**Animal study:** Two weeks post-HFD +Ino, ki/ki mice developed hyperuricemia-associated CKD (serum UA: 10–14 mg/dl; BUN: 80 mg/dl), whereas the ki/ki mice on Chow+Ino diet became hyperuricemic without CKD. Control +/-mice on both diets did neither develop hyperuricemia nor CKD. Interestingly, the number of infiltrating neutrophils into the air pouch was reduced in hyperuricemic ki/ki mice with CKD as well as in hyperuricemic ki/ki mice without CKD compared to +/-control mice. We observed less inflammation indicated by decreased IL-1 $\beta$ , TNF $\alpha$ , CXCL1 and myeloperoxidase levels, and a down-regulation of adhesion molecules on infiltrated neutrophils in hyperuricemic ki/ki mice with CKD compared to +/-control mice.

**Conclusions:** Our data show that neutrophils from CKD patients are less able to migrate, which was consistent with data from our novel mouse model demonstrating that hyperuricemia impairs neutrophil chemotaxis in MSU crystal-induced inflammation. This indicated that the mechanism for defective neutrophil migration might be responsible for the lower incidence of acute gouty arthritis in hyperuricemic CKD patients.

## Big data in pre-clinical research

OP0359

### EXPLORATION OF T-CELL SIGNATURES FOLLOWING TCR STIMULATION USING SINGLE CELL RNA-SEQ TO INFORM TREATMENT RESPONSE STUDIES IN RHEUMATOID ARTHRITIS

P. Martin<sup>1</sup>, J. Ding<sup>1</sup>, B. Mulhearn<sup>1</sup>, S. Viatte<sup>1</sup>, S. Eyre<sup>1,2</sup>, <sup>1</sup>Arthritis Research UK Centre for Genetics and Genomics, Centre for Musculoskeletal Research, Manchester Academic Health Science Centre, The University of Manchester, <sup>2</sup>NIHR Manchester Musculoskeletal Biomedical Research Centre, Manchester University NHS Foundation Trust, Manchester, UK

**Background:** For rheumatoid arthritis (RA), as with many other rheumatic diseases, the importance of determining which therapy will work best, early in disease, to prevent further progression, is an important area of research. Progress in treatment response has been limited, possibly due to the complex interplay between various cell types. As such, specific T-cell signatures, determined by single cell RNA-Seq (scRNA-Seq), could be predictive of future response to treatments such as anti-TNF biologic therapies.

**Objectives:** Our aim was therefore to determine the optimal study design and to assess the potential of scRNA-Seq to identify T-cell signatures under resting and stimulated conditions to inform future studies.

**Methods:** Primary CD4 +T cells were either stimulated using anti-CD3/CD28 beads or subjected to the same conditions without stimulation for 4 hours. Single cells were isolated using the 10X Genomics Chromium Controller with a target recovery of 6000 cells. Each scRNA-Seq library was sequenced on 4 Illumina HiSeq 4000 lanes (~200K reads/cell) and processed using the cellranger pipeline. Further quality control and cluster analysis was performed using Seurat.

**Results:** For the unstimulated sample 5,586 cells were recovered and after quality control and filtering, 5,387 cells remained. Similarly, for the stimulated sample, 4,621 cells were recovered and 4,473 remained. This resulted in an average of 1094 and 1456 genes per cell. Similar clusters were seen after downsampling the stimulated dataset to 1 lane (~379M reads, ~82K reads/cell), suggesting that

CD4 +T cells are defined by large gene expression changes rather than subtle variations, consistent with protein expression data. Cluster exploration allowed the identification of several typical CD4 +T cell populations, including naïve, helper and regulatory. Furthermore, alignment of the two conditions in Seurat, identified classical and non-classical markers of activation, such as CD69, CCR7, MYC and PIM3. Finally, the relative cluster location and the expression of indicative markers suggested evidence of a progression from a naïve cell state to an 'active' effector state.

**Conclusions:** This data has provided important insights into future study design and confirmed the potential of scRNA-Seq to identify T-cell signatures. Importantly, despite obvious expression changes, cluster identity was maintained between stimulatory conditions. This implies it is possible to directly compare scRNA-Seq expression profiles between patient samples showing different disease activity without confounding the conclusions and enable the use of scRNA-Seq to investigate its predictive potential in RA treatment response. We are therefore in the process of expanding this work to study patient samples and different cell types. For example we have already generated similar data for monocytes on 3 RA samples and 3 healthy samples.

OP0360

### RNA-SEQUENCING OF 800 HUMAN BLOOD SAMPLES REVEALS SHARED AND UNIQUE EXPRESSION PROFILES ACROSS SEVEN SYSTEMIC AUTOIMMUNE DISEASES

S. Babaei<sup>1</sup>, Z. Makowska<sup>1</sup>, S. Hayat<sup>1</sup>, A. Buttgerit<sup>1</sup>, G. Barturen<sup>2</sup>, J. Kageyama<sup>1</sup>, B. Weiss<sup>1</sup>, J. Wojcik<sup>3</sup>, R. Lesche<sup>1</sup>, M. Alarcón Riquelme<sup>2</sup>, F. McDonald<sup>1</sup>, on behalf of Precisesads Clinical Consortium. <sup>1</sup>BAYER AG, Berlin, Germany; <sup>2</sup>GENYO (Centre for Genomics and Oncological Research), Granada, Spain; <sup>3</sup>Quartz Bio, Geneva, Switzerland

**Background:** Systemic autoimmune diseases (SADs) are chronic inflammatory conditions with limited treatment options. Although SADs encompass different clinical diagnoses, many of them share common pathophysiological mechanisms and have similar clinical manifestations. Therefore, defining a precise diagnosis and consequently an appropriate treatment is complex.

**Objectives:** We aimed to identify characteristic expression profiles for patients diagnosed with different SADs and find specific biomarkers for each disease based on whole blood RNA-seq data.

**Methods:** As part of the ongoing IMI PreciseSADS project we generated and analysed globin-depleted, polyA-selected RNA-seq data from an initial subset of 800 peripheral blood samples of healthy controls and patients with seven different SADs: systemic lupus erythematosus (SLE), rheumatoid arthritis (RA), systemic sclerosis (SSc), Sjögren's syndrome (SSj), mixed connective tissue disease (MCTD), undifferentiated connective tissue disease (UCTD) and primary antiphospholipid syndrome (PAPS). Differential gene expression analysis was performed with DESeq2 and biomarker discovery was achieved using linear support vector classifier-based feature elimination and logistic regression-based estimator with cross-validation.

**Results:** We identified unique and common genes that were differentially expressed between controls and each of the seven SADs. The greatest extent of transcriptional dysregulation was found in SLE and MCTD patients, while UCTD, SSc and RA showed fewest differentially expressed genes. We found large and statistically significant overlaps between the lists of differentially expressed genes for each disease, with SLE, MCTD, Sjs and UCTD showing most pronounced similarity at the gene expression level. The overlapping genes were enriched in interferon signalling pathway and the classical complement pathway. Low overlap was found between Sjs and RA, and Sjs and SSc.

We also looked for unique gene expression patterns in each disease with the aim of identifying potential biomarkers. We were able to define gene signatures differentiating between SADs and controls and also between SAD pairs.

**Conclusions:** Even though we were able to identify a limited number of disease specific signature genes, there are extensive and statistically significant overlaps in gene expression profiles of the seven investigated SADs. Similar to the clinical manifestations, the data presented here suggest that also on the molecular level, these diseases share a large portion of their pathophysiology. Work is ongoing to expand the dataset for confirmation of these preliminary data.

**How do you sleep?****OP0361-HPR SLEEPING PROBLEMS AND ANXIETY IS ASSOCIATED TO CHRONIC MULTISITE MUSCULOSKELETAL PAIN IN SWEDISH HIGH SCHOOL STUDENTS**

J.S. Malmberg<sup>1</sup>, A. Bremlander<sup>1</sup>, M.C. Olsson<sup>1</sup>, A.-C. Bergman<sup>2</sup>, S. Brorsson<sup>2</sup>, S. Bergman<sup>3</sup>. <sup>1</sup>The Rydberg Laboratory for Applied Sciences, Halmstad University; <sup>2</sup>Spenshult Research and Development Center, Halmstad; <sup>3</sup>Primary Health Care Unit, Department of Public Health and Community Medicine, Institute of Medicine, The Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden

**Background:** The relationship between chronic multisite musculoskeletal pain (CMP) and sleep is complex, where pain can lead to sleeping problems and lack of sleep can intensify the pain perception. Most previous studies relates to adults, but adolescents may also suffer from CMP, and there is a need for more knowledge regarding the relationships between CMP and sleeping problems, stress, anxiety, depression, and health status.

**Objectives:** To study background factors associated to CMP in first year Swedish high school students.

**Methods:** First year Swedish high school students (n=296) were invited to complete questionnaires on chronic pain (mannequin with 18 body regions), sleeping problems (Uppsala Sleep Inventory, four items scored from 1–5), stress (ELO questions, scored from 1–5), anxiety and depression (Hospital Anxiety and Depression Scale, scored from 0–21), health status (EQ-5D, scored from 0 to 1, worst to best) and physical activity (International Physical Activity Questionnaire, categorised into low, moderate and high levels). Stress and sleeping items were dichotomized into 1–3 points (best) vs 4–5 points (worst). Individuals scoring at least severe problems (4 points) at one or more sleeping items were classified as having severe sleeping problems. HADS were categorised as non-cases (0–7), possible<sup>7–10</sup> and probable cases (11–21 points). Students were grouped as having CMP (pain present in ≥3 regions) or not (no chronic pain or chronic pain in 1–2 regions). Multiple logistic regression analyses (adjusted for sex) with CMP as dependent variable were performed in SPSS, version 24.

**Results:** 254 students (86% of total sample, 87 boys and 167 girls) with a mean age of 16.1 (SD 0.6) years participated in the study. CMP was present in 25 (9.8%) students with no differences between boys and girls (8.0% vs 10.8%; p=0.488). Having CMP was associated with reporting severe sleeping problems (OR 2.49, 95% CI: 1.06 to 5.81, p=0.035) with initiating sleep, maintaining sleep, early morning awakenings and/or not feeling restored after sleep in comparison to the other students. Students with CMP were more likely to be categorised as probable cases for anxiety (OR 3.06, 95% CI: 1.09 to 8.61, p=0.034), but there were no associations for possible cases for anxiety (OR 1.15, 95% CI: 0.38 to 3.51, p=0.800), possible cases (OR 2.03, 95% CI: 0.63 to 6.54), or probable cases for depression (OR 3.35, 95% CI: 0.33 to 33.83). There was a nearly significant association between stress and belonging to the CMP group (OR 2.31, 95% CI: 0.97 to 5.53, p=0.059). A higher self-reported health status was associated to a lower likelihood for CMP (OR 0.04, 95% CI: 0.01 to 0.27, p=0.001). Distribution of physical activity levels of low, moderate and high was not significantly associated to having CMP in comparison with not having it.

**Conclusions:** One in ten high school students fulfilled criteria for having chronic multisite musculoskeletal pain. CMP was associated to sleeping problems, anxiety, and a worse health status. The results from this study may be used by school health-care professionals in their preventive work to promote student's health.

**Background:** Patients with Systemic Lupus Erythematosus (SLE) and Rheumatoid Arthritis (RA) have increased risk of cardiovascular disease (CVD).

**Objectives:** We investigated whether single nucleotide polymorphisms (SNPs) at autoimmunity risk loci were associated with CVD in SLE and RA.

**Methods:** SLE patients (n=1045) were genotyped using the 200K Immuchip SNP array (Illumina). The allele frequency was compared between patients with and without different manifestations of CVD. Results were replicated in a second SLE cohort (n=1043) and in an RA cohort (n=824). We analysed publicly available genetic data from the general population, performed electrophoretic mobility shift assays and measured cytokine levels and occurrence of anti-phospholipid antibodies (aPLs).

**Results:** We identified two new putative risk loci associated with increased risk for CVD in two SLE populations, which remained after adjustment for traditional CVD risk factors. An *IL19* risk allele was associated with stroke/myocardial infarction in SLE (OR 2.3 (1.5–3.4), p=8.5×10<sup>-5</sup>) and RA (OR 2.8 (1.4–5.6), p=3.8×10<sup>-3</sup>), meta-analysis (OR 2.5 (2.0–2.9), p=3.5×10<sup>-7</sup>), but not in population controls. The *IL19* risk allele affected protein binding and SLE patients with the risk allele had increased levels of plasma-IL10 (p=0.004) and aPL (p=0.01). An *SRP54-AS1* risk allele was associated with stroke/transient ischaemic attack in SLE (OR 1.7 (1.3–2.2), p=2.5×10<sup>-5</sup>) but not in RA. The *SRP54-AS1* risk allele is an expression quantitative trait locus for four genes.

**Conclusions:** The *IL19* risk allele was associated with stroke/myocardial infarction in SLE and RA, but not in the general population, indicating that shared immune pathways may be involved in the CVD pathogenesis in inflammatory rheumatic diseases.

**OP0363 OPTIMISINGPRECISION MEDICINE BY USING GENETICS TO ASSIGN DIAGNOSTIC PRIOR PROBABILITIES TO PATIENTS WITH SYNOVITIS – PROOF OF PRINCIPLE**

R. Knevel<sup>1,2,3</sup>, C. Terao<sup>4,5</sup>, J. Cui<sup>2</sup>, K. Slowikowski<sup>3,6</sup>, T. Huizinga<sup>1</sup>, B. Karlson<sup>2</sup>, K. Liao<sup>2</sup>, S. le Cessie<sup>7</sup>, S. Raychaudhuri<sup>3,8,9</sup>. <sup>1</sup>Rheumatology, LUMC, Leiden, Netherlands; <sup>2</sup>Rheumatology, Brigham and Women's Hospital, Harvard Medical School, Boston; <sup>3</sup>Broad Institute, Cambridge, USA; <sup>4</sup>Rheumatology, University of Shizuoka, Shizuoka; <sup>5</sup>RIKEN Center for Integrative Medical Sciences, Kanagawa, Japan; <sup>6</sup>Genetics, Brigham and Women's Hospital, Harvard Medical School, Boston, USA; <sup>7</sup>Epidemiology, LUMC, Leiden, Netherlands; <sup>8</sup>Rheumatology/Genetics, Brigham and Women's Hospital, Harvard Medical School, Boston; <sup>9</sup>Rheumatology, university of Manchester, Manchester, USA

**Background:** In patients with synovitis, the question is 'Which disease does this patient have?' However, traditional tests often only inform us about disease presence yes/no and disease discriminating symptoms often take a while to arise. Time independent information, such as genetics, might accelerate the diagnostic process. As increasing number of patients have genotyping data available in medical records prior to their visit, the question emerges: can genetic data facilitate disease differentiation in early disease?

**Objectives:** Proof of principle study to test the differentiating ability of genetic profiles in patients with synovitis.

**Methods:** We studied the most common rheumatologic diseases: rheumatoid and psoriatic arthritis, SLE, spondyloarthritis and Gout. The population level

disease probability for each disease comprised a sex adjusted disease prevalence and a weighted genetic risk score comprised of risk SNPs' odds ratio from literature. Within case genetic probabilities (GProb) were obtained through normalisation of the population risk assuring a patient's total disease probability of 1. So, each patient got a probability for each disease. GProb was developed in a simulated dataset and tested in

- Validation dataset of 1,211 rheumatology cases identified with ICD codes from 62,512 patients
- Replication dataset of 248 rheumatology cases identified by chart-review from 15,047 patients
- Clinical setting of prospective selected patients that presented with synovitis at the rheumatology outpatient clinic (n=242). Here, GProb was calculated for the five diseases plus the category 'Other'.

Having multiple GProbs for each patient, we tested whether the GProbs referring to the patient's real disease were higher than those that referred to the other phenotypes.

We used multinomial logistic regression with the six diseases as the dependent variables to test the additive value of GProb on top of clinical information.

**Results:**

- There was a strong significant correlation between GProb and the disease status ( $r=0.27$   $P<0.0001$ ) with an AUC of 0.68.
- We observed a higher correlation with disease status in the more precisely identified cases ( $r=0.49$   $P<0.0001$ ) and a high AUC 0.82
- Also in a prospective setting, the GProb performed well ( $P<0.0001$  AUC 0.74 figure 1) especially in ruling out diseases (table 1).

The clinical information alone explained 41% of the variance in the final diagnosis. Adding GProb significantly improved the predictive value (expl. variance increased to 51%  $p=0.0008$ ).

Sensitivity analysis showed that the results were not driven by one disease.

**Abstract OP0363** – Table 1 Performance of G-Prob in ruling out diseases in the prospective dataset (n=242)

Selection	% of total G-Probs	% of G-Prob that correctly rejected disease
G-Prob < 0.05	14%	97%
G-Prob < 0.20	70%	89%

**Abstract OP0363** – Figure 1 Ability of GProb to differentiate six disease outcomes (RA, PsA, SLE, SpA, Gout, Other) in a prospective selection of patients with synovitis.

The graph depicts the mean GProb (with range) of each quintile of GProbs on the x-axis and the corresponding proportion of those GProbs that matched with the patient's real disease on the y-axis. The graph demonstrates that the genetic probability of the disease highly resembles the real disease risk. In case of a perfect test performance, the dots would lie exactly on the diagonal (dashed) line.

**Conclusions:** This study developed methodology for disease-discriminating tests.

In patients with synovitis, genetic data can facilitate decision making in early disease by ruling out and pointing towards the most likely phenotype. Seeing the increasing importance of an early diagnosis in patients with synovitis, genetics can be considered as part of a patient's medical history.

Additional prospective studies will further need to validate this proof of principle study.

**Work and rehabilitation – key priorities for people with RMDs**

**OP0364-PARE WORK STATUS AND WORK BARRIERS IN PATIENTS RECEIVING bDMARDs AS INFUSIONS IN RHEUMATOLOGY HOSPITAL CLINICS IN NORWAY. A CROSS-SECTIONAL STUDY**

M. Klokkerud<sup>1</sup>, E. Hasselknippe<sup>2</sup>, A. Rønningen<sup>2,3</sup>, H. Haveråen<sup>3</sup>, A.-L. Sand-Svartrud<sup>1</sup>. <sup>1</sup>Rheumatology, NKRR, Diakonhjemmet Hospital, Oslo; <sup>2</sup>Rheumatology, Lillehammer Hospital for Rheumatic Diseases, Lillehammer; <sup>3</sup>Rheumatology, Diakonhjemmet hospital, Oslo, Norway

**Background:** Preventing work disability is an important treatment goal for people with rheumatic diseases. New treatment modalities with introduction of bDMARDs have led to better control of disease activity, symptoms and improvement of functional capacity. Still, sick leave and forced retirement is common, and studies have shown that work status at start of therapy is a predictor of work ability later in the disease course.

**Objectives:** The objective of this study was to explore work status, concerns about future work capacity and work barriers in a group of patients receiving bDMARDs as infusions in rheumatology hospitals in Norway.

**Methods:** This is a cross-sectional study. In March and April 2017, patients at two rheumatology hospitals were invited to participate in a survey. Participation was voluntary with anonymous response. Information about background, disease, and start of bDMARD infusions was self-reported in a questionnaire. Further, respondents who were working or on sick leave (full- or part time), answered questions about work capacity and degree of concern about future work capacity on NRS-scales from 1–10 (10=best capacity and high degree of concern). They also scored their experienced barriers related to seven different topics selected from the Work Experience Survey-Rheumatic Conditions (WES-RC) on 5 point Likert scales (5=severe problems).

**Results:** Of 343 eligible patients, 317 responded (92%). Mean (SD) age were 52.3 (14.9) years, 81% were under 67 (age of retirement in Norway). The largest diagnostic groups were rheumatoid arthritis (47%) and spondylarthritis (26%). Mean (SD) disease duration was 13.8 (10.6) years. Half of the respondents aged <67 years reported reduced work ability, of these 27% were on sick leave and 23% were on disability pension. The proportion of patients on sick leave was highest among those who started with bDMARD infusions within the last 3 months (42.3%), and lowest in the group who had started 25 to 36 months earlier (21.4%). For disability pension the numbers were opposite, with the largest amount in the group that received treatment for more than 36 months (29.7%).

There were significant differences in ratings of work capacity and concerns about future work capacity among respondents working full time and those on sick-leave. Mean (SD) scores of work capacity were 8.0 (1.7) and 5.5 (3.0) ( $p<0.001$ ) in full time workers and participants on sick-leave, respectively. Corresponding scores for concerns about future work capacity were 5.2 (2.5) and 7.0 (2.7), ( $p<0.001$ ). Thirty percent of respondents in full-time work scored 7 or higher on degree of concern about future work capacity. Regardless of work status, 'physical work demands', 'mental work demands' and 'balance between work and private life' was rated as the most severe barriers for work ability.

**Conclusions:** This cross-sectional study shows that approximately half of the patients receiving bDMARD infusions at two hospitals in Norway report reduced work ability, and nearly one third was concerned about future work capacity. Early identification of patients who, despite optimal treatment, experience work barriers is important. Activity regulation, ergonomic advice and self-management strategies for managing work demands and imbalance between work and private life should be further tested.

**OP0365-PARE** **WORK MATTERS: A UK WIDE SURVEY OF ADULTS WITH RHEUMATOID ARTHRITIS AND JUVENILE IDIOPATHIC ARTHRITIS ON THE IMPACT OF THEIR DISEASE ON WORK**

M. Bezzant<sup>1</sup>, A. Bosworth<sup>2</sup>, L. Lunt<sup>3</sup>, S. Verstappen<sup>3</sup>. <sup>1</sup>Policy and Public Affairs; <sup>2</sup>CEO, National Rheumatoid Arthritis Society, Maidenhead; <sup>3</sup>Division of Musculoskeletal and Dermatological Sciences, University of Manchester, Manchester, UK

**Background:** 10 years ago, NRAS ran a survey and found that people with RA are less likely to be in employment than the general population, and that there are significant barriers to work.

**Objectives:** To understand how the situation has changed over the last 10 years, NRAS surveyed over 1500 people with RA to understand their experiences.

**Methods:** NRAS worked with the University of Manchester (UoM) to develop open and closed questions to explore the current state of employment of people with RA, as well as barriers to remaining in and returning to employment. The survey was developed jointly with UoM and contained validated questionnaires on absenteeism and presenteeism. The survey was distributed by NRAS to its members through email and non-members through social media.

**Results:** 63.3% of people surveyed were in employment, an increase from 2007 when this figure was at 54.8%. However, a significant number of people were concerned about the possibility of remaining in the job if there were any changes to the nature of the work. Participants commented on the challenges and advantages of work, with the primary advantages being financial security, sense of purpose and enjoyment, and the employer/working environment. However, many of the barriers to work included the role being too demanding, RA symptoms, lack of reasonable adjustments, the commute, and the lack of an understanding employer/colleagues. Almost 40% of participants stated that their employers did not understand the disease and that help that was not available. Nearly half of all respondents had to use annual leave in order to deal with their RA; this being just one example of how employers had breached the Equality Act 2010. The survey found that low numbers of people claimed benefits with Disability Living Allowance and/or Personal Independence Payments and Blue Badge being the most commonly claimed. Many participants had co-morbidities, with high numbers of people reporting mental health issues.

**Conclusions:** Fewer people are losing their job or retiring early due to the disease which may be due to better and earlier treatment. However, the attitudes of employers and colleagues can have a great impact on the ability of someone with RA to remain in work. Progress must be made to raise awareness of employers' responsibilities in relation to employees with disabilities, but also to signpost employers to help that is readily available for them.

**The challenges of rheumatology trainees in the clinical learning environment**

**OP0366** **AMBULATORY RHEUMATOLOGY TEACHING DAY – A 360-DEGREE EVALUATION OF STAKEHOLDER EXPERIENCES**

L. Ward, S. Stebbings. *University of Otago, Dunedin, New Zealand*

**Background:** The Dunedin School of Medicine, New Zealand, include an ambulatory teaching day for 5th year medical students within their rheumatology

curriculum. This day involves clinical lectures, examination skills, and clinical assessment of patient volunteers. This is often the students' first experience of conducting a rheumatology consultation.

**Objectives:** To evaluate the effectiveness of the Ambulatory Rheumatology Teaching Day from the perspective of all involved stakeholders, to inform ongoing development of this teaching programme.

**Methods:** Independent focus groups of patients (two groups, n=12), consultants/clinical lecturers (one group, n=4), and 5th year medical students (four groups, n=19) involved in ambulatory rheumatology teaching days were conducted. Transcripts were analysed using thematic analysis, and themes compared across the three stakeholder groups.

**Results:** All stakeholder groups found the ambulatory day well-structured, educational, and inclusive. Patient contact provided a bridging opportunity between theory and practice; students reported a broader perspective on the lived experience of rheumatic conditions, and improved clinical and examination skills. Consultants found the one-day format created scheduling issues with their clinical workload, and suggested two half-day sessions would enable all rheumatology consultants to input into at least one of the sessions. Students and patients supported this format; students further suggested radiology and laboratory diagnostic tutorials prior to the ambulatory day, to aid their clinical assessment experience. All stakeholders observed that student diagnosis was mainly dependent on pronounced clinical presentation. Students were competent in diagnosing rheumatoid arthritis and gout, but failed to diagnose ankylosing spondylitis and calcium pyrophosphate dihydrate crystal deposition (CPPD). Greatest knowledge gains were reported for the conditions of ankylosing spondylitis and psoriatic arthritis. While students reported no interaction issues with the patients, both consultants and patients observed that several students were hesitant to conduct the physical examination, appearing concerned they may cause pain to the patient. Accordingly, students expressed a preference for more clinical supervision during the patient examinations; whereas the consultants favoured the student being independent, developing their questioning skills to improve their examination technique. Patients supported this independent approach to teaching the clinical assessment, and suggested the use of prompt sheets to engage the students in questioning regarding clinical presentation, symptoms, and medications.

**Conclusions:** The ambulatory rheumatology teaching day provided a supportive and effective learning environment for introducing 5th year medical students to the patient consultation process. Students gained both clinical skills and a valuable understanding of the patient perspective of a variety of rheumatic conditions. Students would further benefit through prior tutorials on diagnostic skills, with a focus on interpretation of radiology and laboratory results. Additionally, enhancing the role of the patient as teacher will aid the examination process, and highlight the importance of both clinical and patient outcome priorities.

**OP0367** **USING YOUTUBE TO TEACH THE FUNDAMENTALS OF RHEUMATOLOGY: A TWO-YEAR RETROSPECTIVE ANALYSIS OF FOUR ONLINE LECTURES**

R. Sengewein<sup>1</sup>, E. Schmok<sup>2</sup>. <sup>1</sup>Poliklinik Für Rheumatologie, Uniklinik Düsseldorf, Düsseldorf; <sup>2</sup>Universität zu Lübeck, Lübeck, Germany

**Background:** Duesseldorf has a dedicated rheumatology unit; therefore, education in rheumatology takes up an increased portion of the medical curriculum. Furthermore, most medical schools in Germany have very few or no lectures on topics in rheumatology. According to the German Society of Rheumatology, one reason for the lack of lectures is the absence of dedicated rheumatology teaching units. To improve education in rheumatology offered to medical students at these universities, we hypothesise the use of online platforms such as YouTube to be a potential in delivering content.

**Objectives:** Investigating the potential of YouTube to deliver online lectures in rheumatology.

**Methods:** Online lectures were created by a physician from the Department of Rheumatology at University in Duesseldorf and the e-Learning platform Amboss. Content was matched with the educational goals of the Department of Rheumatology from the 2016 curriculum and the educational goals for rheumatology from the IMPP ('Institut für medizinische und pharmazeutische Prüfungsfragen'), which is responsible for the medical state examination ('Staatsexamen') in Germany. Lectures were produced in German and the overall length of the content was 36 min and 27 s. The content was divided into four short lectures (range, between 6:49 min and 13:27 min) and made available to the public via the online streaming platform YouTube. Information on the age, sex, and location of viewers was collected and analysed. Lectures were analysed for the number of clicks, total watch time, average watch time, and the types of devices used to access content. Analysis was performed over a 20 month period (04/16–01/18). The integrated feature of the platform YouTube Analytics was used for analysis.

**Results:** Viewers from 108 different countries accessed the content, with 95.1% streaming from three countries with German as a native language (Germany,

Austria, Switzerland). Males comprised 55.6% of the viewers and females 44.4%. Twenty percent of viewers were aged between 18 and 24 years, 56% were between 24 and 34 years of age, 14% were aged between 35 and 44 years old, and the remaining 10% were over the age of 45 years.

All four videos were clicked 82 373 times (first video, 31,296; second, 18,674; third, 15,928; fourth, 16 475 times). Viewers spent an average of 4:37 min watching the videos. In total, 381,514 min of content was delivered. Approximately 58% of the content was accessed through mobile devices such as smartphones and tablets.

**Conclusions:** YouTube and YouTube Analytics were found to be exceptionally successful in delivering and analysing online lectures. Mobile phones were the

most commonly used device by viewers, demonstrating the growing importance of adapting content for these devices. A comparison of the delivered educational minutes with the traditional setting of delivering knowledge at a university in a 45 min lecture to an average audience of 100 individuals amounts to approximately 847 lessons. In conclusion, the use of online lectures to deliver medical content especially in universities where rheumatology is not represented by a dedicated faculty is highly recommended.

### Genomics, genetic basis of disease and antigen presentation

#### THU0001 DIFFERENTIAL METHYLATION AS A PREDICTOR OF METHOTREXATE RESPONSE IN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Nair<sup>1</sup>, D. Plant<sup>1,2</sup>, S.M. Verstappen<sup>3</sup>, J.D. Isaacs<sup>4</sup>, A.W. Morgan<sup>5</sup>, K.L. Hyrich<sup>3</sup>, A. Barton<sup>1</sup>, A.G. Wilson<sup>6</sup>, on behalf of MATURA. <sup>1</sup>Arthritis Research UK Centre for Genetics and Genomics, University of Manchester; <sup>2</sup>NIHR Manchester Musculoskeletal BRC, CMFT; <sup>3</sup>Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester; <sup>4</sup>NIHR Newcastle BRC, Newcastle upon Tyne Hospitals NHS Foundation Trust and Newcastle University, Newcastle; <sup>5</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; <sup>6</sup>University College Dublin School of Medicine and Medical Science, University College Dublin, Dublin, Ireland

**Background:** Methotrexate (MTX) is recommended as the first-line disease modifying anti-rheumatic drug (csDMARD) for the treatment of rheumatoid arthritis (RA), but up to 40% patients do not respond adequately, or experience adverse effects<sup>1</sup>; therefore, identifying blood-based biomarkers that predict treatment response is a research priority. DNA methylation is an epigenetic marker that modifies but does not alter DNA sequence; MTX may act, at least in part, by inhibiting intracellular methyl donor transfer leading to DNA hypomethylation<sup>2</sup> so DNA methylation may act as a biomarker of MTX response.

**Objectives:** To identify differential DNA methylation signatures in whole blood associated with response to MTX in patients with RA.

**Methods:** DNA methylation was measured using the HumanMethylation450 BeadChip in DNA samples from individuals recruited to the Rheumatoid Arthritis Medication Study (RAMS). Demographic and clinical data were collected prior to starting MTX (baseline) and at 6 months after commencing MTX. DNA was extracted from whole blood samples collected at baseline and at 4 weeks from patients who, at 6 months, had a EULAR good response (n=36) or EULAR poor response (n=36) to MTX. Differentially methylated positions (DMPs) between baseline and 4 weeks, and between good and poor response groups were identified using a linear model, adjusting for gender, age, cell composition, baseline disease activity score (DAS28), and smoking status. Additional analyses were performed to assess the association between methylation and change in DAS28 score and the individual DAS28 components over 6 months. DMPs with significant differences were selected for replication by pyrosequencing in an independent group of 100 patients with both baseline and 4 week samples available for testing. Using genome-wide genotype data for the same patients, replicated DMPs were investigated for methylation QTLs (meQTLs).

**Results:** The initial analysis identified differential methylation between good and poor responders at 2 CpG sites (DMPs) in samples taken at 4 weeks, with response status determined at 6 months (p-value<10<sup>-5</sup>). Three other DMPs were associated with change in tender joint count, another 3 DMPs with change in swollen joint count, and a further 4 DMPs were associated with change in C-reactive protein (CRP). Of the 12 DMPs, 4 showed replicated association with improvement of swollen joint count and lower CRP levels at 6 months in the pyrosequencing dataset (p-value<0.01). However, there were no meQTLs identified at these loci.

**Conclusions:** These results suggest DNA methylation may provide a biomarker of MTX response but requires replication in other larger data sets.

#### THU0002 NOVEL PATHOGENIC STOP CODON MUTATION IN THE NF-KB P65 SUBUNIT (RELA) ASSOCIATED WITH BOTH BEHÇET'S DISEASE LIKE SYNDROME AND NEUROMYELITIS OPTICA IN AN IRISH FAMILY

F. Adeb<sup>1,2</sup>, E.R. Dorris<sup>3</sup>, S. Tariq<sup>2</sup>, W.L. Ng<sup>2</sup>, A.G. Stack<sup>1</sup>, A.G. Wilson<sup>3</sup>, A. D. Fraser<sup>2</sup>. <sup>1</sup>Graduate Entry Medical School, University of Limerick; <sup>2</sup>Department of Rheumatology, University Hospital Limerick, Limerick; <sup>3</sup>EULAR Centre of Excellence/UCDCentre for Arthritis Research, Conway Institute of Biomolecular and Biomedical Research, Dublin, Ireland

**Background:** Behçet's disease (BD) has a complex multifactorial pathogenesis and presents with phenotypic heterogeneity predominantly mucocutaneous ulcerations, ocular lesions and skin manifestations. More recently, there have been reported cases of monogenic spectrum defects presented with BD-like similarities or phenotype.

**Objectives:** We investigated an Irish Caucasian family of eleven that included two half-sisters with early-onset BD, and another sister with neuromyelitis optica, all who were born to asymptomatic non-consanguineous parents. More recently, one of the sisters' daughter developed recurrent oral aphthosis at the age of 10 years old.

**Methods:** Peripheral blood mononuclear cells were extracted from patients and non-affected donor blood using standard fractionation methods. Following quality assessment and quantification whole exome sequencing was performed on all participants.

**Results:** Whole exome sequencing data identified segregation of a novel pathogenic stop codon mutation in the nuclear factor NF-κB p65 subunit (RelA) resulting in a non-functional protein. The mutation involves cytosine deletion and results in a His487ThrfsTer7 frameshift (His487ThrfsTer7) *RelA* resulting in loss of transcription activation-1 (TA1) and a portion of TA2 from RelA. The mutation was seen within the three generations, including the three half-sisters, their father as well as one of the proband's daughter, potentially describing a new syndrome.

**Conclusions:** Our study suggests that loss-of-function mutations in the NF-κB pathway, a pivotal mediator of inflammation and apoptosis, are linked with the development of familial early-onset BD-like syndromes. Better insights and further understanding of this "orphan" immunogenetic syndrome carries high clinical impact to assist early disease recognition and potential discoveries of novel targeted therapies.

**Background:** Gout is the most common form of inflammatory arthritis and is caused by hyperuricemia. Many previous studies have indicated that common dysfunctional variants of the gene encoding ATP-binding cassette transporter subfamily G member 2/breast cancer resistance protein (ABCG2/BCRP) increase the risk of gout and hyperuricemia. In addition, we recently showed that rare non-synonymous variants are also risk factors for gout. However, we have not evaluated the effects of synonymous and splice-site variants of

*ABCG2*. Thus, to estimate the risk of genetic variants of *ABCG2* more comprehensively, we analysed the association between all exonic variants and gout susceptibility.

**Objectives:** The main purpose of this study was to perform comprehensive *in silico* evaluation of the effects of all types of rare and common exonic *ABCG2* variants on gout susceptibility in Japanese population.

**Methods:** We previously sequenced all the exons of *ABCG2* in 480 patients with gout and 480 healthy controls (Japanese males) and performed functional analyses of non-synonymous variants. In this present study, we analysed the correlation between urate transport function and scaled C-score of CADDv1.3 (CADD score) of non-synonymous variants. We additionally performed Receiver Operating Characteristic (ROC) curve analysis and selected variants with altered function of more than 50% compared to wild-type *ABCG2*. Stratified association analyses and multivariate logistic regression analysis were performed to evaluate the effects of selected rare and common *ABCG2* variants on gout susceptibility.

**Results:** We identified 4 common and 26 rare exonic or closely situated intronic variants of *ABCG2*. CADD scores showed significant correlation with the results of functional analyses on urate transport ( $p=0.014$ ,  $r=-0.539$ ). ROC curve analysis showed an area under the curve (AUC) of 0.775. The optimal cutoff value of CADD score was 15 for classifying variants with altered function of more than 50% compared to wild-type *ABCG2* (sensitivity=0.88, specificity=0.67). Therefore, we selected variants with a CADD score greater than 15 for downstream analyses. All intronic or synonymous variants had low CADD scores and thus were removed. Multivariate logistic regression analysis showed that the rare variants of *ABCG2* were associated with a significantly increased risk of gout and the size effect of these rare variants (odds ratio [OR]=2.7,  $p=0.012$ ) was similar to that of the common variants, Q126X (OR=3.3,  $p=4.8 \times 10^{-6}$ ) and Q141K (OR=2.3,  $p=8.6 \times 10^{-6}$ ).

**Conclusions:** This study confirmed that both common and rare variants in *ABCG2* increase gout susceptibility. Furthermore, our *in silico* analyses suggest that synonymous and splice-site variants of *ABCG2* may not play a key role in the pathogenesis of gout.

#### THU0004 A DE NOVO NON-SENSE ERAP1 POLYMORPHISM IN TWO HLA-B\*27-NEGATIVE TWINS WITH AXIAL SPONDYLOARTHRITIS

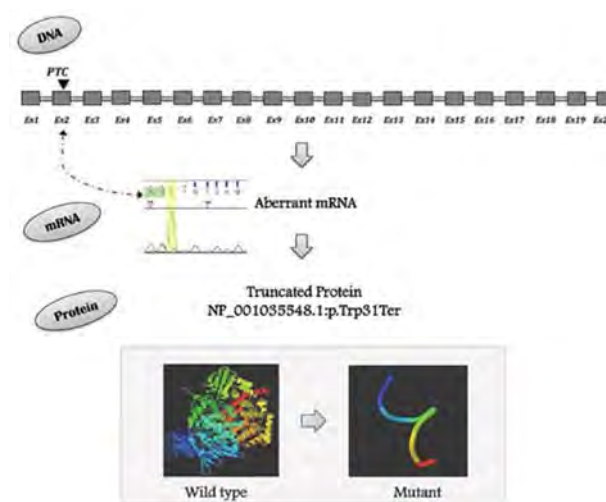

M.C. Padula<sup>1,2</sup>, G. Martelli<sup>2</sup>, R. Giuzio<sup>2</sup>, C. Amato<sup>2</sup>, T. Carbone<sup>1</sup>, M. Gilio<sup>1</sup>, P. Leccese<sup>1</sup>, G. Tramontano<sup>1</sup>, A.A. Padula<sup>1</sup>, S. D'Angelo<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Rheumatology Institute of Lucania (IReL) and Rheumatology Department of Lucania, San Carlo Hospital of Potenza and Madonna delle Grazie Hospital of Matera, Italy; <sup>2</sup>Department of Science, University of Basilicata, Potenza, Italy

**Background:** Axial spondyloarthritis (axSpA) is a group of inflammatory disorders primarily affecting the spine that includes ankylosing spondylitis (AS) and non-radiographic axSpA. AS is strongly associated with HLA-B\*27. A small percentage of HLA-B\*27-positive subjects develop AS, suggesting the role of other genes in AS susceptibility.<sup>1,2</sup> Among these genes, *ERAP1* acts as "molecular ruler". It encodes the endoplasmic reticulum aminopeptidase 1 protein, responsible for the peptides trimming for the efficient binding to class I major histocompatibility complex (MHC). Several common gene SNPs (single nucleotide polymorphisms) were associated with the susceptibility to AS, but the presence of other *ERAP1* polymorphisms was supposed to explain the genotype-phenotype correlation.<sup>1,3,4</sup>

**Objectives:** The aim of this study is to genotype the *ERAP1* gene whole structure searching for common and additional polymorphisms in two HLA-B\*27-negative twins.

**Methods:** We integrated a bioinformatics and a second level molecular approach in order to characterise *ERAP1* gene. Specific primer pairs were designed for the coverage of all gene regions. Genomic DNA was isolated from the whole blood of two 36 years-old axSpA male twins. They are HLA-B\*27-negative (HLA-A\*02, HLA-A\*32; HLA-B\*07; HLA-CW\*07). The coexistence of Crohn's disease (CD) was documented in both patients after the initial diagnosis of axSpA. Primer-specific polymerase chain reaction (PCR) was carried out. PCR products were sequenced and bioinformatics tools (BlastN and Mutation Surveyor) were queried for the mutational analysis. Phyre2 on line software was used for predicting the protein tertiary structure.

**Results:** Molecular characterisation of *ERAP1* gene identified a *de novo* homozygous guanine to adenine substitution at 15 132 position of exon 2 nucleotide sequence (NG\_027839.1:g.15312G>A). This substitution is a stop-codon variation that directly generates an early premature termination codons (PTC). The 3D model of the protein showed a significant difference of the folding when wild-type and mutant protein were compared. The non-sense transcript could result in the production of a truncated protein, formed by 30 amino acids (NP\_001035548.1:p.Trp31Ter) (figure 1).

**Abstract THU0004 – Figure 1.** The effect of the novel stop-codon variant at DNA, RNA and protein level. The novel substitution generates a PTC in *ERAP1* exon 2, that could be responsible for the production of an aberrant mRNA and of the truncated protein. The protein tertiary structure prediction by Phyre2 software is shown.

**Conclusions:** A *de novo* stop-codon *ERAP1* variant was identified for the first time in axSpA. We suggest that the PTC-related *ERAP1* protein could contribute to AS risk by affecting the protein role.

#### THU0005 WHOLE GENOME LINKAGE AND EXOME SEQUENCING ANALYSES IN TAKAYASU ARTERITIS FAMILIES

E. Tahir Turanlı<sup>1</sup>, I. Karacan<sup>1</sup>, S.N. Esatlioglu<sup>2</sup>, S. Sahin<sup>3</sup>, O. Kasapcopur<sup>3</sup>, A. Tolun<sup>4</sup>, E. Seyahi<sup>2</sup>. <sup>1</sup>Molecular Biology and Genetics, ITU; <sup>2</sup>Division of Rheumatology; <sup>3</sup>Department of Paediatric Rheumatology, Cerrahpaşa Faculty of Medicine; <sup>4</sup>Molecular Biology and Genetics, Bogazici University, Istanbul, Turkey

**Background:** Takayasu arteritis (TA) is an inflammatory large vessel vasculitis affecting mainly aorta and its branches. Inflammation in vessels causes thickening

of walls, fibrosis, dilatation and nonspecific symptoms such as fever, hypertension and arthralgia. It is a rare disorder with unknown etiology and the worldwide incidence is 0.4 to 2.6 per million.

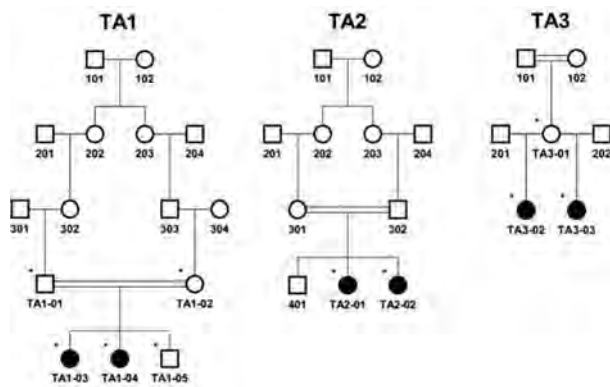

**Objectives:** We studied three consanguineous families with consisting of two affected daughters each and their healthy parents in order to identify the disease locus and the causative mutation

**Methods:** In two of the families, genome-wide single nucleotide polymorphism (SNP) genotyping was performed for available family members using Illumina OmniExpress-24 BeadChip targeting ~700,000 SNP markers. Using genotyping data, we performed multipoint parametric linkage analysis assuming recessive inheritance and complete penetrance. Also exome sequencing was performed for four of the patients to search for rare, homozygous deleterious variants. For TA1 and TA2 families whether the variants were located in a region IBD (identical by descent) in affected sisters or not was investigated.

**Results:** Whole genome linkage and exome analyses identified homozygous, rare (MAF <0.01) candidate variants shared by the affected sister pairs in the first two families. Candidate variants for the first family were in *ANXA8L1*, *EHBP1L1*, *TULP2*, *MYH14* and *SHANK1* and for the second family in *AP4B1*, *RIMBP3*, *VCX3B* and *NXF2*. In the third family, no candidate homozygous variant was common for the affected sibs, who had different fathers. *In silico* functional predictions of the candidate variants shared by each sister-pair were determined.

Abstract THU0005 – Table 1. *In silico* functional predictions of candidate variants

Family	Gene	Change	SIFT	PolyPhen2	MutationTaster
TA1	<i>ANXA8L1</i>	c.449C>T (p.T150M)	Deleterious	Probably damaging	Disease Causing
	<i>EHBP1L1</i>	c.3595C>T (p.R1199C)	Deleterious	Probably damaging	Polymorphism
	<i>TULP2</i>	c.1300T>C (p.Y434H)	Tolerated	Benign	Polymorphism
	<i>MYH14</i>	c.565C>T (p.R189C)	Deleterious	Probably damaging	Disease Causing
	<i>SHANK1</i>	c.3947G>A (p.G1316D)	Tolerated	Possibly damaging	Disease Causing
TA2	<i>AP4B1</i>	c.263C>T (p.T88I)	Tolerated	Benign	Disease Causing
	<i>RIMBP3</i>	c.3788A>C (p.E1263A)	Tolerated	Benign	Polymorphism
	<i>VCX3B</i>	c.44A>G (p.K15R)	Tolerated	Possibly damaging	Polymorphism
	<i>NXF2</i>	c.1301+1G>A	-	-	Disease Causing

**Conclusions:** This is the first whole genome linkage analysis and subsequent exome sequencing in TA patients with suggestive recessive inheritance. Possible candidate variants in two out of the three families were determined. However, we could not find any genetic change in terms of genetic mutations, exonic deletions or structural variations shared by these families. We had hoped that the study in these rare families with a pair of TA sibs would unravel a gene responsible for TA. We now question whether the inheritance is dominant with reduced penetrance which requires more familial cases to be studied.

THU0006

## APPLICATION OF MACHINE LEARNING METHODS FOR PREDICTION MODELLING OF PSORIATIC ARTHRITIS IN PATIENTS WITH PSORIASIS

F. Jalali-najafabadi<sup>1</sup>, N. Dand<sup>2</sup>, P. Ho<sup>1,3</sup>, C. H. Smith<sup>4</sup>, on behalf of BSTOP and BADBIR study groups, J. N. Barker<sup>2,4</sup>, on behalf of BSTOP and BADBIR study groups, N. McHugh<sup>5</sup>, R. B. Warren<sup>6</sup>, on behalf of BSTOP and BADBIR study groups, A. Barton<sup>1,3</sup>, J. Bowes<sup>1</sup>. <sup>1</sup>Centre for Musculoskeletal Research, The University of Manchester, Manchester, <sup>2</sup>Division of Genetics and Molecular Medicine, King's College London, London, <sup>3</sup>NIHR Manchester Musculoskeletal Biomedical Research Unit, Central Manchester NHS Foundation Trust, Manchester, <sup>4</sup>St John's Institute of Dermatology, Guys and St Thomas' Foundation Trust, London, <sup>5</sup>Royal National Hospital for Rheumatic Diseases and Dept Pharmacy and Pharmacology, University of Bath, Bath, <sup>6</sup>The Dermatology Centre, Salford Royal NHS Foundation Trust, Manchester, UK

**Background:** Approximately 30% of patients with psoriasis develop a chronic inflammatory arthritis referred to as psoriatic arthritis (PsA). The ability to accurately predict which psoriasis patients will develop PsA would enable early intervention and help prevent disability. Both psoriasis and PsA have a substantial genetic risk component, however the utility of using genetic risk factors for the prediction of PsA is currently unknown. Alleles of the human leukocyte antigen (HLA) genes represent the largest genetic effects observed for both psoriasis and PsA (HLA-C\*0602 and HLA-B\*27 respectively); these genes are highly polymorphic with extensive linkage disequilibrium (LD) which will make variable (feature) selection using statistical models very challenging. Machine learning methods, such as information theoretic criteria, are well suited to this challenge and will find a subset of the original variables that enable more accurate prediction.

**Objectives:** To apply machine learning methods for feature selection of HLA alleles and evaluate the accuracy of these feature for the prediction of PsA.

**Methods:** Feature selection was performed using information theoretic criteria methods which are classifier independent methods that provide a ranking of genetic features that differentiate PsA from cutaneous-only psoriasis. Multiple methods were tested; mutual information maximisation (MIM), joint mutual information (JMI), minimal-Redundancy-Maximal-Relevance (mRMR) and conditional mutual information maximisation (CMIM). Two principal components (population stratification) and age of psoriasis onset were included as potential confounders. The Bagged Trees method was used for classification and the performance of the predictive models were assessed using area under the receiver operating characteristic curve. These methods were applied to a dataset of 1462 PsA cases and 1132 cutaneous-only psoriasis cases using 2-digit and 4-digit classical HLA alleles imputed using the SNP2HLA algorithm.

**Results:** The single most important features based on rank were identified as HLA-B\*27 (2-digit) and HLA-B\*2705 (4-digit) by the four different feature selection techniques; this is consistent with previous analyses of this data using regression based methods. However, the predictive accuracy of these single features was found to be poor (AUC 0.55 HLA-B\*27). Sequentially adding additional HLA features based on rank substantially improved the performance of the classification model where 20 2-digit features selected by JMI demonstrated an average AUC of 0.84 based on 10 cross-fold validation (figure 1).

**Conclusions:** The results demonstrate that classification models constructed from multiple HLA alleles substantially outperform classification based solely on

the previously reported PsA risk allele (HLA-B\*27). Importantly, the study demonstrates that this additional information is efficiently captured using information theoretic criteria methods which capture correlations between markers.

**THU0007 GENETIC VARIANTS IN SLE SUSCEPTIBILITY LOCI, XKR6 AND GLT1D1, ARE ASSOCIATED WITH CHILDHOOD-ONSET SLE IN A KOREAN COHORT**

Y.B. Joo<sup>1</sup>, J. Lim<sup>2</sup>, B.P. Tsao<sup>3</sup>, S.K. Nath<sup>4</sup>, K. Kim<sup>2</sup>, S.-C. Bae<sup>5</sup>. <sup>1</sup>St. Vincent's hospital, The catholic university of Korea, Suwon; <sup>2</sup>Kyung Hee University, Seoul, Korea, Republic of Ireland; <sup>3</sup>Medical University of South Carolina, Charleston, South Carolina; <sup>4</sup>Oklahoma Medical Research Foundation, Oklahoma, USA; <sup>5</sup>Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of Ireland

**Background:** Systemic lupus erythematosus (SLE) is a polygenic autoimmune disease that occurs in all ages. It has been well documented that younger age of SLE onset is associated with more severe clinical manifestations and worse outcomes. However, impact of genetic variants on age of SLE onset was not fully understood.

**Objectives:** We investigated a cumulative effect of reported SLE-risk variants on childhood-onset SLE and searched for new risk loci of childhood-onset SLE using a genome-wide SNP analysis.

**Methods:** We analysed 96 Korean childhood-onset (<16 years old) and 685 adult-onset SLE (≥16 years old) who were previously genotyped by both Immuno-chip and genome-wide SNP arrays. Individual genetic risk scores (GRS) from well-validated SLE susceptibility loci (45 Asian confirmed non-HLA loci and an HLA-DRB1 amino acid haplotype model) were calculated and tested for their association with childhood-onset SLE. Association of each genetic variant with childhood-onset SLE was analysed using a multivariable logistic regression adjusting for population substructure.

**Results:** Mean age of SLE onset was 12.5±2.5 years in childhood-onset SLE and 29.0±9.4 in adult-onset SLE. GRS from SLE susceptibility loci was significantly higher in childhood-onset SLE than adult-onset SLE (p=0.001). Two SNPs, rs7460469 in *XKR6* and rs7300146 in *GLT1D1*, showed the most significant associations with childhood-onset SLE (p=1.26×10<sup>-8</sup>, OR=0.18, and p=1.49×10<sup>-8</sup>, OR=0.35, respectively). Especially, rs7300146 in *GLT1D1* was the cis expression quantitative trait locus (eQTL) for *SLC15A4*, which has been known an SLE susceptibility gene in a Chinese population. The model consisting of SLE GRS and the two newly identified loci to predict childhood-onset SLE attained an area under curve (AUC) of 0.71 in a receiver operating characteristics (ROC) curve.

**Abstract THU0007 – Figure 1.** A) association of genetic risk score else. cSLE; childhood-onset, aSLE; adult-onset SLE, GRS; genetic risk score and B) ROC curve for SLE-GRS, GWAS-hitand full model. ROC; receiver operating characteristics, SLE; Systemic lupus erythematosus, GWAS; genome-wide association study

**Conclusions:** Childhood-onset SLE is associated with a high cumulative SLE-risk effect and two novel SNPs rs7460469 and rs7300146, providing the first predictive model for childhood-onset SLE in Koreans.

**THU0008 LINKING GENETICS TO T-CELL PHENOTYPE IN JIA: RATIONAL FOR IL-2 THERAPY**

A. Yarwood<sup>1,2</sup>, A. Hinks<sup>1</sup>, S. Smith<sup>1</sup>, J. Bowes<sup>1</sup>, S. Eyre<sup>1</sup>, W. Thomson<sup>1,2</sup>. <sup>1</sup>Arthritis Research UK, Centre for Genetics and Genomics; <sup>2</sup>NIHR Manchester Musculoskeletal Biomedical Research Centre, Manchester University NHS Foundation Trust, The University of Manchester, Manchester, UK

**Background:** Several genetic regions associated with susceptibility to juvenile idiopathic arthritis (JIA), harbour genes involved in the interleukin-2 (IL-2) response which is pivotal in the function of regulatory T cells (T-regs) and their ability to suppress effector T cells. Genetically JIA is similar to type 1 diabetes (T1D) which also demonstrates an enrichment of genes related to IL-2 regulation and response. Early clinical trial data has indicated recombinant IL-2 to be successful in enhancing T-regs in T1D. I hypothesise that IL-2 regulation and response is critical to the development of JIA and therefore IL-2 therapy represents an exciting and viable therapeutic option for JIA.

**Objectives:** We aim to identify a subset of JIA patients who carry a high burden of genetic risk variants in genes related to IL-2 regulation and response, who could then be targeted for IL-2 therapy. Secondly we will link genetics to cellular phenotypes using CyTOF to identify a subset of cells that are most perturbed in JIA and determine the effects of IL-2 on these cellular subsets.

**Methods:** A weighted genetic risk score (wGRS) was generated using 9 JIA susceptibility SNPs considered to be within or near to genes involved in interleukin (IL-2) regulation and response.<sup>1</sup> The IL-2 wGRS was tested in an independent set of UK cases (1435) and controls (5181). The risk of developing JIA was assessed by subtype, using logistic regression. A CyTOF panel containing 33 antibodies targeting markers of T cells and T-regulatory cells was developed and tested in CD3 +T cells from two healthy individuals after 12 hour stimulation (anti CD3/CD28 beads plus recombinant IL-2). Cells were stained for all antibodies, iridium and cisplatin and analysed on the CyTOF Helios. Data will be analysed with traditional biaxial gating as well commercially available packages such as cytofit.

**Results:** The IL-2 wGRS demonstrated an increased percentage of individuals in the high risk group in the extended oligoarthritis, RF negative and RF positive polyarthritis subtypes suggesting a higher burden of IL-2 related loci. The odds of developing JIA for those in the highest risk group (quintile 5) compared to all others was increased in these subtypes (OR 2 95% CI 1.45–2.76, OR 2.39 95% CI 1.87–3.04, OR 2.14 95% CI 1.49–3.09, respectively). Comparing this to a wGRS generated from JIA susceptibility loci excluding IL-2 related genes shows that this enrichment is specific to the IL-2 wGRS. Biaxial gating of CyTOF data showed increases in activation markers after stimulation (CD25, CD69, CD38 and HLA-DR, decrease CCR7). We demonstrated that our panel can successfully identify traditional CD4 +T cell subsets showing differences between stimulated and unstimulated cells and between individuals.

**Conclusions:** Our analysis has shown that patients with oligoarthritis and polyarthritis have an increased burden of JIA susceptibility variants in genes related to IL-2 regulation and response suggesting these individuals may benefit from IL-2 therapy. Using the CyTOF panel we can now analyse individuals with high and low GRS allowing us to identify cellular subsets which may be altered by these genetic variants.

### TOWARDS PRECISION MEDICINE IN CONNECTIVE TISSUE DISEASES: GENOMIC AND TRANSCRIPTOMIC STUDIES

T. Briggs<sup>1,2</sup>, J.A. Reynolds<sup>3</sup>, G. Rice<sup>4</sup>, V. Bondet<sup>5</sup>, E. Bruce<sup>3</sup>, Y. Crow<sup>6,7</sup>, D. Duffy<sup>5</sup>, B. Parker<sup>3</sup>, I.N. Bruce<sup>3</sup>. <sup>1</sup>Manchester Centre for Genomic Medicine, St Mary's Hospital, Manchester University Hospitals NHS Foundation Trust Manchester Academic Health Sciences Centre, University of Manchester; <sup>2</sup>Division of Evolution and Genomic Sciences; <sup>3</sup>Division of Musculoskeletal and Dermatological Sciences, School of Biological Sciences, University of Manchester; <sup>4</sup>Division of Evolution and Genomic Sciences, University of Manchester, Manchester, UK; <sup>5</sup>Immunobiology of Dendritic Cells, Institut Pasteur; <sup>6</sup>Laboratory of Neurogenetics and Neuroinflammation, INSERM UMR1163, Institut Imagine, Paris, France; <sup>7</sup>MRC Institute of Genetics and Molecular Medicine, The University of Edinburgh, Crewe Road, Edinburgh, UK

**Background:** To date, 18 genotypes linked with enhanced interferon signalling and severe inflammatory multi-system disease, have been identified. Functional studies in these disorders has led to significant advances in the understanding of type I interferon signalling. Understanding the role of these same genes in the pathogenesis of Connective Tissue Diseases (CTDs) may help guide precision medicine in this field.

**Objectives:** To study the relationship between phenotypic, serological, genomic and transcriptomic characteristics in adults with Connective Tissue Diseases (CTDs).

**Methods:** Following clinical and serological phenotyping, targeted exome sequencing was performed in 100 adults with CTDs. The CTDs include: systemic lupus erythematosus, Sjogren's syndrome, mixed and undifferentiated CTD, limited and diffuse cutaneous systemic sclerosis and dermatomyositis. The targeted 200-gene panel was designed based on data from human or animal studies associating gene function with autoimmune diseases, particularly lupus. Type I interferon stimulated gene (ISG) signature score was calculated from quantitative PCR assessment of six interferon stimulated genes<sup>1</sup> and interferon alpha was directly assayed by single-molecule array (Simoa) digital ELISA technology<sup>2</sup> in all cases.

**Results:** Targeted exome sequencing in adults with CTD identified potential monogenic causes in 5% of cases, with causative genes including known type I interferon-associated genes, such as TREX1, C1q and PEPD.

An ISG signature was present in 35% of the cohort and showed significant correlation with the Simoa interferon alpha assay ( $r=0.854$ ) (figure 1).

**Conclusions:** Drug development in CTDs is notoriously slow. However, recent drug developments in type I interferon modulation in terms of JAK-STAT inhibition and interferon receptor antibodies offer great promise for a subset of patients. Our work demonstrates that through deep phenotyping of patients with corollary 'omic studies, a CTD subset, that is not restricted to a single diagnostic grouping, can be identified in whom targeted anti-interferon therapy would likely be of great value.

**Background:** Although the etiology of rheumatoid arthritis (RA) remains unclear, there are evidences suggesting a role of sex steroid hormones in determining the onset and progression of the disease.

**Objectives:** The aim of this study was to evaluate whether 47 single nucleotide polymorphisms (SNPs) in steroid hormone-related genes are associated with the risk of RA and anti-TNF drug response.

**Methods:** We conducted a case-control study in 3 European populations including 2936 RA patients and 2197 healthy controls. Of those a total of 1985 RA patients were treated with anti-TNF blockers. The association of potentially interesting markers with RA risk or drug response in the discovery population was validated through meta-analysis with data from DREAM and DANBIO registries. Results were corrected for multiple testing (Meff method;  $p=0.0011$ ).

The value of steroid hormone-related variants for prediction of anti-TNF drug response was also assessed using stepwise logistic regression analyses. The area under the curve (AUC) of a receiver operating characteristic (ROC) curve analysis and a  $-2 \log$  likelihood ratio (LR) test were used to assess whether the genetic model fitted significantly better the data compared to the reference model. A randomization test (50.000 iterations) was run to confirm the consistency of the results.

**Results:** Although none of the selected variants played a relevant role in modulating RA risk, the meta-analysis of the linear regression data with those from the DREAM and DANBIO registries showed a significant correlation of the CYP3A4<sub>rs11773597</sub> and CYP2C9<sub>rs1799853</sub> variants with changes in DAS28 after the administration of anti-TNF drugs ( $p=0.00074$ , and  $p=0.006$ ). An overall haplotype

analysis also showed that the *ESR2*<sub>GGG</sub> haplotype significantly associated with a reduced chance of having poor response to anti-TNF drugs ( $p=0.0009$ ). Finally, a ROC curve analysis confirmed that a model built with 8 steroid hormone-related variants significantly improved the ability to predict drug response compared with the reference model including demographic and clinical variables (AUC=0.633 vs. 0.556;  $P_{LRtest}=1.52 \cdot 10^{-6}$ ).

**Conclusions:** These data suggest that steroid hormone-related genes play a role in determining the response to anti-TNF drugs.

#### LOCATION AND INTERACTION OF IGG HYPERVARIABLE REGIONS WITH PORPHYROMONAS GINGIVALIS PEPTIDYLARGININE DEIMINASE CITRULLINATED PEPTIDES, A HIGHLIGHT TO UNDERSTAND THE ASSOCIATION MODEL OF RHEUMATOID ARTHRITIS AND PERIODONTAL DISEASE: IN SILICO ANALYSIS

M. Acevedo-Godoy<sup>1</sup>, P. Hernandez<sup>2</sup>, A. Amaya<sup>1</sup>, D.M. Castillo<sup>1</sup>, J.E. Castellanos<sup>2</sup>, J.M. Bello-Gualtero<sup>3,4</sup>, W. Bautista-Molano<sup>1,4</sup>, C. Romero-Sanchez<sup>1,3,4</sup>. <sup>1</sup>Unit of Oral Basic Investigation – UIBO; <sup>2</sup>Vice-rectory for Research, Universidad El Bosque; <sup>3</sup>Rheumatology and Immunology, Hospital Militar Central; <sup>4</sup>Clinical Immunology Group, Universidad Militar Nueva Granada, Bogotá D.C., Colombia

**Background:** IgG antibodies against citrullinated peptides are one of the most specific biomarkers used in the classification of the disease. The relationship between RA and periodontal disease is based on the process of citrullination. The enzyme in the most important bacteria related with periodontitis (*Porphyromonas gingivalis*) the Peptidylarginine Deiminase (PPAD) modify arginine residues to citrulline

**Objectives:** To model *in silico* the binding of PPAD peptides with the hypervariable regions of IgG

**Methods:** One PPAD peptide with 15 residues was selected *in silico* by its recognition by B cells (Bcepred y ABCpred) and T lymphocytes (ProPred, MHCpred). The peptide arginines were changed *in silico* by citrulline (Cit) with the ACD/ChemSketch software, obtaining four different peptides, natural, Arg1 changed, Arg1-Arg8 changed and a random sequence. The 3D peptide modelling was obtained using PEP-FOLD Server and the 3D structure of variable domains of the heavy and light chain of IgG was obtained with the SwissModel. The amino acids of the hypervariable regions capable of interacting were defined using ConSurf Server. The peptides and variable domains were prepared using Openbabel. Docking models were performed by Patchdock and PyMOL tool was used to rendering the structural complexes obtained

**Results:** The 3D structure of IgG variable domains had a QMEN6 z-score <1. Modelling of the topological disposition of the amino acids was obtained and the interaction scores between the four peptides and light and heavy chain hypervariable regions were high, although the better score was in the natural peptide and light chain interaction. The heavy chain showed also a high score during the *in silico* interaction with the Cit1-Cit8 modified peptide. The approximate interface area of the receptor-ligand complex and the contact atomic energy (ACE) between the ligand and the receptor revealed the energy required for the interaction allowing its stability. The PPAD-IgG complexes showed the atomic contact maps in which the heavy chain hypervariable region contacted seven amino acids in all four peptides while only six contacts occurred between light chain and the peptides. The model showed the interactions between light chain and natural peptide (Arg1 with Gly100, Arg8 with Glu1) and for Cit1-Cit8 peptide, Cit8 interact with Thr10 (Cit1 has no contact). Regarding the heavy chain, Arg1 of natural peptide interacted with Trp47 while for Cit1-Cit8 peptide were Cit1 with Lys43 and Cit8 with Pro40

**Conclusions:** The *in silico* model shows bacterial PPAD peptides with and without citrullination interact with the hypervariable regions of human IgG. The citrulline residues modify the 3D structure influencing the contact area with the heavy and light chain variable regions. Peptide with modifications of two arginine residues by citrulline presented a high interaction score indicating that may have an effective recognition for IgG

#### TARGETED RE-SEQUENCING OF 128 RHEUMATOID ARTHRITIS SUSCEPTIBILITY GENES UNCOVERS NOVEL RISK LOCI IN THE SINGAPORE CHINESE POPULATION

J.M.Y. Yong<sup>1</sup>, L.L. Goh<sup>1</sup>, C.W. Lim<sup>1</sup>, P.P.Q. Lim<sup>1</sup>, G. L.-X. Toh<sup>1</sup>, E.T. Koh<sup>2</sup>, K. P. Leong<sup>2</sup>, the TTSH RA Study Group<sup>2</sup>. <sup>1</sup>Clinical Research and Innovation Office; <sup>2</sup>Rheumatology, Allergy and Immunology, Tan Tock Seng Hospital, Singapore, Singapore

**Background:** Rheumatoid arthritis (RA) is a fairly common inflammatory autoimmune disease with a prevalence of 1% to 1.5%. Patients experience chronic joint pain, swelling and overtime irreversible joint damage. Genetic variants known to contribute to rheumatoid arthritis (RA) susceptibility have been reported in more than 120 genes, including the HLA, PTPN22, CTLA4, TNFAIP3, PADI4, FCRL3, CD4, CD244 and CD40. The genetic susceptibility to RA has not been studied in the Singapore population.

**Objectives:** To identify novel risk variants in candidate genes previously reported to be associated with rheumatoid arthritis (RA) in Singapore Chinese RA patients positive for anti-citrullinated peptide antibodies (ACPA).

**Methods:** All the 128 known candidate genes associated with RA identified through GWAS were sequenced in 48 RA patients and 45 controls. The resultant data was analysed for association using single variant association and pathway-based association enrichment tests. In addition, the genetic burden due to rare variants was assessed using the C-alpha test. The candidate variants that showed significant association were validated in a larger cohort of 500 RA cases and 500 controls using mass array and Taqman technologies.

**Results:** 39 variants in 18 genes were identified using single variant association analysis and C-alpha test. IL6ST, with stepwise filtering. Among these, the missense variant in IL6ST, 5:55260065 (p.Cys47Phe) was significantly associated with RA in the Singapore Chinese patients ( $p=0.0194$ ). The insignificant results of additional potential rare variants such as IL6ST, 5:55237103 and PXR rs199881366 is highly due to the limitations of our small sample size.

**Conclusions:** Our results suggest that IL6ST, 5:55260065, 5:55237103 and PXR rs199881366 confer risk of RA in ACPA-positive Chinese patients.

**THU0013 DOWNREGULATION OF MICRORNA MAY CONTRIBUTE TO ACTIVATION OF THE INTERFERON SIGNALLING PATHWAY IN THE IDIOPATHIC INFLAMMATORY MYOPATHIES**

J.E. Parkes<sup>1</sup>, H. Chinoy<sup>2</sup>, P.J. Day<sup>3,4</sup>, J.A. Lamb<sup>1</sup>. <sup>1</sup>Division of Population Health, Health Services Research and Primary Care; <sup>2</sup>National Institute for Health Research Manchester Biomedical Research Centre; <sup>3</sup>Manchester Institute of Biotechnology; <sup>4</sup>Division of Evolution and Genomic Sciences, University of Manchester, Manchester, UK

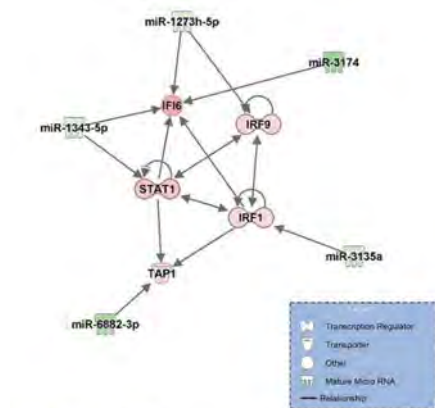

**Background:** The idiopathic inflammatory myopathies (IIM) are a group of rare autoimmune conditions characterised by weakness and inflammation of skeletal muscle. MicroRNA are short single stranded RNA which regulate gene expression by binding to particular target mRNA and suppressing translation or inducing degradation. MicroRNA are known to play a role in muscle homeostasis and immune regulation and therefore may be involved in IIM pathology.

**Objectives:** To profile both microRNA and mRNA in whole blood samples from polymyositis (PM), dermatomyositis (DM) and inclusion body myositis (IBM) patients compared to non-myositis controls using next generation RNA sequencing.

**Methods:** Whole blood samples in tempus tubes were collected as part of the myositis research tissue bank held at the University of Manchester. Total RNA was extracted from 7 PM, 7 DM, 5 IBM and 5 non-myositis control samples and both microRNA and mRNA profiles were determined by sequencing on the Illumina HiSeq 4000.

**Results:** Analysis of microRNA expression identified 19 microRNAs as significantly differentially expressed (DE) ( $p < 0.05$ ) for PM, 11 for DM and 27 for IBM, compared to controls. Analysis of myositis specific autoantibody anti-Jo1 positive cases (four PM and one DM) vs controls identified 18 DE microRNAs, 12 of which were not identified for any of the clinical subgroups.

Gene expression analysis identified 129 significantly DE genes for PM (false discovery rate  $< 0.05$ ), 53 for DM, 24 for IBM and 691 for anti-Jo1 compared to controls. Ingenuity pathway analysis (IPA) of RNAseq data identified the most significant canonical pathway as 'Interferon signalling' which was predicted to be upregulated in PM, DM and anti-Jo1 subgroups. The anti-Jo1 subgroup had a higher number of DE genes and a higher activation score in the interferon signalling pathway compared to PM or DM. The IPA tool microRNA target filter was used to match DE microRNA with corresponding DE mRNA predicted or previously observed to be targets. When mRNA targets were filtered for involvement in interferon signalling, two downregulated microRNA targeted two upregulated mRNA in PM and five downregulated microRNA targeted five upregulated mRNA in the anti-Jo1 group as shown in figure 1. No microRNAs targeting mRNA involved in the interferon signalling pathway were identified for DM or IBM.

© 2005-2018 QIAGEN. All rights reserved.

**Abstract THU0013 – Figure 1.** Relationship between differentially expressed microRNA in anti-Jo1 samples versus controls and mRNA targets involved in the interferon signalling pathway. Green colouring indicates downregulation; red colouring indicates upregulation and darker shades indicate greater fold change.

**Conclusions:** To our knowledge this is the first mRNA and microRNA profiling study in whole blood from myositis patients using RNA sequencing. Grouping by anti-Jo1 positivity identified different microRNA and increased predicted activation of interferon signalling compared to the clinical subgroups analysed. Our results suggest that increased activation of the interferon pathway in anti-Jo1 positive patients may be due to downregulation of microRNAs which target genes in this pathway.

**THU0014 GENETIC SCREENING FOR IDENTIFYING HUMAN GENES REGULATING FIBROSIS IN SYSTEMIC SCLEROSIS**

M. Krishnan<sup>1</sup>, U. Unniyampurathu<sup>1</sup>, S. Albani<sup>2</sup>, A.H.L. Low<sup>3</sup>. <sup>1</sup>Program on Emerging Infectious Diseases, Duke-National University Hospital, Singapore; <sup>2</sup>SingHealth Translational Immunology and Inflammation Centre; <sup>3</sup>Singapore General Hospital, Duke-National University Hospital, Singapore, Singapore

**Background:** Systemic sclerosis (SSc) is a prototypic multi-systemic fibrotic disease. Fibrosis involves exacerbated collagen production. A lack of effective therapies has partly been due to incomplete understanding of the mechanisms of fibrosis and inadequate subsetting of this heterogeneous disease to allow targeted treatment. Identification of a collagen-synthesis gene signature in SSc will enhance our ability to molecularly subset SSc patients. We reasoned that there exists several unidentified genes regulating collagen synthesis, whose dysregulation play key roles in fibrosis underlying SSc.

**Objectives:** To discover novel genes/pathways involved in elevated collagen synthesis

**Methods:** We conducted a pioneering forward-genetics approach using genome-wide ribonucleic acid interference (RNAi) –screening. We performed RNAi-screening in dermal fibroblasts from three patients with early diffuse cutaneous systemic sclerosis (onset from the first non-Raynaud's manifestation of less than 3 years). Dermal fibroblasts were immortalised using ectopic expression of human telomerase. The assay used a collagen promoter driver reporter system for identifying genes regulating collagen transcription.

**Results:** The genetic screen identified 187 genes whose silencing altered the activation of collagen promoter activity. This included 82% and 18% positive and negative regulators, respectively. A system-level view of genes and signalling pathways regulating collagen synthesis was generated using bioinformatics analysis.

**Conclusions:** We anticipate that this catalogue of collagen expression regulating genes will help to unravel the dysregulated genetic regulatory modules of fibrosis and may aid in the diagnostics of different clinical subsets of SSc.

**THU0015 OESTROGEN DEPENDENT REGULATION OF MICRO-RNA IN RHEUMATOID ARTHRITIS**

K. Andersson<sup>1</sup>, R. Pullerits<sup>1</sup>, H. Forsblad-d'Elia<sup>1,2</sup>, M. Erlandsson<sup>1</sup>, S. T. Silfverswärd<sup>1</sup>, M. Bokarewa<sup>1</sup>. <sup>1</sup>Dept Rheumatology and inflammation research, Inst Medicine, Göteborg university, Göteborg; <sup>2</sup>Depr Public Health and Clinical Medicine, Inst Rheumatology, Umeå University, Umeå, Sweden

**Background:** Oestrogen has ameliorating effects on rheumatoid arthritis (RA). Oestrogen receptor (ER) signalling affects micro-RNA (miR) expression and processing in breast cancer, while its effect on miR profile in RA have never been studied.

**Objectives:** To study the effect of the oestrogen replacement therapy and oestrogen receptor signalling on the miR transcription and bioprocessing in RA patients.

**Methods:** The expression of the key miR processing enzymes Dicer, Drosha and DGCR8 was measured in the leukocytes of the peripheral blood of 145 female RA patients (age 53 years, disease duration 9.8 years) by RT-PCR and analysed with respect to the levels of ER $\alpha$ , used as surrogate marker of active ER $\alpha$  signalling. Total RNA was prepared from the serum samples of 46 postmenopausal female RA patients who received treatment with oestradiol (E2), noretisterone acetate, vitamin D<sub>3</sub> and calcium (n=22, mean E2 levels 229.4 $\pm$ 143.2 pg/ml) or vitamin D<sub>3</sub> and calcium supplementation only (n=24, mean E2 levels 30.8 $\pm$ 8.7 pg/ml). Serum was obtained after 12 and 24 months of treatment and was stored at  $-70^{\circ}\text{C}$  until the time of analysis. MicroRNA transcription was performed by 3D-Geno microarray measuring >2560 miRs (TATAA Biocenter, Gothenburg).

**Results:** A higher ER $\alpha$  expression in RA female patients was associated with increased transcription of the major miR processing proteins Dicer ( $p=0.0057$ ), Drosha ( $p=0.019$ ) and DGCR8 ( $p=0.0095$ ). This activated transcription of miR biomachinery could indicate a higher demand and a facilitated miR maturation. The E2-treatment significantly changed the profile, but not the levels, of miRs in serum, where only 50% of the miR transcripts were present both in E2-treated and control samples. Also the profile of miRs related to RA and of those regulating translation of ER $\alpha$  and Dicer, Drosha, and DGCR8 proteins was affected. Extensive bioinformatic analysis of the miR-targeting genes affected during E2-treatment, revealed a reduction of gene clusters aiding autoimmune pathology and the RA-associated molecular processes including DNA replication ( $p=2.6 \times 10^{-4}$ ), peptidyl-serine phosphorylation ( $p=2 \times 10^{-4}$ ), protein localization to nucleus and nuclear import ( $p=5 \times 10^{-4}$ ).

**Conclusions:** Activation of ER $\alpha$  significantly enhances the miR processing, and affects the profile of miR transcription in female RA patients. The change in miR profile during E2-treatment could contribute to a significantly change in the miR landscape and disposition of intracellular processes in RA.

**THU0016 TRANSMITOCHONDRIAL CYBRIDS SHOW THAT OXPHOS VIA, BUT NO GLYCOLYSIS VIA, IS INVOLVED IN THE ATP REDUCTION OF OA HUMAN CHONDROCYTES**

M. Fernández-Moreno<sup>1,2</sup>, A. Dalmao-Fernandez<sup>2</sup>, T. Hermida-Gomez<sup>2</sup>, A. Rustan<sup>3</sup>, J. Lund<sup>3</sup>, M.E. Vazquez-Mosquera<sup>2</sup>, S. Relano-Fernandez<sup>2</sup>, I. Rego-Perez<sup>2</sup>, F. Blanco-Garcia<sup>2</sup>. <sup>1</sup>CIBER-BBM, Madrid; <sup>2</sup>INIBIC, A Coruña, Spain; <sup>3</sup>Department of Pharmaceutical Biosciences, Oslo University, Oslo, Norway

**Background:** Mitochondrial dysfunction is well documented in OA and has the capacity to alter chondrocyte function and viability, contributing to cartilage degeneration. It is important to evaluate the influence of mitochondria in the pathogenesis of OA using an *in vitro* model to explain the functional consequences of this association and help us to identify potential diagnostic biomarkers and/or therapeutic targets. Transmitochondrial cybrids are a useful cellular model to study the mitochondrial biology and function implications in the cellular behaviour, since they carry different mitochondrial variants with the same nuclear background, therefore, excluding the variations because of nuclear genome.

**Objectives:** The aim of this work is test mitochondrial activity in the OA chondrocytes using transmitochondrial cybrids with mtDNA from healthy donors (without OA) and from patients with OA.

**Methods:** Cybrids were developed using 143B.TK<sup>-</sup> Rho-0 cell line (nuclear donor) and platelets (mitochondrial donors) from healthy and OA donors. Human articular chondrocytes were obtained from patients with hip replacement. The mtDNA copy number was measured by real-time PCR method. The ROS production was evaluated using flow cytometry. The metabolic status was evaluated by glucose consumption and glucose oxidation. The glycolytic activity was measured after addition of glucose, oligomycin and 2-dioxylglucose using Seahorse XFp (ECAR). The OXPHOS function was evaluated by SeaHorse XFp (OCR) after addition of oligomycin, FCCP and Rotenone/Antimycin. Appropriate statistical analyses were performed with GraphPad Prism v6.

**Results:** The analysis of mtDNA copy number showed that the OA have higher levels than N in cybrids and human chondrocytes. The analysis of ROS production showed that OA had higher levels than N in both types of cells. The metabolic status analysing glucose consumption, glucose oxidation and total glucose cellular uptake reflected higher values in OA cybrids than N cybrids. But the analysis of glycolysis data showed lower values in OA than N cybrids. The analysis of ATP obtained through glycolysis did not show any difference between cybrids. The analysis of OXPHOS function showed that OA had lower basal respiration and maximal respiratory capacity than N in both types of cells. The ATP obtained via OXPHOS was lower in OA than in N.

**Conclusions:** The analysis of OXPHOS function supports the participation of mitochondria in cybrids and human chondrocytes metabolism. Both types of cells use the mitochondria to obtain ATP and OXPHOS via, but no glycolysis, is involved in the reduction of ATP synthesis by OA cells. All these data support that N cybrids and chondrocytes use mitochondria with more efficiency.

**THU0017 DNA METHYLATION OF REGULATORY SITES OF HAND OSTEOARTHRITIS SUSCEPTIBILITY GENES IN FINNISH WOMEN**

S. Hämäläinen, S. Solovieva, T. Vehmas, A. Hirvonen, P. Leino-Arjas. *Finnish Institute of Occupational Health, Helsinki, Finland*

**Background:** Despite the hard effort in OA genetic studies only a small part of the estimated effect has been found so far and thus the focus has been changing from genetic to epigenetic studies. The most widely studied epigenetic control mechanism is DNA methylation. There are only few studies on hand OA concerning DNA methylation but their results are promising.

**Objectives:** Our aim was to study methylation of the regulatory sites of our previously found hand OA susceptibility genes and to replicate some previously reported methylation sites associated with hand OA, in our Finnish women hand OA material.

**Methods:** The study design was cross-sectional. Bilateral hand radiographs of 542 occupationally active Finnish female dentists and teachers aged 45 to 63 and

classified them according to the presence of OA by using reference images. Radiographic hand OA at least mild, in at least three joints (ROA2\_3), and radiographic findings summary score (OASUM) were used to define hand OA status. The methylation percentages were determined by bi-sulfite converted DNA pyrosequencing with commercial CpG Assays. Statistical analyses were performed using hierarchical multiple linear regression.

**Results:** Of the studied methylation sites the COL2A1\_1 methylation site was associated with ROA2\_3 (p=0.04). Also ALDH1A2\_01 methylation site was associated with OASUM (p=0.02). When the data was stratified by occupation the association was only significant, and stronger, in teachers but not in dentists (COL2A1\_1 p=0.02 vs. p=0.36 for ROA2\_3, and ALDH1A2\_1 p=0.01 vs. p=0.36 for OASUM, respectively). The studied methylation sites in TGFB1, RRP9 and TRAPP5 genes had methylation percentages under the detection limit and they were excluded from the analysis.

**Conclusions:** Our results lend further support to COL2A1 and ALDH1A2 being hand OA susceptibility genes at the epigenetic level.

**Acknowledgements:** The study was financially supported by a grant from the Finnish Work Environment Fund (113369).

**THU0018 MIRNAS-146A AND -499 GENE EXPRESSION AND THEIR POLYMORPHISMS AS DIAGNOSTIC MARKERS FOR RHEUMATOID ARTHRITIS**

G.A. Ayeldeen<sup>1</sup>, Y.H. Nassar<sup>1</sup>, H.A. Ahmed<sup>1</sup>, O.G. Shaker<sup>1</sup>, T.A. Gheita<sup>2</sup>. <sup>1</sup>Medical Biochemistry and Molecular Biology; <sup>2</sup>Rheumatology and Clinical Immunology, Faculty of Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo, Egypt

**Objectives:** To investigate the expression of miRNAs-146a and -499 and their polymorphisms in Egyptian patients with RA and to evaluate their relationship to clinical manifestations and disease activity.

**Methods:** Fifty-two RA patients and 56 matched controls were studied. Disease activity score-28 was assessed. MicroRNAs expression and polymorphisms were assayed by polymerase chain reaction (PCR).

**Results:** Patients mean age was 39.5±10.8 years and the disease duration of 7±5.1 years. The DAS28 was 3.1±1.7; 23 were in remission, 5 had mild disease activity, 18 moderate and 6 severe. There was a 15.5±27.2 fold increase in miRNA-146a and 3.3±6.1 in miR-499. The fold change of miRNA-146a was significantly higher in those without joint deformities (n=18) (28.1±42.6) compared to those with (8.8±8.4; p=0.01). Both miRNA-146a and -499 fold change were significantly decreased in those with a positive ANA (n=7) (2.5±2.1 and 0.07±0.08) compared to those with a negative test (18.1±29.6 and 3.8±6.5; p=0.002 and p=0.001 respectively). The fold changes tended to be higher in those in remission compared to active patients. However, miRNA-499 in those with severe disease activity tended to be higher. There was no significant correlation of the fold change of the miRNAs with the clinical manifestations or medications received. Only ANA positivity significantly inversely correlated with the fold increase in miRNA-146a (r=-0.42, p=0.003). The fold change in miRNA-146a significantly correlated with miRNA-499 (r=0.56, p<0.0001).

**Conclusions:** Both miRNAs-146a and -499 are highly expressed in RA patients and can be considered as diagnostic markers. Increased expression of miRNA-146a expression is protective in those with negative ANA and both in those without joint deformities.

**THU0019 ARE MICRORNAS A MOLECULAR CLOCK? THE NEWCASTLE THOUSAND FAMILIES COHORT STUDY**

T.L. Jones<sup>1</sup>, D.A. Young<sup>2</sup>, M.S. Pearce<sup>3</sup>, A. Skelton<sup>4</sup>, F.N. Birrell<sup>1</sup>. <sup>1</sup>Institute of Cellular Medicine; <sup>2</sup>Institute of Genetic Medicine; <sup>3</sup>Institute of Health and Society; <sup>4</sup>Bioinformatics Support Unit, Newcastle University, Newcastle-upon-Tyne, UK

**Background:** No single biomarker has been identified for monitoring ageing trajectory. To date, biological clocks are based on DNA methylation, telomere length, p16<sup>ink4a</sup> expression and microsatellite mutations<sup>1</sup>. Body ageing is a complex phenomenon, including a progressive, pro-inflammatory state, termed 'inflammaging'. MicroRNAs have been linked with cellular senescence and inflammaging. MicroRNAs are short, non-coding sequences of RNA regulating post-transcriptional gene expression with impressive stability and ubiquitous presence, making them ideal candidate biomarkers. Previous studies of circulating microRNAs in ageing were small-scale<sup>2</sup> or compared individuals of different ages, which is methodologically less robust<sup>3</sup>. MicroRNA biomarkers can bring greater understanding to

ageing mechanisms, diagnosis/prognosis of age-related disease and even novel treatment targets.

**Objectives:** To quantify relationships between circulating microRNA expression and biological ageing and determine whether microRNAs may be a molecular clock.

**Methods:** This pilot work is a nested substudy within a prospective, longitudinal birth cohort from May/June 1947 (the Newcastle Thousand Families Study NTFs). Serum samples from 23 subjects taken at ages 50 and 62 years were extracted from the biobank. HTG EdgeSeq microRNA whole transcriptome assay was performed, measuring expression of 2083 human microRNA transcripts using an array followed by next generation sequencing. Global microRNA expression profiles were generated and analysed using this technology, profiling all known microRNAs from a small volume of serum (<15  $\mu$ L). NIHR funding has been secured for whole cohort analysis.

**Results:** Resulting data has shown very strong associations (up to  $p < 10^{-12}$ ) for biological ageing, with 84 microRNAs meeting  $p$ -values  $< 0.05$  (see heat map). Analysing the whole cohort will independently validate and extend the findings, in order to identify an ageing signature; the molecular clock.

**Conclusions:** This study suggests very strong changes in microRNAs in individuals between 50 and 62, suggesting microRNA signature is a molecular clock. These observations need to be confirmed and extended to validate serum microRNAs as biomarkers for ageing, for early detection of age-related disease and as tools to monitor ageing trajectory.

#### THU0020 TOCILIZUMAB DECREASES THE PRO-INFLAMMATORY ROLE OF PLATELETS IN RHEUMATOID ARTHRITIS: IDENTIFICATION OF A NEW MECHANISM OF ACTION ASSOCIATED WITH POSITIVE RESPONSE?

C. Prum Delepine<sup>1,2</sup>, C. Derambure<sup>3</sup>, F. Vidal<sup>2</sup>, A. Pinta<sup>4</sup>, D. Pau<sup>4</sup>, E. Conde da Silva Fraga<sup>4</sup>, O. Boyer<sup>2</sup>, E. Senbel<sup>5</sup>, P. Gaudin<sup>6,7</sup>, O. Vittecoq<sup>1,2</sup>, T. Lequerre<sup>1,2</sup>.  
<sup>1</sup>rheumatology department, CHU Rouen; <sup>2</sup>Inserm U 1234; <sup>3</sup>Inserm U 1245, Normandie University, UNIROUEN, Rouen; <sup>4</sup>Roche SAS, Boulogne-Billancourt; <sup>5</sup>rheumatology department, Hôpital Sainte Marguerite, Marseille; <sup>6</sup>rheumatology department, Grenoble hospital, Echirolles; <sup>7</sup>GREPI AE7405, Grenoble Alpes University, Grenoble, France

**Background:** Tocilizumab (TCZ), a humanised monoclonal antibody directed against IL-6 receptor, is an efficient treatment for rheumatoid arthritis (RA) but its mechanisms of action are not yet well understood.

**Objectives:** To identify new mechanisms of action of TCZ, by the study of gene expression fluctuations, between baseline (BL) and 3 months of treatment (T<sub>3m</sub>), in RA patients.

**Methods:** TOSCA study has been realised to evaluate efficiency and tolerance of TCZ administrated subcutaneously in active RA patients. Among the 125 patients of TOSCA study, 38 were ranked according to their treatment response after 3 months: 29 good responders (GR), 19 of which were also treated by methotrexate (MTX) and 10 non responders (NR), 7 of which were treated by MTX (GR: DAS 28-ESR<sub>3m</sub> <3,2 and Delta DAS28-ESR<sub>(BL-3m)</sub> ≥3; NR: DAS 28-ESR >3,2 and Delta DAS28-ESR<sub>(BL-3m)</sub> <3). A transcriptomic analysis was performed using a 44K whole human genomic DNA microarray (Agilent) on whole blood cells collected at BL and at T<sub>3m</sub>. We identified genes with statistically significant expression fluctuations between BL and T<sub>3m</sub> specifically in GR group (and not in NR group), treated by TCZ in monotherapy (excluding genes which fluctuated only with the association TCZ-MTX). Functional bio-informatics analysis was applied to this set of transcripts, by interrogation of Gene Ontology database, using Single Experiment Analysis tool and Natural Language Processing algorithms.

**Results:** Overall, 1089 transcripts significantly dysregulated were identified only in GR group at T<sub>3m</sub> (t test,  $p < 0.05$ ). This first set of transcripts was reduced to 783 by exclusion of transcripts that were fluctuated specifically when MTX was associated with TCZ in GR group. The functional analysis with these 783 genes dysregulated under TCZ in monotherapy enabled the identification of 8 transcripts (*CLU*, *F13A1*, *ITGA2B*, *ITGB3*, *SELP*, *SNCA*, *SPARC*, *TREML1*) whose relative abundances were significantly reduced at T<sub>3m</sub>. These genes were enriched in "platelet alpha granule" GO functional category. Proteins encode by these genes, either released in blood circulation or expressed at the cell membrane in case of platelet activation, have a pro-inflammatory activity through an interaction between platelets and immune cells.

**Conclusions:** This transcriptomic analysis suggests a new mechanism of action of TCZ in RA and the importance of platelets activation in RA pathophysiology. Indeed, genes linked with the pro-inflammatory role of platelets were down regulated. Further functional studies will be necessary to validate the direct effect of TCZ on platelets in RA.

#### THU0021 DIFFERENTIAL EFFECTS OF TR14 VERSUS DICLOFENAC ON COX/LOX PATHWAYS REVEALED BY RNASEQ

G. St. Laurent, III<sup>1</sup>, I. Toma<sup>2</sup>, B. Seilheimer<sup>3</sup>, M. Tackett<sup>4</sup>, J. Zhou<sup>1</sup>, M. Ri<sup>5</sup>, D. Shtokalo<sup>6</sup>, Y. Vyatkin<sup>5</sup>, T. Jepson<sup>1</sup>, K. Cesnulevicius<sup>3</sup>, T. Mccaffrey<sup>2</sup>.  
<sup>1</sup>The St. Laurent Institute, Vancouver, WA; <sup>2</sup>Department of Medicine/Division of Genomic Medicine, The George Washington University, Washington, DC, USA; <sup>3</sup>Biologische Heilmittel Heel GmbH, Baden-Baden, Germany; <sup>4</sup>SeqLL, Inc., Woburn, MA, USA; <sup>5</sup>AcademGene, LLC; <sup>6</sup>A.P. Ershov Institute of Informatics Systems, Novosibirsk, Russian Federation

**Background:** Anti-inflammatory agents are used widely in treating numerous pain and inflammatory conditions. With a focus on the COX/LOX pathways in cutaneous wound repair in mice, the therapeutic activities of Tr14 (Traumeel), a multicomponent/multitarget natural product, and diclofenac (NSAID), a non-selective cyclooxygenase (COX) inhibitor were compared. The COX enzymes convert arachidonic acid into prostaglandins and thromboxanes, while the lipoxygenase (LOX) pathway generates more pro-inflammatory leukotrienes. Differential effects were identified via transcriptome analysis (RNAseq).

**Objectives:** To compare the transcriptomic changes after administration of Tr14 or diclofenac in a mouse cutaneous wound healing model, with particular emphasis on the COX/LOX pathway.

**Methods:** After abrasive wounding, the wounds were treated with topical Tr14 (34 mg/ml) in combination with subcutaneous Tr14 injections (9.5 mg/ml), or with subcutaneous Tr14 injections only, or topical diclofenac at clinically relevant doses (2 mg/ml). Skin samples were analysed for RNA transcript profiling by RNAseq at specific times (12 hour, 24 hour, 36 hour, 72 hour, 96 hour, 120 hour, 192 hour) after injury. Differentially expressed genes (DEGs) were computed at each time point between diclofenac vs control or Tr14 vs control, using EdgeR.

**Results:** At early time points (12–36 hour), both control and Tr14-treated wounds showed marked increase in the inducible COX2 enzyme mRNA, while diclofenac-treated wounds did not, likely due to blocking the PGE2 necessary for the feedback induction. Tr14, in contrast, had a striking inhibitory effect on mRNA levels

for leukotriene A4 hydrolase, which converts LTA4 to LTB4; microsomal glutathione S-transferase, which converts LTA4 to LTC4; and gamma-glutamyltransferase (LTC4 >LTD4). In contrast, Tr14, but not diclofenac strongly induced Nrf2 mRNA at 12–36 hours.

**Conclusions:** Tr14 and diclofenac had very different effects on the COX/LOX synthetic pathway after cutaneous wounding. Tr14 allowed normal autoinduction of COX2 mRNA by PGE2, but suppressed mRNA levels for the key enzymes in the leukotriene synthetic pathway. A likely explanation for these effects is that Tr14 strongly induced Nrf2 mRNA, which is known to co-repress the leukotriene enzymes via transcription factor Bach1.

### THU0022 ANALYSIS OF 47 NON-MHC ANKYLOSING SPONDYLITIS SUSCEPTIBILITY LOCI REVEALS SHARED ASSOCIATED VARIANTS ACROSS CAUCASIANS AND CHINESE HAN

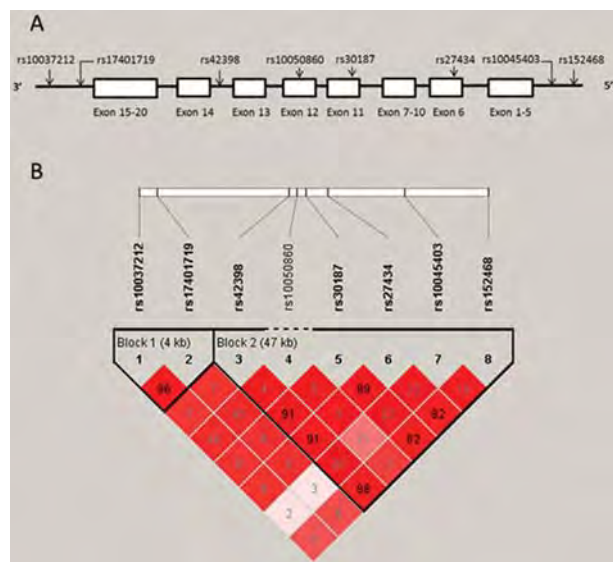

X. Zheng<sup>1</sup>, Q. Li<sup>1</sup>, X. Li<sup>1</sup>, Y. Zhang<sup>1</sup>, X. Wu<sup>1</sup>, Q. Wei<sup>1</sup>, S. Cao<sup>1</sup>, M. Yang<sup>1</sup>, Z. Lin<sup>1</sup>, Z. Liao<sup>1</sup>, J. Qi<sup>1</sup>, Q. Lv<sup>1</sup>, L. Wang<sup>2</sup>, J. Liu<sup>1,2</sup>, J. Gu<sup>1</sup>. <sup>1</sup>Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-sen University, Guangzhou, China; <sup>2</sup>Human Genetics, Genome Institute of Singapore, Singapore, Singapore

**Background:** Genetic factors play a prominent role in AS pathogenesis. So far over 40 non-MHC Ankylosing Spondylitis(AS) susceptibility loci with genome-wide or suggestive significance have been initially reported in Caucasians, however, lack of association evidence of most loci was seen in Chinese Han and some results seemed controversial.

**Objectives:** Here, we present a systematic evaluation of 47 non-MHC AS susceptibility loci using GWAS datasets in Chinese Han.

**Methods:** Totally 1853 AS cases and 4048 newly matched controls in 4 cohorts were obtained, after imputation meta-analysis results of 93 589 variants within 47 reported loci were extracted. Best-guess genotype data were used for interaction analysis and weighted genetic risk score model construction which was then assessed by receiver operator characteristic analysis. Functional annotation was conducted using HaploReg, RegulomeDB and rVarBase Database.

**Results:** We revealed 14 AS-associated variants with nominal association in Chinese Han, including rs10865331(p=2.96E-9), rs10050860 (p=1.84E-4) and rs8070463(p=2.81E-4) and found potential associated variants within these loci. We then extracted variants in ERAP1 as well as HLA-B27 tag snp rs13202464 for HLA-B27-ERAP1 interaction analysis (figure 1). Epistatic association between ERAP1 (rs30187, rs10045403) and HLA-B27 (rs13202464) was confirmed. Among those 14 variants, rs30187 showed weaker risk effect in Chinese while rs10050860 and rs12504282 seemed to attribute more risk (Table 1). Genetic prediction model combining 14 variants in 11 loci with HLA-B27 achieved better discrimination ability(AUC=0.884, 95%CI=0.873~0.895) than HLA-B27 alone (p=2.17E-6). We also identified some likely functional variants at these loci.

Abstract THU0022 – Figure 1

**Abstract THU0022 – Table 1.** Comparison of 14 shared associated non-MHC SNPs across European and Chinese

THURSDAY, 14 JUNE 2018:

### Adaptive immunity (T cells and B cells) in rheumatic diseases

#### THU0023 COMPLEX IMMUNOPHENOTYPING STRATIFIES PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME, SYSTEMIC LUPUS ERYTHEMATOSUS AND SECONDARY SJÖGREN'S SYNDROME ASSOCIATED WITH SYSTEMIC LUPUS ERYTHEMATOSUS INTO DISTINCT CLINICALLY RELEVANT GROUPS WITH POTENTIAL THERAPEUTIC IMPLICATIONS

N. Thompson<sup>1</sup>, A. Gandhi<sup>2</sup>, R. Radmore<sup>2</sup>, V. Gupta<sup>2</sup>, G. Robinson<sup>1</sup>, L. Martin-Gutierrez<sup>1</sup>, D. Isenberg<sup>2</sup>, E. Jury<sup>1</sup>, C. Ciurtin<sup>2</sup>. <sup>1</sup>Inflammation; <sup>2</sup>Rheumatology, University College London, London, UK

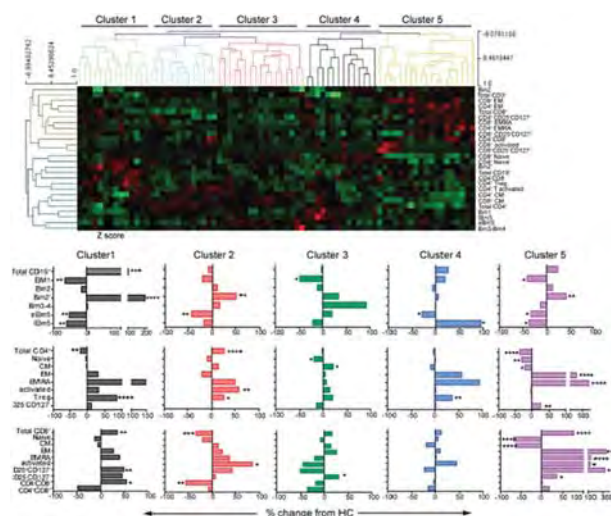

**Background:** Similarities in the clinical and laboratory features of patients with primary Sjögren's syndrome (pSS) and systemic lupus erythematosus (SLE) have led to attempts to treat pSS and SLE patients with similar biologic therapeutics. However, the results of many clinical trials are disappointing and no effective treatments are available for pSS and few for SLE patients with refractory disease.

**Objectives:** To identify novel patient endotypes using in depth immune phenotyping that facilitates the selection of biological therapies for patients regardless of diagnostic labels.

**Methods:** Peripheral blood was collected from patients with pSS (n=55), SLE (n=38), SS/SLE (n=15) and age/sex-matched healthy controls (HCs) (n=34). In-depth phenotyping of peripheral B and T-cell subsets by flow-cytometry, followed by unsupervised cluster analysis were performed. ROC analysis identified immune signatures characteristic for every cluster (endotype).

**Results:** Patients with pSS, SLE and SS/SLE had both unique and shared defects in immune cell phenotype. Hierarchical clustering of CD19<sup>+</sup> B-cells, CD4<sup>+</sup> and CD8<sup>+</sup> T-cells across the three disease groups identified five distinct endotypes spanning diagnostic boundaries. Three of the endotypes had distinct immune signatures, characterised by predominantly B-cell, T-cell memory or CD4<sup>+</sup>/CD8<sup>+</sup> T-cell subset fingerprints respectively, while two clusters had no distinct immune profiles. Notably, clinical and disease features were not significantly different between clusters.

**Conclusions:** The results demonstrated that immune cell biomarkers could be used to re-classify patients in a manner that reflects their underlying immunopathogenesis. Characterisation of a patient's endotype could lead to better stratification of patients for selection of therapeutic targets in clinical trials.

#### THU0024 TREATMENT WITH IMMUNE CHECKPOINT INHIBITORS AND THE BREAK OF B-CELL TOLERANCE TO AUTOANTIGENS

E.C. de Meel<sup>1</sup>, L. Rozeman<sup>2</sup>, A. Grummels<sup>3</sup>, E.M.E. Verdegaal<sup>4</sup>, J.A. Bakker<sup>3</sup>, E. H. Kapiteijn<sup>4</sup>, T.W.J. Huizinga<sup>1</sup>, J.B. Haanen<sup>2</sup>, R.E.M. Toes<sup>1</sup>, D. van der Woude<sup>1</sup>.  
<sup>1</sup>Rheumatology, Leiden University Medical Center, Leiden; <sup>2</sup>Medical Oncology and Immunology, Netherlands Cancer Institute, Amsterdam; <sup>3</sup>Clinical Chemistry and Laboratory Medicine; <sup>4</sup>Medical Oncology, Leiden University Medical Center, Leiden, Netherlands

**Background:** The field of autoimmunity may benefit from the knowledge gained by studying immune checkpoint inhibitors. These agents, which have proven remarkably successful in treating various types of cancer, inhibit negative costimulatory signals to T-cells, thereby enhancing anti-tumour T-cell responses. This can come at the cost of severe immune-related adverse effects (irAEs) including arthritis, colitis, endocrine diseases, hepatitis, and various skin abnormalities. However, it is currently unknown to which extent or to which autoimmune disease-associated autoantigens autoantibodies are formed (as a reflection of breaking of tolerance to self-antigens) under checkpoint inhibitor therapy and whether this is associated with irAEs.

**Objectives:** To investigate whether patients treated with immune checkpoint inhibitors develop autoantibodies, and whether this trait is associated with irAEs.

**Methods:** In pre- and (12 weeks) post-treatment sera of 133 patients with Stage III or IV melanoma treated with ipilimumab (anti-CTLA-4), we determined antibodies associated with rheumatoid arthritis (RF IgM, anti-CCP2), autoimmune hepatitis (anti-smooth muscle, anti-mitochondria, anti-liver-kidney-microsome), thyroiditis (anti-thyroid peroxidase (TPO), anti-thyroglobulin (TG)), Coeliac's disease (anti-endomysium, anti-gliadin IgG), adrenal insufficiency (anti-adrenal cortex), and autoimmune connective tissue diseases (anti-nuclear antibodies, anti-dsDNA, anti-ENA, and specific ENA tests: anti-SSA, anti-SSB, anti-RNP70, anti-U1RNP, anti-Sm, anti-Jo1, anti-CENP, anti-PMSCL, anti-RNA polymerase 3, anti-Scl70). We used McNemar's exact test for paired data to test whether autoantibody positivity increased post-treatment, and investigated by Fisher's exact tests whether developing autoantibodies was associated with system-specific (Grade 3 or 4) irAEs.

**Results:** In total, post-treatment positivity for any autoantibody was seen in 19.2% (19/99) of patients that were fully autoantibody-negative pre-treatment ( $p < 0.0001$ ). A significant association was observed between development of any

autoantibodies and any irAEs: 14/19 (73.7%) patients that developed autoantibodies had irAEs, versus 37/80 (46.3%) patients that did not develop autoantibodies (OR: 3.3 [95% CI: 1.1 to 9.9]). Regarding specific autoantibodies, predominantly anti-TPO (4.8%, 6/125) and anti-TG antibodies (6.0%, 8/132) developed in patients negative for these autoantibodies at baseline ( $p=0.03$  and  $p=0.008$ , respectively). However, development of these antibodies was not associated with development of thyroid disease. For most other autoantibodies, including RA-associated antibodies, post-treatment positivity increased only marginally and was not associated with occurrence of irAEs in the organ system related to the specificity of the autoantibody.

**Conclusions:** Breaking of humoral tolerance as measured by development of autoantibodies is relatively common under treatment with ipilimumab and is associated with the development of irAEs. The nature of the autoantigens towards which tolerance is broken is not reflected in the phenotype of the irAEs.

#### THU0025 FLORID SYNOVITIS AFTER PD1 ANTAGONIST THERAPY IS CHARACTERISED BY A MARKED ABSENCE OF PD1+ INFILTRATING T CELLS

W. Murray-Brown<sup>1</sup>, T. Wilsdon<sup>2</sup>, H. Weedon<sup>1</sup>, S. Proudman<sup>3</sup>, M.D. Smith<sup>1</sup>, J. Walker<sup>2</sup>, M.D. Wechalekar<sup>1,2</sup>. <sup>1</sup>Rheumatology, Flinders University, Flinders Medical Centre; <sup>2</sup>Royal Adelaide Hospital, Adelaide, Australia

**Background:** Although immunological blockade of checkpoint inhibitors (CIs) for cancer therapy is known to be associated with exacerbated inflammation recapitulating many features of autoimmunity<sup>1</sup>, including synovitis resembling rheumatoid arthritis (RA)<sup>2</sup>, no reports have investigated cellular infiltrates in synovial tissue (ST) of these patients. Here we provide the first report on ST cell infiltration, in particular PD1 expressing T cells, after a PD1 inhibitor-induced (Nivolumab) immune related adverse event (irAE) and severe synovitis.

**Objectives:** To characterise ST cellular infiltration in PD1 inhibitor induced arthritis with particular reference to PD1 positive T cells and compare these changes with active early RA ST.

**Methods:** Arthroscopic ST biopsies, parallel synovial fluid (SF) and PBMCs were collected from a DMARD-naïve nivolumab-treated small cell lung cancer (SCLC) patient with severe peripheral inflammatory polyarthritis (negative RF and ACPA; no axial or extra-articular irAE); 3 DMARD-naïve patients with seropositive early RA (<12 months duration; fulfilling 2010 ACR/EULAR criteria) were used as comparators.

Serial sections from fresh-frozen ST blocks were stained with H and E, CD3, CD45RO, CD55 and CD68 and semi-quantitatively scored as described<sup>3</sup>. ST, SF and PBMC cell suspensions were stained with Zombie UV (BioLegend), CD45RO, PD1, CD3, ICOS, CD8, CD4, CD20 (all BD) prior to flow cytometry. Cells were gated on live, singlet, lymphocytes, CD3+ and CD4+ T cells, and CD20+ and CD8+ T cells were excluded from endpoint PD1+, ICOS+ and CD45RO+ analysis.

**Results:** CD68 +macrophage, CD20+ B cell and CD3+ T cell and CD45RO +memory T cell infiltration in IC-irAE was comparable to RA ST on semi-quantitative scoring, while TNF; staining was markedly elevated in CI-irAE compared to RA (CI-irAE-TNF; 4, RA-TNF; 2). Flow cytometry identified a striking absence of PD1+ ICOS+ CD4+T cells in IC-irAE SCLC in all compartments (CI-irAE: ST; 0.06, SF; 0.01, PBMCs; 0.00) compared to RA (RA: ST mean and SEM; 22.13 ±3.63; SF; 45.95±1.85; and to a lesser extent in PBMCs; 0.41±0.13; n=3 for each), despite comparable CD4 +T cell frequency in each compartment (frequency of CD3 +cells, CI-irAE: ST; 57.8, SF; 64.7, PBMCs; 38.2, RA: ST; 45.9 ±15.3, SF; 49.5±11.2, PBMCs; 62.2±13.8, figure 1).

Figure 1 PD-1 +ICOS + T cells are absent in CI-irAE. Showing the PD-1 +ICOS + frequency of CD4 +T cells gated on live, singlet, lymphocytes, and

CD3+, CD20- and CD8-cells. (RA: ST mean and SEM; 22. 13±3.63: SF; 45.95 ±1.85 n=3 for each, CI-irAE: ST; 0.06, SF; 0.01, PBMCs; 0.00, n=1 for each).

**Conclusions:** While ST infiltration in CI-irAE SCLC recapitulates many features of RA histopathology, PD1 expression principally distinguishes RA from irAE ST T-cell infiltration. Despite abundant CD4 and CD45RO memory T cell infiltration in CI-irAE comparable with RA, we found a conspicuous absence of PD1 positive T-cells. Further research is needed to fully understand the nature of reduced PD1 expression in this setting and the source of elevated TNF, which could shed light on the pathogenesis of CI-irAE and guide CI-irAE management.

#### THU0026 ORGANISED B CELLS AND PLASMA CELLS IN THE AORTA OF GIANT CELL ARTERITIS PATIENTS

J. Graver, M. Sandovici, E. Haacke, A. Boots, E. Brouwer. *University of Groningen, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Giant cell arteritis (GCA) is the most common type of systemic vasculitis. Currently, two forms of GCA are described: a cranial(C)-GCA and a systemic, large-vessel (LV)-GCA. LV-GCA frequently occurs without specific symptoms and late complications are aortic aneurysms or aortic rupture. Based on the analysis of temporal artery biopsies (TAB), GCA is postulated to start at the adventitial site and to be T cell-mediated. In the temporal artery infiltrates, T cells clearly outnumber B cells. Interestingly, we recently documented decreased numbers of B cells and elevated BAFF levels in newly diagnosed GCA patients prompting further research into the pathogenic role of B cells in GCA. Recent work in TAB of C-GCA patients demonstrated the presence of B cells and their organisation into artery tertiary lymphoid organs (ATLOs).

**Objectives:** Our objective was to investigate the presence and organisation of B cells in the aorta of patients with

#### LV-GCA:

**Methods:** Aorta tissue samples of 9 histologically-proven LV-GCA patients who underwent surgery due to an aortic aneurysm were studied by immunohistochemistry. Staining was performed with antibodies detecting CD20 (B cells), CD3 (T cells), CD21 (follicular dendritic cells (FDC)), PNA<sup>ad</sup> (high endothelial venules (HEV)), bcl6 (germinal centre B cells), CD138 (plasma cells) and adipophilin (atherosclerotic plaque/macrophages). None of the patients received immunosuppressive treatment at the time of surgery. For comparison, 22 aorta samples from age- and sex-matched atherosclerosis patients with an aortic aneurysm were included.

**Results:** Aorta tissues of LV-GCA patients showed massive infiltration of B cells. The infiltrating B cells were mainly found in the adventitia and were frequently organised into high density B cell areas. In contrast to the temporal artery, B cells clearly outnumbered T cells in the aorta. ATLOs contained co-localised high density B cells and T cells, a FDC network, HEV and sometimes a germinal centre. ATLOs were observed in 77.8% of LV-GCA patients as opposed to only 36.4% of atherosclerosis patients. The number of ATLOs per patient was significantly higher in the LV-GCA group. Strikingly, ATLOs in aortas of LV-GCA patients contained more plasma cell niches and these niches also contained more plasma cells compared to aorta's of the atherosclerosis group. No association between the number of ATLOs and the number of atherosclerotic plaques was observed.

**Conclusions:** In conclusion, aorta tissues from patients with histologically-proven LV-GCA showed massive B cell infiltrates, predominantly located in the adventitia, that were organised into ATLOs. Moreover, these ATLOs frequently contained plasma cell survival niches. The predominance of organised B cells and plasma cells at the site of inflammation in LV-GCA suggests an involvement of B cell-mediated immune mechanisms in LV-GCA to be further explored.

#### THU0027

#### NON-RESPONSE TO RITUXIMAB THERAPY IN RHEUMATOID ARTHRITIS ASSOCIATES WITH INCOMPLETE DISRUPTION OF THE B-CELL RECEPTOR REPERTOIRE IN THE PERIPHERAL BLOOD

S. Pollastro<sup>1</sup>, P.L. Klarenbeek<sup>1</sup>, M. Doorenspleet<sup>1</sup>, B.D. van Schaik<sup>2</sup>, R. Esveld<sup>1</sup>, R.M. Thurlings<sup>3</sup>, M. Boumans<sup>1</sup>, D.M. Gerlag<sup>1</sup>, P.P. Tak<sup>1</sup>, K. Vos<sup>1</sup>, F. Baas<sup>4</sup>, A. H. van Kampen<sup>2</sup>, N. de Vries<sup>1</sup>. <sup>1</sup>*Clinical Immunology and Rheumatology | ARC*; <sup>2</sup>*Clinical Epidemiology, Biostatistics and Bioinformatics, AMC, Amsterdam*; <sup>3</sup>*Rheumatology, Radboud University, Nijmegen*; <sup>4</sup>*Genome Analysis, AMC, Amsterdam, Netherlands*

**Background:** Rituximab (RTX) induces more than 98% depletion of the CD20 +B cells in blood after a single injection, yet 35% to 50% of RA treated patients show a poor response to the therapy<sup>1</sup>. Despite the identification of many different biomarkers, mostly in the B cell compartment<sup>2</sup>, adequate prediction of response to RTX treatment is still quite challenging.

**Objectives:** To test the hypothesis that non-response to rituximab can be predicted by analysing B-cell receptor (BCR) repertoire characteristics before and shortly after rituximab therapy.

**Methods:** Paired peripheral blood (PB) samples and synovial tissue (ST) samples were available from a total of 21 patients before therapy with RTX, and at 4 and 16/24 weeks after treatment. Next-generation sequencing was used to analyse the BCR repertoire, and assess the frequency of high expanded clones (HECs: >0.5% of the sequenced reads)<sup>3</sup> and load of somatic hypermutation (SHM). Clinical response was evaluated at 6 month following EULAR response criteria.

**Results:** In spite of the complete depletion of B cells (measured using CD19) with conventional flow cytometry, we detect a complete BCR repertoire at week 4 and 16/24 after RTX treatment. The post-treatment PB BCR repertoire is composed of fewer, but more expanded and more mutated clones compared to baseline (figure 1). Non-response associates with a higher number of HECs at week 4 (p<0.01) and with a higher overlap in the top-50 clones between the baseline and week 4 repertoire (p=0.03). In fact, in all non-responders some of the HECs detected at week 4 were already present at baseline. In these persisting clones the SHM load was higher than the median in the total repertoire. In the synovial tissue BCR repertoire the number of clones and HECs does not significantly change after RTX treatment. Like in PB, an increase in SHM load is observed after treatment but at the later time point (week 16). In ST the overlap within the top-50 clones with baseline is largely maintained at week 4, but then decreases at week 16. No baseline predictors of response to RTX treatment were identified.

**Abstract THU0027 – Figure 1.** HECs (A) and SHM load (B) in PB BCR repertoire before (FU0) and after (FU1 and FU2) treatment with RTX.

**Conclusions:** Incomplete depletion of the baseline BCR clonal repertoire in peripheral blood within the first month of treatment predicts poor clinical response at 6 months, revealing the persistence of “rituximab-resistant” BCR clonal signatures associated with treatment failure. In all patients the PB BCR repertoire at 4 weeks after rituximab is dominated by few but highly expanded and highly mutated BCR clones, most likely CD20-negative plasmablasts, while less pronounced and delayed effects are observed in the ST BCR repertoire.

**THU0028 INTERLEUKIN-6 RECEPTOR INHIBITION, AS FIRST-LINE B-DMARD, AFFECTS B CELL SUBPOPULATIONS DISTRIBUTION THROUGH EPIGENETIC MODIFICATIONS IN RHEUMATOID ARTHRITIS PATIENTS**

S. Alivernini, B. Tolusso, A.L. Fedele, C. Di Mario, L. Petricca, G. Di Sante, M. R. Gigante, G. Ferraccioli, E. Gremese. *Uoc of Rheumatology, Fondazione Policlinico Universitario A. Gemelli – Catholic University of the Sacred Heart, Rome, Italy*

**Background:** Despite IL-6R inhibition was found to influence B cell subpopulations distribution in Rheumatoid Arthritis (RA), no data are available on the effect on epigenetic signature of RA B cells by this treatment. It is well known that B cell maturation is under control of the microRNA-155 (miR-155)/PU.1 axis significantly influenced by IL-6 stimulation<sup>1</sup>.

**Objectives:** To investigate the effect of IL-6R inhibition on the epigenetic signature of B cells (miR-155/PU.1 axis) in RA patients.

**Methods:** Twenty-nine RA patients [18 (62.1%) female; 57.2±14.9 years old; disease duration 1.3±0.7 years] starting IL-6R inhibitor treatment as first b-DMARD, have been enrolled. At study entry and after 3–6–12–18 months follow-up, CD19<sup>+</sup> cells were isolated from peripheral blood (PB) by magnetic microbeads (Miltenyi) and B cells subpopulations were assessed through FACS according to the IgD/CD27 classification. MiR-155 and PU.1 endogenous expression was determined in PB-derived CD19<sup>+</sup> cells by RT-PCR at baseline and after 3–6–12–18 months follow-up. IL-6 plasma level was assessed by ELISA at study entry for each patient. ACR/EULAR criteria were used to assess the response rate to IL-6R inhibitor treatment for each RA patient. PB-derived CD19<sup>+</sup> cells of healthy individuals (HC) were used as comparison group.

**Results:** At study entry, RA patients showed higher percentage of IgD<sup>+</sup>/CD27<sup>+</sup> CD19<sup>+</sup> cells (p<0.05) and IgD<sup>+</sup>/CD27<sup>+</sup> CD19<sup>+</sup> cells (p<0.05) than HC. Moreover, IgD<sup>+</sup>/CD27<sup>+</sup> CD19<sup>+</sup> cells percentage directly correlated with Disease Activity Score (p=0.04) and IL-6 plasma levels (p=0.06) in RA patients. IL-6R inhibition lead to DAS and SDAI remission achievement in 73.9% and 52.2% of RA patients after 18 months follow-up, respectively, and significantly reduced IgD<sup>+</sup>/CD27<sup>+</sup> CD19<sup>+</sup> cells percentage after 18 months follow-up (p<0.02). Stratifying RA patients based on the remission achievement during the follow-up, RA patients who achieved DAS remission under IL-6R inhibition showed a significant decrease of IgD<sup>+</sup>/CD27<sup>+</sup> CD19<sup>+</sup> cells percentage compared to patients not achieving this outcome (p<0.05), reaching IgD<sup>+</sup>/CD27<sup>+</sup> CD19<sup>+</sup> cells percentage comparable to HC (p>0.05). Analysing the epigenetic profile in B cells of RA patients, at baseline, PB-derived CD19<sup>+</sup> cells of RA patients showed significantly higher endogenous expression of miR-155 (p=0.04) than HC. Moreover, RT-PCR showed that IL-6R inhibition significantly represses endogenous miR-155 expression in PB-derived RA B cells already after 3 months of treatment (p<0.05) and restores PU.1 expression in PB-derived B cells after 6 months (p<0.05) only in RA patients achieving disease remission.

**Conclusions:** IL-6R inhibitor, used as first b-DMARD treatment, acts restoring B cells homeostasis through epigenetic modulation in RA. In particular, IL-6R inhibition significantly represses endogenous expression of miR-155 in PB-derived CD19<sup>+</sup> cells conversely restoring PU.1 expression mirrored by the decrease of IgD<sup>+</sup>/CD27<sup>+</sup> B cell rate in RA patients achieving disease remission.

**THU0029 CTLA-4-IG TREATMENT INDUCES MODULATION OF B-CELL FUNCTION AND DIFFERENTIATION**

J. Thiel, R. Lorenzetti, I. Janovska, C.R. Smulski, L. Walter, J. Staniek, T. Schleyer, R.E. Voll, N. Venhoff, M. Rizzi. *Internal Medicine; Clinic for Rheumatology/Clinical Immunology, University Hospital Freiburg, Freiburg, Germany*

**Background:** CTLA-4 modulates T-cell activation by inducing inhibitory signalling in T-cells. To date the direct effect of CTLA-4-Ig (abatacept) on B-cells has not been studied in detail. We hypothesise that CTLA-4 modulates B-cell function, B-cell homeostasis and B-cell receptor signalling in a T-cell-dependent and T-cell-independent manner.

**Objectives:** To assess the impact of abatacept on 1. B-cell activation and function *in vitro*; 2. B-cell signalling *in vitro*; 3 maintenance and specificity of memory B-cells specific for citrullinated protein antigens *in vivo*.

**Methods:** The time kinetic of CD80 and CD86 expression was measured by flow cytometry on isolated B-cells after stimulation via CD40, IL-21R, TLR9, and BCR in presence and absence of CTLA-4-Ig. Human B-cells lines (BJAB) deficient either for CD80 or CD86 were created using the CRISPR Cas9 technology and the effect of abatacept on CD80 respectively CD86 expression was assessed in

these K.O. cell lines. CD80 and CD86 internalisation upon abatacept binding was studied by fluorescence microscopy. The effect of abatacept on PI3K-, NF-κB, PLCγ-signalling and Ca-flux in B-cells was assessed. The effect of CTLA-4-Ig *in vivo* on the pool of memory cells specific for anti-citrullinated protein antigens was studied by limiting dilution assays performed before and during CTLA-4-Ig treatment.

**Results:** The expression of CD80 and CD86 on isolated human B-cells peaked at day 2–3 of culture after stimulation with CD40-L and IL-21. CTLA-4-Ig led to a decrease in CD80 and CD86 expression. These results were confirmed in human B-cell lines deficient either for CD80 or CD86. By fluorescence microscopy we were able to demonstrate, that abatacept treatment of cultured B-cells leads to a reduction in CD80 and CD86 expression mediated by a mechanism that involves internalisation of the receptors and bound CTLA-4-Ig. To test if CTLA-4-Ig binding activates signalling pathways, we stimulated B-cells with CTLA-4-Ig or via BCR or CD40. We detected phosphorylation of p65 indicating activation of the canonical NF-κB pathway. The effect of CTLA-4-Ig *in vivo* on the pool of memory cells specific for autoantigens (anti-citrullinated protein antigens) was studied by limiting dilution assays in patients with rheumatoid arthritis. This assay is based on polyclonal stimulation of memory B-cells that leads to blast formation and antibody secretion in the supernatant. We performed limiting dilution experiments before and after start of CTLA-4-Ig treatment and observed a significant reduction of the absolute frequency of citrullinated antigen specific memory B-cells in response to treatment.

**Conclusions:** CTLA-4-Ig-treatment leads to a decrease in B-cells' CD80 and CD86 expression, mediated by a mechanism that involves internalisation of the receptors and bound CTLA-4-Ig. CTLA-4-Ig activates the canonical NF-κB pathway in B-cells. *In vivo* CTLA-4-Ig treatment reduces the frequency of citrullinated antigen specific memory B-cells in patients with rheumatoid arthritis.

Albani<sup>1</sup>. <sup>1</sup>Translational Immunology Institute, Singhealth/Duke-NUS Academic Medical Centre; <sup>2</sup>Duke-NUS Graduate Medical School and Rheumatology and Immunology Service, KK Women's and Children's Hospital, Singapore; <sup>3</sup>Second Pediatrics Division; <sup>4</sup>Second Pediatrics Division, University of Genoa and G Gaslini Institute, Genoa, Italy; <sup>5</sup>Scripps Clinic, La Jolla; <sup>6</sup>Department of Molecular Medicine, The Scripps Research Institute, La Jolla, California, USA

**Background:** One of the key elements of immune pathogenesis of human autoimmune arthritis is the resilience of pathogenic T cells. We have previously described that CD4 +T cells in patients with arthritis have an increased level of autophagy than their healthy equivalents. Here, we sought to explore at epigenetic and transcriptional levels the concept of persisting increased autophagy as the consequence of "autophagic memory", as one of the mechanisms conferring resilience to pathogenic T cells, in particular to a subset of CD4 +T cells (CPL: Circulating Pathogenic-like Lymphocytes), which are significantly more represented in patients with active arthritis and resistant to therapy with biologics

**Objectives:** To understand molecular mechanism of resilience and persistence in pathogenic T cells in rheumatoid arthritis.

**Methods:** Autophagy in T cells were analysed using CytoID autophagy detection kit. Jurkat cells pre-starved and control were harvested at various time points, and RNA was extracted for RNA-sequencing and DNA methylation analysis. Illumina paired end sequencing was performed and data was analysed using open source tools in R statistical programming software. CD4 +memory and naive T cells were sorted using flow cytometer for qPCR analysis. The CD4 +memory and naive cells were sorted using Flow cytometer. RNA extracted and converted to cDNA for qPCR analysis of key genes

**Results:** First, we demonstrated elevated autophagic levels in CD4 +memory T cells when compared to naive CD4 +T cells. Second, we showed that autophagic levels are increased in naive and CD4 +T cells from RA patients compared to healthy controls. Using next generation RNA-sequencing, transcription factor gene regulatory network (TF-GRN) and methylation analyses, we identified MYC as key regulator of autophagic memory in a human T cell line. Transcriptome and network analysis of RNA-seq data from patients' CPLs confirmed MYC as key modulator of autophagy. Importantly, inhibitor of MYC increases autophagy

**Conclusions:** The present study suggests that autophagic memory is retained both at the transcriptional and epigenetic levels as an integral part of mechanisms of efficient activation and survival of memory T cells. This mechanism is particularly relevant for cells subsets, such as CPLs, which are relevant to the immunopathogenesis of autoimmune diseases, such as arthritis. These studies have a direct translational valency as they identify autophagy and its metabolic controllers as a novel therapeutic target.

**THU0031 PHENOTYPE OF FOXP3+ REGULATORY T-CELLS EXPANDED BY THE IL-2 MUTEIN, AMG 592 IN HEALTHY SUBJECTS IN PHASE 1, FIRST-IN-HUMAN STUDY**

K.S. Gorski<sup>1</sup>, J. Stern<sup>1</sup>, Y.-H. Hsu<sup>2</sup>, A. Anderson<sup>3</sup>, M. Boedigheimer<sup>3</sup>, N. Tchao<sup>4</sup>.

