activation have been described in SSc patients, suggesting a role for platelets in the disease itself.<sup>1,2</sup>

**Objectives:** To evaluate platelet indices in systemic sclerosis (SSc) patients and identify their clinical significance as novel inflammatory biomarkers in correlation to markers of endothelial dysfunction: vascular endothelial growth factor (VEGF) and flow mediated dilatation (FMD).

**Methods:** Thirty-five SSc patients were enrolled in addition to thirty-five age and sex matched healthy volunteers as controls. All patients and controls underwent full medical history taking, thorough clinical examination, assessment of severity extent of skin sclerosis using the modified Rodnan skin score, erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), complete blood count with special consideration to mean platelet volume (MPV), platelet distribution width and platelets count, assay for serum VEGF concentration, and brachial FMD assessment by colour duplex sonography.

**Results:** There was a highly significant decrease in the mean MPV in SSc patients compared to the controls (8.65±0.6 fl vs. 9.55±0.52 fl). There was a significant increase in the mean platelet count in SSc patients compared to controls (331.63±64.66 × 10<sup>3</sup>/ml vs. 297.80±44.48 × 10<sup>3</sup>/ml). In SSc patients, a significant negative correlation was found between the mean MPV and each of ESR, CRP and VEGF (r=-0.42, -0.368 and -0.55 respectively, p<0.05); and a significant positive correlation was found between the mean MPV and mean FMD (r=0.378, p<0.05). Linear regression test, showed an association between mean MPV and each of ESR and CRP (t=-3.312, -2.92 respectively, p<0.05).

**Conclusions:** MPV levels could be an easily measurable parameter to reflect the inflammatory condition and disease activity in systemic sclerosis patients.

#### AB0808 MULTICENTRIC STUDY OF SYSTEMIC SCLERODERMA IN TUNISIA

S. Hammami<sup>1</sup>, S. Bouomrani<sup>2</sup>, O. Berriche<sup>3</sup>, A. Barhoumi<sup>4</sup>, on behalf of The Study Group for Scleroderma, STM. <sup>1</sup>Department of Internal Medicine, CHU F Bourguiba Monastir, Monastir; <sup>2</sup>Internal medicine, Military hospital Gabes, Gabes; <sup>3</sup>Department of Internal Medicine, CHU T Star Mahdia, Mahdia; <sup>4</sup>CHU F Bourguiba, University of Monastir, Monastir, Tunisia

**Background:** Scleroderma is an autoimmune connective tissue disorder which is characterised by fibrosis of visceral organs, skin and blood vessels. This condition can be localised or systemic. Its estimated prevalence is 250 cases in a million and it is more common in women than in men.

**Objectives:** The aim of this retrospective multicenter study was to analyse demographic, clinical, laboratory features and outcome of SSc in Tunisia throughout 8 Departments of Internal Medicine and to compare them with those of other geographic groups.

**Methods:** One hundred and eight cases of SSc were recorded (American College of Rheumatology criteria) during a 15 years period. They were 93 women and 15 men with an average age at SSc onset of approximately 46.9 years.<sup>17-75</sup>

**Results:** Only 18 patients had limited cutaneous SSc, 11 patients had a CREST syndrome. Our Tunisian patients were characterised by a high frequency of cutaneous signs: sclerodactyly (80.6%), proximal sclerosis (81%), telangiectasia (34.3%), Raynaud's syndrome (91%), pigmentation disorders (36%), ulceration (24%) and subcutaneous calcification (4.6%). The other clinical manifestations were dysphagia in 54% (n=59), pulmonary involvement in 55.6% (n=60), cardiac

manifestation in 27% (n=29), arthritis in 19.4% (n=21), renal involvement in 13.8% (n=15), and neurological involvement in 12 cas. 78.7% were antinuclear antibody (ANA) positive, 25% were Antitopoisomerase-I antibodies (anti-Scl-70 antibody) positive and 10% with anti-centromere antibodies.

SSc was associated to Sjögren's syndrome n=27, systemic lupus erythematosus (n=8), Polymyositis (n=5) and Rheumatoid arthritis (n=1)

Treatment regimen included, calcium channel blockers (65.7%), steroids (47%), Colchicine (47.2%), D penicillamine (21%), immunosuppressive therapy was added in patient with partial control (n=13). Median follow-up period was 3.7 years. With the above treatment protocol, (29.6%) patients achieved disease control on treatment, (43.3%) had partial control while (26.8%) showed no response or progressive disease, Six patients died, three of them with scleroderma renal crisis.

**Conclusions:** The findings of this study documents The high frequency of extensive cutaneous sclerosis, Potential limitations and biases in our study need discussion. Specific recruitment of patients in tertiary referral centres may be the source of selection bias. Patients were evaluated by different doctors. The therapeutic management and outcome monitoring were heterogeneous. This study remains the most representative of Tunisian Scleroderma patients recruited from all parts of Tunisia

#### AB0809 A NEW SCORE TO PREDICT DIGITAL ULCERS COMBINING CLINICAL DATA, IMAGING AND PATIENT HISTORY IN SYSTEMIC SCLEROSIS

S. Friedrich<sup>1,2</sup>, S. Lüders<sup>1,3</sup>, G.-R. Burmester<sup>1</sup>, G. Riemekasten<sup>4</sup>, S. Ohrndorf<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology; <sup>2</sup>Department of Radiology; <sup>3</sup>Department of Gastroenterology and Rheumatology, Charité Universitätsmedizin Berlin, Berlin; <sup>4</sup>Department of Rheumatology and Clinical Immunology, University of Schleswig-Holstein, Lübeck, Germany

**Background:** Ischaemic complications such as digital ulcers (DU) are a common complication in systemic sclerosis (SSc) patients.

**Objectives:** The aim of this study was to combine clinical characteristics and imaging methods to a composite predictive score.

**Methods:** Seventy-nine SSc patients received clinical examination and their patient history was taken. Furthermore, we performed nailfold capillaroscopy (NC), colour Doppler ultrasonography (CDUS) and fluorescence optical imaging (FOI) of the hands at baseline. Newly developed digital ulcers over a period of approximately 12 months were registered. We used criteria with significant (p<0.5) OR values above 3.5 in regard to the development of these new DU to create the score (CIP-DUS, clinical features, imaging, patient history – digital ulcer score)

**Results:** Twenty-nine percent of the patients developed new DU during follow-up (48.1% diffuse SSc, 18.4% limited SSc). The following criteria were used: SSc diffuse subtype (OR 4.127, p=0.0087), modified Rodnan skin score >8 (OR 9.429 [95%CI: 3.0–29.2], p<0.0001), pulmonary arterial hypertension (OR 6.854 [95%CI: 1.6–9.7], p=0.0088), present digital ulcers or pitting scars at baseline (OR 15.71 [95%CI: 3.3–74.3], p<0.0001), history of digital ulcer or pitting scars (OR 36.15 [95%CI: 2.1–626.9], p<0.0001), NC pattern (OR 18.6 [95%CI: 1.1–326.4], p=0.0035), reduced capillary density (n<7/mm) in digit III of the right hand in NC (OR 9.0 [95%CI: 1.1–73.6], p=0.0266), missing initial enhancement in FOI in digit III of the right hand (OR 3.857 [95%CI: 1.2–12.8], p=0.0323), percentage of pathologic (i. e. narrowed or occluded) vessels>35% in CDUS (OR 4.286 [95%CI: 1.5–12.4], p=0.0099). Criteria with greater OR should impact the score to a higher degree so we appointed three points to dichotomous criteria with OR >10, two points for criteria with OR between 5–10, and one point for criteria with OR <5. Regarding the NC pattern, 3 points were given to patients with late pattern, 2 points for active and 1 point for early pattern.

Best results were found for a cut-off of >10 points with obtained sensitivity levels of 95% and specificity levels of 74% in regard to new DU (AUC=0.8687, p<0.0001). In the absence of CDUS and FOI data, specificity levels dropped slightly to 72% with unchanged sensitivity values of 95%.

**Conclusions:** A new score was introduced with the aim to predict digital ulcers. If applied correctly and with the new imaging techniques proposed, 95% of patients at risk of digital ulcers throughout 12 months could be identified.

AB0810

#### A COMPARISON OF CLINICAL PRESENTATION AND INCIDENCE RATE OF CARDIOPULMONARY INVOLVEMENT BETWEEN MALE AND FEMALE PATIENTS WITH EARLY SYSTEMIC SCLEROSIS

S. Wangkaew<sup>1</sup>, S. Tungteerabunditkul<sup>1</sup>, V. Sawangduan<sup>1</sup>, N. Prasertwittakij<sup>2</sup>, J. Euathrongchit<sup>3</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Cardiology, <sup>3</sup>Diagnostic Radiology, CHIANG MAI UNIVERSITY, Chiang Mai, Thailand

**Background:** Data regarding the incidence rate (IR) of cardiopulmonary involvement in comparison between male and female patients with early systemic sclerosis (SSc) are limited.

**Objectives:** To compare the prevalence of clinical manifestations and the IR of cardiopulmonary involvement comparing between male and female patients with early SSc.

**Methods:** An inception cohort of early SSc patients (disease duration  $\leq 3$  years from the first non-Raynaud's phenomenon) seen at the Rheumatology clinic, Maharaj Nakorn Chiang Mai Hospital, Thailand, between January 2010 and June 2016, was used. All patients were assessed for clinical manifestations and underwent ECG, echocardiography, and HRCT at the study entry and every 12 months thereafter. In the last visit, the cumulative clinical manifestations were recorded. Patients who continue to follow up at least 12 months were included for analysis.

**Results:** One hundred and fifteen patients (89 dcSSc) with a mean (SD) disease duration of 11.6 (8.8) months at cohort entry were enrolled during a mean (SD) observation period of 3.8 (1.6) years. There were 46 male patients (40%). Tests for anti-topoisomerase I and anti-centromere antibodies were positive in 91 (79.1%) and 7 (6.1%) patients, respectively. The male group had higher prevalence of dcSSc subtype (91.3% vs. 69.5%,  $p=0.006$ ) and positive test for anti-topoisomerase I antibody (89.1% vs. 72.5%,  $p=0.031$ ) compared with the female group. At enrollment, the male group had higher prevalence of hypo-hyperpigmentation (84.8% vs. 65.2%,  $p=0.021$ ), suspected myositis (26.1% vs. 10.1%,  $p=0.024$ ), and right ventricular dysfunction (8.7% vs. 0%,  $p=0.024$ ) compared with the female group. In the last visit, the male group had higher cumulative prevalence of digital ulcer (47.8% vs. 27.5%,  $p=0.026$ ), telangiectasia (93.5% vs. 69.6%,  $p=0.002$ ), joint contracture (69.6% vs. 43.5%,  $p=0.006$ ), tendon friction rub (39.1% vs. 20.3%,  $p=0.027$ ), LVEF  $<50\%$  (21.7% vs. 8.7%,  $p=0.048$ ) and right ventricular dysfunction (34.8% vs. 7.2%,  $p<0.001$ ) compared with the female group. The male group had significant higher IR of right ventricular dysfunction (8.21 vs. 1.99 per 100 person-years,  $p=0.006$ ) and interstitial lung disease (ILD) determined by HRCT (63.66 vs. 39.19 per 100 person-years,  $p=0.022$ ) compared to the female group. However, no significant IR of LVEF  $<50\%$  (5.63 vs. 2.10 per 100 person-years,  $p=0.078$ ), and elevated systolic pulmonary artery pressure  $\geq 50$  mmHg determined by echocardiography (2.81 vs. 1.55 per 100 person-years,  $p=0.339$ ) were observed among the two groups.

**Conclusions:** Our study cohort found that male gender had higher proportion of dcSSc subtype and had more severe clinical manifestations compared with female. In addition, during the follow-up period, the IR of right ventricular dysfunction and ILD were higher in male than that in female patients in the early stage of SSc.

#### INCREASED LEVELS OF SERUM WISTERIA FLORIBUNDA AGGLUTININ-POSITIVE MAC-2 BINDING PROTEIN IN SYSTEMIC SCLEROSIS

Y. Yokoyama<sup>1</sup>, T. Yoshikawa<sup>1</sup>, T. Furukawa<sup>1</sup>, T. Hashimoto<sup>1</sup>, M. Morimoto<sup>1</sup>, N. Azuma<sup>1</sup>, M. Kitano<sup>1</sup>, T. Iwasaki<sup>2</sup>, K. Matsui<sup>1</sup>, H. Sano<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Hyogo college of Medicine, 1-1 Mukogawa-cho, Nishinomiya-city, Hyogo; <sup>2</sup>Department of Pharmacy, Hyogo University of Health Sciences, Kobe, Japan

**Background:** Mac-2 binding protein is a cell-adhesive glycoprotein of the extracellular matrix secreted as a ligand of galectin-3 (Mac-2). Recently, a Wisteria floribunda agglutinin positive-M2BP (M2BP) assay developed using a lectin-antibody sandwich immunoassay has shown promise as a new fibrotic marker in liver fibrosis and interstitial lung disease (ILD) to detect unique fibrosis-related glycoalteration. Systemic sclerosis (SSc) is an intractable connective tissue disease that causes skin and organ fibrosis. Progressive fibrosis is now recognised to be one of the major causes of morbidity and mortality in SSc.

**Objectives:** The aim of this study is to evaluate the utility of serum M2BP levels in patients with SSc.

**Methods:** We retrospectively measured serum M2BP levels in 76 patients with SSc and 16 healthy controls (HC). We excluded patients of viral hepatitis and cirrhosis. Serum levels of M2BP were measured using HISCL<sup>®</sup> M2BP glycosylation isomer Assay Kit. IHC was performed on 5 samples of normal skin, 7 stored samples of SSc skin and 2 samples of SSc-ILD lung tissue. We examined the relationship between serum M2BP levels and clinical parameters in patients with SSc.

**Results:** The mean age was 62.7 years in SSc patients and 54.6 years in HC. There were 57 limited cutaneous SSc patients and 19 diffuse cutaneous SSc patients. The mean duration of SSc patients was 9.8 years. Serum M2BP levels were significantly higher in patients with SSc than in HC (0.853 $\pm$ 0.701 cutoff index [COI], 0.325 $\pm$ 0.111 COI, respectively;  $p<0.00001$ ). Receiver operating characteristic (ROC) curve analysis indicated that serum M2BP correctly differentiated between SSc patients and HC with a sensitivity of 81.6% and specificity of 87.5%. In patients with SSc, a significant correlation was not found between serum M2BP levels and age, sex, mRSS, ILD, pulmonary artery hypertension (PAH), SSc-types, dermatoscopy findings. In multivariate analysis, disease duration was a only independent factor for higher serum M2BP levels more than 0.64 COI, serum M2BP median (odds ratio 0.935, 95% CI 0.878–0.996,  $p=0.0385$ ). We detected the protein level of M2BP in SSc patient's fibroblast of skin and SSc Patient's proliferating type II alveolar cells adjacent to fibrotic lesions of lung tissue.

**Conclusions:** In this study, for the first we demonstrated that M2BP is expressed in skin and lung tissue in SSc patients in IHC and more over the serum M2BP level tends to be higher in patients with short disease duration. It is reveal that M2BP play an important role of fibrosis in early stage of SSc. The serum level of M2BP may be a novel biomarker of SSc.

#### ULTRASONOGRAPHY FOR THE ASSESSMENT OF SKIN IN SYSTEMIC SCLEROSIS: A SYSTEMATIC REVIEW

T. Santiago<sup>1,2</sup>, M. Santiago<sup>3</sup>, B. Ruaro<sup>4</sup>, M.J. Salvador<sup>1</sup>, M. Cutolo<sup>4</sup>, J.A. Pereira da Silva<sup>1</sup>. <sup>1</sup>Rheumatology Department, Centro Hospitalar e Universitário de Coimbra, Portugal; <sup>2</sup>Faculty of Medicine, University of Coimbra; <sup>3</sup>Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal; <sup>4</sup>Research Laboratories and Academic Division of Clinical Rheumatology, Department of Internal Medicine, University of Genova, San Martino Polyclinic, Genova, Italy

**Background:** Skin involvement is the clinical hallmark of systemic sclerosis (SSc). A palpation-based semi-quantitative tool, the modified Rodnan skin score, is the current gold standard for the assessment of skin involvement. However, this method has significant limitations, with emphasis on low sensitivity to change and a high inter-observer variability. Ultrasound has been explored, in the past decades, as a basis for more objective, sensitivity and reproducible measure of skin involvement.

**Objectives:** To identify and synthesise the best available evidence on the use of ultrasound as a source of skin outcome measures in patients with SSc.

**Methods:** Two independent reviewers systematically searched Pubmed MEDLINE and Embase (up to December 2017). A study was eligible if it included at least one defined group of patients with SSc, and reported a structured evaluation of the skin with ultrasound and/or ultrasound elastography. This search was augmented by review of bibliographic references from the included studies. The same two reviewers independently extracted the data and classified the quality of evidence of the included studies by the Effective Public Health Practice Project system.

**Results:** A total of 30 studies (21 observational cross-sectional and 9 longitudinal) were included. They enrolled a total of 1171 SSc patients, mostly middle-aged, female and with a limited form of SSc (59.0%). The most common ultrasound outcome measure used was skin thickness (in 28 studies), although the definition of this parameter was a highly heterogeneous. Other outcome measures were echogenicity (in 7), and/or stiffness (in 6) and/or vascularity (in 1). There was a substantial discordance in the number and exact location of skin sites examined. The main comparator was global and site specific mRSS.

There was a lack of construct and criterion validity (only 1 study assessed the correspondence between ultrasound measures and histological findings). Few studies reported information about inter- and intra-rater reproducibility, but when reported, it showed excellent results. Data regarding evidence for responsiveness to change and feasibility were also scarce.

**Conclusions:** This systematic review highlights a remarkable literature heterogeneity and limited quality of most reported studies. This hinders the evidence currently supporting the use of skin ultrasound evaluation in clinical practice, but the very promising data (e.g good reliability and early detection of skin involvement) support its use in clinical research. Further well-designed and dimensioned studies are needed to support the role of skin ultrasound assessment in the early diagnosis and monitoring SSc patients. These may be crucial to improve our

understanding the disease process and to foster the development of much-needed new intervention strategies.

#### AB0813 SEVENTEEN MYOSITIS AUTOANTIBODIES: SEROLOGICAL PROFILE OF HISPANIC PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

T.S. Gracia-Arechiga, M.A. Villarreal-Alarcon, J. Hermosillo-Villafranca, I. Pérez-Onofre, A. Guillén-Lozoya, D. Galarza-Delgado, J.P. Carrizalez Luna. *Rheumatology and Immunology UANL, UANL, MEDICAL UNIVERSITY, Monterrey, Mexico*

**Background:** The idiopathic inflammatory myopathies (IIM) are a heterogeneous group of subacute, chronic, or acute acquired diseases of skeletal muscle, they can be classified into the following clinical pathologic groups: dermatomyositis (DM), polymyositis (PM), and inclusion body myositis (IBM) which differ in clinical presentation, season of onset, genetics, and prognosis.<sup>(1)</sup> Furthermore, the seropositivity of antibodies in these diseases can help to predict the evolution of the disease, and influence therapeutic strategies.<sup>(2)</sup> Anti-Mi-2 is a classic marker for DM and its associated with good response for steroid treatment and good prognosis. Anti-SRP is specific for PM and its associated with treatment-resistant myopathy, histologically characterised as necrotizing myopathy. Several new myositis specific antibodies (MSA), autoantibodies with strong clinical significance have been described in IIM manifestations.<sup>(3)</sup> The literature about this topic is limited in Hispanic population. This study represents an effort for a better understanding of this group of diseases.

**Objectives:** To determine the prevalence of myositis specific and myositis associated autoantibodies in a cohort of patients with idiopathic inflammatory myopathies, who were treated from January 2016 to January 2018 in a Rheumatology Service from a University (Hospital Jose E. Gonzalez) from UANL and a centre for arthritis at north of Mexico.

**Methods:** Cross-sectional, retrospective descriptive study cohort of 95 patients who attended the rheumatological clinic in the period from January 2016 to January 2018 who met Bohan and Peter's classification criteria. The determination of antibodies was performed by the Immunoblot technique with Euroimmun kit. The following serotypes were included: OJ, Ro 52, Mi2  $\alpha$ , MDA-5, TIF 1 gamma, PM/Sc1 75, Mi 2B, SRP, PL12, PL 7, PM/Sc1 100, Ku, Jo1, EJ, cN1A, NXP2, SAE 1. Statistical analysis was performed with univariate, for the categorical variables, absolute frequencies and percentages were analysed and for the numerical means and standard deviation with the SPSS V22 (Armonk, NY: IBM Corp.)

**Results:** From a cohort of 95 patients, 68.42% were women and 31.75% were men. The average age was 47 $\pm$ 15.42. A prevalence of seropositive antibodies were observed for Mi2  $\alpha$  of 29 (30.52%), 14 (14.73%) in *Tif 1 gamma* and 12 (12.63%) has positive *Mda 5*.

**Abstract AB0813 – Table 1.** Positive Antibodies.

Antibody	IIM n= 95	
	mean $\pm$ SD	n (%)
Mi2 $\alpha$	21.79 $\pm$ 14.85	29 (30.52)
Mi2 $\beta$	19.60 $\pm$ 12.81	10 (10.52)
Tif1 $\gamma$	42.42 $\pm$ 24.36	14 (14.73)
Mda5	28.83 $\pm$ 25.84	12 (12.63)
Nxp2	66 $\pm$ 54.11	3 (3.15)
Sae1	48.50 $\pm$ 58.68	2 (2.10)
Ku	9.75 $\pm$ 2.87	4 (4.21)
PM-Sc1100	45 $\pm$ 29.10	7 (7.36)
PM-Sc175	37.63 $\pm$ 27.72	9 (9.47)
Jo1	44.08 $\pm$ 24.40	5 (5.26)
Srp	20.20 $\pm$ 8.13	5 (5.26)
Pl-12	9.85 $\pm$ 4.81	7 (7.36)
Ej	–	1 (1.05)
Oj	25 $\pm$ 26.81	6 (6.31)
Ro-52	42.70 $\pm$ 27.67	24 (25.26)
Cn-1 $\alpha$	1.14 $\pm$ 0.05	5 (5.26)
Pl7	23.50 $\pm$ 11.79	8 (8.42)
CpK	525.11 $\pm$ 110.49	54 (56.84)

\*SD: Standard Deviation

**Conclusions:** The systematic and standardised evaluation of the determination of antibodies in patients with inflammatory myopathies play an important role in the predictive evaluation. Knowledge of the prevalence and clinical scenarios in various cohorts increase the standardisation and prompt use of antibodies in the classification of inflammatory myopathies

#### AB0814 SODIUM THIOSULFATE 10% INTRALESIONAL TO TREAT CALCINOSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS AND DERMATOMYOSITIS: CASE SERIES

A.F. Tonia<sup>1</sup>, M.P.M. Cathcart<sup>1</sup>, I.A.F.G. Santos<sup>1</sup>, P.M. Azevedo<sup>1</sup>, T.L. Skare<sup>1</sup>, P. Martin<sup>1,2</sup>. <sup>1</sup>Departamento de Reumatologia, Hospital Universitário Evangélico de Curitiba; <sup>2</sup>Escola de Medicina, Pontifícia Universidade Católica do Paraná, Curitiba, Brazil

**Background:** Calcinosis is a frequent complication of systemic sclerosis and dermatomyositis, causing local pain, joint mobility reduction, ulcerations, secondary infections and disability. Currently, there is no effective treatment to calcinosis, but the use of topical dressing or intralesional sodium thiosulfate (STS) has showed promising results.

**Objectives:** To evaluate efficacy of intralesional STS 10% in calcinosis of patients with dermatomyositis and systemic sclerosis.

**Methods:** Prospective and open-labelled study including dermatomyositis and systemic sclerosis patients with calcinosis. The primary endpoints were: pain relief evaluated through visual analogue scale (VAS) and reduction of major diameters of calcinosis in x-ray. The secondary endpoints were: improvement in the quality of life and function evaluated by SF12 and HAQ respectively.

**Results:** A total of 10 calcinosis from 7 patients, one with dermatomyositis and 6 with systemic sclerosis were treated. The average dosage of STS per application was 9.27 mg at intervals ranging between 15 and 30 days (mean=17.85) between each injection. The number of injections per each calcinosis ranged between 3 and 8 (mean 3.3). All patients reported improvements in pain, however the results were not statistically significant (table 1). There were no reductions in calcinosis diameters, nor improvement of quality of life and function.

**Conclusions:** Low doses of sodium thiosulfate applied through intralesional injections, in a restrict number of applications and long intervals were not effective to treat calcinosis.

### AB0815 HEALTH RELATED QUALITY OF LIFE IN PATIENTS WITH SYSTEMIC SCLEROSIS TREATED WITH TWO DIFFERENT INTRAVENOUS ILOPROST REGIMENS

T. Schioppo<sup>1</sup>, L. Scalone<sup>2,3</sup>, P. Cozzolino<sup>2</sup>, L. Mantovani<sup>2,3</sup>, G. Cesana<sup>2</sup>, O. De Lucia<sup>1</sup>, A. Murgo<sup>1</sup>, F. Ingegnoli<sup>1,4</sup>. <sup>1</sup>Rheumatology, Pini, Milan; <sup>2</sup>CESP, University of Milan Bicocca, Monza; <sup>3</sup>Fondazione CHARTA; <sup>4</sup>University of Milan, Milan, Italy

**Background:** In systemic sclerosis (SSc), Raynaud's phenomenon (RP) and digital ulcers (DU) can decrease health related quality of life (HRQoL). Intravenous (IV) iloprost (ILO) is administered for RP, after oral therapy failure, and DU healing. HRQoL is considered fundamental to assess the impact of the disease and therapy on patients: EQ-5D-5L has been satisfactory used to assess the general HRQoL in SSc.

**Objectives:** Aim of our study was to estimate HRQoL in SSc patients treated with two different IV ILO regimens and in patients not requiring IV ILO.

**Methods:** This was a monocentric, prospective, pragmatic and non-randomised study. Enrolled SSc patients were divided into 3 groups: no IV ILO (group A), IV ILO once monthly (B) or IV ILO for 5 consecutive days every 3 months (C). HRQoL was assessed using EQ-5D-5L through a telephone interview. Group A patients were evaluated at baseline and after 3 months; group B 2 days before each infusion and 2 weeks after each infusion; group C 2 days before each therapy cycle, and after 2 and 6 weeks after the first cycle of therapy. The EQ-5D-5L describes HRQoL, measures the overall health state with a 0–100 visual analogue scale (VAS) and values health with a utility index. Multiple regression analyses was performed to calculate VAS and mean utility index in each group (confounders: age, sex, treatment group, baseline utility or VAS score, average outdoor temperature the week before the evaluation at patient's place of residence, RP VAS, disease duration and modified Rodnan skin score).

**Results:** 96 patients were enrolled: 52 in group A, 24 in B, and 20 in C. Of these 35, 21 and 16 completed the study respectively. Utility and VAS score at the end

of the three months, as adjusted for the possible confounders, were not statistically different in the three groups.

**Conclusions:** Utility and VAS, at 3 months follow-up, were not different in the 3 groups as if IV ILO was able to make patients requiring IV ILO as similar as patients not requiring IV ILO. Moreover, in this model there was no difference between the two ILO regimens (1 days monthly vs 5 every 3 months). These results suggest that our therapeutic approach, based on various criteria such as demographic, clinical characteristics, logistic aspects and patients' preferences, allows to reach or to maintain HRQoL at comparable levels between the three groups considered.

However, whether the nailfold capillaroscopy pattern is distinct in SSc patients with malignancy remained unknown.

**Objectives:** The aim of this study was to investigate the incidence rate of malignancy in SSc patients. Nailfold capillaroscopy morphology patterns in SSc patients with cancer were also compared to those without cancer.

**Methods:** During 2004 to 2014, consecutive 310 SSc patients who visited outpatient clinics at Taichung Veterans General Hospital, Taiwan were enrolled. Nailfold capillaroscopy was performed at a magnification of 200x. Abnormal morphology description were analysed and categorised by the scoring system proposed by Dr. Cutolo<sup>2</sup>. SSc with malignancy was defined if the subject had a cancer diagnosis during the follow-up period.

**Results:** Among 310 SSc patients, 28 (10.9%, 13 males, 25 females) patients had cancer. The mean age of SSc with malignancy is 62±10.9 years. Sixty-four percent SSc patients with cancer is diffuse type, but only 42% of them were tested positive for anti-Scl-70 antibodies. The most common cancer were genitourinary tract and gastrointestinal tract, accounting for almost two-thirds patients. Cancer and SSc were frequently diagnosed at the same year. In SSc patients with cancer, 19 patients received nailfold capillary microscope exams when SSc was diagnosed. The assessment of nailfold capillaroscopy morphology patterns in SSc patients with cancer demonstrated neither enlarged loop, giant loop, microhemorrhage nor angiogenesis. However, prominent avascular areas could be observed universally in SSc patients with malignancy.

**Conclusions:** Rheumatologists should be aware of malignancy in SSc patients, especially those with diffuse type and within the 1st year of symptoms onset. SSc patients with malignancy tend to present atypical capillaroscopic pattern of prominent avascular area without loop dilatation, microhemorrhage and angiogenesis.

#### AB0818 THE COMPARATIVE STUDY OF SYSTEMIC SCLEROSIS AND SYSTEMIC LUPUS ERYTHEMATOSUS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION

Y. Feng, J. Wang, Y. Lei, X. Zhang. *Department of Rheumatology, Guangdong Academy of Medical Sciences/Guangdong General Hospital, Guangzhou, China*

**Background:** Systemic Sclerosis(SSc) is the main cause of Connective Tissue Disease-associated pulmonary arterial hypertension (CTD-PAH) in western countries, while Systemic Lupus Erythematosus(SLE) is the first cause in Asian.

Systemic Sclerosis(SSc) is the main cause of Connective Tissue Disease-associated pulmonary arterial hypertension (CTD-PAH) in western countries, while Systemic Lupus Erythematosus(SLE) is the first cause in Asian.

**Objectives:** This study aimed to identify the clinical difference between SSc-PAH and SLE-PAH.

This study aimed to identify the clinical difference between SSc-PAH and SLE-PAH.

**Methods:** SSc and SLE patients with pulmonary arterial hypertension who visited Guangdong General Hospital in China from 2009 to 2017 were recruited. PAH was diagnosed by transthoracic echocardiography or right heart catheterization and clinical data of patients was collected. Comparative study between SSc-PAH and SLE-PAH was conducted to identify the difference.

SSc and SLE patients with pulmonary arterial hypertension who visited Guangdong General Hospital in China from 2009 to 2017 were recruited. PAH was diagnosed by transthoracic echocardiography or right heart catheterization and clinical data of patients was collected. Comparative study between SSc-PAH and SLE-PAH was conducted to identify the difference.

**Results:** Twenty-nine SSc-PAH and 55 SLE-PAH patients were enrolled. The baseline characteristics of two groups was shown in table 1. In comparative study: the gender( $p=0.018$ ), the age of PAH diagnosis( $p=0.001$ ), Raynaud's phenomenon( $p<0.001$ ), WHO function state( $p=0.019$ ), PASP ( $p=0.013$ ), the diameter of RA( $p=0.045$ ) and RV( $p=0.029$ ) showed significant difference between SSc and SLE-PAH.

**Abstract AB0818 – Table 1.** Baseline Characteristics of SSc-PAH and SLE-PAH Patients

	SSc-PAH(29)	SLE-PAH(55)	<i>p</i>
Female	23(79.3%)	53(96.4%)	<b>0.018</b>

#### AB0819 Tfh CELLS CONTRIBUTE TO ABNORMAL B CELL PROFILES IN DERMATOMYOSITIS

X. Zhang, X. Ma, H. Wang, Z. Chen, L. Sun. *Department of Rheumatology And Immunology, THE AFFILIATED DRUM TOWER HOSPITAL, NANJING UNIVERSITY MEDICAL SCHOOL, NANJING, CHINA., Nanjing, China*

**Background:** CD4 +CXCR5+PD-1+T follicular helper (Tfh) cells assist B cells in their proliferation, differentiation and antibody class switch.<sup>1</sup> Several studies indicate that Tfh cells play important roles in autoimmune diseases such as SLE, RA and pSS, which are characterised by the production of multiple antibodies.<sup>2-4</sup> The frequency of Tfh cells in the peripheral blood from patients with dermatomyositis(DM) and whether they participate in the development of DM remain to be elucidated.

**Objectives:** To investigate the frequencies of Tfh cells and B cell profiles in DM patients. To further determine the association of Tfh cells and B cells in DM patients and clarify the possible mechanism.

**Methods:** Peripheral blood mononuclear cells (PBMCs) were isolated from DM patients and age, gender-matched healthy controls (HCs), respectively. The frequency of Tfh (CD4 +CXCR5+PD-1+) cells, total B (CD19+) cells naïve B (CD19 +CD27-) cells, memory B(CD19 +CD27+) cells and plasmablasts (CD19 +CD38+) were examined by flow cytometry. The serum levels of IL-21, IgG, IgM, IgE and IgA were tested by enzyme linked immunosorbent assay (ELISA).

**Results:** The percentages of circulating Tfh cells are significantly higher in DM patients than HCs ( $p < 0.0001$ ). Compared to HCs, the absolute numbers of circulating Tfh cells also upregulate markedly in DM patients ( $p < 0.05$ ). The mRNA expression levels of Bcl-6, a typical transcription factor of Tfh cells, increase apparently in PBMC from DM patients ( $p < 0.05$ ). Serum levels of IL-21, a Tfh-specific cytokine, are obviously higher in DM patients ( $p < 0.01$ ). The percentages of total B cells ( $p < 0.01$ ) and Naïve B cells ( $p < 0.01$ ) upregulate significantly in DM patients while Memory B cells ( $p < 0.05$ ) downregulate markedly when compared with HCs. The absolute numbers of plasmablasts ( $p < 0.05$ ) and Naïve B cells ( $p < 0.05$ ) increase notably while memory B cells decreased obviously ( $p < 0.01$ ). Serum levels of IgG ( $p < 0.01$ ), IgM ( $p < 0.0001$ ), IgE ( $p < 0.01$ ) and IgA ( $p < 0.05$ ) are obviously higher in DM patients ( $p < 0.05$ ). The frequencies of Tfh cells are positively correlated with total B cells ( $r = 0.633$ ,  $p < 0.001$ ) and Naïve B cells ( $r = 0.643$ ,  $p < 0.01$ ).

**Conclusions:** Tfh cells may contribute to abnormal B cell profiles and antibodies production in DM and participate in the pathogenesis of DM. Tfh cell-targeted therapy might be a potential strategy for DM.

#### AB0820 ANTI-KS AUTOANTIBODY IS ASSOCIATED WITH SICCA SYNDROME AND INTERSTITIAL LUNG DISEASE

Y. Kondo, S. Sasaki, T. Kurabayashi, Y. Koyama, S. Sato. *Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Kanagawa, Japan*

**Background:** Anti-aminoacyl-tRNA synthetase (anti-ARS) autoantibodies have been found in patients with polymyositis/dermatomyositis (PM/DM). Anti-KS, an anti-ARS antibody, often presents with interstitial lung disease (ILD) without other clinical symptoms of connective tissue disease (CTD). However, the clinical manifestations of anti-KS-positive patients are not well-studied.

**Objectives:** To clarify the clinical and laboratory characteristics of Japanese patients with antibodies against anti-KS antibody.

**Methods:** Sera from 326 patients with CTD (including PM/DM) or ILD at Tokai University were screened for anti-KS antibody using RNA and protein immunoprecipitation assays. Demographic data, clinical symptoms, laboratory findings and chest computed tomography (CT) scan results were retrospectively reviewed from medical charts.

**Results:** Five patients with anti-KS autoantibody were identified. All five patients were female with a mean age ( $\pm$ SD) of 59.4 ( $\pm$ 13.9) years at onset, presenting with respiratory symptoms without any sign of myositis. In all patients, ILD was chronic and chest CT scan revealed a non-specific interstitial pneumonia pattern in three patients and the remaining two showed a usual interstitial pneumonia pattern. Three patients (60%) had arthritis, mechanic's hand, while one (20%) had Gottron's sign and was diagnosed as amyopathic DM with ILD. Interestingly, three patients (60%) showed symptoms of the Sicca syndrome with presence of anti-SSA antibody and two of those were diagnosed as Sjögren's syndrome. The frequency of Sicca syndrome in anti-KS-positive patients was significantly higher compared with other anti-ARS antibody-positive patients (60% vs. 14%, respectively,  $p = 0.031$ )

**Conclusions:** These results highlight that the presence of anti-KS antibody is associated with the Sicca syndrome as well as ILD without muscle symptoms.

#### AB0821 EARLY DETECTION OF THE CHANGES IN PULMONARY ARTERIAL PRESSURE AND VASCULAR FUNCTIONS IN SYSTEMIC SCLEROSIS: EXPLORING NON-INVASIVE CLINICAL TEST METHODS AND UNDERLYING GENE EXPRESSIONS

Y. Koyama<sup>1</sup>, S. Fuke<sup>2</sup>, T. Ohno<sup>3</sup>, Y. Sato<sup>4</sup>, T. Higuchi<sup>1</sup>. <sup>1</sup>Center for Autoimmune Diseases, Division Of Rheumatology; <sup>2</sup>Department of Cardiology; <sup>3</sup>Department of Dermatology, Japanese Red Cross Okayama Hospital, Okayama; <sup>4</sup>DNA Chip Research Inc, Tokyo, Japan

**Background:** Pulmonary arterial hypertension (PAH) is prominent as a vascular involvement in systemic sclerosis (SSc), which remains a leading cause of death in spite of current best treatments. Although recent studies focused on early diagnosis of established PAH, it is known that more than a half of the pulmonary circulation is impaired before early PAH is detected. However, there is little study about the changes of vascular functions or the underlying gene expressions during its subclinical stage.

**Objectives:** I. To detect the pathological changes in pulmonary arterial pressure (PAP) and vascular functions before PAH is manifested. II. To explore the changes in its underlying gene expressions of peripheral blood.

**Methods:** Total of 103 cases without PAH symptoms (NYHA I) with either Raynaud phenomenon (RP: n=87), skin sclerosis (n=65) or SSc-related autoantibody (n=68) were enrolled. To detect the pathological change of PAP, exercise Doppler echocardiography was carried out, and exercise induced pulmonary hypertension (exPH) group was segregated from normal response group (exN) with using the definition described in R. Naeije *et al.*<sup>1)</sup> Vascular function was evaluated with thermography after 0°C-stress and determination of ankle-brachial index (ABI) and cardio-ankle vascular index (CAVI). Furthermore, reactive hyperemic index (RHI), augmentation index (AI) and second derivative of photoplethysmogram ageing index (SDPTGAI) were assessed with using EndoPAT. Micro-vascular changes were also recorded with nailfold videocapillaroscopy. Meanwhile, genome-wide gene expression analysis was performed with using whole peripheral blood. The genes correlated with each vascular function tests were analysed by weighted gene co-expression network analysis (WGCNA) and pathway enrichment analysis (PathVisio).

**Results:** There were significant differences between exPH and exN group in the result of thermography after 0°C-stress test, CAVI and AI normalised to heart rate of 75bpm (AI@75bpm). As the CAVI and AI are known to correlate positively with age, careful interpretation was necessary because the mean age of exPH group was higher as compare with exN group (69.05 $\pm$ 11.04 vs. 60.23 $\pm$ 14.73). However, the fact that recovery of blood-flow from RP was significantly delayed in exPH group suggested the additional pathological changes of vascular and endothelial functions. Gene expression analysis revealed that several mutual pathways such as "type2 interferon signalling", "oxidative damage" and "fatty acid omega oxidation" seemed to underlie some vascular changes.

**Conclusions:** The results of vascular function tests including thermography after 0°C-stress, CAVI and AI@75bpm were significantly different between exPH and exN group. On the other hand, gene expression analysis showed that many factors such as ageing, arteriosclerotic and immunological mechanisms were involved in the changes of these vascular functions. Although further prospective study is required to select appropriate set of the tests, it is possible that evaluation of these vascular functions may be useful as a non-invasive test to assess the pulmonary vascular disease before PAH is manifested.

#### AB0822 A MEASUREMENT OF ANTI-ARS ANTIBODIES, ANTI-MI-2 ANTIBODY, ANTI-TIF1 GAMMA ANTIBODY AND ANTI-MDA5 ANTIBODY BY ENZYME-LINKED IMMUNOSORBENT ASSAY AS A DIAGNOSTIC TOOL OF IDIOPATHIC INFLAMMATORY MYOPATHY AT RHEUMATOLOGY DAILY PRACTICE

Y. Miyoshi<sup>1,2</sup>, T. Kise<sup>1</sup>, N. Yokogawa<sup>1</sup>, K. Shimada<sup>1</sup>, S. Sugii<sup>1</sup>. <sup>1</sup>Department of rheumatic diseases, Metropolitan Tama Medical Center, Fuchu, Tokyo; <sup>2</sup>Department of rheumatic diseases, Tama-Hokubu medical center, Higashimurayama, Tokyo, Japan

**Background:** Enzyme-linked immunosorbent assay (ELISA) tests of anti-ARS antibodies, anti-Mi-2 antibody, anti-TIF1 $\gamma$  antibody and anti-MDA5 antibody

became available at daily clinical practice on Oct. 2016 in Japan. Diagnostic accuracy study of myositis-specific autoantibodies (MSAs) except for anti-Jo-1 antibody in daily clinical practice is scarce.<sup>1</sup>

**Objectives:** This study investigated the diagnostic utility of newly available myositis-specific autoantibodies (ELISA) in idiopathic inflammatory myopathy (IIM) suspected patients at a rheumatology clinic with muscle and skin biopsy as a reference standard.

**Methods:** This study is a retrospective, cross-sectional study. The electrical medical records of patients who visited the department of rheumatic diseases at Tokyo Metropolitan Tama Medical Centre between Nov. 2016 and Aug. 2017 were retrospectively searched for clinical variables and laboratory data. Patients with serum creatine phosphokinase (CK) greater than two-fold of normal upper limit (over 300 IU/ml) or suspected dermatomyositis skin rash were included. Anti-ARS antibodies, anti-Mi-2 antibody, anti-TIF1 $\gamma$  antibody and anti-MDA5 antibody were measured by ELISA.<sup>2-4</sup> Two muscle pathologists interpreted muscle biopsy. The skin biopsies with interface-dermatitis were considered positive. The biopsy results of patients who did not have biopsy procedure but whose symptoms and signs improved without immunosuppressive therapy were assumed negative. IIM diagnosis was based on 2017 EULAR/ACR classification criteria.<sup>5</sup> We calculated likelihood ratio of MSAs for biopsy results and IIM diagnosis.

**Results:** Eight hundred and eighty-six new patients visited an outpatient clinic of rheumatic disease department and 38 patients met inclusion criteria. 14 patients were excluded because of apparent causes (1 each for sepsis, rhabdomyolysis, macro CK, serotonin syndrome, motor neuron disease, statin myopathy, SSC, idiopathic IP, seborrheic dermatitis, 3 for symptoms not compatible with IIMs.) and no biopsy results (2 patients). 17 (71%) of 24 patients analyses were female. The median age was 56.5 (IQR 41–65) years, median CK 658 (IQR 105–1866) IU/ml. 11 (46%) patients had the positive biopsy result (6 muscle biopsy and 5 skin biopsy) and IIM diagnosis. 10 (42%) patients were positive for MSAs (anti-ARS antibodies in 3, anti-Mi-2 antibody in 1, anti-TIF1 $\gamma$  antibody in 2, anti-MDA5 antibody in 3 and double positive for anti-ARS and anti-MDA5 antibody in 1). The positive likelihood ratio of MSAs for the biopsy result and IIM diagnosis was  $\infty$  (95% CI cannot be calculated). The negative likelihood ratio was 0.091 (95% CI 0.086–0.097).

**Conclusions:** Our analysis demonstrated that MSAs measured by ELISA efficiently differentiated biopsy-proven IIMs from other medical conditions at rheumatology daily practice.

#### AB0823 PATIENTS WITH CONNECTIVE TISSUE DISEASE HAVE MORE ANXIETY IN COMPARISON WITH PATIENTS WITH OTHER RHEUMATIC DISEASES

Y. Jiang<sup>1</sup>, D. Lin<sup>1</sup>, P. Zhang<sup>2</sup>, X. Zhang<sup>1</sup>, Z. Liao<sup>1</sup>, Y. Pan<sup>1</sup>, J. Gu<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pediatrics, the Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China

**Background:** Rheumatic diseases often coexists with psychological disorders. Psychological symptoms not only have a substantial negative impact on the quality of life, but also on the course and outcome of the chronic disorders.<sup>1</sup>

**Objectives:** Our study was to investigate psychological disorders in Chinese patients with rheumatic diseases and to compare the differences of psychological disorders among different diseases.

**Methods:** Patients with rheumatic diseases were enrolled from July to December in 2017 in rheumatology department of the Third Affiliated Hospital of Sun Yat-sen University. Participants were required to complete a set of questionnaires and examinations, including demographic and clinical information, Zung self-rating anxiety scale (SAS), and Zung self-rating depression scale (SDS). The Statistical Package for Social Sciences (SPSS) software version 21 was used for all data management and analysis. The Mann-Whitney U test and Student's t test were used to compare patients with different rheumatic diseases and psychological disorders. Stepwise linear multiple regression was used to determine the contributors to SAS and SDS.

**Results:** Of all the 153 patients, 49 (32%) were male patients. 14.4% had only primary education, while 32% received education in university. Numbers of the patients were stated as follows. Lupus, 44; rheumatoid arthritis, 11; Sjogren's syndrome, 11; systemic sclerosis, 9; myositis, 7; vasculitis, 6; spondyloarthritis, 9; gout, 10; other diseases 46. Mean age was 37.64±15.23 years. Mean disease

duration was 3.78±5.07 years. Mean SAS scores were 43.44±8.51, and mean SDS scores were 46.66±12.43. 35 (22%) of the patients had anxiety, while 6 (3.9%) had moderate anxiety. 50 (32.7%) patients suffered from depression, of which 5 (3.3%) had severe depression, and 13 (8.5%) had moderate depression. Patients with connective tissue diseases had more anxiety (30.5%) than average score ( $p<0.05$ ), especially in patients with lupus. SDS ( $B=1.073$ ,  $p<0.001$ ), educational scale ( $B=-2.147$ ,  $p<0.05$ ) contributed to SAS scores.

**Conclusions:** Psychological disorders could occur with rheumatic diseases, especially in connective tissue diseases. Physicians should be aware of psychological status in these patients.

#### AB0824 EVALUATION OF THE DETECTION OF MYOSITIS-SPECIFIC ANTIBODIES BY LINEBLOT AS A TOOL FOR THE CHARACTERISATION OF A PROSPECTIVE MULTICENTER COHORT

Y. Piette<sup>1,2</sup>, C. Bonroy<sup>3</sup>, J. Dehorne<sup>4</sup>, J. De Bleeker<sup>5</sup>, M. De Sloovere<sup>3</sup>, L. Van Praet<sup>2</sup>, A.-S. Vander Mijnsbrugge<sup>2</sup>, P. Jacques<sup>2</sup>, S. Vandendriessche<sup>3</sup>, M. Versaevel<sup>3</sup>, F. De Keyser<sup>6,7</sup>, V. Smith<sup>2</sup>. <sup>1</sup>Rheumatology, AZ St.-Jan, Brugge; <sup>2</sup>Rheumatology; <sup>3</sup>Laboratory Medicine; <sup>4</sup>Pediatric Rheumatology; <sup>5</sup>Neurology, Ghent University Hospital, Ghent; <sup>6</sup>Praktijk 10A, Maldegem; <sup>7</sup>Internal Medicine, Ghent University, Ghent, Belgium

**Background:** Traditionally, the diagnosis of idiopathic inflammatory myopathies (IIM) is based on clinical findings, muscle enzyme levels, electromyography and biopsy. Newer approaches include the detection of myositis-specific autoantibodies (MSA), with MSA identified in about 50% of patients.

Today, several commercial platforms for MSA detection have become commercially available. In the context of the start-up of a prospective multicentre cohort, we evaluated the usefulness of a multiparameter line blot for the serological characterisation of patients with clinical suspicion of IIM.

**Objectives:** To evaluate the usefulness of a multiparameter line blot for the serological characterisation of patients with clinical suspicion of IIM.

**Methods:** A total of 225 samples (118 consecutive routine samples for which MSA were requested and 107 controls [50 systemic sclerosis (SSc), 29 systemic lupus erythematosus (SLE) and 28 rheumatoid arthritis patients (RA)]) was analysed on indirect immunofluorescence (HEp-2000, Immunoconcepts) and lineblot (MYO12 blot, D-Tek). All consecutive samples were retrospectively categorised by the treating medical specialist as definite IIM (n=16), probable IIM (n=10), immune mediated inflammatory disease (IMID) – myositis overlap not excluded (n=28), myopathic features without IIM (n=1), IIM excluded (n=44), and lost from follow-up/no data available (n=19). Data to calculate the EULAR/ACR probability score were also collected.

**Results:** MSA were detected in 12% of the 225 samples, showing no multiple reactivities. A sensitivity of 50% in the IIM patients (definite and probable n=13/26 – based on judgement of the clinician) was observed, with the highest frequencies observed for anti-HMGCR (15%, n=4), anti-Mi2 (12%, n=3) and anti-Jo1 (12%, n=3). Less frequent antibodies were anti-EJ (n=1), anti-MDA5 (n=1) and anti-NXP2 (n=1). All these patients had a MSA-compatible clinical IIM subtype. The median minimal EULAR/ACR probability score was 97% (range 6%–100%, no biopsy data entry), with the lowest score observed in the anti-EJ patient. In contrast, MSA were also observed in 8 patients with no convincing clinical diagnosis of IIM or myositis overlap syndrome (anti-TIF1 $\gamma$  in 4 [3 SSc and 1 SLE]; anti-SRP in 1 [1 RA]; anti-SAE in 3 [1 SSc, 1 RA and 1 IIM excluded], mostly showing low antibody titres (n=6/8) and no compatible immunofluorescence pattern on HEp-2000 (n=7/8). For 2 other positive samples the results were not conclusive (anti-PL7 in patient with myopathic features and anti-SRP in an unspecified IMID patient).

**Conclusions:** The detection of MSA by lineblot will be useful for the prospective serological characterisation of patients with clinical suspicion of IIM. Nevertheless, careful interpretation in correlation with the clinical findings and other technical examinations is necessary in case of low titres and absence of a compatible immunofluorescence pattern.

**AB0825** **MANAGING SYSTEMIC SCLEROSIS: ASSESSING THE EDUCATIONAL NEEDS OF RHEUMATOLOGISTS**

Z. Ahmad, S. Johnson. *Toronto Scleroderma Program, Division of Rheumatology, Department of Medicine, Sinai Health System, University Health Network, University of Toronto, Toronto, Canada*

**Background:** Systemic sclerosis (SSc) is an uncommon, complex and heterogeneous condition, making it challenging to manage. Individual rheumatologists see relatively few cases and patient surveys identify numerous gaps in clinical care. There are no published data on the educational needs of rheumatologists caring for patients with SSc. We aimed to determine rheumatologists' self-rated knowledge and learning needs.

**Methods:** Survey questions were adapted from the EULAR Recommendations for the Treatment of SSc with reference to patient-identified care gaps. The survey was conducted on paper and on SurveyMonkey (a cloud-based online survey development software program). The target audience was Ontario rheumatologists, serving a population of 13.6 million. We sought to explore self-reported knowledge, experience, attitudes and perceived barriers in caring for SSc patients. Physician demographics and preferred educational methods were also collected. Gaps between perceived and desired knowledge were calculated to identify the greatest unmet learning needs.