<sup>1</sup>Clinical Biomarkers, Amgen, Inc., South San Francisco; <sup>2</sup>Computational Biology, Amgen, Inc., Cambridge; <sup>3</sup>Computational Biology, Amgen, Inc., Thousand Oaks; <sup>4</sup>Early Development, Amgen, Inc., South San Francisco, USA

**Background:** Low-dose interleukin-2 (IL-2) therapy expands regulatory T cells (Treg) and provides clinical benefit for inflammatory diseases. AMG 592 is an investigational IL-2 mutein designed to expand Treg more selectively than recombinant IL-2 (aldesleukin). In a phase 1, double-blind, placebo (PBO)-controlled first-in-human (FIH) study, we investigated the safety and tolerability of AMG 592 and pharmacodynamic (PD) effects on Treg.

**Objectives:** We recently presented FIH study results including summary of safety, PK and PD.<sup>1</sup> Here we extend those findings by exploring phenotypes of AMG 592 expanded Foxp3<sup>+</sup> Treg subsets using flow cytometry. We compared both analysis using predefined gates and unsupervised gating. Potential implications for dose selection and mechanism of action will be discussed.

**Methods:** In the FIH study, healthy subjects in multiple ascending dose cohorts received a single subcutaneous dose of AMG 592 (n=6 per cohort) or placebo (n=2 per cohort). Pharmacodynamic response was evaluated for 28 days after treatment. In addition to enumerating CD4<sup>+</sup> Foxp3<sup>+</sup> Treg we evaluated changes in Treg subsets after AMG 592 treatment. Changes from baseline were analysed with linear mixed effects models with visit, dose level, and baseline result as main effects. To identify cell subsets, independent of predefined gates the same data were also evaluated with unsupervised gating tools using raw data from days 1, 8, 15 and 22.

**Results:** We observed a robust, dose-dependent expansion of Tregs that peaked at day 8 (~4–5 fold increase) and remained elevated above baseline up to day 29 for the highest doses. Expanded Tregs had increased levels of CD25 and Foxp3, and were enriched for CD31<sup>+</sup> recent thymic emigrants (RTE). Both naïve and memory Treg increases peaked at day 8, however, naïve Treg including RTE persisted at elevated levels through day 29 while memory Treg returned to normal levels earlier. The majority of Treg expressed the transcription factor Helios. Furthermore, expanded Tregs expressed higher proportions of PD-1. Unsupervised gating analysis identified several primary clusters of expanded Treg, one including naïve and RTE Treg and another including memory Treg with elevated levels of HLA-DR expression. Evaluation of these clusters over time suggests that both increase initially at day 8 followed by preferential persistence of cells in the naïve over memory Treg cluster by day 22.

**Conclusions:** Foxp3<sup>+</sup> Treg were expanded in a dose dependent fashion in healthy subjects treated with AMG 592. The phenotype of expanded Treg included elevation of CD25 and Foxp3 as well as enrichment for PD-1 positive subsets. Taken together the increase in Treg with an RTE phenotype and persistence of naïve Treg suggests that AMG 592 may increase diversity of the Treg pool as a possible mechanism of action in addition to effects on memory Treg.

**Background:** The IL-23/IL-17A immune pathway is important for the progression of T cell-mediated arthritis. However, it is not known where IL-23R<sup>+</sup> T cells locate during the different stages of arthritis and which IL-23R<sup>+</sup> T cells drive joint inflammation.

**Objectives:** We aimed to identify IL-23R<sup>+</sup> T cells in the secondary lymphoid organs and synovium during the development and progression of antigen-induced arthritis (AIA). Furthermore, we studied which IL-23R<sup>+</sup> T cells drive full-blown AIA.

**Methods:** To induce AIA, IL-23R<sup>+/+</sup> (WT), heterozygous IL-23R<sup>+GFP</sup> (IL-23R-GFP, KI reporter), and IL-23R<sup>GFP/GFP</sup> (IL-23RKO) mice were immunised with methylated bovine serum albumin (mBSA) in Complete Freund's Adjuvant. After 7 days mice were injected in the knee joints with mBSA. Mice were macroscopically scored at different time points and knees were used for histological analysis of inflammation and bone erosion. The spleen, inguinal and popliteal lymph nodes (LN), and the synovium were collected and analysed for the expression of GFP<sup>+</sup>/IL-23R<sup>+</sup> T cells.

To study which T cells drive AIA, CCR6<sup>+</sup> T helper (CD4<sup>+</sup>) cells and  $\gamma\delta$  T cells from CFA/mBSA immunised WT mice were adoptively transferred into IL-23RKO recipient mice prior to AIA induction and disease severity was assessed at the peak of AIA.

**Results:** AIA disease progression was mainly driven by the IL-23R pathway since IL-23RKO mice had significantly lower arthritis scores and less bone damage. During arthritis, total cell numbers of lymphoid tissues were lower in IL-23RKO mice, suggesting involvement of IL-23R pathway in cell proliferation. Heterozygous IL-23R reporter mice had similar disease scores to WT mice, indicating that half of the receptor expression is sufficient to drive disease. Flow cytometric analysis of GFP/IL-23R in T cells of naïve and arthritic IL-23R reporter mice revealed that a fraction of CCR6<sup>+</sup>CD4<sup>+</sup> T cells and  $\gamma\delta$  T cells, but not CD8<sup>+</sup> T cells, expressed IL-23R in the lymphoid tissues. Already one day after AIA induction, the fractions of both IL-23R<sup>+</sup> CCR6<sup>+</sup>CD4<sup>+</sup> T cells and  $\gamma\delta$  T cells were increased in the draining LNs from the joints. However, these IL-23R<sup>+</sup> T cells were decreased during the peak of disease, possibly due to their migration towards the synovium. Indeed, CD4<sup>+</sup> T cells and  $\gamma\delta$  T cells were abundantly present in the WT joints during the peak of disease, but decreased in IL-23RKO joints. Adoptively transferred CCR6<sup>+</sup>CD4<sup>+</sup> T cells, but not  $\gamma\delta$  T cells, were able to restore AIA in IL-23RKO mice, indicating that CCR6<sup>+</sup>CD4<sup>+</sup> T cells are the main drivers of AIA.

**Conclusions:** The IL-23R signalling pathway is essential for full-blown AIA. Both CCR6<sup>+</sup>CD4<sup>+</sup> T cells and  $\gamma\delta$  T cells, but not CD8<sup>+</sup> T cells, express IL-23R during naïve and inflammatory conditions. Total cell number in the lymphoid tissues of arthritic IL-23R deficient mice is lower. Interestingly, adoptive transfer of CCR6<sup>+</sup>CD4<sup>+</sup> T cells but not  $\gamma\delta$  T cells, can rescue arthritis in IL-23R deficient mice.

**THU0033 AGE-ASSOCIATED B CELLS IN EARLY DRUG-NAÏVE RHEUMATOID ARTHRITIS PATIENTS**

A.E. Anderson<sup>1</sup>, G. Vidal-Pedrola<sup>1</sup>, D. Scheel-Toellne<sup>2</sup>, A. Pratt<sup>1</sup>, A. Mellor<sup>3</sup>, J. Isaacs<sup>1</sup>. <sup>1</sup>Musculoskeletal Research Group, Newcastle University, Newcastle upon Tyne; <sup>2</sup>Centre for Translational Inflammation Research, University of Birmingham, Birmingham; <sup>3</sup>Institute of Cellular Medicine, Newcastle University, Newcastle upon Tyne, UK

**Background:** Rheumatoid arthritis (RA) is a chronic autoimmune disorder characterised by joint inflammation and bone destruction. The presence of autoantibodies, years before the clinical onset of disease, and the efficacy of Rituximab, a B-cell depleting therapy, highlight a pathogenic role for B cells. Different groups have recently identified a novel subset of B cells named age-associated B cells (ABCs). Studies in mice autoimmune models and patients suffering from autoimmune diseases described these cells as CD19<sup>high</sup> CD21<sup>-</sup> CD11c<sup>+</sup>. Moreover, a subset of synovial fluid B cells with low levels of CD21, expresses FcRL4 and produces the cytokine RANKL, which stimulates the differentiation and activation of osteoclasts. The ABCs found in peripheral blood could therefore be the precursors of this FcRL4 positive subset found in synovia.

**Objectives:** We aimed to investigate the proportion and phenotype of peripheral blood ABCs in patients suffering from early drug naïve RA.

**Methods:** Newly presenting patients, naïve to immunomodulatory treatment, were recruited from the Newcastle Early Arthritis Clinic, and followed until diagnoses were confirmed. B-cell subsets in peripheral blood were detected and phenotyped using flow cytometry.

**Results:** Our work showed increased proportions of ABCs in seropositive RA compared to other inflammatory arthritis controls, highlighting a potential link between autoantibody production and ABCs. Moreover, patients with high disease activity had higher proportions of ABCs in peripheral blood. Interestingly, the FcRL4<sup>+</sup>, the proliferating Ki67<sup>+</sup> and the T-bet expressing B cells were enriched in the ABC population compared to the other B cell subsets. Furthermore, ABCs expressed high levels of MHC class II and co-stimulatory molecules, as well as the activation marker, CD69.

**Conclusions:** These data supports a possible pathogenic role of ABCs in RA, potentially via autoantibody and T cell stimulatory ability, but further characterisation of this subset and functional studies are needed.

#### THU0034 SALMONELLA TYPHI VI IGG AS A MARKER OF IMMUNOSUPPRESSION IN RHEUMATIC DISEASE

L. Williams<sup>1</sup>, G. Candelas<sup>2</sup>, C. Tange<sup>1</sup>, J. Ochoa-Grullón<sup>3</sup>, P. Macarrón<sup>2</sup>, C. Morado<sup>2</sup>, K.H. Llano<sup>3</sup>, C. Martínez-Prada<sup>2</sup>, A. Rodríguez de la Peña<sup>3</sup>, B. Fernandez<sup>2</sup>, J.-Á. Jover<sup>2</sup>, S. Harding<sup>1</sup>, S. Sanchez-Ramón<sup>3</sup>, A. Parker<sup>1</sup>. <sup>1</sup>The Binding Site Group Ltd, Birmingham, UK; <sup>2</sup>Department of Rheumatology; <sup>3</sup>Department of Clinical Immunology, Hospital Clínico San Carlos, Madrid, Spain

**Background:** Measurement of vaccine response may be used as a diagnostic tool to aid determination of antibody deficiency. The IgG response to pneumococcal polysaccharide vaccination (PPV) is currently used to assess T cell independent responses, however additional polysaccharide vaccines are under evaluation. In patients with rheumatic diseases (RD) treatment regimens can result in immunosuppression and subsequently secondary immune deficiency (SID).

**Objectives:** To measure the IgG response to Typhi Vi vaccination (TV) in RD patients presenting with antibody deficiency. To correlate immunosuppression with TV responses, as well as TV responses to clinical presentations, B cells and total IgG. Further, we interpret the responses in combination with the responses to PPV.

**Methods:** 35 RD patients were referred for immunological evaluation at Hospital Clínico San Carlos, Madrid, Spain. The responses to TV and PPV were measured using commercial human anti-*Salmonella* Typhi Vi IgG and pneumococcal capsular polysaccharide (PCP) IgG ELISAs kits. A TV responder was defined as achieving  $\geq 32$  IU/mL (lower limit of the normal range), a PCP IgG responder ( $>50$  mg/L), B cells were measured by flow cytometry (responder  $\geq 6.6\%$ ) and total IgG by nephelometric assay (responder  $\geq 600$  mg/dL). For all measurements (+) indicates a responder and (-) indicates a non-responder.

**Results:** A greater percentage of TV- patients previously received non-biological treatment (79% vs 43%), specifically steroid treatments (68% vs 28%) and biological treatments (particularly CD20 and TNF alpha targets; 46% vs 14%). At presentation, TV non-responsiveness was associated with a higher frequency of upper respiratory tract infections (75% vs 57%), serious bacterial infections (21% vs 14%) and required slightly higher antibiotic usage (93% vs 71%).

Stratification of the RD patients using the response to the TV and PPV identified four groups of activity: TV+/PCP+, TV-/PCP+, TV+/PCP- and TV-/PCP-. In the presence of a normal response to PPV, the failure to respond to TV (TV-/PCP+) correlated with a higher frequency of previous non-biological treatment (84% vs 43%), biological treatment (47% vs 14%), steroids treatment (68% vs 29%) and were currently undergoing treatment (84% vs 29%,  $p=0.01$ ) compared to those who responded to TV (TV+/PCP+). At presentation TV-/PCP+ patients had a greater incidence of upper respiratory tract infections (74% vs 57%), serious bacterial infections (16% vs 14%) and antibiotic usage (95% vs 71%). Non-responders to both vaccinations (TV-/PCP-) had a higher incidence of serious bacterial infections (25% vs 16%) and pneumonia (50% vs 32%) when compared to the TV+/PCP- group. When correlated with B cell number, 58% of B cells had a concentration of TV antibodies  $<32$  U/mL.

**Conclusions:** The response to TV correlated with underlying disease treatment and immunological presentation. Assessing the response to two polysaccharide vaccinations, TV and PPV, may provide a greater understanding of the T cell independent pathway and provide more clinical information for the clinician.

#### THU0035 A CD8 ALPHA-NEGATIVE SUBSET OF CD4+SLAMF7+ CYTOTOXIC T CELLS IS EXPANDED IN PATIENTS WITH IGG4-RELATED DISEASE AND DECREASES FOLLOWING GLUCOCORTICOID TREATMENT

E. Della Torre<sup>1</sup>, E. Bozzalla Cassione<sup>1</sup>, C. Sciorati<sup>1</sup>, M. Lanzillotta<sup>1</sup>, E. Bozzolo<sup>1</sup>, L. Rovati<sup>1</sup>, H. Mattoo<sup>2</sup>, C. Perugino<sup>3</sup>, J. Stone<sup>3</sup>, L. Dagna<sup>4</sup>, S. Pillai<sup>4</sup>, A. Manfredi<sup>5</sup>. <sup>1</sup>Unit of Immunology, Rheumatology, Allergy and Rare Diseases, IRCCS-Ospedale San Raffaele, Milan, Italy; <sup>2</sup>Ragon Institute of MGH, MIT, Harvard; <sup>3</sup>Unit of Rheumatology, Massachusetts General Hospital, Boston; <sup>4</sup>Ragon Institute of MGH, MIT, Harvard, Cambridge, USA; <sup>5</sup>Autoimmunity and Vascular Inflammation, IRCCS-Ospedale San Raffaele, Milan, Italy

**Background:** IgG4-Related Disease (IgG4-RD) is a fibro-inflammatory disorder characterised by tumefactive lesions, frequent elevation of serum IgG4 levels, and tissue fibrosis.<sup>1</sup> Glucocorticoids represent the treatment of choice to induce IgG4-RD remission but their effect on the cells orchestrating the disease remains unknown.<sup>1</sup> We recently described an unconventional population of clonally expanded CD4<sup>+</sup>SLAMF7<sup>+</sup> cytotoxic T effector memory (T<sub>EM</sub>) cells (CD4<sup>+</sup>CTLs) and causally linked it to IgG4-RD in view of their capacity to secrete pro-fibrotic molecules and to infiltrate affected organs.<sup>2-4</sup>

**Objectives:** In order to better clarify the mechanisms of action of glucocorticoids in IgG4-RD and the pathogenic relevance of CD4<sup>+</sup> CTLs, we herein aim to describe the effects of corticosteroid treatment on CD4<sup>+</sup> CTLs.

**Methods:** CD8 $\alpha$ , granzyme A, perforin, and SLAMF7 expression within the effector/memory compartment of CD45RO (T<sub>EM</sub>) and CD45RA (T<sub>EMRA</sub>) CD4<sup>+</sup> T cells was quantified by flow cytometry in 18 active IgG4-RD patients at baseline and after 6 months of glucocorticoid treatment. Eighteen healthy subjects were studied as controls. Next-generation sequencing of the T-cell receptor  $\alpha$  and  $\beta$  chain gene was performed on circulating CD4<sup>+</sup>CTLs in patients with IgG4-RD before and after treatment, and in affected tissues.

**Results:** Circulating CD4<sup>+</sup> T<sub>EM</sub> and T<sub>EMRA</sub> cells were not expanded in IgG4-RD patients compared to healthy controls. CD4<sup>+</sup>SLAMF7<sup>+</sup> T<sub>EM</sub> cells (but not T<sub>EMRA</sub> cells) were significantly increased among IgG4-RD patients. Within CD4<sup>+</sup>SLAMF7<sup>+</sup> T<sub>EM</sub> cells, CD8 $\alpha$ <sup>+</sup> but not CD8 $\alpha$ <sup>low</sup> cells were elevated in IgG4-RD patients. The same dominant clones of CD8 $\alpha$ <sup>+</sup>CD4<sup>+</sup>SLAMF7<sup>+</sup> T<sub>EM</sub> cells found in the peripheral blood were also identified in affected tissue. Both CD8 $\alpha$ <sup>+</sup> and CD8 $\alpha$ <sup>low</sup> CD4<sup>+</sup>SLAMF7<sup>+</sup> T<sub>EM</sub> cells expressed cytolytic molecules. Clonally expanded CD8 $\alpha$ <sup>+</sup> but not CD8 $\alpha$ <sup>low</sup> CD4<sup>+</sup>SLAMF7<sup>+</sup> T<sub>EM</sub> cells decreased following glucocorticoid-induced disease remission.

**Conclusions:** A subset of CD8 $\alpha$ <sup>+</sup>CD4<sup>+</sup>SLAMF7<sup>+</sup> cytotoxic T<sub>EM</sub> cells is oligoclonally expanded in patients with active IgG4-RD. This population contracts following glucocorticoid-induced remission. Further characterisation of this cell population may provide prognostic information and targets for therapeutic intervention.

#### THU0036 ABATACEPT INCREASES REGULATORY B CELL EFFECT ON T CELL PROLIFERATION THROUGH THE PRODUCTION OF IL-10 AND TGF-BETA IN VITRO AND IN RHEUMATOID ARTHRITIS PATIENTS

G. Carvajal Alegria<sup>1</sup>, P. Gazeau<sup>1</sup>, A. Saraux<sup>1</sup>, V. Devauchelle-Pensec<sup>1</sup>, D. Cornec<sup>1</sup>, J.-O. Pers<sup>2</sup>, P. Pochard<sup>2</sup>. <sup>1</sup>Rheumatology, CHRU Cavale Blanche; <sup>2</sup>UMR 1227 LBAI, CHRU Morvan, Brest, France

**Background:** Abatacept is a CD152 agonist known to inhibit T cell proliferation but recent data suggest that it could act directly on B cells.<sup>1-2</sup>

**Objectives:** To demonstrate the effect of Abatacept (versus IgG control) on regulatory functions of B cells on T cell proliferation in an established *in vitro* co-culture model. To evaluate its role, *in vivo*, by measuring the regulatory functions of B cells from rheumatoid arthritis patients before and after the Abatacept treatment.

**Methods:** Peripheral and tonsillar T cell and B cell from healthy controls were purified. The biotinylation of Abatacept was used to study its binding on T and B cells by flow cytometry and confocal microscopy. A well-established co-culture model between CpG-stimulated B cells and anti-CD3/anti-CD28 stimulated T cells was set up in which Abatacept or an IgG control was added to evaluate any change in B cell regulatory functions. Activation markers (e.g. CD25, CD69, CD40, CD152) and regulation markers (e.g. FoxP3, TGF- $\beta$ ) were assessed by flow cytometry. Similar analysis was also performed on rheumatoid arthritis patients before and three months after Abatacept therapy. All patients gave their informed consent.

**Results:** Abatacept increases the inhibition of T cell proliferation by B cells compared to IgG control in the co-culture model ( $p=0.03$ ). Interestingly, alone, Abatacept does not modify T cell proliferation. This can be explained by the increase in IL-10 and TGF- $\beta$  producing B cells and the CD152 expression. Abatacept is able to bind B cells at day 0 of co-culture and B and T cells at day 4.5 of co-culture. Abatacept has a direct effect on B cells by increasing the CD25 ( $p=0.03$ ) and CD152 expression ( $p=0.02$ ) reflecting a higher activation level. Nevertheless, Abatacept had no direct effect on B cell proliferation. In RA patients, the treatment with Abatacept resulted in an increased regulation of T cell proliferation and this effect is related to a higher percentage of IL-10 secreting B cells 3 months after the therapy ( $p=0.03$ ).

**Conclusions:** In our *in vitro* and *in vivo* models, Abatacept has a direct effect on B cells leading to an increase capability of regulation of T cell proliferation which directly linked to higher production of IL-10 and TGF $\beta$ .

#### THU0037 LEPTIN ENHANCED THE EXPRESSION OF AUTOANTIBODIES AND INFLAMMATORY CYTOKINES OF B CELLS VIA ACTIVATING ERK1/2 AND JAK/STAT3,5 PATHWAYS IN SYSTEMIC LUPUS ERYTHEMATOSUS

H. Chen, F. Yuan, Y. Zou. *Wuxi People's Hospital Affiliated to Nanjing Medical University, Wuxi, China*

**Background:** B lymphocytes derived from patients with systemic lupus erythematosus (SLE) displayed abnormal activation and overexpression of auto-antibodies. It was reported that leptin was elevated in the sera of SLE patients and lupus mice, and blockade of leptin also remarkably improved the disease activity and renal pathology of lupus mice. Therefore, our study is to explore whether leptin in SLE regulates the activation and function of B cells.

**Objectives:** Our study is to explore whether leptin in SLE regulates the activation and function of B cells.

**Methods:** The sera and peripheral blood monocyte cells (PBMC) were isolated from healthy controls and SLE patients with Ficoll, then B cells were acquired through magnetic activated cell sorting (MACS). The sera were incubated in 56° for 30 min (complement inactivation). B cells were cultured in normal or SLE serum, with or without recombinant leptin. Anti-leptin antibody or inhibitions of the signalling pathways were added in SLE sera in order to observe the effects of B cells induced by leptin. Cell proliferation was detected by flow cytometry and carboxyfluorescein diacetate succinimidyl ester (CFSE), and the levels of auto-antibodies and inflammatory cytokines were examined by ELISA. The total and phosphorylated protein was tested with Western Blot analysis.

**Results:** Leptin R on B cells showed increased levels in SLE patients [(3.33  $\pm$  1.28)% v.s. (2.76  $\pm$  1.06)%,  $p<0.01$ ]. Leptin could upregulate the activated markers (CD80, CD86), also increase the proliferation (CFSE) of B cells. Recombinant leptin promotes IgG/IgM production [ IgG: leptin 0 (45.50  $\pm$  3.87)ng/ml vs. leptin 100 (61.24  $\pm$  3.66)ng/ml,  $p<0.01$ ; IgM: leptin 0 (60.75  $\pm$  19.60)ng/ml vs. leptin 100 (118.90  $\pm$  26.16)ng/ml,  $p<0.01$ ], as well as inflammatory cytokines (IL-6, IL-10, TNF- $\alpha$ ) secreted by B cells derived from SLE patients. [IL-10: leptin 0 (20.45  $\pm$  5.17)pg/ml vs. leptin 100 (23.81  $\pm$  5.45)pg/ml,  $p<0.01$ ; IL-6: leptin 0 (156.10  $\pm$  32.64)pg/ml vs. leptin 100 (244.20  $\pm$  54.23)pg/ml,  $p<0.05$ ; TNF- $\alpha$ : leptin 0 (13.33  $\pm$  2.38)pg/ml vs. leptin 100 (18.85  $\pm$  2.69)pg/ml,  $p<0.001$ .] Compared with Nor serum, SLE serum enhanced the levels of IgG/IgM and inflammatory cytokines, such as IL-6, IL-10, TNF- $\alpha$ . Moreover, blockade of leptin could partially reverse these effects. SLE serum or recombinant leptin could activate p38 MAPK, ERK1/2, and Jak/stat3,5 pathways, but not PI3K/Akt or Jak/stat1 pathways. In addition, blocking ERK1/2 and Jak/stat3,5 pathways could partially reverse the effects of enhanced secretion of autoantibodies and inflammatory cytokines induced by recombinant leptin or SLE serum.

**Conclusions:** Leptin promote the activation and proliferation of B cells in SLE. Recombinant leptin or serum leptin from SLE patients both enhanced the

expression of autoantibodies and inflammatory cytokines (IL-6, IL-10, TNF- $\alpha$ ) of B lymphocytes. Additionally, ERK1/2, and Jak/stat3,5 signalling pathways might play a vital role in this process.

#### THU0038 INCREASE OF CIRCULATING MEMORY B CELLS AFTER GLUCOCORTICOID-INDUCED REMISSION IDENTIFIES PATIENTS AT RISK OF IGG4-RELATED DISEASE RELAPSE

M. Lanzillotta<sup>1</sup>, E. Della Torre<sup>1</sup>, R. Milani<sup>2</sup>, E. Bozzolo<sup>1</sup>, E. Bozzalla Cassione<sup>1</sup>, L. Rovati<sup>2</sup>, M. Falconi<sup>3</sup>, F. Ciceri<sup>2</sup>, L. Dagna<sup>4</sup>. <sup>1</sup>Internal Medicine, Allergy And Clinical Immunology; <sup>2</sup>Unit of Hematology and Bone Marrow Transplantation; <sup>3</sup>Unit of Pancreatic Surgery – Pancreas Translational and Clinical Research Center; <sup>4</sup>Unit of Allergy, Clinical Immunology and Rare Disease – UniRAR, San Raffaele Scientific Institute, Milan, Italy

**Background:** IgG4-related disease (IgG4-RD) is relapsing-remitting systemic fibro-inflammatory condition characterised by elevated serum IgG4 concentration and by tumor-like lesions<sup>1</sup>. Glucocorticoids represent the treatment of choice to induce IgG4-RD remission but relapses occur in almost 50% of patients at two years.<sup>2</sup> Several evidences suggest that B cells are central to the pathogenesis of IgG4-RD, the most significant being (i) the clinical improvement induced by B-cell depletion with rituximab, and (ii) the oligoclonal expansion of circulating plasmablasts in the vast majority of patients.<sup>3</sup>

**Objectives:** To describe alterations of B-lymphocyte subpopulations that might predict IgG4-RD relapse in patients treated with a first course of glucocorticoids according to international guidelines

**Methods:** Thirty patients with IgG4-RD were treated with glucocorticoids according to international consensus guidelines. Flow cytometry analysis of circulating CD19<sup>+</sup> and CD20<sup>+</sup> cells, naïve B cells, memory B cells, plasmablasts, and plasma cells was performed at baseline and every 6 months after the initiation of corticosteroid treatment.

**Results:** Patients with active untreated IgG4-RD showed reduced CD19<sup>+</sup> B cells, CD20<sup>+</sup> B cells, and naïve B cells compared to healthy controls ( $p<0.05$ ), but expanded plasmablasts and plasma cells ( $p<0.01$ ). Glucocorticoids treatment led to disease response in all patients. Clinical improvement was accompanied by a significant reduction of naïve B cells, circulating plasmablasts, and plasma cells, and by a significant increase of memory B cells compared to baseline ( $p<0.01$ ). Increase of circulating memory B cells was observed only in patients experiencing disease relapse and not in patients who maintained remission at two years of follow-up (HR:14.40, 95% CI 2.96–70.1,  $p<0.01$ , figure 1 A-B). Relapse rates at 12 and 24 months were 25% and 100% with memory B cell increase at 6 months (figure 1C), respectively. No B-cell subpopulations were found to predict IgG4-RD relapse at disease onset.

**Conclusions:** The efficacy of glucocorticoids in IgG4-RD is associated with selective effects on different B-cell subpopulations. IgG4-RD relapse may be predicted by the increase of memory B-cells after glucocorticoid-induced remission

**THU0039 INSULIN-LIKE GROWTH FACTOR 1 RECEPTOR REGULATES THE PHENOTYPE AND FUNCTION OF CD21+ B CELLS**

M. Erlandsson, C. Wasen, G. Gravina, M.I. Bokarewa. *Rheumatology and Inflammation Research, GOTHENBURG UNIVERSITY, Gothenburg, Sweden*

**Background:** Ligand to the inducible T cell costimulator (ICOSL) on B cells is essential for the ICOS-dependent follicular recruitment of activated T cells. In patients with rheumatoid arthritis (RA) the IGF1-IGF1R axis is altered. Inhibition of IGF1R alleviated arthritis by reducing IL-6-dependent formation of Th17 cells.<sup>1</sup> Here we study the role of IGF1R on CD21+ cells in experimental arthritis.

**Methods:** Female Balb/c mice were immunised with methylated BSA or with CII. Consequences of the IGF-1R inhibition for arthritis were studied in mBSA and CII-immunised mice treated with NT157 compound promoting degradation of insulin receptor substrates or using shRNA producing construct (shIGF1R). At termination three sub-populations of CD21+ cells were analysed: follicular dendritic cells (FDc, CD21+CD19-CXCR5-); marginal zone B cells (MZBc, CD21+CD19+CXCR5-); follicular B cells (FBc, CD21+CD19+CXCR5+). Supernatants of LPS-stimulated splenocytes were analysed for production of cytokines, chemokines using Cytokine Array. Serum levels of antigen specific and autoantibodies were measured in an ELISA.

**Results:** In spleen of mBSA-immunised mice, ICOSL expression on CD21+ cells correlated to IGF1R ( $r=0.70$ ,  $p=0.007$ ). Inhibition of IGF1R induced a 20% reduction in ICOSL expression in all CD21+ subsets ( $p=0.007$ ) followed by an increase in the number of MZBc ( $p=0.003$ ), while FDc and FBc were unchanged. Inhibition of IGF1R had no effect on the expression of ICOSL on CD4 T cells or the subset of CXCR5+follicular T cells. Reduction of the ICOSL+CD21+B cells was associated with lower production of IL-13. Inhibition of IGF1R signalling by NT157 and by shRNA, reduced production of CXCL13 and CXCL12, the chemokines essential for B cell migration towards follicles. In contrast, the production of chemokines CCL5 and CXCL12 preventing intra-follicular migration was increased, which explains the increase of MZBc. Additionally, the insufficient ICOSL signalling significantly reduced the production of IL-7 and IL-4, regulating class switching of B cells in germinal centres and differentiation of B cells into plasma cells. The described disbalance in the cytokines aiding B cell development led to the reduced production anti-inflammatory IL-10 and of mBSA-specific IgM ( $p=0.005$ ) and increased production of autoreactive RF-IgM levels ( $p=0.001$ ).

**Conclusions:** The study shows that IGF1R controls B cell development through the expression of ICOSL on CD21+ cells. Insufficient ICOSL signalling disturbs a balance between antigen-specific response and autoantibody production in experimental arthritis.

**THU0040 ENHANCEMENT OF EARLY HUMAN B CELL DEVELOPMENT BY JAK INHIBITION**

J. Thiel<sup>1</sup>, N. Venhoff<sup>1</sup>, I. Janowska<sup>1</sup>, A. Troilo<sup>1</sup>, N. Frede<sup>1</sup>, M. Erlacher<sup>2</sup>, M. Kunze<sup>3</sup>, R. Lorenzetti<sup>1</sup>, J. Staniek<sup>1</sup>, B. Bannert<sup>1</sup>, D. Kyburz<sup>4</sup>, C. Glaser<sup>1</sup>, M.-T. Schleyer<sup>1</sup>, R. E. Voll<sup>1</sup>, M. Rizzi<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Clinic for Pediatrics and Juvenile Medicine; <sup>3</sup>Gynecology Department, University Medical Center Freiburg, Freiburg, Germany; <sup>4</sup>Department of Rheumatology, University of Basel, Basel, Switzerland

**Background:** Rheumatoid arthritis is an immune-mediated disease, in which immune cell activation leads to destructive inflammation of the joints. In this context the treatment with JAK inhibitor tofacitinib has been proven to be effective. In mice treatment with tofacitinib resulted in reduced specific antibody responses, failure to generate germinal centres, and partial block of B cell development in the bone marrow. Conversely *in vivo* treatment of psoriasis arthritis patients as well as of rheumatoid arthritis patients with tofacitinib results in an increase of relative

and absolute numbers of B cells in the first 4–8 weeks from beginning of treatment. It is known that mouse early B cell development is strongly dependent on IL-7 signalling, while this is not essential in humans. Nevertheless other cytokines are important in determining the fate and development of B lymphocytes. Hence, the outcome of JAK inhibition in early B cell development remains to be studied

**Objectives:** To assess the impact of JAK inhibition on early B cell development *in vitro*

**Methods:** We used a *in vitro* model in which CD34+ cells isolated from cord blood are cultivated subsequently in SCF, Flt3-L and IL-6, then SCF, Flt3-L and IL-7 and finally in cytokine-free medium.<sup>1</sup> The culture reproduces all stages of development from common lymphocytes progenitors to immature B cells.

**Results:** With the addition of tofacitinib to the *in vitro* culture we observed an increase in the absolute numbers of lymphoid precursors developing *in vitro* especially at week 5 and 6 of culture. Specifically, JAK inhibition led to an increase of pre-B and immature B cells by week 5 and 6. These data are in contrast with the early B cell development block observed in the tofacitinib treated mouse, but are in line with the rapid increase of B cells in peripheral blood after 4–8 weeks of tofacitinib treatment in patients. Analysis of induction of fate determining genes (EBF, E2A, PAX-5) showed an earlier and stronger induction of fate determining genes.

**Conclusions:** Our data indicate that JAK inhibition may promote early B cell development by enhancing the commitment of lymphoid precursors to the B cell compartment, contributing to a temporary increase in relative and absolute numbers of B cell in peripheral blood of treated patients. These data contribute to our understanding of human B cell development, prompt us to further analyse the quality of B cell output from the bone marrow in JAK inhibited patients, and may provide cues to understand the outcome of JAK inhibition treatment in rheumatic diseases.

**THU0041 THE EFFECTS OF ABATACEPT ON HUMAN B CELL ACTIVITIES**

M.-H. Chen<sup>1</sup>, C.-T. Ssu<sup>2</sup>, C.-Y. Tsai<sup>1</sup>, C.-M. Leu<sup>3</sup>. <sup>1</sup>Division of Allergy, Immunology and Rheumatology, Department of Medicine, Taipei Veterans General Hospital; <sup>2</sup>Institute of Microbiology and Immunology; <sup>3</sup>Institute of Microbiology and Immunology, and Infection and Immunity Center, National Yang-Ming University, Taipei City, Taiwan, Province of China

**Background:** Abatacept is a cytotoxic T lymphocyte antigen-4 (CTLA-4) fusion protein approved for rheumatoid arthritis (RA) treatment worldwide. Abatacept mimics the natural CTLA-4 and competes with CD28 for binding the CD80/CD86 on antigen presenting cells to prevent T cell activation. However, the impacts of CTLA-4-Ig through its interaction with CD80/CD86 on B cells are not fully understood.

**Objectives:** The aim of this study was to test whether CTLA-4 regulates human B cell functions

**Methods:** We assayed the effect of abatacept on human B cells in both *in vitro* and *in vivo* conditions. Blood was taken from 20 patients with RA before and after abatacept treatment and the expression of surface proteins on B cells was detected using immunofluorescent staining. Serum level of rheumatoid factor (RF) and anti-cyclic citrullinated protein antibody (ACPA) was measured by ELISA. Purified human B cells from healthy donors were stimulated in the presence of abatacept and cell proliferation, cytokine production, plasma cell differentiation, and antibody production were measured.

**Results:** In RA patients, abatacept treatment transiently reduced the level of CD80/CD86 on peripheral blood memory B cells and increased the naïve to memory B cell ratio. Also, abatacept reduced IgM-RF level in 10 out of 12 patients, which correlates with patients' disease activity, but it had no significant effects on serum levels of anti-citrullinated protein antibody or anti-tetanus toxoid antibodies during the 6 months of abatacept treatment. In the *in vitro* assays, we observed that the CD80 and CD86 induced by T-independent (TI) but not T-dependent (TD) stimulation was significantly downregulated by abatacept at both the mRNA level and protein level. Some TI-induced cytokine production by B cells from healthy donors was also reduced by abatacept. Neither TI nor TD-stimulated B cell proliferation was reduced by abatacept in <sup>3</sup>H-thymidine incorporation assay. Abatacept had no significant effect on CD38<sup>high</sup> CD27<sup>high</sup> plasma cell differentiation. Finally, abatacept inhibited Daudi-B cell induced allogeneic T cell proliferation, indicating a significant blockade of T-B interaction by abatacept.

**Conclusions:** In RA patients, abatacept may decrease RF level by interfering the interaction of CD28 with CD80/CD86, therefore preventing B cells from T cells'

**THU0044 IMPAIRED AUTOPHAGY INDUCES DEFECTIVE FUNCTION OF REGULATORY B CELLS IN ANKYLOSING SPONDYLITIS**

C. Shuizhong, X. zhongyu, Z. guan, S. huiyong, W. yanfeng. *Department of Orthopedics, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, China*

**Background:** Ankylosing spondylitis (AS) is an autoimmune disease characterised by pathological osteogenesis and chronic inflammation. Large number studies shown that Regulatory B cells (Bregs) has immunosuppressive function, which could be involved in many rheumatic disease, such as systemic lupus erythematosus (SLE), rheumatoid arthritis (RA). But the Bregs in AS are poorly understood.

**Objectives:** To investigate the ratio and function of Bregs in AS, and illuminate the under lying mechanism, which might help to further understand the pathology of AS.

**Methods:** (1) Peripheral blood mononuclear cells (PBMCs) were collected from 9 AS patients and 9 healthy controls, then the Bregs were detected by using flow cytometry with the following antibodies: CD19-PE, CD24-FITC and CD38-APC.<sup>2</sup> B cells were purified with a CD19 magnetic bead, the Bregs were sorted by using the flow cytometry. Bregs were added to the upper chamber with 1.5 ml medium, while CD4 +T cells were added to the lower chamber with 2.6 ml medium at a ratio of 1:1 Bregs(1 × 10<sup>6</sup> cells): CD4 +T cells(1 × 10<sup>6</sup> cells). CD4 +T cells were incubated with 5 μM CFDA-SE. The CD4 +T cell proliferation was analyse in the fifth day.<sup>3</sup>The cytokines of Bregs were detected with a proteome profiler kit, and confirmed by using Elias and Western Blot.<sup>4</sup> We detected the Bregs autophagy between AS and HD. And we regulate the autophagy with rapamycin and 3-methyladenine (3-MA), then detected the IL-10 secretion of Bregs and the CD4 +T cell proliferation among groups.

**Results:** (1) The ratio of Bregs in AS was higher that in healthy group.<sup>2</sup> Bregs from AS shown a impaired function in suppressed the CD4 +T cell proliferation compared with HD.<sup>3</sup> Bregs of AS expressed and secreted less IL-10 than healthy control, and might explain the impaired function of Bregs of AS.<sup>4</sup> Exogenous IL-10 recovered the immunosuppressive capacity of AS Bregs, whereas exogenous anti-IL-10 antibody reduced the immunosuppressive capacity of HD Bregs.<sup>5</sup> Autophagy impaired in AS Bregs compared with HD Bregs. Induce autophagy in AS Bregs could increase the IL-10 secretion and strengthened its immunosuppressive capacity, while 3-MA shown the opposite results.

**Conclusions:** Even increasing ratio of Bregs in AS, but they had a impaired function in suppressed CD4 +T cell proliferation compared with the HD. We further found that impaired autophagy could induces less IL-10 secretion, which further affected the immunosuppressive capacity of Bregs of AS.

ULisboa), Faculdade de Farmácia, Universidade de Lisboa, Lisboa, Portugal

**Background:** T follicular helper (Tfh) cells are essential for the generation of high affinity neutralising antibodies elicited following vaccination and are involved in the pathogenesis of rheumatoid arthritis (RA). Interleukin (IL)-6 has been shown to be critical for Tfh differentiation in mice, while its importance in humans has been less clear, given the lack of adequate *in vivo* assessment.

**Objectives:** To investigate the importance of IL-6 for the *in vivo* differentiation of human Tfh cells, taking advantage of influenza vaccination in patients under anti-IL-6R therapy.

**Methods:** Blood was collected before, 7 and 28 days after vaccination from established RA patients treated with tocilizumab (TCZ, IL-6R blocker), methotrexate (MTX) ± other DMARDs and age- and sex-matched healthy donors (HD). We analysed the frequency of Tfh (CD3<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>-</sup>CXCR5<sup>+</sup>CD45RO<sup>+</sup>), T follicular regulatory (Tfr, CD3<sup>+</sup>CD4<sup>+</sup>CD25<sup>+</sup>Foxp3<sup>+</sup>CXCR5<sup>+</sup>) and B cell populations at each time point. We used non-parametric tests, deemed significant at p<0.05.

**Results:** We included 137 participants (42 TCZ, 42 MTX, 53 HD) with similar age and gender distribution. Patients from the TCZ group had more active and severe disease. At baseline, patients treated with TCZ had higher frequency of Tfh and Tfr-Th2-like cells (CXCR3<sup>+</sup>CCR6<sup>-</sup>) and lower frequency of Tfr-Th1-like (CXCR3<sup>+</sup>CCR6<sup>+</sup>) and B cells. Following influenza vaccination, the overall blood Tfh and Tfr populations remained unchanged in all groups. However, as previously reported, there were marked changes in specific subsets at day 7 of HD following vaccination. We found a marked expansion of activated CXCR5<sup>+</sup>ICOS<sup>+</sup> Tfh cells at day 7, in HD and MTX-treated patients, but this was impaired in the TCZ group (figure 1). The increase in activated CXCR5<sup>+</sup>ICOS<sup>+</sup> Tfh cells was mainly due to a Tfh-Th1-like subpopulation, greatly increased in HD and MTX-treated patients (figure 1). Of note, CXCR5<sup>+</sup>ICOS<sup>+</sup> Tfh-Th17-like cells also accumulated in HD but not in RA patients. The proliferative capacity of CXCR5<sup>+</sup>ICOS<sup>+</sup> Tfh cells seemed to be partially impaired in patients under IL-6R blockade, that displayed marked reduction of Ki67<sup>+</sup>CD38<sup>+</sup> proliferative cells within that compartment (figure 1). Anti-IL-6R treatment also impaired expansion of CD19<sup>+</sup>IgD<sup>-</sup>CD27<sup>+</sup>CD38<sup>hi</sup> plasmablasts following vaccination, when compared with both MTX and HD groups (figure 1). Changes in CXCR5<sup>+</sup>ICOS<sup>+</sup> Tfh and plasmablasts were significantly correlated in all groups.

Abstract THU0045 – Figure 1. Frequency of cell populations within the CD4+ in the blood. All tests are paired and non-parametric. Healthy N=53, MTX N=42, TCZ N=42.

**Conclusions:** Anti-IL-6R treatment limits proliferative ability of activated CXCR5<sup>+</sup>ICOS<sup>+</sup> Tfh cells, blocking their emergence as well as plasmablast accumulation following influenza vaccination. Our data suggest that IL-6 is crucial for optimal *in vivo* generation of activated Tfh cells in humans.

**THU0046 SMALL MOLECULE INHIBITOR OF THE WNT PATHWAY (SM04755) AS A POTENTIAL TOPICAL TREATMENT FOR PSORIASIS**

V. Deshmukh, M. Pedraza, L. Lamangan, Y. Yazici. Samumed, LLC, San Diego, USA

**Background:** Psoriasis (PSO) is an autoimmune disease, causing patches of thick, inflamed, scaly skin due to excessive proliferation of skin cells<sup>1</sup>. Wnt signaling plays an important role in PSO, regulating inflammation and keratinocyte proliferation. SM04755, a novel, topical small-molecule Wnt pathway inhibitor was previously shown to inhibit inflammation and keratinocyte proliferation *in vitro* and in an IMQ-induced mouse PSO model<sup>2</sup>.

**Objectives:** In this study, the effects of SM04755 on inflammation and skin health were evaluated in two models that closely resemble human PSO pathophysiology: reconstitution of ICR *scid* mice with minor histocompatibility mismatched naïve CD4<sup>+</sup> T lymphocytes<sup>3</sup> and an IL-23 intra-dermal injection model<sup>4</sup>.

**Methods:** For (A) immune reconstitution model, peripheral blood mononuclear cells were isolated from F<sub>2</sub> (BALB/c x 129/SvJ) mice and analysed by flow cytometry to identify H-2D<sup>d</sup> haplotype donor mice. CD4<sup>+</sup>/CD45RB<sup>Hi</sup> cells from donor mice spleens were purified and injected intravenously into CB17/ICR-Tac Prkdc/*scid* (ICR *scid*) mice (5 × 10<sup>5</sup> cells/mouse). Skin appearance and ear thickness were evaluated weekly. At the first visible PSO-like signs, mice were randomised and treated with SM04755 (400 µg/cm<sup>2</sup>) or vehicle. After 14 weeks, body and spleen weights were measured, and inflammation was evaluated by measuring cytokines (IL-1β, TNF-α, IL-6) in tissues from skin, ears, spleen and plasma using ELISA. Epidermal thickness and skin immune cell infiltration were histologically evaluated. For (B) the IL-23 model, rIL-23 was injected intra-dermally into mouse ears, every other day for 35 days. Mice were randomised on Day 16 and treated with SM04755 (400 µg/cm<sup>2</sup>) or vehicle or Clobetasol daily for 20 days. Ear thickness was measured every 3 days. Skin immune cell infiltration was histologically evaluated.

**Results:** (A) Immune reconstitution of ICR *scid* mice resulted in PSO-like signs, with skin lesions and increased thickness of the skin and ears. Treatment with topical SM04755 (400 µg/cm<sup>2</sup>) significantly (p<0.01) decreased skin and ear thicknesses and improved skin appearance compared to vehicle. Body weights were significantly (p<0.05) higher in treated compared to vehicle mice. SM04755 significantly reduced histologically measured epidermal thickness (p<0.05) and immune cell infiltration in the skin compared to vehicle. Further, inflammatory cytokine levels in the skin, ears, spleen and plasma and spleen weight were significantly (p<0.05) reduced in SM04755 treated animals compared with vehicle. (B) Intra-dermal IL-23 injection into mouse ears resulted in inflammation and ear thickening by day 16 compared to sham. Treatment with topical SM04755 (400 µg/cm<sup>2</sup>) significantly (p<0.05) decreased ear thickness, immune cell infiltration, and improved appearance compared to vehicle.

**Conclusions:** In two mouse models of (A) minor histocompatibility mismatched T lymphocyte reconstitution-induced PSO and (B) IL-23 injection-induced PSO, topically applied SM04755 inhibited key pathophysiological features of PSO at macro- and microscopic levels, compared to vehicle. SM04755 has potential as a topical therapy for PSO. Clinical trials are ongoing.

**THU0047 1,25(OH)<sub>2</sub>D<sub>3</sub> AND DEXAMETHASONE ADDITIVELY SUPPRESS SYNOVIAL FIBROBLAST ACTIVATION BY CCR6+ TH MEMORY CELLS AND ENHANCE THE EFFECT OF TNF-ALPHA BLOCKADE**

W. Dankers<sup>1,2</sup>, W. Dankers<sup>1,2</sup>, N. Davelaar<sup>1,2</sup>, P.S. Asmawidjaja<sup>1,2</sup>, A.M. Mus<sup>1,2</sup>, J. M. Hazes<sup>1</sup>, E.M. Colin<sup>3</sup>, E. Lubberts<sup>1,2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Immunology, Erasmus MC, Rotterdam; <sup>3</sup>Rheumatology, Hospital Group Twente, Almelo, Netherlands

**Background:** Despite improvement in treatment of rheumatoid arthritis (RA) over the past decades, insufficient treatment response and treatment resistance in many patients demonstrate the need to develop new therapeutic strategies. Chronic synovial inflammation could be suppressed by targeting activation of RA synovial fibroblasts (RASf) by for example IL-17A-producing CCR6 +T helper memory (memTh) cells. Previously, we have shown that dexamethasone (DEX) combined with the active vitamin D metabolite 1,25(OH)<sub>2</sub>D<sub>3</sub> reduces pathogenicity of memTh cells.

**Objectives:** To study the additive effect of 1,25(OH)<sub>2</sub>D<sub>3</sub> and DEX on suppressing the pro-inflammatory loop between RASf and CCR6 +memTh cells and explore potential therapeutic applications.

**Methods:** CCR6 +memTh cells from PBMC of healthy donors or treatment-naïve early RA patients were cultured alone or with RASf from established RA patients for three days and treated with or without 1,25(OH)<sub>2</sub>D<sub>3</sub>, DEX or etanercept. Treatment effects were assessed using ELISA and flow cytometry.

**Results:** CCR6 +memTh produces less of the pro-inflammatory cytokines IL-17A, IL-22 and IFNγ upon exposure to 1,25(OH)<sub>2</sub>D<sub>3</sub>, and to a lesser extent by DEX. TNFα was only inhibited by the combination of 1,25(OH)<sub>2</sub>D<sub>3</sub> and DEX. In contrast, in RASf cultures DEX was the strongest inhibitor of IL-6, IL-8 and tissue-destructive enzymes. As a result, 1,25(OH)<sub>2</sub>D<sub>3</sub> and DEX additively inhibited inflammatory mediators in CCR6 +memTh RASf co-cultures. Interestingly, low doses of mainly DEX, but also 1,25(OH)<sub>2</sub>D<sub>3</sub>, combined with etanercept better suppressed synovial inflammation in this co-culture model compared to etanercept alone.

**Conclusions:** This study suggests that 1,25(OH)<sub>2</sub>D<sub>3</sub> and DEX additively inhibit synovial inflammation through targeting different pro-inflammatory mechanisms. Furthermore, low doses of DEX and 1,25(OH)<sub>2</sub>D<sub>3</sub> enhance the effect of TNFα blockade in inhibiting RASf activation, providing a basis to improve RA treatment.

**THU0048 PRO-INFLAMMATORY IL-17A-PRODUCING CCR6+ T HELPER MEMORY CELLS CHANGE INTO ANTI-INFLAMMATORY CELLS WITH REGULATORY CAPACITY UPON EXPOSURE TO ACTIVE VITAMIN D**

W. Dankers<sup>1,2</sup>, N. Davelaar<sup>1,2</sup>, J.P. van Hamburg<sup>1,2</sup>, J. van de Peppel<sup>3</sup>, E. M. Colin<sup>4</sup>, E. Lubberts<sup>1,2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Immunology; <sup>3</sup>Internal Medicine, Erasmus MC, Rotterdam; <sup>4</sup>Rheumatology, Hospital Group Twente, Almelo, Netherlands

**Background:** In autoimmune diseases such as rheumatoid arthritis (RA), an important therapeutic goal is to normalise the imbalance between pro- and anti-inflammatory cells. In RA, especially pro-inflammatory CCR6 +T helper (Th) memory cells, characterised by IL-17A production and RORC expression, are elevated and more activated compared to healthy controls. Therefore, modulating these cells to become anti-inflammatory could contribute to restoring the immunological balance. Interestingly, the active vitamin D metabolite 1,25(OH)<sub>2</sub>D<sub>3</sub> inhibits pro-inflammatory cytokine production by CCR6 +Th memory cells.

**Objectives:** We investigated whether 1,25(OH)<sub>2</sub>D<sub>3</sub> can induce an anti-inflammatory phenotype in these memory CCR6 +Th cells.

**Methods:** CCR6 +Th memory cells, excluding Tregs, were sorted from treatment-naïve early RA patients or healthy controls and cultured with or without 1,25(OH)<sub>2</sub>D<sub>3</sub>. Effects were analysed using microarray, RT-PCR, ELISA or flow cytometry. Functional properties were assessed via suppression and chemotaxis assays.

**Results:** 1,25(OH)<sub>2</sub>D<sub>3</sub> inhibits pro-inflammatory cytokines such as IL-17A, IL-17F and IL-22 in CCR6 +Th memory cells from both healthy controls and RA patients. This is accompanied by induction of anti-inflammatory factors, including IL-10 and CTLA4. Interestingly, these formerly pathogenic cells suppress proliferation of autologous CD3 +T cells, similar to classical Tregs. Importantly, the modulated memory cells still migrate towards the site of inflammation, modelled by synovial fluid, and retain their suppressive capacity in this environment.

**Conclusions:** Committed pro-inflammatory IL-17A-producing CCR6<sup>+</sup>Th memory cells shift towards anti-inflammatory cells with functional regulatory capacities upon exposure to active vitamin D. This process can contribute to restoring the immunological balance and inhibiting synovial inflammation in RA.

**THU0049 DEVELOPMENT OF TFH-TH1 LIKE CELLS THROUGH EPIGENETIC MODIFICATION BY STATS FAMILY FACTORS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

X. Ma<sup>1,2</sup>, S. Nakayama<sup>1</sup>, S. Kubo<sup>1</sup>, K. Sakata<sup>1,3</sup>, K. Yamagata<sup>1</sup>, Y. Tanaka<sup>1</sup>.  
<sup>1</sup>First Department of Internal Medicine, School of Medicine, University of Occupational and Environmental Health, Japan, Kitakyushu, Japan; <sup>2</sup>Department of Pediatrics, The First Hospital of China Medical University, Shenyang, China; <sup>3</sup>Mitsubishi Tanabe Pharma, Yokohama, Japan

**Background:** Systemic lupus erythematosus (SLE) is a prototype of autoimmune disease characterised by chronic immune activation and multiple immunologic phenotypes<sup>(1)</sup>. Among several types of immune cells, T follicular helper (Tfh) cells serve important roles in the development and progression of SLE<sup>(2)</sup>.

**Objectives:** To assess the characteristics and mechanisms of differentiation of Tfh cells, we probed the phenotype of T helper cells in patients with SLE and underlying epigenetic modifications by cytokine-induced signal transducer and activators of transcription (STAT) family factors.

**Methods:** Naive CD4<sup>+</sup> T cells and memory CD4<sup>+</sup> T cells were isolated and stimulated by various cytokines and T cell receptor (TCR) *in vitro*. Expression of characteristic markers of Tfh-Th1-cells and phosphorylation of STATs were analysed by flow cytometry and qPCR. Histone modifications were evaluated by chromatin immunoprecipitation. Peripheral blood mononuclear cells from SLE patients and healthy controls were analysed by flow cytometry and productions of cytokines in serum were tested by cytometric bead array.

**Results:** Differentiation of CXCR5<sup>+</sup>CXCR3<sup>+</sup>Bcl-6<sup>+</sup>T-bet<sup>+</sup>IL-21<sup>+</sup>IFN- $\gamma$ <sup>+</sup> Tfh-Th1-like cells was induced by IL-12. Among STAT family, STAT1 and STAT4 were phosphorylated simultaneously by IL-12 independent of IFN- $\gamma$  and directly bound on Bcl-6 and T-bet gene loci accompanied by suppression of trimethylated histone 3 lysine 27. Compared with healthy controls, responsiveness of activation of STAT1 and STAT4 by IL-12 and proportion of activated Tfh-Th1-like cells were increased in patients with SLE.

**Conclusions:** Our findings suggest that IL-12-mediated co-activation of STAT1 and STAT4 alter histone modification, resulting in development of Tfh-Th1-like cells that are characteristically expanded in patients with SLE. These findings could be one of underlying pathogenesis of SLE and potentially helpful towards development of cell-specific treatment.

**THU0050 HYPOXIA INDUCES PRODUCTION OF CITRULLINATED PROTEINS IN HUMAN FIBROBLAST-LIKE SYNOVIOCYTES THROUGH REGULATING HIF1A**

R. Yu, C. Li, L. Sun, L. Jian, Z. Ma, J. Zhao, X. Liu. *Department of Rheumatology and Immunology, Peking University Third Hospital, Beijing, China*

**Background:** Hypoxia is a prominent microenvironment feature in a range of disorders including cancer, rheumatoid arthritis (RA), atherosclerosis, inflammatory bowel disease (IBD), infection and obesity. Hypoxia promotes biological functions of fibroblast-like synoviocytes via regulating hypoxia-inducible factor 1 $\alpha$  (HIF1 $\alpha$ ). Dysregulated protein citrullination in RA drives the production of antibodies to citrullinated proteins, a highly specific biomarker of RA. However, the mechanisms promoting citrullination in RA are not yet fully elucidated.

**Objectives:** In the present study, we investigated whether pathophysiological hypoxia as found in the rheumatoid synovium modulates the citrullination in human fibroblast-like synoviocytes (HFLS).

**Methods:** HFLS were incubated in a hypoxic chamber (5% CO<sub>2</sub> and 1% O<sub>2</sub>, balanced with N<sub>2</sub> as indicated) or in a normal incubator containing 5% CO<sub>2</sub> and approximately 20% O<sub>2</sub>. The realtime quantitative PCR and western blotting were used to detect the expression of peptidylarginine deiminase 2, peptidylarginine deiminase 4 and citrullinated proteins. HFLS were transfected with HIF1 $\alpha$  siRNA to block the HIF1 $\alpha$  pathway.

**Results:** In the present study, we found that peptidylarginine deiminase 2 (PAD2) and citrullinated proteins were increased in HFLS after exposed to hypoxia. Moreover, knocking down HIF1 $\alpha$  by hif1 $\alpha$  siRNA ameliorated the expression of PAD2 and citrullinated proteins.

**Conclusions:** Collectively, the present study provide a new mechanism involved in generating citrullinated proteins: hypoxia promote citrullination and PAD production in HFLS. Concurrently, we also proposed a novel hypoxia involved mechanism in RA pathogenesis. The present study deepens our understanding of the role of hypoxia in the pathogenesis of RA and provides potential therapeutic strategy for RA.

Williams<sup>1</sup>. <sup>1</sup>The Kennedy Institute of Rheumatology, University of Oxford, Oxford, UK; <sup>2</sup>Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital at Keelung, Keelung, Taiwan, Province of China

**Background:** Despite the overall success of TNF $\alpha$  inhibitors in rheumatoid arthritis (RA), up to half of patients are classified as either primary or secondary non-responders<sup>1</sup>. One hypothesis put forward to explain resistance to anti-TNF $\alpha$  therapy is an ascendant effect of dysregulated regulatory T cells and increased Th17 responses following TNF $\alpha$  blockade. Previous studies have demonstrated that TNFR2 is critical for stabilisation and suppressive function of regulatory T cells<sup>2,3</sup>. However, TNFR2 also activates pro-inflammatory signalling cascades and, to date, the net effect of TNFR2 on the pathogenesis of RA remains unclear.

**Objectives:** In this study we address this question by assessing the progression of collagen-induced arthritis (CIA) in mice deficient for TNFR1 or TNFR2.

**Methods:** C57Bl/6N.Q (H-2<sup>q</sup>) mice were immunised with bovine type II collagen emulsified in complete Freund's adjuvant. The mice were monitored daily for arthritis and scored clinically from the day of onset of disease. Mice were culled on day 10 after arthritis onset and spleens, lymph nodes, serum and paws were collected for further analysis.

**Results:** As expected, TNFR1<sup>-/-</sup> mice were found to be largely resistant to arthritis both clinically and histologically (figure 1). In contrast, there was significantly enhanced disease activity at the clinical and histological levels in TNFR2<sup>-/-</sup> mice (figure 1) and this was accompanied by increased expression of the pro-inflammatory cytokines, TNF $\alpha$  and IL-6, reduced numbers of regulatory T cells, reduced FoxP3 expression and reduced expression of the immune inhibitory molecules, PD-1 and LAG3, in TNFR2<sup>-/-</sup> mice compared to WT mice.

Abstract THU0051 – Figure 1. Progression of CIA in mice deficient for TNFR1 or TNFR2

**Conclusions:** This study has shown that TNFR2 signalling plays immunoregulatory and anti-inflammatory roles in CIA. First, it contributes to promotion of regulatory T cell generation and FoxP3 expression, and second, it limits the expression of pro-inflammatory cytokines. TNFR2 also regulates the expression immune inhibitory

molecules during inflammation. The results support the rationale to for development of TNFR1 specific antagonists or TNFR2 agonists for the treatment of RA.

### THU0052 A CIRCULATING PROTEIN SIGNATURE CORRELATES WITH SYNOVIAL PATHOTYPES IN RHEUMATOID ARTHRITIS PATIENTS

C. Ruiz-Romero<sup>1</sup>, F. Picchi<sup>1</sup>, P. Fernández-Puente<sup>1</sup>, L. González-Rodríguez<sup>1</sup>, R. Hands<sup>2</sup>, V. Calamia<sup>1</sup>, M. Camacho-Encina<sup>1</sup>, C. Bessant<sup>3</sup>, C. Pitzalis<sup>2</sup>, F. J. Blanco<sup>1</sup>. <sup>1</sup>Unidad de Proteómica-ProteoRed/ISCIII, Grupo de Investigación en Reumatología, INIBIC – CHUAC, A Coruña, Spain; <sup>2</sup>Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Barts and the London School of Medicine and Dentistry, Queen Mary University of London; <sup>3</sup>School of Biological and Chemical Sciences, Queen Mary University of London, London, UK

**Background:** Rheumatoid arthritis (RA) is a disease characterised by high clinical variability and an underlying cellular and molecular heterogeneity. Efforts to find tools for the classification of the different disease phenotypes and patient stratification are essential to develop tailored therapies and improve its management. According to this, specific pathological phenotypes of synovial tissue (pathotypes) have emerged as associated with diverse clinical evolution and response to therapy.<sup>1</sup>

**Objectives:** To identify signatures of circulating proteins associated with specific synovial pathotypes in RA patients.

**Methods:** A proteomic analysis was carried out on samples from patients enrolled in the Pathobiology of Early Arthritis Cohort. Ultrasound-guided synovial biopsies from these patients allowed their classification into three groups: lymphoid (L), myeloid (M) or fibroid (F), according to the pathotype. The study was performed using 54 serum samples at baseline. Sera were analysed by nanoliquid chromatography coupled to mass spectrometry using a SWATH strategy on a triple TOF (Sciex). The proteomic data were processed using ProteinPilot and PeakView. A two-stage support vector machine (TSSVM) with RBF kernel and 10 cross-fold validation for each meta-model was applied using the Classyfire, e1071 and caret R packages.

**Results:** The proteomic analysis led to the identification and quantification of 229 proteins in all samples. A screening was performed on a group of 30 samples (Train set: 10 L, 10 M and 10 F). Data were pre-processed by PCA for dimension reduction. Then, application of machine learning tools led to the identification of a panel of 11 proteins whose different abundance is associated with a specific synovial phenotype (either L, M or F) in RA patients. As shown in the table 1, a very high accuracy and Kappa coefficient were achieved with this classification tool. The results were confirmed on an independent validation set of 24 samples (12 L, 8 M and 4 F) with also good performance. This protein signature allowed the correct classification of the samples into the three pathotypes with very high sensitivity and specificity (see table 1).

**Abstract THU0052 – Table 1.** Metrics of the classification performance of the 11-protein panel identified in this work as associated with the synovial pathotype of the patient. Cut-off for significance was p-value<0.05.

Train set	Classes in the train set

### THU0053 ANTI-FRACTALKINE MONOCLONAL ANTIBODY AMELIORATES JOINT DESTRUCTION IN COLLAGEN-INDUCED ARTHRITIS MODEL BY INHIBITION OF OSTEOCLAST PRECURSOR CELL SURVIVAL AND MIGRATION

Y. Kuboi<sup>1</sup>, K. Hoshino-Negishi<sup>1</sup>, M. Ohkuro<sup>2</sup>, W. Ikeda<sup>1</sup>, T. Nakatani<sup>1</sup>, N. Ishii<sup>1</sup>, N. Yasuda<sup>1</sup>, T. Imai<sup>1</sup>. <sup>1</sup>KAN Research Institute, Inc., Kobe; <sup>2</sup>EA Pharma Co., Ltd., Kawasaki-ku, Kawasaki-shi, Japan

**Background:** In the Phase 1/2 clinical study, E6011, a novel humanised anti-fractalkine (FKN) mAb demonstrated a promising efficacy in active RA patients who were inadequately controlled by MTX and/or TNF- $\alpha$  inhibitors (NCT 02196558). FKN is expressed on endothelial cells and fibroblast-like synoviocytes in synovium and also expressed on osteoblasts. CX3CR1 is expressed on monocytes/macrophages and osteoclast precursor cells (OPCs). Therefore, FKN-CX3CR1 interaction could play pivotal roles in migration, differentiation and activation of those cells. However, the precise mechanism(s) of FKN-CX3CR1 axis in RA, especially on joint destruction remains to be elucidated.

**Objectives:** We examined the roles of FKN-CX3CR1 axis in joint destruction, particularly focused on osteoclast precursor cells in *in vitro* and *in vivo* by using anti-mouse FKN mAb (anti-mFKN mAb).

**Methods:** DBA/1J mice were immunised with intradermal injections of bovine type II collagen to induce arthritis (CIA). Anti-mFKN mAb or control IgG were intraperitoneally injected twice a week. The clinical arthritis score was monitored, and joint destruction was evaluated by soft X-ray and histopathology. Plasma levels of joint destruction markers were assessed by ELISA. FKN expression in joint tissues were assessed by immunohistochemistry. Cell survival of bone marrow-derived OPCs without or with immobilised FKN was also assessed by FACS. In *in vivo*, OPCs were labelled by fluorescein and transferred to CIA mice to evaluate migration of OPCs into inflamed synovium. Anti-mFKN mAb or control IgG were injected before the cell transfer. The number of fluorescein-labelled OPCs that migrated into the CIA joint tissue were analysed.

**Results:** In both prophylactic and therapeutic treatments, anti-mFKN mAb clearly reduced the clinical arthritis score, soft X-ray score. Plasma levels of cartilage oligomeric matrix protein (COMP) and matrix metalloproteinase-3 (MMP-3) were also decreased after treatment with anti-mFKN mAb. Histological analysis revealed that anti-mFKN mAb inhibited synovitis, pannus formation, cartilage destruction, and that it suppressed bone damage with marked reductions in the number of tartrate-resistant acid phosphatase (TRAP)-positive cells. In *in vitro*, RANKL-induced osteoclast differentiation was enhanced by immobilised FKN, and anti-mFKN mAb suppressed FKN-dependent enhancement of osteoclast formation. FKN also enhanced cell survival of OPCs and eventually increased the number of OPCs. In *in vivo*, increasing expression of FKN was detected on endothelium in synovial tissue of CIA mice, and fluorescein-labelled OPCs migrated into the affected synovium. Anti-mFKN mAb clearly abrogated their migration into synovium.

**Conclusions:** Anti-mFKN mAb remarkably ameliorated the joint destruction with the marked reduction of osteoclasts by the inhibition of both OPC survival and OPC migration in inflamed joint tissues. These results strongly indicate that inhibition of FKN-CX3CR1 axis by a humanised anti-FKN mAb, E6011, is an attractive and affected joints-selective therapeutic strategy for the treatment of both inflammatory synovitis and joint destruction in RA patients.

### THU0054 LONG NON-CODING RNA GAPLINC PROMOTES PROLIFERATION AND INVASION OF FIBROBLAST-LIKE SYNOVIOCYTES AS MICRORNA SPONGING IN RA PATIENTS

B.Y. Mo, Y.F. Pan, X. Bi, X.Q. Luo. *Department of Rheumatology, The Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** Accumulating evidence suggested that long non-coding RNAs (lncRNAs) play diverse functional roles in many autoimmune diseases including

rheumatoid arthritis (RA). However, there is a dearth of knowledge in what role these transcripts play in fibroblast-like synoviocytes (FLSs) of RA patients. LncRNA GAPLINC, a novel long non-coding RNA, was first described in gastrointestinal cancer tissues and associated with bad behaviours of tumour cell as well as poor prognosis in patients.

**Objectives:** This study was undertaken to explore the expression and roles of LncRNA GAPLINC in RA-FLSs and investigate its possible mechanism.

**Methods:** RA-FLSs and trauma-FLSs were cultured from synovial specimens. The expression of RNA was detected by qRT-PCR. GAPLINC suppression was transfected by siRNA. Cell viability analysis was taken by CCK-8 assay and flow cytometry. Cell invasion was using transwell chamber methodology. The bioinformatics analysis was performed using miRanda, PITA, RNAhybrid algorithms, as well as KEGG and Gene Ontology(GO) analysis.

**Results:** The relative expression of LncRNA GAPLINC was significantly higher in RA-FLSs than trauma-FLSs ( $p < 0.05$ ). Transfection of GAPLINC-siRNA significantly decreased the expression of LncRNA GAPLINC in RA-FLSs. GAPLINC suppression in RA-FLSs revealed significant alterations in cell proliferation and invasion. In the GAPLINC-siRNA group, a inhibition rate in growth was first observed ( $15.29\% \pm 0.38\%$ ) at 24 hour after transfection, then a significant suppression was observed ( $28.75\% \pm 2.34\%$ ) at 48 hour, more apparent ( $36.63\% \pm 7.93\%$ ) at 72 hour and largely maintained ( $35.97\% \pm 3.67\%$ ) at 96 hour after siRNA treatment, compared to the negative control group (NC-siRNA). Moreover, flow cytometry assay showed GAPLINC-siRNA group had an accumulation of cells in the G0/G1 phase and the decreased number of RA-FLSs in the S and G2/M phase. In the invasive assay, the membrane-invading RA-FLSs numbers decreased significantly in the treatment group with GAPLINC knockdown ( $45.0 \pm 3.0$ ) compared to values observed in the NC-siRNA group ( $149.0 \pm 7.0$ ). Above comparisons were all statistically significant ( $p < 0.05$ ). The bioinformatics analysis predicted that some of microRNAs and mRNA may be the downstream molecules of LncRNA GAPLINC, we thus simulated a gene co-action network model based on the competitive endogenous RNA (ceRNA) hypothesis. Further verification of this model demonstrated that silencing of GAPLINC increased miR-382-5 p and miR-575 expression.

**Conclusions:** The results suggest that elevated LncRNA GAPLINC expression promote the proliferation and invasion of RA-FLSs and it may function as a novel microRNAs sponging agent. Additionally, LncRNA GAPLINC may regulate RA-FLS pathological behaviours in an miR-382-5 p-dependent and miR-575-dependent manner. Based upon these findings, LncRNA GAPLINC may provide a novel valuable therapeutic target for RA patients.

#### THU0055 AN ANATOMICALLY DISTINCT PATHOGENIC FIBROBLAST SUBSET DRIVES INFLAMMATION IN ARTHRITIS

A.P. Croft, J. campos, J. Marshall, J. Turner, F. Barone, A. Filer, C. Buckley.  
*Rheumatology, University of Birmingham, Birmingham, UK*

**Background:** Fibroblasts are key effector cells in the persistence of synovial inflammation and joint damage. It is not yet known whether specific subsets of synovial fibroblasts exist, and if so, if they are responsible for the distinct fibroblast mediated features observed in inflammatory arthritis, such as invasion of cartilage, bone damage, and persistence of inflammation.

**Objectives:** Here we identify and describe the biology of a functionally distinct pathogenic fibroblast cell type marked by the co-expression of Thy1.2 and Podoplanin (Pdpn), that is responsible for persistence of synovial inflammation.

**Methods:** We used the serum transfer arthritis (STA) model to induce joint inflammation. To identify putative subsets of fibroblasts we used flow cytometry using established markers of stromal cells, on enzymatically digested synovial tissue. These cells were localised in tissue sections using immunohistochemistry or immunofluorescence staining. Proliferation of subsets *in vivo* during the time course of STA was determined by BrdU incorporation studies. Transcriptomic analysis was performed using ultra-low input RNA sequencing on flow sorted populations of cells and single cell analysis performed on CD45 negative gated cells.

**Results:** Using FAP as a biomarker of activated synovial fibroblasts we have been able to identify and define distinct subsets of synovial fibroblasts based on their co-expression of Thy1.2 and Pdpn. These subsets reside in distinct compartments of the synovial microanatomy including the lining layer (LL), sub-lining layer (SL) and a subset of pericytes. We found that FAP +cells within the SL are highly proliferative and their expansion in cell number positively correlates with

inflammation. Global deletion of FAP +mesenchymal cells in the synovium using a FAP-DTR mouse attenuated synovial inflammation; protected against erosive bone damage and lead to reduced leucocyte accumulation as a result of reduced chemokine and cytokine production by synovial fibroblasts within the membrane. Collectively these data suggest a pathogenic pro-inflammatory role for these cells.

Transcriptomic analysis by both ultra-low input bulk RNA sequencing and single cell analysis revealed these subsets to be transcriptionally distinct with the greatest transcriptional differences observed between LL and SL cells, demonstrating a site specific transcriptional program for cells within these compartments. Gene signature analysis of SL FAP +cells was consistent with an immune effector cell phenotype, in contrast to lining layer cells that express genes associated with matrix remodelling. Finally, to test this hypothesis we injected FAP +LL cells and FAP +SL cells into inflamed ankle joints of mice. The injection of FAP +SL cells lead to more severe and prolonged joint inflammation, whereas injection of LL FAP +cells had no effect. Finally, we identified these cell subsets within human synovial tissue and have demonstrated the expansion of SL cells with inflammation.

**Conclusions:** Synovial inflammation is associated with the expansion, activation and differentiation of fibroblasts into distinct functional subsets of cells that regulate those specific aspects of inflammatory joint pathology. Direct targeting of specific pathogenic subsets of synovial fibroblasts may provide a novel, non-immunosuppressive approach to the treatment of inflammatory arthritis.

**Disclosure of Interest:** None declared

#### THU0056 14-3-3 IS A MOLECULAR SWITCH REGULATING MACROPHAGE POLARISATION IN INFLAMMATORY ARTHRITIS

W. Fu, A. Hettinghouse, C. Liu. *Department of Orthopaedic Surgery, New York University Medical Center, New York, USA*

**Background:** Functional heterogeneity is a hallmark of macrophages, which can be classified into 2 major phenotypes with opposite role in inflammation termed M1 (inflammatory or classically activated) macrophages and M2 (alternatively activated) macrophages. In addition, M1-M2 polarisation of macrophages is a highly dynamic process and the phenotype of polarised macrophages can be switched under physiological and pathological conditions. Progranulin (PGRN), a multiple functional growth factor, binds to TNF receptor 2 (TNFR2) and activates the protective and anti-inflammatory pathway in inflammatory arthritis. In addition, 14-3-3e was identified as a component of PGRN/TNFR2 complexes in Raw264.7 macrophages.

**Objectives:** In this study, we examined whether 14-3-3e regulated macrophage polarisation and if so, whether this was important for PGRN's anti-inflammatory action in inflammatory arthritis.

**Methods:** LysMCre and 14-3-3e F/F mouse line was obtained from Jackson Laboratory.

**Results:** 14-3-3e regulates macrophage polarisation *in vitro*. We found that 14-3-3e deficiency enhanced M1 while inhibited M2 polarisation (figure 1a, b). Interestingly, PGRN showed reverse effects on macrophage polarisation. In addition, PGRN's effects were largely lost in 14-3-3e deficient BMDMs (figure 1a, b). Together, these data indicate that 14-3-3e is a critical downstream mediator of PGRN regulation of macrophage polarisation.

**Macrophage-specific 14-3-3e contributes to control of inflammatory arthritis and is critical for PGRN's anti-inflammatory action.** We then explored the role of macrophage-specific 14-3-3e in inflammatory arthritis and whether PGRN's anti-inflammatory activity depended on 14-3-3e *in vivo*. We established CIA in 14-3-3eF/F (serve as WT) and 14-3-3eΔ/Δ mice, followed by i.p. injection of recombinant PGRN. The clinical arthritis score demonstrated that 14-3-3eΔ/Δ mice displayed increased severity of CIA compared with WT CIA. In addition, PGRN's protective effects against inflammatory arthritis was compromised in 14-3-3eΔ/Δ mice (figure 1c), suggesting that 14-3-3e is critical downstream mediator of PGRN's anti-inflammatory effects. In addition, FACS analysis showed that total numbers of F4/80 cells were not different in all WT and knockout CIA mice. However, analysis of CD45 +CD11b+cell population in spleen demonstrated a significant increase in mean fluorescence intensity (MFI) of iNOS and a significant decrease of CD206 +cells in PBS treated 14-3-3eΔ/Δ CIA mice as compared with PBS treated WT CIA mice; moreover, there was a significant decrease of iNOS MFI while a dramatic increase of CD206 +cells in PGRN-treated WT mice compared to that in PBS-treated mice. Further PGRN-mediated effects on macrophage polarisation was lost in 14-3-3eΔ/Δ CIA mice (Fig 1d, e). Collectively, these results indicate that PGRN skews macrophage toward M2 polarisation to resolve inflammation and this effect depends on 14-3-3e.

**Abstract THU0056** – Figure 1. 14–3–3 $\epsilon$  is a critical mediator of PGRN<sup>1</sup> regulation of macrophage polarisation and contributes to PGRN's anti-inflammation action. (a, b) qPCR analysis of Il1b and Nos2 (a), or Arg1 and Mgl1 (b) mRNA expression in WT, or 14–3–3 $\epsilon$ -/- macrophages which are polarised to M1 (a) or M2 (b) in the absence or presence of PGRN (200ng/ml). (c) Clinical arthritis score of WT or 14–3–3 $\epsilon$  $\Delta\Delta$  CIA mice treated with or without PGRN. n=8 (d, e) CD45+CD11b+ cells were analysed for MFI of iNOS (d) and percentage of CD206+ cells (e). \* p<0.05, \*\* p<0.01, NS=no significance

**Conclusions:** Both *in vitro* and *in vivo* results indicate that 14–3–3 $\epsilon$  is a key molecule regulating macrophage polarisation which plays an important role in inflammatory arthritis, and it is an essential component for PGRN/TNFR2 mediated protective effect against inflammatory arthritis.

Callewaert<sup>3</sup>, G. Kollias<sup>6</sup>, R. Lories<sup>4</sup>, G. Schett<sup>7</sup>, D. Elewaut<sup>1</sup>. <sup>1</sup>Rheumatology, UGENT/VIB; <sup>2</sup>Rheumatology, UZ Gent; <sup>3</sup>Biochemistry and Microbiology, UGENT/VIB, Ghent; <sup>4</sup>Development and Regeneration, KUL, Leuven; <sup>5</sup>Physics and astronomy, UGent; <sup>6</sup>Experimental Physiology, Biomedical Sciences Research Center 'Alexander Fleming'; <sup>7</sup>Rheumatology and Immunology, Friedrich Alexander University of Erlangen-Nuremberg and Universitätsklinikum, Ghent, Belgium

**Background:** Many pro-inflammatory pathways leading to arthritis act systemically on the immune system rather than locally in the joint. However, the reason behind the regional and patchy distribution of arthritis represents a longstanding paradox.

**Objectives:** To explore the relation between mechanical strain and joint inflammation and to understand the underlying basis of joint pattern involvement in inflammatory rheumatic diseases.

**Methods:** Arthritis was induced by collagen-induced arthritis (CIA) and passive collagen antibody induced arthritis (CAIA) in respectively C57BL/6 and RAG2-/- (T- and B-cell deficient) mice. Animals were subjected to different regimens of mechanical strain. Increased strain occurred in voluntary running mice whereas tail suspension (unloading) abolished mechanical strain; both were compared to control housing conditions. The impact of different loading conditions was measured on clinical disease score, histology, micro-CT images and erosion quantification, gene induction in tendon and synovial tissue, immune cell recruitment *in situ*, development of anti-collagen antibodies and their pattern of sialylation and galactosylation.

**Results:** Voluntary running of CIA in C57BL/6 mice markedly induced an early onset and increased progression whereas no disease onset could be observed in the hind paws from animals in unloaded conditions. CAIA in running RAG2-/- mice also induced early arthritic symptoms and severe progression. Intriguingly, running conditions were sufficient to induce arthritis without the need of LPS as an inflammatory trigger. Mechanical strain did not alter however IgG autoantibody levels nor their levels of galactosylation and sialylation. Furthermore, we demonstrate that mechanical strain on stromal cells results in recruitment of classical monocytes into specialised mechano-sensitive regions characterised by a unique microanatomy. This promotes local inflammation and differentiation into local osteoclasts which induce regional erosions. A striking similarity was observed in the pattern of joint erosions in human patients with RA and SpA which were also confined to these mechanosensitive regions.

**Conclusions:** This study provides the first evidence that mechanical strain controls the transition from systemic autoimmunity into site-specific joint inflammation.

Homing of inflammation and development of erosions was confined to specific mechano-sensitive regions, characterised by a high number of attachment- and contact points for tendons. This represents a novel paradigm and explains why arthritis in mice and humans is characterised by a regional and patchy distribution. Curiously, this pathway does not rely on adaptive immunity but rather on stromal cells. Mechano-stimulation of mesenchymal cells induced CXCL1 and CCL2 permitting recruitment of classical monocytes which can differentiate into bone-resorbing osteoclasts. Thus, mechanical strain controls the site-specific direction of inflammation and tissue damage in arthritis.

### THU0058 TAS8274, A HIGHLY SELECTIVE JANUS KINASE 3 INHIBITOR, SHOWS POTENT EFFICACY, BUT DOES NOT AFFECT HOST DEFENSE, IN PRECLINICAL MOUSE MODELS

H. Hayashi, S. Demizu, K. Tanaka, M. Mitsuya, A. Saito, T. Utsugi, E. Sasaki, Y. Iwasawa. Taiho Pharmaceutical co., LTD., Tsukuba, Ibaraki, Japan

**Background:** The family of Janus kinases (JAKs) plays important roles in signalling pathway mediated by various cytokine receptors. An aberrant activation of JAK-STAT signalling has been reported to be involved in the pathogenesis of autoimmune diseases<sup>1</sup>. Pan-JAK inhibitors have shown a good efficacy in patient with rheumatoid arthritis (RA)<sup>2</sup>. However, their use is limited due to safety concerns, including severe herpes zoster infection, by inhibiting JAK1-mediated interferon signaling<sup>3</sup>. Therefore, a selective JAK3 inhibitor would provide a better balance between efficacy and safety than pan-JAK inhibitors.

**Objectives:** We identified the characteristics of TAS8274, a novel highly selective inhibitor of JAK3, using *in vitro* assays, a mouse model of collagen-induced arthritis (CIA), and a mouse model of herpes simplex virus (HSV)-1 infection.

**Methods :** *In vitro* biochemical assay was performed using available kinase assay panels. The effects on anti-inflammatory responses were assessed by examining cytokine productions. IL-2, IL-3, and IFN- $\alpha$ -induced phosphorylation of STAT proteins in peripheral blood mononuclear cells (PBMCs) were analysed by a flow cytometry method. NK cell cytotoxicity in the presence of IFN- $\alpha$  was evaluated by Cr<sup>51</sup> release assay. In a mouse skin HSV-1 infection model, TAS8274 and tacrolimus were administered for 7 days before inoculation of the virus on the back skin, and then were administered for another ten consecutive days. At the end of this experiment, the number of papules on the back was counted. To evaluate the therapeutic efficacy using mouse CIA model, TAS8274 was orally administered to CIA mice after the disease onset. Disease severity was evaluated by clinical score of paw swelling, and the scores of inflammation, pannus, cartilage, and bone damage were performed using a modified Mankin score system.

**Results:** TAS8274 inhibited the enzymatic activity of JAK3 (IC<sub>50</sub>=0.16 nM), and showed more than 1000-fold selectivity against other JAK kinases. In the cell-based assays, TAS8274 strongly inhibited IL-17 production from differentiated Th17 cells. TAS8274 also suppressed the IL-2-induced STAT5 phosphorylation in PBMCs, but had much lower inhibitory effects on the IFN- $\alpha$ -induced STAT1 phosphorylation. In contrast, Tofacitinib and Baricitinib had robust inhibitory effects on the IFN- $\alpha$ -induced STAT1 phosphorylation. Furthermore, Tofacitinib and Baricitinib dose-dependently reduced the NK cell cytotoxicity, while TAS8274 had little effect on that. Tacrolimus-treated group significantly increased the number of papules compared with vehicle-treated group in a mouse HSV-1 infection model, but TAS8274-treated group did not increase the number of papules. In an established mouse CIA model, TAS8274 dose-dependently reduced the severity of arthritis and histopathological scores compared with vehicle-treated mice.

**Conclusions:** TAS8274 did not inhibit the JAK3-independent STAT signalling pathway *in vitro* and showed potent efficacy at dose range without exacerbation of the risk of HSV-1 infection. Our study demonstrates that TAS8274 would be an attractive therapeutic agent with excellent balance between efficacy and safety.

**THU0059 PLASMA EXOSOMAL MIR-92A ARE INVOLVED IN THE OCCURRENCE AND DEVELOPMENT OF BONE DESTRUCTION IN RA PATIENTS BY INHIBITING APOPTOSIS OF FIBROBLAST-LIKE SYNOVIOCYTES**

Y. Xin, Z.S. Yang, X.Y. Fei, L.Y. Ke, J. Juan, F. Ting, Z.Z. Xu, Z. Gu. Department of Rheumatology, Affiliated Hospital of Nantong University, Nantong, China

**Background:** Rheumatoid arthritis (RA) is a chronic and progressive autoimmune disease that mainly affects joints. Bone erosion and bone destruction are the characteristic features of RA.<sup>1</sup> The mechanism of bone destruction is not fully understood at present. The decrease of apoptosis of human fibroblast-like synoviocytes (FLSs) originating from mesenchymal is involved in the occurrence and development of bone destruction in RA.<sup>2</sup> Exosomes are important mediators of biological information and play a part in the occurrence and development of various diseases including RA.<sup>3</sup>

**Objectives:** The aim of study was to find whether exosomes participate in the pathogenesis of bone destruction in RA.

**Methods:** plasma was collected from 10 healthy people and 20 RA patients. According to Sharp-van der Heijde score (SHS), patients were divided into two groups named bone destruction group and non bone destruction group. Exosomes were extracted by Total Exosome Isolation reagent and confirmed by transmission electron microscope and western blot. The internalisation of exosomes was detected by immunofluorescence. Normal FLSs were stimulated with exosomes. Flow cytometry was utilised to detect the alteration of cell cycle and apoptosis rate. The cell proliferation was determined by CCK-8 assay. Apoptosis proteins (Bax, BCL-2 and caspase-3) were examined by western blot. The concentrations of TNF- $\alpha$  and IL-1 in the cell supernatants were measured by enzyme-linked immunosorbent assay (ELISA). High-throughput sequencing was used to detect the expression of miRNAs in exosomes.

**Results:** There is no difference between exosomes of normal people and RA patients in promoting cell proliferation. However, the exosomes of RA patients can prohibit the cell apoptosis and promote the release of TNF- $\alpha$  and IL-1 from FLSs more effectively. Of these two RA groups, the abilities of bone destruction group exosomes are higher. The expressions of Bcl-2 and caspase-3 in bone destruction group are also significantly higher than that in the non bone destruction group and the normal group. Inversely the expression of Bax in bone destruction group is lower. Additionally, exosomal miR-92a are significantly over expressed in bone destruction group.

Table 1. The SHS and SHS/RF score of RA patients

Abstract THU0059 – Figure 3

Abstract THU0059 – Figure 1

Abstract THU0059 – Figure 4

Abstract THU0059 – Figure 2

Abstract THU0059 – Figure 5

**Conclusions:** The study showed that exosomes in the serum of RA patients can prohibit the apoptosis of FLSs and enhance the secretion of inflammatory cytokines to promote bone destruction. Exosomes play an important role in the pathogenesis of RA. Exosomes can be used as a potential predictor for early bone destruction.

#### THU0060 ALTERATIONS OF SPLICING IN LEUKOCYTES FROM RHEUMATOID ARTHRITIS PATIENTS AND ITS INFLUENCE ON THE AUTOIMMUNE, INFLAMMATORY AND ATHEROTHROMBOTIC PROFILE OF THE DISEASE. POTENTIAL ROLE OF U4ATAC

A. Ibáñez-Costa, C. Perez-Sanchez, S. Pedraza-Arévalo, M. del Río-Moreno, P. Ruiz-Limón, N. Barbarroja, Y. Jiménez-Gómez, M.C. Ábalos, P. Seguí, E. Collantes, J.P. Castaño, R.M. Luque, C. Lopez-Pedraza. *IMIBIC/Reina Sofía University Hospital/University of Cordoba, Cordoba, Spain*

**Objectives:** The aim of this study was the identification, in leukocytes of Rheumatoid Arthritis (RA) patients, of the alterations present in the spliceosome and the machinery responsible for the splicing, as well as their influence on the activity of the disease and its atherothrombotic profile.

**Methods:** We evaluated, using a microfluidic qPCR array (Fluidigm), a set of 45 elements of the splicing machinery: the complete major and minor spliceosome components and a series of splicing factors with potential pathological role. Monocytes, neutrophils and lymphocytes of purified from 74 RA patients and 29 healthy donors (HD) were assessed. In parallel, extensive clinical/serological evaluation, and correlation and association analyses were carried out.

**Results:** A significant alteration in several components of the spliceosome was observed in all the three leukocyte subtypes from RA patients compared to HD. Various spliceosome components were specifically altered in different leukocyte subtypes; it should be noted that a general downregulation was observed. Likewise, it was striking that 7 elements, including two small nuclear RNA (snRNA) of the major spliceosome (U1 and U5), the snRNA of the minor spliceosome, U4atac, and the splicing factors RBM3, RBM17, SAM68 and SRSF10 showed the same alteration pattern: all significantly reduced in the 3 leukocyte subtypes of patients with RA, except for U4atac, which was consistently over expressed and virtually absent in HD leukocytes. Although this process needs further analysis, it is likely that the overexpression of U4atac could interfere in the normal functioning of the major spliceosome, by binding to U5, thus altering the splicing of most introns (>99%), favouring non-canonical splicing, and generating aberrant proteins involved in the development of this pathology. Correlation and association studies showed a significant association between the expression levels of the 7 splicing factors cited and several clinical/serological parameters, including the activity of the disease, the positivity for anti-CCP and RF antibodies, and the expression of different inflammatory mediators. Likewise, reduced values of other splicing factors, differentially deregulated in the three leukocyte subtypes, were associated with radiological involvement, as well as with the presence of atheroma plaques, hyperlipidemia and arterial hypertension.

**Conclusions:** We have identified specific alterations in the splicing machinery of leukocytes from RA patients, associated with the activity of the disease, as well as with its inflammatory and atherothrombotic profile. Altogether, the generalised reduction of multiple elements of the splicing machinery and the consistent elevation of U4atac will deem necessary to examine the possible role of this snRNA in the alteration of the spliceosome in the near future, as well as its specific implication in the regulation of the expression of key proteins in the pathology of RA.

#### THU0061 RESTRICTED AXL SYNOVIAL EXPRESSION AND INCREASED CLEAVAGE OF AXL ECTODOMAIN CORRELATE WITH HIGHLY INFLAMED SYNOVITIS AND MORE SEVERE RHEUMATOID ARTHRITIS

A. Nerviani, D. Mauro, S. Pagani, G. Lliso-Ribera, F. Rivellese, M. Lewis, M. Bombardieri, F. Humby, C. Pitzalis. *Experimental Medicine and Rheumatology, Queen Mary University of London, London, UK*

**Background:** Tyrosine kinase Axl, member of the TAM family, is expressed by antigen presenting cells and behaves as a negative regulator of the inflammatory cascade. Inflammatory stimuli up-regulate Axl expression in bone-marrow-derived macrophages<sup>1</sup>. Soluble (s) Axl, generated by ADAM10, is a potent decoy for the TAM-ligand Gas6 and can impair TAM axis activation in lupus<sup>2</sup>. In rheumatoid arthritis (RA) dendritic cells, Axl is epigenetically down-regulated<sup>3</sup>. Emerging evidence has emphasised the significant role of Axl/sAxl in the pathogenesis and progression of autoimmune diseases, but little is known about TAM expression and regulation within the rheumatoid synovium.

**Objectives:** We aimed to quantify Axl/ADAM10 in synovial tissue (ST) and sAxl/Gas6 in synovial fluid (SF) and to correlate Axl/sAxl expression with synovial inflammation and disease severity in RA patients.

**Methods:** ST/SF were sampled from early treatment-naïve RA patients undergoing ultrasound (US)-guided synovial biopsy of the most inflamed accessible joint. RA was diagnosed according to ACR/EULAR2010 criteria. The Krenn's synovitis score of inflammation was determined by H and E. Immunohistochemistry (IHC) staining of CD3/CD20/CD138/CD68 allowed to define the synovial immune infiltrate. Axl/ADAM10/CD68 were assessed in ST by IHC/immunofluorescence (30 patients). sAxl/Gas6 were quantified in 17 SF by ELISA. Synovial gene expression data were obtained by next-generation sequencing (80 patients).

**Results:** Axl was predominantly expressed only by CD68-positive macrophages of the lining and co-localised with ADAM10. AXL synovial mRNA significantly negatively correlated with the Krenn's score and with the degree of infiltration by B/T lymphocytes, plasma cells, and sub-lining macrophages, but not lining macrophages. In SF, sAxl positively correlated with Gas6 and was significantly more abundant in patients with highly inflamed synovitis and more active disease. AXL synovial gene expression showed strong negative correlation with indexes of disease severity, including ESR, CRP, DAS28, and US synovial thickening/power-doppler, and with the mRNA of pro-inflammatory cytokines, e.g. TNF and IL6.

**Conclusions:** Our data demonstrate that, despite the highly-inflamed environment characterising RA synovia, Axl expression is restricted to the synovial lining, where it can be cleaved and released into the synovial fluid by ADAM10. There, sAxl can bind Gas6 with high affinity, preventing its interaction with transmembrane functional TAM receptors. Raised levels of sAxl and down-regulated AXL mRNA expression correlate with highly inflamed synovitis and more severe disease. Defects in the TAM system could provide an original mechanistic explanation of the persistent inflammation in the RA joints, representing a novel therapeutic target exploitable to regain tissue homeostasis.

#### THU0062 WNT5A INVOLVEMENT IN MIGRATION, INVASION AND THE PRO-INFLAMMATORY PHENOTYPE OF RHEUMATOID SYNOVIOCYTES

A. Rodríguez-Trillo, N. Mosquera, A. Mera, A. González, C. Conde. *Experimental and Observational Rheumatology and Rheumatology Unit, IDIS, CHUS, Santiago de Compostela, Spain*

**Background:** Fibroblast-like synoviocytes (FLS) are pivotal in the inflammation and joint damage of rheumatoid arthritis (RA). These cells acquire an aggressive phenotype; they migrate and invade articular structures perpetuating synovial inflammation. Also, they contribute to cartilage and bone damage by secretion of cytokines, metalloproteinases and cathepsins. The mechanisms modulating migration and invasion of FLS are not yet completely known. Recently, the role of the non-canonical pathway of Wnt5a has been highlighted in these processes, as well as, its contribution to osteoclastogenesis. Moreover, Wnt5a could be involved in other pathogenic aspects of RA, as suggested by its involvement in tissue

inflammation through regulation of cytokine, chemokine and metalloprotease expression. Thus, the study of the non-canonical pathway of Wnt5a in the aggressive phenotype of FLS and the inflammatory response may provide new therapeutic targets for the RA.

**Objectives:** To analyse the involvement of Wnt5a in the proliferation, migration, invasion and inflammatory responses of FLS from RA patients.

**Methods:** FLS were obtained from eight RA patients. Expression of Wnt5a was suppressed by siRNA transfection (Dharmacon). Cellular proliferation was determined using the CellTiter-Glo Luminescent Cell Viability Assay (Promega). Migration was analysed by the wound-healing assay using Ibidi inserts. The occupation area was determined by Image J. Invasion was tested by quantifying Giemsa stained cells on the bottom side of Matrigel coated trans-membrane (Millipore). The expression of inflammatory mediators and metalloproteases was analysed by real-time PCR after stimulation with recombinant Wnt5a protein (rWnt5a), TNF and combined treatment.

**Results:** We analysed the effect of the absence of Wnt5a and rWnt5a on the proliferation, migration and invasion of RA FLS. FLS lacking Wnt5a showed a significant migration decrease, 27.9% in basal condition and 16.9% after TNF stimulation, when compared with FLS transfected with siRNA control. Accordingly, migration of RA FLS treated with rWnt5a was increased by 48.5% when compared with cells treated with the vehicle. No change in migration was observed in TNF-stimulated FLS. Invasive capacity was reduced, reaching 71.4% of that observed in FLS transfected with siRNA control in basal conditions. In addition, invasion in FLS treated with rWnt5a was 35.7% higher than in controls. We also analysed the effect of rWnt5a on the inflammatory response of RA FLS. We found a significant increase of IL6, IL8, CCL2, CXCL5, MMP9 and MMP13 basal expression and the TNF-induced expression of IL6, IL8, CXCL5 and MMP3. Nevertheless, the lack of Wnt5a or the addition of rWnt5a did not modify the spontaneous or the TNF-induced proliferation.

**Conclusions:** These results indicate that Wnt5a contributes to the aggressive phenotype of FLS by potentiating their migration and invasion, and by stimulating the inflammatory response.

#### THU0063 CD11c+ DENDRITIC CELLS IN INFLAMMATORY ARTHRITIS

A. Puchner<sup>1</sup>, V. Saferding<sup>1</sup>, M. Bonelli<sup>1</sup>, H. Leiss<sup>1</sup>, R. Pfeifle<sup>2</sup>, G. Kroenke<sup>2</sup>, J. Smolen<sup>1</sup>, K. Redlich<sup>1</sup>, S. Blüml<sup>1</sup>. <sup>1</sup>Medical University of Vienna, Vienna, Austria; <sup>2</sup>University Hospital Erlangen, Erlangen, Germany

**Background:** Dendritic cells (DCs) are important antigen presenting cells (APCs) and therefore they play an important role in bridging the innate and the adaptive immune response. DCs can be divided in different subsets with specific functions. As powerful APCs, DCs are thought to play an important role in the induction of autoimmune diseases such as rheumatoid arthritis. However, the active role of DCs in joint inflammation is not known yet.

**Objectives:** We analysed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of CD11c+ cells by immunohistochemistry. We also performed synovial biopsies and analysed the cellular composition of the inflammatory infiltrate with respect to DCs. We used CD11c-diphtheria toxin receptor (DTR) transgenic mice, which express the human diphtheria toxin receptor under the CD11c promoter, allowing for specific depletion of CD11c+ cells by administration of diphtheria toxin (DT). K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BARF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

**Methods:** We analysed histological sections of K/BxN serum transfer arthritis as well as hTNFtg arthritis for the presence of CD11c+ cells by immunohistochemistry. We also performed synovial biopsies and analysed the cellular composition of the inflammatory infiltrate with respect to DCs. We used CD11c-diphtheria toxin receptor (DTR) transgenic mice, which express the human diphtheria toxin receptor under the CD11c promoter, allowing for specific depletion of CD11c+ cells by administration of diphtheria toxin (DT). K/BxN serum transfer arthritis was induced, and mice were given either DT or PBS or in wt and BARF3 deficient mice. In addition CD11c DTR mice were crossed into hTNFtg animals and also received either DT or PBS. The severity of arthritis was determined clinically and histologically.

**Results:** We show that CD11c+ cells are present in significant numbers in the synovia of K/BxN and TNF driven arthritis. Both CD8+CD11c+ and CD11b+CD11c+, can be found in synovial tissue. Upon depletion of CD11c+ cells clinical signs of K/BxN serum transfer arthritis were significantly reduced. Histological analysis found reduced synovial inflammation after the depletion of CD11c+ cells in K/BxN arthritis. In addition, local bone destruction and the number of

osteoclasts was also significantly reduced. Analysis of K/BxN arthritis in wt mice and BATF3<sup>-/-</sup> mice, which lack a subset of DCs, namely CD8+CD11c+DCs, revealed no difference in arthritis severity between the two groups. In addition to K/BxN arthritis, we found that also in TNF-driven arthritis depletion of CD11c+ cells led to a striking reduction of synovial inflammation and a complete depletion of osteoclasts.

**Conclusions:** These data show that in addition to initiating an adaptive immune response, CD11c+ dendritic cells, are also involved in innate effector mechanisms of inflammatory arthritis. Especially CD11b+CD11c+ and monocyte derived inflammatory seem to play a role in inflammatory arthritis, suggesting that they could be an important therapeutic target for patients suffering from inflammatory arthritis.

#### THU0064 ANTIBODIES AGAINST CARBAMYLATED PROTEINS FROM PATIENTS WITH RHEUMATOID ARTHRITIS ACTIVATE ENDOTHELIAL CELLS

A. Pecani, T. Colasanti, F.R. Spinelli, C. Barbati, F. Conti, G. Valesini, C. Alessandri. Department of Internal Medicine and Medical Specialties, Rheumatology Unit, Sapienza University of Rome, Roma, Italy

**Background:** Inflammation contributes to the excess of cardiovascular morbidity in rheumatoid arthritis (RA), by promoting endothelial activation; this brings toward the production of adhesion molecules and the activation of signalling mediators. Antibodies against carbamylated proteins (anti-CarP) detected in RA patients correlate with subclinical atherosclerosis.

**Objectives:** Aims of the present study were: 1) to determine the effect of anti-CarP antibodies purified from the sera of RA patients, on the production of VCAM1 and ICAM1 as well as the activation of IRAK1 and NF- $\kappa$ B by human endothelial cell line EAhy926. 2) To evaluate endothelial cell apoptosis induced by anti-CarP.

**Methods:** An indirect ELISA was used to detect the presence of anti-CarP in the sera of RA patients. To purify anti-CarP, carbamylated-FCS used as an antigen was spotted onto a nitrocellulose filter and incubated with patient's sera that recorded the highest titer. Antibodies were eluted with glycine 100 mM, pH 2.5 and neutralised with Tris-HCl 1M, pH 8. Antibodies concentration was measured by using a colorimetric Bradford assay. The immortalised hybridoma cell line EAhy926 was cultured in Dulbecco's Modified Medium containing 10% fetal bovine serum, 1 mM l-glutamine, 100 U/ml penicillin and 10 ml HAT. After cell stimulation with purified anti-CarP at different time points (30 min-48 h) and different concentrations (5–20–50  $\mu$ g/ml), supernatants were gathered to investigate the production of VCAM-1, ICAM-1 using commercial ELISA kits while activation of IRAK1 and NF- $\kappa$ B was detected by Western Blot analysis using cell lysates. Apoptosis was measured using FITC-conjugated annexin V (AV) and a propidium iodide (PI) apoptosis detection kit at different times (30 min-48 h).

**Results:** After EAhy926 stimulation with anti-CarP we observed: 1) induction of VCAM-1 but not ICAM production in cell supernatants; 2) activation of IRAK1 and NF $\kappa$ B transcription factor in cell lysates and 3) induction of endothelial cell apoptosis.

**Abstract THU0064 – Figure 1.** Expression of adhesion molecules (A, B), activation of IRAK1 (C), NF $\kappa$ B (D) signalling and apoptosis (E) in EAhy 926.

**Conclusions:** These data suggest a potential involvement of anti-CarP antibodies in endothelial cell activation allowing to further speculate on its possible effect in excess cardiovascular risk in RA patients.

#### THU0065 RESULTS OF TREATMENT OF ARTHROSCOPIC AND TRADITIONAL SYNOVECTOMY OF THE KNEE JOINT IN RHEUMATOID ARTHRITIS

A. Kasimov, I. Khujanazarov. *Traumatology, Tashkent Medical Academy, Tashkent, Uzbekistan*

**Background:** Rheumatoid arthritis is a systemic inflammatory autoimmune disease of connective tissue with a predominant joint injury that occurs at any age, more often in women. It is characterised by a chronic course with periods of exacerbations and remissions

**Objectives:** To evaluate the results of arthroscopic and traditional synovectomy of the knee joint in patients with rheumatoid arthritis

**Methods:** The study involved 48 patients, 29 of them were women and 19 men, aged from 25 to 65 years old, who had a chronic synovitis of the knee joints. It was implemented at the department of traumatology, orthopaedics and GPH with neurosurgery of Tashkent Medical Academy and 1-Republic Clinical Hospital. In all patients, on the background of basic therapy and intraarticular injections of SCS, a persistent recurrent synovitis was formed within a few months. Sixteen patients underwent sinocapsulectomy (SCE) with the traditional method. 32 patients underwent arthroscopic synovectomy (ASE), for which the standard basic arthroscopic technique Dyonics (Smith and Nephew) was used. The functional condition of the knee joint before and after the operation was assessed using the KOOS scale (Knee and Osteoarthritis Outcome Score)

**Results:** The study showed that movements in the operated joint were allowed 3–5 hours after the operation, from the first day, isometric exercises were prescribed, active movements in the knee joint before the onset of pain. Results of treatment in terms of up to 3 months were tracked in all 48 patients. The degree of intraarticular changes determined by arthroscopy was evaluated according to the Outerbridge classification. In patients after SCE, pain in the joint, limiting the amplitude of motion, crunching during movement were noted. After ASE, there was a significant improvement in the function and condition of the knee joint: patients could walk for longer distances without additional support, did not experience discomfort while walking the stairs, complaints of pain, and no swelling. Repeated ASE with tunnelling was required in 2 patients with grade III chondromalacia

**Conclusions:** Thus, the SCE of the knee is indicated if the conservative treatment of recurrent synovitis in RA is unsuccessful for a long time. The ASE should be performed in the early stages of the RA, which drastically reduces the activity of the pathological process, makes it possible to maintain the functional capacity of the joint, and the timely adequate administration of the basic therapy allows the maximum achieved long-term functional result to be maintained for the longest time and reduces the risk of relapse and the need for repeated operations

#### THU0066 CIRCULATING MIRNAS AS POTENTIAL BIOMARKERS OF DISEASE AND CARDIOVASCULAR RISK IN RHEUMATOID ARTHRITIS PATIENTS

C. López-Pedreira<sup>1</sup>, N. Barroja<sup>1</sup>, P. Ruiz-Limón<sup>1</sup>, S. Remuzgo-Martínez<sup>2</sup>, I. Arias de la Rosa<sup>1</sup>, M.C. Ábalos-Aguilera<sup>1</sup>, Y. Jiménez-Gómez<sup>1</sup>, R. Ortega<sup>1</sup>, E. Collantes<sup>1</sup>, A. Escudero<sup>1</sup>, R. López-Mejías<sup>2</sup>, M.A. González-Gay<sup>2</sup>, C. Pérez-Sánchez<sup>1</sup>.

<sup>1</sup>IMBIC/Reina Sofía Hospital/University of Córdoba, Córdoba; <sup>2</sup>Hospital Universitario Marqués de Valdecilla. IDIVAL. Santander. Universidad de Cantabria, Santander, Spain

**Background:** Circulating miRNAs have been proposed as attractive candidates as both diagnostic and prognostic biomarkers in various diseases, including a spectrum of autoimmune and cardiovascular conditions. Yet, the contribution of

circulating miRNAs to the cardiovascular pathogenesis of Rheumatoid Arthritis (RA) patients and their potential role as biomarkers are still unknown.

**Objectives:** To identify circulating miRNAs as potential biomarkers of disease features and cardiovascular (CV) risk in RA.

**Methods:** Plasma samples of 48 healthy donors (HDs) and 124 RA patients were collected. In the discovery phase, an array of 2083 human miRNAs was performed by using HTG EdgeSeq miRNA Whole Transcriptome Assay (Next generation sequencing) in 9 plasma samples (3 HDs, and 6 RA patients). Then, differentially expressed miRNAs, were selected and validated by RT-PCR in the whole cohort of patients and HDs. Potential targets of the validated miRNAs were identified by using Ingenuity Pathway Analysis (IPA) software and analysed at protein levels (Multiplex Assay). Correlation and association studies of altered miRNAs with analytical and clinical variables were also performed.

**Results:** The miRNA whole Transcriptome assay showed that 360 miRNAs were differentially expressed in RA patients in relation to HDs, including 261 upregulated and 97 downregulated. Functional classification (IPA) demonstrated that deregulated miRNAs were mainly involved in processes such as inflammatory response, connective tissue development and function, haematological disease, tissue development, and immunological disease. Nine microRNAs, selected among the most differentially expressed in the array, were selected for validation in all the subjects recruited (miR-299, miR-567, miR-4293, miR-135b, miR-6816, miR-346, miR-143, miR-199a, miR-106a, miR-148b). *In silico* analyses showed that these miRNAs had potential targets related to cytokine signalling, atherosclerosis pathway and intracellular signalling. The altered levels of selected miRNAs and its putative target proteins were validated in the whole cohort of patients.

A number of serum miRNAs in all the RA patients analysed were found inter-related and associated to autoimmunity (positivity for anti-CCPs and RF), bone erosion, inflammation (CRP, ESR, TNF $\alpha$ , IL6, IL8, IFN and IL-2), and evolution time. We could further identify a specific signature of four miRNAs (miR143, miR106, miR148b and miR567) that identified RA patients that had suffered previous CV events and specifically associated with the increase in the carotid intima-media thickness (CIMT) and with 'Framingham CV risk factors' such as diabetes, obesity or dyslipidemia.

**Conclusions:** We have branded novel and specific circulating miRNAs related to disease features and CV risk in RA patients, including, their autoimmune and inflammatory profile, the presence of Framingham risk factors and incipient atherosclerosis. These circulating miRNAs might be thus considered useful tools for the management of the disease in this autoimmune condition.

#### THU0067 ASSOCIATION OF HIGH TITERS OF ANTI-CARBAMYLATED PROTEINS ANTIBODIES WITH DECREASED BONE MINERAL DENSITY IN EARLY ARTHRITIS PATIENTS

I. Arias de la Rosa<sup>1</sup>, A.M. Ortiz<sup>2</sup>, M.D. Boveda<sup>1</sup>, S. Castañeda<sup>2</sup>, I. González-Alvaro<sup>2</sup>, A. González<sup>1</sup>. <sup>1</sup>Instituto Investigación Sanitaria- H. Clínico Universitario de Santiago, Santiago de Compostela; <sup>2</sup>Hospital Universitario La Princesa – ISS-IP, Madrid, Spain

**Background:** Rheumatoid arthritis (RA) has a negative impact on bone homeostasis, in which multiple inflammatory mediators are involved together with the anti-citrullinated proteins antibodies (ACPA). These antibodies are able to promote osteoclastogenesis and bone loss even before the onset of synovitis. Accordingly, ACPA are associated with the three aspects of bone loss: joint bone erosion, juxta-articular bone loss and, as recently demonstrated<sup>1</sup>, decreased bone mineral density (BMD). Other RA specific autoantibodies, the anti-carbamylated protein antibodies (anti-CarPA), are associated with the presence, severity and progression of erosions with independence of ACPA. However, their implication in the other aspects of bone loss has not been studied.

**Objectives:** To evaluate the association of anti-CarPA with BMD in a cohort of early arthritis (EA) patients.

**Methods:** Clinical data and samples were obtained at the first visit of 548 patients from the Princesa Early Arthritis Register Longitudinal (PEARL) study, which recruits patients within one year from arthritis onset. BMD was assessed by dual-energy x-ray absorptiometry (Hologic QDR-4500, Elite, Mass, USA) at the lumbar spine (LS), total hip (TH) and metacarpophalangeal (MCP) joints. BMD was considered as Z-scores, except for MCP due to lack of reference data. Anti-CarPA were determined by ELISA using carbamylated fetal calf serum. The ELISA results were considered as negative, below the 98 percentile of healthy controls, low-positive, below the median of positive patients, and high-positive, otherwise. Data were analysed with linear regression including sex, age, BMI, and menopause as covariates.

**Results:** Anti-CarPA were positive in 25.9% of the EA patients. The positive patients did not show significant differences in BMD with the negative patients.

However, this lack of association was due to the similarity of negative and low-positive patients, because the high-positive patients showed significant decrease of BMD at LS ( $\beta = -0.39$ ,  $p = 0.01$ ) and TH ( $\beta = -0.30$ ,  $p = 0.02$ ). Nevertheless, we did not find significant association at the juxta-articular bone of the MCP joints. Given the overlap between anti-CarPA and ACPA, we included the two autoantibodies in multivariate analysis. The association with BMD was significant only in the ACPA positive/anti-CarPA high-positive subgroup at LS and TH ( $p = 0.007$  and  $0.005$ , respectively). In addition, the coefficients of regression were similar between the ACPA positive/anti-CarPA high-positive and the ACPA negative/anti-CarPA high-positive subgroups ( $\beta = -0.50$  vs.  $-0.52$  at LS, and  $\beta = -0.37$  vs.  $-0.30$  at TH).

**Conclusions:** We found significantly lower BMD at LS and TH in the patients with high anti-CarPA titers. These associations seem to be independent from the presence of ACPA, suggesting that anti-CarPA could contribute to systemic bone loss in EA patients.

#### THU0068 IDENTIFICATION AND VERIFICATION OF BIOMARKER CANDIDATES FOR MONITORING RHEUMATOID ARTHRITIS ACTIVITY BY MASS SPECTROMETRY

L. González-Rodríguez<sup>1</sup>, V. Calamia<sup>1</sup>, P. Fernández-Puente<sup>1</sup>, C. Ruiz-Romero<sup>1</sup>, L. Lourido<sup>1</sup>, M. Camacho-Encina<sup>1</sup>, A. Juliá<sup>2</sup>, A. Fernández-Nebro<sup>3</sup>, J. Tomero<sup>4</sup>, S. Marsal<sup>2</sup>, F.J. Blanco<sup>1</sup>, on behalf of IMID Consortium. <sup>1</sup>Unidad de Proteómica-ProteoRed/ISCIII, Grupo de Investigación en Reumatología, INIBIC – CHUAC, A Coruña; <sup>2</sup>Rheumatology Research Group, Vall d'Hebron Hospital Research Institute, Barcelona; <sup>3</sup>UGC Reumatología, Instituto de Investigación Biomédica (IBIMA), Hospital Regional Universitario de Málaga, Málaga; <sup>4</sup>Hospital Universitario Guadalajara, Guadalajara, Spain

**Background:** Rheumatoid arthritis (RA) is a long-lasting inflammatory autoimmune disorder that ultimately leads to the destruction of joint architecture. The activity of this disease is measured by the assessment of clinical symptoms.

**Objectives:** To apply a proteomic strategy to find serum biomarkers able to discriminate patients with different RA activities.

**Methods:** To facilitate the complex measurement of serum by proteomics, a simple, fast and reproducible albumin-specific depletion method using ethanol was optimised and applied to the samples employed in this study. 80 samples from the IMID consortium, classified according to the DAS28 score into low activity<sup>40</sup> and high activity<sup>40</sup> were analysed by mass spectrometry. Four independent pools of the high RA activity samples (10 samples per pool) and 4 pools of the low RA activity samples were firstly albumin-depleted, and then the remnant serum proteins were digested and differentially labelled with iTraQ 8-plex reagents. Subsequently, the 8 labelled pools were combined and cleaned using StageTips-C18. Finally, the pool mixture was fractionated by HPLC (Zorbax-C18) and the resulting fractions were analysed by nanoLC-MS/MS using MALDI-TOF/TOF, TripleTOF and LTQ-Orbitrap.

**Results:** The mass spectrometry analysis led to the identification of 186 proteins. In this screening step, the abundance of 9 proteins was found to be significantly different between patients with high (H) and low (L) RA activity. Orthogonal experiments, using Western Blot, protein bead arrays and Multiple Reaction Monitoring (MRM) with synthetic heavy-labelled peptides, were conducted in order to verify some of these biomarker candidates of RA activity. The results obtained from the verification phase, conducted by MRM on 50 samples from the same cohort, show a decrease of Apolipoprotein B (ratio H/L=0.84,  $p = 0.00$ ), Histidine Rich Glycoprotein (ratio H/L=0.86,  $p = 0.01$ ) and Plasma protease C1 inhibitor (ratio H/L=0.84,  $p = 0.02$ ). Furthermore, this verification phase shows also an increase of Haptoglobin (ratio H/L=1.34,  $p = 0.01$ ) and Serum Amyloid A1 (ratio H/L=1.64,  $p = 0.05$ ), in accordance with that observed in the screening. These proteins are related with the RA process and the effects caused by this type of disease (inflammation and immune disorder in joints).

**Conclusions:** In this proteomic study, 5 proteins were found to be quantitatively altered between patients with high and low RA activity using shotgun and targeted mass spectrometry.

**Disclosure of Interest:** None declared

#### THU0069 IN RA, BECOMING SERONEGATIVE OVER THE 1ST YEAR OF DMARD TREATMENT DOES NOT TRANSLATE TO BETTER CHANCES OF SUSTAINED DRUG-FREE REMISSION IN THE LONG-TERM

E.C. de Moel<sup>1</sup>, V. F. A. M. Derksen<sup>1</sup>, L.A. Trouw<sup>2</sup>, H. Bang<sup>3</sup>, Y.P. Goekoop-Ruiterman<sup>4</sup>, G.M. Steup-Beekman<sup>1</sup>, T.W.J. Huizinga<sup>1</sup>, C.F. Allaart<sup>1</sup>, R.E.M. Toes<sup>1</sup>, D. van der Woude<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Immunohematology and Blood Transfusion, Leiden University Medical Center, Leiden, Netherlands; <sup>3</sup>Orgentec Diagnostika GmbH, Mainz, Germany; <sup>4</sup>Rheumatology, Haga Hospital, The Hague, Netherlands

**Background:** In rheumatoid arthritis (RA), autoantibodies are a reflection of the underlying B cell autoimmunity and an important predictor of long-term outcome. Baseline seropositivity is a poor prognostic factor for sustained drug-free remission (SDFR). However, autoantibody levels may change and patients may become seronegative under treatment. It is unknown how often this happens and whether some autoantibodies (depending on isotype use or antigen recognition) disappear more often than others. Furthermore, it is unclear whether becoming seronegative early in disease, indicating disappearance of serological autoimmunity, improves chances of SDFR.

**Objectives:** To longitudinally characterise the levels and presence of autoantibodies in RA patients and to investigate whether changes in these levels and/or presence associates with SDFR.

**Methods:** In sera of 399 seropositive RA patients in the IMPROVED study<sup>1</sup>, we measured, at 4-month-intervals over the first year of treatment: IgG, IgM, and IgA isotypes for anti-cyclic citrullinated peptide-2 (anti-CCP2) and anti-carbamylated protein antibodies (anti-CarP), IgM and IgA for rheumatoid factor (RF), and IgG autoantibodies against 4 citrullinated and 2 acetylated peptides. We investigated whether changes in antibody levels and seroconversion from positive to negative for each individual antibody was favourable for SDFR (drug-free DAS44 <1.6 lasting  $\geq 1$  year until last follow-up).

**Results:** For all 14 antibodies, median levels decreased significantly between baseline and 4 months and then stabilised. Most seroconversion to negative happened within the first 4 months of treatment (with prednisone and methotrexate), after which some patients converted back to seropositive. The prevalence of seroconversion varied substantially depending on the autoantibody. The percentage of patients who were seropositive at baseline and became seronegative by 12 months varied substantially depending on the autoantibody: 2% (anti-CCP2 IgG) to 66% (anti-CarP IgA) (see figure 1). We hypothesised that greater level decreases and seroconversion to negative might be favourable for the long-term outcome SDFR, but surprisingly, greater median decreases in levels were not associated with higher chance of SDFR for any antibody. Furthermore, using Chi-squared tests, we found no evidence that rates of SDFR were higher in patients who seroconverted to negative compared to those who stayed seropositive, for any of the 14 antibodies analysed (see figure 1).

Abstract THU0069 – Figure 1. Percentage of patients reaching SDFR (drug-free DAS44 <1.6 lasting  $\geq 1$  year until last follow-up), separated by whether patients

seroconverted from positive to negative ("Pos to neg") or remained positive ("Stable pos") or for the specified antibody, between 0–12 months.

anti-CCP2=Anti cyclic citrullinated peptide-2; RF=rheumatoid factor, anti-CarP=anti carbamylated protein antibodies; Anti-cit. pept. Abs=anti citrullinated peptide antibodies; Anti-acetyl. pept. Abs=anti acetylated peptide antibodies (IgG).

**Conclusions:** Autoantibody levels decrease and seroconversion from positive to negative occurs under treatment, but these changes do not translate to apparent clinical long-term benefits with regard to SDFR. This suggests that the disappearance of measurable serological autoimmunity does not lead to eradication of disease.

#### THU0070 THE TRANSCRIPTION FACTORS IKAROS AND AIOLOS ARE EXPRESSED IN THE SYNOVIAL MEMBRANE OF EARLY RHEUMATOID ARTHRITIS PATIENTS IN ASSOCIATION WITH SYNOVIAL LYMPHOID AGGREGATES

F. Rivellese<sup>1</sup>, M. Congia<sup>2</sup>, D. Mauro<sup>1</sup>, M. Bombardieri<sup>1</sup>, M. Lewis<sup>1</sup>, C. Pitzalis<sup>1</sup>.

<sup>1</sup>Centre for Experimental Medicine and Rheumatology, William Harvey Research Institute, Barts and the London School of Medicine And Dentistry, London, UK;

<sup>2</sup>Rheumatology Unit, University and AOU of Cagliari, Monserrato, Italy

**Background:** IKZF1 (Ikaros) and IKZF3 (Aiolos) are transcription factors acting as regulators of the immune system development. Specifically, they are essential for the maturation, differentiation and survival of B cells. Polymorphisms of IKZF1 and 3 have been linked to systemic autoimmunity, and they are being explored as therapeutic targets in Systemic Lupus Erythematosus. However, their involvement in other autoimmune diseases is currently unknown.

**Objectives:** To evaluate the expression of IKZF1 and 3 in the synovia of patients with early Rheumatoid Arthritis (RA) naïve to treatment, in correlation with the clinical phenotype, including treatment response.

**Methods:** DMARD-naïve patients with early (<12 months) RA (n=41) fulfilling the 2010 ACR/EULAR criteria were recruited as part of the Pathobiology of Early Arthritis Cohort at Barts Health NHS Trust. Sections of paraffin embedded synovial tissue obtained by ultrasound-guided synovial biopsy were stained by immunohistochemistry (IHC) for IKZF1 and IKZF3, and a semi-quantitative score (0–3) was used to classify patients (IKZF1 +ve or IKZF3 +ve cells/visual field <5=0; 5–20=1; 20–50=2; >50=3). Sequential sections were stained by IHC for immune cells and patients were categorised into 3 synovial pathotypes according to the following criteria: i) Lymphoid (L) presence of grade 2–3 CD20+aggregates, (CD20 ≥2) and/or CD138 >2; ii) Myeloid (M) CD68SL ≥2, CD20 ≤1 and/or CD3 ≥1, CD138 ≤2 and iii) Fibroid (F) CD68SL <2 and CD3, CD20, CD138 <1.

**Results:** Ikaros and Aiolos were expressed in the synovia of 43.1% and 56.7% of early RA patients, respectively. IKZF1 +ve patients (defined as IKZF1 score ≥2) showed a higher prevalence of a lymphoid pathotype (9/9 in IKZF1 +ve vs 4/22 in IKZF1 -ve, p<0.001) and a higher prevalence of ACPA (9/9 vs 13/22, p=0.04) and RF (9/9 vs 12/22, p=0.02). IKZF3 +ve patients showed a similar association with local and systemic inflammation and autoantibody positivity. As shown in table 1, ikaros and aiolos synovial scores were significantly correlated with synovial cell infiltrate and systemic inflammation. Remarkably, ikaros showed a significant correlation with the baseline Sharp score. Accordingly, patients with high expression of Ikaros (sq score ≥2) had a significantly higher Sharp score (mean ±SD 4.75 ±3.3 vs 1.33±2.54, p=0.008).

**Conclusions:** Here, we show the expression of the transcription factors Ikaros and Aiolos in the synovia of early RA patients in correlation with lymphoid aggregates and systemic inflammation, and, for Ikaros, with baseline radiographic erosions. While additional analyses are needed in order to confirm the expression and function of ikaros and aiolos by synovial immune cells, our preliminary work suggest that they might be relevant in the pathogenesis of RA and therefore be considered as therapeutic targets in a subset of patients.

#### MUSCLE LIPOTOXICITY ON SARCOPENIA DEVELOPMENT IN A MODEL OF COLLAGEN-INDUCED ARTHRITIS

G. Via<sup>1</sup>, A. Pinef<sup>2</sup>, D. Bechet<sup>2</sup>, F. Wauquier<sup>2</sup>, Y. Wittrant<sup>2</sup>, C. Chevenet<sup>3</sup>, M. Soubrier<sup>1,2</sup>, A. Toumadre<sup>1,2</sup>, F. Capel<sup>2</sup>. <sup>1</sup>Rheumatology, CHU Gabriel Montpied, <sup>2</sup>INRA, <sup>3</sup>Anatomical Pathology, CHU Gabriel Montpied, Clermont Ferrand, France

**Background:** Alterations of body composition in Rheumatoid arthritis (RA) may contribute to the development of cardiometabolic disorders. RA patients have a decrease in muscle mass with a preserved or increased fat mass, notably accumulation of ectopic fat in the muscles, which define the sarcopenic obesity. The mechanisms leading to this sarcopenic obesity phenotype remain poorly understood. Accumulation of intramuscular lipids and the formation of lipotoxic compounds may affect intracellular signalling pathways and energy production, alter protein synthesis and thus promote sarcopenia.

**Objectives:** Our objective was to determine if muscular lipotoxicity promotes the development of sarcopenia in joint inflammatory condition, using rats with collagen-induced arthritis.

**Methods:** Male Sprague Dawley rats were divided into a control group (CO, n=12) and a collagen-induced arthritis group (CIA, n=11). After 5 weeks, hind leg muscles and epididymal adipose tissue were removed. Tissues were weighed at sacrifice and stored for histological analyses and evaluation of mitochondrial function, lipotoxicity, protein and gene expression levels. Statistical analyses were performed with t-test.

**Results:** Animals, adipose tissue and muscle weights tended to be lower in the CIA group. Only EDL muscle weight was significantly lower in the CIA group (p=0.05). Muscle histological analyses showed larger CSA (cross sectional area) in CO group. In the CIA group we observed a nonhomogeneous distribution of muscle fibre CSA with a predominance of small fibres (figure 1). Mean perimeter and mean diameter were also significantly decrease in CIA group but the shape of fibres remained similar between groups. Furthermore, there was an increased expression of MAFBx (a marker of catabolism) mRNA (40%, p=0.04) in the CIA group, while MyoD (a myogenesis marker) mRNA was decreased by 18% (p=0.01), indicating a catabolic state. Lipid content analysis showed an accumulation of intramuscular TAG (x 1.5, p=0.05), as well as an increased expression of cellular fatty acid transporter FATP1 (about 35%, p=0.01) and mitochondrial fatty acid transporter CPT1b (about 27%, p=0.02). Mitochondrial DNA copy number was decreased by 27% in CIA rats (p=0.01) and complex IV activity of mitochondrial respiratory chain also tended to be reduced in CIA group (-20%, p=0.18).

**Abstract THU0071 – Figure 1.** Fibre cross sectional area distribution

**Conclusions:** Collagen-induced arthritis induced fibres alterations in skeletal muscle. The association of increased muscle protein catabolism, mitochondrial dysfunction and fatty acid accumulation in skeletal muscle of animals with arthritis supports the hypothesis that lipotoxicity is involved in sarcopenia development during joint inflammation.

### GENE SIGNATURE OF PLASMACYTOID DENDRITIC CELLS REVEALS NOVEL PATHWAYS CONTRIBUTING TO TOLERANCE IN RHEUMATOID ARTHRITIS PATIENTS

G. Papadaki<sup>1</sup>, P. Goutakoli<sup>1</sup>, J.R. Grün<sup>2</sup>, A. Grützkau<sup>3</sup>, A. Fanouriakis<sup>1</sup>, G. A. Pavlopoulos<sup>4</sup>, I. Iliopoulos<sup>4</sup>, G. Bertias<sup>1</sup>, D. Boumpas<sup>5</sup>, P. Sidiropoulos<sup>6</sup>, P. Veginis<sup>7</sup>. <sup>1</sup>Medical School, University of Crete, Heraklion, Crete, Greece; <sup>2</sup>Bioinformatics; <sup>3</sup>Immune monitoring, German Rheumatism Research Centre, Berlin, Germany; <sup>4</sup>Division of Basic Sciences, Medical School, University of Crete, Heraklion, Crete; <sup>5</sup>4th Department of Medicine– Attikon University Hospital, National and Kapodestrian University of Athens, Athens; <sup>6</sup>Department of Rheumatology, Medical school, University of Crete, Heraklion, Crete; <sup>7</sup>Division of Immunobiology, Biomedical Research Foundation Academy of Athens, Athens, Greece

**Background:** Reestablishing immune tolerance and long term remission represent major therapeutic goals in rheumatoid arthritis (RA). Our laboratory previously demonstrated that plasmacytoid dendritic cells (pDCs) from RA patients in remission have the ability to induce IL-10 producing regulatory T cells (Tregs) *in vitro*.<sup>1</sup> However, the molecular pathway of RA pDC-mediated Treg induction remains elusive.