**Results:** One hundred and eighteen responses were received with a response rate of 54%. The greatest unmet learning needs were seen in the management of sexual dysfunction (average gap of 1.4 on a 5-point scale), pulmonary hypertension (1.1), interstitial lung disease (1.0) and gastrointestinal manifestations of the disease (1.0). The smallest learning gap concerned screening recommendations (0.7). 19% of rheumatologists agreed with the statement "Scleroderma is an untreatable disease." Agreement with this statement was highest (33%) among rheumatologists who treat relatively small numbers<sup>1-10</sup> of scleroderma patients.

**Conclusions:** We have identified several unmet learning needs regarding the management of SSc among rheumatologists. These can be used to inform future educational resources and programs for rheumatologists regarding SSc and to direct further research into their needs.

**AB0826** **PROFILE OF MYOSITIS-SPECIFIC ANTIBODIES IN PATIENTS WITH POLYMYOSITIS/DERMATOMYOSITIS AND ASSOCIATION WITH CLINICAL MANIFESTATIONS AND OUTCOME: EXPERIENCE FROM A TERTIARY REFERRAL CENTRE**

Z. Chen, X.-P. Li, X.-M. Li. *Rheumatology and Immunology, The First Affiliated Hospital of University of Science and Technology of China, Hefei, China*

**Background:** Myositis-specific antibodies (MSAs) have been found to be associated with distinct clinical phenotype and prognosis in patients with Idiopathic Inflammatory Myopathies.

**Objectives:** To assess the profile of MSAs in Chinese patients with polymyositis (PM)/dermatomyositis (DM) and explore association of antibody profile with clinical characteristics, laboratory findings and prognosis.

**Methods:** 90 patients with PM/DM were enrolled. 12 MSAs (mi-2 $\alpha$ , mi-2 $\beta$ , TIF1 $\gamma$ , MDA5, NXP2, SAE1, Jo-1, SRP, PL-7, PL-12, EJ, OJ) were measured by immunoblotting. Associations between antibody profile and clinical manifestations, laboratory data and outcome were determined.

**Results:** The study population comprised 20 patients with PM and 70 patients with DM, in which 17 DM patients were identified as clinically amyopathic dermatomyositis (CADM). Overall, the most common MSA was anti-ARS (Jo-1/PL-7/PL-12/OJ/EJ) (41.1%), followed by anti-MDA5 (33.3%), anti-SRP (15.6%), anti-NXP2/anti-SAE1 (13.3%), anti-TIF1 $\gamma$  (12.2%) and anti-mi-2 $\alpha$ /mi-2 $\beta$  (5.6%). Anti-MDA5 antibody was exclusively seen in DM and CADM patients and the prevalence was higher in CADM than in conventional DM (82.4% vs 30.2%,  $p < 0.001$ ). Compared with those who were anti-MDA5 negative, patients with positive anti-MDA5 had more rapidly progressive interstitial lung disease (ILD) and Gottron sign (93.3% vs 61.7%,  $p < 0.05$ ; 93.3% vs 38.3%,  $p < 0.001$ ) as well as lower creatine kinase concentrations (70.0 vs 992.5 IU/L,  $p < 0.001$ ). Anti-Jo-1 antibody was more prevalent in PM (55.0% vs 20.8%,  $p < 0.05$ ) and patients with positive anti-Jo-1 demonstrated higher prevalence of mechanic's hands (18.2% vs 1.5%,  $p < 0.05$ ). Anti-SRP positive patients had higher creatine kinase levels than those with negative, although there is no statistical significance (1649.5 vs 199.0 IU/L,  $p = 0.056$ ). Moreover, anti-TIF1 $\gamma$  antibody was associated with more frequent tumour (18.2% vs 0.0%,  $p < 0.01$ ). In logistic regression analysis, anti-MDA5 [OR=9.601, 95% CI (1.940, 47.515),  $p < 0.01$ ] was an independent risk factor for ILD. During the follow-up period (median 8 months), 13 patients died, among

which 9 were anti-MDA5 positive. The survival time of anti-MDA5 positive patients was significantly less than those who were negative (3.0 vs 11.0 months,  $p < 0.01$ ). **Conclusions:** Anti-ARS antibodies are the most common MSAs in Chinese PM/DM patients. Anti-MDA5 is predominantly seen in patients with CADM and closely associated with rapidly progressive ILD and high mortality thus serve as a marker of poor prognosis. Anti-TIF1 $\gamma$  positive patients routinely screened for tumours will be of clinical significance.

**Spondyloarthritis – treatment**

**AB0827** **HIP ARTHRITIS REMAIN FREE FROM RADIOGRAPHIC PROGRESSION FOR 24 MONTHS FOLLOWING TREATMENT OF ANKYLOSING SPONDYLOARTHRITIS WITH TNF-A INHIBITORS: A PROSPECTIVE STUDY**

A. Djebbari, S. Bouakkaz, S. Bennedjma, S. Oulebsir, M. Houbi, R. Boutefnouchet, A. Beguiret, S. Bounihi, F.Z. Najji, A. Abiayed. *Rheumatology, HCA Hospital, Algiers, Algeria, Algiers, Algeria*

**Background:** Hip involvement is the most frequent extra-spinal arthritic manifestation of ankylosing spondyloarthritis (AS). It can be severe and may worsen outcomes for patients. There is a large body of high quality evidence for clinical efficacy of TNF- $\alpha$  inhibitors at treating this condition. However, their structural hip benefit remains unknown.

**Objectives:** In this prospective study undertaken in Algeria, we aimed to evaluate clinical and structural efficacy of TNF- $\alpha$  inhibitor therapies on non-synostose hip involvement in AS, for a 24 months period.

**Methods:** This study pursued a follow-up of patients SA using modified New York criteria or ASSAS criteria. Patients were TNF- $\alpha$  inhibitors naïf diagnosed with SA, with hip involvement (identified using clinical and/or radiological findings). Patients were treated with one of the following: adalimumab, infliximab or etanercept. Exclusion criteria were: history of tuberculosis, serious infections, hepatitis, neoplasms, other inflammatory conditions, and hip involvement due to any other causes. The following data were collected: clinical rating of hip involvement using the Harris Hip scoring system, biological characteristics (CRP), and radiological characteristics of hip lesions using Bath Ankylosing Spondylitis Radiology Index of the hip (BASRI hip). Specific disease indexes such as BASDAI and BASFI were also collected. Follow up was undertaken at the following time periods in months: 0, 3, 6, 12 and 24. Statistical analysis of findings was performed using SPSS 11.0 software

**Results:** The study recruited a total of 30 patients, 22 males and 8 females. Mean age was (24, 1 $\pm$ 3, 1 years). Bilateral and unilateral hip involvements were identified in 67% and 33% of patients, respectively. Mean time for appearance of hip lesions was (3, 9 $\pm$ 2, 1 years). HLAB 27 was present in 30% of this study population. Baseline characteristics of hips examined have shown an altered function (Harris Hip mean score of 56, 1 $\pm$ 5, 1) and a relatively advanced structural score (BASRI hip mean score 2, 4 $\pm$ 1, 1). These scores correlated with high disease activity (BASDAI mean score 5, 5 $\pm$ 1, 2) and a poor mean BASFI score (5, 4 $\pm$ 2, 0). This was accompanied by a mean CRP score of 22, 1 $\pm$ 8, 1. Non-steroidal anti-inflammatory drugs were ineffective. During the 24 months treatment period using TNF- $\alpha$  inhibitors, there was a statistically significant improvement in hip scores from the third month onwards with mean Harris Hip scores of 70, 3 $\pm$ 21, 5 ( $p < 0,001$ ), and 81, 3 $\pm$ 11, 5 ( $p < 0,001$ ) at months 3 and 6, respectively. This was maintained until the end of the study period at 94, 2 $\pm$ 10, 5 ( $p < 0,001$ ). There have also been statistically significant improvements in BASDAI and BASFI scores as well as CRP (all  $p < 0,001$ ). Mean BASRI score, however, remained unchanged after 24 months. Treatment was well tolerated, and no significant complications (e.g. serious infections or tuberculosis) were observed. No prosthesis was indicated for any patient

**Conclusions:** Hip involvement is associated with severe and rapidly evolving AS. In this study, we have demonstrated improved outcomes and stability of radiographic lesions of hip arthritis for a period of 24 months, when SA was treated with TNF- $\alpha$  inhibitors.

**Objectives:** In this retrospective study we assess the 1 to 3 year probability of persistence on golimumab in patients with spondyloarthritis (SpA), axial SpA or psoriatic arthritis (PsA) who started treatment with golimumab as second biological (after withdrawal of a first anti TNF-alpha drug)

**Methods:** GO-BEYOND was a retrospective study undergone in 20 Spanish rheumatology clinics. Information was collected on all axial SpA and PsA patients who initiated golimumab between January 2013 and December 2015 as second anti TNF-alpha (i.e. after discontinuation of a first anti TNF-alpha drug). Centres in which all the patients could not be included were excluded from the analysis. The probability of persistence was calculated with a Kaplan-Meier test and comparisons were done with the log-rank test.

**Results:** 210 patients were included (131 with axial SpA and 79 with PsA, mean age 49 years [SD=12], 40% women, median duration of disease at the initiation of golimumab 80.5 months). Reasons for discontinuation of the first anti TNF-alpha were loss of efficacy (71.4%), poor tolerability or adverse event (11.0%) and patient or physician preference (17.6%). During a median follow-up of 29.3 months, 72 of 210 patients (34.3%) discontinued golimumab, due to primary failure (n=21), disease reactivation or secondary failure (n=29), poor tolerability (n=4), adverse events (n=10), inactive disease or patient-physician agreement (n=8). The probability of persistence on golimumab since treatment initiation was 80% at year 1 (95% CI 75–86), 70% at year 2<sup>64–77</sup> and 65% at year 3 [59–72]. The figures were similar in patients with axial SpA or PsA, and in patients who discontinued the first anti TNF-alpha due to loss of efficacy or to other reasons (p=0.121 and p=0.835, table 1).

Abstract AB0829 – Table 1

	All SpA patients			Baseline disease			Reason for discontinuation of the first anti TNF-alpha		
	n	Probability of persistence	p	Axial SpA patients	PsA patients	Probability of persistence	Loss of efficacy	Other	p
Baseline	210			131	79		150	60	
Year 1	166	80%		102	65	81%	119	49	81%
Year 2	132	70%	0.121	83	49	67%	94	38	71%
Year 3	82	65%		52	30	59%	60	22	66%
Year 4	43	65%		30	13	59%	30	13	66%

n=number at risk, SpA=Spondyloarthritis; PsA=Psoriatic arthritis  
**Conclusions:** After discontinuation of a first anti TNF-alpha, patients with spondyloarthritis showed a high probability of persistence on golimumab. The probability of persistence was similarly high in patients with axial SpA or PsA, and in

patients who discontinued the first anti TNF-alpha due to loss of efficacy vs other reasons. Real life effectiveness of golimumab as second anti TNF-alpha is high and durable in SpA patients.

**AB0830 MRI EVALUATION OF THE EFFECT OF ANKYLOSING SPONDYLITIS TREATMENT ON HIP JOINTINVOLVEMENT**

E. Agafonova<sup>1</sup>, T. Dubinina<sup>2</sup>, A. Dyomina<sup>2</sup>, O. Rumyantseva<sup>1</sup>, S. Erdes<sup>1</sup>.  
<sup>1</sup>Laboratory Spondyloarthritis; <sup>2</sup>Laboratory of Scientific Organizational Problems in Rheumatology, V.A.nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Coxitis is one of the leading causes of early disability in ankylosing spondylitis (AS) patients. There's no mild course of the disease as soon as hip joints (HJ) are involved, but epidemiological surveys in Russia show that only 7% of AS associated hip damage require total hip replacement.

**Objectives:** To evaluate case follow-up data in treated AS patients with hip involvement using hip MRI and radiography for dynamic assessment.

**Methods:** 30 AS patients (mean age of 27.7±17 y.) meeting modified 1984 N-Y criteria with MRI signs of HJ inflammation were followed up for 2 years. Patients' mean age at the onset of the disease was 22.3±18,3 years, 77% of the population were HLA-B27 positive. Median AS duration was 47 (12–144) months, and median BASDAI score was 5.9±3,1. The median duration of clinically manifest coxitis by the time of the study was 45 months. [25%<sup>c</sup>; 75%<sup>c</sup>], and pain intensity by numeric ranking scale (NRS) was 6 (2; 8). HJ MRI using T1 and STIR modes was performed in all participants in addition to clinical and radiological examinations. All patients were grouped into three arms based on therapeutic regimens: Group I was administered non-steroidal anti-inflammatory drugs (NSAIDs), Group II – genetically engineered biological agents (GEBAs) +NSAIDs, and Group III was treated with a combination of NSAIDs+DMARD (methotrexate or sulfasalazine). In case of baseline regimen failure patients from Group III were switched to NSAIDs+DMARD+ GEBAs combination at Mo 6 after initiation of treatment.

**Results:**

Abstract AB0830 – Table 1

Parameters	Group (I) n=5		Group (II) n=17		Group (III) n=8	
	Baseline	2 years FUP	Baseline	2 years FUP	Baseline	2 years FUP
AS duration, mo, Me [25% <sup>c</sup> , 75% <sup>c</sup> ]	27 [12;32]	51 [36;56]	32 [18;40]	56 [42;64]	38 [18;42]	62 [42;66]
BASDAI, Me [25% <sup>c</sup> , 75% <sup>c</sup> ]	2,5 [2,0;3,7]	2,4 [1,8;3,5]	5,6 [4,1;8,2]	1,8 [0,4;2,6]	4,1 [3,6;5,2]	3,2 [2,4;4,6]
BASFI, Me [25% <sup>c</sup> , 75% <sup>c</sup> ]	1,7 [0,8;3,2]	2,8 [1,8;4,2]	3,2 [2,6;4,7]	2,8 [1,8;3,6]	3,6 [2,2;5,0]	3,2 [1,9;4,8]
HLA-B27, n (%)	95%	95%	93%	93%	75%	75%
ASDAS (CRP) Me [25% <sup>c</sup> , 75% <sup>c</sup> ]	2,0 [1,8;3,0]	2,3 [1,9;3,4]	4,3 [3,8;5,6]	2,6 [1,3;3,7]	3,9 [2,6;4,2]	2,3 [1,8;3,6]
ESR, mm/h, Me [25% <sup>c</sup> , 75% <sup>c</sup> ]	10 [3;15]	12 [5;15]	30 [15;60]	10 [0,8;4,5]	18 [12;28]	12 [6;18]
CRP, mg/mL, Me [25% <sup>c</sup> , 75% <sup>c</sup> ]	7,0 [4,3;10,7]	6,8 [4,2;11,0]	36 [15;47]	10,8 [0,8;34]	15,8 [8,4;28,9]	6,9 [4,7;17,8]
NRS, Me [25% <sup>c</sup> , 75% <sup>c</sup> ]	4 [2;6]	4 [2;6]	6 [4;8]	5 [2;6]	4 [2;7]	2 [0;4]
MRI Synovitis n (%)	5 (100%)	5 (100%)	17 (100%)	4 (24%)	8 (100%)	1 (12,5%)
Osteitis n(%)	0	0	6 (35%)	2 (12%)	2 (25%)	0 (0%)
BASRI (0-I) n(%)	4 (80%)	1 (20%)	12 (70%)	9 (53%)	7 (88%)	7 (88%)
BASRI (II-IV)	1 (20%)	4 (80%)	5 (30%)	8 (47%)	1 (12%)	1 (12%)

- Conclusions:** 1. Long-standing MRI symptoms of HJ synovitis should be viewed as the factor predisposing to radiographic progression of coxitis in AS patients.
- 2. NSAIDs therapy does not modify the radiographic progression of coxitis.
- 3. GEBAs+NSAIDs in combination with DMARDs reduce the risk of further radiographic progression.
- 4. Future studies are warranted to better understand potential factors contributing to radiographic progression of coxitis.

**AB0831 THE INFLUENCE OF REMISIVE AND ANTI-INFLAMMATORY TREATMENT ON AXIAL MOBILITY IN PATIENTS WITH ANKYLOSING SPONDYLOARTRITIS**

E. Rusu, L. Chislari, R. Larisa, V. Cazac. *Rheumatology and Nephrology, SMPU "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

**Background:** In advanced ankylosing spondyloarthritis (AS), bone ankylosis or ossification of the involved joints can make the chest practically immobile, decrease its compliance, or even lead to intercostal muscle atrophy.

**Objectives:** The purpose of the study was to evaluate chest involvement in AS by measuring toracoabdominal movements during quiet breathing, by dividing the chest and abdominal contribution to the current volume, by inductive plethysmography methods.

**Methods:** 60 consecutive patients were recruited from the Rheumatology Department of the Republican Clinical Hospital. They were selected based on AS diagnosis, with no existing cardiovascular or neuromuscular diseases that would alter respiratory mechanisms and the absence of severe obesity.

**Results:** Monotherapy with DMARD was 27 out of 60 patients (45%) (Sulfasalazine 3 g/day) for a period of 1–48 months (mean value=19.4 (15.5) months). There were no differences in the angle of the Ct-Abd curve between patients with DMARD and DMARD-naive treatment (38.2 (14.5)° and 34.7 (19.5)° for sitting position, 49.3 (18.1)° and 47.2 (23.1)° in orthostatism, and 19.1 (15.6)° and 16.1 (14.6)° for clinostatism,  $p < 0.05$ ). In the baseline study, the Ct-Abd patient angle was lower than the control group in sitting position (36.3 (17.3)° and 51.5 (8.9)°,  $p = 0.0002$ ) in orthostatism (48.1 (20.8)° and 62.4 (12.5)°,  $p < 0.01$ ) or orthostatism (17.4 (15.0)° and 24.5 (9.8)°  $p < 0.05$ ). In the entire patient group, the Ct-Abd angle correlated negatively with BASFI in all three body positions ( $r = -0.50$ ,  $p < 0.0001$  in the sitting position,  $r = -0.36$ ,  $p < 0.01$  in orthostatism,  $r = -0.47$ ,  $p < 0.0001$  in clinostatism); did not correlate with BASDAI, BASMI, or the modified Schoeber test in either of the three body positions.

In 15 AS patients who underwent repeated measurements of toracoabdominal movements while receiving their associated DMARD treatment (Methotrexate 15 mg/week and Sulfasalazine 3 g/day) 3 months after treatment, the angle of the Ct-Abd slope was significantly higher than that of the fundamental study, in all bodily positions.

The Ct-Abd angle continued to increase, with increments less pronounced and reached significant value only between measurements of 3 months and 12 months. Improvements in standardised clinical signs following associated DMARD treatment followed a similar pattern, with scores at each interval significantly different from those measured in the baseline study, improvements continuing at a faster pace slowly after the third month.

In the control group, the angle of the slope of the Ct-Abd curve was not different in the two measurements in any of the body positions (51.4 (8.9)° and 50.7 (9.3)° in the sitting position, 62.4 (12.4)° and 61.6 (11.8)° in orthostatism, and 24.6 (9.8)° and 24.8 (10.4)° in clinostatism,  $p < 0.05$ ). In orthostatism, the difference between the measurements was 0.8° (confidence interval 95%–0.9 to 2.52, upper and lower boundaries of 6.6° and 8.2°).

**Conclusions:** The slope of the Ct – Abd curve during quiet breathing correlates negatively with BASFI and responds significantly to associated DMARD treatment and NSAIDs. Our data suggest that this measure can be targeted for further evaluation of its usefulness in monitoring chest involvement and its response to treatment in AS patients.

**AB0832 THE EFFECTS OF ANTI-TNF BIOLOGICAL AGENTS IN PATIENTS WITH SPONDYLOARTRITIS: A COMPARATIVE STUDY**

E. Essafi, O. Saidane, I. Mahmoud, A. Ben Tekaya, R. Tekaya, L. Abdelmoula. *rheumatology, Charles Nicolle Hospital, Tunis, Tunisia*

**Objectives:** The aim of the present study was to compare the efficacy of three anti-TNF agents (adalimumab, infliximab and etanercept) in patients with spondyloarthritis (SpA) at 24 weeks.

**Methods:** We achieved a retrospective descriptive and comparative monocentric study, on 49 patients, with SpA including ankylosing spondylitis (AS), psoriatic arthritis (PsA), enteropathic arthritis (EA), reactive arthritis (ReA) and undifferentiated spondyloarthritis (uSpA) (according to Amor criteria, <sup>ASAS 2009</sup> and CASPAR criteria), during 12 years (2004–2015). The patients were treated with at least one anti-TNF, during at least 6 months. Disease activity was assessed by the BASDAI, ASDAS, ESR and CRP. To compare mean differences between time points (week 0 versus week 24), a Wilcoxon test was applied. To compare efficacy between the 3 anti-TNF, a Mann-Whitney test was applied.

**Results:** Twenty three patients (47%) had AS, 13 patients (27%) had PsA and 11 patients (22%) had EA. One patient had an uSpA, and 1 patient had a ReA. The mean age was 42,81 years±11,77. The median age at disease onset was 29,41

years±11,29. The mean disease duration was 10,16 years. Nineteen patients received etanercept (ETN), 18 infliximab (IFX) and 12 adalimumab (ADA). At six Months, the 3 anti-TNF showed improvement in the disease activity scores: BASDAI ( $p < 0,0001$ ), ASDAS CRP ( $p < 0,0001$ ), ESR ( $p < 0,0001$ ) and CRP ( $p < 0,0001$ ). Sixty two percent of the patients have reached BASDAI 50 response at 6 months.

**Abstract AB0832 – Table 1.** Summary of median change from baseline to week 24 in clinical outcomes

	Week 0	Week 24	p
BASDAI	6,04±2,28	2,5±2,32	<0,0001
ASDAS	4,27±1,13	2,17±1,3	<0,0001
CRP			
CRP (mg/l)	44,68	14,03	<0,0001
	±33,45	±10,09	
ESR (mm)	62,24	25,65	<0,0001
	±39,16	±24,97	

BASDAI: Bath Ankylosing Spondylitis Disease Activity Index, ASDAS: Ankylosing Spondylitis Disease Activity Score, C-Reactive protein, ESR: Erythrocyte Sedimentation Rate

At week 24, patients on ETN achieved more frequently a significant reduction of BASDAI (–5,13 vs –2,53;  $p = 0,004$ ), ESR (–52,69 vs –16,64;  $p = 0,006$ ) and CRP (–36,7 vs –21,34;  $p = 0,009$ ) than IFX. The efficacy comparison between ETN and ADA showed ETN superiority concerning BASDAI (–5,13 vs –2,04;  $p = 0,004$ ) and ASDAS CRP (–3,03 vs –1,4;  $p = 0,006$ ). The comparison ADA vs IFX had shown no significant efficacy differences.

**Conclusions:** Our results showed a BASDAI 50 response in 62% of patients. The comparison between the three biologics was consistent with a better efficacy of the ETN.

**Disclosure of Interest:** None declared

**AB0833 REAL-WORLD EFFICACY AND SAFETY OF SECUKINUMAB: DATA FROM VERONA'S COHORT**

F. Martinis, C. Caimmi, A. Carletto, E. Fracassi, M. Rossini. *Rheumatology, AOUI Verona, Verona, Italy*

**Background:** Secukinumab has been approved for the treatment of active ankylosing spondylitis (AS) and psoriatic arthritis (PsA). Its efficacy has been demonstrated in phase III trials where eligibility criteria ensured a homogeneous population. Although this strategy reduces confounding factors, it does not guarantee the same results in the real world, where clinicians deal with advanced disease, comorbidities, adherence and persistence challenges.

**Objectives:** Aim of this study was to assess efficacy and safety of Secukinumab in real-world clinical practice.

**Methods:** Patients received Secukinumab (150 or 300 mg) at weeks 0,1,2,3 and 4 as induction therapy and then every 4 weeks as maintenance therapy. Assessment of disease activity was done at months 0,6 and 12 using DAPSA, ASDAS, BASDAI, BASFI, pain VAS.

**Results:** 61 patients affected by PsA (65% females, 35% males) and 29 affected by AS (70% males, 30% females) were included. 64% of patients reached 12 months follow up. Baseline characteristics of both groups are shown in the tables below.

In the PsA cohort, the median DAPSA at baseline was 19.5 (IQR 9.6), at 6 months 9.09 (IQR 6.5,  $p < 0.001$ ), at 12 months 8.53 (IQR 6.9,  $p < 0.001$ ). Median pain VAS showed a downward trend as well, from 6 at baseline (2 IQR) to 4.5 at 6 months (2 IQR) and 4 at 12 months (IQR 1.4). No differences emerged among PsA patterns. Clinical trials did not assess efficacy of Secukinumab in patients previously treated with biologic agents other than anti-TNF agents, due to exclusion criteria. We performed subgroup analysis to evaluate its efficacy in patients previously treated with Ustekinumab, finding a reduction in median DAPSA from 19.4 (IQR 9.8,  $p < 0.001$ ) at baseline to 8.7 (IQR 8.3,  $p < 0.001$ ) at 1 year.

In the AS cohort, the median BASDAI at baseline was 5.5 (IQR 2.2), at 6 months 3.6 (IQR 1.2,  $p < 0.001$ ), at 12 months 3.1 (IQR 1,  $p < 0.001$ ). Median BASFI decreased from 4.8 (IQR 2.7) to 3.8 (IQR 2.4,  $p < 0.001$ ) and 3 (IQR 2.4,  $p < 0.001$ ) at 6 and 12 months respectively. ASDAS recuded from 3.02 (IQR 1.65), to 1.21 (IQR 1.92,  $p < 0.001$ ) at 6 months and to 1.05 (IQR 0.7,  $p < 0.001$ ) at 1 years follow up. Median pain VAS dropped off from 7 at baseline (IQR 2) to 4 (IQR,  $p < 0.001$ ) at 6 months and 3 (IQR,  $p < 0.001$ ) at 12 months. Of note, patients with advanced disease (ankylosis of the spine) reported a decrease in pain and morning stiffness, thus improving their quality of life.

4 patients switched therapy at 6 months due to partial response, 1 patient experienced an expected adverse event (Candida infection). Overall, no serious side effects were observed and none resulted in Secukinumab discontinuation.

Abstract AB0833 – Table 1

Psoriatic Arthritis Cohort		Ankylosing Spondylitis Cohort	
Mean age (years)	54.3 ± 8.5	Mean age (years)	47 ± 13.4
Disease duration (years)	9.7 ± 7.9	Disease duration (years)	12 ± 9.5
Symmetrical polyarthritis	32 (52.4%)	Presence of syndesmophytes	2 (6.9%)
Asymmetric oligoarthritis	12 (19.7%)	hDMARDs Naive	17 (58.6%)
Spondyloarthritis	12 (19.7%)	Previous anti-TNF therapy	12 (41.4%)
Digital arthritis	4 (6.5%)		
Arthritis mutilans	1 (1%)		
hDMARDs Naive	15 (24.6%)		
Previous anti-TNF therapy	43 (70.5%)		
Previous anti-IL1/2/3 therapy	12 (19.7%)		

**Conclusions:** In this first real-world cohorts of patients with PsA and AS Secukinumab has proven to be effective, regardless of PsA subtype, radiographic progression in AS and previous exposure to biologic therapy. The safety profile was favourable and similar to previous studies.

**AB0834 BETTER IMPROVEMENT OF ASDAS WERE ACHIEVED IN 841 AS PATIENTS AMONG 6 MONTHS OF ANTI-TNF USERS COMPARED TO NON-ANTI-TNF USERS: RESULTS FROM A REAL WORLD PROSPECTIVE COHORT MANAGED BY SMART PHONE SYSTEM**

X. Ji, J. Zhu, J. Zhang, F. Huang, on behalf of SMSP co-authors. *Rheumatology, Chinese PLA General Hospital, Beijing, China*

**Background:** Ankylosing spondylitis (AS) is a chronic and progressive condition of the spine, which is the most common form of spondyloarthritis (SpA). Although anti-TNF agents are the most effective therapy for AS or SpA, it is recommended as the second-line treatment for individuals who have persistently high disease activity despite treatment with at least 2 non-steroidal anti-inflammatory drugs (NSAIDs), intolerance or contraindication to NSAIDs. Changes in ankylosing spondylitis disease activity score (ASDAS) are often measured to reflect outcomes in AS trials. However, anti-TNF does not always maintain long-term remission. There is limited evidence about remission rate of 6 months treatment from real-world AS cohorts.

**Objectives:** The purpose of this study is to compare the remission rate of AS patients among biologics users or non-biologics users from China Ankylosing Spondylitis/Spondyloarthritis Prospective Imaging Cohort (CASPIC).

**Methods:** CASPIC is an ongoing prospective cohort established by a smart management system [Smart Management System for Spondyloarthritis (SMSP)]. Clinic visits were scheduled based on visits reminder set by rheumatologists (1~6 months). Anti-TNF users were defined as patients who used biological agents during the follow-up period and the baseline was defined as the start time to use the biological agents. Non-biologics users were served as control groups. ASDAS was calculated to assess disease activity in AS. Generalise additive mixed model and curve fitting were used to show the difference between two groups.

**Results:** There were 841 AS patients in this cohort, 83.4% were male, with mean (±SD) age 30.8 (±8.8) years, mean time since diagnosis 8.3 (±6.1) years (table 1). Mean duration of anti-TNF treatment was 4.1 (±3.5) months. Significant improvements were observed in ASDAS (table 2). Anti-TNF users had more serious disease activity, and better clinical improvement (figure 1). If the duration of anti-TNF treatment was less than 6 months, relapsed rates were higher than those with longer than 6 months of anti-TNF (figure 1).

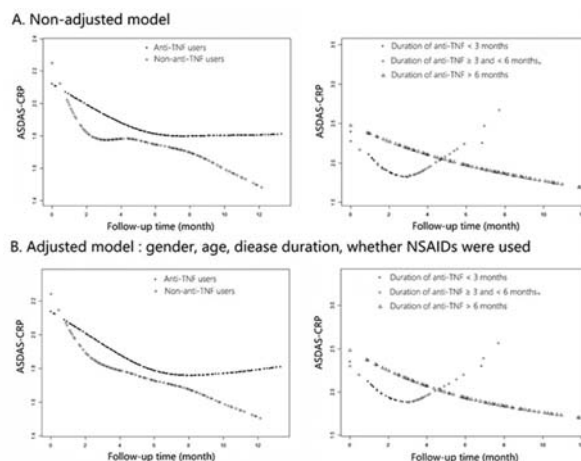

Abstract AB0834 – Table 1. Baseline characteristics

mean(SD)/N(%)	Anti-TNF users (n=633)	Non-anti-TNF users (n=208)	P
Age	31.2 (9.0)	29.7 (8.1)	0.040
Disease duration	8.3 (6.2)	8.4 (5.7)	0.869
ASDAS-CRP	2.1 (1.0)	2.6 (1.1)	<0.001
Male	535 (84.5%)	166 (79.8%)	0.114
HLA-B27 positivity	495 (87.3%)	176 (89.3%)	0.451
With NSAIDs	526 (99.1%)	162 (98.2%)	0.356

Abstract AB0834 – Table 2. Change in ASDAS per month

	Anti-TNF users	Non-anti-TNF users	P
Non-adjusted	-0.027 (-0.043,-0.011)	-0.065 (-0.094,-0.036)	<0.01
Adjusted	-0.032 (-0.048,-0.015)	-0.063 (-0.092,-0.033)	<0.01

Adjusted model: gender, age, disease duration, whether NSAIDs were used

Abstract AB0834 – Figure 1. Curve Fitting of Change in ASDAS

**Conclusions:** Anti-TNF therapy had superior improvement than NSAIDs therapy. Anti-TNF should be used for more than 6 months to achieve better and sustained remission and prevent recurrence.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3186

**AB0835 COMPARISON OF LONG TERM ANTI-TNF SURVIVAL IN PATIENTS WITH ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS; DATA FROM TURKBIO REGISTRY**

G. Can<sup>1</sup>, E. Dalkilic<sup>2</sup>, Y. Pehlivan<sup>2</sup>, S. Senel<sup>3</sup>, S. Akar<sup>4</sup>, D. Solmaz<sup>4</sup>, S.S. Koca<sup>5</sup>, N. Inanc<sup>6</sup>, P. Atagunduz<sup>6</sup>, A. Yazici<sup>7</sup>, A. Cefle<sup>7</sup>, B. Goker<sup>8</sup>, B. Zengin<sup>1</sup>, S. Uslu<sup>1</sup>, N. Akkoc<sup>9</sup>, F. Onen<sup>1</sup>. <sup>1</sup>Rheumatology, Dokuz Eylul University, Izmir; <sup>2</sup>Rheumatology, Uludag University, Bursa; <sup>3</sup>Rheumatology, Erciyes University, Kayseri; <sup>4</sup>Rheumatology, Katip Celebi University, Izmir; <sup>5</sup>Rheumatology, Firat University, Elazig; <sup>6</sup>Rheumatology, Marmara University, Istanbul; <sup>7</sup>Rheumatology, Kocaeli University, Kocaeli; <sup>8</sup>Rheumatology, Gazi University, Ankara; <sup>9</sup>Rheumatology, Private Doctor, Izmir, Turkey

**Background:** Limited data are available on anti-TNF survival in non-radiographic axial spondyloarthritis (nr-axSpA) patients and their long-term survival in ankylosing spondylitis (AS).

**Objectives:** The aim of the study was to evaluate long term survival of the first anti-TNF drug treatment among patients with AS and nr-axSpA enrolled in the TURKBIO database and to compare the discontinuation rates for infliximab (INF), etanercept (ETN), and adalimumab (ADA) in each of the two groups.

**Methods:** All AS and nr-axSpA patients receiving biological therapies registered in the TURKBIO database between the dates of October 2011 and April 2017 were included in the study. AS diagnosis was made according to modified New York classification criteria and nr-axSpA according to ASAS AxSpA classification criteria. Demographic and clinical data, the date of starting to use biological drug, using frequency and dose of biological drugs, BASFI, BASDAI, BASMI, ASDAS scores, date and reason for discontinuing to use drug were collected. Baseline characteristics and drug survival rates were compared between AS and nr-axSpA patients. Drug survival was calculated by the Kaplan-Meier method and risk for discontinuation among treatment groups compared by Long Rank test.

**Results:** A total of 924 patients were included in the study (AS, n=871 and nr-axSpA, n=53). More than half of the patients with AS were male (60.7% in AS vs 34.0% in nr-axSpA group, p<0.001). AS patients had longer symptom duration (104.90±79.06 vs 75.11±45.29 months, p<0.036) compared to nr-axSpA. Median levels of CRP and ESR were similar for nr-axSpA (CRP: 27.03±34.71, ESR: 30.50±25.77) and AS (CRP: 22.32±29.95, ESR: 35.40±22.91). The scores of

BASFI, BASMI and ASDAS were found to be similar in both groups. Median BASDAI scores at first TNFi initiation were higher in patients with nr-axSpA than in patients with AS ( $58.65 \pm 18.21$ ,  $51.06 \pm 18.91$ ,  $p=0.030$ ). Cumulative drug survival rates did not show significant difference among INF (at 59. months:18,5%), ADA (at 71. months: 39,5%) and ETN (at 51. months: 24,2%) in nr-axSpA group ( $p=0,699$ ) (figure 1). Similarly, drug survival rates at 78, 77, 78. months for 3 anti-TNF drugs had shown no difference in AS patients (INF (at 78. months: 38,1%), ADA (at 77. months: 52,4%), ETN (at 78. months: 39,0%)) ( $p=0,151$ ) (Figure 2). Cumulative survival rates in AS patients (at 78. months:42,2%) were found to be significantly higher than that (at 71. months:28,2%) in nr-axSpA patients ( $p<0,001$ ) (Figure 3).

**Abstract AB0835 – Figure 1.** Drug survival rates anti-TNF in nr-axSpA. **Abstract AB0835 – Figure 2.** Drug survival rate by anti-TNF in AS. **Abstract AB0835 – Figure 3.** Overall drug survival on first anti-TNF in nr-axSpA and AS patients.

**Conclusions:** In contrast to the literature that revealed similar short term survival rates for anti-TNF drugs in patients with AS and nr-axSpA, we found higher survival rates in patients with AS compared to patients with nr-axSpA in this long-term observational study. A limitation of the study may be the low number of nr-axSpA patients using anti-TNF, related to the requirements of social insurance system.

**Disclosure of Interest:** None declared

AB0836

#### DRUG RETENTION RATE OF THE FIRST TNF INHIBITOR IN RADIOGRAPHIC AND NON RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS: DATA FROM A MULTICENTER STUDY

G. Lopalco<sup>1</sup>, V. Venerio<sup>1</sup>, L. Cantarini<sup>2</sup>, G. Emmi<sup>3</sup>, F. Salaffi<sup>4</sup>, S. Tafuri<sup>1</sup>, F. P. Bianchi<sup>1</sup>, M. Di Carlo<sup>4</sup>, S. Gentileschi<sup>2</sup>, G. Di Scala<sup>3</sup>, M. Nivuroi<sup>1</sup>, S. Perniola<sup>1</sup>, M. Fornaro<sup>1</sup>, M.G. Anelli<sup>1</sup>, F. Cacciapaglia<sup>1</sup>, C. Scioscia<sup>1</sup>, C. Fabiani<sup>5</sup>, M. Galeazzi<sup>2</sup>, G. Lapadula<sup>1</sup>, F. Iannone<sup>1</sup>. <sup>1</sup>University of Bari, Bari; <sup>2</sup>University of Siena, Siena; <sup>3</sup>University of Florence, Firenze; <sup>4</sup>Università Politecnica delle Marche, Jesi; <sup>5</sup>Humanitas Clinical and Research Center, Rozzano, Italy

**Background:** Good survival rates of TNF inhibitors (TNFi) have been shown in patients affected with axial Spondyloarthritis (axSpA) treated in a real-life setting, irrespective of administered anti-TNF agent.<sup>1</sup> Although the use of these drugs in patients with non radiographic axSpA (nr-axSpA) remains topic of debate,<sup>2</sup> several RCTs support their employment in these patients.<sup>3</sup>

**Objectives:** To assess the retention rate of the first TNF inhibitor between axSpA and nr-axSpA patients. Additional aims: i) to evaluate any difference in persistence rates between anti-TNF monoclonal antibodies and etanercept (ETN) ii) to assess any impact of clinical, therapeutic and demographic features as well as radiographic findings on drug survival.

**Methods:** We retrospectively assessed 221 patients with axSpA, all fulfilling the ASAS criteria, who underwent first line therapy with TNFi from January 1st 2012 to September 30th 2016. Clinical, therapeutic and demographic features as well as radiographic findings were recorded at baseline and at the moment of therapy discontinuation. 126/221 patients (57.01%) were treated with Adalimumab, 45/221 with ETN, 22/221 with Infliximab, 20/221 (9.05%) with Golimumab, whereas 8/221 (3.62%) with Certolizumab Pegol. Drug retention rates were analysed using Kaplan-Meier curves; log-rank test was performed to demonstrate differences in the survival function. Cox regression models were used to estimate the inference of several clinical and disease characteristics on drug discontinuation. Goodness of fit of the final model was assessed comparing Cox-Snell residuals to Nelson-Aalen cumulative hazard function.

**Results:** Drug survival in first line therapy was significantly lower in patients who had nr-axSpA than in those with radiographic sacroiliitis ( $p=0.005$ , figure 1) whereas survival rate did not differ significantly between patients treated with ETN and anti-TNF $\alpha$  monoclonal antibodies ( $p=0.057$ ). Multivariate Cox model shown that nr-axSpA (HR 1.90), higher BMI (HR 1.18), higher HAQ, (HR 1.82) and higher

BASDAI (HR 1.25), were predictors of drug discontinuation, Nelson-Aalen hazard function following very closely Cox-Snell residuals for drug persistence in first line therapy showed that the final model fitted well the data, except for large values of time (figure 2).

**Abstract AB0836 – Figure 1.** Kaplan-Meier curves. **Abstract AB0836 – Figure 2.** Cox-Snell residuals vs Nelson-Aalen cumulative Hazard function

**Conclusions:** Effectiveness of TNFi, estimated by drug survival, seems to be lower in patients with nr-AxSpA than those affected with axSpA. The reason of these findings remain to be elucidated. However, a possible explanation may be found in the limit of the classification criteria for nr-axSpA. In addition overweight and high disease activity negatively impact the persistence on first line anti-TNF $\alpha$  treatment in axSpA patients in real life setting.

AB0837

#### THE EFFECT OF ANTI-TNF ON RENAL FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A PROSPECTIVE COHORT STUDY

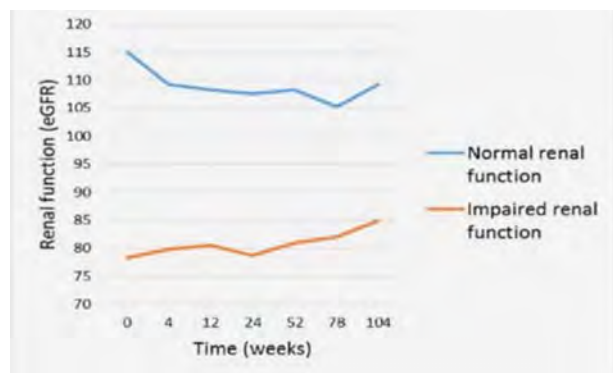

I.A. Swart, M. Heslinga, I.M. Visman, I.E. van der Horst-Bruinsma, C. van Denderen, M.T. Nurmohamed. *AMSTERDAM RHEUMATOLOGY AND IMMUNOLOGY CENTER | READE, Amsterdam, Netherlands*

**Background:** Impaired renal function is common in patients with ankylosing spondylitis (AS) and patients also have an increased risk of cardiovascular disease (CVD). Previous studies showed that biologicals, such as anti-Tumour Necrosis Factor (anti-TNF) reduce CVD in patients with inflammatory rheumatic disease. Impaired renal function is a known predictor of CVD (also elevated in AS). We postulated that the favourable cardiovascular effect of anti-TNF might be mediated by improving renal function. However, data about the effect of biologicals on renal function in patients with AS are lacking.

**Objectives:** To assess the effect of anti-TNF on renal function in patients with AS.

**Methods:** Biological-naïve consecutive AS patients treated with etanercept or adalimumab were prospectively followed from 2005 to 2014. Renal function was determined by calculation of the estimated Glomerular Filtration Rate (eGFR), which was estimated with the abbreviated Modification of Diet in Renal Disease (MDRD) formula. Patients were divided into two groups: patients with normal renal function at baseline and patients with impaired renal function at baseline, to investigate whether the effect is different for these groups. Normal renal function was defined by  $eGFR \geq 90$  mL/min/1.73 m<sup>2</sup> at baseline and impaired renal function was defined by  $eGFR < 90$  mL/min/1.73 m<sup>2</sup> at baseline. The effect of anti-TNF on eGFR was analysed using mixed model analysis.

**Results:** 211 AS patients were followed for a median of 156 (36 – 286) weeks. 153 patients had normal renal function and 58 had impaired renal function at baseline. In patients with normal renal function at baseline eGFR decreased significantly over time ( $\beta = -0.041$ ,  $p=0.001$ ), although this association did not remain significant after adjustment for disease activity ( $\beta = -0.015$ ,  $p=0.212$ ). Patients with impaired renal function at baseline did not have a significant change in eGFR over time ( $\beta = 0.022$ ,  $p=0.087$ ) and this association remained not significant after adjustment for alcohol consumption, BMI, disease duration and disease activity ( $\beta = 0.008$ ,  $p=0.593$ ). The change in eGFR on average over time after starting anti-TNF in AS patients with normal and impaired kidney function are presented in figure 1.

Abstract AB0837 – Figure 1

**Conclusions:** This study demonstrates that anti-TNF is not associated with renal function in AS patients, which means that use of anti-TNF is safe concerning renal function in patients with AS. From our results it seems that the effect of anti-TNF on CVD in AS patients is not mediated by an effect on renal function.

#### AB0838 THE EFFICACY OF ADALIMUMAB AND SULFASALAZINE IN ALLEVIATING AXIAL AND AORTIC INFLAMMATION DETECTED IN PET/CT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

J.-P. Kaijasilta<sup>1</sup>, A. Kerola<sup>1</sup>, R. Tuompo<sup>2</sup>, M. Kauppi<sup>3</sup>, H. Relas<sup>2</sup>, A. Loimaala<sup>4</sup>, H. Koivu<sup>5</sup>, J. Schildt<sup>4</sup>, T. Kerola<sup>1</sup>, K. Eklund<sup>2</sup>, T. Nieminen<sup>6</sup>. <sup>1</sup>Internal Medicine, Päijät-Häme Central Hospital, Lahti; <sup>2</sup>Inflammation Center, Helsinki University Hospital, Helsinki; <sup>3</sup>Rheumatology, University of Tampere School of Medicine, Tampere; <sup>4</sup>Medical Imaging Center, Helsinki University Hospital, Helsinki; <sup>5</sup>Department of Nuclear Medicine, Päijät-Häme Central Hospital, Lahti; <sup>6</sup>Heart and Lung Center, Helsinki University Hospital, Helsinki, Finland

**Background:** Inflammatory pathways are likely the central link from axial spondyloarthritis to the known increased risk of cardiovascular morbidity. Literature on positron emission tomography imaging together with computed tomography (PET/CT) in the context of spondyloarthritis is limited.

**Objectives:** The aim was to grade the inflammatory signals in the sacroiliac joints and aorta in the PET/CT imaging before and after antirheumatic treatment of clinically active axial spondyloarthritis with either sulfasalazine (SSZ), the firstline antirheumatic drug in Finland for axial spondyloarthritis, or adalimumab (ADA).

**Methods:** Fourteen patients aged 18–75 years with axial spondyloarthritis and radiologic sacroiliitis as detected either by MRI or X-ray and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and visual analogue scale (VAS)  $\geq 4$  have been recruited to the pilot study. DMARD-naïve patients started SSZ for 12 weeks. Those who failed to reach remission (BASDAI and VAS  $\geq 4$ ) with SSZ or were known to be resistant to conventional DMARDs before inclusion, adalimumab was started for 16 weeks. The patients were scanned with 18F-fluorodeoxyglucose (FDG) PET/CT after inclusion and after treatment with SSZ and/or ADA. Target-to-background ratio (TBR) was assessed from the aortic root to abdominal aorta as well as for the sacroiliac joints. For statistical comparisons before and after antirheumatic treatment, paired t-test was used. Mean  $\pm$ SD are shown.

**Results:** Our pilot study comprised of nine patients with ADA and five with SSZ. In the SSZ patients (three men, age 36.0 $\pm$ 13.4 years), mean BASDAI was 4.7  $\pm$ 1.6 before and 3.4 $\pm$ 1.8 after the treatment ( $p=0.091$ ). In the ADA patients (six men, age 35.1 $\pm$ 9.8 years), BASDAI decreased from 4.9 $\pm$ 1.2 to 2.3 $\pm$ 1.8 ( $p=0.004$ ). Among the SSZ patients, maximal TBR in sacroiliac joints declined from 2.35 $\pm$ 0.55 to 1.51 $\pm$ 0.22 (-35.8%,  $p=0.03$ ) (figure 1). Aortic maximal TBR declined from 2.44 $\pm$ 0.46 to 2.07 $\pm$ 0.43 (-15.0%,  $p=0.23$ ). In the ADA patients, maximal TBR in sacroiliac joints was 1.89 $\pm$ 0.37 before and 1.90 $\pm$ 0.51 after treatment (+0.3%,  $p=0.97$ ), and in aorta 2.15 $\pm$ 0.54 before and 2.37 $\pm$ 0.53 after treatment (+10.4%,  $p=0.19$ ).

Abstract AB0838 – Figure 1. Maximal TBR in PET/CT in sacroiliac joints and aorta are shown before and after treatment with either sulfasalazine (five patients) or adalimumab (nine patients). Each colour depicts one unique patient.

**Conclusions:** As detected by reduced 18F-FDG uptake, SSZ reduced inflammation in sacroiliac joints. There was also clear trend towards reduction of inflammation in aorta. ADA and SSZ both reduced clinical symptoms, but only ADA reached statistical significance. PET/CT could not show any reduction in FDG uptake in the ADA group. This may be due to the fact that ADA was used as the second line treatment, when the inflammation had already been reduced to the limit detectable by the method.

#### AB0839 RADIOLOGIC PARAMETERS OF ANKYLOSING SPONDYLITIS PATIENTS TREATED WITH ANTI-TNF- $\alpha$ VERSUS NON-STEROIDAL ANTI-INFLAMMATORY DRUGS AND SULFASALAZINE

S.M. Son<sup>1</sup>, J.S. Lee<sup>2</sup>, T.S. Goh<sup>2</sup>, W. Park<sup>2</sup>. <sup>1</sup>Orthopaedics, Pusan National University Yangsan Hospital, Yangsan; <sup>2</sup>Orthopaedics, Pusan National University Hospital, Busan, Korea, Republic of Ireland

**Background:** The introduction of anti-tumour necrosis factor- $\alpha$  (anti-TNF- $\alpha$ ) has significantly altered the treatment landscape of inflammatory arthritis. It has proven to be an excellent treatment option for reducing Ankylosing spondylitis(AS) symptoms. The impact of anti-TNF- $\alpha$  on the radiographic progression of AS has been difficult to characterise, in part because of the relatively slow rate of radiographic change in AS and the hurdles it imposes on longer-term placebo-controlled trials. Despite symptomatic improvement, conclusions concerning effect of anti-TNF- $\alpha$  treatment on radiographic progression in patients with AS remain inconsistent. Furthermore, while many studies have reported the impact of anti-TNF- $\alpha$  on radiographic progression, limited data are available on the relationship between treatment agents and sagittal balance in AS.

**Objectives:** Limited data are available on the relationship between treatment agents and sagittal balance in AS. We investigated radiological features related to treatment agents and compared sagittal balance between patients treated with anti-tumour necrosis factor- $\alpha$  (anti-TNF- $\alpha$ ) or non-steroidal anti-inflammatory drugs (NSAIDs) and sulfasalazine.

**Methods:** We prospectively enrolled 133 consecutive AS patients. Patients were eligible for the trial if they were under medical treatment with the same treatment agents for at least 1 year. All patients were treated initially with NSAIDs and

sulfasalazine. Sixty-nine patients were achieved an excellent pain control outcome with these agents (Group A). Sixty-four patients who complained of intractable low back pain were switched to anti-TNF- $\alpha$  treatment (Group B). Twelve radiographic parameters were measured. Clinical outcome was assessed with the Bath AS Disease Activity Index (BASDAI), erythrocyte sedimentation rate (ESR), and C-reactive protein (CRP). All parameters were measured at enrolment, upon changing treatment agents, and every 6 months during follow-up.

**Results:** Mean ESR, CRP, BASDAI, and thoracic kyphosis at baseline were significantly higher in group B. After treatment, group B had significantly higher lumbar lordosis and significantly better clinical outcomes. Correlation analysis revealed significant relationships between radiologic parameters and BASDAI. On multiple regression analysis, lumbar lordosis was a significant predictor of BASDAI.

Abstract AB0839 – Figure 1

**Conclusions:** This study demonstrated a clear association between treatment agents and radiologic parameters in AS. Anti-TNF- $\alpha$  treatment improved lumbar lordosis and slowed thoracic kyphotic progression with improvement of clinical outcomes. Lumbar lordosis was a significant predictor of clinical outcome in AS patients treated with anti-TNF- $\alpha$ .