**Objectives:** Herein, we sought to identify the molecular mechanism through which pDCs contribute to restoration of tolerance in RA.

**Methods:** pDCs were isolated from peripheral blood of RA patients responding to anti-TNF therapy (remission based on disease activity score DAS28 <5.1) and healthy control subjects and DNA microarrays were performed. Flow cytometry and real time PCR were used to verify the expression of de-regulated genes in RA pDCs. Finally, *in vitro* cultures of pDCs activated with CpG A in the presence or absence of recombinant IL-6 (rIL-6) were performed to assess the functional importance of these gene signatures.

**Results:** pDCs from RA patients (n=5) exhibited a differential gene signature (6741 deregulated genes) compared to pDCs from healthy controls (n=5). Notably, IL-6 receptor (IL-6R) gene, exhibited increased expression levels in pDCs isolated from RA patients compared to healthy pDCs and the surface expression levels of IL-6 receptor were verified in a subsequent cohort of patients responding to therapy (n=9) versus active patients or healthy donors. Moreover, assessment of IL-6 signalling pathway in RA patients versus healthy donors revealed a significant increase of pSTAT1 expression levels in RA patients (n=9) compared with healthy donors (n=6) (mean fluorescence intensity  $\pm$ SEM, 7.98 $\pm$ 0.8 versus 12.65 $\pm$ 1.18, p value=0.0076). Importantly, IL-6-treated pDCs exhibited a vast decrease in TNF- $\alpha$  production (p value=0.0002) whereas no differences were found in the production of IFN- $\alpha$  and in their antigen presenting capacity between CpG-treated pDCs in the presence or absence of rIL-6. Moreover, confocal experiments in progress will assess the expression levels of TNF- $\alpha$  in pDCs isolated from RA patients in remission versus active or healthy donors. The functional importance of the previous findings will be addressed in coculture experiments of IL-6 stimulated pDCs with monocytes isolated from healthy donors and monitor their activation and maturation status.

**Conclusions:** We found that pDCs from RA patients in remission display increased IL-6R expression levels and an activated IL-6 signalling pathway. Activation of IL-6 signalling on pDCs *in vitro* significantly decreases the production of TNF- $\alpha$  whereas it does not alter IFN- $\alpha$  production and their antigen presenting capacity. This novel finding and the underlying mechanism that may drive pDCs towards a previously described tolerogenic phenotype, need to be further addressed.

### A SUBSET OF NEUTROPHIL HIGHLY EXPRESSING CD49D AND VEGFR1 CAN ENHANCE PANNUS FORMATION VIA INCREASE FLS MIGRATION AND INVASION ABILITY BY UP-REGULATING MMP3 AND 13

H.Y. Li<sup>1</sup>, Y.L. Cao<sup>2</sup>, X. cao<sup>1</sup>, C.L. su<sup>1</sup>, Q.P. yang<sup>1</sup>, Q.P. yang<sup>1</sup>, Y. liu<sup>1</sup>, B.Y. luo<sup>1</sup>, Y. zhao<sup>1</sup>, T.N. Marion<sup>3</sup>. <sup>1</sup>Department of Rheumatology and Immunology, West China Hospital, Sichuan University; <sup>2</sup>State Key Laboratory of Biotherapy, Sichuan University, Chengdu, China; <sup>3</sup>Department of Microbiology, Immunology, and Biochemistry, The University of Tennessee Health Science Center, Tennessee, USA

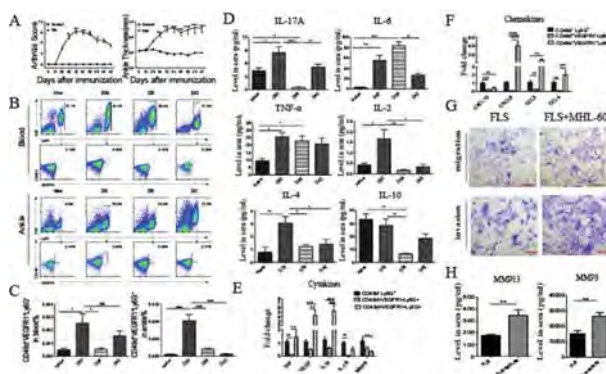

**Background:** Neutrophil is known to play an important role in the progression of rheumatoid arthritis (RA). Pannus formation requires hypoxia microenvironment

(<sup>1,2</sup>) and a small population of neutrophil highly expressing CD49d, VEGFR1 and CXCR4 is reported to induce angiogenesis at the sites of hypoxia(<sup>3</sup>).

**Objectives:** In the current study, we aim to identify this subset of neutrophil and investigate its function and role during the pannus formation.

**Methods:** Collagen-induced arthritis (CIA) model was applied in this study and CD49d<sup>+</sup>VEGFR1<sup>+</sup>Ly6G<sup>+</sup> neutrophil was monitored at the onset and remission of arthritis. The levels of IL-17, IL-4, IL-6, IL-10, TNF- $\alpha$  and IFN- $\gamma$  in CIA model sera were tested by ELISA at day 30, 36 and 42, respectively. mRNA expressions of cytokines including TNF- $\alpha$ , VEGF, IL18 and MMP9 were detected by RT-PCR. Meanwhile, chemokines genes of CXCL10, CXCL9, CLL3 and CLL4 expressed in CD49d<sup>+</sup>VEGFR1<sup>+</sup>neutrophil were also measured. *In vitro*, synovial fibroblast-like cells (FLS) was co-cultured with MHL60, expressing CD49d and VEGFR1, and the migration and erosion was measured.

**Results:** CD49d<sup>+</sup>VEGFR1<sup>+</sup> neutrophil was detected in the peripheral blood and ankle at various time points with the peak on day 30. The gene expression of TNF $\alpha$ , VEGF, IL-18 as well as CXCL10, CXCL9, CLL3 and CLL4 was significantly increased in CD49d<sup>+</sup>VEGFR1<sup>+</sup> neutrophil. Pre-coculture with MHL60 was able to increase FLS migration and erosion. Meanwhile, the expression of MMP13, MMP3 was robustly enhanced at the mRNA and protein level.

**Conclusions:** A subset of neutrophil highly expressing CD49d and VEGFR1 was detected for the first time in CIA mice. CD49d<sup>+</sup>VEGFR1<sup>+</sup> neutrophil is able to secrete various chemokine and cytokines. Meanwhile, it can enhance FLS migration and invasion ability via up-regulating MMP3 and 13.

### EFFECTS OF RITUXIMAB ON THE INFLAMMATORY AND PRO-THROMBOTIC PROFILES OF NON-B CELLS OF THE IMMUNE AND VASCULAR SYSTEMS OF RHEUMATOID ARTHRITIS AND SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

I. Cecchi<sup>1</sup>, C. Pérez-Sánchez<sup>2</sup>, M. Á. Aguirre<sup>2</sup>, L. Pérez-Sánchez<sup>2</sup>, P. Ruiz-Limón<sup>2</sup>, I. Arias de la Rosa<sup>2</sup>, M.C. Ábalos-Aguilera<sup>2</sup>, Y. Jiménez-Gómez<sup>2</sup>, R. Ortega<sup>2</sup>, E. Collantes<sup>2</sup>, A. Escudero<sup>2</sup>, M. Radin<sup>1</sup>, N. Barbarroja<sup>2</sup>, D. Roccatello<sup>1</sup>, S. Sciascia<sup>1</sup>, C. Lopez-Pedraza<sup>2</sup>. <sup>1</sup>University of Turin, Turin, Italy; <sup>2</sup>IMBIC/Reina Sofia Hospital/University of Cordoba, Cordoba, Spain

**Background:** Treatment with B-cell depletion, including rituximab (RTX), has been proven successful in achieving remission from the active disease in Rheumatoid Arthritis (RA) and Systemic Lupus Erythematosus (SLE) patients. However, the effect of RTX on the Cardiovascular disease (CVD) associated to both autoimmune conditions has not been elucidated yet. The aim of this study was to investigate whether B-cell depletion therapy with RTX has an impact on activation of non-B cells of the immune and vascular systems in the context of CVD in RA and SLE patients

**Methods:** The analysis was carried out in plasma and purified leucocytes from 25 subjects, including 12 RA and 13 SLE patients. To evaluate the influence of B-cells depletion on the inflammatory profile of T-cells, purified lymphocytes from 6 RA and 7 SLE patients were treated with RTX (1 µg/ml) for 24 hours. B-cells depletion was assessed by flow cytometry and the changes occurred in the inflammatory profile of T cells were analysed by RT-PCR. The changes promoted in the activity of key intracellular regulators of pro-inflammatory cytokines were analysed by western blot in proteins purified from lymphocytes. In a second set of experiments, supernatants from cultured lymphocytes of 6 RA and 7 SLE patients was added—either, in the presence or in the absence of RTX—to cultured endothelial cells (HUVECs), monocytes, and neutrophils isolated from Healthy Donors (HDs) and incubated for 6 hour. The changes induced in the inflammatory/pro-thrombotic profile of these cells was analysed by RT-PCR. Finally, serum obtained from 6 RA and 6 SLE patients at baseline and after 3 months of therapy with RTX, was added to HUVECs, monocytes, and neutrophils isolated from HDs and the response was analysed by RT-PCR

**Results:** In parallel to the significant decline of B-cells, a downregulation of the pro-inflammatory profile of T-lymphocytes from RA and SLE patients was demonstrated, revealed by the significant drop of IL1, IL6, IL17, IFN $\gamma$ , and TNF $\alpha$  gene expression levels. A decrease in the phosphorylation status and protein expression levels of STAT-3 and p38 was also found in T-cells treated with RTX. HUVECs, monocytes, and neutrophils incubated with the supernatant of RTX-treated lymphocytes from RA and SLE patients showed a decrease in the expression levels of various pro-thrombotic factors (i.e. TF, IL8, and VEGF) and cell-adhesion molecules (i.e. V-CAM, I-CAM and e-Selectin). Likewise, HUVECs, monocytes, and neutrophils treated with serum of RA and SLE patients after 3 months of therapy with RTX, showed a reduced expression of genes related to their pro-thrombotic and pro-inflammatory profiles

**Conclusions:** Depletion of B-cells induced by RTX might promote a beneficial effect in the CV risk-profile of RA and SLE patients through the modulation of the inflammatory and pro-thrombotic shapes of leukocytes and vascular endothelial cells

**THU0075** **IMPACT OF OBESITY ON RHEUMATOID ARTHRITIS (RA) ONSET AND PROGRESSION. IN VIVO AND IN VITRO EFFECTS OF SYNTHETIC DMARDS ON THE RA-ASSOCIATED METABOLIC ALTERATIONS**

*I. Arias De La Rosa, M. Ruiz-Ponce, A. Escudero, P. Ruiz-Limón, C. Pérez-Sánchez, M.D.C. Ábalos-Aguilera, Y. Jiménez-Gómez, E. Collantes, C. López-Pedreira, N. Barbarroja. Rheumatology service, IMBIC/Reina Sofía Hospital/University of Córdoba, Córdoba, Spain*

**Objectives:** 1) To evaluate the impact of obesity in RA onset and progression, 2) To analyse the *in vivo* effects of synthetic disease-modifying antirheumatic drugs (sDMARDs) on the obesity and IR in an obese collagen-induced arthritis (CIA) mouse model. 3) To study the *in vitro* effects of sDMARDs on the lipid and glucose homeostasis in adipose tissue (AT).

**Methods:** CIA was developed in obese and lean mice. 55 C57Bl/6 mice (4–5 weeks) were used. Forty-one mice were fed with high fat diet (60%) until reaching 30 g (obese) (OB). OB-mice were treated with leflunomide (LFN)(10 mg/kg daily), methotrexate (MTX)(3 mg/kg three times/week) or hydroxychloroquine (HCQ) (60 mg/kg daily) for 15 days. After treatment, glucose tolerance test (GTT) was performed. Buffy coat, plasma and adipose tissue (AT) samples were collected. 3 T3-L1 adipocytes were treated with serum from RA patients (10%) alone or in combination with sDMARDs at day 9 of differentiation. Human subcutaneous AT samples were treated *ex vivo* with serum from RA patients (10%) alone or in combination with sDMARDs. Protein and gene expression of molecules involved in inflammation, insulin signalling and lipid accumulation was analysed through RT-PCR, western blot and ELISA in all the experiments.

**Results:** CIA-OB mice developed the arthritis earlier and more severe compared with CIA-lean mice. On the hand, arthritis increased the systemic levels of inflammation and HOMA-IR of OB-mice. The induction of arthritis in OB mice increased the inflammatory burden, accompanied by a reduction of genes involved in insulin signalling and lipid accumulation, inducing an aggravation of the insulin resistance (IR) state in AT.

The therapies more effective inhibiting the generation of inflamed digits were HCQ and MTX. HCQ significantly reduced the body weight, accompanying by a reduction in insulin and glucose plasma levels leading to a decrease of HOMA-IR values. AT of CIA-OB mice treated with MTX and HCQ had restored levels of genes involved in lipid accumulation, adipogenesis and insulin signalling.

Serum from RA patients elevated the levels of inflammatory markers, reduced the expression of genes related to lipid accumulation, adipogenesis and insulin signalling in 3 T3L1 adipocytes. Although LFN, MTX and HCQ *in vitro* treatment reduced inflammation, only MTX and HCQ regulated insulin sensitivity and lipid accumulation. These results were recapitulated in *ex vivo* treatments in human AT explants.

**Conclusions:** 1) Obesity accelerates the development and aggravates the outcome of the arthritis in mice. Arthritis exacerbates the inflammatory burden and the metabolic alterations in an obesity context. 2) *In vivo*, HCQ promotes a beneficial effect on the metabolism of CIA-OB mice, improving the insulin sensitivity at systemic and AT levels and reducing body weight. 3) *In vitro*, HCQ and MTX revert the metabolic alterations induced by RA serum in AT. Thus, HCQ and MTX might be considered as a valuable therapeutic strategy in RA patients to ameliorate the metabolic complications associated.

**THU0076** **ANTIBODIES TO CITRULLINATED PROTEIN ANTIGENS (ACPAS) INDUCE ADIPOSE TISSUE DYSFUNCTION IMPAIRING ADIPOCYTE DIFFERENTIATION, LIPID ACCUMULATION AND PROMOTING MACROPHAGE POLARISATION. IN VITRO EFFECT OF BIOLOGIC DMARDS**

*I. Arias De La Rosa, M. Ruiz-Ponce, P. Ruiz-Limón, Y. Jiménez-Gómez, C. Pérez-Sánchez, I. Cecchi, M.D.C. Ábalos-Aguilera, E. Collantes-Estévez, A. Escudero, C. López-Pedreira, N. Barbarroja. Rheumatology service, IMBIC/Reina Sofía Hospital/University of Córdoba, Córdoba, Spain*

**Background:** Adipose tissue (AT) dysfunction is an important determinant of inflammation- or lipid-induced metabolic complications. Rheumatoid arthritis (RA) is closely associated with metabolic comorbidities such as obesity or insulin resistance (IR). ACPAs are involved in the development of cardiovascular disease associated to this disorder. However, the role of ACPAs on the adipose tissue (AT) function is unravelled.

**Objectives:** 1) To analyse the direct effects of ACPAs on the AT function: adipocyte differentiation, macrophage polarisation and lipid accumulation, and 2) To evaluate the effects tocilizumab (TCZ) or infliximab (IFX) on the metabolic alterations induced by ACPAs on AT.

**Methods:** IgGs-NHS (Normal Human Serum) and IgGs-ACPAs were isolated from serum of 20 controls and 20 RA patients. 3 T3-L1 fibroblast were treated with IgG-NHS or IgG-ACPAs alone or in combination with IFX or TCZ during several stages of the differentiation to adipocytes (day 0 and day 9). Lipid accumulation was analysed by oil red 0 (ORO) staining. M0 macrophages from THP-1 cells were treated with IgG-NHS or IgG-ACPAs alone for 12 hour or in combination with IFX and TCZ for another 12 hour. Macrophage polarisation was analysed by flow cytometry. Visceral and subcutaneous AT samples were obtained from 8 obese patients through bariatric surgery. AT samples were treated *ex vivo* with IgGs-NHS or IgG-ACPAs alone or in combination with biological DMARDs. Protein and gene expression of molecules involved in adipogenesis, inflammation, insulin signalling and lipid accumulation was analysed through RT-PCR, western blot and ELISA in all the experiments.

**Results:** *In vitro* treatment of M0 macrophages with IgG-ACPAs induced M1 polarisation state and impaired insulin signalling. 3 T3-L1 fibroblast treated with IgG-ACPAs at day 0 showed an impaired adipocyte differentiation shown by a reduction of genes involved in adipogenesis and lipid accumulation. Levels of accumulated lipids were also significantly reduced. Likewise, genes involved in insulin signalling were reduced. Treatment with IFX and TCZ after differentiation reverted the expression of these genes. At human adipose tissue level, the treatment with IgGs-ACPAs increased the levels of inflammatory markers, accompanied by a downregulation of genes involved in lipid accumulation, adipogenesis and insulin signalling. After treatment with biological DMARDs, inflammatory and metabolic alterations were reverted on human AT explants.

**Conclusions:** 1) ACPAs impairs AT function, acting in both, macrophages and adipocytes, inducing M1 macrophage polarisation and impairing adipogenesis and lipid accumulation in adipocytes, favouring an IR state. 2) TCZ and IFX might reverse the metabolic alterations induced in AT by ACPAs. 3) Targeting these autoantibodies would be an excellent therapeutic strategy to restore AT function and reduce the metabolic complications related to RA.

### INCREASED FOLLICULAR HELPER T CELL REGULATES AUTOANTIBODY HYPOSIALYLATION IN GLUCOSE-6-PHOSPHATE ISOMERASE INDUCED ARTHRITIS

I. Kurata, I. Matsumoto, A. Osada, H. Ebe, H. Kawaguchi, Y. Kondo, H. Tsuboi, T. Sumida. *Internal Medicine, University of Tsukuba, Tsukuba, Ibaraki, Japan*

**Background:** Circulating follicular helper T (Tfh) cells were reported to be increased and promote B cell activation and antibody production in rheumatoid arthritis. Recently, IL-23-Th17 cells axis and hyposialylation of antibodies were proved to be linked to the inflammation of experimental and rheumatoid arthritis. However it remains uncertain how Tfh, including IL-17 producing Tfh (Tfh17), is associated to arthritis and whether its function includes promotion of antibody hyposialylation.

**Objectives:** The aim of this study is to explore the relation between Tfh and auto-antibody hyposialylation in glucose-6-phosphate isomerase (GPI) induced arthritis (GIA), which mouse model was dependent on T cells, B cells and IL-17.

#### Methods:

1. Fluctuation of Tfh and its subsets in draining lymph nodes (dLNs) were analysed and expression of co-stimulatory molecules were assessed among these subsets. Their localization were examined by immunofluorescence (IF) staining. In order to explore the counterpart reaction, serial changes of plasmablast and plasma cell population in dLNs were also analysed.
2. To elucidate Tfh function in ex-vivo, naïve B cells were co-cultured with Tfh and the ratio of differentiated plasmablast was quantified. Anti-GPI antibody production from plasmablast was measured in the existence of Tfh.
3. The titers of anti-GPI antibodies in GIA sera were measured by ELISA.
4. DCs were stimulated with purified anti-GPI antibodies from day 7 (arthritis onset phase) and day 28 (resolving phase) GIA to examine the pathogenicity change of antibody. MRNA of ST6 beta-galactoside alpha-2,6-sialyltransferase 1 (st6gal1), the responsible protein for antibody sialylation, in plasmablast was quantified by PCR and detection of sialic acid in anti-GPI antibody was performed by lectin blotting.
5. Naïve B cells were co-cultured with Tfh and the st6gal1 expression in differentiated plasmablast was measured by flow cytometry.

#### Results:

1. Tfh cells were increased in GIA. It peaked at day 7, the onset of arthritis, and Tfh17 was specifically increased at the same time. Moreover, OX40 expression in Tfh17 was higher than other subsets. IF showed that Tfh and Tfh17 were accumulated in germinal centre of dLNs. As counterparts, plasmablasts and plasma cells were most increased at day 7 as well.
2. When co-cultured with Tfh, the frequency of differentiated plasmablast was much higher than other conditions, and anti-GPI antibody production was up-regulated in the existence of Tfh and GPI.
3. Conflicting with the results above, anti-GPI antibody titers in the sera were gradually elevated even after day 7 and this elevation continued while GIA peaked out.
4. DCs produced higher level of TNF-alpha when stimulated with the antibody from day 7 GIA than day 28. St6gal1 expression in plasmablast was significantly decreased at day 7 and recovered at day 28. In addition, the day 7 antibodies were tended to be contain less sialic acid.
5. Decreased expression of st6gal1 was observed in differentiated plasmablast co-cultured with Tfh.

**Conclusions:** Tfh, especially Tfh17 were increased in the induction phase of arthritis. Also, Tfh could have a crucial role in the development of arthritis via plasmablast activation and regulation of autoantibody hyposialylation in GIA.

### BERBERINE AMELIORATES BONE EROSIONS IN COLLAGEN-INDUCED ARTHRITIS RAT MODELS SUPPRESSING THE EXPRESSION OF IL-17A

J. Yue<sup>1</sup>, J. Xu<sup>2</sup>, H. Li<sup>2</sup>, J. Wang<sup>2</sup>, N. Zheng<sup>2</sup>, H. Yao<sup>2</sup>, L.-S. Tam<sup>1</sup>, L. Qin<sup>2</sup>. <sup>1</sup>The department of Rheumatology, <sup>2</sup>Department of Orthopedics and Traumatology, Prince of Wales Hospital, The Chinese University of Hongkong, Hongkong, Hong Kong

**Background:** Rheumatoid arthritis (RA) is a chronic progressive disease characterised by synovial inflammation, autoantibody production, cartilage and bone destruction. Bone erosions are a key feature of RA reflecting both disease severity and disease progression. An imbalance between Th17 and regulatory T cells (Treg cells) has been extensively recognised in both patients and model animals

of RA. Oral administration of berberine, an isoquinoline alkaloid, has been showed to ameliorate various symptoms of autoimmune diseases including RA.

**Objectives:** To verify whether berberine may prevent bone erosions during RA progression and to explore the potential mechanisms in Collagen-induced arthritis (CIA) rat model.

**Methods:** The severity of arthritis was expressed as mean arthritic index on a 0–4 scale according to the following criteria: 0=no oedema or swelling; 1=slight oedema and erythema limited to the foot and/or ankle; 2=slight oedema and erythema from the ankle to the tarsal bone; 3=moderate oedema and erythema from the ankle to the tarsal bone; and 4=severe oedema and erythema from the ankle to the entire leg. Each limb was graded, and thus the maximum possible score was 16 for each animal. The threshold score of rats with established CIA is 2. The CIA rats were divided into 3 groups: placebo group (n=4), low dose berberine group (50 mg/kg/day, n=4) and high dose berberine group (200 mg/kg/day, n=4). Placebo and berberine were intragastrically administered to all rats for 4 and 8 weeks after the CIA models were established. TNF- $\alpha$ , IL-1 $\beta$ , IL-6, IL-17A, and IgG in the serum were measured by ELISA kits (purchased from Abcam). The hind paws of rats were scanned by micro CT (Scanco, Switzerland).

**Results:** The thickness of the swollen hind paws was reduced in the high dose berberine group (200 mg/kg/day) compared with the placebo group (Fig A). No significant differences were observed in the levels of TNF- $\alpha$ , IL-1 $\beta$ , and IL-6 between the three groups. However, the levels of IL-17A and IgG were significantly decreased in the high dose berberine group when compared with the placebo group (Fig A). Micro CT data revealed that berberine could significantly improve the microstructure of CIA rats including the bone volume ratio (BV/TV), areal bone mineral density (aBMD) and trabecular separation (Tb Sp) (Fig B and C). Development of bone erosion had also been partially prevented.

**Figure 1** A; B microstructure; C 3D reconstruction

**Conclusions:** Berberine attenuated the symptoms of CIA rats and may prevent bone erosion progression by suppressing IL-17A in CIA. Human studies are required to confirm whether it may serve as a potential treatment for RA in the future.

### ADIPONECTIN AGGRAVATES BONE EROSION BY PROMOTING OSTEOPONTIN PRODUCTION IN SYNOVIAL TISSUE OF RHEUMATOID ARTHRITIS

J. Qian<sup>1,2</sup>, L. Xu<sup>1</sup>, X. Sun<sup>1</sup>, Y. Wang<sup>1</sup>, W. Xuan<sup>1</sup>, Q. Zhang<sup>1</sup>, P. Zhao<sup>1</sup>, Q. Wu<sup>1</sup>, R. Liu<sup>1</sup>, N. Che<sup>1</sup>, F. Wang<sup>3</sup>, W. Tan<sup>1</sup>, M. Zhang<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Immunology, The First Affiliated Hospital of Nanjing Medical University, Nanjing; <sup>2</sup>Department of Rheumatology and Immunology, Affiliated Hospital of Nantong University, Nantong; <sup>3</sup>Department of Cardiology, The First Affiliated Hospital of Nanjing Medical University, Nanjing, China

**Background:** We have previously reported that adiponectin (AD), an adipokine that is secreted by adipocytes, correlates closely with progressive bone erosion in rheumatoid arthritis (RA). The exact mechanism of AD towards promoting joint destruction remain unclear.

**Objectives:** Osteopontin (OPN) is required for osteoclast recruitment. We hypothesised that AD exacerbates bone erosion by inducing OPN expression in synovial tissue. This study aimed to evaluate a novel role for AD in RA.

**Methods:** The serum levels of AD and OPN were determined in 38 RA, 40 osteoarthritis (OA) patients, and 20 healthy controls using enzyme-linked immunosorbent assay (ELISA). AD and OPN production were measured by double immunofluorescence of RA and OA synovial tissue. Quantitative real-time PCR and immunofluorescence were used to evaluate the mRNA and protein expression levels of OPN in RA synovial fibroblasts (RASFs) and OA synovial fibroblasts after preincubation with AD, respectively. Migration of the RAW264.7 osteoclast precursors cell line was assessed using the Transwell migration assay and co-culture system. Bone destruction and osteoclastogenesis were assessed by immunohistochemistry, microcomputed tomography, and tartrate-resistant acid phosphatase (TRAP) staining in AD-treated collagen-induced arthritis (CIA) mice with or without OPN silencing. The expression levels of OPN and integrin  $\alpha_v\beta_3$  in the ankle joint tissues of the mice were examined by double immunofluorescence.

**Results:** Our results indicated that the AD and OPN expression levels increased noticeably and were associated with each other in the RA serum. The AD distribution was coincident with that of OPN in the RA synovial tissue. AD stimulation of RASFs increased OPN production in a dose-dependent manner. AD-treated RASFs promoted RAW264.7 cell migration, and the effect was blocked with a specific antibody against OPN. Silencing of OPN using lentiviral-OPN short hairpin RNA reduced the number of TRAP-positive osteoclasts and the extent of bone erosion in the AD-treated CIA mice. When bound to integrin  $\alpha_v\beta_3$ , OPN functions as a mediator of AD and osteoclasts.

**Conclusions:** Our study provides new evidence of AD involvement in bone erosion. AD induces the expression of OPN, which recruits osteoclasts and initiates bone erosion. These data highlight AD as a novel target for RA treatment.

#### THU0080 SERUM IRISIN AND MYOSTATIN LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

J.M.D.S. Silva<sup>1,2</sup>, R. C. D. E. Santo<sup>1,2</sup>, E.C. Freitas<sup>1,2</sup>, N.F.T. Braz<sup>3</sup>, É. L. M. Vieira<sup>3</sup>, M. F. B. R. Guimarães<sup>4</sup>, A. C. S. E. Silva<sup>3</sup>, A.M. Kakehasi<sup>5</sup>, R. M. Xavier<sup>2,6</sup>. <sup>1</sup>Laboratório de Doenças Autoimunes, Hospital de Clínicas de Porto Alegre; <sup>2</sup>Universidade Federal do Rio Grande do Sul, Porto Alegre; <sup>3</sup>Laboratório Interdisciplinar de Investigação Médica, Universidade Federal de Minas Gerais; <sup>4</sup>Serviço de Reumatologia, Hospital das Clínicas da Universidade Federal de Minas Gerais; <sup>5</sup>Universidade Federal de Minas Gerais, Belo Horizonte; <sup>6</sup>Serviço de Reumatologia, Hospital de Clínicas de Porto Alegre, Porto Alegre, Brazil

**Background:** Rheumatoid arthritis (RA) patients have loss of muscle mass. The balance between muscle protein synthesis and degradation is regulated by cytokines and growth factors, named myokines, such as irisin and myostatin. Myokines are mainly expressed by skeletal muscle and exert systemic effects promoting crosstalk among different tissues. Irisin increases cortical bone mass and its low levels are related to muscle atrophy and obesity<sup>1, 2</sup> while myostatin is a negative regulator of muscle growth and regeneration and has a direct role in osteoclastogenesis of inflammatory bone destruction<sup>3, 4</sup>.

**Objectives:** To evaluate serum levels of irisin and myostatin and body composition of RA patients and controls.

**Methods:** 122 female patients with RA, mean age 53 years, mean disease activity score (DAS28) 4.09, mean disease duration 11.2 years and mean body mass index 27.33 kg/m<sup>2</sup> were included. 69 age and sex-matched healthy subjects were enrolled as control group. Irisin (Phoenix Pharmaceuticals) and myostatin (R and D Systems) serum levels were evaluated by ELISA. Fat mass index (FMI;Kg/m<sup>2</sup>) and appendicular lean mass index (ALMI;Kg/m<sup>2</sup>) were assessed by total body dual-energy x-ray absorptiometry. Student's t test and Spearman correlation were performed. Significance was set at p<0.05.

**Table 1.** Irisin and myostatin serum levels of RA patients and controls

	n	Irisin (mean ±SD)	Myostatin (mean ±SD)
RA patients treated with biologics	13	31,71±7,69 <sup>#</sup>	2448,64±1114,90 <sup>#</sup>
RA patients non-treated with biologics	27	25,93±6,89	3261,66±1156,28 <sup>*</sup>
Controls	30	30,36±10,95	4049,08±1610,01

\*p<0,05 RA patients treated with biologics vs controls; <sup>#</sup>p<0,05 RA patients treated with biologics vs RA patients non-treated with biologics; <sup>p</sup>>0,05 RA patients non-treated with biologics vs controls.

**Results:** RA patients had decreased serum levels of irisin (25,61±8,25 vs 30,36 ±10,95 ng/ml; p<0.05) and myostatin (3011,28±1271,11 vs 4049,08±1610,01 pg/

ml; p<0.05), decreased ALMI (6,09±0,88 vs 6,50±1,10; p<0.05) and increased FMI (11,26±3,30 vs 9,44±2,65; p<0.05), compared to controls. No correlations were observed among irisin and myostatin levels and ALMI and FMI. Of the 122 RA patients, 40 were analysed for the use of biologic medication. Serum levels of irisin and myostatin were different between RA patients treated and non-treated with biologics (table 1).

**Conclusions:** RA patients presented loss of lean mass and gain of fat mass, as well as lower irisin and myostatin serum levels, in comparison with controls. Additionally, the use of biologic medication by patients impacted on myokines serum levels. Further analyses are needed for a better comprehension of irisin and myostatin roles in RA, and to verify their correlation to other RA features.

#### THU0081 IDENTIFICATION OF NOVEL AUTOANTIBODIES IN THE SYNOVIAL FLUID FROM PATIENTS WITH RHEUMATOID ARTHRITIS

K.-I. Goto<sup>1</sup>, T. Kawamoto<sup>2</sup>, A. Nakajima<sup>3</sup>, M. Tahara<sup>4</sup>, T. Ebata<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Sakura Orthopaedic Hospital, Sakura; <sup>2</sup>Orthopaedic Surgery, Matsudo City Hospital, Matsudo; <sup>3</sup>Orthopaedic Surgery, Toho Univ. Sakura Hospital, Sakura; <sup>4</sup>Orthopaedic Surgery, Chiba-East National Hospital, Chiba, Japan

**Background:** Rheumatoid arthritis (RA) is a chronic, autoimmune and inflammatory joint disease with a poorly understood etiology. Despite widespread diagnostic use of anti-citrullinated protein antibodies and rheumatoid factor, there is strong demand for novel biomarkers to improve the diagnosis of this disease.

**Objectives:** The purpose of present study is to investigate novel autoantibodies in the synovial fluid of RA patients.

**Methods:** 1) By using SEREX (Serological identification of antigens by recombinant cDNA expression cloning), we identified ten and several antigens from sera of RA patients. 2) Three epitope sites in the candidate antigens proteins were predicted and 18 mer peptides were synthesised. 3) Synovial fluid of the knees was obtained from 48 RA and 48 osteoarthritis (OA) patients. 4) Furthermore, Alpha-LISA was used to analyse the antibody levels in synovial fluid using synthetic polypeptide as antigens.

**Results:** Significantly higher proportion of antibodies against lamin A (LMNA, RA 19871+13924 VS OA 6726+3975, p<0.000001) and cell growth-regulating nucleolar protein (CGRN, RA 19673+13314 VS OA 10614+6391, p<0.00007) were found in synovial fluid of RA as compared with OA.

**Conclusions:** We identified two novel autoantibodies in the knee synovial fluid of RA patients. These antibodies would have the potential to become diagnostic biomarkers of RA.

#### THU0082 IMPAIRED LEFT VENTRICULAR RELAXATION AND ITS ASSOCIATION WITH INFLAMMATORY MARKERS IN COLLAGEN-INDUCED ARTHRITIS

L. Mokotedi<sup>1</sup>, F.S. Michel<sup>1</sup>, C. Mogane<sup>1</sup>, P.H. Dessein<sup>2</sup>, A.M. Millen<sup>1</sup>. <sup>1</sup>Physiology, University of the Witwatersrand, Parktown, Johannesburg, South Africa; <sup>2</sup>Rheumatology Division, Vrije Universiteit Brussel, Brussels, Belgium

**Background:** Patients with rheumatoid arthritis (RA) experience an increased risk of developing heart failure with a preserved ejection fraction. Although there is some evidence to support a role of chronic inflammation in the pathogenesis of impaired left ventricular (LV) function in RA,<sup>1</sup> the direct effects of inflammatory cytokines on the LV function in collagen-induced arthritis (CIA) (an experimental model most similar to RA) require further elucidation.

**Objectives:** The aim of this study was to determine LV systolic and diastolic function and their association with circulating inflammatory markers in CIA.

**Methods:** Male Sprague Dawley rats were randomly divided into two groups: a control group (n=12) and a collagen-induced arthritis group (CIA, n=21). Rats in the CIA group were immunised with 0.2 ml type-II bovine collagen emulsified in incomplete Freund's adjuvant at the base of the tail followed by a 0.1 ml booster injection 7 days later. Eight weeks post-immunisation, markers of LV systolic function and geometry including ejection fraction (EF), fractional shortening (FS), stroke volume (SV) and LV end systolic diameter (ESD) were assessed echocardiographically using two-dimensional directed M-mode imaging. Markers of LV diastolic function including the early-to-late diastolic filling velocity ratio (E/A), the lateral (Lat e') and septal (Sep e') wall myocardial tissue lengthening at the mitral annulus and the ratio between early mitral inflow velocity and mitral annular early diastolic velocity (E/e') were assessed using pulsed Doppler and tissue Doppler echocardiography. Serum concentrations of interleukin 6 (IL-6), interleukin 1 $\beta$  (IL-1 $\beta$ ), tumour necrosis factor alpha (TNF- $\alpha$ ) and C-reactive protein (CRP) were determined by an enzyme-linked immunosorbent assay.

**Results:** No significant differences in markers of systolic function or geometry (EF, FS, SV and ESD) were observed between the groups (p>0.05). Compared to the control group, E/A (control=2.17 $\pm$ 0.39; CIA=1.46 $\pm$ 0.46; p=0.0001) and Sep e' (control=3.75 $\pm$ 0.69; CIA=3.23 $\pm$ 0.47; p=0.04) were lower in the CIA group. By contrast, E/e' (control=29.94 $\pm$ 6.99; CIA=24.17 $\pm$ 8.49; p=0.13) and Lat e' (control=3.99 $\pm$ 0.43; CIA=3.79 $\pm$ 0.78; p=0.31) did not differ amongst the two groups. IL-6 (115 $\pm$ 70.09 versus 365.3 $\pm$ 88.96 pg/mL; p<0.0001), IL-1 $\beta$  (14.1 $\pm$ 55.7 versus 238.6 $\pm$ 49.01 pg/mL; p<0.0001), TNF- $\alpha$  (293.5 $\pm$ 87.16 versus 626.0 $\pm$ 119.7 pg/mL; p<0.0001) and CRP concentrations (0.23 $\pm$ 0.34 versus 0.97 $\pm$ 0.35 ng/mL; p<0.0001) were higher in the CIA compared to control group. A lower E/A was associated with TNF- $\alpha$  (r=-0.63; p=0.0003), IL-6 (r=-0.56; p=0.0001), IL-1 $\beta$  (r=-0.48; p=0.001) and CRP concentrations (r=-0.60; p=0.001) in the total sample. Lower TNF- $\alpha$  (r=-0.39 p=0.04) and IL-1 $\beta$  (r=-0.47, p=0.01) levels were associated with E/e' in the total sample.

**Conclusions:** Diastolic function is impaired in male Sprague Dawley rats with CIA. Our results indicate that exposure to high grade inflammation can reduce LV relaxation without impairing systolic function in CIA. Markers of inflammation were also associated with increased filling pressures in this animal model. Systemic inflammation may directly impact myocardial diastolic function in CIA.

THU0083

#### CD30 APTAMER-SLAT-SHRNA CHIMAERAS INHIBIT TH17 DIFFERENTIATION BY ROR $\gamma$ T IN RHEUMATOID ARTHRITIS

L. Hui<sup>1</sup>, G.-D. Zhang<sup>1</sup>, B.-B. Cui<sup>1</sup>, H.-H. Tang<sup>1</sup>, L.-J. Xue<sup>1</sup>, Y. Liu<sup>1</sup>, C.-Q. Chu<sup>2</sup>.  
<sup>1</sup>West China Hospital, Sichuan University, Chengdu, Sichuan, China; <sup>2</sup>Oregon Health and Science University and VA Portland Health Care System, Oregon, USA

**Background:** T helper 17 (Th17) cells play a central role in rheumatoid arthritis (RA) via the production of pro-inflammatory cytokines interleukin (IL)-17. SWAP-70-like adapter of T cells (SLAT) has recently emerged as an important regulator of Th17 differentiation. Aptamer-facilitated cell specific delivery of shRNA represents an attractive novel approach for efficient RNAi delivery. However, the role of CD30 aptamer-SLAT-shRNA chimaeras in regulating Th17 differentiation in patients with RA is unclear.

**Objectives:** SLAT play a crucial role in regulating Th17 cell differentiation and function. This study was undertaken to investigate the role and mechanism of SLAT in Th17 cells differentiation in patients with RA.

**Methods:** Peripheral blood CD4<sup>+</sup> T cells and synovial fluid CD4<sup>+</sup> T cells derived from RA patients and healthy controls were used to test the effect of SLAT *in vitro*. CD30 aptamer-SLAT-shRNA chimaeras were generated *in vitro* and transfected into CD4<sup>+</sup> T cells. The effect of CD30 aptamer-SLAT-shRNA chimaeras on Th17 production and differentiation was detected.

**Results:** SLAT was expressed mostly in cytoplasm and cell membrane of CD4<sup>+</sup> T cells. The protein levels of SLAT in peripheral blood and synovial fluid CD4<sup>+</sup> T cells of RA patients were higher than that of healthy controls. The effect of CD30 aptamer-SLAT-shRNA chimaeras on Th17 differentiation was due to its ability to sequester SLAT and prevent it from targeting the transcription factor ROR $\gamma$ T.

**Abstract THU0083 – Figure 1.** A. SLAT was expressed mostly in cytoplasm and cell membrane of CD4<sup>+</sup> T cells. D. CD30 aptamer-SLAT-shRNA chimaeras reduced the percentage of CD4<sup>+</sup>ROR $\gamma$ T<sup>+</sup> T cells and CD4<sup>+</sup>IL-17<sup>+</sup> T cells.

**Conclusions:** This study reveals new evidence of the role of SLAT in Th17 differentiation in CD4<sup>+</sup> T cells of RA patients.

#### HISTONE DEACETYLASE 1 (HDAC1): A NOVEL THERAPEUTIC TARGET IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Göschl<sup>1</sup>, L. Mueller<sup>1</sup>, V. Saferding<sup>1</sup>, S. Knapp<sup>2</sup>, J. Backlund<sup>3</sup>, C. Scheinecker<sup>1</sup>, J. Smolen<sup>1</sup>, W. Ellmeier<sup>4</sup>, G. Steiner<sup>1</sup>, M. Bonelli<sup>1</sup>. <sup>1</sup>Division of Rheumatology; <sup>2</sup>Laboratory of Infection Biology, MEDICAL UNIVERSITY OF VIENNA, Vienna, Austria; <sup>3</sup>Department of Medical Biochemistry and Biophysics, Karolinska Institute, Stockholm, Sweden; <sup>4</sup>Division of Immunobiology, MEDICAL UNIVERSITY OF VIENNA, Vienna, Austria

**Background:** Despite enormous efforts to develop new therapeutic strategies for treatment of rheumatoid arthritis (RA), the large number of non responding

patients to currently available drugs underlies the unmet need to identify new therapeutic targets.

**Objectives:** Certain CD4<sup>+</sup>T cell subsets, especially Th17 cells, have been shown to be major drivers of inflammation in patients with RA. The expression of their key transcription factors is controlled by histone modifications which includes acetylation of *lysine residues* mediated by histone deacetylases (HDAC). Indeed, pan HDAC inhibitors have been shown to be a potential therapeutic strategy. However, major side effects limited the clinical use and underline the need of more specific HDAC inhibitors. We therefore addressed the individual role of HDAC1 on the development of collagen-induced arthritis model (CIA).

**Methods:** Mice with a T cell specific deletion of HDAC1 (HDAC1 cKO) were generated by using the CD4Cre/LoxP system. Collagen induced arthritis (CIA) was induced at week 8. Animals were scored for paw swelling and grip strength. After 10 weeks, mice were sacrificed and paraffin sections of the affected joints were analysed for histomorphological signs of inflammation, cartilage and bone destruction. Anti-CII antibody levels were determined by ELISA. Serum samples were analysed for various cytokines by multiplex assays. CCR6 expression in CD4 T cells was analysed by flow cytometry.

**Results:** To address potential effects of HDAC1 in the pathogenesis of RA, CIA was induced in *HDAC1cKO* mice and *WT* mice. Surprisingly *HDAC1cKO* mice were completely protected from the development of arthritis. In line with the clinical data, histological analysis revealed no signs of inflammation, no bone erosion and no osteoclasts in the joints of *HDAC1cKO* mice. Anti-CII antibodies, including total IgG and IgG2c were detected in *HDAC1cKO* and *WT* mice. Surprisingly, IL-17 was significantly decreased in the serum of *HDAC1cKO* mice as compared to *WT* mice, suggesting a role of HDAC1 in the development of Th17 cells. To see whether HDAC1 is involved in the regulation of the chemokine receptor 6 (CCR6), the main marker of Th17 cells, we compared the upregulation of CCR6 in CD4<sup>+</sup> T cells from *WT* and *HDAC1cKO* mice. Indeed, CCR6 could not be upregulated in CD4<sup>+</sup> T cells from *HDAC1cKO* mice upon IL-6 *in vitro*. These data support the role of HDAC1 in the regulation of CCR6, an important chemokine receptor, which is necessary for the migration of pathogenic Th17 cells and therefore for the development of arthritis.

**Conclusions:** Our data show the importance of HDAC1 as a key immune regulator in the pathogenesis of T cell driven collagen induced arthritis. Therefore, it might be considered as an interesting novel therapeutic target in RA.

**THU0085** CR6086, A NOVEL EP4 ANTAGONIST WITH IMMUNOMODULATORY PROPERTIES, DECREASES BONE LOSS IN THE RAT COLLAGEN-INDUCED ARTHRITIS (CIA) MODEL: A MICROTOMOGRAPHY (MICROCT) STUDY

M. Lanza<sup>1</sup>, G. Caselli<sup>1</sup>, F. Ferrari<sup>1</sup>, A. Grotti<sup>1</sup>, R. Cavagnoli<sup>1</sup>, M. Perrella<sup>1</sup>, F. Daubine<sup>2</sup>, V. Ayer<sup>2</sup>, L.C. Rovati<sup>1</sup>. <sup>1</sup>Rottapharm Biotech, Monza, Italy; <sup>2</sup>Atlantic Bone Screen, Saint-Herblain, France

**Background:** CR6086 is a novel PGE2 EP4 receptor antagonist showing favourable immunomodulatory properties, striking DMARD effects in rodents, and an anti-inflammatory activity targeted to immune-mediated diseases and distinct from that of NSAIDs. Besides its role in controlling T cells, PGE2 is implicated in the aggressive bone erosion of rheumatoid arthritis (RA).

**Objectives:** To characterise CR6086 activity on the bone compartment mostly affected by erosion in the CIA model in rats.

**Methods:** 15 male Lewis rats were immunised by intradermal injection with collagen II in CFA. 5 naïve animals were the sham group. 3 days after boost, oedema was assessed and rats assigned to treatment with vehicle or CR6086 (3 or 10 mg/kg qd). Oedema was measured again on days 7 and 14, and hindlimb joints were blindly scored for clinical signs of arthritis (scale 0–4; from normal=0 to maximally inflamed limb with involvement of multiple joints=4). At sacrifice, hindlimb calcaneus underwent high-resolution X-ray microCT (total and cancellous bone), a sensitive method that allows the reduction of experimental animals in compliance with the 3R rule. Parameters were expressed as the mean of left and right paw. Joints were then scored for histological features. Statistics were performed by ANOVA, correlations by Spearman analysis.

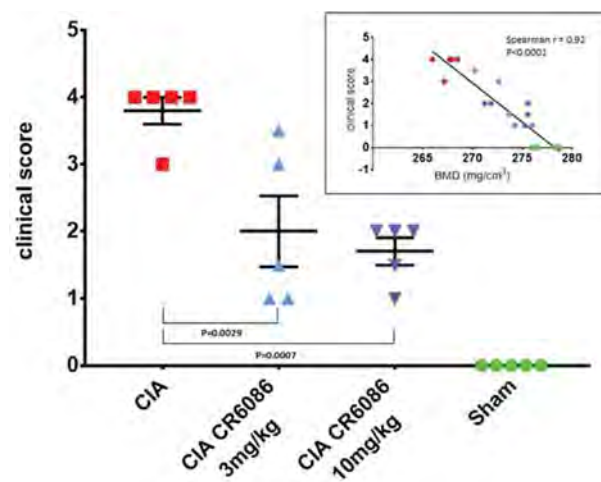

**Results:** CR6086 significantly reduced bone loss in CIA rats (table 1), even at the low dose of 3 mg/kg. The effect on cancellous bone plateaued already at 3 mg/

kg, confirming the sensitivity of the metabolically more active districts of bone to the action of EP4 antagonists.

There was a strict correlation between clinical score and bone parameters (BMD; figure 1 inset), confirming that bone erosion in CIA is closely associated with arthritis severity.

**Conclusions:** CR6086 is an EP4 antagonist in clinical development for RA (NCT03163966). Besides its immunomodulatory activity, CR6086 effectively decreases the aggressive bone erosion that characterises both the CIA model and the early phases of human RA.

**THU0086 INTERLEUKIN 17 RECEPTOR D (IL-17RD) REDUCES INCIDENCE OF COLLAGEN INDUCED ARTHRITIS**

M. Molendijk<sup>1</sup>, A.M. Mus<sup>1</sup>, P.S. Asmawidjaja<sup>1</sup>, D. Baeten<sup>2</sup>, E. Lubbers<sup>1</sup>. <sup>1</sup>Erasmus MC, Rotterdam; <sup>2</sup>AMC, Amsterdam, Netherlands

**Background:** IL-17RD is a member of the IL-17 receptor family. In contrast to the other IL-17 receptors, IL-17RA, -RB, -RC and -RE, little is known about the ligand and function of IL-17RD. Recently, IL-17RD has been described to negatively regulate a selection of IL-17A responsive genes. IL-17RD is therefore proposed to limit IL-17A signalling.

**Objectives:** In this study we examined IL-17RD expression in multiple cells types and its role in the development of collagen induced arthritis.

**Methods:** Human synovial fibroblasts from Rheumatoid Arthritis (RA) patients were stimulated with tumour necrosis factor  $\alpha$  (TNF $\alpha$ ), interleukin 1  $\beta$  (IL-1 $\beta$ ) or IL-17A for multiple time points. IL-17RD expression levels were measured via qPCR. Collagen induced arthritis (CIA) was induced in IL-17RD knockout mice and wildtype littermates. At days 1 and 21, mice were immunised intradermally with chicken collagen type II in complete Freund's adjuvant (CFA). Mice were scored 3 times a week for clinical disease defined as swollen joints with a maximum score of 8. Due to ethical reasons, mice were removed from the experiments when they reached a score of 6. CD4<sup>+</sup> memory T cells, CD8<sup>+</sup> memory T cells, CD19<sup>+</sup> B cells and monocytes were isolated from WT spleens and analysed for IL-17RD expression. Blood neutrophil migration assays were performed *in vitro* using WT and IL-17RD deficient (IL-17RD KO) mouse synovial fibroblasts.

**Results:** Human synovial fibroblasts from RA patients have baseline expression of IL-17RD. Upon stimulation with TNF $\alpha$  a significant downregulation of IL-17RD expression was measured from 24 hours onwards. IL1 $\beta$  stimulation had a similar effect as TNF $\alpha$  on IL-17RD expression. Lack of IL-17RD did not result in differences in CIA severity, but the incidence of CIA was reduced. IL-17RD is mainly expressed in synovial fibroblasts. IL-17RD KO synovial fibroblasts attract less neutrophils likely by lower production of neutrophil attractants.

**Conclusions:** An inflammatory environment causes synovial fibroblasts to downregulate IL-17RD expression. Lack of IL-17RD reduces the incidence CIA, which is an IL-17-driven model. The decrease in CIA incidence is likely explained via the reduced attraction of neutrophils to the site of inflammation.

**THU0087 MICRORNA-1915-3P IN SERUM EXOSOME IS ASSOCIATED WITH DISEASE ACTIVITY OF RHEUMATOID ARTHRITIS IN KOREA**

M.-K. Lim<sup>1</sup>, J. Song<sup>2</sup>, S.A. Kim<sup>3</sup>, J. Yoo<sup>1</sup>. <sup>1</sup>Internal medicine, School of Medicine, Eulji University; <sup>2</sup>Rheumatology, Sun General Hospital; <sup>3</sup>Pharmacology, School of Medicine, Eulji University, Daejeon, Korea, Republic of Ireland

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease that is characterised by severe tissue damage and chronic synovial inflammation.<sup>1</sup> Using analysis of gene polymorphism, biochemical assays, and proteomics approaches, several promising biomarkers for treatment response have been proposed, including red blood cell (RBC) MTX polyglutamate levels, as well as serum levels of proteins such as cytokines, growth factors, and autoantibodies.<sup>2</sup> However, these markers need further development and refinement to attain sufficient sensitivity and specificity.

**Objectives:** In this study, we used a miRNAarray approach to identify new miRNA in exosome that are related to disease activity in patients with RA who showed inadequate response to treatment. We also examined the relationship between the levels of expression of the RNAs and various serologic parameters of the patients.

**Methods:** Forty-two RA patients were included in the study. Disease activity was measured using the 28-joint disease activity score with ESR (DAS28-ESR). Patients with RA were stratified according to the following criteria: the clinical remission (CR) group (n=22), DAS28-ESR $\leq$ 2.6; and the non-CR group (n=20), DAS28-ESR $>$ 2.6. By exosome preparation, miRNA array, and Reverse Transcription-qPCR reactions, several miRNAs were as potent markers for disease activity.

**Results:** After data processing for relative quantification of miRNA in exosome between the CR and non-CR groups, we identified 47 miRNAs with a relative fold change (non-CR/CR) $>$ 2. The expression levels of 37 miRNAs were found decreased in non-CR group, while 10 miRNAs increased in non-CR group. To validate these results, five miRNAs were selected (hsa-miR-1915-3 p, hsa-miR-4516, hsa-miR-6511b-5p, hsa-miR-3665, hsa-miR-3613) showing at least 2-fold change between the CR and non-CR groups. Both levels of hsa-miR-1915-3 p and hsa-miR-6511b-5p were significantly increased in CR group; hsa-miR-1915-3 p was 43.75 in the CR group and 24.68 in the non-CR group (p=0.004), and

hsa-miR-6511b-5p was 3.02 in the CR group and 2.45 in the non-CR group (p=0.03).

**Conclusions:** hsa-miR-1915-3 p showed promise as additional markers for evaluating disease activity in patients with RA. Prospective investigation of hsa-miR-1915-3 p may facilitate development of new diagnostic tools to assess disease activity and prognosis in RA and other autoimmune diseases.

**THU0088 MONOCYTE DOWNREGULATION OF MITOCHONDRIAL TRANSLOCATOR PROTEIN MAY BE A CONTRIBUTORY MECHANISM TO INFLAMMATION IN RA**

N. Narayan, H. Mandhair, T. Sekine, A. Sabokbar, P.C. Taylor. *Nuffield Department of Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, UK*

**Background:** The translocator protein is an 18 kDa mitochondrial transporter, increasingly thought to play a critical role in cholesterol efflux in macrophages. Recent work demonstrates that macrophages engineered to over-express TSPO, exhibit increased cholesterol efflux, and reduced ability to form a pro-inflammatory ('M1') phenotype, with significant reduction in the ability to produce TNF- $\alpha$ . Additionally, there is growing data to demonstrate a difference in TSPO expression in monocytes in those with inflammatory disease compared with healthy, as exemplified by studies of multiple sclerosis, suggesting a role for TSPO in the generation of inflammation.

**Objectives:** In this study, we investigate the expression of TSPO in healthy and RA peripheral blood monocytes, and in monocyte derived macrophages (MDM), differentiated to an M1 (pro-inflammatory), and M2 (reparative) phenotype.

**Methods:** Using positive magnetic-activated cell sorting, we use peripheral blood mononuclear cells from 24 RA patients with active disease (as determined by clinical examination, and DAS28 CRP score), and 24 healthy controls, to isolate peripheral blood monocyte mRNA and protein, to ascertain any differences in TSPO expression at monocyte level. MDM were generated *in vitro* through differentiation of monocytes with 100 ng/ml M-CSF for 7 days, followed by activation to an M1 phenotype using LPS and IFN- $\gamma$ , and a reparative 'M2' phenotype using IL-4, TGF- $\beta$  or glucocorticoid, followed by quantification of TSPO mRNA utilising real-time PCR, and TSPO protein, utilising western blotting and radioligand binding.

**Results:** Our data establishes that both healthy and RA peripheral blood monocyte derived macrophages (MDM) exhibit a statistically significant downregulation of TSPO at mRNA and protein level, when activated to a pro-inflammatory 'M1' macrophage phenotype, with no change in TSPO expression in MDM activated to a reparative 'M2' phenotype. Our mRNA data also suggests that M1 macrophages from both healthy and RA donors, exhibit a significant reduction in expression of key cell components promoting cholesterol efflux in macrophages, including CYP27A1, and ABCA1. Our data additionally demonstrates a significant reduction in expression of TSPO between healthy and RA monocytes, at both mRNA and protein level (mean fold change TSPO mRNA of 1.00 for healthy monocytes, and 0.47 $\pm$ 0.24, p<0.001 for RA monocytes and mean TSPO optical densitometry of 1.01 $\pm$ 0.10 for healthy monocytes and 0.85 $\pm$ 0.02 p<0.05 for RA monocytes relative to  $\beta$ -actin).

**Conclusions:** Our findings indicate that pro-inflammatory activation of both healthy and RA monocyte-derived macrophages downregulates TSPO, and is also associated with reduction in key components of the cholesterol efflux pathway, in line with pre-existing studies of TSPO silencing and over-expression in human macrophages. Furthermore, we demonstrate that RA peripheral blood monocytes themselves may have a predisposition to a pro-inflammatory phenotype through downregulation of TSPO expression, which could indicate an as yet uninvestigated cellular mechanism contributing to synovial inflammation in RA.

**THU0089** **IL-17A+GM-CSF+ NEUTROPHILS ARE THE MAJOR INFILTRATING CELLS IN INTERSTITIAL LUNG DISEASE IN AN AUTOIMMUNE ARTHRITIS MODEL**

O.C. Kwon<sup>1</sup>, E.-J. Lee<sup>1</sup>, E.-J. Chang<sup>2</sup>, W.J. Seo<sup>3</sup>, J.S. Oh<sup>4</sup>, S. Hong<sup>1</sup>, C.-K. Lee<sup>1</sup>, B. Yoo<sup>1</sup>, Y.-G. Kim<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Medicine, University of Ulsan, College of Medicine, Asan Medical Center; <sup>2</sup>Department of Biomedical Science, University of Ulsan, College of Medicine, Asan Medical Center; <sup>3</sup>Division of Rheumatology, Department of Medicine, Seoul Veterans Hospital; <sup>4</sup>Clinical Research Center, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of Ireland

**Background:** Interstitial lung disease (ILD) is a common extra-articular manifestation of rheumatoid arthritis (RA). Discrepancy in the effect of biologic agents on synovial and lung inflammation exists, indicating that the nature of inflammation in the synovium and lung may be different in RA.

**Objectives:** To gain a better understanding of the pathogenesis of rheumatoid arthritis-associated interstitial lung disease (ILD), we sought to identify the characteristics of lung-infiltrating cells in SKG mice with ILD.

**Methods:** We injected curdlan in SKG mice at 8 weeks of age, and identified the presence of ILD by PET-MRI at 20 weeks post-injection and histological analysis at 22 weeks post-injection. Lung-infiltrating cells were examined by flow cytometry. Analysis of serum cytokines by the Luminex multiplex cytokine assay was performed at 14 and 22 weeks post-injection, and cytokine profiles before and after the development of ILD were compared. Opal multiplexed immunofluorescent staining of lung tissue was also performed.

**Results:** At 20 weeks post-injection, curdlan-treated SKG mice developed not only arthritis but also lung inflammation combined with fibrosis, which was identified by PET-MRI and histological analysis. The majority of inflammatory cells that accumulated in the lungs of curdlan-treated SKG mice were CD11b<sup>+</sup>Gr1<sup>+</sup> neutrophils, which co-express IL-17A and GM-CSF, rather than TNF- $\alpha$ . Compared with 14 weeks post-injection, serum levels of GM-CSF, MCP1, IL-17A, IL-23, TSLP, and IL-7R $\alpha$  had increased at 22 weeks post-injection, whereas those of IFN- $\gamma$ , IL-22, IL-6, and TNF- $\alpha$  remained unchanged. Furthermore, IL-23, CXCL5, IL-17A, and GM-CSF, but not TNF- $\alpha$ , were observed in immunofluorescent-stained lung tissue.

**Conclusions:** We found that IL-17A<sup>+</sup>GM-CSF<sup>+</sup> neutrophils represented the major inflammatory cells in the lungs of curdlan-treated SKG mice. In addition, GM-CSF and IL-17A appear to play a more important role than TNF- $\alpha$  in ILD development.

**THU0090** **PREVALENCE AND CLINICAL PHENOTYPE OF ANTI-CARBAMYLATED PROTEIN ANTIBODIES IN PALINDROMIC RHEUMATISM**

R. Castellanos-Moreira<sup>1</sup>, S. Cabrera-Villalba<sup>1</sup>, M. José Gomara<sup>2</sup>, V. Ruiz-Esqueda<sup>1</sup>, G. Salvador<sup>3</sup>, S.D.C. Rodríguez-García<sup>1</sup>, O. Camacho<sup>1</sup>, J. Ramírez<sup>1</sup>, M. V. Hernández<sup>1</sup>, A. Cuervo<sup>1</sup>, J.A. Gómez-Puerta<sup>1</sup>, J.D. Cañete<sup>1</sup>, I. Haro<sup>2</sup>, R. Sanmartí<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Clínic de Barcelona; <sup>2</sup>Unit of Synthesis and Biomedical Applications of Peptides, IQAC-CSIC; <sup>3</sup>Rheumatology, Hospital Universitario Mutua Terrassa, barcelona, Spain

**Background:** Anti-carbamylated protein antibodies (anti-CarP) are a newly-identified antibody family present in the sera of rheumatoid arthritis (RA) patients whose specificity is close to that of ACPA but whose sensitivity is lower. Palindromic rheumatism (PR) is an intermittent form of arthritis that may progress to RA. Patients with PR may present the characteristic autoantibody profile seen in RA, even in the absence of evolution to RA. There are no studies on the presence of anti-CarP antibodies in PR.

**Objectives:** To analyse the prevalence of anti-CarP in patients with PR and evaluate their clinical phenotype and relationship with ACPA.

**Methods:** Patients diagnosed with PR attended by the Arthritis Unit, Rheumatology Service, Hospital Clínic de Barcelona were included according to the criteria of Guerne et al. Only patients considered as pure PR (patients without evidence of RA or other chronic rheumatic disease at the time of the first determination of anti-CarP) were analysed. An established RA control group was included. Anti-CarP were analysed by a home-made ELISA using a fibrin/chimeric flaggrin homocitrullinated peptide as antigen. IgG, IgA and IgM isotypes were measured. ACPA were analysed with a commercial CCP2 test. The clinical and therapeutic characteristics were compared according to anti-

CarP positivity/negativity and to the clinical evolution, including the progression to RA during the follow-up.

**Results:** Anti-CarP were analysed in 54 patients with pure PR and 53 RA patients. Anti-CarP were detected in 16.7% and 37.7% (p: NS) of patients with PR and RA, respectively. All PR patients positive for anti-CarP were ACPA positive and had higher ACPA titers. IgG was the predominant isotype (100%), only one patient presented IgA (11.1%) and none IgM. In the RA group, the percentages of IgG, IgA and IgM were 55%, 50% and 40%, respectively, in anti-CarP positive patients. More anti-CarP positive patients developed RA (33.3% vs. 13.6%), although the difference was not significant, during a mean follow-up of 3.8 $\pm$ 1.1 years. Remission at the last follow-up visit was more frequent in patients who were anti-CarP negative (22% vs. 60.5% p<0.05). Anti-CarP positive patients were receiving DMARD more frequently than anti-CarP negative patients (100% vs. 60% p<0.05).

**Conclusions:** This is the first study to demonstrate the presence of anti-CarP in patients with pure PR. Anti-CarP was associated with ACPA positivity and higher ACPA titers. Anti-CarP isotypes differed between PR and RA, with lower isotype use in PR. Anti-CarP positivity in PR patients could indicate a more refractory disease, with lower rates of remission and greater predisposition to evolve to RA.

Baeten<sup>2</sup>, P.P. Tak<sup>5</sup>, J. Connor<sup>6</sup>, K. A. Reedquist<sup>1</sup>, T.R. Radstake<sup>1</sup>. <sup>1</sup>Laboratory for Translational Immunology (LTI) and Department of Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht; <sup>2</sup>Department of Clinical Immunology and Rheumatology, Academic Medical Center, University of Amsterdam, Amsterdam, Netherlands; <sup>3</sup>Laboratorio de Investigación 8 y Servicio de Reumatología, Instituto de Investigación Sanitaria (IDIS), Hospital Clínico Universitario de Santiago de Compostela (CHUS), Santiago de Compostela, Spain; <sup>4</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, New York, USA; <sup>5</sup>GlaxoSmithKline, Stevenage, UK; <sup>6</sup>MedImmune LCC, Maryland, USA

**Background:** Several studies have shown that angiopoietin signalling to Tie2 may play a role in the initiation and perpetuation of disease rheumatoid arthritis (RA) and psoriatic arthritis (PsA). However, the cell type(s) involved in this process, as well as the specific role of Tie2 signalling in the synovium of arthritis patients, remain unclear.

**Objectives:** To examine the role Tie2 signalling in macrophages and fibroblast-like synoviocytes (FLS) within the context of the synovial microenvironment of arthritic patients.

**Methods:** Peripheral blood (PB) monocytes from healthy donors (HD) were differentiated with synovial fluid (SF) of RA and PsA patients. PB and SF monocytes from RA and PsA patients were differentiated into pro-inflammatory macrophages with IFN- $\gamma$ . Tie2 expression was analysed by flow cytometry and quantitative PCR. Macrophages, RA FLS and synovial tissue explants were stimulated with Ang-1 or Ang-2 (200 ng/ml) alone or in combination with TNF (10 ng/ml) for 4 hour or 24 hour. mRNA and protein expression of inflammatory mediators was analysed by quantitative PCR and ELISA and luminex, respectively. Arthritis was induced in wild type (WT) and Tie2 over-expressing (Tie2-TG) mice by intraperitoneal injection of 100 ml of K/BxN serum on day 0 and day 2. Mice were sacrificed on day 14 after serum transfer.

**Results:** Tie2 expression was observed IFN- $\gamma$ -differentiated macrophages, from RA and PsA patients, as well as HD macrophages differentiated with RA and PsA SF. In all cases, both Ang-1 and Ang-2 stimulation significantly enhanced TNF-induced expression of pro-inflammatory cytokines (IL-6, IL-12B) and chemokines (IL-8, CCL-3 and CXCL-6). Tie2 activation also enhanced TNF-mediated production of these inflammatory mediators in RA FLS. The clinical severity of serum-induced arthritis was significantly higher in Tie2-TG mice compared to WT mice, associated with enhanced synovial expression of IL-6, IL12B, iNOS, CCL-2 and CXCL-10.

Finally, we found that Ang-2, and to a lower extent Ang-1, induced the production of IL-6, IL-12B, IL-8, and CCL-3 in the synovial tissue explants of RA and PsA patients. Importantly, Ang-2 blockade with a specific neutralising anti-Ang2 antibody suppressed the production of IL-6 and IL-8 in synovial tissue of RA patients.

**Conclusions:** These results suggest that Tie2 signalling, even within the complex microenvironment of affected synovial tissue, has an important pro-

inflammatory role in the pathology of RA and PsA. As this effect can be reversed by Ang-2 neutralisation, interfering with Tie2 activity may be a promising therapeutic target in arthritic diseases.

#### THU0092 INTRA-CYTOPLASMIC CYTOKINES IN CD20 POSITIVE LYMPHOCYTE SUBPOPULATIONS IN RHEUMATOID ARTHRITIS (RA) PATIENTS

S. Amar<sup>1</sup>, A. Kerpel<sup>2</sup>, R. Rabinowitz<sup>2</sup>, P. Levy<sup>2</sup>, O. Zelig<sup>1</sup>, N. Schlesinger<sup>3</sup>, M. Schlesinger<sup>2</sup>. <sup>1</sup>Hadassah hospital; <sup>2</sup>Hebrew University Medical School, Jerusalem, Israel; <sup>3</sup>Rutgers Robert Wood Johnson Medical School, New Brunswick, USA

**Background:** The administration of biological drugs inactivating various elements of the immune system such as cytokines and immune cells, induces a significant ameliorating effect on rheumatoid arthritis (RA) patients. The mechanisms involved in the pathogenesis of RA are unclear, and the precise role of different cellular elements of the immune system in its pathogenesis remain to be elucidated.

**Objectives:** In the present study we concentrated on one cellular target for a biologic treatment in RA (Rituximab), the CD20 positive lymphocytes. Various types of lymphocytes are positive to CD20. Based on its expression, these lymphocytes include dim and bright CD20 +types. These cells' capacity to secrete various cytokines was determined among lymphocytes of healthy controls (HC) and RA patients.

**Methods:** Peripheral blood lymphocytes (PBL) of RA patients (n=20) and HC (n=15) were isolated using Ficoll Hypaque gradient columns. To  $5 \times 10^5$  cells in 0.5 ml RPMI-1640 medium, 1.25 ng PMA, 0.5  $\mu$ g Ionomycin and 5  $\mu$ g Brefeldin were added for 5 hours of activation after which cells were incubated for 30 min at 4°C with Phycoerythrin-(PE) conjugated anti-CD20 monoclonal antibody (mab). Thereafter, suspensions were incubated in fixation buffer for 45 min, washed and re-suspended in 100  $\mu$ l of permeabilization buffer and 20  $\mu$ l of fluorescent (FITC) conjugated anti-cytokine mabs, and were incubated at 4°C for 30 min. A t-test for independent samples, was performed.

**Results:** Intra-cytoplasmic detection of various key-role cytokines, such interleukins 4 (IL-4), 17 (IL-17), 10 (IL-10) and interferon gamma (INF- $\gamma$ ) was determined. The percentage of IL-4 positive lymphocytes among CD20 +cells in HC was higher in CD20 +dim cells (4.5%) than in CD20 +bright cells (1.2%) (p value 0.0001). Among lymphocytes of RA patients the proportion of IL-4 positive cells was much higher than in HC (p<0.0002) and was comparable between dim (54.5%) and bright (48.6%) CD20 +lymphocytes. The proportion of IL-10 positive cells among both dim and bright CD20 +lymphocyte subpopulations was significantly lower in RA patients than in HC (p<0.0002). While in HC, 56% of CD20 +dim and 61% of CD20 +bright lymphocytes, showed IL-10 positivity, among RA lymphocytes it constituted only 17.8% and 9.3% of the CD20 +dim and bright lymphocytes, respectively.

Staining with anti-IL-17 mab yielded in low proportions of IL-17 positive cells in all CD20 +populations tested, in both HC and RA. Among dim CD20 +lymphocytes, IL-17 positive cells constituted 1.4% (HC) and 3.6% (RA). IL-17 staining appeared on only 0.74% of CD20 +bright lymphocytes in HC and similarly in RA (0.54%). While the proportion of INF- $\gamma$  positive lymphocytes was similar in HC and RA, it was significantly higher among dim (11.8% HC, 9.5% RA) than in bright CD20+ (1% HC, 1.4% RA) indicating a different cell pattern (p=0.0001).

**Conclusions:** The present study demonstrates that CD20 +lymphocytes, targeted in RA treatment, expressing different levels of CD20, in RA differ from HC in their capacity to produce various cytokines. Although there was no difference in IL-17 and INF- $\gamma$  they may modulate the immune response in RA due to higher levels of IL-4 and reduced IL-10 levels produced by both CD20 +cell populations; dim and bright lymphocytes.

#### THU0093 NADPH OXIDASES ASSOCIATED PRODUCTION OF REACTIVE OXYGEN SPECIES IN RHEUMATOID ARTHRITIS

S.-J. Yoo, S.W. Kang, J. Kim, I.S. Yoo, C.K. Park. Internal Medicine, Chungnam National University School of Medicine, Daejeon, Korea, Republic of Ireland

**Background:** Reactive oxygen species (ROS) is produced during metabolism of Oxygen. ROS is important in cell signalling and homeostasis. Production of ROS can be elevated in stressful condition. Oxidative stress has been known to be related with the disease like infection and malignancy. NADPH oxidases (Nox) are membrane proteins which produce ROS.

**Objectives:** In this study we aimed to investigate the role of Nox in rheumatoid arthritis (RA) associated with production of ROS.

**Methods:** Nox and Granulocyte macrophage colony-stimulating factor (GM-CSF) messenger ribonucleic acid (mRNA) were analysed in fibroblast like synoviocyte (FLS) of patients with RA and osteoarthritis (OA) by reverse transcription polymerase chain reaction. Amount of ROS which is produced in FLS of patients with RA and OA is determined using the cell permeant fluorophore 5-(and-6)-chloromethyl-2',7'-dichlorodihydrofluorescein diacetate acetyl ester (CM-H2DCFDA) by flowcytometry. Same experiments were performed after treatment with cytokine, interleukin (IL)-17 and tumour necrosis factor- $\alpha$  (TNF- $\alpha$ ).

**Results:** Among Nox subunits (Nox1, Nox2, Nox4, Nox5, DUOX1, DUOX2, NOXA1, NOXO1), NOXA1 and NOXO1 mRNA were expressed higher in RA FLS than in OA FLS. After treatment with IL-17 and TNF- $\alpha$  for 24 hours GM-CSF, Nox1 and NOXO1 mRNA in RA FLS were elevated. Amount of ROS production was also elevated after treatment with IL-17 and TNF- $\alpha$ . When RA FLS were treated with bromopyruvic acid (BrPa), glycolysis inhibitor by inhibition of hexokinase II, GM-CSF mRNA and ROS were decreased and Nox1 and Nox4 mRNA showed no difference.

**Conclusions:** Several factors may be involved between ROS and Nox in RA FLS. Both ROS and Nox were elevated in inflammatory condition in RA FLS. From this result we expect that Nox-targeted therapy may be effective for treatment with RA.

**THU0094** **ROLE OF SPHINGOSINE-1-PHOSPHATE RECEPTOR 3 SIGNALLING IN COLLAGEN-INDUCED ARTHRITIS**

T. Inoue, H. Nagahara, S. Kaneshita, T. Kida, Y. Kukida, K. Fujioka, M. Wada, M. Kohno, Y. Kawahito. *Department of Inflammation and Immunology, Kyoto Prefectural University of Medicine, Kyoto, Japan*

**Background:** Sphingosine-1-phosphate (S1P) is a biologically active phospholipid, which is derived from membrane lipid. It binds to the receptors, named S1P1–5, and regulates several signalling pathways involved in inflammation, cell survival, angiogenesis and cell migration. Concentration of S1P and expression of S1P receptors can vary according to local tissue conditions. RA is a chronic inflammatory disorder of joints and the concentration of S1P in synovial fluid is higher in RA patient than in OA patient. *In vitro*, S1P3 expression in RA synovio-cyte is upregulated by TNF $\alpha$  treatment. On the other hand, it is not clarified whether S1P/S1P3 signalling pathway contributes to arthritis in RA.

**Objectives:** The objective of this study is to investigate the role of S1P/S1P3 signalling in inflammatory arthritis.

**Methods:** Collagen-induced arthritis (CIA) was induced by subcutaneous injection of bovine type II collagen emulsified in complete Freund's adjuvant in wild-type (WT) or S1P3-knock-out (S1P3-KO) 7–9 week-old DBA/1J mice. Arthritis severity were evaluated by visual scoring and histological analysis. The severity was assessed over time by using the arthritis score, in which each paw was scored on a scale of 0–4 and the scores of all four paws were cumulated, resulting in a maximum possible score of 16 per mouse. For histopathological examination, mice were sacrificed on the 42nd day and the hindlimbs were removed and fixed in 4% buffered formaldehyde. Paraffin embedded sections of the knee joints stained with hematoxylin and eosin were systematically scanned in a microscope and scored based on cell infiltration, cartilage destruction and bone erosion parameters. S1P3 mRNA expression was examined by realtime PCR method with total RNA extracted from knee joint capsules of CIA or normal WT mice. Murine primary fibroblast like synoviocytes (FLS) were obtained from CIA mice. We examined S1P3 expression after TNF $\alpha$  treatment and measured cytokine produced after S1P treatment with or without TNF $\alpha$  pretreatment in FLS.

**Results:** S1P3 deficiency resulted in modest symptoms of arthritis and a significant reduction in synovial inflammation and bone erosions in histological analysis. S1P3 mRNA expression in knee joint capsule in CIA mice was about five times as high as that in normal mice. TNF $\alpha$  treatment upregulated S1P3 expression and S1P treatment enhanced IL-6 production in WT-FLS significantly. TNF $\alpha$ -priming enhanced S1P-induced IL-6 production, which is significantly higher in WT-FLS than in KO-FLS. This effect was not observed in MCP-1 production of WT-FLS.

**Conclusions:** S1P3-KO reduced severity of arthritis, inflammation and bone erosions in CIA. S1P3 mRNA was upregulated in inflamed joint capsule. S1P induces IL-6 production via S1P3 upregulation by TNF $\alpha$  in CIA-FLS. S1P3 inhibition could be a good target of the therapy for arthritis.

**THU0095** **DIFFERENTIAL COMPLEMENT ACTIVATION IN RHEUMATOID ARTHRITIS PATIENTS**

T.C.R. McDonnell<sup>1</sup>, C. Bradford<sup>1</sup>, D. Raj<sup>1,2</sup>, C. Ciurtin<sup>1,2</sup>, E.C. Jury<sup>1</sup>, J.J. Manson<sup>1,2</sup>. <sup>1</sup>Division of Medicine, University College London; <sup>2</sup>Rheumatology Department, UCLH, London, UK

**Background:** An atypical subgroup of patients with seropositive rheumatoid arthritis (RA) has been identified with active disease but normal levels of the acute phase protein C-reactive protein (CRP), considered an accurate marker of disease activity. Previously we identified that patients with normal CRP (nCRP) during flares of RA had an altered immunological profile, had diagnostic delays and seemed to respond less well to conventional treatment compared to RA patients who mounted an appropriately high CRP (hCRP) response. Activation of the complement pathway has been associated with disease activity in RA patients and it is suggested both the presence of autoantibodies and activation of complement are required during the inflammatory processes that lead to joint damage. CRP plays a crucial role in the regulation of complement activation via both the alternative and classical pathways, either through interaction with C4 binding protein or degrading C3 fragment-C3b to C3i via factor H. However, it is not known whether these pathways are altered in RA patients with nCRP compared with hCRP during active flares.

**Objectives:** To investigate how altered CRP response may differentially regulate C3 cleavage in RA patients with nCRP compared to hCRP levels during flares of RA.

**Methods:** 24 RA patients with active synovitis were recruited, defined by  $\geq 1$  joint with Power Doppler detected by US, 15 had normal (n)CRP ( $\leq 5$  mg/L) and 9 had high (h)CRP ( $> 5$  mg/L) levels. Serum and detailed clinical data were collected. 18 age and sex matched healthy donors (HCs) were also analysed. Serum was subjected to SOMAscan Proteomic Assay. Complement components were analysed by Western blot following 1:400 serum dilution and assessed for C3/C3a and albumin expression. Densitometric analysis was applied to the Western blots and the C3a values were normalised against albumin, resultant values were expressed as fold change from HC. Results were correlated with clinical and disease features using linear regression curves in Prism.

**Results:** Proteomics identified differential expression of complement components in serum from hCRP compared to nCRP patients; specifically a significant upregulation of alternative complement pathway factors (eg Factors I, H and B) was seen in hCRP patients and a downregulation of kallistatin, an inhibitor of the classical pathway in nCRP patients. Average C3 cleavage product was 4.8 (0.18–14.4) for hCRP and 3.05 (0.28–6.6) for nCRP, both significantly higher compared to HCs ( $p < 0.01$  HC vs nCRP,  $p < 0.05$  HC vs hCRP). The levels of C3 cleavage were then correlated against ESR, CRP and anti-anti-cyclic citrullinated peptide (CCP) levels in both sets of patients. In hCRP patients, strong correlations ( $R^2 > 0.5$ ) were observed for C3 vs ESR ( $p < 0.05$ ), C3 vs CRP ( $p < 0.03$ ) and ESR vs CRP ( $p < 0.0003$ ) but no correlation was found between C3 and levels of anti-CCP antibodies ( $R^2 = 0.208$ ,  $p = 0.255$ ). In contrast nCRP patients demonstrated a strong correlation between C3 levels vs anti-CCP antibodies ( $R^2 = 0.53$ ,  $p < 0.05$ ) whilst no correlation was seen with CRP or ESR levels ( $R^2 = 0.0004$ ,  $p = 0.236$ ).

**Abstract THU0095 – Table 1.** A table of proteins related to complement and coagulation found differentially expressed between hCRP and nCRP patients by SOMAscan proteomics.

hCRP	nCRP
Factor H	Kallistatin
Factor B	IL17F
Factor I	
C3b	
F1xab	
C5a	
C9	
F Xa	
F IX	

**Conclusions:** Cleavage of complement factor C3 appears to be driven by a different mechanism in hCRP compared to nCRP patients suggesting that complement is activated via different pathways. This supports the hypothesis that nCRP and hCRP patients have an altered disease pathogenesis.

**Disclosure of Interest:** None declared

**THU0096** **A MAPK ACTIVATED KINASE 2 INHIBITOR ATTENUATES INFLAMMATORY AND DESTRUCTIVE ARTHRITIS IN HUMAN EX VIVO MODELS**

T.W. Kragstrup<sup>1,2</sup>, A. Mellekjær<sup>1</sup>, M. Nielsen<sup>1</sup>, L. Hefdal<sup>1</sup>, P. Schafer<sup>3</sup>, B. Deleuran<sup>1,4</sup>. <sup>1</sup>Department of Biomedicine, Aarhus University, Aarhus C; <sup>2</sup>Department of Internal Medicine, Randers Regional Hospital, Randers, Denmark; <sup>3</sup>Department of Translational Development, Celgene Corporation, Summit, USA; <sup>4</sup>Department of Rheumatology, Aarhus University Hospital, Aarhus C, Denmark

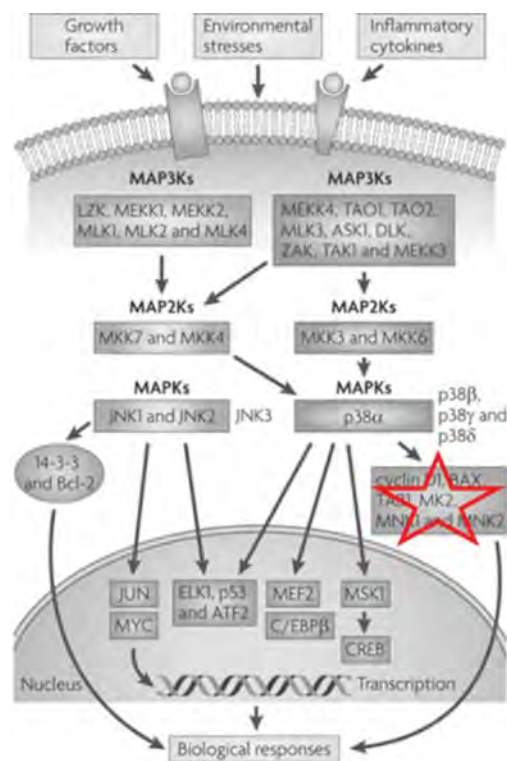

**Background:** Targeting intracellular pathways with oral small molecules is an attractive therapeutic approach for treating immune mediated inflammatory diseases. The mitogen-activated protein kinase (MAPK) pathway is activated by environmental stressors, growth factors and inflammatory cytokines. However, the inhibition of central MAPK proteins has so far had undesirable side effects. The MAPK-activated protein kinase 2 (MK2) is a downstream mediator in the MAPK signalling pathway and could therefore be inhibited without the same side effects (see figure 1).

**Objectives:** The objective of this study was to study the effects of a small molecule inhibiting MK2 on inflammation and structural changes in *ex vivo* models of immune mediated inflammatory arthritis.

**Methods:** Synovial fluid mononuclear cells (SFMCs), fibroblast like synovial cells (FLSs) and peripheral blood mononuclear cells (PBMCs) were obtained from a study population consisting of patients with active RA or peripheral SpA with at least one swollen joint (for obtaining synovial fluid) (n=14). SFMCs were cultured for 48 hours with and without addition of a MK2 inhibitor (Celgene) at 1000 nM, 333 nM and 111 nM and supernatants were analysed by the Olink proseek multiplex interferon panel and commercially available ELISA assays. Because FLSs are only found in small amounts among SFMCs, autologous co-cultures of FLS and PBMCs and SFMCs were also used. SFMCs cultured for 21 days were used to study inflammatory macrophage differentiation and osteoclastogenesis.

**Results:** In SFMCs cultured for 48 hours, the MK2 inhibitor decreased the production of CXCL9 ( $p<0.001$ ), CXCL10 ( $p<0.01$ ), HGF ( $p<0.01$ ), CXCL11 ( $p<0.01$ ), TWEAK ( $p<0.05$ ), and IL-12B ( $p<0.05$ ) and increased the production of CXCL5 ( $p<0.0001$ ), CXCL1 ( $p<0.0001$ ), CXCL6 ( $p<0.001$ ), TGF $\alpha$  ( $p=0.01$ ), MCP-3 ( $p<0.01$ ), LAP TGF $\beta$  ( $p<0.05$ ) dose-dependently after Bonferroni correction (all corrected P values). At the highest concentration, the MK2 inhibitor also decreased MCP-1 production ( $p<0.05$ ). In FLS-SFMC co-cultures, the MK2 inhibitor decreased MCP-1 production ( $p<0.05$ ) but did not change the production of DKK1 and MMP3. In FLS-PBMC co-cultures, the MK2 inhibitor decreased the production of MCP-1 ( $p<0.0001$ ), increased MMP3 production ( $p<0.05$ ) but did not change DKK1 production. In SFMCs cultured for 21 days as a model of inflammatory macrophage differentiation and osteoclastogenesis, the MK2 inhibitor decreased the production of MCP-1 ( $p<0.05$ ) and tartrate-resistant acid phosphatase (TRAP) ( $p<0.05$ ) but did not change the production of IL-10.

**Abstract THU0096 – Figure 1.** Modified from Wagner & Nebreda, *Nature Review Cancer*, 2009.

**Conclusions:** This study reveals the effects of a MK2 inhibitor in *ex vivo* models of immune mediated inflammatory arthritis. The MK2 inhibitor changed the secretory profile of SFMCs and decreased inflammatory osteoclastogenesis. Taken together, this points to a role of this MK2 inhibitor in attenuating inflammatory and destructive arthritis.

#### THU0097 PHOSPHODIESTERASES 4 (PDE4) INHIBITOR AMELIORATES EXPERIMENTAL ARTHRITIS

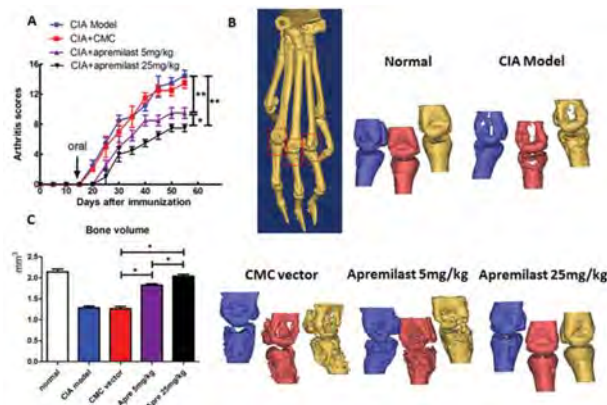

W. Chen<sup>1</sup>, Z. Xu<sup>2</sup>, H. Wee<sup>3</sup>, G.S. Lewis<sup>3</sup>, N. Olsen<sup>2</sup>, J. Lin<sup>1</sup>, S.G. Zheng<sup>2</sup>. <sup>1</sup>the first affiliated hospital, college of medicine, zhejiang university, Hangzhou, China; <sup>2</sup>Division of Rheumatology, Department of Medicine, Penn State University Hershey College of Medicine Hershey; <sup>3</sup>Department of Orthopaedics and Rehabilitation, Penn State University Hershey College of Medicine Hershey, Hershey, USA

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory bone-destructive disorder with autoimmune features. Apremilast is a novel phosphodiesterases 4 (PDE4) inhibitor suppressing immune and inflammatory responses.

**Objectives:** We assessed the anti-inflammatory and bone protection effects of apremilast in collagen CII induced arthritis (CIA) models.

**Methods:** Apremilast was given starting from day 14 after immunisation, we investigated whether apremilast (5 mg/kg or 25 mg/kg) can ameliorate arthritis onset. Bone erosion was measured by histological and micro-computed tomographic analysis. Anti-mouse type II collagen (CII) antibody levels were measured by enzyme-linked immunosorbent assay. Human cartilage and rheumatoid arthritis (RA) synovial fibroblasts (RASFs) implantation in the severe combined immunodeficiency (SCID) mouse model of RA were used to study the role of apremilast in suppression of RASFs destroying cartilage *in vivo*.

**Results:** We found that apremilast therapy delayed arthritis onset and reduced arthritis scores in CIA model at a different dose, compared to CIA model and blank vector (figure 1A). Total serum IgG, IgG1, IgG2a, and IgG2b were all decreased in apremilast groups. Furthermore, apremilast can prevent CIA mice from bone erosion by CT analysis. High dose of apremilast (25 mg/kg) was superior to low dose (5 mg/kg) in treating CIA (figure 1B, C). Apremilast treatment can inhibit destroy and migratory ability of RASFs to cartilages. Compared to the model group, Apremilast treatment significantly reduced the invasion scores in both primary implant and contralateral implant.

**Conclusions:** Our data suggest that apremilast was effective in preventing arthritis and bone erosion in CIA model, implicating a potential promise of therapy on rheumatoid arthritis.

#### THU0098 COMBINATION THERAPY OF RAPAMYCIN AND A GLUTAMINE ANTAGONIST FACILITATES THE EXPANSION OF MYELOID-DERIVED SUPPRESSOR CELLS AND AMELIORATES ARTHRITIS IN SKG MICE

Y. Ueda, J. Saegusa, T. Okano, S. Sendo, H. Yamada, Y. Ichise, I. Naka, S. Takahashi, K. Akashi, A. Onishi, A. Morinobu. *Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan*

**Background:** Myeloid-derived suppressor cells (MDSCs) are a heterogeneous population of immature cells that increase in the pathological state such as tumour or inflammation and have the immunosuppressive ability. MDSCs have been

reported to ameliorate arthritis in several mice models. Mechanistic target of rapamycin (mTOR) pathway and glutaminolysis activate cooperatively in the differentiation from myeloid progenitors to mature myeloid cells such as dendritic cells, macrophages, or osteoclasts as well as the activation of effector T cells and the differentiation of Th1 and Th17 cells. Although rapamycin has reported to facilitate the expansion of MDSCs and their immunosuppressive ability, the effect of the inhibitor of glutaminolysis on MDSCs is still unknown.

**Objectives:** The aim of this study is to evaluate the facilitative effects of the inhibition of mTOR pathway and glutaminolysis on MDSCs in a mouse model of rheumatoid arthritis.

**Methods:** Bone marrow (BM) cells from untreated Balb/c mice were cultured for 5 days under granulocyte-macrophage colony-stimulating factor (GM-CSF) stimulation with four patterns of drugs; 1) DMSO (control), 2) rapamycin (Rapa), 3) 6-Diazo-5-oxo-L-norleucine (DON; a glutamine antagonist), or 4) the combination of rapamycin and DON (Rapa +DON). Cultured BM cells were analysed by flow cytometry. Cultured MDSCs were isolated by manual MACS and analysed their immunosuppressive characters by co-culture with CFSE-dyed CD4<sup>+</sup> T cells. Rapa or Rapa +DON were administered intraperitoneally to arthritic SKG mice induced by Zymosan A injection.

**Results:** We found that DON suppressed the differentiation of dendritic cells (DC) in a dose-dependent manner and the addition of Rapa on DON inhibited the differentiation of macrophages *in vitro*. The proportions of the phenotype of MDSCs were increased with administrations of Rapa or DON, and large part of them were Ly6G<sup>+</sup> cells (the phenotype of polymorphonuclear MDSCs; PMN-MDSCs). Rapa ±DON significantly increased the expressions of TGF-β and PD-L1 and the inhibitory capacity of Ly6G<sup>+</sup> PMN-MDSCs. Rapa +DON significantly suppressed arthritis more efficiently in SKG mice than Rapa *in vivo*. (see figure 1)

**Conclusions:** The combination of rapamycin and a glutamine antagonist facilitates the expansion of PMN-MDSCs *in vitro* and ameliorates arthritis in SKG mice *in vivo*.

**Disclosure of Interest:** None declared

**Background:** Rheumatoid arthritis (RA) is an autoimmune inflammatory disease of the joints and is characterised by immune cell infiltration, synovial hyperplasia, and destruction of cartilage and underlying bone<sup>1</sup>. Myeloid derived monocytes and macrophages secrete a variety of cytokines such as tumour necrosis factor-α (TNF-α), interleukin (IL)-1β and IL-6, all of which perpetuate and amplify the vicious cycle of chronic inflammatory pathways<sup>2</sup>. Indeed, macrophage numbers in the synovium and serum levels of monocyte-derived cytokines correlate well with clinical symptoms and degree of joint damage in RA<sup>3</sup>.

**Objectives:** We recently reported that myeloid sirtuin 6 (Sirt6) is a critical determinant of phenotypic switching and the migratory responses of macrophages<sup>4</sup>.

Given the prominent role of macrophages in rheumatoid arthritis (RA) pathogenesis<sup>5</sup>, we tested whether myeloid Sirt6 deficiency affects the development and exacerbation of RA.

**Methods:** Arthritis was induced in wild type and myeloid Sirt6 KO (mS6KO) mice using collagen-induced and K/BxN serum transfer models. Peripheral blood mononuclear cells (PBMC) and synovial fluid macrophages were obtained from patients with RA and osteoarthritis and used for comparisons of Sirt6 expression and inflammatory activities.

**Results:** Based on clinical scores, ankle thickness, pathology and radiology, arthritis was more severe in mS6KO mice relative to wild type with a greater accumulation of macrophages in the synovium. Consistently, myeloid Sirt6 deficiency increased the migration potential of macrophages toward synovioctes-derived chemoattractants. Mechanistically, Sirt6 deacetylates forkhead box protein O1 to trigger its nuclear export and proteasomal degradation. Lastly, PBMC and macrophages isolated from RA patients exhibited lower Sirt6 expression compared with those from osteoarthritis patients or healthy subjects and their Sirt6 activity was inversely correlated with disease severity of the patients.

**Conclusions:** Our data identify a role of myeloid Sirt6 in clinical and experimental RA and suggest that myeloid Sirt6 may be an intriguing therapeutic target.

#### Rheumatoid arthritis – prognosis, predictors and outcome

THU0100

#### WORK IMPAIRMENT IN RHEUMATOID ARTHRITIS IS HIGHLY CORRELATED WITH DEPRESSION

A.D. Houssien, J. Galloway. *Academic Rheumatology department, King's College London, London, UK*

**Background:** Work outcomes are highly relevant in rheumatoid arthritis. Almost a third of people are no longer in employment by 2 years after diagnosis. Remaining in the workforce has positive attributes in terms of health outcome and quality of life.

**Objectives:** We set out to study the relationship between work and depression in rheumatoid arthritis.

**Methods:** We used routinely collected data from a hospital rheumatoid arthritis cohort that has systematically collected longitudinal data on disease measures, mental health, and work impairment. The Work and Social Adjustment Scale was used to estimate work impact, and we used question 2 (scale 0–8, above 6 indicating severe impairment) for analyses. Mood was assessed using the PHQ2. Cross sectional analyses were used to describe the relationship between work impairment and depression, adjusting for disease severity factors. We then analysed the temporal relationship between work impairment and mood.

**Results:** In total 283 patients had data available for analysis. Mean age was 53 years (SD 15), 81% were female, median disease duration 6 years (IQR 0 to 10). 74% were seropositive (RF or CCP), mean baseline DAS28 score 3.8 (SD 1.7), baseline HAQ 1.2 (SD 0.9). At baseline 69% reported no depression, 13% reported some symptoms, 18% had probable major depression. 72% of patients reported some degree of work impairment, 14% reported severe impairment. There was a strong relationship between baseline depressive symptoms and work impairment: coefficient 2.4, 95% CI 1.7 to 3.0, p<0.001. Adjusting for age, gender, DAS28, HAQ: 1.3, 95% CI 0.5 to 2.0, p=0.004. Over time work impairment increased (linear regression coefficient: 0.2 per year 95% CI 0.1 to 0.4), see figure 1. People with baseline low mood had an accelerated worsening of work impairment.

**Conclusions:** Work impairment is highly prevalent in contemporary rheumatoid arthritis patients. It is significantly correlated with mental health, even after adjusting for disease severity factors. Baseline mental health also predicts progression of work impairment. The relationship is likely bidirectional, and future research is justified to evaluate whether mental health interventions could improve work outcomes.

#### THU0101 TISSUE METABOLITE OF TYPE I COLLAGEN, C1M, AND CRP PREDICTS STRUCTURAL PROGRESSION OF RHEUMATOID ARTHRITIS

A.C. Bay-Jensen<sup>1</sup>, A. Platt<sup>2</sup>, M. Jenkins<sup>3</sup>, M. Weinblatt<sup>4</sup>, I. Byrjalsen<sup>1</sup>, K. Musa<sup>1</sup>, M. C. Genovese<sup>5</sup>, M.A. Karsdal<sup>1</sup>. <sup>1</sup>Rheumatology, Nordic Bioscience Biomarkers and Research, Herlev, Denmark; <sup>2</sup>Precision Medicine and Genomics; <sup>3</sup>Global Medicines Development, AstraZeneca, Cambridge, UK; <sup>4</sup>Division of Rheumatology, Brigham and Women's Hospital, Boston, MA; <sup>5</sup>Division of Immunology and Rheumatology, Stanford University, Palo Alto, CA, USA

**Background:** Biomarkers of rheumatoid arthritis (RA) disease activity typically measure inflammation or autoimmunity (e.g. CRP, rheumatoid factor (RF)). Another class of biomarkers are structural proteins of the joint. C1M and C3M, metabolites of type I and III collagen, are such biomarkers. These biomarkers have previously been documented to provide additional value as compared to standard inflammation biomarkers, for prognosis and prediction of response to treatment<sup>1</sup>.

**Objectives:** We investigated the relationship of high serum levels of C1M or C3M to radiographic progression, and benchmarked to CRP levels and RF status, demonstrated to be associated with structural progression<sup>2</sup>.

**Methods:** Placebo treated patients of the OSK123 studies (Ph3 clinical trials testing efficacy of fostamatinib) with baseline serum biomarkers C1M, C3M, CRP and RF were included ( $n_{BL}=474$ ). Van der Heijde mTSS was calculated at baseline and 24 week ( $n_{24}=264$ ). Progression was defined as moderate or rapid ( $\geq 0.5$  or  $\geq 5$  mTSS units/y). Patients were divided into subgroups; low, high or very high C1M, C3M and CRP (above/below median and highest quartile), or RF negative, positive and high positive ( $\geq 110$  U/L)<sup>2</sup>. Difference in clinical parameters were analysed by Mann-Whitney/Chi-squared tests, and multivariate predictive calculations by *Classification And Regression Tree* analysis including covariates (age, BMI, gender and disease activity assessment scores).

**Results:** High C1M, C3M and CRP levels were significantly associated with measures of disease activity ( $p<0.05$ ) and patient reported scores ( $p<0.05$ ). RF<sub>pos</sub> was also associated with disease active scores ( $p<0.05$ ). RF<sub>pos</sub> and CRP ( $p<0.001$ ), as well as C1M and C3M ( $p<0.05$ ), were significantly associated with mTSS at baseline. For prognostic measures, there were 2.5 and 4-fold as many rapid progressors in the C1M<sub>high</sub> and CRP<sub>high</sub> ( $p<0.05$ ), and in the C1M<sub>veryhigh</sub> and CRP<sub>veryhigh</sub> groups ( $p<0.001$ ) compared C1M<sub>low</sub> and CRP<sub>low</sub>, respectively. C1M and CRP performed similarly in the predictive analysis with AUCs of 0.67 and 0.69 (table 1). The best model involving C1M in predicting rapid progressor included BMI, SJC and HAQ (AUC 0.85), whereas the best model for CRP included CRP, BMI, SJC and HAQ (AUC 0.85). C3M and RF did not provide prognostic value.

Model description	Progressors (delta mTSS $\geq 0.5$ units per year)			Rapid progressors (delta mTSS $\geq 5$ units per year)		
	AUC	Specificity	Model parameters	AUC	Specificity	Model parameters
C1M alone	0.600	Sensitivity	C1Mveryhigh	0.672	Sensitivity	C1Mveryhigh
	59.7	Correctly identified	C1Mhigh	83.1	Correctly identified	C1Mhigh
C1M with demo, clinical ass., and X-ray	53.8			45.8		
	56.7			64.3		
CRP alone	0.712		C1Mveryhigh	0.849		C1Mveryhigh
	87.8		Age	78.4		BMI
CRP with demo, clinical ass., and X-ray	40.5		BMI	73.9		Disease duration
	64.1		Disease duration	76.2		HAQ
CRP alone	0.594		HAQ			
	85.1		CRPveryhigh	0.687		CRPveryhigh
CRP with demo, clinical ass., and X-ray	28.8		CRPhigh	84.0		CRPhigh
	56.9			50		
CRP alone	0.717		CRPhigh	67.0		
	76.1		Age	84.7		CRPhigh

	64.0		Disease duration	95.7		SJC
			SJC	74.2		HAQ
			HAQ			

**Conclusions:** Of the four markers analysed only C1M and CRP were associated with structural progression. They seem to perform equally well, but reflect two different aspects of disease pathogenesis (tissue turnover vs. inflammation), thus may provide individual, but supplementary, information. These simple measures may be important for enrichment of clinical trials with structural progressors.

Vassilopoulos<sup>1</sup>, on behalf of Greek Rheumatology Society RA Study Group. <sup>1</sup>Joint Rheumatology Program, National and Kapodistrian University of Athens School of Medicine, Athens; <sup>2</sup>Rheumatology Clinic, University of Ioannina, Ioannina; <sup>3</sup>Rheumatology Unit, KAT Hospital; <sup>4</sup>Rheumatology Unit, Sismanoglio Hospital, Athens; <sup>5</sup>Department of Rheumatology, University of Thessaly, Larissa; <sup>6</sup>Rheumatology Unit, NIMTS Hospital, Athens; <sup>7</sup>4th Department of Medicine, Aristotle University, Thessaloniki; <sup>8</sup>Rheumatology Unit, Agios Andreas Hospital, Patras; <sup>9</sup>Private Practice, Livadeia; <sup>10</sup>Private Practice, Athens; <sup>11</sup>Private Practice, Thessaloniki, Greece

**Background:** It is unclear if the widespread use of biologic DMARDs (bDMARDs) and the implementation of the treat to target approach have led to better disease control in patients with rheumatoid arthritis (RA) in daily clinical practice.

**Objectives:** To study the longitudinal changes in disease activity in a large, real life, longitudinal RA cohort.

**Methods:** Multicenter (11 hospitals, 3 private offices), prospective, RA epidemiological study in Greece. Demographics, disease characteristics, treatments and co-morbidities were collected via a web-based platform in registered patients at baseline and one year after their 1st visit.

**Results:** 1.096 RA patients with available paired evaluations one year apart (mean interval: 13.4 $\pm$ 3.6 months) were included (women: 78%, mean age: 62.8 years, mean disease duration: 11 years, RF and/or anti-CCP positive: 60%, mean HAQ: 0.44 $\pm$ 0.56). At baseline, 50% (n=548) of patients were on conventional DMARDs (csDMARDs) alone, 35% on cs- and b-DMARD combination (n=379) and 11% on bDMARD monotherapy (n=124). Among bDMARD treated patients, 60% were

receiving tumour necrosis factor inhibitors (TNFi) while 40% were on corticosteroids (mean daily dose: 4.7 mg). Despite these therapies, 43% of patients had active disease (DAS28-ESR>3.2); 34% moderate (MDA, DAS28-ESR=3.2–5.1) and 9% high (HDA, DAS28-ESR>5.1) disease activity. During the 1 year observation period, among the group of patients with MDA who were only on csDMARDs, 15% started a bDMARD while among those on bDMARDs, 11% switched to another bDMARD. The respective rates of starting a bDMARD (in those on csDMARDs) or switching to another bDMARD (in those on bDMARDs), were much higher for patients in the HDA group (41% and 32% respectively,  $p<0.001$  for both groups). At the end of the 1st year, the proportion of patients on TNFi and corticosteroids was 57% and 32%, respectively. Overall, despite a decrease in the DAS28-ESR score (from  $3.2\pm 1.2$  to  $2.9\pm 1.3$ ,  $p<0.001$ ), 37% of patients had still active disease (6% improvement after 1 year; MDA: 30%, HDA: 7%).

**Conclusions:** In a large, real life, RA cohort with almost half of patients on bDMARD-based therapies, more than one third of patients had still active disease at the end of the 1st year of follow-up. These findings could be explained in part by the low rate of bDMARD initiation or switching in this cohort or they could indicate the limitations of current therapeutic approaches in RA patients with longstanding disease in Greece.

### THU0103 EVALUATION OF SERUM B-2 MICROGLOBULIN LEVELS AND ITS RELATIONSHIP WITH DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

A.B. Kelesoglu Dincer, M. Torgutalp, E.G. Aydemir Gülöksüz, M.E. yayla, E. Uslu Yurteri, I.E. Okatan, S. Sezer, G. Kinikli, T.M. Turgay, A. Ates. *Rheumatology, Ankara University Faculty of Medicine Rheumatology Department, Ankara, Turkey*

**Background:**  $\beta$ -2 microglobulin ( $\beta$ 2MG) is produced and secreted from T and B lymphocytes. In autoimmune diseases, due to lymphocyte activation and proliferation, serum  $\beta$ 2MG level is expected to be higher than normal. In a few studies, increased serum and synovial fluid  $\beta$ 2MG levels in rheumatoid arthritis (RA) were reported.

**Objectives:** The aim of this study was to evaluate the concentration of  $\beta$ 2MG in peripheral blood in RA patients and to show its relationship with disease activity.

**Methods:** In this study, 121 RA patients and 50 sex and age matched healthy controls were enrolled. Patients who had other inflammatory diseases or any kind of malignancy were excluded.

**Results:** The mean age of RA patients (97 female and 24 male) were 55 years ( $\pm 10.9$  years) and mean disease duration was 9 years (min: 6 months, max: 42 years). The demographic data of patients and healthy controls are shown in table 1. There was a statistically significant difference between haemoglobin, erythrocyte sedimentation rate and C-reactive protein levels between two groups ( $p<0.001$ ,  $p<0.001$ ,  $p=0.001$  respectively). Serum  $\beta$ 2MG levels were higher in RA group than healthy controls ( $p<0.001$ ). When RA patients were grouped according to disease activity as remission to low disease activity (DAS28-ESR<3.2) ( $n=65$ ) and moderate to severe disease activity (DAS28-ESR $\geq$ 3.2) ( $n=56$ ), the serum  $\beta$ 2MG levels were higher in DAS28-ESR $\geq$ 3.2 group than in DAS28-ESR<3.2 group ( $p=0.003$ ). The difference between serum  $\beta$ 2MG levels were statistically significant in low and high disease activity groups when grouped both according to DAS-ESR and DAS-CRP ( $p=0.003$  and  $p=0.006$ , respectively). The seropositivity between two groups were similar ( $p=0.385$ ), although serum ESR, CRP levels and the rate of morning stiffness were significantly higher in high disease activity group. The results were shown in table 2. According to Spearman correlation test, the serum  $\beta$ 2MG level and DAS-ESR and DAS-CRP were positively correlated which were both statistically significant. ( $r=0.378$ ,  $p<0.001$  and  $r=0.324$ ,  $p<0.001$  respectively).

**Abstract THU0103 – Table 1.** Baseline characteristics of RA patients and healthy controls

Characteristics	RA(n=121)	Control (n=50)	p value
Female Sex, n (%)	97 (80.2)	35 (70.0)	0.150
Age, years	55.0 $\pm$ 10.9	52.6 $\pm$ 10.6	0.183
WBC	7736 $\pm$ 3177	7170 $\pm$ 1759	0.139
Hb	12.6 $\pm$ 1.5	14.1 $\pm$ 1.7	<0.001
Thrombocyte	290.4 $\pm$ 88.9	279.7 $\pm$ 65.2	0.441
ESR	24.3 $\pm$ 17.0	12.2 $\pm$ 8.2	<0.001
CRP (IQR)	2.5 (4.7)	6.1 (10.7)	0.001
$\beta$ 2-microglobulin	2.93 $\pm$ 1.20	2.21 $\pm$ 0.54	<0.001
DAS28-ESR	3.30 $\pm$ 1.16		
DAS28-CRP	3.60 $\pm$ 1.39		

**Abstract THU0103 – Table 2.** Baseline characteristics of RA patients

	DAS28-ESR $\leq$ 3.2 (n=65)	DAS28-ESR>3.2 (n=56)	p value
Female Sex, n (%)	48 (73.8)	29 (87.5)	0.060
Age, years	53.4 $\pm$ 11.3	56.9 $\pm$ 10.1	0.079
ESR	17.8 $\pm$ 12.3	31.9 $\pm$ 18.6	<0.001
CRP (IQR)	4.0 (7.9)	10.2 (12.6)	<0.001

### THU0104 THE TEMPORAL PROFILE OF ANTIBODIES DIRECTED AGAINST POST-TRANSLATIONAL MODIFICATIONS VARIES ACCORDING TO ISOTYPE AND TARGET IN PATIENTS WITH NEW-ONSET RHEUMATOID ARTHRITIS

B. Dyke<sup>1</sup>, M. Juarez<sup>2</sup>, H. Bang<sup>3</sup>, C.D. Buckley<sup>1</sup>, A. Filer<sup>1</sup>, K. Raza<sup>1</sup>. <sup>1</sup>University of Birmingham, Birmingham; <sup>2</sup>UCB Pharma, Slough, UK; <sup>3</sup>Orgentec Diagnostika GmbH, Mainz, Germany

**Background:** Autoantibodies directed against antigens with post-translational modifications (PTMs), such as citrullination (ACPA), are a hallmark of rheumatoid arthritis (RA)<sup>1</sup>. ACPA titres increase prior to disease onset, but are thought to be relatively stable after symptomatic inflammation is established<sup>2</sup>. The temporal profile of antibodies against acetylated (AAPA) and carbamylated (ACarPA) peptides has not been so comprehensively characterised following the onset of joint swelling<sup>3</sup>.

**Objectives:** We aimed to track serum levels of anti-PTM antibodies over 18 months in patients with newly-presenting RA in our prospective observational cohort.

**Methods:** Patients with treatment-naïve inflammatory arthritis donated serum at baseline, 6 and 18 months. 103 patients satisfying ACR<sup>EULAR 2010</sup> criteria for RA underwent testing for IgG and IgA antibodies against peptides with citrulline (ACPA), carbamylated lysine (ACarPA), and acetylated lysine (AAPA) PTMs using ELISA as previously described<sup>4</sup>.

**Results:** 57% of participants were female, and 48% and 50% patients were anti-CCP2 or rheumatoid factor positive respectively. Mean age was 56 years (s.d. 15.2), symptom duration 55 days (s.d. 22.4), and DAS28CRP 4.4 (s.d. 1.3) at enrolment.

Comparing baseline and 18 month median antibody levels measured by optical density, a decrease was observed over time for IgG (0.26 vs 0.17,  $p<0.0001$ ) and IgA AAPA (0.23 vs 0.09,  $p<0.0001$ ), as well as both IgG and IgA antibodies against citrullinated peptides (0.47 vs 0.40,  $p<0.0001$  and 0.16 vs 0.12,  $p<0.0001$  respectively). Significant reductions occurred between baseline and 6 months for both IgG ( $p<0.0001$ ) and IgA ( $p<0.0001$ ) AAPA antibodies, but not between 6 and

18 month timepoints after correction for multiple testing. A similar pattern was observed for IgA ACPA antibody levels, although IgG ACPA levels did not vary significantly comparing baseline with 6, and 6 with 18 month timepoints. Antibody levels were not influenced by exposure to therapy. Patients seropositive for anti-CCP2 at baseline demonstrated less labile antibody levels, with the exception of sustained increases in IgG ACPA reactivity compared with seronegative individuals. **Abstract THU0104 – figure 1.** demonstrates bidirectional changes in anti-PTM antibody reactivity at the patient level.

**Abstract THU0104 – Figure 1.** Fold change in anti-PTM autoantibody levels between baseline and 18 months in patients with newly-presenting rheumatoid arthritis (n=130)

**Conclusions:** Median ACPA and, to a lesser extent, ACPA levels fell over time, regardless of therapy. This was most marked for the IgA isotype. Differential isotype effects may represent maturation of the autoantibody repertoire from mucosal IgA antibodies involved in the breach of tolerance. Lability of ACPA levels may reflect the relative reversibility of acetylation of a lysine amino acid residue by comparison with citrullination and carbamylation modifications. By contrast, and as observed previously<sup>3</sup>, IgG ACPA levels increased over time, perhaps reflecting the tendency of the human proteome to accrue carbamylation modifications due to ageing, and metabolic or inflammatory stress.

THU0105

#### RELATIONSHIP BETWEEN DAS28 CATEGORIES AND RAID PATIENT REPORTED OUTCOME IN RHEUMATOID ARTHRITIS; SIGNIFICANT ADVANTAGE OF TARGETING DAS REMISSION

C. Smith<sup>1</sup>, M. Sharif<sup>1</sup>, A.A. Prideaux<sup>2</sup>, P.D. Kiely<sup>1</sup>. <sup>1</sup>Rheumatology, ST Georges University Hospitals NHS Foundation Trust, London; <sup>2</sup>School of Clinical Medicine, University of Cardiff, Cardiff, UK

**Background:** EULAR/ACR guidelines recommend remission or low DAS28 as the treat to target goal for patients with rheumatoid arthritis (RA). The DAS28 is a composite score derived from objective (swollen joint count and ESR/CRP) and subjective (tender joint count and patient global) measures of disease activity, restricted to 28 joints. It has been criticised as not being representative of the whole patient or completely allied to patient experience. Alternative patient reported outcomes (PROM) have been developed, including the rheumatoid arthritis impact of disease (RAID) which is a self-reported index which assesses seven domains by visual analogue scale: pain, disability, fatigue, sleep, coping,

physical and emotional well-being. Responses are weighted differently producing a final score from 0–10 and a score <2 is considered a patient-acceptable status.

**Objectives:** Given uncertainty over the necessity to aim for DAS remission (RDAS) as opposed to low DAS (LDAS) as a treatment target, we sought to explore the relation between DAS outcomes and RAID scores in routine clinical practice.

**Methods:** RA patients attending for routine review in the outpatient clinic at St George's Hospital were assessed by a physician associate between June 2016 and September 2017. DAS28 CRP and ESR scores were recorded and RAID questionnaires completed by patients and calculated using the on-line EULAR tool. Data were analysed on Excel for summary statistics and Spearman correlation coefficient and socscistatistics.com for Mann-Whitney U tests.

**Results:** 117 RA patients were assessed, 84% female, mean age 59.6 years, 77% RF positive and 85% ACPA positive. The prevalence of DAS28 ESR categories was RDAS ( $\leq 2.6$ ) n=57 (49%), LDAS (2.6–3.2) n=17 (14.5%), moderate (MDAS 3.21–5.1) n=35 (30%), high (HDAS  $\geq 5.1$ ) n=8 (6.5%). RAID scores correlated strongly with patient global (r=0.62), DAS28 CRP (r=0.58) and DAS28 ESR (r=0.54) but poorly with tender joint count (r=0.32), swollen joint count (r=0.10), ESR (r=0.13) and CRP (r=0.09). The mean RAID score in DAS28 ESR categories was RDAS 2.49, LDAS 3.77, M+HDAS 5.92, see figure 1, box and whisker plots. RAID scores were significantly different (Mann-Whitney U) between M+HDAS versus RDAS (p<0.0001), M+HDAS versus LDAS (p=0.0048) and also between RDAS versus LDAS (p 0.013). Similar significant differences in RAID scores were found with DAS28 CRP categories. There were no significant differences in RAID scores between RF positive versus negative or ACPA positive versus negative patients.

Of 30 patients with RAID <2, DAS28 ESR was <2.6 in 27 (90%) and <3.2 in 29 (97%). Of 74 patients with DAS28 ESR <3.2, RAID was >2 in 45 (61%) with fatigue followed by sleep being the worst scoring domains.

**Conclusions:** RAID scores strongly correlate with patient global and total DAS28 (ESR or CRP) scores, and are significantly different between all DAS categories, including RDAS versus LDAS. Patients with RAID <2 are almost all at LDAS target, but high numbers at LDAS have unacceptable RAID, largely driven by high fatigue and sleep scores. This suggests that achieving RDAS has significant benefit over LDAS from a PROM perspective, and attention should be paid to fatigue and sleep if RAID is unacceptable in LDAS patients.

**Disclosure of Interest:** None declared

THU0106

#### CONVERTING PATIENT-REPORTED OUTCOME MEASURES OF FATIGUE AND PAIN TO PROMIS SCORES: DATA FROM PHASE 3 BARICITINIB RHEUMATOID ARTHRITIS TRIALS

C.O. Bingham III<sup>1</sup>, C. Gaich<sup>2</sup>, A.M. DeLozier<sup>2</sup>, A. Quebe<sup>2</sup>, L. Sun<sup>2</sup>, S. Otawa<sup>2</sup>, J. Pope<sup>3</sup>. <sup>1</sup>Johns Hopkins Univ, Baltimore; <sup>2</sup>Eli Lilly and Company, Indianapolis, USA; <sup>3</sup>Joseph's Health Care, London, Alberta, Canada

**Background:** Fatigue and pain in patients (pts) with RA are often measured with the Functional Assessment of Chronic Illness Therapy-Fatigue (FACIT-F) and the Medical Outcomes Study Short-Form-36 (SF-36). Patient-Reported Outcomes Measurement Information System (PROMIS) was developed using a population-calibrated T-score metric (Mean 50, SD 10). Crosswalk tables were developed linking legacy instruments to PROMIS instruments, including Fatigue and Pain

Interference (PI). Comparisons to the general population can be made from PROMIS scores.<sup>1-2</sup>

**Objectives:** To convert FACIT-F and SF-36 Bodily Pain (BP) scores to PROMIS Fatigue and PI scores to determine how PROMIS performs in 2 phase 3 baricitinib (bari) RA trials.

**Methods:** In RA-BEAM, pts with inadequate response (IR) to MTX were randomised 3:3:2 to placebo (PBO) once daily (QD), bari-4 mg QD, or adalimumab (ADA) 40 mg biweekly.<sup>3</sup> In RA-BEACON, pts with IR to bDMARDs were randomised 1:1:1 to receive PBO or bari 2 mg or 4 mg QD.<sup>4</sup> FACIT-F assessed fatigue and SF-36 BP, pain. Pt-level PROMIS scores were converted from FACIT-F/SF-36 BP using validated crosswalk tables.<sup>1-2</sup> Analysis of covariance was conducted on PROMIS score conversions to compare bari to all treatment arms.

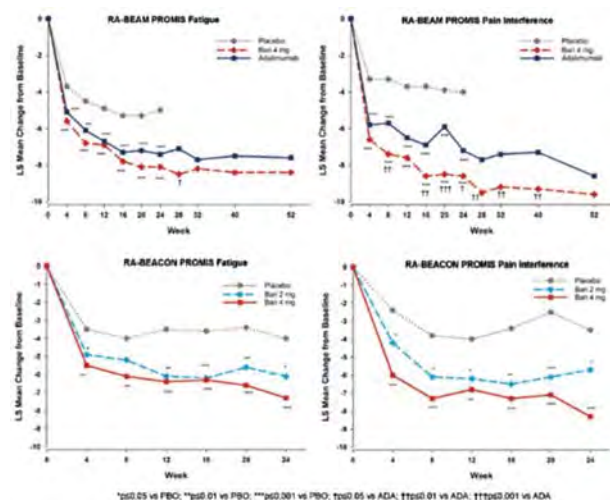

**Results:** Pts had considerable baseline fatigue/pain; mean scores approached or exceeded 1 SD (10 points on the metric) from population norms. Bari was associated with clinically relevant improvements (exceeding 0.5 SD/5 points on the T-score metric) vs PBO for PROMIS fatigue/PI scores (table 1). PROMIS fatigue/PI scores in RA-BEAM reached population norms (<55) by week 12 for bari and ADA (table 1). Bari remained associated with significant improvements in PROMIS fatigue/PI vs PBO through 24 weeks in both studies and vs ADA for PI in RA-BEAM (figure 1).

Data are mean (SD)

<sup>a</sup>Higher PROMIS scores mean more fatigue/pain

<sup>b</sup>BEACON was a 24 week study

ADA=adalimumab; bari=baricitinib; PBO=placebo

**Abstract THU0106 – Figure 1.** Change from baseline for PROMIS Fatigue and Pain Interference in RA-BEAM and RA-BEACON

**Conclusions:** While PROMIS was not used in the studies directly, pt-level crosswalk tables provide an estimate of effect that may be demonstrated when using PROMIS in clinical trials. These results provide preliminary evidence of the ability of PROMIS to demonstrate treatment benefit.

#### THU0107 EVALUATION OF CARDIOVASCULAR RISK IN PATIENTS WITH RHEUMATOID ARTHRITIS AND ANTI-TNF-ALPHA THERAPY

D. Anghel<sup>1</sup>, L. Panturu<sup>2</sup>, V.C. Jurcut<sup>1</sup>, M.M. Muresan<sup>3</sup>, E.L. Diliroci<sup>1</sup>, M.M. Negru<sup>2</sup>, R.A. Bursuc<sup>1</sup>. <sup>1</sup>Dr. Carol Davila Central Military Emergency University Hospital; <sup>2</sup>Sfanta Maria Hospital; <sup>3</sup>Medlife Clinical Hospital, Bucharest, Romania

**Background:** Rheumatoid arthritis is a chronic inflammatory autoimmune disease that causes systemic inflammation associated with increased risk of coronary, cerebral and peripheral ischaemic accidents. Biological therapy, by decreasing systemic inflammation, implicitly reduces cardiovascular risk in patients with rheumatoid arthritis. The assessment of carotid atheromatosis in Doppler ultrasound examination can be a useful element in the diagnosis of patients with cardiovascular risk.

**Objectives:** We followed the cardiovascular risk as well as the development of the carotid artery plaque by carotid Doppler ultrasound, lipid profile and arterial hypertension in patients with rheumatoid arthritis who have undergone biological treatment with anti-TNF-alpha. We also studied the correlation of the intima-medium thickness index in the carotids with the activity of rheumatic disease (DAS28, CRP, VSH) and the evolution of these parameters under biological therapy.

**Methods:** Our study included 37 patients with rheumatoid arthritis in treatment with DMARD's (group 1) and 50 patients with rheumatoid arthritis in treatment with anti-TNF-alpha (etanercept, adalimumab, infliximab) biological therapy (group 2). The following parameters were assessed in all patients: DAS28, lipid profile (total cholesterol, LDL, HDL, triglycerides), which were followed at 0, 6, and 12 months. The Intima-Medium Thickness Index was measured by Mode B sonography at the level of the common carotid artery, bifurcation of both arteries and the external carotid artery. The value of the index above 0.7 mm was considered pathological.

**Results:** In lot 1, after the carotid Doppler ultrasound, of the 37 patients, 21 presented the carotid artery plaque, and in lot 2 of the 50 patients, 34 showed these changes. A full evaluation (DAS28, lipid profile, arterial tension, carotid ultrasound) of all patients was performed at the start of the study. At 6 months, inflammatory markers and DAS28 showed a decrease in baseline values in both groups, more significant in the biological therapy group. Reduction of the intima-medium thickness index and blood pressure was observed in both groups, with no significant differences. At 12 months, CRP and DAS28 in the DMARD-treated group corresponded to disease remission values in 33 patients (89%), and in the group treated with biological therapy, the same remission rates of the disease were recorded in 49 patients (97.7%). The intima-medium thickness index in the DMARD-treated group decreased from the 6 month values. In patients with biological therapy, the reduction in the mid-thickness index recorded a progressive decrease from the previous assessment.

**Conclusions:** There is a direct correlation between the markers of inflammation and the evolution of carotid atheromatosis in patients with rheumatoid arthritis. The intima-medium thickness index is a paraclinical feature useful in assessing cardiovascular risk in patients with rheumatoid arthritis.

Biological therapy, by controlling the underlying disease, also improves cardiovascular prognosis. Treatment with anti-TNF-alpha makes good control, together with lipid-lowering and antihypertensive medication of associated cardiovascular pathology, in patients with rheumatoid arthritis.

#### THU0108 PATIENT REPORTED OUTCOME MEASURES FOLLOWING KNEE AND HIP REPLACEMENT FOR INDIVIDUALS WITH RHEUMATOID ARTHRITIS: EVIDENCE FROM ROUTINELY-COLLECTED DATA

E. Burn<sup>1</sup>, N.K. Arden<sup>1</sup>, C.J. Edwards<sup>2</sup>, C. Cooper<sup>1</sup>, D. Murray<sup>1</sup>, R. Pinedo-Villanueva<sup>1</sup>, D. Prieto-Alhambra<sup>1</sup>. <sup>1</sup>NDORMS, University of Oxford, Oxford; <sup>2</sup>NIHR Clinical Research Facility, University Hospital Southampton, Southampton, UK

**Background:** Most estimates of patient-reported outcome measures (PROMs) following total knee replacement (TKR) and total hip replacement (THR) are from individuals with osteoarthritis (OA). It is not well-known whether individuals with rheumatoid arthritis (RA) achieve similar results.

**Objectives:** To assess the association between RA, relative to OA, with 1) post-operative PROMs and 2) the change between pre- and post-operative PROMs for TKR and THR.

**Methods:** PROMs for TKR and THR between 2009 and 2015 identified using Hospital Episode Statistics (HES), with diagnosis of RA or OA identified in the Clinical Practice Research Datalink (CPRD). The condition-specific Oxford Knee Score/Oxford Hip Score (OKS/OHS), with pain and function subscales, and Euro-Qol 5-dimension (EQ-5D) overall quality of life were collected prior to and six months following surgery. OKS/OHS ranges from 0 to 48, OKS/OHS function from 0 to 20, OKS/OHS pain from 0 to 28, and EQ-5D from -0.5 to 1, with higher scores being better for each. The effect of RA, relative to OA, on post-operative PROMs was estimated using multivariable linear regressions, which adjusted for age, gender, comorbidities (measured by the Charlson score) and socioeconomic status (measured by IMD Quintile). The effect of RA, relative to OA, on change in PROMs was assessed by adding pre-operative scores as an explanatory factor in the models.

**Results:** 2212 (2,070 OA and 142 RA) and 2128 (2,030 OA and 98 RA) individuals informed the analyses of TKR and THR, respectively. A diagnosis of RA, relative to OA, was associated with a one-point lower post-operative OKS and a 3-point lower OHS, although only the latter difference was significant. These lower estimates of post-operative OKS/OHS were primarily due to significantly lower scores on the function subscales. The estimated change in OKS/OHS, after accounting for pre-operative scores, was similar for those with RA and OA. RA was also associated with a 0.1 lower post-operative EQ-5D, which was significant for both TKR and THR. The expected change in EQ-5D remained significantly lower for those with RA. The effect of diagnosis from the models is summarised in table 1, with estimated change in OKS/OHS shown in figure 1.

**Abstract THU0108 – Table 1.** Effect of RA, relative to OA, on 1) total post-operative scores and 2) change in scores. Estimated coefficients with 95% confidence intervals. Significant differences in bold.

	TKR		THR	
	Total	Change	Total	Change
OKS/OHS (0 to 48)	-1.33 (-2.92 to 0.27)	-0.07 (-1.59 to 1.46)	<b>-2.80 (-4.43 to -1.18)</b>	-1.57 (-3.15 to 0.01)
OKS/OHS function (0 to 20)	<b>-1.22 (-1.90 to -0.54)</b>	-0.50 (-1.13 to 0.14)	<b>-1.91 (-2.75 to -1.07)</b>	<b>-0.97 (-1.76 to -0.18)</b>
OKS/OHS pain (0 to 28)	-0.13 (-1.12 to 0.87)	0.34 (-0.63 to 1.30)	-0.89 (-1.80 to 0.02)	-0.66 (-1.56 to 0.25)
EQ-5D (-0.5 to 1)	<b>-0.12 (-0.16 to -0.08)</b>	<b>-0.09 (-0.13 to -0.06)</b>	<b>-0.12 (-0.17 to -0.08)</b>	<b>-0.08 (-0.13 to -0.04)</b>

**Abstract THU0108 – Figure 1.** Estimated effect of diagnosis on expected change in OKS/OHS by pre-operative score

**Conclusions:** Individuals with RA undergoing TKR and THR appear to achieve similar improvements in condition-specific scores as those with OA, although the gain in function may be slightly less. The gain in overall quality of life is less for those with RA, however, which is likely due to the systemic nature of the disease.