AB0840

**DETERMINATION OF SERUM LEVELS OF AND ANTI-DRUG ANTIBODY PRODUCTION AGAINST TNF INHIBITORS IN ANKYLOSING SPONDYLITIS: TESTING MAY BE USEFUL FOR THE ASSESSMENT OF COMPLIANCE BUT NOT THAT OF TREATMENT EFFECTIVENESS**

K. Gulyás, A. Medelle, N. Bodnár, Z. Szekanez, S. Szántó. *Department of Rheumatology, University of Debrecen, Faculty of Medicine, Debrecen, Hungary*

**Background:** Targeted therapies, such as TNF-alpha inhibitors revolutionised the treatment of spondyloarthritis including ankylosing spondylitis (AS).

**Objectives:** To determine the correlation between serum TNF-alpha inhibitor levels of patients receiving biological therapy and concentration of anti-drug antibodies, disease activity (treatment effectiveness), age of patients and elapsed time since the onset of the diagnosis and from the initiation of the therapy.

**Methods:** Serum levels of TNF-alpha inhibitors (mg/ml) and concentration of anti-drug antibodies (AU/ml) were measured in 37 AS patients. Altogether 12 patients were treated with infliximab (IFX), 15 received adalimumab (ADA) and 10 received etanercept (ETN). Demographic data and parameters measuring disease activity (BASDAI) were also included in the analysis.

**Results:** A strong negative correlation was found between the concentration of anti-drug antibodies and drug serum levels (IFX:  $R^2=0.833$ ; ADA:  $R^2=0.426$ ; ETN:  $R^2=0.587$ ). On the other hand, similar correlation could not be demonstrated between serum concentrations of IFX, ADA or ETN and other factors, such as age of the patient (IFX:  $R^2=0.050$ ; ADA:  $R^2=0.090$ ; ETN:  $R^2=0.016$ ), BASDAI (IFX:  $R^2=0.099$ ; ADA:  $R^2=0.071$ ; ETN:  $R^2=0.015$ ), disease duration (IFX:  $R^2=0.024$ ; ADA:  $R^2 < 0.001$ ; ETN:  $R^2=0.182$ ) and time since the initiation of therapy (IFX:  $R^2=0.008$ ; ADA:  $R^2=0.052$ ; ETN:  $R^2=0.062$ ).

**Conclusions:** As anti-TNF-alpha antibodies decrease the serum concentration of TNF inhibitors. In our study, drug serum levels and anti-drug antibody concentrations significantly correlated with each other. However, similarly to some other reports, drug levels did not correlate with treatment efficacy. Therefore, routine assessment of serum drug and anti-drug antibody levels should not be recommended in the everyday practice in order to determine treatment effectiveness. However, the parallel evaluation of drug and anti-drug antibody levels may be effectively used in order to determine patient compliance in the case of subcutaneously administered drugs.

AB0841

**ASSESSMENT OF RELATIONSHIP BETWEEN LONELINESS, PERCEIVED SOCIAL SUPPORT, DEPRESSION AND MEDICATION ADHERENCE IN ANKYLOSING SPONDYLITIS PATIENTS**

E. Öksüz<sup>1</sup>, F.I. Cinar<sup>1</sup>, M. Cinar<sup>2</sup>, E. Tekgoz<sup>2</sup>, S. Yilmaz<sup>2</sup>. <sup>1</sup>University of Health Sciences, Gulhane Faculty of Nursing; <sup>2</sup>University of Health Sciences, Gulhane Faculty of Medicine, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

**Background:** Ankylosing spondylitis (AS) is a chronic, progressive, inflammatory disease which can cause labour loss and deformities and requiring long-term treatment. Loneliness, perceived social support, depression, patients' beliefs about medicines and treatment may affect their medication adherence and treatment success.

**Objectives:** In this study, we aimed to investigate the relationship between loneliness, perceived social support, depression and medication adherence in AS patients.

**Methods:** This cross-sectional study was conducted in a tertiary rheumatology outpatient clinic. One hundred and nineteen AS patients were enrolled to the study. The socio-demographic and clinical features of the patients agreeing to participate were recorded to the "Patient Assessment Form". The patients' disease activity and functional status were determined with the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), and the Bath Ankylosing Spondylitis Functional Index (BASFI), respectively. The pain and global assessment of the patients' were assessed with a numerical visual analogue scale (nVAS; 0–10 cm). The medication adherence of the patients was assessed with the Morisky Green Levine Scale (MGLS). The UCLA Loneliness Scale, the Multidimensional Scale of Perceived Social Support (MSPSS) and the Beck Depression Inventory (BDI) were used to determine loneliness, perceived social support, and depression of the patients.

**Results:** One hundred five patients (88.2%) were male, the mean age was 35.80  $\pm$  9.08 years, and the mean disease duration was 9.88  $\pm$  6.34 years. The mean BASDAI, BASFI and patient global assessment scores were; 4.57  $\pm$  2.63, 3.23  $\pm$  2.76, and 4.13  $\pm$  3.23, respectively. According to the MGLS medication adherence groups, patients with low medication adherence had higher BASDAI, spinal pain, spinal pain at night, fatigue and patient global assessment scores and had lower mean ages ( $p < 0.05$ ). Among the MGLS medication adherence groups, patients with low medication adherence had lower MSPSS scores, and had higher UCLA Loneliness Scale and Beck Depression Inventory scores ( $p = 0.037$ ,  $p < 0.001$ ,  $p = 0.022$ , respectively) (table 1).

**Abstract AB0841 – Table 1.** Comparison of the perceived social support, depression and loneliness scores with the Morisky Green Levine Scale subgroups.

Characteristics	Morisky Green Levine medication adherence groups				F	p
	Overall	High (n=43) <sup>a</sup>	Medium (n=66) <sup>b</sup>	Low (n=10) <sup>c</sup>		
Multidimensional Scale of Perceived Social Support total score <sup>12-84</sup>	63.52 ±17.13	65.09 ±16.85	64.65 ±16.59	49.30 ±17.01	3.958	0.022
Beck Depression Inventory (0-63)*	13.65 ±10.41	13.07 ±11.29	12.15 ±8.51	26.10 ±10.73	8.952	<0.001
UCLA Loneliness Scale <sup>20-80</sup>	37.34 ±11.22	35.19 ±11.26	37.56 ±10.90	45.20 ±10.56	3.388	0.037

F: Oneway ANOVA, Statistically significant between a and c, and b and c (p<0.05). \* It shows the lowest-highest scores that can be taken from the scale and its sub-dimensions.

**Conclusions:** In this study, it was shown that as the average age and social support scores of patients decreased, and as the BASDAI, spinal pain, spinal pain at night, fatigue, patient global assessment, loneliness and depression scores increased, adherence to treatment were decreased. It is thought that patients should be handled holistically in terms of biopsychosocial aspect in order to improve adherence to medical treatment.

#### AB0842 DRUG SURVIVAL AND EFFECTIVENESS OF THE FIRST TNF INHIBITORS IN PATIENT WITH LATE ONSET SPONDYLARTHRTIS: TREASURE REAL-LIFE RESULTS

N. Alpay Kanitez<sup>1</sup>, S. Kiraz<sup>2</sup>, I. Ertenli<sup>2</sup>, O. Küçükşahin<sup>2</sup>, E. Dalkılıç<sup>3</sup>, C. Bes<sup>1</sup>, T. Kaşifoğlu<sup>4</sup>, H. Emmungil<sup>5</sup>, S.S. Koca<sup>6</sup>, M. Çınar<sup>2</sup>, S. Yılmaz<sup>2</sup>, V. Yazısız<sup>7</sup>, B. Keleşoğlu Dinçer<sup>2</sup>, S. Akar<sup>8</sup>, O. Gercik<sup>8</sup>, A. Ateş<sup>2</sup>, S. Erten<sup>2</sup>, S. Turan<sup>5</sup>, B. Yağız<sup>3</sup>, B. Öz<sup>6</sup>, S. Yaşar Bilge<sup>4</sup>, L. Kılıç<sup>2</sup>, G.K. Yardımcı<sup>2</sup>, B.N. Coşkun<sup>3</sup>, U. Kalyoncu<sup>2</sup>. <sup>1</sup>TReasure biological registry, İstanbul; <sup>2</sup>TReasure biological registry, Ankara; <sup>3</sup>TReasure biological registry, Bursa; <sup>4</sup>TReasure biological registry, Eskişehir; <sup>5</sup>TReasure biological registry, Edirne; <sup>6</sup>TReasure biological registry, Elazığ; <sup>7</sup>TReasure biological registry, Antalya; <sup>8</sup>TReasure biological registry, İzmir, Turkey

**Background:** Spondylarthritis (SpA) are usually observed in young patients and a clinical onset after 45 years is rare. The average life expectancy is getting longer and the proportion of late onset of SpA in rheumatology practice may become more common. SpA patients with late onset may have a distinctive clinical pattern in terms of functional impairment, extra-articular disease, co-morbidities and treatment status.

**Objectives:** The aim of this study was to compare the drug survival and effectiveness of tumour necrosis factor (TNF) inhibitors in patients with late onset SpA (LoSpA) compared with early onset SpA (EoSpA).

**Methods:** TReasure is a prospective, multicenter biological treatments registry from Turkey since 2016. It includes 15 different rheumatology centres. Patients with SpA fulfilling the ASAS criteria from TReasure database were divided into two groups as LoSpA (symptom onset >45 years of age) and EoSpA (symptom onset ≤45 years of age). Drug retention rates of first TNF inhibitors were calculated using the time until drug discontinuation independent of the reason that drug interruption. Specific reasons for discontinuing drugs were also assessed.

**Results:** Of 1382 SpA patients treated with TNF inhibitors, 9.4% (n=130) were included in the LoSpA and 90.6% (n=1252) were included in the EoSpA group. LoSpA had more female, enthesitis and psoriasis. The median treatment duration was 53 months in LoSpA and 61 months in EoSpA. The baseline disease activity measures were similar except from ASDAS-ESH which is higher in LoSpA (table 1). The rate of major treatment response (BASDAI50) was lower in LoSpA than EoSpA at the last visit (26.1% vs 46.2%; p=0.009). Regarding the survival rates of TNF inhibitors, there was no significant difference between the patient groups (figure 1). The major cause of discontinuation in both of the groups was drug ineffectiveness (68.6% in LoSpA and 60% in EoSpA, p>0.05).

**Abstract AB0842 – Table 1**

	LoSpA n: 130	EoSpA n:1252	p values
Age [median (min-max)]	56,5 (45-75)	35 (0-76)	<0.001*
Female n (%)	90 (69)	494 (40)	<0.001*
Disease duration [median (min-max)]	61 (1-334)	108 (0-686)	<0.001*
BASDAI [median (min-max)]	6.1 (0-10)	6 (0-10)	0.748
BASFI [median (min-max)]	5.3 (0-10)	4.5 (0-10)	0.098
ASDAS-ESH [median (min-max)]	3.29 (1.23-4.92)	2.91 (0-5.7)	0.001*
ASDAS-CRP [median (min-max)]	3.55 (1.49-5.92)	3.35 (0.7-8)	0.251

**Abstract AB0842 – Figure 1**

**Conclusions:** LoSpA patients were almost 10% of all biological registry. LoSpA patients were predominantly female, and they had relatively higher baseline disease activity and lower biological treatment response. On the other hand the drug survival rate and discontinuation reasons of TNF inhibitors in the LoSpA group was comparable to that in the younger group.

#### AB0843 EFFECT OF TNF INHIBITORS ON BONE MICROARCHITECTURE IN PATIENTS WITH ANKYLOSING SPONDYLITIS: A LONGITUDINAL STUDY BASED ON HIGH-RESOLUTION PERIPHERAL QUANTITATIVE BASED (HRPQCT)

N. Nigil Haroon<sup>1</sup>, E. Szabo<sup>2</sup>, A.M. CHEUNG<sup>3</sup>, R. Inman<sup>4</sup>. <sup>1</sup>Medicine, Northern Ontario School of Medicine, Sudbury; <sup>2</sup>Osteoporosis program, UHN; <sup>3</sup>Medicine, Univ of Toronto; <sup>4</sup>Medicine, unit of Toronto, Toronto, Canada

**Background:** Ankylosing spondylitis (AS) is associated with high risk of fractures. BMD, bone microarchitecture and strength are negatively affected in AS. TNF inhibitors such as etanercept, adalimumab, golimumab and infliximab are the mainstay of treatment in AS. However no data is available on the effect of TNF inhibitors on bone microarchitecture and strength.

**Objectives:** This study aimed to assess the effect of TNF inhibitors on bone microarchitecture in patients with AS.

**Methods:** AS was defined by Modified New York criteria. Areal BMD was measured by DXA. Volumetric BMD (vBMD) and bone microarchitecture were measured using high-resolution peripheral quantitative CT (HRpQCT) at the radius and tibia at baseline and after one year of treatment with TNF inhibitors. Intake of calcium and vitamin D were optimised.

**Results:** There were 31 subjects (58% men). Mean (+SD) age and BASDAI were 40+14 years and 4.1+2.1 respectively. Median duration of disease was 14 (IQ: 6.5-25.5) years. Mean duration of follow-up was 15 months. Areal BMD (n=22) at lumbar spine (1.053+0.235 vs. 1.049+0.202, p=0.89), total hip (0.944+0.152 vs. 0.912+0.164, p=0.5), and femoral neck (0.955+0.151 vs. 0.954+0.191, p=0.2) did not change significantly. HRpQCT (n=31) on follow-up demonstrated that total, trabecular and cortical volumetric BMD were unchanged at both radius and tibia (table 1). Also, HRpQCT based trabecular parameters such as trabecular number, thickness and separation, BV/TV and cortical parameters such as cortical porosity and thickness remained stable (table 1). FEA estimates of bone stiffness and

stress tended to be lower at the radius on follow-up however these parameters were not significantly different at the tibia (table 1).

Abstract AB0843 – Table 1

	RADIUS			TIBIA		
	Baseline	Follow-up	p	Baseline	Follow-up	p
Total volumetric BMD (mg/cm <sup>3</sup> )	318.93 ±311.80	317.37 ±378.61	0.49	301.89 ±48.99	302.06 ±50.71	0.70
Cortical volumetric BMD (mg/cm <sup>3</sup> )	857.22 ±51.43	851.48 ±52.96	0.08	869.69 ±38.21	866.62 ±39.91	0.11
Trabecular volumetric BMD (mg/cm <sup>3</sup> )	158.33 ±42.34	156.81 ±41.88	0.21	155.200 ±44.34	154.26 ±45.25	0.35
BV/TV (%)	0.132 ±0.035	0.131 ±0.035	0.19	0.129 ±0.037	0.129±0.04	0.37
Trabecular number (per mm <sup>3</sup> )	1.985 ±0.302	2.017 ±0.319	0.32	1.793 ±0.36	1.809±0.37	0.56
Trabecular thickness (mm)	0.067 ±0.013	0.065 ±0.013	0.12	0.072 ±0.01	0.071±0.01	0.17
Trabecular separation (mm)	0.435 ±0.104	0.429 ±0.106	0.46	0.483 ±0.13	0.478±0.13	0.06
Cortical thickness (mm)	0.765 (0.72–0.85)	0.760 (0.71–0.82)	0.80	0.751 (0.58–0.84)	0.745 (0.55–0.83)	0.78
Cortical porosity (%)	0.019 (0.71–0.82)	0.017 (0.016–0.024)	0.81	0.049 (0.02–0.06)	0.048 (0.017–0.065)	0.80
Stiffness (N/mm)	1.37±0.42	1.33±0.34	0.03	1.57±0.31	1.58±0.31	0.72
Stress (MPa)	27.23 ±10.52	26.30±9.83	0.03	32.78±7.8	32.70±7.71	0.71

**Conclusions:** This is the first study to document the changes in bone strength in AS patients with the use of TNF inhibitors. Treatment with TNF inhibitors might maintain bone microarchitecture at cortical and trabecular sites in patients with AS.

#### EFFECTIVENESS AND RETENTION RATE OF CERTOLIZUMAB PEGOL IN SPONDYLOARTHRITIS. REAL LIFE DATA

R. Expósito-Moliner<sup>1</sup>, R. Garcia-Portales<sup>2</sup>, J.R. Lamua-Riazuelo<sup>3</sup>, A. Urruticoechea-Arana<sup>4</sup>, P. Navarro-Alonso<sup>5</sup>, J.S. Rey-Rey<sup>6</sup>, M. Fernandez-Prada<sup>7</sup>, C.M. Gonzalez Fernandez<sup>8</sup>, on behalf of RENACER Study Group.  
<sup>1</sup>Rheumatology, Hospital Comarcal de Laredo, Laredo; <sup>2</sup>Rheumatology, Hospital Virgen de la Victoria, Malaga; <sup>3</sup>Rheumatology, Hospital del Henares, Alcala de Henares; <sup>4</sup>Rheumatology, Hospital Can Misses, Ibiza; <sup>5</sup>Rheumatology, Hospital de Fuenlabrada, Fuenlabrada; <sup>6</sup>Rheumatology, Hospital Virgen de la Salud, Toledo; <sup>7</sup>Rheumatology, Hospital Universitario de Guadalajara, Guadalajara; <sup>8</sup>Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain

**Background:** Certolizumab pegol (CZP) is available for patients with axial spondyloarthritis (axSpA), including ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nr-axSpA). The efficacy and the safety of CZP are well established from clinical trials. However, evidence of its effectiveness in regular clinical practice is limited.

**Objectives:** To evaluate the effectiveness and safety of CZP in a real word setting in axSpA patients.

**Methods:** Multicentric cohort of SpA patients treated with CZP according to routine clinical practice. The study was approved by the local Ethics Committee. Maximum follow-up was 12 months. Clinical response was evaluated through BASDAI, ASDAS, BASFI and MASES scores. Safety variables: discontinuation rate.

**Results:** 336 patients with axSpA were included: 56.5% male, mean age 45.8 (±12.1) years, median disease time 4.3 (0, 49.5) years, 68.5% of patients were HLAB27 positive, and never smokers 64.7%. Prior bDMARD received (27.2% none; 37.9% 1, 35%≥2). At baseline 36.8% had concomitant DMARDs and 82.8% NSAIDs. 31.8% of patients had peripheral arthritis and 42.7% entesitis at baseline. CZP retention time 10.3 months. Statistically significant differences in BASDAI, BASFI, ASDAS y MASES were observed at the last visit comparing to baseline (table 1). In the last observation, 41.0% of the patients achieved BASDAI50, 34% were in ASDAS remission (ASDAS <1.3) and 49% presented a minimal clinical improvement (ASDAS at least 1.1). 46.3% of patients had resolution of the entesitis (MASES=0). According to Kaplan-Meier analysis, the drug survival of CZP was 83.3%, and no differences were observed in retention rates

when CZP were used as first option (83.3%) or after failure to other biologicals (79.1%) (figure 1). 56/336 (16.7%) withdrawn CZP treatment: 34/336 (10.1%) due to lack of effectiveness, 16/336 (4.8%) due to adverse event and 6/336 (1.8%) for other reason. Serious adverse event was found in 23/336 (6.8%) patients.

Abstract AB0844 – Table 1. Evolution of clinical variables of activity

	Baseline	Last visit
BASDAI evolution	6,2±1.6(n=263)	3,9±2.2(n=260)*
BASFI evolution	5,6±2.1(n=225)	3,7±2.3 (n=241)*
ASDAS evolution	3,7±2.7(n=322)	2,4±2.2 (n=321)*
MASES score	3,9±2.7(n=78)	1,2±1.8(n=51)*

\*p<0,001, Wilcoxon's test

Abstract AB0844 – Figure 1. CZP Retention rate in axSpA patients without and with previous biological experience.

**Conclusions:** Real life experience from this nationwide rheumatology study, demonstrated the effectiveness and safety of CZP in patients with axSpA, with a significant reduction of BASDAI, BASFI, ASDAS and MASES scores. No differences were observed in the retention rate regardless previous biological treatment.

#### THE EFFECT OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS PATIENT REPORTED OUTCOMES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS; A SYSTEMATIC LITERATURE REVIEW AND A CALL FOR ACTION

S. Rodrigues-Manica<sup>1,2</sup>, J. Leite Silva<sup>3</sup>, A.R. Machado<sup>4</sup>, C. Coelho<sup>5</sup>, J. Duarte<sup>6</sup>, E. Vieira-Sousa<sup>4</sup>, J. Tavares-Costa<sup>3</sup>, F.M. Pimentel-Santos<sup>1,2</sup>. <sup>1</sup>CEDOC; <sup>2</sup>Egas Moniz, Centro Hospitalar de Lisboa Ocidental, Lisbon; <sup>3</sup>Unidade Local de Saúde do Alto Minho, Ponte de Lima; <sup>4</sup>Centro Hospitalar de Lisboa Norte, EPE, Hospital de Santa Maria, Lisbon Academic Medical Centre; <sup>5</sup>Genetics Laboratory, Institute of Environmental Health, Lisbon School of Medicine, University of Lisbon; <sup>6</sup>Medical Department, Novartis Pharma, Pharmaceutical products, Lisbon, Portugal

**Background:** Patient reported outcomes (PROs) have gained relevance in the evaluation of several diseases such as axial spondyloarthritis (axSpA). They allow the clinician to have a quantitative measurement of several aspects of the disease, according to the patient perspective.

**Objectives:** In this review we intended to evaluate the efficacy of different biologic disease-modifying anti-rheumatic drugs (bDMARD) in achieving the minimum clinically important difference (MCID) in several PROs's. Data from randomised controlled trials (RCT) conducted in radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-AxSpA) patients were included.

**Methods:** A systematic literature review (SLR) was performed using the MEDLINE database (August 17 2017) with the filters "published in the last 10 years" and "humans". Abstracts from the EULAR 2017 were also considered. The PICO (P,

population; I, intervention; C, comparison; O, outcome) concept was used to perform the analysis according to: Patients: adults (>18 years old) with r-axSpA or nr-axSpA; Intervention: any bDMARD regardless of formulation or duration; Comparison: placebo and/or any different drug; Outcomes: The Bath Ankylosing Spondylitis Functional Index (BASFI), the Ankylosing Spondylitis Quality of Life (ASQoL), the EuroQoL-5D (EQ-5D), the Short Form 36 Health Survey physical component summary (SF36-PCS), the Short Form 36 Health Survey mental component summary (SF36-MCS), and the Functional Assessment of Chronic Illness Therapy – Facit (FACIT-F). For each outcome we assessed whether the treatment group was superior, equal or inferior to the placebo (PBO) group regarding the achievement of the MCID of the assessed PRO over time.

**Results:** After screening 557 references (after de-duplication), 16 RCTs were included, studying interleukin 17 inhibitors (IL17i) and tumour necrosis factor inhibitors (TNFi). In r-axSpA, the treatment group (for both TNFi and IL17i) reached the MCID for all the assessed PROs, except for a single study in which both the treatment and PBO groups reached the MCID for the SF36-PCS. For nr-axSpA the results were more heterogeneous (table 1).

Abstract AB0845 – Table 1

Phenotype	PRO and MCID cut-off for improvement	Difference between MCID from baseline to RCT end in favour of treatment arm (against PBO)	Drug (reference)
r-AxSpA	BASFI (0-10) (≥7mm)	YES	ADA (Maksy 2008); SEC (Deodhar 2017); ADA (van der Heijde 2009)
	ASQoL (0-18) (≥1.8)	YES	SEC (Deodhar 2017); GOL (Deodhar 2017)
	EQ-5D (≥10.0)	YES	SEC (Deodhar 2017; Marzo-Ortega 2017); GOL (Reveille 2017)

PRO: Patient reported outcome; RCT: Randomised control trial; PBO: Placebo; r-axSpA: radiographic axial spondyloarthritis; nr-axSpA: non-radiographic axial spondyloarthritis; BASFI: The Bath Ankylosing Spondylitis Functional Index; ASQoL: Ankylosing Spondylitis Quality of Life Questionnaire; EQ-5D; the EuroQoL-5D; SF36-PCS: Short Form 36 Health Survey physical component summary; SF-36-MCS: the Short Form 36 Health Survey mental component summary; FACIT-F: the Functional Assessment of Chronic Illness Therapy – Facit; ADA: Adalimumab; SEK: Secukinumab; GOL: Golimumab; ETN: Etanercept; IFX: Infliximab; CZP: Certolizumab pegol; YES: There was an improvement on treatment but not on PBO groups; YES# There was a MCID improvement in both treatment and PBO groups; NO: there was no improvement in neither treatment nor PBO group.

**Conclusions:** The assessment of PROs in RCT is scarce. The profile of PROs response seems to be different between r-axSpA and nr-axSpA patients; these differences must be further validated in future trials.

This study launches a call for action in PROs reporting standardisation.

## AB0846 PERSONALISING CARE: USING INFLIXIMAB DRUG TROUGH AND ANTI-DRUG ANTIBODY LEVELS IMPROVES CLINICAL TREATMENT DECISIONS AND IS A COST EFFECTIVE STRATEGY IN SPONDYLOARTHRITIS

S. Dubash<sup>1,2</sup>, D. Bryer<sup>2</sup>, J. Fitton<sup>1,2</sup>, A. Barr<sup>1,2</sup>, C. Vandeveld<sup>1,2</sup>, H. Marzo-Ortega<sup>1,2</sup>, J. Freeston<sup>1,2</sup>. <sup>1</sup>Rheumatology, Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>Rheumatology, NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK

**Background:** Personalised medicine tailors treatment to the individual's needs. The advent of biosimilars has led to therapy re-appraisals driven by healthcare commissioning bodies' demand for cost-effective interventions. Yet, biologic drug dosing is standardised and little is known about the rationale and efficacy of dose adjustment.

**Objectives:** As part of a service evaluation exercise, we measured serum drug trough levels (DLs) and anti-drug antibodies (ADABs) in our cohort of patients with axial spondyloarthritis (axSpA) and Psoriatic arthritis (PsA) receiving bio-originate infliximab with the aims of a) informing our decision making upon switching to a biosimilar and b) assessing the impact of this approach to our clinical practice.

**Methods:** Eligible subjects identified, were counselled and consented by an experienced specialist nurse on DLs and ADAB testing and possible associated outcomes including change in drug class, dose, infusion time interval and switching from bio-originate infliximab to the biosimilar infliximab CT-P13. A treatment algorithm was developed to guide the treating physician. Clinical and outcome data were recorded as per routine practice including disease status, DLs and ADAB titre, and clinical outcome.

**Results:** We identified 53 subjects. Based upon disease activity, DL and ADAB level, bio-originate infliximab was discontinued in 3 (6%) subjects, the infusion interval was extended in 8 (15%), shortened in 3 (6%), and the dose reduced in 3 (6%) subjects. Four patients (8%) changed to an alternative biologic due to persistent high disease activity on infliximab. ADABs were absent in 20/28 (71%) subjects on concomitant methotrexate (MTX). Very high titre ADABs were identified in 8 (15%) subjects with corresponding very low (n=2) or undetectable (n=6) DLs suggesting likely drug-neutralisation. The total estimated cost-savings from drug discontinuation and interval extension or dose reduction were £28,689 per annum in addition to the biosimilar switch saving of £41,184 per annum.

Abstract AB0846 – Table 1

	axSpA (n=32, 60%)	PsA (n=21, 40%)
M:F	30:1	7:14
Bio-originate infliximab duration (years), (median, IQR)	11 (8–15)	9 (6–14)
Concomitant csDMARD, n (%)	12 (36%)	17 (81%)
MTX, n (%), (median dose)	12 (100%, 15 mg/week)	16 (94%, 10 mg/week)
Previous biologic (bDMARD)	5 (16%)	5 (24%)
Positive ADABs (median, IQR) AU/mL	12 (37%), 46.5 (18–74)	8 (38%), 86.5 (29–212)
Therapeutic range DL	14 (44%)	10 (48%)
High ADAB/very low or undetectable drug (likely drug-neutralising)	4 (13%)	4 (27%)
Drug discontinued (no alternative bDMARD required)	1 (3%)	2 (10%)
Dose reduced or interval extended	8 (25%)	3 (14%)
Alternative bDMARD (either TNFi or different mode of action)	1 (3%)	3 (14%)
Switched to biosimilar	14 (44%)	10 (48%)

**Conclusions:** These data from a small cohort suggest that measuring ADABs and DLs to characterise treatment response, tailor treatment regime and inform biosimilar switching is a clinically efficacious and cost-effective strategy in infliximab-treated SpA patients. We anticipate further significant savings with our

cohort receiving subcutaneous therapies. This approach unlocks the potential of "personalised medicine" which supports individualised treatment and brings significant savings to the healthcare provider.

#### AB0847 IMPACT OF SPONDYLOARTHRITIS ON LIFE QUALITY: BEFORE AND AFTER TREATMENT

X. Grapton<sup>1</sup>, on behalf of CREER, P. Lemesle<sup>2</sup>, on behalf of CREER, L. Arabian<sup>3</sup>, on behalf of CREER, V. Strotz<sup>4</sup>, on behalf of CREER. <sup>1</sup>Private Rheumatology Practice, Colombes; <sup>2</sup>Private Rheumatology Practice, Bois-Colombes; <sup>3</sup>Private Rheumatology Practice, Clamart; <sup>4</sup>Private Rheumatology Practice, Antony, France

**Background:** Life quality issues in spondyloarthritis (SPA) are often spontaneously mentioned by patients or identified by rheumatologists. Besides classic follow up parameters, we have to consider those issues to improve our patients life quality.

**Objectives:** Explore and quantify the impact of SPA on life quality via everyday's life and psychological items and the effect of treatment on them.

**Methods:** SPA cases were collected by a group of 14 private practice rheumatologists (Rh) in the Paris area. Basic informations about the patient and his disease were provided by his rheumatologist. Questionnaire including 12 themes and 41 items was filled in by the patient.

**Results:** 50 cases collected, 59.5% men, mean age 45 years, 82% working Axial SPA 42%, peripheral 4%, mixt 52%. Mean duration before study: 14 years. Moderate disease 57%, severe 26.5%. HLA B27 positive 84%

Drugs: NSAIDS 96%, classic DMARDS 31%, biological DMARDS 84%, corticosteroids 36%, combination therapy 42%.

Associated measures were suggested by the Rh: Physical activity (62%), rest (56%), psychological support, physiotherapy, yoga, adapting professional activity and environment...

Life quality issues are spontaneously mentioned by 40% of the patients.

Before treatment, 72% of the patients report consequences on their hobbies, 68% on their psychological well-being, 54% on their getting about, 50% on their family relations. The less impacted items are food (26%) and economy (24%).

Life quality is mostly altered by pain (71%), then fatigue (17%), handicap (7%) and other people's attitude (5%).

After treatment, social repercussions diminish by 47%, then getting about, house-work, family relations, holidays, sexual life, psychological well-being, hobbies and work (between -21% and -44%).

Drug intolerance: 36%.

The items improving by more than 50% after treatment are in this order: cultural life, transports, house-keeping, do-it-yourself, sleep, going out, work (53% less sick leave).

The treatment is less efficient (<22%) on economy, dependance, disillusion, depression and sexual life.

Family circle lacks empathy in 66% of the cases, family relations stay difficult after treatment.

**Conclusions:** SPA diminishes quality of life in 75% of our patients, but only 40% mention it spontaneously. All the parameters impacted by SPA were significantly improved after treatment. The best improvement concerned hobbies, including culture, do-it-yourself and going out. One patient of two found correct sleep and felt psychologically better. Sick leave was reduced by half, but, unfortunately, family relations didn't improve.

The rheumatologist has to track, in a trusting patient-physician relation, the daily situation impacted by the SPA.

**Disclosure of Interest:** None declared

## Spondyloarthritis – clinical aspects (other than treatment)

#### AB0848 FOUR YEARS OF DELAY IN THE DIAGNOSIS OF SAPHO SYNDROME: SINGLE TERTIARY CENTRE EXPERIENCE

A. Erden<sup>1</sup>, M. Ekici<sup>2</sup>, B. Armagan<sup>1</sup>, A. Sari<sup>1</sup>, G.K. Yardımcı<sup>1</sup>, L. Kılıç<sup>1</sup>, S. Apras Bilgen<sup>1</sup>, A. Akdoğan<sup>1</sup>, O. Karadag<sup>1</sup>, S. Kiraz<sup>1</sup>, I. Ertenli<sup>1</sup>, U. Kalyoncu<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine; <sup>2</sup>Department of Internal Medicine, Hacettepe University, Ankara, Turkey

**Background:** SAPHO syndrome is a chronic disease with bone, joint and skin involvement characterised by synovitis, acne, pustulosis, hyperostosis and osteitis. It is a rare disease and its diagnosis may depend on detailed clinical examination as well as radiological evaluation

**Objectives:** In this study, we aim to present clinical features and diagnostic course of patients with SAPHO syndrome who are followed in our tertiary referral clinic.

**Methods:** All patients with SAPHO syndrome diagnosed since February 2014 have been registered with a standard form. Patients are prospectively monitored since then. Diagnosis was based on the criteria by Benhamou et al.<sup>1</sup> In the questionnaire, demographic data (age, sex, duration of illness), clinical features (skin and joint involvement), laboratory characteristics (acute phase reactants, HLA-B27), radiological imaging (bone scintigraphy (increased activity in the sternum, bilateral sternoclavicular joints and clavicles), MRI) disease activity parameters (BASDAI, BASFI) were questioned. There were 24 patients with SAPHO syndrome. The data of 21 patients were presented because the clinical findings of 3 patients were insufficient.

**Results:** Data of 21 patients with SAPHO syndrome were available and 11 (52.4%) patients were female. Mean age at diagnosis was 39.9±12.9, mean age of symptom onset was 35.2±12.9, mean follow-up duration was 18.1±25.1 months. The mean delay time of diagnosis SAPHO syndrome was calculated as 49.0±82.5 months. Thirteen patients (61.9%) were followed up with another clinical diagnosis before SAPHO diagnosis. The clinical characteristics of the patients are shown in Figure 1. HLA-B27 was positive in 3 of 13 patients. Mean activity scores of our patients at initial visit were; BASDAI: 4.8±2.8, BASFI: 4.6±2.2, CRP2.3±4.2 mg/dL and erythrocyte sedimentation rate 23.8±22.6 mm/h. Scintigraphy findings were positive in 16 (94.1%) of 17 patients. The diagnosis of 2 patients was supported by MRI. The remaining 2 patients were diagnosed with X-ray and clinic findings.

Involvement pattern	n (%)
Spinal involvement	14 (66.7)
Peripheral joint involvement	8 (38.1)
Skin involvement	16 (76.2)
- PPP	10 (47.6)
- Serious acne	5 (23.8)
- Psoriasis vulgaris	5 (23.8)
- Hidradenitis suppurativa	1 (4.8)
Skin involvement time	
- Before muscle skeletal symptoms	7 (43.8)
- Muscle skeletal symptoms at the same time	1 (6.3)
- After musculoskeletal symptoms	8 (50)
Osteoarticular symptoms	19 (90.5)
- Cervical pain	10 (47.6)
- Thoracic pain	15 (71.4)
- Lumbosacral pain	15 (71.4)
Anterior chest wall pain	20 (95.2)
IBP	12 (57.1)
Morning stiffness (more than 1 hour)	10 (47.6)
Sternocostal joint involvement	7 (33.3)
Sternoclavicular joint involvement	18 (85.7)
Manubrium sternal involvement	11 (52.4)
Costochondral joint involvement	6 (28.6)
Hip joint involvement	10 (47.6)
Sacroiliitis	10 (47.6)
Osteitis	10 (47.6)
Entesis	4 (19)
Ulcers	3 (14.3)

**Abstract AB0848 – Figure 1.** Clinical characteristics of patients at diagnosis

PPP: palmoplantar pustulosis, IBP: Inflammatory Back pain

**Conclusions:** There is a certain diagnostic problem in the SAPHO syndrome. Delay of SAPHO diagnosis was almost 4 years and 62% of patients had wrong diagnosis before SAPHO syndrome. Anterior chest wall involvement with dermatological findings should be alerting to the physicians. Bone scintigraphy can be helpful to diagnose SAPHO syndrome. It is important to distinguish SAPHO syndrome from other spondyloarthritis and/or psoriatic arthritis because of the potential different treatment strategies.

**AB0849 CORRELATION BETWEEN RAPID3 AND PROMIS10 IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

A. Ogdie<sup>1</sup>, W.B. Nowell<sup>2</sup>, R. Reynolds<sup>2</sup>, K. Gavigan<sup>2</sup>, S. Venkatchalam<sup>2</sup>, M. de la Cruz<sup>2</sup>, E. Flood<sup>3</sup>, E.J. Schwartz<sup>3</sup>, B. Romero<sup>3</sup>, Y. Park<sup>4</sup>. <sup>1</sup>Perelman School of Medicine at The University of Pennsylvania, Philadelphia; <sup>2</sup>Global Healthy Living Foundation, Upper Nyack; <sup>3</sup>ICON, Gaithersburg; <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA

**Background:** Patient-reported outcome (PRO) measures are important in managing and improving the quality of care in patients with chronic rheumatic conditions including ankylosing spondylitis (AS). The RAPID3 was developed for use in patients with rheumatoid arthritis, but it has shown good correlation with the BASDAI and ASDAS in patients with AS.<sup>1</sup> The PROMIS10 is a universal (non-disease specific) PRO measure that quantifies physical and mental health;<sup>2</sup> validity of PROMIS10 has not been examined in patients with AS.

**Objectives:** To evaluate the relationship between RAPID3 and PROMIS10 in patients with AS.

**Methods:** US patients aged ≥18 years with a self-reported diagnosis of AS were recruited through CreakyJoints (www.CreakyJoints.org), an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers and via outreach on social media. Respondents completed a web-based survey designed to collect data on socio-demographics and clinical symptoms, RAPID3, and PROMIS10. The RAPID3 score consists of three patient self-reported scores (0–10): functional impairment, pain, and patient global assessment; total scores ≤3.0=near remission, 3.1 to 6.0=low disease severity, 6.1 to 12.0=moderate disease severity, and ≥12.1 = high disease severity. PROMIS10 is a 10-item questionnaire measuring physical, mental, and social domains; physical and mental health domain scores are transformed to T-score distributions normalised to the general population (mean score=50). PROMIS10 individual scores and global physical and mental health T-scores were stratified by RAPID3 disease severity and compared across RAPID3 severity levels using Kruskal-Wallis or ANOVA or tests, respectively. Spearman's correlation coefficient was calculated between the RAPID3 total score and the PROMIS10 physical health and mental health T-scores, respectively.

**Results:** Among 235 respondents, 174 (74%) were female, with a mean (SD) age of 49.8 (10.7) years. The mean (SD) RAPID3 cumulative score was 15.4 (5.4) The mean (SD) PROMIS10 global physical and mental health T-scores were 35.60 (7.39) and 39.89 (8.76), respectively, with individual domain scores and global T-scores decreasing with worsening RAPID3 disease activity (table 1; p<0.0001 for all). PROMIS10 physical and mental health T-scores showed a strong correlation with RAPID3 (r<sub>s</sub>=−0.84 and −0.63, respectively).

**Abstract AB0849 – Table 1.** PROMIS10 Scores by RAPID3 Disease Activity in Patients with AS

PROMIS10 domain, mean (SD)	RAPID3 Disease Activity*				P value
	Near Remission (n = 5)	Low Severity (n = 9)	Moderate Severity (n = 52)	High Severity (n = 169)	
Overall health	4.20 (0.45)	3.89 (0.60)	2.77 (0.70)	2.09 (0.77)	< 0.0001
Quality-of-life	4.80 (0.45)	3.67 (0.71)	3.10 (0.63)	2.28 (0.88)	< 0.0001
Physical health	4.40 (0.55)	3.44 (0.53)	2.65 (0.65)	1.97 (0.78)	< 0.0001
Mental health	4.80 (0.45)	3.44 (0.53)	3.06 (0.78)	2.56 (0.96)	< 0.0001
Satisfaction with social activities/relationships	5.00 (0.00)	3.00 (0.71)	2.94 (1.00)	2.15 (1.01)	< 0.0001
Ability to carry out every day physical activities	4.80 (0.89)	3.67 (0.71)	2.98 (1.11)	2.09 (0.85)	< 0.0001
Emotional distress	4.40 (0.89)	3.22 (0.83)	2.75 (0.78)	2.20 (0.78)	< 0.0001
Fatigue	4.40 (0.89)	3.22 (0.83)	2.75 (0.78)	2.20 (0.78)	< 0.0001
Pain	4.20 (0.45)	4.00 (0.00)	3.25 (0.44)	2.38 (0.54)	< 0.0001
Global physical health T-score	57.84 (3.90)	47.62 (4.24)	40.92 (4.40)	32.66 (5.37)	< 0.0001
Global mental health T-score	63.56 (5.63)	46.72 (4.05)	44.26 (6.27)	37.48 (7.90)	< 0.0001

AS, ankylosing spondylitis; PROMIS10, Patient-Reported Outcome Management Information System Global Health short form; RAPID3, Routine Assessment of Patient Index Data 3.

\* Disease severity classified by RAPID3 scores: ≤3.0=near remission; 3.1 to 6=low severity; 6.1 to 12.0=moderate severity; ≥12.1= high severity.

**Conclusions:** RAPID3 and PROMIS10 are relatively short questionnaires that can be used in the real world to track and monitor disease symptoms and health-related quality of life in patients with AS. RAPID3 and PROMIS10 were strongly correlated in patients with AS; although, the PROMIS mental health T-score likely measures a slightly different construct than RAPID3.

**AB0850 DO SYMPTOMS OF DEPRESSION AND ANXIETY INFLUENCE TREATMENT RESPONSE AND LONG-TERM PHYSICAL HEALTH OUTCOMES IN ANKYLOSING SPONDYLITIS?**

M. Eusébio<sup>1</sup>, C.A. Lopes<sup>2,3</sup>, M. Bernardes<sup>4</sup>, P. Pinto<sup>5</sup>, H. Santos<sup>6</sup>, J.L. Gomes<sup>2,3</sup>, J. Tavares-Costa<sup>7</sup>, J. Dias<sup>8</sup>, A. Bernardo<sup>4</sup>, L. Domingues<sup>3</sup>, C. Crespo<sup>3</sup>, S. Maia<sup>3</sup>, F. Martins<sup>1</sup>, J.C. Branco<sup>2,3</sup>, F.M. Pimentel-Santos<sup>2,3</sup>. <sup>1</sup>SPR, Portuguese Rheumatology Society; <sup>2</sup>Rheumatology, Hospital Egas Moniz – CHLO; <sup>3</sup>CEDOC, NOVA Medical School, NOVA University of Lisbon, Lisbon; <sup>4</sup>Rheumatology, Centro Hospitalar São João, Porto; <sup>5</sup>Rheumatology, Centro Hospitalar Vila Nova de Gaia/Espinho, Gaia; <sup>6</sup>Rheumatology, Instituto Português de Reumatologia, Lisbon; <sup>7</sup>Rheumatology, Unidade Local de Saúde de Alto Minho, Ponte de Lima; <sup>8</sup>Rheumatology, Centro Hospitalar Médio Tejo, Torres Novas, Portugal

**Background:** Psychological disturbances, frequently observed in inflammatory rheumatic diseases, seem to negatively influence patient's clinical status and treatment response.

**Objectives:** The aim of this study was to examine the longitudinal impact of depression (D)/anxiety (A) in treatment response, disease activity, physical disability and quality of life in patients with Ankylosing Spondylitis (AS).

**Methods:** Data from patients who fulfilled the modified New York criteria for AS were collected at baseline, weeks 2 and 14 post-treatment with Adalimumab. The Hospital Anxiety and Depression Scale (HADS) was used to evaluate D/A symptoms severity. The primary outcomes were AS disease activity score – C reactive protein (ASDAS-CRP), Bath AS Disease Activity Index (BASDAI), Bath AS Functional Index (BASFI) and AS Quality of Life (ASQoL) Scale. Secondary outcomes were patient and physician global assessment by Visual Analogue Scale (VAS), erythrocyte sedimentation rate (ESR), CRP and BASDAI question 1 (fatigue). Difference-in-differences estimation took into account the covariates gender, age at baseline and disease duration.

**Results:** Data from 54 patients were included. At baseline, D/A symptoms significantly influenced the mean value of BASFI (p=0.006; p=0.003) and ASQoL (p<0.001; p=0.004). On the other hand, BASDAI (p=0.009), CRP (p=0.017), patient's VAS (p=0.003) and fatigue (p=0.015) were only influenced in the individuals with A symptoms, while the physician's VAS (p=0.005) was only influenced in patients with D symptoms. After 14 weeks of treatment, significant differences in ASQoL mean values were found in patients with both D/A symptoms at baseline (p=0.005; p=0.022) and in BASFI (p=0.044) and patient VAS (p=0.006) for the population showing only A symptoms at the baseline. Apart from the physician VAS (p=0.023), D/A baseline symptoms did not affect the treatment's response.

**Abstract AB0850 – Table 1.** Difference-in differences estimation results. †p-value<0.05.

**AB0851** **CLINICAL ASSOCIATIONS OF UVEITIS IN ASAS DEFINED AXIAL SPONDYLOARTHRITIS GROUP AND MODIFIED NEW YORK CRITERIA DEFINED ANKYLOSING SPONDYLITIS GROUP**

C. Chiu Wai Shirley<sup>1\*</sup>, C.S. Lau<sup>2</sup>, H.H.L. Tsang<sup>1</sup>, O.M. Wong<sup>3</sup>, H.Y. Chung<sup>2</sup>.  
<sup>1</sup>Medicine, QUEEN MARY HOSPITAL; <sup>2</sup>Medicine, University of Hong Kong;  
<sup>3</sup>Ophthalmology, Hong Kong Eye Hospital, Hong Kong, Hong Kong

**Objectives:** To identify and compare the associated factors for uveitis in Chinese patients with axial spondyloarthritis (SpA) and ankylosing spondylitis (AS).

**Methods:** Patients fulfilling the Assessment of SpondyloArthritis (ASAS) axial SpA criteria were recruited consecutively from three rheumatology centres in Hong Kong. Clinical and biochemical parameters were collected. History of uveitis was enquired from both history and medical records. All patients received lumbosacral spine x-rays, and whole spine and sacroiliac (SI) joint magnetic resonance imaging (MRI). MRIs were scored according to the Spondyloarthritis Research Consortium of Canada (SPARCC) scores. Patients were defined as axial SpA if they fulfilled the ASAS criteria, and AS if they fulfilled the modified New York (mNY) criteria. Clinical and radiological findings were compared between patients with and without uveitis in the two groups. Factors associated with uveitis were identified with univariate analyses and multivariate logistic regression analyses.

**Results:** Among 253 patients, 67 (26.5%) patients had a history of uveitis. The male to female ratio was 55.7 to 44.3. Disease duration was 12.3±11.7 years. In the axial SpA group, univariate analyses showed that the following factors were associated with uveitis: back pain duration, age, HLA-B27 positivity, history of inflammatory bowel disease (IBD), tender joint count, Ankylosing Spondylitis Disease Activity Index (ASDAS) and SPARCC score of spine. Multivariate regression showed that older age (OR 1.05; p=0.01), HLA-B27 positivity (OR 11.79; p=0.01) and history of IBD (OR 9.74; p=0.04) were positively associated with uveitis. In the AS group, univariate analyses showed that the following were associated with uveitis: back pain duration, age, male sex, HLA-B27 positivity, tender joint count, ASDAS, SPARCC score of spine and SPARCC score of SI joints. Multivariate regression showed that back pain duration (OR 1.05; p=0.01) and male sex (OR 3.46; p=0.03) were associated with uveitis.

**Conclusions:** Clinical factors associated with uveitis are similar in the axial SpA and AS groups. The former group is associated more with IBD, and the latter with male sex.

**AB0852** **GENDER DIFFERENCES IN AXIAL AND PERIPHERAL SPONDYLOARTHRITIS: RESULTS FROM THE ESPERANZA COHORT**

C. Urrego Laurín<sup>1</sup>, V. Navarro-Compán<sup>2</sup>, P. Zurita<sup>1</sup>, T. Ruiz Jimeno<sup>3</sup>, C. Campos fernandez<sup>4</sup>, J. Mulero Mendoza<sup>5</sup>, E. De Miguel Mendieta<sup>2</sup>, on behalf of ESPERANZA Group. <sup>1</sup>Hospital General de Segovia, Segovia; <sup>2</sup>Hospital Universitario la Paz, IdiPaz, Madrid; <sup>3</sup>Hospital Sierrallana. Torrelavega, Santander; <sup>4</sup>Hospital Universitario de Valencia, Valencia; <sup>5</sup>Hospital Universitario Puerta de Hierro, Madrid, Spain

**Background:** In patients with spondyloarthritis (SpA), published data indicate different manifestations and outcomes between genders. Nevertheless, the evidence in patients with early and peripheral disease is lacking.

**Objectives:** To evaluate differences in the presentation of the disease between genders in patients with early axial and peripheral SpA (axSpA, pSpA).

**Methods:** This study was carried out within the framework of the ESPERANZA program, which was a Spanish multicenter initiative aiming to facilitate early diagnosis and follow-up of patients with SpA between 2008–11. Out of 775 patients referred, 377 patients fulfilled the ASAS classification criteria for SpA:291(77%) axSpA and 86 (23%) pSpA. Demographic and disease characteristics were compared between genders using Chi-square (for categorical variables) and Student t (for continuous variables) tests.

**Results:** In total, 241 (64%) patients were males (191 axSpA and 50 pSpA). In the axSpA group, males had more frequently radiographic sacroiliac damage, elevated CRP, HLA-B27 positive and morning stiffness, while females had higher values of ESR and more frequency of peripheral arthritis (table 1). Within the pSpA group, male gender was significantly associated with higher diagnostic delay, psoriasis and elevated CRP while women had higher rates of functional limitation and ESR values.

ASQoL (0-18)	5.5 ± 4.9	6.6 ± 4.5	0.08	4.1 ± 4.7	4.9 ± 5.3	0.5

**Conclusions:** In patients with SpA, different disease manifestations between genders are observed already from the first stages of the disease. In patients with axSpA, males have worst prognostic factors compared with females. However, in pSpA, females report poorer functionality despite being diagnosed earlier than male patients. This difference in phenotypes may be relevant when therapeutic decision-making.

**AB0853** **THE ASSOCIATION OF VITAMIN D RECEPTOR LEVELS WITH DISEASE ACTIVITY PARAMETERS IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

T. Kultur<sup>1</sup>, D. Öztaş<sup>2</sup>, D. Keskin<sup>1</sup>, G. Keskin<sup>3</sup>, A. İnal<sup>4</sup>, H. Kara<sup>5</sup>. <sup>1</sup>PMR, Kırıkkale University, Kırıkkale; <sup>2</sup>Public Health, Yıldırım Beyazıt University; <sup>3</sup>Immunology, Ankara University, Ankara; <sup>4</sup>Immunology, Baskent University, Istanbul; <sup>5</sup>Pharmacology, Yıldırım Beyazıt University, Ankara, Turkey

**Background:** Ankylosing Spondylitis (AS) is a chronic, systemic, inflammatory disease that involves sacroiliac, axial and peripheral joints with an unknown etiology. The role of vitamin D receptor (VDR) in the regulation of multiple pathophysiological processes, like inflammation, infection and malignancies and systemic disease is not fully understood.

**Objectives:** The aim of this study, was to investigate the relationship between serum VDR levels and disease activity parameters in patients with AS.

**Methods:** Sixty-two patients with AS and 32 healthy volunteers were included into the study. Demographic features like age, duration of illness, medication, history of uveitis and peripheral involvement of the patients were recorded. Erythrocyte sedimentation rate (ESR), serum C-reactive protein (CRP) levels were recorded. The Bath AS Disease Activity Index (BASDAI) scores were calculated to determine disease activity. Serum Vitamin D receptor (VDR) level was measured by ELISA.