#### THU0109 AUTOANTIBODY PROFILING FOR RESPONSE TO BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS AND NO OR LIMITED EXPOSURE TO METHOTREXATE

L. Martinez Gamboa<sup>1</sup>, H. Bang<sup>2</sup>, M. Issa<sup>3</sup>, S. Zuckerman<sup>3</sup>, A. Cardoso<sup>3</sup>, T. Holzkaemper<sup>3</sup>, F. De Leonardis<sup>3</sup>, I. de la Torre<sup>3</sup>, Y. Tanaka<sup>4</sup>, E. Feist<sup>1</sup>. <sup>1</sup>Charité-Universitätsmedizin Berlin, Berlin; <sup>2</sup>Orgentec Diagnostika GmbH, Mainz, Germany; <sup>3</sup>Eli Lilly and Company, Indianapolis, USA; <sup>4</sup>University of Occupational and Environmental Health, Kitakyushu, Japan

**Background:** Posttranslational antigen modification plays a role in the pathogenesis of rheumatoid arthritis (RA). The associated autoantibodies are considered unfavourable prognostic factors with respect to disease severity and radiographic outcome. Limited information is available for different serotypes and prediction of treatment response to Janus kinase inhibitors including baricitinib (BARI).

**Objectives:** To clarify whether fine profiling of baseline autoantibodies against different modified isoforms of vimentin correlate with clinical or radiographic outcome in patients (pts) with active RA and no or limited prior DMARD treatment who initiate treatment with BARI.

**Methods:** Baseline sera samples from DMARD-naïve pts participating in the randomised, active comparator-controlled Ph3 trial RA-BEGIN<sup>1</sup> [methotrexate (MTX) n=210, BARI 4 mg (mono) n=159 and BARI 4-mg+MTX (combo) n=215] were investigated for autoantibody class (IgG, IgM and IgA) reactivity towards vimentin (V), modified by citrullination (MCV), carbamylation (Carb) or acetylation (Acct), using enzyme-linked immunosorbent assay. Pts were stratified according to negative (<20 U/ml), low-positive (20–60 U/ml) and high-positive (>60 U/ml, 3-fold above the ULN) antibody titre or with respect to the antibody titre tertiles. Change in clinical outcomes (DAS28-CRP, CDAI) and radiographic progression (modified Total Sharp Score) were analysed from baseline to Week 24 using modified last observation carried forward and linear extrapolation, respectively, by baseline autoantibody subclass and titre.

**Results:** Comparison of least squares mean difference in clinical scores showed more consistent improvement in pts treated with BARI combo vs MTX irrespective of baseline autoantibody subclass and titre. In general, pts with low-titre anti-CarbV, AcctV and MCV subclass antibodies showed numerically less improvement in most of the analyses under BARI mono vs MTX compared to BARI combo vs MTX although for anti-CarbV subclass seronegative pts, no significant differences were found in the clinical response between BARI mono vs MTX. Furthermore, anti-MCV IgA and IgM as well as anti-CarbV IgA negative status was also associated with significant reduction of radiographic progression in pts treated with BARI combo vs MTX. For seropositive pts, response to treatment with BARI mono or combination therapy was higher in pts with highest titres of anti-MCV and anti-CarbV. However, a significant difference with respect to radiographic progression was detectable only for BARI combo vs MTX. By stratifying pts according to their antibody profile, these observed radiographic differences were achieved in the anti-MCV and anti-CarbV IgG high-positive as well as anti-CarbV IgM low-positive pts.

**Conclusions:** In these exploratory analyses, seropositive pts with high titres of anti-MCV and anti-CarbV at baseline showed better responses to BARI mono or combo vs MTX for composite scores, and to BARI combo in structural progression outcomes.

THU0110

#### EARLY TREATMENT AND LOW DOSE CORTICOSTEROIDS MIGHT DECREASE MORTALITY IN EARLY ARTHRITIS: RESULTS FROM THE RECORD LINKAGE OF CLINICAL AND ADMINISTRATIVE DATABASES

G. Sakellariou<sup>1</sup>, C.A. Scirè<sup>2,3</sup>, F. Rumi<sup>3</sup>, G. Carrara<sup>3</sup>, C. Cerra<sup>4</sup>, S. Migliazza<sup>4</sup>, R. Caporali<sup>1</sup>, C. Montecucco<sup>1</sup>. <sup>1</sup>Chair And Division Of Rheumatology, IRCCS Policlinico San Matteo Foundation, Pavia; <sup>2</sup>Rheumatology Unit, Department of Medical Sciences, University of Ferrara, Ferrara; <sup>3</sup>Epidemiology Unit, Italian Society of Rheumatology, Milano; <sup>4</sup>Department of information and control management, ATS Pavia, Pavia, Italy

**Background:** In patients with rheumatoid arthritis (RA) increased mortality, especially for cardiovascular (CV) events, is still described, despite the advances in RA management.

**Objectives:** To evaluate the impact of early diagnosis and treatment with disease modifying anti-rheumatic drugs (DMARDs) on mortality in patients with early RA and undifferentiated arthritis (UA) through record linkage between clinical and administrative databases.

**Methods:** Consecutive patients with RA or UA from an early arthritis clinic (2005–2016), treated with tight control to achieve DAS28 <3.2, were included. Health assessment Questionnaire (HAQ) and date of symptom onset were recorded at baseline. Data on mortality, cause of death and drug prescription derived from administrative healthcare databases, linked to the clinical database. Cox regression models were used to evaluate the impact of the interval from symptom onset to diagnosis (categorised <3 months, 3–6 months, >6 months), from diagnosis to treatment (<3 months, >3 months, never) and from onset to treatment (<3 months, 3–6 months, >6 months, never) on overall mortality. Analyses were adjusted for age, gender, ACPA positivity, Charlson comorbidity index, HAQ and median daily prednisone dose. Results were presented as hazard ratios (HR) with 95% CI. Secondary analyses categorising prednisone in low dose (≤5 mg/day) or medium-high dose (>5 mg/day) were performed, as well as analyses evaluating CV mortality as outcome. Moreover, analyses excluding patients not receiving DMARDs and patients dying in the first year of observation were conducted.

**Results:** A total of 857 patients (62% RA, 73% female, median (IQR) age 59,<sup>47–71</sup> mean (sd) baseline DAS28 3.08 (0.97)) were included. After a median (IQR) follow-up of 80<sup>51–109</sup> months, 77 patients died (2 in the first year); of the 41 patients with known cause of death, 9 were for CV causes. An interval >3 months between diagnosis and introduction of DMARDs or never introducing DMARDs related to higher mortality (table 1). The mean daily prednisone dose was not a significant predictor of mortality, while in all secondary analyses patients receiving low-dose prednisone, compared to those never receiving corticosteroids, had a lower mortality (eg. HR (95% CI) 0.45 (0.26,0.78) in the model including time between symptom onset and diagnosis). Patients not starting DMARDs, compared to these starting within 3 months from diagnosis, had a higher CV mortality, while the intervals between onset and diagnosis and onset and treatment were not significant predictors. Analyses limited to patients receiving DMARDs and with the exclusion of patients dying in the first year yielded to similar results.

**Conclusions:** In patients with early RA and UA treatment delay significantly increases mortality, while low-dose corticosteroids seem to decrease mortality. These results support strategies aiming at early access to treatment and the use of low dose corticosteroids in the initial treatment strategy.

THU0111

#### FREQUENCY AND PREDICTORS OF SUSTAINED REMISSION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS TREATED WITH CONVENTIONAL SYNTHETIC DISEASE MODIFYING DRUGS

G. Zanframundo, S. Bugatti, A. Manzo, F. Benaglio, G. Sakellariou, C. Montecucco, R. Caporali. *Early Arthritis Clinic, Division of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia, Italy*

**Background:** The management of patients with early rheumatoid arthritis (RA) should be aimed at reaching the target of disease remission as soon as possible. In order to prevent joint damage and disability, and eventually allow treatment withdrawal, the state of disease remission should be also maintained. Whilst point remission is frequently achieved in early RA, the sustainability of remission in clinical practice remains poorly investigated.

**Objectives:** To investigate the prevalence and predictors of sustained remission in patients with early RA treated with conventional synthetic disease anti-rheumatic drugs (csDMARDs).

**Methods:** We evaluated 533 RA patients from the Pavia early arthritis inception cohort not in remission at baseline with at least 24 months of follow-up. Patients had arthritis of short duration (<12 months of symptoms) and were treatment-naïve at presentation. After diagnosis, patients were initiated a treat-to-target regimen with methotrexate aiming at low disease activity according to the 28-joint disease activity score (DAS28 ≤3.2), and were seen at regular intervals (2 months in the first 6 months, then trimestraly). Point remission was defined as the achievement of DAS28 remission (<2.6) or SDAI (simplified disease activity index) remission (≤3.3) at any time point within the first 12 months. Sustained remission was defined as mean DAS28 <2.6 and mean SDAI ≤3.3 in the 3 visits following first remission. The frequency and predictors of point remission and sustained remission were analysed by Cox and binary regression respectively.

**Results:** 287/533 (53.9%) patients achieved point DAS28 remission and 234/533 (43.9%) point SDAI remission. Independent predictors of point DAS28 remission were male gender (HR [95% CI] 1.84 [1.36–2.50]), shorter symptoms' duration (HR [95% CI] 0.99 [0.98–0.99]), a lower tender joint count at baseline (HR [95% CI] 0.97 [0.94–0.99]), better functional status (HR [95% CI]

0.74 [0.59–0.94]), absence of radiographic erosions (HR [95% CI] 1.52 [1.06–2.20]) and use of prednisone (HR [95% CI] 1.51 [1.36–1.74]). The same predictors were confirmed for point SDAI remission. Irrespective of the criterion, remission was maintained by only half of the patients at follow-up, resulting in sustained remission rates of 28% for DAS28 and 19% for SDAI in the entire cohort. At multivariate analysis, independent predictors of sustained remission according to either the DAS28 or the SDAI were lower time to achieve remission and deeper remission, whilst demographic factors, baseline disease activity and use of prednisone were not significant (figure 1). Using ROC curve analysis, the best discriminative ability for sustained remission were time to remission  $\leq 4$  months, DAS28 at remission  $\leq 2.2$  and SDAI at remission  $\leq 1$ .

**Conclusions:** Despite early diagnosis and prompt institution of goal-steered treatment strategies with csDMARDs, only a minority of RA patients experience sustained remission. Remission is more likely to be maintained if the target is attained rapidly after treatment institution and if joint and systemic inflammation are effectively suppressed.

#### THU0112 THE INFLUENCE OF AGE AND SEX ON THE PROGRESSION OF RHEUMATOID ARTHRITIS

L. Gjerdtsson<sup>1</sup>, J. Nilsson<sup>1</sup>, M. Andersson<sup>2</sup>, M. Leu Agelii<sup>1</sup>, on behalf of BARFOT study group. <sup>1</sup>Rheumatology and Inflammation Research, University of Gothenburg, Gothenburg; <sup>2</sup>Clinical Sciences, Section of Rheumatology, Lund University, Lund, Sweden

**Background:** In Europe, life expectancy is increasing and so does the incidence rheumatoid arthritis (RA), which peaks for both men and women at 70–79 years of age. Further, more than 50% of patients with RA are >65 years of age. To correctly treat and handle all patients with RA irrespective of age there is a need to study the outcome and progression of the disease depending on age of onset as this, to our knowledge, is largely unknown.

**Objectives:** To study how age at onset of RA influence the course of disease in men and women.

**Methods:** This study included 2825 patients, 68% females, from the BARFOT (Better Anti-Rheumatic Pharmacotherapy) early RA cohort. Patients were divided into males and females and into the following age groups: <40 years (yr) n=415, 40–54 year n=658, 55–69 year n=986 and  $\geq 70$  year n=766 at onset of disease and inclusion in the study. They were assessed at 3, 6 months and 1, 2, 5, 8 years. The following parameters were analysed: DAS28 (disease activity), VAS pain, VAS global health, 28 joint count of tender and swollen joints, respectively, ESR, rheumatoid factor (RF), antibodies to citrullinated proteins (APCA) and Health Assessment Questionnaire (HAQ). The median and 95% bootstrap confidence interval were calculated in MATLAB R2015a using the bias corrected and accelerated percentile method with 2000 bootstrap samples. Mann-Whitney U-test and Wilcoxon Rank test were used to compare groups,  $p < 0.01$  was considered as significant due to multiple comparisons.

**Results:** At inclusion, there were no significant differences in DAS28, VAS global health, VAS pain or tender and swollen joint counts in any of the groups. From 3 months and onward, the DAS28 score were significantly lower for men compared to women in the age groups <40 year, 55–69 year and  $\geq 70$  year, whereas in the age group 40–54 year there were no significant differences between the sex groups (figure 1). The lowest DAS28 score, at each assessment point, was seen for RF and ACPA positive men <40 year and this group had a significantly lower DAS28 score at 8 years compared to all other groups except RF and ACPA negative men and women  $\geq 70$  year. At the same time, the worst outcome was seen for RF positive women and for men  $\geq 70$  year irrespective of RF, compared to all other groups.

In the age groups <40 year, 55–69 year and  $\geq 70$  year, both VAS pain and VAS global health were significantly lower in men compared to women from 3–6 month and onward. However, no differences were obtained between the sexes in the age group 40–54 year. As expected, HAQ was significantly higher among women than men in all age groups.

**Conclusions:** Depending on age at onset, the course of disease, measured as DAS28, differs significantly where seropositive men <40 year have the most favourable prognosis compared to both men and women  $\geq 70$  year the worst. No differences in DAS28, VAS global health or pain was found between men and women aged 40–54 year, which is in contrast to previous studies<sup>1</sup> comparing men and women without considering the age of onset. The causes for these findings need to be further investigated.

#### THU0113 LINKING SYSTEMIC ANGIOGENIC MARKERS TO SYNOVIAL VASCULARISATION IN RHEUMATOID ARTHRITIS

A. Leblond<sup>1</sup>, S. Pezet<sup>1</sup>, A.P. Trouvin<sup>2</sup>, M. Elhai<sup>2</sup>, V. Gonzalez<sup>1</sup>, Y. Allanore<sup>2</sup>, J. Avouac<sup>2</sup>. <sup>1</sup>INSERM U1016, Institut Cochin; <sup>2</sup>Rhumatologie A, Hôpital Cochin, Paris, France

**Background:** Neoangiogenesis is a crucial event to promote the development of the hyperplastic proliferative pathologic synovium in Rheumatoid arthritis (RA). Ultrasound (US) is sensitive for detection of power Doppler (PD) vascularisation.

**Objectives:** To explore the associations between a set of complementary circulating angiogenic markers reflecting different angiogenic processes and a comprehensive US assessment in patients with RA.

**Methods:** Serum levels of eight angiogenic markers (Vascular Endothelial Growth Factor (VEGF), Placenta Growth Factor (PlGF), Tie-2, Angiopoietin-1, soluble Vascular Cell Adhesion Molecule-1 (sVCAM-1), Interleukin-8 (IL-8, CXCL8), CYR61 (CCN1) and Angiostatin), reflecting endothelial cell activation, proliferation, survival, growth and migration, as well as vessel maturation and stabilisation, were measured by quantitative ELISAs in a total of 125 patients with RA, who were all systematically assessed in parallel by PDUS, performed on 32 joints.

**Results:** Synovitis was detected in 84 patients with RA (67.2%). Among these patients, 53 patients (42.4%) had positive Doppler signal, including 31 with moderate to marked hyperemia. Serum levels of soluble Vascular Cell Adhesion Molecule-1 (sVCAM-1) ( $808 \pm 293$  ng/mL vs.  $697 \pm 240$  ng/mL,  $p = 0.022$ ) and Tie-2 ( $16.2 \pm 7.5$  ng/mL vs.  $13.8 \pm 4.9$  ng/mL,  $p = 0.038$ ), were more likely to be increased in patients with synovial hyperemia detected on at least one joint (Power Doppler grade  $\geq 1$ ). sVCAM-1, Tie-2 and Angiostatin concentrations gradually increased together with the grade of the semiquantitative PDUS scale (figure 1A-C) and concentrations of these three markers were markedly increased in patients with

moderate to marked hyperemia (Power Doppler grade 2 and 3). Levels of sVCAM-1 ( $r=0.20$ ,  $p=0.028$ ), Tie-2 ( $r=0.28$ ,  $p=0.001$ ), and Angiostatin ( $r=0.25$ ,  $p=0.006$ ) correlated with a global arthritis sum score, defined by the sum of the semiquantitative PDUS scores for all joints examined.

Among the 81 patients with a DAS28-CRP $\leq 3.2$ , 22 patients had synovial hyperemia detected on at least one joint (Power Doppler grade 1 in 13 patients, grade 2 in 6 patients and grade 3 in 3 patients). Patients with synovial hyperemia on at least one joint were more likely to have significantly increased levels of PIGF ( $18.9 \pm 11.2$  pg/mL vs.  $13.1 \pm 9.5$  pg/mL,  $p=0.022$ ) and Tie-2 ( $15.7 \pm 5.8$  ng/mL vs.  $12.6 \pm 3.4$  ng/mL,  $p=0.004$ ) than patients with absence of synovial hyperemia.

**Conclusions:** Serum levels of the angiogenic markers Tie-2, sVCAM-1 and Angiostatin were strongly associated with synovial vascularisation and inflammation assessed by PDUS among patients with established RA. Moreover, Tie-2 and PIGF were associated with persistent disease activity in RA patients in low disease activity. These findings suggest that it may be possible to find surrogate serum angiogenic biomarkers of active synovitis that might replace PDUS examination, in case of further confirmation of their pertinence.

**THU0114 INFLUENCE OF AUTOANTIBODY STATUS IN TIME TO INITIATE DMARDS IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

J. Molina Collada, M.G. González Álvarez, V. Navarro-Compán, L. Nuño Nuño, D. Peiteado, A. Villalba, P. Bogas, A. Balsa. *Rheumatology, Hospital La Paz, Madrid, Spain*

**Background:** Factors contributing to an early referral to Rheumatologist and DMARDs initiation following symptom onset in rheumatoid arthritis (RA) patients are unclear. Recent data suggest that ACPA/RF double seropositivity is associated with delayed presentation to primary care and DMARDs initiation. Identification of these factors is mandatory to facilitate an early diagnosis and treatment of RA patients.

**Objectives:** To determine whether time to DMARDs initiation and time to first visit at early arthritis clinic (EAC) following symptoms onset differs between RA patients according to autoantibody status.

**Methods:** A prospective analysis of an EAC cohort including 1377 referred patients from 1993 to 2017 was undertaken for this study. Patients diagnosed of RA (according to physician's diagnosis) were selected. Based on the serological status, we classified patients in 4 groups: RF+/ACPA+, RF-/ACPA+, RF+/ACPA-, RF-/ACPA-. A baseline clinical assessment was completed including time (months) from symptoms onset to first assessment at EAC and to DMARD initiation. First, differences between serotypes were tested using chi-squared and student-t tests. Second, univariable and multivariable logistic regression models taking into account confounding factors (age, smoking and baseline DAS28) were employed to evaluate the association between autoantibody status and both periods: time to first visit at EAC and to DMARDs initiation.

**Results:** A total of 463 RA patients were included for analysis, of whom 292 (63.1%) were RF/ACPA double-seropositive (RF+/ACPA+), 35 (7.6%) RF-/ACPA+, 39 (8.4%) RF+/ACPA- and 92 (19.9%) RF-/ACPA-. Demographic and clinical data are shown in table 1. In the univariate analysis, statistically significant differences were observed for both periods when patients were stratified by autoantibody serotype, where RF+/ACPA+ individuals experienced the longer delay to presentation at EAC compared with RF-/ACPA- ( $5.0 \pm 4.6$  vs  $3.5 \pm 3.4$  months;  $p < 0.05$ ). RF+/ACPA+ patients experienced also significantly longer symptom duration before DMARD initiation than RF-/ACPA- ( $7.4 \pm 11.2$  vs  $4.9 \pm 5$  months;  $p < 0.05$ ). In the univariable analysis, autoantibody status (double seropositive and RF-/ACPA+ vs RF-/ACPA-) was significantly associated with time to DMARDs initiation. However, after adjusting by confounding factors in the multivariable analysis, the autoantibody status did not remain significantly associated with time to initiate DMARDs (RF+/ACPA-;  $\beta$  0.186;  $p=0.1$ , RF-/ACPA+;  $\beta$  0.112;  $p=0.3$ , RF+/ACPA+;  $\beta$  0.228;  $p=0.1$ )

**THU0115 PSYCHOLOGICAL AND FUNCTIONAL STATES PREDICT DISEASE FLARE FOLLOWING TNF INHIBITOR TAPERING IN PATIENTS WITH RHEUMATOID ARTHRITIS: A POST-HOC ANALYSIS OF DATA FROM THE OPTIMISING TNF TAPERING IN RA (OPTTIRA) COHORT**

K. Bechman, F.E. Sin, F. Ibrahim, S. Norton, D. Scott, A. Cope, J. Galloway. *Rheumatology, King's College London, London, UK*

**Background:** Tapering or discontinuation of anti-TNF therapy appears to be feasible, safe and effective in a selected proportion of Rheumatoid Arthritis (RA) patients. Depression is highly prevalent in RA and may impact on flare incidence through a number of mechanisms. It is an independent predictor for flare in patients with active disease and is negatively associated with remission.<sup>1</sup> To date, there are no studies directly addressing the role of depression, anxiety or low mood in predicting flares in patients tapering their biological therapy.

**Objectives:** To investigate if psychological and functional states predict flare in RA patients with low disease activity (LDA) or in remission who undergo treatment tapering of their anti-TNF agents.

**Methods:** This study is a post-hoc analysis of the OPTTIRA trial,<sup>2</sup> a multi-centre, prospective, randomised, open label study investigating anti-TNF tapering in established RA patients in sustained LDA. Baseline patient-reported outcomes including HAQ-DI, EQ-5D, FACIT-F, and SF-36 including the Mental Health Index (MHI) component were collected. The MHI has been validated as a screening tool for depression in RA patients.<sup>3</sup> The primary outcome was flare, defined as an increase in DAS28  $\geq 0.6$ , and at least one additional swollen joint. Logistic regression was used to identify patient-reported outcomes that predict flare, adjusting for baseline covariates (age, gender, treatment arm, DAS28 and BMI).

**Results:** 97 were randomised into a tapering arm, either by 33% or 66% of their anti-TNF dose. The majority of patients were on methotrexate in combination with their anti-TNF therapy (n=67, 69%) and the median disease duration was 11 years [IQR: 7–17]. Seventy three (75%) fulfilled DAS28 remission criteria (DAS28 < 2.6). The median SF36 MHI score was 84. A score of  $\leq 56$ , the cut off used to detect depression was observed in 11% of patients. Forty one patients (42%) flared. Baseline DAS28 score was associated with flare, remaining significant after

adjusting for covariates [HR 1.96 (95% CI: 1.18, 3.24)  $p=0.01$ ]. Disability (SF-36 physical component), fatigue (FACIT-F) and mental health (SF-36 MHI) predicted flare in univariate models (figure 1). In multivariate analyses, only MHI score remained a statistically significant independent predictor of flare [HR per 10 units 0.74 (95% CI: 0.60, 0.93)  $p=0.01$ ].

**Conclusions:** Baseline DAS28 and mental health predict flare events in patients in LDA who taper their anti-TNF agents. Other psychological and functional states, measured by patient-reported outcome do predict flare events although the effect size is small and does not persist when adjusting for known predictors. Based on these findings, an assessment of functional and mental health states should be considered prior to biologic tapering.

#### THU0116 LIPID PROFILE AND CARDIOVASCULAR RISK IN SUBJECTS AT RISK FOR DEVELOPING RHEUMATOID ARTHRITIS

L. van Boheemen, M. van Beers - Tas, D. van Schaardenburg, M.T. Nurmohamed. *Rheumatology, Reade, Amsterdam, Netherlands*

**Background:** Rheumatoid arthritis (RA) is a systemic inflammatory autoimmune disease associated with an increased cardiovascular (CV) risk that is already present at the time of diagnosis. However, it is unclear at what point in the period before diagnosis of RA the CV risk increases. Therefore, we assessed the 10 year risk of CV morbidity and mortality in a cohort of subjects at risk for RA and analysed associations with anti-citrullinated protein antibody (ACPA) status and arthritis development.

**Methods:** In a cohort of 594 consecutive arthralgia patients with positivity for rheumatoid factor (RF) and/or ACPA, demographics, medical history, medication use and comorbidities were assessed. Lipid profile was determined and blood pressure was measured in a subset of patients. The 10 year CV risk score according to the Dutch CV risk management guideline (Dutch Systematic Coronary Risk Evaluations (SCORE)) was calculated for patients of whom data were complete.

**Results:** ACPA positive subjects ( $n=382$ ) were younger (mean age 48.6 vs 51.6,  $p=0.003$ ), more often smokers (31.8% vs 23.9%,  $p=0.045$ ) and had lower cholesterol (mean level 5.2 vs 5.5,  $p=0.001$ ) and HDL (mean level 1.1 vs 1.2,  $p=0.004$ ) than ACPA negative subjects. Subjects who developed arthritis ( $n=205$ ) had lower cholesterol (mean level 5.2 vs 5.4,  $p=0.008$ ) and HDL levels (mean level 1.0 vs 1.2,  $p=0.001$ ) and a higher TC/HDL ratio (median ratio 5.2 vs 4.8,  $p=0.047$ ) compared to subjects who did not develop arthritis. Lower cholesterol (OR 1.24, CI 1.04–1.48), lower HDL (OR 2.01, CI 1.29–3.13) and higher TC/HDL ratio (OR 1.07, CI 1.000–1.138) predicted arthritis development.

The Dutch SCORE was calculated in 177 subjects (median 2, IQR 1–9). 76.4% had a low risk (SCORE <10%), 12.5% a medium risk (SCORE 10–<20%) and 11.4% had a high 10 year risk (SCORE >20%) of cardiovascular morbidity and mortality. The score was not associated with ACPA status or arthritis development.

**Conclusions:** Dyslipidemia as known in RA patients with active disease was also present in seropositive arthralgia patients at risk for RA, and predicted development of RA. However, arthralgia subjects who developed arthritis did not have a higher CV risk score than those who did not develop arthritis. Also, despite differences in lipid profile and smoking, the CV risk score does not differ between ACPA positive and ACPA negative subjects at risk for RA. Overall, differences in lipid profile predicted development of RA but were too small to have an effect on the 10 year risk of CV morbidity and mortality as calculated by the Dutch CV risk score.

#### THU0117 CHEMOKINE CCL18 ENRICHED IN SYNOVIAL FLUID IS INVOLVED IN JOINT DESTRUCTION THROUGH PROMOTING MIGRATION OF FIBROBLAST-LIKE SYNOVIOCYTES IN RHEUMATOID ARTHRITIS

Y.-Q. Mo<sup>1</sup>, G.-C. Zhang<sup>2</sup>, J. Jing<sup>1</sup>, J.-D. Ma<sup>1</sup>, L. Dai<sup>1</sup>. <sup>1</sup>Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University; <sup>2</sup>Zhongshan School of Medicine, Sun Yat-Sen University, Guangzhou, China

**Background:** CC chemokine ligand 18 (CCL18) which is either constitutively expressed or induced in monocytes/macrophages and dendritic cells has been reported to be highly expressed in peripheral blood and synovial fluid of rheumatoid arthritis (RA) patients compared with healthy controls, indicating the possible role of CCL18 in the development and pathogenesis of RA.

**Objectives:** To explore the association of serum and synovial fluid CCL18 with clinical and radiographic outcome in RA patients and its potential effect on RA fibroblast-like synoviocytes (FLS).

**Methods:** Consecutive patients with active RA (DAS28-CRP>2.6) were recruited. Synovial fluid was collected from inflamed joints if available. Demographic and clinical data were collected according to the 2017 EULAR recommendation. Serum and synovial fluid CCL18 was detected by ELISA. RA-FLS was cultured *in vitro* with RA synovial fluid and neutralising antibody to CCL18. Migration/invasion ability was analysed by Transwell assay.

**Results:** (1) Among 83 RA patients, age (median and IQR, similarly hereinafter) was 50 (41~58) years old and 65 patients (78%) were female, with median disease duration 36 (12~102) months, median DAS28-CRP 5.0 (4.6~6.1). (2) Serum CCL18 was 107 (80~126) ng/mL, which was significantly higher than healthy controls [ $n=25$ , 51 (29~70) ng/mL,  $p<0.001$ , figure 1A]. Serum CCL18 correlated slightly but significantly with CRP ( $r=0.385$ ,  $p<0.001$ ), ESR ( $r=0.239$ ,  $p=0.03$ ), PrGA ( $r=0.249$ ,  $p=0.03$ ), DAS28-CRP ( $r=0.368$ ,  $p=0.001$ ), DAS28-ESR ( $r=0.336$ ,  $p=0.003$ ), SDAI ( $r=0.360$ ,  $p=0.001$ ), CDAI ( $r=0.328$ ,  $p=0.004$ ) and HAQ ( $r=0.325$ ,  $p=0.004$ ). (3) Synovial fluid CCL18 of 31 patients was 719 (415~1271) ng/mL, which was significantly higher than corresponding serum level (Paired test,  $p<0.001$ , figure 1A). Among them, 13 patients who were treated according to treat to target strategy received X-ray assessment of hand/wrist both at baseline and month 12. Six patients who had one-year radiographic progression (a change of the Sharp/van der Heijde modified sharp score  $\geq 0.5$  units) showed higher synovial fluid CCL18 than other 7 patients without radiographic progression [1481 (1244~2034) ng/mL vs. 458 (405~681) ng/mL,  $p=0.004$ , figure 1B). (4) When incubated with RA synovial fluid, the migration ability of RA-FLS was significantly increased; but this effect was inhibited by neutralising antibody to CCL18 (figure 1C).

**Abstract THU0117 – Figure 1.** Chemokine CCL18 which was enriched in RA synovial fluid promoted migration of fibroblast-like synoviocytes in Rheumatoid Arthritis (RA), but was inhibited by neutralising antibody to CCL18. A: Comparison of RA synovial fluid CCL18 with serum CCL18 of RA patients and health controls. B: Comparison of RA synovial fluid CCL18 between patients with and without one-year radiographic progression. C: Transwell assay, crystal violet staining for RA-FLS (purple), with original magnification of  $\times 100$ .

\*\* $p<0.001$ , \*\*\* $p<0.0001$

**Conclusions:** CCL18 elevates especially in synovial fluid of RA patients, which may correlate with one-year radiographic progression through promoting migration of RA-FLS.

THU0118

### PATIENT-AND PHYSICIAN-REPORTED BARRIERS TO ACHIEVING RHEUMATOID ARTHRITIS (RA) DISEASE CONTROL

M.I. Danila<sup>1</sup>, L. Chen<sup>1</sup>, R. O'Beirne<sup>2</sup>, E.M. Ruderman<sup>3</sup>, L.R. Harrold<sup>4</sup>, J.A. Melnick<sup>1</sup>, M.M. Safford<sup>5</sup>, J.M. Kremer<sup>6</sup>, J.R. Curtis<sup>1</sup>. <sup>1</sup>Medicine: Rheumatology; <sup>2</sup>Continuing Medical Education, University of Alabama at Birmingham, Birmingham; <sup>3</sup>Medicine: Rheumatology, Northwestern University, Chicago; <sup>4</sup>Medicine: Orthopedics and Physical Rehabilitation, University of Massachusetts Medical School, Worcester; <sup>5</sup>Medicine, Cornell University, New York City; <sup>6</sup>Corrona LLC, Waltham, USA

**Background:** Many patients with RA do not achieve guideline-recommended treat-to-target (T2T) goals in clinical practice. Little is known about the challenges that patients and rheumatologists face when attempting to achieve better control of RA disease activity.

**Objectives:** To identify and prioritise patient- and rheumatologist-perceived barriers to achieving RA disease activity control.

**Methods:** Participants were recruited from the Consortium of Rheumatology Researchers of North America (Corrona) registry and invited to participate in nominal groups (NGs), 4 with patients and 3 with rheumatologists. Each group generated a list of barriers to reaching RA disease control (patients) and T2T goals (rheumatologists). Two separate lists containing the generated items were created and were subjected to a card sort procedure to create common themes. A random sample of Corrona RA patients were invited by email to complete a compensated online survey and asked to rank their top 3 barriers. A weighted score was assigned for each barrier by considering the number of respondents who ranked it and the priority rank they assigned. The barriers/themes were sorted into domains. The patient survey also included knowledge items about T2T strategy and attitudes about RA treatment.

**Results:** Nominal groups with 37 RA patients identified 17 themes to achieving control of RA activity. Similarly, 8 themes emerged from the physician NGs, 7 of which were also found in the patient NGs (table 1). Cost of RA care was ranked highest by both patients and physicians, while medication risk aversion ranked second and third among the physician- and patient-generated barriers, respectively. We sent 1694 invitations to complete the survey and 450 patients with RA for whom clinical data was available responded within 3 weeks. There were no differences in age, sex, or disease duration between survey-respondents and non-respondents. A higher proportion of respondents were college-educated. A total of 344 (77%) respondents considered RA to be a high priority for their health, 225 (51%) reported being familiar with T2T as a treatment strategy, and 312 (85%) displayed core beliefs favouring medications. Among the challenges to controlling RA disease activity, the domain that received the highest score was unpredictability of RA and its treatment (figure 1). Symptoms and illness burden domain received the second highest score, followed by the health system factors domain (figure 1).

**Abstract THU0118 – Table 1.** Common Patient- and Physician- Reported Barriers to Achieving RA Control Identified by Nominal Groups (NGs)

Barriers (Themes)	Proportion of Total Votes	
	Patient NGs	Physician NGs
Cost/Administrative	13.0%	27.0%
Medication Effectiveness	7.4%	3.0%
Medical Risk Aversion	6.5%	20.0%
Access to Care	4.6%	8.0%
Medication Adherence	1.9%	9.0%
Patient-Physician Communication	1.9%	12.0%
Education	0.9%	5% (Physician)

**Figure 1.** Patient-prioritised Barriers to Achieving RA Control in Corrona Registry

**Conclusions:** There are common patient- and physician-perceived barriers to achieving RA disease control. From the patient perspective important barriers are unpredictability of how RA may progress, medication risk aversion and cost of RA care. Addressing these barriers, when possible, may improve goal-directed RA care.

THU0119

### SMOKING IS NEGATIVELY ASSOCIATED WITH CLINICAL RESPONSE TO CONCOMITANT PREDNISONE USE IN EARLY RHEUMATOID ARTHRITIS

M. Safy, M. De Hair, P. Welsing, J. Van Laar, J. Jacobs. *Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands*

**Background:** Smoking and overweight increase the risk of development of rheumatoid arthritis (RA) and have been associated with a reduced clinical response to several biological disease modifying anti-rheumatic drugs (bDMARDs) and methotrexate (MTX).<sup>1-6</sup> The effect of smoking and overweight on clinical response to prednisone (pred) has not been investigated

**Objectives:** To determine whether smoking and overweight are negatively associated with clinical response to pred in RA, as assessed by the disease activity score using 28 joints (DAS28). Second, to similarly determine the effect of smoking and overweight on the four individual components of DAS28.

**Methods:** In the second Computer Assisted Management in Early Rheumatoid Arthritis trial (CAMERA-II), patients with early, DMARD naïve RA were randomised to an MTX based treatment strategy with addition of 10 mg pred or placebo daily for 2 years. We used data from the patients concomitantly treated with pred, n=127. We performed linear mixed model analyses with DAS28 over the 2 year trial period as outcome variable and smoking status (current yes/no) and BMI (in mg/kg<sup>2</sup>) as predictor variables, corrected for baseline DAS28, gender, rheumatoid factor (RF-test negative or positive), MTX administration route (subcutaneous or oral), MTX dosage (mg/week) and bDMARD use (yes/no), time (in months) and time<sup>2</sup>. For the second aim, we performed an extended mixed model analysis with a multivariate outcome, consisting of the individual components of the DAS28 (tender joint count 28, swollen joint count 28, erythrocyte sedimentation rate and VAS general health) and as predictor variables smoking status and BMI, correcting for important confounders.

**Results:** Smoking data was available of 104/127 patients. Smoking was significantly associated with higher DAS28 over time, corrected for baseline DAS28, compared to non-smoking (table 1). No significant associations were found between BMI and response to pred, nor between smoking or BMI and any of the individual components of DAS28.

Table 1 The association between smoking and DAS28 in patients treated with concomitant prednisone for 2 years

Parameter	Estimate (95% CI)	P-value
Smoking (vs non-smoking)	0.60 (0.19 to 1.00)	0.01
Subcutaneous MTX administration route (vs oral)	-0.17 (-0.40 to 0.05)	0.13
MTX dose (mg/week)	-0.01 (-0.02 to -0.00)	0.00
bDMARD use (vs no bDMARD use)	0.45 (0.19 to 0.70)	0.00
DAS28 at baseline	0.36 (0.22 to 0.50)	0.00
Time	-0.25 (-0.27 to -0.23)	0.00
Time <sup>2</sup>	0.01 (0.01 to 0.01)	0.00
BMI (mg/kg <sup>2</sup> )	0.03 (-0.02 to 0.07)	0.26
Female gender (vs male)	-0.48 (-0.86 to -0.10)	0.02
Negative RF test status (vs positive)	-0.22 (-0.60 to -0.16)	0.25

Outcome measure: DAS28 over 2 years; CI: confidence interval; MTX: methotrexate; bDMARD: biological disease modifying anti-rheumatic drug; BMI: body mass index; RF: rheumatoid factor. A positive estimate reflects a higher DAS28 over time, corrected for baseline DAS28, and thus a lesser effect of the concomitant prednisone therapy

**Conclusions:** To our knowledge, this is the first time that smoking is shown to be a negative predictor for clinical response to pred in RA patients. Cessation of smoking needs to be encouraged in patients initiating bDMARDs, MTX and pred and in those already on these drugs

#### THU0120 VITAMIN D IN INDIVIDUALS BEFORE ONSET OF RHEUMATOID ARTHRITIS – RELATION TO VITAMIN D BINDING PROTEIN AND ITS ASSOCIATED GENETIC VARIANTS

M. Brink<sup>1</sup>, L. Johansson<sup>1</sup>, E. Nygren<sup>1</sup>, L. Årlestig<sup>1</sup>, J. Hultdin<sup>2</sup>, S. Rantapää-Dahlqvist<sup>1</sup>. <sup>1</sup>Public Health and Clinical Medicine, *Rheumatology*; <sup>2</sup>Department of Medical Biosciences, Umeå University, Umeå, Sweden

**Background:** Vitamin D has been implicated as being involved in the aetio-pathogenesis of several autoimmune diseases including rheumatoid arthritis (RA). Previous studies present contradictory results. Vitamin D binding protein (DBP), the major transport protein, is also involved in various inflammatory processes.

**Objectives:** The aim of this study was to investigate the relationship between circulating levels of 25-hydroxyvitamin D [25(OH) D], DBP and polymorphisms in group-specific component (GC) in pre-symptomatic individuals and matched controls within prospective cohorts of the Northern Sweden.

**Methods:** Blood samples donated to the Medical Biobank prior to the onset of symptoms of RA (n=515, mean [SD] time before the onset of symptoms 6.2 [9.3] years) and from matched (2:1) population-based controls (n=267) were used. Plasma 25(OH) vitamin D levels were analysed using liquid chromatography tandem-mass spectrometry and DBP levels were analysed using enzyme-linked immunosorbent assay. GC polymorphisms (rs4588 and rs7041) were analysed with TaqMan assays (Applied Biosystems).

**Results:** Levels of 25(OH) D or DBP were not statistically different between pre-symptomatic individuals and controls in a crude, or a multiple-adjusted logistic regression model. However, an increased risk for future RA was found in females of DBP (OR 1.0001 [95%CI 1.000–1.0003]), adjusted for carriage of the minor allele of rs4588, in a multiple-adjusted model (p<0.05).

**Conclusions:** This study indicated that vitamin D is not associated with the future risk of RA although increasing levels of DBP were however, associated with an increased risk of disease in females carrying the minor allele of a DBP encoding SNP.

**Acknowledgements:** Samples and data for the cohort were obtained through the Västerbotten Intervention Program, the Northern Sweden MONICA Study,

and the mammary screening program of Västerbotten. Staff of the Department of Biobank Research, Umeå University, aided in acquisition of samples and data.

**Disclosure of Interest:** None declared

#### THU0121 MORTALITY RATE AND PREVALENCE OF CARDIOVASCULAR DISEASE IN RHEUMATOID ARTHRITIS: 5-YEAR KARRA PROSPECTIVE STUDY

N.R. Kim, J.W. Kang, J.S. Eun, J.H. Kim, J.Y. Kang, J.S. Seo, G.B. Bae, S.J. Lee, E.J. Nam, Y.M. Kang. *Division of Rheumatology, Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Korea, Republic of Ireland*

**Background:** Rheumatoid arthritis (RA), which is an autoimmune chronic arthritis, leads to elevated rates of disability and mortality.

The main causes of mortality identified among RA patients are increased incidences of cardiovascular (CV) disease, which accounts for one-third to one-half of the premature deaths, infection and cancer.

In our previous study, we identified that cumulative inflammatory burden contributes to the development of carotid atherosclerosis through a synergistic interaction with conventional CV risk factors in patients with RA.

During the 2 years follow-up period, the mortality rate was 2.4% (10/412), and the main causes of death were infection (4/10) and CV disease (3/10).

**Objectives:** To investigate the incidences of mortality and CV disease in patients with RA in the 5 year Kyungpook National University Hospital Atherosclerosis Risk in Rheumatoid Arthritis (KARRA) prospective study.

**Methods:** A total of 372 patients with RA and 162 healthy controls were followed up for 5 years or until deaths in a prospective KARRA cohort study (412 patients and 221 controls at baseline).

To detect the presence and progression of carotid atherosclerosis, we performed carotid ultrasound at baseline and 5 year.

We analysed the incidence of CVD, conventional CV risk factors, RA disease activity and severity markers, medication histories, mortality rate, and causes of death.

**Results:** During 5 year follow-up period, the mortality rate was 10.7% (44/412) in RA patients and 1.4% (3/221) in healthy controls (p<0.001), while the incidence of CVD were 11.4% (47/412) in RA patients and 0.9% (2/221) in healthy controls (p<0.001).

Among CVD in RA patients, cerebrovascular accident (CVA) and cardiovascular event (CVE) were 17 (36.2%) and 30 (63.8%) events, respectively.

Major causes of death included infection (21/44, 47.7%), CVD (12/44, 27.3%), and others (11/44, 25%).

The mean age, presence and number of carotid plaques, functional class, modified Korean version of the HAQ (mKHAQ), tender joint count (TJC), swollen joint count (SJC), ESR and CRP, and conventional CV risk factors at baseline and cumulative ESR (ESR area under the curve), DAS28-ESR and DAS28-CRP at year 5 were significantly associated with mortality in RA patients.

Multivariate logistic regression analysis showed that the presence of carotid plaque (OR 6.22 [95% CI 1.08–24.99; p=0.031]), mKHAQ (OR 1.04 [95% CI 1.01–1.12; p=0.014]), and ESR (OR 1.09 [95% CI 1.03–1.16; p<0.001]) at baseline and cumulative ESR (ESR area under the curve) (OR 1.047 [95% CI 1.01–1.13; p=0.048]) and DAS28-ESR (OR 1.55 [95% CI 1.08–2.21; p=0.016]) at year 5 were independent risk factors for mortality of RA patients.

**Conclusions:** During the follow-up period of 5 years, the mortality rate and prevalence of CV disease were significantly increased in RA patients, compared to the controls. Furthermore, main causes of death were infectious disease and CV disease. Furthermore the risk factor for CVD and mortality is carotid plaque which is determined by disease activity and CV risk factors.

#### THU0122 IMAGING CHARACTERISATION OF REMISSION IN RHEUMATOID ARTHRITIS

N. Purkayastha<sup>1</sup>, W.S. Tan<sup>1</sup>, A. Mahto<sup>1</sup>, M. Lewis<sup>1</sup>, G. Lliso<sup>1</sup>, A. Nerviani<sup>1</sup>, V. Rocher<sup>1</sup>, F. Humby<sup>1</sup>, C. Pitzalis<sup>1</sup>, S. Kelly<sup>2</sup>. <sup>1</sup>Experimental Medicine and Rheumatology, *William Harvey Research Institute*; <sup>2</sup>Rheumatology, *Bart's Health NHS Trust, London, UK*

**Background:** Remission in rheumatoid arthritis (RA) is now achievable in a significant proportion of patients using a combination of a treat to target strategy and biologic therapy. A number of clinical assessment tools exist for assessing remission. Several reports have shown that ultrasound (US) may have a role in better characterising this group of patients suggesting that subclinical synovitis increases the risk of erosive disease and flares in patients in DAS28 remission.<sup>1–3</sup>

These observations hint at a stratum of patients where remission is incomplete and may require a more tailored approach to therapy.

**Objectives:** In an early RA cohort we examine the relationship between US imaging and histological synovitis in the context of clinical remission and examine the predictive value of US to confirm synovial inflammation.

**Methods:** A prospective, observational study of 122 DMARD naïve, early RA patients classified according to the 1987 ACR criteria, with a maximum disease duration of 12 months (MRC PEAC study [www.peacmrc.mds.qmul.ac.uk](http://www.peacmrc.mds.qmul.ac.uk)). One hundred and three synovial biopsies were analysed at baseline and 75 at 6 months, with 85 paired US 12 joint scores (US 12: 10 metacarpophalangeal joints (MCPJ) and 2 wrists). US images were analysed using a semi-quantitative score for synovial thickness (ST) and power Doppler (PD).<sup>4</sup> Synovial inflammation was assessed using the Krenn synovitis scoring system. Fisher exact statistical test and Spearman's rank was used to determine the association and correlations.

**Results:** Demographics of this cohort are listed in table 1. There was a good correlation between US ST and PD scores with the Krenn histology score at the level of the single biopsied joint (ST:  $r=0.47$ ,  $p<0.001$ , PD:  $r=0.5$ ,  $p<0.001$ ). An association continued to be demonstrated when extending the US data set to 12 joints (ST  $r=0.27$   $p<0.01$ , PD  $r=0.28$   $p<0.01$ ).

Twenty-two patients with paired histology and ultrasound data were in DAS28 remission at 6 months and were eligible for analysis. A significant association between low PD ( $\leq 3/36$ ) signal (but not ST) and low Krenn score ( $\leq 4$ ) was demonstrated (Fisher exact test  $p<0.03$ ) with a predictive value of 90%. This reduced to 80% in patients not in DAS remission at 6 months ( $n=42$ ). Lastly, a clear relationship was noted between patients with US PD score recorded after 6 months of DMARD therapy ( $n=62$ , flares  $n=19$ ). No subsequent flares were recorded during the course of the follow up period of 6 months with a low US PD score ( $p<0.002$ , negative predictive value 76%) and a high US PD score had a 86% positive predictive value for disease flare within this time course.

**Conclusions:** This study demonstrates that there is considerable validity in the use of US to assess disease activity, which reflects histological synovitis in patients in low disease activity states and remission. Ultrasound imaging may demonstrate a distinct clinical and histological remission cohort of patients and may be a useful predictive tool in terms of predicting subsequent clinical disease activity.

#### THU0123 MEDICATION ADHERENCE AND COST-RELATED MEDICATION NON-ADHERENCE IN PATIENTS WITH RHEUMATOID ARTHRITIS, A MIXED METHOD STUDY IN IRAN

P. Heidari<sup>1</sup>, W. Cross<sup>1</sup>, M. Nazarinia<sup>2</sup>, K. Crawford<sup>1</sup>. <sup>1</sup>Monash Nursing and Midwifery, Monash University, Melbourne, Australia; <sup>2</sup>Rheumatology Department, Shiraz University of Medical Sciences, Shiraz, Iran, -

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory disease that often requires long term treatment with multiple medications. Medication adherence is essential in patients with RA to manage the disease.

**Objectives:** This study aimed to assess medication adherence and cost-related medication non-adherence (CRN) among patients with RA in Shiraz, Iran from the perspective of patients and rheumatologists.

**Methods:** A convergent parallel mixed method study was employed. A survey targeted RA patients attending the outpatient clinics in Shiraz. The survey collected demographic information followed by an assessment of adherence using the Compliance Questionnaire Rheumatology (CQR)<sup>1</sup> and featured 4 questions on CRN.<sup>2</sup> The cut-off point of 80% was used to identify patients as adherent or non-adherent. Semi-structured interviews were conducted with rheumatologists exploring their experiences in regard to medication adherence and its determinants. Descriptive data analysis of the surveys was undertaken using SPSS version 24. Interviews were transcribed and analysed using thematic analysis.

**Results:** A total of 308 surveys were collected and 10 interviews were conducted. The majority of patients were female (86%), married (79.7%), living in urban areas (66.2%), housewives (73.1%), with no income (68.2%) and illiterate (41.9%). Six of the interviewed rheumatologists were male and participants had a mean of 8.6 years of experience as a physician. According to the CQR questionnaire; 59.7% of patients were considered non-adherent. In terms of cost, 26.3% of patients had

not refilled their prescription; 52.1% had delayed refilling their prescription; 18.2% had skipped doses; or 18.5% had taken less medication to make the medication last longer. In contrast, the rheumatologists considered that the majority of their patients were adherent to their prescribed medication. However, they saw medication side effects, poor patient-doctor relationship and high costs of biologics as barriers of adherence. Surveys found that only 19.9% of patients were using biologic agents. This is in concordance with rheumatologists' discussion about high costs of biologics and they will not prescribe biologics because they know that the majority of patients cannot afford the medication.

**Conclusions:** Although the findings of the survey suggested that medication adherence is sub-optimal among Iranian patients with RA, rheumatologists consider the majority of their patients as adherent. The high costs of the medication was found to contribute to medication non-adherence. Therefore, health policy makers should consider this issue while identifying the medication prices.

#### THU0124 LOW INFLAMMATION ON MAGNETIC RESONANCE IMAGING IN PATIENTS WITH RHEUMATOID ARTHRITIS THAT ACHIEVED SUSTAINED CLINICAL REMISSION ON ADALIMUMAB: DATA FROM THE PREDICTRA STUDY

P. Emery<sup>1</sup>, G. Burmester<sup>2</sup>, E. Naredo<sup>3</sup>, I. Lagunes<sup>4</sup>, Y. Zhang<sup>4</sup>, X. Wang<sup>4</sup>, M. Hojnik<sup>5</sup>, P.G. Conaghan<sup>1</sup>. <sup>1</sup>University of Leeds and NIHR Leeds Biomedical Research Centre, Leeds, UK; <sup>2</sup>Charité-University Medicine, Berlin, Germany; <sup>3</sup>Hospital Universitario Fundación Jiménez Díaz, Madrid, Spain; <sup>4</sup>ABBVIE, N Chicago, USA; <sup>5</sup>ABBVIE, Ljubljana, Slovenia

**Background:** ACR and EULAR recommend bDMARD tapering in patients (pts) with rheumatoid arthritis (RA) who achieved stable clinical remission. However, there are limited systematically collected data on objective magnetic resonance imaging (MRI)-assessed levels of musculoskeletal inflammation, especially tenosynovitis, in RA pts in stable clinical remission with previous data derived from a range of cohorts with differing definitions of clinical remission.

**Objectives:** To evaluate within the PREDICTRA study, the extent of disease control, in particular MRI inflammation, in RA patients in DAS28-based stable clinical remission, attained on adalimumab (ADA) at the standard dosing of 40 mg every other week (eow).

**Methods:** PREDICTRA is a multicenter, randomised, double-blind study generating data on pt and disease characteristics that may predict the clinical course of ADA dose-tapering for RA pts in stable clinical remission. RA pts with DAS28-CRP or -ESR $<2.6$  for  $\geq 6$  months following treatment with originator ADA 40 mg eow for  $\geq 12$  months in clinical practice were eligible to enter a 4 week (wk) lead-in study period with continued standard ADA dosing. Pts must have had confirmed DAS28-ESR $<2.6$  at the beginning and end of the lead-in period and quality-verified MRI of the most affected or, if both equally affected, the dominant hand to be eligible for randomization. Study assessments included multiple measures of disease activity (SJC28 and 68, TJC28 and 68, DAS28, CDAI, SDAI, patient's and physician's global assessment of disease activity), physical function (HAQ-DI, SF-36 PCS), and OMERACT RAMRIS scores for synovitis, tenosynovitis, bone marrow oedema, and erosions. Data of the randomised pts at the end of the lead-in period are presented.

**Results:** Of the 149 pts that entered the lead-in period, 122 (82%) were randomised. The randomised pts were 75% female, mean age of  $59.7 \pm 10.3$  years, RA duration of  $12.8 \pm 9.8$  years, prior ADA exposure for  $5.1 \pm 3.0$  years, and DAS28 remission duration of  $2.2 \pm 2.1$  years. Most pts received concomitant methotrexate (83.6%; mean dose 13.2 mg) and few received concomitant corticosteroids (9.8%; mean dose 3.2 mg). All the clinical disease activity measures showed very low disease activity. There was very low disease activity also in terms of the MRI inflammation scores (synovitis [ $3.5 \pm 3.13$ ], osteitis [ $1.0 \pm 2.01$ ], tenosynovitis [ $2.7 \pm 2.7$ ]). The mean MRI erosion score was low given the disease duration and the physical function scores were within normal levels (table 1).

Abstract THU0124 – Table 1. Summary of Patient Characteristics

Patient Characteristic (N=122)	Mean (SD)*
Duration of prior adalimumab, years	5.1 (3.0)
Duration of remission, years	2.2 (2.0)
Concomitant csDMARDs dose, mg	
Methotrexate (weekly)	13.2 (5.5)
Hydroxychloroquine (daily)	228.6 (75.6)
Sulfasalazine (daily)	750.0 (288.7)
Concomitant oral corticosteroids dose, mg (daily)	3.2 (1.7)
Anti-cyclic citrullinated peptide (ACCP), Unit	286.6 (206.4)
ACCP positive, n (%)	63 (52.9)
Rheumatoid factor (RF), IU/L	139.5 (395.4)
RF positive, n (%)	90 (76.3)
C-reactive protein (CRP), mg/L	5.3 (28.0)
Erythrocyte sedimentation rate (ESR), mm/hr	11.4 (8.4)
Tender joint count (TJC) 66	0.3 (0.6)
Swollen joint count (SJC) 66	0.1 (0.3)
DAS28 (ESR)	1.7 (0.6)
Clinical Disease Activity Index (CDAI)	1.3 (1.4)
Simplified Disease Activity Index (SDAI)	1.6 (3.0)
Patient's Global Assessment of Disease Activity –VAS, 0-100 mm	6.4 (8.9)
Physician's Global Assessment of Disease Activity –VAS, 0-100 mm	3.7 (5.0)
Pain –VAS, 0-100 mm	8.5 (11.5)
HAQ-DI	0.3 (0.4)
SF-36 MCS	54.4 (7.7)
SF-36 PCS	50.1 (7.8)
MRI OMERACT scores	
Synovitis, Range 0-24	3.5 (3.1)
Osteitis, Range 0-75	1.0 (2.0)
Tenosynovitis, Range 0-30	2.7 (2.7)
Erosion, Range 0-250	21.4 (26.9)

\* All values are Mean (SD), unless otherwise specified.  
 ACCP = Anticyclic citrullinated peptide; CRP = C-reactive protein; ESR = Erythrocyte sedimentation rate; EAM = extra-articular manifestations; HAQ-DI = Health Assessment Questionnaire – Disability Index; IBD = inflammatory bowel disease; MCS = mental component summary; OMERACT = Outcome Measures in Rheumatology; PCS = physical component summary; Pts = patients; RF = rheumatoid factor; SD = standard deviation; SF-36=Short form 36-item health survey; VAS = Visual Analogue Scale.

**Conclusions:** Pts with long-standing RA randomised to the tapering phase of the PREDICTRA study based on sustained DAS28-based clinical remission on prior standard dose ADA therapy showed very low levels of clinical disease activity and normal physical function. This concurred with low MRI inflammation scores, especially for osteitis and tenosynovitis, the latter pathology being reported for the first time in RA clinical remission pts.

## THU0125 PREVENTION OF THE PROGRESSIVE BIOCHEMICAL CARTILAGE DESTRUCTION UNDER METHOTREXATE THERAPY IN EARLY RHEUMATOID ARTHRITIS

P. Sewerin<sup>1</sup>, A. Müller-Lutz<sup>2</sup>, S. Odendahl<sup>2</sup>, M. Eichner<sup>2</sup>, M. Schneider<sup>1</sup>, B. Ostendorf<sup>1</sup>, C. Schleich<sup>2</sup>. <sup>1</sup>Department for Rheumatology, University Hospital Duesseldorf, <sup>2</sup>Department of Diagnostic and Interventional, Radiology, Heinrich-Heine University, Düsseldorf, Germany

**Background:** Can methotrexate (MTX) stop cartilage loss measured by Delayed gadolinium-enhanced MRI of the cartilage (dGEMRIC) in patients with early rheumatoid arthritis (eRA)?

**Objectives:** Objective of the study was to investigate biochemical cartilage composition under MTX therapy and to intra-individually assess the impact of inflammation severity on cartilage composition by using dGEMRIC MRI in patients with eRA.

**Methods:** dGEMRIC of MCP joints of the index and middle finger of 28 patients from the AthroMark cohort were examined prior to MTX-therapy as well as after 3 and 6 months. OMERACT RA MRI score and clinical parameters (CRP and DAS28) were registered at any time point. Each patient's second and third MCP joints were dichotomized into the joint with more severe synovitis versus the joint with less severe synovitis according to the RAMRIS synovitis subscore.

**Results:** MCP joints with more severe synovitis ('bad joints') demonstrated significantly lower dGEMRIC values compared to MCP joints with less severe synovitis ('good joints') at time-points 0 and 3 months (p=0.002; p=0.019, respectively). After 6 months of MTX therapy no significant difference of dGEMRIC index was found between good and bad joint (p=0.086).

**Conclusions:** Under MTX therapy, biochemical cartilage integrity remains stable; no further cartilage destruction occurred if patients are treated early in the course of the disease. In addition, six months of MTX therapy triggered an alignment of

dGEMRIC index of MCP joints with initially severe synovitis and less severe synovitis in an intra-individual assessment. This underlines the importance of an early treatment in eRA to reduce further cartilage damage of the inflamed joints.

## THU0126 IMPACT OF RESIDENTIAL AREA ON THE PROFILE OF RHEUMATOID ARTHRITIS PATIENTS INITIATING THEIR FIRST BIOLOGIC DMARD: RESULTS FROM THE ONTARIO BEST PRACTICES RESEARCH INITIATIVE (OBRI)

R. Joshi<sup>1</sup>, M. Movahedi<sup>2,3</sup>, E. Rampakakis<sup>2</sup>, C. Thorne<sup>4</sup>, A. Cesta<sup>3</sup>, J.S. Sampalis<sup>5</sup>, C. Bombardier<sup>3,6,7</sup>, on behalf of Other OBRI Investigators. <sup>1</sup>William Osler Health System, Brampton Civic Hospital, Brampton; <sup>2</sup>JSS Medical Research, St-Laurent-QC; <sup>3</sup>Ontario Best Practices Research Initiative, Toronto General Research Institute, University Health Network, Toronto; <sup>4</sup>Southlake Regional Health Centre, Newmarket; <sup>5</sup>McGill University, Montreal-QC; <sup>6</sup>Department of Medicine (DOM) and Institute of Health Policy, Management, and Evaluation (IHPE), University of Toronto; <sup>7</sup>Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada

**Background:** Access to care and management of Rheumatoid Arthritis (RA) patients may differ based on residential area which, in turn, can affect the real-world effectiveness of anti-rheumatic medications.

**Objectives:** We aimed to describe differences in the profile of patients initiating their first biologic disease modifying antirheumatic drug (bDMARD) based on their residence in urban vs. rural areas.

**Methods:** RA patients enrolled in the OBRI initiating their first bDMARD within 30 days prior to or anytime following enrolment were included in the analysis. Patients excluded if they had less than 2 years of follow-up and less than 2 visits during this period of time. Patients characteristics included sociodemographics (age, gender, race, education level, marital status, smoking status, annual household income, health insurance coverage), disease duration, disease severity parameters (Disease Activity Score (DAS), Clinical Disease Activity Index (CDAI), Swollen and Tender Joints (SJC28, TJC28), Physician Global Assessment (PhGA), Patient Global Assessment (PGA), Health Assessment Questionnaire – Disability Index (HAQ-DI), presence of erosion), bDMARD type, and concomitant anti-rheumatic medications including conventional synthetic disease modifying antirheumatic drug (csDMARDs), non-steroidal anti-inflammatory drugs (NSAIDs), and oral steroids.

**Results:** A total of 629 RA patients were included of whom 522 (83%) resided in urban areas and 107 (17%) in rural areas. Other than marital status (urban vs. rural: 64.6% vs. 82.2% married; p<0.001) and race (urban vs. rural: 78.0% vs. 95.3% Caucasian; p=0.001) no significant differences in sociodemographics were observed between groups. However, patients from urban areas were less likely to have an erosion (46.6% vs. 50.5%; p=0.23), had lower TJC28 (7.2 vs. 7.9; p=0.43), and lower SJC28 (6.6 vs. 7.1; p=0.42) at bDMARD initiation. Type of bDMARD (anti-TNF vs. other mechanism of action) was comparable between groups (87.9% on anti-TNF) as was concomitant treatment with csDMARDs (84.9% on csDMARDs), and NSAIDs (19.6% on NSAIDs). Concomitant use of oral steroids was significantly lower in patients from urban areas (21.5% vs 29.9%; p=0.04).

**Conclusions:** Important differences may exist in the profiles of RA patients initiating their first bDMARD, and residing in rural versus urban areas. The implications on treatment outcomes should be assessed.

THU0127

### THE SEVERITY OF KERATOCONJUNCTIVITIS SICCA IN RHEUMATOID ARTHRITIS CORRELATES WITH THE MEDICAL OUTCOME STUDY 36-ITEM SHORT FORM HEALTH SURVEY (SF-36) SCORE BUT NOT THE DISABILITY INDEX (HAQ-DI)

R.O. Akintayo<sup>1</sup>, B.H. Olaosebikan<sup>2</sup>. <sup>1</sup>Department of Medicine, University of Ilorin Teaching Hospital, Ilorin; <sup>2</sup>Medicine, Lagos State University Teaching Hospital, Ikeja, Nigeria

**Background:** Keratoconjunctivitis sicca (KCS) is the most frequent ocular manifestation of rheumatoid arthritis (RA). It is highly heterogeneous and exhibits a considerable variability of presentation. Whereas a significant proportion of patients with KCS may be asymptomatic; it is unknown if the degree of dryness of the eyes, irrespective of symptomatology, has an association with the overall quality of life and functional ability.

**Objectives:** To determine the correlation between the Schirmer's score and the Medical Outcome Study 36-Item Short Form Health Survey (SF-36) score as well as the disability index measured by the Health Assessment Questionnaire-Disability Index (HAQ-DI).

**Methods:** A total of 50 Nigerian patients satisfying the 2010 American College of Rheumatology/European League Against Rheumatism classification criteria for RA were studied. Tear production was measured by unstimulated 5 min Schirmer's test (using 5 mm by 35 mm Whatman filter paper) and ocular staining with fluorescein stain. Each patient also completed the SF-36 and HAQ-DI questionnaires.

**Results:** The mean age of the patients was 47.2±12.5 years. Among them, 42 (84%) were females, giving a female-to-male ratio of 5.25:1. Rheumatoid factor and anti-citrullinated protein antibody were positive in 38 (76%) and 30 (60%) patients respectively. KCS was found in 15 (30%) patients among whom only 6 patients were symptomatic for dry eyes. The mean visual acuity [LogMAR (Snellen equivalent)] among the patients with and without KCS were 0.70 (6/30) and 0.10 (6/7.5). Among all patients, there was a positive correlation between the mean Schirmer's score (between each patients two eyes) and the Physical Component Summary ( $r=0.292$ ,  $p=0.008$ ) as well as the Mental Component Summary ( $r=0.228$ ,  $p=0.030$ ) of the SF-36. There is however no significant correlation between the mean Schirmer's score and the HAQ-DI ( $r=0.148$ ,  $p=0.188$ ).

**Conclusions:** Ocular manifestation is very common in RA and KCS is particularly rampant. Even in asymptomatic patients, the degree of xerophthalmia may give a reliable insight into both the physical and mental quality of life but not into the degree of functional disability.

THU0128

### DO BIOLOGICAL DMARDS PREVENT LONG TERM ARTICULAR DAMAGE BY RHEUMATOID ARTHRITIS IN ROUTINE CLINICAL CARE?

S. Baghban<sup>1</sup>, L. Krens<sup>1</sup>, M. Henstra<sup>1</sup>, M. Vermeer<sup>2</sup>, K. van der Elst<sup>1</sup>, H. Bemelot Moens<sup>3</sup>. <sup>1</sup>Hospital Pharmacy; <sup>2</sup>Clinical Epidemiology; <sup>3</sup>Rheumatology and Clinical Immunology, Ziekenhuisgroep Twente, Hengelo, Netherlands

**Background:** Treatment of rheumatoid arthritis is primarily aimed to achieve remission and thereby reduce the risk of permanent joint damage. Preventing disabling joint damage is an important long term goal for patients. Effectiveness of bDMARDs on disease activity has been proven in randomised controlled studies; however studies on long term joint damage are scarce and show conflicting results.<sup>1,2</sup>

**Objectives:** To compare joint damage more than 5 years after RA diagnosis in patients who have never used bDMARDs and in patients treated with bDMARDs. Joint damage is measured with the Rheumatoid Arthritis Articular Damage (RAAD) score, a clinical method comprising all joints that may be affected by RA.<sup>3</sup>

**Methods:** Retrospective cohort study in RA patients in a Dutch teaching hospital diagnosed between 2006 and 2011. Inclusion criteria were receiving a DMARD for at least 12 months and availability of a RAAD-score after a disease duration of 5 years or more. Exclusion criteria was receiving a DMARD for an other indication than RA. The exposure of interest was the type of treatment (sDMARD or bDMARD).

**Results:** Among 305 patients included, 101 used a bDMARD (table 1). Baseline characteristics were not significantly different in terms of prognostic factors for

joint damage progression, with the exception of patients in the bDMARD group being younger. During follow up, the highest DAS28 was higher in the bDMARD group 5.0 vs 4.3,  $p<0.001$ . After 8.5 years, more than half of the patients in bDMARD (55.4%) and sDMARD (57.4%) groups had no joint damage (RAAD-score 0). No significant differences in long term joint damage were observed, even after adjusting for potential confounders ( $b=-0.26$ , 95% CI  $-1.9-1.4$ ,  $p=0.76$ ).

Table	bDMARD n=101	sDMARD n=204
Values as median (IQR) unless indicated otherwise;		
Age yrs mean (SD)	49 (13)	57 (14)*
Female n (%)	63 (62.4)	129 (63.2)
ESR	22.0 (14.0-37.5)	27.5 (13.2-43.7)
CRP	10.0 (3.0-21.0)	15.0 (4.0-36.0)
≥6 ACR2010 criteria n%	79 (78.2)	158 (78.2)
Rheumatoid factor n%	81 (81.0)	145 (71.1)
ACPA n%	54 (76.1)	90 (70.9)
Bone erosions	17 (16.8)	46 (22.9)
DAS28	4.9 (4.3-5.60)	4.7 (3.8-5.5)
Disease duration yrs mean (SD)	8.5 (1.9)	8.5 (2.2)
Prednisolone use n%	57 (56.0)	63 (30.0)*
Highest measured DAS	5.0 (4.2-5.8)	4.3 (2.9-5.1)*
RAAD-score	0.0 (0.0-2.0)	0.0 (0.0-2.0)
HAQ	0.3 (0.0-0.9)	0.1 (0.0-0.4)*

**Conclusions:** In this cohort joint damage is not significantly different between patients treated with sDMARD(s) alone and those also using a bDMARD. Given the higher disease activity in the bDMARD group it is possible that this treatment prevented long-term joint damage by RA. Since there was limited joint damage in these groups this analysis should be repeated after longer disease duration and preferably in randomised cohorts.

THU0129

### PREDICTIVE VALUE OF CD19 SERUM LEVELS FOR LONG TERM THERAPEUTIC RESPONSE AND UTILITY AS BIOMARKER FOR OPTIMISATION, IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH RITUXIMAB

S. Melchor, E. Rodríguez, J.L. Pablos, P.E. Carreira. *Rheumatology, Hospital 12 Octubre, Madrid, Spain*

**Background:** Rituximab (RTX) is a chimeric monoclonal antibody directed against CD20 antigens in B lymphocytes (BL) surface, producing selective depletion of BL, without affecting mature plasmatic cells. Current guidelines recommend optimisation of biologic therapy once remission has achieved in rheumatoid arthritis (RA) patients. A serum biomarker able to predict what patients would maintain remission after optimisation in RTX treated RA patients is lacking.

**Objectives:** To analyse the predictive value of CD19 serum level prior to RTX infusion for the long term maintenance of therapeutic response, and it's utility as a biomarker for optimisation in RA patients treated with RTX.

**Methods:** all RA patients treated with RTX in our centre during 2016 and 2017 for at least 6 months, and with 12 months follow-up, were included. Demographic data, clinical data related to RA, including activity parameters (DAS28, HAQ, ESR, RCP), number of infections, optimisation and serum levels of lymphocytic subpopulations (CD19, CD3 and CD56) and immunoglobulins (Ig) prior to each RTX cycle were collected. Optimisation was defined as any dose decrease (lower dose for cycle and/or increase interval between cycles). Recurrent infections were defined as three or more infections in one year. Descriptive statistics, correlation between basal levels of CD19, CD3 or CD56, and activity parameters or Ig levels at 6 and 12 months, and association studies between lymphocyte subpopulations and optimisation or recurrent infections were performed.

**Results:** Thirty patients (25 females, 60±12 year) with RA (24 RF/aCCP +, 17 ±11 years from disease onset), treated with RTX during 52±40 months, with an accumulated dose of 13±10 g were included. At study inclusion, DAS28 was 3,77 ±1,65, HAQ was 1,28±0,78 and 22 had been optimised. CD19 levels were lower

than 2% in 22 patients (79%), including 10 with undetectable levels. CD19 levels (cells/mm<sup>3</sup>) were lower in optimised patients (73 vs 14,  $p=,03$ ), and were correlated with DAS28 at 6 months ( $r=0,5$ ;  $p=,007$ ) and 12 months ( $r=0,44$ ;  $p=,03$ ), and with ESR at 6 m ( $r=0,6$ ;  $p=,002$ ). CD19 levels did not correlate with IgG levels, and were not associated with recurrent infections. CD3 and CD56 levels did not show any relevant association or correlation.

**Conclusions:** In RA patients treated with RTX for more than 6 months, CD19 levels correlate with long term therapeutic response, being low or undetectable levels predictors of good outcome, without association with Ig levels or increased infections. Our results suggest that CD19 levels before every RTX cycle might be a useful biomarker to select candidate patients for optimisation with this therapy.

#### THU0130 EXPLORING THE MINIMUM PAIRED JOINT SET OF ULTRASONOGRAPHY TO PREDICT CLINICALLY SIGNIFICANT RESIDUAL SYNOVITIS IN RHEUMATOID ARTHRITIS PATIENTS WITH REMISSION

T. Wibowo, S. Kawada, Y. Ishida, Y. Yoshimine, Y. Manabe, K. Kawamoto, H. Nakahara, S. Higa, K. Maeda, A. Ogata. *Division of Allergy, Rheumatology and Connective Tissue Diseases, Department of Internal Medicine, NTT West Osaka Hospital, Osaka, Japan*

**Background:** Patients with rheumatoid arthritis (RA) who achieved clinical remission sometimes have synovitis detected by joint ultrasonography (US) <sup>(1)</sup>. This residual synovitis has been shown to be predictive of insidious radiographic progression, flares after tapering or cessation of DMARDs. Since it is difficult to examine all joints by US in daily clinical practice, several joint combinations have been proposed for optimal and/or feasible assessments of joint inflammation in patients with RA.

**Objectives:** To find the minimum number of paired joint set for US to predict clinically significant residual synovitis.

**Methods:** A comprehensive US assessment of joints was performed in 109 RA patients who achieved DAS28-CRP remission or low disease activity. Totally 40 (20 pairs) of joints including metacarpophalangeal (MCP) 1 to 5, proximal interphalangeal (PIP) 1 to 5, wrist, elbow, shoulder, knee, ankle, metatarsophalangeal (MTP) 1 to 5 joints were evaluated according to the EULAR recommendation <sup>(2)</sup>. Residual synovitis was defined as synovial hypertrophy with grey scale (GS) score greater than 1 or GS score 1 with any power Doppler (PD) signal, using semi quantitative scoring system (scale 0 to 3).

**Results:** 73 of 109 patients (67%) had at least one residual synovitis, and 39 of 73 patients (53.4%) had residual synovitis at least two different joints. As shown in table 1, residual synovitis at wrist and knee joints were found in 54.8% and 53.4% of 73 patients respectively, while for residual synovitis of another joints were less than 20% of patients. Solitary residual synovitis was most frequent in wrist and knee joints. By adding and combining joints which frequently found to have residual synovitis, we found that combination of wrist, knee, ankle, elbow, MCP1, and MCP2 joints (6 pairs) could detect residual synovitis in 94.5% of patients (table 2). Using the fact that one patients can have more than one residual synovitis at different joints and the tendency of residual synovitis to be found at some particular joints, we might find minimum pairs set of joint ultrasonography to detect residual ultrasound-defined synovitis. This could minimise the efforts needed to perform thorough joint US, while keeping the sensitivity high enough to detect any residual synovitis.

**Abstract THU0130 – Table 1.** Residual synovitis distribution

	n (%) total 73		n (%) total 73
Wrist	40 (54.8)	MTP 5	7 (9.6)
Knee	39 (53.4)	MCP 5	6 (8.2)
Ankle	14 (19.2)	PIP 3	4 (5.5)
Elbow	12 (16.4)	MCP 4	4 (5.5)
MCP 2	9 (12.3)	MTP 1	4 (5.5)
MCP 3	8 (10.9)	PIP 4	3 (4.1)
MCP 1	8 (10.9)	MTP 3	3 (4.1)

**Abstract THU0130 – Table 2.** Detectability of residual synovitis with each paired joint set.

Combination of Joints	Detectability (%)
wrist	40 (54.8)
wrist+knee	59 (80.8)
wrist+knee+ankle	63 (86.3)
wrist+knee+ ankle+elbow	66 (90.4)
wrist+knee+ankle+elbow+MCP1	68 (93.2)
wrist+knee+ankle+elbow+MCP1+MCP2	69 (94.5)

**Conclusions:** Patients achieved DAS28-CRP remission often had residual synovitis. The residual synovitis had tendency to be distributed at wrist, knee, ankle, elbow, MCP1, and MCP2, joints frequently used in activities of daily life. We propose this combination of joints as the minimum paired joint set to predict ultrasonographic remission.

#### THU0131 LEVELS OF CXCL13 AND sICAM1 CORRELATE WITH DISEASE ACTIVITY SCORE IN RHEUMATOID ARTHRITIS (RA) PATIENTS TREATED WITH TOCILIZUMAB (TCZ)

T. Sommasse<sup>1</sup>, C. Gabay<sup>2</sup>, M. Townsend<sup>1</sup>, R. Laubender<sup>3</sup>, J. Wang<sup>4</sup>, K. Tuckwell<sup>1</sup>. <sup>1</sup>Genentech, Inc., South San Francisco, USA; <sup>2</sup>University Hospital of Geneva, Geneva, Switzerland; <sup>3</sup>Roche Diagnostics, Penzberg, Germany; <sup>4</sup>Roche Diagnostics, Welwyn Garden City, UK

**Background:** The biomarkers CXCL13 and sICAM1 have been associated with outcomes in patients with RA treated with TCZ.

**Objectives:** To determine the association of CXCL13 and sICAM1 with response to TCZ and disease activity in early RA and DMARD-IR patients.

**Methods:** Patient subsets from the FUNCTION (early RA) and LITHE (DMARD-IR) clinical trials were selected based on baseline and Week 24 sample availability; serum CXCL13 and sICAM1 levels were measured. Correlations between CXCL13 and sICAM1 levels and DAS28-ESR at baseline, and between change in CXCL13 and sICAM1 levels and change in DAS28-ESR at Week 24, were determined. Changes in CXCL13 and sICAM1 levels from baseline to Week 24 were compared between treatment arms using Welch *t* test. The effect of treatment, baseline DAS28-ESR and baseline CXCL13 and sICAM1 levels on the likelihood of DAS28-ESR remission and ACR50 response at Week 24 was determined via logistic regression. DAS28-ESR remission and ACR50 rates were compared against CXCL13 and sICAM1 status (high vs low based on median values) within each trial arm using a Cochran-Mantel-Haenszel test.

**Results:** Overall, 458 of 872 patients from FUNCTION (TCZ +MTX, n=60; TCZ monotherapy [TCZ-mono], n=157; placebo [PBO]+MTX, n=141) and 287 of 791 patients from LITHE (TCZ +MTX, n=137; PBO+MTX, n=150) were included. In these patient subsets, mean disease duration in FUNCTION was significantly shorter than in LITHE (0.45 vs 8.65 years). At baseline, correlation of serum CXCL13 levels with DAS28-ESR was moderate in the early RA population and weak in the DMARD-IR population (table 1). Correlation between baseline serum sICAM1 levels and DAS28-ESR was low in both populations. Serum levels of CXCL13 decreased significantly at Week 24 in all treatment arms in both populations, with greater reductions in the TCZ +MTX and TCZ-mono arms; sICAM1 levels decreased significantly at Week 24 in the TCZ-mono arm in patients with early RA and the TCZ +MTX arms in both populations but not in the PBO+MTX arms. Change in CXCL13 levels correlated moderately with change in DAS28-ESR at Week 24 in both populations (table 1). Change in sICAM1 levels correlated moderately with change in DAS28-ESR at Week 24 in the DMARD-IR population but weakly in the early RA population. Although the treatment arm had a significant effect on the likelihood of DAS28-ESR remission and achievement of ACR50, the effect of baseline levels of CXCL13 and sICAM1 were not significant. DAS28-ESR remission and ACR50 response rates at Week 24 within each treatment arm of the early RA and DMARD-IR populations were not significantly different between patients with high vs low baseline CXCL13 and sICAM1 levels.

**Abstract THU0131 – Table 1.** Correlation Between Serum CXCL13 and sICAM1 Levels and DAS28-ESR

	Baseline						Week 24*					
	CXCL13			sICAM1			ΔCXCL13			ΔsICAM1		
	n	r	P value	n	r	P value	n	r	P value	n	r	P value
FUNCTION (early RA)	458	0.38	<0.0001	458	0.14	0.0029	458	0.33	<0.0001	458	0.16	0.0005
LITHE (DMARD-IR)	287	0.21	0.0002	287	0.17	0.0045	287	0.33	<0.0001	287	0.26	0.0002

CXCL13, C-X-C motif chemokine ligand 13; DAS28-ESR, Disease Activity Score in 28 joints per erythrocyte sedimentation rate; DMARD-IR, inadequate response to disease-modifying antirheumatic drugs; RA, rheumatoid arthritis; sICAM1, soluble intercellular adhesion molecule 1.

\* Correlation between change in CXCL13 and sICAM1 levels from baseline to Week 24 and change in DAS28-ESR from baseline to Week 24; all patients combined.

**Conclusions:** The association of baseline CXCL13 levels with RA disease activity was stronger in the early RA population than in the DMARD-IR population. Changes in CXCL13 and sICAM1 correlated significantly with changes in DAS28-ESR at Week 24. However, baseline levels of CXCL13 and sICAM1 did not predict response to TCZ at Week 24, suggesting that although these biomarkers are associated with disease activity, they do not predict response to TCZ in all RA populations.

**THU0132 THE PATIENT GLOBAL ASSESSMENT RATING VARIES MINIMALLY IF USING ARTHRITIS OR GLOBAL HEALTH CONDITION AND AGREEMENT IS HIGH BETWEEN COMMON COMPOSITE DISEASE ACTIVITY MEASURES AND REMISSION CLASSIFICATION USING EITHER: RESULTS FROM A NATIONAL EARLY RA COHORT STUDY**

V.P. Bykerk<sup>1,2</sup>, O. Schieir<sup>3</sup>, M.-F. Valois<sup>4</sup>, E.C. Keystone<sup>2</sup>, G. Boire<sup>5</sup>, J.E. Pope<sup>6</sup>, D. Tin<sup>7</sup>, B. Haraoui<sup>8</sup>, C. Hitchon<sup>9</sup>, C. Thorne<sup>7</sup>, S.J. Bartlett<sup>4</sup>, on behalf of on behalf of CATCH Investigators. <sup>1</sup>Rheumatology, Hospital for Special Surgery, New York, USA; <sup>2</sup>Rheumatology, <sup>3</sup>U Toronto, Toronto; <sup>4</sup>Epidemiology, McGill University, Montreal; <sup>5</sup>Rheumatology, U Sherbrooke, Sherbrooke; <sup>6</sup>Rheumatology, U Western Ontario, London; <sup>7</sup>South Lake Regional Health Ctr, Newmarket; <sup>8</sup>Institute de Rheumatologie, Montreal; <sup>9</sup>Rheumatology, U Winnipeg, Winnipeg, Canada

**Background:** The patient global assessment (PtGA) is a core domain in several RA composite disease activity (CDA) measures for trials, treat-to-target paradigms and practice, and can be asked differently, either referring to the patient's global health or condition (PtGA-GH), or specifically to arthritis disease activity (PtGA-AR).

**Objectives:** To assess agreement between PtGA-GH vs. PtGA-AR ratings and commonly used CDA indices calculated using both versions of the PtGA.

**Methods:** We included classifiable RA patients enrolled in CATCH (Canadian Early Inflammatory Arthritis Cohort) between 2011 and 2017 who simultaneously completed both PtGA-GH and PtGA-AR using a 10 cm VAS (scored 0–10) at each of baseline, 6- and 12 months visits. Differences in descriptive statistics were compared using Wilcoxon-sign rank tests and chi-square tests for baseline characteristics, PtGA ratings and CDA indices. Agreement was assessed using Intraclass correlation coefficients (ICC) for continuous measures and weighted kappa coefficients for categorical measures. Stratified analyses were also performed by age (older >65) and sex.

**Results:** Of 571 eligible early RA patients, 71% were female, 83% were white, 17% were current smokers, 17% had erosions, and 60% had completed high-school. Baseline mean(SD) age was 55<sup>(15)</sup> symptom duration was 5 (3) months and there were 2 (2) comorbid conditions. Agreement between PtGA ratings, composite CDA measures and remission classification by PtGA-GH and PtGA-AR are summarised in table 1. Mean(SD) PtGA-GH ratings were only marginally higher than PtGA-AR ratings and agreement was high between PtGA ratings at baseline and over the first year follow up (all ICCs>0.8). Agreement in CDA scores calculated with either PtGA was higher at baseline and over time (all ICCs>0.95). Concordance in classification of remission using either PtGA was also high at all time points (Kappa's>0.85). Results of stratified analyses showed that relative to men, women tended to report slightly higher differences in PtGA-GH vs. PtGA-AR (all p's<0.0001) but overall agreement in PtGA ratings, CDA scores and remission classification was high and similar in both sexes. Age stratified analyses were similar to those in the whole sample.

**Conclusions:** Results from this large longitudinal study of early RA patients followed in routine practice settings, showed patients rated the PtGA-GH marginally higher than PtGA-AR but differences had minimal impact on commonly used CDA indices and remission classification. These findings suggest that common composite measures of RA disease activity can be calculated using either the PtGA-GH or PtGA-AR.

**Table 1.** Agreement in Patient Global Assessment, RA Composite Disease Activity Indices and Classification of Remission calculated using PtGA-GH vs PtGA-AR

Variable	Baseline (N = 571)		6-Months (N = 571)		12-Months (N = 571)

**THU0134 ULTRASOUND DETECTED TENOSYNOVITIS PREDICTS ARTHRITIS ONSET IN INDIVIDUALS AT RISK OF DEVELOPING RHEUMATOID ARTHRITIS**

Y. Kisten<sup>1</sup>, H. Rezaei<sup>1</sup>, E. af Klint<sup>1</sup>, G. Fei<sup>1,2</sup>, A. Antovic<sup>1,2</sup>, A.H. Hensvold<sup>1,2</sup>, A. I. Catrina<sup>1,2</sup>. <sup>1</sup>Rheumatology Unit, Department of Medicine, Karolinska University Hospital, Karolinska Institute; <sup>2</sup>Academic Specialist Centre, Stockholm Health Services, Stockholm, Sweden

**Background:** The pathophysiological processes leading from musculoskeletal (MSK) complaints to clinically manifest rheumatoid arthritis (RA) are not fully understood. The urgency for imaging and serological markers that predict arthritis development in individuals at risk of RA is of clinical importance.

**Objectives:** To identify ultrasound (US) markers that can predict arthritis development.

**Methods:** Patients presenting with MSK complaints and a positive Anti-Citrullinated Protein Antibody (ACPA) test were referred from primary care units to the Rheumatology Unit. Those lacking clinical signs of arthritis, confirmed by absence of synovial hypertrophy with Doppler activity on US examination, were recruited into the Risk-RA prospective program. A total of 66 patients with complete US records were included between years 2015 up to December 2016. Hands and feet, including symptomatic joints were US-evaluated for synovitis, hyperemia and bone erosions. The presence of wrist (compartments 1–6) and finger (flexor and extensor) tenosynovitis, according to OMERACT guidelines were also recorded in all patients. Serum samples from inclusion were analysed on a multiplex immunoassay

**Results:** 66 Risk-RA patients (85% female, median age 50 years, range 22–82) were included and followed up to arthritis onset (median 8 months, range 1–27), or to the end of year 2017 (median 25 months, range 11–43). 27 patients (41%, 86% female, median age 52 years, range 22–74) developed arthritis. Of these 7 had tenosynovitis detected by US at inclusion and 7 more developed tenosynovitis at follow-up visits (in total n=14). At the time of diagnosis, 20 out of 27 patients presented with both tenosynovitis and synovitis.

A large majority of patients with tenosynovitis (12 out of 14, 86%) and a minority without tenosynovitis (15 out of 52, 29%) developed arthritis, resulting in an increased relative risk of 3.0 (95% CI 1.8–4.8) to develop arthritis for patients presenting with tenosynovitis at baseline or follow-up visits (p=0.001).

Concentrations of the anti-CCP antibodies, anti-CEP antibodies and anti-citrullinated vimentin<sup>60–75</sup> antibodies tended to be higher in patients with tenosynovitis developing arthritis (n=12, median of 70 AU/ml, range 2–175 for anti-CCP, median of 68 AU/ml, range 0–673 for anti-CEP, median of 53, range 0–644 for anti-vim) than those without tenosynovitis developing arthritis (n=15, median of 35 AU/ml, range 1–100 for anti CCP, median of 12, range of 0–1179 for anti-CEP, median of 29, range 0–332 for anti-vimentin). Same trend was observed when comparing

patients with tenosynovitis developing arthritis to those without-tenosynovitis not-developing arthritis. The 2 patients with tenosynovitis not developing arthritis, had lower levels of the antibodies as compared to those with tenosynovitis developing arthritis. No significant differences in other patient baseline characteristics were seen between those with, and those without tenosynovitis (86 vs 85% female, median (range) 54 years<sup>29-71</sup> vs 50 years,<sup>22-82</sup> mean visual analogue scale pain 34 vs 31, mean c-reactive protein 2.7 vs 3.2; tender joint count 1.2 vs 0.7).

**Conclusions:** Ultrasound detected tenosynovitis in the context of ACPA positivity is a good clinical predictor of rapid arthritis onset in individuals at risk of developing RA.

## Rheumatoid arthritis – comorbidity and clinical aspects

### THU0135 USING FRAX® AND PERIPHERAL BONE MINERAL DENSITY FOR IDENTIFYING POTENTIAL CANDIDATES FOR OSTEOPOROSIS THERAPY AMONG RHEUMATOID ARTHRITIS PATIENTS

O. Nikitinskaya, N. Toroptsova. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Rheumatoid arthritis (RA) and glucocorticoids (GC) therapy are proven risk factors (RF) for osteoporosis (OP) and osteoporotic fractures (OPF). Along with these factors, patients with RA have other diseases and conditions that can affect the increase of the risk of OPF.

**Objectives:** To determine the frequency of RA in the epidemiological random sample of persons aged  $\geq 50$  years and to identify among them patients who need the prevention of OPF.

**Methods:** The epidemiological sample included 18 018 people (13 941 women and 4 077 men, mean age  $62 \pm 10$  years). A survey was conducted using a unified questionnaire that included possible risk factors for osteoporosis (age, body mass index, individual or family history of fragility fracture, smoking, alcohol misuse, confirmed diagnosis of RA, long-term use of GC, premature menopause, physical inactivity, disorder strongly associated with osteoporosis) and daily calcium intake with food. The 10 year probability of fracture was calculated using the FRAX. Bone mineral density (BMD) was measured in the distal forearm using Osteometer Meditech DTX-200 as a screening method.

**Results:** The prevalence of RA in the epidemiological sample was 1.7% (1.9% for women and 1.2% for men,  $p=0.0047$ ). The mean FRAX values for the major OPF in RA patients were significantly higher than those without RA:  $18.4\% \pm 10\%$  and  $13.2\% \pm 7.9\%$ , respectively ( $p < 0.0001$ ) for women and  $8.9 \pm 6.4$  and  $6.2 \pm 3.7$ , respectively ( $p < 0.0001$ ) for men. Forty-two percent of RA patients had a high risk of OPF: 48% of women and 8% of men. The percentage of women with RA who had FRAX above the threshold of therapeutic intervention was significantly higher than among those without RA (31%),  $p=0.00001$ . At the same time, in men, the frequency of high fracture risk was the same in patients with RA and without RA (8% and 7%, respectively,  $p > 0.05$ ). Among the most common RF OP and OPF in RA patients were previous fractures (33%), causes of secondary OP (30%) and taking GC (18%), for men an additional factor - smoking (33%). Women with RA had significantly more concomitant diseases and other secondary causes of OP and OPF (33%) than those without RA (23%),  $p=0.0004$ . More of them used GC compared to control (17% and 8%, respectively,  $p < 0.0001$ ). Among men significant differences were obtained only for the using of GC: 20% in RA patients and 5% in control group ( $p < 0.0001$ ). Other RF were found with the same frequency. The average calcium intake with food was  $683 \pm 231$  mg per day among women and  $635 \pm 276$  mg per day in men without statistical differences between RA patients and control. 20% of men and 16% of women had less than half of daily calcium intake norm ( $p=0.53$ ). OP in the distal forearm was diagnosed in 47% RA women and 20% RA men compared to control: in 22% women ( $p < 0.0001$ ) and 19% men ( $p > 0.05$ ). Among RA patients, 13% of women and 20% of men had low FRAX and OP in the distal forearm.

**Conclusions:** Every third woman with RA had at least one more comorbid disease or condition associated with an increased risk of OPF and about every second - low BMD. 48% of women and 8% of men with RA had a high risk of OPF and needed prevention of OP. Additionally, among RA patients, 13% of women and 20% of men with low BMD in the distal forearm require axial densitometry.

### THU0136 MAJOR CARDIOVASCULAR EVENTS IN 434 RHEUMATOID ARTHRITIS PATIENTS TREATED WITH RITUXIMAB FROM A SINGLE-CENTRE

A. Giollo<sup>1,2,3</sup>, S. Gandrala<sup>4</sup>, T. Vojinovic<sup>5</sup>, A. Burska<sup>1,2</sup>, M.Y. Md Yusof<sup>1,2</sup>, E. M. Vital<sup>1,2</sup>, E.M.A. Hensor<sup>1,2</sup>, M.H. Buch<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>NIHR Leeds Biomedical Research Centre, Leeds, UK; <sup>3</sup>Rheumatology Unit, University of Verona, Verona, Italy; <sup>4</sup>Leeds Teaching Hospitals NHS Trust, Leeds, UK; <sup>5</sup>University of Pavia, Pavia, Italy

**Background:** Increased cardiovascular (CV) risk due to excess atherosclerosis in rheumatoid arthritis (RA) is attributed to systemic inflammation. Effective disease modifying drugs have been associated with reduced CV burden. Pre-clinical models of atherosclerosis suggest atheroprotective IgM and atherogenic IgG B-cell populations; with reduced atherosclerosis in murine models treated with depleting anti-CD20 monoclonal antibody suggesting relative preservation of protective B-cell population. The specific impact of rituximab (RTX) on the development of CV disease in RA has not been evaluated thus far.

**Objectives:** To determine the incidence of major cardiovascular events (MACE) in RA patients treated with rituximab and factors associated with any increased risk.

**Methods:** This was a single-centre, cohort study of patients with RA treated with  $\geq 1$  RTX cycle recruited prospectively. MACE outcomes were retrospectively identified as myocardial infarction, cerebrovascular accident, or death due to CV disease. Patients with and without MACE were compared for age, sex, CV risk factors (diabetes mellitus, hypertension, hyperlipidaemia, smoking, prior CV disease), disease characteristics (disease duration, ACPA, RF, methotrexate use, DAS28) and immunoglobulin levels. Association between the proportion of MACE and these variables of interest was analysed using the Student T test or Chi squared test as appropriate.

**Results:** A total of 434 patients were studied (mean age 58 years [SD 13], 80% females). Total follow-up was 3211 patient-years (PY). Of these, 32/434 (7.4%) had a MACE (incidence rate 10 per 1000 PY). Forty-three deaths (any cause; 9.9%) were recorded, 6/43 and 26/391 deaths respectively in patients with and without MACE (14% vs 7%,  $p=0.114$ ). Patients with MACE were older (64 [SD 9] vs 58 [SD 13] years,  $p=0.001$ ), more likely to be diabetics (22% vs 6%,  $p=0.001$ ), smokers (11% vs 5%,  $p=0.027$ ), and were treated less frequently with methotrexate (4% vs 13%,  $p=0.002$ ), but did not differ for hypertension, hyperlipidaemia, prior CV disease nor RA characteristics. Data on immunoglobulins at baseline and after the first cycle were available in the first instance in 287/434 patients. There were no significant differences in baseline immunoglobulin levels between patients with MACE and those without. However, the proportion of patients with MACE was significantly lower among those who had a reduction in their IgM levels from baseline (5% vs 21%,  $p=0.006$ ), but not for IgG or IgA. No significant differences in the clinical profile of patients with decreased IgM and those without were observed.

**Conclusions:** These preliminary data suggest decrease of IgM is associated with decreased risk of MACE in RA patients treated with RTX. Planned analysis on serial Ig with cumulative RTX exposure will clarify this initial observation. Whether and how any such association is related to a specific RTX-mediated effect and/or the overall reduction in the inflammatory burden deserves further investigation.

### THU0137 RHEUMATOID ARTHRITIS AS AN EMERGENCY DEPARTMENT RISK FACTOR FOR ACUTE CORONARY SYNDROME

M. Bergström<sup>1</sup>, J. Askling<sup>1</sup>, A. Discacciati<sup>2</sup>, M. Frick<sup>3,4</sup>, T. Jernberg<sup>4</sup>, R. Linder<sup>4</sup>, L. Ljung<sup>3,5</sup>, P. Svensson<sup>1,3,5</sup>. <sup>1</sup>Department of Medicine; <sup>2</sup>Institute of Environmental Medicine, Karolinska Institute, Solna; <sup>3</sup>Department of Cardiology, Södersjukhuset; <sup>4</sup>Department of Clinical Sciences, Danderyd University Hospital; <sup>5</sup>Department of Clinical Science and Education, Södersjukhuset, Karolinska Institute, Stockholm, Sweden

**Background:** In rheumatoid arthritis (RA), the risk of myocardial infarction (MI) is 1.5–2.0 times higher than for the general population. However, it is unknown whether RA is a risk factor also in high-risk populations, such as among patients subjected to a cardiac diagnostic work-up at the emergency department (ED).

**Objectives:** To study 1) whether RA is a risk factor for acute coronary syndrome (ACS) in a population-based sample of individuals seen in the ED, and 2) how any association with RA relates to the presence of chest pain.

**Methods:** A total of 96 220 patients (of whom 1 312 had RA) seen in the ED of the four hospitals in the larger Stockholm area, due to chest pain and/or tested for

troponin T, were identified through records of ED visits and cross-referenced to other registers. The outcome measure was ACS, defined as a discharge diagnosis of MI, unstable angina requiring urgent revascularisation, or death within 30 days (for directly discharged only). The association between RA and the outcome was assessed using logistic regression.

**Results:** ACS was more common in patients with RA (4.7%) than in subjects without RA (3.3%) – but this difference was largely attributable to RA patients being older and, upon taking age and gender into account, not statistically significant ( $p=0.13$ ). Overall and across all individuals with chest pain and/or a troponin T test taken, RA was not associated with ACS when adjusting for age, demographics and comorbidity, odds ratio (OR) 1.24, 95% confidence interval (CI): 0.95–1.61. In analyses restricted to patients presenting with chest pain (irrespective of troponin T test status,  $n=49$  283), a significant association between RA and ACS was observed (adjusted OR 1.40 95% CI 1.01–1.96).

**Figure 1 Odds ratios for myocardial infarction (MI) in rheumatoid arthritis (RA) patients compared with unexposed.** Patients with suspected MI in the emergency department (ED) grouped by presence of chest pain. Other chief complaints than chest pain labelled as atypical complaints. MI refers to combined outcome of MI or 30 day major cardiac event (MACE). \* Model 1: adjusted for age, gender, hospital, year of ED visit. † Model 2: adjusted for age, gender, hospital, year of ED visit, smoking, estimated glomerular filtration rate (eGFR), hypertension, hyperlipidaemia, diabetes mellitus, obesity, atrial fibrillation, heart failure and previous cardiovascular disease. Previous cardiovascular disease meant having one of the following diagnoses: previous stroke or MI, angina pectoris or peripheral vascular disease.

**Conclusions:** Although RA was not an independent risk factor for ACS among all patients subjected to a cardiac diagnostic work-up in the ED, RA was an independent risk factor among patients presenting with chest pain as chief complaint, an association that was not readily explained by traditional cardiovascular risk factors. The combination of RA and chest pain should thus increase the suspicion of ACS.

#### THU0138 OCCURRENCE OF IN-STENT RESTENOSIS AFTER CORONARY DRUG-ELUTING STENT IMPLANTATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

O.C. Kwon<sup>1</sup>, W.J. Seo<sup>2</sup>, J.S. Oh<sup>3</sup>, S. Hong<sup>1</sup>, C.-K. Lee<sup>1</sup>, B. Yoo<sup>1</sup>, Y.-G. Kim<sup>1</sup>.  
<sup>1</sup>Division of Rheumatology, Department of Medicine, University of Ulsan, College of Medicine, Asan Medical Center, <sup>2</sup>Division of Rheumatology, Department of Medicine, Seoul Veterans Hospital, <sup>3</sup>Clinical Research Center, University of Ulsan College of Medicine, Asan Medical Center, Seoul, Korea, Republic of Ireland

**Background:** Rheumatoid arthritis (RA) is associated with increased risk of cardiovascular events. Thus, patients with RA have a greater chance of undergoing coronary drug-eluting stent (DES) implantation. However, it is not known whether the rate of in-stent restenosis (ISR) is also increased in RA patients.

**Objectives:** To investigate characteristics of in-stent restenosis (ISR) after drug-eluting stent (DES) implantation in patients with rheumatoid arthritis (RA), and to evaluate the effect of disease modifying anti-rheumatic drugs (DMARDs) on ISR.

**Methods:** Patients with RA who underwent DES implantation between January, 2005 and March, 2017 were included. Characteristics of the patients and the vessel lesions were reviewed retrospectively. To evaluate the effect of DMARDs on ISR, previously known ISR risk factors and ISR incidence were compared between the treated vessels of patients who did and did not receive specific DMARDs.

**Results:** In total, 30 RA patients (43 vessel lesions) were included. 4 treated vessel lesions developed ISR (4/43, 9.3%) in median 106.8 (81.1–109.0) months after DES implantation. Compared with the previous data in general population (occurrence of ISR: 3%–20%, mean time of ISR occurrence: 13 months), the

**Abstract THU0138 – Table 1.** Comparison between treated vessels in the MTX group and treated vessels in the non-MTX group

Diameter (mm)	3.00 (3.00–3.50)	3.00 (2.81–3.00)	0.243
Length (mm)	29.0 (24.0–48.0)	21.0 (15.0–30.3)	0.018
ISR, n (%)	0 (0.0)	4 (33.3)	0.004

incidence was similar, but the time to ISR occurrence was much longer. In the comparison of patients receiving MTX ( $n=31$  vessel lesions) and those not receiving MTX ( $n=12$  vessel lesions), the ISR incidence was significantly different [0/31 (0.0%) vs. 4/12 (33.3%),  $p=0.004$ ].

**Conclusions:** ISR after DES implantation in RA patients occurs in a similar rate, but after a much longer period of time than in the general population. Administration of MTX in patients with RA might have potential benefit to prevent ISR after DES implantation.

#### THU0139 INCREASED HOMOCYSTEINE LEVEL FOR 7 YEARS IN PATIENTS WITH RHEUMATOID ARTHRITIS: TOMORROW STUDY

K. Inui<sup>1</sup>, T. Koike<sup>2,3</sup>, Y. Sugioka<sup>3</sup>, T. Okano<sup>1</sup>, K. Mamoto<sup>1</sup>, Y. Yamada<sup>1</sup>, K. Mandai<sup>4</sup>, M. Tada<sup>5</sup>, H. Nakamura<sup>1</sup>.  
<sup>1</sup>Department of Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka; <sup>2</sup>Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Hamayu Hospital, Shirahama; <sup>3</sup>Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine; <sup>4</sup>Department of Orthopaedic Surgery, Osaka Social Medical Center Hospital; <sup>5</sup>Department of Orthopaedic Surgery, Osaka City General Hospital, Osaka, Japan

**Background:** Osteoporosis is a disease in which not only bone density but also bone quality is low. Patients with rheumatoid arthritis (RA) are at higher proven risk of osteoporosis. Increased homocysteine (Hcy), one of the main markers of bone quality, is caused by insufficiency of folate or vitamin B. Elevation of Hcy inhibits physiological crosslink of collagen, which yields worse bone quality.

**Objectives:** In this study, we evaluated Hcy level as a bone quality marker in patients with RA for a period of 7 years and compared Hcy in RA patients with that in healthy volunteers (Vo).

**Methods:** We used the data for 7 years from a prospective cohort study (TOMORROW Study: UMIN000003876), which started in 2010 and compares data from RA patients with age- and sex-matched volunteer controls (Vo) recruited through mass media. Laboratory data were collected for all participants, including bone metabolic markers (urinary pentosidine, Hcy, collagen type 1 crosslinked N-telopeptide (NTX), and osteocalcin) and anthropometric parameters. Bone mineral density (BMD) of the lower leg was determined using whole-body dual-energy X-ray absorptiometry (DXA). Their parameters were compared with those of healthy controls, and multiple regression analysis was carried out

only in the RA population. In RA patients, treatment regimen and Disease Activity Score 28 were recorded.

**Results:** There were 413 participants (208 RA patients and 205 in the Vo group; mean age, 58 years) enrolled in the study, 349 of whom were female. In RA patients (mean disease duration, 13 years), bone density was significantly lower ( $p < 0.001$ , repeated-measures ANOVA) and Hcy ( $p < 0.0001$ , repeated-measures ANOVA) was higher in comparison with the Vo group during the 7 year study period. In the analysis of change in Hcy level over 7 years, "RA" and "time" were found to interact with each other ( $p = 2.58e-7$ , repeated-measures ANOVA) (figure 1). Multiple linear regression analysis in the RA population revealed a relationship between the level of Hcy and MTX dose at baseline ( $p = 0.048$ ), but no relationship between the level of Hcy and MCV ( $p = 0.165$ ).

**Abstract THU0139 – Figure 1.** Homocysteine level during the study period in the patients with rheumatoid arthritis (RA) and healthy volunteer (Vo)

**Conclusions:** MTX intake leads to folate deficiency, which is thought to cause elevation of the Hcy level. Ageing is another significant factor related to Hcy increase.

**Acknowledgements:** We thank Atsuko Kamiyama and Tomoko Nakatsuka for serving as research coordinators in terms of recruiting participants, collecting data and managing the quality of the data.

#### THU0140 EFFECTS OF STATIN-TREATMENT ON CORONARY PLAQUES IN PATIENTS WITH INFLAMMATORY JOINT DISEASES

M. Svanteson<sup>1,2</sup>, S. Rollefstad<sup>3</sup>, N.E. Kløv<sup>1,4</sup>, E. Ikdahl<sup>3</sup>, J. Sexton<sup>5</sup>, Y. Haig<sup>6</sup>, A. G. Semb<sup>3</sup>. <sup>1</sup>Institute of Clinical Medicine, Faculty of Medicine, University of Oslo; <sup>2</sup>Division of Radiology and Nucléarmedicine, Oslo University Hospital; <sup>3</sup>Preventive Cardio-Rheuma clinic, Department of Rheumatology, Diakonhjemmet Hospital; <sup>4</sup>Division of Radiology end Nucléarmedicine, Oslo University Hospital; <sup>5</sup>Department of Rheumatology, Diakonhjemmet Hospital; <sup>6</sup>Division of Radiology and Nuclear Medicine, Oslo University Hospital, Oslo, Norway

**Background:** Statins have an established preventive effect on coronary artery disease in the general population. The effect of statins on coronary plaque progression and characteristics in patients with inflammatory joint diseases (IJD) is unknown.

**Objectives:** Our aim was to evaluate the change in coronary atherosclerosis in long-term statin-treated patients with IJD.

**Methods:** Sixty-eight patients with IJD and carotid artery plaque, underwent coronary computed tomography angiography before and after 4.7 (range 4.0–6.0) years of statin treatment. The treatment target for low density lipoprotein cholesterol (LDL-c) was  $\leq 1.8$  mmol/L. Changes in coronary artery calcification (CAC) and coronary artery plaque volume (calcified, mixed/soft and total) from baseline to follow-up were assessed using the 17-segment model of the American Heart Association. Linear regression analysis was used to identify predictors of atherosclerotic progression.

**Results:** Coronary plaques were present in 42% of the patients at baseline and in 51% at follow up. Mean CAC score increased with  $173 \pm 284$ , calcified plaque volume with  $39.4 \pm 78.3$  mm<sup>3</sup> and total plaque volume with  $22.8 \pm 54.6$  mm<sup>3</sup> ( $p \leq 0.01$ , for all) (figure 1). Mean mixed/soft plaque volume decreased with  $-10.4 \pm 27.5$  mm<sup>3</sup> ( $p \leq 0.01$ ). At follow-up, 51% of the patients had obtained LDL-c treatment target. Compared to patients above LDL-c target, patients with an LDL-c  $\leq 1.8$  mmol/L experienced reduced median progression of both CAC ( $21^{2-143}$  vs.  $69$  [ $16-423$ ],

$p < 0.01$ ) and total plaque volume ( $0.08$  [ $-1.0-13.9$ ] vs.  $13.0$  [ $0.0-60.8$ ],  $p = 0.02$ ) (table 1).

	LDL $\leq$ 1.8 mmol/L n=34	LDL $>$ 1.8 mmol/L n=34	p-value*
LDL-c level baseline, mean $\pm$ SD	3.7 $\pm$ 0.9	4.4 $\pm$ 1.0	<0.01
LDL-c level follow-up, mean $\pm$ SD	1.5 $\pm$ 0.2	2.4 $\pm$ 0.7	<0.01
Change LDL-c level, mean $\pm$ SD	-2.2 $\pm$ 0.9	-1.9 $\pm$ 1.3	0.38
Change in CAC, median (IQR)	21 (2-143)	69 (16-423)	<0.01
Change in soft/mixed plaque volume, median (IQR)	0 (-3.5-0.0)	0 (-15.7-0.0)	0.71
Change in calcified plaque volume, median (IQR)	1.7 (0.0-17.3)	13.4 (1.5-107.6)	0.02
Change in total plaque volume, median (IQR)	0.08 (-1.0-13.9)	13.0 (0.0-60.8)	0.02

\*independent samples t-test

**Abstract THU0140 – Figure 1.** Mean change in plaque volume (mm<sup>3</sup>)

**Conclusions:** We revealed a progression of atherosclerotic plaque volume in statin-treated patients with IJD, mainly due to calcifications. However, soft, unstable plaques were reduced, probably as a result of an alteration in plaque composition from mixed/soft plaques into calcified plaques. Patients with recommended LDL-c levels at follow-up experienced a reduced atherosclerotic progression compared to patients with LDL-c levels above the treatment target. Our results support the importance of treatment to guideline recommended lipid targets in IJD patients.

#### THU0141 LONG-TERM EFFECTS ON BONE MINERAL DENSITY AFTER FOUR YEARS OF TREATMENT WITH TWO INTENSIVE COMBINATION STRATEGIES, INCLUDING INITIALLY HIGH DOSE PREDNISOLONE, IN EARLY RHEUMATOID ARTHRITIS PATIENTS: THE COBRA-LIGHT TRIAL

M.J. Lucassen<sup>1,2</sup>, M.M. ter Wee<sup>1,2</sup>, D. den Uyl<sup>1</sup>, N.P. Konijn<sup>1</sup>, M. T. Nurmohamed<sup>1,3</sup>, D. van Schaardenburg<sup>3,4</sup>, P.J. Kerstens<sup>3,5</sup>, I.E. Bultink<sup>1</sup>, L. H. Van Tuyl<sup>1</sup>, M. Boers<sup>1,2</sup>, W.F. Lems<sup>1,3</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Epidemiology and Biostatistics, VU University Medical Center; <sup>3</sup>Rheumatology, Research Institute Reade; <sup>4</sup>Rheumatology, Amsterdam Medical Center, Amsterdam; <sup>5</sup>Rheumatology, Westfriesgasthuis, Hoor, Netherlands

**Background:** Combinatie therapie Bij Reumatoïde Artritis (COBRA)-light therapy (methotrexate and initially 30 mg/day prednisolone) has proven to be non-inferior to COBRA therapy (methotrexate, sulfasalazine and initially 60 mg/day prednisolone) in the first year of treatment of early rheumatoid arthritis (RA) patients.

**Objectives:** This study assessed changes in bone mineral density (BMD) after four years in early RA patients initially randomised to one year of COBRA or COBRA-light therapy.

**Methods:** In the open-label, randomised, non-inferiority trial patients were assigned to COBRA or COBRA-light therapy. After one year, treatment was at the discretion of the treating rheumatologists. BMD in g/cm<sup>2</sup> was measured at baseline, after one, two and four years at total hip, femoral neck, and lumbar spine with dual-energy X-ray absorptiometry (DXA).

**Results:** Of the 164 original patients, 154 could be assessed after a follow-up of four years (range 34 to 74 months); 68% were female; mean (SD) age at follow-up 52<sup>13</sup> years. In the COBRA-light group, 11% of the patients used bisphosphonates after four years; the mean cumulative prednisolone dosage was 2.6 g (inter quartiles: 1.9; 5.9) and 49% of the patients had minimal disease activity (DAS44 <1.6).

**Abstract THU0141 – Table 1.** BMD values and changes in BMD during four years of treatment

	Baseline	COBRA-Light		Baseline	COBRA		Mean difference	GEE analyses CI	P
		Bone Loss			Bone Loss				
		Absolute	% of baseline		Absolute	% of baseline			
Lumbar Spine	1.10 (0.15)	-0.01 (0.08)	-0.5	1.12 (0.18)	-0.01 (0.08)	-1.0	-0.01	-0.03–0.02	0.56
Total Hip	0.96 (0.13)	-0.03 (0.05)	-3.3	0.95 (0.15)	-0.02 (0.05)	-1.7	-0.01	-0.03–0.02	0.56
Femoral Neck	0.88 (0.12)	-0.03 (0.05)	-3.7	0.90 (0.16)	-0.03 (0.06)	-3.0	-0.01	-0.03–0.02	0.59
								0.00–0.02	0.05+
								-0.02–0.00	0.05+
								-0.03–0.00	0.02+
								-0.04–0.02	0.38
								-0.04–0.01	0.37
								-0.04–0.01	0.29

In the COBRA group, these numbers were 10%, 3.2 g (2.5; 6.2) and 49%, respectively. At the lumbar spine, both groups showed no significant decline in BMD over four years and no difference between treatment groups in BMD change (table 1). At the hips, 1.7% to 3.7% BMD loss over four years was found with slightly but significantly more loss in the COBRA-light group (table 1).

Outcomes are mean (SD) unless stated otherwise. BMD in g/cm<sup>2</sup>. +Significant difference between COBRA-light and COBRA on average over time. \*Adjusted for bisphosphonate usage (yes vs no). \*\*Adjusted for bisphosphonate usage (yes vs no), cumulative prednisolone usage, age, gender and disease activity based on DAS44 (DAS44 <1.6 in remission vs DAS44 ≥1.6 not). CI, confidence interval; GEE, Generalised Estimating Equations; T4, measurement after four years; SD, Standard Deviation.

**Conclusions:** In modern treat-to-target management of RA, including bone surveillance, a high starting dose of prednisolone, either 30 or 60 mg/day, was not associated with a dramatically increased bone loss at the lumbar spine, and minor losses at the hip over four years.

#### THU0142 THE PROGNOSIS OF HEART FAILURE IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Meissner<sup>1</sup>, M. Schäfer<sup>1</sup>, B. Manger<sup>2</sup>, M. Zänker<sup>3</sup>, W. Ochs<sup>4</sup>, J. Listing<sup>1</sup>, A. Strangfeld<sup>1</sup>. <sup>1</sup>German Rheumatism Research Center, Berlin; <sup>2</sup>Scientific Advisory Board, Erlangen; <sup>3</sup>Rheumatologist, Bernau; <sup>4</sup>Rheumatologist, Bayreuth, Germany

**Background:** Heart failure (HF) is a condition with high rates of hospital admission and mortality. The impact of rheumatoid arthritis (RA) and its treatment on the prognosis of prevalent HF has been insufficiently studied.

**Objectives:** To evaluate deterioration of HF and mortality in patients with RA and concomitant HF.

**Methods:** The prospectively followed cohort of the German register RABBIT continuously includes RA patients with a new start of a DMARD after at least one csDMARD failure. Among all patients enrolled between 05/2001 and 10/2017 (n=15,037) patients with prevalent HF were selected (n=393). HF patients were followed until their end of observation or death. Deterioration of HF requiring hospital admission, and death were analysed as composite outcome. Incidence rates (IR) were calculated for current treatment at time of event (9 months risk window after last infusion of rituximab). Generalised estimation equations (GEE) were used to investigate risk factors for the composite outcome. To avoid uncertainties when allocating therapies, only treatment episodes >6 months were included in the GEE analysis. Missing values (DAS28, CRP, physical function) were addressed by multiple imputations.

**Results:** Of the 393 patients with prevalent HF and 1490 patient years (PY) of follow-up, a total of 131 patients had at least one outcome (19 HF deteriorations, 123 deaths). Infections (30%) and cardiovascular events (25%) were most frequently

reported as causes of death. The mean time until deterioration/death was 30/35 months. At baseline, patients with an event were older (69 vs. 67 years), more often male (43 vs. 32%), rheumatoid factor positive (80 vs. 74%), had higher CRP-values (39 vs. 23 mg/L) and a worse FFbH (% of physical function: 43 vs. 50) than patients without event. All HF patients had high numbers of comorbidities (mean of 7/6 in patients with/without event).

Crude IR were highest in patients under csDMARD only exposure (figure 1). IR were similar during the first 3 or 6 months after start of treatment and thereafter (data not shown). Biologic treatment was not associated with the outcome (table 1). Male gender, higher age, a higher glucocorticoid dose, worse physical function and elevated CRP under treatment were significantly associated with hospitalisation due to HF or a fatal outcome.

**Abstract THU0142 – Table 1.** Adjusted relative risk of HF deterioration or death in RA patients with underlying HF. CRP, FFbH and glucocorticoid doses were averaged for the time of a therapy episode.

	Relative risk	95% Confidence interval	
csDMARD	Ref.		
TNF inhibitors	0.7	0.4	1.3
Abatacept	0.8	0.3	2.3
Rituximab	0.5	0.2	1.1
Tocilizumab	0.9	0.3	2.6
Baseline age per 5 years	1.3	1.1	1.5
Male vs. female	2.4	1.4	3.9
CRP per 5 mg/L	1.03	1.004	1.1
% of physical function per 10 points	0.9	0.8	0.999
Sum of baseline comorbidities	1.1	0.96	1.3
Glucocorticoids per 5 mg/d	1.4	1.03	1.8
Smoker vs non-smoker	1.7	1.02	3.0

**Abstract THU0142 – Figure 1.** Incidence rates of composite outcome per 100 patient years

**Conclusions:** Patients with RA and HF have an unfavourable prognosis. One third of them were hospitalised for HF or died during follow-up. In addition to patient characteristics, smoking, insufficiently controlled inflammation and treatment with glucocorticoids significantly increased the risk of hospitalisation or death.

**THU0143 VASCULAR WALL INFLAMMATION IN RHEUMATOID ARTHRITIS PATIENTS DECREASES AFTER 6 MONTHS OF ANTI-INFLAMMATORY THERAPY WITH METHOTREXATE OR ADALIMUMAB AS MEASURED BY 18F-FDG-PET/CT**

A. Blanken<sup>1</sup>, R. Agca<sup>1</sup>, A. Voskuil<sup>1</sup>, R. Boellaard<sup>2</sup>, C. van der Laken<sup>1</sup>, M. Nurmohamed<sup>1</sup>, <sup>1</sup>Amsterdam Rheumatology and immunology Center, Reade, VUmc and AMC; <sup>2</sup>Radiology and Nuclear Medicine, VU University Medical Centre, Amsterdam, Netherlands

**Background:** Patients with rheumatoid arthritis (RA) have an elevated cardiovascular (CV) disease risk, mostly explained by both an increased prevalence of traditional CV risk factors and the presence of systemic inflammation that accelerates atherosclerosis. There is accumulating evidence that anti-inflammatory treatment for RA reduces this CV risk. A non-invasive tool for detecting vascular wall inflammation in atherosclerosis is 18F-Fluorodeoxyglucose-Positron Emission Tomography/Computed Tomography (18F-FDG-PET/CT).

**Objectives:** To study the effect of anti-inflammatory treatment with methotrexate (MTX) or adalimumab on vascular wall inflammation in RA assessed by 18F-FDG-PET/CT.

**Methods:** 18F-FDG-PET/CT was done in patients with active early RA starting MTX (n=25) and active established RA starting adalimumab (n=24) before and after 6 months of therapy, and in osteoarthritis controls (OA; n=29). 18F-FDG uptake in arterial wall was determined by standardised uptake values (SUV). Volumes of interest covering the arterial segment with the highest 18F-FDG were defined to derive the maximum SUV (SUVmax) in the ascending, descending and abdominal aorta and the aortic arch. Global arterial uptake was estimated using the mean SUVmax of the four arterial segments.

**Results:** Mean age was 65±9 for early RA, 61±7 for established RA and 63±5 years for OA controls. Median disease duration was 2.1 (interquartile range (IQR) 1.3–3.3) weeks for early RA and 6.9 (IQR 1.8–13.9) years for established RA. DAS28 was 4.9±1.0 and 4.4±1.0 at baseline and declined to 3.1±1.3 and 2.8±1.4 after 6 months therapy, respectively.

At baseline mean SUVmax was 1.86±0.38 for early RA, 1.68±0.43 for established RA and 1.56±0.41 for OA controls. SUVmax tended to decline more in early RA patients when compared to established RA (1.86±0.38 to 1.79±0.43 (-3.7%) and 1.68±0.43 to 1.63±0.43 (-3.0%), respectively). SUVmax in most arterial segments declined after 6 months of therapy (table 1). The most prominent decline in SUVmax was in the abdominal aorta in established RA patients (-9.8%).

**Conclusions:** A decline in global arterial SUVmax and in most of arterial segments was found in both early and established RA patients after 6 months of MTX and/or adalimumab, suggesting that anti-inflammatory therapy with either MTX and/or adalimumab decreases arterial wall inflammation and thus CV risk in RA.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.5660

**Abstract THU0143 – Table 1.** Arterial 18F-FDG uptake in RA patients before and after 6 months of therapy

	OA		Early RA 6 months MTX		Established RA 6 months adalimumab		
	Baseline	Baseline			Baseline		
SUVmax ascending aorta	1.55±0.44	1.82±0.38	1.77±0.38	-2.7%	1.69±0.61	1.60±0.44	-5.3%
SUVmax descending aorta	1.57±0.42	1.93±0.53	1.81±0.47	-6.2%	1.65±0.39	1.71±0.47	+3.6%
SUVmax abdominal aorta	1.62±0.43	1.84±0.44	1.81±0.58	-1.6%	1.73±0.61	1.56±0.45	-9.8%

Mean SUVmax over 4 segments	1.56±0.42	1.86±0.38	1.79±0.43	-3.7%	1.68±0.43	1.63±0.43	-3.0%

**THU0144 PERFORMANCE OF THE ERS-RA CARDIOVASCULAR RISK PREDICTION TOOL: EXTERNAL VALIDATION IN A LARGE SWEDISH COHORT WITH RA**

L. Ljung<sup>1,2</sup>, P. Ueda<sup>2</sup>, K.P. Liao<sup>3</sup>, J.D. Greenberg<sup>4,5</sup>, C.J. Etzel<sup>5</sup>, D.H. Solomon<sup>3</sup>, J. Askling<sup>2</sup>, <sup>1</sup>Umeå University, Umeå; <sup>2</sup>Karolinska Institutet, Stockholm, Sweden; <sup>3</sup>Brigham and Women's Hospital., Boston, MA; <sup>4</sup>New York University School of Medicine, New York; <sup>5</sup>Corrora LLC, Waltham, MA, USA

**Background:** Risk prediction tools developed for the general population tend to underestimate the risk of cardiovascular (CV) disease in patients with RA<sup>1</sup>. An accurate and RA-specific CV risk prediction tool would ideally be integrated as a routine part of clinical practice in rheumatology, to identify patients with increased CV risks. For example, 10 year CV risks above 7.5%, or 10%, could warrant specific preventive measures<sup>2,3</sup>. The ERS-RA was derived and internally validated in the US Corona RA registry<sup>4</sup>. ERS-RA estimates the 10 year CV risk using dichotomous clinical variables, and includes variables on RA disease severity and activity.

**Objectives:** To assess the external validity of the ERS-RA in Swedish cohorts of patients with RA, with focus on the risk intervals of main clinical interest.

**Methods:** We identified two cohorts of patients with RA: (i) an "incident 2006 cohort" with RA patients in the Swedish Rheumatology Register from Jan 1, 2006 – Dec 31, 2011 who were also in the EIRA case-control study (n=2047, mean age 55±13 years, 72% women), and (ii) a "prevalent 2012 cohort" that included all RA patients in the Swedish Rheumatology Register between Jan 1, 2012 – Dec 31, 2015 (n=14485, mean age 61±14 years, 74% women). The 10 year CV risk was estimated using ERS-RA. Patients with a history of myocardial infarction or stroke were excluded. All patients were followed for the first of any of the following: a CV event (myocardial infarction, stroke, cardiovascular death), death, 10 years of follow-up, or Dec 31, 2015. Ten-year CV rates were expressed using the Kaplan-Meier method. In the prevalent 2012 cohort, the 10 year event rates were extrapolated from the observed (maximally four-year) rates.<sup>5</sup> The C-statistic was estimated to assess discrimination. A measure of model calibration, the observed event rates were compared with the mean predicted 10 year risks.

**Results:** The C-statistic was 0.75 for both cohorts. Most patients had an estimated CV risk <5% or of >10% (See table 1). An accurate risk prediction was observed for estimated risks in the intervals <5%, and 5.0 to <7.5%. ERS-RA underestimated risk in the interval 7.5 to <10% (see table 1 and figure 1).

**Abstract THU0144 – table 1.** and figure 1. Comparisons of the mean estimated and the observed 10-year CV risks within groups of estimated risk levels.

	Groups of estimated 10 year risk	N patients (%)	Mean estimated 10 year risk (%)	Observed 10 year rate (%)	Difference Observed rate – Mean estimated risk
<b>Incident 2006 Cohort</b>	<5%	884 (48)	2.5	2.3	-0.2
	5.0 to <7.5%	282 (15)	6.2	5.7	-0.5
	7.5 to <10%	43 (2)	8.6	13.4	4.8
<b>Prevalent 2012 Cohort</b>	≥10.0%	638 (35)	18.3	18.3	0
	<5%	4691 (32)	2.7	1.9	-0.8
	5.0 to <7.5%	1604 (11)	6.2	4.0	-2.2
	7.5 to <10%	1485 (10)	8.6	12.0	3.4
	≥10.0%	6705 (46)	22.2	24.5	2.3

**Conclusions:** In a Swedish population with RA, ERS-RA performed well in identifying patients with a very low and very high CV 10 year CV risk. In clinical routine practice, ERS-RA could be used to identify low and high risk individuals, who might be considered for additional CV risk factor evaluation and subsequent intervention.

THU0145

#### CHANGES IN BONE METABOLISM AND TRABECULAR BONE SCORE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

A. Corrado, A. Mele, E. Sanpaolo, A. Trotta, R. Colia, F.P. Cantatore. *Department of Medical and Surgical Sciences, Rheumatology Clinic -University of Foggia, Foggia, Italy*

**Background:** Rheumatoid arthritis (RA) is a systemic inflammatory disease which can lead to bone and joint damage including local bone erosion and general osteoporosis. Dual X-ray Absorptiometry (DXA) is the established standard for measuring Bone Mineral Density (BMD), but it does not provide any informations about the bone microarchitecture, which is an essential parameter to define bone strength. The Trabecular Bone Score (TBS) is a new structural parameter that can be obtained by DXA scanning and it is related to bone microarchitecture and provides data on bone quality irrespective of bone density.

**Objectives:** The aim of this study is to evaluate the changes of BMD, TBS and bone remodelling parameters in subjects with recent-onset rheumatoid arthritis, treated or not with high doses of glucocorticoid, compared to age and sex matched healthy controls

**Methods:** The study included 42 subjects (31F, 11M), fulfilling the 2010 EULAR/ACR diagnostic criteria for RA and recent onset of joint symptoms (<6 months of synovitis) (Early RA), which were treated according to the current EULAR guidelines. As control group, 25 sex and age matched healthy subjects (21F, 4 M) were recruited. Post-menopausal women were excluded from the study. Lumbar spine and femoral BMD and TBS were evaluated at recruitment and after 12 months. The following parameters of bone remodelling and regulatory cytokines were measured at recruitment and every 3 months for 12 months: type I N-terminal propeptide (P1NP), osteocalcin, alkaline phosphatase, sclerostin, dickkopf-1 (DKK1), osteoprotegerin (OPG), Receptor Activator of Nuclear Factor Kappa-B ligand (RANKL). The clinical and demographic characteristics, including disease activity index and quality of life, were also evaluated

**Results:** No difference in BMD (spine and hip) and TBS values were detected between Early RA and control group at recruitment time (0,893 g/cm<sup>2</sup> vs 0,972 g/cm<sup>2</sup>; 0,790 g/cm<sup>2</sup> vs 0,770 g/cm<sup>2</sup>; 1598 vs 1521 respectively). After 12 months, the BMD at spine and hip and TBS values were significantly lower in patients with Early RA compared to healthy controls (0,601 g/cm<sup>2</sup> vs 1,011 g/cm<sup>2</sup>; 0,560 g/cm<sup>2</sup> vs 0,981 g/cm<sup>2</sup>; 1335 vs 1488 respectively). After 12 months, patients treated with high-dose of corticosteroids showed lower mean TBS values compared to patients untreated or treated with low-dose of corticosteroids (1,210 vs 1,430), whereas BMD values were similar. No differences were observed in osteocalcin and ALP between Early RA patients and healthy subjects at any time. Compared to healthy subjects, Early RA patients showed a significantly higher RANKL/OPG ratio and DKK1 serum levels, beginning from 6 month of observation, that correlated with disease activity (DAS28)

**Conclusions:** These preliminary data confirm that even in the early stages of disease, RA exert a negative effect on bone metabolism, whose pathogenesis is very complex and involves regulatory cytokines of bone homeostasis. This lead to a reduction of BMD and to changes of parameters of bone quality (TBS), that are more pronounced in patients treated with higher doses of corticosteroids compared to patients treated with lower corticosteroid doses

THU0146

#### GLYCEMIC PROFILE AND INSULIN RESISTANCE IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS

A.M. Brandy-García, A. Lorenzo Martín, S. Alonso Castro, M. Alperi López, F. J. Ballina García. *Rheumatology, Hospital Universitario Central de Asturias, Oviedo, Spain*

**Background:** In established rheumatoid arthritis (RA) there is a high incidence of patients with increased insulin resistance, which can favour the development of Diabetes Mellitus (DM) and the appearance of cardiovascular complications. These aspects, however, have not been studied in depth in patients with early rheumatoid arthritis.

**Objectives:** To describe the glycemic profile and insulin resistance (IR) in patients with early diagnosis of RA who had not received any background treatment or steroids.

**Methods:** Observational study in which patients were included 18 years old, diagnosed with RA according to criteria <sup>ACR 1987</sup> and/or <sup>ACR-EULAR 2010</sup> from the service of Arthritis of Recent Beginning of the Hospital Universitario Central de Asturias, between December 2016 and December 2017. In the basal visit, values of insulin, glucose, fasting glycosylated haemoglobin (HbA1c), body mass index (BMI) and abdominal perimeter were collected. In addition, RI and beta cell dysfunction were estimated with HOMA-IR and HOMA-B respectively.

**Results:** 66 patients were collected, of which 4 were excluded because they were known to be DM and 17 because they had not completed the analytical studies. Of the 45 that were finally studied, 80% (36 patients) are women, the mean age of 54.13±12.9 years, the progression of the disease to diagnosis is 22.8±15.3 weeks, 46.7% (21 patients) are FR and ACPA positive, and the mean disease activity measured by SDAI is 28.03±12.2.

Eighteen patients (45%) and 71.1% (31.5 patients) had HOMA-IR, with both 17 patients (37.7%) showing a statistically significant association of SDAI>11 (p=0.001), BMI >24 (p=0.03) and an increased abdominal perimeter (p=0.013).

Based on the WHO's diagnostic criteria for DM, 2 patients (4.4%) were diagnosed with DM (all based on a previously unknown HbA1c>6.5%) and 21 (46.7%) as pre-diabetic (14 with glucose between 100–125, 16 with HbA1c>5.7 and 9 patients with both alterations). In this subgroup the mean of HOMA-IR and HOMA-B was higher than the mean of the complete sample, 3.4 and 139 respectively. These patients compared with the rest of the sample had a statistically significant association with BMI >24 (p=0.07), SDAI >11 (p=0.01).

No correlations were found between these metabolic alterations and the sex, age or positivity for RH.

**Conclusions:** In patients with AR of less than one year of evolution and who have not received previous treatment with FAME or steroids, a high percentage of RI, pancreatic B cell dysfunction and alterations of the glycemic profile are detected. These alterations are significantly correlated with the presence of overweight and obesity, as well as with the high degree of activity of the disease. Follow-up of these patients is necessary to determine the effect of therapy for rheumatoid arthritis on these metabolic alterations.

THU0147

#### TREATMENT RESPONSE IN ANTIDEPRESSANTS-TREATED RA PATIENTS WITH DEPRESSIVE AND ANXIETY DISORDERS RECEIVING DMARDS AND BIOLOGICS ON A FIVE-YEAR FOLLOW-UP

A. Abramkin<sup>1</sup>, T. Lisitsyna<sup>1</sup>, D. Veltishchev<sup>2</sup>, O. Seravina<sup>2</sup>, O. Kovalevskaya<sup>2</sup>, E. Nasonov<sup>1</sup>. <sup>1</sup>Nasonova Research Institute of Rheumatology, <sup>2</sup>Moscow Research Institute of Psychiatry MoH, Moscow, Russian Federation

**Background:** Anxiety and depressive disorders (ADD) significantly affect disease activity and prognosis, treatment compliance and response in rheumatoid

arthritis (RA) patients (pts). Personalised antidepressant treatment of ADD could be beneficial in managing of RA in this group of patients.

**Objectives:** To compare treatment response and remission rates in 4 groups of RA patients with ADD treated with DMARDs, biologics and antidepressants at the endpoint of a prospective 5 years study.

**Methods:** 128 RA-pts were enrolled in pilot study. All of them met the full ACR criteria for RA classification. 86% RA-pts were women with a mean age of 47.4±1.0 (M±m) yrs. RA activity was evaluated with DAS28 and SDAI, remission was defined according to DAS28 (<2,6) and ACR/<sup>EULAR 2011</sup> (SDAI <3,3) remission criteria, response to treatment was classified according to EULAR and ACR/<sup>EULAR 2011</sup> (SDAI) response criteria. Average DAS28 and SDAI scores at baseline were high and moderate (5.25±0.16 and 33.5±1.38 (M±m)). 62.6% RA-pts were taking prednisone (9 (5; 10) mg/day (Me (25%; 75%)), 75,1% - DMARDs, 32% - biologics (rituximab – 12,5%, anti-TNF-α – 11%, anti-IL6 – 6,2%). ADD were diagnosed in 123 (96,1%) of RA-pts by psychiatrist in accordance with ICD-10 in semi-structured interview. Severity of anxiety and depression was evaluated with Montgomery–Asberg Depression Rating Scale (MADRS) and Hamilton Anxiety Rating Scale (HAM-A). RA-pts with ADD were divided into the following treatment groups: 1 – DMARDs (n=39), 2 – DMARDs+antidepressants (sertraline or mianserine) (n=43), 3 – DMARDs+biologics (n=32), 4 – DMARDs+biologics+ antidepressants (sertraline or mianserine) (n=9). Biologics treatment duration varied from 1 to 6 years, antidepressants – from 6 to 96 weeks. Differences in baseline disease activity scores were significant only in DAS28 for group 1 versus group 4 (4.95 ±0.24 vs 6.45±0.52; p=0,026).

**Results:** The RA-treatment efficacy was evaluated at 5 years endpoint in 83 RA-pts. The percentage of patients who achieved good response according to EULAR (DAS28) criteria was higher (p<0,05) in groups 2 (41,4%) and 3 (28,6%) vs DMARDs (4,2%) group. In biologics groups (3 and 4) good response according to SDAI criteria was more (p<0,05) prevalent (52,4% and 88,8% respectively) than in group 2 (25%), and vice versa for moderate response. In addition, patients in biologics groups achieved good response significantly more often than moderate (p<0,05). EULAR and SDAI nonresponse rates were significantly lower in 2–4 vs DMARDs groups. Patients treated with DMARDs+antidepressants achieved remission significantly more often (p=0,024) than ones receiving DMARDs only. Remission by ACR/<sup>EULAR 2011</sup> criteria was reached exclusively by DMARDs+antidepressants patients.

**Conclusions:** our findings demonstrate that successful treatment of ADD with antidepressants provides more significant positive influence on treatment response to DMARDs and biologics in rheumatoid arthritis patients on a five-year follow-up. Diagnosis and treatment of ADD would potentially play an important role in individualised management of RA patients

#### THU0148 SCREENING SYSTEM FOR EARLY ARTHRITIS WITH HEALTH PROFESSIONAL ASSISTANTS – A PROJECT OF THE T2T INITIATIVE IN GERMANY

C. Jacobsen<sup>1</sup>, V. Höhne-Zimmer<sup>1</sup>, T. Braun<sup>1</sup>, V. Köhler<sup>1</sup>, T. Leipold<sup>2</sup>, B. Tenckhoff<sup>2</sup>, K. Karberg<sup>3</sup>, G.R. Burmester<sup>1</sup>, J. Detert<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin; <sup>2</sup>Clinpath GmbH; <sup>3</sup>Rheumapraxis Steglitz, Berlin, Germany

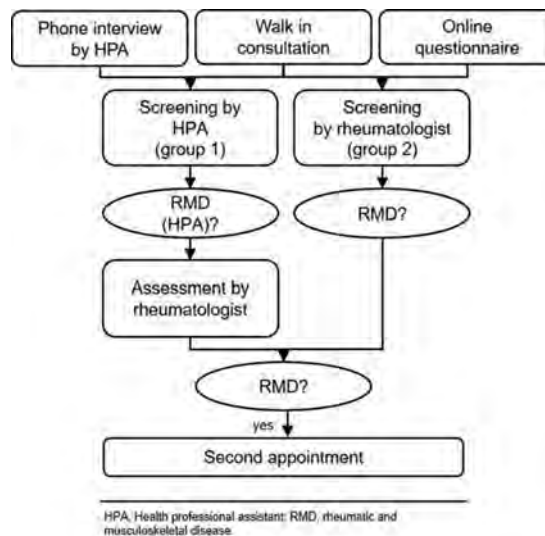

**Background:** Early stages of rheumatic diseases are still difficult to diagnose and treatment is delayed often due to the lack of practicing rheumatologists. Therefore, novel ways of diagnostic strategies are urgently needed.

**Objectives:** Evaluation of a structured screening system for selecting and treating patients (pts) with rheumatoid arthritis (RA) or rheumatic and musculoskeletal diseases (RMD) with health professional assistants (HPA, trained specialist nurses).

**Methods:** 177 pts visited a screening appointment for early arthritis (EA) between February 2015 and July 2016 in a specialised EA clinic. Inclusion criterion was arthritis in ≥one joint for less than one year. Pts had three options for accessing the screening: phone call with qualified HPAs, online questionnaire or attending a walk in clinic (figure 1). Upon screening, all pts filled in a digital questionnaire about their symptoms and comorbidities. In group 1 an HPA performed the joint count and analysed the questionnaire for 116 pts before giving a suspected diagnosis. Subsequently, a rheumatologist saw these pts and also made a suspected diagnosis. 61 pts in group 2 were examined directly by a rheumatologist. In case of a suspected RMD or abnormal laboratory parameters, pts received a new appointment for completing diagnostics, or in acute cases, treatment was started immediately. All pts had the opportunity of a new appointment in case of persistency or worsening of the symptoms.

**Results:** Pts had a mean age of 50.9±15.2 years and 135 (76.3%) pts were female. 160 (90.4%) pts had access to the screening by phone call. 10 (5.7%) pts used the online questionnaire, and 7 (3.9%) pts used the walk-in consultation. Pts waited 3.1±1.8 weeks for a screening appointment. According to the digital questionnaire pts had symptoms for 58.1±90.5 weeks at the screening appointment.

34 (56.7%) pts with RMD visited the screening clinic within six months after symptom onset. 2 (1.7%) pts had an RMD that had not been suspected by the HPA upon screening in group 1 and subsequently received conventional disease modifying antirheumatic drugs (cDMARDs) and glucocorticoids (GC). In group 2, 3 (4.9%) pts received cDMARDs although in the screening an RMD had not been initially suspected by the rheumatologist. In total 69 (39.0%) pts finally had an RMD, whereof 43 (24.3%) pts had an RA. 44 (24.9%) pts received therapy with a cDMARDs and 6 (3.4%) had the recommendation for a therapy with cDMARDs but refused treatment. Therapy with cDMARDs started 44.8±41.9 days after screening. 21 (11.9%) pts could already start with GC at the screening appointment. 27 (15.2%) pts without a diagnosed RMD visited the rheumatologist at least twice.

**Abstract THU0148 – Figure 1.** HPA, Health professional assistant; RMD, rheumatic and musculoskeletal disease.

**Conclusions:** HPAs can select pts with RMDs efficiently in a structured screening system which leads to treating RMDs at an early stage in times of limited resources.

#### THU0149 TRENDS IN THE INCIDENCE OF INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SPAIN: AN OBSERVATIONAL COHORT STUDY OF HOSPITAL DISCHARGES FROM 1999 TO 2015 (TREND-AR STUDY)

C. Martínez-Prada<sup>1</sup>, R. Mazzuccheli<sup>2</sup>, I. Morado<sup>1</sup>, E. Perez-Fernández<sup>2</sup>, J. Quirós<sup>2</sup>, J.L. Morell-Hita<sup>3</sup>, M. Peña<sup>3</sup>, N. Crespi<sup>4</sup>, C. Barbadillo<sup>5</sup>, H. Godoy<sup>5</sup>, M. Fernández-Prada<sup>6</sup>, M. Galindo<sup>7</sup>, O. Guzón-Illescas<sup>2</sup>, A. Herranz<sup>8</sup>, V. Villaverde<sup>9</sup>, A. García-Vadillo<sup>10</sup>. <sup>1</sup>Hospital Clínico San Carlos; <sup>2</sup>Hospital Universitario Fundación Alcorcón; <sup>3</sup>Hospital Universitario Ramón y Cajal; <sup>4</sup>Centro de Salud La Rivota; <sup>5</sup>Hospital Universitario Puerta de Hierro; <sup>6</sup>Hospital Universitario Guadalajara; <sup>7</sup>Hospital Universitario Doce de Octubre; <sup>8</sup>Hospital del Henares; <sup>9</sup>Hospital Universitario de Móstoles; <sup>10</sup>Hospital Universitario La Princesa, Madrid, Spain

**Background:** Rheumatoid Arthritis (RA) patients are at an increased risk of infection compared with healthy individuals, related to immune dysfunction. New treatments have revolutionised RA management; however, serious infection especially in elderly remains a concern.

**Objectives:** To analyse the incidence and trend of hospital admissions for all infections in patients with RA in Spain during the period between 1999 and 2015.

**Methods:** This is a national retrospective population based study. We analysed a national administrative database that includes a Minimum Basic Data Set (MBDS) in all hospital admissions of patients with RA. Period: 1999 to 2015. Cases were identified by the presence of ICD9 codes. The population at risk was estimated through the population census of the National Institute of Statistics. The adjusted rates of infection were calculated, by sex and age. The trend was analysed by Generalised Linear Models (GLM). Statistical analysis was made using SPSS statistical package version 20 (SPSS Inc, Chicago, IL).

**Results:** 338.343 RA hospital admissions were detected in the study period, being 81.468 (24,07%) due to infections. The main clinical-demographic characteristics are shown in table 1:

	Women	Men	Total	1999–2002	2003–2006	2007–2010	2010–2015
<b>N (%)</b>	53 528 (65.7%)	27 939 (34.3%)	81 467 (100)	10 518	15 644	21 280	34 025
<b>Mean Age (SD)</b>	71.38 (13.3)	70.62 (12.47)	71.12 (13.02)	68.39 (12.73)	69.65 (12.93)	71.21 (13.12)	72.60 (12.89)
<b>Dead during admission, n (%)</b>	5139 (9.6)	2957 (10.5)	8096 (9.93)	ND	ND	ND	ND
<b>Mean Charlson Index (SD)</b>	2.05 (1.5)	2.45 (1.8)	2.19 (1.63)	1.90 (1.40)	2.0 (1.51)	2.18 (1.60)	2.37 (1.75)
<b>Average length of stay (SD)</b>	13.86 (16.3)	14.14 (15.5)	13.9 (16.1)	15.94 (18.84)	15.36 (17.23)	14.43 (16.77)	12.42 (13.93)

The annual age-adjusted rate of infections increased during the study period, especially in men (fig 1). The annual trend of infections age-adjusted increased during the study period 5.29%, women 5.08% and men 5.92%. For age groups the annual increase was 3.51% for 20–40 years, 3.2% for 40–60 years, 4.5% for 60–80 years and 9.27% for >80 years.

**Conclusions:** Rate of infection in RA hospitalised patients in Spain has increased during study period. The patients are progressively elderly and has more comorbidities. However the average hospital stay decrease.

**THU0150 IMPACT OF COMORBIDITY BURDEN AND OBESITY ON THE EFFECTIVENESS OF TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS**

D. Pappas<sup>1,2</sup>, C. Etzel<sup>2</sup>, M. Crabtree<sup>2</sup>, J. Best<sup>3</sup>, S. Zlotnick<sup>3</sup>, J. Kremer<sup>4</sup>. <sup>1</sup>Columbia University, New York; <sup>2</sup>Corrona, LLC, Waltham; <sup>3</sup>Genentech, Inc, South San Francisco; <sup>4</sup>Albany Medical College and The Center for Rheumatology, Albany, USA

**Background:** Few real-world studies have evaluated the impact of comorbidity burden or obesity on the effectiveness of tocilizumab (TCZ) for the improvement of rheumatoid arthritis (RA) disease activity.

**Objectives:** To compare the effectiveness of TCZ in treating RA in patients with high vs low comorbidity burden and in obese vs nonobese patients in US clinical practice.

**Methods:** Patients in the Corrona RA registry who initiated TCZ and had follow-up visits at 6 and 12 months after initiation were included. To assess the impact of comorbidity burden on TCZ effectiveness, outcomes were stratified by patients with low Charlson Comorbidity Index (CCI=1) vs high (CCI ≥2). To assess the impact of obesity, outcomes were stratified by patients with BMI <30 (nonobese) vs ≥30 (obese). The primary outcome was mean change in CDAI at 6 and 12 months. Secondary outcomes were mean change in HAQ, the proportions of patients with change ≥ the minimum clinically important difference (MCID) in CDAI and HAQ and the proportion who achieved low disease activity (LDA; CDAI≤10). Baseline demographics, clinical characteristics, disease activity and treatment history in the comorbidity and BMI cohorts were compared separately using standardised differences; characteristics with |standardised difference|>0.1 were identified as covariates for inclusion in adjusted comparisons. Outcomes were compared between cohorts using two-sample t-tests or  $\chi^2$  tests in unadjusted analyses and linear or logistic regression models to adjust for covariates.

**Results:** Of 770 patients who initiated TCZ and had CCI data available at baseline (93.8% treated with intravenous [IV] TCZ and 6.2% with subcutaneous [SC]

TCZ), 575 (74.7%) had a low CCI and 195 (25.3%) a high CCI. Patients with a high CCI were older (mean [SD] age, 61.5 [12.3] vs 56.9 [13.1] years), were more likely to be obese (52.8% vs 41.7%), had a longer disease duration (mean [SD], 12.8 [9.9] vs 11.6 [8.9] years) and had higher mean (SD) baseline CDAI (25.7 [13.4] vs 23.9 [13.9]) and HAQ (0.71 [0.57] vs 0.57 [0.51]) scores than those with a low CCI.

Of the 805 TCZ initiators with BMI data available at baseline (93.9% treated with IV TCZ and 6.1% with SC TCZ), 449 (55.8%) were not obese and 356 (44.2%) were obese. Obese patients were younger (56.7 [12.0] vs 59.0 [13.7] years), had shorter disease duration (11.4 [8.6] vs 12.6 [9.7] years) and had higher baseline CDAI (25.4 [14.3] vs 23.6 [13.4]) and HAQ (0.65 [0.53] vs 0.57 [0.53]) scores than nonobese patients.

Patients in all cohorts had improvement from baseline in CDAI at 6 and 12 months, with no significant differences between those with a low vs high CCI or between obese vs nonobese patients (table 1). Secondary outcomes yielded similar results (table 1).

**Abstract THU0150 – Table 1.** Study Outcomes at 6 and 12 Months in Patient With RA Who Initiated TCZ, Stratified by Comorbidity Burden and Obesity Status

	Comorbidity Burden				Obesity			
	Low* (CCI = 1) [n = 575]	High (CCI ≥ 2) [n = 195]	Unadjusted Difference†	Adjusted Difference‡	Nonobese* (BMI < 30) [n = 449]	Obese (BMI ≥ 30) [n = 356]	Unadjusted Difference†	Adjusted Difference‡

BMI, body mass index; CCI, Charlson Comorbidity Index; CDAI, Clinical Disease Activity Index; eCDAI, e-comorbidity-adjusted CDAI; HAQ, Health Assessment Questionnaire; LDA, low disease activity; MCID, minimum clinically important difference; OR, odds ratio.  
 \* Reference group.  
 † The CCI used for this analysis is a modified CCI and is the sum of prior reported comorbid conditions that are reported in Canada in the final 4th digit position, including myocardial infarction, congestive heart failure, cerebral vascular disease, cardiovascular disease, chronic obstructive pulmonary disease, specific liver disease, diabetes mellitus, leukemia, lymphoma, solid tumor cancer (excluding non-melanoma of the skin) and liver disease. The CCI also includes cardiovascular disease, which was added as 1 to account for misclassification.  
 ‡ Adjusted for age, duration of RA, race, college education, smoking status, alcohol consumption, BMI, work status, insurance type, comorbidity burden category at initiation, number of prior eCDAI use, number of prior biologics used, CCI at initiation, HAQ at initiation, patient-reported fatigue at initiation and patient-reported pain at initiation.  
 § The 6-month visit occurred in a window of 4 to 8 months; the 12-month visit occurred in a window of 10 to 14 months.  
 ¶ CDAI ≤ 10 at baseline; MCID = 2; CDAI = 19 or ≥ 22 at baseline; MCID = 8; CDAI = 22 at baseline; MCID = 11.  
 \*\* LDA, CDAI ≤ 10.

**Conclusions:** In this real-world analysis, the effectiveness of TCZ for the improvement of RA disease activity was comparable among patients regardless of comorbidity burden or obesity.

**THU0151 ASSESSMENT OF COMPLIANCE OF RHEUMATOID ARTHRITIS PATIENTS IN COGNITIVE DYSFUNCTION**

E. Grunina<sup>1</sup>, A. Tkachev<sup>2</sup>. <sup>1</sup>N. Novgorod State Medical Academy, N. Novgorod; <sup>2</sup>Milton H. Erickson Institute of West Siberia, Novosibirsk, Russian Federation

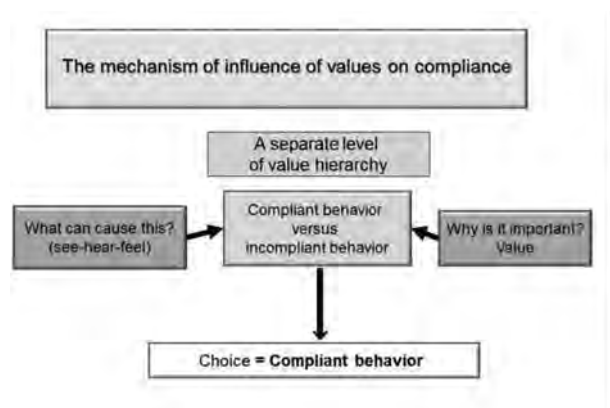

**Background:** Compliance decline may result in a decrease of treatment effectiveness in rheumatoid arthritis. RA patients had global cognitive impairment, which was associated with disease activity and immune changes.<sup>1</sup> Cognitive dysfunction may have a negative effect on the results of traditional methods of compliance assessment.

**Objectives:** Our aim was to develop the method of structured and algorithms interview to assess compliance and cognitive functions in patients with rheumatoid arthritis.

**Methods:** 240 patients fulfilling EULAR 2010 classification criteria for rheumatoid arthritis were examined. Pain in the joints was assessed using a visual analogue scale, the clock-drawing test was used, the structured and algorithms interview with clear determination of at least 3 levels of patient values was performed.<sup>2</sup>

Each patient chose the subject of the interview: compliance, pain or side effects of drugs. Subjective values that determine the choice and behaviour of the patient with dichotomy, for example, taking or missing drugs were revealed.

**Results:** 162 patients chose the theme of the interview concerning of pain, 50 patients chose the theme compliance with drug therapy, 38 patients - side effects of drugs. The criteria of cognitive dysfunction were the following: inability for the patient to determine subjective values influencing the process of decision-making, repeating one value with inability to build a value hierarchy, a limited number of the levels of the value hierarchy. The indirect criterion was the duration of the structured interview as the measure of patient's and interviewer's efforts. Cognitive dysfunction determined by the method of the structured interview was connected with the low score of the clock-drawing test. Compliance decline was noticed in the presence as well as in the absence of cognitive dysfunction. Determining values and their hierarchy may lead to the increase of patients' compliance.

**Conclusions:** The method of the structured and algorithms interview with the assessment of the hierarchy of values is used to assess compliance and cognitive functions in patients with rheumatoid arthritis as well as to reveal the ways to increase compliance.

#### THU0152 SERUM PRESEPSIN AS A NOVEL BIOMARKER FOR BACTERIAL INFECTION IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TOCILIZUMAB

E. Oguro<sup>1</sup>, S. Tsuji<sup>1</sup>, K. Kuzuya<sup>1</sup>, Y. Okita<sup>1</sup>, H. Matsuoka<sup>1</sup>, S. Teshigawara<sup>1</sup>, M. Yoshimura<sup>1</sup>, Y. Harada<sup>1</sup>, M. Matsushita<sup>1</sup>, S. Ohshima<sup>2</sup>, J. Hashimoto<sup>1</sup>, Y. Saeki<sup>2</sup>. <sup>1</sup>Department of Rheumatology and Allergology, <sup>2</sup>Department of Clinical Research, NHO Osaka Minami Medical Center, Kawachinagano, Osaka, Japan

**Background:** Tocilizumab (TCZ), an inhibitor of interleukin-6 (IL-6), has been widely used to treat rheumatic diseases such as rheumatoid arthritis (RA) and juvenile idiopathic arthritis. Recently, TCZ was approved for use in patients with giant cell aortitis and Takayasu aortitis. However, TCZ treatment sometimes obscures changes in the conventional biomarkers for infection such as serum levels of C-reactive protein (CRP) and procalcitonin (PCT). Presepsin (P-SEP), a subtype of soluble CD14, has been recently identified as a biomarker for sepsis. In addition, we have reported the usefulness of P-SEP for the diagnosis of bacterial infection in RA patients because it is less affected by the disease activity.

**Objectives:** To examine the usefulness of P-SEP in RA patients complicated with bacterial infections during TCZ treatment.

**Methods:** In this study, 49 RA patients with bacterial infections (i-RA), 76 RA patients without bacterial infections (RA) and 23 healthy controls (HC) were enrolled. The presence of infection was strictly diagnosed by bacteriological examinations, typical clinical characteristics such as fever (38.0°C) and/or CRP elevation and/or increased white blood cell count, and improvements of these manifestations with antibiotics. Serum P-SEP levels were measured by an immunoassay. The CRP and PCT levels were measured simultaneously.

**Results:** The median serum P-SEP levels were 186.0 [interquartile range (IQR), 134.0-236.0], 691.0 [IQR, 345.5-842.0], 154.5 [IQR, 145.8-165.5] l,

and 161.0 [IQR, 146.5-166.0] pg/mL for TCZ (n=25), i+TCZ (pre-antibacterial treatment; n=7), i+TCZ (post-antibacterial treatment; n=7) and the HC group, respectively. The P-SEP levels of the i+TCZ group were significantly elevated compared with those of the TCZ group (p<0.001). The i+TCZ group displayed elevated P-SEP levels despite normal CRP and PCT levels. After antibacterial treatment, P-SEP levels of the i+TCZ group were significantly decreased (p=0.016).

**Conclusions:** These results suggest that serum P-SEP levels are less affected by TCZ treatment compared with other conventional inflammatory biomarkers such as CRP and PCT. Moreover, P-SEP levels are useful for the assessment of bacterial infections in RA patients treated with TCZ.

#### THU0153 THE EFFECT OF 5-YEARS B-DMARDS TREATMENT ON DIFFERENT 10-YEARS CARDIOVASCULAR RISK SCORES APPLIED IN RHEUMATOID ARTHRITIS PATIENTS

F. Cacciapaglia, M. Fomaro, D. Renna, F. Cafarelli, G. Lopalco, M.G. Anelli, C. Scioscia, G. Lapadula, F. Iannone. *Rheumatology Unit; Department of Emergency and Organs Transplantation (DETO), University of Bari, BARI, Italy*

**Background:** Patients with rheumatoid arthritis (RA) have an excess risk of cardiovascular (CV) disease.

**Objectives:** We aimed to assess whether 5 years treatment with biologic DMARDs can impact on the 10 year CV risk assessed with different scores.

**Methods:** In this monocentric study we retrospectively evaluated data available at 2012 and 2017 to calculate the CV scores according to the Italian CV risk score Cuore project,<sup>1</sup> QRISK2-2017 score<sup>2</sup> and the score proposed by Solomon DH et al.<sup>3</sup> Moreover, RA characteristics were registered and correlated to the risk scores at baseline and after 60 months of treatment with RA approved biologic agents. Any CV event was registered.

**Results:** 110 patients with RA treated for the first time with a bDMARDs, and no prior CV events were included (mean age 52±11.3 years; 80% women; median disease duration 36 months). During the evaluated period 47 (42%) patients switched to a different bDMARD, 10 (9%) patients stopped the treatment for side effects and 3 (2.7%) patients with high CV risk scores at baseline presented a CV event within 4 years (2 myocardial infarction and 1 stroke). At baseline we observed a mean CV risk of 3.69 (95% confidence interval [CI], 2.70-4.68) assessed as moderate by the Cuore project, 10.64 (95%CI 8.48-12.8) and 10.43 (95%CI 8.61-12.24) considered as high risk according to the QRISK2-2017 and Solomon's scores, respectively. After 5 years we recorded a significant increase in CV risk assessed by the Cuore project and the QRISK2-2017 score [4.20 (95% CI 3.23-5.18) and 13.12 (95%CI 10.72-15.53), respectively; p<0.001 vs

baseline]. In comparison with baseline the change in the Solomon's score did not reach the statistical significance [10.68 (95%CI 8.78–12.58);  $p=0.66$ ]. In 38 (39.2%) patients that achieved persistent CDAI remission/low disease activity during the entire 5 years follow-up we observed a statistically significant reduction in the Cuore project score [4.1 (95%CI 2.1–6) vs 3.8 (95%CI 2.3–5.3);  $p=0.02$ ] and in the Solomon's score [9.3 (95%CI 5.6–13) vs 7.8 (95%CI 5.2–10.5);  $p=0.04$ ]. No statistical significance was found in CV risk scores stratifying patients for disease duration, RA specific disease characteristics, and mechanism of action and/or number of switch in bDMARD treatment.

**Conclusions:** RA patients are at moderate/high CV risk as assess by the different CV risk scores used, more consistent if inflammatory or disease specific items are considered in the score. Sustained CDAI remission obtained with bDMARDs can invert CV risk progression for 5 years estimated by Cuore project and Solomon's score, despite ageing.

#### THU0154 A PROGRAM FOR SCREENING AND TREATMENT OF CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH CHRONIC ARTHRITIS: 2-YEAR RESULTS

G. Albert-Espi, N. Martinez-Alberola, R. Martin-Domenech, C. Fernandez-Carballido, T. Pedraz-Penalva, F. Sivera. *Dpt Reumatology, Hospital General Universitario De Elda, Elda, Spain*

**Objectives:** Assess the efficacy of a program for the screening and management of cardiovascular risk factors (CVRF) in patients with chronic arthritis at 2 year follow-up.

**Methods:** Longitudinal and prospective study of patients included in a program aimed at the screening and improvement of the management of CVRF. Patients diagnosed with rheumatoid arthritis (RA), spondyloarthritis (SpA) and psoriatic arthritis (PsA) were included in the program. In the baseline and follow-up visits, CVRF were recorded, as was their treatment and whether treatment targets were achieved. SCORE index was calculated and modified according to EULAR 2010 recommendations. Tailored education was performed by the nurse and (if needed) referral to the rheumatologist or GP was performed for CVRF drug treatment.

For this analysis, we selected patients who completed baseline assessment and the 2 year follow-up. Prevalence and degree of control of CVRF were compared at both time points.

**Results:** Out of a total of 416 patients included in the program, 123 have completed both the baseline visit and the 2 year follow-up: 79 (64%) women with a mean age of 59.3±10 years. Patients with RA (n=85), SpA (n=14) and PsA (n=24) were included.

	BASELINE		2 YEAR FOLLOW UP	
	N (%)	Poor control N (%)	N (%)	Poor control N (%)
DM	14 (11%)	4 (3%)	14 (11%)	4 (3%)
Hypertension	77 (63%)	54 (44%)	84 (68%)	42 (34%)
Hypercholesterolemia (CT>220 mg/dL)	66 (54%)	37 (31%)	83 (67%)*	20 (16%)*
Smoker	28 (23%)	—	20 (16%)	—
Obesity (BMI>30)	47 (38%)	—	45 (37%)	—
CV events	6 (5%)	—	6 (5%)	—

\* $p<0.05$  comparison baseline – 2 year follow-up

The mean modified SCORE index was 4.6±4 at baseline and 4.6±4 at follow-up. Risk stratification (according to European guidelines) was 73 patients with intermediate risk, 20 with high risk and 20 with very high risk. Meanwhile, at 2 year follow-up, 74 patients showed an intermediate risk, 25 a high risk and 19 a very high risk.

**Conclusions:** A specific program aimed at detecting CVRF increases the proportion of patients with a CVRF diagnosis. However, it is also associated with an

increase rate of well-controlled hypercholesterolemic patients, with a trend observed in hypertensive patients and smokers. In case the improvement in CVRF control is confirmed, programs such as this could improve the CV prognosis of patients with chronic arthritis.

#### THU0155 CUSTOMISED CONSTRUCTION OF DEVICES AS INTEGRATION OF OCCUPATIONAL THERAPY INTERVENTION IN RHEUMATOLOGY BY 3D PRINTING TECHNOLOGY AND CO-DESIGN: FURTHER DEVELOPMENT AND VERIFICATION OF LONG-TERM EFFECTIVENESS

G. Sandri<sup>1</sup>, F. Gherardini<sup>2</sup>, C. Anastasio<sup>3</sup>, V. Bettelli<sup>3</sup>, A. Bottini<sup>3</sup>, M.T. Mascia<sup>1</sup>.

<sup>1</sup>Department of Clinical, Diagnostic and Public Health, Service of Rheumatology;

<sup>2</sup>Department of Engineering, Enzo Ferrari; <sup>3</sup>Department of Clinical, Diagnostic and Public Health, Occupational Therapy, Modena, Italy

**Background:** In our previous study<sup>1</sup> we have analysed the potentiality to create customised personalised aids through the 3D printing technique for patients with chronic physically and psycho-socially progressively disabling rheumatic diseases. It has been shown that the active involvement of the patient in the aid prototyping process through co-design sessions allows a greater acceptance of the aid itself in daily activities.

**Objectives:** To confirm the effectiveness of custom co-designed aids made with 3D printing technique. To check long-term patient's satisfaction in their daily use. To demonstrate that a client-centred intervention leads to aids greater acceptance, reduces social stigma and improves self-esteem.

**Methods:** 9 patients affected by long term rheumatoid arthritis were enrolled overall. They expressed their specific needs regarding the aid devices and therefore subsequent meetings were organised that have allowed us to produce and deliver customised objects.

Tools: Autodesk Fusion360 and Dassault Systemes SolidWorks for object modelling; Ultimaker Care for slicing; 3D printing DeltaWASP 20 40

Following a co-design approach, 6 aid devices were customised: hand grip holder for chalk, tablespoon, aid to open the moka coffee machine (2 different models), cans opener, zip puller. For the collection of the design features the product analysis of the USERfit tool was used. The psycho-social impact assessment of the assistance by PIADS (Psychosocial Impact of Assistive Devices Scale) and the patient's satisfaction by QUEST (Quebec User Evaluation of Satisfaction with Technical Aids, scale 1–5) were analysed after 1 week and after 1 year

**Results:** After 1 year all co-designed aids are still in use and the patients' satisfaction remains unchanged. The psychosocial assessment of delivered aid devices, collected through PIADS (– scale –3+3), showed an overall positive outcome (mean competence +1.92; adaptability:+1.590; self-esteem:+1.70). The assessment of patient satisfaction through QUEST, was good (scale 1–5: satisfaction aid: 4.65; service satisfaction: 4.9). There are no significant changes between scores after 1 week and 1 year except for a reduction in the self-esteem score ( $p=0.006$ )

**Conclusions:** This work shows that an interactive co-design, made possible by 3D printing, allows patients with long-established strategies in the activities of daily life to change habits, satisfactorily. The decrease of self-esteem scores could be probably due to a lower patient's emotional involvement with respect to an object that has become a regular part of his life.

#### THU0156 DEPRESSION AMELIORATED BY ORTHOPAEDIC SURGICAL INTERVENTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

H. Ishikawa<sup>1</sup>, A. Abe<sup>1</sup>, T. Kojima<sup>2</sup>, M. Kojima<sup>3</sup>, N. Ishiguro<sup>2</sup>, S. Ito<sup>1</sup>, A. Murasawa<sup>1</sup>.

<sup>1</sup>Rheumatology, Niigata Rheumatic Center, Shibata city, Niigata; <sup>2</sup>Orthopedic Surgery, Nagoya University Hospital; <sup>3</sup>Medical Education, Nagoya City Medical Hospital, Graduate School of Medicine, Nagoya city, Japan

**Background:** Depression is the most frequently seen comorbidity in the patients with rheumatoid arthritis (RA) <sup>1</sup>. Inflammatory mediators, including TNF- $\alpha$ ,

interleukin-1 and interleukin-6, affect serotonin transporters in the brain and promote low stress tolerance and depression<sup>2</sup>.

**Objectives:** To investigate the effect of orthopaedic surgery on the mental condition of patients with RA by assessing the Beck depression inventory II (BDI-II) and to investigate the factors associated with changes in the BDI-II.

**Methods:** A prospective cohort study was performed in 294 sites of primary elective surgery in 276 patients with structural damage due to RA. The average (range) age was 64<sup>19–89</sup> years old, and the average (range) disease duration was 16<sup>1–60</sup> years. The surgical site was the shoulder in 6 patients, elbow in 26, wrist in 74, hand in 63 (with wrist in 18), hip in 13, knee in 50, ankle in 12, and forefoot in 50. The BDI-II, EuroQol 5 dimensions (EQ-5D), Japanese version of the Stanford Health Assessment Questionnaire (J-HAQ), and disease activity score 28 using C-reactive protein<sup>4</sup> (DAS28-CRP<sup>4</sup>) were assessed at the baseline and at 12 months after surgery. During the observational period, the number of patients using methotrexate (MTX), prednisolone (PSL), and biological disease-modifying anti-rheumatic drugs (bDMARDs) did not change significantly. The mean dose of MTX and PSL was reduced by 0.4 mg/w and 0.2 mg/d, respectively, at 12 months after surgery.

**Results:** In total, the mean BDI-II significantly improved from 13.0 to 11.5 at 12 months after surgery ( $p < 0.01$ ). The number of patients with depression (BDI-II  $\geq 14$ ) decreased from 42.8% to 34.8% (figure 1). A significant improvement in the BDI-II was noted in the elbow, wrist, hand, and forefoot surgeries ( $p < 0.05$ ). EQ-5D, J-HAQ, and DAS28-CRP<sup>4</sup> also improved significantly ( $p < 0.01$ )<sup>3</sup>. A multiple regression analysis showed that the magnitude of decrease in the BDI-II ( $\Delta$ BDI-II) was independently related to the Steinbrocker's stage (95% confidence interval [CI]: 0.42, 2.39,  $p = 0.005$ ) and pain-visual analogue scale (VAS) (95% CI: 0.01, 0.10,  $p = 0.02$ ) at baseline and inversely related to matrix metalloproteinase-3 (MMP-3) (95% CI:  $-0.01, -0.001$ ,  $p = 0.03$ ) at baseline. The BDI-II was correlated with the EQ-5D ( $\gamma = -0.049$ ,  $p < 0.01$ ) and J-HAQ ( $\gamma = 0.387$ ,  $p < 0.01$ ) at 12 months after surgery.

Abstract THU0156 – Figure 1. Distribution of BDI-II at baseline and a postop. 12mos.

**Conclusions:** Depression was ameliorated by surgical intervention in patients with RA. The mental condition is associated with the quality of life and physical function.

### THU0157 ALTERED DNA-METHYLATION IN CHILDREN BORN TO MOTHERS WITH RHEUMATOID ARTHRITIS DURING PREGNANCY

H. Ince-Askan, J.M. Hazes, R.J. Dolhain. *Rheumatology, Erasmus Medical Centre, Rotterdam, Netherlands, Rotterdam, Netherlands*

**Background:** Exposures during early life are associated with later-life health, which is referred to as the Developmental Origins of Health and Disease hypothesis<sup>1</sup>. Epigenetic processes are thought to be one of the mechanisms underlying this hypothesis. DNA-methylation is the best studied and understood epigenetic modification. DNA-methylation of the fetus *in utero* may be influenced by multiple factors, including maternal disease<sup>2</sup>.

**Objectives:** To determine whether the DNA-methylation profile of children born to women with RA is different from children born to women from the general

population. Furthermore to determine which pathways are associated with the significantly differentially methylated CpG sites.

**Methods:** For the current study, blood from 80 children with a mean age of 6.82 (SD=1.28) born to women with RA, who were followed prospectively during pregnancy and postpartum in the PARA-study<sup>3</sup>, was used to measure genome-wide DNA-methylation using the Infinium Illumina Human-Methylation 450 k BeadChip. DNA from 345 children with a mean age of 6.04 (SD=0.39) born to women from the population-based Generation R study<sup>4</sup> were used as controls, also followed prospectively during pregnancy and postpartum. Linear mixed models were used to analyse differences in methylation between these groups. The models were corrected for age, BMI(SDS) and sex of the child, gestational age at delivery, maternal age, folic acid use during pregnancy, socioeconomic status, maternal smoking during pregnancy, white blood cell subtypes and technical batch.

**Results:** In total 770 CpGs were significantly different between the 2 groups at Bonferroni threshold  $p = 1.08 \times 10^{-7}$  (see table 1. for top 10 sites). In addition, pathway analysis resulted in 4 statistically significant enriched pathways. The top 2 pathways were the FOXO signalling pathway consisting of 16 genes ( $p = 3.39 \times 10^{-4}$ ) and mTOR signalling pathway consisting of 17 genes ( $p = 5.65 \times 10^{-4}$ ). These pathways are known for regulating the glucose and lipid metabolism, respectively.

Table 1 Top 10 methylation sites from the linear mixed model

### THU0158 INCREASED PROGRESSION OF ATHEROSCLEROSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS IS PARTIALLY REFLECTED BY DISEASE SEVERITY AT THE TIME OF DIAGNOSIS- 11-YEAR PROSPECTIVE FOLLOW-UP

L. Björnsenius, S. Rantapää-Dahlqvist, S. Wällberg-Jonsson, A. Södergren. *Rheumatology, Dept of public health and clinical medicine, Umeå University, Sweden*

**Background:** Patients with Rheumatoid arthritis (RA) have increased mortality and morbidity due to cardiovascular disease (CVD) compared to general population. While it has been established that atherosclerosis is increased, there is much yet to reveal about the underlying cause. Contributing factors, such as

inflammation, traditional CVD risk factors and metabolic disease have been suggested, but no full explanation is currently present.

**Objectives:** In this prospective case-control study, we investigated how the progression of subclinical atherosclerosis is associated with CVD risk factors and parameters of inflammation in patients with RA compared with matched controls.

**Methods:** By the time of diagnosis, patients from northern Sweden diagnosed with early RA are consecutively recruited into an ongoing prospective study. From these, a subgroup aged  $\leq 60$  years was consecutively included for ultrasound measurements of intima media thickness (IMT) of a. carotis communis at inclusion (T0) (n=79), after 5 years (T5) (n=71) and after 11 years (T11) (n=55). 44 age-sex-matched controls were included and 31 could be reevaluated at T11. Pharmacological treatment, previous CVD, markers of inflammation, lipid status, blood pressure, body mass index as well as measurements of disease activity were registered. Any previous CV events were verified by medical records. European Systematic Coronary Risk Evaluation (SCORE) and Reynolds Risk Score were calculated and Larsen score (of hands and feet) were registered. IMT progression rate ( $\Delta$ IMT T0-T11) was calculated by subtracting baseline values from IMT after eleven years follow up.

**Results:** IMT increased significantly between T0 and T11 among patients with RA (IMT T0: 0.51 (0.12) T11: 0.68 (0.16)  $p < 0.0001$ ) and controls (IMT T0: 0.54 (0.12) T11: 0.63 (0.13)  $p < 0.0001$ ). There was a higher progression rate between T0 and T11 in the RA group compared with the controls ( $p < 0.05$ ). In simple regression models, IMT T11 was significantly associated with several traditional CVD risk factors as well as Larsen score at T0 among RA patients (table 1). Moreover, in simple regression models  $\Delta$ IMT T0-T11 was significantly associated with Larsen score and age at T0 (both  $p < 0.01$ ) among patients with RA. A multiple regression model, with  $\Delta$ IMT T0-T11 as dependent variable, including traditional CVD risk factors at T0 (age, systolic blood pressure (BP), cholesterol and smoking), resulted in a  $R^2$  of 0.32 where age and cholesterol ( $p < 0.01$  for both) were significantly associated with  $\Delta$ IMT T0-T11. When also adding CRP and Larsen score the  $R^2$  increased to 0.50 and age ( $p < 0.05$ ) and Larsen score ( $p < 0.01$ ) were significantly associated with IMT T11.

**Abstract THU0158 – Table 1.** Simple regression models among 55 patients with RA with IMT after 11 years of follow up as the dependent variables.

Variable	IMT T11		
	$\beta$	95% CI	p
Age, T0	0.104/year	0.071–0.136	<0.001
Systolic BP, T0	0.035/ mmHg	0.009–0.061	0.009
SCORE, T0	0.534/unit	0.261–0.807	<0.001
Reynolds risk score, T0	0.182/unit	0.048–0.315	0.009
Larsen score, T0	0.122/unit	0.004–0.239	0.043
DAS 28, T0	-0.236/unit	-0.771– 0.298	0.364

**Conclusions:** In this prospective study, we found that there was an increased progression of atherosclerosis among RA patients, compared with controls, eleven years after diagnosis, and that this increase is associated with Larsen score and age at baseline.

**Disclosure of Interest:** None declared

DOI: 10.1136/annrheumdis-2018-eular.2831

#### THU0159 BARRIERS TO RHEUMATOID ARTHRITIS TREATMENT OPTIMISATION: REAL-WORLD DATA FROM THE ARTHRITISPOWER REGISTRY

J.L. Stark<sup>1</sup>, M. Yassine<sup>1</sup>, W.B. Nowell<sup>2</sup>, K. Gavigan<sup>2</sup>, S. Ginsberg<sup>2</sup>, M.S. Serna<sup>1</sup>, J. R. Curtis<sup>3</sup>. <sup>1</sup>UCB Pharma, Smyrna, GA; <sup>2</sup>Global Healthy Living Foundation, Upper Nyack, NY; <sup>3</sup>University of Alabama at Birmingham, Birmingham, AL, USA

**Background:** Few research studies have investigated treatment (Tx) goals in rheumatoid arthritis (RA) from the patients' (pts) perspective, including factors preventing achievement of Tx targets and reasons why pts tolerate sub-optimal disease control.

**Objectives:** To identify barriers to Tx optimisation, using real-world data from the ArthritisPower registry. Secondary objectives were to understand pts' Tx goals and why pts tolerate active disease.

**Methods:** This was an observational, cross-sectional sub-study of pts in the ArthritisPower registry. Pts were aged  $\geq 19$  years, had physician-diagnosed RA, no change to Tx within 3 months of baseline, and had access to a computer/smartphone. Pt-reported outcomes (PROs) included pain, fatigue, sleep, physical function, and general health. Pts also completed an online survey on barriers to Tx escalation, and were classified into 3 groups based on physician and pt attitudes to Tx change (change not offered, change offered and accepted, change offered

and rejected). Disease activity was reported using Routine Assessment of Patient Index Data 3 (RAPID3) scores.

**Results:** 257 pts met the inclusion criteria (table 1). 195/257 (76%) pts were treated with DMARDs (non-biologic or biologic). 180/257 (70%) pts had high disease activity by RAPID3 (median 18.0 on 0–30 scale), of which only 67/180 (37%) were offered a Tx change at their last physician visit. Most of these pts accepted the Tx change (48/67 [72%]). There were few differentiating factors in demographics, RA-related features, and background therapy among pts who were offered a Tx change versus not. Most pts (33/44 [75%]) who intensified Tx did so because their symptoms remained bad or worsened, whereas only 16/44 (36%) changed because they did not reach pre-defined Tx goals. The most common reason (21/32 [66%]) for deciding not to change therapy was the rheumatologist's satisfaction with the current therapy; pt concerns related to safety of the new therapy were less common (8/32 [25%]). There was a weak correlation between the RAPID3 score and pts' self-reported perception of their own disease activity. The majority of pts (176/257 [69%]) valued being actively involved in making decisions with their doctor about Tx.

**Abstract THU0159 – Table 1.** Patient demographics at baseline

	Demographics		
	Survey participants (N=257)	High disease activity (n=180)	Moderate or low disease activity, or near remission (n=77)
Age, mean years (SD)	51.9 (11.0)	51.1 (10.8)	53.7 (11.3)
Females, n(%)	236 (91.8)	187 (92.8)	69 (89.6)
Ethnicity, n (% white)	231 (89.9)	157 (87.2)*	74 (96.1)*
Years since diagnosis, mean (SD)	11.4 (9.9)	10.9 (9.2)	12.4 (11.3)
PRO scores, median (IQR)			
RAPID3	15.0 (12.0–19.0)	18.0 (15.0–20.0)*	9.0 (6.0–11.0)*
Pain	53.2 (50.0–58.9)	55.7 (52.7–57.6)*	58.7 (54.5–61.5)*
Fatigue	54.0 (50.7–60.0)	54.0 (52.3–59.3)*	57.1 (50.7–62.5)*
Physical function	37.3 (33.9–40.7)	36.3 (32.5–39.6)*	42.6 (36.8–45.9)*
Sleep	59.4 (54.3–63.0)	61.2 (55.8–64.8)*	55.8 (50.4–61.9)*

\*Statistical significance between patient groups,  $p < 0.05$ ; p values were nominal in nature and should be interpreted in an exploratory manner. Chi square tests were used to compare patient groups. IQR: interquartile range; PRO: patient reported outcome; RAPID3: Routine Assessment of Patient Index Data 3; SD: standard deviation.

**Conclusions:** Despite treat-to-target recommendations,<sup>1</sup> about two-thirds of RA pts with high disease activity in this sample were not offered a Tx change by their rheumatologist. Only a minority changed because they had not met predefined targets for disease control. Pts commonly followed their rheumatologist's decision that no Tx change was needed and placed greater importance on their doctor's Tx goals than their own. These findings suggest that pts may be more deferential to their physicians' satisfaction with poor RA disease control than is appropriate. Encouraging pts (not just physicians) to overcome the status quo by changing medications and striving for low disease activity/remission may be worthwhile, but traditional metrics (e.g. RAPID3) may not reflect the most relevant target for pts' goals for therapy.

#### THU0160 JUXTA-ARTICULAR BONE HEALTH AFFECTS NEW CAROTID PLAQUE FORMATION INDEPENDENT WITH GLUCOCORTICOID THERAPY IN POSTMENOPAUSAL PATIENTS WITH RHEUMATOID ARTHRITIS

J.W. Kang, N.R. Kim, J.S. Eun, J.H. Kim, J.Y. Kang, J.S. Seo, G.B. Bae, S.J. Lee, E.J. Nam, Y.M. Kang. Division of Rheumatology, Department of Internal Medicine, Kyungpook National University School of Medicine, Daegu, Korea, Republic of Ireland

**Background:** Rheumatoid arthritis (RA) is a chronic and systemic inflammatory disease.

The incidence of cardiovascular (CV) disease is increased in patients with RA, compared with the general population, which is related to the fact that atherosclerosis has an inflammatory etiology.

Several studies revealed that RA is associated with systemic bone loss, and long-term glucocorticoid therapy is also known to affect CV events as well as bone health such as osteoporosis.

Especially in postmenopausal women, the prevalence of osteoporosis and its complications are important medical issues.

**Objectives:** In the present study, we investigated the bone mineral density (BMD) for the carotid plaque formation in RA patients in the Kyungpook National University Hospital Atherosclerosis Risk in Rheumatoid Arthritis (KARRA) cohort study.

**Methods:** After a baseline evaluation for KARRA enrollment, RA patients were prospectively followed up for 5 years or until deaths.

We analysed the demographic findings, conventional CV risk factors and RA disease activity.

Carotid ultrasound at baseline and year 5 was performed to evaluation of the intima-medial thickness (IMT) and presence and progression of carotid plaque.

A total 323 patients (272 female) with RA, who performed dual-photon x-ray absorptiometry and carotid ultrasound, were included.

We assessed disease activity of RA, risk factors for atherosclerosis including hypertension, diabetes mellitus and dyslipidemia, presence of carotid plaque, BMD and cumulative glucocorticoid doses.

**Results:** A total of 417 RA patients were included in the baseline KARRA cohort, and 327 patients with RA were followed for the 5 year period.

Of the 417 baseline RA patients, 212 patients had no carotid plaque. At year 5, new carotid plaque formation was found in 91 of 214 patients who underwent BMD examination.

The BMD in the l-spine, femur, and radius was significantly lower in patients with carotid plaques (n=154), compared to patients without plaques (n=172) (1.016 g/cm<sup>2</sup>±0.22 vs. 1.066±0.18, p=0.013 for l-spine; 0.817±0.15 vs. 0.865±0.14, p<0.001 for femur; 0.542±0.14 vs. 0.605±0.13, p<0.001 for radius).

In postmenopausal patients, the BMD was significantly lower in carotid plaque group (n=93) than non-plaque group (n=109) (0.962±0.171 vs. 1.056±0.174, p<0.001 for L spine; 0.780±0.14 vs. 0.857±0.12, p<0.001 for femur; 0.502±0.110 vs. 0.593±0.112, p<0.001 for radius).

The cumulative steroid dose was confirmed in postmenopausal female patients, and the glucocorticoid dose was correlated with new carotid plaque formation. (r=0.334, p=0.04). Multivariate logistic regression analysis revealed that but radius BMD (p=0.04) was independent risk factors for new carotid plaque formation during the 5 year followed period after correlation with cumulative glucocorticoid dose, but l-spine (p=0.06) and femur BMD (p=0.07) were not statistically significant.

**Conclusions:** This study shows formation of new plaques after long-term follow-up depends on the juxta-articular bone health in postmenopausal RA patients.

**Disclosure of Interest:** None declared

#### THU0161 TRENDS IN THE INCIDENCE OF AMYLOIDOSIS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SPAIN: AN OBSERVATIONAL COHORT STUDY OF HOSPITAL DISCHARGES FROM 1999 TO 2015 (TREND-AR STUDY)

J.L. Morell Hita<sup>1</sup>, R. Mazzucchelli<sup>2</sup>, E. Perez Fernandez<sup>3</sup>, J. Quiros<sup>2</sup>, C. Macía Villa<sup>4</sup>, N. Crespi<sup>5</sup>, M. Peñá<sup>2</sup>, C. Barbadillo<sup>6</sup>, M. Espinosa<sup>6</sup>, H. Godoy<sup>6</sup>, M. Fernandez Prada<sup>7</sup>, M. Galindo<sup>8</sup>, A. Garcia Vadillo<sup>9</sup>, O. Guzon Illescas<sup>2</sup>, A. Herranz<sup>10</sup>, C. Martinez Prada<sup>11</sup>, C. Morado Quiñoa<sup>11</sup>, V. Villaverde<sup>12</sup>, on behalf of TREND-AR. <sup>1</sup>Rheumatology, Hospital Universitario Ramón y Cajal; <sup>2</sup>Rheumatology; <sup>3</sup>Hospital Universitario Fundación Alcorcón; <sup>4</sup>Rheumatology, Hospital Universitario Severo Ochoa; <sup>5</sup>CS La Rivota; <sup>6</sup>Rheumatology, Hospital Universitario Puerta de Hierro, Madrid; <sup>7</sup>Rheumatology, Hospital Universitario de Guadalajara, Guadalajara; <sup>8</sup>Rheumatology, Hospital Universitario Doce de Octubre; <sup>9</sup>Rheumatology, Hospital Universitario La Princesa; <sup>10</sup>Rheumatology, Hospital del Henares; <sup>11</sup>Rheumatology, Hospital Universitario Clínico San Carlos; <sup>12</sup>Rheumatology, Hospital Universitario Móstoles, Madrid, Spain

**Background:** Treatment and evolution of Rheumatoid Arthritis (RA) have had an important change in the last years. However the trend of amyloidosis, habitually related to long-standing and active RA, in Spain is unknown.

**Objectives:** To analyse the incidence and trend of hospital admissions for amyloidosis in RA patients in Spain from 1999 to 2015.

**Methods:** We performed an observational retrospective population study analysing the Spanish administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of RA patients from 1999 to 2015. We selected the MBDSs for amyloidosis. Cases were identified by the presence in primary and secondary diagnosis of its ICD9 code. The population at risk was estimated with an estimated prevalence of RA of 0.5% (0.8% women and 0.2% men). Crude and adjusted rates were calculated, and the trend was analysed using the Generalised Linear Model (GLM) with the year as the analysis variable. SPSS version 20 (SPSS Inc, Chicago, IL) was used.

**Results:** 338.343 RA hospital admissions were detected, being 3085 (0.9%) due to amyloidosis with 2298 (74.5%) women and 787 (25.5%) men. Mean age 65.42 (SD 13.08). There were 366 (11.9%) deaths. Age-adjusted rate during the period was 122.87/10<sup>5</sup> inhab. per year (98.96 women and 146.79 men). Amyloidosis age-adjusted rate decreased from 138.88/10<sup>5</sup> inhab. per year in 1999 to 71.47 in 2015, both women (128.18 in 1999 to 61.35 in 2015) and men (162.36 in 1999 to 107.95 in 2015). An annual decrease in the amyloidosis rate of 4.6% is estimated (RRI 0.953; CI 95% 0.939–0.968).

**Conclusions:** In Spain from 1999 to 2015 amyloidosis hospital admissions in patients with RA decreased, with an estimation of 4.6% annual reduction. This finding concurs with a greater knowledge of RA and its treatment advances with "treat-to-target" strategies.

#### THU0162 RESIDUAL SYNOVITIS IN ANKLES AND FEET DETECTED BY ULTRASONOGRAPHY IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. Inamo, Y. Kaneko, K. Sakata, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Twenty eight joints that are usually evaluated for disease activity score of rheumatoid arthritis (RA) do not include ankles and metatarsophalangeal joints. Although foot synovitis of patients in remission is clinically important in that it associates to relapse and worse physical function,<sup>1</sup> composite markers without an assessment of foot have demonstrated poor performance in detecting foot synovitis.<sup>2</sup>

**Objectives:** The aim of this study was to investigate the frequency and impact of residual synovitis in ankles and feet in patients with RA.

**Methods:** Patients with RA who underwent both physical examination and ultrasonography (US) on 44 joints including hands, fingers, ankles, and metatarsophalangeal joints between April 2016 and January 2018 in Keio University Hospital were enrolled. We compared patients with swollen joints of feet and ankles and those without, and then analysed those who did not have swollen joints by physical examination but were detected to have synovitis by US.

**Results:** Sixty one patients were enrolled in the study. The mean age was 58.5 years old, the disease duration was 7.1 years, and 85% were female. Among them, 21 patients had joint swelling in feet and ankles and 40 patients did not by physical examination. The patients in the former group showed significantly higher disease activity (DAS28 4.0 vs 2.4, p<0.05), higher doctor visual analogue scale (VAS, 33 vs 8 mm, p<0.05) and higher serum matrix metalloproteinase (MMP)-3 (165 vs 51 mg/dL, p<0.05). In the 40 patients with no swollen joints in ankles and feet by physical examination, 24 (60%) had active synovitis detected by US in those joints (US positive group) and the other 16 patients showed no synovitis in ankles and feet by US (US negative group). Whereas age and disease duration were not different between two groups, body mass index tended to be higher in the US positive group than the US negative group. Although the majority of both groups were in remission according to DAS28, fewer patients in the US positive group achieved remission according to Boolean criteria (29% vs 63%, p<0.05). The residual disease activity in ankles and feet was reflected in pain visual analogue scale most sensitively (33 mm vs 9 mm, p<0.05). The discordance in global assessments between patient and estimator of more than 30 mm was significantly frequent in the US positive group than the US negative group (33% vs 6%, p<0.05).

**Conclusions:** The residual synovitis in ankles and feet did not reflect in remission criteria by DAS28 but did by Boolean criteria. It caused a discordance in global assessments between patient and estimator.

Castelar-Pinheiro<sup>3</sup>. <sup>1</sup>Hospital das Clínicas da Universidade de São Paulo, São Paulo; <sup>2</sup>Universidade de Brasília, Brasília; <sup>3</sup>Universidade do Estado do Rio de Janeiro, Rio de Janeiro; <sup>4</sup>Instituto de Assistência Médica ao Servidor Público Estadual, São Paulo; <sup>5</sup>Universidade Federal do Paraná, Curitiba; <sup>6</sup>Universidade Federal de Santa Catarina, Florianópolis; <sup>7</sup>Universidade Federal de Minas Gerais, Belo Horizonte; <sup>8</sup>Universidade Estadual de Campinas, Campinas; <sup>9</sup>Universidade de São Paulo – Ribeirão Preto, Ribeirão Preto; <sup>10</sup>Universidade Federal do Pará, Belém; <sup>11</sup>Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

**Background:** Although Rheumatoid Arthritis (RA) extra-articular manifestations (ExRA) occurrence have been decreasing over time, they are still a major mortality risk factor for patients, and also a challenge for rheumatologists.

**Objectives:** To determine the prevalence of ExRA in a large cohort, and its association with several clinical data.

**Methods:** A cross-sectional and observational study, based on a multi-centric database from a prospective cohort (The REAL – RA in real life in Brazil), in which 11 public rheumatology centres enrolled RA patients (1987 ARA or 2010 ACR-EULAR). Data collection began in 08–2015, using a single online electronic medical record, and included demographic, socioeconomic, clinical and therapeutic characteristics.

**Results:** 1116 patients from 11 centres were included: 89% women, age [mean ±SD] 58.2±11.5 year, disease duration 14.5±12.2 year, positive Rheumatoid Factor (RF) in 77%. Regarding ExRA, 334 occurrences (detailed in table 1) were registered in 261 patients, summing for an overall prevalence of 23.4% in our cohort. Comparison among ExRA and No-ExRA groups reveals significant higher age, disease duration, Clinical Disease Activity Index (CDAI), Health Assessment Questionnaire (HAQ) and Disease Activity Index (DAS 28) in ExRA group (table 2). Unexpectedly, some well-known factors associated with ExRA, such as Rheumatoid factor (RF) and tobacco use, were similar among the two groups.

Abstract THU0163 – Table 1. - ExRA

Subcutaneous nodules	92		
Anaemia	78		
Sicca Syndrome	65		
Interstitial lung disease	45		
Peripheral neuropathy	15		
Vasculitis	14		
Scleritis/Episcleritis	12		
Pleuritis/Pericarditis	12		
Glomerulonephritis	1		
Table 2	ExRA (n=261)	No-ExRA (n=855)	p
n=1116			
Age [mean±SD] yr	60.4±10.1	57.5±11.8	<b>0.0003</b>
Sex (female) [n,%]	236 (90%)	762 (89%)	0.645
RF positive [n,%]	204 (78%)	659 (77%)	0.7363
Disease duration [mean±SD] yr	17.5±10.3	13.7±9.1	<b>0.0001</b>
Smoker, ever [n,%]	110 (42%)	331 (39%)	0.3471
Smoker, current [n,%]	25 (9%)	96 (11%)	0.496
CDAI; DAS28 [mean±SD]	18.2±16; 4.3±1.6	11.5±10.6; 3.4±1.4	<b>&lt;0.0001</b>
HAQ [mean±SD]	1.15±0.8	0.87±0.7	<b>&lt;0.0001</b>

**Conclusions:** ExRA still shows an expressive occurrence that should not be underestimated. Our findings reinforce that long-term disease, associated with significant disability and persistent inflammatory activity, are the key factors related to ExRA development. Early aggressive treatment with effective therapies should lower the risk and severity of ExRA.

**EFFICACY OF BIOLOGIC DMARDS IN DEPRESSIVE SYMPTOMS IN PATIENTS WITH RHEUMATOID ARTHRITIS**

K.J. Ng<sup>1,2</sup>, K.-Y. Huang<sup>1</sup>, C.-H. Tung<sup>1</sup>, M.-C. Lu<sup>1,2</sup>, N.-S. Lai<sup>1</sup>. <sup>1</sup>Division of Allergy Immunology and Rheumatology, Dalin Buddhist Tzu Chi Hospital, Chiayi; <sup>2</sup>Department of Medicine, Tzu Chi University, Hualien, Taiwan, Province of China

**Background:** Rheumatoid arthritis (RA) affects people both physically and psychologically. Comorbid depression is common, with a prevalence of 13%–42%.<sup>1</sup> According to 2015 ACR Guideline, RA patients should be treated with conventional synthetic or biologic Disease Modifying Anti-Rheumatic Drugs (csDMARDs or bDMARDs) according to their disease activity.<sup>2</sup> Correlating depression with RA disease activity, it is thought that patients with lower disease activity are less likely to be depressed.<sup>1</sup> A study comprising 83 RA patients revealed lower frequency of depressive disorders in anti-TNF group regardless of disease activity, however the data is limited by small case number.<sup>3</sup> A review of inflammation in depression in 2016 reported IL-1β, IL-6, TNF and CRP as the most reliable biomarkers of inflammation in depression.<sup>4</sup> Thus, chronic inflammatory status in RA might contribute to a high risk of depression.

**Objectives:** This aim of this study was to investigate the independent effect of the use of bDMARDs on the risk of depression in RA patients.

**Methods:** Using a cross-sectional study design, patients with definitive diagnosis of RA were recruited during regular outpatient follow-up in a regional hospital in southern Taiwan. Data was ascertained by questionnaires, laboratory measurements, and medical records. RA disease activity and depressive symptoms were recorded with the Disease Activity Score 28 (DAS 28) and the depression subscale of the Hospital Anxiety and Depression Scale (HADS-D), respectively. Patients were considered to be depressive cases if their HADS-D score >11. Patients who were prescribed with csDMARDs were considered as the non-biologic group, and those who were under bDMARDs or combination of csDMARDs and bDMARDs were considered as the biologic group.

**Results:** A total of 378 RA patients were recruited with 60 patients in the non-biologic group and 318 patients in the biologic group. Baseline characteristics including sex, educational level, marital status, socioeconomic status, working status, vegetarian dietary habit, and religion were similar between two groups. 4.1% of the biologic patients and 13.3% of the non-biologic patients were classified as depressive. Results from the multiple logistic regression analysis adjusted for the possible confounders including disease activity showed that biologic treatment was significantly associated a lower risk of depression (odds ratio=10.11, 95% CI=2.72–37.64, p=0.001).

**Conclusions:** Patients receiving bDMARDs showed a significant lower risk of depression, despite their higher RA disease activity. Further studies on the association between the use of bDMARDs and risk of depression are warranted.

### OBESITY AS ONE OF THE COMMODITIES WAS THE ROBUSTEST PREDICTION FACTORS FOR POST THERAPEUTIC CLINICAL REMISSION OF RHEUMATOID ARTHRITIS WITH SHORT DISEASE DURATION – RESULTS FROM KANSAI CONSORTIUM FOR WELL-BEING OF RHEUMATOID DISEASE PATIENTS

K. Murakami<sup>1</sup>, M. Hashimoto<sup>2</sup>, K. Murata<sup>2</sup>, W. Yamamoto<sup>2,3</sup>, R. Hara<sup>4</sup>, M. Katayama<sup>5</sup>, A. Ohnishi<sup>6</sup>, K. Akashi<sup>6</sup>, S. Yoshida<sup>7</sup>, K. Nagai<sup>7</sup>, Y. Son<sup>8</sup>, H. Amuro<sup>9</sup>, T. Hirano<sup>9</sup>, K. Ebina<sup>10</sup>, K. Nishitani<sup>2</sup>, M. Tanaka<sup>2</sup>, H. Ito<sup>11</sup>, K. Ohmura<sup>1</sup>, T. Mimon<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, <sup>2</sup>Department of Advanced Medicine for Rheumatic Diseases, Kyoto University Graduate School of Medicine, Kyoto; <sup>3</sup>Department of Health Information Management, Kurashiki Sweet Hospital, Kurashiki; <sup>4</sup>The Center for Rheumatic Diseases, Nara Medical University, Nara; <sup>5</sup>Department of Rheumatology, Osaka Red Cross Hospital, Osaka; <sup>6</sup>Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe; <sup>7</sup>Department of Internal Medicine (IV), Osaka Medical College, Takatsuki; <sup>8</sup>First Department of Internal Medicine, Kansai Medical University, Hirakata; <sup>9</sup>Department of Respiratory Medicine, Allergy and Rheumatic Disease; <sup>10</sup>Department of Orthopaedic Surgery, Osaka University Graduate School of Medicine, Osaka; <sup>11</sup>Department of Orthopaedic Surgery, Kyoto University Graduate School of Medicine, Kyoto, Japan

**Background:** A part of rheumatoid arthritis (RA) patients are resistant to clinical remission (CR) irrespective of therapies. In addition to known risk factors, systemic organ complications are assumed to interfere with CR.

**Objectives:** To extract the predictive comorbidities of clinical response of disease activities.

**Methods:** In Kansai consortium for well-being of rheumatic disease patients (ANSWER) cohort, which was the real world cohort of clinical database of rheumatic diseases, RA patients within 3 years of disease duration were included and followed. Using logistic regression analysis, background factors at the initial visit were extracted in order to predict CR after 1 year (1 year-non CR).

**Results:** 651 patients met in the inclusion criteria were under the analysis. Of those, 245 (37.6%) cases were resulted in 1 year-non CR. The average scores of DAS28-CRP at first visit and one year later was 3.51 and 2.02, respectively. Logistic regression analysis revealed that DAS28-CRP at first visit (OR 1.42/unit, 95% CI 1.24–1.63), concomitant use of methotrexate (MTX) or biologic disease modifying rheumatic drugs (bDMARDs) (OR 2.04, 95% CI 1.41–2.96) and body mass index (BMI) (OR 1.07/unit, 95% CI 1.02–1.12) were significant predictive factors of 1 year-non CR, but not in the case with gender, age, disease duration, hypertension, diabetes, dyslipidemia, lung diseases, heart diseases, digestive tissue diseases, history of malignancy nor concomitant autoimmune diseases. Using propensity score matching (1:1) stratified by gender, age, disease duration, concomitant use of MTX or bDMARDs and DAS28-CRP at baseline, the 49 pairs were matched between obese (defined as body mass index (BMI) over than 28) and non-obese patients. In these cohort, mean score of DAS28-CRP after 1 year was significantly higher in obese patients than in non-obese patients (2.63 and 2.18, respectively, see the figure 1).

**Conclusions:** In these early arthritis cohort, obese patients tend to remain higher disease activities even considering with gender, age and therapeutic management, although validation studies should be added to confirm these findings.

THU0166

### THE DIASTOLIC DYSFUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

L. Feiskhanova. Department of hospital therapy, Kazan state medical University, Kazan, Russian Federation

**Background:** Rheumatoid arthritis is autoimmune rheumatic disease characterised by injury not only the joints but also other organs, including the heart. It is known that the presence of rheumatoid arthritis increases the risk of fatal cardiovascular complications by 1.5 times compared to the general population.

**Objectives:** to identify features of development of diastolic dysfunction in patients with rheumatoid arthritis.

**Methods:** we examined 180 patients with rheumatoid arthritis. The activity of disease was defined according to the scale of the DAS-28. By echocardiography in 101 patients (group 1) were identified diastolic dysfunction of the left or both ventricles and in 79 patients (group 2) it was absent. Both groups were matched for age and sex. We determined the following echocardiographic parameters: mitral E/A, tricuspid E/A, end-diastolic dimension of left ventricle. In addition to echocardiography, patients underwent the vectorcardiography with the assessment of electrophysiological parameters: the squares of loops P, QRS, T, maximum vector (MV), MV-azimuth and MV- ascent. To compare two independent groups on quantitative grounds used nonparametric methods, the rank correlation and Mann-Whitney test. Differences were considered to be valid when  $p < 0.05$ .

**Results:** when comparing the groups revealed that in the 1st group, DAS-28 was higher than in the 2nd ( $p < 0.05$ ): 5.57<sup>5,17</sup>; 6.15 and 5.32<sup>4,8</sup>; 5.8 respectively. In the 1st group, the square of loop QRS and the MV- ascent directly correlated with E/A of mitral valve ( $p < 0.05$ ), whereas in the 2nd group, we have established a direct relationship with end-diastolic dimension ( $p < 0.05$ ).

**Conclusions:** the results indicate that increased activity of rheumatoid arthritis contributes to the development of diastolic dysfunction of the myocardium. In addition, the decrease in E/A observed in diastolic dysfunction, accompanied by electrophysiological remodelling and reduction in electrical activity of the myocardium of the left ventricle, diagnosed during registration of vectorcardiogram. Moreover, even in the absence of diastolic dysfunction, a tendency to its development in the presence of electrophysiological remodelling. This demonstrates the relationship between early electrophysiological, structural-geometric changes in patients with rheumatoid arthritis. Early diagnosis allows for timely start prevention of remodelling in patients with rheumatologic diseases.

### FALLS IN RHEUMATOID ARTHRITIS (RA) AND ITS RELATION TO DISEASE ACTIVITY, DISABILITY AND PHYSICAL PERFORMANCE TESTS

J.Z. Gajno<sup>1</sup>, M.B. Bertolo<sup>2</sup>, C.S. Nunes<sup>1</sup>, C.M. Barbosa<sup>1</sup>, Z. Sachetto<sup>2</sup>, M. Davitt<sup>1</sup>, E.D.P. Magalhães<sup>2</sup>. <sup>1</sup>UNICAMP, Campinas, Brazil; <sup>2</sup>Rheumatology, UNICAMP, Campinas, Brazil

**Background:** Rheumatoid patients(RA)are known to have an increased falls incidence with a threefold increased risk of hip fracture. Few studies have been conducted to evaluate the relation between falls, disease activity, disability and physical functioning.

**Objectives:** To evaluate the prevalence of falls in RA and its relation with disease activity, disability and physical performance tests.

**Methods:** 113 RA patients were evaluated from the outpatient clinic of the Rheumatology Division of the State University of Campinas/Unicamp. Patients were assessed for occurrence of falls in last year, fear of falling, sociodemographic and clinical data (medication, visual impairment, vertigo, physical activity, body mass index, disease duration, rheumatoid factor, lower limb swollen and tender joints, foot tactile sensitivity, disease activity-CDAI and disability-HAQ). Subjects were submitted to Berg Balance Scale-BBS, the Timed Up and Go Test-TUG and 5-Time Sit Down-to-Stand Up Test-SST5 and were divided in "Fallers" and "Non-Fallers" groups. For comparison of groups the chi-squared test, Fisher's exact test and Mann-Whitney were used. Univariate linear regression and multivariate analysis were used to analyse the relation between sociodemographic, clinical data and physical tests with the occurrence of falls. Kruskal-Wallis test was used for analysis of the association of BBS, TUG and SST5 with CDAI and HAQ. The data were analysed with a 5% level of significance.

**Results:** 52.21% reported the occurrence of falls in the past 12 months and 62.8%were fearful of falling. Comparing "Fallers" and "Non-Fallers", significant differences were noted for HAQ( $p=0.0242$ ), fear of falling( $p=0.0196$ ) and BBS ( $p=0.0120$ ). After univariate logistic regression there was association of falls with income(OR 1.05), HAQ(OR 1.945), fear of falling(OR 2.586) and TUG (OR 1.09). In multivariate model, income was independently linked to falls(OR 1.07). BBS, TUG, SST5 were correlated with CDAI and HAQ( $p < 0.05$ ).

**Conclusions:** RA patients have high prevalence of falls and fear of falling. Income was an independent fall risk factor. BBS seems to be higher among fallers and TUG can be considered a fall risk predictor. BBS, TUG and SST5 are related to CDAI and HAQ. CDAI does not seem to be a good instrument to predict falls due to its variability over time. In clinical practice, HAQ can be a valuable tool to recognise patients with an increased risk of falls.

THU0168

#### RELATIONSHIPS BETWEEN BODY FAT COMPOSITION ASSESSED WITH BIOELECTRICAL IMPEDANCE ANALYSIS, SERUM ADIPOKINES AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

M.G. Anelli, V. Venerito, G. Lopalco, F. Cacciapaglia, C. Scioscia, M. Giannotta, G. Righetti, F. Montini, D. Natuzzi, R. Bizzoca, N. Lacarpia, R. Fanizzi, G. Lapadula, F. Iannone. *Department of Emergency and Organ Transplantations, Rheumatology Unit, University of Bari "Aldo Moro", Bari, Italy*

**Background:** High-grade inflammation in patients affected with Rheumatoid Arthritis (RA) leads to an imbalanced body composition characterised by increased fat mass and decreased lean mass, with stable or increased body weight, resulting in little or no change in body mass index (BMI).<sup>1</sup> This condition, known as rheumatoid cachexia, is proven to be reversible once inflammatory process has been shut down. BMI and waist-to-hip ratio (WHR) are used as indirect measurements of visceral fat even if not capable of discriminating it from subcutaneous fat tissue. An alternative method proposed for assessment of fat composition, indicating nutritional status, is bioelectrical impedance analysis (BIA).

**Objectives:** To analyse body fat composition of patients with RA assessed using either BIA and anthropometric measures, investigating relationships between the related indices, serum adipokines and disease activity.

**Methods:** The body composition of 87 consecutive patients (72 female, 82.76%) affected with RA according to 2010 ACR/EULAR classification criteria, mean age of 52.42±13.29, mean disease duration of 10.71±8.58 years, treated with DMARDs and/or biologics, was assessed during their visit to our outpatient department. Data including demographic characteristics clinical manifestations, disease activity indices (DAS28-ESR, DAS28-CRP, CDAI, SDAI), Health Assessment Questionnaire (HAQ), lipid profile, as well as radiological findings were collected. Patients underwent to anthropometric measures (WHR and BMI) and BIA for the evaluation of fat-free mass (FFM), fat mass (FM) and the derived indices (fat-free mass index (FFMI) and fat mass index (FMI)). In addition for each patient blood samples were collected to determine serum levels of several adipokines (leptin, adiponectin, visfatin, resistin). Statistical tests as well as linear and logistic regression analysis were carried out.

**Results:** DAS28-ESR was found to be related to FMI ( $p=0.02$ ;  $r=0.22$ ) and to BMI ( $p=0.03$ ;  $r=0.22$ ). In addition, in patients in whom DAS28-ESR remission was not achieved, FMI but not BMI was found to be related to the latter disease activity index ( $p=0.007$ ,  $r=0.37$ ). FMI was shown to correlate to HAQ ( $p=0.01$ ,  $r=0.31$ ). Higher serum levels of leptin were found to predict higher FMI and BMI ( $p<0.0001$  for both,  $r=0.68$  and  $r=0.57$ , respectively) with DAS28 being also related to the latter adipokine ( $p=0.02$ ;  $r=0.24$ ). FFMI was inversely related to adiponectin serum levels ( $p=0.0003$ ;  $r=-0.40$ ). Both male and female patients classified as underweight for BMI were found to have a normal mean FFMI, with both groups presenting a mean DAS28-ESR score indicating remission.

**Conclusions:** Either body fat composition assessed with BIA-related indices and serum leptin have been noticed to predict disease activity. Moreover nutritional status of patients in remission according to DAS28-ESR may be better assessed by determining indices brought by BIA along with BMI, in order to rule out rheumatoid cachexia on the basis of FMI and FFMI.

THU0169

#### RELATIONSHIP OF FRAILTY AND DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE CHIKARA STUDY

M. Tada<sup>1</sup>, Y. Yamada<sup>2</sup>, K. Mandai<sup>2</sup>, N. Hidaka<sup>1</sup>. <sup>1</sup>Orthopaedic Surgery, Osaka City General Hospital; <sup>2</sup>Orthopaedic Surgery, Osaka City University Graduate School of Medicine, Osaka, Japan

**Background:** Frailty is defined as degradation of physical and cognition function in elderly adult<sup>1</sup>. The characteristics of frailty include not only physical problems as co-morbidity and disability, but also mental and social problems. It is unclear of relationship between frailty and disease activity of patients with rheumatoid arthritis (RA).

**Objectives:** We investigated the relative factors about frailty in patients with RA from a prospective observational study.

**Methods:** 95 from 100 patients entered the CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease Activity in Rheumatoid Arthritis) were investigated by frailty check list (maximal score is 25). According to reported article, frailty was defined from 8 to 25 and pre-frailty was from 4 to 7, and normal was from 0 to 3. We investigated relationship of disease activity in frailty, pre-frailty and normal groups, and analysed the relative factors for frailty.

**Results:** The prevalence of frailty, pre-frailty, and normal was 19%, 39% and 42%, respectively. The character of groups indicated at table 1. Frailty group was the oldest of three groups. Disease activity score 28 erythrocyte sedimentation rate (DAS28ESR) and matrix metalloproteinase 3 (MMP3) of frailty group was higher than those of pre-frailty and normal groups. Whereas, modified health assessment questionnaire (mHAQ) of frailty group was lower than those of pre-frailty and normal groups. Normal was 66.6% and frailty was 6.7% in remission patients. However, Normal was 13.3% and frailty was 46.7% in moderate and high disease activity patients (figure 1). The prevalence of frailty was increased with disease activity. The relative factors for frailty were age, locomotive syndrome, DAS28ESR, mHAQ, and Steinbrocker class, positively and leg muscle score and grip strength, negatively by univariate analysis. Steinbrocker class (odds ratio: 3.25 95% CI: 1.11–9.51,  $p=0.031$ ) and mHAQ (odds ratio: 1.29, 95% CI: 1.13–1.46,  $p<0.001$ ) were independent relative factors by multivariate analysis.

**Abstract THU0169 – Table 1.** The character of frailty, pre-frailty, and normal in patients with RA

	Frailty	Pre-frailty	Normal	P value
Age, years	72.5±10.3	68.6 ±11.3	60.7 ±16.4	0.01
Leg muscle score	84.9±5.9	86.2±6.4	93.2±9.7	<0.001
Grip, kg	12.6±6.9	17.7±7.1	18.1±6.2	0.013
Locomotive 5 score	11.1±5.8	6.4±4.9	2.6±4.0	<0.001
MMP3, ng/dl	143.7 ±122.0	95.9 ±66.0	88.6 ±52.0	0.033
DAS28ESR	3.62±0.97	3.27 ±1.02	2.83 ±0.96	0.015
mHAQ	0.9±0.7	0.4±0.2	0.1±0.1	<0.001
Sarcopenia,%	39	41	18	0.063

**Conclusions:** It was revealed that frailty involved disease activity and physical function in patients with RA. Control of disease activity is important to prevent not only disease progression, but also frailty.

### THU0170 RISK FACTOR FOR SERIOUS PULMONARY COMPLICATION IN PATIENTS WITH PRE-EXISTING LUNG DISEASE IN RHEUMATOID ARTHRITIS

N. Sugitani, T. Gono, S. Watanabe, E. Watanabe, H. Yabe, C. Terai. *Rheumatology, Jichi Medical University Saitama Medical Center, Saitama-city, Japan*

**Background:** Lung diseases, such as airway disease and interstitial lung disease (ILD), are often complicated in patients with rheumatoid arthritis (RA). The presence of those pre-existing lung diseases is one of the poor prognostic factors and risk factors for infectious pneumonia in patients with RA. There have been several concerned issues regarding pulmonary complications in RA patients with pre-existing lung diseases during treatment with disease-modifying antirheumatic drugs (DMARDs) because of infectious pneumonia or acute exacerbation in ILD, occasionally resulting in fatal outcome.

**Objectives:** We identified risk factors for serious pulmonary complications in patients with pre-existing lung disease during treatment with DMARDs in RA.

**Methods:** This study enrolled consecutive 487 RA patients at our hospital from 2005 to 2016 retrospectively. 110 of those 487 patients had pre-existing lung disease at the first visit to our hospital. At first, we divided those 110 patients into two subsets, one with development of serious pulmonary complication and the other without that during observational periods. We defined hospitalisation due to lung disease as a serious pulmonary complication regardless of the causes. Demographic and clinical data at enrollment as well as treatment regimens were collected by review of medical charts. We conducted a univariate analysis to compare the differences of clinical characteristics between the subsets. In multivariate analysis, the Cox proportional hazard model was employed to identify factors independently associated with serious pulmonary complication. The explanatory variables were chosen based on candidates ( $p < 0.25$ ) identified by the univariate analysis. In addition, we focused on 42 RA patients during treatment

with biological DMARD (bDMARD), and identified their risk factors by the same procedure mentioned above.

**Results:** In 110 RA patients with pre-existing lung disease, the median age and disease duration at enrollment was 70 and 3 years, and 71% were female. Rheumatoid factor and anti-cyclic citrullinated protein antibody (anti-CCP) were detected in 97 (88%) and 95 (86%) patients. Methotrexate (MTX), sulfasalazine (SSZ), bDMARDs and corticosteroid were prescribed in 37 (34%), 48 (44%), 42 (38%) and 65 (59%) patients. During the median observation periods of 11 months, 17 (15%) patients had serious pulmonary complications due to pulmonary infection in 11, exacerbation of ILD in 5, and drug-induced pneumonia in 1. The univariate analysis identified candidate variables for serious pulmonary complications as follows: use of MTX and bDMARDs, and no use of SSZ. In multivariate analysis, use of bDMARDs (HR 2.9, 95% CI 0.99–9.0;  $p = 0.05$ ) was identified as the independent risk factor. In 42 patients during treatment with bDMARDs, the univariate analysis identified candidate variables as follows: elder age, male, higher levels of anti-CCP, use of MTX, and no use of SSZ. In multivariate analysis, the higher levels of anti-CCP (HR 1.002, 95% CI 1.0003–1.004;  $p = 0.0007$ ) and no use of SSZ (HR 441.8, 95% CI 1.1–4658460.2;  $p = 0.04$ ) were identified as the independent risk factors.

**Conclusions:** Serious pulmonary complications should be more careful for RA patients with pre-existing lung disease during treatment with bDMARDs, particularly those with higher levels of anti-CCP or no use of SSZ.

### THU0171 IDENTIFICATION OF METHOTREXATE-INDUCED PULMONARY TOXICITY CASES IN A FULLY SEARCHABLE ROUTINE CLINICAL DATABASE

N. Hasler<sup>1</sup>, S. Irani<sup>2</sup>, P. Schütz<sup>3</sup>, P. Hasler<sup>1</sup>. <sup>1</sup>Klinik für Rheumatologie, Medizinische Universitätsklinik; <sup>2</sup>Abteilung für Pneumologie und Schlafmedizin, Medizinische Universitätsklinik; <sup>3</sup>Allgemeine Innere und Notfallmedizin, Endokrinologie, Diabetologie und Metabolismus, Medizinische Universitätsklinik, Kantonsspital Aarau, Aarau, Switzerland

**Background:** Methotrexate (MTX) remains the favoured disease-modifying anti-rheumatic drug for the treatment of rheumatoid arthritis (RA) and is frequently used in other inflammatory conditions. However, side effects are frequent and toxicity is of concern, especially since MTX-induced pulmonary side effects, including pneumonitis, are potentially fatal. Estimates of MTX-induced pneumonitis in the literature range from 0.3% to 7.5% of exposed cases (Barrera et al., 1994 Kremer et al., 1997).

**Objectives:** We aimed to identify and characterise MTX-induced lung injury in patients exposed to low-dose MTX at the Rheumatology Division of the Kantonsspital Aarau, Switzerland.

**Methods:** The revised diagnostic criteria for adverse pulmonary events due to MTX treatment as defined by Kremer et al 1997 were used to categorise MTX-induced lung injury. The electronic patient files of the Rheumatology Division are stored in a NoSQL-database (MongoDB), which is fully addressable by the Solr search platform (Apache Lucene). The entire database was searched for terms associated with methotrexate exposure and potential pulmonary side effects.

**Results:** Of 9'550 cases, 11 fulfilled the criteria for definite MTX-induced pulmonary injury, while three additional patients could be classified as suffering from probable MTX-induced pulmonary side effects. To determine the number of exposed cases, the case files were queried for the mention of MTX and related terms. 1'947 case files contained a reference to MTX. In a random sample of 395 of these cases, an exposure to MTX was verified in 328 (83%). Assuming a calculated exposure of 1'639 cases, MTX-induced lung injury was present in 0.85%.

**Conclusions:** In a comprehensive survey of patients exposed to MTX in a fully searchable routine clinical database, MTX-induced pulmonary injury occurred in a low frequency.

### THU0172 SLEEP QUALITY IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS SHOULD BE KEPT IN MIND

O. Deniz<sup>1</sup>, H. Satis<sup>2</sup>, C. Cavusoglu<sup>1</sup>, R.B. Salman<sup>2</sup>, O. Varan<sup>2</sup>, N. Atas<sup>2</sup>, S. Coteli<sup>1</sup>, R.T. Dogrul<sup>1</sup>, H. Babaoglu<sup>2</sup>, A. Oncul<sup>1</sup>, H.D. Varan<sup>1</sup>, M.C. Kizilarslanoglu<sup>1</sup>, A. Tufan<sup>2</sup>, B. Goker<sup>1</sup>. <sup>1</sup>Geriatrics; <sup>2</sup>Rheumatology, Gazi University School of Medicine, Ankara, Turkey

**Background:** Sleep disturbance is one of the most important geriatric syndromes and its evaluation is part of the routine comprehensive geriatric assessment (CGA). Elderly patients with poor sleep quality are at risk of worse clinical outcomes such as falling, impairment of activities of daily living, depression and anxiety. Rheumatoid arthritis (RA) is an inflammatory disorder characterised by joint pain and may worsen sleep quality. Previous clinical trials in the literature have shown that elderly patients with RA have poorer sleep quality compared to younger patients. However, there is lack of data on sleep quality of elderly patients with RA.

**Objectives:** We aimed to investigate sleep quality of elderly patients with and without RA and also explore the effects of sleep quality on quality of life (QoL) and its association with disease activity.

**Methods:** This study was conducted in the Geriatric and Rheumatology outpatient clinics at a tertiary University Hospital. Fifty elderly RA patients diagnosed according to the ACR criteria and 30 age-matched controls without inflammatory arthritis were included in the study. All patients underwent CGA including evaluation of Basic Activities of Daily Living (ADL), Instrumental ADL, Yesavage Depression Scale (YDS), Mini-Mental State Examination, handgrip strength and Mini-Nutritional Assessment-Short Form. Sleep quality was assessed by Pittsburg Sleep Quality Index (PSQI), disease activity with Disease Activity Score 28 (DAS28-CRP) and QoL with RA QoL questionnaire (RAQoL).

**Results:** The median age was 70 years (min-max: 65–86) and 62.5% was female. Age, gender and co-morbidities, such as hypertension, coronary artery disease, osteoporosis, urinary incontinence, depression and chronic obstructive pulmonary disease, and comprehensive geriatric assessment parameters were similar between two groups. Diabetes mellitus frequency was higher in the control group compared to RA patients (43.3% vs. 22.0%,  $p=0.044$ ). Median PSQI global score was higher in elderly patients with RA compared to controls [9 (min-max: 1–20) vs. 5 (min-max: 1–13),  $p=0.029$ ], indicating poorer sleep quality. In elderly patients with RA, DAS28-CRP score significantly correlated with PSQI global ( $r=0.514$ ,  $p<0.001$ ) and RAQoL scores ( $r=0.493$ ,  $p<0.001$ ). PSQI global score also significantly correlated with RAQoL score ( $r=0.689$ ,  $p<0.001$ ), number of medication ( $r=0.324$ ,  $p=0.022$ ), handgrip strength ( $r=-0.370$ ,  $p=0.017$ ) and YDS score ( $r=0.417$ ,  $p=0.005$ ).

**Conclusions:** Our results suggest that elderly patients with RA may have poorer sleep quality compared to elderly control patients. Disease activity of RA had adverse effects on both sleep quality and QoL. In daily practice, when evaluating an elderly RA patient, sleep quality should also be assessed. Further studies are needed to investigate if management of sleep disturbances improve quality of life in elderly patients with RA.

### THU0173 TRENDS IN HIP FRACTURE INCIDENCE IN RHEUMATOID ARTHRITIS: A NATIONAL OBSERVATIONAL COHORT STUDY

R. Mazucchelli<sup>1</sup>, E. Perez-Fernandez<sup>2</sup>, N. Crespi<sup>3</sup>, J. Quirós<sup>2</sup>, C. Macía Villa<sup>4</sup>, M. Espinosa<sup>5</sup>, J.L. Morell Hita<sup>6</sup>, M. Peña<sup>2</sup>, V. Villaverde<sup>7</sup>, C. Martínez-Prada<sup>8</sup>, C. Morado Quiroga<sup>8</sup>, C. Barbadillo<sup>5</sup>, M. Fernández-Prada<sup>9</sup>, H. Godoy<sup>5</sup>, M. Galindo<sup>10</sup>, A. García-Vadillo<sup>11</sup>, O. Guzón Illescas<sup>2</sup>, A. Herranz<sup>12</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>H. U. Fundación Alcorcón; <sup>3</sup>C.S. La Rivota; <sup>4</sup>H. U. Severo Ochoa; <sup>5</sup>H. U. Puerta de Hierro; <sup>6</sup>H. U. Ramón y Cajal; <sup>7</sup>H. U. Móstoles; <sup>8</sup>H. Clínico San Carlos, Madrid; <sup>9</sup>H. U. Guadalajara, Guadalajara; <sup>10</sup>H. U. 12 de Octubre; <sup>11</sup>H. La Princesa; <sup>12</sup>H. U. del Henares, Madrid, Spain

**Background:** During the last 20 years there have been significant changes in the treatment of patients with rheumatoid arthritis (RA) and in the prevention and treatment of osteoporosis. The potential impact of these strategies on important outcomes as the incidence of hip fracture in RA is unknown.

**Objectives:** To analyse the incidence and trend of hospital admissions for hip fracture in patients with RA, in Spain, during the period between 1999 and 2015.

**Methods:** This is a retrospective population based study. We analysed a national administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of patients with RA. Period: 1999 to 2015. The hip fracture cases were identified by the presence in primary and secondary diagnosis of ICD 9 codes. The population at risk was estimated through the population census of the

National Institute of Statistics, with an estimated prevalence of RA of 0.5%. The crude and adjusted rates of hip fracture were calculated. The trend was analysed using Generalised Linear Models (GLM) using the year variable as the analysis variable.

**Results:** Of a total of 338.343 admissions of patients with RA, 6.656 (2%) was due to hip fracture, 5.608 (84.2%) in women and 1.048 (15.7%) in men. The mean age was 77.54 (SD 9.6). Mean age increased linearly during the study period (from 75,3 years in 1999 to 79,9 in 2015). There was a total of 326 (4.9%) deaths during admission. The fracture age-adjusted rate during the study period was 243,66/100.000 RA-patients\*year (245,24 in women and 198,05 in men). The fracture age-adjusted rate increased from 150.11/100.000\*year in 1999, to 303.12 in 2015 (in both sex). In women from 134.71 in 1999 to 304.83 in 2015) and in men from 99.63 in 1999 to 268.5 in 2015). An annual increase in the fracture rate of 3.1% is estimated.

**Conclusions:** In Spain, during the period from 1999 to 2015, although the mean age has increased, the incidence of hip fracture has not been reduced. We estimate an annual increase of 3.1%.

### THU0174 SEXUAL FUNCTION OF WOMEN WITH RHEUMATOID ARTHRITIS IN COMPARISON WITH HEALTHY VOLUNTEERS

A. Fazaa, R. Ben Saad, K. ouennich, S. Miladi, S. Kassab, C. salma, K. Ben Abdelghani, A. laatar. Mongi slim Hospital, tunis, Tunisia

**Background:** Rheumatoid Arthritis (RA) is one of the first diseases where quality of life (QoL) measurements are considered as a therapeutic goal. Sexual health is an important part of a quality of life. Persons with RA often experience decreased sexual health, due to pain, fatigue and physical disability.

**Objectives:** To assess the prevalence of sexual dysfunction in married women with RA and to compare it with a control group.

**Methods:** We conducted a cross-sectional study including seventy one married women with RA (ACR/EULAR Criteria), having sexual activity and seventy one, healthy volunteers women matched for socio-demographic characteristics. Sexual function was assessed by a self-reported questionnaire the Index of Female Sexual Function (FSFI).

The comparison of qualitative variables was performed with the Chi square test and the comparison of qualitative variable and quantitative ones was performed with the Student's test. The significance level was set at 0.05.

**Results:** The prevalence of female sexual dysfunction in women with RA and in controls was 49% and 23,9% respectively. There was a significant difference in the total FSFI score between patients and controls (24±6,7 versus 27,05±5,34;  $p=0,002$ ). We found statistically significant differences between the two groups in dimensions of sexual function: desire ( $p=0,050$ ), arousal ( $p=0,038$ ) and satisfaction ( $p=0,024$ ). However, no significant differences were found for pain ( $p=0,757$ ), lubrication ( $p=0,069$ ) and orgasm ( $p=0,083$ ).

**Conclusions:** Our findings showed that RA adversely affects women's sexual function. The FSFI, easy and quick to use, could be proposed for the assessment of female sexual function to optimise the management of patients with RA.

**Objectives:** To assess insulin resistance (IR) in patients with rheumatoid arthritis (RA) and compare it with healthy controls and to analyse the association between the accumulated inflammatory burden in patients with RA and IR

**Methods:** **Design:** Nested case-control study. **Population:** consecutive RA-patients (ACR/EULAR 2010 criteria), >16 years, selected from a prospective inception cohort (diagnosis of RA between 2007 and 2011). Patients with Diabetes Mellitus (according to ADA 2010 criteria) were excluded. **Controls:** sex- age and BMI -matched controls were collected from a health centre in our hospital area. **Protocol:** Cases and controls were evaluated by a rheumatologist. Clinical data of disease activity (RA patients), analytical values and oral glucose tolerance test (OGTT) were determined. **Main outcome:** IR measured by the homeostasis model for insulin resistance (HOMA-IR) (IR >2.29µU\*mmol/ml). **Secondary outcome:** RI measured by quantitative insulin sensitivity check index (QUICKI) (<0.337µU \*mmol/ml) and by the homeostatic model assessment of β-cell function (HOMA β). **Variables:** Demographic, clinical-analytical variables, Disease Activity Score of 28 joints (DAS28-ESR), Health Assessment Questionnaire (HAQ), BMI (OMS classification) and glucose and insulin before and after OGTT values. **Statistical analysis:** Descriptive and paired T-test or Chi-square test followed by Multivariate linear regression in RA patients (Dependent variable: HOMA-IR)

**Results:** One hundred and fifty six subjects were studied, 4 of them were excluded after OGTT (2 diabetics and their respective controls). Finally, 1522 subjects were included; 89 RA and 63 controls. The mean age of patients with RA was 56.6 (10.9%) years. Most of them were women (76.4%), with seropositive (FR 83.1% y ACPA 79.1%) and erosive (62%) RA. The mean duration of the disease was 86 (±23) months and mean DAS28 index at the cut-off date of 2.8 (±1.1). Differences between clinical characteristics and in relation to IR between cases and controls are shown in table 1. No significant differences in the proportion of subject with IR in cases and controls were observed and 28.7% of patients with RA had IR. Of the 25 patients with IR, 75% had an average of DAS28 ≥3.2. In multivariate analysis, the independent variables associated with IR in patients with RA were: Obesity (β=1.7494 [p=0.003]), diagnosis delay (β=0.034 [p=0.003]) and disease activity (β=1.045 [p=0.058]). This model would explain 23% of the variability of the IR (R<sup>2</sup>=0.23).

VARIABLE	CASES n=89	CONTROLS n=63	P- VALUE
Age, years; mean(±SD)	56.6 (10.9)	56.1 (11.0)	0.756
Sex, women; n(%)	68(76.4)	52(82.5)	0.361
<b>Comorbidities</b>			
BMI > 30 (obesity) n(%)	30(34.1)	17(27.4)	0.386
BMI, mean(±SD)	28.2 (5.0)	27.2 (5.0)	0.205
Dyslipemia, n(%)	20 (22.7)	11 (18.6)	0.552
Hypertension, n(%)	23 (25.5)	16(25.8)	0.996
<b>Insulin Resistance Indexes</b>			
HOMA-IR>2.25, n(%)	25 (28.7)	17 (27.9)	0.908
HOMA-IR, mean(±SD)	25 (28.7)	17 (27.9)	0.908
HOMA-β, mean(±SD)	2.24 (2.6)	2.05 (1.5)	0.578
QUICKI, mean(±SD)	46.7 (32.3)	45.1 (32.1)	0.848

**Conclusions:** We did not find an increased IR in patients with RA compared with healthy controls, which may be due to adequate treatment and good control of inflammatory activity in the most of patients with RA. Obesity, diagnosis delay and inflammatory activity (measured by mean DAS28 index since the onset of the disease), were the predictors of IR in patients with RA in our study

THU0176

### THE EFFECT OF METHOTREXATE ON GASTROINTESTINAL SYMPTOMS IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Asai<sup>1</sup>, K. Nagai<sup>2</sup>, T. Kojima<sup>1</sup>, N. Takahashi<sup>1</sup>, N. Ishiguro<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Nagoya University Graduate School of Medicine; <sup>2</sup>Department of Nursing, Nagoya University Hospital, Nagoya, Japan

**Background:** Methotrexate (MTX) can cause gastrointestinal (GI) symptom in patients with rheumatoid arthritis (RA); however, it is uncertain how much dose of MTX affects GI symptoms. RA patients may receive various drugs besides MTX. NSAIDs are known to be a risk factor for GI disorders, and folic acid has been reported to reduce GI side effects of MTX. Moreover, obesity is a risk factor for reflux. Therefore, it is necessary to evaluate comprehensively the causes of GI symptoms in RA patients.

**Objectives:** To compare prevalence of GI symptoms for the patients with RA treated with low and high dose MTX, and investigate factors associated with GI symptoms.

**Methods:** A total of 529 patients with RA treated with MTX were included in this cross-sectional study. GI Symptom Rating Scale (GSRS) was used to evaluate GI symptoms. The GSRS has five subscales (Reflux, Abdominal pain, Indigestion, Diarrhoea and Constipation) and a seven-point graded Likert-type scale. Symptomatic was defined as a score of ≥2 on GSRS subscale. Patients were divided into two categories according to their MTX dosage: low dose (≤8 mg/week) and high dose (>8 mg/week). Prevalence was compared by two groups with the chi-square test, and factors associated with GI symptoms were assessed with multivariate logistic regression analysis.

**Results:** Patient characteristics are shown in table 1. Of all patients, 313 (59%) received low dose MTX at a mean (SD) dose of 6.2 (1.7) mg/week, whereas 216 (41%) received high dose MTX at a mean (SD) dose of 11.8 (1.8) mg/week. Relative to patients receiving low dose MTX, those receiving high dose MTX had a higher prevalence of reflux (24% vs 32%, p=0.047) and abdominal pain (18% vs 28%, p=0.008) (figure 1). Multivariate analysis revealed that higher dose MTX was independently associated reflux (OR: 1.62, 95% CI: 1.07–2.43) and abdominal pain (OR: 1.70, 95% CI: 1.12–2.59) (table 2). The odds ratio of reflux or abdominal pain in patients receiving high dose MTX was similar to that in patient receiving NSAIDs.

**Abstract THU0176 – Table 1.** Demographic and clinical characteristics of patients

	MTX≤8 mg/w (n=313)	MTX>8 mg/w (n=216)	P value
Age, years	64±12	60±15	<0.001
Gender, female, n (%)	258 (82)	170 (79)	0.312

#### THU0177 CAN SIMPLE EDUCATIONAL FLASHCARDS CHANGE ATTITUDES TO VACCINATION IN AN UNDER-VACCINATED RHEUMATOID ARTHRITIS COHORT?

S. Raghunath<sup>1,2</sup>, T. Kovitwanichkanont<sup>1,3</sup>, D. Wang<sup>2</sup>, N. Walpole<sup>2</sup>, L. Kyi<sup>1</sup>, S. Pignataro<sup>1</sup>, S. Morton<sup>1</sup>, E. Thompson<sup>2</sup>, M. Leech<sup>1,2</sup>. <sup>1</sup>Monash Health; <sup>2</sup>Monash University, Melbourne; <sup>3</sup>University of Sydney, Sydney, Australia

**Background:** There is increased infection risk in RA which relates to immune system dysregulation, comorbidities and immunosuppression.<sup>1,2</sup> Therefore, there is a need to improve currently suboptimal vaccination rates reported globally.<sup>3</sup>

**Objectives:** To re-examine vaccination rates and to determine if educational flashcards with messages targeted to patient perceptions can change attitudes towards vaccination in a tertiary hospital RA clinic cohort.

**Methods:** Vaccination status and attitudes were examined in 126 consecutive rheumatoid arthritis clinic patients (data collection ongoing). Patients were then shown two simple educational flashcards and any shift in attitude to vaccination was recorded. Insights gleaned from a 2016 study on attitudes to vaccination in the same cohort were used to design the flashcards based on unvaccinated patients' main concerns.<sup>4</sup>

**Results:** The RA cohort was representative of a typical RA population. 67% of patients were female with a mean age of 57 years (range 18 to 88 years). 40% of patients were on biologic medication and 34% were on prednisolone. 13% of patients were previously hospitalised for influenza or pneumonia and 15% had a close contact hospitalised for these infections. 37% of patients had not received the influenza vaccine. In patients over 65 years old, 51% had not received the pneumococcal vaccine within the last 5 years, and of those, 80% had never been vaccinated against pneumococcal. Reasons reported for not being vaccinated included "I forgot", "I worry about the side effects of vaccine", "I don't think I need the vaccine as I don't get the flu", and "I had the vaccine and it made me sick". 33% of patients were not aware of the hospital's free vaccination service, and of those that were aware of this service 13% cited this as their main reason for getting the vaccine.

After reading the education flashcards 49% of currently unvaccinated patients reported "I feel more informed and am more likely to get the vaccine next year". Rates of vaccination, infection and attitudes both pre and post flashcards did not differ between patients on biologics and not on biologics (all p-values > 0.05).

##### Reasons reported for not vaccinating (in order of frequency)

1	I forgot
2	I am worried about the side effects of the vaccine.
3	I don't think I need the vaccine as I don't get the flu.
4	I had the vaccine and it made me sick.
5	I don't think the vaccine will work.,
6	I have received it before so I don't need it or want it this year.
7	I am afraid of needles

#### Vaccine Education Flashcards

**Conclusions:** This at-risk RA cohort continues to be under-vaccinated in studies over the past two years. Simple flashcards showed potential to change attitudes in unvaccinated patients who were previously comfortable to express resistance. Insights from this study could be used to refine and reiterate this educational intervention for implementation in a larger cohort to measure impact on vaccination rates in subsequent years.

#### THU0178 CLINICAL SIGNIFICANCE OF PERIODONTITIS IN RHEUMATOID ARTHRITIS PATIENTS: ASSOCIATION WITH DISEASE ACTIVITY, FUNCTIONAL STATUS AND RADIOLOGRAPHIC SCORE

I.A. Gheita<sup>1</sup>, H.M. Fathi<sup>2</sup>, N. Khairy<sup>3</sup>, W.A. El-Battawy<sup>4</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Faculty of Medicine, Kasr Al-Ainy School of Medicine, Cairo University, Cairo; <sup>2</sup>Rheumatology, Faculty of Medicine, Fayoum University, Fayoum; <sup>3</sup>Rheumatology, Faculty of Medicine, Cairo University; <sup>4</sup>Oral Medicine and Periodontology, Faculty of Oral and Dental Medicine, Cairo University, Cairo, Egypt

##### Background:

**Objectives:** To evaluate frequency of periodontitis (PD) in rheumatoid arthritis (RA) patients and relate it with clinical characteristics, disease activity, functional status, anti-cyclic citrullinated peptide (anti-CCP) and radiographic scores.

**Methods:** The study included 60 RA patients and 30 controls. Clinical Disease activity index (CDAI), Modified Health Assessment Questionnaire (MHAQ), visual analogue scale of pain and Scott's modification to Larsen scoring method were assessed. Rheumatoid factor (RF) positivity and antiCCP titer were measured. Periodontal examination was performed and relevant indices calculated

**Results:** The mean age of the patients was 49.1±13 years and they were 52 females and 8 males. PD was present in 71.7% of RA patients versus 46.7% in control (p=0.02). PD was predominantly generalised (p=0.004) and moderate-severe degree (p=0.01). Age (p=0.007), disease duration (p<0.0001), morning stiffness (p=0.01), CDAI (p<0.0001), MHAQ (p=0.02), CRP (p=0.02), anti-CCP titer (p=0.01) and methotrexate treatment (p=0.005) were significantly higher in RA-PD versus RA. However, gender, smoking, oral hygiene, erythrocyte sedimentation rate, RF, anti-CCP positivity and radiographic scoring were insignificantly different. PD positivity was 96.3%, predominant generalised in 92.6%, moderate (40.7%) and severe degree (37%) in early RA versus (51.5%, 24.2%, 24.2%, 12.1% respectively) in late RA patients. All PD indices were higher in early patients (p≤0.05) while teeth loss (p=0.03) was higher in late cases. CDAI, VAS and ACPA titer all significantly correlated with PD indices (p<0.05).

**Conclusions:** Periodontitis is frequent in RA patients' especially in early cases and is remarkably associated to disease activity and reduced functional status.

**THU0179** **MIR-382-5P TARGETING IL-33 GENE AS BIOMARKER TO PREDICT SUBCLINICAL ATHEROSCLEROSIS PROGRESSION IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS**

T.H. Cheng<sup>1</sup>, Q. Shang<sup>1</sup>, E. K. M. Li<sup>1</sup>, M. Li<sup>1</sup>, W.Y. Mak<sup>1</sup>, K.Y. Kwok<sup>2</sup>, I.C.W. Yim<sup>3</sup>, P.C.H. Wong<sup>4</sup>, V.W.N. Lao<sup>4</sup>, S.H.T. Pang<sup>5</sup>, E.W.L. Kun<sup>5</sup>, L.S. Tam<sup>1</sup>. <sup>1</sup>Department of Medicine and Therapeutics, The Chinese University of Hong Kong; <sup>2</sup>Department of Medicine, Queen Elizabeth Hospital; <sup>3</sup>Department of Medicine, Tseung Kwan O Hospital; <sup>4</sup>Department of Medicine, Kwong Wah Hospital; <sup>5</sup>Department of Medicine, Tai Po Hospital, Hong Kong, Hong Kong

**Background:** Patients with rheumatoid arthritis(RA) had increased risk of cardiovascular disease(CVD). IL-33, a member of the IL-1 family, plays an important role in the pathogenesis of RA and development of CVD. Yet, plasma IL-33 level was not detectable in most subjects which limits its utility as a biomarker for CVD. Meanwhile, microRNAs(miRNAs) targeting IL-33 gene expression might play a role.

**Objectives:** To ascertain if dysregulated miRNAs targeting *IL-33* gene expression in early RA patients were associated with subclinical atherosclerosis progression

**Methods:** 73 ERA patients were recruited for this 1 year cohort study. Potential miRNAs binding to *IL-33* gene were predicted by miRanda. 10 miRNAs with the highest possibility of targeting functional sites of *IL-33* gene were quantified in cell free plasma samples. cel-miR-39 was used as spike-in control. Carotid plaque (CP) was identified using high-resolution ultrasound annually. Plaque progression (PP) was defined as an increased region harbouring plaque.

**Results:** CPs were identified in 25 (34%) and 31 (43%) subjects at baseline and month 12 respectively. 16 (22%) subject had plaque progression(PP +group). At baseline, subjects in PP +group were older, with lower pain and patient global scores, a higher proportion on conventional synthetic DMARDs, and higher cardiovascular risk compared to patients without plaque progression (PP-) (table 1). Plasma level of miR-382-5 p in the PP +group was significantly higher than that in the PP- group after adjusting for baseline difference (table 1). Using multivariate logistic regression, miRNA-382-5 p was an independent predictor for plaque progression(OR:2.534, 95%CI=1.079-5.952, p=0.033) after adjustment of baseline characteristics. [AUC:0.66,95% CI:0.51-0.81,p=0.048]. Other independent predictor included higher baseline Framingham risk score, diastolic BP and lower pain score.

**Abstract THU0179 – Table 1.** Characteristics of patients with and without plaque progression

	No plaque progression (n=57)	Plaque progression (n=16)	p	p*
Age	50±12	56±7	0.011

**THU0180** **SHOULD WE INCLUDE ULTRASOUND IN THE 1987 ACR AND 2010 ACR/EULAR CLASSIFICATION CRITERIA FOR RHEUMATOID ARTHRITIS?**

W. Hamdi<sup>1</sup>, M. Sellami<sup>1</sup>, H. Riahi<sup>2</sup>, K. Maatallah<sup>1</sup>, D. Kaffel<sup>1</sup>, M. Chelli-Bouaziz<sup>2</sup>, M. F. Ladeb<sup>2</sup>, M.M. Kchir<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Kassab Orthopedics Institute, Manouba, Tunisia

**Background:** Ultrasound imaging (US) is actually considered as a crucial element of the diagnostic process in rheumatic diseases and could be the method of choice in imaging peripheral synovitis, typical feature during rheumatoid arthritis (RA). The 2010 American College of Rheumatology/European League Against Rheumatism (ACR/EULAR) classification criteria focused on early-stage RA, and were designed to remedy the deficiencies in the 1987 ACR criteria, but still lacking sensitivity.

**Objectives:** We undertook this study to investigate whether including the ultrasonographic data in calculating the 1987 ACR and 2010 ACR/EULAR criteria is useful in diagnosing RA.

**Methods:** We performed a cross-sectional study of one hundred patients with inflammatory joint pain or synovitis for more than 6 weeks and less than 2 years.

An experienced radiologist performed the MSUS scan of 22 joints (2 wrists, 10 metacarpophalangeal joints MCP and 10 proximal interphalangeal joints PIP) unaware of clinical and biological findings. After US assessment, patients were classified as having RA according to ACR/ EULAR 2010 criteria using clinical, biologic and radiographic data (clinical ACR87 or clinical ACR/EULAR2010). Then we calculate those criteria using US data: US-ACR87 including erosion detected in US as a criterion and US-ACR/EULAR2010 including the number of synovitis detected in US as a criterion.

**Results:** One hundred RA patients were included (77 women and 23 men) with a mean age of 51.8 years. <sup>16-77</sup> The mean disease duration was 10.96. <sup>24</sup> Rheumatoid factor and antibodies against cyclic citrullinated peptides were positive in 53% and 25% cases respectively. Sixty-five patients (65%) accomplished the clinical ACR87 criteria and 55 patients (55%) fulfilled the clinical ACR/EULAR2010 criteria for the diagnosis of RA. Using US data eighty patients (80%) accomplished the US-ACR87 criteria and 68 patients (68%) fulfilled the US-ACR/EULAR2010 criteria for the diagnosis of RA. A good correlation was found between clinical and US ACR/EULAR criteria (k=0.684, p=0.000). US score showed a very good sensitivity of 100%, specificity of 67.5%, positive predictive value of 76.9% and negative predictive value of 100% compared to clinical score. In table 1 we summarise correlation between clinical and US ACR/EULAR criteria.

**Abstract THU0180 – Table 1.** Correlation between clinical and US ACR/EULAR criteria

	Clinical ACR/EULAR2010			
	Yes	No	Total	
US-ACR/EULAR2010	Yes	50	18	68
	No	5	27	32
	Total	55	45	100

**Conclusions:** Our study showed that including US data in the classification criteria of RA, will improve diagnostic impact of those criteria during RA management.

**THU0181** **GLUCOCORTICOID USE IS AN INDEPENDENT RISK FACTOR FOR SARCOPENIA IN PATIENTS WITH RHEUMATOID ARTHRITIS – FROM THE CHIKARA STUDY -**

Y. Yamada<sup>1</sup>, M. Tada<sup>2</sup>, K. Mandai<sup>3</sup>, N. Hidaka<sup>2</sup>, K. Inui<sup>1</sup>, H. Nakamura<sup>1</sup>.

<sup>1</sup>Department of orthopedics surgery, OSAKA CITY UNIVERSITY; <sup>2</sup>Department of orthopedics surgery, Osaka City General Hospital; <sup>3</sup>Department of orthopedics surgery, Osaka Social Care Center Hospital, Osaka City, Japan

**Background:** Patients with rheumatoid arthritis (RA) are at higher risk of sarcopenia due to joint dysfunction and chronic inflammation. The prospective observational CHIKARA study (Correlation research of sarcopenia, skeletal muscle and disease activity in rheumatoid arthritis; registration number UMIN000023744) was

started in 2016 to clarify the correlation between RA disease activity and sarcopenia.

**Objectives:** We investigated risk factors for developing sarcopenia in patients with RA.

**Methods:** We analysed baseline and 1 year data from the CHIKARA study. The body composition (body weight, muscle mass, fat mass, predicted bone mass, etc.) of 100 patients (78% women; mean age, 68 years) enrolled in this study was examined using a body composition analyzer (MC-780A; TANITA, Tokyo, Japan). Grip strength and walking speed were also measured. Laboratory data, disease activity, Health Assessment Questionnaire (HAQ) and treatment were investigated. Sarcopenia was diagnosed using the criteria of the Asia Working Group on Sarcopenia. Patients with sarcopenia onset at 1 year were detected and their characteristics were analysed. Predictors for development of sarcopenia were also investigated by uni- and multivariate analyses.

**Results:** Nine patients developed sarcopenia during 1 year. Glucocorticoid (GC) use was significantly more frequent among patients with sarcopenia onset (55.6%) than among those without sarcopenia onset (22.1%,  $p=0.029$ ). Univariate analysis revealed that GC dosage ( $r=0.217$ ,  $p=0.035$ ), body fat mass at baseline ( $r=-0.211$ ,  $p=0.040$ ) and change in CRP at 1 year ( $r=-0.205$ ,  $p=0.046$ ) were significantly associated with sarcopenia onset. GC use  $>2$  mg/day (Odds ratio (OR) 8.0, 95% confidence interval (CI) 1.2–54.8,  $p=0.034$ ) and body fat mass (OR 0.78, 95% CI 0.61–0.98,  $p=0.037$ ) were detected as significant factors by multivariate analysis. (table 1)

**Abstract THU0181 – Table 1.** Risk factors for developing sarcopenia in patients with rheumatoid arthritis

		Univariate		Multivariate		
		R value	p value	Odds ratio	95% CI	P value
GC	Dosage $>2$ mg/day	0.217	0.035	8.0	1.2–54.8	0.034
		-	-	-	-	-
Body fat mass		-0.211	0.040	0.78	0.61–0.98	0.037
		-	-	-	-	-
$\Delta$ CRP		-0.205	0.046	-	-	-

GC: glucocorticoids, CI: confidence interval,  $\Delta$ : change from baseline to 1 year

**Conclusions:** RA patients using GC at  $>2$  mg/day or with low fat mass were more likely to develop sarcopenia.

## Rheumatoid arthritis – biological DMARDs

THU0182

### A COMPARATIVE CLINICAL STUDY OF PF-06410293, A CANDIDATE ADALIMUMAB BIOSIMILAR, AND REFERENCE ADALIMUMAB FOR THE TREATMENT OF ACTIVE RHEUMATOID ARTHRITIS

R. Alten<sup>1</sup>, R.M. Fleischmann<sup>2</sup>, M. Pilecky<sup>3</sup>, S.Y. Hua<sup>4</sup>, C. Cronenberger<sup>5</sup>, A. E. Bock<sup>6</sup>, K.L. Sewell<sup>6</sup>. <sup>1</sup>Schlosspark-Klinik, University Medicine, Berlin, Germany; <sup>2</sup>University of Texas, Southwestern Medical Center, Metroplex Clinical Research Center, Dallas, USA; <sup>3</sup>Lithuanian University of Health Sciences, Kaunas, Lithuania; <sup>4</sup>Pfizer Inc, San Diego; <sup>5</sup>Pfizer Inc, Collegeville; <sup>6</sup>Pfizer Inc, Cambridge, USA

**Background:** To confirm the efficacy, safety and immunogenicity of biosimilars, a comparative clinical study is typically required.

**Objectives:** This double-blind, randomised, 78 week (wk) study compared the efficacy, safety and immunogenicity of PF-06410293, a candidate adalimumab biosimilar, with reference adalimumab sourced from the EU (ADA-EU), in biologic-naïve patients (pts) with active rheumatoid arthritis (RA) despite methotrexate (MTX; 10–25 mg/wk).

**Methods:** Pts with active RA ( $n=597$ ) were stratified by region and randomised (1:1) to PF-06410293 or ADA-EU (40 mg subcutaneous injection every 2 wks), with continued MTX. The primary endpoint was American College of Rheumatology 20% improvement (ACR20) at Wk 12. Therapeutic equivalence was concluded if the 2-sided 95% confidence interval (CI) for the difference in Wk 12 ACR20 between arms was within the symmetric equivalence margin of  $\pm 14\%$ . Additionally, a 2-sided 90% CI was requested by the US Food and Drug Administration, using the asymmetric equivalence margin of  $-12\%$  to  $+15\%$ . Secondary efficacy endpoints to Wk 26 included ACR20/50/70, change from baseline Disease Activity Score in 28 joints [DAS28(CRP)], European League Against Rheumatism (EULAR) response, achievement of DAS28(CRP)  $<2.6$ , and ACR/EULAR remission. QuantiFERON-TB testing was performed at Screening and Wk 26.

**Results:** Pts (78.7% female, 81.6% seropositive) had a mean age of 52.5 years, and mean RA duration of 6.8 years. Mean baseline DAS28(CRP) was 5.9 (PF-06410293) and 6.1 (ADA-EU). The observed Wk 12 ACR20 was 68.7% (PF-06410293) and 72.7% (ADA-EU) in the intent-to-treat population (figure 1). Using non-responder imputation ( $n=19$ ; 3.2%), the treatment difference in Wk 12 ACR20 was  $-2.98\%$ , and the corresponding CIs [95% CI ( $-10.38\%$ ,  $+4.44\%$ ); 90% CI ( $-9.25\%$ ,  $+3.28\%$ )] were entirely contained within both equivalence margins (symmetric and asymmetric). The ACR20 difference ranged from  $-3.98\%$  to  $+5.50\%$  (Wks 2–26). Mean DAS28(CRP) change from baseline at Wk 26 was  $-2.7$  and  $-2.8$  in the PF-06410293 and ADA-EU arms, respectively. ACR50/70, EULAR response, DAS28(CRP)  $<2.6$  and ACR/EULAR remission were similar between arms at each visit. Incidence of treatment-emergent adverse events (AEs) was 48.1% vs 47.8%, serious AEs were 4.0% vs 4.3% (with a fatal myocardial infarction in the ADA-EU arm) and serious infections were 0.7% vs 1.3% for PF-06410293 and ADA-EU, respectively. Injection site reactions occurred at 1.7% vs 2.0%, hypersensitivity events at 4.4% vs 8.4%, pneumonia at 0.7% vs 2.0%, and latent tuberculosis (based on specialist consultation for Wk 26 QuantiFERON-TB+) at 1.7% vs 0.3% for PF-06410293 and ADA-EU, respectively. Post-dose anti-drug antibody rates to Wk 26 were 44.4% (PF-06410293) and 50.5% (ADA-EU).

ACR=American College of Rheumatology; ITT=Intent-to-treat.

Figure 1. ACR20 response rates (ITT population)

**Conclusions:** The efficacy, safety and immunogenicity of PF-06410293 and ADA-EU were similar up to Wk 26 in pts with active RA on MTX. At Wk 26, pts on ADA-EU were blindly re-randomised (1:1) to continue ADA-EU or transition to PF-06410293 for ongoing treatment in the study.

THU0183

### LESS PAIN OVER 2 YEARS WITH BIOLOGICAL COMPARED TO CONVENTIONAL COMBINATION THERAPY IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE RANDOMISED CONTROLLED SWEFOT TRIAL

T. Olofsson<sup>1</sup>, J.K. Wallman<sup>1</sup>, A. Jöud<sup>2</sup>, M.E. Schelin<sup>3</sup>, S. Ernestam<sup>4,5</sup>, R. van Vollenhoven<sup>5</sup>, S. Saevarsdottir<sup>5</sup>, J. Lampa<sup>5</sup>. <sup>1</sup>Rheumatology, Department of Clinical Sciences Lund; <sup>2</sup>Occupational and Environmental Medicine; <sup>3</sup>Oncology, Department of Clinical Sciences Lund, Lund University, Lund; <sup>4</sup>Academic Specialist Centre, Stockholm Health Services; <sup>5</sup>Rheumatology Unit, Department of Medicine, Karolinska Institute, Stockholm, Sweden

**Background:** Pain is a common and debilitating feature of rheumatoid arthritis (RA) and a level >40 mm on a Visual Analogue Scale (VAS) of pain (scale 0–100 mm) has been suggested as a measure of unacceptable pain.<sup>1</sup> While many studies have focused on the effect on inflammation of different pharmacological options, few earlier reports have directly compared pain outcomes between common treatment strategies.

**Objectives:** The aim of this study was to investigate pain development and unacceptable pain over 2 years after start of biological as compared to conventional combination therapy in early RA patients.

**Methods:** The multicentre SWEFOT (SWEdish FarmacOTherapy) trial was designed as a randomised, active-controlled, open-label study, enrolling new-onset (<1 year) patients fulfilling 1987 American College of Rheumatology criteria for RA Oct 2002 to Dec 2005. After a 3 month run-in period on methotrexate (MTX), patients who did not reach low disease activity (Disease Activity Score using 28-joint count; DAS28 ≤3.2) were randomised to addition of infliximab (IFX) or sulfasalazine +hydroxychloroquine (SSZ +HCQ). Results for disease activity, radiographic data and health-related quality-of-life have been published earlier.<sup>2,3</sup> Here, unacceptable pain (VAS pain >40 mm) at 2 years follow-up and area under the curve (AUC) for VAS pain were used as outcome measures. We used intention-to-treat with last observation carried forward in case of protocol breach as study approach. Statistical analyses were performed by logistic regression for unacceptable pain and analysis of covariance for AUC for VAS pain, adjusting for age, sex, and VAS pain at randomisation.

**Results:** 487 RA patients were enrolled of whom 258 (who did not respond sufficiently to MTX) were randomly allocated to either addition of IFX (n=128) or SSZ +HCQ (n=130). Baseline characteristics were similar between the two groups. Of patients assigned to IFX, 32% had unacceptable pain at 2 years follow-up (21 months after randomisation), while the same figure for SSZ+HCQ (n=130) was 45% (adjusted odds ratio 0.41 [95%CI 0.23–0.73]; p=0.003). Serial VAS pain measurements are displayed in figure 1. An AUC analysis for mean VAS pain levels from randomisation to 2 years follow-up confirmed significantly lower levels for patients randomised to IFX compared to SSZ+HCQ (p=0.01).

**Conclusions:** Despite early active treatment, a large share of new-onset RA patients showed unacceptable pain after 2 years. Interestingly, both the fraction of patients with unacceptable pain and assessment of pain over time were substantially lower for patients randomised to addition of IFX compared to SSZ+HCQ, contrasting to earlier SWEFOT reports where significant between-group differences at 2 years follow-up for disease activity and health-related quality-of-life were not seen.<sup>2,3</sup> This suggests a better effect on long term pain for the biological therapy, which could be taken into account when choosing treatment strategy in patients responding insufficiently to MTX.