**Results:** There was no difference in Serum VDR levels between the patient and the control group (p=0.658). In patients with active AS (BASDAI score ≥4) serum VDR level was significantly high (p=0,000). Also serum VDR levels were statistically significantly high in patients with peripheral joint involvement and enthesitis (p=0,000, non-steroidal anti inflammatory drugs (NSAID) compared to patients treated with biological agents (p=0.00). Serum VDR levels were also significantly correlated with BASDAI, CRP and ESR in the patient group (p=0.00, r=0,751, p=0.00, r=0751 p=0.00, r=0806 respectively).

**Conclusions:** In our study, serum VDR levels are related with disease activity, clinical parameters, peripheral joint involvement and enthesitis in patients with AS. Our results suggest that serum VDR level may be used to predict disease activity and prognosis. Further studies in large cohorts are needed to determine the role of Serum VDR level in the pathophysiology of AS.

### AB0854 DYSFUNCTIONAL PAIN COMPONENT IN ANKYLOSING SPONDYLITIS PATIENTS

E. Filatova, S. Erdes. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

**Background:** As a result of chronic inflammation, repetitive activation of primary afferent fibres changes the functional state and activity of Central nervous pathways. On this patients when describing their complaints use neuropathic pain descriptors include numbness, burning, tingling, increased pain response to a stimulus nabulivou etc.

**Objectives:** The study of chronic pain syndrome in patients with ankylosing spondylitis (AS) to identify dysfunctional component of pain (DCP).

**Methods:** Was studied 150 patients as 127 men and 23 women. The average age of 35, and 52±10,55, mean disease duration of 7.19±0.631. All the patients were performed clinical and rheumatological examination (indices BASDAI, BASFI), the assessment of pain intensity on visual analogue scale (VAS), to identify DCP were investigated neurological status with the use of questionnaires neuropathic pain DN4 and PainDETECT, and identifying the emotional-affective disorders (HADS questionnaire).

**Results:** 22 patients (14.7%) on the DN4 questionnaire revealed 4 or more points, but lesions of the somatosensory nervous system in these patients was not detected, hence 14,7% of patients were identified DCP. When comparing patients with the presence of TCS group I (22 people) and no DCP group II (128) it has been found that statistically significantly in patients in group I had higher pain intensity on VAS (6,09±1,85 vs 4,55±2,06, p=0.001, respectively); active disease BASDAI index (of 7.05±vs 1,58 4,87±2,16, p=0.001, respectively); the expression of functional impairment index BASFI (6,46±2,24 vs 4,05±2,81, p=0.001); the indicators of the questionnaire HADS in group I, consistent with the presence of clinically significant anxiety and lack of it in group II (10,09±2,86 vs 6,17±3,35, p=0.0001). However, duration of disease distinguish authentic in the groups was not (9,41±6,89 6,81 vs ±6,13 p=0,07). Correlation analysis revealed a significant relationship between DCP and the intensity of the pain in VAS back, as well as with the severity of anxiety, disease activity, functional disorders (p=0.05)

**Conclusions:** The study identified 22 patients, the presence of neuropathic pain descriptors in combination with anxiety disorders, resulting in the conclusion that, along with nociceptive component of pain in 14.7% of cases detected by the DCT. So the pain of some AS patients should be considered as a multicomponent syndrome, providing a comprehensive approach with the use of antidepressants (TCA and SSRI's).

### AB0855 IDENTIFYING PATIENTS WITH AXIAL SPONDYLOARTHRITIS BY DATA MINING MRI RADIOLOGY REPORTS

E. Reilly, A. Szachowicz, R. Sengupta. Royal National Hospital for Rheumatic Diseases, Bath, UK

**Background:** Axial Spondyloarthritis (axSpA) encompasses ankylosing spondylitis (AS) and non radiographic axSpA (nr-axSpA) as part of the ASAS classification criteria<sup>1, 2</sup>. The role of MRI is now central in identifying patients early in the disease course<sup>3</sup>, but our use of this needs to be standardised to ensure appropriate requesting and correct interpretation of MRI axSpA features.

**Objectives:** (1) To identify the MRI protocols used to investigate patients with back pain

(2) To describe the prevalence of axSpA associated spinal lesions in patients with known axSpA

(3) To describe the prevalence of axSpA associated spinal lesions in patients with back pain and their relevance in subsequently diagnosed axSpA

**Methods:** MRI reports between 4th January 2015 and 25th February 2017 containing the key words 'ankylosing spondylitis' (AS), 'bone marrow oedema' (BMO), 'spondyloarthritis' and 'sacroiliitis' were identified using a computerised word finding programme, in a tertiary referral hospital for Rheumatology.

**Results:** 194 patients had MRI features of axSpA. 60.8% were female; mean age 39.3 years (SD 13.3). 96.4% (n=187) contained the term 'sacroiliitis', with 'AS', 'BMO' and 'spondyloarthritis' in 2.6%, 0.5% and 0.5% respectively. 63.4% were referred by a rheumatologist, and 19.1% from primary care. Musculoskeletal radiologists reported 16.0%, general radiologists 37.1%, and external radiology services 46.4%. The most common MRI protocol was the inflammatory spinal protocol (ISP-MRI, 57.2%), with sacroiliac (SIJ) MRI in 17%. 87.4% ISP-MRI and 48.5% MRI SIJ were requested by Rheumatology. GPs requested more ISP-MRI than other sequences (29.7% of their total MRIs). 144 cases had a diagnosis stated on the MRI request; 100 (69.4%) had an existing diagnosis of axSpA, and 20 (13.9%) of a peripheral arthritis. In patients with known AxSpA, the most frequent findings were BMO (70.3%), and erosions (67%). Ankylosis was only seen in 4 patients. Features of axSpA were identified in 26 MRIs requested for mechanical back pain, and 11 for unrelated medical reasons. 33 cases of BMO and 29 of SIJ erosions were identified in patients who did not have a pre existing diagnosis of AxSpA, and one showed ankylosis. 16 patients went on to have a diagnosis of axSpA.

**Abstract AB0855 – Table 1.** Radiological features seen on MRI imaging, and by diagnosis

MRI finding	Frequency n (%)	Pre existing axSpA diagnosis, n (%)	Without pre existing axSpA diagnosis, Total n=44		
			peripheral arthritis, n (%)	back pain as yet undiagnosed, n (%)	alternative diagnosis, n (%)
<b>Total n</b>	194	100	20	13	11
<b>Oedema</b>	150 (77.3)	78 (70.3)	15 (13.5)	8 (7.2)	10 (9.0)
<b>Irregularity or erosions</b>	111 (57.2)	59 (67.0)	16 (18.2)	6 (6.8)	7 (8.0)
<b>Sub-articular sclerosis</b>	81 (41.8)	39 (63.9)	13 (21.3)	4 (6.6)	5 (8.2)
<b>Fatty infiltration</b>	29 (14.9)	18 (75.0)	5 (20.8)	0	1 (4.2)
<b>Corner inflammatory spinal lesions</b>	30 (15.5)	18 (69.2)	4 (15.4)	2 (7.7)	2 (7.7)
<b>Ankylosis</b>	5 (2.6)	4 (80.0)	0	1 (20.0)	0
<b>Fracture</b>	4 (2.1)	4 (100)	0	0	0
<b>Post MRI diagnosis:</b>		<b>axSpA, n (%)</b>	16 (36.4)		
		<b>Mechanical, n (%)</b>	8 (18.2)		
		<b>Seronegative arthritis, n (%)</b>	8 (18.2)		
		<b>Isolated sacroiliitis (without full criteria for axSpA), n (%)</b>	7 (15.9)		

**Conclusions:** Through data mining of MRI reports, we have found that appropriate MRI sequences are being requested when features of AxSpA are suspected. The rate of chronic features of AxSpA such as ankylosis was low, suggesting this cohort may have short disease durations. Multiple features of AxSpA were identified in patients without an existing diagnosis prior to imaging. 16 new cases of AxSpA were identified.

**AB0856 THE IMPACT OF SYSTEMIC INFLAMMATION AND RADIOLOGICAL CHANGES ON MOBILITY IN ANCHYLOSING SPONDYLITIS**

E. Russu, L. Chislari, R. Larisa, V. Cazac. *Rheumatology and Nephrology, SMPU "Nicolae Testemitanu", Chisinau, Moldova, Republic of*

**Objectives:** The purpose of the study was to investigate the relationship between disease activity, structural lesions and physical function by testing the hypothesis that the level of structural lesions contributes independently to physical impairment.

**Methods:** For this analysis, the database of Rheumatology Department was used and included 78 consecutive SA patients who have been observed for many years, implying that they have used NSAID's and DMARD for progression disease, no one has used TNF blocking agents.

**Results:** BASFI and DFI correlated significantly ( $r = 0.88$ ). The correlation coefficient for mSASSS and BASFI was 0.508 and for mSASSS and DFI equal to 0.464, suggesting a moderate correlation relationship. The correlation coefficient for the relationship between BASDAI and BASFI was equal to 0.79 and for BASDAI and DFI equal to 0.69 suggesting a moderate to significant correlation. The correlation between mSASSS and BASFI or DFI was dependent on the BASDAI level.

To further investigate the relationship between mSASSS and BASFI/DFI, concurrently adjusting for BASDAI and other covariates, a multivariate analysis was performed using GEE with BASFI or DFI as dependent variables, and mSASSS and BASDAI as covariates, concurrently adjusting for age, sex, duration of illness, HLA-B27 status and hip involvement.

Both BASDAI and mSASSS contributed independently to the BASFI and DFI explanations with significant parameter estimates. Regression coefficients describe the independent relationship between the explanatory variables and the dependent variable: in the environment, compared to a patient with mSASSS 40, a patient with the mSASSS score 50 has a BASFI of 0.57 times greater, independent of BASDAI.

All mSASSS subscripts contributed independently to the explanation of BASFI variations ( $p < 0.001$ ). Compared to the mSASSS model, which had the best result, the model with the total score of the syndesmofite, the number of the affected vertebral units, the number of vertebral vertebral units, and the model with the non-syndesmofite summary score, it was deduced that the syndesmofites are in much but not exclusively responsible for explaining variations in BASFI. A model with the syndesmofites summary score ( $p < 0.001$ ) and the non-syndesmofite ( $p = 0.002$ ) shows that both components contribute significantly to the explanation of BASFI variations. Results with DFI were similar.

Using mSASSS, the syndesmofite subservices, the affected vertebral units or vertebral vertebral units, we showed that lumbar and cervical spine involvement contributed independently and almost similarly to explaining variations in BASFI and DFI.

**Conclusions:** The study conducted by us demonstrates that the patient's physical function is not only dependent on signs and symptoms reported by the patient (activity of the disease), but also on the degree of structural lesions. Optimal AS treatment should not only include strategies aimed at removing pain, redness and fatigue, but also strategies aimed at preventing the formation and growth of syndesmofite.

**Background:** According to the 2009 ASAS classification criteria, a patient with chronic low back pain (CLBP) may be classified as axial spondyloarthritis (ax-SpA), with or without radiographic evidence of sacroiliitis, if at least one other SpA feature is present in the first case and positive HLA-B27 and at least two SpA features in the second one. There is concern about whether the classification "axial non-radiographic spondyloarthritis" (ax-SpA-nr) includes patients with a mild disease that do not require treatment or special care by rheumatology.

**Objectives:** To compare disease burden between patients fulfilling criteria for AS and ax-SpA-nr.

**Methods:** Sub-analysis of Spanish patients from the PROOF study, an international prospective observational longitudinal study conducted in rheumatology clinics. All patients who attended rheumatology clinics due to CLBP ( $\geq 3$  months, start  $< 45$  years of age) from <sup>Jan 2015</sup> to <sup>Feb 2017</sup> not previously diagnosed were consecutively included. The ASAS criteria were applied to all, with centralised image reading. Patients with AS and ax-SpA-nr were compared.

**Results:** 192 patients with CLBP were included, of whom 151 (79%) met criteria of SpA-axe, 56 (43%) of AS and 74 (57%) of ax-SpA-nr (21 patients had X-ray missing or no central reading had been done so far). The table shows the description of patients with AS and ax-SpA-nr and their comparison.

**Abstract AB0857 – Table 1**

Characteristic	AS (n=56)	ax-SpA-nr (n=74)	p

Abbreviations: m, mean; SD, standard deviation; BASDAI, Bath Ankylosing Spondylitis Disease Activity Score; ASDAS-CRP, Ankylosing Spondylitis Disease Activity Score calculated with C-reactive protein; BASFI, Bath Ankylosing Spondylitis Functional Index; SF-12, Short Form questionnaire, 12 items version; WPAI-SHP, Work Productivity and Activity Impairment Questionnaire related to disease; TNF, tumour necrosis factor.

**Conclusions:** Patients referred by CLBP to rheumatology clinics meeting ASAS criteria for AS or ax-SpA-nr differ little in terms of impact and disease activity; therefore, non-radiographic forms of ax-SpA require as much attention as classic AS.

**AB0858 IMPACT OF APPLICATION OF ASAS CRITERIA FOR AXIAL SPONDYLOARTHRITIS ON THE DIAGNOSTIC DELAY IN EGYPTIAN PATIENTS**

F.I. Abdelrahman, M. Mortada. *Rheumatology, ZAGAZIG UNIVERSITY, zagazig, Egypt*

**Background:** Diagnostic delay is a major challenge in axial spondyloarthritis (SpA). The 2009 Assessment of SpondyloArthritis international Society

classification (ASAS) criteria for axial SpA formally recognised the utility of MRI in diagnosis.<sup>1</sup> There are conflicting reports whether there had been any recent improvement in the period of diagnostic delay after application of ASAS criteria.<sup>2</sup>

**Objectives:** To evaluate the period from symptoms onset to diagnosis in Egyptian patients with axial SpA before and after application of ASAS criteria for axial SpA and to examine possible reasons for delayed diagnosis.

**Methods:** The study included all axial SpA patients attending a university tertiary referral centre for regular follow up in the period between May 2016 to November 2017. The patients were divided into 2 groups; group 1 included patients with a diagnosis of axial SpA before the beginning of 2010 (when ASAS criteria became widely available and in use) and group 2 included patients with a diagnosis of axial SpA after the beginning of 2010. A face-to-face interview was applied for both groups to take medical history, and a questionnaire that contains some clinical aspects of disease was used. Diagnosis delay was described as the gap between first SpA symptom and correct diagnosis of axial SpA. Clinical and functional assessment of axial SpA measured by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Bath Ankylosing Spondylitis Metrology Index (BASMI). The direct medical cost during years of delay (including costs of medical consultations, medications, investigations, physiotherapy and surgical treatment) had been estimated.

**Results:** As presented in table 1; more axial SpA cases were in group 2 (diagnosed after the beginning of 2010) with significantly narrower gap of delay, younger age at diagnosis, lesser number of doctor visits, lesser number of unnecessary spinal surgeries, lower total direct estimated costs and better BASDI, BASFI and BASMI.

**Abstract AB0858 – Table 1.** comparison between axial SpA patients diagnosed before and after 2010

Variable	Group 1 (n=56)(44.4%)	Group 2 (n=70) (55.6%)	p-value
<b>Delay in years:</b> <i>Mean±SD</i>	11.3±3.9	4.6±2.8	<b>0.02**</b>
<b>Sex:</b>			<b>0.3*</b>
Male:	49 (83.3)	56 (7.9)	
Female:	7 (16.7)	14 (92.1)	
<b>Age at diagnosis (years):</b> <i>Mean±SD</i>	34.9±6.4	25.8±4.5	<b>0.03**</b>
<b>Cost of delay period by \$:</b> <i>Mean±SD</i>	9879.3 ±3827.2	2373.9±881.8	<b>&lt;0.001**</b>
<b>Doctor Visits during years of delay:</b> <i>Mean±SD</i>	14.3±6	5.6±3.4	<b>&lt;0.001**</b>
<b>Spinal Surgery:</b>	34 (65.4%)	18 (34.6%)	<b>&lt;0.001*</b>
<b>Loss of work at time of diagnosis:</b>	36	7	<b>&lt;0.001*</b>
<b>BASDAI:</b> <i>Mean±SD</i>	9.1±1.4	4.3±2.2	<b>&lt;0.001**</b>
<b>BASFI:</b> <i>Mean±SD</i>	9.1±1.4	3.9±2.2	<b>&lt;0.001**</b>
<b>BASMI:</b> <i>Mean±SD</i>	8.9±1.2	2.2±2	<b>&lt;0.001**</b>

\*: Chi-square test. SD: Standard Deviation. \*\*: Independent sample t test. Significance p value<0.05.

**Conclusions:** Application of ASAS criteria for axial SpA has resulted in a significant decrease in the diagnostic gap which is reflected in a significant decrease in age at diagnosis and in the costs of unnecessary medications. On the other side, the gap is still large and more sensitive criteria are still needed.

#### SIMILARITIES AND DIFFERENCES BETWEEN NON-RADIOGRAPHIC AND RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS IN PROOF CHINA COHORT

F. Huang<sup>1</sup>, C. Bao<sup>2</sup>, Y. Fang<sup>3</sup>, L. Wu<sup>4</sup>, L. Jiang<sup>5</sup>, D. He<sup>6</sup>, J. Xu<sup>7</sup>, F. Zhang<sup>8</sup>, X. Zhang<sup>9</sup>, L. Bi<sup>10</sup>, M. Hohnik<sup>11</sup>, D. Poddubnyy<sup>12</sup>. <sup>1</sup>Chinese PLA General Hospital, Beijing; <sup>2</sup>Renji Hospital of Shanghai Jiao Tong University School of Medicine, Shanghai; <sup>3</sup>Southwest Hospital, Third Military Medical University, Chongqing; <sup>4</sup>People's Hospital of Xinjiang Uygur Autonomous Region, Urumqi; <sup>5</sup>Zhongshan Hospital affiliated with Fudan University; <sup>6</sup>Guanghua Integrative Medicine Hospital, Shanghai; <sup>7</sup>First Affiliated Hospital of Anhui Medical University, Hefei; <sup>8</sup>Peking Union Medical College Hospital, Beijing; <sup>9</sup>Guangdong General Hospital and Guangdong Academy of Medical Sciences, Guangzhou; <sup>10</sup>China-Japan Union Hospital of Jilin University, Changchun, China; <sup>11</sup>AbbVie, Ljubljana, Slovenia; <sup>12</sup>Charité Universitätsmedizin Berlin, Berlin, Germany

**Background:** National observational studies, mostly from Europe, have reported some differences between radiographic axial spondyloarthritis (axSpA) and non-radiographic axSpA (nr-axSpA).

**Objectives:** To compare demographic and clinical characteristics of patients (pts) with nr-axSpA and radiographic axSpA (ankylosing spondylitis, AS) in a Chinese subpopulation in the PROOF study.

**Methods:** PROOF is a prospective observational study evaluating clinical and radiographic outcomes in axSpA pts in rheumatology clinical practice in 29 countries over 5 years. Pts diagnosed ≤1 year before study enrollment with axSpA fulfilling ASAS classification criteria were eligible. Investigator confidence with the axSpA diagnosis was ascertained on a numeric rating scale (0–10) at enrollment and end of follow-up. Baseline characteristics are reported, including demographics and clinical characteristics (table 1). Classification as nr-axSpA or AS was according to the radiologic criterion of the modified New York criteria. If there was a disagreement in classification (nr-axSpA or AS) between a local and central reader, the radiograph was evaluated by a second central reader, who was blinded to previous assessments; the final classification was based on the decision of 2 of 3 readers.

**Results:** 464 (21.8%) pts in PROOF were enrolled in China; 307 (66.2%) were classified as AS and 157 (33.8%) as nr-axSpA according to the investigators. Confidence with the axSpA diagnosis was 9.0±1.5. The final classification based on central assessment of sacroiliac radiographs was confirmed in 372 (80%) pts included in further analyses; 301 pts (80.9%) were classified as AS and 71 (19.1%) as nr-axSpA. AS pts had longer time since diagnosis, more frequent and higher CRP elevations, and were more often male and treated with TNF inhibitors (table 1). HLA-B27 positivity and prevalence of other SpA features were comparable between the 2 groups. Most disease burden assessments were comparable, but ASDAS-CRP, BASFI, and SF-12v2 physical component score were higher in AS pts (table 1).

**Abstract AB0859 – Table 1.** Baseline Demographics and Clinical Characteristic of the Chinese PROOF Subpopulation

### AB0860 ACUTE PHASE REACTANT CHANGE IN ANKYLOSING SPONDYLITIS PATIENTS

F. Demire Aydemir<sup>1</sup>, G. Kenar<sup>1</sup>, B. Zengin<sup>1</sup>, H. Yarkan Tugsal<sup>1</sup>, S. Capar<sup>2</sup>, M. Birlik<sup>1</sup>, F. Onen<sup>1</sup>, N. Akkoc<sup>3</sup>, G. Can<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Department of Statistics, Dokuz Eylul University; <sup>3</sup>Rheumatology, Private Doctor, Izmir, Turkey

**Background:** The aim of this study is to investigate the levels of acute phase reactants (APRs) in patients with ankylosing spondylitis (AS) at the time of diagnosis and during follow-up. We also evaluated the associations between APR levels and disease activity.

**Methods:** The study included 948 patients with AS who were followed-up at Dokuz Eylul University School of Medicine Rheumatology outpatient clinic. The patients' erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels across all visits were retrospectively reviewed through the Turkbio registry and the hospital's database. Disease activity and follow-up parameters as BASDAI, ASDAS, BASFI and BASMI were taken from Turkbio visit charts. The correlation between APR and follow-up parameters were evaluated with Spearman correlation coefficient analysis.

**Results:** There were 948 AS patients (69% male, mean age 46.6±12.1 years) who fulfilled the 1984 modified New York criteria. At first visit, high levels of CRP and ESR were observed in 626 (68.5%) and 578 (64.6%) patients respectively. During follow-up 84.6% of patients had high CRP and 69.5% patients had high ESR at any visit (figure 1). However in 10% of AS patients APRs did not increase at any visits.

There was good correlation between ESR and CRP ( $r=0.666$ ,  $p<0.001$ ). A better correlation was observed at first visit between CRP and BASDAI ( $r=0.81$ ,  $p=0.23$ ) or ASDAS ( $r=0.468$ ,  $p<0.001$ ) compared to ESR and BASDAI ( $r=0.111$ ,  $p=0.02$ ) or ASDAS ( $r=0.334$ ,  $p<0.001$ ) (table 2). Compared to BASDAI, ASDAS with either ESR ( $p<0.001$ ) or CRP (*very high disease activity*- $p<0.001$ , *inactive disease*- $p=0.001$ ) had better performance in evaluating the activity of the patient in inactive and very high levels of severe disease (table 2).

**Abstract AB0860 – Table 1.** Demographic and clinical features

Age; Mean±SD (yrs)	46,6±12,1
Age at onset of illness; Mean±SD (yrs)	27,3±10,5
Age of diagnosis; Mean±SD (yrs)	34,5±12,0
Females/Males sex, n (%)	293 (%30,9)/655 (%69,1)
HLA-B27 Positive/Negative/Unknown	237 (%25)/100 (%10,5)/611 (%64,5)

**Abstract AB0860 – Table 2.** Correlation between first visit ESR/CRP and disease activity parameters

	ESR		CRP	
	r	p	r	p
BASDAI	0111	0,02	0,81	0023
BASMI	0123	0003	0205	0,00
BASFI	0219	0,00	0224	0,00
ASDAS	0334	0,00	0468	0,00

**Abstract AB0860 – Figure 1**

**Abstract AB0860 – Figure 1.** Ven diagram of patients that elevation only ESR/CRP or with both elevation together at any visit

**Conclusions:** In over 80% patients with AS had elevated levels of CRP, the most frequently used laboratory parameter, during follow-up. CRP is well correlated with ESR, and disease activity parameters as BASDAI, ASDAS, BASFI and BASMI. Compared to BASDAI; ASDAS had better agreement between activity and APRs. Interestingly, in 10% of AS patients APRs did not increase in follow-up.

SANDOVAL-GARCIA<sup>13</sup>, B. Mota Mondragón<sup>14</sup>, L. Silveira Torre<sup>15</sup>, N. SANTANA<sup>16</sup>, F. MERAYO<sup>17</sup>, M. MARADIAGA-CECENA<sup>18</sup>. <sup>1</sup>Rheumatology, Hospital General de Mexico, Mexico, Mexico; <sup>2</sup>HGM, CDMX, -; <sup>3</sup>Rheumatology, UNAM; <sup>4</sup>Rheumatology, Hospital General de Mexico, CDMX; <sup>5</sup>UAG, Guadalajara; <sup>6</sup>Rheumatology, CMN LA RAZA, CDMX, Mexico; <sup>7</sup>Hospital Regional General, CD; <sup>8</sup>Hospital Civil de Guadalajara, Guadalajara, -; <sup>9</sup>UNIVERSIDAD AUTONOMA DE CHIHUAHUA; <sup>10</sup>HOSPITAL GENERAL, CHIHUAHUA; <sup>11</sup>HOSPITAL CENTRAL MILITAR, CDMX; <sup>12</sup>HOSPITAL BELISARIO DOMINGUEZ, TIUXTLA GUTIERREZ; <sup>13</sup>HOSPITAL GENERAL DEL ESTADO SONORA, HERMOSILLO; <sup>14</sup>Rheumatology, HOSPITAL CENTRAL MILITAR; <sup>15</sup>Rheumatology, Instituto Nacional de Cardiología, CDMX; <sup>16</sup>HOSPITAL DE ESPECIALIDADES MORELOS, CHIHUAHUA; <sup>17</sup>INSTITUTO NACIONAL DE LA NUTRICION, CDMX; <sup>18</sup>HOSPITAL GENERAL DE YUCATAN, CULIACAN, Mexico

**Background:** The ASAS-HI is a new instrument based in the International Classification of Functioning, Disability and Health to assess the impact of axSpA; ASAS-HI has been validated in Mexican patients.

**Objectives:** To investigate the status of health in Mexican patients with axSpA using the ASAS-HI

**Methods:** This is multicenter, cross-sectional study of 377/423 patients with axSpA (ASAS criteria) referred by 64 rheumatologists with private or institutional practice across the country in a period of six months. Sociodemographic and clinical data were collected at each site and analysed centrally.

**Results:** The ASAS imaging arm were fulfilled 87.5% and the clinical by 61.8%; HLA-B27 was positive in 80.1%; 71.6% were males; 51.9% received bDMARDs. Mean ages at onset and diagnoses were 25.8 (9.9) and 32.8 (11.7) years; median age was 41.6 (13.7) years. The correlation between ASAS-HI and BASDAI, BASFI, and EQ-5D was significant. ASAS-HI mean score was 6.4 (4.2); the cut off was six; values below six meant good health, which corresponded to 203 (53.84%) patients. Univariate analysis disclosed significant differences between groups in variables that were significant in the regression models (see below) and in health care coverage, enthesitis, joint counting, glucocorticoids, HLA-B27, sacroiliitis, BASMI, and ASDAS. In the multivariate analysis, two models were associated ASAS-HI: 1) sex, education, comorbidities, joint surgery, and physician global assessment; 2) BASDAI, BASFI, and EQ-5D

**Conclusions:** ASAS-HI cut off of six identified good health in 46.15% of patients with axSpA. ASAS-HI correlated with other measures of disease activity, functioning, and quality of life. In multivariate analysis, ASAS-HI associated with those measures as we all as with demographic and clinical variables.

**AB0862 ANTERIOR THORACIC FATTY CORNER LESIONS ARE USEFUL IN AXIAL SPONDYLOARTHRITIS (SPA) DIAGNOSIS—DATA FROM A MULTICENTER BACK PAIN-MRI COHORT IN HONG KONG**

H.Y. Chung<sup>1</sup>, S.W.R. Yiu<sup>1</sup>, H.H.L. Tsang<sup>2</sup>. <sup>1</sup>The University of Hong Kong, <sup>2</sup>QUEEN MARY HOSPITAL, Hong Kong, Hong Kong

**Background:** A fatty corner lesion (FCL), as defined by fat infiltration at the vertebral corner in T1 Magnetic Resonance Imaging (MRI) sequence, has been reported to be useful in Spondyloarthritis (SpA) diagnosis.

**Objectives:** Our objective is to systematically evaluate the diagnostic utility of FCLs in a large, multicenter back pain-MRI cohort in Hong Kong.

**Methods:** Three hundred and one patients with back pain were recruited from 3 rheumatology centres. Clinical, biochemical and radiological parameters were collected and all patients underwent a whole spine and sacroiliac (SI) joints MRI. FCLs from C4 to L5 levels were scored. Results were compared to expert-diagnosed axial SpA to determine the usefulness of FCLs in disease diagnosis.

**Results:** Anterior FCLs of whole or thoracic spine were found to be useful in axial SpA diagnosis. (AUC 0.622; p=0.003, AUC 0.640; p=0.001 respectively) Applying FCLs to the Modified New York (MNY) criteria and Assessment of SpondyloArthritis international Society (ASAS) axial SpA criteria, a minimum of 5 FCLs at whole spine level had a sensitivity of 66.4% and 91.6%, specificity of 98.4% and 91.9% respectively. Applying a minimum of 3 FCLs at thoracic spine level to the MNY criteria and ASAS axial SpA criteria yielded a sensitivity of 68.5% and 92.0%, specificity of 95.2% and 93.5% respectively. Three FCLs improves both classification criteria.

**Conclusions:** FCLs are useful in axial SpA diagnosis. A minimum of 3FCLs at the thoracic level is useful for the disease diagnosis.

**AB0863 ANALYSIS OF THE FREQUENCY OF UVEITIS IN SPONDYLOARTHRITIS PATIENTS AND ASSOCIATIONS WITH CLINICAL PARAMETERS OF THE DISEASE**

I.M.S. Vale, M.D.S. Mastella, R.B. Trevisol, M.M. Pereira, M.J. do Carmo, I. A. Pereira. Universidade do Sul de Santa Catarina (UNISUL), Florianópolis, Brazil

**Background:** Acute anterior uveitis is the most common extra-articular manifestation of spondyloarthritis (SpA). The ocular inflammation in SpA is restricted to the uvea, usually unilateral and in some cases may precede the clinical characteristics of SpA.

**Objectives:** The aim of this study is to analyse if the presence of uveitis is associated with a different clinical manifestation, laboratorial, radiological and therapeutic among spondyloarthritis patients.

**Methods:** This was an observational retrospective study with 153 patients with spondyloarthritis attended in the period from 1997 to 2017 in Florianópolis, Brazil. It was analysed demographical, laboratorial, clinical and therapeutic data in spondyloarthritis patients with or without uveitis.

**Results:** 26,8% of the patients with spondyloarthritis presented uveitis. The presence of complications was rare, with cataract occurring in only four patients and glaucoma in two of them. A higher frequency of acute anterior uveitis in males (p=0.06) was observed in patients with a family history (p=0.19) and HLA-B27 positive (p=0.14). Patients with spondyloarthritis and uveitis more frequently used anti-TNF (p=0.04) and presented sacroiliitis on imaging tests (p=0.02). There was no association between uveitis and cardiovascular (p=0.44), cutaneous (p=0.13) or gastrointestinal involvement (p=0.10).

**Conclusions:** Uveitis in patients with spondyloarthritis is common, predominantly in males and more frequently, in HLA-B27 positive patients. Ocular manifestation in spondyloarthritis has a low degree of complication when compared to uveitis from other etiologies. The use of immunobiological agents such as anti-TNF is common in patients with uveitis.

**AB0864 THE IMPACT OF DISEASE ACTIVITY, STRUCTURAL DAMAGE, AND FATIGUE ON PHYSICAL FUNCTION IN PATIENTS WITH ANKYLOSING SPONDYLITIS: DIFFERENCES IN EARLY AND LATE DISEASE**

J. He<sup>1,2</sup>, I. Sari<sup>1</sup>, R. Inman<sup>1</sup>, N. Haroon<sup>1</sup>. <sup>1</sup>Rheumatology, Toronto Western Hospital, Toronto; <sup>2</sup>Rheumatology, Western University, London, Canada

**Background:** In patients with ankylosing spondylitis (AS), the physical function impairment caused by the disease is among the biggest concerns for both patients and clinicians. Previous studies have shown that disease activity and structural damage are the main underlying causes for physical function impairment. There is accumulating evidence that suggests fatigue as well contributes to functional limitations. However, the differential impact of these factors on physical function at early and late stage of disease remains unclear.

**Objectives:** Study the strength of association in AS patients with varying disease duration, between physical function and the three potential determinants of interest: disease activity, structural damage, and fatigue.

**Methods:** AS patients satisfying the modified New York criteria were followed from 2003 to 2017. Patients completed a standardised annual protocol including demographic and clinical factors, with radiographic data collected biennially. Baseline physical function (BASFI) was analysed for association with factors including disease activity (BASDAI), radiographic changes (mSASSS), and fatigue (FSS). The same analysis was conducted again with patients sub grouped with respect to disease duration (<5 years, 5–9 years, 10–20 years, >20 years), and again with respect to change in BASFI between the first and last patient visit. Multivariable regression analysis was performed to identify independent predictors of physical function at baseline and the change with time.

**Results:** A total of 611 patients were followed and completed the standard protocol (mean age at initial visit 38.2 years; 74% male; 76.5% HLA-B27+). At baseline BASFI was independently associated (table 1) with BASDAI (p<0.0001), CRP (p<0.0001), mSASSS (p<0.0001), and FSS (p<0.0001). In the disease duration subgroup analysis, BASFI was independently associated with BASDAI (p<0.05) and mSASSS (p<0.05) in all disease durations, and with FSS in subgroups with disease duration of 5 years or greater (p<0.05). In the longitudinal analysis, change in BASFI was independently associated with changes in BASDAI (p<0.0001) and FSS (p<0.05), but not with change in mSASSS (p=0.283).

**Abstract AB0864 – Table 1**

	Univariable analysis		Multivariable analysis	
	$\beta$ (95% CI)	P	$\beta$ (95% CI)	P
Sex	0.001 (–0.063–0.066)	0.975	–0.01 (–0.07–0.05)	0.776
CRP	0.282 (0.200–0.364)	<0.0001	0.15 (0.09–0.21)	<0.0001
BASDAI	0.728 (0.672–0.783)	<0.0001	0.62 (0.51–0.73)	<0.0001
mSASSS	0.294 (0.204–0.378)	<0.0001	0.24 (0.18–0.31)	<0.0001
BASDAI	0.61 (0.54–0.67)	<0.0001	0.06 (–0.6–0.17)	0.313
Q1				

**Conclusions:** The study demonstrated that disease activity and structural changes consistently contributes to physical function impairment in both early and late stages of disease. Fatigue does not associate with physical function at early stages of the disease, but it increases in contribution to functional impairment as disease duration increases.

#### AB0865 DO ASAS, ASDAS AND BASDAI THERAPY RESPONSE EVALUATION TRANSLATE THE SAME INFORMATION?

M. Eusébio<sup>1</sup>, J.L. Gomes<sup>2,3</sup>, M. Bernardes<sup>4</sup>, P. Pinto<sup>5</sup>, H. Santos<sup>6</sup>, J. Tavares-Costa<sup>7</sup>, J. Dias<sup>8</sup>, S. Pimenta<sup>4</sup>, L. Domingues<sup>3</sup>, C. Crespo<sup>3</sup>, S. Maia<sup>3</sup>, F. Martins<sup>1</sup>, J. C. Branco<sup>2,3</sup>, F.M. Pimentel-Santos<sup>2,3</sup>. <sup>1</sup>SPP, Portuguese Rheumatology Society; <sup>2</sup>Rheumatology, HOSPITAL EGAS MONIZ – CHLO; <sup>3</sup>CEDOC, NOVA Medical School, NOVA University of Lisbon, Lisbon; <sup>4</sup>Rheumatology, Centro Hospitalar São João, Porto; <sup>5</sup>Rheumatology, Centro Hospitalar Vila Nova de Gaia/Espinho, Gaia; <sup>6</sup>Rheumatology, Instituto Português de Reumatologia, Lisbon; <sup>7</sup>Rheumatology, Unidade Local de Saúde do Alto Minho, Ponte de Lima; <sup>8</sup>Rheumatology, Centro Hospitalar Médio Tejo, Torres Novas, Portugal

**Background:** The ASAS-EULAR recommendations for the continuation of biological Disease-Modifying Anti-rheumatic Drugs (DMARD) suggest the evaluation of patients after at least 12 weeks of treatment by either the Ankylosing Spondylitis (AS) Disease Activity Score – C reactive protein (ASDAS-CRP) or by the Bath AS Disease Activity Index (BASDAI). For ASDAS-CRP, a Minimal Clinical Important Difference (MCID)  $\geq 1.1$  is necessary, while for the total BASDAI score a 50% reduction or a change of  $\geq 2.0$  points is considered clinically relevant. In clinical trials, the Assessment in Ankylosing Spondyloarthritis (ASAS) response criteria – ASAS 20, ASAS 40 and ASAS 70 – are still the most frequent primary outcome measures to evaluate improvement in treatment response. However, in clinical practice the BASDAI is still routinely used.

**Objectives:** The aim of this work was to assess the concordance/agreement between different therapeutic outcome measures, such as the ASAS response criteria,  $\Delta$ ASDAS-CRP and BASDAI 50.

**Methods:** Data from 54 patients who fulfilled the modified New York criteria for AS were collected at baseline, weeks 2 and 14 post-treatment with Adalimumab. Pearson's correlation (PCCs) and the Cohen's Kappa coefficients were calculated for the three scores.

**Results:** A strong correlation was found between the three scores throughout the visits:  $\rho = -0.676$  for ASDAS/ASAS,  $\rho = -0.807$  for ASAS/BASDAI, and  $\rho = 0.786$  for BASDAI/ASDAS (all PCCs with  $p < 0.001$ ). Additionally, when the categorization in different disease activity states and response levels was performed, PCCs revealed significant concordance/agreement between the three scores' cut-offs (see table 1).

The individuals categorised as responders, by either BASDAI50 or  $\Delta$ ASDAS  $\geq 1.1$ , have shown similar clinical characteristics (Erythrocyte Sedimentation Rate, CRP, AS Quality of Life Scale and Bath AS Functional Index).

Importantly, when more stringent measures of ASAS response criteria and ASDAS were used (i.e. ASAS 70 and ASDAS  $\geq 2.1$ ) the agreement with BASDAI values decreased.

**Abstract AB0865 – Table 1.** Summary information of the Agreement and Cohen's kappa.

Concordance/agreement	n	Agreement	Cohen's $\kappa$	p-value
$\Delta$ ASDAS $\geq 1.1$ and ASAS $\geq 0$	130	76.92%	0.496	<0.001†
$\Delta$ ASDAS $\geq 1.1$ and ASAS $\geq 40$	130	74.62%	0.492	<0.001†
$\Delta$ ASDAS $\geq 1.1$ and ASAS $\geq 70$	133	57.14%	0.259	<0.001†
$\Delta$ ASDAS $\geq 2.1$ and ASAS $\geq 0$	130	61.54%	0.310	<0.001†
$\Delta$ ASDAS $\geq 2.1$ and ASAS $\geq 40$	130	73.08%	0.462	<0.001†
$\Delta$ ASDAS $\geq 2.1$ and ASAS $\geq 70$	133	75.19%	0.365	<0.001†
BASDAI50 and ASAS $\geq 0$	150	82.67%	0.638	<0.001†
BASDAI50 and ASAS $\geq 40$	152	84.21%	0.687	<0.001†
BASDAI50 and ASAS $\geq 70$	156	61.54%	0.301	<0.001†
BASDAI50 and $\Delta$ ASDAS $\geq 1.1$	134	79.85%	0.571	<0.001†
BASDAI50 and $\Delta$ ASDAS $\geq 2.1$	134	64.93%	0.351	<0.001†

†p-value < 0.05, n: number of visits

**Conclusions:** Our results suggest that the ASAS response criteria,  $\Delta$ ASDAS-CRP and BASDAI 50 report the same clinical information. Hence, the clinician's decision should still be consistent independently of the score adopted. However, this study also highlights the importance of establishing a new and more stringent BASDAI cut-off, in alignment with ASDAS-CRP  $\geq 2.1$  and ASAS 70.

#### AB0866 ADVANCED METROLOGY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: LUMBAR OR THORACIC +LUMBAR MEASUREMENTS FOR SPINAL MOBILITY ASSESSMENT?

I.C. Aranda-Valera<sup>1</sup>, L. Garcia-Luque<sup>2</sup>, S. Alcaraz-Clariana<sup>2</sup>, J.L. Garrido-Castro<sup>2</sup>, I. Martinez-Sanchez<sup>2</sup>, C. Gonzalez<sup>2</sup>, P. Gardiner<sup>2</sup>, P.M. Machado<sup>4</sup>, E. Collantes<sup>1</sup>, on behalf of iMaxSpA Study Group. <sup>1</sup>HU Reina Sofia; <sup>2</sup>IMIBIC, Cordoba, Spain; <sup>3</sup>WHSC, Londonderry; <sup>4</sup>UCL, London, UK

**Background:** Advanced technologies for measuring human mobility have recently emerged: motion capture, inertial measurement units (IMU) and wearable devices. Some of them are used for mobility assessment of rheumatic patients.<sup>1</sup> Certain devices analyse only lumbar mobility of the patients. Axial Spondyloarthritis (axSpA) reduces spinal mobility at all levels and not only at the lumbar level.

**Objectives:** To analyse what is the contribution of the thoracic spine to spinal mobility, and if this contribution should be taken into account in the metrological assessment of patients with axSpA.

**Methods:** 20 patients with axSpA and 20 age, BMI and sex-matched healthy subjects were recruited. An IMU sensor-based system (ViMove©) was used to measure spinal mobility. This system uses two IMU sensors and the angle between both is obtained in real time. Two tests were recorded: one with the recommended anatomical location (pelvis and L1) and another one aimed at combining lumbar +thoracic movement (pelvis and T3). Conventional metrology, radiographic structural damage (axSpA patients) and PROs were also collected.

**Results:** The table shows the results obtained for measuring only lumbar or lumbar +thoracic mobility, in both groups. The contribution of the thoracic spine is expressed in% of the total movement. Pearson correlation coefficients (only for patients) with conventional metrology (BASMI), PRO questionnaires (BASDAI, BASFI and ASQoL) and structural damage (mSASSS) scores are also presented.

**Abstract AB0866 – Table 1**

	Anterior Flexion	Extension	Lateral Left Flexion	Lateral Right Flexion	Rotation Left	Rotation Right

mSASSS	-0.74**/ -0.76**	0.49/0.59	0.74**/0.56	-0.69†/ -0.78**	0.07/ 0.64*	-0.28/- 0.47

\*\*\*p < 0.001; \*\*p < 0.01; \*p < 0.05.

**Conclusions:** Thoracic +Lumbar results reflect better the spinal mobility impairment of axSpA patients compared to lumbar spine assessments only. Compared to isolated lumbar spine assessment, the combined assessment showed better correlations with conventional metrology, disease activity, physical function, health-related quality of life and spinal structural damage. Despite this, the magnitude of the differences is not enough to reject the use of a system that only considers assessment of lumbar spinal mobility.

**AB0867 AXIAL SPONDYLOARTHRITIS POSTURE ASSESSMENT USING INERTIAL SENSORS**

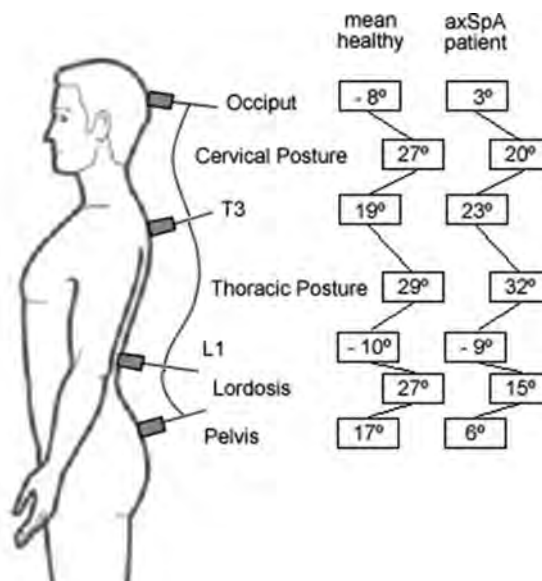

J.L. Garrido-Castro<sup>1</sup>, I.C. Concha-Aranda<sup>2</sup>, P. Gardiner<sup>3</sup>, P.M. Machado<sup>4</sup>, J. Williams<sup>5</sup>, E. Collantes-Estevéz<sup>2</sup>, on behalf of iMaxSpa Study Group. <sup>1</sup>IMIBIC; <sup>2</sup>HURS, Cordoba, Spain; <sup>3</sup>WHST, Londonderry; <sup>4</sup>UCL, London; <sup>5</sup>BU, Bournemouth, UK

**Background:** Axial Spondyloarthritis (axSpA) often causes spinal deformity in patients, most commonly a flexed kyphotic posture. In the early stages a flattening of the lumbar spine or reduced lordosis may become apparent. Kyphosis of the thoracic and cervical spine is also common in severe cases, resulting in an increased 'tragus to wall distance' as clinically assessed in the BASMI score. No other measurement related to posture is routinely recorded in clinical practice. Inertial Measurement Units (IMU) is a new technology that can measure angles of anatomical regions where the sensor is located.

**Objectives:** To compare the spinal curvature of axSpA and healthy individuals to analyse if there are any significant differences between them and to correlate these with conventional assessment variables.

**Methods:** 20 axSpa patients and 20 healthy age, BMI and sex matched controls, were recruited. An IMUs system (ViMove©) was used to obtain angles at key points along the spine. Sensors were located at Pelvis, L1, T3 and occiput (figure 1). Calibrated angles for all the participants were obtained with the subject in quiet standing position looking to a point in front of her/him. PRO questionnaires (only patients) and metrology for axSpA (both groups) were also assessed. ROM for cervical and lumbar spine was also measured using IMUs.

Posture. Lordosis angle shown a good correlation with mobility measured by Schöber and by IMU system, especially for flexion movements. Pelvis angle correlates better than L1 angle with all mobility variables. For cervical angles, occiput angle appears to be the best indicator for functional assessment. Thoracic angle is very similar between patients and healthy subjects. Figure represents the location of sensors with mean angles obtained by healthy group and the worst patient of axSpA group.

Abstract AB0867 – Figure 1

Abstract AB0867 – Table 1

	Pelvis	Lordosis	L1	Thor. Posture	T3	Cerv. Posture	Occiput

Rotation							

Results in degrees(standard deviation). Pearson correlations: \*p<0.05; \*\*p<0.01; \*\*\*p<0.001

**Results:** Greater values of posture angles were obtained in healthy controls. Despite this, differences where significant (p<0.05) only for Lordosis and Cervical

**Conclusions:** IMU based sensors are a useful new tool for the assessment of axSpA patients. This is the first formal evaluation of posture in axSpA and seems to be a promising tool in the functional evaluation of axSpA patients. More studies (reliability, feasibility, sensitivity to change, etc.) are needed for validating these measures.

\*p<0.05, \*\*p<0.01, \*\*\*p<0.001

loss function. Myotonometry is being used to quantify stiffness muscles in a valid and reliable way.

**Objectives:** To measure and compare the stiffness in the erector spinae muscles of axSpA patients and healthy subjects to analyse if there are any significant differences between them.

**Methods:** 20 axSpA patients and 20 healthy subjects matched in age, BMI and sex, were recruited. The stiffness of the lumbar erector spinae (ES) muscles was assessed at L4–5 using myotonometry (MyotonPRO®) (figure 1). Measures were obtained twice in the left and right muscles, in a first test and five minutes later. PRO questionnaires, radiographic structural damage and metrology for axSpA were also assessed. Lumbar spinal mobility was also measured using an inertial sensor system (ViMove®).

**Results:** No statistical differences were found between left and right muscles neither after five minutes, so the mean values were used for analyses. All muscular measures, except Decrement showed statistically significant differences between groups. The table shows results of muscular stiffness parameters analysed, statistical differences in all parameters between groups and correlations of these parameters with conventional metrology, patient reported questionnaires (only patients) and structural damage. For control subjects, the only significant correlation was between stiffness and age. However in the axSpA patients, the myoton readings correlated with mobility measures, especially with BASMI, frontal flexion (not extension), lateral flexion and rotation, measured with the inertial sensors system. Some correlations ( $p < 0.05$ ) were also found for BASFI and BAS-G but not for BASDAI or ASQoL.

Abstract AB0868 – Figure 1

**Conclusions:** axSpA increases lumbar muscle stiffness with respect to healthy individuals. Muscle stiffness, as measured by myotonometry, was related to loss of movement and this could be contributing to a loss of function independently of structural damage and inflammation in axSpA. These new outcome measures could be helpful for understanding the evolution of the disease and for the functional assessment.

#### AB0869 PREVALENCE OF SPONDYLOARTHRITIS IN PATIENTS WITH ANTERIOR UVEITIS

K. Bubová<sup>1</sup>, M. Gregová<sup>1</sup>, K. Zegzulková<sup>1</sup>, K. Pavelka<sup>1</sup>, J. Heissigerová<sup>2</sup>, L. Šenolt<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Institute of Rheumatology, First Faculty of Medicine, Charles University; <sup>2</sup>Department of Ophthalmology, First Faculty of Medicine, Charles University and General University Hospital in Prague, Prague, Czech Republic

**Background:** Anterior uveitis (AU) is a common extraarticular manifestation in spondyloarthritis (SpA). The disease can precede the typical axial and peripheral features. Additionally, some studies had described the imaging signs of sacroiliac involvement in patients with AU lacking chronic back pain.

**Objectives:** The aim of this study was to examine patients with AU, to determine whether the patients already fulfil criteria for axial and/or peripheral SpA and to stratify risk factors for SpA development.

**Methods:** We recruited 27 patients without prior rheumatologic diagnosis who developed at least one episode of AU. The clinical data were collected and

rheumatology examinations were performed by trained rheumatologists. Magnetic resonance imaging (MRI) of sacroiliac joints (SIJ) was read by trained rheumatologist who was blinded to the patient data. Patients were further divided into SpA subsets (axial: imaging and clinical arm and peripheral SpA) fulfilling The Assessment of SpondyloArthritis international Society (ASAS) classification criteria<sup>1</sup> and non-SpA subset. The ASAS modified Berlin algorithm for diagnosis of axial SpA<sup>2</sup> (axSpA) was also applied.

**Results:** Bone marrow oedema (BME) was found in 63.0% (n=17) of all patients with AU, however 40.7% (n=11) had highly suggestive BME<sup>3</sup> corresponding to typical findings in sacroiliitis. Altogether, 22.2% (n=6) referred inflammatory back pain, 48.1% (n=13) referred non-inflammatory back pain and 29.6% (n=8) did not refer back pain. The diagnosis of SpA was confirmed in 44.4% (n=12) of all patients with AU, 33.3% (n=9) patients fulfil the imaging arm and 7.4% (n=2) fulfil the clinical arm of ASAS classification criteria for axSpA, 7.4% (n=2) patients fulfil ASAS classification criteria for peripheral SpA (one patient fulfil both axial and peripheral criteria). The diagnosis of axSpA according to the ASAS modified Berlin algorithm was confirmed in 37.0% (n=10) patients. Analysis of clinical characteristics showed significant difference between Ankylosing Spondylitis Disease Activity Score (ASDAS) in SpA vs. non-SpA (1.5±0.7 vs 0.7±0.6,  $p=0.01$ , respectively), and remained significant in axSpA and also in those fulfilling only imaging arm of axial SpA (i-axSpA) (1.4±0.7, 1.3±0.7 vs. 0.7±0.6,  $p=0.01$ ,  $p=0.04$ , respectively). The levels of CRP were significantly higher in SpA and axSpA compared to non-SpA subsets (8.3±10.5, 7.1±10.1 vs. 1.8±1.6 mg/L,  $p=0.02$ ,  $p=0.05$ , respectively). Presence of back pain was increased in SpA and similarly in axSpA as well as i-axSpA compared to non-SpA subsets (91.7%, 100%, as well as 100% vs. 53.3%,  $p=0.04$ ,  $p=0.01$ ,  $p=0.02$ , respectively). Furthermore inflammatory back pain was more frequently described in axSpA and i-axSpA compared to non-SpA subsets (45.5%, 44.4% vs. 6.7%,  $p=0.05$ ,  $p=0.01$ , respectively).