### IMPACT OF IMMUNOGENICITY ON CLINICAL EFFICACY AND ADMINISTRATION RELATED REACTION IN TNF INHIBITORS: A POOLED-ANALYSIS FROM THREE BIOSIMILAR STUDIES IN PATIENTS WITH RHEUMATOID ARTHRITIS

P. Emery<sup>1</sup>, M. Weinblatt<sup>2</sup>, J.S. Smolen<sup>3</sup>, E. Keystone<sup>4</sup>, M. Genovese<sup>5</sup>, J. Vencovsky<sup>6</sup>, J. Kay<sup>7</sup>, E. Hong<sup>8</sup>, Y. Baek<sup>8</sup>, J. Ghil<sup>8</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, UK; <sup>2</sup>Brigham and Women's Hospital, Boston, USA; <sup>3</sup>Medical University of Vienna, Vienna, Austria; <sup>4</sup>Mount Sinai Hospital, Toronto, Canada; <sup>5</sup>Stanford University Medical Center, Stanford, USA; <sup>6</sup>Institute of Rheumatology, Prague, Czech Republic; <sup>7</sup>University of Massachusetts Medical School, Worcester, USA; <sup>8</sup>Samsung Bioepis Co., Ltd., Incheon, Korea, Republic of Ireland

**Background:** SB4, SB2, and SB5 are biosimilars of reference etanercept, infliximab, and adalimumab, respectively. The phase III randomised, double-blind clinical studies comparing the efficacy and safety of each biosimilar with its reference product had similar study designs, patient demographics, and the same primary endpoint of the ACR20 response rate. In each study immunogenicity was measured using a validated ECL assay tagged with the biosimilar.

**Objectives:** To assess the immunogenicity of three TNFi and examine the potential impact of anti-drug antibodies (ADAb) on efficacy and injection site reactions (ISR) or infusion related reactions (IRR) by a pooled analysis of three biosimilar studies.<sup>1–3</sup> Data to the time of the primary endpoint for each study (week 24 for etanercept and adalimumab studies and week 30 for infliximab study) are presented.

**Methods:** Data from patients who had immunogenicity results from each phase III study were pooled. Efficacy (ACR responses, clinical response [defined as good or moderate EULAR response], change in disease activity [DAS28, SDAI, CDAI]) and ISR/IRR were evaluated in relation to the presence of ADAb (at least one ADAb positive result up to when the primary endpoint was measured).

**Results:** The analysis included 1710 patients and the incidence of ADAb by treatment group is presented in the table 1.

Across treatment groups, efficacy was greater in patients without ADAb compared to those with ADAb. In all treatments combined, the ACR20 response rate was lower in the presence of ADAb (OR 2.06, 95% CI: 1.63–2.60, p<0.0001) (figure 1) and the mean improvement in DAS28 was significantly greater in patients without ADAb (estimated difference: 0.383, 95% CI: 0.24–0.52, p<0.0001). The ADAb effect on reducing ACR20 response rates as well as other efficacy parameters was similarly observed in other treatment groups.

In all treatments combined, the presence of ADAb was associated with increased ISR/IRR (OR 1.73, 95% CI: 1.02–2.96, p=0.043), predominantly with the infliximab combined (OR 2.67, 95% CI: 1.04–6.89, p=0.041) rather than the etanercept combined (OR 1.72, 95% CI: 0.38–7.77, p=0.478) and adalimumab combined (OR 1.00, 95% CI: 0.35–2.88, p=0.998).

Abstract THU0184 – Table 1. Incidence of Anti-drug Antibody (n/n)

Treatment	SB4	ETN	SB2	INF	SB5	ADA
ADAb	2/299	39/297	158/287	145/292	88/266	86/269
Incidence	(0.7%)	(13.1%)	(55.1%)	(49.7%)	(33.1%)	(32.0%)
Treatment	SB4 +ETN	SB2+INF	SB5 +ADA	Biosimilars combined	RP combined	All treatments combined
ADAb	41/596	303/579	174/535	248/852	270/858	518/1710
Incidence	(6.9%)	(52.3%)	(32.5%)	(29.1%)	(31.5%)	(30.3%)

ADA, adalimumab reference product; ADAb, anti-drug antibody; ETN, etanercept reference product; INF, infliximab reference product; RP: reference product

Abstract THU0184 – Figure 1. Effect of Anti-drug Antibody on ACR20 Response Rates

**Conclusions:** In a pooled analysis, the development of ADABs to TNFi is associated with reduced clinical efficacy and increased incidence of ISR/IRR in patients with RA.

**THU0185 THE VALUE OF ADALIMUMAB TROUGH LEVELS AND CLINICAL ASSESSMENTS IN PREDICTING CLINICAL RESPONSE IN PATIENTS WITH ESTABLISHED RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO METHOTREXATE**

J. Smolen<sup>1</sup>, N. Mostafa<sup>2</sup>, X. Huang<sup>2</sup>, P. Noertersheuser<sup>3</sup>, B. Klueder<sup>3</sup>, K. Chen<sup>2</sup>, J. Kalabic<sup>3</sup>, I. Sainsbury<sup>2</sup>, R. Oerlemans<sup>4</sup>, S. Florentinus<sup>4</sup>, G. Burmester<sup>5</sup>. <sup>1</sup>Medical University of Vienna, Vienna, Austria; <sup>2</sup>AbbVie Inc., North Chicago, USA; <sup>3</sup>AbbVie GmbH and Co. KG, Ludwigshafen, Germany; <sup>4</sup>AbbVie B.V., Hoofddorp, Netherlands; <sup>5</sup>Charité – Universitätsmedizin, Berlin, Germany

**Background:** Low trough levels of the tumour necrosis factor inhibitor, adalimumab (ADL), and anti-ADL antibodies (AAA) were reported to be correlated with lack of response at later time points in patients (pts) with rheumatoid arthritis (RA).<sup>1</sup>

**Objectives:** To assess the ability of ADL trough levels and clinical assessments at Week 12 to predict clinical remission (REM) after 24 weeks (wks) of treatment with ADL ±methotrexate (MTX) in established RA pts.

**Methods:** Data from MTX inadequate responders (MTX-IR) pts with established RA with available measurement of ADL trough levels and clinical assessments at Wks 12 and 24 from several clinical trials were pooled: for pts who received ADL +MTX combination therapy from DE009, DE019, M10–261 and M13–390; for pts who received ADL monotherapy from DE011, M10–261 and M13–390. Efficacy endpoints at Wk 24 were DAS28-CRP<2.6 and DAS28-CRP low disease activity (LDA,<3.2), remission (REM) and LDA by simplified disease activity index (SDAI)≤3.3 and≤11 respectively; REM and LDA by clinical disease activity index (CDAI)≤2.8 and≤10 respectively). Each of the pooled datasets was randomly and equally split into training and testing sets. Predictive modelling was performed on

the training set, and the best-performing model was selected and validated in the testing set. The performance of the final model was reported based on the testing set.

**Results:** Based on the cutoffs selected by the predictive model, ADL concentrations at Wk 12 were only slightly predictive for Wk 24 clinical assessment in the ADL monotherapy group, but not in the ADL+MTX group (table 1). However, based on achievement of the specified CDAI, SDAI or DAS28-CRP score at Wk 12 (selected by the model), pts were correctly predicted to reach Wk 24 REM or LDA with an accuracy of 80%–90% and area under the receiver operating characteristic curve (AUC) of 75%–90% (table 2). As an example, pts on ADL monotherapy with DAS28 <3.3 at Wk 12 had 60% and 70% chance of reaching Wk 24 DAS28-CRP<2.6 and LDA respectively, whereas pts with DAS28 ≥3.3 had 0% and 7% chance of achieving Wk 24 DAS28-CRP<2.6 and LDA, respectively (table 1). Pts on ADL+MTX with Wk 12 SDAI<12.5 had a 25% and 77% chance of achieving SDAI REM and LDA at Wk 24, respectively.

<b>ADL + MTX Combination Therapy</b>											
DAS28 <2.6	DAS28 <3.3	11	0.49	95	0.15	0.56	0.81	0.49	0.83	0.75	0.69
CDAI REM	CDAI <7.0	29	0.41	103	0.02	0.86	0.86	0.41	0.96	0.86	0.56
SDAI REM	SDAI <7.9	22	0.38	100	0.02	0.80	0.83	0.38	0.96	0.83	0.64
DAS28 LDA	DAS28 <3.5	61	0.72	71	0.16	0.80	0.78	0.72	0.85	0.79	0.79
CDAI LDA	CDAI <12.2	57	0.74	79	0.19	0.75	0.80	0.74	0.81	0.78	0.78
SDAI LDA	SDAI <12.5	57	0.77	75	0.23	0.72	0.82	0.77	0.77	0.77	0.77

**Conclusions:** The ADL concentrations at Week 12 selected by the prediction model were weak predictors of disease control at 6 months, especially for pts on ADL+MTX combination therapy. However, using the model-selected cutoffs of composite clinical endpoints at Wk 12, disease control after 6 months of ADL ±MTX treatment could be correctly predicted in 70%–80% of pts.

**Background:** Interstitial lung disease (ILD) associated with Rheumatoid Arthritis (RA) has a poor prognosis. Treatments such as anti-TNF, have been implicated in the exacerbation of an ILD.

**Objectives:** Our objective is to evaluate and compare the evolution of ILD in patients with RA treated with Abatacept (ABA), Rituximab (RTX) and Tocilizumab (TCZ) after 1 year of treatment.

**Methods:** Retrospective multicentre study of patients with ILD and AR treated with ABA, RTX and TCZ at standard doses. The ILD was diagnosed by CT. The efficacy was evaluated with the following measures: i) Dyspnea by modified scale of the Medical Research Council (mMRC); considering variations of 1 point. ii) Respiratory function tests; considering variations in FVC and DLCO  $\geq 10\%$ . iii) Imaging test (CT).

**Results:** We included 118 (72 women/46 men) patients, mean age of 62.27  $\pm$  10.55 years. The ILD had a median evolution of 12 12–37 months. The RA was ACPA+in 102 cases (86.4%). At diagnosis, the mean DLCO onset of biological treatment was 65.63 $\pm$ 19.38. Table 1 shows the characteristics by subgroups. The Figure expresses the evolution in the cases available at 12 months. There is an improvement in CT in 36.4% of patients with ABA, 28.6% of patients with RTX and only 8.3% of patients with TCZ.

Abstract THU0186 – Table 1

	ABA	RITU	TCZ	p
AGE median years	65 (57–70)	64 (54,75–72)	60 (48–68,5)	0.187

### CIRCULATING AUTOANTIBODIES AS INDICATORS TO PREDICT THE CLINICAL RESPONSE TO INFLIXIMAB IN RHEUMATOID ARTHRITIS

L. Lourido<sup>1,2,3</sup>, C. Ruiz-Romero<sup>1,4</sup>, F. Picchi<sup>1</sup>, E. Pérez-Pampin<sup>5</sup>, C. Regueiro<sup>2,5</sup>, A. Mera-Varela<sup>5</sup>, A. Gonzalez<sup>2,5</sup>, K. Hambardzumyan<sup>6</sup>, S. Saevarsdotiir<sup>6</sup>, P. Nilsson<sup>7</sup>, F.J. Blanco<sup>1,2</sup>. <sup>1</sup>Rheumatology Division, ProteoRed/ISCIII Proteomics Group, INIBIC – Hospital Universitario de A Coruña, A Coruña; <sup>2</sup>RIER-RED de Inflamación y Enfermedades Reumáticas, Madrid, Spain; <sup>3</sup>Affinity Proteomics, SciLifeLab, School of Biotechnology, KTH – Royal Institute of Technology, Stockholm, Sweden; <sup>4</sup>CIBER-BBN Instituto de Salud Carlos III, Madrid; <sup>5</sup>Laboratorio Investigación 10 and Rheumatology Unit, Instituto de Investigación Sanitaria-Hospital Clínico Universitario de Santiago, Santiago de Compostela, Spain; <sup>6</sup>Unit of Rheumatology, Department of Medicine, Karolinska Institutet and Rheumatology Clinic, Karolinska University Hospital, Stockholm, Sweden

**Background:** Approximately a third of Rheumatoid Arthritis (RA) patients treated with tumour necrosis factor (TNF)- $\alpha$  inhibitors such as Infliximab (IFX) fail to respond. This has prompted a widespread interest in the finding of measures for predictors of response to TNF $\alpha$  inhibitors.

**Objectives:** To search for serum autoantibodies that aid to identify RA patients most likely to benefit from IFX.

**Methods:** We analysed serum of 170 biologic-naïve RA patients at baseline assigned to receive IFX plus methotrexate. The serum samples were distributed in 3 independent samples sets that were provided by 3 different sources: 1 discovery sample set (n=24) collected from Hospital Clínico Universitario de Santiago de Compostela (Spain) and 2 validation sample sets collected from Hospital Universitario de A Coruña (Spain), (n=61); and the Swedish Pharmacotherapy (SWEFOT) trial (Sweden), (n=85). The European League Against Rheumatism (EULAR) criteria were used to assess the clinical response at six months of follow-up: good response (GR, n=60), moderate (MR, n=60) and non-response (NR, n=50). A suspension bead array platform built on protein fragments within Human Protein Atlas and selected from an initial screening using an array containing 42 000 antigens was employed to identify the IgG and IgA autoantibodies in the discovery sample set and validate the results within the 2 validation sets. Thresholds for autoantibodies were calculated by Receiver Operating Characteristics (ROC) curve analysis performed with SPSS 24.

**Results:** Our data revealed a more prevalent IgG reactivity and higher IgG autoantibody levels against the antigen Centromere Protein F (CENPF) in GR when compared with NR, showing an overall reactivity of 31% vs 0%, 45% vs. 26% and 17% vs 4% in the three sample sets analysed respectively. The area under the ROC curve was 0,649 [p-value=0.049; IC 95% (0.510–0.789)]. CENPF is a proliferation-associated and cell cycle-dependent centromere autoantigen that might be involved in the increased or abnormal cell proliferation that occurs during RA process. Interestingly, our results also showed that IgA autoantibodies levels toward the antigen Solute Carrier family 39 member 2 (SLC39A2), a zinc transporter protein, were decreased in GR when compared with MR in the discovery sample set and this trend was significantly validated (p=0.018) in the SWEFOT cohort. The area under the ROC curve was 0,681 [p-value=0,019; IC95% (0,543–0,818)].

**Conclusions:** We have identified two autoantibodies in RA that associate with IFX response. Our findings could potentially be useful to guide the treatment decisions for IFX and lead to further studies focusing on the role of the autoantibodies against CENPF and SLC39A2 within RA.

THU0188

### EFFICACY OF INFLIXIMAB FOR SUPPRESSING RADIOGRAPHIC PROGRESSION OF CERVICAL LESIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARISON WITH METHOTREXATE; THREE YEARS OF FOLLOW-UP – A MULTICENTER REGISTRY STUDY ~

Y. Kanayama<sup>1</sup>, T. Kojima<sup>2</sup>, Y. Hirano<sup>3</sup>, N. Takahashi<sup>2</sup>, N. Ishiguro<sup>2</sup>, on behalf of TBCR study group. <sup>1</sup>Orthopedic Surgery And Rheumatology, TOYOTA KOSEI HOSPITAL, Toyota; <sup>2</sup>Orthopedic Surgery, Nagoya University Graduate School of Medicine, Nagoya; <sup>3</sup>Rheumatology, Toyohashi Municipal Hospital, Toyohashi, Japan

**Background:** Cervical lesions are known to occur at high frequency as a complication of rheumatoid arthritis (RA). Treatment with biological agents are more clinically effective than the DMARDs that were in use previously, in particular, with their efficacy in suppressing joint destruction having been emphasised. We reported the efficacy of infliximab (IFX), anti-tumour necrosis factor antibodies for suppressing the radiographic progression of RA cervical lesions at ACR2009, EULAR2010, 11, 12, 13, 14 and 16. However there is still few studies of efficacy of against RA cervical lesions of IFX comparison with methotrexate (MTX).

**Objectives:** To evaluate the efficacy of IFX for suppressing the radiographic progression of RA cervical lesions comparison with MTX for 3 years.

**Methods:** We used MTX or MTX +IFX for treating Japanese patients with active RA who fulfilled the ACR criteria in 1987. The final study cohort of each 64 and 70 patients received continuous MTX and IFX treatment for at least 3 years. MTX was used in all patients receiving IFX. For evaluation of cervical lesions, the atlanto-dental interval (ADI), the space available for the spinal cord (SAC), and the Ranawat value were measured by plain lateral radiographs in the flexion position, at initiation, Year 1, 2 and 3.

**Results:** In the patients receiving MTX (n=64) and IFX (n=70), the number of female were each 46 (72%) and 60 (86%) cases (p=0.049). The mean age was 63.4±11.0 and 54.2±12.8 years old (p<0.001); disease duration was 8.5±9.8 and 10.5±9.3 years (p=0.027) and the mean dose of MTX was 7.9±2.8 and 7.5±1.7 mg/w (p=0.607). Clinical findings related to RA were as follows; CRP 1.5±2.1 and 3.3±3.0 mg/dl (p<0.001); ESR 29.9±21.1 and 54.9±23.9 mm/h (p<0.001); MMP3 223±373 and 355±328 ng/ml (p<0.001); DAS28 4.21±1.35 and 5.43±1.29 (p<0.001); ADI 2.7±1.6 and 3.4±1.7 mm (p=0.005); SAC 20.7±2.6 and 18.4±2.5 mm (p<0.001) and Ranawat value 15.9±1.5 and 14.5±2.3 mm (p<0.001). The respective changes in cervical lesion parameters after 3 years were as follows: ADI: 0.70±0.77 and 0.47±0.74 mm (p=0.042); SAC: -0.69±0.85 and -0.44±0.79 mm (p=0.043); and Ranawat value: -0.48±0.69 and -0.34±0.51 mm (p=0.359) between MTX and IFX patients (figure 1). The numbers of patients who did not showed progression in ADI, SAC and Ranawat value were each 30 (47%) vs 45 (64%) cases (p=0.043); 33 (52%) vs 48 (69%) cases (p=0.044) and 40 (63%) vs 47 (67%) cases (p=0.574) after 3 years. Also the number who was able to suppress progression in all three parameters were each 30 cases (47%) receiving MTX and 39 cases (56%) receiving IFX (p=0.307) after 3 years (figure 2).

Figure 1: Respective changes in ADI, SAC and Ranawat value from Year 0 to Year 3 between MTX and IFX patients

Figure 2: The rate of patients who did not showed progression in ADI, SAC, Ranawat value and all three parameters after 3 years

**Abstract THU0188 – Figure 1.** Respective changes in ADI, SAC and Ranawat value from Year 0 to Year 3 between MTX and IFX patients. **Abstract THU0188 – Figure 2.** The rate of patients who did not showed progression in ADI, SAC, Ranawat value and all three parameters after 3 years

**Conclusions:** This study suggested that IFX treatment can be used to suppress the progression of RA cervical lesions more than MTX treatment.

THU0189

### ONE-YEAR TREATMENT RETENTION AFTER A NATIONWIDE NON-MEDICAL SWITCH FROM ORIGINATOR TO BIOSIMILAR ETANERCEPT IN 2,061 PATIENTS WITH INFLAMMATORY ARTHRITIS FOLLOWED IN THE DANBIO REGISTRY

B. Glinborg, I.J. Sørensen, E. Omerovic, F. Mehnert, N. Manilo, K. Danebod, D. V. Jensen, H. Nordin, A.G. Loft, O. Hendricks, S. Chrysidis, B.L. Andersen, J. L. Raun, H. Lindegaard, J. Espesen, S.H. Jakobsen, I.M.J. Hansen, E. B. Dalsgaard, D.D. Pedersen, S. Kristensen, A. Linauskas, L.S. Andersen, J. Grydehøj, N. Krogh, M.L. Hetland. *The DANBIO registry and the Danish Departments of Rheumatology, Copenhagen, Denmark*

**Background:** In Denmark, rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (AxSpA) patients (pts) treated with originator etanercept (ETA) 50 mg SC conducted a mandatory non-medical switch to biosimilar Etanercept (SB4) in April 2016 (switchers). Pts treated with 25 mg ETA or 50 mg powder solution were not mandated to switch (non-switchers).

**Objectives:** To characterise switchers and non-switchers, and to compare 1 year treatment retention in switchers with non-switchers and a historic cohort of ETA treated pts.

**Methods:** Pt data were retrieved from the DANBIO registry and national registries. We applied Chi-square/Mann-Whitney for comparisons and Kaplan-Meier/Cox regression analyses (crude, adjusted for gender/age/MTX/remission/comorbidities/ETA-start-year) for drug retention. The historic cohort encompassed pts treated with ETA by Jan 1st 2015.

**Results:** Of 2,061 ETA treated pts by April 2016, 79% switched to SB4 (933RA/351PsA/337AxSpA), whereas 21% (286RA/56PsA/98AxSpA) continued ETA. In RA, compared to switchers, non-switchers more often received 25 mg ETA, had higher disease activity and HAQ (table 1). Similar patterns were seen for PsA and AxSpA. Median (IQR) follow-up was 383 (314–414) days. In all 3 cohorts, withdrawals were mainly due to lack of effect. Retention rate was lowest in non-switchers (figure 1). 1 year adjusted rates were 83% (95% CI 79–87) in switchers, 77% (72–82) in non-switchers and 90% (88–92) in historic cohort. Pts not in remission had poorer retention than pts in remission both in switchers (hazard ratio 1.7 (1.3–2.2) and non-switchers (2.4 (1.7–3.6)).

Numbers are medians (IQR) unless otherwise stated. \* DAS28 <2.6 (RA, PsA), ASDAS <1.3 (AxSpA)

**Conclusions:** Of >2000 ETA treated pts, ≈80% switched to SB4. Non-switchers had higher disease activity and more often received 25 mg ETA. Switchers had poorer retention rate than a historic ETA-cohort, but better than non-switchers. Withdrawal was most common in pts not in remission. These real-world data indicate that a switching-to-biosimilar option facilitated clinical decision making in

**CLINICAL OUTCOMES AMONG RHEUMATOID ARTHRITIS PATIENTS RECEIVING ADALIMUMAB WHO DID OR DID NOT PARTICIPATE IN THE PATIENT SUPPORT PROGRAM: A SUBANALYSIS OF THE PASSION STUDY**

A. Ostor<sup>1</sup>, S. Wassenberg<sup>2</sup>, P. Zueger<sup>3</sup>, J. Kalabic<sup>4</sup>, M. Wu<sup>3</sup>, I. Lagunes Galindo<sup>3</sup>, F. Van den Bosch<sup>5</sup>, <sup>1</sup>Cabrini Medical Centre, Melbourne, Australia; <sup>2</sup>Rheumazentrum Ratingen, Ratingen, Germany; <sup>3</sup>Abbvie, N Chicago, USA; <sup>4</sup>Abbvie Deutschland Co. GmbH, Ludwigshafen, Germany; <sup>5</sup>Ghent University Hospital, Ghent, Belgium

**Background:** The AbbVie Patient (pt) Support Program (PSP) is offered to pts prescribed adalimumab (ADA) for rheumatoid arthritis (RA) and other indications.

**Objectives:** This subanalysis evaluated the impact of ADA in achieving clinical, functional, and pt-reported outcome treatment targets and sustained responses by PSP use.

**Methods:** PASSION was a 78-wk postmarketing, multinational, observational study enrolling pts with moderate to severe RA receiving ADA in routine clinical care. Pts with an insufficient response to  $\geq 1$  disease modifying antirheumatic drug (DMARD; 1 prior biologic DMARD was allowed) and newly initiating ADA were enrolled. Pts were divided into 2 groups based on PSP participation: ever (PSP users) vs never (PSP non-users). Outcome measures included proportion of pts with low disease activity (LDA)/remission defined by Clinical Disease Activity Index (CDAI)  $\leq 10$ , Simplified Disease Activity Index (SDAI)  $\leq 11$ , and Disease Activity Score (DAS)28(C-reactive protein [CRP])  $\leq 3.2$ ; proportion with mild to moderate disability (Health Assessment Questionnaire Disease Index [HAQ-DI] 0 to 1); and proportion with 20%/50%/70% improvement from baseline (BL) in ACR components (table 1). Missing values were imputed using last observation carried forward, and differences in proportions between PSP users and PSP non-users were compared with Chi-square tests.

**Results:** Of 1025 pts treated with ADA in the study, 499 were PSP users and 526 were PSP non-users. A significantly greater proportion of PSP users vs PSP non-users had LDA/remission as defined by CDAI at wks 24, 52, and 78 and as

defined by SDAI or DAS28(CRP) at weeks 52 and 78 ( $p < 0.05$  for all). A significantly greater proportion of PSP users vs PSP non-users also had mild to moderate disability defined by HAQ-DI at wk 78 ( $p = 0.0239$ ). Compared with PSP non-users, a significantly greater proportion of PSP users had 70% improvement from BL in PtGA, pain, and CRP at wks 24, 52, and 78; SJC28 at wks 52 and 78; and TJC28 and PhGA at wk 78 (table 1). At wks 24, 52, and 78, a significantly greater proportion of PSP users vs PSP non-users had 20% and 50% improvements from BL in all ACR components (all  $p < 0.05$ ), except for 50% improvement from BL in TJC28 at wks 24 and 78 and PhGA at wk 24.

Abstract THU0190 – Table 1. Proportion of Patients With 70% Improvement in ACR Individual Components (LOCF) by PSP Utilisation Category by Visit (Intent-To-Treat Population)

	Visit	PSP User n/N (%)	PSP Non-user n/N (%)	P-value

The intent-to-treat (ITT) population includes patients who received  $\geq 1$  dose of study drug. n=number of patients in the ITT population; N=number of patients with non-missing values at each visit. \*\*\*, \*\*, \*, statistically significant at  $P = 0.001$ , 0.01, and 0.05 levels, respectively. P-values derived from Chi-square test.

Missing data were imputed for each efficacy endpoint using LOCF. The differences between groups in efficacy endpoints at wk 24, 52, and 78 were based on ANCOVA models adjusting for baseline and demographic variables (sex, race, ethnicity, age [years], PSP participation [ever (PSP users) vs never (PSP non-users)], diagnosis RA duration [years]).

ANCOVA, analysis of covariance; CRP, C-reactive protein; LOCF, last observation carried forward; Pain, Patient Global Assessment of Pain; PhGA, Physician Global Assessment of Disease Activity; PtGA, Patient Global Assessment of Disease Activity; PSP, patient support program; SJC28, Swollen 28-Joint Count; TJC28, Tender 28-Joint Count.

**Conclusions:** Among pts with moderate to severe RA initiating ADA treatment, participation in the PSP resulted in significantly greater improvements in clinical, functional, and pt-reported outcomes at wks 24, 52, and 78 in comparison to the PSP non-users.

**Acknowledgements:** AbbVie funded the study and analysis, and approved the abstract for submission. Medical writing support was provided by Aric Fader, PhD, of Complete Publication Solutions, LLC (North Wales, PA, USA) and was funded by AbbVie.

### NOVEL FORMULATION OF CT-P13 FOR SUBCUTANEOUS ADMINISTRATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: INITIAL RESULTS FROM A PHASE I/III RANDOMISED CONTROLLED TRIAL

R. Westhovens<sup>1</sup>, D.H. Yoo<sup>2</sup>, J. Jaworski<sup>3</sup>, E. Matyska-Piekarska<sup>3</sup>, S. Smiyan<sup>4</sup>, D. Ivanova<sup>5</sup>, A. Zielinska<sup>6</sup>, E.-K. Raussi<sup>7</sup>, A. Batalov<sup>8</sup>, S.J. Lee<sup>9</sup>, S.Y. Lee<sup>9</sup>, J. H. Suh<sup>9</sup>. <sup>1</sup>University Hospital KU Leuven, Leuven, Belgium; <sup>2</sup>Hanyang University Hospital for Rheumatic Diseases, Seoul, Korea, Republic of Ireland; <sup>3</sup>REUMATIKA – Centrum Reumatologii NZOZ, Warszawa, Poland; <sup>4</sup>State Higher Educational Institution "I. Ya. Horbachevskiy Ternopil State Medical University of MOH of Ukraine", Ternopil, Ukraine; <sup>5</sup>Diagnostic-Consultative Center Aleksandrovska EOOD, Sofia, Bulgaria; <sup>6</sup>Medycyna Kliniczna, Warszawa, Poland; <sup>7</sup>North Estonia Medical Centre Foundation, Tallinn, Estonia; <sup>8</sup>Medical University – Plovdiv, University Hospital Kaspela, Clinic of Rheumatology, Plovdiv, Bulgaria; <sup>9</sup>Celltrion, Inc., Incheon, Korea, Republic of Ireland

**Background:** While the treatment with intravenous (IV) CT-P13, an infliximab biosimilar, is effective and well tolerated, a new subcutaneous (SC) CT-P13 formulation (CT-P13 SC) is developed to provide additional, more convenient treatment options and opportunity for self-injection.

**Objectives:** To find the optimal dose of CT-P13 SC and to evaluate efficacy, PK and safety over the first 30 weeks in patients with rheumatoid arthritis.

**Methods:** This study consists of 1 cohort with CT-P13 IV, and 3 cohorts with 3 different doses of CT-P13 SC injected biweekly. All enrolled patients initially received CT-P13 IV at Weeks 0 and 2 and patients who received 2 full doses and displayed no safety concerns were randomly assigned to receive either CT-P13 SC or IV at Week 6. Using part 1 result, PK-PD modelling was conducted for the 3 regimens.

**Results:** A total of 50 patients were enrolled, of whom 48 patients were randomly assigned into 4 cohorts.

Overall, the efficacy results of CT-P13 SC up to Week 30 were comparable to those of CT-P13 IV. Disease improvement by DAS28 and ACR20 were comparable across all 4 cohorts, regardless of the route of administration or dosage of CT-P13 (table 1).

The safety profiles in CT-P13 SC cohorts were generally comparable to CT-P13 IV. One of the 2 patients who experienced a hypersensitivity reaction became anti-drug antibody (ADA) positive at Week 6 and experienced hypersensitivity from Week 2 to 8. All injection site reactions were grade 1 or 2. The proportion of ADA (positive) was lower in the SC cohorts.

In PK-PD modelling, bioavailability was 59% (95% CI, 52%–67%). The dose linearity in SC regimens was confirmed based on Weeks 22 to 30  $C_{trough}$ ,  $AUC_{0-24}$ , and  $C_{max, ss}$  (figure 1).  $C_{trough}$  were greater (above 4  $\mu\text{g/mL}$ ) than the target exposure (1  $\mu\text{g/mL}$ )<sup>[1][2]</sup> in all SC regimens. There was a trend towards slightly lower DAS28 score in all SC regimens, which was consistent with the higher  $C_{trough}$  comparing with CT-P13 IV. Based on the exposure-response safety analyses, there was no correlation between PK ( $AUC_{0-24}$  or  $C_{max, ss}$ ) and safety (IRRs or infections).

Abstract THU0191 – Table 1. Efficacy and safety up to Week 30

		Cohort 1 IV 3 mg/ kg (n=13)	Cohort 2 SC 90 mg (n=11)	Cohort 3 SC 120 mg (n=12)	Cohort 4 SC 180 mg (n=12)
DAS28 (CRP), mean ±SD	Week 0	5.4±0.8	6.3±0.8	5.7±0.9	5.5±0.8
	Week 6	3.9±1.5	4.6±1.1	3.9±1.2	3.4±1.2
	Week 22	3.9±1.6	3.7±1.0	3.3±1.4	2.8±1.3
Week 30 ACR20, n (%)	Week 6	3.3±1.3	3.0±1.1	3.1±1.0	2.7±1.0
	Week 22	8 (61.5)	8 (72.7)	7 (58.3)	7 (58.3)
	Week 30	8 (61.5)	8 (72.7)	9 (75.0)	11 (91.7)
Safety, n (%)	Week 30	11 (84.6)	10 (83.3)	10 (83.3)	12 (100)
	Hypersensitivity/ IRR	0	1 (9.1)	1 (8.3)	0
	Injection site reactions	0	2 (18.2)	0	2 (16.7)
	Infections	4 (30.8)	2 (18.2)	0	4 (33.3)

Solid line = Period 1 (IV reference regimen: IV loading + IV maintenance dose)  
Dashed line = Period 2 (SC test regimen: IV loading + SC maintenance dose)

**Abstract THU0191 – Figure 1.** Mean (± SD) Simulated CT-P13 Serum Concentration vs Time Profiles for the Simulated Fixed Dose SC Maintenance Dosing Regimens with Overlaid IV Maintenance Reference Treatment (Semi-Logarithmic Scale). Solid line=Period 1 (IV reference regimen: IV loading+IV maintenance dose). Dashed line=Period 2 (SC test regimen: IV loading+SC maintenance dose)

Abstract THU0191 – Table 2. Summary of Steady State Median (Prediction Interval 5<sup>th</sup>-95<sup>th</sup> percentile) CT-P13 Exposure Results

Simulated Dose Regimen	$C_{trough}$ ( $\mu\text{g/mL}$ )	$AUC_{0-24}$ ( $\text{h}\cdot\mu\text{g/mL}$ )	$C_{max}$ ( $\mu\text{g/mL}$ )
3 mg/kg IV every 8 weeks	1.53 (0.18 - 5.2)	16725.64 (9328.94 - 26297.08)	76.01 (52.73 - 103.21)
120 mg SC every 2 weeks	13.66 (6.66 - 24.25)	22717.66 (12849.49 - 37845.41)	18.95 (11.38 - 30.81)
180 mg SC every 4 weeks	6.66 (2.55 - 13.7)	17060.69 (9660.52 - 28442.43)	17.47 (11.13 - 26.76)
120 mg SC every 4 weeks	4.44 (1.7 - 9.14)	11375.19 (6440.93 - 18976.74)	11.65 (7.42 - 17.84)

Treatment continuation in patients enrolled with SB4 or oETN who were bionative until enrollment.

**Conclusions:** CT-P13 SC showed comparable efficacy and safety with CT-P13 IV. The preliminary results suggest CT-P13 SC as a future alternative treatment of infliximab.

THU0192

### RETENTION RATES FOR ETANERCEPT: COMPARING THE ORIGINAL WITH A BIOSIMILAR

A. Strangfeld<sup>1</sup>, L. Baganz<sup>1</sup>, P. Herzer<sup>2</sup>, J. Braun<sup>3</sup>, A. Gräßler<sup>4</sup>, A. Zink<sup>1,5</sup>. <sup>1</sup>German Rheumatism Research Center, Berlin; <sup>2</sup>Scientific Advisory Board, Munich; <sup>3</sup>Rheumazentrum Ruhrgebiet, Herne; <sup>4</sup>Rheumatologist, Pima; <sup>5</sup>Charité University Medicine, Berlin, Germany

**Background:** Since the first approval of a biosimilar in 2015, the number of biosimilars approved for the treatment of rheumatoid arthritis (RA) in Germany has been increasing. Until now, there are just a few analyses investigating retention rates of biosimilars and the respective originators.

**Objectives:** To compare treatment survival on SB4 to the originator etanercept (oETN) using real-world data.

**Methods:** We used data gathered until December 2017 from the prospective, longitudinal RABBIT (Rheumatoid Arthritis: Observation of biologic therapy) cohort. RA patients are enrolled in RABBIT when they start a biologic, biosimilar or new csDMARD treatment. For comparative analyses, patients starting SB4 either at enrollment or during follow-up were compared to patients enrolled with oETN since 2015. The drug survival rates during the first six months were analysed in biologic naive patients prior to enrollment using Kaplan-Meier curves.

**Results:** Overall, 283 patients were included in the register starting SB4 and 369 with oETN. Another 355 patients who had already been enrolled in RABBIT switched to SB4 during follow up. Compared to oETN patients, those enrolled with SB4 had slightly lower disease duration (8 vs. 9 years) and significantly fewer patients had three or more comorbidities (40% vs. 47%,  $p=0.04$ ). 88% ( $n=250$ ) of patients enrolled with SB4 and 86% ( $n=317$ ) enrolled with oETN were bionative. Out of all patients who started SB4 during follow up, 40% had been treated with oETN, and 39% with another biologic before switching. 21% had received csDMARD or no drug treatment before treatment start. Kaplan-Meier curves show comparable retention rates over 6 months for SB4 and oETN (figure 1). Adjusting the curves for disease duration and comorbidities had no significant influence on the results. 8% ( $n=20$ ) of bionative SB4 patients and 17% ( $n=54$ ) of bionative oETN patients stopped treatment during the first 90 days. Additional 6% ( $n=14$ , SB4)/15% ( $n=46$ , oETN) stopped the treatment within 180 days after enrolment. The reasons for discontinuation of both treatments were adverse events (AE) in 59% ( $n=20$ , SB4)/49% ( $n=49$ , oETN) and loss of response in 26% ( $n=9$ , SB4)/31% ( $n=31$ , oETN). The most common cause for discontinuation within 180 days due to AE were skin reactions at the injection site in 35% (7 of 20) of SB4, and 49% (24 of 49) of oETN patients).

**Abstract THU0192 – Figure 1.** Treatment continuation in patients enrolled with SB4 or oETN who were bionative until enrollment.

**Conclusions:** The retention rates for bionative patients starting either the biosimilar SB4 or the originator oETN were similar. The distribution of adverse events was also comparable. A selection bias cannot fully be ruled out since patients on oETN had more comorbidities.

#### THU0193 EFFICACY AND SAFETY OF BCD-055 (INFLIXIMAB BIOSIMILAR) IN RHEUMATOID ARTHRITIS. RESULTS OF BCD-055-3/LIRA PHASE 3 CLINICAL STUDY

A. Lila<sup>1</sup>, L. Denisov<sup>2</sup>, T. Plaksina<sup>3</sup>, S. Smakotina<sup>4</sup>, E. Kunder<sup>5</sup>, N. Soroka<sup>6</sup>, A. Kastanayan<sup>7</sup>, O. Nesmeyanova<sup>8</sup>, O. Antipova<sup>9</sup>, E. Ilivanova<sup>10</sup>, A. Ereemeeva<sup>11</sup>, E. Dokukina<sup>11</sup>, E. Chernyaeva<sup>11</sup>, R. Ivanov<sup>11</sup>. <sup>1</sup>North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg; <sup>2</sup>V.A. Nasonova Research Institute of Rheumatology, Moscow; <sup>3</sup>N.A. Semashko N. Novgorod Regional Clinical Hospital, N. Novgorod; <sup>4</sup>S.V. Belayev Kemerovo Regional Clinical Hospital, Kemerovo, Russian Federation; <sup>5</sup>Clinical Hospital No1; <sup>6</sup>Clinical Hospital No9, Minsk, Belarus; <sup>7</sup>Rostov State Medical University, Rostov-on-Don; <sup>8</sup>Chelyabinsk Regional Clinical Hospital, Chelyabinsk; <sup>9</sup>Irkutsk Municipal Clinical Hospital No1, Irkutsk; <sup>10</sup>Leningrad Region Clinical Hospital; <sup>11</sup>JCS BIOCAD, Saint-Petersburg, Russian Federation

**Background:** Equivalent efficacy of BCD-055 and infliximab (INF) innovator has been previously established (the primary endpoint: ACR20 at Wk14)<sup>1</sup>.

**Objectives:** The impact of BCD-055 and INF innovator on RA activity has been analysed within 14 week study period. DAS28-CRP,<sup>4</sup> CDAI and SDAI were evaluated. Additionally, safety data has been collected.

**Methods:** The study was conducted as international multicenter randomised double-blind placebo controlled study. The study enrolled 426 adults with active RA. Patients were randomised into 2 study arms in 2:1 ratio to receive BCD-055 or INF innovator in dose of 3 mg/kg. In the analysed period of the study, patients received the iv infusions on Wk0, Wk2, Wk6, Wk14.

**Results:** Efficacy: BCD-055 and INF innovator showed similar impact on RA activity: in both groups significant decline of DAS28-CRP<sup>4</sup> was observed (figure 1). This result corresponds to positive CDAI and SDAI dynamics (table 2). Medians of CDAI/SDAI on screening indicated high RA activity, while on Wk 14 – moderate activity. Analyses of inflammatory markers (ESR and C-reactive protein) revealed pronounced decline in ESR and CRP levels by Wk 2. No further elevation has been observed.

**Safety:** No differences in safety profiles of BCD-055 and INF innovator has been shown. One of the most frequent AEs were arterial hypertension, anaemia, neutropenia and increase of transaminases. Number of patients with binding and neutralising antibodies also did not differ between groups. Babs were detected in 6.83% patients in BCD-055 arm and in 7.81% in INF innovator arm ( $p=0.888$ ), Nab were observed in 1.61% and 0.78% patients in same arms ( $p=0.666$ ).

**Abstract THU0193 – Table 1.** SDAI, CDAI dynamics.

		Screening	Wk14	p-value
SDAI	BCD-055 (n=280)	42.46 [35.15–51.11]	16.22 [8.45–25.03]	<0.00000
	INF innovator (n=138)	41.22 [34.21–47.52]	16.15 [9.06–27.11]	<0.00000
CDAI	BCD-055 (n=280)	39.15 [31.50–46.00]	15.40 [8.00–24.00]	<0.00000
	INF innovator (n=138)	36.85 [31.90–42.00]	15.55 [8.30–25.50]	<0.00000

**Abstract THU0193 – Table 2.** Summarised safety data

Percentage of patients with	Arm		p-value
	BCD-055 (n=280)	INF innovator (n=138)	
Any AE/SAE	53.57% (150)	44.93% (62)	0.119
Therapy-related AEs	26.43% (74)	24.64% <sup>34</sup>	0.784
Any SAE	2.14% <sup>6</sup>	1.45% <sup>2</sup>	1.00
Grade 3–4 AEs	10.00% <sup>28</sup>	5.80% <sup>8</sup>	0.966
Therapy-related grade 3–4 AEs	5.71% <sup>16</sup>	4.35% <sup>6</sup>	0.722
Therapy-discontinuation due to AE	2.50% <sup>7</sup>	2.90% <sup>4</sup>	0.757

**Conclusions:** Treatment with BCD-055 and INF innovator leads to significant decline in RA activity and inflammatory markers by Wk14, which corresponds with previous results of ACR20 assessment<sup>1</sup>. Both drugs are well tolerated with no differences in safety profiles. The frequency of ADA formation is also comparable.

#### THU0194 CD4+ T CELLS, IMMUNOGLOBULINS AND RISK OF INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS OVER MULTIPLE CYCLES OF RITUXIMAB

F. Martins<sup>1</sup>, A. Bensalem<sup>2</sup>, T. Bejan-Angoulvant<sup>2,3</sup>, A. Lhommas<sup>1</sup>, J. Mélet<sup>1,2</sup>, S. Mammou<sup>1</sup>, G. Thibault<sup>2,4,5</sup>, L. Bernard<sup>6</sup>, P. Goupille<sup>1,2</sup>, D. Mulleman<sup>1,2</sup>,

<sup>1</sup>Rheumatology, CHRU de Tours; <sup>2</sup>EA GICC, University of Tours; <sup>3</sup>Clinical Pharmacology, CHRU de Tours; <sup>4</sup>CNRS ERL 7001, University of Tours;

<sup>5</sup>Immunology; <sup>6</sup>Infectious diseases, CHRU de Tours, Tours, France

**Background:** Rituximab (RTX) may be responsible for infectious event in RA patients. Immunological markers may be associated with the occurrence of infections.

**Objectives:** To evaluate lymphocyte counts and immunoglobulin concentrations over multiple cycles of RTX in RA patients, and to analyse the relationship between these markers and the occurrence of infections.

**Methods:** Retrospective monocentric study on 94 RA patients treated with RTX. At baseline and during follow up, lymphocyte phenotyping (CD4+, CD3+, CD19 +cells), gammaglobulin, IgG, IgM and IgA concentration were assessed. Patients were dichotomized according to the absence or presence of infectious events. A student's test was used to compare the continuous variables and a Chi2 test or the Fisher test was used for the dichotomous variables.

**Results:** A total of 119 infectious events occurred during follow-up, of which only 11 were serious, with respective incidences of 65 per 100 patient-years and 6 per 100 patient-years. Low IgM concentration at RTX initiation and low IgG concentration (<5 g/L) throughout follow-up were associated with an increased risk of infection. Both gammaglobulin and IgG concentrations decreased along with successive cycles of RTX in patients with infection, while they remained stable in patients without infection. Twelve patients had a CD4 +cell count<200/mm<sup>3</sup> during follow up, of which one with a CD4 +cell count 233/mm<sup>3</sup> at baseline, who subsequently presented an opportunistic infection.

**Conclusions:** Gammaglobulin, IgM and IgG concentrations and CD4 +cell count are valuable before RTX initiation in RA patients. IgG or gammaglobulin concentration should also be monitored before each cycle. CD4 +lymphocytes monitoring should be considered in patients with low value at initiation.

**Disclosure of Interest:** F. Martins: None declared, A. Bensalem: None declared, T. Bejan-Angoulvant: None declared, A. Lhommas: None declared, J. Mélet: None declared, S. Mammou: None declared, G. #### THU0195 PREVALENCE OF OCCULT HEPATITIS B CARRIER STATUS AND ITS ASSOCIATED FACTORS IN PATIENTS WITH RHEUMATIC DISEASES UNDERGOING BIOLOGICAL THERAPIES

C.C. Mok<sup>1</sup>, L.Y. Ho<sup>1</sup>, K.L. Chan<sup>1</sup>, S.M. Tse<sup>1</sup>, C.H. To<sup>2</sup>. <sup>1</sup>Medicine, Tuen Mun Hospital; <sup>2</sup>Medicine, Pok Oi Hospital, HK, Hong Kong

**Objectives:** To study the prevalence of occult hepatitis B carrier status and its associated factors in patients with rheumatic diseases undergoing biological therapies

**Methods:** Consecutive adult patients with various rheumatic diseases who were currently receiving biological therapies between November 2016 and April 2017 were recruited in this cross-sectional study. Blood was taken for evidence of hepatitis B infection (HBsAg, anti-HBs, anti-HBc-IgG). For patients tested positive for HBsAg or anti-HBc-IgG, assay of serum HBV-DNA level was also performed. Occult hepatitis B carrier was defined as patients who were HBsAg negative but anti-HBc-IgG positive. Logistic regression was performed to study factors independently associated with occult hepatitis B carrier status in these patients.

**Results:** 310 Chinese patients were studied (60% women, age at biological therapy 44.0±13.0 years). The underlying rheumatic diseases requiring biological therapies were rheumatoid arthritis (46%), spondyloarthritis (31%), psoriatic

arthritis (12%) and systemic lupus erythematosus (8.1%). The biologics being used were the TNF inhibitors (66%), tocilizumab (16%), abatacept (2.9%), rituximab (7.7%), belimumab (5.8%) and tofacitinib (1.3%). Hepatitis B carrier (HBsAg +) status was detected in 11 (3.5%) patients and they were all put on preemptive anti-viral therapy (entecavir). A total of 105 patients (34%) were occult hepatitis B carriers (HBsAg- but anti-HBc-IgG+). Anti-HBs was present in 83/105 (79%) of these patients. Occult hepatitis B carriers were significantly older than the non-carriers (49.9±11.1 vs 40.9±13.3 years; p<0.001), and were more frequently identified in rheumatoid arthritis than other rheumatic diseases (45% vs 25%; p<0.001). However, there was no gender difference in the prevalence of the occult hepatitis B carrier status (37% in women vs 28% in men; p=0.10). Logistic regression revealed that older age (RR 1.05 [1.03–1.08] per year; p<0.001) was the only independent factor significantly associated with occult hepatitis B infection. Rheumatoid arthritis was not significantly associated with occult hepatitis B carrier status after adjustment for age and sex. Of the occult hepatitis B carriers, 9 (8.6%) had detectable HBV-DNA levels but all were very low titers (<100 IU/ml). Five (56%) patients with detectable HBV-DNA levels received entecavir treatment during biological therapies, while 19 (20%) patients without detectable HBV-DNA were put on preemptive entecavir treatment (including all patients who were receiving rituximab). None of the overt (HBsAg+) or occult hepatitis B (HBsAg-anti-HBc-IgG+) carrier patients developed clinical reactivation of hepatitis B during a mean of 5.0±3.7 years of biological therapies.

**Conclusions:** Occult hepatitis B carrier status was present in one-third of Hong Kong Chinese patients with various rheumatic diseases undergoing biological therapies. Older age was the only independent factor associated with occult hepatitis B infection. Despite the relatively low rate of preemptive anti-viral treatment in these patients, clinical reactivation of hepatitis B was not reported over 5 years of biological therapies.

**Disclosure of Interest:** None declared

#### THU0196 DO CONTEXTUAL FACTORS INFLUENCE SURVIVAL ONDRUG OF BIOSIMILARS IN CLINICAL PRACTICE?

D. Di Giuseppe<sup>1</sup>, T. Frisell<sup>2</sup>, E. Lindqvist<sup>3</sup>, L. Jacobsson<sup>4</sup>, C. Turesson<sup>5</sup>, C. Sjöwall<sup>6</sup>, J. Askling<sup>1</sup>, on behalf of ARTIS group. <sup>1</sup>Department of MedicineSolna, Karolinska Institutet; <sup>2</sup>Department of MedicineSolna, SRQ, Stockholm; <sup>3</sup>Lund University and Skåne University Hospital, Malmö; <sup>4</sup>Sahlgrenska Academy, University of Gothenburg, Gothenburg; <sup>5</sup>Linköping University, Linköping, Sweden

**Background:** The introduction of biosimilars has been linked to concerns regarding their effectiveness and safety compared to their originator products. Whilst randomized controlled trials may address their relative efficacy, the outcome of biosimilars in clinical practice may be influenced by contextual factors, such as the treating rheumatology unit's experience with biosimilars and non-medical switching.

**Objectives:** To analyze whether contextual factors, such as department size and use of biosimilars, and calendar period of treatment start, influence time until treatment discontinuation (i.e. drug survival) of biosimilars as compared to corresponding originator products.

**Methods:** We used data from the Swedish Rheumatology Quality register to identify all patients with rheumatoid arthritis, ankylosing spondylitis, psoriatic arthritis, or other spondyloarthropathies who started infliximab between March 1st 2015 and Sept 30th 2017 or etanercept between April 1st 2016 and Sept 30th 2017, as their first ever biologic. Kaplan-Meier curves and Cox models were used to assess the association between drug survival and the size of the rheumatology unit, its use of biosimilars (extent of biosimilar use above/below national median at teach time point), and whether the treatment start occurred soon after biosimilar introduction (infliximab: first 12 months, etanercept: 6 months counting from first date of availability of the biosimilar in question). To avoid artefacts, patients were censored if switching from the originator to a biosimilar (or vice versa).

**Results:** During the study period, 368 and 738 patients started infliximab originator or biosimilar, and 125 and 2079 started etanercept originator or biosimilar, as first ever biological treatment. Overall, the hazard ratio (HR) of discontinuing treatment (comparing the biosimilar vs its originator) was 1.21 (95% CI: 0.96–1.51) for infliximab and 0.88 (95% CI: 0.57–1.35) for etanercept, adjusted for indication, age (quartiles), gender, region, and HAQ (quartiles), DAS28 (quartiles) and global health (quartiles) at treatment start. Patients treated in large clinics (more than 1695 patients (75th percentile) at the end of the study period) were at a lower risk of drug discontinuation (table 1). We noted no association between overall biosimilar use in the rheumatology clinic in question and survival on drug (neither originator nor biosimilar). By contrast, those who started infliximab biosimilar later had a lower risk of discontinuing (HR: 0.65 (95% CI: 0.50–0.85)) compared to those who started in the first year of availability. For etanercept biosimilar, no such association was noted.

**Abstract THU0196 – Table 1.** Hazardratios among patients starting their first biologic treatment during the studyperiod according to contextual factors

	Infliximab- originator	Infliximab biosimilar	Etanercept originator	Etanercept biosimilar
Number of patients	368	738	125	2079
Number of discontinuations	165	265	23	392
Dept. size				
Low [quartile I & II]	0.88 (0.37-2.13)	1.47 (0.88-2.46)	30.66 (6.16-152.68)	1.69 (1.12-2.55)
Medium [quartile III]	1.29 (0.81-2.08)	1.90 (1.36-2.65)	19.96 (2.13-56.49)	1.80 (1.08-1.82)
High [quartile IV]	Ref	Ref	Ref	Ref
Dept. use of biosimilars				
Low	Ref	Ref	Ref	Ref
High	0.88 (0.58-1.34)	1.30 (0.82-1.75)	1.90 (0.64-5.70)	1.90 (0.77-1.29)
Period of biologic start*				
Early period	Ref	Ref	Ref	Ref
Later period	0.98 (0.67-1.42)	0.65 (0.50-0.85)	0.06 (0.01-0.53)	0.94 (0.76-1.17)

\*Additionally adjusted for department size and use of biosimilar;  
§ Only 2 discontinuation in the later period of etanercept originator

**Conclusions:** Contextual factors, presumably related to expectations and differences in clinical monitoring, influence the observed survival on drug of biologics, including biosimilars, and must be considered when the comparative effectiveness of biosimilars is evaluated.

#### EFFECTS OF TOCILIZUMAB, AN ANTI-INTERLEUKIN-6 RECEPTOR ANTIBODY, ON SERUM LIPID AND ADIPOKINE LEVELS IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Hoffman<sup>1</sup>, M.A. Rahat<sup>1,2</sup>, J. Feld<sup>3</sup>, M. Elias<sup>3</sup>, I. Rosner<sup>1,4</sup>, L. Kaly<sup>4</sup>, I. Lavi<sup>5</sup>, D. Zisman<sup>1,3</sup>. <sup>1</sup>The Ruth and Bruce Rappaport Faculty of Medicine, Technion; <sup>2</sup>The Immunotherapy Laboratory; <sup>3</sup>Rheumatology Unit, Carmel Medical Center; <sup>4</sup>Rheumatology Unit, Bnai Zion Medical Center; <sup>5</sup>Department of Community Medicine and Epidemiology, Carmel Medical Center, Haifa, Israel

**Background:** Patients with rheumatoid arthritis (RA) are at increased risk of cardiovascular disease.<sup>1</sup> Dyslipidemia is a known adverse reaction to tocilizumab (TCZ), the anti-interleukin-6 receptor antibody, used in RA treatment.

**Objectives:** To assess the effect of TCZ on lipid and adipokine levels in the serum of RA patients

**Methods:** Forty RA patients with active disease initiating TCZ treatment and 40 healthy matched controls were included. Height, weight, disease activity score (DAS28), lipid profile and atherogenic indices (AI) were measured before and four months after TCZ treatment initiation. Serum concentrations of leptin, adiponectin, resistin, interleukin-6 and high sensitivity CRP were measured by ELISA in both study groups.

Statistical analysis: The differences in clinical and laboratory data of RA patients between baseline and follow up were assessed by paired t-test and by linear mixed models with repeated measures for adipokines levels after adjustment to BMI, statin treatment and disease duration. To compare the adipokines levels between RA and control groups adjusted to baseline BMI and statin treatment we used ANCOVA models. HsCRP and IL-6 were compared between the two groups by two-tailed Mann Whitney test. The results were considered statistically significant when  $p \leq 0.05$ .

**Results:** The average age of the study population was  $57.5 \pm 11$  years, 82.5% were women, with a disease duration of  $8.7 \pm 5.6$  years. The majority of the patients responded to TCZ and reduced their diseases activity from DAS28 score of  $5.45 \pm 1.06$  to  $3.46 \pm 1.37$  ( $p < 0.0001$ ). Following treatment, a significant elevation of total cholesterol ( $199 \pm 52$  to  $221 \pm 53$  mg/dl,  $p < 0.01$ ), HDL ( $55 \pm 19$  to  $59 \pm 23$  mg/dl,  $p < 0.01$ ) and triglycerides ( $140 \pm 69$  to  $168 \pm 107$ ,  $p = 0.04$ ), and no significant changes in weight, BMI, low density lipoprotein (LDL) and AI were found. Significantly higher adiponectin levels ( $5.59 \pm 2.39$  vs.  $3.75 \pm 1.63$  ng/ml,  $p < 0.0001$ ), lower resistin levels ( $16.25 \pm 7.17$  vs.  $21.53 \pm 8.19$  pg/ml,  $p = 0.007$ ) and leptin/adiponectin ratio ( $6.44 \pm 6.44$  vs.  $5.52 \pm 6.08$ ,  $p = 0.03$ ) were measured in the RA group compared to controls after adjustment to BMI and statin treatment. Four months after TCZ treatment a statistically significant decrease in adiponectin ( $4.53 \pm 2.12$  ng/ml  $p < 0.0001$ ), resistin levels ( $20.42 \pm 8.06$  pg/ml,  $p = 0.01$ ) and leptin/adiponectin ratio ( $7.99 \pm 7.84$ ,  $p = 0.002$ ) were measured after adjustment to BMI, statin treatment and disease duration. The levels of hsCRP decreased significantly

( $3.37 \pm 2.0$  vs  $0.74 \pm 1.36$  mg/dl,  $p < 0.001$ ) and IL-6 increased significantly ( $13.15 \pm 25.43$  vs  $99.80 \pm 97.97$  pg/ml,  $p < 0.001$ ) following treatment.

**Conclusions:** The impact of TCZ treatment on lipid metabolism is complex. The elevation in HDL without change in AI, and the tendency toward normalisation of the adipokine profile observed, suggests a protective role of TCZ treatment against the cardiovascular burden in RA patients.

THU0198

#### IMMUNOGENICITY ASSOCIATED WITH A TRANSITION FROM ADALIMUMAB REFERENCE PRODUCT TO ABP 501 IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Krishnan, D. Mytych, N. Zhang, H. Wang, A. Kaliyaperumal. *Biosimilars Development, Amgen Inc., Thousand Oaks, USA*

**Background:** In clinical practice, patients treated with an originator product may be transitioned to a biosimilar. Therefore, it is important to ensure that such transition is safe and is not associated with increased immunogenicity.

**Objectives:** To study the incidence of binding anti-drug antibodies (bADAs) and neutralising anti-drug antibodies (nADAs) after patients with rheumatoid arthritis (RA) are transitioned from adalimumab reference product (RP) to ABP 501, an approved biosimilar for adalimumab.

**Methods:** We analysed data from the open-label extension (OLE) of a randomised 26 week phase 3 study (NCT 01970475) comparing ABP 501 and adalimumab. In this OLE study (NCT02114931), patients originally randomised to ABP 501 in the parent study continued on ABP 501 while patients originally randomised to adalimumab (RP) were switched to ABP 501 so that all patients received ABP 501. Specifically, we studied the incidence of new ADAs in patients who were ADA negative at the time of entry into the OLE study. The incidence after excluding transiently elevated ADAs was also examined.

**Results:** The Table summarises the incidence of ADAs.

**Abstract THU0198 – Table 1**

Original randomization arm	ABP 501/ ABP 501	Adalimumab RP/ ABP 501
Number of patients with negative bADA at OLE baseline	147	149
New cases of +bADA post OLE baseline	50	35
New cases of +nADA post OLE baseline	20	12
Transient cases of +bADA	33	13
Transient cases of +nADA	8	2
Overall incidence of new cases of +bADA	34.0%	23.5%
Overall incidence of new cases of +nADA	13.6%	8.1%
Incidence of non-transient cases of +bADA	11.6%	14.8%
Incidence of non-transient cases of +nADA	8.2%	6.7%

**Conclusions:** Transitioning from adalimumab reference product to ABP 501 was not associated with increased immunogenicity over the observational period of 72 weeks.

#### A PILOT STUDY TO ASSESS THE RELATIONSHIP BETWEEN SMOKING AND DRUG INEFFECTIVITY IN RHEUMATOID ARTHRITIS – PART OF A QUALITY IMPROVEMENT PROJECT AIMED AT SMOKING CESSATION

G. Starritt, D. Brennan. *Rheumatology, Musgrave Park Hospital, Belfast Health and Social Care Trust, Belfast, UK*

**Background:** It has long been known that patients with rheumatoid arthritis who smoke have more severe disease. This results in greater joint destruction and disability, and further increase in cardiovascular risk<sup>1</sup>. Patients' disease may be more difficult to control with disease modifying anti-rheumatic drugs (DMARDs) and biologic drugs. Smoking may also interfere with the pharmacokinetics of biologic

drugs<sup>2</sup>. Clinicians could then cycle through more of these expensive drugs because of inefficacy. As a modifiable risk factor smoking should be targeted to improve outcomes for patients.

**Objectives:** To complete a pilot study examining for an association between smoking and drug inefficacy in rheumatoid arthritis. This baseline data was used in a quality improvement project aimed at reducing the prevalence of smoking in our rheumatology patients.

**Methods:** We identified patients using a dataset and a database including all patients currently receiving biologics in Musgrave park hospital. Each patient had a diagnosis of rheumatoid arthritis and was being treated with a biologic. We randomly selected 100 patients with rheumatoid arthritis, 50 of whom were current smokers and 50 non-smokers. We then performed a search on Northern Ireland's electronic care record for each patient and identified how many DMARDs and biologics were discontinued due to inefficacy. Inefficacy was defined as ongoing synovitis despite receiving the drug at adequate dosage for 3–6 months resulting in the drug being discontinued. We also identified patients who received rituximab and the number of patients for which it was stopped due to inefficacy.

**Results:** DMARDs and inefficacy: non-smokers had on average 0.98 stopped and smokers had on average 2.2 stopped. Biologics and inefficacy: non-smokers had on average 0.5 stopped and smokers had on average 0.82 stopped. Twenty smokers and twenty non-smokers were treated with rituximab. Non-smokers: 4 out of 20 had rituximab discontinued due to inefficacy. Smokers: 8 out of 20 had rituximab discontinued due to inefficacy.

**Conclusions:** In this small sample of patients, we found that smokers had greater DMARD and biologic inefficacy, particularly with rituximab where smokers had double the rate of inefficacy compared to non-smokers. Our quality improvement project aims to reduce the prevalence of smoking in our rheumatology patients which could result in better disease control, reduction in cardiovascular risk, and less drugs being cycled through. Aiming to achieve this, steps have been taken to set up a rheumatology smoking cessation clinic in our health trust.

#### SUBCUTANEOUS TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS; A HIGH NUMBER OF PATIENTS ACHIEVE DOPPLER REMISSION AFTER 24 WEEKS

H.B. Hammer<sup>1</sup>, I.M.J. Hansen<sup>2</sup>, P. Jarvinen<sup>3</sup>, M. Leirisalo-Repo<sup>4</sup>, M. Ziegelsch<sup>5</sup>, B. Agular<sup>6</sup>, L. Terslev<sup>7</sup>. <sup>1</sup>Dept Of Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; <sup>2</sup>Dept of rheumatology, Svendborg Hospital, Svendborg, Denmark; <sup>3</sup>Dept of rheumatology, Kiljavan Lääketutkimus, Kiljavan; <sup>4</sup>Dept of rheumatology, Helsinki University Hospital and University, Helsinki, Finland; <sup>5</sup>Dept of rheumatology, University Hospital, Linköping, Sweden; <sup>6</sup>Med.dept, Roche; <sup>7</sup>Centre for Rheumatology and Spinal Diseases, Copenhagen University Hospital at Glostrup, Copenhagen, Denmark

**Background:** Clinical remission in rheumatoid arthritis (RA) is evaluated by Composite Disease Activity Scores (CDAS) including DAS28 and CDAI. Ultrasound (US) is more sensitive than clinical examination for detection of synovitis and assessed by use of Grey Scale (GS) and vascularisation by power/colour Doppler.

**Objectives:** To explore the number of patients reaching Doppler compared to CDAS remission in moderate to severe biologically naïve RA patients (pts) treated with subcutaneous tocilizumab (TCZ-SC) over 24 weeks and to evaluate the safety of TCZ-SC.

**Methods:** A regional multi-country (Denmark, Finland, Norway, Sweden) open-label, single-arm study (part of TOZURA<sup>1</sup>), enrolled pts with inadequate response to csDMARDs. Pts received TCZ-SC 162 mg qw for 24 weeks as monotherapy or in combination with a csDMARD. Stable oral NSAIDs and corticosteroids (CS) ( $\leq 10$  mg/day prednisone or equivalent), were allowed. Clinical (tender and swollen joints), laboratory tests, safety assessments as well as US examination (36 joints and 4 tendons, scored according to the Norwegian US atlas<sup>2</sup>) were performed at baseline, 4, 12 and 24 weeks. US reliability between centres was assessed prior to the study. There is no consensus on definitions of Doppler remission, and Doppler sum scores of 0 to 3 were presently explored as definitions of US remission. CDAS and EULAR/ACR Boolean remission were calculated.

**Results:** 133 pts were included, and 110 pts were followed with US assessments (83% female, mean (SD) age 55.6 (12.1) years and RA duration 8.7 (9.5) years, 81% anti-CCP positive and 62% with erosive disease). All clinical, laboratory and US variables decreased significantly, already after 4 weeks ( $p < 0.001$ ) (table 1). Table 2 illustrates the high percentages of patients reaching remission, especially for DAS28(ESR) and Doppler. Fourteen serious AE were reported in 12 pts and 15 AEs led to permanent withdrawal of treatment.

	Baseline Median (IQR) n=110	4 weeks Median (IQR) n=102	12 weeks Median (IQR) n=95	24 weeks Median (IQR) n=91
DAS28(ESR)	5.0 (4.3–5.8)	3.1 (2.1–3.8)	2.1 (1.5–2.9)	1.6 (1.1–2.4)
CDAI	23.8 (17.1–31.2)	12.9 (7.3–21.9)	7.2 (3.6–11.4)	4.3 (1.8–9.8)
CRP	5.5 (2.6–13.1)	0.2 (0.2–0.4)	0.2 (0.2–0.6)	0.2 (0.2–0.4)
ESR	21 (12–34)	4 (2–7)	3 (2–5)	3 (2–5)
Patient's global VAS (0–100)	55 (36–70)	32 (18–49)	16 (7–31)	12 (4–28)
Assessor's global VAS (0–100)	35 (25–49)	17 (11–31)	10 (5–18)	5 (2–11)
Tender joint count	8 (5–12)	4 (1–9)	2 (0–5)	1 (0–3)
Swollen joint count	6 (2–10)	2 (0.5–6)	1 (0–2.5)	0 (0–2)
Sum score GS	21 (13–36)	16 (8–30)	12 (5–21)	9 (3–19)
Sum score PD	8 (2–20)	4 (1–10)	1 (0–4)	0 (0–2)
<b>Remission criteria</b>		<b>Percentages of Pts in remission at 12 weeks</b>	<b>Percentages of Pts in remission at 24 weeks</b>	
CDAI		19.2	34.7	
DAS28(ESR)		64.6	83.5	
Boolean		14.0	27.4	
PD sum score=0		42.6	53.3	
PD sum score $\leq 1/\leq 2/\leq 3$		60.6/68.1/73.4	65.6/75.6/78.9	

**Conclusions:** This open label study showed TCZ-SC to significantly reduce inflammation assessed by both CDAS and Doppler US. A high number of pts (53%–79%) obtained Doppler remission at 24 weeks using the different definitions. The safety profile was similar to what has previously been reported.

#### A POOLED ANALYSIS OF THREE TNF-A INHIBITOR BIOSIMILAR STUDIES IN PATIENTS WITH RHEUMATOID ARTHRITIS COMPARING RADIOGRAPHIC PROGRESSION BY DISEASE ACTIVITY STATES

J.S. Smolen<sup>1</sup>, M. Weinblatt<sup>2</sup>, P. Emery<sup>3</sup>, E. Keystone<sup>4</sup>, M. Genovese<sup>5</sup>, G. Myung<sup>6</sup>, E. Hong<sup>6</sup>, I. Baek<sup>6</sup>, S. Lee<sup>6</sup>, J. Ghil<sup>6</sup>. <sup>1</sup>Medical University of Vienna, Vienna, Austria; <sup>2</sup>Brigham and Women's Hospital, Boston, USA; <sup>3</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds, UK; <sup>4</sup>Mount Sinai Hospital, Toronto, Canada; <sup>5</sup>Stanford University Medical Center, Stanford, USA; <sup>6</sup>Samsung Bioepis Co., Ltd., Incheon, Korea, Republic of Ireland

**Background:** SB4, SB2, and SB5 are biosimilars of the reference etanercept (ETN), infliximab (INF), and adalimumab (ADA), respectively. Radiographic progression using the modified Total Sharp Score (mTSS) at week 0 and final week (week 52 for etanercept and adalimumab and week 54 for infliximab) was measured in phase III randomised, double-blind studies comparing efficacy and safety of biosimilar to its reference product.

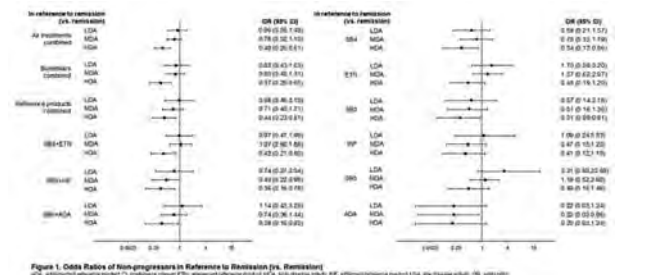

**Objectives:** Assess and compare radiographic progression by disease activity states at week 24 (for etanercept and adalimumab) or week 30 (for infliximab) in terms of DAS28 from a pooled analysis of three biosimilar studies.<sup>1–3</sup>

**Methods:** Patients with radiographic data from each phase III study were pooled and grouped based on their disease activity state (remission, low disease activity [LDA], moderate disease activity [MDA], and high disease activity [HDA]) at week 24 or 30 in terms of DAS28. The mean change in mTSS and the proportion of radiographic non-progressors of higher disease activity groups (LDA, MDA, and HDA) in reference to remission were summarised descriptively and odds ratios (OR) were compared using 95% confidence interval (CI) obtained from logistic model with baseline DAS28.

**Results:** A total of 1263 patients from phase III studies had radiographic assessment available and the results are summarised in table 1. Across all treatment groups, radiographic progression was the highest in HDA followed by MDA, LDA, and remission. In all treatments combined, the mean change in mTSS was 0.03, 0.38, 0.27, and 1.27 and the proportion of non-progressors was 79.7% (181/227), 78.1% (125/160), 74.1% (473/638), 58.4% (139/238) in remission, LDA, MDA, and HDA groups, respectively. In all treatments combined, compared to remission group, the estimated difference in mTSS was greater in HDA (1.15, 95% CI: 0.63–1.66) than MDA (0.20, 95% CI: –0.22–0.62) and LDA (0.36, 95% CI: –0.20–0.91) groups and the OR of the proportion of the non-progressors was the smallest in HDA (OR 0.40, 95% CI: 0.26–0.61) followed by MDA (OR 0.76, 95% CI: 0.52–1.10) and LDA (OR 0.90, 95% CI: 0.55–1.49) (figure 1). This trend was similarly observed in other treatment groups.

**Abstract THU0201 – Table 1.** Summary of Change in Mean mTSS and a Proportion of Non-progressors

Treatment	Change in mTSS Mean±SD	Non-progressors n/n (%)
All Treatments Combined	0.43±2.78	918/1263 (72.7%)
Biosimilars Combined	0.33±2.40	523/702 (74.5%)
Reference Products Combined:	0.55±3.18	395/561 (70.4%)
SB4+ETN	0.59±2.94	324/477 (67.9%)
SB2+INF	0.38±2.83	313/422 (74.2%)
SB5+ADA	0.28±2.46	281/364 (77.2%)
SB4	0.45±2.50	174/249 (69.9%)
ETN	0.74±3.36	150/228 (65.8%)
SB2	0.38±2.15	157/213 (73.7%)
INF	0.37±3.39	156/209 (74.6%)
SB5	0.17±2.49	192/240 (80.0%)
ADA	0.50±2.40	89/124 (71.8%)

**Abstract THU0201 – Figure 1.** Odds Ratios of Non-progressors in Reference to Remission (vs. Remission)

**Conclusions:** A pooled radiographic assessment data from three different biosimilar studies showed that radiographic progression was greater as disease activity worsened.

Gabay<sup>1,2</sup>. <sup>1</sup>Rheumatology, University Hospitals of Geneva, Geneva; <sup>2</sup>SCQM, Zürich, Switzerland; <sup>3</sup>Diakonhjemmet Hospital, Oslo, Norway; <sup>4</sup>Center of Rheumatic Diseases, University of Medicine and Pharmacy, Bucharest, Romania; <sup>5</sup>Rheumatology, Hospital Clinic Barcelona, Barcelona, Spain; <sup>6</sup>GISEA, University Hospital of Bari, Bari, Italy; <sup>7</sup>ARBITER, Institute of Rheumatology, Moscow, Russian Federation; <sup>8</sup>ROB-FIN Helsinki University Hospital and Helsinki University, Helsinki, Finland; <sup>9</sup>Charles University, Prague, Czech Republic; <sup>10</sup>BioRx.si, University Medical Centre Ljubljana, Ljubljana, Slovenia; <sup>11</sup>Rheumatology Department, Hospital Garcia de Orta, Almada, Portugal; <sup>12</sup>Genentech, South San Francisco, CA, USA; <sup>13</sup>F. Hoffmann-La Roche, Basel, Switzerland

**Background:** Tocilizumab (TCZ) as monotherapy was more efficacious than the TNF inhibitor (TNFi) adalimumab as monotherapy for treatment of rheumatoid arthritis (RA) patients refractory to methotrexate (MTX) or in whom MTX was deemed inappropriate (ADACTA study).<sup>1</sup> However, data are lacking regarding the comparative real life effectiveness of TCZ as monotherapy versus TNFi combined with conventional synthetic DMARDs (csDMARDs).

**Objectives:** To analyse treatment effectiveness by comparing drug retention rates and disease activity level in RA patients naïve to biological DMARDs (bDMARDs) treated with TCZ as monotherapy (TCZ mono) or TNFi combined with csDMARDs (TNFi combo).

**Methods:** We included patients with RA across 10 European registries (TOCERRA collaboration) who were naïve to bDMARDs and received treatment with either TCZ mono or TNFi combo from 2009 to 2016. Drug retention rate was analysed using a Kaplan–Meier model. The proportions of patients reaching CDAI low disease activity (LDA) and remission after one year were adjusted for attrition with the LUNDEX index.<sup>2</sup>

**Results:** A total of 6315 patients were eligible, 253 on TCZ mono and 6062 on TNFi combo. Patients with TCZ mono were younger, smoked less, and used less glucocorticoids at baseline compared with TNFi combo patients (table 1). The crude median retention was 2.8 years (95% CI: 2.0–3.3) and 2.0 years (95% CI: 1.8–2.1) for TCZ mono and TNFi combo, respectively (p=0.21). At 1 year, the rates of LUNDEX corrected CDAI LDA (CAI ≤10) and remission (CAI ≤2.8) were similar between both groups (figure 1). The results were unchanged when considering the type of combination with csDMARDs and the dosage of MTX.

**Abstract THU0202 – Table 1.** Baseline characteristics

	TCZmono (n=253)	TNFi combo (n=6062)	p
Age, yr (median [IQR])	54.7 [45.1; 62.6]	59.1 [48.0; 66.0]	<0.001
Female gender, n (%)	202 (80.2%)	4715 (77.8%)	0.42
Ever smoker, n (%)	23 (15.8%)	1254 (26.3%)	0.006
Disease duration, yr (median [IQR])	5.6 [2.1; 12.5]	5.4 [1.9; 11.4]	0.44
Seropositivity (RF and/or ACPA), n (%)	158 (80.2%)	4158 (81.5%)	0.72
Glucocorticoids, n (%)	56 (22.1%)	2932 (48.4%)	<0.001
GC dose mg/day	5.0 [5.0; 7.5]	5.0 [5.0; 10.0]	0.02
Concomitant csDMARD, n (%)			
MTX		3528 (58.2%)	
MTX+other csDMARDs		1377 (22.7%)	
Other csDMARDs than MTX		1157 (19.1%)	
Route of administration, n (%)			<0.001
Intravenous	154 (80.6%)	441 (13.3%)	
Subcutaneous	37 (19.4%)	2870 (86.7%)	

**Abstract THU0202 – Figure 1.** Patients in LUNDEX corrected CDAI or low disease activity (LDA) at 1 year

**Conclusions:** In routine care across 10 European countries, the retention and proportion of RA patients in LUNDEX corrected CDAI LDA and remission at 1 year were similar if treated with TCZ mono or TNFi combo.

#### THU0203 COMPARISON OF THE RETENTION RATE OF BIOLOGICAL DMARDS ~ THE DATA FROM PATIENTS WITH RA WHO WERE FOLLOWED UP FOR OVER 10 YEARS

K. Fukuda<sup>1</sup>, T. Matsubara<sup>2,3</sup>, K. Funahashi<sup>2,3</sup>, T. Itami<sup>2</sup>, K. Okuda<sup>2</sup>, S. Hayashi<sup>1</sup>, Y. Sakai<sup>4</sup>, R. Kuroda<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Kobe University Graduate School of Medicine, Kobe, Japan, Kobe; <sup>2</sup>Matsubara mayflower hospital, Kato; <sup>3</sup>Research Institute of Joint Disease; <sup>4</sup>Division of Rehabilitation Medicine, Kobe University Graduate School of Medicine, Kobe, Japan, Kobe, Japan

**Background:** The use of biological disease modifying anti-rheumatic drugs (bDMARDs) or synthetic DMARDs for the treatment of rheumatoid arthritis (RA) has improved the management of RA and prevented patients with RA from joint destruction. However, there are some cases in which it is difficult to continue the treatment with these medicines due to insufficient therapeutic effect or complications. In Japan, 8 of bDMARDs and 2 of synthetic DMARDs can be used for the treatment of RA. Among them, infliximab (INF) and etanercept (ETN) were applied for RA treatment in 2003 and 2005, respectively, and have been utilised for more than 10 years. Although adalimumab (ADA) and tocilizumab (TCZ) were applied in 2008, RA treatment by ADA and TCZ had been conducted by clinical trials since 2003, and they have also been utilised for more than 10 years.

**Objectives:** In this study, we evaluated the retention rate of these 4 bDMARDs (INF, ETN, ADA, and TCZ) for over 10 years.

**Methods:** RA patients who started the treatment with INF, ETN, ADA, or TCZ before 2007 in Matsubara mayflower hospital and were observed for over 10 years were included in this study. INF was used in the treatment for 111 patients with RA, and 95 out of them were observed for over 10 years (INF group). 95 out of 119 RA patients treated with ETN (ETN group), 24 out of 27 RA patients treated with ADA (ADA group), and 21 out of 25 RA patients treated with TCZ (TCZ group) were included in this study. Kaplan-Meier analysis was applied to determine the differences in the retention rate of these bDMARDs.

**Results:** Kaplan-Meier analysis showed no statistically significant difference in the retention rate of these bDMARDs. The retention rate of INF group and TCZ group decreased with time and was 10.5% and 33.3% at the final survey in November 2017, respectively. That of ETN group and ADA group plateaued at 9 years after the start of treatment and was 22.1% and 8.33% at the final survey, respectively.

**Conclusions:** In this study, there was no statistically significant difference in the retention rate of these bDMARDs. The retention rate of over 10 years was the highest in TCZ group and the lowest in ADA group. The rate of INF group and TCZ group continued to decrease, and that of ETN group and ADA group was almost constant after 9 years from the start of treatment.

#### THU0204 REAL WORLD EXPERIENCE OF BIOSIMILAR SWITCHING AT THE NORFOLK & NORWICH UNIVERSITY HOSPITAL, UNITED KINGDOM

L. Steel<sup>1</sup>, T. Marshall<sup>2,3</sup>, M. Loke<sup>2</sup>. <sup>1</sup>Rheumatology, Mid Essex Hospitals NHS Trust, Chelmsford; <sup>2</sup>Rheumatology, Norfolk and Norwich University Hospital; <sup>3</sup>Honorary Senior Lecturer, University of East Anglia, Norwich, UK

**Background:** Tumour Necrosis Factor (TNF) inhibitors are routinely used in managing rheumatoid arthritis (RA), psoriatic arthritis (PsA) and spondyloarthritis (SpA). In 2012 and 2015, the patents for the Etanercept (ETN) and Infliximab (IFX) originator molecules expired in Europe respectively and the use of biosimilar ETN and IFX was approved for use in England.

**Objectives:** To determine the proportion of rheumatology patients who experienced a flare of their disease following a switch from originator to biosimilar IFX or ETN and in those who flared, to determine whether disease control can be re-captured following reverting to the originator product.

**Methods:** This was a retrospective study of all patients switched from their originator IFX or ETN to their corresponding biosimilar product between July 2016 and July 2017 at a UK tertiary rheumatology centre. A total of 475 patients were identified by our Biologics team. Seventeen patients experienced a flare defined by: an increase in Disease Activity Score (DAS)28 > 1.2 points in RA, worsening of any of the Psoriatic Arthritis Response Criteria (PsARC) in PsA, an increase in Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) of at least 1 unit in SpA, and worsening of swollen and tender joint count in our patient with adulthood juvenile idiopathic arthritis (JIA). Follow-up at 3 months determined disease re-capture, defined by an improvement in DAS28 score > 1.2 units, improvement in at least two of the PsARC, one to be tender or swollen joint score, an improvement of BASDAI score and improved swollen and tender joint count in our patient with adulthood JIA.

#### Results:

	Diagnosis	Flare	Re-capture of disease control following switch back to originator	Side effects
<b>INFLIXIMAB</b>				
	RA	4/63 (6.3%)	1/4 (25.0%)	1/63 (1.6%)
	PsA	2/15 (13.3%)	0/2	0
	SpA	2/19 (10.5%)	1/2 (50.0%)	1/19 (5.3%)
	JIA	1/1 (100%)	1/1 (100%)	0
<b>ETANERCEPT</b>				
	RA	4/238 (1.7%)	4/4 (100%)	6/238 (2.5%)
	PsA	1/55 (1.8%)	1/1 (100%)	2/55 (3.6%)
	SpA	3/84 (3.6%)	2/3 (66.7%)	2/84 (2.4%)

Nine patients (9.2%) who switched to biosimilar IFX flared: four with RA, two with PsA, two with SpA and one with JIA. Of those, three patients (33.3%) were able to re-capture disease control on switching back to originator IFX. Two patients (2.0%) experienced side effects on switching to biosimilar IFX.

Eight patients (2.1%) experienced a flare on switching to biosimilar ETN: four with RA, one with PsA and three with SpA. Of those, seven patients (87.5%) re-captured disease control on switching back to originator ETN. Ten patients (2.7%) experienced side effects on switching to biosimilar ETN.

**Conclusions:** The majority of our patients did well following the switch to biosimilar IFX and ETN.

Patients who did flare on biosimilar ETN are more likely to re-capture their disease control than those who flared on biosimilar IFX.

This adds to real-world evidence to support the European League Against Rheumatism recommendations to utilise biosimilar therapy in rheumatology practice, which is likely to include patients who differ from those enrolled in clinical trials; important when considering health economy implications.

**THU0205 THE EFFECT OF CERTOLIZUMAB DRUG CONCENTRATION AND ANTI-DRUG ANTIBODIES ON TNF NEUTRALISATION**

L.C. Berkhout<sup>1</sup>, E.H. Vogelzang<sup>2</sup>, M.H. Hart<sup>1</sup>, N.I. Derksen<sup>1</sup>, R. Wieringa<sup>3</sup>, W. A. van Leeuwen<sup>3</sup>, C.L. Kriekkaert<sup>2</sup>, A. de Vries<sup>3</sup>, M.T. Nurmohamed<sup>2,4</sup>, G. Wolbink<sup>1,2</sup>, T. Rispen<sup>1</sup>. <sup>1</sup>Department of Immunopathology, Sanquin Research; <sup>2</sup>Amsterdam Rheumatology and Immunology Center, Reade; <sup>3</sup>Biologics Lab, Sanquin Diagnostic Services; <sup>4</sup>Amsterdam Rheumatology and Immunology Center, VU University Medical Center, Amsterdam, Netherlands

**Background:** Although tumour necrosis factor- (TNF) inhibitors have proven to be a successful treatment option for patients with rheumatoid arthritis (RA), TNF-inhibitors, including certolizumab, elicit an immunogenic response leading to the formation of anti-drug antibodies (ADAs) (reported range ~5%–39% of the patients).

**Objectives:** We sought to investigate the relationship between certolizumab concentrations, ADAs, and the effective TNF neutralising capacity in sera of RA patients. TNF neutralising capacity of certolizumab was compared to the neutralising capacity of adalimumab.

**Methods:** Blood was collected of 35 consecutive certolizumab-treated RA patients at baseline and 4, 16, 28 and 52 weeks after treatment initiation. Certolizumab and ADA levels were quantified using a certolizumab bridging enzyme-linked immunosorbent assay (ELISA) and a drug-tolerant radioimmunoassay (RIA), respectively. TNF neutralisation of certolizumab and adalimumab in patient sera, in presence or absence of ADAs, was analysed using the TNF-sensitive WEHI bioassay.

**Results:** Despite a high incidence of ADAs during one year of follow-up (69%; 24/35 patients), certolizumab levels of ~>10 µg/mL were measured in most patients (Spearman's  $r = -0.7155$ ,  $p < 0.0001$  ( $n = 118$ ); **figure 1A**). Furthermore, TNF neutralisation, expressed by EC50 values, was highly correlated with certolizumab serum concentration, while there was no association with ADAs (Pearson  $r = 0.9087$ ,  $p < 0.0001$  ( $n = 12$ ) and Pearson  $r = -0.4712$ ,  $p = 0.1220$  ( $n = 12$ ); **figure 1B and C**, respectively). Grey lines indicate log-log linear fit, weight by  $1/Y^2$ ). Similar results were obtained for adalimumab, although TNF neutralisation by adalimumab was less potent; the relative *in vitro* neutralising potency was 43 times higher for certolizumab compared to the neutralising potency of adalimumab.

**Conclusions:** Our study shows that certolizumab is highly immunogenic. In most cases where ADAs are detected, certolizumab is also present in high amounts, and can still potently neutralise TNF. Furthermore, TNF neutralisation is highly correlated with certolizumab concentrations. Therefore, measurement of certolizumab concentrations is the relevant parameter to assess clinically relevant immunogenicity.

**THU0206 ADD-ON SHORT-COURSE TOCILIZUMAB ACCELERATES DOSE TAPERING OF GLUCOCORTICOIDS IN RHEUMATOID ARTHRITIS: RESULTS FROM A CHINESE PROSPECTIVE COHORT STUDY**

J.-W. Wang<sup>1</sup>, Y.-Q. Mo<sup>1</sup>, X.-Y. Wang<sup>2</sup>, L.-F. Chen<sup>1</sup>, J.-D. Ma<sup>1</sup>, J.-Z. Lin<sup>1</sup>, D.-H. Zheng<sup>1</sup>, L. Dai<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Immunology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, Guangzhou; <sup>2</sup>Department of Rheumatology and Immunology, The First Affiliated Hospital of Zhengzhou University, Zhengzhou, China

**Background:** In real-world clinical practice, self-paid and expensive price limit the application of bDMARDs and only a few patients especially in developing countries could afford long-term use. Only 9.1%>11% of Chinese rheumatoid arthritis (RA) patients were treated with bDMARDs with mean course no more than 6 months. Such short course of bDMARDs had always been raised doubt about their efficacy and benefit for rare reported evidence.

**Objectives:** To explore the efficacy of additional short-course of Tocilizumab (TCZ) combined with csDMARDs in real-world RA management.

**Methods:** Consecutive patients with active RA (DAS28-ESR>2.6) who had completed 6 month follow-up were retrospectively recruited from a prospective RA cohort ( $n = 582$ ). All patients were treated according to the treat-to-target strategy and patient's willingness especially biologics use. RA patients who finished at least 3 infusions of TCZ (8 mg/Kg/4 weeks) were included as add-on TCZ group, and matched RA patients without any bDMARDs by age, sex and disease activity at baseline with the ratio of 1:1 were included as csDMARDs group. Clinical data were collected according to the 2017 EULAR recommendation at baseline and regular visits at week 4, 12 and 24.

**Results:** (1) The baseline characteristics of 101 paired RA patients showed no significant difference except for lower csDMARDs-naïve percentage between two groups (table 1). (2) During 24 week follow up, there were significantly higher percentage of patients in add-on TCZ group achieving therapeutic target (DAS28-ESR<3.2, at Week 4: 59% vs. 39%,  $p = 0.005$ ; at Week 12: 71% vs. 52%,  $p = 0.006$ , figure 1) or remission (DAS28-ESR<2.6, at Week 4: 46% vs. 16%,  $p < 0.001$ ; at Week 12: 53% vs. 28%,  $p < 0.001$ ) than those in csDMARDs group. Furthermore, there were significantly higher percentage of patients in add-on TCZ group achieving deep remission (DAS28-ESR<1.98, at Week 4: 16% vs. 5%,  $p = 0.015$ ; at Week 12: 28% vs. 9%,  $p = 0.001$ ; at Week 24: 20% vs. 9%,  $p = 0.046$ ). (3) There were 76% RA patients in add-on TCZ group with glucocorticoids (GC) therapy which is significantly lower than that in csDMARDs group (92%,  $p = 0.002$ ). Among patients with GC therapy, the GC dosage per day was tapered more rapidly at each visit and the cumulative dose at week 24 was significantly lower in add-on TCZ group than that in csDMARDs group ( $826 \pm 616$  vs.  $1128 \pm 519$  mg,  $p < 0.001$ ).

**Table 1.** Baseline characteristics of RA patients in add-on TCZ group or csDMARDs group

	Total (n=102)	Add-on TCZ group (n=51)	csDMARDs Group (n=51)	P

**THU0207 FINDING THE OPTIMAL TREATMENT STRATEGY FOR DISEASE ACTIVITY-GUIDED DOSE REDUCTION OF ADALIMUMAB AND ETANERCEPT IN RHEUMATOID ARTHRITIS: A MODELLING STUDY**

L.M. Verhoeff<sup>1</sup>, D.P. Bos<sup>1</sup>, C.H. van den Ende<sup>1,2</sup>, F.H. van den Hoogen<sup>1,2</sup>, B. Fautrel<sup>3</sup>, M.E. Hulscher<sup>4</sup>, W. Kievit<sup>5</sup>, A.A. den Broeder<sup>1,2</sup>. <sup>1</sup>Rheumatology, Sint Maartenskliniek; <sup>2</sup>Rheumatology, Radboudumc, Nijmegen, Netherlands; <sup>3</sup>Rheumatology, Pitié-Salpêtrière Hospital, Paris, France; <sup>4</sup>IQ healthcare, RIHS; <sup>5</sup>Health Evidence, RIHS, Radboudumc, Nijmegen, Netherlands

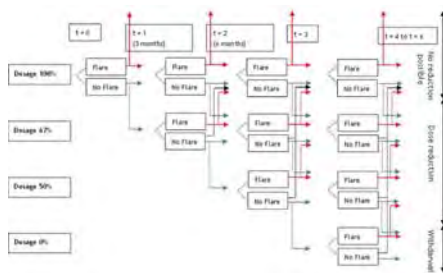

**Background:** Several studies have shown that disease activity-guided dose reduction without deterioration of disease activity is possible, while saving costs in patients with stable and low disease activity.<sup>(1)</sup> Despite these positive results, questions remain on the optimal tapering strategy. Different strategies are conceivable, with varying results regarding the balance between number of flares, utilities and costs.

**Objectives:** The objective of this study was to investigate the most cost-effective TNFi dose reduction strategy for RA patients using a modelling design.

**Methods:** In a cost-utility analysis using Markov modelling based on data from the DRESS study, STRASS study, and the RA Nijmegen cohort, the following strategies were tested against continuation: 1. Four-step DRESS tapering (figure 1: 100%–67%–50%–0%); 2. Tapering with an extra dosage step of 33%; 3. Tapering without withdrawal; 4. Use of a stricter flare criterion (DAS >2.6); and 5. Use of a predictor (biomarker: 80% specific, 80% sensitive, € 100 per test) for successful tapering. Scenario analyses with 30% and 50% drug price discount and no discounting were executed. Also, it was examined how well a biomarker should be able to predict to become cost-effective compared to the other strategies.

**Results:** All examined tapering strategies were found to be cost saving but yielded more short-lived flares compared to continuation (table 1). The change in utilities was minimal and not clinically relevant. Strategy 1 was cost-effective compared to all other strategies (highest incremental Net Monetary Benefit (iNMB)). However, there was a large overlap in credible intervals, especially between strategy 1 and 2. Scenario analyses showed that 50% reduction of drug prices would result in the highest iNMB for strategy 2. A biomarker only becomes cost-effective when it has a sensitivity and specificity of at least 86%.

Data is mean values per patient over 1.5 years (95% credible intervals). \*Stricter flare criterion (DAS28 >2.6). \*\* NMB=QALYs \* WTP/WTA – costs; iNMBs are given at a WTP/WTA of € 80 000.

**Conclusions:** All dose reduction strategies dominated the continuation strategy regarding cost-effectiveness. Because our study showed a comparable iNMB for tapering in four or five steps, we recommend a choice between these strategies, based on shared decision making.

MADRID; <sup>2</sup>Reumatología, Hospital General Hospitalet-Moisès Broggi, Hospitalet Llobregat; <sup>3</sup>Reumatología, Hospital Comarcal de Laredo, Laredo; <sup>4</sup>Reumatología, Hospital Universitario Virgen del Rocío, Sevilla; <sup>5</sup>Reumatología, Complejo Hospital Universitario Lucus Augusti, Lugo; <sup>6</sup>Reumatología, Hospital Universitario del Henares, Coslada; <sup>7</sup>Reumatología, Hospital Germans Trias i Pujol, Badalona; <sup>8</sup>Reumatología, Hospital General Universitario de Elche, Elche, Spain

**Background:** Between 30%–40% of patients with rheumatoid arthritis (RA) dis- continue at their first line biological therapy due to inadequate response or adverse events. There is currently a great controversy about using a second anti- TNF, after failure to the first one, or a therapeutic target change, due to the avail- ability of a wide pharmacological arsenal for patients with RA.

**Objectives:** The objective of this study is to determine the effectiveness and safety during one year of Certolizumab pegol (CZP) in patients with RA in second line (after failed to a previous antiTNF) and compare it with those who received this therapy as first line (bio-naïve).

**Methods:** National, observational, prospective, longitudinal and multicenter study in patients with RA who received CZP as the first line of biological treatment or fail- ure to a previous anti-TNF for lack of efficacy, during one year of follow-up. Demo- graphic and clinical variables were collected (gender, age, disease duration, TJC, SJC, ESR, CRP, DAS28, HAQ), at baseline visit, 3 and 12 months of treatment. As response variables, DAS28 remission, low disease activity by DAS28 (LDA) and EULAR response, were used. The Student t test and the Mann-Whitney U test were used for the statistical analysis and a survival analysis (Kaplan-Meier) was performed

**Results:** A total of 360 patients were included, of which 272 (75.6%) were bio- naïve and 88 (24.4%) previous anti-TNF failure. Baseline characteristics of both groups are shown in table 1. Clinical variables of effectiveness at 3 and 12 months are summarised in table 2. Statistically significant differences in DAS28, HAQ and % patients with corticosteroids were observed in both groups at year of treatment comparing with baseline, even though bio-naïve group had a statistically lower DAS28 and a higher percentage response than the antiTNF failure group. Accord- ing to Kaplan-Meier analysis, similar retention rates were observed independently if CZP were used as first (77.2%) or second line (73.9%). No differences were found in terms of safety at one year of treatment between both groups.

**Conclusions:** This study, derived from the experience of national clinical practice with CZP, demonstrates the effectiveness and safety of this drug in patients with RA regardless of its use in the first line or after failure to a previous antiTNF, with better response scores in bio-naïve patients. No differences were observed in the retention rate in both groups.

#### THU0209 4 YEARS FOLLOW-UP OF A COHORT OF PATIENTS WITH RHEUMATOID ARTHRITIS IN SUSTAINED CLINICAL REMISSION AND OPTIMISATION OF BIOLOGICAL THERAPY

M.L. Ladehesa Pineda<sup>1,2,3</sup>, M.C. Castro Villegas<sup>1,2,3</sup>, M. Romero Gómez<sup>1,2,3</sup>, L. Bautista Aguilar<sup>1,2,3</sup>, C. López Medina<sup>1,2,3</sup>, L. Pérez Sánchez<sup>1,2,3</sup>, I. Gómez García<sup>1,2,3</sup>, P. Carreto Font<sup>4</sup>, A. Escudero Contreras<sup>1,2,3</sup>, E. Collantes Estévez<sup>1,2,3</sup>, P. Font Ugalde<sup>2,3</sup>. <sup>1</sup>Rheumatology, Hospital Universitario Reina Sofía of Córdoba; <sup>2</sup>IMBIC, <sup>3</sup>Universidad de Córdoba, Córdoba; <sup>4</sup>Centro de Salud Tudela de Duero. Área Este de Valladolid, Valladolid, Spain

**Background:** The objectives of Rheumatoid Arthritis (RA) treatment comprise achieving persistent Clinical Remission (CR) or sustained low clinical activity. Nowadays management follows a “treat to target” strategy based on adjustment of treatment in accordance with protocols. In patients with persistent disease activity after treatment with at least two of the classic disease-modifying antirheumatic drugs the use of biological therapy is recommended. Once sustained CR is achieved, the most efficient strategy is optimisation, by tapering the dose of the biological therapy or by increasing administration intervals. Searching for the lowest effective dose for each patient could minimise the risk of adverse effects and improve the cost-effectiveness of RA treatment.

**Objectives:** To prove that the performance of an optimisation strategy in patients with RA and sustained CR under biological treatment maintains the proportion of patients with DAS28 ≤2.6 after 4 years, to assess the maintenance of the effectiveness of the optimisation at 4 years in terms of clinical manifestations, and to analyse the time until relapse.

**Methods:** An open observational prospective study that included 70 patients with RA (CREATE registry) in CR at least for 6 months, under treatment with tapered dose of biological therapy (TNFi, abatacept or tocilizumab). Treatment effectiveness was assessed with the main variable DAS28 ≤2.6. Statistical analysis included a descriptive study of variables and a confidence interval of 95% (95% CI) was estimated. For bivariate analysis, we used Student t-test for independent samples, repeated measures analysis of variance and mixed analysis of variance, and as a post-hoc contrast, Sidak adjustment. The log-rank test was used to compare the time until relapse according to the biological therapy.

**Results:** The mean age of the patients was 56,9 (13,7) years, 78,6% were women, 68,8% were rheumatoid factor (RF) positive and 66,7% ACPA positive; the mean DAS28 at the beginning of the optimisation was 2,24 (0,73). After 4 years, 27,7% (95%CI:16,82%–38,58%) of patients maintained CR with the optimised dose, with a DAS28 2,15 (0,81). Through the first year, the percentage of relapses was 15,71%, in the second year, 7,35% and 4,61% relapsed during the third year. The median time of optimisation until relapse was 13,83<sup>3,18</sup> months (95% CI:7,6–20,06). No significative differences were found at comparing the survival curves of the optimised patients until relapse for 4 years according to the biological therapy (TNFi vs no TNFi) (log-rank test:0,865, p:0,352) (graphic).

**Conclusions:** After 4 years, all of the patients maintained DAS28 levels of low disease activity, including those who had suffered a previous relapse and had turned back to the previous dose of biological treatment. In view of this outcomes, optimisation strategy in clinical practice is possible and effective in patients with persistently controlled RA.

#### THU0210 SAFETY, TOLERABILITY AND EFFICACY OF SUBCUTANEOUS TOCILIZUMAB ADMINISTERED AS MONOTHERAPY OR IN COMBINATION WITH CSDMARDS IN RHEUMATOID ARTHRITIS: RESULTS FROM THE OSCAR STUDY

M. Sañy<sup>1</sup>, M.J. De Hair<sup>1</sup>, M.E. Born<sup>2</sup>, M.R. Kok<sup>3</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht; <sup>2</sup>Roche, Woerden; <sup>3</sup>Rheumatology and Clinical Immunology, Maastradziekenhuis, Rotterdam, Netherlands

**Background:** Efficacy and safety of intravenously (IV) administered tocilizumab (TCZ) in rheumatoid arthritis (RA) has been shown. Recently, efficacy and safety was confirmed for subcutaneous (SC) administration of TCZ.<sup>1</sup> The possible effects of SC TCZ upon tapering of GCs/NSAIDs has not been investigated.

**Objectives:** First, to establish the safety and efficacy of SC TCZ monotherapy or in combination with csDMARDs in DMARD-IR RA. Second, to assess GC/NSAID dose reduction and/or discontinuation under SC TCZ treatment.

**Methods:** The OSCAR study was a Dutch multicenter, open-label, single arm phase IV study within the phase 4 TOZURA program.<sup>1</sup> RA patients with an inadequate response (IR) to csDMARDs and 1 bDMARD were treated with weekly SC

Abstract THU0208 – Table 2. Effectiveness of CZP. Comparing at 12 months bionaive and bioexperience groups

	Baseline		3 months		12 months		P
	Bionaive	Bioexperience (after antiTNF failure)	Bionaive	Bioexperience (after antiTNF failure)	Bionaive	Bioexperience (after antiTNF failure)	
HAQ, mean (SD)	1.2 (±0.7)	1.2 (±0.7)	1.1 (±0.7)	1.1 (±0.7)	0.9 (±0.6)	0.9 (±0.7)	0.925
DAS28, mean (SD)	4.7 (±1.1)	4.7 (±1.1)	3.5 (±1.3)	3.7 (±1.2)	3.0 (±1.3)	3.4 (±1.3)	0.011
Corticosteroids (yes), %	72.8	63.6	61.8	56.8	43.8	45.5	0.780
DAS28 remission,%	-	-	25.2	17.9	45.5	32.1	0.031
DAS28 LDA,%	-	-	43.6	31.0	61.7	45.2	0.008
EULAR Response,%	-	-	60.2	54.8	77.1	64.3	0.020

injections of TCZ monotherapy or in combination with csDMARDs up to 24 weeks. From week 16 onwards dose reduction and/or discontinuation of glucocorticoids (GC) and NSAIDs was allowed. Primary endpoints were occurrence of adverse events (AEs), serious AEs (SAEs) and AEs of special interest (AESI). Secondary endpoints were time to GC/NSAID dose reduction and/or discontinuation, and DAS28 (remission), ACR 50 response, EULAR response, SDAI, CDAI and HAQ-DI. Occurrence of AEs was analysed using descriptive statistics. Changes over time in efficacy endpoints and response rates were analysed using Wilcoxon test. **Results:** Of the 150 patients 121 (81%) patients completed the treatment period. In 91% of the patients there was  $\geq 1$  AE, in 9% an SAE, and in 4% an AESI. Most AEs were mild or moderate in intensity and resolved without sequelae. Permanent TCZ treatment discontinuations due to AEs occurred in 7% of the 150 patients; of these, five patients were prematurely withdrawn from the study due to AEs. From week 16 onwards, 8 (5.3%) and 13 (8.7%) patients discontinued or reduced (for any reason) the dose of NSAIDs or GCs, respectively. Between weeks 16 and 20, 2 (1.3%) patients discontinued or reduced the dose of NSAIDs due to safety and other reasons. The dose of GCs was discontinued or reduced in 3 patients (2.0%) between weeks 16 and 20, and in another 3 between weeks 20 and 24 (2.0%), in all 6 patients mainly due to safety reasons (1.3%), while NSAIDs dosage remained stable. The safety profile observed in this trial was in line with the known TCZ safety profile. Efficacy parameters improved over time for all of the endpoints. A selection of these results is shown in table 1.

Abstract THU0210 – Table 1. Efficacy results

Table. Efficacy results.

Week 24	3.2 (-0.06, -7.57)	
<b>DAS28 remission, % (n/N)</b>		
Week 4	52.1 (75/144)	
Week 12	77.4 (103/133)	
Week 24	86.8 (105/121)	
<b>ACR 50 response rate, %</b>		P<0.0001
Week 4	21.5	
Week 12	45.1	
Week 24	66.1	
<b>EULAR good response, % (n/N)</b>		P<0.0001
Week 4	59.7 (86/144)	
Week 12	85.0 (113/133)	
Week 24	85.0 (113/133)	
<b>Change from BL in SDAI, median (min, max)</b>		P<0.0001
Week 4	-11.0 (-30.9,8.2)	
Week 12	17.1 (-46.5,16.9)	
Week 24	-19.7 (-53.3,-0.07)	
<b>Change from BL in CDAI, median (min, max)</b>		P<0.0001
Week 4	-9.1 (-30.8,8.3)	
Week 12	-15.1 (-45.1,6.9)	
Week 24	17.3 (-60.2,0.1)	
<b>Change from BL in HAQ-DI, median (min, max)</b>		P<0.0001
Week 4	-0.25 (-1.25,1.13)	
Week 12	-0.38 (-2.13,0.38)	
Week 24	-0.50 (-2.38,0.88)	

DAS28: disease activity score of 28 joints; ACR: American College of Rheumatology; EULAR: European League Against Rheumatism; BL: baseline; SDAI: simple disease activity index; CDAI: clinical disease activity index; HAQ-DI: health assessment questionnaire disease activity; P-values refer to the differences between baseline and week 4, week 12 and week 24 measured per parameter.

The median time of follow-up of the studied population was 822 days, IQR 429–727 days.

**Conclusions:** The OSCAR study showed that SC TCZ is safe, well-tolerated and effective in RA patients with an inadequate response to csDMARDs and max 1 bDMARD. Importantly, a subset of patients could reduce GC and/or NSAID use during SC TCZ treatment. These findings support the notion that SC TCZ can be safely used in clinical practice.

THU0211

#### SIX MONTHS AFTER TREATMENT DISCONTINUATION TNF IS STILL IN COMPLEX WITH ADALIMUMAB

M.J. l'Ami<sup>1</sup>, L.C. Berkhout<sup>2,3</sup>, M.T. Nurmohamed<sup>1,4</sup>, R.F. van Vollenhoven<sup>1,4,5</sup>, M. Boers<sup>4,6</sup>, J. Ruwaard<sup>1</sup>, F. Hooijberg<sup>1</sup>, T. Rispens<sup>2,3</sup>, G. Wolbink<sup>1,3</sup>. <sup>1</sup>Amsterdam Rheumatology and immunology Center, location Reade; <sup>2</sup>Immunopathology, Sanquin; <sup>3</sup>Landsteiner Laboratory, Academic Medical Center; <sup>4</sup>Amsterdam Rheumatology and immunology Center, location VU University Medical Center; <sup>5</sup>Amsterdam Rheumatology and immunology Center, location Academic Medical Center; <sup>6</sup>Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands

**Background:** Many patients with rheumatoid arthritis (RA) are successfully treated with tumour necrosis factor inhibitors (TNFi). We recently developed a novel assay that can quantify TNF in the presence of large amounts of TNFi, i.e. a 'drug-tolerant' assay. We showed in RA patients that TNF levels increased and stabilised during adalimumab treatment due to complex forming between TNF and adalimumab. In the presence of adalimumab, all TNF was in complex and biologically inactive. Once in remission, some patients can discontinue the TNFi for a prolonged period. It is unclear how long adalimumab levels are detectable and TNF complexes are formed after the last adalimumab administration.

**Objectives:** To investigate adalimumab levels and complexed TNF levels 6 months after the last adalimumab administration.

**Methods:** TNF and adalimumab levels were measured using a novel drug-tolerant competition enzyme-linked immunosorbent assay (ELISA), and a regular ELISA, respectively, in 11 consecutive RA patients with stable low disease activity (disease activity score of 28 joints < 3.2) who discontinued adalimumab for 6 months (prior dose: 40 mg every 2 weeks). Blood samples were drawn prior to adalimumab discontinuation and 3 and 6 months thereafter.

**Results:** After the last adalimumab administration, mean adalimumab level decreased from 5.5 (SD 2.9) to 0.55 (0.52) and 0.11 (0.13)  $\mu\text{g/mL}$  at 3 and 6 months after treatment discontinuation, respectively (figure 1A). In contrast, complexed TNF levels remained stable for prolonged periods of time: in 8 patients TNF levels at 3 months were indistinguishable from levels seen at baseline, on standard-dose adalimumab (figure 1B). After 6 months, TNF still remained stable in patients with adalimumab concentrations above 0.1  $\mu\text{g/mL}$  (n=4). Overall, mean TNF levels decreased from median 381 (inner quartiles 16; 707) to 290<sup>2</sup>:<sup>755</sup> and 83<sup>2</sup>:<sup>532</sup>  $\text{pg/mL}$  at 3 and 6 months after treatment discontinuation, respectively. In 5 patients, TNF levels decreased significantly. In those patients, adalimumab levels dropped to, or below the detection limit.

**Conclusions:** This is the first study showing that TNF is still in complex with adalimumab in the majority of patients 6 months after the last administration. Therefore, one may wonder at which point in time a patient has truly discontinued adalimumab treatment.

### THU0212 REINVESTMENT OF BIOSIMILAR SAVINGS: WHAT ARE THE BEST OPTIONS?

M. Martin, R. Campbell, J. Jacob. *Consulting, Syneos Health, London, UK*

**Background:** Biosimilars are becoming available for many of the biologic compounds in rheumatoid arthritis (RA). Biosimilars provide similar benefit at a reduced cost, therefore generating potential savings to the health care system.

**Objectives:** To investigate whether it is most beneficial to reinvest biosimilar savings to treat additional RA patients or whether this same budget would be more beneficially spent on alternative treatments from a UK payer perspective.

**Methods:** We developed a model to first estimate the savings obtained from using biosimilars from a UK National Health Service (NHS) perspective. Then we identified five treatment alternatives, in addition to RA: melanoma, hepatitis C (HepC), multiple sclerosis (MS), Duchenne's disease (MD), and non-small cell lung cancer (NSCLC). These indications were considered because of their burden of illness, high cost but high efficacy treatments being available which are associated with investment pressures. The treatments selected were: ataluren (MD), natalizumab (MS), pembrolizumab (melanoma), crizotinib (NSCLC), sofosbuvir + ribavirin (HepC), and etanercept biosimilar. We estimated the health gain (expressed as QALYs) that could be obtained from treating the patients in the four indications of interest using the available savings to identify the most cost-effective way to spend the savings. Data on QALY gains were obtained from published sources, mostly HTA assessments.

**Results:** Based on a biologics expenditure of ~£430 million, we estimated that ~£5 million in savings would be generated over a 5 year period.

Based on the outcome of QALY maximisation, over a 5 year period, biosimilar savings in the UK are best spent on treatments in hepatitis C, followed by NSCLC and melanoma. Re-investment in an RA biosimilar only came in 5th place, before cystic fibrosis.

**Conclusions:** In a country like the UK, where patients have ready access to biologics, the savings from prescribing biosimilars can be better spent, if QALY maximisation is desired, on non-RA therapies where over a 5 year period more QALYs are generated. On the basis of the research, payers should consider the potential to reinvest biosimilar savings in disease areas with higher QALY yields.

### THU0213 ADHERENCE AND PERSISTENCE TO DISEASE MODIFYING ANTI RHEUMATIC DRUGS IN COLOMBIAN PATIENTS WITH RHEUMATOID ARTHRITIS

N. Pertuz-Charris<sup>1</sup>, F.L. Ochoa-Jaramillo<sup>2</sup>, D. Gil-Calderón<sup>1</sup>, M.A. Alzate-Vinasco<sup>1</sup>, V. Vélez-Marín<sup>1</sup>, D. Hernández-Parra<sup>3</sup>, R. Pineda-Tamayo<sup>1</sup>. <sup>1</sup>*Rheumatology, Artmedica IPS;* <sup>2</sup>*Public health group, CES University;* <sup>3</sup>*Clinical research department, Artmedica IPS, Medellín, Colombia*

**Background:** Adherence in the treatment of rheumatoid arthritis (RA) ranges 20% to 70% in worldwide population.<sup>1</sup> In Colombia there are no studies comparing adherence and persistence to conventional and biological treatment.

**Objectives:** To determine adherence and persistence and associated factors to the treatment of conventional disease-modifying anti-rheumatic drugs (cDMARD) and biological DMARD (bDMARD) in patients with RA under real world data.

**Methods:** We conducted an observational, analytical retrospective cohort study from January 2015 to December 2016. The study population was 552 RA patients older than 18 years who received any cDMARD treatment in monotherapy or combined with two or more cDMARD and bDMARD (Rituximab and Tofacitinib were excluded). Clinical information was obtained from electronic clinical records and Morisky-Green test was performed during the follow-up. Univariate analysis (proportions and medians), bivariate analysis [relative risk (RR)] and multivariate analysis (logistic regression and Kaplan-Meier survival curve) were developed.

**Results:** Eighty nine percent were women, the median age was 59 years, 50% have  $\geq 12$  years of duration of disease. Adherence for cDMARD was 61% and for bDMARD 56%. There was an association between adherence and high degree education level (adjusted RR=2.1; **CI: 1.09–4.14**) and non-adherence with clinical factors such as high disease activity (adjusted RR=0.41; **CI: 0.22–0.75**); in the cDMARD group the greatest persistence was leflunomide (mean: 631 days) followed by methotrexate (mean: 526 days) and in the bDMARD group was etanercept (mean 1577 days) and tocilizumab (mean 1064 days). Patients with social support had greater persistence in the treatment with cDMARD (adjusted HR=2.1; **CI: 1.11–4.28**).

**Abstract THU0213 – Table 1.** Sociodemographic, clinical and therapeutic characteristics in 552 Colombian patients with rheumatoid arthritis

Characteristics	n	(%)
Rheumatoid factor	415	81
ACPA	150	71

DAS-28	<2,6	267	49
	2,6–3,2	68	12
	3,2–4,9	129	23
	>5	88	16
	Methotrexate	281	55
cDMARD	Leflunomide	130	25
	Sulfasalazine	71	14
	Chloroquine	30	6
bDMARD	Tocilizumab	41	24
	Adalimumab	38	22
	Abatacept	32	19
	Etanercept	29	17
	Infliximab	14	8,2
	Golimumab	11	6,4
	Certolizumab	6	3,5

IQR: interquartile range, ACPA: anti-cyclic citrullinated protein/peptide antibodies

**Abstract THU0213 – Figure 1.** The median time of follow-up of the studied population was 822 days, IQR 429–727 days.

**Conclusions:** In real world data, education level and disease activity significantly impact adherence level in RA patients. Social support positively impacts the persistence of the treatment of RA patients, which suggest the implementation of care programs taking this aspect into consideration in order to improve outcomes.

### THU0214 PREDICTIVE FACTORS FOR ACHIEVEMENT OF LOW DISEASE ACTIVITY AT 52 WEEKS ARE DIFFERENT BETWEEN YOUNG AND ELDERLY RHEUMATOID ARTHRITIS PATIENTS TREATED WITH ABATACEPT

N. Takahashi, T. Kojima, S. Asai, N. Ishiguro, on behalf of the TBCR study group. *Orthopaedic Surgery, Nagoya University Graduate School Of Medicine, Nagoya, Japan*

**Background:** Japanese post-marketing survey (PMS) data demonstrated that the clinical efficacy of abatacept was similar between the young and elderly rheumatoid arthritis (RA) patients, while they have quite different characteristics including age, disease duration, and concomitant drugs. We hypothesised that the predictive factors for clinical outcomes of abatacept were different between the young and elderly patients.

**Objectives:** We studied the predictive factors for good clinical response of abatacept in the young and elderly patients, respectively, in this study.

**Methods:** Participants were consecutive 463 RA patients treated with abatacept and observed for longer than 52 weeks in the TBCR, a Japanese multicenter registry system for RA patients treated with biologics. Univariate and multivariate logistic regression analysis was used to study predictive factors for achievement

of low disease activity (LDA) at 52 weeks, separately in the young (<65 years, n=215) and the elderly (>65 years, n=248) group.

**Results:** Mean age was 55.3/74.0 years (young/elderly), disease duration was 10.2/12.8 years, DAS28-CRP was 4.34/4.40 at baseline, concomitant MTX was used in 55.4/37.1%, concomitant steroid was used in 51.0/49.6%, and proportion of bio-naïve was 49.3/63.3%. As shown in table 1, multivariate analysis revealed that no history of previous biologics and lower DAS28 score at baseline was the independent positive predictors in both young and elderly group. Interestingly, ACPA positivity was significant predictor only in the young group. The ACPA positive patients showed the significantly higher proportion of LDA achievement at 52 weeks, only in the young group (figure 1).

**Conclusions:** It has been reported that lower proportion of the elderly onset RA (EORA) patients has ACPA positivity, and some reports have previously demonstrated that the ACPA negative was negatively associated with good clinical outcomes of abatacept. Our current results suggested that the effect of ACPA positivity on the clinical results of abatacept treatment was different between ages. Abatacept would be a valuable treatment option in the ACPA negative elderly RA patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3382

**THU0215 EFFICACY OF SARILUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS WITH AND WITHOUT PREVIOUS RESPONSE TO TOCILIZUMAB**

P. Verschueren<sup>1</sup>, P. Emery<sup>2</sup>, H. van Hoogstraten<sup>3</sup>, Q. Dong<sup>3</sup>, E.K. Mangan<sup>4</sup>, A. den Broeder<sup>5</sup>. <sup>1</sup>Division of Rheumatology, University Hospital Leuven, Leuven, Belgium; <sup>2</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; <sup>3</sup>Sanofi Genzyme, Bridgewater, NJ, USA; <sup>4</sup>Regeneron Pharmaceuticals, Inc, Tarrytown, NY, USA; <sup>5</sup>Sint Maartenskliniek Nijmegen, Nijmegen, Netherlands

**Background:** Sarilumab is an IL-6R inhibitor recently approved for the treatment of rheumatoid arthritis (RA). To help clinical decision making, we studied the response rate on open-label sarilumab treatment in patients previously treated with tocilizumab, the other IL-6R inhibitor approved for RA. In the ASCERTAIN trial (NCT01768572), patients were randomised 1:1:2 to 24 weeks of sarilumab 150 mg sc every 2 weeks (q2w; n=49), sarilumab 200 mg sc q2w (n=51), or tocilizumab 4 mg/kg iv q4w (n=102) increased to 8 mg/kg at investigator's discretion if clinically indicated as per the US label; each added to conventional synthetic disease-modifying antirheumatic drug (csDMARD) background therapy. Patients who completed ASCERTAIN were eligible to enrol in an open-label extension study of sarilumab 200 mg sc q2w (EXTEND, NCT01146652), with csDMARDs as specified in the previous study.

**Objectives:** To examine outcomes for patients who switched from tocilizumab in ASCERTAIN to open-label sarilumab in EXTEND.

**Methods:** In this post-hoc analysis, patients were recorded as responders or non-responders at the end of ASCERTAIN and at Weeks 12 and 24 of EXTEND according to each of: clinical disease activity index (CDAI)≤2.8, CDAI≤10.0, disease activity score (DAS)-28 CRP <2.6, DAS-28 CRP <3.2, and American College of Rheumatology (ACR)20/50/70 response criteria.

**Results:** A total of 168 patients entered EXTEND from ASCERTAIN, of whom 93 had been in the tocilizumab group (last tocilizumab dose 4 mg/kg in 37 patients and 8 mg/kg in 56 patients). After switch to sarilumab, response was achieved in an additional number of patients who were non-responders on tocilizumab at the end of ASCERTAIN (table 1). The reverse, response loss in tocilizumab responders, was infrequent. Patients who switched from tocilizumab 4 mg/kg or 8 mg/kg achieved similar response rates.

Last tocilizumab dose, mg/kg	Week in EXTEND	CDAI		DAS28-CRP		ACR20	ACR50	ACR70
		<2.8	≤10	<2.6	<3.2

	24	4/25 <sup>16</sup>	7/16 <sup>44</sup>	9/22 <sup>41</sup>	10/17 (59)	3/4 (75)	6/17 <sup>35</sup>	5/22 <sup>23</sup>
8	12	7/48 <sup>15</sup>	9/31 <sup>29</sup>	13/36 <sup>36</sup>	8/21 <sup>38</sup>	2/11 <sup>18</sup>	14/30 <sup>47</sup>	9/43 <sup>21</sup>
	24	10/46 <sup>22</sup>	13/29 <sup>45</sup>	16/35 <sup>46</sup>	7/20 <sup>35</sup>	6/10 (60)	13/28 <sup>46</sup>	13/41 <sup>32</sup>
Responders at the end of ASCERTAIN with response in EXTEND (%) <sup>a,b</sup>								
4	12	8/89 (89)	15/83 (83)	11/100 (100)	16/100 (100)	28/90 (90)	16/94 (94)	10/91 (91)
	24	6/75 (8)	15/88 (88)	9/90 (90)	14/93 (93)	27/93 (93)	27/94 (94)	9/90 (90)
8	12	4/57 (7)	21/88 (88)	13/76 (76)	26/81 (90)	38/90 (90)	19/83 (83)	7/64 (64)
	24	5/71 (7)	20/83 (83)	14/78 (78)	28/85 (85)	39/91 (91)	19/79 (79)	9/75 (75)

<sup>a</sup>responder status according to measure listed in column heading; <sup>b</sup>subjects with missing measurements are excluded from numerator and denominator

**Conclusions:** These results may indicate that clinical improvements can be attained in a relevant proportion of tocilizumab non-responders with switch to sarilumab, irrespective of previous tocilizumab dose, and the majority of patients responding to tocilizumab maintain response when switching to sarilumab.

**THU0216 SERUM CXCL16 LEVELS IN RF+/ACPA+RHEUMATOID ARTHRITIS PATIENTS BEFORE AND AFTER TREATMENT WITH DMARDS**

R. Ramamoorthy, T.N. Tamilselvam, B. Kumar. *Institute of Rheumatology, Madras Medical College, Chennai, India*

**Background:** Rheumatoid arthritis (RA) is characterised by profound mononuclear cell (MNC) recruitment into synovial tissue (ST). Studies have shown that chemokine CXCL16 is a premier MNC recruiter in RA. CXCL16 contributes to chronic inflammation, since it is highly expressed in RA synovial fluid (SF), is a potent chemoattractant for mononuclear cells (MNCs) *in vitro*, and is chemotactic for peripheral blood mononuclear cells (PBMCs) to RA ST *in vivo*. Hence treatment for RA will reflect change in serum CXCL16 levels

**Objectives:** The aim of this study was to analyse the change of serum chemokine level of CXCL16, in patients with either RF +or ACPA +rheumatoid arthritis (RA), by DMARDs treatment.

**Methods:** This was a prospective interventional study done in a tertiary care centre. 31 patients with RA were recruited for a period of 12 months. Serum CXCL16 levels were assayed in them along with other baseline investigations. The patients were treated with DMARDs. CXCL16 levels post treatment were measured after 6 months. For comparison another group of age and sex matched controls was taken (n=18) and their serum CXCL16 was also recorded. The serum CXCL16 levels were correlated with disease activity.

**Results:** After treatment with conventional DMARDs 26 patients showed lowering of mean serum CXCL16 levels from 56.07 pg/ml to 21.79 pg/ml (62% reduction) after 6 months. The patients who showed inadequate response to conventional DMARD treatment (n=5) underwent therapy with biological DMARDs (TNF- $\alpha$  blocker) which reduced their CXCL16 levels from 63.81 pg/ml to 12.36 pg/ml (80.6% reduction) in subsequent 6 months. There was a corresponding improvement in the disease activity of RA. Lowering of CXCL16 was found to correlate positively with improvement of symptoms and lowering of disease activity

**Conclusions:** DMARDs treatment significantly lowered the serum levels of CXCL16 in patients with RA. CXCL16 is one of the crucial chemokines regulated by DMARDs treatment

**THU0217 SIMILAR EFFICACY AND SAFETY OF SARILUMAB 150 MG OR 200 MG Q2W REGARDLESS OF PRIMARY (1°) OR SECONDARY (2°) FAILURE WITH TNF INHIBITORS**

R. Fleischmann<sup>1</sup>, A. Spindler<sup>2</sup>, A. Kivitz<sup>3</sup>, D. Ching<sup>4</sup>, E.K. Mangan<sup>5</sup>, T. Kimura<sup>5</sup>, M. Iglesias-Rodriguez<sup>6</sup>, G.R. Burmester<sup>7</sup>. <sup>1</sup>*Metrex Clinical Research Center, University of Texas Southwestern Medical Center, Dallas, TX, USA;* <sup>2</sup>*Universidad Nacional de Tucumán, Tucuman, Argentina;* <sup>3</sup>*Altoona Center for Clinical Research, Duncansville, PA, USA;* <sup>4</sup>*Timaru Medical Specialists Ltd, Timaru, New Zealand;* <sup>5</sup>*Regeneron Pharmaceuticals, Inc, Tarrytown, NY;* <sup>6</sup>*Sanofi Genzyme, Bridgewater, NJ, USA;* <sup>7</sup>*Free University and Humboldt University Berlin, Berlin, Germany*

**Background:** Sarilumab (150 or 200 mg subcutaneously [SC] every 2 wks [q2w]) +csDMARDs demonstrated efficacy in adults with moderate-to-severely active

rheumatoid arthritis (RA) with intolerance or inadequate response to prior TNFi treatment in TARGET (NCT01709578). Patients with an initial refractory response (1° failure) to TNFi may respond differently to subsequent treatment vs those who initially respond but lose TNFi effectiveness (2° failure).

**Objectives:** This post hoc analysis examined efficacy and safety of sarilumab +csDMARDs in patients who had previously demonstrated 1° vs 2° TNFi failure.

**Methods:** TNFi failure (1° vs 2°) was investigator-determined on enrolment to TARGET. Patients who experienced 1° or 2° failure were randomised to placebo (pbo; n=75 and n=99), sarilumab 150 mg (n=72; n=91), or sarilumab 200 mg q2w (n=64; n=103), respectively. Disease activity, physical function (HAQ-DI), and safety were assessed at Wk 24.

**Results:** By Wk 24, ACR20/50/70 response rates and improvements in LS mean HAQ-DI were similar in both sarilumab dose groups and superior to pbo, irrespective of 1° vs 2° TNFi failure (table 1). Odds ratios for the benefit of sarilumab over pbo according to ACR response rates, HAQ-DI, DAS28-CRP, CDAI and SDAI (figure 1) showed no differences between patients with 1° vs 2° failures. No significant treatment by subgroup (1° vs 2° failure) interactions were observed. In the 1° failure group, treatment emergent adverse events (TEAEs; table 1) occurred in 59.7%, 65.6% vs 45.3% (sarilumab 150, 200 mg vs pbo, respectively) of patients; and in 73.6% and 63.1% vs 52.5% with sarilumab 150, 200 mg vs pbo, respectively, in the 2° failure group. There was only one TEAE leading to death (pbo group) and one case each of venous thrombosis (200 mg sarilumab q2w, 2°) and pulmonary embolism (150 mg sarilumab q2w, 2°).

**Conclusions:** Key efficacy and safety measures were similar in patients treated with sarilumab +csDMARDs, regardless of previous 1° or 2° failure with TNFis.

**Acknowledgements:** Study funding and medical writing support (Vicki Cronin, Adelphi) provided by Sanofi and Regeneron Pharmaceuticals, Inc.

### THE EFFICACY AND DRUG SURVIVAL OF THE BIOSIMILAR INFLIXIMAB (CT-P13) COMPARED TO THE ORIGINAL REFERENCE INFLIXIMAB IN INFLAMMATORY RHEUMATIC DISEASES; RESULTS FROM THE TURKBIO REGISTRY

S. Uslu<sup>1</sup>, G. Can<sup>1</sup>, S. Senel<sup>2</sup>, E. Dalkılıç<sup>3</sup>, N. Inanc<sup>4</sup>, S. Akar<sup>5</sup>, S.B. Kocaer<sup>1</sup>, M. Birlik<sup>1</sup>, S. Capar<sup>6</sup>, N. Akkoc<sup>7</sup>, F. Onen<sup>1</sup>. <sup>1</sup>Rheumatology, Dokuz Eylul University, Izmir; <sup>2</sup>Rheumatology, Erciyes University, Kayseri; <sup>3</sup>Rheumatology, Uludağ University, Bursa; <sup>4</sup>Rheumatology, Marmara University, Istanbul; <sup>5</sup>Rheumatology, Katip Celebi University; <sup>6</sup>Department of Statistics, Dokuz Eylul University; <sup>7</sup>Rheumatology, Private Doctor, Izmir, Turkey

**Background:** Biosimilar infliximab (CT-P13) has been used to treat patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS) and psoriatic arthritis (PsA) in Turkey since 2013.

**Objectives:** The aim of this study was to examine its efficacy, drug survival and compare it to the original reference infliximab (inf) in patients with inflammatory rheumatic diseases based on the database from the TURKBIO registry.

**Methods:** All patients with RA, SpA, PsA, and other diseases receiving CT-P13 and inf registered in the TURKBIO database between the dates of June 2013 and January 2017 were included in the study. Demographic information, laboratory parameters and disease indices were collected (at baseline, and months 6 and 12). We used Kaplan Meier survival curves to examine drug survival patterns.

**Results:** Data collected from a total number of 614 patients were analysed (table 1). The analysis of each treatment group was made according to gender, age, and diagnosis. In both groups most of the patients were diagnosed as having axial SpA, followed by RA, PsA and other diseases. CT-P13 group had female predominance. In patients with RA and PsA, baseline DAS28 scores were found to be higher in CT-P13 group. Baseline values of ASDAS-CRP in SpA patients and CRP in all patients were similar for both groups (table 2). Mean CRP levels at month 6 and ASDAS scores at month 12 were found to be higher in inf group. The ratio of males was higher in axial SpA patients receiving inf, but did not statistically affect the 12th month ASDAS results. The results of the database analysis showed that the drug survival rate of CT-P13(78,4%) is higher than inf(63,6%) at year 4 (figure 1). At 4 year follow-up, drug withdrawal was observed in both groups due to ineffectiveness (CT P13;n=13 54,16%, inf;n=89 41,58%) and side effects (CT-P13;n=8 33,33%, inf;n=43 20,09%). In CT-P13 group, six patients had switched from inf to biosimilar and other 20 had used  $\geq 1$  previous biologicals. Of the 503 patients who used inf, 164 had used  $\geq 1$  biologicals previously.

**Abstract THU0218 – Table 1.** Baseline characteristics of CT-P13 and original infliximab, by diagnostic group

	CT-P13 (n=111)	infliximab (n=503)	P value

### THU0219 BENEFICIAL EFFECT OF ANTI-IL-6 BLOCKADE ON INSULIN RESISTANCE AND INSULIN SENSITIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

S. Remuzgo-Martínez<sup>1</sup>, R. López-Mejías<sup>1</sup>, F. Genre<sup>1</sup>, V. Mijares<sup>1</sup>, J. Calvo-Alen<sup>2</sup>, R. Blanco<sup>1</sup>, J. Llorca<sup>3</sup>, S. Castañeda<sup>4</sup>, M.A. González-Gay<sup>1,5</sup>. <sup>1</sup>Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander; <sup>2</sup>Rheumatology Department, Hospital Universitario Araba, Vitoria; <sup>3</sup>Epidemiology and Computational Biology Department, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander; <sup>4</sup>Rheumatology Department, Hospital Universitario La Princesa, IIS-IPrincesa, Madrid; <sup>5</sup>School of Medicine, University of Cantabria, Santander, Spain

**Background:** Systemic inflammation, insulin resistance (IR), and endothelial dysfunction have been implicated in the development of cardiovascular disease in rheumatoid arthritis (RA).<sup>1-3</sup> In this regard, it has been described that the blockade of IL-6, a cytokine involved in the pathogenesis of both RA and atherosclerosis, yields a rapid improvement of endothelial function in RA.<sup>4</sup> However, there are no studies on the role of anti-IL-6 treatment on IR in patients with RA.

**Objectives:** To assess whether IL-6 blockade may result in a reduction of insulin serum levels and an improvement of IR in patients with RA.

**Methods:** 50 Spanish patients on treatment with anti-IL-6 monoclonal antibody-Tocilizumab who fulfilled the 2010 classification criteria for RA<sup>5</sup> were recruited. Patients with diabetes mellitus or plasma glucose >110 mg/dl were excluded. Fasting blood samples were taken for determination of plasma glucose and serum insulin levels immediately prior to (time 0) and after (time 60 min) Tocilizumab infusion. IR was assessed by the homeostasis model assessment (HOMA) and insulin sensitivity was evaluated by the quantitative insulin sensitivity check index (QUICKI).

**Results:** A marked reduction in the serum insulin levels was observed following Tocilizumab infusion (mean ±standard deviation (SD): 10.60±5.80 μU/ml versus 7.61±5.08 μU/ml, p<0.0001). In addition, a decrease in the insulin/glucose index was observed in patients with RA after Tocilizumab dose (mean ±SD: 0.12 ±0.06 versus 0.08±0.05, p<0.0001). Finally, our results disclosed a significant improvement of insulin resistance (HOMA: mean ±SD: 2.61±2.05 versus 1.65 ±1.14, p=0.0003) and insulin sensitivity (QUICKI: mean ±SD: 0.34±0.003 versus 0.37±0.04, p<0.0001) following Tocilizumab infusion.

**Conclusions:** Our study confirms a rapid beneficial effect of Tocilizumab on IR and insulin sensitivity in RA patients treated with this drug. It may support the long-term use of drugs that act blocking IL-6 function to reduce the mechanisms implicated in the development of atherosclerosis in RA patients.

### THU0220 DISCONTINUATION OF BIOLOGIC DMARDs IN A REAL-LIFE POPULATION OF PATIENTS IN REMISSION: OUTCOME AND PREDICTORS

S. Arnold<sup>1</sup>, V.K. Jaeger<sup>1</sup>, A. Scherer<sup>2</sup>, U.A. Walker<sup>1</sup>, D. Kyburz<sup>1</sup>. <sup>1</sup>University Hospital Basel, Basel; <sup>2</sup>SCQM, Zurich, Switzerland

**Background:** Data from randomised controlled trials have shown that in patients with sustained remission discontinuation of bDMARD therapy is feasible. However, the criteria for selecting patients that will successfully remain in remission after bDMARD discontinuation remain to be defined.

**Objectives:** To assess the rate of loss of remission after discontinuation of bDMARDs in a real life setting and to identify predictors in a large cohort of patients.

**Methods:** Adult RA patients in bDMARD-free remission from the Swiss clinical quality management in rheumatic diseases registry (SCQM) were included. bDMARD-free remission was defined as a discontinuation of the bDMARD and a DAS28 ≤2.6 at a clinical visit within 90 days prior to 30 days after the bDMARD discontinuation. Loss of remission was defined as a DAS28 >2.6 or restart of a bDMARD. Patients treated with rituximab were excluded. Kaplan-Meier methods were applied and cox regression was used for multivariable analyses (adjusted for sex, anti-CCP, RF, DAS28, bDMARD Type, CDAI, therapy with conventional DMARDs, number of previous bDMARDs). Missing data were imputed using multiple imputation.

**Results:** Between 1997 and 2017, 318 patients achieved a bDMARD-free remission (table1). Median observation time was 2.8 years (IQR 1.2–4.9). 241 patients lost remission (76%), 54% of those re-started a bDMARD. 34% experienced a DAS28 flare and 12% did both. The median time to loss of remission was 0.9 years (95% CI 0.7–1.0). 76% discontinued a TNFα-inhibitor, 6% stopped abatacept, 14% tocilizumab and 4% tofacitinib. Women lost remission faster than men (figure 1A; p=0.005); this was also seen in multivariable analysis (HR 1.4, p=0.03). Longer disease duration was associated with a faster loss of remission (figure 1B; p=0.03) also in multivariable analysis (HR[4–8 years] 1.6, p=0.03, HR [8–13 years] 1.6, p=0.01, HR[>13 years] 1.5, p=0.035 vs 0–4 years disease duration). Remission was lost faster by patients who discontinued tofacitinib compared to those who stopped a TNFα-inhibitor (HR 2.3, p=0.01) also after adjustment (HR 2.0, p=0.047). There was a trend for a faster loss of remission in patients with a higher disease activity as measured by the CDAI at baseline (figure 1C; p=0.7); this association was significant in multivariable analysis (HR[CDAI low disease activity] 1.6, p=0.03, HR[CDAI moderate/high disease activity] 2.5, p=0.003, both vs CDAI remission). Patients who received MTX/leflunomide during the observation period lost remission less rapidly (figure 1D; p=0.006) also in multivariable analysis (HR 0.8, p=0.046).

**Abstract THU0220 – Table 1.** Baseline demographic and disease characteristics of patients with bDMARD-free remission

Characteristics	% or median (IQR)
Male sex	26
Age	57 (46–66)
Disease duration in years	8 (4–13)
Number of previous bDMARDs	0 1–2 ≥3
cDMARD any time during Remission	68 27 5
Anti-CCP/RF positive	64/72
DAS28	2.0 (1.5–2.3)
HAQ	0.4 (0–1.0)
CDAI	Remission Low Activity Moderate-High Activity
	27 54 19

**Abstract THU0220 – Figure 1.** Kaplan-Meier for time in biologic-free remission according to sex (A), disease duration (B), CDAI (C), conventional DMARD therapy (D)

**Conclusions:** In a large real-life cohort of RA patients that achieved DAS28 remission and stopped therapy with bDMARD the majority lost remission within less than a year. Predictors for loss of remission included female sex, longer disease duration, a higher CDAI score and absence of cDMARD therapy. This

suggests that discontinuation of bDMARD should be considered in patients on cDMARD therapy, fulfilling the more stringent remission criteria by CDAI.

THU0221

### CLINICAL OUTCOMES OF ABATACEPT VERSUS TNF INHIBITORS IN ACPA-POSITIVE PATIENTS WITH RHEUMATOID ARTHRITIS: DATA FROM THE BIOLOGIC REGISTER KOBIO

S.-K. Lee<sup>1</sup>, S. Oh<sup>2</sup>, H.-A. Kim<sup>3</sup>, Y.-B. Park<sup>4</sup>, S.-S. Lee<sup>5</sup>, K. Shin<sup>1</sup>. <sup>1</sup>Division of Rheumatology; <sup>2</sup>Department of Biostatistics, Seoul Metropolitan Government-Seoul National University Hospital Boramae Medical Center, Seoul; <sup>3</sup>Division of Rheumatology, Ajou University School of Medicine, Suwon; <sup>4</sup>Division of Rheumatology, Yonsei University College of Medicine, Seoul; <sup>5</sup>Division of Rheumatology, Chonnam University Hospital, Gwangju, Korea, Republic of Ireland

**Background:** Determining the optimal, patient-tailored biologic agent is a new challenge for future guidelines in rheumatoid arthritis (RA) management. Recent studies demonstrated that anti-citrullinated protein antibody (ACPA) -positive patients have better disease activity improvement with abatacept (ABA), yet validation studies are in need.

**Objectives:** To investigate disease activity changes after treatment with ABA versus TNF inhibitors (TNFi) in Korean ACPA-positive, RA patients.

**Methods:** Data of RA patients were obtained from the Korean College of Rheumatology Biologics Registry (KOBIO). ACPA-positive patients who were treated with ABA and TNFi were selected through propensity score matching (1:2, calliper=0.2\*SD). Clinical outcomes including CDAI changes at the first year of therapy were evaluated, and adjusted drug survival in each group was analysed.

**Results:** The baseline characteristics of the ABA (n=97) and TNFi (n=194) groups were comparable. The CDAI reduction after 1 year treatment was significant in the ABA group compared with patients who received TNFi (-13.61 versus -13.61, p=0.0198) [figure 1]. This was confined when used as the first-line agent (p=0.0213). Proportion of remission and low disease activity in ABA was significant as well (p=0.041). Patients with the lower tertile of ACPA titers treated with ABA had the most significant CDAI reduction compared with the TNFi group (p=0.0201). Drug retention rate (median follow-up 48 months) of ACPA-positive ABA users was also notable compared with TNFi yet did not meet statistical significance (adjusted hazard ratio 0.774, p=0.086).

**Conclusions:** Our data further support that ACPA could also be an important marker to help determine first-line biologic agent of choice among the armamentarium of biologic therapy for RA patients.

**Acknowledgements:** We would like to thank Song Wha Chae and Evo Alemao for their input and support.

THU0222

### MULTISWITCHING – FROM REFERENCE PRODUCT ETANERCEPT TO BIOSIMILAR AND BACK AGAIN – REAL-WORLD DATA FROM A CLINIC-WIDE MULTISWITCH EXPERIENCE

V. Sigurdardottir, A. Svård. Center for Clinical Research Dalarna, Falun, Sweden

**Background:** The etanercept (ETN) biosimilar SB4 was introduced in Sweden in 2016 at a lower price than the reference product etanercept (RPE). Now the reverse is true, as the price of RPE dropped. Switching ETN-treated patients to the lowest priced ETN available is economically favourable. The safety of multiple switches between RPE and biosimilar has been addressed in a psoriasis trial,<sup>1</sup> finding no indications of harm. No reports on outcomes of multiswitching in a rheumatology setting are available.

**Objectives:** To describe the impact of a clinic-wide switch from RPE to SB4 and then back to RPE on disease activity and drug-survival, relating outcomes to a historical cohort of RPE-treated patients.

**Methods:** Observational study of 145 patients switched from RPE to SB4 (day 0=20/4/2016) and back to RPE (day 544=16/10/2017) for economical reasons. Letters were mailed to patients on day 0 and 544, informing them that prescriptions had been changed from RPE to SB4 and from SB4 to RPE respectively. During days 1–543, clinicians were allowed to switch patients back to RPE if requested by the patient or if medically indicated. Disease activity data was entered into the Swedish Rheumatology Quality Register (SRQ) at visits. The SRQ was searched retrospectively for data from day –365 to 771 (May 31, 2018). Visits were categorised into visits occurring a) on days –365 to day 0, b) on days 1–543 and c) on days 544–771. A reference cohort of all RPE-treated patients on April 20, 2013 at the clinic was used for comparison.

**Results:** Numbers and proportions of patients discontinuing SB4 during days 1–543 in the switching cohort and RPE in the historical cohort are shown in the table 1. On day 544, the 97 patients still treated with SB4 were switched back to RPE. In the switching cohort, DAS28 and CRP did not change significantly when comparing data from visits occurring before the switch from RPE to SB4 to data from visits that occurred on days 1–543 and days 544–636 (figure 1). Data from 5 months of additional follow-up, up until day 771 will be presented at the congress. Among the 24 patients that discontinued SB4 during days 1–543 and went back to RPE, no worsening of disease activity parameters was seen during SB4 treatment.

	Switching cohort, n=145	Historical RPE-treated cohort, n=98	p
Discontinued SB4/RPE, total*	48 (33)	15 (15)	0.002
‡Back to RPE	24 (17)	Not applicable	N/A
‡No biologic	14 (10)	6 (6)	0.32
‡Non ETN biologic	10 (7)	9 (9)	0.52
On ETN (SB4 or RPE) at day 544	121 (83)	83 (85)	0.80

\*During days 1–543 ‡ Treatment after discontinuation of SB4/RPE

**Abstract THU0222 – Figure 1.** Mean DAS28 and CRP with 95% CI for 145 patients in the switching cohort according to timepoint of visit...n.s refer to number of visits contributing to data during each period.

**Conclusions:** The strategy of multiswitching ETN-treated patients has thus far not impacted disease activity negatively in our population. An additional 5 months of follow-up data after the second switch will be presented at the congress. A high proportion of patients discontinued SB4 after the initial switch, as no worsening in disease activity measures was seen in the data we believe this to have been due to nocebo effects.

**THU0223 IMPACT OF TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS AND DEPRESSIVE SYMPTOMS IN THE MONARCH PHASE 3 TRIAL OF SARILUMAB**

V. Strand<sup>1</sup>, O. Hagino<sup>2</sup>, S. Guillonnet<sup>3</sup>, S. Boklage<sup>4</sup>, M. Reaney<sup>5</sup>, J. Sadeh<sup>2</sup>, N. Narcisse<sup>6</sup>, E. Mangan<sup>4</sup>, T. Kimura<sup>4</sup>. <sup>1</sup>Stanford University, Palo Alto; <sup>2</sup>Sanofi, Bridgewater, USA; <sup>3</sup>Sanofi, Chilly-Mazarin, France; <sup>4</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, USA; <sup>5</sup>Sanofi, Guildford, UK; <sup>6</sup>AIXIAL, Boulogne-Billancourt, France

**Background:** In the MONARCH Phase 3 randomised controlled trial (RCT) [NCT02332590], sarilumab subcutaneous (SC) 200 mg every 2 weeks (q2w) improved clinical outcomes and multiple aspects of health status/health-related quality of life (HRQoL), as measured by the Medical Outcomes Survey Short Form (SF-36) questionnaire, to levels greater than adalimumab SC 40 mg q2w. Both treatments were administered as monotherapy in patients with active rheumatoid arthritis (RA) who had discontinued treatment with methotrexate. Depression/mood disorder is a common co-morbidity in people with RA.

**Objectives:** To explore whether observed differences in health status/HRQoL following treatment with sarilumab compared with adalimumab are also seen in the subgroup of patients in the MONARCH trial with probable depressive symptoms.

**Methods :** Post-hoc statistical analyses were performed. Patients were categorised as having probable major depressive disorder<sup>1</sup> (PMDD; SF-36 mental health (MH) domain score ≤56) or probable depressed mood and anhedonia<sup>2</sup> (PDMA; score ≤10 on both items of the MH domain: "Have You Felt Downhearted and Depressed" and "Have You Felt So down in the Dumps that nothing could cheer you up"). Least squares mean (LSM) differences in changes from baseline (CFB) in SF-36 domains at Week 24 were calculated for sarilumab PMDD/PDMA versus adalimumab PMDD/PDMA. Sensitivity analysis included adjustment for Disease Activity Score 28 C-reactive protein (DAS28-CRP) at baseline.

**Results:** Of the 369 patients from MONARCH, 250 (67.78%) were categorised with PMDD (mean age 52 years, 85% female) and 194 (52.6%) with PDMA (mean age 52 years, 87% female). Disease duration, DAS-28 CRP, tender and swollen joint counts (table 1) and SF-36 domain scores (figure 1) were similar between sarilumab and adalimumab within the PMDD and PDMA subpopulations at baseline. LSM differences in CFB in SF-36 domains were greater for sarilumab versus adalimumab at Week 24 in physical functioning (PF), bodily pain (BP), vitality (VT) and social functioning (SF) domains in both the PMDD and PDMA subgroups, and role-physical (RP) in the PMDD subgroup (nominal p<0.05) (figure 1). Sensitivity analysis showed similar results.

Abstract THU0223 – Table 1

Table Baseline characteristics in MONARCH patients with PMDD or PDMA	PMDD: SF-36 MH domain score ≤56 (N=250)		PDMA: ≤10 on both items of SF-36 MH domain (N=194)	
	Sarilumab 200mg q2w (n=128)	Adalimumab 40mg q2w (n=122)	Sarilumab 200mg q2w (n=98)	Adalimumab 40mg q2w (n=96)
Duration of RA since diagnosis, (years, mean (SD))	8.29 (8.13)	7.01 (8.51)	7.92 (7.50)	7.46 (8.47)
SAS28 CRP, mean (SD)	6.13 (0.85)	6.18 (0.88)	6.17 (0.96)	6.18 (0.83)
Tender joint count (0-68), mean (SD)	29.03 (14.05)	28.36 (14.71)	28.99 (14.34)	28.69 (14.46)
Swollen joint count (0-66), mean (SD)	19.20 (11.87)	19.89 (10.74)	19.68 (11.78)	19.53 (11.09)

**Conclusions:** Among patients with RA and probable depressive symptoms, sarilumab SC 200 mg q2w monotherapy was more effective than adalimumab SC 40 mg q2w monotherapy in demonstrating clinically meaningful improvements in some domains of health status/HRQoL. This may be a function of the different

target of sarilumab (soluble IL-6 receptor [sIL-6R]) and associated improvements in disease activity versus adalimumab (tumour necrosis factor [TNFα]).

**THU0224 RENACER STUDY: EFFICACY AND SAFETY ASSESSMENT OF CZP THERAPY IN THE TREATMENT OF 501 PATIENTS WITH RHEUMATOID ARTHRITIS(RA) AMONG SPANISH POPULATION IN CLINICAL PRACTICE**

V. Torrente-Segarra<sup>1</sup>, M. Fernandez<sup>2</sup>, R. Expósito<sup>3</sup>, N.P. Garrido<sup>4</sup>, A. Sanchez-Andrade<sup>5</sup>, J.R. Lamua<sup>6</sup>, A. Olivé<sup>7</sup>, J.V. Tovar<sup>8</sup>, on behalf of On behalf of RENACER Study Group. <sup>1</sup>Rheumatology, Hospital General Hospitalet-Moisès Broggi, Hospitalet Llobregat; <sup>2</sup>Rheumatology, Hospital Universitario de Guadalajara, Guadalajara; <sup>3</sup>Rheumatology, Hospital Comarcal de Laredo, Laredo; <sup>4</sup>Rheumatology, Hospital Universitario Virgen del Rocío, Sevilla; <sup>5</sup>Rheumatology, Complejo Hospital Universitario Lucus Augusti, Lugo; <sup>6</sup>Hospital Universitario del Henares, Alcalá de Henares; <sup>7</sup>Hospital Germans Trias i Pujol, Badalona; <sup>8</sup>Hospital General Universitario de Elche, Elche, Spain

**Background:** Certolizumab PEGol (CZP) differs from other anti-TNFs in that it is monovalent and it lacks the Fc region found in monoclonal antibodies. CZP is also PEGylated. Its efficacy in patients with rheumatoid arthritis (RA) has been evaluated in previous clinical trials.

**Objectives:** The purpose of the current study is to assess effectiveness, safety and survival rate in patients with RA after 12 months of treatment and also within specific subgroups, in clinical practice settings.

**Methods:** Observational longitudinal prospective study of RA patients from 40 sites in Spain. Variables (baseline, 3- and 12 month assessment): socio-demographics, smoking status, previous synthetic DMARD (sDMARD) and biological DMARD (bDMARD) use; TJC, SJC, ESR, CRP, DAS28. Response variables EULAR Moderate/Good Response and DAS28 remission and Safety were assessed. Descriptive, comparative and Logistic regression analyses were performed. Kaplan-Meier survival curve was performed.

**Results:** A total of 501 patients were included: 78.6% women, mean age 53.6 year (±13.2 SD) and 77% were aged <65 year Mean disease duration 7.5 year (±7.3 SD) and 27.7% having early RA. Baseline features are shown in table 1. Mean number of prior sDMARD 1.5 (±1.1 SD). Mean number of prior bDMARD was 0.8 (±1.2 SD). Mean duration of exposure to CZP was 9.8 months (±3.4 SD); Concomitant steroids intake 12.6%, sDMARD 24.2% and sDMARD plus steroids 54.9%; Smoking status: 69.8% never smoked, 12.9% former smoker and 17.3% current smoker.

Baseline predictors of response: lower prior number sDMARD; low number prior bDMARD; higher CRP, ESR, TJC, SJC and DAS28 (p<0.05) scores.

Patients<65 year had shown better DAS28 Remission rates as well as those who had previously received <2 sDMARDs, those who were "bionaive" at CZP initiation and those who used CZP in combination.

CZP survival rates are shown in *Figures 1 and 2*.

Adverse effects from treatment were reported in 65 patients (13%), mostly mild.

**Conclusions:** CZP showed benefit in active RA patients, with clear improvement in all clinical parameters, mostly in <65 yo patients and those who had received low number of previous sDMARD and bDMARD. Survival rate at 12 month assessment was high, demonstrating a reasonable safety profile.

**Background:** Lung involvement is one of the extra-articular manifestations that is shown to be related to morbidity and mortality in Rheumatoid arthritis (RA).

**Objectives:** We evaluated the progression of lung involvement in RA patients receiving biological treatment.

**Methods:** Eighty RA patients fulfilling ACR/EULAR classification criteria (2010) receiving biologics who had high-resolution computerised tomography (HRCT) of chest within 6 months of respiratory symptoms (cough/dyspnea) and/or any pathology in chest radiography were included. Warrick score, evaluating alveolitis and fibrosis, was calculated in RA patients by using HRCT of chest.

**Results:** The demographics and clinical findings were summarised in table 1. In 29 RA patients with interstitial findings in HRCT of chest; 7 (24%) were regressed and 1 (4%) was progressed with biologic drugs. Findings of alveolitis and fibrosis were completely regressed in 2, only alveolitis component was completely regressed in 3 and partially in 2 patients. The patient who progressed had new findings of alveolitis (table 2). Twenty-one patients in whom Warrick scores did not change, 5 received rituximab (RTX) and 10 received TNF inhibitors (TNF-inh). The mean Warrick scores was improved after biologics (11,3±9 (3–30) vs 10,3±9 (0–30), p=0,035). The improvement in alveolitis scores was significant (2,1 ±1,6 vs 1,5±1,6, p=0,031) while fibrosis scores were not (9,2±7,7 vs 8,8±8). Initial and control Warrick scores were higher in RTX receivers (16±9 vs 9,2±8, p=0034 and 14,8±10,1 vs 8,4±8,1), but the improvement after biologics was not different.

**Abstract THU0225 – Table 1.** Demographics in Rheumatoid Arthritis Patients

	n=80
Age(year)	53±12
Gender(F/M)	61/19
Disease duration(year)	12±9

**THU0226 SERIAL INTERFERON-GAMMA RELEASE ASSAYS IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH BIOLOGIC AGENTS**

Y.J. Huang, Y.F. Fang, Y.F. Chen, P.H. Tsai, C.F. Kuo, K.H. Yu, S.F. Luo. Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital and Chang Gung University, Taoyuan, Taiwan, Province of China

**Background:** It is increasing attention about the risk of latent tuberculosis infection (LTBI) reactivation during the treatment of biologic agents for patients with rheumatoid arthritis. Taiwan rheumatology association recommend performing at least annual interferon-gamma release assays (IGARs) testing during biologic treatment course because of the moderate prevalence of tuberculosis in Taiwan. [1] Although several studies have reported the risk of active tuberculosis infection in patients with rheumatoid arthritis (RA), the long-term serial IGARs testing in patients with RA is limited.

**Objectives:** The aims of this study is to use serial interferon-gamma release assays(IGRAs) as a screening tool in patients with rheumatoid arthritis treated with different biologic agents in Taiwan.

**Methods:** We retrospectively collected 189 patients with rheumatoid arthritis receiving biologic agents between 2013 to 2017 in Chang Gung Memorial hospital in Taiwan. All RA patients underwent semi-annual IGRA test during biologic agents treatment.

**Results:** The seroconversion rate of IGAR in patients with rheumatoid arthritis after biologic treatment is 6.9%. The median seroconversion period is 19 months. Out of the 13 patients with seroconversion, 8 (61.5%) patients were treated with TNF block and 5 (38.5%) patients were treated with non-TNF blocker. All the patients with seroconversion evaluate the possible active TB infection and 69.2% (9/13) received chemoprophylactic therapy by isoniazid. There is no active tuberculosis infection during serial IGAR tests. The risk factor included high baseline TBAg-nil/nil (OR 3.44, CI 6.64–1.78), leflunomide(OR 11.51, CI 61.34–2.16).

**Abstract THU0226 – Table 1**

	Total (n=189)	Seroconversion (n=13)	Non-seroconversion (n=176)	p-value
Female	162(14.3%)	10(76.9%)	152(86.4%)	0.348
Age (Mean± standard deviation)	54.7±12.2	60.0±13.6	54.3±12.1	0.104
Disease duration (Mean± standard deviation)	4.9±1.4	4.6±1.4	4.9±1.4	0.591
Prednisolone Mean dose (mg/day)	132/189(69.8%)	9/13(69.2%)	123/176(69.88%)	0.873
	8.8±9.5	8.3±3.5	8.8±9.8	
Methotrexate	146(77.2%)	9(69.2%)	137(77.8%)	0.475
Sulfasalazine	99(52.4%)	9(69.2%)	90(51.1%)	0.207
Leflunomide	24(12.7%)	5(38.5%)	19(10.8%)	0.015*
Hydroxychloroquine	104(55%)	11(84.6%)	93(52.8%)	0.026*
TNF blocker	143(75.7%)	8(61.5%)	135(76.7%)	0.219
Non-TNF blocker	46(24.3%)	5(38.5%)	41(23.3%)	0.219
TB Ag-nil	0.02±0.12	0.14±0.12	0.01±0.12	<0.001*
Mitogen-nil	6.66±5.2	8.16±4.84	6.52±5.23	0.278
DAS28	6.06±1.09	6.42±0.91	6.03±1.1	0.261
Characteristics	OR(95%CI)		p value	
Age	1.02 (1.09, 0.95)		0.474	
Disease duration	1.31 (2.36, 0.72)		0.366	
TB Ag-nil/nil	3.44 (6.64, 1.78)		<0.001*	
Leflunomide	11.51 (61.34, 2.16)		0.004*	
Hydroxychloroquine	6.49 (43.88, 0.96)		0.055	

**Conclusions:** Our study revealed patients with rheumatoid arthritis receiving long-term biologic therapy had a low rate IGAR seroconversion rate (6.9%). Patients with background Leflunomide had higher odds ratio of seroconversion. However, the clinical importance of IGAR seroconversion remain controversial and further long-term large scale investigation is needed.

## Spondyloarthritis – clinical aspects (other than treatment)

### THU0227 SPINAL FRACTURE RISK IN ANKYLOSING SPONDYLITIS IN WESTERN AUSTRALIA

M. Ognjenovic<sup>1</sup>, W. Raymond<sup>1</sup>, H. Keen<sup>1,2</sup>, C. Inderjeeth<sup>1,3</sup>, D. Preen<sup>4</sup>, J. Nossent<sup>1,3</sup>. <sup>1</sup>School of Medicine, University of Western Australia; <sup>2</sup>Rheumatology, Fiona Stanley Hospital; <sup>3</sup>Rheumatology, Sir Charles Gairdner Hospital; <sup>4</sup>UWA School of Population and Global Health, University of Western Australia, Perth, Australia

**Background:** In Ankylosing Spondylitis (AS) chronic spinal inflammation contributes to spinal osteoporosis and rigidity. Large scale studies on vertebral fractures in AS patients are scarce with rates reported between 0.4% and 32%<sup>1-3</sup>. While biological therapy for AS has been associated with better clinical outcomes, the long-term effect on spinal osteoporosis remains uncertain.

**Objectives:** To longitudinally investigate population wide spinal fracture rates in AS patients and compare the risk, disease burden and survival rates between AS and age/gender matched controls.

**Methods:** A case-control study sourced from linked health data on Emergency Department visits, Hospital Morbidity and Mortality Registry data for the period 1980–2015. Vertebral fractures prevalence (ICD-9: 733.13, 805X and 806X, ICD-10: M48.4X, M48.5X, M80.0X, S12.X, S22.X, S32.X), burden of disease and mortality were compared between AS patients (ICD-9: 720.0, ICD-10: M45X or M08.1) with up to 5 controls matched for age, gender, Indigenous status and event date.

**Results:** We included 1285 AS patients (70% males) with mean age of 42.87 ± 18.4 years at first event, followed for a median of 24 years.<sup>19, 30</sup> Spinal fractures were more frequent in AS patients than controls (52, 2.8% vs. 39, 0.6%,  $p < 0.0001$ , respectively), and among the AS patients, 27 (2%) had a single and 9 (0.7%) had multiple fractures. Thoracic fractures were most common (17, 33%), followed by cervical (10, 19%), lumbar (9, 17%), sacral and coccyx (4, 8%) and one unspecified vertebral fracture.

Overall AS participants were at greater risk (OR: 4.78; 2.9, 7.7 CI) for spinal fractures than controls. The risk remained relatively consistent; ranging from OR: 4.72 (2.75, 8.08 CI) during 1980–89 to OR: 4.90 (1.68, 14.25 CI) throughout 1990–99. However, during 2000–2013, all 4 newly AS diagnosed patients experienced a total of 7 fractures compared to none in controls. Greater age at first hospital contact among AS patients increased the risk in having a vertebral fracture (OR: 1.035; 1.01, 1.05 CI), while presence of psoriasis and inflammatory bowel disease were not risk factors.

Survival rates following vertebral fractures at end of follow-up (35 years) were significantly lower for AS patients, (92%, vs. 98.5%,  $p < 0.0001$ ) compared to controls.

**Conclusions:** The absolute risk for spinal fractures in AS patients is 2.8%, which is nearly 5 times the risk in controls. The risk has not improved in the era of TNFi therapy and the associated increased mortality indicates that spinal fractures remain a severe complication of AS.

### THU0229 ABSOLUTE REGULATORY OF PERIPHERAL CD4+CD25+FOXP3+T REGULATORY CELLS IN PATIENTS WITH SPONDYLOARTHROPATHY-RELATED OCULOPTHY

X. Liu<sup>1</sup>, G. Chai<sup>1</sup>, Y. Duan<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>. <sup>1</sup>Department of Rheumatology, The Second Hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Department of Pathology, Brigham and Women's Hospital, Harvard Medical School, Boston, USA

**Background:** Spondyloarthritis is a group of systemic chronic autoimmune diseases, which is characterised by the spine, peripheral joint, joint tissue inflammation and high morbidity. And ocular inflammatory disorders are the most common and important extra-articular manifestations with unclear pathogenesis. The imbalance of T help 17 cells (Th17)/regulatory T cells is considered to be a pivotal cause of autoimmune diseases, their roles in spondyloarthritis, especially the related oculoopathy, are rare studied.

**Objectives:** To explore the status of both absolute number and percentage of CD4 +CD25+Foxp3+T regulatory (CD4Treg) cells and Th17 cells in peripheral blood (PB) of patients with spondyloarthritis-related oculoopathy.

**Methods:** Ninety six patients were enrolled, including fifty spondyloarthritis without related oculoopathy (Group A), mean age of 43.23±11.49 years, and forty six spondyloarthritis-related oculoopathy (Group B), mean age of 43.50±13.51 years. BD Trucount tubes with the lyophilized pellet of a known number of internal counting beads were used for determining absolute counts of total CD4 +T cells in PB and then calculating the absolute number of Th17 cells and CD4Treg. Ninety three healthy volunteers, matched for patients' age and gender, were also included for the estimation of CD4 +T cell subsets.

**Results:** As compared to healthy controls (median of CD4Treg cells: 33.06 cells/ul), the frequencies of circulating CD4Treg cells were significantly decreased in both spondyloarthritis without related oculoopathy (median: 25.07 cells/ul,  $p < 0.05$ ) and spondyloarthritis-related oculoopathy (median: 17.65 cells/ul,  $p < 0.001$ ). The median ratios of Th17/CD4Treg cells in each group of patients were greatly higher than those of healthy volunteers [Group A: 0.29 (0.22, 0.47) vs. 0.21 (0.15, 0.34),  $p < 0.01$ ; Group B: 0.32 (0.21, 0.55) vs. 0.21 (0.15, 0.34),  $p < 0.01$ ]. Nevertheless, there were not significantly different in circulating Th17 cell changes among the three groups. Moreover, there was more absolute reduction of peripheral CD4Treg cells in Group B than Group A ( $p = 0.006$ ), while greater increase in the ratio of Th17/CD4Treg despite no statistical significance ( $p > 0.05$ ).

**Abstract THU0229 – Figure 1.** The numbers of different CD4+ T cells were compared between various groups and healthy controls. (A) The absolute counts of CD4Treg and Th17 cells were compared among various groups; (B) The ratios of Th17/CD4Treg cells were compared among various groups. HC: Healthy Controls, Group A: Spondyloarthritis Without Related Oculoopathy, Group B: Spondyloarthritis-related Oculoopathy. \*  $P < 0.05$ , \*\*  $P < 0.01$ , \*\*\*  $P < 0.001$ .

**Conclusions:** The reduction of CD4Treg but not the elevation of Th17 cells may be the major reason for imbalance of Th17/CD4Treg. It is speculated that spondyloarthritis-related oculoopathy is an autoimmune disease triggered by the defect of immunotolerance. More importantly, the recovery of CD4Treg may be a potential target treatment for patients with spondyloarthritis-related oculoopathy.

**PERFORMANCE OF AN ONLINE SELF-REFERRAL QUESTIONNAIRE COMPARED TO A PHYSICIAN-BASED REFERRAL APPROACH TO IDENTIFY PATIENTS WITH A HIGH PROBABILITY OF AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE OPTIREF STUDY**

F. Proft<sup>1</sup>, L. Spiller<sup>1</sup>, M. Protopopov<sup>1</sup>, M. Schmidt<sup>1</sup>, V. Rios Rodriguez<sup>1</sup>, B. Muehe<sup>1</sup>, J. Rademacher<sup>1</sup>, S. Lüders<sup>1</sup>, A.-K. Weber<sup>1</sup>, I. Spiller<sup>1</sup>, J. Sieper<sup>1</sup>, D. Poddubnyy<sup>1,2</sup>.  
<sup>1</sup>Charité – Universitätsmedizin Berlin; <sup>2</sup>German Rheumatism Research Centre, Berlin, Germany

**Background:** The diagnostic delay in axial spondyloarthritis (axSpA) has been reported to be 9 years and still remains unacceptably high. One of the major reasons for this delay is a late referral of patients with suspicion of axSpA by primary care (PC) physicians dealing with patients with chronic back pain (CBP). Physician-based referral programs have performed well in recognition of patients with high probability of axSpA among CBP patients. However, there is still an unmet need for patients who do not receive a referral to a rheumatologist because of lack of awareness on PC level.

**Objectives:** To develop and evaluate an online self-referral tool for CBP patients and suspicion of axSpA.

**Methods:** Patients with CBP were included in the Identification of the Optimal Referral Strategy for Early Diagnosis of Axial Spondyloarthritis (OptiRef) Study and assessed by a rheumatologist if they either 1) were referred by a physician using the Berlin referral tool (CBP >3 months and CBP onset <45 years of age +at least 1 of the following 3 parameters: inflammatory back pain (IBP), HLA-B27 positivity, sacroiliitis on imaging), or 2) completed an online referral tool (www.bechterew-check.de) and indicated the presence of CBP >3 months with CBP onset <45 years of age +at least 1 additional SpA parameter (IBPsymptoms, good response to NSAID's, peripheral symptoms suggestive of arthritis/enthesitis, HLA-B27 positivity, elevated CRP, psoriasis, inflammatory bowel disease, uveitis, familyhistory). Rheumatologist then performed a structured assessment of SpA features and made the diagnosis of axSpA/non-axSpA.

**Results:** A total of 339 patients were included in the study: 162 patients (47.8%) were referred by a physician and 177 (52.2%) entered the study via the online self-referral tool. A total of 60 patients (37%) in the physician-referral group and 33 (18.6%) in the self-referral group were finally diagnosed with axSpA (p<0.001). The main patient characteristics are shown in table 1. Patients who were included via the online referral tool had a longer symptom duration, were more often females, less often HLA-B27 positive and had less often elevated CRP as compared to physician-referred patients. Furthermore, the physician global assessment of disease activity done by a rheumatologist was significantly lower in the self-referred group. In patients diagnosed with axSpA there were no significant differences concerning demographics, clinical features or disease activity parameters between the two groups, except of HLA-B27, which was significantly more often positive in subjects referred by a physician (p<0.001).

**Abstract THU0230 – Table 1.** Characteristics of patients with CBP and suspicion of axSpA referred by a physician or by a self-referral online tool.

Characteristics	Referral by a physician N=162	Self-referral N=177	p-value*
Diagnosis of axSpA, n (%)	60 (37.0%)	33 (18.6%)	<0.001
Age, years (mean±SD)	37.3 ± 11.8	36.6 ± 9.2	0.99
Female sex, n (%)	71 (43.8%)	101 (57.1%)	0.02
Back pain duration, (mean±SD)	6.2 ± 6.6	9.3 ± 8.0	<0.001
HLA-B27 positivity, n (%)	90 (55.6%)	36 (20.3%)	<0.001
Elevated CRP (>5 mg/l), n (%)	28 (17.3%)	16 (9.2%)	0.02
Good response to NSAIDs, n (%)	85 (52.5%)	85 (48%)	0.45
Peripheral arthritis, current, n (%)	5 (3.1%)	4 (2.3%)	0.74
Enthesitis, current, n (%)	12 (7.4%)	13 (7.3%)	1.00
Psoriasis, ever, n (%)	13 (8%)	21 (11.9%)	0.28
Inflammatory bowel disease, ever, n (%)	2 (1.2%)	4 (2.3%)	0.69
Uveitis, ever, n (%)	14 (8.6%)	9 (5.1%)	0.20
Family history of SpA, n (%)	19 (11.7%)	21 (11.9%)	1.00
BASDAI, 0-10 (mean±SD)	4.2 ± 2.0	4.2 ± 1.8	0.90
BASFI, 0-10 (mean±SD)	2.5 ± 2.2	2.4 ± 1.8	0.87
Patient global (0-10), mean±SD	5.3 ± 2.7	4.8 ± 2.5	0.07
Physician global (0-10), mean±SD	3.9 ± 2.3	2.5 ± 2.2	<0.001

\*Mann-Whitney U-test or Fisher's exact test, whatever appropriate.

axSpA=axial spondyloarthritis; BASDAI=the Bath Ankylosing Spondylitis Disease Activity Index; BASFI=the Bath Ankylosing Spondylitis Functional Index; CBP=chronic back pain; CRP=C-reactive protein; SD=standard deviation.

**Conclusions:** The self-referral strategy resulted in the diagnosis of axSpA in 19% of the patients as compared to 37% with a referral done by a physician. However, the proportion of axSpA among self-referred patients was clearly higher than the expected 5% prevalence of axSpA in patients with CBP. The online self-referral tool can be used, therefore, in addition to a physician based referral program to improve the early diagnosis and to increase awareness of axSpA.

THU0231

**DO DEGREE OF FAMILY RELATIONSHIP AND ETHNICITY IMPACT THE ASSOCIATION BETWEEN A POSITIVE FAMILY HISTORY FOR SPONDYLOARTHRITIS AND PRESENCE OF HLA-B27? RESULTS FROM THE WORLDWIDE ASAS COHORT**

M. van Lunteren<sup>1</sup>, A. Sepriano<sup>1,2</sup>, R. Landewé<sup>3,4</sup>, J. Sieper<sup>5,6</sup>, M. Rudwaleit<sup>5,7</sup>, D. van der Heijde<sup>1</sup>, F.A. van Gaalen<sup>1</sup>. <sup>1</sup>LUMC, Leiden, Netherlands; <sup>2</sup>NOVA Medical School, Universidade Nova de Lisboa, Lisbon, Portugal; <sup>3</sup>ARC, Amsterdam; <sup>4</sup>Zuyderland Hospital, Heerlen, Netherlands; <sup>5</sup>Charité Campus Benjamin Franklin; <sup>6</sup>German Rheumatism Research Centre, Berlin; <sup>7</sup>Klinikum Bielefeld, Bielefeld, Germany

**Background:** The ASAS definition of a positive family history (PFH) of spondyloarthritis (SpA) consists of the following diseases in first (FDR)- or second-degree relatives (SDR): ankylosing spondylitis (AS), acute anterior uveitis (AAU), reactive arthritis (ReA), inflammatory bowel disease (IBD), and psoriasis. In two European cohorts (SPACE and DESIR) a PFH of AS and AAU, but not a PFH of ReA, IBD, and psoriasis, were associated with HLA-B27 carriership in patients suspected of axSpA<sup>1</sup>. However, it is unknown what the role of the degree of family relationship or ethnicity is.

**Objectives:** To investigate the impact of the degree of family relationship and ethnicity on the association between the current ASAS definition of a PFH and the presence of HLA-B27 in an international cohort of patients suspected of axSpA.

**Methods:** Baseline data from patients suspected of axSpA in the worldwide ASAS cohort were analysed. Univariable analyses were performed. Each disease (AS, AAU, psoriasis, IBD, ReA) in a PFH according to ASAS expert opinion was a determinant in separate models with HLA-B27 carriership as outcome. Analyses were stratified for FDR, SDR, and self-reported ethnicities (white, Asian, and other). Analyses were repeated in multivariable models.

**Results:** In total, 594 patients suspected of axSpA were analysed. Patients had a mean age (SD) of 33.7 (11.7) years, 46% were male, had a mean symptom duration of 7.1 (9.0) years, had 3.5 (2.2) SpA features including HLA-B27 and imaging, 52% were HLA-B27 positive, 20% had sacroiliitis according to the mNY criteria, and 32% had active inflammation on MRI-SI. Sixty-two percent of the patients were diagnosed as axSpA and of these diagnosed patients 83% fulfilled the ASAS axSpA criteria. A PFH was reported by 23% of the patients; a PFH of AS was the most (15%) and PFH of AAU (1%) the least often reported family history among all patients. Any PFH was associated with HLA-B27 carriership in patients with a PFH in FDR, whites, and Asians but not in SDR. A PFH of AS was positively associated with HLA-B27 carriership in all subgroups (table 1). A PFH of AAU, ReA, IBD, or psoriasis was never positively associated with HLA-B27 carriership. In the multivariate analysis, similar results were found.

**Abstract THU0231 – Table 1.** Univariable associations between each disease of a positive family history and HLA-B27 carriership in chronic back pain patients suspected of axSpA included in the ASAS cohort (n=594)

	HLA-B27+ n=310	HLA-B27- n=284	OR (95% CI)	p-value
<b>Any positive family history</b>				
<i>Stratified by degree of family relationship</i>				
First-degree relatives	79	31	2.9 (1.8-4.5)	<0.001
Only second-degree relatives	15	10	1.7 (0.7-3.8)	0.212
<i>Stratified by self-reported ethnicity</i>				
white	54	26	2.3 (1.4-3.9)	0.001
Asian	38	14	3.1 (1.6-5.8)	0.001
Other ethnicities*	2	1	2.3 (0.2-25.0)	0.509
<b>Family history of ankylosing spondylitis</b>				
<i>Stratified by degree of family relationship</i>				
First-degree relatives	61	9	7.8 (3.8-16.0)	<0.001
Only second-degree relatives	13	4	3.7 (1.2-11.6)	0.023
<i>Stratified by self-reported ethnicity</i>				
white	37	6	7.1 (2.9-17.1)	<0.001
Asian	35	7	5.7 (2.5-13.2)	<0.001
Other ethnicities*	2	0	n.a.	n.a.

Statistically significant results are printed in bold.

\* Self-reported ethnicity was missing for 5 patients, who are included in this category, and other ethnicities are black, East-Indian, Hispanic/Latino, mixed, or Turkish).

**Conclusions:** In the international ASAS cohort, a PFH of AS, but not of AAU, ReA, IBD, or psoriasis, was associated with HLA-B27 carriership in both first- and second-degree of family members and self-reported white and Asian ethnicity in patients suspected of axSpA. These data, in combination with data from two European cohorts, show that a PFH of AS and possibly also a PFH of AAU could be valuable in the general practice or other low SpA prevalence settings for identifying patients who are HLA-B27 positive and therefore have an increased risk of axSpA.

THU0232

### IS A POSITIVE FAMILY HISTORY OF SPONDYLOARTHRITIS RELEVANT FOR DIAGNOSING AXIAL SPONDYLOARTHRITIS ONCE HLA-B27 STATUS IS KNOWN? DATA FROM THE ASAS, DESIR AND SPACE COHORTS

M. van Lunteren<sup>1</sup>, A. Sepriano<sup>1,2</sup>, R. Landewé<sup>3,4</sup>, I.J. Berg<sup>5</sup>, M. Dougados<sup>6</sup>, L. Gossec<sup>7,8</sup>, L. Jacobsson<sup>9</sup>, R. Ramonda<sup>10</sup>, M. Rudwaleit<sup>11,12</sup>, J. Sieper<sup>11,13</sup>, D. van der Heijde<sup>1</sup>, F.A. van Gaalen<sup>1</sup>. <sup>1</sup>LUMC, Leiden, Netherlands; <sup>2</sup>NOVA Medical School, Universidade Nova de Lisboa, Lisbon, Portugal; <sup>3</sup>ARC, Amsterdam; <sup>4</sup>Zuyderland Hospital, Heerlen, Netherlands; <sup>5</sup>Diakonhjemmet Hospital, Oslo, Norway; <sup>6</sup>Paris Descartes University; <sup>7</sup>Sorbonne Université; <sup>8</sup>Pitié Salpêtrière Hospital, Paris, France; <sup>9</sup>University of Gothenburg, Gothenburg, Sweden; <sup>10</sup>University of Padova, Padova, Italy; <sup>11</sup>Charité Campus Benjamin Franklin, Berlin; <sup>12</sup>Klinikum Bielefeld, Bielefeld; <sup>13</sup>German Rheumatism Research Centre, Berlin, Germany

**Background:** Knowledge of a positive family history (according to the ASAS definition (ASAS PFH)) for spondyloarthritis (SpA), in particular a PFH of ankylosing spondylitis (AS) or acute anterior uveitis (AAU), is considered valuable in making a diagnosis of axSpA but clusters with HLA-B27 positivity<sup>1</sup>. So a relevant clinical question is if a PFH is still important for making a diagnosis of axSpA if HLA-B27 status is known.

**Objectives:** To investigate in three independent axSpA cohorts if an ASAS PFH, a PFH of AS or a PFH of AAU contributes to a diagnosis of axSpA in patients with known HLA-B27 status.

**Methods:** Baseline data of patients suspected of axSpA in the ASAS, DESIR and SPACE cohorts were analysed. In each cohort, univariable logistic regression models were performed with HLA-B27 status and ASAS PFH as determinants and a clinical axSpA diagnosis as outcome. The analyses were repeated in multivariable models with both determinants. Relative risks for axSpA diagnosis were calculated stratified on both HLA-B27 status and ASAS PFH (HLA-B27-/ASAS PFH- as reference). Analyses were repeated with a PFH of AS and a PFH of AAU.

**Results:** In total, 1964 patients suspected of axSpA were analysed (ASAS n=594, DESIR n=647, SPACE n=723). ASAS, DESIR and SPACE patients had a mean (SD) symptom duration of 85.7 (108.4), 18.2 (10.5) and 13.3 (7.0) months; 54%, 47% and 38% were male; 52%, 58% and 44% were HLA-B27+; 44%, 40% and 35% had sacroiliitis on imaging (MRI and/or radiographs); 62%, 45% and 53% received a clinical diagnosis of axSpA; an ASAS PFH was reported in 23%, 39% and 43%, respectively. In the univariable analysis, HLA-B27 status was significantly associated with an axSpA diagnosis in all three cohorts; ASAS: OR 6.7 (95%CI 4.7–9.8), DESIR: OR 2.1 (95%CI 1.5–2.9), SPACE: OR 6.6 (95%CI 4.7–9.2). An ASAS PFH was univariately associated with an axSpA diagnosis in SPACE (OR 1.5 (95%CI 1.01–2.0)), but not in ASAS (OR 1.4 (95%CI 0.9–2.0)) and DESIR (OR 1.0 (95%CI 0.7–1.4)). In the multivariable models, HLA-B27 status was independently associated with a diagnosis of axSpA but such an independent association was not found for ASAS PFH in any cohort (ASAS: HLA-B27 OR 6.9 (95%CI 4.7–10.2), ASAS PFH OR 0.9 (95%CI 0.6–1.4); DESIR: HLA-B27 OR 2.1 (95%CI 1.5–2.9), ASAS PFH OR 1.0 (95%CI 0.7–1.3); SPACE: HLA-B27 OR 6.6 (95%CI 4.7–9.3), ASAS PFH OR 1.0 (95%CI 0.7–1.4)). In all cohorts, the relative risk of an axSpA diagnosis was highest in HLA-B27+/ASAS PFH- patients (**Abstract THU0232 – figure 1**). Similar results were found for a PFH of AS and AAU (data not shown).

**Abstract THU0232 – Figure 1.** Relative risks of axSpA diagnosis in patients suspected of axSpA stratified on HLA-B27 status and a positive family history according to the current ASAS definition (ASAS PFH) per cohort. HLA-B27-/ASAS PFH- is the reference category (RR=1).

**Conclusions:** A PFH does not contribute to the likelihood of an axSpA diagnosis in back pain patients with a known HLA-B27 status. This suggests that asking for a PFH of SpA in patients presenting with back pain is redundant if HLA-B27 status is known.

### SICK LEAVE AND ITS PREDICTORS IN ANKYLOSING SPONDYLITIS: LONG-TERM RESULTS FROM THE OUTCOME IN ANKYLOSING SPONDYLITIS INTERNATIONAL STUDY

C. Webers<sup>1,2</sup>, S. Ramiro<sup>3</sup>, R. Landewé<sup>4,5</sup>, D. van der Heijde<sup>3</sup>, F. van den Bosch<sup>6</sup>, M. Dougados<sup>7</sup>, A. van Tubergen<sup>1,2</sup>, A. Boonen<sup>1,2</sup>. <sup>1</sup>Rheumatology, MUMC; <sup>2</sup>Care and Public Health Research Institute (CAPHRI), Maastricht; <sup>3</sup>Rheumatology, LUMC, Leiden; <sup>4</sup>Rheumatology, Amsterdam Rheumatology Center, Amsterdam; <sup>5</sup>Rheumatology, Zuyderland Medical Center, Heerlen, Netherlands; <sup>6</sup>Rheumatology, Ghent University Hospital and University of Ghent, Ghent, Belgium; <sup>7</sup>Rheumatology, Paris Descartes University and Cochin Hospital, Paris, France

**Background:** Sick leave (SL) among patients with ankylosing spondylitis (AS) is a relevant outcome for individuals and for society. Disease related factors, contextual factors, but also SL itself may be risk factors for future adverse work outcome. To reveal predictors of SL over time, longitudinal studies are necessary. If SL itself is an independent predictor for further SL, this further underpins initiatives in clinical care to support worker participation.

**Objectives:** To investigate the occurrence of AS-related SL over 12 years and to explore which factors predict or explain SL.

**Methods:** Data from employed patients from the Outcome in Ankylosing Spondylitis International Study were used. At each visit, patients indicated the occurrence of SL (yes/no) in the previous inter-assessment period. Cox regressions were used to predict the hazard for a first episode of SL using baseline predictors. Generalised estimating equations (GEE) were used to investigate the association between SL and (time-lagged) predictors. To investigate whether SL predicts future SL, SL in the first year was included as covariate in a separate GEE analysis. Due to collinearity between ASDAS, BASDAI and BASFI, separate multivariable models were computed.

**Results:** 139 patients (76% males, mean [SD] age 38.7 [10.0] years) were at risk for SL during a mean (SD) period of 7.9 (3.9) years. Among the 88 patients (63%) who ever reported SL, 62 (70%) reported SL at more than 1 assessment. In separate multivariable Cox baseline predictors models, baseline ASDAS (HR 1.67 [95%CI 1.23–2.28]), BASDAI (HR 1.33 [95%CI 1.18–1.51]) and BASFI (HR 1.17 [95%CI 1.02–1.34]) were associated with increased hazard of SL, but only in male patients with a low level of education. In separate multivariable time-varying GEE models, 1 year time-lagged ASDAS (OR 1.48 [95%CI 1.07–2.03]), BASDAI (OR 1.31 [95%CI 1.15–1.49]) and BASFI (OR 1.31 [95%CI 1.16–1.47]) were associated with SL, but only in patients with a low level of education. Further adjustment for job type did not lead to different results, and job type itself was not significantly associated with SL. SL during the first year predicted SL over time (OR: 2.62–8.37 in different models, all p<0.05), independently of educational level, disease activity or physical function.

**Conclusions:** Disease activity and physical function predict and explain variation in SL, but only in patients with a low level of education. Prior SL results in future SL, and SL should be considered an actionable factor for support to prevent future adverse work outcome. Research into which SL is beneficial with regard to recovery and which SL is a risk for work disability is needed.

THU0234

### BMI DOES NOT AFFECT CLINICAL OUTCOME IN PSORIATIC ARTHRITIS PATIENTS TREATED WITH TIGHT CONTROL STRATEGY

D. Birra, G. Peluso, L. Gigante, E. De Lorenzis, G. Canestrari, G. Tanti, G. Natalello, D. Bruno, G. Ferraccioli, E. Gremese. *UOC of Rheumatology, Fondazione Policlinico Universitario A. Gemelli Catholic University of the Sacred Heart, Rome, Italy*

**Background:** Psoriatic arthritis (PsA) is characterised by several comorbidities; among these obesity and overweight have a major impact on patients' quality of

life and on disease treatment. Obesity increases the risk of developing psoriatic arthritis in the general population compared to normal-weight subjects. Obesity increases the risk of developing arthritis in patients with psoriasis, especially for HLA B27 negative and late onset forms.

**Objectives:** Aim of the study was to evaluate the incidence of overweight and obesity in a cohort of PsA patients, the differences between disease phenotypes and therapeutic response between patients with normal weight and overweight/obesity.

**Methods:** In this retrospective observational study 332 PsA patients, afferent to our unit between 2010 and 2017, were assessed. At each visit data on disease characteristics, BMI, ongoing treatment, joint count and clinimetric indexes were collected.

The baseline was defined as the onset of the disease in bio-naive patients or the start of the last bDMARD therapy for patients previously treated with cs or bDMARDs, while the last follow-up is considered the last visit at our unit

**Results:** The 332 patients had a mean age of 52.5±7.3 years;35% of the patients were normal weight, 39.5% were overweight and 25.5% obese. No differences were observed in terms of disease characteristics according to BMI category at baseline and during follow-up, with comparable percentages of peripheral arthritis, enthesitis, dactylitis, axial arthritis or uveitis, as well as cutaneous psoriasis among the groups.

At baseline, obese patients had more tender(4.4±5.2 vs 2.3±3.6 p=0.003)and swollen joints(mean value 2.3 vs 1 p=0.03)and higher activity indexes, as for DAS28(3.3±1.2 vs 2.7±1.2 p=0.002)and DAPSA(15.6±9.9 vs 11.5±9 p=0.004) compared to normal weight patients. The same difference was observed between normal-weight and overweight patients, with higher values of DAS28(3.04±1.4 vs 2.7±1.2,p=0.17)and DAPSA(13.6±11 vs 11.5±9, p=0.025)in overweight patients. No significant difference was observed in patients treated with NSAIDs, csDMARDs or bDMARDs according to BMI category.

In 190 patients followed according to the tight control strategy, with evaluations every 3 months, the disease activity indexes after two years of follow-up became similar in obese patients compared to normal weight patients.

Among the normal-weight patients, 69.4% took csDMARDs,48.7% were treated with bDMARDs. 74.7% of obese patients took csDMARDs, while 36.1% took bDMARDs, with no statistically significant differences between the two groups (p=ns).

In particular low-disease activity according to DAPSA was achieved in 76% of normal weight patients, compared with 68.9% of obese patients (p=ns), and also the percentage of patients reaching Minimal Disease Activity in the two groups was comparable (28.4% vs 22.7%, p=ns).

**Conclusions:** Clinical manifestations of psoriatic disease do not seem to differ according to BMI category;however, at the first evaluation, obese patients appear to have more disease activity than non-obese patients.

At the same treatment intensity, obese patients seem to achieve a percentage of remission comparable to normal weight patients, suggesting that the an intensive treatment strategy allows to obtain optimal results also in a more challenging group of patients.

**THU0235 ANKYLOSING SPONDYLITIS AND RHEUMATOID ARTHRITIS HOSPITALISATION TRENDS IN THE US: DATA FROM NATIONAL INPATIENT SAMPLE**

P. Karmacharya<sup>1,2</sup>, P. Shrestha<sup>2</sup>, R. Dhital<sup>2</sup>, D.R. Poudel<sup>2</sup>. <sup>1</sup>Rheumatology, Mayo clinic, Rochester, <sup>2</sup>Reading Hospital and Medical Center, Reading, USA

**Background:** Ankylosing spondylitis (AS) imposes significant morbidity and disability in the affected population. Hospitalisation trends provide an insight as to

burden of disease and long-term data is lacking. We evaluated AS related hospitalisation trends in the US from 2001–13, comparing it to the more common inflammatory arthritis- rheumatoid arthritis (RA).

**Objectives:** To evaluate AS related hospitalisation trends in the US in comparison to the more common inflammatory arthritis- RA

**Methods:** Using the Nationwide Inpatient Sample (NIS) data from 2009–2011, we identified patients ≥18 years with AS and RA at primary diagnosis positions based on ICD-9 codes 720.0 and 714.0, 714.2, 714.30–714.33 respectively. We also excluded patients with psoriatic arthritis and inflammatory bowel disease to improve the specificity of codes used. We used the trend weight (contained in the variable TRENDWT) supplied by HCUP to study the annual trends of hospitalizations in AS and RA (2001–13). We used Stata version 13.0 (College Station, TX) and Joinpoint regression analysis software to calculate yearly trends.

**Results:** NIS database from 2001–2013 contained 36 883 (weighted count, n=175,356) patients with RA and 1377 (weighted count- 6,554) patients with AS. A decreasing trend in AS and RA hospitalizations was noted with an annual percentage change (APC) of 5.35 and 4.28 respectively (p<0.05) (table 1 and figure 1).

**Conclusions:** While recent studies have shown a rise in incidence of AS, the hospitalisation rates have declined similar to RA. Our study findings may reflect increased recognition of inflammatory back pain in the primary care setting and prompt referral and diagnosis due to improved imaging techniques of the spine and pelvis. Furthermore, the use of biologics, such as TNF and IL-6 inhibitors have significantly improved outcomes.

<b>APR</b>		<b>(-5.39)*</b>		<b>(-5.35)*</b>			<b>(-4.03)</b>		<b>(-4.28)*</b>	

**Objectives:** To describe electrocardiographic (ECG) alterations in a cohort of patients with AS and if AS related factors at baseline predict the presence of CCD at 5 year follow-up.

**Methods:** In total 210 patients diagnosed with AS at 3 rheumatology clinics from Western Sweden participated 2009 in an observational longitudinal cohort study with a planned follow-up after 5 years. At follow-up 2014 physical examination, ECG, questionnaires, laboratory tests and radiographic examinations were repeated in 172 patients (82%). CCD was defined in the presence of AV block I (PQ duration  $\geq 220$  ms), AV block Ix (PQ duration 200–219 ms), AV block II-III, right and left bundle branch block (RBBB and LBBB), left anterior and posterior fascicular block (LAFB and LPFB) and pacemaker. Descriptive statistics and logistic regression analyses were performed in order to find predictors at baseline for the presence of CCD at follow-up. Baseline characteristics with a p-value $<0.2$  in univariate analyses (dependent variable *present CCD* (yes=1, no=0)) were included as independent variables in a forward stepwise multiple logistic regression analysis.

**Results:** In total 23 of the 172 patients (13.4%) had CCD at 5 year follow-up. Eight had developed a new CCD out of which 2 had required pacemaker implantation, 3 had a more aggravated CCD, whereas 10 patient had an unchanged and 2 a less pronounced. CCD compared with 2009 CCD and some of the patient characteristics are presented in table 1. (None had LPFB or AV block II-III). According to multiple logistic regression analysis, male sex (Odds ratio (OR) (95% CI) 4.7 (1.1–20.6)), increasing age (OR 1.1 (1.0–1.1) per 1 year), a history of anterior uveitis (OR 6.4 (1.1–36.2)), higher ASDAS-CRP (OR 3.6 (1.6–7.9)) and existing CCD at baseline (OR 42.4 (8.9–202.2)) were predictors for the presence of CCD at follow-up.

Abstract THU0236 – Table 1

	Patients without CCD (n=149)	Patients with CCD (n=23)
<b>BASELINE CHARACTERISTICS 2009</b>		
Male sex	74 (49.7)	19 (82.6)
Age, years	48.5 $\pm$ 12.3	58.7 $\pm$ 11.4
Symptom duration, years	22.5 $\pm$ 12.3	33.5 $\pm$ 14.3
HLA-B27	127 (85.2)	22 (95.7)
ASDAS-CRP	2.0 $\pm$ 0.8	2.7 $\pm$ 1.0
History of anterior uveitis	69 (46.3)	19 (82.6)
Aortic regurgitation <sup>#</sup>	20 (13.4)	6 (26.1)
At least one syndesmophyte	63 (42.3)	17 (73.9)
<b>Reported comorbidity</b>	36 (24.2)	11 (47.8)
1. Hypertension	5 (3.4)	0 (0.0)

### THU0237 INFLAMMATORY LESIONS OF THE SACROILIAC JOINTS, BUT NOT OF THE SPINE, ARE OF HIGH UTILITY FOR AXSPA RECOGNITION: RESULTS OF THE ILOS-DESIR STUDY

A. Molló<sup>1</sup>, L. Gossec<sup>2</sup>, M. Lefevre-Colau<sup>1</sup>, V. Foltz<sup>2</sup>, R. Beaufort<sup>1</sup>, J. Laredo<sup>3</sup>, P. Richette<sup>3</sup>, P. Dieudé<sup>4</sup>, P. Goupille<sup>5</sup>, A. Feydy<sup>1</sup>, M. Dougados<sup>1</sup>. <sup>1</sup>Cochin; <sup>2</sup>Pitié-Salpêtrière; <sup>3</sup>Lariboisière; <sup>4</sup>Bichat, Paris; <sup>5</sup>CHU Tours, Tours, France

**Objectives:** To evaluate the performance of MRI inflammatory lesions suggestive of axSpA for the axSpA recognition

**Methods:** Observational cross-sectional national multicentre study. **Patients:** a) Recent onset axSpA patients: first, a sample of 100 patients representative in terms of imaging abnormalities of the global DESIR recent onset axSpA cohort were selected. b) Recent onset CBP patients: consecutive in- and outpatients consulting for recent (>3 months but <5 years) mechanical CBP, initiating before the age of 45 y and with a maximum age of 50 y, in four tertiary care Hospitals were included in the study. **Imaging:** MRI scans (T2-STIR and T1 sequences) of the SIJ and full spine were performed in both groups with identical protocol. **Central reading:** an experienced reader (AM) centrally read all MRI scans, blinded for clinical diagnosis. **Statistical analysis:** Sensitivity, specificity and positive likelihood ratio of each lesion were calculated.

**Results:** A total of 98 patients with recent onset CBP were included, and compared to 100 recent onset axSpA patients. Age and gender were comparable (mean (SD) 36.2 (9.9) vs. 32.2 (8.7)y, and 41.8% and 45% males, in the CBP vs. axSpA groups, respectively). MRI inflammatory lesions of the SIJ were quite frequent in the CBP group (25% patients with at least one inflammatory lesion) but were significantly more frequently observed in the axSpA group (table 1), with a mean SIJ - SPARCC score of 4.9 (8.8) vs. 0.6 (1.3), p<0.001. The ASAS definition of MRI sacroiliitis presented a high specificity and a good positive likelihood ratio. Conversely, prevalence of inflammatory lesions of the spine was very frequent in the CBP group and not significantly lower compared to the axSpA group (SPARCC spine 5.6 (13.5) vs. 3.3 (5.8), NS, in the axSpA vs. CBP groups, respectively). Regardless the definition of a positive MRI for the spine applied, performances were not good

**Conclusions:** ASAS definition of a positive MRI-sacroiliitis performed very well for axSpA recognition; however, definitions proposed for a positive MRI-spine suggestive of axSpA did not seem to perform adequately in this recent disease stage. This supports the idea of not including a positive MRI of the spine in the ASAS classification criteria.

### ULTRASONOGRAPHIC EVALUATION OF DISTAL PATELLAR ENTHESIS IN PATIENTS AFFECTED BY ENTEROPATHIC SPONDILOARTHRITIS

A. Batticciotto<sup>1</sup>, G. Prato<sup>1</sup>, M. Antivalle<sup>1</sup>, M.C. Ditto<sup>2</sup>, M. Agosti<sup>1</sup>, E. Cumbo<sup>1</sup>, R. Talotta<sup>1</sup>, F. Atzeni<sup>3</sup>, P. Sarzi-Putti<sup>1</sup>. <sup>1</sup>Rheumatology Department, ASST-Fatebenefratelli-Sacco. "L. Sacco" University Hospital, Milano; <sup>2</sup>Rheumatology Department, Città della Salute e della Scienza di Torino, Torino; <sup>3</sup>Rheumatology Unit, Rheumatology Unit, University of Messina, Messina, Italy

**Background:** Enteropathic arthritis (EA) belongs to the spondyloarthritis (SpA) spectrum of diseases and occurs in patients affected by inflammatory bowel diseases (IBD). Several works demonstrated that ultrasonography (US) is a feasible, reliable and easily accessible tool for detecting chronic and active enthesal abnormalities even in a subclinical contest in SpA patients.<sup>1,2</sup>

**Objectives:** To evaluate the prevalence of US enthesal involvement of the distal insertion of patellar ligament in patients affected by EA.

**Methods:** Twenty-two consecutive AE patients (12 with Crohn's disease and 10 with ulcerative colitis; 8 females and 14 males; mean age 44.7 years, range 18–72 years; mean AE duration 10.1 years range 4–21 years) and 18 healthy age- and gender-matched controls (8 females and 10 males; mean age 48 years, range 24–68 years) underwent an US examination (ESAOTE MyLAB 70 6–18 MHz linear array transducer) according to the validated Madrid Sonographic Enthesis Index (MASEI). Clinical and clinimetric variables were assessed in both groups according with daily clinical practice.

**Results:** Focusing on the 44 distal patellar entheses we identified a higher prevalence of all the elementary lesion analysed. In 34 entheses we identify a dishomogeneous echostructure (77.3% vs 33.3%;  $p=0.0001$ ), in 38 structural thickness (86.4% vs 66.7%;  $p=0.03$ ), in 16 power Doppler positivity (36.3% vs 16.7%;  $p=0.04$ ), in 17 presence of calcifications (38.6% vs 16.7%;  $p=0.03$ ) and in 8 entheses the presence of erosions (18.8% vs 0%;  $p=0.007$ ). In the 45% of the examined patients we detected a simultaneous presence of dishomogeneous echostructure, structural thickness and power Doppler positivity suggestive for US active enthesitis at the level of the same entheses.

**Conclusions:** US detectable signs of enthesopathy and enthesitis are very frequent in EA patients even when we analyse the distal entheses of the patellar ligament alone. Further studies involving a larger number of patients are needed to confirm these preliminary data.

### PROGRESSION OF STRUCTURAL DAMAGE ON MRI OF THE SPINE AND SACROILIAC JOINTS IN PATIENTS WITH AXIAL SPONDILOARTHRITIS IS LIMITED: THE 5 – YEAR RESULTS IN THE DESIR COHORT

A. Sepriano<sup>1</sup>, S. Ramiro<sup>1</sup>, R. Landewé<sup>2</sup>, M. Dougados<sup>3</sup>, D. van der Heijde<sup>1</sup>. <sup>1</sup>Rheumatology, Leiden University Medical Centre, Leiden; <sup>2</sup>Rheumatology, Amsterdam Rheumatology and Clinical Immunology Center (ARC), Amsterdam, Netherlands; <sup>3</sup>Rheumatology, Hôpital Cochin, Hôpitaux de Paris, Paris, France

**Background:** Reliably detecting radiographic structural change in patients with axial spondyloarthritis (axSpA), especially in the sacroiliac joints (SIJ), is notoriously difficult. Magnetic resonance imaging (MRI) is an alternative for radiographs to assess structural damage. However, so far the utility of MRI in capturing change in structural damage over time has been poorly studied.

**Objectives:** We aimed to evaluate the change over time of structural lesions on MRI of the SIJ and spine in patients with axSpA.

**Methods:** Patients with recent onset ( $\leq 3$  years) axSpA (according to the treating rheumatologist) from the DESIR cohort were included. MRI of the SIJ (MRI-SIJ) and spine (MRI-spine) were obtained at baseline and 5 years and scored by 3 trained central readers unaware of the chronology. Structural damage in the SIJ (MRI-SIJ-STR) and in the spine (MRI-spine-STR) was defined according to 3 binary rules (A1:  $\geq 5$  fatty lesions and/or erosions; B1:  $\geq 3$  erosions; and C1:  $\geq 3$  fatty lesions) and 3 continuous scores (A2: number of fatty lesions/erosions; B2: number of erosions; and C2: number of fatty lesions). For binary outcomes, structural damage was defined by the agreement of at least 2 out of 3 readers and the % of net progression by subtracting the number of patients that 'improved' from those that 'worsened' divided by the total number of patients with complete

baseline and 5 year data. For continuous outcomes, the mean of the 3 readers was used and the difference between year 5 and baseline was calculated.

**Results:** In total, 151 and 145 patients had complete MRI-SIJ and MRI-spine data available from 3 readers, respectively. The percentages of net progression at SIJ level are summarised in the figure 1. These were 6.6%, 0.7% and 7.9% for the binary outcomes A1, B1 and C1 respectively. Notably, the percentage of 'improvement' (4.6%) was almost as high as the percentage of 'worsening' (5.3%) for definition B1 ( $\geq 3$  erosions); while no 'improvements' were seen by the 3 readers for definition C1 ( $\geq 3$  fatty lesions). Similar differences were seen for the mean (standard deviation) change of the 3 MRI-SIJ-STR continuous outcomes (A2: 1.02 (2.60); B2: 0.20 (1.39); and C2: 0.83 (2.20);  $p<0.01$  for all). MRI-spine-STR net change over time was almost absent (A1:  $-0.7\%$ ; B1: 0.0%; C1: 0.7%) considering the binary outcomes, and small (though statistically significant) considering definition A2 (0.18 (0.52);  $p<0.01$ ) and C2 (0.14 (0.48);  $p<0.01$ ) but absent for definition B2 (0.03 (0.24);  $p=0.109$ ).

**Abstract THU0239 – Figure 1.** Changes in different binary MRI-SIJ-STR outcome measures. All outcomes are assessed according to the '2 out of 3' definition in the completers population (N=151). MRI-SIJ-STR, structural damage on magnetic resonance imaging of the sacroiliac joints

**Conclusions:** These results suggest that patients with early axSpA only show modest structural progression in the MRI of the SIJ and that fatty lesions are more sensitive to change compared to erosions. In this early axSpA population, MRI-detected structural progression in the spine is very limited/absent.

THU0240

### THE SIZE AND FREQUENCY OF BONE MARROW OEDEMA ON SACROILIAC JOINT MRI DIFFERS IN A CLUSTER-WISE COMPARISON OF PATIENTS WITH FINDINGS SUGGESTIVE OF AXIAL SPONDILOARTHRITIS

A.A. Christiansen<sup>1</sup>, A.G. Loft<sup>2</sup>, K. Hørslev-Petersen<sup>1</sup>, S. Juhl-Pedersen<sup>3</sup>, U. Weber<sup>1</sup>, L.T. Hermansen<sup>1</sup>, B. Arnbak<sup>4</sup>, A. Zejden<sup>2</sup>, B. Schiøtz-Christensen<sup>4</sup>, C. Manniche<sup>4</sup>, O. Hendricks<sup>1</sup>. <sup>1</sup>King Christian 10th Hospital for Rheumatic Diseases and Hospital of Southern Jutland, Gråsten; <sup>2</sup>Aarhus University Hospital, Aarhus; <sup>3</sup>Rigshospitalet, Copenhagen; <sup>4</sup>Spine Centre of Southern Denmark, Middelfart, Denmark

**Background:** Multiple correspondence analysis (MCA) is a statistical method that allows for the translation of data from multiple categorical variables into single coordinates per individual. When combined with cluster analysis, individuals that share phenotypic characteristics can be grouped together. The Assessment of Axial Spondyloarthritis international Society (ASAS) published classification criteria for axial spondyloarthritis (axSpA) in 2009<sup>1</sup> that included active sacroiliitis on magnet resonance imaging (MRI) of the sacroiliac joints (SIJ) defined as bone marrow oedema (BME) present in either as 2 lesions on one slice, or 1 lesion on 2 consecutive slices.<sup>2</sup> It has been shown that extent of BME is associated with risk of radiographic progression.<sup>3</sup>

**Objectives:** To identify phenotypes in low back pain (LBP) patients recruited from primary care with findings suggestive of early axSpA and to assess differences in size and frequency of BME lesions on SIJ MRI.

**Methods:** Age, gender and the ASAS SpA features (SIJ BME on MRI, HLA-B27, inflammatory back pain, arthritis, heel enthesitis, uveitis, psoriasis, inflammatory bowel disease, good response to NSAIDs, family history of SpA, but not dactylitis (not observed) or radiographic sacroiliitis) of 134 LBP patients who either met or were one feature short of meeting the ASAS classification criteria for axSpA were analysed by MCA and subsequent k-means cluster analysis in order to identify various clinical phenotypes. The above listed SpA features, and if present, the

size and frequency of SIJ BME as defined by the Aarhus scoring module,<sup>4</sup> were compared across clusters.

**Results:** MCA and cluster analysis revealed 3 clusters. Cluster 1 was predominantly HLA-B27 positive (96.7%) with SIJ BME in half of the cases. Cluster 2 and 3 had SIJ BME in all cases. Cluster 3 had fewer features suggestive of axSpA than clusters 1 and 2. There were significant differences in frequency (3.0 vs 2.0 vs 1.0) and extent of BME (4.0 vs 2.0 vs 1.0) across clusters 1, 2 and 3.

**Abstract THU0240 – Table 1.** Cluster-wise comparison of the construction variables, frequency and size of sacroiliac joint bone marrow oedema\*

Characteristic	All (n=134)	Cluster 1 (n=30)	Cluster 2 (n=45)	Cluster 3 (n=59)	p-value†
Male	42.5	53.3	40.0	39.0	NS
Age category (years)					
≤25	18.7	26.7	6.7	23.7	<0.05 <sup>‡</sup>
26-32	29.9	23.3	40.0	25.4	NS

Elevated CRP	13.4	30.0	4.4	11.9	<0.01 <sup>§</sup> , <0.05 <sup>§</sup>
Among patients with SIJ BME					
Frequency of BME (1-4) <sup>‡</sup>	2.0 (2.0)	3.0 (5.0)	2.0 (2.0)	1.0 (1.0)	<0.01 <sup>§</sup> , <0.001 <sup>§</sup> , <0.05 <sup>§</sup>
Size of BME (1-24) <sup>‡</sup>	2.0 (2.0)	4.0 (7.0)	2.0 (3.0)	1.0 (1.0)	<0.01 <sup>§</sup> , <0.001 <sup>§</sup> , <0.05 <sup>§</sup>

\* Values are percent of patients or medians with interquartile ranges; †Kruskal-Wallis and Dunn's test for multiple comparisons; ‡Cluster 1 vs Cluster 2; ‡Cluster 1 vs Cluster 3; ‡Cluster 2 vs Cluster 3; ‡missing in 2 patients; ‡Frequency of BME was defined as the total count of lesions, i.e. 4 locations per joint; ‡Size of BME was graded as slight (<25%), moderate (25% to <50%), or severe (≥50%) extent of BME in the cartilaginous and ligamentous part of the corresponding sacral and iliac subcortical bone area, i.e. 4 locations per joint, and combined into a total score.

Abbreviations: SIJ, sacroiliac joints; BME, bone marrow oedema; MRI, magnet resonance imaging; HLA-B27, Human Leukocyte Antigen B27; NS, not significant; NSAIDs, non-steroidal anti-inflammatory drugs; CRP, C-reactive protein; NS, not significant

**Conclusions:** Three clusters were identified among LBP patients with findings suggestive of axSpA: 1 predominantly HLA-B27 positive cluster with SIJ BME in half of the subjects, and 2 clusters having less features suggestive of SpA and with SIJ BME in all subjects. The predominantly HLA-B27 positive cluster had more and larger BME lesions than the other 2, which may indicate individuals at risk for progression.

#### THU0241 MUSCULOSKELETAL INVOLVEMENT IN INFLAMMATORY BOWEL DISEASE'S PATIENTS: A MONO CENTRIC EXPERIENCE

A. Delle Sedie<sup>1</sup>, L. Ceccarelli<sup>2</sup>, L. Carli<sup>1</sup>, F. Costa<sup>2</sup>, S. Marchi<sup>2</sup>, M. Mosca<sup>1</sup>.  
<sup>1</sup>Rheumatology Unit, <sup>2</sup>University Gastroenterology Unit, University of Pisa, Pisa, Italy

**Background:** Musculoskeletal symptoms are frequently reported by patients with inflammatory bowel diseases (IBD). Those symptoms may vary from arthralgia to arthritis, involving peripheral or axial joints, with a prevalence ranging from 17% to 62% when considering any SpA manifestation (with a similar range for axial or peripheral involvement from 5% to 30%) and a definite SpA diagnosis up to 46%.<sup>1–10</sup> To date, a more comprehensive approach is needed, also because the use of DMARDs or biologics could improve both gastrointestinal and musculoskeletal symptoms.

**Objectives:** To evaluate the rate of MSK involvement in a mono centric cohort of IBD patients.

**Methods:** A questionnaire based on the features of SpA was used in the IBD out-patient clinic from January 1st to December 31st 2017. When there was a positivity for any feature, the patients were evaluated by a rheumatologist (with more than 18 years of experience in SpA). All the visits were performed in 2–3 weeks from the moment the questionnaire was performed (varying according to the seasonal time for holidays). When there were some doubts about the diagnosis, further examinations were requested.

**Results:** A total of 403 patients were visited in the out-patient clinic (220 affected by CD, 172 affected by UC and 11 with a not defined IBD). Fifty-nine patients were sent to the rheumatologist (33 CD, 24 UC and 2 not defined IBD). Eleven patients had 2 or more rheumatologic visits (to follow-up the disease and check the results

of the exams requested). To allow a diagnosis, 4 sacroiliac joints MRI and 1 ultrasound assessment of the feet were requested. A diagnosis of peripheral SpA was given in 9 patients while axial SpA was diagnosed in 7 subjects. The diagnosis was fibromyalgia, osteoarthritis and arthralgia in 1, 2 and 40 patients, respectively. Therapy was modified in 16/59 patients after the rheumatologic assessment (DMARDs were prescribed in 12 subjects while anti-TNFa in 4 of them). In 1 patient (with absolute contraindication for biologic therapy), two courses of SI joint injection were performed, improving local pain.

**Conclusions:** The results of our study confirm the already published prevalence of musculoskeletal involvement in IBD patients (15% of our IBD population complained musculoskeletal pain and 27% of the patients sent to the rheumatologist were given an enteropathic arthritis diagnosis). As for the already existing literature, we did not notice any evident difference in the prevalence of axial and peripheral involvement. An established collaboration between gastroenterologists and rheumatologists is necessary to provide an integrated and more comprehensive management of IBD, improving the quality of life of the patients.<sup>11–12</sup>

#### THU0242 PREGNANCY OUTCOMES AND DISEASE ACTIVITY IN WOMEN WITH AXIAL SPONDYLOARTHRITIS: A SYSTEMATIC LITERATURE REVIEW

A. Molló<sup>1</sup>, L. Gensler<sup>2</sup>, M.E.B. Clowse<sup>3</sup>, H. Marzo-Ortega<sup>4</sup>, A. Artignan<sup>5</sup>, D. Goff-Leggett<sup>6</sup>, S. Leonard<sup>6</sup>, H.K. Resemann<sup>5</sup>, E. Thurtell<sup>5</sup>, N. de Peyrecave<sup>6</sup>, C. Ecoffet<sup>7</sup>, F. Förger<sup>8</sup>.  
<sup>1</sup>Rheumatology Department, Hôpital Cochin, AP-HP, Paris, France; <sup>2</sup>University of California, San Francisco, San Francisco, CA; <sup>3</sup>Duke University Medical Center, Durham, NC, USA; <sup>4</sup>NIHR LBRC, Leeds Teaching Hospitals Trust and LIRMM, University of Leeds, Leeds; <sup>5</sup>Costello Medical, Cambridge; <sup>6</sup>UCB Pharma, Slough, UK; <sup>7</sup>UCB Pharma, Brussels, Belgium; <sup>8</sup>University of Bern, Bern, Switzerland

**Background:** Women with axial spondyloarthritis (axSpA) are often affected by the disease during their reproductive years,<sup>1</sup> but reports on disease activity and pregnancy outcomes in these patients (pts) are sparse. In women with ankylosing spondylitis (AS), also currently termed as radiographic axSpA, a higher risk of disease activity flares and prevalence of adverse pregnancy outcomes have been reported vs healthy controls; however, in non-radiographic (nr)-axSpA pts, such data are virtually non-existent.<sup>2,3</sup>

**Objectives:** To review the available evidence on the relationship between axSpA disease activity and pregnancy, including foetal outcomes.

**Methods:** A systematic literature review was conducted in October 2017 by searching EMBASE, MEDLINE<sup>®</sup>, the Cochrane Database of Systematic Reviews, and the Database of Abstracts of Reviews of Effects. Publications were systematically screened for English language articles on observational studies of axSpA pts reporting pregnancy outcomes or disease activity during pregnancy. Studies utilising agents contraindicated in pregnancy were excluded. Supplementary searches of selected, 2016–17 conference proceedings and bibliographies of relevant review articles were also conducted.

**Results:** 2216 publications were reviewed, with 20 publications on 15 unique studies meeting the inclusion criteria. When utilising the verified disease activity measurement instruments, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) or Ankylosing Spondylitis Disease Activity Score C-Reactive Protein (ASDAS-CRP), 5 studies (3 prospective, 2 retrospective) reported active disease (as described by individual studies; table 1) both during pregnancy and postpartum in most pts. Pregnancy outcomes in axSpA pts were compared with healthy controls in 6 studies (3 retrospective, 2 prospective, 1 case-control), the 3 largest of which (including 1 prospective) revealed higher risk or odds of preterm births in axSpA pts. Higher rates or risk of low birth weight/small-for-gestational-age neonates were shown in pts vs controls in 2/5 studies reporting such outcomes. Stillbirths, miscarriages or foetal loss/abortion were found to occur at similar rates in both populations.

**Conclusions:** Robust, prospective data on disease activity during pregnancies of women with axSpA are limited. Within the samples reported here, available data suggest that there may be a small increase in pre-term births; no signal for increased pregnancy loss was detected. Further research is needed to investigate relationships between maternal disease activity and pregnancy outcomes in axSpA.

**Abstract THU0242 – Table 1.** Maternal disease activity and pregnancy outcomes in axSpA patients

**THU0243 CASE FATALITY OVER 365 DAYS AFTER FIRST ACUTE CORONARY SYNDROME IN PATIENTS WITH ANKYLOSING SPONDYLITIS**

A. Södergren<sup>1</sup>, J. Asklind<sup>2</sup>, K. Bengtsson<sup>3</sup>, H. Forsblad-D’Elia<sup>1</sup>, T. Jernberg<sup>4</sup>, U. Lindström<sup>3</sup>, L. Ljung<sup>1,2</sup>, Å. Mantel<sup>2</sup>, L.T. Jacobsson<sup>3</sup>. <sup>1</sup>Dept of public health and Clinical medicine/Rheumatology, Umeå University, Umeå; <sup>2</sup>Clinical Epidemiology Section, Department of Medicine Solna, Karolinska Institutet, Stockholm; <sup>3</sup>Department of Rheumatology and Inflammation Research, Sahlgrenska Academy at University of Gothenburg, Gothenburg; <sup>4</sup>Dept of clinical sciences, Danderyd University Hospital, Karolinska Institutet, Stockholm, Sweden

**Background:** Ankylosing spondylitis (AS) is characterised by systemic and local inflammation of the axial skeleton, joints, and entheses. Studies have suggested a higher risk of acute coronary syndrome (ACS) among patients with AS compared with the general population, but whether patients with AS also have an increased fatality following ACS is not known.

**Objectives:** Is AS associated with an increased case fatality after a first-time ACS compared with the general population?

**Abstract THU0243 – Table 1.** Mortality and hazard ratios (HR) for patients with AS and general population referents during 365 days of follow up after a first ACS

	Start		At 30 days follow up		At 365 days follow up		
	Individuals at risk	Individuals at risk	n deaths	HR (95% CI) day 0–30	Individuals at risk	n deaths	HR (95% CI) day 31–365
AS	292	273	26	0.9 (0.6;1.5)	266	56	2.0 (1.3;3.1)
General population comparator	1276	1204	118	ref	1158	184	ref

**Methods:** From the Swedish National Patient Register (NPR) we identified all patients registered with AS Jan 2001 through Dec 2014 and a later registration of a first time ACS between Jan 2006 and Dec 2014 (n=292). As a general population comparator, we identified up to 5 individuals per index-patient (n=1276), matched on year of first ACS and birth, gender, and place of living. The follow-up period began at the date of admission for ACS and extended until death, emigration, 365 days of follow-up or 31 December 2014, whichever occurred first. Hazard ratios (HR) for death in the AS group vs. the general population comparator was assessed using Cox regression. We assessed HRs for death in two intervals: 30 day mortality (day 1 through 30), and mortality day 31 through 365.

**Results:** During the 365 days following the ACS, 56 (19%) of the 292 AS patients and 184 (14%) of the 1276 population controls died (table 1). Whereas the 30 day mortality in the AS group was not elevated (HR=0.9), the mortality day 31 through 365 was doubled compared with the general population (HR=2.2, table 1 and figure 1).

**Abstract THU0243 – Figure 1.** Kaplan-Meier curves showing survival after first ACS in patients with AS and general population referents during 365 days follow up.

**Conclusions:** Patients with AS were at increased risk of death during the first year, though not during the first month, following ACS. It is yet not clear whether this could be due to factors associated with the AS disease *per se*, or differences in ACS characteristics or treatment.

**THU0244 HIGH PREVALENCE OF CLINICAL SPONDYLOARTHRITIS FEATURES IN PATIENTS WITH HIDRADENITIS SUPPURATIVA**

A. Rondags<sup>1</sup>, K.R. van Straalen<sup>2</sup>, S. Arends<sup>3</sup>, H.H. van der Zee<sup>2</sup>, E. Prens<sup>2</sup>, B. Horvath<sup>1</sup>, A. Spoorenberg<sup>3</sup>. <sup>1</sup>Dermatology, University of Groningen, University Medical Center Groningen, Groningen; <sup>2</sup>Dermatology, Erasmus Medical Center, Rotterdam; <sup>3</sup>Rheumatology and Clinical Immunology, University of Groningen, University Medical Center Groningen, Groningen, Netherlands

**Background:** Hidradenitis suppurativa (HS) is a chronic debilitating inflammatory skin disease and is associated with several comorbidities. HS and spondyloarthritis (SpA) share several pathophysiological and clinical features, such as elevated cytokine levels of TNF-α and IL-17 and the association with inflammatory bowel

disease. Recognition of clinical axial and peripheral SpA features might help to identify patients with a higher chance of having SpA.

**Objectives:** To investigate the prevalence of self-reported clinical SpA features in HS patients and to identify HS patient characteristics associated with the presence of these features.

**Methods:** In this cross-sectional study, a questionnaire concerning clinical SpA features was sent to all patients with a billing code of HS (between 2010 and 2016) in two tertiary HS referral centres in the Netherlands. First, questions were formulated based on the ASAS definitions for axial and peripheral SpA entry classification criteria: "back pain for  $\geq 3$  months with age of onset  $< 45$  years" and "peripheral arthritis, enthesitis or dactylitis" in past or present, respectively. Additionally, questions concerning other clinical SpA features (table 1) in past or present were asked. Questions were provided with proto-typical coloured pictures of SpA features for clarification. Prevalence of self-reported SpA features was calculated and comparative analysis was performed.

**Results:** Overall, 47.2% (620/1313) of questionnaires were eligible for analyses. Included patients had a mean age of  $43 \pm 14$  years, 70% were female, mean BMI was  $28.0 \pm 5.8$ , 84% were ex- or current smokers, and 25% had no HS symptoms at the time of the survey.

In total, 67.1% (416/620) of HS patients fulfilled  $\geq 1$  of the four ASAS entry criteria. The entry criteria for axial and peripheral SpA were reported by 72.8% (303/416) and 27.2% (113/416), respectively. The large majority of patients (87%) reported  $\geq 1$  clinical SpA features in addition to the entry criteria: one feature by 137 (32.9%) patients, two by 121 (29.1%), three by 67 (16.1%), and  $\geq 4$  by 37 (8.9%). An overview and percentage of the clinical SpA features is presented in table 1.

In comparison to patients without self-reported SpA entry criteria features (n=204), patients fulfilling the ASAS entry criteria were more frequently female (p<0.001), had higher BMI (p<0.001), more often positive smoking history (p=0.001), longer HS disease duration (p=0.012), and showed more active HS symptoms at time of the survey (p<0.001).

**Abstract THU0244 – Table 1.** Overview of self-reported clinical SpA features in patients with HS fulfilling the axial or peripheral ASAS entry criteria (n=416).

Self-reported clinical SpA features	Number of patients (%)
Inflammatory back pain	84 (20.2)
Good response to NSAIDs on back pain	63 (22.0)
Peripheral arthritis (swollen joints)	248 (59.6)
Enthesitis (Achilles tendon)	66 (15.9)
Dactylitis	83 (20.0)
Inflammatory bowel disease	31 (7.6)
Psoriasis	39 (9.4)
Uveitis	13 (3.2)
Positive family history of SpA	125 (30.0)

**Conclusions:** Clinical axial and peripheral SpA features are common in HS patients, especially in the 'classic' HS patient (female, overweight, smoker), with longer HS disease duration and symptoms of active HS.

#### THU0245 RELATIVE RISK CHART SCORE FOR THE ASSESSMENT OF THE CARDIOVASCULAR RISK IN YOUNG PATIENTS WITH ANKYLOSING SPONDYLITIS

B. Atienza-Mateo<sup>1</sup>, J.L. Martín-Varillas<sup>1</sup>, L.C. Domínguez-Casas<sup>1</sup>, N. Vegas-Revenga<sup>1</sup>, J. Rueda-Gotor<sup>1</sup>, F. Genre<sup>1</sup>, A. Corrales<sup>1</sup>, R. Blanco<sup>1</sup>, P. Fuentevilla<sup>1</sup>, V. Portilla<sup>1</sup>, R. Expósito<sup>2</sup>, C. Mata<sup>2</sup>, T. Pina<sup>1</sup>, C. González-Juanatey<sup>3</sup>, L. Rodríguez-Rodríguez<sup>4</sup>, M. Á. González-Gay<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander; <sup>2</sup>Rheumatology, Hospital Comarcal de Laredo, Laredo; <sup>3</sup>Cardiology, Hospital Lucus Augusti, Lugo; <sup>4</sup>Rheumatology, Hospital Clínico San Carlos, Madrid, Spain

**Background:** Ankylosing spondylitis (AS) is associated with increased rates of cardiovascular (CV) mortality. CV events can be prevented by identifying patients with high CV risk who can benefit from strict primary prevention measures. The systematic coronary risk evaluation (SCORE) is the predictive model recommended in Europe, but it underestimates the CV risk in individuals under 50 years old.

**Objectives:** To determine if the use of the relative risk (RR) chart score (figure 1) may help to identify young AS patients at high risk of CV disease.

**Methods:** A set of 73 AS patients younger than 50 years old without history of CV events, diabetes mellitus or chronic kidney disease was assessed. CV risk was calculated according to the total cholesterol systematic coronary risk evaluation (TC-SCORE) and the RR chart score. A value of C-reactive protein (CRP)  $> 3$  mg/L at diagnosis, cut-off point associated with an increased risk of CV events, and carotid ultrasound data performed at the time of the assessment were also analysed.

**Results:** Twenty (27.4%) of 73 patients exhibited carotid plaques and, consequently, they were classified into the category of very high CV risk. CRP  $> 3$  mg/L at disease diagnosis was associated with the presence of carotid plaques after adjustment for confounding factors (odds ratio 5.66, 95% confidence interval 1.11–28.77; p=0.03). None of these young patients were included in the category of high/very high CV according to the TC-SCORE. Whereas only 5 (14.2%) of the 35 patients with RR=1 had carotid plaques, 15 (39.5%) of 38 with RR  $> 1$  showed plaques. A model that included the performance of carotid US in patients with RR  $> 1$  who had CRP  $> 3$  mg/L at disease diagnosis allowed us to identify 60% of young AS with very high CV risk, with a specificity of 77.4% (area under the curve [AUC]: 0.69). The performance of carotid US in young AS patients with RR  $> 1$  regardless of CRP data at diagnosis increased the sensitivity up to 75% at the expense of a significant decline in the specificity to 56.6% (AUC: 0.66) (table 1).

**Abstract THU0245 – Table 1.** Study of 73 AS patients between 35 and 50 years without cardiovascular events, diabetes mellitus or chronic kidney disease to establish the presence of high/very high cardiovascular risk.

	Sensitivity	Specificity	Correctly classified	ROC [95% CI]
<b>Model 1.</b> TC-SCORE $\geq 5\%$ OR TC-SCORE $\geq 1\%$ $< 5\%$ plus carotid US (presence of plaques)	40%	88.7%	75.3%	0.64 [0.53–0.76]
<b>Model 2.</b> RR $> 1$ and CRP $> 3$ mg/L at time of disease diagnosis plus carotid US (presence of plaques)	60.0%	77.4%	72.6%	0.69 [0.56–0.81]
<b>Model 3.</b> RR $> 1$ plus carotid US (presence of plaques)	75.0%	56.6%	61.6%	0.66 [0.53–0.78]

TC-SCORE: Total Cholesterol systematic coronary risk evaluation, US: ultrasound, RR: relative risk, CRP: C-reactive protein.

The gold standard used to define high/very high cardiovascular risk was the presence of TC-SCORE  $\geq 5\%$  or carotid plaques.

Based on the ESC 2016 guidelines

**Abstract THU0245 – Figure 1.** Relative Risk chart, derived from SCORE. Based on the ESC 2016 guidelines

**Conclusions:** RR chart score assessment may help to identify young AS at high risk who are underdiagnosed as having very high CV risk by the SCORE.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrhumdis-2018-eular.3906

THU0246

### CAN DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS BE ADEQUATELY ASSESSED BY A MODIFIED DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA) BASED ON 28 JOINTS?

B. Michelsen<sup>1</sup>, J. Sexton<sup>1</sup>, J. Smolen<sup>2</sup>, D. Aletaha<sup>2</sup>, N.S. Krogh<sup>3</sup>, D. van der Heijde<sup>4</sup>, T.K. Kvien<sup>1</sup>, M.L. Hetland<sup>5</sup>. <sup>1</sup>Diakonhjemmet Hospital, Oslo, Norway; <sup>2</sup>Medical University of Vienna and Lainz Hospital, Vienna, Austria; <sup>3</sup>ZiteLab ApS, Frederiksberg, Denmark; <sup>4</sup>Leiden University Medical Center, Leiden, Netherlands; <sup>5</sup>DANBIO, Center for Rheumatology and Spine Diseases, Rigshospitalet, Glostrup, Denmark

**Background:** 66/68 vs. 28 joint count has higher face validity in PsA. However, many databases/registries routinely collect only 28-joint count. It is not known if these data can be used to provide sufficient information on disease activity and response to therapy.

**Objectives:** To compute and test the potential validity of a simplified Disease Activity index for Psoriatic Arthritis (DAPSA) using 28 instead of 66/68 joint count.

**Methods:** We included PsA patients from the Danish national quality registry DANBIO, divided into examination (n=3157 patients, 24160 visits) and validation cohorts (n=3154 patients, 24160 visits) according to odd/even IDs. We defined: DAPSA28=(28TJCxconversion factor<sub>1</sub>)+(28SJCxconversion factor<sub>2</sub>)+patient global[0–10VAS]+pain[0–10VAS]+CRP[mg/dL]. Identification of conversion factors was performed by Generalised Estimating Equations (GEE, multiple visits per patient) in the examination cohort, and criterion, correlational and construct validity explored in the validation cohort.

**Results:** Mean(SD) age: 52.0 (13.8) years, 54.4% females. GEE: Conversion factor<sub>1</sub>=1.6, 95% CI(1.6–1.7), conversion factor<sub>2</sub>=1.6, 95% CI(1.5–1.6), leading to: DAPSA28=(28TJC+28 SJC)x1.6+patient global[0–10VAS]+pain[0–10VAS]+CRP[mg/dL]. Criterion validity: Physician global and DAPSA/DAPSA28 were similarly correlated (r=0.63/r=0.61, p<0.001). DAPSA/DAPSA28 had comparable discriminative power, expressed as standardised mean difference (DAPSA,0.90; DAPSA28,0.93) to distinguish between patients in high (starting bDMARD) and low (not starting/changing s/bDMARD for ≥60 days) disease activity. Agreement between DAPSA/DAPSA28 disease activity states was best for remission/low disease activity (table 1).

Kappa with quadratic weighting of DAPSA/DAPSA28 disease activity states indicated very good agreement; 0.92 95% CI (0.92–0.92). Standardised response means for DAPSA/DAPSA28 were –0.96/–0.92 (n=572) for visits after start of bDMARD. Correlational validity: Baseline DAPSA/DAPSA28 had strong correlation with DAS28CRP (r=0.87/r=0.93), SDAI (r=0.92/r=0.99), p<0.001. Bland-Altman plot showed better agreement between DAPSA/DAPSA28 for low than high disease activity (figure 1). Construct validity: DAPSA/DAPSA28 were similarly correlated to HAQ; r=0.60/0.62, p<0.001. DAPSA/DAPSA28 discriminated patients reporting their symptom state as acceptable (n=1140) vs. not acceptable (n=1045) equally well: mean(SD) 9.1 (8.7)/8.4 (8.0) and 24.2 (14.9)/22.5 (13.8), respectively.

**Conclusions:** DAPSA28 showed good criterion, correlational and construct validity, and sensitivity to change. However, agreement between DAPSA and

DAPSA28 was better for low than high disease activity levels. We recommend that 66/68 joint count should be performed and the original DAPSA should be preferred in PsA. However, our study suggests that data sets with only 28-joint counts available can use DAPSA28, especially in patients with low disease activity.

THU0247

### SPA-NET: A DISEASE-SPECIFIC INTEGRATED EHEALTH SYSTEM AND QUALITY REGISTRY FOR SPONDYLOARTHRITIS IN DAILY PRACTICE IN THE NETHERLANDS

C. Webers<sup>1</sup>, E. Beckers<sup>1</sup>, Y. van Eijk<sup>1</sup>, H. Vonkeman<sup>2</sup>, M. van de Laar<sup>2</sup>, P. van Riel<sup>3</sup>, M. Efdé<sup>4</sup>, A. Boonen<sup>1</sup>, A. van Tubergen<sup>1</sup>. <sup>1</sup>Rheumatology, MUMC, Maastricht; <sup>2</sup>Rheumatology, MST, Enschede; <sup>3</sup>Rheumatology, Bernhoven, Uden; <sup>4</sup>Rheumatology, VieCuri, Venlo, Netherlands

**Background:** Regular and personalised monitoring of disease activity, physical activity, medication use and side effects is essential to improve and maintain patients' health-related quality of life in spondyloarthritis (SpA). Transparency on outcomes, safety, practice variation and efficiency of care are increasingly demanded. Furthermore, patient empowerment and shared decision making are advocated. An integrated eHealth system including an electronic patient medical record (EMR) and real-time quality management system could provide a solution to meet these demands.

**Objectives:** To develop and test the feasibility of a disease-specific integrated eHealth system and quality registry for SpA in the Netherlands ('SpA-Net'), in order to 1) improve the quality of care for the individual patient, 2) provide transparency on treatment results, practice variation and costs and 3) to produce data for scientific research.

**Methods:** The eHealth system was developed in four phases. First, the content and design were discussed with experts in the field of SpA and patients (pts). Second, the database, EMR and quality management system were developed. Third, multiple rounds of internal and external testing were performed in collaboration with IT specialists, care providers and pts. Fourth, the eHealth system was implemented in practice and feasibility was tested among pts and care providers through semi-structured focus interviews.

**Results:** SpA-Net was designed and developed in 2015 and implemented into practice in May 2016. All pts entered into SpA-Net have a diagnosis of SpA according to their treating rheumatologist. There are no inclusion or exclusion criteria towards the subtype of SpA or treatment. Information prospectively collected at routine outpatient consultations on diagnosis, demographics, specific SpA manifestations, patient reported outcome measures, clinical outcomes, comorbidities, medication use and safety, supplemented with data from the hospital information system, is directly stored in a database. The comprehensive individual patient data are readily available to the physician and an excerpt of this can be accessed by the patient. Prior to each visit, pts complete online questionnaires. The information is presented in graphs wherever possible (figure 1).

In December 2017, 1078 pts participated in SpA-Net (mean [SD] age 53.7 [14.3] years, 46.6% females), and inclusion is ongoing. Focus group interviews were held with 16 pts, 9 rheumatologists, and 5 nurses. Pts considered the layout of SpA-Net as clear, accessible and intuitive. They felt the use of questionnaires resulted in better quality of care and communication, and appreciated having access to their EMR with lay-term explanations. Points of improvement were the login process and providing more details about the care provider's notes. Care providers appreciated the additional information for (preparing) consultations. Barriers against use of SpA-Net were the initial time required to adopt the EMR and the quantity of data entry.

DAPSA28 (n=6421)	DAPSA(n=6421) n(%) stratified by DAPSA disease activity states			
	DAPSA≤4	DAPSA>4 and≤14	DAPSA>14 and≤28	DAPSA>28
DAPSA28≤4	1135 (98.4)	126 (5.6)	4 (0.2)	0 (0)
DAPSA28>4 and≤14	18 (1.6)	2073 (91.5)	345 (17.8)	14 (1.3)
DAPSA28>14 and≤28	0 (0)	66 (2.9)	1509 (77.9)	248 (23.3)
DAPSA28>28	0 (0)	80 (4.1)	803 (75.4)	

Abstract THU0247 – Figure 1. Example of graph in SpA-Net reporting the evolution of ASDAS in relation to medication use over time

**Conclusions:** SpA-Net enables regular monitoring of pts with SpA and can serve as a first step to optimise knowledge and communication between pts and care providers. Both pts and care providers thought SpA-Net improves quality of care in daily practice.

THU0248

#### ASSOCIATION OF KINESIOPHOBIA, AEROBIC EXERCISE, FUNCTIONAL IMPAIRMENT AND DISEASE ACTIVITY OF PATIENTS WITH RHEUMATOID ARTHRITIS AND SPONDYLOARTHRITIS

D. peres<sup>1</sup>, N. tordi<sup>1</sup>, Y. sagawa<sup>2</sup>, D. wending<sup>3</sup>, C. Prati<sup>1,3</sup>. <sup>1</sup>Pepite ea4267, Univ. Bourgogne Franche-Comté; <sup>2</sup>Laboratoire de l'Exploration Fonctionnelle et Clinique du Mouvement (LEFCM); <sup>3</sup>rheumatology unit, Hopital jean minjoz, besancon cedex, France

**Background:** Rheumatoid arthritis (RA) and spondyloarthritis (SA) are the most common chronic inflammatory rheumatism, leading to functional disability, but also cardiovascular mortality. Aerobic exercise (AE) is one of the most effective non-pharmacological resources for cardiovascular rehabilitation while the patients RA and SA have difficulty to join the practice of physical exercise. It can be explained by the presence of kinesiophobia, fear that the movement exacerbates the pain and disease.

**Objectives:** To compare the level of AE of patients with RA and SA with healthy subjects and to verify the association between kinesiophobia, the level of activity of the disease and the functional disability

**Methods:** Fifty RA patients and fifty SA patients followed by the rheumatology department of the University Hospital of Besançon and fifty healthy age-matched subjects were included. The main inclusion criteria: between 18 and 80 years old and without orthopaedic surgery <1 year. The disease activity (DAS-28 and ASDAS), the functional disability (HAQ and BASFI), the level of AE (SQUASH questionnaire) and kinesiophobia (TSK questionnaire) were evaluated. The control group answered to the SQUASH questionnaire. The t-test was used to compare inflammatory rheumatism groups with the control group (healthy subjects). The Pearson Correlation Test for each group (RA and SA) was used to verify the associations between variables.

**Results:** The level of AE is significantly higher in healthy subjects ( $p=0.022$ ). In the RA group, kinesiophobia is associated with disease activity, functional disability and level of AE. In the SA group, kinesiophobia is associated only with the functional disability. Patients have a low level of AE compared to healthy subjects. However, only the RA group has an association between kinesiophobia and AE. In the SA group, functional disability appears to be a factor limiting the practice of AE.

Abstract THU0248 – Table 1. Results of pearson correlation test between variables

	Aerobic Exercise	Kinesiophobie	Functional Disability	Disease Activity
RA				
Aerobic Exercise	-	$r = -0.280^*$	$r = -0.414^{**}$	$r = -0.149$
Kinesiophobie	$r = -0.280^*$	-	$r = 0.522^{**}$	$r = 0.327^*$
Functional Disability	$r = -0.414^{**}$	$r = 0.522^{**}$	-	$r = 0.531^*$
SA				
Aerobic Exercise	-	$r = -0.165$	$r = -0.40$	$r = -0.064$
Kinesiophobie	$r = -0.165$	-	$r = 0.345^*$	$r = 0.224$
Functional Disability	$r = -0.040$	$r = 0.345^*$	-	$r = 0.737^{**}$

\*  $p < 0.005$ ; \*\*  $p < 0,005$

**Conclusions:** RA and SA patients need to be encouraged and better informed about the benefits of physical exercise.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.6741

THU0249

#### MORE THAN 60% PATIENTS WITH SPONDYLOARTHRITIS REPORT PERIPHERAL MANIFESTATIONS: AN ANCILLARY ANALYSIS OF THE ASAS-COMOSPA STUDY

C. López-Medina<sup>1,2</sup>, A. Moltó<sup>1,3</sup>, M. Dougados<sup>1,3</sup>. <sup>1</sup>Rheumatology, Cochin Hospital, Paris, France; <sup>2</sup>Rheumatology, Hospital Universitario Reina Sofía/IMBIC/ Universidad de Córdoba, Córdoba, Spain; <sup>3</sup>Inserm (U1153), clinical epidemiology and biostatistics., PRES Sorbonne Paris-Cité, Paris, France

**Background:** Peripheral manifestations (arthritis, enthesitis and dactylitis) can be observed in patients with Spondyloarthritis (SpA)<sup>1</sup>, but the factors associated with their presence are not well known. Studies are needed in order to thoroughly evaluate these symptoms.

**Objectives:** a) To describe the prevalence of peripheral manifestations in patients with SpA in a world-wide population; and b) to determine the factors associated with the presence of these manifestations.

**Methods:** Data from the ASAS-COMOSPA study were analysed. The prevalence of each peripheral manifestation was evaluated with regard to the criteria fulfilled by the patient (ASAS axial, ASAS peripheral, CASPAR) and with regard to the time of occurrence of axial symptoms (before/concomitant/after). Factors associated with the presence of these peripheral manifestations were also explored by univariate and multivariate logistic regression.

**Results:** Out of the 3984 patients included in ASAS-COMOSPA, 2562 (64.3%) reported, at least, one peripheral manifestation. Among these, 2051 patients (51.5% from the total database) had current or past history of peripheral arthritis, being more frequent among patients who met CASPAR and Peripheral ASAS criteria (see figure 1). Involvement was more frequently oligoarticular (40.2%) and appearing after axial symptom onset (48.9%). Multivariate analysis showed that patients from South America [OR 2.45, (95%CI 1.93–3.11)], the presence of enthesitis [OR 2.46, (95%CI 2.11–2.86)], dactylitis [OR 6.46, (95%CI 4.78–8.71)], skin psoriasis [OR 2.46, (95%CI 1.79–3.37)], HLAB27+ [OR 0.83, (95%CI 0.72–0.97)] and inflammatory back pain (IBP) [OR 0.37, (95%CI 0.29–0.47)] were associated with peripheral arthritis.

A total of 1506 (37.8%) and 618 (15.6%) patients reported enthesitis and dactylitis, respectively. Both occurred after axial symptoms onset in 58.3% and 60.8% of the patients, respectively. Similar results than peripheral arthritis were obtained in the multivariate analysis regarding these two peripheral manifestations, with exception of IBP and HLAB27+, which were not associated with enthesitis.

\*434 patients fulfil neither axial ASAS, nor peripheral ASAS, nor CASPAR criteria.

(P.A. 43.8%, Ent. 34.8%, Dac. 11.3%).

P.A.: Peripheral Arthritis, Ent.: Enthesitis, Dac.: Dactylitis.

Abstract THU0249 – Figure 1. \*434 patients fulfil neither axial ASAS, nor peripheral ASAS, nor CASPAR criteria.

**Conclusions:** Peripheral manifestations appear in 64% of patients with SpA and in more than 50% after axial symptoms onset. Peripheral arthritis, were more frequently mono- or oligo- rather than poly-articular, and the presence of psoriasis or any of the three peripheral manifestations acts as risk factor for the development of other peripheral symptoms.

#### THU0250 IMPACT OF GUT INVOLVEMENT IN EARLY SPONDYLOARTHRITIS. THE DESIR COHORT

D. Wendling<sup>1</sup>, X. Guillot<sup>1</sup>, C. Prati<sup>1</sup>, C. Miceli-Richard<sup>2</sup>, A. Molto<sup>2</sup>, R. Lories<sup>3</sup>, M. Dougados<sup>2</sup>. <sup>1</sup>Rheumatology, CHRU Besançon, Besançon; <sup>2</sup>Rheumatology, Cochin Hospital, Paris, France; <sup>3</sup>Skeletal Biology, KU Leuven, Leuven, Belgium

**Background:** Inflammatory bowel disease (IBD) is a well-known extra articular feature of spondyloarthritis (SpA), with increasing evidence of a pathophysiological relationship.

**Objectives:** The aims of this study were to evaluate in the DESIR cohort a) the prevalence of IBD at baseline and M60, and b) the incidence of IBD over the first 5 years of follow-up, c) factors (epidemiological, clinical, imaging, biological data available in the database) associated with IBD, a on the prevalent cases at baseline and at year 5 and also on the incident cases.

**Methods:** DESIR is a prospective observational cohort of patients with recent onset (<3 years) inflammatory back pain, suggestive of axial SpA. All available factors in the database were compared between patients with and without past or present IBD at baseline and at M60, and with and without incident cases of IBD over the 5 years of follow-up, by uni and multivariate analysis.

**Results:** At baseline, 706 patients were analysed, 35 had a past history or a concomitant IBD: prevalence 4.94% [CI 95%: 3.3–6.5]. IBD was significantly associated (univariate) with family history of IBD, DMARD use, steroid use, history of uveitis, elevated ESR and negatively associated with psoriasis, HLA-B27 and NSAID score. In multivariate analysis IBD was positively and independently associated with history of uveitis; OR 3.62 [1.95–6.74], levels of DKK-1: OR 1.03 [1.02–1.05] and TNF serum levels: OR 1.17 [1.08–1.26]. IBD was not associated with phenotypic presentation (peripheral arthritis, enthesitis, dactylitis, uveitis) or baseline serum levels of other cytokines (IL-6, IL-17 A, IL-17 F, IL-23, IL-23).

At M60, 480 patients were analysed, 58 with IBD: prevalence 12.1% [9.17–14.99]. In univariate analysis on prevalent cases, IBD was associated with lower NSAID score, worse activity and function indexes (ASDAS-CRP, BASFI, SF-36, HAQ, ASQoL), use of DMARD anti TNF, more sick leave. In multivariate analysis, IBD was associated with fulfilment of modified New York criteria: OR 4.85 [2.23–10.57], sick leave: OR 1.01 [1.005–1.014], BASDAI: OR 1.10 [1.05–1.16], and with smoking: OR 2.79 [1.53–5.07]. No association with MRI scores, enthesitis, psoriasis, BMD.

After a 5 year follow-up period, 23 new incident cases of IBD were recorded, giving an estimated occurrence rate of 0.95/100 [0.57–1.35] patient-years in this population. Incidence of IBD was independently associated (multivariate) with: HLA B27: OR 0.36 [0.22–0.59], fulfilment of modified New York criteria at M0: OR 3.35 [1.85–6.08], family history of IBD: OR 3.31 [1.62–6.77].

**Conclusions:** In early SpA, IBD occurs with an incidence of around 1/100 patient-years, and is associated with poor outcome at 5 years, family history of IBD, absence of HLA-B27, fulfilment of modified New York criteria.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.3205

#### THU0251 CHARACTERISTICS OF NEWLY DIAGNOSED AXIAL SPONDYLOARTHRITIS PATIENTS IN RHEUMATOLOGY PRACTICES ACROSS GERMANY

D. Poddubnyy<sup>1</sup>, E. Edelmann<sup>2</sup>, V. Rios Rodriguez<sup>1</sup>, S. Saringen<sup>3</sup>, T. Mosch<sup>3</sup>, J. Sieper<sup>1</sup>. <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin; <sup>2</sup>Rheumazentrum Bad Aibling, Bad Aibling; <sup>3</sup>AbbVie Deutschland GmbH and Co KG, Wiesbaden, Germany

**Background:** There is still limited knowledge about early axial spondyloarthritis (axSpA) patients in primary rheumatology care.

**Methods:** Rheumatologist from n=70 study centres across Germany recruited patients with spondyloarthritis (SpA) diagnosed for the first time (time since diagnosis <1 year) over three consecutive years. Patients were evaluated and

documented regarding clinical, laboratory and imaging characteristics, fulfilment of ASAS classification criteria and treatment. In addition, participating centres (n=36) documented the frequency of newly diagnosed SpA among all patients seen for the first time in their practice in one week.

**Results:** A total of 427 newly diagnosed SpA patients were recruited. 342 patients (mean age 38.9 years, range 18–73; 55.3% males) had a new diagnosis of axSpA (mean symptom duration 81.5 months (range 0–599)) and are presented here in more detail. 36.5% were classified as radiographic axSpA according to the modified New York criteria and 19.3% were imaging (magnetic resonance imaging and X-rays) negative. The laboratory, clinical and imaging characteristics of these patients are shown in the table 1. 85.4% of these patients diagnosed as axSpA by the rheumatologist fulfilled the ASAS classification criteria. 69.9% were treated with NSAIDs, 3.8% with conventional DMARDs and 1.2% with biologics when seen for the first time by the rheumatologist. The therapy has been continued or changed as follows by the rheumatologist at first visit after making the diagnosis of axSpA: NSAIDs in 80.7%, conventional DMARDs in 8.8% and biologics in 10.5%. However, additional treatment with biologics might be initiated at follow-up visits.

The proportion of SpA patients among all newly diagnosed patients with rheumatic conditions documented in one week was 17.5% (10.1% axSpA and 7.4% peripheral SpA).

**Abstract THU0251 – Table 1.** Clinical, laboratory and clinical characteristics of patients with axial SpA (n=342)

Parameter	Prevalence,%
Inflammatory back pain, current	74.9
Arthritis, current	14.6
Enthesitis, current	10.5
Positive family history	18.1
Uveitis, ever	12.0
Psoriasis, ever	10.5
Inflammatory bowel disease, current	1.8
HLA-B27 positiv	69.6
CRP positive, current	37.7
MRI sacroiliac joints positive, current	60.8
MRI spine positive, current	11.7
Definite radiographic sacroiliitis (X-ray positive)	29.5
MRI and X-ray negative	19.3

**Conclusions:** The characteristics of axSpA patients seen in primary rheumatology practices are comparable to what has been reported. The majority of patients are still in the stage of non-radiographic axSpA when diagnosed first and the majority of patients have active MRI inflammation in the sacroiliac joints but not in the spine. In about 10% of patients a TNF-blocker was started already at first visit.

#### THU0252 THE RATE OF US VERIFIED HIP INVOLVEMENT IN PATIENTS WITH ANKYLOSING SPONDYLITIS

E. Agafonova<sup>1</sup>, T. Dubinina<sup>2</sup>, A. Dyomina<sup>2</sup>, O. Rumyantseva<sup>1</sup>, S. Erdes<sup>1</sup>. <sup>1</sup>Laboratory Spondyloarthritis; <sup>2</sup>Laboratory of Scientific Organizational Problems in Rheumatology, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Hip joint (HJ) involvement is one of the most common extra-axial manifestations of ankylosing spondylitis (AS).

**Objectives:** To correlate clinical manifestations of coxitis with the ultra-sound findings in AS patients.

**Methods:** 224 consecutive AS patients (mean age 33.2±14.2 y) meeting 1984 modified N-Y criteria and hospitalised in V.A. Nasonova Research Institute of Rheumatology with hip pain were evaluated. Patients' mean age at the onset of the disease was 26.3±20.3 y., 93% of them were HLA-B27-positive. Median AS duration was 57 [12–444] months, the BASDAI score was 5.7±3.1. The diagnosis of coxitis was based on clinical signs and symptoms, such as inguinal pain and/or limitation in the range of hip motion (ROM) at the time of patients' admission to the clinic. All patients (regardless current complaints) were subjected to ultrasound

(US) examination of the HJ (Sono Diagnost 360 (Philips)) using linear (7,5 MHz) and convex (5,0 MHz) transducers. A neck capsular pattern (NCP – the distance between the signals from inner surface of the femoral neck and the joint capsule) more than 7 mm was used as the US criterion, verifying the clinical diagnosis of coxitis.

**Results:** The US criterion of coxitis was found in 119 (53%) out of 224 patients, and two groups of pts were analysed based on NCP values with 7 mm threshold.

Parameters	P		
	Group <sup>1</sup> without US signs of coxitis (n=105)	Group <sup>2</sup> US confirmed coxitis (n=119)	
Gender(f/m), n	79/26	77/40	<b>0,01</b>
AS duration, mo, Me[25%; 75%;]	43 <sup>19;80</sup>	102 <sup>24;120</sup>	<b>0,0006</b>
BASDAI, Me <sup>25;75</sup>	4,1 <sup>2;6;</sup> 5,5	5,2 <sup>4;2;</sup> 6,7	<b>0,0001</b>
BASFI, Me <sup>25;75</sup>	2,4 <sup>2;0;</sup> 3,8	3,4 <sup>2;0;</sup> 5,4	<b>0,0001</b>
HLA-B27, n (%)	96 (91%)	113 (95%)	<b>0,4</b>
ASDAS (?RP) ?? <sup>[25;75]</sup>	2,8 <sup>2;0;</sup> 3,8	3,5 <sup>2;6;</sup> 3,8	0002
ESR, mm/h, Me [25%; 75%]	10 <sup>5;</sup> 25	25 <sup>8;</sup> 35	0001
CRP, mg/mL, Me [25%; 75%]	10,5 <sup>3;8;</sup> 28,5	23,0 <sup>4;9;</sup> 43,5	<b>0,06</b>
Peripheral arthritis%	38 (36%)	28 (30%)	<b>0,06</b>

**Conclusions:** US criterion of coxitis, i.e, increased NCP, was found in 53% of patients with clinical AS manifestations. Patients with US-confirmed coxitis demonstrate more active disease with greater functional impairment and longer history of AS, as compared to AS population without US signs of hip involvement.

THU0253

#### THE CHRONIC SPINAL PAIN IN SPONDYLOARTHROPATHIES, OSTEOARTHRITIS, AND FIBROMYALGIA: THE ROLE OF CENTRAL SENSITISATION

E.F. Ayhan<sup>1,2</sup>, Ö. F. Çelik<sup>1</sup>, M.A. Güler<sup>1</sup>. <sup>1</sup>Department of Physical Medicine and Rehabilitation, Divisions of Rheumatology, Pain Medicine, Health Science University, Ankara Health Research and Training Hospital, Ankara; <sup>2</sup>Department of Physical Therapy and Rehabilitation, Usak University, High School of Health Sciences, Usak, Turkey

**Background:** Central sensitisation (CS) is a new phenomenon associated with several medical diagnoses, including post-cancer pain, low back pain, osteoarthritis (OA), whiplash, and fibromyalgia (FMS).<sup>1</sup> Central sensitisation inventory (CSI) suggest the tool generates reliable and valid data that quantify the severity of several symptoms of CS.<sup>2</sup>

**Objectives:** To the best of our knowledge, there is no study to evaluate CS pain in patients with Spondylarthritis (SpA). The aim of this study was to show the role of CS pain in patients with painful spine of SpA, OA, and FMS.

**Methods:** Totally 137 patients with chronic spinal pain (42 SpA, 45 OA and 50 FMS) were included. CSI consists of 2 parts<sup>1,2</sup>: CSI-A and CSI-B (restless leg, chronic fatigue, FMS, temporomandibular disorders, migraine/tension type headache, irritable bowel, multiple chemical sensitivity, whiplash, anxiety/panic attack, and depression).

**Results:** Only 4 patients (9.52%) had active SpA (BASDAI $\geq$ 4). Twelve patients (28.57%) have used anti-TNF drugs. Age, BASDAI and VAS-pain scores were not related with SS-A or SS-P positivity. Spine in patients with SpA was less painful compared with them of OA and FMS (p=0.001). The CS pain was detected in most with FMS, compared with OA, and SpA patients (p<0.001). Similarly, CSI-A score was the highest in patients with FMS group (p<0.001) and similar in both OA and SpA groups (p=0.197). CS-related syndromes (CSI-B) were also detected similarly in both SpA and OA groups, but less than FMS group (p<0.001). The numbers of CS syndromes were also similar in both SpA and OA (p=0.551) and lower than FMS group (p=0.003). Table 1 shows the clinical parameters in all groups.

**Abstract THU0253 – Table 1.** The comparisons of clinical characteristics

Depression	%16,22	%15,55	%28	0222	0215

**Conclusions:** Central sensitisation should be considered in patients with chronic persistent pain, not only having FMS, but also half of the patients having SpA and OA. It is not a rare phenomenon and if it exists, effective pain management strategies could be needed in addition to the specific pharmacologic treatment.

THU0254

#### RELATION BETWEEN SUBCLINICAL ULTRASONOGRAPHIC CHANGES OF THE ANTERIOR CHEST WALL JOINTS AND PULMONARY FUNCTION TESTS IN ANKYLOSING SPONDYLITIS PATIENTS

F.I. Abdelrahman<sup>1</sup>, M. Mortada<sup>1</sup>, W. Mansour<sup>2</sup>, A.B. Abdulsattar<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pulmonology, Zagazig University, Zagazig, Egypt

**Background:** Ultrasonography can detect subclinical changes in anterior chest wall (ACW) joints of patients with ankylosing spondylitis (AS).<sup>1</sup> Pulmonary functions may be affected during the course of AS.<sup>2</sup>

Up to the best of our knowledge, there are no previous studies of the relationship between ultrasound detected subclinical changes in ACW and the pulmonary functions in AS patients.

**Objectives:** To detect the relation between ultrasonographic changes of asymptomatic ACW joints and pulmonary function tests (PFTs) in patients with AS.

**Methods:** The study included 88 sternoclavicular joints (SCJ) and 44 manubri-sternal joints (MSJ) in 44 subjects (22 AS and 22 control). None of the participants had a history of respiratory complaints such as dyspnea, chronic cough, or chest pain. High resolution Computed Tomography (HRCT) was done on the chest to exclude interstitial lung problem that may affect chest expansion and PFTs.

Ultrasound (US) assessments were performed to detect synovitis, erosions, ankylosis, osteophytes, or Doppler signals. Chest expansion was measured. PFTs was done and included measurement of the forced expiratory volume in 1 s (FEV1), forced vital capacity (FVC), and the ratio of forced expiratory volume in 1 s to the forced vital capacity (FEV1/FVC). In AS group, Ankylosing Spondylitis Disease Activity Score (ASDAS), Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) and Bath Ankylosing Spondylitis Functional Index (BASFI) were recorded.

**Results:** US detected subclinical changes of ACW joints in (77.3%) of AS patient with significant difference between total US changes in AS(77.3%) and control (21.2%) (p<0.001). MSJ ankylosing was highly associated with limited chest

expansion in AS group ( $p < 0.001$ ). PFTs were found to be restrictive in 14 AS patient (63.6%) with mean of FVC ( $70.3 \pm 9\%$ ),  $FEV1$  ( $55.2 \pm 15.9\%$ ),  $FEV1/FVC$  ( $80.1 \pm 2$ ) and these restrictive PFTs were associated with SCJ synovitis ( $p = 0.03$ ), SCJ PD activity ( $p = 0.03$ ), SCJ erosions (0.05) and highly associated with MSJ ankylosing ( $p < 0.001$ ). All AS patients (100%) with ankylosed MSJ by US had limited chest expansion and restrictive PFTs.

In AS group, ultrasonographic changes and restrictive PFTs were found to be higher with older age, male sex, smoking, longer disease duration and high BASDAI and BASFI.