**Conclusions:** More than one third of patients with anterior uveitis fulfilled the criteria for axial or peripheral SpA. Furthermore, these patients had significantly higher presence of back pain, ASDAS and serum CRP levels. Inflammatory back pain was significantly increased in patients classified as axSpA.

#### AB0870

#### THIRTEEN-YEAR CLINICAL FOLLOW-UP OF SPONDYLOARTHRITIS PATIENTS: DATA FROM THE REGISPONSER DATABASE

L. Pérez Sánchez<sup>1,2,3</sup>, C. López<sup>1,2,3</sup>, P. Font<sup>1,2,3</sup>, L. Bautista<sup>1,2,3</sup>, M. L. Ladehesa<sup>1,2,3</sup>, I. Gómez<sup>1,3</sup>, A. Escudero<sup>1,2,3</sup>, E. Collantes<sup>1,2,3</sup>, M.C. Castro<sup>1,2,3</sup>. <sup>1</sup>Reina Sofía University Hospital of Córdoba; <sup>2</sup>IMBIC; <sup>3</sup>University of Córdoba, Córdoba, Spain

**Objectives:** To describe the clinical characteristics of the SpA patients included in the REGISPONSER database during 13 years of follow-up, regarding the evolution of the clinical manifestations and the treatment used.

**Methods:** An observational and analytical study of a retrospective cohort was carried out, in which 78 patients were analysed at the Reina Sofía University Hospital of Córdoba for the first time in the year 2004/05. The last visit registered was reviewed during the years 2016/17. Data about his clinical condition, including extra-axial manifestations, and treatment was collected.

**Results:** Seventeen out of 78 SpA patients included in the registry were lost. The characteristics of this cohort are shown in table 1. Recurrence of uveitis was observed in 10 out of 14 (71.4%) patients ( $p < 0.001$ ), with a low recurrence at the end of the follow-up (5%). At the time of inclusion, uveitis was not present in 45 SpA patients, however was present in 8 of them (17.8%) during follow-up. Three out of the 15 patients who had history of lower limbs peripheral arthritis in the first registry, presented new flares at the end of the study, showing a low level of recurrence (3%). During follow-up, enthesitis was present in 8 out of 45 SpA patients (17.8%) who didn't have a previous history of enthesitis. In addition, only one episode of dactylitis was detected from the 55 SpA patients who didn't have a previous history of dactylitis. The last CRP value was mean of 5.90 (8.13) mg/dl. Besides, three patients required placement of a hip prosthesis during follow-up. At last visit, we found a response to NSAIDs in 54 patients (88.5%), 33 of them (61.1%) with daily treatment. Biological therapy was present in 25% of the patients,<sup>15</sup> showing a mean time of 18.8 (7.4) years from the appearance of the first symptoms until their indication. A good response was achieved in 50% of

patients with the first biologic indicated. Loss of efficacy was the most frequent cause (62%) of therapy change. Currently golimumab and etanercept are the most commonly used, prescribed in 5 (33%) and 4 (26%) patients respectively.

**Abstract AB0870 – Table 1.** Baseline characteristics of the cohort (first recorded visit) (N=78)

Type of SpA N(%)	AS 78 (100%)	Inflammatory back pain (%)	75 (96.2%)
HLA-B27 + N(%)	70 (89.6%)	Sacroiliitis (NY criteria) N (%)	Mild: 8 (10.3%) Moderate: 25 (32.1%) Severe: 45 (57.7%)
Sex N (%)	Male 67 (85.9%) Female 11 (14.1%)	CRP Mean(DS) mg/dL	12.2 (13.4)
Age Moment of registration	48 (9.7)	Extra-axial manifestations	19 24.7% 19 (24.4%) 34 (43.6%)
Start of symptoms	25.9 (10.2)	Uveitis	6 (7.7%)
Moment of the diagnosis	35.01 (10.3)	Lower limbs peripheral arthritis	
Mean (DS) years		Enthesitis	
		Dactylitis N(%)	
Time of evolution	13 (9.2)	Hip prosthesis N (%)	5 (6%)
Diagnosis-inclusion in the registry			

**Conclusions:** The results obtained suggest that the follow-up of a cohort of patients with spondyloarthritis in a specialised monographic medical centre allows a control of the symptoms, with a low recurrence of extra-axial manifestations. We can conclude from this study that most patients with spondyloarthritis (75%) could have good control of their disease with NSAIDs in the long term.

**AB0871 PREDICTIVE VALUES OF INFLAMMATORY LOW BACK PAIN, POSITIVE HLA B 27 ANTIGEN, INCREASED C REACTIVE PROTEIN, POSITIVE MAGNETIC RESONANCE AND OTHER FEATURES IN AXIAL SPONDILOARTHRITIS (SPA). A PROSPECTIVE 2 YEARS FOLLOW UP**

L.Y. Komsalova<sup>1</sup>, A. Valdivia<sup>2</sup>, P.M. Salinas<sup>3</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Epidemiology and preventive medicine; <sup>3</sup>Radiology department, Hospital Marina Salud, Denia, Spain

**Background:** Diagnosis of Spondyloarthritis remains challenging in the daily practise. Inflammatory back pain might be a good tool for early diagnosis.

**Objectives:** To analyse sensitivity, specificity and predictive values of inflammatory back pain (IBP), positive HLA B27 antigen, increased C-reactive protein (CRP), positive sacroiliac joints (SI) magnetic resonance (MRI) imaging, additional features (AF) such as peripheral arthritis, dactylitis, psoriasis, uveitis, inflammatory bowel disease (IBD) and familiar history (FH) and assess probabilities to develop SPA.

**Methods:** We prospectively collected and follow up 82 patients referred to our department with suspicion of SPA from September 2014 to December 2016. Data such as IBP, HLA B27, additional features, familiar history of SPA, increased CRP, sacroiliac x-Rays and sacroiliac MRI imaging was performed for each patient. Each MRI image was separately and independently evaluated by rheumatologist and radiologist.

**Results:** The average age in our study was 39.8 years with male/female ratio 0.4/1. 37 (45.1%) patients were diagnosed with axial SPA. Radiographic sacroiliitis had only 5 (6.1%) patients. AF had 21 (25.6%) patients. IBP was found in 36 (43.9%) patients, positive HLA B 27 antigen in 24 (29.3%) and increased CRP in 22 (26.8%). Sacroiliac joints (SI) MRI images were assessed as clearly positive if patients had more than 2 highly specific for SPA bone marrow oedema (BME) lesions, at least 3 fatty lesions and more than 1 erosion, positive MRI image if patients had at least 2 highly specific BME lesions, and clearly negative MRI images if patients had not got any of those features. We found 83.78% sensitivity and 88.89% specificity for IBP, 37.84% sensitivity and 80.95% specificity for positive HLA B27 antigen, 43.24% sensitivity and 88.1% specificity for increased CRP. AF such as such as peripheral arthritis, dactylitis, psoriasis, uveitis and IBD, evaluated together reached sensitivity 37.84% and specificity 84.44%. Positive FH only contributed to the diagnosis with 13.51% sensitivity, but showed higher specificity (84.44%). Sensitivity for positive SIJ MRI imaging were poor (51.35%) but reached excellent specificity (100%). Predictive values in our study were as follows: 86.11% predictive positive values (PPV) and 86.96% predictive negative value (PNV) for IBP, 63.64% PPV and 59.65% PNV for HLA B27, 76.19% PPV and 63.79% PNV for increased CRP, 66.67% PPV and 62.30% PNV for AF.

Positive FH contributed to the diagnosis with 66.67% PPV and 62.30% PNV. Positive MRI reached 100% PPV and showed high PNV –71.43. Multivariate analysis displayed 81.8% likelihood to be diagnosed for SPA if only IBP without AF at the onset of the diagnosis and 94.8% if both IBP and AF were presented.

**Conclusions:** At the onset, IBP may be a good indicator for SPA with high sensitivity and acceptable specificity. Additional feature such as peripheral arthritis, dactylitis, psoriasis, uveitis and IBD might increase the possibility of SPA. HLA B27 antigen, increased CRP and FH brings low sensitivity for SPA nevertheless, specificity is better. Positive SI MRI imaging is highly specific but lacks sensibility. Normal SI radiography at the onset does not rule out diagnosis of SPA.

**AB0872 QUANTIFERON TB GOLD TEST IN DIAGNOSIS OF LATENT TUBERCULOSIS INFECTION AMONG A MOROCCAN POPULATION WITH SPONDILOARTHRITIS**

J. Eddarami, L. Ichchou. Department of Rheumatology, Mohamed VI University Hospital, Mohammed I University, Oujda, Morocco

**Background:** Patients treated with anti-tumour necrosis factor-alpha (anti-TNF- $\alpha$ ) are at increased risk for latent tuberculosis reactivation. However, the best method for latent tuberculosis infection (LTBI) detection before initiation of anti-TNF therapy remains to be determined.

**Objectives:** The aim of this study is to investigate the role of QuantiFERON-TB Gold test as one of the interferon-gamma release assays (IGRAs) in detecting LTBI before initiation of biotherapy in a population of Moroccan patients suffering from spondyloarthritis (SpA).

**Methods:** We have conducted a cross-sectional study over two months in our department of rheumatology. All SpA patients fulfilled ASAS 2009 criteria.

Tuberculin skin test (TST), QuantiFERON-TB Gold in Tube (QFT-GIT) assay and chest radiographs were performed before starting anti-TNF-alpha. Computed tomography was performed in patients with abnormal chest radiographs.

**Results:** We included ninety two patients with SpA. Among them, 35 (38%) received anti-TNF- $\alpha$  therapy. A history of tuberculosis disease was noted in 6 patients (6.6%) (3 Pulmonary TB and 3 extrapulmonary TB). Two patients (2.2%) had contagious tuberculosis. The positive QFT-GIT rate was 15.2% (14/35). The TST was negative in 16.3% of cases (15/35). The results of QFT-GIT and TST performed in the same patients were discordant in 5 cases (5.4%). Sputum smears were negative. Chest CT performed in 29 patients had shown bronchiectasis in 3 cases (3.7%), interstitial syndrome in 2 cases (2.5%) and was normal in 24 cases (29.6%).

The chemoprophylaxis was prescribed in 14 persons with a positive QFT-GIT. It was based on Isoniazid (INH) alone in 12 cases (13%), a triple therapy (RHZ) in one case (1.1%) and a quadritherapy (RHZE) in another case with active tuberculosis. The duration of chemoprophylaxis varied between 6 and 9 months in the case of monotherapy, 2 months in the case of triple therapy because of biologic hepatotoxicity and 6 months in the case of quadritherapy because of active TB occurring during anti-TNF alpha therapy. The delay in initiating biotherapy varied between 1 and 6 months. At the time of blood sampling for QFT-GIT, patients were receiving: steroids in one case (1.1%), Methotrexate (MTX) and steroids in 3 cases (3.3%), Sulfasalazine (SZP) in 3 cases (3.3%), MTX in 4 cases (4.3%) and MTX and SZP in 2 cases (2.2%).

**Conclusions:** QTB-G may be a more sensitive screening tool for LTBI before initiating anti-TNF therapy in immunocompromised patients, especially in a TB endemic country.

**AB0873** **US RHEUMATOLOGISTS HAVE MIXED PERCEPTIONS ABOUT MANAGING PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS AND ANKYLOSING SPONDYLITIS**

J. Robinson, L. Price. *Advanced Analytics Group, Spherix Global Insights, Exton, USA*

**Background:** Non-radiographic axial spondyloarthropathy (nrAxSpA) is a relatively new term used to describe patients who clinically appear to have ankylosing spondylitis (AS) but do not exhibit radiographic sacroiliitis. Though several biologics are currently FDA approved for the treatment of AS, there are no agents approved for patients in which there is not radiographic evidence of sacroiliitis. With several agents under investigation with the hopes of gaining a line-extension label for nr-axSpA, it is important to understand how the current treating rheumatologists view these two diseases and their current and future plans for spondyloarthropathy management.

**Objectives:** The study sought to (a) evaluate the differences between AS and nr-axSpA diagnosis and treatment patterns (b) highlight the challenges clinicians face in managing patients with nr-AxSpa and (c) understand rheumatologists' willingness to use biologic agents to treat nr-AxSpa.

**Methods:** An independent market analytics firm collaborated with US rheumatologists (n=98) to learn about current and anticipated changes to the management of Ankylosing Spondylitis and Non-radiographic Axial Spondylitis. Participants were administered an online survey, lasting approximately 30 min in length and respondents were compensated for their professional time. Following the fieldwork, data were analysed in SPSS, a statistical software, to determine significant differences.

**Results:** 87% of the surveyed rheumatologists agree that AS and nr-AxSpA are part of a spectrum, and 37% report that they often find it challenging to differentiate between the two conditions. The majority of the respondents report that they treat these conditions in a very similar manner. In fact, 40% agree that distinguishing between the two has no relevance to their treatment decisions. Use of biologics is significantly more pronounced in AS (56% vs. 39%, respectively), largely because there is currently no FDA indicated biologic for nr-AxSpA and because many rheumatologists view nr-AxSpA simply as a less severe precursor to AS, where aggressive treatment with a biologic is not warranted. In order to gain reimbursement for a biologic in patients with nr-AxSpA, rheumatologists frequently classify patients as having AS (as opposed to nr-AxSpA). Although adalimumab is the most frequently prescribed biologic in both conditions, rapid adoption of an IL-17 inhibitor (secukinumab) is occurring in the US market.

**Conclusions:** There is a need to educate both primary care physicians and rheumatologists about the differences between AS and nr-AxSpA. The official FDA approval of biologic agents in nr-AxSpA is anticipated to lead to more aggressive treatment of these patients earlier in the spectrum.

**AB0874** **MENTAL HEALTH DISORDERS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: INCREASING OUR UNDERSTANDING OF THE DISEASE. RESULTS FROM THE ATLAS-2017**

M. Garrido-Cumbrera<sup>1,2</sup>, V. Navarro-Compan<sup>3</sup>, D. Gálvez-Ruiz<sup>1</sup>, C. Delgado-Dominguez<sup>1</sup>, P. Font Ugalde<sup>4</sup>, O. Braçe<sup>1</sup>, P. Zarco<sup>5</sup>, J. Chacón-García<sup>1</sup>, P. Plazuelo-Ramos<sup>2</sup>. <sup>1</sup>Universidad de Sevilla, Sevilla; <sup>2</sup>CEADE; <sup>3</sup>Rheumatology, Hospital La Paz, IdiPaz, Madrid, Madrid; <sup>4</sup>Medicina, Universidad de Córdoba, Cordova; <sup>5</sup>Rheumatology, Hospital Fundación Alarcón, Madrid, Spain

**Background:** Depression and other mental disorders are among the most prevalent comorbidities in patients with axial spondyloarthritis (axSpA).

**Objectives:** To assess the association between sociodemographic characteristics, disease progression, and mental health comorbidity with risk of mental disorders (RMD).

**Methods:** In 2016 a sample of 680 axSpA patients was interviewed as part of the Spanish Atlas. To quantify the RMD, GHQ-12 scale was employed. Possible RMD predictors taken into account in the analysis were: sociodemographic characteristics (age, gender, being part of a couple, patient association membership, job status); disease characteristics (BASDAI, spinal stiffness, functional limitation in 18 daily activities; and mental health comorbidities. All clinical variables showed a Cronbach's alpha coefficient guaranteeing the reliability of the scales used. First, a descriptive analysis was employed to describe the sample and study

variables. Second, univariate correlation and homogeneity analyses between each predictor (independent variable) and RMD (GHQ-12) were performed.

**Results:** All variables except educational level and thoracic stiffness showed significant univariate correlation with RMD. BASDAI, functional limitation and age showed higher coefficient ( $r=0.543$ ,  $p<0.001$ ;  $r=0.378$ ,  $p<0.001$ ;  $r=-0.174$ ,  $p<0.001$ , respectively).

Multiple hierarchical regression analysis showed as sociodemographic variables explained in great detail the RMD ( $R^2=83.2\%$ ). By contrast, having established sociodemographic as a control variable, the inclusion of depression and anxiety to the model increased the  $R^2$  value to just 0.6% ( $p<0.001$ ), while the inclusion of variables related to the disease characteristics add 5.5% ( $p<0.001$ ) to the GHQ-12 punctuation variability. The only variables presenting a significant coefficient different from 0 were BASDAI (0.52,  $p<0.001$ ) and functional limitation (0.14,  $p<0.01$ ). This suggests that once the sociodemographic and mental comorbidity variables are established, a change in BASDAI levels or functional limitation impacts the GHQ-12 score.

In the stepwise regression analysis, four variables (BASDAI, functional limitation, association membership, cervical stiffness) showed a significant relation to GHQ-12 and explained the majority of RMD variability. BASDAI displayed the highest explanatory degree ( $R^2=0.875$ ,  $p<0.001$ ).

**Abstract AB0874 – Table 1.** Sample characteristics (n=474, unless other specified)

Variables	Values (means $\pm$ SD or percentage)
Age, mean $\pm$ SD	45.43 $\pm$ 10.78
Sex, No. of men	233 (49.2%)
Having a couple, No. of participants (N=444)	386 (86.9%)
Education level, No. of university studies	185 (39.3%)
Job status, No. of unemployed	68 (14.4%)
Association Membership	227 (47.9%)
BASDAI (0-10) mean $\pm$ SD (N=442)	5.49 $\pm$ 2.17
Cervical stiffness, No. (N=447)	201 (45.0%)
Thoracic stiffness No. (N=435)	186 (42.8%)
Lumbar stiffness No. (N=458)	288 (62.9%)
Functional Limitation, (0-54) mean $\pm$ SD (N=473)	27.54 $\pm$ 12.78
Depression, No. (%) (N=474)	99 (20.9)
Anxiety, No. (%) (N=474)	134 (28.3)
GHQ-12, (0-36) mean $\pm$ SD	18.30 $\pm$ 8.01

**Conclusions:** In axSpA, patients at certain sociodemographic levels are more prone to present a higher BASDAI. Taking these conditions for granted, the degree of disease progression measured by BASDAI is a good indicator of RMD. Therefore, in those patients with higher disease activity, psychiatric evaluation and intervention should be considered within the medical treatment.

**AB0875** **QUALITY OF LIFE IMPROVEMENT IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS TREATED WITH NSAIDS AND BIOLOGICAL THERAPY FROM THE PATIENT'S PERSPECTIVE: RESULTS FROM THE ATLAS-2017**

M. Garrido-Cumbrera<sup>1,2</sup>, D. Gálvez-Ruiz<sup>1</sup>, J. Gratacós<sup>3,4</sup>, C. Blanch Mur<sup>5</sup>, V. Navarro-Compan<sup>6</sup>. <sup>1</sup>Universidad de Sevilla, Sevilla; <sup>2</sup>CEADE, Madrid; <sup>3</sup>Rheumatology, Hospital Universitari Parc Taulí, Sabadell; <sup>4</sup>I3PT, UAB; <sup>5</sup>Novartis, Barcelona; <sup>6</sup>Rheumatology, Hospital Universitario La Paz, IdiPaz, Madrid, Spain

**Background:** In patients with axial spondyloarthritis (axSpA), the main long-term outcome is quality of life. Clinical trials and observational studies have shown the efficacy of biological therapy (BT) on improving the signs and symptoms of the disease. However, data assessing the impact of BT on quality of life is scarce and mainly comes from clinical trials.

**Objectives:** To assess in clinical practice the improvement in quality of life from the patient's perception as a result of pharmacological treatments in axSpA.

**Methods:** A sample of 680 patients diagnosed with axSpA was interviewed through an online survey as part of the Spanish Atlas-2017, which aimed to promote early referral, improve healthcare, and the use of effective treatments in patients with axSpA. For this study, self-reported data from patients who had received both NSAIDs and BT were analysed. Patients were asked about the improvement they had experienced on 7 different aspects of quality of life after starting treatment with NSAIDs or BT: independence, leisure and free time, social relations, sport and physical activity, and mood and sexual relations. Improvements were measured on a 0 to 10 Likert Scale and classified as low ( $\leq 5$ ) and high ( $\geq 6$ ). Non-parametric (Wilcoxon) tests were used to compare the degree of improvement between patients with biological therapy and those with NSAIDs.

**Results:** A total of 189 patients who had received both types of drugs were included. The mean (SD) age was 44.03 ( $\pm 10.11$ ) years, 50.3% were females, 70.9% married and 47.1% belong to a patients' association. The mean (SD) disease duration was 21.3 $\pm$ 10.7 years and 67.7% were HLA-B27+. A higher percentage of patients perceived a high level of improvement after receiving a BT than after receiving an NSAID, for both overall quality of life assessment (57% vs 22%, respectively) and the different quality of life-related aspects. Additionally, the mean degree of improvement for overall quality of life assessment and the different aspects related to this were reported to be significantly higher after receiving BT than after NSAIDs (overall improvement: 5.46 $\pm$ 2.59 vs 3.19 $\pm$ 2.45;  $p < 0.001$ , respectively).

**Abstract AB0875 – Table 1.** Mean improvement degree and percentage of patients who reported high improvement ( $\geq 6$  in 0–10) in different aspects related to quality of life after receiving biological therapy and NSAIDs

	NSAID		Biological Therapy		p value Wilcoxon
	High improvement (%)	Degree of improvement, Mean (SD)	High improvement (%)	Degree of improvement, Mean (SD)	
Independence	22.6	3.40 (2.79)	53.0	5.83 (3.01)	<0.001
Leisure & Spare Time	22.9	3.41 (2.73)	58.2	5.81 (2.80)	<0.001
Employment	20.7	3.01 (2.84)	53.6	5.48 (3.36)	<0.001
Social Relations	19.4	3.05 (2.50)	52.1	5.45 (2.95)	<0.001
Sport & Physical Activity	14.4	2.62 (2.71)	41.3	4.88 (3.05)	<0.001
Emotional Wellbeing	17.4	2.70 (2.83)	53.9	5.78 (2.88)	<0.001
Sexual Activity	16.0	2.52 (2.66)	53.4	4.65 (3.28)	<0.001
Global	22.2	3.19 (2.45)	57.0	5.46 (2.59)	<0.001

**Conclusions:** In clinical practice, patients' self-reported satisfaction overall and related to different aspects of quality of life is substantially greater after being treated with BT than with NSAIDs. However, these results need to be confirmed in a longitudinal study

#### AB0876 CORRELATION BETWEEN FAECAL CALPROTECTIN LEVELS AND TOBACCO USE IN PATIENTS WITH SPONDYLOARTHRITIS AND WITHOUT PREVIOUS DIAGNOSIS OF INFLAMMATORY BOWEL DISEASE

M. Espinosa Malpartida<sup>1</sup>, C. Ramos Giráldez<sup>1</sup>, C. Merino Argumániz<sup>1</sup>, M.B. Ruiz-Antorán<sup>2</sup>, J. Campos Esteban<sup>1</sup>, C. Barbadillo Mateos<sup>1</sup>, H. Godoy Tundidor<sup>1</sup>, B. Agudo Castillo<sup>3</sup>, Y. González Lama<sup>3</sup>, J.L. Andreu Sánchez<sup>1</sup>, J. Sanz Sanz<sup>1</sup>.

<sup>1</sup>Rheumatology, <sup>2</sup>Clinical Pharmacology, <sup>3</sup>Digestive, H. U. Puerta de Hierro Majadahonda, Madrid, Spain

**Background:** It is estimated that between 5% and 10% of patients with spondyloarthritis (SpA) are associated with inflammatory bowel disease (IBD). It has also been proven through endoscopic and histological studies that up to 60% of patients with SpA have microscopic inflammatory intestinal lesions, with a subclinical character and of which the true clinical relevance is unknown, although a greater percentage of these are those that will evolve to IBD.

**Objectives:** To assess whether tobacco use may be associated with higher faecal calprotectin (FC) levels in patients with diagnosis of SpA and without clinical suspicion or previous diagnosis of IBD.

**Methods:** This is a single centre, cross-sectional, observational study with prospective collecting data. Data were included for consecutive patients from Rheumatology consultation who had been previously diagnosed of SpA, fulfilled ASAS criteria and without digestive symptoms suggestive of IBD (chronic diarrhoea, rectal bleeding, perianal disease, chronic abdominal pain – persistent or recurrent). Details about demographic characteristics, clinical and laboratory variables related with SpA (BASDAI, HLA B27, acute phase reactants), treatments and FC were collected. A pathological cut-off point of FC > 50 mg/kg was determined. Patients on NSAIDs treatment were advised to discontinue its use 2 weeks before collecting stool samples. This study was approved by the Clinical Research Ethics Committee.

**Results:** 99 patients were included: 53.5% women, with a mean age of 46 $\pm$ 11 years. nonspecific digestive disorders (dyspeptic symptoms, H. pylori y gastroesophageal reflux) were observed in 9% of the patients. Among all, 18% were smokers. Mean BASDAI was 3.7 $\pm$ 2.5; 39% of patients were being treated with any concomitant DMARD and 67% were on NSAIDs. 49.5% of the patients<sup>49</sup> showed elevated FC determinations, with an mean level of 276 mg/kg (range 52–3,038). The percentage of patients with high levels of FC was significantly increased in smokers (72.2% vs. 44.4%,  $p = 0.033$ ), with higher levels of FC in smokers than non-smokers (262 mg/L vs. 121 mg/L.  $p = 0.126$ ). The remaining analysed variables did not show any significant differences in terms of FC levels.

**Conclusions:** Microscopic bowel inflammation is described in approximately 50% of patients with SpA and it is related with more severe disease. Tobacco use has been associated with worse prognosis and response to treatment in SpA. A relationship between elevated FC levels (inflammatory activity biomarker) and tobacco use in patients with SpA without previous diagnosis or clinical suspicion of IBD is established in this study.

#### AB0877 ANALYSIS OF THE ASSOCIATION OF THE PERIPHERAL INVOLVEMENT OF THE SPONDYLOARTHRITIS WITH THE EXTRA-ARTICULAR MANIFESTATIONS

M.D.S. Mastella, I.M.S. Vale, M.M. Pereira, M.J. Carmo, G.R.W. Castro, I. A. Pereira. UNISUL, Florianópolis, Brazil

**Objectives:** Patients with SpA present peripheral involvement, such as arthritis and enthesitis, or only axial involvement, such as sacroiliitis and spondylophytes. The differentiation of the peripheral and axial presentation is important, being able to guide different therapeutic strategies.

**Methods:** This is a retrospective observational study, conducted in two clinics in Florianópolis. The population was composed of patients with AS and non-radiographic and peripheral axial SpA, according to the criteria of modified New York and ASAS group, respectively, served from 1997 to 2017.

**Results:** 153 patients were analysed, 82 were male (53.59%), 71.29% were HLA B27 positive (77/108 tested), 87.3% had sacroiliitis detected on x-ray, CT or MRI, 104 presented peripheral involvement (67.97%) and 49 (32.02%) purely axial involvement. Arthritis occurred in 86 (56.2%) and enthesitis in 57 (37.3%) patients. The use of synthetic DMARD occurred in 78.4% of the patients, more frequently in the group with peripheral involvement, with methotrexate being used in 74% versus 56.3% of those with purely axial involvement ( $p < 0.05$ ). The use of biological DMARD occurred in 104 (68%), in the majority of the anti-TNF class (96.1%), with the highest frequency of use in patients with axial involvement (77.1% versus 64.4%), but not statistically significant ( $p > 0.05$ ). Extra-articular manifestations were found in 72 (47.1%) of the patients, with uveitis being the most frequent (26.8%). The presence of uveitis occurred in 68.3% of patients with isolated axial involvement versus 31.7% of patients with peripheral involvement ( $p = 0.179$ ). The cutaneous involvement occurred in 18.3% of the patients with peripheral involvement compared to 8.3% of those with an isolated axial condition. Regarding bowel involvement and cardiovascular impairment, there was no significant difference in prevalence between the two groups.

**Conclusions:** Extra-articular manifestations are frequent in SpA, but are not more frequent in patients with peripheral involvement versus patients with pure axial involvement. Peripheral involvement is associated with greater use of synthetic DMARDs when compared to pure axial involvement.

**Disclosure of Interest:** None declared

**AB0878** **COMPARISON OF CLINICAL FEATURES IN PATIENTS WITH PSORIATIC ARTHRITIS AND PATIENTS WITH SPONDYLOARTHRITIS WITH INFLAMMATORY BOWEL DISEASE**

M. Uematsu<sup>1,2</sup>, K. Inui<sup>1</sup>, T. Okano<sup>1</sup>, Y. Yamada<sup>1</sup>, K. Mandai<sup>1</sup>, Y. Sugikoka<sup>3</sup>, K. Mamoto<sup>1</sup>, T. Koike<sup>3,4</sup>, H. Nakamura<sup>1</sup>. <sup>1</sup>Department of Orthopedic surgery, Osaka City University Graduate School of Medicine; <sup>2</sup>Department of Orthopedic surgery, Higashiumiyoshi morimoto hospital; <sup>3</sup>Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka; <sup>4</sup>Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Foundation for Health and Welfare, Wakayama, Japan

**Background:** Spondyloarthritis (SpA) is one of the representative comorbidity in patients with psoriasis (PsO) and inflammatory bowel disease (IBD) disease. However, the difference of clinical features between SpA due to PsO (PsA) and SpA due to IBD (IBD-SpA) are unclear.

**Objectives:** The purpose of this study is to compare the clinical features between patients with PsA and IBD-SpA.

**Methods:** Overall, 192 patients with PsO and 37 patients with IBD were included in this cross-sectional study. Clinical classification of PsA and IBD-SpA were performed according to the CASPAR<sup>1</sup> criteria and ASAS criteria.<sup>2</sup> Disease activity (DAS28-CRP), C-reactive protein (CRP), matrix metalloproteinase-3 (MMP-3), anti-cyclic citrullinated peptide antibody (ACPA), rheumatoid factor (RF), biologic disease modifying anti-rheumatic drugs (bDMARDs) use, and proportion of peripheral and axial disease were evaluated in patients with PsA and IBD-SpA.

**Results:** In this analysis, 74 patients were classified as PsA, 65 patients as PsO, 17 patients as IBD-SpA and 20 patients as IBD. The mean age was 56.0±14.7 years in PsA, 44.7±10.9 years in IBD-SpA (p=0.003). The mean BMI was 24.2±4.5 kg/m<sup>2</sup> in PsA, 23.3±7.2 kg/m<sup>2</sup> in IBD-SpA (p=0.18). DAS28-CRP was 3.26±1.26 in PsA, 4.02±1.5 in IBD-SpA (p=0.12). Axial SpA was observed in 4 (5.4%) in PsA, 5 (29.4%) in IBD-SpA (p=0.01). Biologics were used in 29 (39.2%) patients in PsA, 13 (76.5%) patients in IBD-SpA (p=0.007). Proportion of seropositive ratio was not significant in this two groups.

**Abstract AB0878 – Table 1.** Characteristics in patients with PsO, PsA, IBD and IBD-SpA.

	PsA (n=74)	PsO (n=65)	IBD-SpA (n=17)	IBD (n=20)	P value*
Age, years	56.0±14.7	60.2±14.0	44.7±10.9	45.0±12.8	0.003
Female, n (%)	36 (48.6)	29 (44.6)	8 (47.0)	16 (80.0)	1.0
Height, m	1.63±0.09	1.61±0.09	1.65±0.07	1.59±0.06	0.43
Body weight, kg	65.3±16.8	61.7±13.1	64.7±24.8	51.8±12.2	0.34
BMI, kg/m <sup>2</sup>	24.2±4.5	23.7±3.9	23.3±7.2	20.4±3.9	0.18
DAS28-CRP	3.26±1.26	1.91±0.9	4.02±1.5	2.53±0.8	0.12
CRP, mg/dl	1.32±3.3	0.32±0.6	1.0±1.1	0.78±2.4	0.12
MMP-3, ng/ml	99.9±95.3		92.1±59.0		0.90
ACPA positive, n (%)	6 (8.1)		0 (0)		0.59
RF positive, n (%)	7 (9.5)		1 (5.9)		1

\*Mann-Whitney U-test and Fisher's exact test were performed in comparison with PsA and IBD-SpA.

**Abstract AB0878 – Table 2.** Prevalence of axial SpA and peripheral SpA in patients with PsA and IBD-SpA.

	PsA (n=74)	IBD-SpA (n=17)	P value
Axial SpA, n (%)	4 (5.4)	5 (29.4)	0.01
Peripheral SpA, n (%)	70 (94.6)	12 (70.6)	

**Conclusions:** The clinical features between patients with PsA and IBD-SpA were compared. The patient with IBD-SpA was younger than patient with PsA and the prevalence of axial disease was more frequent in IBD-SpA.

**AB0879** **FIBROMYALGIA IN PATIENTS WITH ANKYLOSING SPONDYLITIS: PREVALENCE AND RELATIONSHIP WITH DISEASE ACTIVITY**

M. Sahli, O. Saidane, I. Mahmoud, A. Ben Tekaya, R. Tekaya, L. Abdelmoula. *Rheumatology, Charles Nicolle Hospital, Tunis, Tunisia*

**Background:** Spondyloarthritis (SpA) is an inflammatory rheumatic disease, characterised by spinal involvement, peripheral arthritis, or enthesitis with marked pain, stiffness, and fatigue. Fibromyalgia (FM) may be associated with SpA, and shares some common symptoms.

**Objectives:** We aimed to estimate the prevalence of FM in SpA and its influence on the assessment of SpA disease activity.

**Methods:** This single-centre cross-sectional study included consecutive patients with SpA according to the Assessment of SpondyloArthritis International Society criteria. FM was diagnosed according to the 2010 American College of Rheumatology criteria. All patients underwent clinical evaluation of disease activity using the Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), the Bath Ankylosing Spondylitis Functional Index (BASFI) and the Ankylosing Spondylitis Disease Activity Score (ASDAS) and then compared in patients with and without FM.

**Results:** The study included 100 patients with SpA, 67 males and 33 females with a median age of 44.65 years. The prevalence of fibromyalgia was 20%. Patients fulfilling the criteria of FM presented a higher total BASDAI (5.86 (±1.97) vs. 3.15 (±1.99), p<0.01), higher ASDAS-CRP (3.43 (±1.13) vs. 2.41 (±1), p<0.01), higher ASDAS-VS (3.5 (±1.12) vs. 2.53 (±1.02), p<0.01) and poorer function scores (BASFI) (6.76 (±1.97) vs. 3.8 (±2.59), p<0.01).

**Conclusions:** FM is a frequent comorbidity in patients with SpA. In patients with SpA-FM, disease activity may be overestimated and this overestimation could lead to inappropriate treatment escalation.

**AB0880** **THE OBJECTIVE AUTOMATED MEASUREMENT OF FLUORESCENCE-SIGNAL INTENSITIES IN FLUORESCENCE-OPTICAL IMAGING TECHNIQUE DISCRIMINATES BETWEEN DISEASE ACTIVITY AND ITS RESPONSE IN ANTITNF TREATED PSORIATIC ARTHRITIS PATIENTS – AN INTERIMS ANALYSIS OF THE XPLORE-STUDY**

M. Köhm<sup>1,2</sup>, S. Ohrndorf<sup>2</sup>, T. Rossmann<sup>2</sup>, A. Foldenauer<sup>2</sup>, U. Henkemeier<sup>4</sup>, G. Schmitt<sup>5</sup>, J. Berger<sup>6</sup>, H. Burkhardt<sup>1,2</sup>, F. Behrens<sup>1,2</sup>, on behalf of The Xplore-Study Group. <sup>1</sup>Rheumatology, Goethe-University Frankfurt/Main; <sup>2</sup>Clinical Research, Fraunhofer IME TMP, Frankfurt/Main; <sup>3</sup>Rheumatology and Immunology, Universitätsmedizin Charité, Berlin; <sup>4</sup>CIRI, Goethe-University Frankfurt/Main; <sup>5</sup>Rheumatology and Immunology, Universitätsmedizin Charité, Frankfurt/Main; <sup>6</sup>Xiralite GmbH, Berlin, Germany

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disorder combining joint and musculoskeletal inflammation. AntiTNF-therapy is induced after failure of NSAID and DMARD treatment. Up to 30%–40% of the patients are primary not responding adequately to the induced biological therapy. In daily practice response is calculated by improvement of disease activity measured by clinical examination and calculated using composite indices. Feasible and robust biomarkers for prediction of response are missing.

**Methods:** Fluorescence optical imaging (FOI) is used as method for detection of changes in microvascularisation of the hands as potential marker for inflammation. ICG is injected as fluorescence agent, that is than stimulated by light and recorded by a specific camera system. An automated computer-based reading of the disease activity (DACT) is used as an objective method to display overall fluorescence-signals and their intensities. In a prospective multicentre study, the value of FOI in measurement of disease activity and its predictive value to discriminate responders in newly treated PsA patients is currently investigated in the XPLORE-study. This interim analysis investigates the value of baseline (BL) DACT to discriminate between responders (at least low disease activity (LDA) with DAS28 ≤3.2) and non-responders compared to standard clinical disease measurements (SJC, TJC, DAS28) over the 52 weeks observational period.

**Results:** Data from 23 patients were analysed during the 52 weeks observational period. Mean age was 54.7 years, 60% of the patients were female. Mean DAS28 at baseline was 4.26, mean BSA 9%, whereas mean values for SJC were 5.9 and TJC 11.4 using 66/68 joint count. All patients were negative for ACPA and rheumatoid factor.

ROC analysis revealed that a DACT cut-off of 4.55 at baseline, indicating moderate expression of fluorescence intensities in context of disease activity, shows a predictive quality to LDA achievement at W52 with 80% specificity, 78% sensitivity and likelihood ratios of 3.89 (LQ+) and 0.28 (LQ-). The corresponding AUC value is 0.717 (95%CI=[0.393, 1]; p=0.146). Compared to clinical disease measurements such as baseline DAS28, TJC or SJC, the DACT at BL is more discriminative to identify patients who attain LDA at W52.

**Conclusions:** This interim analysis of the XPLORE study shows promising data for the use of FOI as possible imaging biomarker for disease activity measure and prediction of response in PsA-patients newly treated with antiTNF-therapy: Baseline values evaluated using the automated computer-based reading of the fluorescence intensities with a cut-off of 4.55 are predictive for later achievement of DAS28 low-disease activity or remission within the treatment course. Data will be verified in a larger cohort of the XPLORE study.

**AB0881 ASSOCIATION OF RS12218 POLYMORPHISM IN SAA1 GENE WITH LUMBAR SPINE SYNDESMOPHYTES IN THE RUSSIAN ANKYLOSING SPONDYLITIS POPULATION. A PILOT STUDY**

M. Krylov<sup>1</sup>, S. Erdes<sup>1</sup>, A. Starkova<sup>1</sup>, E. Samarkina<sup>1</sup>, I. Guseva<sup>1</sup>, N. Konovalova<sup>2</sup>, D. Varlamov<sup>2</sup>. <sup>1</sup>V.A. Nasonova Research Institute of Rheumatology; <sup>2</sup>All-Russian Research Institute of Agricultural Biotechnology, Moscow, Russian Federation

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory disease from the group of spondyloarthritis (SpA). Earlier studies showed a correlation between SAA1 gene polymorphism, encoding serum amyloid A, and the development of secondary AA-amyloidosis in familial Mediterranean fever and rheumatoid arthritis in Caucasian and Asian populations. The Moriguchi et al (2005) study showed that the -13 T/C polymorphism in the gene 5'-flanking region (rs12218) is a better marker of AA-amyloidosis than mapping of polymorphisms in SAA1 exon 3 (SAA1.1 and SAA1.1.3). Data on rs12218 polymorphism contribution into predisposition to AS and its clinical phenotypes are very scarce. One of the clinical phenotypes, determining the severity of spine damage, is associated with presence of syndesmofytes (SM) in the lumbar (SMl), thoracic (SMt) and cervical (SMc) spine, confirmed by x-ray data.

**Objectives:** To study potential associations of rs12218 polymorphism in SAA1 gene with AS and phenotypes of radiographic progression, with the presence of SMl, SMt and SMc, and correlation with BASDAI, BASFI and ASAS indices.

**Methods:** rs12218 polymorphism was studied in 112 subjects: 47 AS patients (37 males and 10 females, mean age 40y, mean disease duration 213 weeks, mean age at onset 22y, positive for HLA-B27), and 65 healthy volunteers (controls). Genotyping was performed using allele-specific polymerase chain reaction in real time (PCR-RT).

**Results:** The Pearson Correlation analysis showed negative correlation between rs12218 polymorphism and presence of SMl, as well as BASDAI, BASFI scores ( $r=-0.39$ ,  $r=-0.35$  and  $r=-0.36$ ,  $p=0.006$ ,  $p=0.017$ ,  $p=0.014$ , respectively). There were no correlations between rs12218 and pts' age, AS duration and pts' age at AS onset. There were similar rs12218 allele distribution rates between AS patients and the controls. rs12218C allele rates were significantly higher in SMl group (n=23) compared to subjects without SMl (n=24) [50.0% vs. 15.2%,  $p=0.001$ ]. No association was established between C allele and presence of SM in other parts of the spine. A correlation between BASDAI and BASFI scores and SAA1 gene rs12218 polymorphism was established. Mean BASDAI score was significantly higher in carriers of TC and CC genotypes compared to carriers of TT genotype ( $5.6\pm 1.3$  vs.  $3.9\pm 2.3$ ,  $p=0.004$ ). The mean BASFI scores in carriers of the respective genotypes were ( $6.1\pm 2.3$  vs  $4.1\pm 2.8$ ,  $p=0.012$ ). No significant correlation was found between rs12218 genotypes and mean ASDAS score values.

**Conclusions:** Therefore, this pilot study is the first to show the possible participation of rs12218 polymorphism in SAA1 gene in AS pathogenesis in Russian population. We suggest that C allele may be a risk factor predisposing to SMl [OR 5.14 95% CI(1.75–16.17),  $p=0.001$ ]. The data obtained on a limited sample of patients require further validation on larger samples of patients involving different population groups.

**AB0882 ACHILLES ENTHESITIS IN THE PATIENTS WITH SPONDYLOARTHRITIS: RELATIONSHIP WITH MUSCLE STRENGTH, ACTIVITIES OF DAILY LIVING AND QUALITY OF LIFE**

Ö. Kuru, B. Farisoğulları, G. Alaylı, A. Bilgici, D. Durmuş. *Physical Medicine and Rehabilitation, Ondokuz Mayıs University Medical Faculty, Samsun, Turkey*

**Background:** Enthesitis is a central feature of spondyloarthritis (SpA). In SpA, the entheses of the lower extremities are more commonly involved than those of the upper limbs, and the heel is the most frequent site. Investigation of peripheral enthesitis in SpA is based on clinical findings and/or imaging findings. The involvement of Achilles tendon may lead to pain, movement restrictions, decrease in muscle strength, and eventually a diminished quality of life (QoL).

**Objectives:** In the present study, we aimed to evaluate clinical enthesopathy and relation with ankle muscle strength, activities of daily living (ADLs) and foot and ankle related QoL in the patients with SpA.

**Methods:** Sixty SpA patients fulfilling the Assessment of SpondyloArthritis International Society (ASAS) classification criteria for SpA (M/F=39/21) ( $35.61\pm 9.85$  years) and 50 healthy controls (M/F=32/18) ( $35.40\pm 10.62$  years) were enrolled in the study. Clinical enthesopathy was defined by the presence of at least one of the spontaneous pain, tenderness elicited by pressure, mobilisation and contraction against resistance of the corresponding tendons and local swelling of the enthesis. Pain by visual analogue scale (VAS), disease activity by Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), functional capacity by Bath Ankylosing Spondylitis Functional Index (BASFI), enthesitis severity by SPARCC index was assessed in the patients. Isokinetic measurements of ankle dorsiflexion and plantarflexion were performed by the isokinetic dynamometer. The participants were tested at 30° and 120°/sec angular velocities. Pain, other symptoms (stiffness, swelling, range of motion), ADLs, sport and recreational activities, and foot and ankle-related QoL were evaluated by the Foot and Ankle Outcome Score (FAOS) in which higher scores indicate lesser problems and/or functional limitations.

**Results:** There was no significant difference between the patients and controls regarding age, sex, and body mass index. Clinical enthesopathy was detected in 36.7% of the SpA patients. Although ankle plantarflexion and dorsiflexion muscle strength in all angular velocities were lower in the SpA patients, the difference did not reach statistical significance ( $p>0.05$ ). All of the FAOS subscales were found to be significantly lower in the patients with SpA than in the controls ( $p<0.001$ ). When the SpA patients were divided into two groups as with clinical enthesopathy (n=22) and without clinical enthesopathy (n=38), there were significant differences between the groups regarding VAS pain, BASDAI, BASFI and SPARCC scores whereas there was no significant difference in muscle strength. Also, all FAOS subscale scores were significantly lower in the patients with clinical enthesopathy. Additionally, in the patients with SpA, while there were negative correlations between VAS pain, BASDAI, BASFI, SPARCC and FAOS subscale scores, there was a positive correlation between ankle muscle strength and FAOS scores ( $p<0.05$ ).

**Conclusions:** We found that all the FAOS subscale scores were lower in the SpA patients and they were correlated with clinical findings. The results of our study indicate that even though there was not a significant decrease in the muscle strength, ADLs, sport and recreation activities, foot-related QoL are poorly affected in the SpA patients with Achill enthesitis.

**AB0883 ASSESSMENT OF EARLY MYOCARDIAL DYSFUNCTION USING SPECKLE TRACKING ECHOCARDIOGRAPHY IN PATIENTS WITH RADIOGRAPHIC AND NONRADIOGRAPHIC AXIAL SPONDYLOARTHRITIS**

V. Emren<sup>1</sup>, O. Gercik<sup>2</sup>, E. Ozdemir<sup>1</sup>, D. Solmaz<sup>2</sup>, S. Gucenmez<sup>2</sup>, N. Eren<sup>1</sup>, M. Tokac<sup>1</sup>, G. Kabadayi<sup>2</sup>, S. Akar<sup>2</sup>. <sup>1</sup>Cardiology; <sup>2</sup>Rheumatology, Izmir Katip Celebi University School of Medicine, Izmir, Turkey

**Background:** Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly affects axial skeleton. Although some differences like sex and objective signs of inflammation were described between these two subgroups, overall disease burden was found to be similar in radiographic (r-) and non-radiographic (nr-) axSpA patients. The association of chronic inflammation with cardiac dysfunction was well documented in many inflammatory rheumatic diseases. However it was not assessed in the subgroups of axSpA patients. Advanced two-dimensional (2D) speckle tracking echocardiographic analysis is more sensitive and accurate method of early detection of myocardial dysfunction than the conventional 2D transthoracic echocardiography (TTE).

**Objectives:** To evaluate the left ventricular function by using speckle tracking echocardiography in patients with both r- and nr-axSpA.

**Methods:** In total 64 patients with r-axSpA (70% male) and age- and sex-matched 27 patients with nr-axSpA (63% male) and 30 healthy control subjects

(63% male) were included in the analysis. Patients with hypertension, diabetes and known cardiac disease were excluded. All patients underwent detailed echocardiographic examination including M-mode, pulsed-wave Doppler imaging, pulsed-wave tissue Doppler imaging and 2D speckle tracking.

**Results:** Age and sex distribution were not different between groups. Some demographic and disease related characteristics were shown in the table. BASDAI, BASFI, global assessment of disease activity and ASAS-HI scores were found to be similar between r- and nr-axSpA patient groups. Although ejection fraction (EF) ( $p=0.112$ ) and the other echocardiographic variables were similar between groups, global longitudinal strain (GLS) ( $p=0.045$ ) were found to be different among groups (table 1). Post-hoc analysis showed that GLS was similar between nr-axSpA and control groups however GLS was significantly low in r-axSpA patients. In univariate analysis GLS was correlated with age ( $p=0.025$ ), EF ( $p<0.001$ ), peripheral arthritis ( $p=0.047$ ), and smoking ( $p=0.019$ ). However in regression only peripheral arthritis ( $p=0.032$ ) and EF ( $p=0.015$ ) were found as the independent predictors of GLS.

**Abstract AB0883 – Table 1.** The demographic and disease related characteristics of study groups.

	Radiographic axSpA patients (n=64)	Non-radiographic axSpA patients (n=27)	Control subjects (n=30)	P
Age, years (mean±SD)	40.9±10.2	37.6±9.4	42.3±4.3	0.056
Duration of disease, years (mean±SD)	14.1±7.8	10.6±8.1	N/A	N/A
BASDAI, (mean±SD)	2.7±2.1	3.0±1.8	N/A	N/A
BASFI, (mean±SD)	2.5±2.3	2.6±2.0	N/A	N/A
Ejection fraction, (mean ±SD)	58.9±5.2	60.1±4.7	61.2±4.9	0.112
<b>Global Longitudinal Strain, (mean±SD)</b>	<b>20.4±3.3</b>	<b>21.3±3.8</b>	<b>22.3±2.5</b>	<b>0.045</b>

**Conclusions:** The results of the present study showed that left ventricular function had impaired in r-axSpA patients and speckle tracking echocardiography may be a useful tool for early demonstration of left ventricular dysfunction.

**Disclosure of Interest:** None declared

#### AB0884 SERUM FIBROBLAST GROWTH FACTOR-23 LEVELS WERE HIGHER IN PATIENTS WITH AXIAL SPONDYLOARTRHRITIS AND MAY BE ASSOCIATED WITH DISEASE ACTIVITY

O. Gercik<sup>1</sup>, E. Coban<sup>2</sup>, B. Ozbek Iptec<sup>3</sup>, G. Avcioglu<sup>3</sup>, D. Solmaz<sup>1</sup>, O. Bayindir<sup>1</sup>, G. Kabadayi<sup>1</sup>, D. Kozaci<sup>3</sup>, S. Akar<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Internal Medicine, Izmir Katip Celebi University School of Medicine, Izmir; <sup>3</sup>Medical Biochemistry, Ankara Yıldırım Beyazıt University School of Medicine, Ankara, Turkey

**Background:** Axial spondyloarthritis (axSpA) is a chronic inflammatory disease that mainly affects axial skeleton. The disease is characterised by new bone formation; it usually starts with the bony fusion of sacroiliac joints (SIJs) and also causes syndesmophyte formation in the intervertebral space, enthesophytes in the tendon and ligament insertion sites. Underlying mechanisms of new bone formation in axSpA patients is not completely understood and low levels of sclerostin may be associated with the development of syndesmophyte in patients with ankylosing spondylitis (AS). Beside sclerostin another osteocyte factor is fibroblast growth factor-23 (FGF-23) and it has been first described as a phosphaturic hormone. It was also shown that FGF-23 may inhibit osteoblast differentiation and matrix mineralization.

**Objectives:** To evaluate serum FGF-23 and sclerostin levels in patients with axSpA and to compare them with those of healthy control subjects. We also assessed relationship between the serum FGF-23, sclerostin levels and disease related variables in particular the presence of structural changes.

**Methods:** In total 109 axSpA patients according to ASAS classification criteria and age- and sex-matched 57 healthy control subjects were included in the analysis. Subjects with renal failure and significant comorbid conditions and axial SpA patients who were using anti-TNF agents were excluded. Demographic and disease related characteristics were collected by using a standard questionnaire. Serum levels of FGF-23 and sclerostin were measured using commercially available enzyme-linked immunosorbent assay (ELISA) kits in accordance with the supplier's instructions.

**Results:** In the present study there were 55 patients with non-radiographic axSpA and 54 patients with AS. Serum levels of FGF-23 levels were significantly higher in axSpA patients than healthy subjects. Although there was a trend towards a lower sclerostin levels in axSpA patients this difference did not show statistical significance (table 1). In axSpA patients serum FGF-23 levels were found to be correlated with erythrocyte sedimentation rate (ESR) ( $p=0.006$  and  $r=0.265$ ), C-

reactive protein (CRP) ( $p=0.017$  and  $r=0.229$ ) and patients' height ( $p=0.027$  and  $r=-0.221$ ). There was no relationship between FGF-23 and mSASSS score or the presence of syndesmophyte. Subgroup analysis revealed that the duration of disease ( $p=0.005$ ), ESR ( $p=0.007$ ), CRP ( $p<0.001$ ) and mSASSS ( $p=0.008$ ) scores were significantly higher in AS patients than nr-axSpA patients. However serum sclerostin levels were significantly higher in nr-axSpA patients ( $1464.4±728.1$  vs  $1150.8±754.3$  pg/mL and  $p=0.029$ ).

**Abstract AB0884 – Table 1.** Demographic characteristics and serum FGF-23 and sclerostin levels in study groups

	Axial spondyloarthritis (n=109)	Healthy controls (n=57)	P
Mean age (years)	39.8±10.3	37.0±8.2	0.055
Male (%)	51	44	0.513
Mean fibroblast growth factor-23 (pg/mL)	188.5±160.7	130.8±100.3	0.005
Mean sclerostin (pg/mL)	1309.0±754.4	1365±676.7	0.633

**Conclusions:** Our results suggested that serum FGF-23 is increased in axSpA patients. And also disease activity may contribute to an up-regulation in serum FGF-23 levels.

**Disclosure of Interest:** None declared

#### AB0885 CHARACTERISTICS OF JUVENILE ONSET HIP ARTHRITIS IN PATIENTS WITH SPONDYLOARTRHRITIS

W. Hamdi, R. Ben Saad, H. Riahi, K. Maatallah, D. Kaffel, T. Bouaziz, L. Ledab, M. Kchir. *institut national de Mohamed el Kassab, tunis, Tunisia*

**Background:** Axial spondyloarthritis (AS) is a chronic inflammatory rheumatic disease that affects the axial skeleton. It typically occurs in the late teens or early twenties and rarely in childhood, defining the juvenile onset (JoAS).

The adult-onset AS (AoAS) and Juvenile-onset (JoAS) may share many common features including hip involvement. But their impact on function and quality of life may differ.

**Objectives:** To compare demographic, clinic and functional outcome of patients with hip involvement in JoAS, with that of patients with AoAS

**Methods:** Cross-sectional study including patients with AS according to the <sup>ASAS</sup> criteria of 2009 with hip involvement. The juvenile onset of coxitis was defined by an onset before 16 years of age. An analysis of demographic and clinical comparisons between the two groups was performed including HLA B27 status. Mobility spine outcomes were assessed by the Bath AS Metrology Index (BASMI) and radiographic disease severity by the Bath AS Radiology Index (BASRI).

**Results:** There were 100 AS aged on average  $36.4±12.2$  years old.<sup>16-69</sup> The sex ratio was 4.6. The mean duration of progression of AS was  $10.93±9.89$  years [0.5–24]. It was a JoAS in 15 cases. All patients had a hip involvement. The juvenile onset of hip arthritis was associated with male gender ( $p=0.042$ ), younger age of patient with AS at the time of recruitment ( $p=0.007$ ), less severe clinical spinal involvement assessed by schober index ( $p=0.029$ ) and more frequent and severe enthesitis assessed by MASES ( $p=0.024$ ). Extra-articular manifestations were significantly more frequent in patients with juvenile onset of hip arthritis ( $p=0.008$ ). Otherwise the comparison of the two groups showed no difference in the presence of uveitis ( $p=0.407$ ) and pulmonary involvement ( $p=0.097$ ). HLAB27 antigen was significantly more common in JoAS ( $p=0.037$ ). BASRI and BASMI as well as ESR and CRP, were comparable between the two groups ( $p=0.976$ ,  $p=0.626$ ,  $p=1.000$ , respectively)

**Conclusions:** Hip involvement is common in the AS, particularly in JoAS. Our study showed that juvenile onset hip arthritis was associated with male gender, less severe spine involvement, enthesitis and the presence of HLA B27. This would help physicians to identify patients at higher risk of developing hip involvement, to enable early diagnosis.

AB0886

### DOES RADIO-ANATOMIC FEATURE OF HIP ARTHRITIS IN SPONDYLOARTHRITIS PREDICT FUNCTIONAL IMPAIRMENT?

W. Hamdi, R. Ben Saad, H. Riahi, K. Maatallah, D. Kaffel, T. Bouaziz, L. Ledab, M. Kchir. *Institut national de Mohamed El Kassab, Tunis, Tunisia*

**Background:** Axial spondyloarthritis (AS) is a chronic inflammatory disease that primarily affects the axial skeleton. Hip involvement is common in AS patient. The reported prevalence of clinical hip involvement in AS ranges from 24% to 36% and prevalence of radiographic hip arthritis ranges from 9% to 22%.<sup>1, 2</sup> Several radio-anatomic features are described with often significant clinical impact.

**Objectives:** To assess for an association between the radio-anatomic feature of hip arthritis and its clinical impact in patients with AS.

**Methods:** Cross-sectional study including patients with AS according to the <sup>ASAS</sup> criteria of 2009 with hip arthritis. All patients had pelvic X-rays. This one allowed to distribute the patients according to five radio-anatomic features of the hip arthritis: destructive, protrusive, ankylosing, mimicking osteoarthritis and early hip arthritis. To evaluate the functional impairment, two clinical indices were calculated: Lequesne index and Intermalleolar distance between the two medial malleoli in centimetre. The comparison of qualitative variables was performed with the Chi square test and the comparison of quantitative variables was performed with the Student's test. The significance level was set at 0.05.

**Results:** One hundred patients were included with 176 hips arthritis. The delay between onset of AS and hip arthritis was on average 5.6 years [0–34]. The distribution of coxitis according to the radio-anatomic feature was as following: destructive (110 cases), protrusive (10 cases), mimicking osteoarthritis (29 cases), ankylosing (7 cases) and early hip arthritis (20 cases). According to the Larsen classification for destructive hip arthritis: a grade 4 was found in 41 cases, a grade 2 in 33 cases, a grade 3 in 33 cases and a grade 1 in 3 cases.

The destructive form had the most important functional impairment with the highest Lequesne index in comparison with other forms (13,05 vs 9,7, p=0,000) and the smallest intermalleolar distance (74,40 vs 87,29, p=0,010).

The early hip arthritis and protrusive forms had the least important functional impact in with the following scores: Lequesne index (8,83 vs 12,29, p=0,015) and (10,78 vs 11, 96, p=0,000) and the intermalleolar distance (76,36 vs 65,00 p=0,015) and (105,56 vs 70,22, p=0,002) respectively.

Scores were comparable for osteoarthritis and ankylosing forms.

**Conclusions:** Our study showed that radio-anatomic feature of hip arthritis could influence functional impairment. Distinguishing these forms may allow the rheumatologist to select the hip arthritis that deserves more attention because of the highest risk of functional impairment.

AB0887

### JIA PATIENTS WITH HIGH DISEASE ACTIVITY HAVE INCREASED ACTIVITY OF BOTH THE IDO AND GTP-CH1 PATHWAY, BUT DECREASED BH4 EFFICACY: CONSEQUENCES FOR FATIGUE AND WELL-BEING

S. Korte<sup>1</sup>, E. Albers<sup>1</sup>, W. van den Bogaard<sup>2</sup>, G. Korte-Bouws<sup>2</sup>, S. de Roock<sup>3</sup>, S. Vastert<sup>3</sup>. <sup>1</sup>Dept of Pharmacology; <sup>2</sup>Onderwijscentrum Farmacie, Utrecht University; <sup>3</sup>Paediatric Rheumatology, Wilhelmina Children's Hospital, University Medical Center, UTRECHT, Netherlands

**Background:** Juvenile idiopathic arthritis (JIA) patients suffer from an inflammatory condition, resulting in painful joints. In addition, JIA patients often report symptoms of sickness behaviour, including depressive symptoms and fatigue. Recent animal studies suggest that proinflammatory cytokines produce sickness behaviour by increasing the activity of indoleamine-2,3-dioxygenase (IDO) and guanosinetriphosphate-cyclohydrolase-1 (GTP-CH1). Here it is hypothesised that inflammation in JIA patients affects the enzymatic activity of IDO and GTP-CH1

and the co-factor BH4. These compounds play a crucial role in the metabolism of the neurotransmitters serotonin and dopamine.

**Objectives:** The aim of our study was to reveal whether inflammation affects BH4, IDO and GTP-CH1 (enzymatic) activity in JIA patients.

**Methods:** Serum samples were collected of twenty-four JIA patients. In these samples, the concentrations of tryptophan, kynurenine, tyrosine, neopterin and phenylalanine were measured. An HPLC method with electrochemical detection was developed to quantify tryptophan, kynurenine and tyrosine. Neopterin and phenylalanine were quantified by ELISA. Kyn/trp ratio was measured as an index of IDO activity, while Phen/Tyr ratio was measured as an index of BH4 activity. Neopterin concentrations were used as an indirect measure of GTP-CH1 activity.

**Results:** JIA patients with high disease activity showed higher levels of both neopterin and kynurenine, and a higher ratio of both Kyn/Trp and Phen/Tyr and lower tryptophan levels than clinically inactive patients.

**Conclusions:** Altogether, these data support our hypothesis that inflammation increases the enzymatic activity of both IDO and GTP-CH1 and decreases the efficacy of the co-factor BH4. Further animal studies are needed to investigate whether inflammation-induced changes in these enzymatic pathways and co-factor lower the levels of the brain neurotransmitters dopamine and serotonin, and consequently produce sickness behaviour and fatigue.

AB0888

### PLATELET COUNT IN ANKYLOSING SPONDYLITIS: CAN IT SHOW THE DISEASE ACTIVITY ?

S. Rahmouni, M. Slouma, R. Dhahri, L. Metoui, N. Boussetta, N. Gueddiche, F. Laajili, I. Gharsallah, B. Louzir. *Internal medicine, Military hospital of instruction of Tunis, TUNIS, Tunisia*

**Background:** C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) are the main inflammatory biomarkers used in assessment of disease activity in numerous inflammatory diseases such as ankylosing spondylitis (SA). In recent years, it has been shown that Platelet count (PC) provided additional information on inflammatory status.

**Objectives:** The present study aimed to investigate the correlation between PC and clinical activity indices assessed by Bath ankylosing spondylitis disease activity index (BASDAI)

**Methods:** The study included 68 patients who fulfilled Assessment of Spondyloarthritis International Society Criteria. A cell blood count, including platelet count, ESR (mm/h), CRP (mg/L) and albumin (g/L), was obtained for each patient.

Disease activity measures at the time of blood sampling were obtained using the BASDAI. Statistical Package for Social Sciences (SPSS) was used for analysis.

**Results:** Of the 68 patients, 73.5% were male (Sex Ratio: 2.7). The mean age was 36±12.9 years. The mean disease duration was 40 months [0–192]. The average age of the onset of the disease was 36.6±11.9 years. No patient had ongoing infection at time of study. The mean BASDAI score was 5.1 [1.55–9.2]. Forty-one% of our patients (n=28) had active AS (BASDAI >4)

The mean ESR, CRP, albumin and PC were 39.4 (mm/h), 34.1 (mg/dL), 39.32 g/L and 311 (10<sup>3</sup>/mL), respectively.

There was a positive correlation between platelet count and following biomarkers: ESR (r: -0.481; p: 0.000), CRP (r: 0.417; p: 0.000) and albumin levels (r: -0.556; p: 0.000). A negative correlation between and Haemoglobin (Hb) was noted (r: -0.643; p: 0.000).

There was no significant difference in laboratory parameters (ESR, CRP, albumin, PC, Hb) between patients with active AS (BASDAI >4) and those with inactive AS (BASDAI <4) patients.

**Conclusions:** Although acute phase reactant such as ESR, CRP and PC mirror disease activity in AS,<sup>1</sup> their values were not associated with disease activity assessed by BASDAI in our study. However, new prospective studies including larger study groups are required to verify the findings of the present study.

**AB0889 CLINICAL CHARACTERISTICS OF 88 PATIENTS WITH PUSTULOTIC ARTHRO-OSTEITIS (PAO) IN JAPAN**

S. Tsujii<sup>1</sup>, Y. Ishihara<sup>2</sup>, H. Nishikawa<sup>3</sup>, Y. Taniguchi<sup>3</sup>, M. Kishimoto<sup>4</sup>. <sup>1</sup>Department of Rheumatology and Allergology, National Hospital Organization, Osaka Minami Medical Center, Kawachinagano City, Osaka; <sup>2</sup>Department of Orthopaedic Surgery, Kasumigaseki Urban Clinic, Tokyo; <sup>3</sup>Department of Nephrology and Rheumatology, Kochi Medical School Hospital, Kochi; <sup>4</sup>Immuno-Rheumatology Center, St. Luke's International Hospital, Tokyo, Japan

**Background:** The prevalence rate of PPP in Japan is somewhat as 0.13%<sup>1)</sup>, accounting for 61% of cutaneous manifestations diseases associated with SAPHO syndrome<sup>2)</sup>. SAPHO syndrome<sup>3)</sup> is not a new disease concept in which the cause of the disease has been clarified but is a name that classified diseased groups by collecting known diseases. On the other hand, PAO is a concept of disease that is a "proper subset" of SAPHO syndrome and is the smallest unit disease concept. Therefore, detailed information on PAO was sought.

**Objectives:** To examine the clinical features and treatment of PAO

**Methods:** We conducted a multicenter, non-intervention retrospective study of 88 PAO patients who were able to visit directly in 4 hospitals in Japan from January to June 2017. the criteria of "Sonozaki et al. 1981 4)" was used for PAO diagnosis. Evaluation items were clinical features, image/blood biochemical examination, treatment methods.

**Results:** The average age at the time of visit was 55.4 years old, palmoplantar pustulosis/PAO onset age was 44.4 years old, 49.3 years old, the onset pattern was skin leading type/simultaneous onset/joint advanced type (66.7/25.6/7.7%). The clinical features were pain joints of 33.0% of the thoracic joints, 22.7% of the shoulder joints and 10.2% of the joints of the ankle joints, and the adhesion flame was the most abundant in the Achilles tendon at 21.4%. ASDAS-CRP was 1.4 ± 0.8 on average, breakdown was inactive disease 52.3%, moderate 22.7%, severe 22.7%, very high disease activity 2.3%, and insufficient disease activity remained in 25% of cases. Radiographic change showed in 81.8% of the sternum/the sternocostoclavicular joint, 33.0% of the spine, 31.0% of the sacroiliac joint (NY Ilor more), and 9.8% of the peripheral joint. MRI findings showed changes in intraosseous luminance in 76.9% around the sternum, 52.2% in the spine and 65.2% in the sacroiliac joint. Bone scintigraphy showed abnormal findings in the anterior chest 96.4%, spine 23.6% and sacrum 30.9%. Blood biochemical examination showed CRP 0.35±0.52 mg/dl, RF positive rate 9.4%, ACPA positive rate 5.1%. First-line drugs (NSAIDs, biotin, anti-bacterial drugs) and second-line drugs (Iguratomod sulfasalazine MTX) were selected as therapeutic agents. For other treatments, 64.8% of topical therapy, 12.5% of phototherapy and 18.6% of tonsillectomy were performed.

**Conclusions:** In this study, we reported the clinical features, radiological findings and treatments in 88 Japanese patients with PAO in Japan. The treatment outcome for PAO in Japan is not sufficient, and it is necessary to try to elucidate further disease condition.

**AB0890 EFFICIENCY OF 8-YEAR EDUCATIONAL PROGRAMS FOR PRIMARY CONTACT PHYSICIANS IN DIAGNOSIS AND TREATMENT OF AXIAL SPONDYLOARTHRITIS IN KAZAN**

S. Lapshina<sup>1</sup>, L. Myasoutova<sup>2</sup>, R. Mukhina<sup>2</sup>. <sup>1</sup>49 Butlerov street, Kazan State Medical University; <sup>2</sup>Clinical Hospital # 7, Kazan, Russian Federation

**Background:** In recent years, there have been cardinal changes in terminology, understanding of pathogenesis of axial spondylitis (AxsSpA) and ankylosing spondylitis (AS), early diagnosis has improved. An important role is played by the level of awareness of primary care physicians in the early diagnosis of AxsSpA and AS.

**Objectives:** To evaluate the effectiveness of educational activities for primary contact physicians in AxsSpA (including AS) diagnostics for a long time.

**Methods:** From 2010 to the present time, educational activities are conducted for primary care physicians in diagnostics and tactics of managing patients with AS with discussion of the criteria for inflammatory back pain, options for onset and the algorithm for diagnosis and examination of patients with AxsSpA for primary contact physicians in Kazan. Since 2014, educational modules have been integrated into the system of continuing education of doctors. Assessment of the results of educational schools was carried out according to the analysis of reports of outpatient admission to rheumatologist of the City Rheumatological Centre in Kazan (Clinical Hospital # 7) and the analysis of medical records of patients sent to a rheumatologist in 2009 (base year) in comparison with 2010–2017 in the process of schools.

**Results:** In the process of conducting schools (2010–2017) the number of patients with AxsSpA and AS significantly increased for the first time this year. In 2010–2011, the number of patients almost doubled (575 pts in 2010, 683 pts in 2011) compared to 2009 (378 pts). The second sharp increase in the number of patients was observed in 2016 (1178 pts) and in 2017 (1298 pts).

The same dynamics was observed for AxsSpA patients (including AS) who applied for the first time to rheumatologist with a significant increase in patients in 2010–2011 (2009–118 pts, 2010–190 pts, 2011–204 pts) and in 2016–506 pts, 2017 year – 711 patients

"Peak" increase in the number of patients in 2010–2011 can be explained by the beginning of educational activities for doctors; in 2016–2017 – an increase in the number of activities (including remote ones), the amount of information, increased availability of MRI examinations for patients with AxsSpA.

Primary care physicians were more likely to refer patients with suspected AxsSpA or diagnosed AS, the percentage of discrepancies between diagnoses (referral and rheumatology) decreased from 78% in 2009 to 18.1% in 2011, 8.9% in 2013, 2.1% in 2015 and 3.3% in 2017.

The number of patients coming from the primary contact physician to rheumatologist with the required volume of examination (description of back pain, laboratory tests, HLAB27 determination, radiographs and/or MRI) increased significantly from 23.7% in 2009 to 87% in 2017, which allows to verify diagnosis without repeated consultations.

**Conclusions:** Educational programs for primary care physicians (lectures, schools, remote programs) have great importance for the timely diagnosis of AxsSpA, reducing the number of consultations before the diagnosis and with the subsequent appointment of adequate therapy.

**AB0891 DISEASE ACTIVITY PREDICTS FUNCTIONAL IMPAIRMENT AND SPINAL MOBILITY IN AXIAL SPONDYLOARTHRITIS**

T. Williams<sup>1</sup>, A. Wadeley<sup>2</sup>, C. Cavill<sup>1</sup>, M. Freeth<sup>1</sup>, J. Hole<sup>1</sup>, R. Sengupta<sup>1</sup>. <sup>1</sup>Rheumatology, Royal National Hospital for Rheumatic Diseases; <sup>2</sup>College of Liberal Arts, Bath Spa University, Bath, UK

**Background:** Axial Spondyloarthritis (axSpA) is a chronic inflammatory disease, mainly affecting the spine and sacroiliac joints. This results in progressive spinal immobility and can result in a level of disability comparable to Rheumatoid Arthritis<sup>1</sup>. The natural history of axSpA and relationships between active inflammation,

structural damage and functional impairment remain poorly understood. Previous studies have hypothesised that functional impairment and spinal mobility in axSpA are independently influenced by disease activity and radiographic damage<sup>1,2,3</sup>.

**Objectives:** To define the relationship between disease activity, spinal mobility and radiographic damage with other patient-reported outcome measures in axSpA.

**Methods:** We performed a cross-sectional analysis of axSpA patients attending the Royal National Hospital for Rheumatic Diseases, Bath. The most recent outcome measures for each patient were compared. Spinal mobility was assessed using the BASMI; structural radiographic damage by the mSASSS; disease activity by the BASDAI; functional impairment by the BASFI; fatigue by the FACIT score; work disability by the WPAI-overall; quality of life by the ASQoL; overall health by the EQ5D. We analysed the correlation between these variables, separately for patients with Ankylosing Spondylitis (AS) and non-radiographic axSpA (nr-axSpA).

**Results:** 721 axSpA patients were included for analysis (548 AS; 42 nrAxSpA; 39 inflammatory bowel disease-related SpA; 47 juvenile-onset SpA; 24 psoriatic SpA; 3 reactive SpA; 18 undifferentiated SpA). Results are summarised in table 1:

Abstract AB0891 – Table 1

AS (n=185–655)	BASMI	BASDAI	mSASSS
BASFI	.52**	.67**	.10
ASQoL	.26**	.69**	–0.14
FACIT	–0.14**	–0.61**	.18*
WPAI-overall	.18**	.54**	–0.07
EQ5D	–0.34**	–0.65**	.11
mSASSS	.63**	–0.13	
BASDAI	.18**		
nr-axSpA (n=15–41)	BASMI	BASDAI	
BASFI	.67**	.71**	
ASQoL	.38*	.64*	
FACIT	–0.34	–0.55**	
WPAI-overall	.10	.56**	
EQ5D	–0.24	–0.58	
BASDAI	.68**		

\*\*Correlation is significant at the 0.01 level (2-tailed); \*Correlation is significant at the 0.05 level (2-tailed)

**Conclusions:** Spinal mobility and disease activity are both correlated with functional impairment, along with other measures of disability and poor health in axSpA, with BASDAI the strongest predictor of BASFI. Consistent with other studies, BASDAI was more predictive of spinal mobility in nrAxSpA than AS patients ( $p=0.002$ , 1-tailed). Structural radiographic damage is the strongest predictor of spinal mobility in AS. BASMI scores merit further investigation to ascertain their potential as a surrogate for radiographic disease burden in axSpA.

#### AB0892 PREDICTING SYNDESMOPHYTE FORMATION IN AXIAL SPONDYLOARTHROPATHY

T. Anachebe, G. Fitzgerald, F.O. Shea. *Rheumatology Department, St James Hospital, Dublin, Ireland*

**Background:** Axial spondyloarthropathy (axSpA) is a chronic inflammatory arthritis affecting the sacroiliac joints and spine. The consequence of inflammation in axSpA is new bone formation, or syndesmophytes, which can result in complete ankylosis of the spine. The pathogenesis of syndesmophyte formation is incompletely understood. It is agreed that presence of baseline syndesmophytes predicts further syndesmophytes, but other predictive factors have been difficult to define. In particular, the impact of extra-articular manifestations (EAMs) on syndesmophyte formation is unclear.

**Objectives:** 1. To assess the burden of radiographic disease in a well-characterised axSpA cohort.

2. To investigate demographic and disease-related variables associated with syndesmophytes (specifically EAMs).

**Methods:** A cross-sectional study of AxSpA patients was performed, comprising standardised clinical assessment and structured interviews. Validated measures of disease severity were used: BASDAI and ASDAS-CRP (disease activity), BASMI (spinal mobility), HAQ (disability), BASFI (function). Lateral x-rays of the lumbar and cervical spine were performed to quantify syndesmophytes using a validated score (mSASSS) ranging from 0–72, with higher numbers indicating a higher burden. BASRI-hip was used to determine hip involvement, assessed on x-ray of pelvis.

**Results:** One hundred and four patients with axSpA were included: 78.8% (n=82) male, 98.1% (n=102) Caucasian, average (SD) age 50.8 (12) years and average disease duration 25<sup>13</sup> years. Modified New York (mNY) criteria were fulfilled by 84.6% (n=88) of the cohort. An EAM was present in 29.1% (n=30) of patients. Uveitis was the most prevalent EAM (29%), followed by inflammatory bowel disease (IBD) (18.4%) and psoriasis (17.5%). Average (SD) BASDAI was 3.9 (2.2), ASDAS-CRP 2.3 (1), BASMI 4.2 (1.9), indicating a mild to moderate disease burden in the cohort.

Median (IQR) mSASSS was 9.5 (33.8), 10.6% (n=11) of patients had an mSASSS of 0% and 7.7% (n=8) had a bamboo spine. There was no significant difference in the median cervical and lumbar spine mSASSS scores (4 v 6,  $p>0.05$ ). The distribution of mSASSS was similar in males and females. HLA-B27 status had no effect on mSASSS scores.

Increasing mSASSS correlated significantly ( $p<0.05$ ) with increasing age ( $\rho=0.6$ ), longer disease duration ( $\rho=0.5$ ), rising BASMI ( $\rho=0.8$ ), higher BASFI ( $\rho=0.4$ ) and higher HAQ ( $\rho=0.3$ ). Worsening hip disease, as measured by BASRI, also correlated with an increasing mSASSS ( $\rho=0.4$ ,  $p<0.01$ ). There was also a statistically significant difference between patients who met mNY criteria compared to those that didn't (median 14.4 v 2.5,  $p<0.01$ ).

Patients with hypertension had a significantly higher median mSASSS score than patients without (25.4 v 7,  $p<0.01$ ). Smoking status, hypercholesterolaemia, ischaemic heart disease and diabetes had no impact on mSASSS.

The presence or absence of uveitis, psoriasis or IBD had no effect on syndesmophyte formation. Equally, peripheral arthritis had no effect. Patients with moderate or severe hip disease were more likely to have a higher mSASSS score (OR 3.8, 95% CI 1.5–9.3).

**Conclusions:** In keeping with previous literature, higher mSASSS was associated with more severe disease. However, in contrast to other published studies, gender had no effect on the severity of mSASSS in our cohort. EAMs did not affect the mSASSS score, but worse hip disease did. It remains a challenge to predict which patients will develop syndesmophytes.

**Disclosure of Interest:** None declared

#### AB0893 INFLUENCE OF INFLAMMATION AND STRUCTURAL DAMAGE ON GLOBAL FUNCTIONING IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS – USING THE ASAS HEALTH INDEX IN ROUTINE CARE

U. Kiltz, T. Wiatr, X. Baraliakos, J. Braun. *Rheumatology, Rheumazentrum Ruhrgebiet, Herne, Germany*

**Background:** Global functioning of patients with spondyloarthritis (SpA) can be influenced by many different factors. ASAS Health Index (ASAS HI) has aims to measure global functioning in patients with SpA. So far, its association with inflammatory spinal changes and structural damage has not been examined.

**Objectives:** To investigate the relationship between spinal mobility and self-report global functioning as assessed by the ASAS HI, and to study the influence of structural and inflammatory spinal changes on global functioning.

**Methods:** Patients from the outpatient clinic of our hospital suffering from axial or peripheral SpA completed questionnaires assessing disease activity and functioning (ASAS HI, pain, BASDAI, ASDAS, BASFI). Axial inflammation as detected by magnetic resonance imaging (MRI) was assessed by the Berlin score, structural damage by the modified Stokes ankylosing spondylitis (AS) Spine Score (mSASSS) and spinal mobility by the Bath AS Metrology Index (BASMI). Imaging were scored by two independent readers. Correlations between the ASAS HI and other health outcomes were analysed by Spearman's test. Logistic regression analyses were performed to investigate the association between functioning and other clinical characteristics.

**Results:** A total of 203 patients (76 non-radiographic (nr)-axSpA, 115 AS patients, and 12 with peripheral SpA (pSpA) were included: 63.5% male, mean (SD) age 46.6 (14.1), symptom duration 18.8 (12.8) years, and 76.4% HLA-B27 positive. The mean values of clinical assessments were ASAS HI 7.9 (4.0), BASDAI 5.0 (2.2), ASDAS 2.8 (1.1), BASMI 3.3 (1.8), pain 6.0 (2.6), and BASFI 5.0 (2.6). Elevated CRP levels were found in 37.4% of the patients, while 59.1% of the AS patients had syndesmophytes and 11.3% a bamboo spine. The median (IQR)

mSASSS value was 3.8 (IQR 1.0–22.1) in AS and 0.0 (IQR 0.0–1.4) in nr-axSpA patients. The mean Berlin AS Spine Score for patients with axSpA was 5.3 (SD 7.1). Patients received a treatment with NSAIDs (62.7%), DMARDs (20.9%) and/or biologics (49.4%). A significant correlation of the ASAS HI was found for BASMI ( $r=0.5$ ), BASDAI ( $r=0.7$ ), ASDAS ( $r=0.5$ ), BASFI ( $r=0.8$ ), BMI (0.3) and Berlin Score (0.3). ASAS HI did not correlate with radiographic damage (mSASSS  $r=0.2$ , presence of bamboo spine  $r=0.2$ ) and CRP ( $r=0.07$ ). Stratifying patients by symptom duration (cut-off 3 years) did not affect these results. Logistic regression showed influence of obesity but not of inflammation or structural damage on global functioning (table 1).

Abstract AB0893 – Table 1

	Univariable		Multivariable	
	OR (CI)	p	OR (CI)	p
Age	1.04 (1.02–1.06)	<b>0.001</b>	-	NS
Male sex	0.47 (0.24–0.93)	0.003	0.09 (0.01–0.71)	<b>0.022</b>
BMI	1.10 (1.03–1.18)	0.006	1.24 (1.05–1.48)	<b>0.013</b>
BASDAI, 0–10	1.35 (1.17–1.57)	<b>&lt;0.001</b>	-	NS
ASDAS	2.51 (1.76–3.57)	<b>&lt;0.001</b>	-	NS
BASFI, 0–10	2.03 (1.66–2.48)	<b>&lt;0.001</b>	1.85 (1.19–2.87)	<b>0.006</b>
BASMI, 0–10	2.0 (1.56–2.54)	<b>&lt;0.001</b>	-	NS
mSASSS, 0–72	1.02 (1.00–1.05)	0.089	-	NS
Berlin Score, 0–72	0.98 (0.91–1.04)	0.490	-	NS

**Conclusions:** The influence of obesity on functioning is remarkable in patients with SpA. In contrast, the influence of structural damage and spinal inflammation on functioning was limited in this study, probably due to the relatively low mSASSS and MRI scores. Further studies with inclusion of more severely affected patients are needed to study the association of functioning, spinal mobility, obesity and radiographic damage over a broader range of affected patients.

AB0894

#### A COMPARISON OF CLINICAL FEATURES IN PATIENTS WITH SPONDYLOARTHRITIS AND UNILATERAL OR BILATERAL HIP ARTHRITIS

W. Hamdi<sup>1</sup>, S. Zrida<sup>1</sup>, H. Riahi<sup>2</sup>, K. Maatallah<sup>1</sup>, D. Kaffel<sup>1</sup>, M. Chelli Bouaziz<sup>2</sup>, M. F. Ladeb<sup>2</sup>, M.M. Kchir<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Institute Mohamed Kassab, Ksar Said, Manouba, Tunisia

**Background:** Axial spondyloarthritis (AS) is a frequent chronic and progressive disease that affects mainly young adults and is characterised by inflammation of the axial skeleton, but peripheral joints such as hips may also be involved. The incidence of hip involvement in AS is around 30%.<sup>1</sup> Nevertheless, data concerning clinical features in patients with spondyloarthritis comparing unilateral and bilateral hip arthritis are lacking.

**Objectives:** To compare clinical, functional and radiologic outcomes in patients with AS with unilateral or bilateral hip arthritis.

**Methods:** Cross-sectional study on 100 patients with AS according to the ASAS criteria of 2009<sup>2</sup> who had unilateral and bilateral hip joint lesions defined by hip pain, limited joint motion and radiographic hip abnormalities. Demographic and clinical outcomes were performed including HLA B27 status. Spinal mobility outcomes were assessed by Schöber index and Bath Ankylosing Spondylitis Metrology Index (BASMI). Radiographic measurements were performed and included Bath Ankylosing Spondylitis Radiology Index (BASRI) and modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS).

**Results:** Bilateral hip joint lesion was reported in 76% of patients which 14 were women and mean age was 37.14 years. Bilateral hip involvement was associated with less height ( $p=0.002$ ), more long disease duration ( $p=0.015$ ), more several clinical spinal involvements with more spinal stiffness ( $p=0.000$ ) and less spinal mobility ( $p=0.004$ ). Extra-articular manifestations were comparable in patients with unilateral and bilateral hip arthritis ( $p=0.55$ ), however HLA B27 antigen was significantly more common ( $p=0.003$ ) in patients with bilateral hip arthritis. BASRI hip ( $p=0.042$ ) and mSASSS ( $p=0.009$ ) scores were used to assess structural damage on plain radiographs and were significantly more important in bilateral involvement. Nevertheless, protrusive form was more frequent in patient with unilateral hip involvement ( $p=0.05$ ).

**Conclusions:** Bilateral hip arthritis seems to be more frequent and more severe than unilateral involvement in patients with AS.

AB0895

#### ARE LATERAL SPINE BONE MINERAL DENSITY MEASUREMENTS USEFUL IN AXIAL SPONDYLOARTHRITIS?

W. Hamdi<sup>1</sup>, D. Ben Nessib<sup>1</sup>, H. Riahi<sup>2</sup>, A. Kasraoui<sup>1</sup>, K. Maatallah<sup>1</sup>, M.D. Kaffel<sup>1</sup>, M. Bouaziz<sup>2</sup>, M.F. Ladeb<sup>2</sup>, M.M. Kchir<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Kassab Hospital, Tunis, Tunisia

**Background:** Bone loss leading to osteoporosis (OP) is a well-known feature of axial spondyloarthritis (AS) although this disease is characterised by calcification in extra osseous tissues and new bone formation. In fact, dual-energy X-ray absorptiometry (DEXA) is the most common imaging method used to measure the bone mineral density (BMD). However, many studies have shown an inferiority of the postero-anterior (PA) spine measurements in reflecting the bone loss compared to lateral spine measurements because of the bridging syndesmophytes which may overestimate the BMD.

**Objectives:** Our aim is to evaluate the Lateral spine BMD (L-BMD) in AS and to assess its association with the disease features.

**Methods:** Seventy-five patients who met the Modified New York Classification criteria for AS were enrolled in this cross-sectional study. BMD was measured using DEXA at PA lumbar, lateral lumbar and hip regions.

**Results:** Sixty-two men and 13 women were enrolled with an average age of 36.8 ± 11.8 years. Bone loss (osteopenia or OP) was noted in 65% of the patients ( $n=46$ ) in PA lumbar and in 63% in lateral lumbar ( $n=45$ ). In L-BMD, BMD was correlated with early menopause and vitamin D level ( $p=0.01$  and  $p=0.04$  respectively). T-score in lateral spine was correlated with coffee consumption ( $p=0.02$ ), physical inactivity ( $p=0.037$ ), sexual hormones disorders ( $p=0.02$ ), hip arthritis ( $p=0.017$ ), BASMI ( $p=0.001$ ), BASFI ( $p=0.03$ ) and ASDAS<sub>vs</sub> ( $p=0.03$ ) scores, ESR ( $p=0.003$ ) and CRP ( $p=0.03$ ) levels, and hip ( $p=0.004$ ), spine ( $p=0.007$ ) and total ( $p=0.001$ ) BASRI.

**Conclusions:** L-BMD seems to be a reliable measurement in AS, and may avoid the overestimation of the BMD values and allows consequently to detect spinal osteoporosis and prevent fractures in AS.

AB0896

#### ASSOCIATION OF IGA ANTIBODIES AGAINST CD74 WITH PRODUCTION OF IL17A BUT NOT OF TNFALPHA IN PATIENTS WITH ACTIVE AXIAL SPONDYLOARTHRITIS

X. Baraliakos<sup>1</sup>, K. Kniesch<sup>2</sup>, N. Baerlecken<sup>2</sup>, J. Braun<sup>1</sup>, T. Witte<sup>2</sup>. <sup>1</sup>Rheumazentrum Ruhrgebiet, Herne; <sup>2</sup>Medizinische Hochschule Hannover, Hannover, Germany

**Background:** Axial spondyloarthritis (axSpA) is strongly associated with HLA-B27. Recently, IgA antibodies (Abs) against CD74 (IgA-anti-CD74) and T-cells carrying CD-74-specific T-cell receptors were also found to be associated with axSpA, especially in patients with ankylosing spondylitis, the radiographic form of axSpA. Tumour necrosis alpha (TNF $\alpha$ ) inhibitors and IL-17 antagonists are efficacious in patients with active axSpA.

**Objectives:** To investigate whether IgA-anti-CD74 Abs are associated with pro-inflammatory cytokines in the sera of patients with HLA-B27-positive and -negative patients with active axSpA.

**Methods:** Blood samples of 62 HLA-B27-positive and 58 HLA-B27-negative patients with axSpA (44% AS) prior to starting a biologic therapy were collected. A cytometric bead-array (CBA Flex Set) was used to measure serum levels of interleukin (IL)-17A, IL-6, IL-1 $\alpha$ , TNF $\alpha$ , and interferon (INF)- $\gamma$ . IgA-anti-CD74 Abs were measured by ELISA, using the predefined cut-off of 15 U/ml. Their mean concentrations were compared between groups using T-tests. The patients who were positive or negative for IgA-anti-CD74 Abs were compared using chi-square test.

**Results:** IgA-anti-CD74 Abs were detected in 54/120 axSpA patients (45%). There were no differences in the baseline demographics and clinical assessments in patients with or without IgA-anti-CD74 Abs. The presence of IgA-anti-CD74 Abs

was associated with higher serum concentrations of IL-17A ( $p=0.01$ ), irrespective of the presence of HLA-B27, CRP and IL-6 (both  $p<0.05$ ) but not TNF $\alpha$  ( $p=0.2$ ).

**Conclusions:** In a cross-sectional study, the presence of IgA Abs against CD74 was associated with serum levels of pro-inflammatory biomarkers such as CRP (and IL-6) and IL-17 but not TNF $\alpha$  irrespective of HLA-B27 status. Longitudinal prospective studies are needed to show that the measurement of IgA anti-CD74 Abs and/or serum cytokines can help to guide treatment decisions.

#### AB0897 THE RELATIONSHIP BETWEEN DISEASE-SPECIFIC INDICES AND BALANCE IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Y. Acar<sup>1</sup>, N. İlçin<sup>1</sup>, B. Gürpınar<sup>1</sup>, G. Can<sup>2</sup>, F. Önen<sup>2</sup>. <sup>1</sup>Physical Therapy and Rehabilitation; <sup>2</sup>Rheumatology, Dokuz Eylül University, izmir, Turkey

**Background:** Axial and periferal joint stiffness, impaired joint mobility and postural deformities may affect balance in AS. However factors affecting balance in AS patients are still unclear. There is limited literature investigating balance-related factors in patients with AS and the results are contradictory.

**Objectives:** The aim of the study was to investigate relationship between disease-specific indices and balance in patients with AS.

**Methods:** 72 patients (46 male, 26 female) with AS were included in the study. The demographic and anthropometric features (age, weight, height, body mass index (BMI)) of patients were recorded. Disease-specific indices used in the study were Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI) and Bath Ankylosing Spondylitis Mobility Index (BASMI). BASDAI for disease activity, BASFI for functional capacity, BASMI for spinal mobility were used. Static and dynamic balance was evaluated with Biodex Balance System SD. Limits of stability and bilateral stance (stable and unstable platform), single leg stance (stable platform) postural stability test results were recorded. Overall stability (OA) indices were used. A high score in the OA index indicates poor balance. Spearman correlation test used for statistical analysing. Correlation analyses were performed between BASDAI, BASFI, BASMI scores and Biodex test results

**Results:** The mean age of patients was 39,95±8,84 years and mean BMI was 26,55±3,82 kg/m<sup>2</sup>. BASDAI, BASFI and BASMI scores of patients are shown in table 1.

**Abstract AB0897 – Table 1.** BASDAI, BASMI and BASFI scores

	AS patients (n=72) Median (IQR 25–75)
BASDAI	2,10 (1,02–3,78)
BASFI	1,10 (0,30–2,74)
BASMI	2,20 (1,00–3,40)

Only positive weak correlation was found between BASFI score and right leg stance overall postural stability index ( $r=0,25$ ,  $p=0,034$ ). No other correlation was detected between BASDAI, BASFI, BASMI scores and Biodex balance test results.

**Conclusions:** The results of our study indicated that there is no relationship between BASDAI, BASFI, BASMI scores and balance except BASFI score and right leg stance postural stability. Our results contradict some previous studies while supporting some studies. This may be due to in our study BASDAI, BASFI and BASMI scores are lower than previous studies or the usage of different methods from previous studies for evaluating balance and postural stability in AS. Further studies are required to establish the actual status of relationship between balance and clinic measurements in AS patients.

#### AB0898 COURSE OF ANKYLOSING SPONDYLITIS IN PREGNANCY

Z. Gandaloeva, O. Kritchevskaya, T. Dubinina, S. Erdes. Laboratory of spondyloarthritis, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Objectives:** To study the effect of pregnancy on ankylosing spondylitis (AS) course.

**Methods:** 86 AS patients having pregnancy in the course of the disease were included into questionnaire survey. Patients' mean age was 34 [30:37] years, mean disease duration was 120 [72:180] month. The questionnaire items were designed to elucidate modifications in AS course during the last pregnancy with live birth outcome. The study is based on patient's self-reported health (SRH) status (improvement, worsening, no change).

**Results:** All responders reported delivery of full-term babies at mean 39 weeks [38:40] of gestation, vaginal delivery was documented by 46 (53,5%) responders, Caesarean section – by 40 (46,5%). AS worsening or improvement during all three trimesters is shown in the table 1.

**Abstract AB0898 – Table 1**

Trimester	Improvement n=42/ 48,8%	Worsening n=58/ 67,4%
I	30/34,8%	15/17,4%
II	21/24,4%	26/30,2%
III	18/20,9%	36/41,8%

Comparison of improvement rates in I and III trimesters,  $p=0,05$ .

Worsening of underlying disease (as compared to the condition 3 months prior to pregnancy) during whole pregnancy was reported by 3 (3,5%) women, absence of noticeable changes was reported by 13 (15,1%) patients, and AS improvement – by 9 (10,4%) participants.

61 (71%) of responders reported fluctuating AS activity during pregnancy. AS worsening was associated with exacerbation of back pain in 44 (51%), emergence and/or recurrence of arthritis – in 15 (17,4%), or uveitis – in 9 (10,4%), and other symptoms – in 11 (12,8%) patients.

**Conclusions:** Therefore, the majority of participants reported the diverse fluctuations in AS course during pregnancy, although 50% of responders reported the improvement in the course of the disease at least during one trimester (more often in the first). Nevertheless, almost 70% of responders reported AS worsening with exacerbations rates increasing in parallel with increasing gestation age. 50% of participants noticed worsening back pain, although special attention should be given to correct evaluation of AS activity in these patients keeping in mind the increased physiological load on the backbone during the second half of pregnancy.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.1968

#### AB0899 ANKYLOSING SPONDYLITIS AND PREGNANCY: DATA FROM THE QUESTIONNAIRE SURVEY-BASED PILOT STUDY

Z. Gandaloeva, O. Kritchevskaya, T. Dubinina, N. Kosheleva, S. Erdes. Laboratory of spondyloarthritis, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia., Moscow, Russian Federation

**Objectives:** To study parity and pregnancy outcomes, as well as causes for not getting pregnant in women with ankylosing spondylitis (AS).

**Methods:** 326 AS female patients were covered by questionnaire survey during the period from November 2016 until October 2017. Mean age of the participants was 32 [28:36] years, mean AS duration – 102 [48:168] months. The questionnaire items covered such issues as prior pregnancies, maternal and neonatal outcomes and potential reasons for not getting pregnant.

**Results:** 194 (59%) (mean age 34,1±5,4 y) females out of 326 surveyed had from 1 to 8 pregnancies, totally 396. Pregnancy outcomes are presented in the table 1.

Abstract AB0899 – Table 1

Pregnancy outcomes	Number of pregnancies (n=396)		p
	before AS onset n=185	after AS onset n=211	
Childbirth: n/%	100/54%	143/67.8%	0.004
-vaginal delivery n	76 (76% of deliveries)	78 (54.5% of deliveries)	0.0005
- Caesarean section n	24 (24% of deliveries)	65 (45.5% of deliveries)	0.0008
Woman's choice abortion	61/33%	30/14.2%	0.0000
Unfavourable maternal outcome *	24/13%	38/18%	0.17
Neonate's birth weight [Me±IQR] (g)	3240 [3050:3600]	3.260 [2950:3600]	0.3
Neonate's birth length [Me±IQR] (cm)	52 [51:53]	51 [50:52]	0.02
Apgar score at 1 min after birth [Me±IQR]	8 [7:8]	8 [7:8]	0.8

\* – non-developing pregnancies, spontaneous abortions, medical abortions and preterm births.

There were no pregnancies in 132 (41%) surveyed females (mean age 29,1 ±5,4 y).

Reasons and causes for not getting pregnant in 132 AS females:

- 48% cases – social, household/domestic and familial, including spouses' unwillingness to have children;

- 44% – presence of AS (fear of teratogenic effect of pharmacotherapeutic agents – 18%, fear of AS inheriting by the baby – 3%, physician's forewarnings – 8%, a combination of abovementioned causes – 15%);

- 8% – infertility.

**Conclusions:** Therefore, data from questionnaire survey of females with AS demonstrates that presence of AS does not increase the incidence of unfavourable maternal outcomes of pregnancies, or negatively affects anthropometric parameters of neonates. Of notice is the fact, that women's choice abortions become more rare after AS diagnosis is established. The rate of Caesarean sections is higher in AS patients. Fear of potentially harmful effects of the disease and it's therapy on the fetus and the baby underlies 30% of all not getting pregnant cases among AS female patients of child-bearing age.

**Disclosure of Interest:** None declared

## Psoriatic arthritis

### AB0900 DESCRIPTIVE STUDY OF PSORIATIC ARTHRITIS IN A HISTORICAL COHORT OF 383 PATIENTS AT A UNIVERSITY HOSPITAL

A. Prior Español<sup>1</sup>, L. Mateo<sup>1</sup>, M. Mihaylov<sup>1</sup>, J. Roca<sup>2</sup>, Y. García Mira<sup>1</sup>, J. Camins<sup>1</sup>, I. Casafont<sup>1</sup>, L. Gifre<sup>1</sup>, A. Riveros<sup>1</sup>, S. Holgado<sup>1</sup>, M. Martínez-Morillo<sup>1</sup>, M. Aparicio<sup>1</sup>, A. Olivé<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Epidemiology, Hospital Germans Trias i Pujol, Badalona, Spain

**Background:** There are few recent large cohort epidemiological studies that analyse the clinical profile of patients with psoriatic arthritis (PsA) who require biological treatment, as well as pharmacological survival and reasons for the suspension of these treatments.

Abstract AB0900 – Table 1

N	383	Basal radiological involvement	
Age at PsA (years), mean (SD)	45.9 (14.5)	Erosive arthritis (%)	33.1
Male sex, n (%)	203 (53)	Mutilating arthritis (%)	1.9
History of psoriasis (%)	84.8	Sacroiliitis (%)	21.2
Nail involvement (%)	46.3	Syndesmophytes (%)	5
Dactylitis (%)	32.9	<b>Immunity</b>	
Enthesitis (%)	36.9	RF positive (%)	6.3
DAS-28 (ESR), mean (SD)	3.5 (1.46)	ANA positive (%)	14.5
CRP mg/L, mean (SD)	8.11 (15.9)	HLA B27 positive (%)	14.1
ESR mm/h, mean (SD)	20.3 (19.2)	<b>Treatment</b>	
<b>Comorbidities</b>		NSAID (%)	96.7
Dyslipidemia (%)	34.2	csDMARDs (%)	84.8
AH (%)	20.9	bDMARDs (%)	32.3
Obesity (%)	28.2		

CRP: C-reactive protein; ESR: erythrocyte sedimentation rate; AH: arterial hypertension; RF: rheumatoid factor; ANA: anti-nucleotide antibodies; NSAID: non-

steroidal anti-inflammatory drugs; csDMARDs: conventional synthetic disease-modifying antirheumatic drugs; bDMARDs: biological disease-modifying antirheumatic drugs.

**Objectives:** To describe the clinical, demographic, epidemiological and radiographic characteristics of patients with PsA in our centre, as well as pharmacological survival and reasons for the suspension of different biological treatments.

**Methods:** Retrospective analysis of patients with PsA treated between 1985 and 2015 at a University Hospital with a referral area of 8 50 000 inhabitants. Demographic, clinical, laboratory and imaging data, as well as patients' clinical and medical treatment records.

**Results:** The main characteristics of the cohort are summarised in table 1:

Approximately one third of patients with PsA (32.3%) required treatment with a biological drug during the course of their disease. The most frequently prescribed first-line drugs (89.5%) were tumour necrosis factor- $\alpha$  inhibitors (TNFi).

During the course of their disease, 27 (21.9%) patients who started biological treatment received a biological drug other than TNFi. Of the 124 patients who started treatment with a biological DMARD, more than half (65, 52.8%) required a change to a second drug, and of these, 27 (41.5%) changed to a third, with up to 7 different biological drugs required in one case. The mean survival time for the first bDMARD was 42.8±42.3 months, with secondary failure the most frequent cause of treatment change (37.8%), followed by adverse effects (27.1%) and primary failure (18.9%). The adverse effects registered were: 20% infections, 20% appearance of neoplasms, 5% allergic reactions and 55% other causes.

**Conclusions:** PsA presents a similar distribution by sex and is usually diagnosed at around the age of 50, having been preceded by cutaneous involvement. PsA is an entity of considerable severity and up to a third of patients will require biological treatments during its evolution. More than half of them will receive a second biological treatment. The retention rate of each drug varies but tends to decrease with each drug change.

### AB0901 VASPIN AND LIPOCALIN2 LEVELS IN PSORIATIC ARTHRITIS

S. Colak<sup>1</sup>, A. Omma<sup>1</sup>, S. Can Sandikci<sup>2</sup>, C. Yucel<sup>3</sup>, T. Turhan<sup>3</sup>. <sup>1</sup>Rheumatology, Ankara Numune Training and Research Hospital, <sup>2</sup>Rheumatology, Diskapi Yildirim Beyazit Training and Research Hospital, <sup>3</sup>Biochemistry, Ankara Numune Training and Research Hospital, Ankara, Turkey

**Background:** Psoriatic arthritis (PsA) is a type of spondyloarthropathies which is affiliated with psoriasis. Metabolic syndrome, diabetes mellitus and cardiovascular diseases are comorbid conditions associated with psoriatic arthritis. Adipokines are suggested to be playing proinflammatory or antiinflammatory roles in the proceeding of inflammatory situations.

**Objectives:** The aim of this study is to investigate the recently interested adipokines vaspin and lipocalin2 levels and their association with disease activity of patients diagnosed with psoriatic arthritis.

**Methods:** The study was conducted between October 2017 and January 2018 at the Rheumatology Clinic of Ankara Numune Training and Research Hospital, Turkey. The vaspin and lipocalin2 levels of 50 PsA patients, diagnosed according to the Classification Criteria for Psoriatic Arthritis (CASPAR), and 36 age- and sex-matched healthy subjects were analysed in current study. The disease activity was assessed by using Psoriasis Area Severity Index, Bath Ankylosing Spondylitis Functional Index, Bath Ankylosing Spondylitis Disease Activity Index and Disease Activity Index for Psoriatic Arthritis. Indexes were applied to the patients in order to evaluate the disease activity.

**Results:** No significant difference was found between groups with respect to age, sex and body mass index. There was significant difference between vaspin (p=0.001) and lipocalin2 (p=0.014) levels among the PsA patients and control groups. There was no significant difference between the groups in terms of disease activity (p>0.05).

Abstract AB0901 – Table 1. The clinical and laboratory parameters in two groups.

	PsA patients (n=50)	Healthy subjects (n=36)	P value
	Mean(±SD)	Mean(±SD)	
Males/Females	15/35	11/25	0.956
Age (years)	44.58 (13.88)	43.08 (11.03)	0.57
Vaspin (ng/L)	391.63 (436.4)	176.67 (122.75)	0.001
Lipocalin2 (ng/L)	5.2 (2.67)	1.94 (2.09)	0.014

PsA: Psoriatic Arthritis, SD:Standard deviation

**Conclusions:** The results of this study points out the possible role of vaspin and lipocalin2 in PsA. In our knowledge, this is the first study comparing the vaspin and lipocalin2 levels of patients with PsA to healthy subjects and these findings

may pioneer further studies investigating the usage of adipokines such as vaspin and lipocalin2 levels as biomarkers in the diagnose and disease course of PsA.

**AB0902 EFFICACY OF TOFACITINIB BY BACKGROUND METHOTREXATE DOSE IN PATIENTS WITH PSORIATIC ARTHRITIS: A POST-HOC ANALYSIS OF POOLED DATA FROM 2 PHASE 3 TRIALS**

A.J. Kivitz<sup>1</sup>, O. FitzGerald<sup>2</sup>, P. Nash<sup>3</sup>, S. Pang<sup>4</sup>, V.F. Azevedo<sup>5</sup>, E. Kudlacz<sup>6</sup>, C. Wang<sup>6</sup>, D. Graham<sup>6</sup>, L. Takiya<sup>7</sup>. <sup>1</sup>Department of Rheumatology, Altoona Center for Clinical Research, Duncansville, PA, USA; <sup>2</sup>Department of Rheumatology, St Vincent's University Hospital, Dublin, Ireland; <sup>3</sup>Department of Medicine, University of Queensland, St Lucia, Brisbane, Australia; <sup>4</sup>St. Jude Medical Center, Fullerton, CA, USA; <sup>5</sup>Universidade Federal do Paraná, Curitiba, Brazil; <sup>6</sup>Pfizer Inc, Groton, CT; <sup>7</sup>Pfizer Inc, Collegeville, PA, USA

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). The efficacy of tofacitinib has been evaluated in 2 Phase 3 studies in patients (pts) with PsA.

**Objectives:** To describe the efficacy of tofacitinib by background methotrexate (MTX) dose in pts with PsA.

**Methods:** This post-hoc analysis utilised efficacy data pooled from 2 Phase 3, randomised, double-blind, placebo-controlled studies (OPAL Broaden [12 months; NCT01877668] and OPAL Beyond [6 months; NCT01882439]) in pts with a diagnosis (≥6 months) of active PsA (≥3 swollen and ≥3 tender joints). Pts in OPAL Broaden were tumour necrosis factor inhibitor (TNFi)-naïve and had an inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD). Pts in OPAL Beyond had an IR to ≥1 TNFi. Pts were randomised to tofacitinib 5 or 10 mg twice daily (BID), placebo or adalimumab 40 mg subcutaneous every 2 weeks (OPAL Broaden; adalimumab data not shown). All pts received a stable dose of 1 csDMARD (eg MTX, leflunomide or sulfasalazine) as background therapy. The maximum dose of MTX allowed per protocol was 20 mg/week. Efficacy outcomes for tofacitinib at Month 3 were evaluated by background MTX dose (≤15 vs >15 mg/week) and included: ACR20/50/70 response rates (≥20/50/70% improvement from baseline, respectively), Health Assessment Questionnaire-Disability Index (HAQ-DI) response rate (reduction from baseline ≥0.35 points) and mean change from baseline in HAQ-DI score. Analyses were based on the full analysis set for pts receiving MTX on Day 1; pts with missing data were considered as having a non-response for binary endpoints. No statistical testing was performed.

**Results:** In total, data from 556 pts who received tofacitinib plus MTX only or placebo plus MTX only (tofacitinib 5 mg BID, n=186; tofacitinib 10 mg BID, n=178; placebo, n=192) were included in this analysis. Most pts were treated with background MTX at doses ≤15 mg/week (n=371, 66.7%; mean [SD] dose, 12.6 [3.1] mg/week) vs >15 mg/week (n=185, 33.3%; mean [SD] dose, 19.8 [0.8] mg/week). Baseline demographics and disease characteristics were generally similar between arms in MTX dose groups (table 1). At Month 3, tofacitinib 5 and 10 mg BID were generally associated with numerically greater ACR and HAQ-DI response rates and greater changes from baseline in HAQ-DI score compared with placebo. The magnitude of tofacitinib effects on efficacy outcomes appeared broadly similar between background MTX dose groups (table 1).

**Abstract AB0902 – Table 1.** Patient demographics and disease characteristics at baseline, and efficacy outcomes at Month 3 by MTX dose

	MTX dose ≤15 mg/week			MTX dose >15 mg/week		
	Tofacitinib 5 mg BID (N=186)	Tofacitinib 10 mg BID (N=178)	Placebo (N=192)	Tofacitinib 5 mg BID (N=186)	Tofacitinib 10 mg BID (N=178)	Placebo (N=192)
<b>Patient demographics and disease characteristics</b>

CRP, mg/L (range)	1.1 (0.1)	1.2 (0.6)	1.2 (0.7)	1.2 (0.6)	1.2 (0.6)	1.1 (0.6)
ESR, mm/h (range)	22.2 (22.1)	19.3 (21.3)	17.7 (21.2)	19.9 (22.0)	18.4 (22.4)	18.1 (22.4)
MTX dose, mg/week (range)	12.6 (3.1)	12.6 (3.1)	12.6 (3.1)	19.8 (0.8)	19.8 (0.8)	19.8 (0.8)
<b>Efficacy outcomes at Month 3</b>						
ACR20 response rate, % (95% CI)	47.4 (35.1-59.8)	54.8 (41.5-68.1)	58.3 (45.0-71.6)	51.4 (38.1-64.7)	51.8 (38.5-65.1)	58.8 (45.5-72.1)
ACR50 response rate, % (95% CI)	37.4 (25.1-49.7)	39.3 (26.0-52.6)	41.5 (28.2-54.8)	37.7 (24.4-51.0)	37.6 (24.3-50.9)	41.5 (28.2-54.8)
ACR70 response rate, % (95% CI)	37.4 (25.1-49.7)	39.3 (26.0-52.6)	41.5 (28.2-54.8)	37.7 (24.4-51.0)	37.6 (24.3-50.9)	41.5 (28.2-54.8)
HAQ-DI response rate (reduction from baseline ≥0.35 points), % (95% CI)	47.4 (35.1-59.8)	54.8 (41.5-68.1)	58.3 (45.0-71.6)	51.4 (38.1-64.7)	51.8 (38.5-65.1)	58.8 (45.5-72.1)
Change from baseline in HAQ-DI score (95% CI)	-0.21 (0.01)	-0.20 (0.04)	-0.27 (0.01)	-0.29 (0.04)	-0.28 (0.04)	-0.21 (0.01)

\*Among pts with baseline HAQ-DI score ≥0.35  
Missing values for ACR20/50/70 response rates and HAQ-DI response rate were considered as non-response to treatment  
LSM were calculated based on a mixed model for repeated measures without imputation for missing values

The maximum permitted dose of MTX was 20 mg/week  
The analyses included all pts who received MTX as background therapy only on Day 1 in the FAS

ACR, American College of Rheumatology; BID, twice daily; CRP, C-reactive protein; FAS, full analysis set; HAQ-DI, Health Assessment Questionnaire-Disability Index; LSM, least squares mean; MTX, methotrexate; n, number of pts with response; N, number of pts included in the analysis; N1, number of pts included in the HAQ-DI response analysis; N2, number of pts evaluable for change from baseline in HAQ-DI at Month 3; pts, patients; SD, standard deviation; SE, standard error

**Conclusions:** The results of this pooled analysis suggest that the efficacy of tofacitinib in pts with PsA was greater than placebo and does not differ when evaluated by background MTX dose (≤15 vs >15 mg/week), although small pt numbers in some groups may limit the conclusions that can be made. These results are consistent with findings from similar analyses of tofacitinib in pts with rheumatoid arthritis.

**AB0903 EFFICACY OF TILDRAKIZUMAB IN ETANERCEPT PARTIAL OR NONRESPONDERS**

J. Crowley<sup>1</sup>, K.A. Papp<sup>2</sup>, C.-H. Hong<sup>3</sup>, J. Parno<sup>4</sup>, A.M. Mendelsohn<sup>4</sup>, Q. Li<sup>5</sup>, N. Cichanowitz<sup>5</sup>, C. La Rosa<sup>5</sup>. <sup>1</sup>Bakersfield Dermatology, Bakersfield, CA, USA; <sup>2</sup>Probit Medical Research, Waterloo, ON; <sup>3</sup>Department of Dermatology and Skin Science, University of British Columbia and Probit Medical Research, Surrey, BC, Canada; <sup>4</sup>Sun Pharmaceutical Industries, Inc., Princeton, NJ; <sup>5</sup>Merck and Co., Inc., Kenilworth, NJ, USA

**Background:** Etanercept (ETN) is an anti-tumour necrosis factor (TNF) medication that was among the first biologics approved for psoriasis. Additional medications have been developed or are in development for psoriasis, and patients who do not adequately respond to ETN may benefit from these more recent biologics.

**Objectives:** Here we report the efficacy of tildrakizumab (TIL), a humanised anti-IL-23p19 monoclonal antibody, as evaluated in patients with moderate to severe chronic plaque psoriasis who were partial (Psoriasis Area and Severity Index [PASI] ≥50 <75) or nonresponders (PASI <50) to ETN and subsequently rerandomized to TIL in the phase 3 reSURFACE 2 trial (NCT01729754).

**Methods:** Patients with psoriasis (≥10% body surface area, Physician's Global Assessment [PGA], and PASI ≥12) participated in reSURFACE 2, a 3-part, 52 week, randomised controlled trial. In Part 1 (Weeks 0–12), patients were randomised to subcutaneous TIL 200 mg, TIL 100 mg, or placebo (PBO) administered at Weeks 0 and 4, or ETN 50 mg administered twice weekly. In Part 2 (Weeks 12–28), TIL and ETN patients remained on the same treatment (TIL administered at Week 16; ETN once weekly), whereas PBO patients were rerandomized to TIL 100 or 200 mg. In Part 3 (Weeks 28–52), ETN responders (PASI ≥75) were discontinued, and partial and nonresponders were switched to TIL 200 mg (administered at Weeks 32, 36, and 48). For this post hoc analysis, the proportion of patients (±SD) with PASI response and PGA response (score of 0 [clear] or 1 [minimal]) with at least a 2-grade score reduction from baseline) were determined at Week 52. Primary results from the trial have been previously reported.<sup>1</sup>

**Results:** In total, 1090 patients were randomised. Of the 313 patients randomised to ETN, by Week 28 there were 83 partial responders and 39 nonresponders. At Week 52 (after 20 weeks of TIL treatment) for ETN partial responders, 75%±5%, 34%±5%, 15%±4%, and 58%±5% had achieved PASI 75, 90, 100, and PGA response of 0/1, respectively, with TIL 200 mg treatment. At Week 52 for ETN nonresponders, 54%±6%, 31%±5%, 10%±3%, and 56%±5% had achieved PASI 75, 90, 100, and PGA response of 0/1, respectively, with TIL 200 mg treatment. Adverse events were similar in patients switched from ETN to TIL at Week 28, compared with the patients who were maintained on TIL through Week 52.

**Conclusions:** A substantial portion of patients with moderate to severe chronic plaque psoriasis who were partial or nonresponders to ETN may respond after switching to treatment with TIL 200 mg. TIL may be a reasonable option for those who do not achieve adequate response to ETN.

#### AB0904 CORRELATION OF RAPID3 AND PROMIS10 IN PATIENTS WITH PSORIATIC ARTHRITIS

A. Ogdie<sup>1</sup>, W.B. Nowell<sup>2</sup>, E. Applegate<sup>2</sup>, K. Gavigan<sup>2</sup>, S. Venkatchalam<sup>2</sup>, M. de la Cruz<sup>3</sup>, E. Flood<sup>3</sup>, E.J. Schwartz<sup>3</sup>, B. Romero<sup>3</sup>, P. Hur<sup>4</sup>. <sup>1</sup>Perelman School of Medicine at the University of Pennsylvania, Philadelphia; <sup>2</sup>Global Healthy Living Foundation, Upper Nyack; <sup>3</sup>ICON, Gaithersburg; <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA

**Background:** In addition to clinician assessment and laboratory tests, patient-reported outcomes (PROs) are important for managing and improving the quality of care in patients with psoriatic arthritis (PsA). The RAPID3 was originally developed for use in patients with rheumatoid arthritis, but it may be used in clinical practice to assess disease activity in patients with PsA.<sup>1</sup> The PROMIS10 is a general (nondisease-specific) PRO instrument that measures physical, mental, and social health.<sup>2</sup> Developed for the general population, PROMIS10 has not yet been specifically validated in PsA.

**Objectives:** To evaluate the relationship between RAPID3 and PROMIS10 in patients with PsA.

**Methods:** US adults with a self-reported diagnosis of PsA were recruited through CreakyJoints (www.CreakyJoints.org), an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers. Respondents completed an online survey that was designed to collect data on socio-demographics and clinical symptoms and included the RAPID3 and PROMIS10 to evaluate disease activity and health-related quality of life (HRQoL), respectively. The RAPID3 consists of three patient self-reported scores (0–10): functional impairment, pain, and patient global assessment; total score  $\leq 3.0$  = near remission, 3.1 to 6.0 = low disease severity, 6.1 to 12.0 = moderate disease severity, and  $\geq 12.1$  = high disease severity. PROMIS10 is a 10-item survey measuring physical and mental domains; individual scores are transformed to T-score distributions normalised to the general population. PROMIS10 individual scores and global physical and mental health T-scores were stratified by RAPID3 disease severity and compared across RAPID3 severity levels using Kruskal-Wallis or ANOVA tests, respectively. Spearman's correlation coefficient was calculated between RAPID3 total score and the PROMIS10 physical health and mental health T-scores, respectively.

**Results:** Among 203 respondents, the mean (SD) age was 51.6 (10.8) years and 172 (84.7%) were female. The mean (SD) cumulative RAPID3 score was 14.7 (5.8) with mean (SD) functional impairment, pain tolerance, and patient's global estimate scores of 3.3 (1.8), 6.0 (2.3), and 5.4 (2.5), respectively. Patients' mean (SD) PROMIS10 global physical and mental health T-scores were 36.4 (7.3) and

40.2 (9.3), respectively. The mean individual domain scores and global T-scores worsened with increasing RAPID3 disease severity levels (all  $p < 0.001$ ) (table 1). PROMIS10 physical and mental health T-scores showed a strong ( $r_s = -0.84$ ) and moderate correlation ( $r_s = -0.57$ ) with RAPID3, respectively.

**Abstract AB0904 – Table 1.** PROMIS10 Scores and Impact of PsA on Work by RAPID3 Disease Activity in Patients with PsA

	RAPID3 Disease Activity*				P value
	Near Remission	Low Severity	Moderate Severity	High Severity	
PROMIS10 domain, mean (SD)	n = 5	n = 14	n = 45	n = 139	
Overall health	3.60 (0.55)	2.93 (0.73)	2.87 (0.69)	2.10 (0.73)	< 0.0001
Quality-of-life	4.20 (0.84)	3.07 (0.83)	3.16 (0.74)	2.29 (0.89)	< 0.0001
Physical health	3.60 (0.55)	2.79 (0.89)	2.73 (0.62)	1.97 (0.73)	< 0.0001
Mental health	4.40 (0.55)	3.14 (1.10)	3.11 (1.05)	2.63 (1.10)	0.0004
Satisfaction with social activities/relationships	4.20 (0.45)	3.00 (0.96)	3.09 (1.06)	2.06 (1.09)	< 0.0001
Ability to carry out every day physical activities	4.80 (0.45)	4.36 (0.63)	3.80 (0.73)	2.68 (0.76)	< 0.0001
Emotional distress	4.80 (0.45)	3.43 (1.16)	3.16 (0.80)	2.65 (1.00)	< 0.0001
Fatigue	4.00 (1.00)	3.50 (0.65)	3.04 (0.71)	2.25 (0.76)	< 0.0001
Pain	4.20 (0.45)	3.93 (0.27)	3.38 (0.49)	2.40 (0.56)	< 0.0001
Global physical health T-score	52.84 (3.07)	46.66 (3.69)	42.35 (4.54)	32.91 (5.06)	< 0.0001
Global mental health T-score	58.44 (5.86)	45.17 (7.60)	44.84 (7.53)	37.50 (8.56)	< 0.0001

PROMIS10, Patient-Reported Outcome Management Information System Global Health short form; RAPID3, Routine Assessment of Patient Index Data 3.

\* Disease severity classified by RAPID3 scores:  $\leq 3.0$  = near remission; 3.1 to 6.0 = low severity; 6.1 to 12.0 = moderate severity;  $\geq 12.1$  = high severity.

**Conclusions:** RAPID3 and PROMIS10 physical health T-scores were strongly correlated in patients with PsA. PROMIS10 mental health scores moderately correlated with RAPID3, suggesting the mental health questions add a different construct. PROMIS10 and RAPID3 are relatively short questionnaires that can be used in the real world to track and monitor disease symptoms and HRQoL in patients with PsA.

#### AB0905 LONG-TERM (5-YEAR) EFFICACY AND SAFETY OF APREMILAST MONOTHERAPY IN DMARD-NAÏVE SUBJECTS WITH ACTIVE PSORIATIC ARTHRITIS

A.F. Wells<sup>1</sup>, C.J. Edwards<sup>2</sup>, A.J. Kivitz<sup>3</sup>, P. Bird<sup>4</sup>, B. Guerette<sup>5</sup>, N. Delev<sup>5</sup>, M. Paris<sup>5</sup>, L. Teng<sup>5</sup>, J.A. Aelion<sup>6</sup>. <sup>1</sup>Rheumatology and Immunotherapy Center, Franklin, USA; <sup>2</sup>University Hospital Southampton, Southampton, UK; <sup>3</sup>Altoona Center for Clinical Research, Duncansville, USA; <sup>4</sup>Combined Rheumatology Practice, Kogarah, Australia; <sup>5</sup>Celgene Corporation, Summit; <sup>6</sup>West Tennessee Research Institute, Jackson, USA

**Background:** Apremilast (APR) is an oral phosphodiesterase 4 inhibitor that helps regulate the immune responses that cause joint inflammation and other manifestations of psoriatic arthritis (PsA), including skin disease.

**Objectives:** To describe the long-term (5 year) efficacy and safety of APR monotherapy in DMARD-naïve subjects with active PsA from the phase 3 PALACE 4 study.

**Methods:** Subjects were randomised (1:1:1) to receive placebo, APR 30 mg BID (APR30), or APR 20 mg BID (APR20). At Week 16, subjects were eligible for early escape; placebo subjects were re-randomised to APR treatment, and APR subjects remained on their assigned dose. At Week 24, all subjects remaining on placebo were re-randomised to APR. Double-blind treatment continued to Week 52, with open-label APR treatment for up to 4 additional years.

**Results:** A total of 527 subjects were randomised and received  $\geq 1$  dose of placebo (n=176), APR30 (n=176), or APR20 (n=175). Among subjects randomised to APR30 at baseline, 45.5% (80/176) completed the Week 260 visit. At Week 52, modified ACR20, ACR50, and ACR70 responses were achieved by 58.0%, 29.8%, and 15.5% of subjects receiving APR30, respectively, regardless of when APR was started (baseline, Week 16, or Week 24). Rates of improvement in PsA signs and symptoms and physical function were sustained up to Week 260 with continued APR30 treatment, including reduction rates in SJC of 84.8% and in TJC of 76.4% (table 1). At Week 260, 65.8%, 39.0%, and 20.3% of subjects achieved a modified ACR20, ACR50, and ACR70 response, respectively, and 71.2% of APR30 subjects with baseline enthesitis achieved a MASES of 0; 95.1% with baseline dactylitis achieved a dactylitis count of 0. At Week 260, 52.9% of subjects achieved a HAQ-DI MCID  $\geq 0.35$ , 60.3% achieved a PASI-50 response, and 47.6% achieved a PASI-75 response (table 1). No new safety concerns were identified with APR up to 260 weeks. During Weeks>208 to $\leq$ 260, the most common adverse event (AEs) among APR30-exposed subjects was nasopharyngitis (6.9%). Serious AEs occurred in 5 APR30 subjects; serious infections were reported in 2 APR30 subjects (pelvic abscess and bacterial urinary tract infection), and no opportunistic infections were reported during Weeks>208 to $\leq$ 260.

#### Abstract AB0905 – Table 1

	Outcomes at Week 260	
	APR30 n=119 <sup>a</sup>	
ACR20, n/m (%)	77/117 (65.8)	
ACR50, n/m (%)	46/118 (39.0)	
ACR70, n/m (%)	24/118 (20.3)	
SJC, mean % change	-84.8	
TJC, mean % change	-76.4	
MASES of 0, n/m (%) <sup>b</sup>	47/66 (71.2)	
Dactylitis count of 0, n/m (%) <sup>c</sup>	58/61 (95.1)	
HAQ-DI (0-3), mean change	-0.38	
HAQ-DI MCID $\geq 0.35^d$ , n/m (%)	63/119 (52.9)	
PASI-50, n/m (%) <sup>e</sup>	38/63 (60.3)	
PASI-75, n/m (%) <sup>f</sup>	30/63 (47.6)	

**Conclusions:** APR monotherapy demonstrated sustained response or improvements in PsA signs and symptoms, including SJC and TJC, enthesitis, dactylitis, physical function, and psoriasis in the population of subjects continuing treatment over 260 weeks. APR continued to demonstrate a favourable safety profile and was generally well tolerated.

#### AB0906 IXEKIZUMAB IMPROVES FATIGUE IN A SUBSET OF PATIENTS WITH PSORIATIC ARTHRITIS

A.-M. Orbai<sup>1</sup>, D.D. Gladman<sup>2</sup>, H. Goto<sup>3</sup>, J. Birt<sup>4</sup>, C.-Y. Lin<sup>4</sup>, T.K. Kvien<sup>5</sup>. <sup>1</sup>Johns Hopkins University School of Medicine, Baltimore, USA; <sup>2</sup>University of Toronto, Toronto, Ontario, Canada; <sup>3</sup>Osaka City General Hospital, Osaka, Japan; <sup>4</sup>Eli Lilly and Company, Indianapolis, USA; <sup>5</sup>Universitetet i Oslo Medisinske Fakultet, Oslo, Norway

**Background:** Psoriatic arthritis (PsA) is a chronic, systemic, inflammatory disease with both articular and extra-articular symptoms including joint pain, enthesitis, dactylitis, and fatigue. Fatigue is increasingly recognised as a priority symptom to patients and has been added to the PsA core set of outcomes for clinical trials.<sup>1</sup> The best instrument to assess fatigue has not yet been defined.

**Objectives:** To assess fatigue improvement following treatment with ixekizumab (IXE), an anti-interleukin (IL)-17A monoclonal antibody, relative to placebo (PBO) in PsA patients.

**Methods:** In two phase 3 randomised controlled trials, patients naïve to and experienced with biologic disease-modifying antirheumatic drugs (SPIRIT-P1, SPIRIT-P2, respectively) received subcutaneous PBO, ADA 40 mg every 2 weeks (SPIRIT-P1 only; reference arm), or IXE 80 mg every 2 weeks (Q2W) or every 4 weeks (Q4W) after a 160 mg starting dose for up to 24 weeks. At Week 16, all patients considered inadequate responders (IR) received rescue therapy. PBO and ADA patients were re-randomised (1:1) to Q2W or Q4W at Week 16 (IR) or Week 24; ADA patients underwent a washout prior to IXE treatment. Patients rated their worst level of fatigue during the past 24 hours at baseline, Week 4, 12, 16, 24, 32, and 52 on the 11-point Fatigue Severity Numeric Rating Scale (Fatigue NRS; not yet validated) where 0=no fatigue and 10=as bad as you can imagine. The minimal clinically important difference (MCID) was defined as an improvement  $\geq 3$  on the Fatigue NRS.

**Results:** At Week 24 significantly more patients in both studies achieved fatigue improvements  $\geq 3$  on the Fatigue NRS with both IXE doses versus PBO (table 1; NRI). When evaluating group level changes, statistically significant improvements on the Fatigue NRS were observed with both IXE doses versus PBO prior to Week 24 in both studies. At Week 24, significance was observed in the SPIRIT-P2 study only (table 1; MMRM). For patients who continued IXE treatment beyond Week 24, mean improvements on the Fatigue NRS persisted through Week 52 (table 1; MI).

Table 1

	SPIRIT-P1				SPIRIT-P2		
	PBO n=106	ADA n=101	Q4W n=107	Q2W n=103	PBO n=118	Q4W n=122	Q2W n=123
Baseline fatigue mean (SD)	5.37 (2.22)	5.45 (2.34)	5.76 (2.29)	5.52 (2.44)	5.9 (2.28)	5.9 (2.48)	6.0 (2.49)
Change from baseline at Week 24 <sup>a</sup>	-1.3 (0.25)	-1.5 (0.24)	-1.6 (0.24)	-1.9 (0.24)	-0.7 (0.37)	-2.0 (0.35)	-2.1 (0.34)
LS mean (SE)					**	**	**
Number (%) of patients achieving MCID at Week 24 <sup>b,c</sup>	19 (20.4)	28 (32.9)	35 (36.8)*	34 (40.5)*	6 (5.6)	33 (30.8)	36 (33.6)
Change from baseline at Week 52 <sup>d</sup> mean (SE)			-2.2 (0.28)	-2.3 (0.28)	-2.2 (0.24)	-2.2 (0.27)	

<sup>a</sup>Mixed models repeated measures (MMRM) analysis was used to calculate change from baseline.

<sup>b</sup>Analysis of patients with Fatigue NRS  $\geq 3$  at baseline. SPIRIT-P1: PBO, n=93; ADA, n=85; Q4W, n=95; Q2W, n=84. SPIRIT-P2: PBO, n=108; Q4W, n=107; Q2W, n=107.

<sup>c</sup>Nonresponder imputation (NRI) was used to impute missing data based on logistic model.

<sup>d</sup>Multiple imputation (MI) was used to impute missing data.

\*p<0.05 vs PBO; \*\*p<0.001 vs PBO.

**Conclusions:** In a subset of PsA patients, clinically meaningful improvements in fatigue level were observed following IXE treatment. Fatigue improvement persisted with up to 1 year of IXE treatment.

**AB0907 TREATMENT PATTERNS IN PSORIATIC ARTHRITIS IN US AND EUROPE: RESULTS FROM A REAL-WORLD INTERNATIONAL SURVEY**

A.-M. Orbai<sup>1</sup>, L. Gossec<sup>2</sup>, S. Lobosco<sup>3</sup>, R. Moon<sup>3</sup>, O. Massey<sup>3</sup>, J. Piercy<sup>3</sup>, J. C. Cappelleri<sup>4</sup>, L. Fallon<sup>4</sup>, P. Young<sup>4</sup>, A.B. Romero<sup>4</sup>, M.-A. Hsu<sup>4</sup>. <sup>1</sup>John Hopkins University, Baltimore, MD, USA; <sup>2</sup>Sorbonne Universités, Paris, France; <sup>3</sup>Adelphi Real World, Bollington, UK; <sup>4</sup>Pfizer, Groton, CT, USA

**Background:** With the availability of a greater range of Psoriatic Arthritis (PsA) treatment options, it is increasingly necessary to understand their use and impact on disease control in real-world practice.

**Objectives:** To assess treatment patterns and their impact on clinical outcomes among PsA patients currently receiving conventional/targeted synthetic disease-modifying anti-rheumatic drugs (cs/tsDMARD) or biologic DMARD (bDMARD).

**Methods:** A point in time survey was conducted in 2015 across the US, France, Germany, Italy, Spain and UK. Patients had physician-confirmed PsA and had to have been receiving their current cs/tsDMARD (bio naïve) or bDMARD (1st or 2nd line) for ≥6 months. Physicians provided information on demographics, treatment history, disease severity, clinical measures included body surface area (BSA), joint count, flare/remission status. Student t-tests, Pearson's chi-squared and Fisher's exact tests were used to compare physician-reported patient profile variables, clinical status and treatment outcomes.

**Results:** 519 physicians (331 rheum, 188 derms) provided data for 2467 PsA patients, 1463 of whom met the inclusion criteria (1136 EU, 327 US). No significant differences were observed between EU and US patients in demographics (male 52.6%, mean age 49.0 years), disease duration 6.3 years; disease severity 29.1% moderate to severe). In the EU, 32.3% patients were on cs/tsDMARDs, 55.4% 1st-line bDMARD, 12.3% 2nd-line bDMARD vs 21.7%, 58.4%, 19.9% respectively in the US.

Time in months (mo) from diagnosis to first cs/tsDMARD was similar in the EU and US (EU mean 4.7 mo; US 8.1 mo, p=0.24), from 1st cs/tsDMARD to 1st bio (EU 37.4 mo; US 29.4 mo, p=0.15). Patients in the EU received more cs/tsDMARDs prior to bDMARD initiation than US patients (mean 1.4 v 0.8; p<0.001). US patients were more likely to have bDMARD without combination cs/tsDMARDs (US 65.1% vs EU 52.3%; p=0.004).

Patients receiving cs/tsDMARDs had a worse clinical profile than those on 1st-line bDMARD in all areas other than joint count. Patients on 2nd-line bDMARD had more symptoms, more affected joints and more likely to flare vs 1st-line bDMARD. They had more affected joints but were less likely to flare vs cs/tsDMARD. These findings were directionally similar in the EU and US (table 1). BSA was higher for cs/tsDMARD patients than for any bDMARD patients.

Table 1

	Current cs/tsDMARD (n=438)	Current ±Line bDMARD (n=820)	P value (cs/tsDMARD v 1st Line bDMARD)	Current 2nd Line bDMARD (n=205)	P value (2nd Line bDMARD v cs/tsDMARD)	P value (2nd v 1st Line bDMARD)
Mean No. of PsA Symptoms	1.7	1.4	<0.001	1.9	0.378	<0.001
Mean No. of Joints Affected	3.2	3.3	0.531	4.0	<0.001	<0.001
Patients currently flaring	6.7%	3.4%	0.032	5.4%	<0.001	<0.001
Currently not in Remission	60.5%	39.5%	<0.001	45.9%	<0.001	0.112
Mean BSA	11.4%	7.8%	<0.001	8.6%	0.001	0.583

**Conclusions:** Only 39%–60% of patients were considered by physicians as in remission, revealing a considerable unmet need in both the EU and US in patients treated with cs/tsDMARDs and bDMARDs. Further research is needed to identify patients on cs/tsDMARDs who may be a candidate for advanced therapy and to recognise patients who might fail on bDMARD who therefore may benefit from a different therapeutic alternative.

**AB0908 ABILITY OF THE REDUCTIVE X-RAY SCORE FOR PSORIATIC ARTHRITIS (REXSPA) TO DETECT CHANGE IN AN OBSERVATIONAL COHORT OF PATIENTS WITH PSA**

A. Antony<sup>1</sup>, A. Allard<sup>1</sup>, G. Shaddick<sup>2</sup>, D. Jadon<sup>3</sup>, C. Cavill<sup>1,4</sup>, E. Korendowych<sup>1</sup>, N. McHugh<sup>1,4</sup>, W. Tillett<sup>1,4</sup>. <sup>1</sup>Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath; <sup>2</sup>Mathematical Sciences, University of Exeter, Exeter; <sup>3</sup>Rheumatology, Cambridge University Hospitals, Cambridge; <sup>4</sup>Pharmacy and Pharmacology, University of Bath, Bath, UK

**Background:** The measurement of radiographic joint damage is important in characterising disease severity, progression, and prognosis in psoriatic arthritis (PsA). Existing radiographic measures are time-consuming to perform, leading to limited data collection from existing longitudinal observational studies.

**Objectives:** We have previously proposed a Reductive X-ray Score for Psoriatic Arthritis (ReXSPA)<sup>1</sup> as more feasible method, and in this study set out to examine the sensitivity of ReXSPA in a new cohort of patients.

**Methods:** A retrospective sample of 28 patients who had hand and feet radiographs at 3 time points (5 years before [T<sup>0</sup>], at the time of [T<sup>1</sup>], and 5 years post [T<sup>2</sup>] commencement of anti-TNF treatment) were taken from the Bath longitudinal PsA cohort. Radiographs were scored for erosion, joint space narrowing and proliferation to calculate the Sharp-van der Heijde modified method (VDH) and ReXSPA scores. A sample of 9 radiographs were scored by all assessors (WT, AA and AA) to determine inter- and intra-rater reliability using intra-class correlation coefficients (ICC). Sensitivity to change was determined from timepoint T<sup>0</sup> to T<sup>2</sup> using the Standardised Response Mean (SRM) and Smallest Detectable Change (SDC).

**Results:** The patients' mean age (SD) at T<sup>0</sup> was 61 years (13.4), the mean disease duration was 11.2 years (11.14). Patients were followed up for a mean (SD) of 10.2 years (2.76). Overall inter- and intra-rater reliability for ReXSPA and VDH were 0.80 and >0.92 and 0.91 and >0.90 respectively. The median (IQR) of ReXSPA score was 8.5 (1–14), 12.5 (5–20) and 14.5 (8–36) at T<sup>0</sup>, T<sup>1</sup>, and T<sup>2</sup> respectively. The percentage SDC was 0.91 for the ReXSPA method and 0.77 for the VDH method, and the SRMs were 0.92 and 0.87 respectively (table 1), demonstrating the sensitivity of both methods in detecting change. There was a trend towards slowing in radiographic progression following the initiation of TNF-inhibitors, but ReXSPA was less sensitive compared to the VDH and was not able to detect a significant change in the rate of progression post-TNF inhibition (p 0.08) (Graphic 1).

Abstract AB0908 – Table 1. Sensitivity to change of each scoring method

Method	Mean Change	SD of change	SEM	SRM	SDC	SDC as% of total score
VDH	22.11	19.14	3.62	0.87	4.09	0.77
Erosion	7.29	10.62	2.01	1.46	2.27	0.71
JSN	16.96	15.17	2.87	0.89	3.24	1.56
ReXPSA	10.9	10.0	1.89	0.92	2.14	0.91
Erosion	3.21	5.31	1.00	1.65	1.13	1.03
JSN	6.36	5.11	0.97	0.80	1.09	1.24
Proliferation	0.96	2.32	0.44	2.40	0.50	1.39

Sharp-van der Heijde modified method (VDH), Standard deviation (SD), Standard error of mean (SEM), Standardised response mean (SRM), Smallest detectable change (SDC).

**Abstract AB0908 – Figure 1.** Cumulative probability plot demonstrating ReXSPA progression pre- and post- TNF inhibition

**Conclusions:** The RexSPA is a reliable and sensitive alternate scoring method for the detection of radiographic progression in an observational cohort of patients with PsA, but not as sensitive to change as the VDH method.

#### CERTOLIZUMAB PEGOL'S EFFECTIVENESS, RETENTION RATE AND SAFETY IN PSORIATIC ARTHRITIS. ROUTINE CLINICAL PRACTICE DATA

A. Conesa Mateos<sup>1</sup>, M. Fernandez-Prada<sup>2</sup>, R. Expósito-Molinero<sup>3</sup>, J. Campos Esteban<sup>4</sup>, P. Rubio Muñoz<sup>5</sup>, J.R. Lamua-Riazuelo<sup>6</sup>, P. Navarro-Alonso<sup>7</sup>, P. Ahijado Guzmán<sup>8</sup>, C.M. Gonzalez Fernandez<sup>9</sup>, on behalf of RENACER Study Group.

<sup>1</sup>Rheumatology, Hospital Clínico Universitario, Valencia; <sup>2</sup>Rheumatology, Hospital Universitario de Guadalajara, Guadalajara; <sup>3</sup>Rheumatology, Hospital Comarcal de Laredo, Laredo; <sup>4</sup>Rheumatology, Hospital Universitario Puerta de Hierro, Madrid;

<sup>5</sup>Rheumatology, Hospital Universitari Germans Trias i Pujol, Badalona;

<sup>6</sup>Rheumatology, Hospital del Henares, Alcala de Henares; <sup>7</sup>Rheumatology,

Hospital de Fuenlabrada, Fuenlabrada; <sup>8</sup>Rheumatology, Hospital General Universitario Gregorio Marañón, Madrid, Spain

**Background:** Certolizumab pegol (CZP) is the only antiTNF pegylated without Fc available for patients with psoriatic arthritis (PsA). The efficacy and safety of CZP in clinical trials is known, but there are few published data on the effectiveness of CZP in a setting of usual clinical practice.

**Objectives:** To evaluate the effectiveness and safety of Certolizumab Pegol (CZP) in a real in PsA patients.

**Methods:** Multicentric cohort of PsA patients treated with CZP according routine clinical practice. Study approved by local Ethics Committee. Maximum time of observation was 12 months. Effectiveness variables: SJC, TJC, PtGA (Patient Global Assessment) and DAS28-CRP. Safety variables: discontinuation rate.

**Results:** 262 patients with PsA were included: 43.5% male, mean (SD) age 49.9 (11.9) years, mean (Q1-Q3) disease duration 6.9 (1.9–9.3) years, 14.9% of patients HLAB27 positive, mean (SD) IMC (kg/m<sup>2</sup>) 26.9 (4.7), never smokers 70.3%. Extra-articular manifestations ever: Psoriasis (90%; PASI<sub>10</sub> ≥10 40.9%), enthesitis (44.4%), dactylitis (41.9%), nail disease (32%), inflammatory bowel diseases (4.9%), 37.3% of the PsA patients had bone erosions and 3% arthritis mutilans. 48.9 patients received 1 prior csDMARD and 52.1% at least 2 csDMARD. Prior bDMARD: 28.4% none; 38.1% 1, 33.5% ≥2. 29.6% of PsA patients received CZP in monotherapy. Mean time on treatment with CZP 10 months.

**Abstract AB0909 – Figure 1.** CZP retention rate and biologics exposure (n° of previous biologics)

Statistically significant differences in SJC, TJC and DAS28-CRP were observed at the last visit comparing with baseline (table 1). Percentage of patients with enthesitis at baseline (25.4%) decrease to 9.5% at the last visit; 73.2% of the patients had a resolution of the enthesitis (MASES=0). The percentage of patients with dactylitis at baseline (29.1%) decrease to 8.6% in the last visit; 82.5% of these patients had a resolution of the dactylitis. Statistically significant reduction of patients with nail disease was observed from 30.6% to 16.4%.

According to Kaplan-Meier analysis, the drug survival of CZP was 78.2%, and no differences were observed in patients who received CZP as first/second biologic or after more than 1 failure to other biologicals agents (Figure1).

262 patients were included in the safety analysis, 21.8% withdrawn treatment: 12.6% due to lack of effectiveness, 5.3% due to intolerance and 3.8% other reasons.

**Abstract AB0909 – Table 1.** Effectiveness

	Baseline	Last visit
DAS28; mean (SD)	4.6 (0.9)	3.8 (1.0)*
TJC; mean (SD)	7.2 (5.1)	4.0 (4.0)*
SJC; mean (SD)	5.0 (3.7)	2.8 (2.8)*
PtGA; mean (SD)	6.9 (1.7)	4.3 (2.5)

\*p<0,001, Wilcoxon's test

**Conclusions:** In this study of routine clinical practice CZP was effective in patients with PsA, with a significant decrease in DAS28-CRP and the percentage of patients with enthesitis and dactylitis. The retention rate of certolizumab pegol was not affected by the number of previous biological treatments.

**Background:** The efficacy of Golimumab treatment in psoriatic arthritis (PsA) patients has been widely documented.

**Objectives:** The aim of this study was to analyse the long-term retention rate of golimumab and to identify independent predictors of drug retention in patients with PsA including concomitant synthetic disease-modifying antirheumatic drugs (sDMARD)

**Methods:** Prospective monocentric cohort of PsA patients treated with golimumab according to clinical practice. Study was approved by local Ethics Committee. Demographic and clinical variables were analysed with Cox proportional hazard regression model.

**Results:** 48 patients were included, 20/48 (41.7%) oligoarticular, 19/48 (39.6%) polyarticular and 9/48 (18.7%) with peripheral and axial PsA. The baseline characteristics of the patients are shown in table 1.

**Abstract AB0910 – Table 1.** Baseline demographic and clinical characteristics of the patients.

Age –mean (SD)-years	48.3 (11.1)
Female gender (%)	25 (52.1%)
Mean evolution time- (SD)- years	8.4 (7.9)
TJC –mean (SD)	4.1 (4.1)
SJC – mean (SD)	2.9 (2.7)
CRP mg/dl – mean (SD)	0.6 (0.7)
DAS 28- CRP – mean (SD)	3.7 (1.5)
Concomitant DMARD (%)	24 (50%)
Biological Therapy naïve (%)	25 (52.1%)

Follow-up time was 89.25 patients-year. Mean survival time was 40.3 months (95% CI: 32.0–48.5). Age, mean evolution time and previous biological use were significant in the univariate analysis. Concomitant sDMARD had no influence on golimumab retention rate (HR: 1.3; 95% CI: 0.5–3.2; p: 0.6). Figure 1. When golimumab was used as first or second biologic treatment, it had a better retention rate than when it was used as third or fourth, but did not reach statistical significance (HR: 2.3; IC 95%: 0.8–6.2; p=0.1). 18/48 patients (37.5%) withdrew golimumab treatment. 13/18 (72.2%) due to lack of efficacy, 1/18 (0.6%) due to adverse events and 4/18 (22.2%) due to other reasons.

**Abstract AB0910 – Figure 1.** Golimumab retention rate and concomitant DMARD

**Conclusions:** Real-world Golimumab retention rate in patients with PsA was good and did not depend on concomitant treatment with sDMARD. When used as first or second biologic, Golimumab retention rate tended to be better.

**AB0911 THE RELATIONSHIP BETWEEN NEUROPATHIC PAIN AND DISEASE ACTIVITY, SLEEP, FATIGUE, QUALITY OF LIFE IN PATIENTS WITH PSORIATIC ARTHRITIS**

C. Unal<sup>1</sup>, F. Ulutatar<sup>1</sup>, M.T. Duruo<sup>2</sup>. <sup>1</sup>PMR Department, <sup>2</sup>PMR Department, Rheumatology Division, Marmara University School of Medicine, Istanbul, Turkey

**Background:** Neuropathic pain (NP) is composed of several abnormal sensations, including burning, prickling hyperalgesia and allodynia. NP is a common problem in rheumatic diseases such as rheumatoid arthritis and ankylosing spondylitis due to inflammatory processes. Previous studies showed that NP in other rheumatic diseases had a negative influence on sleep and quality of life.<sup>1,2</sup>

**Objectives:** To examine the relation of neuropathic pain symptoms in Psoriatic Arthritis (PsA) with demographic, clinical and functional parameters.

**Methods:** PsA patients according to CASPAR criteria were recruited into the study. Demographic and clinical parameters were noted. PainDETECT measurement tool was used for evaluation of NP. Physical examination such as manual muscle testing and sensory examination for hyperalgesia and allodynia was performed (pinprick and light touch test). Disease Activity Score-28 (DAS-28) was noted for disease activity. Associations of NP with quality of life, sleep and fatigue were analysed by filling out Psoriatic Quality of Life (PsAQoL), Pittsburgh Sleep Quality Index (PSQI), Multidimensional Assessment of Fatigue (MAF). PainDETECT scores were categorised as no NP (<12 points), ambiguous NP (13–18 points), probable NP (≥19 points). Group analysis was performed with Independent-Samples Kruskal-Wallis test. Spearman correlation coefficient (rho) was used for correlations between functional parameters. p<0.05 was accepted as significant.

**Results:** Forty eight PsA patients (31 female, 17 male) with a mean age 50.4 years (SD:10.0) and mean disease duration 92.2 months (SD: 90.2) were recruited into the study. The number of patients with ambiguous NP was 6 patients (4 female, 2 male) and probable NP was 12 patients (10 female, 2 male). The mean scores of PSQI, PsAQoL and MAF were significantly higher in patients with NP (p<0.05). There was no difference in mean scores of DAS-28 and disease duration among groups. The correlations between PainDETECT and other functional parameters were found moderate-strong as PSQI (rho=0.43, p=0.002), MAF (rho=0.44, p=0.002), PsAQoL (rho=0.66, p=0.0005). Also, the probability of NP existence increased with the age (rho=0.40, p=0.01). There was no significant correlation between and clinical parameters such as disease duration and DAS-28 (p>0.05).

**Conclusions:** These findings suggest that a substantial number of PsA patients suffering from NP. The neuropathic pain symptoms are found to be associated with worse self-reported quality of life and sleep disturbances. It is important to consider the existence of NP in the assessment and treatment process of PsA.

**AB0912 TWO-YEAR EFFICACY AND SAFETY OF GUSELKUMAB FOR TREATMENT OF MODERATE-TO-SEVERE PSORIASIS: PHASE 3 VOYAGE 1 TRIAL**

C.E. Griffiths<sup>1</sup>, K.A. Papp<sup>2</sup>, A.B. Kimball<sup>3</sup>, B. Randazzo<sup>4</sup>, Y. Wasfi<sup>4</sup>, S. Li<sup>4</sup>, Y.-K. Shen<sup>4</sup>, A. Blauvelt<sup>5</sup>. <sup>1</sup>U of Manchester, Manchester, UK; <sup>2</sup>K. Papp Clinical Research and Probiy Research Inc, Waterloo, Canada; <sup>3</sup>Harvard Medical Faculty Physicians at Beth Israel Deaconess Medical Center, Inc, Boston; <sup>4</sup>Janssen Research and Development, LLC, Spring House; <sup>5</sup>Oregon Medical Research Center, Portland, USA

**Background:** Guselkumab (GUS) is an interleukin-23 inhibitor recently approved in the US for treatment of moderate-to-severe psoriasis.

**Objectives:** Efficacy and safety data for up to 100 wks of GUS treatment are reported.

**Methods:** In the VOYAGE 1 Phase 3, randomised, double-blind, placebo/active comparator-controlled trial, 837 patients were randomised at baseline to placebo (PBO) at wks0/4/12 then GUS 100 mg at wks16/20 and q8w (n=174); GUS at wks0/4/12, and q8w (n=329); or adalimumab (ADA) 80 mg at wk 0, 40 mg at wk1, and q2w through wk47 then GUS at wk52 and q8w (n=334). Efficacy was assessed using nonresponder imputation through wk48 and treatment failure rules from wks52–100.

**Results:** Among patients randomised to GUS, or PBO→GUS at wk16, efficacy (PASI, Psoriasis Area and Severity Index; IGA, Investigator's Global Assessment) was maintained from wks52–100 with continuous GUS treatment. Among those

randomised to ADA (→GUS at wk52), efficacy improved from wks52–100. Similar findings were observed for patient-reported outcomes (PSSD, Psoriasis Symptoms and Signs Diary; DLQI, Dermatology Life Quality Index; table 1). Through wk100, there were no disproportionate increases in rates of Adverse Events (AEs) compared with rates through wk48. Serious AE rates were low and remained stable; no TB, opportunistic infections, or serious hypersensitivity reactions were reported.

#### AB0913 TO DETERMINE THE ASSOCIATION BETWEEN PLAQUE AND NON PLAQUE PSORIASIS WITH THEIR JOINT MANIFESTATION IN PSORIATIC ARTHRITIS PATIENT – A SINGLE CENTRE EXPERIENCE IN MALAYSIA

C.R. Ng<sup>1</sup>, L. Selvarajah<sup>2</sup>, Y.L. Loh<sup>2</sup>. <sup>1</sup>HOSPITAL SULTAN ISMAIL, JOHOR BAHRU, MALAYSIA, Johor Bahru, Malaysia; <sup>2</sup>Internal medicine, HOSPITAL SULTAN ISMAIL, JOHOR BAHRU, MALAYSIA, Johor Bahru, Malaysia

**Background:** Psoriatic arthritis (PsA) which is a member of the spondyloarthritides includes spinal and peripheral joint involvement. It affects women and men equally. The clinical patterns of PsA were classified into 5 groups according to Moll and Wright.<sup>1</sup> Psoriasis is a common chronic inflammatory skin disease and chronic plaque psoriasis is the commonest form.

**Objectives:** To study the relationship between plaque and non-plaque psoriasis with their joint manifestation and to describe the demographic characteristics of PsA patients.

**Methods:** This was a retrospective study. The electronic medical records of all PsA patients under rheumatology clinic Hospital Sultan Ismail followed up from 1/1/2009 to 31/12/2017 were reviewed. Data on demography, type of skin disease, joint manifestation, past medical history, fasting serum lipid and body mass index were obtained and analysed.

**Results:** We identified 163 patients, 84 were male patients with male to female ratio of 1.06. The Malays (84/163) were the majority being affected, followed by the Chinese (46/163), Indians (30/163) and others (3/163). The patients were divided into plaque psoriasis (140/163) and non-plaque psoriasis (23/163). The commonest joint involvement in the study was peripheral joint involvement (121/163), axial involvement (22/163) and both axial and peripheral joint involvement (20/

163). The peripheral joint involvement was categorised as polyarthritis (67/121), followed by oligoarthritis (47/121), distal interphalangeal arthritis (4/121) and arthritis mutilans (3/121). In the study, we divided the patients into plaque psoriasis [peripheral joint involvement (102/140); axial involvement (16/140); both (18/140)] and non-plaque psoriasis [peripheral joint involvement (15/23); axial involvement (6/23); both (2/23)] and analysed the results by using the SPSS logistic regression. It showed no significant association between type of skin psoriasis with its joint manifestation. (p>0.05).

Amongst the 163 patients, 68/163 (42%) had hypertension, 50/163 (31%) had diabetes mellitus, 32/163 (20%) had hypercholesterolemia, 12/163 have ischaemic heart disease, 1 patient had congestive heart disease, 3 had breast cancer, 1 had hepatocellular carcinoma and 2 have chronic kidney disease and cerebral vascular disease respectively.

The fasting serum lipid (FSL) was taken for 140 of them (23 patients no data available) and it was noted in 64/140 (without background history of hypercholesterolemia was noted to have FSL≥5.18 mmol/L). 37/64 have borderline high total cholesterol (5.18 mmol/L –<6.2 mmol/L) and 27/64 have high total cholesterol (≥6.2 mmol/L) according to ATP iii cholesterol classification.<sup>2</sup> 43% (61/142 patients) had body mass index in the overweight group, 29% (41/142 patients) in the obese group and 25% (36/142 patients) in normal group according to WHO classification.<sup>3</sup>

**Conclusions:** There was no association between types of skin psoriasis with their joint manifestation. There was a significant number of patients who had deranged fasting serum lipid and majority of them have BMI in the overweight and obese group.

#### AB0914 COMPARISON OF 25-HYDROXYVITAMIN D3 SERUM LEVELS IN PATIENTS WITH PSORIATIC ARTHRITIS WITH OR WITHOUT PSORIASIS SKIN INVOLVEMENT

C. Pijoan-Moratalla, J.R. Quiñones-Torres, M. Vázquez-Díaz. Rheumatology, HOSPITAL RAMÓN Y CAJAL, MADRID, Madrid, Spain

**Objectives:** To determine 25-hydroxyvitamin D3 (25OH-D3) serum levels in patients with psoriatic arthritis (PA) and to assess differences according to the presence or absence of psoriasis skin involvement. To evaluate the response to vitamin D oral supplements in case of deficiency in both groups.

**Methods:** We conducted an observational retrospective study including patients with diagnosis of PA according to the CASPAR classification criteria who had at least one serum determination of 25OH-D3 in the last 36 months. Clinical and epidemiological data were collected, including arthritis distribution, age of diagnosis, presence of psoriasis skin involvement, treatment received and serum 25OH-D3 levels at baseline and within the subsequent 3 months if treatment with oral supplements had been initiated. Patients already receiving oral vitamin D supplements at baseline were excluded.

**Results:** Sixty patients met the inclusion criteria and were analysed. 42 were female (70%), with a mean age of 47.6 years (range: 30–82). Psoriasis skin involvement was present in 40 patients and preceded onset of arthritis in 80% of them (20% with psoriatic nail dystrophy). Regarding 25OH-D3 levels, mean value was 17.99±13.23 ng/dL. In the global analysis, 7 patients (11.6%) had levels between 0–10 ng/dL, 22 patients (36.6%) between 10–20 ng/dL, 23 patients (38.3%) between 20–30 ng/dL, 6 patients (10%) between 30–40 ng/dL and 2 patients had ≥40 ng/dL. In our sample, 58.53% of patients with psoriasis skin involvement had 25OH-D3 levels higher than 20 ng/dL, in contrast to the group without skin involvement, who reached sufficiency levels only in 37.5% of the cases. In the comparative analysis, patients with psoriasis skin involvement had a mean 25OH-D3 serum level of 20.88 ng/dL whereas patients without skin involvement had lower levels (mean value 19.42 ng/dL). Similarly, patients with skin psoriasis had more frequently 25OH-D3 levels between 20–30 ng/dL (insufficiency) compared to those without this manifestation, who presented lower levels (44% vs 16%) but without statistically significant difference. Results are shown in Figure 1. Finally, all patients presenting 25OH-D3 deficiency at baseline (<20 ng/dL) were treated with oral supplements (calcifediol 0.266 mg every two weeks). Of them, 23 patients had a second determination of 25OH-D3 within the subsequent 3 months, with only 13 patients reaching sufficient levels (56%), whereas the rest did not respond to the dose administered. No statistically significant differences were found in the response depending on the presence or absence of cutaneous psoriasis.

**Abstract AB0914 – Figure 1.** 25-Hydroxyvitamin D3 levels in patients with Psoriatic arthritis with and without psoriasis skin involvement (ng/dL)

**Conclusions:** In patients with PA, the presence of psoriasis skin involvement correlates with higher 25OH-D3 serum levels. This finding could be explained by the treatment received in these patients for moderate-severe skin involvement, which includes topical vitamin D analogues and phototherapy that could increase 25OH-D3 serum levels. After oral supplements, there was no statistically significant difference in the percentage of patients that reached sufficiency levels in both groups.

#### AB0915 BONE MINERAL DENSITY AND FRACTURE FREQUENCIES IN PATIENTS WITH PSORIASIS OR PSORIASIS ARTHRITIS

D. Freier<sup>1</sup>, K. Zeiner<sup>1</sup>, R. Biesen<sup>1</sup>, E. Wiebe<sup>1</sup>, T. Buttgerit<sup>2</sup>, S. Hermann<sup>1</sup>, F. Buttgerit<sup>1</sup>. <sup>1</sup>Rheumatology and clinical Immunology; <sup>2</sup>Dermatology, Charité University Medicine, Berlin, Germany

**Background:** Reports on the prevalence of osteoporosis, osteoporotic fractures and risk factors for osteoporosis in patients with Psoriasis or Psoriasisarthritis are scarce, and the published results on this are, at least in part, contradictory. Additionally, there is no firm understanding of the impact of potential risk factors such as smoking and low Vitamin D (Vit D) levels have on the occurrence of osteoporotic fractures in this patient group.

**Objectives:** Rh-GIOP is an ongoing prospective study monitoring glucocorticoid (GC)-induced osteoporosis of rheumatic patients, established in 2015 at the Charité University Hospital. To date, the database comprises clinical data and bone mineral density data measured by dual x-ray absorptiometry (DXA) of 592 patients with inflammatory rheumatic diseases. (ClinicalTrials.gov Identifier NCT02719314) The objective of this cross-sectional analysis was to evaluate the prevalence of osteoporosis and frequency of fractures in patients with Psoriasis (PSO) or Psoriasisarthritis (PSOA). Additionally, smoking and Vit D status were investigated as possible risk factors for low BMD.

**Methods:** We evaluated the initial visit of 55 patients with PSO (80% female) or PSOA (60% female). Descriptive analyses were performed, and values are displayed as means and standard deviations. For subgroup analyses non-parametric tests were used.

**Results:** Overall mean age was 60 years ( $\pm 12$  years), and 69% of the patients were female. The mean disease duration was 16 $\pm$ 13 years and patients generally showed a good functional status as quantified by the Health Assessment Questionnaire (HAQ mean: 1.0 $\pm$ 0.8). While osteoporosis and osteopenia were present in 16% and 38%, respectively, osteoporotic fractures were found in 33% of all patients. However, the family history for osteoporosis was positive in 20% of the patients. The prevalence of osteopenia and osteoporosis was higher in PSO compared to PSOA patients (70% vs. 45%) without reaching statistical significance. 27% of all patients were treated with glucocorticoids: mean daily dose 3 $\pm$ 8 mg, mean cumulative dose (GCCD) 10.9 g $\pm$ 20.3 g. No significant difference was seen comparing medians of BMD in patients with a GCCD >10 g versus a GCCD <10 g. In terms of risk factors, 27% were smokers and 32% former smokers. 60%

of all patients showed Vit D levels <75 nmol/L. Yet, in subgroup analyses neither smoking nor Vit D deficiency could be identified to have a measurable effect on the BMD. The mean body mass index (BMI) was 28.9 ( $\pm 5.9$ ), and a higher BMI correlated positively with BMD ( $p=0.01$ ).

**Conclusions:** In our patient cohort, the GCCD does not have a measurable impact on the BMD. Additionally, according to current literature the prevalence of osteoporosis seems to be in the same range as in the normal population.<sup>1</sup> Keeping in mind the (still) small number of patients, neither smoking nor Vit D deficiency could be identified as possible risk factors for low BMD, but further investigations are necessary to corroborate these observations.

#### AB0916 EFFICACY AND PREDICTIVE FACTORS OF CLINICAL RESPONSE TO TNF INHIBITORS IN PATIENTS WITH AXIAL AND PERIPHERAL PSORIASIS ARTHRITIS

D. Benavent<sup>1</sup>, C. Plasencia<sup>1</sup>, V. Navarro-Compán<sup>1</sup>, B. Hernández-Breijo<sup>2</sup>, A. Villalba<sup>1</sup>, D. Peiteado<sup>1</sup>, M. de Diego<sup>1</sup>, P. Bogas<sup>1</sup>, E. Fernández<sup>1</sup>, A. Balsa<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Immunology, Hospital Universitario La Paz, Madrid, Spain

**Background:** Patients with psoriatic arthritis (PsA) may have predominant axial (axPsA) or peripheral (pPsA) manifestations. The development of TNF inhibitors (TNFi) has changed the course of PsA. However, most published data is focused on pPsA but almost no data is available for TNFi response in axPsA.

**Objectives:** to analyse the efficacy and the predictive factors of clinical response in patients with axPsA and pPsA starting treatment with TNFi in clinical practice.

**Methods:** An observational study analysing data from a prospective cohort including 93 patients (pts) with axPsA or pPsA treated with TNFi from 2002–2018 was conducted. Demographic information, disease activity indexes (ASDAS for axPsA and DAS28 for pPsA) and laboratory tests were collected before starting TNFi (baseline visit) and 6 months later (6 m visit). At 6 m, the percentage of pts achieving inactive disease (ASDAS <1.3) for axPsA or remission (DAS28 <2.6) for pPsA as well as the percentage of pts achieving clinical improvement (defined as ASDAS-clinically important improvement= $\Delta$ ASDAS>1.1 or  $\Delta$ DAS28 >1.2) were determined. Baseline predictor factors of inactive disease/remission and clinical improvement at 6 m were identified using a univariable and multivariable binary regression models adjusted for confounder factors.

**Results:** Out of 93 included pts, 45 pts had predominant axPsA and 48 pPsA. Administered TNFi was etanercept for most pts (42%), infliximab in 29%, adalimumab in 22% and golimumab in 7%. Baseline characteristics are shown in table 1. Male sex was more frequent in axPsA vs pPsA (62% vs 42%;  $p=0.04$ , respectively). In axPsA, 55% clinically improved and 32% pts achieved inactive disease. After multivariable analysis, male gender (OR 25.8,  $p=0.01$ ) and higher baseline ASDAS (OR 6.3,  $p=0.01$ ) were associated as independent predictors of clinical improvement at 6 m. Also, male gender (OR 15.7,  $p=0.03$ ) and lower BMI (OR

0.7,  $p=0.03$ ) were associated as independent predictor factors for achieving inactive disease. In pPsA, 48% pts clinically improved and 33% pts were on remission at 6 m. The percentage of pts on remission tended to be higher in males than females (47% vs 20%;  $p=0.08$ , respectively). However, after running the regression analyses, none of the baseline predictor factors was significantly associated neither with clinical improvement nor with remission in patients with pPsA.

Abstract AB0916 – Table 1

	Total n=93		p-value
	axPsA n=45	pPsA n=48	
Male, n (%)	28 (62%)	20 (42%)	0.04
BMI, Mean (SD)	27.4 (5.5)	26.4 (5.5)	0.3
Age (years), mean (SD)	56 (12.9)	60 (14.2)	0.2
Smokers, n (%)	18 (41.9%)	15 (31.9%)	0.3
Disease duration (years), mean (SD)	19 (10.8)	18 (8.4)	0.6
HLA B27, n/N (%)	8/22 (36%)	-	
RF, n/N (%)	-	3/44 (6.8%)	
ACPA, n/N (%)	-	0/45	
csDMARDs, n (%)	25 (68%)	24 (68%)	0.9
bASDAS, mean (SD)	3.1 (1.2)	-	
bDAS28, mean (SD)	-	4.7 (1.3)	
bCRP mg/L, mean (SD)	13.2 (14.7)	10.5 (15.3)	0.3
bESR, mean (SD)	26.3 (20.9)	27.8 (19.8)	0.5

**Conclusions:** In clinical practice, 1 out of 3 pts with PsA is on remission 6 m after initiating a TNFi, and 1 out of 2 clinically improve; both proportions are similar for axPsA and pPsA. Male gender, higher baseline disease activity and lower BMI are associated with more probability to achieve inactive disease or an important clinical improvement in axPsA.

#### AB0917 CLINICAL AND RADIOLOGICAL CHARACTERISATION OF AXIAL PSORIATIC ARTHRITIS

E. Alonso Blanco-Morales, M. Lisbona Muñoz, J. Bravo-Ferrer Acosta, R. Gil Vélez, E. Rubio Romero, J. Povedano Gómez. *Reumatología, Hospital Virgen Del Rocío Sevilla España, sevilla, Spain*

**Background:** Defining axial involvement in psoriatic arthritis (PsA) is a challenge; thus, according to which criteria used, the differences in prevalence of axial PsA range from 20% to 70%. Two different phenotypes have been suggested in axial PsA. One of them remind us typical Ankylosing Spondylitis (AS) with bilateral sacroiliitis according to the New York modified criteria (mNY) and a strong association with HLA-B27 and another phenotype with more indolent course, with unilateral and asymmetric sacroiliitis and a lower association to HLA B27

**Objectives:** To define clinical and radiological characteristics of a cohort of patients with axial PsA with associated sacroiliitis in a third level hospital in southern Spain.

**Methods:** Cross-sectional study of an axial PsA cohort with sacroiliitis from a third level hospital. Demographic, clinical and radiological variables were collected. Sacroiliitis was defined as: sacroiliitis according to mNY, or unilateral sacroiliitis grade II in X-ray, and/or according to ASAS criteria of positive MRI. We excluded those patients with axial PsA without sacroiliitis according to definition. The statistical package SPSS v21 was used. The qualitative variables were analysed by the Chi2 and Fisher tests, as required. The quantitative variables were analysed by Student's T Test/Mann-Whitney U Test. Statistical significance was considered, values of  $p<0.05$

**Results:** Of 209 patients with axial SpA with sacroiliitis according to the definition found, 39 patients with diagnosis of PsA were analysed. The main characteristics of the patients are shown in image 1. Of the 39 patients, 62% did not meet mNY criteria. Regarding the patients who met mNY criteria, those who did not comply them had the following differences (specifying the significance). The initial diagnosis was different from PsA more frequently (40% Vs. 17%,  $p=0.124$ ). They presented a lower evolution of the disease (7 Vs. 13 years,  $p=0.052$ ). They presented as initial symptomatology a greater frequency of peripheral arthritis (71% Vs 27%,  $p=0.03$ ); and consequently, a greater presence of mixed forms (92% Vs 53%,  $p=0.015$ ). They presented a lower frequency of positive HLAB27 (21 V. 60,  $p=0.042$ ).

No significant differences were found in reference to the presence of extra-articular involvement (dactylitis, uveitis, psoriasis, onychopathy), nor in reference to the presence of related family history (spondyloarthritis, psoriasis, uveitis).

Abstract AB0917 – Table 1. MAIN CHARACTERISTICS

VARIABLES		
MEN n(%)		27 (69)
AGE median (IQR)		51 (40-57)
AGE AT DIAGNOSIS median (IQR)		41 (29-52)
YEARS OF DISEASE EVOLUTION median (IQR)		6 (2-13)
INITIAL DIAGNOSIS n(%)		
- AS		4 (10)
- PsA		29 (74)
- Indiferenciada SpA		4 (10)
- SAPHO		2 (5)
FINAL DIAGNOSIS n(%)		
- PsA		39 (100)
SAME DIAGNOSIS AS INITIAL n(%)		29 (74)
INITIAL SYMPTOM n(%)		
- Low back pain		17 (43)
- Oligoarthritis		9 (23)
- Poliarthritis		12 (31)
- Dactylitis		1 (3)
INITIAL JOINT PATTERN n(%)		
- Axial		9 (23)
- Peripheral		12 (31)
- Mixed		18 (46)
FINAL JOINT PATTERN n(%)		
- Axial		9 (23)
- Mixed		30 (77)
POSITIVE HLA B27 n(%)		14 (36)
BIOLOGICAL THERAPY n (%)		13 (33)
FAMILY HISTORY n (%)		9 (23)
EXTRAARTICULAR MANIFESTATION n(%)		
- Psoriasis		30 (77)
- Uveitis		3 (8)
- Dactylitis		2 (5)
- Onychopathy		8 (20)

**Conclusions:** Patients with axial PsA with sacroiliitis according to ASAS criteria of positive MRI/unilateral grade II X-ray sacroiliitis presented more peripheral joint involvement, and less association with HLA B27 compared to patients who did not meet mNY criteria. A smaller proportion of patients with axial PsA that meet the mNY criteria suggests a less aggressive structural sacroiliac involvement.

#### AB0918 PATIENT-REPORTED OUTCOMES IMPROVEMENT IN THE RUSSIAN COHORT OF EARLY PERIPHERAL PSORIATIC ARTHRITIS PATIENTS TREATED ACCORDING TO TREAT-TO-TARGET STRATEGY (OPEN-LABEL REMARCA STUDY)

E.E. Gubar, E.Y. Loginova, S.I. Glukhova, T.V. Korotaeva, E.L. Nasonov. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Psoriatic arthritis (PsA) has a significant impact on patients' (pts) mood and quality of life. Patient reported outcome (PRO) measures are an important component to assessing disease impact and therapy response in PsA pts. There is limited data concerning the influence of T2T strategy on PROs.

**Objectives:** To assess the effect of tight control T2T strategy on the PROs dynamics over 1 year (yr) period.

**Methods:** 78 pts (M/F=39/39) with early PsA according to CASPAR criteria were included; mean age  $36.5\pm 10.7$  years, disease duration  $12.2\pm 10.3$  mo. Disease activity indexes (DAS)= $4.0\pm 1.4$ , DAS28= $4.2\pm 1.1$ . Pts underwent standard clinical examination of PsA activity. At baseline all pts were treated with MTX (s/c). The dose of MTX was escalated by 5 mg eow from 10 mg/wk to 20–25 mg/wk. If the patient did not achieve minimal disease activity (MDA) or remission after 3 mo of

MTX mono-therapy, combination therapy with MT +adalimumab 40 mg s/c eow was started. At baseline and after 1 year. of therapy the following PROs were analysed: trends in fatigue (according to FACIT) and in RAPID3 were studied in 64 pts, trends in patient's global disease activity (PGA) and in patient's pain VAS were studied in 78 pts, trends in levels of anxiety and depression (HADS) were studied in 49 pts. The data acquired was analysed with the use of Spearman's correlation.

**Results:** After 1 year of therapy, there was a significant improvement in the following scores: anxiety changed from  $5.7\pm 3.1$  to  $4.3\pm 3.2$ , ( $p=0.003$ ), fatigue from  $35.3\pm 9.6$  to  $41.3\pm 9.9$  ( $p<0.001$ ), RAPID3 from  $13.4\pm 5.1$  to  $6.2\pm 5.2$  ( $p<0.001$ ), PGA from  $56.0\pm 17.8$  to  $18.9\pm 17.1$  ( $p<0.001$ ), pain from  $53.7\pm 18.6$  to  $16.9\pm 16.6$  ( $p<0.001$ ). Depression scores had also changed though not significantly: from  $3.8\pm 3.0$  to  $3.2\pm 3.1$  ( $p=0.235$ ). The dynamics of anxiety and depression indexes correlated with the dynamics of fatigue ( $r=0.64$  and  $r=0.39$ , accordingly), as well as dynamics of FACIT and RAPID3 indexes ( $r=0.36$ ). Correlation of the dynamics of RAPID3 indexes with DAS ( $r=0.45$ ) and DAS28 ( $r=0.41$ ) activity reduction was found. Association of RAPID3 dynamics with the achievement of remission according to DAS ( $p<0.001$ ) and DAS28 ( $p<0.001$ ) was detected. Interrelation between RAPID3 dynamics and the achievement of MDA ( $p<0.001$ ) was found. Correlation between dynamics of anxiety and depression indexes and the reduction of tender joint count (TJC) ( $r=0.38$  and  $r=0.36$ , accordingly) was found. There is correlation between the dynamics of fatigue indexes and TJC, swollen joint count (SJC) and PGA ( $r=0.30$ ,  $r=0.25$  and  $r=0.35$ , accordingly). Dynamics of RAPID3 correlated with TJC and SJC dynamics ( $r=0.33$ ,  $r=0.25$ ), as well as with PGA and pain dynamics ( $r=0.49$  and  $r=0.58$ ). PGA and pain dynamics correlated with TJC and SJC dynamics ( $r=0.34$  and  $r=0.26$ ;  $r=0.43$  and  $r=0.39$ , accordingly).

**Conclusions:** The T2T strategy in the Russian cohort of peripheral early PsA pts demonstrated the improvement of PROs indexes and decrease in PsA activity. Interrelation between the improvement of psychological status according to PROs (anxiety, depression and fatigue) and improvement in joint status (TJC and SJC) was found. RAPID3 is a reliable tool for evaluating patient's status: RAPID3 indexes correlate with the achievement of MDA and DAS/DAS28 remission.

#### AB0919 VALIDATION OF PROTEOMIC BIOMARKERS OBSERVED IN MONOZYGOTIC TWINS CONFIRMS TWO PROTEINS ASSOCIATED WITH PSORIATIC DISEASE

E. Generali<sup>1</sup>, N. Isailovic<sup>1</sup>, A. Ceribelli<sup>1</sup>, F. Sacrini<sup>2</sup>, M. De Santis<sup>1</sup>, M. Meroni<sup>1</sup>, G. M. Guidelli<sup>1</sup>, M. Caprioli<sup>1</sup>, A. Costanzo<sup>2,3</sup>, C. Selmi<sup>1,4</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Dermatology Unit, Humanitas Research Hospital; <sup>3</sup>Dermatology, Hunimed University, Rozzano; <sup>4</sup>BIOMETRA Department, University of Milan, Milan, Italy

**Background:** Skin psoriasis affects 3% of the general population and as much as 20%–40% of patients will develop psoriatic arthritis (PsA), with the two conditions representing a clinical and immunological continuum within a prototype for chronic inflammation. Different from most rheumatic diseases, no serum autoantibody is associated with PsA, and there are currently no biomarkers for an early diagnosis and prediction of PsA onset in psoriasis, frequently causing a delayed diagnosis. Monozygotic twins discordant for psoriasis/PsA represent a unique setting to investigate the influence of environmental and stochastic factors on disease phenotype. Through a high-throughput proteomic analysis (SomaLogic) we have previously identified a set of 13 proteins differentially expressed in the serum of monozygotic twins discordant for psoriatic disease.

**Objectives:** To validate serum proteomic biomarkers of psoriatic disease using commercially available ELISA in monozygotic twins and in unrelated patients with psoriasis or PsA.

**Methods:** Our study included sera from our cohort of monozygotic twins previously described and from 70 unrelated patients with psoriatic disease (psoriasis without PsA 34%–49%, PsA with/without psoriasis 36%–51%; women 46%, median age 52 years, interquartile range 41–59) followed at Humanitas Research Hospital, and 25 healthy subjects (52% women, median age 52 years, IQR 44–62). Candidate serum proteomic biomarkers obtained by SomaLogic analysis were validated using commercially available ELISA kits and proteins are herein anonymized due to a pending patent request.

**Results:** We found a significant correlation between SomaLogic results in monozygotic twins and ELISA results in unrelated psoriatic cases in the serum levels of 2 proteins (figure 1), which are involved in inflammatory and immune response, and one has been previously reported in psoriatic plaques. Four proteins showed

a significantly different expression between psoriasis and PsA versus controls, in particular two proteins have a potential role in disease pathogenesis, as protein #1 acts as cell-surface receptor and regulates differentiation, proliferation and survival of dendritic cells, while protein #2 is involved in regulation of UV radiation-induced apoptosis and protein folding.

**Abstract AB0919 – Figure 1**

**Conclusions:** Two serum proteomic biomarkers, previously identified in a cohort of monozygotic twins discordant for psoriatic disease, can discriminate psoriatic disease, thus representing potential biomarkers of disease and possibly playing a pathogenetic role in disease.

Nero<sup>10</sup>, M. J. Santos<sup>8</sup>. <sup>1</sup>Rheumatology and Metabolic Bone Diseases Department, Hospital de Santa Maria, CHLN and Rheumatology Research Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon, Lisbon Academic Medical Centre; <sup>2</sup>Portuguese Society of Rheumatology, Lisbon; <sup>3</sup>Rheumatology Department, Centro Hospitalar São João do Porto and Faculdade de Medicina da Universidade do Porto, Porto; <sup>4</sup>Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima; <sup>5</sup>Instituto Português de Reumatologia, Lisbon; <sup>6</sup>Rheumatology Department, Hospitais Universitários de Coimbra, Coimbra; <sup>7</sup>Rheumatology Department, Hospital de Egas Moniz, CHLO, Lisbon; <sup>8</sup>Rheumatology Department, Hospital Garcia de Orta, Almada; <sup>9</sup>Rheumatology Department, Centro Hospitalar do Baixo Vouga, Aveiro; <sup>10</sup>Hospital CUF Descobertas, Lisbon, Portugal

**Background:** Tumour necrosis factor inhibitors (TNFi) lead to a dramatic improvement in the management of psoriatic arthritis (PsA). Nevertheless, a significant proportion of patients still do not respond and/or are intolerant to TNFis, requiring treatment switch for an adequate control of disease activity.

**Objectives:** To assess TNFis drug retention and the main reasons for TNFi discontinuation in PsA patients.

**Methods:** This was a non-interventive study of PsA patients registered at the Rheumatic Diseases Portuguese Registry (Reuma.pt), with at least one TNFi prescription. Drug retention for a first, second and third line TNFi was assessed by Kaplan-Meier survival analysis. The reasons for discontinuation were described as frequencies.

**Results:** 750 PsA patients were included, with a mean age of 47.6 years ( $\pm 11.6$ ); 50.3% (n=377) female. 200 patients (26.7%) treated with adalimumab, 335 (44.7%) with etanercept, 114 (12.2%) with golimumab and 101 (13.5%) with infliximab, as first line TNFi. The majority (67.6%) were receiving concomitantly conventional synthetic disease modifying anti-rheumatic drugs (62.3% MTX) and 33.9% corticosteroids. The mean duration of TNFi retention was of  $48.5\pm 40.1$  months, when treated with a 1st TNFi, decreasing to  $35.5\pm 33$  months for the 2nd TNFi, and to  $22.7\pm 22.9$  months for the 3rd TNFi (figure 1). After being treated with a 1st TNFi, the majority of discontinuers (35.8% of the total population), withdraw due to lack or loss of effectiveness (53.5%) and due to adverse events (24.4%). The rates of discontinuation for the 2nd and 3rd TNFi were of 39% and 54%, respectively. Lack or loss of effectiveness and adverse events were maintained the two main reasons of withdrawal for the 2nd (62.3%; 21.6%) and 3rd TNFi (63%; 22.2%).

**Abstract AB0920 – Figure 1.** Drug retention of psoriatic arthritis patients registered at Rheumatic Diseases Portuguese Registry (Reuma.pt), treated with a first (A) second (B) and third (C) tumour necrosis factor inhibitor (TNFi) and overall (D) TNFi drug retention.

**Conclusions:** PsA patients registered at Reuma.pt treated with a 1st TNFi had an overall drug retention of 49 months. We observed a decrease in the average retention of TNFi therapy of 13.0 months in PsA patients who switched to a 2nd TNFi or a 3rd TNFi. Lack or loss of response were the main reason for TNFi discontinuation, independently of TNFi position, responsible for more than half of the discontinuations. The observed short survival of TNFis in PsA, and the inability to regain drug expectancy when switching to another TNFi, highlights the limitations from recycling between TNFi when aiming at long-term disease remission.

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). In a pooled analysis of data from 2 Phase 3 trials in patients (pts) with active PsA, tofacitinib 5 and 10 mg twice daily (BID) significantly improved American College of Rheumatology (ACR) 20 response rates vs placebo (PBO) (50.0, 53.0 vs 28.0%, respectively; p<0.001) and least squares mean (LSM) change from baseline (BL) in Health Assessment Questionnaire-Disability Index (HAQ-DI) score vs PBO (0.38, -0.38 vs -0.16, respectively; p<0.001) at Month 3.<sup>1</sup>

**Objectives:** To compare the efficacy of tofacitinib 5 and 10 mg BID vs PBO in predefined pt subgroups based on differences in BL demographics, disease activity and concomitant medication.

**Methods:** This was an analysis of pooled efficacy data from 2 Phase 3, randomised, double-blind, PBO-controlled studies (OPAL Broaden [12 months; NCT01877668] and OPAL Beyond [6 months; NCT01882439]) in pts with active

PsA (defined as ≥3 swollen and ≥3 tender joints). Pts in OPAL Broaden were tumour necrosis factor inhibitor (TNFi)-naïve with an inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD). Pts in OPAL Beyond had an IR to ≥1 TNFi. Pts were randomised to receive tofacitinib 5 or 10 mg BID, subcutaneous adalimumab 40 mg every 2 weeks (OPAL Broaden; data not included) or PBO. Pts continued to receive a stable dose of a single csDMARD. ACR20 response rates and LSM change from BL in HAQ-DI at Month 3 (primary endpoint data) were evaluated by subgroup category (demographic and disease characteristics at BL or at screening). Analyses were based on the full analysis set (table 1).

**Results:** In total, 238, 236 and 236 pts received tofacitinib 5 mg BID, 10 mg BID, or PBO, respectively. Across all subgroups analysed, tofacitinib 5 and 10 mg BID were generally associated with greater improvements at Month 3 in ACR20 and change from BL in HAQ-DI score than PBO (table 1). In pts classified as current smokers, slightly lower ACR20 response rates and similar changes from BL in HAQ-DI score to corresponding PBO at Month 3 were observed relative to never- or ex-smokers; however, the sample size was small.

**Abstract AB0921 – Table 1.** Pooled efficacy at Month 3 by subgroup

Subgroup	Baseline category	ACR20 response rate (% [n/N1])			LSM change from baseline in HAQ-DI (N2)

**AB0924 EFFICACY OF SUBCUTANEOUS USTEKINUMAB THERAPY IN PATIENTS WITH PSORIATIC ARTHRITIS: A SINGLE CENTRE-STUDY**

I. Añón Oñate, I. Notario Ferreira, L. Pérez Albaladejo, M. Á. Ferrer González, M. Ramírez de la Torre, S. Quirosa Flores, A. García Sánchez, M.C. Ramírez Barberena, J.M. Andreu Ubero, R. Cáliz Cáliz. *Rheumatology, Hospital Universitario Virgen de las Nieves de Granada, Granada, Spain*

**Background:** Ustekinumab is a monoclonal antibody that inhibits IL-12 and 23 that has demonstrated efficacy and safety for the treatment of patients with psoriatic arthritis, plaque psoriasis and Crohn's disease.

**Objectives:** To evaluate the efficacy of subcutaneous Ustekinumab (USTE) in patients with psoriatic arthritis in a real-world clinical setting in Spain.

**Methods:** Descriptive, prospective, longitudinal and open study of 66 patients diagnosed with psoriatic arthritis: 63 patients received subcutaneous USTE 45 mg and 3 patients received USTE 90 mg every 12 weeks, both groups received a first dose of induction according to technical specifications. The following variables were collected: age, sex, years of evolution, previous treatment with Synthetic Disease Modifying Anti-Rheumatic Drugs (DMARDs) and/or biologic DMARD, counting of painful and swollen joints, determination of C-reactive protein, presence of dactylitis, onychopathy and cutaneous psoriasis. Clinical efficacy was evaluated by EULAR response criteria and Disease Activity Score (DAS28) according to low activity criteria (DAS28 >2.6–3.2) and remission clinical (DAS28 <2.6) at 6 and 12 months of treatment. Efficacy was compared between 2 subgroups; one group was: patients with USTE monotherapy vs USTE in combination therapy with DMARDs and the other group was: naïve patients vs patients who received previous treatment with biologic DMARD. Entthesis affectation was evaluated with the MASES index.

**Results:** 66 patients were included, 51.5% were female. The mean age was 47.2 ±11.3 years and the mean disease duration was 6±7.76 years. USTE was prescribed in 44% as a first line therapy and was administered in combination with DMARDs in 51.5% of the patients (mostly, methotrexate). In our cohort, 74.2% of patients had exclusively peripheral involvement, 10.6% had axial involvement and 15.2% had mixed involvement. 21% of our patients had dactylitis and 36% enthesitis, as well as cutaneous psoriasis (74%) and onicopathy (42%). At 6 and 12 months of treatment, we observed a statistically significant decrease in the count of painful and swollen joints, in the DAS28 index and in the MASES index. DAS28 low disease activity rates were 38% at 6 months and 21% at 12 months of treatment. DAS28 remission rates were 21% and 14% at 6 and 12 months respectively. When comparing efficacy by subgroups, we observed higher EULAR response rates in patients with USTE in combination therapy with DMARDs (figure 1) and biologic DMARD-naïve patients (Figure 2) at 6 and 12 months of treatment.

**Abstract AB0924 – Figure 1.** EULAR response rates (%) at 6 (p=0.027) and 12 months

**Conclusions:** Ustekinumab is effective for the treatment of psoriatic arthritis and constitutes an alternative to treatment with anti-TNFα. The dose of Ustekinumab

90 mg may improve the response to treatment in some patients, but we would need a greater number of studies in clinical practice.

**AB0925 COMPARISON OF PSORIATIC ARTHRITIS THERAPEUTIC TARGETS – PSA-MDA AND DAPSA REMISSION/LOW DISEASE ACTIVITY IN PATIENTS TREATED IN THE INSTITUTE OF RHEUMATOLOGY PRAGUE**

J. Stolfa<sup>1,2</sup>, L. Sedova<sup>1,2</sup>, Z. Mares<sup>1</sup>. <sup>1</sup>Institute of Rheumatology, <sup>2</sup>Clinic of Rheumatology, First Medical Faculty, Charles University, Prague, Czech Republic

**Background:** According to the Czech Society of Rheumatology guidelines for therapy and monitoring of psoriatic arthritis from 2016<sup>(1)</sup> which are based on the EULAR recommendations 2015<sup>(2)</sup> the target of the therapy is to attain either minimal disease activity (MDA)<sup>(3)</sup> or remission/low disease activity according to DAPSA<sup>(4)</sup>. In fact, the majority of our patients have only mild skin disease and that's why DAPSA, which is more feasible to use could be sufficient as a target of therapy, even though these two indices assess the disease from different points of view (MDA being more comprehensive, including also entheses, skin and function and DAPSA only joint disease).

**Objectives:** To compare the ability of these two indices in the evaluation of the response to treatment.

**Methods:** We compared both indices from 206 visits in 32 patients with PsA from our database of 247 patients. At first we took the patients who complied with MDA criteria and looked at what percentage of them were in remission/low disease activity, moderate, or high activity respectively at the same time. Then, we took the patients, who did not comply with MDA criteria and again looked at the level of activity according to DAPSA.

**Results:** In the group of patients who fulfilled the MDA criteria (5/7), 99,5% were also in the state of remission or low disease activity according to DAPSA. In only 1 case the activity was assessed as moderate and no patient was in high disease activity state. In the group of patients who did not comply with MDA criteria, 42,6% of pats. were in mild disease activity state and only 57,4% of patients were in moderate, or high activity according to DAPSA – Tab. 1

**Abstract AB0925 – Table 1**

Pats. total. (n):	206	100%	Total:			
Fulfilled MDA	105	50,97%				
				Of total in remission (DAPSA):	40	38,10% 99,05% p<0,01
				Of total in mild activity (DAPSA):	64	60,95%
				Of total in moderate activity (DAPSA):	1	0,95%
				Of total in high activity (DAPSA):	0	0,00%
Not fulfilled MDA	101	49,03%				
				Of total in remission (DAPSA):	0	0,00%
				Of total in mild activity (DAPSA):	43	42,57%
				Of total in moderate activity (DAPSA):	50	49,50% 57,43% p<0,05
				Of total in high activity (DAPSA):	8	7,92%

Abstract AB0925 – Figure 1

**Conclusions:** DAPSA correlates well with MDA in patients with mild skin disease and can be used in these patients instead of MDA. In patients who fail to respond to therapy according to MDA there can be a substantial proportion of patients with mild joint disease, due to more severe skin disease and/or presence of enthesitides, which are nevertheless vaguely defined.

**Background:** Previous literature have investigated that tobacco and weight in patients with psoriatic arthritis (PsA) is associated with a poorer response to antiTNF.

**Objectives:** To investigate the response and survival of Certolizumab pegol (CZP) in PsA patient in daily clinical practice according to their baseline smoking status and Body Mass Index (BMI).

**Methods:** Multicentric cohort of PsA patients treated with CZP according to routine clinical practice. This study was approved by local Ethics Committee. Maximum observation time was 12 months. Effectiveness variables: DAS28 (CRP). Survival rate: Kaplan-Meier.

**Results:** 262 patients with PsA were included: 43.5% male, mean (SD) age 49.9 (11.9) years, mean (Q1-Q3) disease duration 6.9 (1.9–9.3) years, and 14.9% of patients were HLAB27 positive. Among these, 229 (87.4%) had known smoking status (29.7% smokers and 70.3% never smokers) and 85 (32%) had known BMI

(median 26.9 kg/m<sup>2</sup>, SD 4.7). Statistically significant differences in DAS28 were observed at last visit comparing to baseline in both groups according to BMI and smoking status (table 1).

CZP retention rate was 78.5% in non-smokers and 76.7% in smokers. In patients with BMI <25 kg/m<sup>2</sup> CZP retention rate was 78.6% compared to 78.9% in patients with BMI ≥25 kg/m<sup>2</sup> (figure 1). No statistical differences were observed in both sub-groups.

Abstract AB0926 – Table 1

		DAS28
Baseline	BMI <25 kg/m <sup>2</sup>	4.6 (0.9)
	BMI ≥25 kg/m <sup>2</sup>	4.5 (0.8)
	Never smokers	4.6 (0.9)
Last visit	Smokers	4.6 (0.9)
	BMI <25 kg/m <sup>2</sup>	3.6 (1.1)*
	BMI ≥25 kg/m <sup>2</sup>	3.9 (1.0)*
	Never smokers	3.9 (1.0)
	Smokers	# 3.3 (0.8)

\*p<0,05, Wilcoxon test; #p<0.001 T-Student's test (last visit vs basal).

Abstract AB0926 – Figure 1. CZP Retention Rate according to BMI and smoking status in PsA patients.

**Conclusions:** In this daily clinical practice study of patients with PsA treated with certolizumab pegol there was a significant decrease in DAS28-CRP independent of smoking status and BMI. No differences were found in the retention rate of certolizumab pegol based on these two variables.

#### PROBABILITY AND IMPACT OF ACHIEVING LOW DISEASE ACTIVITY OR REMISSION IN PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH APREMILAST: POOLED ANALYSIS OF THE PALACE 1–3 PHASE 3 TRIALS

I. McInnes<sup>1</sup>, P.J. Mease<sup>2</sup>, F. Behrens<sup>3</sup>, A.-M. Orbai<sup>4</sup>, M. Brunori<sup>5</sup>, L. Teng<sup>5</sup>, B. Guerette<sup>5</sup>, J. Smolen<sup>6</sup>. <sup>1</sup>University of Glasgow, Glasgow, UK; <sup>2</sup>Swedish Medical Center and University of Washington School of Medicine, Seattle, USA; <sup>3</sup>Goethe University, Frankfurt, Germany; <sup>4</sup>Johns Hopkins Arthritis Center and Johns Hopkins University School of Medicine, Baltimore; <sup>5</sup>Celgene Corporation, Summit, USA; <sup>6</sup>University of Vienna, Vienna, Austria

**Background:** Baseline (BL) disease characteristics and short-term response status and its implications for long-term achievement of low disease activity (LDA) or remission (REM) in pts with active psoriatic arthritis (PsA) treated with apremilast (APR) are unknown.

**Objectives:** 1) To assess BL clinical Disease Activity for Psoriatic Arthritis (cDAPSA) levels associated with achieving cDAPSA LDA or REM at Week 52 (Wk52); 2) predict cDAPSA response categories at Wk52 based on BL or Wk16 cDAPSA; 3) assess disease activity in different PsA domains associated with cDAPSA categories at Wk52.

**Methods:** Pooled analyses (PALACE 1–3) were performed of pts assigned to receive APR 30 mg BID (APR30) at BL who completed Wk52 and had cDAPSA components available to calculate responses. Pts were grouped according to the cDAPSA categories reached at Wk52 (REM ≤4; LDA>4–≤13; MDA>13–≤27; HDA >27). Shifts of cDAPSA response categories from BL, Wk16 to Wk52 were reported and provided the predictability of BL status or early response to the achievement of cDAPSA categories at Wk52. Mean disease activity in core PsA domains, including swollen (0–76)/tender joint (0–78) (SJ/TJ), enthesitis (MASES), dactylitis count, Patient Global Assessment of Disease Activity (PtGA), Patient Assessment of Pain (PAP), Psoriasis Activity Severity Index (PASI), and Physical Function (HAQ) were reported longitudinally, allocated by cDAPSA category at Wk52. To better describe predictors associated with pts potentially being considered for APR in routine clinical practice, analyses were repeated removing pts in HDA at BL.

**Results:** 374 APR30 pts were included in the analyses. Pts who achieved MDA, LDA or REM at Wk52 indicated sustained improvements in cDAPSA over time; Means of BL cDAPSA scores ≤41 were associated with achievement of MDA, LDA and REM at Wk52 (figure 1). At BL, pts in HDA had 42%, 24% and 5% chances of achieving MDA, LDA or REM at Wk52, respectively. Pts in MDA at BL had 41% and 12% chances of achieving LDA or REM. Pts in LDA had 20% chances of achieving REM. At Wk16, pts in HDA had 43%, 8% and 1% chances of achieving MDA, LDA or REM. Pts in MDA had 38% and 2% chances of achieving LDA or REM. Pts in LDA at BL had a 20% chance of achieving REM and pts in REM a 67% chance of staying in REM. Achieving cDAPSA LDA or REM with APR at Wk52 was associated with residual disease activity as follows: SJ (1.2 vs. 0.24); TJ (2.6 vs. 0.52); MASES (1.2 vs. 0.43); dactylitis (0.47 vs. 0); PtGA (28.0 vs. 7.7); PAP (25.1 vs 7.2); PASI (4.0 vs. 2.7); HAQ (0.62 vs. 0.14). Removing pts with HDA at BL suggested that a mean cDAPSA 21 was associated with achieving LDA or REM at Wk52, corresponding to 5.5 in mean SJC and 9 in mean TJC at BL.

Abstract AB0927 – Figure 1

**Conclusions:** Chances of achieving LDA or REM were greater for pts in MDA at BL or Wk16 vs. HDA. Achieving LDA or REM at Wk52 with APR was associated with good outcomes across core PsA domains. Results suggest that pts with BL moderate cDAPSA disease activity may be particularly suitable for APR therapy.

Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; <sup>8</sup>Amsterdam Rheumatology and Immunology Center, VU University Medical Centre and Reade, Amsterdam, Netherlands; <sup>9</sup>University of Athens Medical School, Athens, Greece; <sup>10</sup>University of Glasgow, UK; <sup>11</sup>Janssen Pharmaceutica NV, Moscow, Russian Federation; <sup>12</sup>Janssen EMEA, Issy-les-Moulineaux, France; <sup>13</sup>Università della Campania "Luigi Vanvitelli", Naples, Italy; <sup>14</sup>Sorbonne Université, Paris, France

**Background:** The purpose of PsABio (ClinicalTrials.gov Id: NCT02627768) is to evaluate the efficacy, tolerability and persistence of TNF inhibitors (TNFi) and ustekinumab (UST) for patients with psoriatic arthritis (PsA) starting 1st, 2nd or 3rd line biologic disease-modifying antirheumatic drugs (bDMARDs) in real-world routine care.

**Objectives:** Here we present the first interim follow-up data on joint-related outcomes.

**Methods:** Of 278 UST- and 285 TNFi-treated patients consecutively enrolled between Dec 2015 and Aug 2017 152 and 151, respectively, had data available at 6 months for their initial line of treatment. Joint-related outcomes, as observed data, were compared between baseline and 6 months within the treatment cohorts.

**Results:** Among all enrolled patients, 7.6% of UST- and 10.2% of TNFi-treated patients stopped or switched to another bDMARD before the 6 month timepoint. For those with 6 month data for their initial bDMARD, UST was used as the first-line bDMARD in 40.1%, as 2nd in 35.5%, and as 3rd in 24.3% of patients; these numbers were 64.2%, 28.5%, and 7.3%, respectively, for TNFi. DAS28 scores improved significantly at 6 months from mean baseline values of 4.3 (SD 1.2) and 4.3 (SD 1.2) for UST and TNFi, respectively, by means of -1.3 (95% CI: -1.6, -1.0) and -1.3 (95% CI: -1.6, -1.1). Significant improvements were seen in both cohorts across all treatment lines (table 1) and subtypes of PsA (data not shown). Minimal disease activity (MDA) was achieved at 6 months for 28.8% of UST- and 29.7% of TNFi-treated patients. CDAI results similarly and significantly improved. For the DAPSA, equally, statistically significant improvements were seen: mean -18.4 (95% CI: -22.2, -14.5) and -19.5 (95% CI: -22.5, -16.5) for UST and TNFi, respectively, with 12.2% and 15.7% reaching DAPSA remission and 37.8% and 37.1% reaching low disease activity. cDAPSA showed similar improvement. For details on components of the DAS28 and of the DAPSA, see table 1. Axial joint involvement was significantly improved with reductions in BASDAI and ASDAS.

**Abstract AB0928 – Table 1.** Baseline and follow-up data for joint-related outcomes for patients having reached 6 months on their initial bDMARD. Values are mean (SD) or mean (95% CI) if not otherwise indicated. na, not applicable.

<sup>a</sup>Among all patients with available data at baseline and month 6 (UST, n=128; TNFi, n=114).

<sup>b</sup>Among all patients with available data at baseline and month 6 (UST, n=82; TNFi, n=87).

**Conclusions:** Both UST- and TNFi-treated patients showed statistically significant and considerable improvements in joint-related measures after 6 months in a real-world setting, irrespective of whether first or further line of treatment.

**AB0929** **BURDEN OF SKIN AND JOINT SYMPTOMS OF PSORIATIC DISEASE: RESULTS OF A MULTI-NATIONAL PATIENT SURVEY**

J.F. Merola<sup>1</sup>, D. Shrom<sup>2</sup>, J. Eaton<sup>2</sup>, C. Dworkin<sup>3</sup>, C. Kresbach<sup>3</sup>, B. Shah-Manek<sup>3</sup>, J. Birt<sup>2</sup>. <sup>1</sup>Brigham and Women's Hospital, Boston; <sup>2</sup>Eli Lilly and Co; <sup>3</sup>Ipsos Healthcare, Indianapolis, USA

**Background:** Psoriatic Arthritis (PsA) and Psoriasis (PsO), have a significant impact on health-related quality of life and work productivity loss. In patients with both PsA and PsO, the full extent of the physical and emotional burden due to either joint related or skin related symptoms is not well understood from the perspective of the patient.

**Objectives:** To evaluate the patients' perspective on the overall burden of skin and joint related symptoms of PsA in a cross-sectional online survey.

**Methods:** A 20 min web based survey was developed based on analysis of 1-on-1 interviews with 30 PsA patients from the US, France and Germany. The final survey contained validated instruments including the PSA Quality of Life (PSAQoL) and Work Productivity and Activity Impairment (WPAI) questionnaires as well as custom questions designed to capture emotional burden of PsA and its impact on daily activities/situations. Additional data collected included demographics, severity of PsO by patient-reported body surface area involvement (BSA), severity of PsA by RAPID3, impact of PsO and PsA by a Patient Global Assessment scale with focus on skin or joint symptoms. In total, 439 psoriatic arthritis (PsA) patients from the US (68%), Germany (20%) and France (12%) were recruited to complete the survey.

**Results:** Among all participants, 30% had mild and 70% had mod-severe PsA based on RAPID-3 cutoffs, while 51% had mild and 48% had mod-severe PsO based on BSA cutoffs. According to multiple regression analyses, severity of joint symptoms and skin symptoms were significantly associated with lower PSAQoL ( $p < 0.0001$ ) as was age ( $p < 0.0001$ ). In patients with mild joint severity, impact of skin symptoms was significantly associated with PSAQoL ( $p < 0.0001$ ) as well as age and gender ( $p < 0.05$ ). Joint severity and impact of joint symptoms were the strongest contributors to the WPAI scores ( $p < 0.05$ ). When asked to select the 2 emotions most associated with the impact of their joint symptoms, patients most often chose fatigue (36%), worry/concern (19%) and depression (17%), and with respect to their skin symptoms, patients most often chose embarrassment (24%), fatigue (23%), worry/concern (14%) and depression (12%). When asked to rate the impact of their disease in certain scenarios or situations, more than 25% of patients reported that their joint symptoms had a severe impact (a choice of 8, 9 or 10 on a 10-point scale with 0=no impact and 10=severe) on fatigue (32%) "leisure activities" (26%), "how they think of themselves" (25%) and "how others felt about them" (26%). More than 25% of patients reported that their skin symptoms had a severe impact on fatigue (28%) "how they think of themselves" (27%), "how others thought of them" (27%) and "making a first impression" (28%).

**Conclusions:** In this survey of patients with PsA, we evaluated the patient's perspective on the burden of both skin-related and joint-related symptoms with the PsAQoL and WPAI as well as with a set of novel questions. Both skin and joint symptoms have a broad and meaningful impact on patient QoL, work productivity and patients reported a range of emotions as well as a variety of impacts on their daily activities with respect to skin and joint symptoms. This data highlights that there is a unique impact of PsA for each patient.

**AB0930** **REAL-WORLD EFFECTIVENESS AND SAFETY OF APREMILAST IN GERMAN PATIENTS WITH PSORIATIC ARTHRITIS: ANALYSIS OF AN ONGOING MULTICENTRE, PROSPECTIVE, NON-INTERVENTIONAL STUDY**

J. Wollenhaupt<sup>1</sup>, T. Klopsch<sup>2</sup>, H. Strothmeyer<sup>3</sup>, S. Morys<sup>4</sup>, C. Bach<sup>4</sup>, N. Nunez-Gomez<sup>4</sup>. <sup>1</sup>Schoen Klinik Hamburg Eilbek, Klinik für Rheumatologie, Hamburg; <sup>2</sup>Praxis Dr. med. Thilo Klopsch, Neubrandenburg; <sup>3</sup>Rheumatologische Gemeinschaftspraxis Düsseldorf, Düsseldorf; <sup>4</sup>Celgene GmbH, München, Germany

**Background:** Apremilast (APR) has been studied extensively in phase III randomised, controlled trials. However, there is a lack of real-world evidence of effectiveness and safety in a broad population of pts with psoriatic arthritis (PsA).

**Objectives:** To assess effectiveness and safety of APR in pts with active PsA from routine clinical practice settings in Germany.

**Methods:** In this multicentre, prospective, non-interventional study, the primary endpoint was the proportion of pts reaching  $\geq 1$  point ( $\geq 20\%$ ) improvement from baseline (BL) in the Physician's Global Assessment of Disease Activity (PhGA) score. Other endpoints included effects on tender and swollen joint counts, psoriasis-affected body surface area (BSA), enthesitis, dactylitis, Patient's Global Assessment of Disease Activity score (PtGA), Psoriatic Arthritis Impact of Disease tool (PsAID), pain and pruritus. The current analysis is based on observed data.

**Results:** The first 202 of a planned 500 German pts receiving APR for  $\geq 4$  month ( $\geq 1$  month [V1],  $\geq 4$  month [V2]) and 127 pts receiving APR for  $\geq 7$  months (V3) were evaluated. Mean age was 54 years, mean BMI was 29 kg/m<sup>2</sup> and 61% were female. The mean duration of psoriasis was 25 years and of PsA was 18 years;  $\approx 30\%$  of pts were biologic-experienced. The mean (SD) PhGA was 2.5 (0.56) at BL. After V1, 60% of pts achieved  $\geq 1$  point improvement in PhGA, which increased to 76% (V2) and 87% (V3). Mean (SD) PhGA decreased to 1.7 (0.69), 1.4 (0.73) and 1.1 (0.74) at V1, V2, and V3 respectively. Achievement of a PhGA of 0-1 increased from 0% of pts at BL to 36.8% (V1), 65.0% (V2) and 77.2% (V3). Median improvements in tender and swollen joint counts from BL to V3 were 57.1% and 60.0%, respectively. BSA improved from 11.4% at BL to 8.3%, 5.1% and 3.5% at V1, V2 and V3, respectively. At BL, 48.4% of pts had enthesitis based on Leeds Enthesitis Index; 46% reached a score of 0 by V1, 57% by V2% and 60% by V3. At BL, 27.3% of pts had dactylitis; a score of 0 was achieved by 40.0%, 66.7% and 71.9% of pts by V1, V2, and V3, respectively. BL mean PsAID score (5.33; max=10.00) decreased to 4.40 (V1), 3.85 (V2) and 3.36 (V3). Improvements were also seen in PtGA, overall pain and pruritus. A sub-analysis suggests that APR was associated with greater benefits in biologic-naive pts compared with pts who previously received biologic therapies. The observed safety and tolerability after V3 was consistent with the known overall safety profile of APR. Common AEs in clinical trials were similar, with a lower incidence: diarrhoea (10.4%), nausea (5.6%), headache (4.0%), and respiratory tract infection (1.2%).