**Conclusions:** Our study demonstrated that ultrasound detected subclinical changes in ACW joints is associated with restrictive pattern of PFTs in AS patients.

#### THU0255 LOW BONE MINERAL DENSITY IS COMMON IN AXIAL SPONDYLOARTHROPATHY

G. Fitzgerald, T. Anachebe, F. O' Shea. *Department of Rheumatology, St James's Hospital, Dublin 8, Ireland*

**Background:** Osteoporosis is a known consequence of inflammatory arthritis (IA). In the general population and IA such as rheumatoid arthritis, the impact of osteoporosis is well outlined. However, it is often ignored in axial spondyloarthritis (axSpA), a form of IA centred on sacroiliac joints and the spine, as axSpA predominantly affects men, in whom osteoporosis is often not considered. As a result, osteoporosis prevalence figures are unclear, with wide variation in the literature. Accurate epidemiology regarding bone mineral density (BMD) in axSpA is crucial to begin understanding the impact of low BMD in this cohort.

**Objectives:** 1. Investigate the prevalence of low BMD in a well-characterised axSpA cohort

2. Explore relationships (demographic, disease-related, laboratory) between BMD and axSpA.

**Methods:** A detailed assessment was performed on axSpA patients, including demographics, clinical characteristics and laboratory investigations. Disease severity was assessed with tools validated in axSpA: ASDAS-CRP and BASDAI (disease activity), BASMI (spinal mobility) and BASFI (function). BMD was assessed using DXA of the spine, hip and radius. Lateral vertebral assessment (LVA) was also performed. The WHO criteria were used to classify low BMD. SPSS was used for statistical analysis.

**Results:** One hundred and four patients with axSpA were consecutively recruited: 77.9% (n=81) male, 98.1% (n=102) Caucasian, mean (SD) age 51<sup>12</sup> years, disease duration 26<sup>13</sup> years. The mean (SD) ASDAS-CRP was 2.3 (1), BASDAI was 3.9 (2.2), BASMI was 4.3 (1.9) and BASFI was 3.8 (2.5), reflecting mild to moderate disease burden. A history of fracture was present in 42.3% (n=44) of the cohort, with only 3 fragility fractures reported.

Of the cohort, 42.3% (n=44) had osteopenia and 16.3% (n=17) had osteoporosis. Low BMD was most prevalent at the spine, with 44% of the cohort affected, followed by the femoral neck (30.1%, n=22). Low BMD at the radius was uncommon (<10% of the cohort). Only 6.4% of the cohort had a prior diagnosis of osteoporosis and only 39.4% had a previous DXA.

Three vertebral fractures were detected on LVA – all patients were unaware of these fractures prior to the study.

Female gender, higher BASFI, lower BMI and lower urate levels were significantly associated with bone loss at both the spine and the hip. ASDAS-CRP and BASDAI had no impact on low BMD. Additionally, longer disease duration was associated with spine BMD loss. Non-obese patients were more likely to have low BMD at any site than obese patients (62.3% v 40%, OR 2.5,  $p = 0.04$ ). The use of biologics didn't influence BMD.

**Conclusions:** Low BMD is common in this axSpA cohort, with over 50% of patients affected. Most cases of low BMD were undiagnosed prior to this study and less than half of the cohort had ever had a DXA, suggesting a continued low awareness of the risk of osteoporosis in a male-dominated disease.

**Disclosure of Interest:** None declared

#### THU0256 HIGH DISEASE ACTIVITY, REDUCED PHYSICAL FUNCTION, LONG DISEASE DURATION, FATIGUE AND LIVING WITHOUT A PARTNER ARE FACTORS RELATED TO WORSE HEALTH RELATED QUALITY OF LIFE IN ANKYLOSING SPONDYLITIS

H. Forsblad-D'elia<sup>1,2</sup>, L. Law<sup>1</sup>, J. Beckman Rehnman<sup>1</sup>, A. Deminger<sup>2</sup>, E. Klingberg<sup>2</sup>, L. T.H. Jacobsson<sup>2</sup>. <sup>1</sup>Department of Public Health and Clinical Medicine, Rheumatology, Umeå University, Umeå; <sup>2</sup>Institute of Medicine, Sahlgrenska Academy at University of Gothenburg, Gothenburg, Sweden

**Background:** Ankylosing spondylitis (AS) begins early in life. The disease often leads to reduced physical function and also reduced health related quality of life (HRQoL). Knowledge is limited about factors related to HRQoL and how it develops over time.

**Objectives:** To assess HRQoL by SF-36 in a cohort of patients with AS compared with controls and to explore associations between HRQoL and spinal radiographic damage, physical function, disease activity and demographic data.

**Methods:** A cohort of patients with AS from Western Sweden were assessed at baseline and after 5 years with; x-ray of the spine for mSASSS, clinical examination and questionnaires, including BASMI, BASFI, ASDAS, BASDAI and SF-36. In this abstract we report the baseline results. Each patient's SF-36 results were compared with 5 age- and sex matched persons (n=1055) from the SF-36 Swedish normative population database. Associations between SF-36 mental component summary (MCS) and physical component summary (PCS) scores and disease related and demographic factors were investigated. Univariate logistic regression analyses were assessed with PCS and MCS below/above their respective median values (below median=1 and above median=0) as dependent variables and disease related and demographic variables as covariates. Variables with  $p$ -values  $\leq 0.2$  in the univariate analyses were entered as covariates in multivariate models after checking for multicollinearity.

**Results:** 210 patients, age (median, IQR) 49.0 (40.0, 61.2) years, symptom duration 24.0 (13.0, 34.0) years, men 58%, HLAB27 87% were included. AS patients scored significantly lower ( $p < 0.001$ ) compared to controls in all SF-36 domains and component summaries. AS women scored significantly lower compared to AS men in three domains, Physical Function, Vitality and Mental Health. Both men and women scored significantly lower in PCS compared with MCS. The results of the multiple logistic regressions are shown in the table 1.

Variables	PCS below median 42.4 (1)			MCS below median 48.0 (1)		
	OR	95% CI	P-value	OR	95% CI	P-value
Civil state, single	2.19	0.95–5.02	0.065	3.12	1.40–6.97	0.006
VAS global fatigue, >median				7.05	3.50–14.20	<0.001
Duration of symptoms, decades	1.59	1.16–2.17	0.004			
BASFI	1.98	1.51–2.58	<0.001			
ASDAS-CRP <sub>≥2.1</sub>	3.37	1.58–7.20	0.002	3.85	1.95–7.60	<0.001

**Conclusions:** Patients with AS had significantly lower HRQoL compared with controls. Women with AS scored lower in some domains compared to men and PCS was more affected compared to MCS in both sexes. Both demographic and disease related factors were associated with HRQoL, partly overlapping for PCS and MCS. By modifying factors, such as ASDAS and fatigue, HRQoL may potentially be improved. The development of SF-36 over 5 years will be investigated.

#### THU0257 ASSOCIATIONS BETWEEN TRABECULAR BONE SCORE AND VERTEBRAL FRACTURES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

H.R. Kim, Y.S. Hong, K.Y. Kang. *Catholic University of Korea, Seoul, Korea, Republic of Ireland*

**Background:** The bone tissue directly exposed to inflammation in axSpA is the trabecular bone of the vertebrae, and consequently, vertebral osteoporosis and resorption of trabecular bone are increased in axial spondyloarthritis. The trabecular bone score (TBS) is a novel tool used to evaluate bone microarchitecture. AxSpA patients showed poor bone quality compared with matched controls.

**Objectives:** This study aims to compare TBS between axSpA patients with and without vertebral fractures and investigate associations between TBS and vertebral fractures.

**Methods:** Two hundred and fifty-five patients fulfilling the imaging arm of the Assessment of SpondyloArthritis International Society axSpA criteria were enrolled. TBS and bone mineral density (BMD) were assessed using dual-energy X-ray absorptiometry. Vertebral fracture of the thoracic and lumbar spine was defined according to the Genant criteria. Osteoporosis risk factors, inflammatory markers, disease activity scores, and spinal structural damage were also assessed. Multivariate logistic regression analysis was performed to identify factors associated with vertebral fractures.

**Results:** Of 255 axSpA patients, 28 (11%) had 31 vertebral fractures. The mean TBS was 1.39±0.11 and 1.30±0.13 in patients without and with vertebral fractures, respectively (<0.001). BMD in the femoral neck was lower in patients with vertebral fractures (p=0.027), but BMDs in the lumbar spine and total hip were not. In the multivariate analyses, low TBS and the presence of syndesmophytes were significantly associated with vertebral fractures, independently of BMD (OR [95% CI]=3.6 [1.2–11.1] and 3.3 [1.0–10.7], respectively). For the total hip, TBS has a better discriminatory value than BMD for prediction of vertebral fractures in axSpA patients (p=0.034).

**Conclusions:** TBS values are lower in axSpA patients with vertebral fractures. Low TBS and syndesmophytes were independently associated with prevalent vertebral fractures. TBS has better predictive value to BMD for the discrimination of vertebral fractures and could help to detect axSpA patients with vertebral fractures.

**THU0258** **DIAGNOSTIC VALUE OF ANTI-CD74 AUTOANTIBODIES IN AXIAL SPONDYLOARTHRITIS AND AXIAL PSORIATIC ARTHRITIS. RESULTS OF OPEN-LABEL, CROSS-SECTIONAL, CONTROLLED, MULTICENTER PROGRESS STUDY**

I.Z. Gaydukova<sup>1</sup>, A. Rebrov<sup>2</sup>, A. Maslyanskiy<sup>3</sup>, S. Lapin<sup>4</sup>, E. Vasilenko<sup>5</sup>, V. Mazurov<sup>5</sup>. <sup>1</sup>North-Western State Medical University n.a.II Mechnikov, St Petersburg, Russian Federation; <sup>2</sup>Saratov State Medical University, Saratov; <sup>3</sup>V.A. Almazov North-Western Federal Medical Research Centre; <sup>4</sup>First Saint Petersburg State Medical University named after I.P. Pavlov; <sup>5</sup>North-Western State Medical University, St Petersburg

**Background:** The problem of axial spondyloarthritis (axSpA) differential diagnostics is not solved, especially in the early stages of the axSpA. Therefore, new diagnostic markers for axSpA are needed.

**Objectives:** of the study were to evaluate the prevalence, sensitivity and specificity of anti-CD74 autoantibodies (anti-CD74-AB) in HLA-B27 associated axSpA in comparison with HLA-B27 associated axial Psoriatic arthritis (axPsA) and with healthy controls.

**Methods:** Anti-CD74-AB (quantitative ELISA) were measured in serum of 114 HLA-B27-positive patients with axSpA, and in 26 age- and sex – matched HLA-B27 positive patients with axPsA, and in 37 healthy controls without HLA-B27. 68 axSpA patients had ankylosing spondylitis (AS) according mNew-York criteria (1984), 46 axSpA persons had non-radiographic axSpA (nr-axSpA) due to ASAS criteria for axSpA (2009). AxPsA patients had psoriatic arthritis with axial involvement and fulfilled both <sup>CASPAR</sup> (2006) and ASAS axSpA criteria (2009). Disease activity in axSpA and axPsA patients was measured according ASAS recommendations.<sup>1</sup>

**Results:** Patients with AS, nr-axSpA and axPsA were comparable in SpA activity: differences in BASDAI, ASDAS indices and C-reactive protein levels were not significant, p≥0.05 for all. Nr-axSpA patients had shorter disease duration as compared with AS and axPsA patients (p<0.001).

The concentration of anti-CD74-AB in patients with axSpA was 3.5±3.0 U/ml (3.1 ±3.0 U/ml in AS and 3.8±2.9 U/ml in nr-axSpA patients), 2.1±1.4 U/ml in patients with axPsA (p≥0.05 compared to controls and ax-SpA) and 1.3±1.4 U/ml in healthy controls (p<0.05 for the difference with ax-SpA, AS and nr-axSpA). Diagnostic values of anti-CD74-AB in axSpA (ROC-analyse results) are presented in table 1.

**Abstract THU0258 – Table 1.** Diagnostic values of anti-CD74 autoantibodies in patients with axial spondyloarthritis

**(ROC-analyse):**

	AUC (95% CI)	Sensitivity of the test, %	Specificity of the test, %	+LR	Upper cut-off value for reference interval, U/ml	p
axSpA	0,74 (0,67–0,82)	64,4	89,2	5,9	>2,0	<0,0001
AS	0,68 (0,59–0,79)	60,3	89,2	5,6	>2,0	0001

nr-axSpA	0,78 (0,58–0,83)	73,1	84,0	4,5	>1,73	<0,0001
axPsA	0,7 (0,69–0,89)	96,1	45,9	1,8	0,7	0005

AS - ankylosing spondylitis, axSpA - axial spondyloarthritis, axPsA – axial psoriatic arthritis, nr-axSpA - non-radiographic axial spondyloarthritis, CI - confidence interval, +LR – positive likelihood ratio.

Cut-off value of anti-CD74-AB>2.0 U/ml in patients with axSpA showed the diagnostic sensitivity of 64.4%, specificity of 89.2%, the positive LR of 5.9, whereas in patients with nr-axSpA at concentrations of 1.7 U/ml - sensitivity 73.1%, specificity 84% and positive LR 4.5.

**Conclusions:** Anti-CD74-AB are strongly associated with nr-axSpA and less – axPsA. The measurement of anti-CD74-AB can be considered as candidate biomarker in the diagnostics of axSpA and in differential diagnostics between HLA-B27 positive ax-SpA and axPsA, especially in early stages of the diseases. Further studies are needed for the evaluation of anti-CD74-AB diagnostic capacity.

**THU0259** **FREQUENCY AND PATTERN OF THE UVEITIS IN SPONDYLOARTHRITIS WITH BIOLOGICAL THERAPY**

I. Calvo<sup>1</sup>, E. Guerrero<sup>1</sup>, O. Ibaranguoitia<sup>1</sup>, D. Montero<sup>1</sup>, M.L. Garcia<sup>1</sup>, E. Ruiz<sup>1</sup>, I. Torre<sup>1</sup>, O. Fernandez<sup>1</sup>, J.M. Blanco<sup>1</sup>, A.R. Intxaurre<sup>1</sup>, C. Perez<sup>1</sup>, I. Gorostiza<sup>2</sup>, E. Galindez<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Research Unit, Basurto University Hospital, BILBAO, Spain

**Background:** Uveitis is the most frequent extra-articular manifestation (EAM) of spondyloarthritis (SpA). Its prevalence is approximately 30% and increases with the duration of the SpA. The characteristic pattern is anterior, acute, recurrent and unilateral uveitis. However, the frequency and characteristics of uveitis in SpA treated with biological therapy (BT) are unknown.

**Objectives:** The main target is to describe the frequency and characteristics of uveitis in SpA with BT in a single centre.

**Methods:** Descriptive and retrospective study (January 2003-December 2017) of SpA that develops uveitis in a reference hospital. The epidemiological variables, type of SpA, presence of uveitis and its characteristics, presence of BT at the time of onset and treatment received are collected. For the analysis, frequencies and percentages were used in qualitative variables, and mean and standard deviation (SD) for quantitative variables. Statistical analysis was performed with IBM SPSS v.23.

**Results:** We studied 246 patients with SpA. The subtypes of SpA were: ankylosing spondylitis (AS) (n=125, 50.8%), psoriatic arthritis (PsA) (n=101, 41.1%), undifferentiated SpA (n=13, 5.3%), non-radiographic axial SpA (n=3, 1.2%), enteropathic arthropathy (n=3, 1.2%) and reactive arthritis (n=1, 0.4%).

Uveitis was observed in 41 patients (16.7%) after an average time of development of 109.47 (73.9) months of the SpA. The incidence rate was 5.5 cases of uveitis/100 patients-year of follow-up. 70.7% were men and the mean age(SD) was 47.4 (12.06) years. 87.8% of the cases were HLAB27 positive and had a family history of SpA 41.5%.

Uveitis was observed in 33 patients (80.5%) with AS, in 6 (14.6%) with PsA, in 1 (2.4%) with non-Rx axial SpA and in 1 (2.4%) with undifferentiated SpA. (table 1)

The uveitis pattern was anterior (100%), acute (92.7%), unilateral (87.8%) and in 12.2% bilateral (80% in PsA). At the time of onset of uveitis, the mean ESR was 30.11 mm1<sup>st</sup>h, CRP 3.56 mg/dL, DAS28 3.66 and BASDAI 3.21.

Regarding the diagnosis of SpA, uveitis was after (85.4%), before (12.2%) and simultaneous (2.4%).

At the time of the onset of uveitis, 14 patients (34.1%) were with BT (35.7% etanercept, 28.6% infliximab, 21.4% adalimumab, 7.1% golimumab and 7.1% certolizumab). BT was modified in 3 of the cases.

The treatment of uveitis was topical (78%), corticoids in oral regimen (57.5%), conventional DMARDs (12.5%), with methotrexate predominating in 60% of cases and BT (15%). The most used biologics were adalimumab (50%), infliximab (33.3%) and sekukinumab (16.7%).

Abstract THU0259 – Table 1. Characteristics of the UVEITIS in SpA subtypes

	MEN/ WOMEN	AGE TO THE DIAG. OF UVEITIS (range in years)	HLA B27*	ANT/ POST	ACUTE/ CHRONIC	UNILATERAL/ BILATERAL	RECURRENT/ NON RECURRENT	INCIDENCE RATE (men/women at follow-up)	BT AT THE DIAG. OF UVEITIS	ETN/ MONOCL. CL.
AS (n=41)	23/18	47.4	32	13/0	11/2	12/1	15/0	5.48	11	4/7
PsA (n=4)	3/1	48.7	3	4/0	3/1	2/0	1/2	1.25	3	0/2
uSpA (n=1)	0/1	58	0	1/0	1/0	1/0	1/0	0.55	0	0
nr-uSpA (n=1)	1/0	35	1	1/0	1/0	1/0	0/1	3.54	1	1/0
TOTAL 43	27/12	47.5	36	18/3	18/3	16/5	19/12	3.3	14	5/9
	(70.9%/29.1%)		(81.4%)	(41.9%)	(42.7%/27.3%)	(47.4%/12.5%)	(76.9%/26.9%)		(34.1%)	(105.9%/34.3%)

AS: ankylosing spondylitis; PsA: psoriatic arthritis; uSpA: undifferentiated spondylarthritis; nr-uSpA: non-radiographic axial spondylarthritis; DIAG: diagnosis; ANT: anterior; POST: posterior; BT: biological therapy; ETN: etanercept; MONOCL. CL.: monoclonal antibody

**Conclusions:** In our series, uveitis was observed in 16.7% of patients with SpA of which 80.5% were AS and 14.6% PsA. The most frequent uveitis was anterior, unilateral, acute and recurrent. In PsA, the association with HLA B27 was less frequent and was more bilateral. In most cases, the diagnosis was later than the SpA.

**THU0260 THE UVEITIS IMPACT STUDY: A SURVEY BY THE SPONDYLITIS ASSOCIATION OF AMERICA**

J.T. Rosenbaum<sup>1,2</sup>, R. Howard<sup>3</sup>, L.M. Savage<sup>4</sup>. <sup>1</sup>Legacy Devers Eye Institute, Portland; <sup>2</sup>Oregon Health and Science University, Portland, OR; <sup>3</sup>Spondylitis Association of America, Van Nuys, CA; <sup>4</sup>Spondylitis Association of America, Van Nuys, CA, USA

**Background:** Uveitis is the most common clinically apparent concomitant of ankylosing spondylitis. The implications of developing uveitis in association with AS could help to understand this association and assist both clinicians and patients.

**Objectives:** To compare survey responses from patients with AS and no history of uveitis to those with AS and a history of uveitis.

**Methods:** Patients associated with the Spondylitis Association of America (SAA) participated in a web based survey with telephone follow-up performed for a subset.

**Results:** 716 respondents replied that a physician had made a diagnosis of AS. 30.4% of these patients had a history of uveitis. Patients with a history of uveitis tended to be older (median age 31 versus 23 years) and the median age for onset of uveitis was 18 years. Although patients with uveitis did not differ from patients without uveitis on many measures of function, medication, or disability, patients with uveitis were more likely to have heel pain (56% v.45%, p<0.005), rib pain (60% v. 50%, p=0.02), gut inflammation (37% v 23%, p=0.0001), hypertension (42% v 33%, p=0.02), fibromyalgia (18% v 12%, p=0.03), psoriatic arthritis (11% v 6%, p=0.02), or acid reflux (57% v 48%, p=0.03). Patients with uveitis were more like to be negatively impacted in the past week for the ability to concentrate (18% v 12%, very limited, p=0.03); the ability to read, listen, or watch TV (15% v 9%, very limited, p=0.01); and the ability to enjoy family life or friends (6% v 2%, totally limited, p=0.005). Prednisone was more commonly used by those with uveitis (16% v 7%, p=0.0002); and while sulfasalazine was more commonly used previously (41% v 24%, p<0.001), it was less commonly used currently (7% v. 10%). Etanercept, which is less effective in preventing uveitis than monoclonal anti-TNF inhibitors, was used equally in the two groups (11% v 12%).

**Conclusions:** This survey suggests associations between uveitis and clinical manifestations such as heel pain, bowel disease, and skin disease. It is one of the first reports to suggest that uveitis affects quality of life such as the ability to enjoy family or friends. Although medications differentially affect uveitis, our study did not indicate an impact on therapy resulting from uveitis except for the current use of prednisone and a prior history of the use of sulfasalazine.

González-Juanatey<sup>3</sup>, L. Rodríguez-Rodríguez<sup>4</sup>, J.A. Parra<sup>5</sup>, M.A. González-Gay<sup>1</sup>. <sup>1</sup>Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Division of Rheumatology, Hospital Universitario Marqués de Valdecilla, IDIVAL, University of Cantabria, Santander; <sup>2</sup>Division of Rheumatology, Hospital Comarcal de Laredo, Laredo; <sup>3</sup>Division of Cardiology, Hospital Lucus Augusti, Lugo; <sup>4</sup>Division of Rheumatology, Instituto de Investigación Sanitaria del Hospital Clínico San Carlos (IDISSC), Hospital Clínico San Carlos, Madrid; <sup>5</sup>Radiology, Hospital Universitario Marqués de Valdecilla, Santander, Spain

**Background:** Ankylosing spondylitis (AS) is associated with increased rates of cardiovascular (CV) disease. CV events in these patients can be prevented by identifying patients at high risk who can benefit from appropriate primary prevention measures. The systematic coronary risk evaluation (SCORE) is the predictive model recommended in Europe, but it underestimates the CV risk in AS.

**Objectives:** To determine if a lateral lumbar radiography, which is available in most of AS patients, may help to identify AS patients at high risk of CV disease.

**Methods:** 125 AS patients older than 35 years old without history of CV events, diabetes mellitus or chronic kidney disease were recruited. All patients underwent a carotid ultrasound (US) and lateral lumbar spine radiography and a multi-detector coronary tomography (MDCT) was also performed in a subgroup of 43 AS patients. Carotid plaques were defined according to the Mannheim consensus and the presence of AAC as calcific densities visible in an area parallel to the lumbar spine and anterior to the lower part of the spine. A Coronary Artery Calcification Score (CACS) superior to 100 were considered as a surrogate marker of coronary atherosclerosis. CV risk was calculated according to the total cholesterol systematic coronary risk evaluation (TC-SCORE).

**Results:** CV risk was categorised according to the TC-SCORE as low (<1%; n=64), moderate (≥1% and <5%; n=54) and high/very high risk (≥5%; n=7). Most patients with low TC-SCORE did not show CAA, which was only present in 3 patients (4,68%). In contrast, 38,9% of patients included in the moderate-risk group had CAA. The lateral lumbar radiography showed a sensitivity to detect subclinical atherosclerosis lower than that observed by carotid US, which found plaques in 61% of patients with moderate TC-SCORE, but superior to the MDCT (61,9% Vs 28,6% in the subgroup of 43 patients). 89% of patients with AAC also had carotid plaques (r=0.49, p<0,0001). We set up a predictive model to disclose the largest number of AS with high/very high CV risk, defined by the presence of carotid plaques or a TC-SCORE ≥5% (table 1). A model including patients with a chart TC-SCORE ≥5% along with the presence of AAC showed a sensitivity of 50,9% (model 4). The combination of a TC-SCORE ≥5% and the performance of carotid US in patients with a moderate SCORE showed the highest sensitivity to detect patients at high/very high risk (72,7%, model 2). Nevertheless, model 4 showed greater specificity than model 2 (70% Vs 95,7%), leading to a higher global diagnostic accuracy (area under curve: 0,73 Vs 0,71).

Abstract THU0261 – Table 1

	Sensitivity	Specificity	Correctly classified	ROC [95% CI]
<b>Model 1.</b> TC-SCORE ≥5%	12.7%	100%	61.6%	0.56 [0.52 - 0.61]
<b>Model 2.</b> TC-SCORE ≥1% OR TC-SCORE ≥1% <5% plus carotid US (presence of plaques)	72.7%	70.0%	71.2%	0.71 [0.63 - 0.79]
<b>Model 3.</b> TC-SCORE ≥5% OR TC-SCORE ≥1% and <5% plus lateral lumbar X-ray (presence of AAC)	45.5%	95.7%	73.6%	0.71 [0.64 - 0.78]
<b>Model 4</b> TC-SCORE ≥5% or TC-SCORE <5% plus lateral lumbar X-ray (presence of AAC)	50.9%	95.7%	76.0%	0.73 [0.66 - 0.8]

The gold standard used to define high/very high cardiovascular risk was the presence of TC-SCORE ≥5% or carotid plaques.

**Conclusions:** Several AS patients at high CV risk who are underdiagnosed as having very high CV risk by the SCORE can be detected by a lateral lumbar radiography.

THU0262

### IDENTIFYING PATIENTS WITH AXIAL SPONDYLOARTHRITIS FROM A COHORT OF PATIENTS WITH CHRONIC BACK PAIN IN ORTHOPAEDICS CARE (AWARE STUDY)

J. Braun<sup>1</sup>, T. Mosch<sup>2</sup>, I. Fischer<sup>3</sup>, U. Kiltz<sup>1</sup>. <sup>1</sup>Rheumazentrum Ruhrgebiet, Herne; <sup>2</sup>Medical Affairs, AbbVie Deutschland GmbH and Co KG, Wiesbaden; <sup>3</sup>Biostatistik-Tübingen, Tübingen, Germany

**Background:** Making an early diagnosis of axial spondyloarthritis (axSpA) has remained a challenge. The combination of clinical items suggestive of inflammatory back pain has proved useful for early identification of patients with axSpA in a pilot study in primary care.<sup>1</sup> It has been shown that at least three of five features have a high prognostic impact.

**Objectives:** To evaluate the performance of these 5 clinical items (called AWARE criteria) to identify patients with axSpA from a large cohort of patients with chronic back pain in orthopaedics care.

**Methods:** In adult patients with chronic back pain (>3 months) and age at onset of symptoms <45 years, who were concerned for referral to rheumatologists, the AWARE criteria were assessed and documented prior referring to the rheumatologists.

**Results:** A total of 1306 patients (pts) first seen by orthopaedic surgeons were included. Of those, 500 pts were also seen by rheumatologists, and 188 (37.6%) were diagnosed as axSpA, and, amongst others, 52.2% with non-specific back pain by clinical judgment. A total of 87 cases (17.4%) were diagnosed with ankylosing spondylitis (AS) and 101 (20.2%) with non-radiographic axSpA. A total of 206 pts fulfilled the ASAS classification criteria. The mean age of patients with axSpA was 38±11.5 years, 46.2% were male, the mean duration of back pain was 94.1±103.6 months. The AWARE criteria had a sensitivity and specificity of 93.6% and 17.0% if ≥3 criteria were chosen, and 6.3% and 83.0% with <3 criteria. In axSpA vs. non-axSpA pts, imaging (MRI or x-ray) was positive in 90.6% vs 9.4%, HLA B27 in 69.4% vs 30.6%, 57.6% vs. 42.1% had a good response to NSAIDs, and an elevated CRP in 70.1% vs. 29.9%. A minority of axSpA patients had arthritis (5.6%), enthesitis (6.2%), dactylitis (1%), uveitis (3.8%), psoriasis (4.8%) and IBD (3.6%). Positive imaging (MRI or x-ray) resulted in the highest likelihood ratio (LR) for a diagnosis of axSpA. In combination with HLA B27 +the LR was highest (127.1).

**Conclusions:** Even though the procedure of how patients were preselected in this study caused a selection bias for statistical analyses we think that this study confirms the usefulness of the original AWARE criteria to improve the identification of young patients with chronic back pain in primary care. The important role of imaging and HLA B27 was confirmed. In future studies the two-step approach with three clinical question first and then HLA B27 testing if necessary will be further investigated.

THU0263

### ANALYSIS ON CHARACTERISTICS OF 82 PATIENTS WITH ANKYLOSING SPONDYLITIS IN JAPAN

K. Tada<sup>1</sup>, S. Kobayashi<sup>2</sup>, E. Hayashi<sup>1</sup>, M. Ogasawara<sup>1</sup>, H. Inoue<sup>3</sup>, K. Yamaji<sup>1</sup>, N. Tamura<sup>1</sup>. <sup>1</sup>Rheumatology and Internal Medicine, Juntendo University School of Medicine, hongo, bunkyo-ku; <sup>2</sup>Internal Medicine, Juntendo Koshigaya Hospital, Koshigaya; <sup>3</sup>Orthopaedic Surgery, Juntendo University School of Medicine, hongo, bunkyo-ku, Japan

**Background:** Ankylosing spondylitis (AS) is the prototype of spondyloarthritis, which affects sacroiliac joints, spine, peripheral joints and entheses. HLA-B27 is known to be related with AS and there is a considerable number of patients

suffering from AS among other rheumatic diseases. In Japan, however, the prevalence of AS was reported to be less than 0.1% much lower than western countries and also other East Asian countries<sup>1) 2) 3)</sup>. This is due to the low frequency of HLA-B27 in Japanese (0.3%) compared to 5%–10% in the countries mentioned above. Because of small number of AS patients, clinical features and HLA-B27 positivity has not been well investigated in Japanese patients with AS. Since our hospital has an outpatient specialising in AS and there are many patients, we conducted a survey on AS

**Objectives:** In this study, we examined the characteristics of patients with AS in our hospital and compared the data of patients with AS in Japan and overseas.

**Methods:** We conducted a questionnaire survey on patients fulfilling the modified New York criteria for AS. A questionnaire included demographic data and histories. We also retrospectively investigated the data of blood test, radiographs and the presence of inflammatory back pain (IBP), HLA-B27, enthesitis, dactylitis, radiographic sacroiliitis and extra-articular manifestation.

**Results:** A total of 82 patients (82.9% male) including Japanese (68), Chinese,<sup>9</sup> Korean<sup>5</sup> with AS who fulfilled the modified New York criteria were enrolled from May in 2013 to April in 2016. Of 68 patients with HLA-B27 test result, 61 patients (89.7%) were HLA-B27 positive. Of 54 Japanese patients, 48 patients (88.9%) were HLA-B27 positive. IBP, enthesitis, dactylitis, bamboo spine and uveitis were found in 67 patients (81.7%), 31 patients (37.8%), 5 patients (6.1%), 44 patients (53.7%) and 30 patients (36.6%), respectively.

**Conclusions:** In Japanese AS patients, the prevalence of HLA-B27 was high (almost 90%) and other characteristics were similar with those of Western countries. In Japan where the frequency of HLA-B27 is very low, B27 positivity is considered to have high diagnostic value.

THU0264

### IMPACT OF EXTRA-ARTICULAR MANIFESTATIONS ON PATIENT-REPORTED OUTCOMES IN ANKYLOSING SPONDYLITIS AND PSORIATIC ARTHRITIS: INTERIM RESULTS FROM THE COMPLETE STUDIES

L. Bessette<sup>1</sup>, M. Khraishi<sup>2</sup>, B. Florica<sup>3</sup>, Y. Setty<sup>4</sup>, M. Teo<sup>5</sup>, V. Remple<sup>6</sup>. <sup>1</sup>Laval University, Centre Hospitalier de l'Université Laval, Quebec; <sup>2</sup>Memorial University of Newfoundland, St. John's; <sup>3</sup>University of Toronto, Toronto; <sup>4</sup>Grey Bruce Health Services, Owen Sound; <sup>5</sup>University of British Columbia, Penticton; <sup>6</sup>AbbVie Corporation, Montreal, Canada

**Background:** Extra-articular manifestations (EAMs) in rheumatic diseases have been previously found to negatively impact health outcomes including quality of life and work capacity. Even though EAMs may be directly associated with worse response to treatment, differences in patient-reported outcomes (PROs) based on the presence of EAMs could be an important contributory variable.

**Objectives:** To assess the impact of EAMs on PROs among patients with active AS or PsA followed in Canadian routine clinical care.

**Methods:** Patients eligible for the COMPLETE studies are anti-TNFα naïve adults, with active AS or PsA per the judgment of the treating physician, who require change in their treatment regimen. In the current analysis patients enrolled between July/2011 - June/2017 were included. EAMs were defined as the presence of the following at baseline: enthesitis, uveitis, inflammatory bowel disease (IBD) or psoriasis (EAM<sub>AS1</sub> for AS); enthesitis, uveitis, or IBD (EAM<sub>AS2</sub> for AS); enthesitis or dactylitis (EAM<sub>PsA</sub> for PsA). PROs included the Short Form Health Survey (SF-12), Work Limitations Questionnaire (WLQ) and Beck's Depression Inventory (BDI). PROs were compared between patients with and without EAMs using the independent samples t-test. The independent association between presence of EAMs and PROs at baseline was assessed with multivariate generalised linear models adjusting for disease state (high/very high vs. inactive/low/moderate disease based on the BASDAI for AS and the DAS28 for PsA), disease type, and ever smoking.

**Results:** A total of 609 AS and 406 PsA patients were included with a mean (SD) age of 43.1 (13.4) and 51.3 (12.3) years, respectively. EAM<sub>AS1</sub> and EAM<sub>AS2</sub> prevalence among AS patients was 33.9% and 25%, respectively, while among PsA patients EAM<sub>PsA</sub> prevalence was 45.4%.

In univariate analysis, presence of EAMs in AS was associated with significantly higher disease activity, BDI total score, WLQ mental interpersonal demands (only for EAM<sub>AS1</sub>), WLQ physical demands, WLQ time demands, SF-12 physical function, SF-12 role physical, SF-12 bodily pain, SF-12 vitality, SF-12 mental health (only for EAM<sub>AS1</sub>), and the SF-12 physical component summary score (PCS). Among PsA patients, patients with EAM<sub>PsA</sub> had higher disease activity but no significant association was observed between EAM<sub>PsA</sub> and PROs.

Upon adjusting for disease state, disease type, and ever smoking, presence of EAM<sub>AS1</sub>/EAM<sub>PsA</sub> for AS/PsA patients was associated with significantly higher BDI total score (14.0 vs. 12.6,  $p=0.046$ ) and lower SF-12 physical function (38.4 vs. 44.8,  $p=0.047$ ). When evaluating the impact of EAM<sub>AS2</sub>/EAM<sub>PsA</sub> for AS/PsA patients no significant differences were observed in PROs; however, BDI was notably higher among patients with EAMs (14.1 vs. 12.7,  $p=0.056$ ).

**Conclusions:** In a Canadian routine clinical care setting, a substantial proportion of AS and PsA patients requiring a change in treatment report EAMs. Presence of EAMs, particularly psoriasis for AS patients, was found to be a significant independent predictor of depressive symptoms and reduced quality of life due to worse physical functioning.

#### THU0265 PATIENTS WITH AXIAL SPONDYLOARTHRITIS RARELY HAVE 1 OR 2 INFLAMMATORY BACK PAIN PARAMETERS

M. de Hooge<sup>1,2</sup>, G.V. Varkas<sup>1,2</sup>, D. Elewaut<sup>1,2</sup>, F. van den Bosch<sup>1,2</sup>.

<sup>1</sup>Rheumatology, Ghent University Hospital, <sup>2</sup>VIB Inflammation Research Centre, Ghent University, Ghent, Belgium

**Background:** The Berlin Algorithm is a tool that assists clinicians in diagnosing axial spondyloarthritis (axSpA). In the modified Berlin Algorithm inflammatory back pain (IBP) is excluded as entry criterion. Although the modified Berlin Algorithm is used in clinical practice some argue that this modification insufficiently emphasises the inflammatory character of axSpA.

**Objectives:** The study aim was to provide an overview of the IBP parameters present in axSpA patients included in the Be-Giant cohort.

**Methods:** Data of an observational multicentre cohort study was used. Patients aged  $\geq 18$  years with a new axSpA diagnosis and fulfilling the ASAS axSpA criteria were included in the Belgian inflammatory arthritis and spondylitis cohort (Be-Giant). All 5 IBP parameters used in the ASAS axSA classification criteria were collected during the clinical visit to the outpatient clinic. IBP parameters collected were: 1) Age at onset  $< 40$  years, 2) insidious onset, 3) improvement with exercise, 4) no improvement with rest and 5) pain at night. IBP is defined when  $\geq 4$  of these parameters are present. Besides these 5 parameters also 'alternating buttock pain' and 'morning stiffness' are reported as these parameters are part of other IBP criteria then the ASAS criteria. All descriptive data was presented as n (%) or means ( $\pm$ SD).

**Results:** All IBP parameters were collected from 228 patients and 49.6% ( $n=113$ ) was male with mean age of 34.7 years (SD 9.7). Individual parameters were present in  $>75\%$  of the patients; the parameter 'age at onset  $< 40$  years' was present in 95.2%, 'insidious onset' in 89%, 'improvement with exercise' in 86%, 'no improvement with rest' in 81.6% and 'pain at night' in 75.9% of the patients. There were 83 patients (36.4%) with alternating buttock pain and 173 patients (75.9%) with morning stiffness.

More than 80% of the patients (183/228) had IBP according to the ASAS criteria as they had  $\geq 4$  IBP parameters. Patients rarely had 1 or 2 IBP parameters; 2 (0.9%) patients with 1 parameter and 12 (5.3%) patients with 2 parameters (table 1).

**Abstract THU0265 – Table 1.** Total number of ASAS-IBP parameters in patients with axSpA diagnosis and classified according to the ASAS criteria in the Be-Giant cohort.

	Be-Giant cohort n=228
0 IBP parameters	0
1 IBP parameters	2 (0.9%)
2 IBP parameters	12 (5.3%)
3 IBP parameters	31 (13.6%)
4 IBP parameters	59 (25.9%)
5 IBP parameters	124 (54.4%)

IBP, inflammatory back pain.

IBP parameters: Age onset back pain  $< 40$  years, insidious onset of back pain, improvement with exercise, no improvement with rest, pain at night.

**Conclusions:** The majority of early axSpA patients had  $\geq 4$  IBP parameters and therefore fulfilled the ASAS IBP criteria. A minority shows 1 or none IBP parameter. Hence, the inflammatory character of axSpA does not seem to subverted now that IBP is not a mandatory feature in classification of axSpA.

#### THU0266 THE VALUE OF BELONGING TO PATIENTS' ASSOCIATION FOR AXIAL SPONDYLOARTHRITIS: RESULTS FROM THE ATLAS-2017

M. Garrido-Cumbrera<sup>1,2</sup>, D. Gálvez-Ruiz<sup>1</sup>, E. Collantes Estevez<sup>3,4</sup>, C. Blanch Mur<sup>5</sup>, V. Navarro-Compán<sup>6</sup>. <sup>1</sup>Universidad de Sevilla, Sevilla; <sup>2</sup>CEADE, Madrid; <sup>3</sup>Medicina, Universidad de Córdoba; <sup>4</sup>Rheumatology, Hospital Universitario Reina Sofía, Cordova; <sup>5</sup>Novartis, Barcelona; <sup>6</sup>Rheumatology, Hospital Universitario La Paz, IdiPaz, Madrid, Spain

**Background:** International guidelines suggest that patients with axial spondyloarthritis (axSpA) become members of patient associations and self-help groups. However, the scientific evidence for this advice is limited and poor.

**Objectives:** To assess the relationship between membership of axSpA patient associations with regard to physical and psychological outcomes of the disease.

**Methods:** A sample of 680 axSpA patients was interviewed as part of the Spanish-2017 Atlas, which aimed to promote early referral, improve healthcare, and the use of effective treatments in patients with axSpA. By means of an online survey, the following self-reported data were collected: sociodemographic, smoking habits, degree of functional limitation in 18 daily activities (graded from 0–3 as none, little, some, moderate), spinal stiffness level at cervical, thoracic, and lumbar spine (0–3 none, little, some, moderate), disease activity through BASDAI (0–10), risk of severe psychiatric illness using General Health Questionnaire – GHQ-12 (0–12), and treatment received (NSAIDs and biological therapy). Differences for all these variables between associated-patients and non-associated patients were tested, using Mann-Whitney or Chi-square tests.

**Results:** Out of 680 patients, 301 (44.3%) were members of patient associations. Compared to non-associated patients, those associated were older, more frequently male, married, and few smoked (table 1). Additionally, despite having longer disease duration and receiving similar treatment, associated patients had lower disease activity (BASDAI 5.1 vs 5.8;  $p=0.001$ ), less functional limitation (26.5 vs 28.7;  $p<0.05$ ), and less risk of severe psychiatric illness (GHQ-12 4.9 vs 6.5;  $p<0.001$ ).

**Abstract THU0266 – Table 1.** Characteristics stratified by patient association membership status

	Associated (mean $\pm$ SD or %)	Non-Associated (mean $\pm$ SD or %)	P
Age (years)	49.7 $\pm$ 11.2	42.4 $\pm$ 9.4	$<0.001$
Gender (Male)	57.8%	39.3%	$<0.001$
Education Level (University)	34.6%	38.8%	0.3
Marital Status (Married)	79.1%	65.4%	$<0.001$
Smoker	32.6%	41.6%	$<0.01$
Disease duration (years) (n=555)	26.0 $\pm$ 12.4	17.0 $\pm$ 10.3	$<0.001$
HLA-B27 (Positive) (n=558)	79.7%	74.9%	0.097
Treatment			
- NSAIDs (without biology)	28.6%	30.9%	0.5
- Biological (monotherapy or with NSAIDs)	39.2%	34.0%	0.2
BASDAI (0–10) (n=442)	5.1 $\pm$ 2.1	5.8 $\pm$ 2.1	0.001
Stiffness			$<0.01$
-Without Stiffness - low	10.2%	11.2%	
- mild			
- high	17.6%	20.0%	
Functional Limitation (0–54) (n=605)	26.5 $\pm$ 13.4	28.7 $\pm$ 12.9	0.038
GHQ-12 (0–12) (n=474)	4.9 $\pm$ 4.5	6.5 $\pm$ 4.4	$<0.001$

**Conclusions:** In axSpA, belonging to patient associations is related to better physical and psychological outcomes. Accordingly, rheumatologists should encourage patients to join these groups. However, further data on longitudinal studies is required to confirm these results.

THU0267

### GASTROINTESTINAL INVOLVEMENT IN SPONDYLOARTHRITIS IS NOT ALL IBD: INCREASED RISK OF DIVERTICULITIS WITH LONGER DISEASE DURATION IN THE ASAS-COMOSPA COHORT

M.H. Derakhshan<sup>1</sup>, N. Goodson<sup>2</sup>, J. Packham<sup>3</sup>, R. Sengupta<sup>4</sup>, A. Molto<sup>5</sup>, H. Marzo-Ortega<sup>6</sup>, S. Siebert<sup>1</sup>, on behalf of BRITSpA and the ASAS-COMOSPA investigators. <sup>1</sup>Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow; <sup>2</sup>Academic Rheumatology Department, University of Liverpool, Liverpool; <sup>3</sup>Haywood Rheumatology Centre, Keele University, Keele; <sup>4</sup>Royal National Hospital for Rheumatic Diseases, Bath, UK; <sup>5</sup>Hôpital Cochin, Paris Descartes University, Paris, France; <sup>6</sup>NIHR LBRC, Leeds Teaching Hospitals Trust and LIRMM, University of Leeds, Leeds, UK

**Background:** Inflammatory bowel disease (IBD) is an established extra-articular manifestation of Spondyloarthritis (SpA). The association of SpA with other gastrointestinal and hepatic comorbidities is less well known.

**Objectives:** To examine the relationship between SpA disease duration and gastrointestinal comorbidities other than IBD.

**Methods:** ASAS-COMOSPA is a large global cross-sectional study comprising 3984 patients with SpA. We evaluated the association between "SpA disease duration" (defined in 5 year blocks) and upper gastrointestinal ulcers, hepatitis B (HBV), hepatitis C (HCV) and diverticulitis. Binary logistic regression models were created, adjusted for age, sex, BMI, smoking, alcohol, NSAIDs, DMARDs, biologics, steroids and IBD history. Subgroup analysis was performed, stratified by peripheral and/or axial joint involvement.

**Results:** The data of 3923 patients (64.9% male) were available for analysis, 5.3% of whom had a history of IBD. The self-reported prevalence of other gastrointestinal conditions was: upper gastrointestinal ulcers 10.7%; viral hepatitis 4.7% and diverticulitis 1.5%, with significant geographic variation. "SpA disease duration" was not associated with the occurrence of the upper gastrointestinal ulcers (OR=0.98, 95% CI: 0.92–1.05), HBV (OR=0.43, 95% CI: 0.28–0.67) or HCV (OR=0.27, 95% CI: 0.11–0.62). In contrast, the risk of diverticulitis was significantly increased by "SpA disease duration" (OR=1.14, 95% CI: 1.01–1.29); increased risk of 14% for every 5 years of disease duration) across the entire cohort, after adjustment for potential confounders, including age. Confounding variables showing significant association with diverticulitis were current age (OR=1.06, 95% CI: 1.04–1.08) and high alcohol (≥3 units/day) intake (OR=3.84, 95% CI: 1.62–9.07) but not medication history (table 1). Subgroup analyses revealed stronger association of SpA disease duration with diverticulitis in those with axial (OR=1.24, 95% CI: 1.08–1.42) than those with peripheral (OR=1.12, 95% CI: 0.98–1.29) SpA disease.

Abstract THU0267 – Table 1. Association between diverticulitis and SpA disease duration

	p value	OR	95% CI for OR
<b>SpA Disease Duration (5 y blocks)</b>	<b>0.032</b>	<b>1.14</b>	<b>1.01–1.29</b>
Delay in SpA Diagnosis	0.477	1.01	0.98–1.04
Age (year)	<0.001	1.06	1.04–1.08
Gender (ref: Female)	0.062	0.57	0.31–1.03
Current BMI	0.965	1.00	0.95–1.05
Smoking (pack-year)	0.354	1.01	0.99–1.02
Alcohol (ref: Never)	0.022		
Ex-drinker	0.731	1.25	0.35–4.51
Current, <3 Units	0.132	1.66	0.86–3.23
Current, ≥3 Units	0.002	3.84	1.62–9.07
Ever use of NSAIDs	0.816	0.90	0.37–2.21
Ever use of Steroids	0.380	1.30	0.73–2.31
Ever use of DMARDs	0.805	0.93	0.51–1.69
Ever use of Biologics	0.613	1.16	0.66–2.04
History of IBD	0.904	1.07	0.37–3.12

**Conclusions:** Patients with SpA have a number of gastrointestinal comorbidities, including increased risk of diverticulitis with increased SpA disease duration, highest in those with axial disease. The reasons for this association are unclear and warrant further investigation. Diverticulitis should be considered, in addition to IBD, when patients with SpA present with lower gastrointestinal symptoms.

THU0268

### THE FREQUENCY OF JUVENILE SPONDYLOARTHROPATHIES IN CHILDHOOD FAMILIAL MEDITERRANEAN FEVER

E. Ozer, D. Seker, H.E. Taner, A. Adrovic, S. Sahin, O. Koker, K. Barut, O. Kasapcopur. *Pediatric Rheumatology, Istanbul University, Cerrahpasa Medical School, Istanbul, Turkey*

**Background:** Familial Mediterranean fever (FMF) is the most common monogenic autoinflammatory disease characterised with fever, recurrent episodes of self-limiting polyserositis and arthritis. FMF arthritis is generally acute monoarthritis especially in the larger joints of the lower extremities, healing without a sequelae. However some of the patients develop different type of chronic arthritis, predominantly oligoarticular juvenile idiopathic arthritis (JIA) and juvenile spondyloarthropathies (JSpA). Studies on JSpA among childhood FMF patients are sparse.

**Objectives:** To evaluate frequency of JSpA in a large childhood FMF cohort. Furthermore, we aimed to define main characteristics of JSpA among childhood FMF patients.

**Methods:** A total of 320 juvenile FMF patients were blindly questioned according to recently proposed criteria for JSpA by 3 researchers (EO, DS, ET) that were previously educated for FMF and JSpA. A standardised case report form was prepared and completed for each patient. This form was including demographic data, clinical features, MEFV mutation and treatment. Patients fulfilled the JSpA criteria and were classified as probable JSpA. Afterwards, an expert in paediatric rheumatology (OK) reevaluated the classified patients and some of them were reconfirmed to be a definite while some of them were accepted as potential JSpA patients.

**Results:** As a result, 37 patients (11.5%) were initially classified as potential JSpA. Furthermore, 32 (10%) of them were accepted as definite and 5 (1.5%) patients as probable JSpA in childhood FMF. Demographic, clinical and treatment data of definitive JSpA patients are shown in Table I. The most frequent MEFV mutation among JSpA patients was M694V (63.33%).

Table I. Demographic, clinical and genetic features of childhood FMF patients.

	FMF + Definite JSpA	FMF + Probable JSpA	FMF patients without JIA and JSpA	FMF+JIA (except ERA or JSpA)
Patients, n	32	5	268	15
Female, n (%)	10 (31.25%)	1 (20%)	148 (55.22%)	10 (66.66%)
Age of disease onset, mean±SD years	7.19 ±3.68	5.60 ±4.93	4.91±3.40	4.93±3.32
Age at study, mean ±SD years	14.84 ±3.70	13.40 ±1.67	12.51±4.43	10.73±3.57
Family History of FMF, n (%)	15 (46.87%)	1 (20%)	132 (49.25%)	6 (40%)
Colchicine resistance in FMF patients, n(%)	2 (6.25%)	0	14 (5.22%)	1 (6.66%)
M694V mutation n(%)	19/30 (63.33%)	3 (60%)	148/245 (60.40%)	11 (73.33%)
Homozygote, n(%)	7 (26.31%)	2 (66.66%)	51 (34.45%)	8 (72.72%)
Heterozygote, n(%)	36.84%	1 (33.33%)	43 (29.05%)	2 (18.18%)
Compound heterozygote, n(%)	5 (36.84%)	0	23 (8.58%)	1 (9.09%)
NA, n(%)	7 (26.31%)	0	0	0
Disease onset over 6 years, n (%)	26 (81.25%)	5 (100%)		6 (40%)
Oligoarthritits, n(%)	21 (65.62%)	1 (20%)		14 (93.33%)
Inflammatory back pain, n(%)	17/32 (53.12%)	3/5 (60%)		0
Enthesopathy	22/32 (68.75%)	3/5 (60%)		0
Sacroiliitis	14/21 (66.66%)	0/1 (0)		0/5 (0)

**Conclusions:** Articular involvement compatible with JSpA could be seen in childhood FMF patients. Spondyloarthropathy was detected in 10% of childhood FMF cases. The M694V mutation is the most common MEFV mutation among JSpA patients with FMF. JSpA should be considered in childhood FMF patients, especially in those chronic arthritis, axial involvement and enthesopathy.

### DEVELOPMENT OF ANKYLOSING SPONDYLITIS IN PATIENTS WITH REACTIVE ARTHRITIS AND PERIPHERAL SPONDYLOARTHROPATHY: HOSPITAL BASED STUDY IN NORTH INDIA

R. Misra, S. Ahmed, A. Chaudhury, A. Lawrence, V. Agarwal, A. Aggarwal. *Clinical Immunology, Sanjay Gandhi Post Graduate Institute of Medical Sciences, Lucknow, India*

**Background:** Reactive arthritis (ReA) is a seronegative spondyloarthropathy (SpA) that is precipitated by urogenital or gastrointestinal infection. Undifferentiated Peripheral spondyloarthropathy (UpSpA) may be indistinguishable from ReA except known preceding infection. It is stated that two-thirds of ReA resolve within three months while a third develop chronic or recurrent course. However, there is a paucity of data on the long-term outcome. Thus, it is difficult to justify treatment decisions like the use of biologicals in ReA

**Objectives:** To determine the outcome of ReA/upSpA patients attending a referral rheumatology centre in North India.

**Methods:** ReA was classified as per Braun's criteria, while UpSpA were included as meeting ASAS criteria but not criteria for psoriatic arthritis or inflammatory bowel disease associated arthritis. Data on this retrospective cohort was updated with telephonic interviews. Follow-up of less than 1 year were excluded. Patients with persistent inflammatory back pain (IBP) were reviewed in the clinic. Radiographs assessed progression to AS (modified New York criteria).

**Results:** Follow-up data on 85 patients (63 ReA; 22 pSpA) was obtained. Median (IQR) age at presentation was 24.5 (20–33) years. 14 (16.5%) were female. At presentation, 23 (30%) had monoarthritis, 44 (57%) had oligoarthritis, 10 (13%) had polyarthritis (data missing for eight). Enthesitis and dactylitis were documented in 20 and 5 respectively. Keratoderma and balanitis were seen in one each. 40 (80%) out of 50 were positive for HLA-B27.

Median (IQR) follow-up was 2 (1–5.25) years. 22 had monophasic illness of which 13 had acute arthritis (<12 weeks). Seven had two episodes, 27 had polycyclic course while 29 had persistent arthritis. 26 had inflammatory back pain (IBP) at any time and eight had persistent symptoms. Out of these, three (3.5%) met criteria for AS (disease duration: 1, 3 and 10 years) while two had unilateral grade 2 sacroiliitis. Three patients without IBP also had sacroiliitis on radiographs. Logistic regression revealed no significant parameter that could predict progression to AS

**Conclusions:** In contrast to general opinion that two thirds attend remission, this study showed that one third undergo drug free remission. Of the remaining, half develop recurrent and half persistent arthritis. 3.5% progressed to AS. As duration of follow-up increases, a greater proportion may progress to AS.

### THE PROPENSITY TO FAT METAPLASIA OF SACROILIAC JOINT IN SPONDYLOARTHROPATHY: RESULTS FROM THE SINGLE REGIONAL CENTRE COHORT

S.Y. Lee, S.W. Lee, W.T. Chung, J.W. Jung. *Rheumatology Of Internal Medicine, Dong-a University Hospital, Pusan, Korea, Republic of Korea*

**Background:** The predictor of radiographic spinal progression is the presence of syndesmophytes at baseline in axial spondyloarthritis (axSpA) and fat metaplasia on spine may predict the formation of new syndesmophytes. Some studies suggest that fat metaplasia may be a potential starting point for new bone formation

and have a general systemic effect on new bone formation in spine, rather than results from local inflammation. Recent studies suggest that fat metaplasia on sacroiliac joint (SIJ) MRI at baseline is associated with spinal radiographic progression in axSpA patients.

**Objectives:** So in this study, we investigated for propensity to fat metaplasia on SIJ in axSpA patients.

**Methods:** The 357 patients who fulfilled the ASAS axSpA criteria were enrolled. All underwent MRI on SIJ with T2 MR image, T1 fat suppressed with enhanced and short τ inversion recovery (STIR) image at baseline and lumbar spine radiographs at baseline and after 2 years. Inflammatory and structural lesions on SIJ MRI was scored using the SPondylo Arthritis Research Consortium of Canada (SPARCC) method. Spinal radiographs were scored using the Stoke AS Spinal Score (SASSS). Multivariate logistic regression analysis was performed to identify for propensity to fat metaplasia on SIJ in axSpA patients.

**Results:** Among the 357 patients on baseline SIJ MRI finding, 182 patients showed fat metaplasia on SIJ, 148 patients showed erosion and 27 patients showed ankylosis. Propensity to fat metaplasia in axSpA patients showed the male, HLA-B27 negative, smoking, back pain onset time within 6–12 months at time of diagnosis, uveitis, peripheral arthritis, compared to erosion and ankylosis on SIJ in axSpA patients. The patient with fat metaplasia or ankylosis on SIJ at baseline showed increased SASSS but there was no significant change in SPARCC over 2 years. univariate logistic regression analysis showed back pain onset time within 6–12 months at time of diagnosis and uveitis as a significant predictors of fat metaplasia. multivariate logistic analysis showed back pain onset time within 6–12 months at time of diagnosis as an affecting factor for fat metaplasia on SIJ (OR,5.67; 95% CI 4.71–17.95).

**Abstract THU0270 – Table 1.** The radiographic spinal progression over 2 years according to structural lesion in the sacroiliac joints observed on baseline MRI

	Fat metaplasia	Erosion	Ankylosis
Baseline SASSS	8.5±11.5	24±4.1	18.5±11.8
Change in SASSS over 2 years	0.7±1.7	0.4±0.6	0.8±1.7

OR: odd ratio CI: confidence interval

**Abstract THU0270 – Table 2.** Univariate and multivariate analysis of affecting factor for fat metaplasia on SIJ

variables	univariate analysis		Multivariate analysis	
	OR(95% CI)	p-value	OR(95% CI)	p-value
Age at time of diagnosis (years)	1.10(1.05-1.15)	0.04		
HLA-B27 positive	0.28(0.09-0.84)	0.07		
Smoking	0.38(0.15-0.96)	0.06		
Back pain within 6-12months at time of diagnosis	1.12(0.89-10.91)	0.02	5.67(4.71-17.95)	0.03
Uveitis	2.59(1.04-6.44)	0.03	2.00(0.47-8.62)	0.07
BAGSMA	1.45(0.69-2.78)	0.05		
Peripheral arthritis	0.32(0.10-1.00)	0.06		
Elevated ESR	2.59(1.04-6.44)	0.06		
Elevated CRP	2.48(1.00-6.19)	0.06		

OR: odd ratio CI: confidence interval

**Conclusions:** The back pain onset time within 6–12 months at time of diagnosis was affecting factor for propensity to fat metaplasia on SIJ in axSpA patients statistically and fat metaplasia on SIJ was associated with radiographic spinal progression in axSpA patients. so the early detection of fat metaplasia on SIJ in axSpA patients was important to protection of radiographic spinal progression.

### EMERGENCE OF SEVERE SPONDYLOARTHROPATHY RELATED ENTHESEAL PATHOLOGY FOLLOWING VEDOLIZUMAB THERAPY FOR INFLAMMATORY BOWEL DISEASE

S. Dubash<sup>1,2</sup>, T. Marianayagam<sup>3</sup>, T. Al-Araimi<sup>4</sup>, C. Pagnoux<sup>4</sup>, A. Weizman<sup>4</sup>, M.-L. Tran Minh<sup>5</sup>, M. Allez<sup>5</sup>, P. Rchette<sup>5</sup>, H. Marzo-Ortega<sup>1,2</sup>, D. McGonagle<sup>1,2</sup>, <sup>1</sup>NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals; <sup>2</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; <sup>3</sup>Rheumatology, East and North Hertfordshire NHS Trust, Stevenage, UK; <sup>4</sup>Division of Rheumatology, Mount Sinai Hospital, Toronto, Canada; <sup>5</sup>Hopital Lariboisiere, University Hospitals Group, Paris, France

**Background:** The Spondyloarthritides (SpA) and inflammatory bowel disease (IBD) share common aetiopathogenetic and clinical manifestations. Vedolizumab, a humanised IgG1 monoclonal antibody to  $\alpha 4\beta 7$  integrin, has been approved for the treatment of inflammatory bowel disease (IBD) and inhibits  $\alpha 4\beta 7$  integrin at the gut level. Vedolizumab therapy for IBD has been associated with mild SpA related features including sacroiliitis and synovitis. Herein, we report the emergence of severe SpA under therapy with Vedolizumab.

**Objectives:** We conducted a clinical evaluation of 7 vedolizumab treated patients with IBD that developed severe active SpA and/or enthesopathy with the aim of characterising the vedolizumab associated SpA/enthesal flares.

**Methods:** Vedolizumab treated IBD patients with SpA/enthesopathy were identified across four hospitals. We identified clinical, biochemical and imaging characteristics within routine case records as part of a clinical evaluation.

**Results:** We identified 6/7 subjects that developed *de novo* SpA/enthesopathy and 1/7 (subject 1) with a severe flare of pre-existing SpA. There were 3/7 patients hospitalised due to the severity of skeletal disease. The median time from vedolizumab initiation to flare was 10 weeks (table 1 below). Subject 4 developed new-onset SpA with severe spinal vertebral end-plate oedema (T6–12) and inflammatory Romanus lesions (L3–4) (image below). Acute sacroiliitis was identified on MRI in 3 subjects, one of which showed evidence of radiographic bilateral grade 2 sacroiliitis. In at least 4 cases the IBD disease activity was considered to be low or well controlled. Following vedolizumab discontinuation, so far 3 patients have switched to alternative biologic therapies including certolizumab pegol, golimumab, and 1 subject to sulphasalazine.

cpd=cigarettes per day, MTX=methotrexate, AZA=azathioprine, OC=oral corticosteroid, Pred=prednisolone, nr=non radiographic, MRI+ve= MRI positive, XR+ve = radiograph positive, NA=not available.

**Conclusions:** This case series demonstrates severe vedolizumab associated SpA/enthesopathy that resulted in hospitalised cases. The severity of vedolizumab related SpA flares is relatively severe disease in comparison to the literature. We recognise that vedolizumab is efficacious in IBD, however our observations highlight the need to monitor symptoms to identify patients that develop axial or peripheral SpA several weeks from commencing vedolizumab.

THU0272

### WHICH SCORING METHOD DEPICTS SPINAL RADIOGRAPHIC DAMAGE IN (EARLY) AXIAL SPONDYLOARTHRITIS BEST? FIVE-YEAR RESULTS FROM THE DESIR COHORT

S. Ramiro<sup>1</sup>, P. Claudepierre<sup>2</sup>, A. Sepriano<sup>1</sup>, M. van Lunteren<sup>1</sup>, A. Molto<sup>3</sup>, A. Feydy<sup>3</sup>, M.A. D'Agostino<sup>4</sup>, D. Loeuille<sup>5</sup>, M. Dougados<sup>3</sup>, M. Reijnen<sup>1</sup>, D. van der Heijde<sup>1</sup>. <sup>1</sup>Leiden University Medical Center, Leiden, Netherlands; <sup>2</sup>Université Paris Est Créteil, Créteil; <sup>3</sup>Paris Descartes University; <sup>4</sup>Université Versailles-Saint Quentin en Yvelines Boulogne-Billancourt, Paris; <sup>5</sup>University of Nancy, Nancy, France

**Background:** Scores capturing spinal radiographic damage have been proposed and compared in r-axSpA. In early phases of the disease, it is still unknown how these perform.

**Objectives:** To compare the performance of different radiographic scores of the spine in patients with early axial spondyloarthritis (axSpA).

**Methods:** Five-year follow-up data (baseline, 2 and 5 years) from the DESIR cohort, including patients with early axSpA, have been used. Spine (cervical, thoracic and lumbar), sacro-iliac joints (SI), and hips were scored on radiographs centrally and independently by 3 readers (scores averaged) for the calculation of different radiographic methods (table 1). Following the OMERACT filter, scores were compared with regard to truth, discrimination (sensitivity to change and reliability) and feasibility. Baseline status scores, and 2- and 5 year change scores were calculated for each of the methods, as well as the proportion of patients with a net change (number of patients with a positive change minus number of patients with a negative change divided by all patients) above the smallest detectable change (SDC). The proportion of total variance explained by the patient ('true variance') was calculated for the change scores of the different instruments and their components using ANOVA, as a measure of reliability.

**Results:** In total, 699 patients (mean age 34 (SD 9) years, 47% males) had at least one radiograph available. Mean baseline and 5 year change scores were: mSASS 0.4(SD 1.5) and 0.4 (1.8), RASSS 0.5 (1.6) and 0.6 (2.2), SASSS 0.2 (0.7) and 0.3 (1.1), BASRI spine 1.0 (1.2) and 0.2 (0.6), BASRI spine with thoracic spine: 1.1 (1.4) and 0.3 (0.7), BASRI total 1.0 (1.3) and 0.3 (0.6) and BASRI total with thoracic spine 1.2 (1.4) and 0.3 (0.7), respectively. SDCs and proportion of 2- and 5 year change, including net change, are presented in the table 1. The

Subject number	1	2	3	4	5	6	7
Age, M/F	28, M	48, M	33, F	50, M	35, F	40, F	21, F
Hospitalised	Y	N	N	N	Y	Y	N
Vedolizumab exposure (weeks)	14	20	20	6	8	10	5
SpA type	per+axSpA (MRI+ve, perifacetal spinal vertebral oedema)	per+axSpA (acute sacroiliitis MRI+ve)	axSpA (MRI +ve sacroiliitis)	nr-axSpA (MRI+ve, extensive thoracolumbar vertebral oedema/osteitis and inflammatory corner lesions)	nr-axSpA	Enthesitis/periostitis distal tibio-fibular (MRI+ve)	per+axSpA (MRI +ve and XR +ve sacroiliitis)
HLA-B27	N	NA	NA	N	Y	NA	N
Smoker (cpd)	15	NA	NA	25	N	NA	N
EIMs (Uveitis, PsO)	N	N	PsO	N	PsO	N	N
IBD activity	Low	NA	NA	High	Low	Low	Low/well controlled
CRP at flare (mg/l)	216	<5	<5	24	24	28	55
Concomitant immunosuppressive therapy	MTX 15 mg s/c/week	AZA 150 mg/day	OC (Pred 0.5 mg/day)	Nil	Nil	OC (4 mg Pred)	Nil

mSASSS and the RASSS performed the best in terms of capturing the signal (i.e. positive change) despite the noise (i.e. negative change), which is taken into account in the net change calculation.

The proportion of variance explained by the patient for the radiographic scores was highest for the mSASSS and RASSS, both for status and progression scores (e.g. 70% for mSASSS 69% for RASSS 2 year progression). However, the proportion of patient variance in the thoracic segment of the RASSS was unsatisfactory (36% for 2 year progression, compared to 54% lumbar segment and 73% cervical segment).

In what concerns feasibility, all scores seemed feasible, but the thoracic segment was missing in up to 7% of the cases, thus not allowing computation of BASRI modifications to include that segment.

**Abstract THU0272 – Table 1.** Two- and 5-year change, above the smallest detectable change, across the different radiographic scores

	2-year Change > SDC				5-year Change > SDC					
	N	SDC	Positive change N (%)	Negative change N (%)	Net change N (%)	N	SDC	Positive change N (%)	Negative change N (%)	Net change N (%)
mSASSS (0-72)	488	0.9	29 (6)	6 (1)	23 (5)	372	1.1	41 (11)	3 (1)	38 (10)
RASSS (0-84)	484	1.0	26 (5)	2 (0.4)	24 (5)	370	1.2	54 (15)	1 (0.3)	53 (14)
SASSS (0-72)	499	0.8	13 (3)	0 (0)	13 (3)	389	1.2	36 (9)	0 (0)	36 (9)
BASRI spine (0-12)	484	0.6	40 (8)	22 (5)	18 (4)	371	0.7	39 (11)	2 (0.5)	37 (10)
BASRI spine with thoracic (0-16)	360	0.6	35 (10)	17 (5)	18 (5)	267	0.9	31 (12)	2 (1)	29 (11)
BASRI total (0-16)	480	0.6	41 (9)	22 (6)	19 (4)	368	0.8	41 (11)	2 (0.5)	39 (11)
BASRI total with thoracic (0-20)	358	0.7	19 (4)	4 (1)	15 (3)	266	0.9	32 (12)	2 (1)	30 (11)

SDC, smallest detectable change; mSASSS, modified Stoke in Ankylosing Spondylitis Spine Score; RASSS, Radiographic Ankylosing Spondylitis Spinal Score; SASSS, Stoke Ankylosing Spondylitis Spine Score; BASRI, Bath Ankylosing Spondylitis Radiology Index.

**Conclusions:** The existing scoring methods to assess spinal radiographic damage performed well in early phases of axSpA. The mSASSS and RASSS captured most change. There was no clear gain in additionally scoring the thoracic spine for the RASSS while an increased noise was introduced. The mSASSS remains the most sensitive and valid scoring method in axSpA, including early phases of the disease.

#### THU0273 PREVALENCE OF VERTEBRAL FRACTURES IN ANKYLOSING SPONDYLITIS: A META-ANALYSIS

J. Sahuguet<sup>1</sup>, J. Mancini<sup>2</sup>, P. Lafforgue<sup>3</sup>, T. Pham<sup>1</sup> *Aphm, Hopital Sainte Marguerite*; <sup>2</sup>Aix Marseille Univ, Inserm, Ird, Umr912 Sesstim; <sup>3</sup>Aix Marseille Univ, Aphm, Hopital Sainte Marguerite, Marseille, France

**Background:** Osteoporosis is a well-recognised feature of ankylosing spondylitis (AS). Patients with AS have an increased risk of vertebral fractures (VF) but prevalence of VF is variable across studies from 4% to 42%. The diagnosis of VF is still problematic because frequently asymptomatic and sometimes difficult to differentiate from vertebral deformities which are not fractures.

**Objectives:** The aim of our study was to determine the prevalence of VF in AS and the risk factors associated.

**Methods:** Two independent investigators conducted a search in Medline and Cochrane databases, including cohorts, cross-sectional, and case-control studies that had assessed the prevalence of VF in patients with AS fulfilling the modified New York criteria. We collected data about study design, demographics, disease activity and severity (HLA B27 antigen status, BASDAI, BASFI, ASDAS, mSASSS, CRP, ESR, treatment history), bone mineral density, method of VF assessment (method of X-rays reading, number of readers) and characteristics of VF (number, prevalence, grade).

**Results:** Among 434 screened studies, 17 were eligible for meta-analysis. The pooled VF prevalence in patients with AS was 19% (95% CI 14%>24%, I<sup>2</sup>90.5%) (figure 1). The CRP (p<0.001) and mSASSS (p=0.046) scores were associated with a higher risk of VF. When focusing only on moderate to severe VF, HLA B27 antigen (p=0.046), lumbar spine osteoporosis (p=0.018) and osteopenia (p=0.024), hip BMD (p=0.024), CRP (p=0.004), ESR (p<0.001), and Genant method (p=0.009) were associated with higher risk of VF.

**Conclusions:** Despite a large heterogeneity among studies, the prevalence of VF in AS patients is high. CRP and mSASSS scores were associated with the prevalence of all VF. Classical VF risk factors, such as osteoporosis, were associated only with moderate and severe VF.

#### THU0274 ASSESSMENT OF RADIOGRAPHIC SACROILIITIS ON ANTERO-POSTERIOR LUMBAR RADIOGRAPHS AS COMPARED TO CONVENTIONAL PELVIC RADIOGRAPHS IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

V. Rios Rodriguez, M. Llop<sup>1</sup>, M. Protopopov<sup>1</sup>, J. Sieper<sup>1</sup>, H. Haibel<sup>1</sup>, M. Rudwaleit<sup>2</sup>, D. Poddubnyy<sup>1,3</sup>, <sup>1</sup>Rheumatology, Charité Universitätsmedizin, Berlin; <sup>2</sup>Internal Medicine and Rheumatology, Klinikum Bielefeld Rosenhöhe, Bielefeld; <sup>3</sup>German Rheumatism Research Centre, Berlin, Germany

**Background:** EULAR guidelines consider conventional radiography of sacroiliac joints (SIJs) as the first recommended imaging method in case of suspected axial spondyloarthritis (axSpA).<sup>1</sup> However, it is not clear whether sacroiliac joints can be reliably assessed on anteroposterior (AP) lumbar radiographs, which are often performed as a part of the diagnostic work-up in patients presented with back pain.

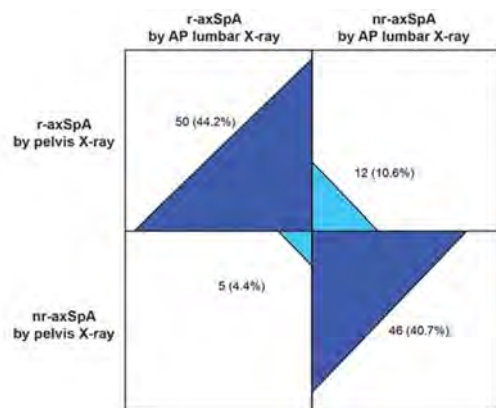

**Objectives:** To investigate reliability and validity of radiographic sacroiliitis assessment on AP lumbar radiographs as compared to conventional pelvic X-rays in patients with axSpA.

**Methods:** Patients from the GERman SPondyloarthritis Inception Cohort (GESPIC) were selected based on the availability of sets of pelvic and AP lumbar radiographs with visible SIJs at baseline and after 2 years of follow-up. Two trained readers (ML and VR) scored the images independently and in a random order according to the radiographic system of the modified New York (mNY) criteria (grade 0 to 4). The sacroiliitis sum score (0–8) was calculated as a sum of the mean grades of 2 readers for the right and left SIJ. We assessed intra- and inter-reader reliability using intraclass correlation coefficients (ICC) of the sacroiliitis sum scores. Patients were classified as having radiographic axSpA (r-axSpA) when both readers agreed on the presence of definite radiographic sacroiliitis according to the mNY criteria, and non-radiographic axSpA (nr-axSpA) otherwise.

**Results:** A total of 226 sets radiographs were scored from the 113 patients included in the present study. Intra-observer agreement was good to excellent for

the sacroiliitis sum score of pelvic vs. AP lumbar radiographs. Inter-observer agreement for pelvic and AP lumbar radiographs was also good to excellent: ICC at baseline: 0.81 and 0.73, respectively, at year 2: 0.76 and 0.79, respectively. A total of 62 (54.9%) and 55 (48.7%) patients were classified as r-axSpA at baseline based on evaluation of pelvic and AP lumbar radiographs, respectively. The absolute agreement on the classification was 84.9% (figure 1). A total of 17 patients (12 (10.6%) with nr-axSpA and 5 (4.4%) with r-axSpA) were classified differently based on assessment of AP lumbar as compared to conventional pelvic radiographs (figure 1).

After 2 years of follow-up, progression from nr- to r-axSpA occurred in 7 patients (6.2%) and 8 patients (7.1%) classified as nr-axSpA at baseline based on pelvic or AP lumbar radiographs assessment, respectively. Regression from r- to nr-axSpA occurred in 4 patients (3.5%) and 3 patients (2.7%) on pelvic or AP lumbar radiographs, respectively, giving a respective net progression rates of 2.7% and 4.4%.

**Abstract THU0274 – Figure 1.** Classification as non-radiographic or radiographic axial spondyloarthritis based on sacroiliitis assessment on conventional pelvic and anteroposterior lumbar radiographs.

**Conclusions:** Radiographic sacroiliitis can be assessed on AP lumbar radiographs with a similar reliability as on conventional pelvic radiographs.

THU0275

#### THE RELATIONSHIP BETWEEN MAASTRICHT ANKYLOSING SPONDYLITIS ENTHESITIS SCORE AND THE SPONDYLOARTHRITIS RESEARCH CONSORTIUM OF CANADA ENTHESITIS INDEX IN ANKYLOSING SPONDYLITIS: FRIENDS OR ENEMIES?

<sup>1</sup>W. Hamdi, M. Sellami<sup>1</sup>, H. Riahi<sup>2</sup>, K. Maatallah<sup>1</sup>, D. Kaffel<sup>1</sup>, M. Chelli-Bouaziz<sup>2</sup>, M. F. Ladeb<sup>2</sup>, M.M. Kchir<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Kassab Orthopedics Institute, Manouba, Tunisia

**Background:** The enthesitis screening is critical for the diagnosis and for monitoring the disease activity in axial spondyloarthritis (AS). Several indices have been developed for the clinical evaluation of enthesitis, including the Maastricht Ankylosing Spondylitis Enthesitis Score (MASES) in 2003 and the Spondyloarthritis Research Consortium of Canada (SPARCC) in 2008. Each of them has advantages and limitations, but could they be complementary?

**Objectives:** The objective of our study was to compare the abilities of MASES and SPARCC in detecting enthesitis and to look for possible correlations between these two scores.

**Methods:** We designed this prospective study in 60 patients meeting modified New York criteria for AS and seen at the rheumatology department. All patients underwent a clinical evaluation, in which scores of MASES (range 0–13) SPARCC (range 0–16) and visual analogue scale (VAS) for enthesial pain were recorded. Ultrasound scans were taken for five entheses sites on both sides in lower limbs (proximal and distal insertions of the patellar tendon, patellar insertion of the quadriceps tendon, and calcaneal insertions of the Achilles tendon and superficial plantar fascia).

**Results:** Sixty AS patients were enrolled (48 men and 12 women) with a mean age of 36 years<sup>20–74</sup> and mean disease duration of 8.8 years [0.5–25]. Biological inflammation was detected in 51 patients with mean erythrocyte sedimentation rate (ESR) of 33<sup>2–98</sup> and mean C reactive protein of 16.9 mg/L [0–240]. Physical examination found 77/600 painful entheses sites (12.8%), of which quadriceps and calcaneum entheses were the most painful in 16% and 15.8% cases respectively. The mean MASES was 3.4 [0–13] and the mean SPARCC was 2.98 [0–16]. A null MASES and SPARCC scores were recorded in 18 (30%) and 23 (38%) patients respectively. US imaging of the entheses showed peritendinous oedema and bursitis mainly at distal insertions of the patellar tendon in 51% and 55% respectively. Erosions were more likely detected at Achilles tendon site (95.8%). MASES and SPARCC scores were both significantly correlated with VAS for enthesial pain ( $r=0.52$ ;  $r=0.46$ ;  $p<0.0001$  respectively), with the BASDAI ( $r=0.39$ ;  $r=0.40$ ;  $p<0.0001$  respectively), with BASFI ( $r=0.45$ ;  $r=0.39$ ;  $p<0.0001$ ), with VAS for global pain ( $r=0.55$ ;  $r=0.51$ ;  $p<0.0001$  respectively) and with ESR ( $r=0.23$ ;  $p=0.012$  for both). The sonographic score for acute enthesitis correlated only with the MASES, however overall sonographic score correlated only with the SPARCC (table 1). The MASES and SPARCC scores were positively correlated ( $r=0.768$ ;  $p<0.0001$ ).

**Abstract THU0275 – Table 1.** Correlations among clinical and sonographic scores.

Enthesitis indices	Sonographic score for acute enthesitis	Overall sonographic score	Sonographic score for chronic enthesitis	Doppler score
MASES	$r=0.24$ $p=0.008$	$r=0.114$ $p=0.2$	$r=0.14$ $p=0.12$	$r=0.1$ $p=0.27$
SPARCC	$r=0.15$ $p=0.09$	$r=0.198$ $p=0.030$	$r=0.17$ $p=0.05$	$r=0.12$ $p=0.18$

**Conclusions:** Good correlations were found between the 2 enthesitis indices in AS with special sonographic features for each, attesting their complementary relationship.

**Disclosure of Interest:** None declared

**Background:** There has been substantial progress in the characterisation of MRI lesions in the sacroiliac joints (SIJ) and spine in axial spondyloarthritis (axSpA) since the last consensus-based descriptive reports from ASAS<sup>1,2</sup>. There is as yet a lack of international consensus on standardised definitions of all the lesions reported to date. Consequently, the ASAS MRI group was convened to generate a consensus update.

**Objectives:** To evaluate the literature describing the spectrum of MRI lesions in axSpA and to generate a consensus update on standardised definitions.

**Methods:** The literature pertaining to MRI lesion definitions in axSpA was discussed at 3 meetings of the ASAS MRI group attended by 26 investigators. The group reviewed the literature for MRI lesion definitions and decided by consensus which definitions would be retained, which required modification, and which required a new definition.

**Results:** For definitions denoting signs of activity in the SIJ, there are no revisions to the most current ASAS definition of a positive MRI<sup>1</sup>. Definitions for capsulitis and enthesitis are revised. A new definition, *joint space enhancement*, denotes increased signal on contrast-enhanced images in the joint space of the cartilaginous portion of the SIJ. This replaces the term 'synovitis' and a separate definition describes what constitutes joint space fluid. For structural change in the SIJ, the definition for sclerosis is unchanged. Revised definition for a fatty lesion incorporates characteristics typical of axSpA, and for erosion requires both loss of cortical bone as well as adjacent marrow matrix. A new definition, *fat metaplasia in the joint space ('backfill')*, denotes the reparative change on a T1W image at the site of erosion when signs of activity recede. The new definition for ankylosis stresses the continuity of bright marrow signal across the joint space. Spinal lesion definitions are divided into those that occur in defined central and lateral sagittal slices. The revised definition of a vertebral corner inflammatory lesion divides this into a regular (type A) and dimorphic (type B) lesion. A new definition for corner erosion requires both loss of cortical bone as well as adjacent marrow matrix. New definitions for new bone growth require bright signal on T1W images extending from the vertebral corner marrow or endplate, which may (ankylosis) or may not (bone spur) be continuous with the adjacent vertebra.

**Conclusions:** The ASAS MRI group has generated a consensus based update on MRI lesions in axSpA.

THU0277

#### WHICH MRI LESIONS IN THE SACROILIAC JOINT ARE ASSOCIATED WITH THE DIAGNOSIS OF AXIAL SPONDYLOARTHRITIS AFTER 2 YEARS FOLLOW UP IN THE ECHOGRAPHY IN SPONDYLOARTHRITIS COHORT (ECHOSPA)?

<sup>1</sup>W.P. Maksymowycz, D. Loeuille<sup>2</sup>, S. Wichuk<sup>1</sup>, J. Paschke<sup>3</sup>, O. Judet<sup>4</sup>, M. Breban<sup>5</sup>, M.-A. D'Agostino<sup>5</sup>, R.G. Lambert<sup>6</sup>. <sup>1</sup>Medicine, University of Alberta, Edmonton, Canada; <sup>2</sup>Rheumatology, CHRU Vandoeuvre les Nancy, Nancy, France; <sup>3</sup>CaRE Arthritis, Edmonton, Canada; <sup>4</sup>Radiology, <sup>5</sup>Rheumatology, Ambroise Paré Hospital, Boulogne-Billancourt, France; <sup>6</sup>Radiology, University of Alberta, Edmonton, Canada

**Background:** MRI of the sacroiliac joint (SIJ) is emerging as an important prognostic tool for assessment of patients presenting with SA and this may have consequences for early treatment. A major challenge in early SA is establishing the diagnosis and this requires prospective follow up to determine which cases have developed SA with more certainty. In addition, it is unclear which MRI lesions have prognostic capacity

**Objectives:** To assess the baseline distribution and prognostic capacity of MRI lesions in the SIJ of patients diagnosed with axSpA after 2 years follow up in the ECHOSPA cohort.

**Methods:** Consecutive outpatients with age <50 years and symptoms >3 months suggestive of SpA (inflammatory back pain, peripheral arthritis or inflammatory arthralgia, enthesitis or dactylitis, uveitis with B27 positivity, a family history of SpA) were enrolled in the prospective French ECHOSPA cohort study. The diagnosis of SpA was ascertained by an expert committee, blind to MRI evaluation, after at least 2 years of follow-up. MRI scans from 223 cases were available for evaluation by 2 readers and an adjudicator who assessed MRI lesions in the SIJ according to updated consensus definitions from the ASAS-MRI group. These were recorded in an ASAS consensus-derived eCRF that comprises global assessment (active and/or structural lesion typical of axSpA present/absent) and detailed scoring of individual lesions (SPARCC SIJ inflammation, SPARCC SIJ structural). Clinical, lab, and imaging variables associated with the diagnosis of axSpA at 2 years were first identified by univariate regression. A base model of all clinical/lab variables associated with axSpA was included as a group in multivariate logistic regression models that tested the independent association with MRI lesions.

**Results:** Mean age of the 223 cases was 39.6 (10.5) years, mean symptom duration was 2.5 (4.1) years, 49.5% were HLA-B27 + and 63.7% were female. Primary inclusion criterion was IBP in 53%, IA in 27%, ED in 9%, B27 +U in 8% and Fam in

4%. At 2 years follow up, 165 (74%) were deemed to have axSpA. In group comparisons (table 1) and univariate regression, both active and structural MRI lesions were associated with diagnosis of axSpA at 2 years (p=0.03, p=0.01, respectively). Age, B27, and psoriasis were the clinical variables associated with diagnosis of axSpA at 2 years in univariate analysis (all p<0.0001) and were included together with gender in multivariate analyses. Active and structural lesions typical of axSpA and SPARCC BME score ≥2 were each independently associated with diagnosis of axSpA at 2 years (OR(95% CI)- 6.8 (1.4–34.1) (p=0.02); 17.9 (2.2–146.6) (p=0.007); 4.9 (1.3–18.4) (p=0.02). With all variables simultaneously added to the model, only structural lesions were significantly associated.

**Abstract THU0277 – Table 1.** Distribution of MRI lesions at baseline according to diagnosis of axSpA after 2 years

MRI Lesion	AxSpA n=165 (74.0%)	NOT SpA n=58 (26.0%)	P value
Active lesion typical for axSpA	26 (16.0%)	2 (3.6%)	0.019
Active lesion typical for axSpA (confidence ≥3, 0-4 scale)	18 (11.9%)	1 (1.8%)	0.027
ASAS MRI positivity	24 (14.6%)	1 (1.7%)	0.006
ASAS MRI positivity (confidence ≥3, 0-4 scale)	17 (10.8%)	1 (1.7%)	0.048
Structural lesion typical for axSpA	32 (19.6%)	1 (1.8%)	0.0004
Structural lesions typical for axSpA (confidence ≥3, 0-4 scale)	27 (17.3%)	0 (0%)	0.0002
Active AND structural lesion typical for axSpA	19 (11.7%)	0 (0%)	0.004
Active OR structural lesion typical for axSpA	39 (23.9%)	3 (5.4%)	0.001
Only active lesion typical of axSpA	7 (4.3%)	2 (3.6%)	1.0
Only structural lesion typical of axSpA	13 (8.0%)	1 (1.8%)	0.12

**Conclusions:** Assessment of both active and structural lesions on MRI may help determine which patients have axSpA with higher diagnostic certainty over time.

THU0278

#### SERUM CALPROTECTIN IS CORRELATED WITH DISEASE ACTIVITY IN EARLY AXIAL SPONDYLOARTHRITIS BUT DOES NOT PREDICT RADIOGRAPHIC PROGRESSION AT 2 YEARS: RESULTS FROM THE DESIR COHORT

<sup>1</sup>X. Romand, M.H. Paclet<sup>2</sup>, A. Courtier<sup>3</sup>, M.-V.-C. Nguyen<sup>4</sup>, F. Berenbaum<sup>5</sup>, D. Wendling<sup>6</sup>, P. Gaudin<sup>1</sup>, A. Baillet<sup>1</sup>. <sup>1</sup>Rheumatology, CHU Grenoble Alpes Hôpital Sud, Université Grenoble Alpes, GREPI, EA 7408, Echirolles; <sup>2</sup>Biology, CHU Grenoble Alpes, GREPI, EA 7408; <sup>3</sup>Sinnovial; <sup>4</sup>Sinnovial, GREPI, EA 7408, Université Grenoble Alpes, Grenoble; <sup>5</sup>Rheumatology, Sorbonne Université, INSERM, DHU i2B, AP-HP Hôpital Saint-Antoine, Paris; <sup>6</sup>Rheumatology, University Teaching Hospital CHRU Besançon, Besançon, France

**Background:** Calprotectin (S100A8/A9), a protein secreted by activated neutrophils and monocytes in inflammatory conditions, is upregulated in active spondyloarthritis and associated with radiographic spinal progression in axial spondyloarthritis (axSpA)<sup>2</sup>

**Objectives:** To determine if serum calprotectin level at baseline can predict the radiographic progression of structural damage in spine at 2 years in the early axSpA cohort DESIR (DEvenir des Spondyloarthrites Indifférenciées Récentes) and to compare the association with spine and sacroiliac joint (SIJ) inflammation on magnetic resonance imaging (MRI).

**Methods:** Patients presenting with inflammatory back pain suggestive of axSpA for less than 3 years from the DESIR cohort were analysed. axSpA patient were defined as patients who fulfilled the Assessment in SpondyloArthritis Society (ASAS) criteria for axSpA at baseline. Calprotectin was assessed in the serum at baseline with ELISA kit (Hycult Biotech, the Netherlands). Spine radiographs, SIJ and spine MRI were centrally scored. Radiographic spinal progression was defined as worsening by ≥2 units of the mSASSS 2 years after the inclusion. Level of MRI spine and SIJ inflammation at baseline and 2 years was evaluated with BERLIN and SPARCC score. The associations between calprotectin level and mSASSS worsening were tested with Wilcoxon test, Berlin and SPARCC score were tested by Spearman's correlation tests.

**Results:** Of all, 426 had a calprotectin dosage and an early axSpA according to the ASAS criteria. Among them, 211 patients have had a mSASSS scoring at baseline and M24. A total of 399 patients have had spinal and SIJ MRI scoring at baseline. Only 15 patients had a radiographic progression with a variation of mSASSS ≥2. We showed a correlation between baseline calprotectin and MRI inflammation in SIJ or spine (Berlin score (r=0.15, p=0.003), SPARCC Sacroiliac score (r=0.12, p=0.012) and SPARCC Spine score (r=0.16, p=0.002)). Calprotectin baseline level was significantly higher in patients who fulfilled axSpA ASAS sacroiliitis arm criteria versus those who fulfilled ASAS HLA B27 arm criteria without any signs of sacroiliitis or versus patients did not fulfil ASAS criteria

(respectively  $p < 0.001$ ,  $p = 0.004$ ). Calprotectin level was correlated with baseline disease activity index (BASDAI ( $r = 0.16$ ,  $p = 0.001$ ), ASDAS-CRP ( $r = 0.26$ ,  $p < 0.001$ )) and disability score (BASFI ( $r = 0.14$ ,  $p = 0.003$ ), ASQoL ( $r = 0.16$ ,  $p = 0.001$ )). Interestingly, calprotectin at baseline did not predict radiographic progression at M24 (mSASSS worsening  $0.27 \mu\text{g/mL} \pm 0.14$  vs without mSASSS worsening  $0.29 \mu\text{g/mL} \pm 0.19$  (mean  $\pm$  SD)). There was also no correlation between calprotectin level and number of syndesmophytes.

**Conclusions:** Calprotectin do not seem to be a helpful biomarker predicting clinically relevant radiographic progression at 2 years although calprotectin levels at baseline are moderately correlated with disease activity in early axSpA.

#### THU0279 GENDER DIFFERENCE IN PSYCHOLOGICAL STATUS AND SLEEP QUALITY IN THE PATIENTS WITH ANKYLOSING SPONDYLITIS

Y. Jiang, Q. Lv, J. Qi, D. Huang, X. Zhang, M. Yang, Y. Zhang, J. Gu.  
Rheumatology, THE THIRD AFFILIATED HOSPITAL OF SUN YAT-SEN UNIVERSITY, Guangzhou, China

**Background:** Ankylosing spondylitis (AS) is a chronic inflammatory disease which mainly involves the spine and sacroiliac joints. Anxiety and depression, are common among people with arthritis and interplay independently and synergistically with clinical outcomes such as pain and disability.<sup>1</sup> Psychological variables can be found either within the body functions or within the personal factors.<sup>2</sup> Meanwhile, AS patients may suffer from various sleep problems. Pain intensity, anxiety, and depression correlated significantly with poorer sleep quality.<sup>3</sup> Whether gender difference exists in psychological status and sleep disturbance in AS patients remains unknown.

**Objectives:** Our aim was to investigate the prevalence of psychological disorders and sleep disturbance in Chinese patients with AS and then to explore gender difference in psychological status and sleep quality in the patients with AS.

**Methods:** Patients fulfilling modified New York criteria were enrolled from several rheumatology centres in China. Participants were required to complete a set of questionnaires and examinations, including demographic and clinical information, Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), Zung self-rating anxiety scale (SAS), Zung self-rating depression scale (SDS) and the Pittsburgh Sleep Quality Index questionnaire (PSQI). Independent T test was performed to compare patients with different gender.

**Results:** Totally 3117 patients were included in the study. 2501 were males, and mean age were  $27.20 \pm 9.13$  years. While 616 were female patients' whose mean age were  $28.84 \pm 9.21$  years. 32.3% of the patients had anxiety. 62.2% had depression according to SDS. 63.4% had sleep disturbance. Male patients had an earlier age of disease onset than females ( $p < 0.01$ ). Although female patients had a shorter disease duration, they had higher scores of SAS and SDS ( $p < 0.05$ ). There was no significant difference in sleep quality between male and female patients.

**Conclusions:** A large number of AS patients were found to have anxiety, depression, sleep disturbance. Male AS patients tend to have an earlier age of disease onset, while female patients are more likely to have psychological disorders. Clinicians should take these factors into account during the assessment of the patients.

THURSDAY, 14 JUNE 2018:

#### Psoriatic arthritis

#### THU0280 EARLY AND LONG-TERM TREATMENT RESPONSE AS WELL AS HIGH TOLERABILITY LEAD TO HIGH TREATMENT SATISFACTION OF A THERAPY WITH USTEKINUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS – RESULTS OF THE NON-INTERVENTIONAL STUDY SUSTAIN

J. Wendler<sup>1</sup>, E. Movshovich<sup>2</sup>, J. Behrens<sup>2</sup>, F. Hamann<sup>3</sup>, P. Wagener<sup>4</sup>, F. Behrens.  
<sup>1</sup>Rheumatologische Schwerpunktpraxis, Erlangen; <sup>2</sup>JANSSEN-CILAG GMBH, Neuss; <sup>3</sup>Gemeinschaftspraxis für internistische Rheumatologie, Leipzig; <sup>4</sup>Gemeinschaftspraxis für internistische Rheumatologie, Bruchhausen-Vilsen; <sup>5</sup>Rheumatologie und Fraunhofer Institut IME -TMP, Goethe-Universität, Frankfurt, Germany

**Background:** SUSTAIN is a prospective, multi-centre non-interventional study in Germany to observe long term efficacy and safety, quality of life and further patient reported outcomes in patients with active psoriatic arthritis under treatment with ustekinumab in routine clinical care.

**Methods:** In this study nearly 400 patients were planned to be documented at 75 centres for 160 weeks with documentation intervals at week 0 and 4 and then every 12 weeks. The treatment with Ustekinumab is according to the label (Stelara®). Besides demographic data, the following data will be documented: Number of swollen and tender joints, tender entheses, amount of skin symptoms (BSA and PASI), patient reported outcome concerning disease activity and pain, Health Assessment Questionnaire (HAQ), quality of life (SF-12), sleep quality (VAS), satisfaction with therapy of patient and physician, safety (adverse events [AE]/serious adverse events [SAE]), pharmacoeconomic aspects, number of patients with "Minimal Disease Activity" (MDA), number of patients with MDA at week 28 and 52. For the present second interim analysis baseline data of all 336 patients and results of the documented visits up to week 76 were analysed.

**Results:** For the present analysis 336 patients (57% women) at 75 centres were observed. The visit at week 4 was documented for 290 patients, at week 16 for 305 patients, at week 28 for 262 patients, and at week 76 for 100 patients. At baseline, the patients had a mean age of 54 years<sup>22-85</sup> and BMI of 30 kg/m<sup>2</sup>.<sup>19-52</sup> 53.9% of the patients had as prior medication a TNF inhibitor and stopped because of inadequate response. Only 38% of the patients used MTX as concomitant medication. The patients showed arthritis at small (73.2%) and/or large (52.1%) joints, spinal involvement (16.7%) and enthesitis (13.1%). Number of tender joints improved from a mean of 10.0 (CI 95% 8.6/11.3) at baseline to 6.4 (5.4/7.3) at week 4 and 2.1 (1.4/2.9) at week 76. Number of swollen joints improved from 4.1 (3.4/4.9) at baseline to 2.6 (2.1/3.1) at week 4 and to 0.7 (0.4/1.0) at week 76. Efficacy of the therapy with ustekinumab was assessed as "very good" or "good" by 76.2% of the treating physicians at week 16 and by 89.9% at week 76. The patients assessed the efficacy as "very good" or "good" by 71.2% at week 16 and by 90.7% at week 76. Until data cut off point (32 months after study start), 67 SAEs have been documented, of which only 13 were related to ustekinumab. All in all, safety of therapy with ustekinumab was assessed as "very good" or "good" by 96.0% of the treating physicians after 16 weeks and by 98% after 76 weeks. The patients assessed the safety as "very good" or "good" by 93.3% at week 16 and by 98.0% at week 76.

**Conclusions:** The non-interventional study SUSTAIN showed relevant improvements with high therapy satisfaction and good safety in patients with active psoriatic arthritis treated with Ustekinumab after 4 weeks up to 76 weeks in daily practice life.

THU0281

### DO IMPROVEMENTS IN HEALTH-RELATED QUALITY OF LIFE DURING DMARD TREATMENT DIFFER BETWEEN PSORIATIC AND RHEUMATOID ARTHRITIS PATIENTS? DATA FROM THE PROSPECTIVE OBSERVATIONAL NOR-DMARD STUDY, INCLUDING BASELINE COMPARISONS WITH NORWEGIAN GENERAL POPULATION CONTROLS

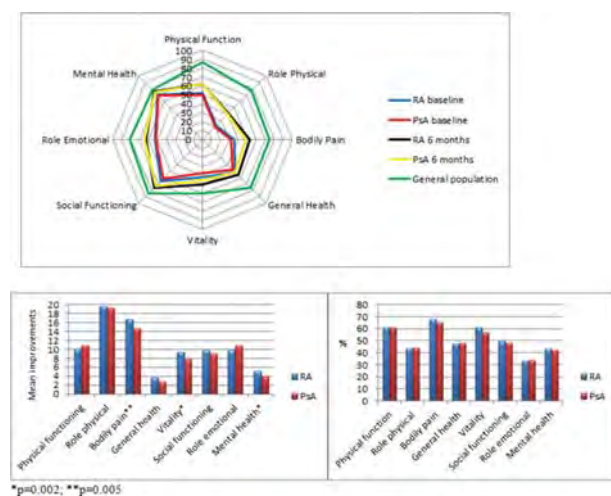

<sup>1,2,3</sup>B. Michelsen, T. Uhlig<sup>1</sup>, J. Sexton<sup>1</sup>, H.B. Hammer<sup>1</sup>, E.K. Kristianslund<sup>1</sup>, G. Haugeberg<sup>3,4</sup>, J.H. Loge<sup>5</sup>, T.K. Kvien<sup>1</sup>. <sup>1</sup>Dept. of Rheumatology, Diakonhjemmet Hospital, Vinderen, Oslo; <sup>2</sup>Dept. of Medicine, Hospital of Southern Norway Trust, Kristiansand; <sup>3</sup>Dept. of Neuroscience, University of Science and Technology, Trondheim; <sup>4</sup>Dept. of Rheumatology, Martina Hansens Hospital, Baerum; <sup>5</sup>Faculty of Medicine, University of Oslo, Oslo, Norway

**Background:** Only few longitudinal observational studies exist on the comparison of Health-related quality of life (HRQoL) between PsA and RA patients using the Medical Outcomes Survey Short Form-36 (SF-36), as well as with general population controls.

**Objectives:** The aims were 1) to explore if improvements in SF-36 scale scores differ between PsA and RA patients, 2) to compare proportions of PsA and RA patients achieving Minimum Clinically Important Improvements (MCII) in scale scores at 6 months follow-up<sup>1</sup>, 3) to compare HRQoL between RA, PsA patients and Norwegian general population controls.

**Methods:** We included first-time enrolled PsA and RA patients from the prospective observational multicenter NORwegian-Disease Modifying Anti-Rheumatic Drug (NOR-DMARD) study, starting conventional synthetic and/or biologic (cs/b) DMARDs between year 2000 and, 2012 as well as data from Norwegian general population controls.<sup>2</sup> Continuous variables were compared using independent t-test or Mann-Whitney U test as appropriate. Prespecified ANCOVA analyses adjusted for age and gender were performed to compare changes in scale scores from baseline to 6 months follow-up between PsA and RA patients. Radar diagram was made to visualise changes in scale scores (0 worst, 100 best) and bar charts to visualise improvements from baseline to 6 months as well as proportions of patients fulfilling MCII ( $\geq 5$ ) in scale scores at 6 months.

**Results:** A total of 1515 PsA and 3898 RA patients as well as 2323 Norwegian general population controls<sup>2</sup> were included (mean (SD) age 48.1 (12.6)/55.9 (31.6)/44.9 (16.5) years, 50.3%/71.4%/51.3% women, respectively; median (25th-75th percentile) disease duration RA; 2.0 (0.1–9.6), PsA: 1.9 (0.1–11.0) years). Mean (SD) DAS28 was lower in PsA vs. RA patients at baseline (4.2 (1.3)/4.9 (1.4)) and at 6 months ((3.1 (1.3)/3.5 (1.5)), as well as median (25th-75th percentile) 28 swollen joint count at baseline (2 (1–5)/6 (3–10)) and at 6 months (0 (0–2)/2 (0–4) follow-up, all  $p < 0.001$ . All scale scores were worse in PsA and RA compared with the general population ( $p \leq 0.001$ ), but improved during cs/bDMARD treatment (figure 1a). The improvements were marginally better in RA versus PsA patients for bodily pain, vitality and mental health (figure 1b). Similar percentages of RA and PsA patients achieved MCII  $\geq 5$  in scale scores from baseline until 6 months.

**Abstract THU0281 – Figure 1a.** Estimated marginal means of scale scores in RA and PsA patients as well as Norwegian general population controls, adjusted for age and gender. **Abstract THU0281 – Figure 1b.** Mean improvements in SF-36 scale scores from baseline to 6 months, adjusted for age, gender and the respective baseline values. **Abstract THU0281 – Figure 1c.** Similar proportions of RA and PsA patients achieved MCII  $\geq 5$  in scale scores from baseline to 6 months follow-up. \* $p = 0.002$ ; \*\* $p = 0.005$

**Conclusions:** These findings indicate that PsA patients have at least as high disease burden in terms of HRQoL as RA patients, in spite of higher levels of joint inflammation in the RA patients. Improvements during treatment were overall similar, except for somewhat larger improvements in bodily pain, vitality and mental health in RA patients. Similar proportions of PsA and RA patients achieved MCII at 6 months.

Barbadillo<sup>12</sup>, J. Bachiller<sup>13</sup>, T. Cobo<sup>14</sup>, A. Turrión<sup>15</sup>, E. Giner<sup>16</sup>, J. Llorca<sup>17</sup>, M. González-Gay<sup>18</sup>. <sup>1</sup>H Elda, Elda; <sup>2</sup>UIFER, Madrid; <sup>3</sup>CST Terrassa, Barcelona; <sup>4</sup>La Princesa, Madrid; <sup>5</sup>L Augusti, Lugo; <sup>6</sup>Negrin, Las Palmas; <sup>7</sup>G Marañón, Madrid; <sup>8</sup>Clínico, Salamanca; <sup>9</sup>Valdecilla, Santander; <sup>10</sup>V Hebrón, Barcelona; <sup>11</sup>H, Mérida; <sup>12</sup>P Hierro; <sup>13</sup>R y Cajal; <sup>14</sup>Inf Sofía, Madrid; <sup>15</sup>P Asturias, Alcalá Henares; <sup>16</sup>O Polanco, Teruel; <sup>17</sup>U Cantabria; <sup>18</sup>IDIVAL, Santander, Spain

**Background:** Regardless of disease activity, functional status gets worse in patients with rheumatoid arthritis (RA) with comorbidities. However, the impact of comorbidities on physical function in ankylosing spondylitis (AS) and psoriatic arthritis (PsA) is less known.

**Objectives:** To assess the impact of comorbidities on physical function (PF) in patients with AS and PsA.

**Methods:** Analysis of the baseline visit from the ongoing multicentric, observational, prospective, CARMA study. Data from patients with AS and PsA were analysed. Two different adjusted multivariate models were performed, where PF was the dependent variable (BASFI in AS and HAQ in PsA) and the following independent variables: comorbidities, a proxy for the Charlson index (ChI) (minimum 0; maximum 11), sociodemographic, disease activity (ESR, CRP and BASDAI in AS; while SJC, TJC, CRP, ESR, DAS, dactylitis count and PASI in PsA) and duration, radiographic damage and treatments. Results are presented as  $\beta$  coefficients and p-values.

**Results:** 738 patients with AS and 721 with PsA included (mean age at inclusion 48.1  $\pm$  11.7 and 51.8  $\pm$  12 years, respectively). AS patients: median BASFI 3.1 [interquartile range (IQR): 1.3–5.2], BASDAI 3.5 [IQR: 1.7–5.3], mean ChI 1.32  $\pm$  0.73. PsA patients: HAQ 0.4 [IQR: 0.0–0.9], DAS28 2.9 [IQR: 2.0–3.8], mean ChI 1.30  $\pm$  0.66. A ChI  $> 1$  found in 21% of the patients. Hypertension in 25.7% and 29.5%; hypercholesterolemia in 27% and 35.6% and diabetes in 7.6% and 9.2% of the patients with AS and PsA, respectively. Cardiovascular events occurred in 7.6% AS and 7.2% PsA, in most cases after the rheumatic disease diagnosis. Only patients with PsA with higher ChI showed worse adjusted physical function ( $\beta$ : 0.09;  $p = 0.03$ ). Also female sex ( $\beta$ : 0.03;  $p = 0.001$ ), obesity ( $\beta$ : 0.09;  $p = 0.04$ ), disease duration ( $\beta$ : 0.01;  $p = 0.009$ ), NSAIDs ( $\beta$ : 0.1;  $p = 0.02$ ), corticosteroids ( $\beta$ : 0.12;  $p = 0.02$ ) and biologics ( $\beta$ : 0.15;  $p = 0.07$ ) were associated with worse function in patients with PsA. In contrast, a higher educational level was associated with less disability. In patients with AS, thyroid disease ( $\beta$ : 1.19,  $p = 0.002$ ) and raised ESR ( $\beta$ : 0.01,  $p = 0.010$ ) were independently associated with function.

**Conclusions:** The presence of comorbidities in patients with PsA is independently associated with worse physical function, similar to what happens in RA. Early detection and control may yield an integral management of the disease and better final outcomes.

THU0283

### PATIENTS WITH PSORIATIC ARTHRITIS WHO ARE NOT ELIGIBLE FOR RANDOMISED CLINICAL TRIALS FOR TNF INHIBITORS HAVE SIMILAR TREATMENT RESPONSE AND DRUG SURVIVAL. RESULTS FROM THE ICEBIO REGISTRY

<sup>1</sup>O. Pálsson, B. Guðbjörnsson<sup>1</sup>, G.A. Jóhannsdóttir<sup>2</sup>, A. Gunnarsdóttir<sup>2</sup>, P. S. Gunnarsson<sup>2</sup>, T.J. Love<sup>2</sup>, E. Rúnarsdóttir<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Landspítali, Reykjavik, Iceland

**Background:** We have recently reported that a majority of patients with psoriatic arthritis who are being treated with TNF inhibitors in Iceland would not have been

eligible for the randomised clinical trials (RCTs) performed leading up to registration of the respective pharmaceutical product.<sup>1</sup>

**Objectives:** To determine whether patients with psoriatic arthritis who did not fulfil the inclusion criteria (group B) in RCTs receive similar benefits and drug survival from TNF inhibitors as those patients who would have fulfilled the inclusion criteria (group A).

**Methods:** All patients with rheumatic disorders who are treated with biologic DMARDs in Iceland are registered in ICEBIO. ICEBIO is based on the Danish Registry for biologic therapies in rheumatology<sup>2</sup> and has data about approximately 98% of all patients with psoriatic arthritis treated with biologic DMARDs in Iceland. On February 1st 2016 there was information on 1058 individuals in ICEBIO. 231 patients with psoriatic arthritis received their first-line treatment and could be classified according to inclusion criteria of respective pharmaceutical RCT.<sup>1</sup> Information on disease activity at baseline was collected and we estimate the treatment response at 6 and 18 months according to ACR20 and DAS28CRP and drug survival.

**Results:** The groups were similar at baseline (table 1), although Group A predictably had higher SJC (5.5 vs 3.8) and subsequently higher DAS28CRP (4.6 vs 4.2). Out of 231 patients we have sufficient data to determine ACR20 and DAS28CRP response in 92 and 91 patients respectively. Treatment response is outlined in table 2, with better response in group A in regards to HAQ and SJC. There was similar drug survival between the groups (figure 1).

	Group A	Group B	p value
VAS pain	65±17	64±22	0.705
VAS global	71±21	66±24	0.222
TJC	6.3±3.8	5.4±4.4	0.198
SJC	5.5±3.3	3.8±3.6	0.003
HAQ	1.2±0.69	1.0±0.65	0.114
DAS28CRP	4.6±0.8	4.2±0.9	0.012

**Abstract THU0283 – Table 1.** Group characteristics, mean values±SD.

Improvement in clinical parameters:	Included in RCTs	Not included in RCTs	p value
HAQ at 6 months	-0.8±0.7	-0.3±0.6	0.008
HAQ at 18 months	-0.6±0.7	-0.3±0.6	0.051
SJC at 6 months	-4.3±2.7	-2.2±2.7	0.001
SJC at 18 months	-4.4±3.4	-2.2±3.6	0.007
TJC at 6 months	-4.2±3.8	-2.8±5.1	0.163
TJC at 18 months	-4.0±4.9	-3.9±4.1	0.889
ACR20 at 6 months	77%	60%	0.207
ACR20 at 18 months	69%	59%	0.545
DAS28CRP at 6 months	77%	71%	0.749
DAS28CRP at 18 months	81%	67%	0.304

**Abstract THU0283 – Table 2.** Response to first-line TNF $\alpha$  inhibitors, mean values and percentage achieving response by ACR20 or decrease in disease activity by DAS28CRP.

**Abstract THU0283 – Figure 1.** First-line TNF inhibitor drug survival

**Conclusions:** Patients with psoriatic arthritis that would not have fulfilled the inclusion criteria in RCTs seem to respond to treatment effectively and have similar drug survival. Thus, treatment outcomes for psoriatic arthritis from RCTs may probably be applied to daily clinical practice, whether patients would have fulfilled RCT criterias or not. However, more detailed studies are needed.

## THU0284 HAQ IN PSORIATIC ARTHRITIS IS DRIVEN BY GENDER, INFLAMMATION AND AGEING: OBSERVATIONAL DATA FROM COHORT STUDIES IN UK, DENMARK, ICELAND AND SWEDEN

<sup>1</sup>L.E. Kristensen, T.S. Jørgensen<sup>1</sup>, L.C. Coates<sup>2</sup>, P. Frederiksen<sup>1</sup>, B. Gudbjornsson<sup>3</sup>, J.K. Wallman<sup>4</sup>, N. McHugh<sup>5</sup>, M.C. Kapetanovic<sup>6</sup>, L. Dreyer<sup>7</sup>, W. Tillett<sup>5</sup>. <sup>1</sup>The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen F, Denmark; <sup>2</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; <sup>3</sup>Centre for Rheumatology Research, University Hospital and Faculty of Medicine, University of Iceland, Reykjavik, Iceland; <sup>4</sup>Department of Clinical Sciences Lund, Rheumatology, Lund University, Lund, Sweden; <sup>5</sup>Royal National Hospital for Rheumatic Diseases, Bath, UK; <sup>6</sup>Department of Clinical Sciences, Lund, Section of Rheumatology Lund University and Skåne University Hospital, Lund, Sweden; <sup>7</sup>Center for Rheumatology and Spine diseases, Rigshospitalet Gentofte, Hellerup, Denmark

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disorder associated with skin and joint involvement, pain and impaired function. HAQ has been widely used but components contributing to HAQ and changes thereof have been sparsely studied.

**Objectives:** The objective of this multinational population-based cohort study was to investigate factors associated with longitudinal changes in HAQ in patients with PsA in independent settings.

**Methods:** Data on PsA patient characteristics, disease activity components and HAQ was obtained from the DANBIO (Denmark), ICEBIO (Iceland), SSATG (southern Sweden) and BATH (UK) cohort registries. Farewell's linear increments model for missing data was used to fit each longitudinal response by regressing the observed increments onto lagged values of the response variables (HAQ, CRP and VAS pain) while also adjusting for other covariates (gender, age and disease duration). Due to homogeneity of the nature of registries, the Nordic data was pooled for patients initiating first course of biologics (anti-TNF therapy, secukinumab or ustekinumab), whereas UK data represents an ongoing cohort with different treatments.

**Results:** In the period 2006 through 2016, we identified 1473 patients from DANBIO, 168 from ICEBIO, 469 from BATH, and 716 from SSATG eligible for analyses. Mean age in years (SD) and percentage of females for the populations were 46 (SD ±12), 55% for DANBIO, 46 (SD ±12), 61% for ICEBIO, 47 (SD ±11), 51% for SSATG, and 58 (SD ±13) 49% for BATH; respectively. The figure displays observed HAQ values (solid lines) and Farewell modelled (broken lines) curves divided on gender for the development of HAQ after initiation of biologic therapy for pooled Nordic data (A) and for the ongoing UK cohort (B). It should be noted, that Farewell modelling inflates HAQ-values in the Nordic registries reflecting a correction for channelling bias due to drop out during biologic treatment. Whereas the modelled HAQ values for the BATH cohort are deflated possibly due to extra visits during flares in this ongoing observational cohort. At all time points and cohorts female HAQ values are higher than males (p<0.001). After initiation of biologic therapy there is a significant decline in the HAQ scores in the Nordic registers of 0.23 (95% CI 0.21–0.25) at 6 months. Changes in CRP, VAS-pain nor disease duration did not appear to affect HAQ during follow-up. However, ageing seemed to have a tendency to increase HAQ over time. The same consistent pattern was present when analyses were done separated by country (data not shown).

**Conclusions:** In PsA, across independent European cohorts, HAQ is higher for women, and significantly decreases for both genders when anti-inflammatory treatment is initiated. HAQ does not depend on CRP, VAS-pain or disease duration during longitudinal follow-up. However, a significant increasing trend was identified with ageing.

Duruo<sup>3</sup>, U. Kalyoncu<sup>7</sup>, <sup>1</sup>S.Z. Aydin, on behalf of PsArt-ID (Psoriatic Arthritis-International Database). <sup>1</sup>PsArt-ID, Ottawa, Canada; <sup>2</sup>PsArt-ID, Gaziantep; <sup>3</sup>PsArt-ID, Istanbul; <sup>4</sup>PsArt-ID, Isparta; <sup>5</sup>PsArt-ID, Izmir; <sup>6</sup>PsArt-ID, Bursa; <sup>7</sup>PsArt-ID, Ankara; <sup>8</sup>PsArt-ID, Kahramanmaraş; <sup>9</sup>PsArt-ID, Eskisehir; <sup>10</sup>PsArt-ID, Van; <sup>11</sup>PsArt-ID, Adana; <sup>12</sup>PsArt-ID, Konya, Turkey

**Background:** Psoriatic arthritis (PsA) has a genetic background, approximately 40% of patients having a family history of psoriasis or PsA in first-degree relatives, which may impact the disease features.

**Objectives:** The aim of this study was to evaluate the effects of family history of psoriasis or PsA on the disease phenotypes.

**Methods:** The demographic and clinical data were retrieved from the longitudinal, multicenter PsArt-ID (Psoriatic Arthritis-International Database). Family history of psoriasis and PsA were investigated for 1st and 2nd degree relatives separately. The effect of the family history of psoriasis and/or PsA on disease phenotypes and severity were analysed, calculating the relative risks (RR).

**Results:** 1393 patients had the data for family history, 444 (31.9%) of whom was positive for psoriasis and/or PsA. The majority of the family history was only psoriasis (333/444; 75%) and 58.5% (260/444) of the patients had first-degree relatives affected. There was no differences in maternal or parental transmission rates however women had more psoriasis and/or PsA in their family (67.3% vs 32.7% p: 0.028). Patients with a family history had an earlier onset of age for psoriasis (29±14.8 vs 31±14.9 p: 0.007), more frequent nail involvement (50.7% vs 29.6% p: 0.032), more frequent enthesitis (28.2% vs 17.7% p<0.001) and deformities (25.2% vs 19.9% p: 0.05) and were able to achieve minimal disease activity (MDA) less often. (38.6% vs 49.5% p: 0.045). Plaque psoriasis was more common if the family history was positive for psoriasis whereas pustular psoriasis was more frequent when the family history was positive for PsA (figure 1). Family history of psoriasis were found as a risk factor for a younger onset (RR: 1.138), for nail disease (RR: 1.179), for enthesitis (RR: 1.504) and for not achieving MDA (RR: 1.246) whereas family history of PsA was a risk factor for having deformities (RR: 1.215) (table 1).

**Abstract THU0285 – Table 1.** Relative Risks in patients with or without family history of psoriasis or PsA

	Family history	p	RR	95% CI
Onset of psoriasis before 40 years age	Psoriasis	<0.05	1.138	1.063–1.219
	PsA	>0.05	1.023	0.879–1.191
Nail involvement (ever)	Psoriasis	<0.05	1.179	1.04–1.335
	PsA	>0.05	1.157	0.917–1.461
Enthesitis (ever)	Psoriasis	<0.05	1.504	1.192–1.898
	PsA	>0.05	1.350	0.871–2.092
Not achieving MDA	Psoriasis	<0.05	1.246	1.003–1.547
	PsA	>0.05	1.044	0.655–1.666
Presence of deformities	Psoriasis	>0.05	1.215	0.928–1.592
	PsA	<0.05	1.786	1.170–2.727

PsA: Psoriatic Arthritis; MDA: Minimal Disease Activity

**Figure:** Distribution of skin lesions according to the family history in patients with PsA. Numbers are given as percentages. PsO: Psoriasis; PsA: Psoriatic Arthritis

**Conclusions:** The family history of psoriasis and PsA has impacts on skin phenotypes, musculoskeletal features and the disease severity. The differences between family history of psoriasis and PsA and pustular vs plaque phenotypes may point out to a different genetic background and pathogenic mechanisms in these subsets.

#### THU0286 PREDICTORS FOR ORTHOPAEDIC SURGERY IN PATIENTS WITH PSORIATIC ARTHRITIS. RESULTS FROM A RETROSPECTIVE COHORT STUDY OF 590 PATIENTS DIAGNOSED 1954–2011, AND FOLLOWED UP UNTIL 2017

<sup>1,2</sup>I.W. Nystad, Y. Husum<sup>1</sup>, O.N. Fumes<sup>2,3</sup>, B.T.S. Fevang<sup>1,2,4</sup>. <sup>1</sup>Bergen group of Epidemiology and Biomarkers in Rheumatic Disease, Department of Rheumatology; <sup>2</sup>The Norwegian Arthroplasty Register, Department of Orthopaedic surgery, Haukeland University Hospital; <sup>3</sup>Department of Clinical Medicine; <sup>4</sup>Department of Clinical Science, University of Bergen, Bergen, Norway

**Background:** Psoriatic arthritis with peripheral joint affection is a progressive disease in most patients, and erosions are seen in 47% within the first two years.<sup>1</sup> Synthetic disease modifying anti rheumatic drugs (DMARDs) are generally prescribed, to inhibit inflammation, but have not been proven to slow or prevent radiographic changes. Biologic treatment is recommended when other agents are not efficient, and has been shown to give better control of structural damage.<sup>2</sup> Orthopaedic corrective surgery has been a necessary part of treating patients with psoriatic arthritis, when medication fails to prevent joint destruction. Surgery can be considered a proxy for joint damage, and studying time trends in orthopaedic surgery thus gives valuable information regarding the prognosis of patients with inflammatory arthritis. In patients with rheumatoid arthritis there has, over time, been a declining incidence of orthopaedic interventions. The change in available medical treatment is believed to be responsible for this.<sup>3</sup> As synthetic

DMARDs may be less efficient in patients with psoriatic arthritis, it is uncertain whether a decline of the same magnitude can be expected among these patients.

**Objectives:** We wished to investigate trends in the incidence of orthopaedic procedures in patients with psoriatic arthritis, and to explore how patient characteristics, time of diagnosis and treatment affect the need for surgery.

**Methods:** We reviewed the medical history of 1432 patients with possible psoriatic arthritis at Haukeland University Hospital in Bergen, Norway from 1954–2011, of which 590 (mean age 49, 52% women) had a confirmed diagnosis of psoriatic arthritis, and sufficient journal information, and were included in the present study. Relevant orthopaedic procedures were obtained from the Norwegian Arthroplasty Register and the hospital's administrative patient records. 171 procedures (25% joint synovectomies, 15% arthrodeses and 53% prostheses) were performed in 117 patients. Survival analyses were completed to evaluate the impact of different factors such as year of diagnosis, age, sex, radiographic changes, disease activity and treatment, on the risk of undergoing surgery.

**Results:** Female sex, older age ( $\geq 70$ ) and maximum ESR 30–59 significantly increased the risk of surgery whereas time period of diagnosis had no effect on the outcome. Anti-rheumatic treatment changed significantly over time.

**Abstract THU0286 – Figure 1.** Cumulative percent operated depending three separate time periods of diagnosis

**Conclusions:** 20% of patients with psoriatic arthritis needed surgery during disease course. In our material, the prognosis of patients with psoriatic arthritis has not changed, with regard to the risk of orthopaedic surgery, despite significant changes in treatment. This is contrary to what is seen for patients with rheumatoid arthritis.

#### THU0287 THE PREVALENCE OF REMISSION IN A REAL-LIFE COHORT OF PSORIATIC ARTHRITIS PATIENTS TREATED WITH SYNTHETIC OR BIOLOGIC DISEASE MODIFYING DRUGS

<sup>1</sup>E.G. Favalli, A. Fassio<sup>2</sup>, S. Bugatti<sup>3</sup>, A. Batticciotto<sup>4</sup>, L. Quartuccio<sup>5</sup>, M. Filippini<sup>6</sup>, S. Parisi<sup>7</sup>, M. Biggioggero<sup>1</sup>, G. Zanframundo<sup>3</sup>, I. Giovannini<sup>5</sup>, M.C. Ditto<sup>7</sup>, L. Idolazzi<sup>2</sup>. <sup>1</sup>Department of Rheumatology, Gaetano Pini Institute, Milano; <sup>2</sup>UOC Reumatologia, Dipartimento di Medicina, Università degli Studi di Verona, Verona; <sup>3</sup>Department of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; <sup>4</sup>Rheumatology Unit, University Hospital L. Sacco, Milano; <sup>5</sup>Department of Medical Area, Rheumatology Clinic, University of Udine, Udine; <sup>6</sup>UO di Reumatologia e Immunologia Clinica, ASST Spedali Civili Brescia, Brescia; <sup>7</sup>Rheumatology Unit, AOU Città della Salute e della Scienza di Torino, Torino, Italy

**Background:** The treat-to-target (T2T) strategy for the management of psoriatic arthritis (PsA) recently proposed by EULAR recommendations suggests to ideally achieve remission/Low Disease Activity (LDA) in all treated patients, but nowadays data on remission/LDA rate in a real-world setting are still lacking.

**Objectives:** To evaluate the disease activity state in a real-life cohort of PsA patients treated with synthetic and/or biologic disease modifying drugs (DMARDs).

**Methods:** We undertook a cross-sectional analysis of all PsA consecutive patients enrolled in a large Italian multicentric registry including 7 Italian tertiary rheumatology centres. Disease activity defined as number of swollen (SJ) and

tender (TJ) joints, Leeds Enthesis Index (LEI), number of dactylitis, Body Surface Area (BSA), patient global assessment (PGA), patient pain (PP), Health Assessment Questionnaire Disability Index (HAQ-DI), and C-reactive protein (CRP, mg/L) were computed and the rates of patients achieving Disease Activity in Psoriatic Arthritis (DAPSA) remission/LDA and Minimal Disease Activity (MDA) were calculated. Subanalysis after stratification according to ongoing treatment (sDMARDs or bDMARDs) were also performed.

**Results:** The study population included 362 PsA patients (56.6% men; mean  $\pm$  standard deviation, SD) age  $53.3 \pm 12.4$  years; mean  $[\pm$ SD] disease duration  $9.4 \pm 8.2$  years), treated with sDMARDs (15.8%, mainly methotrexate [66.6%]) or bDMARDs (79.6%, mainly anti-TNF agents [72.9%]), as monotherapy [78.1%] or in combination with sDMARDs [21.9%]. Oligoarthritis (32%), polyarthritis (42%), axial involvement (11.9%), enthesitis (10.5%), and dactylitis (3.6%) were the reported predominant subsets of PsA. In the overall population the mean values  $[\pm$ SD] of disease activity measures were: SJ count  $1.4 \pm 2.6$ , TJ count  $1.9 \pm 3$ , LEI  $0.5 \pm 1.1$ , number of dactylitis  $0.1 \pm 0.3$ , BSA  $2.6 \pm 6.9$ , PGA  $1.4 \pm 2.6$ , PP  $3 \pm 2.6$ , HAQ-DI  $0.4 \pm 0.5$ , CRP level  $3.4 \pm 8$ , and DAPSA  $9.3 \pm 9.2$ . The rates of DAPSA LDA and remission were 46.9% and 31.7%, respectively. We found 51.6% of patients achieving MDA, without significant difference according to ongoing treatment (53.4% and 51% in bDMARD versus sDMARD treated patients, respectively;  $p=0.87$ ).

**Conclusions:** In our real-life cross-sectional analysis, an acceptable comprehensive disease control was reported only in half of patients, irrespectively of ongoing therapy. These findings suggest the need to further improve the real-world application of T2T strategy for the management of PsA.

#### THU0288 IMPLEMENTATION OF THE TREAT TO TARGET CONCEPT IN EVALUATION OF PSORIATIC ARTHRITIS PATIENTS

<sup>1</sup>M. Abu Elhija, A. Haddad<sup>1</sup>, I. Lavi<sup>2</sup>, T. Gazitt<sup>1</sup>, D. Zisman<sup>1,3</sup>. <sup>1</sup>Rheumatology Unit, <sup>2</sup>Department of Community Medicine and Epidemiology, Carmel Medical Center, <sup>3</sup>The Ruth and Bruce Faculty of Medicine, Technion, Haifa, Israel

**Background:** Minimal disease activity (MDA) in psoriatic arthritis (PsA) is a composite outcome measure that represents the multifaceted domains of psoriatic disease including the joints, enthesitis and skin, as well as patient's reported outcomes (PRO). MDA is currently used as a goal of treatment in the "treat-to-target" (T2T) approach in PsA management.<sup>1</sup>

**Objectives:** To assess the implementation of the T2T concept in PsA patients.

**Methods:** A retrospective analysis of all the patients included in a PsA registry during 2016–2017 was performed. Medical charts were reviewed by an independent rheumatologist and the following data were collected: patient demographics, duration of PsA and psoriasis, alcohol and tobacco use, treatment changes, as well as items that constitute the MDA including the tender and swollen joint count, enthesitis, psoriasis area skin score (PASI), physician and patient evaluation of disease activity and pain and the health assessment questionnaire (HAQ) score. Medical records were reviewed to assess whether T2T concept was indeed followed by the treating rheumatologist to determine whether MDA was achieved and medication changes were made. The associations between T2T concept implementation and categorical and continuous variables were assessed by Chi square test, or t-test as appropriate. The association between the physician's assessment at each visit with each of the MDA parameters (active versus inactive) was assessed by Chi square test.

**Results:** The records of 117 consecutive patients were evaluated, one patient was excluded due to lack of data. The mean age was  $58.4 \pm 13$  years, of whom 76 (65.5%) were women. The T2T approach was implemented in 76 (65.5%) patients. There was no correlation between the T2T implementation and patient age, gender, alcohol and tobacco use, disease activity parameters at the patient's visit and the various treatment regimens. The physician assessment of disease activity did not correlate with the MDA score in 40 (34.5%) patients. In most cases 30 (75%), this discrepancy occurred because physicians labelled patients as having inactive disease while disregarding the PRO category of the MDA score, including 29 patients who reported a high VAS pain score, 22 patients reporting a high patient global disease activity and 25 patients reporting a high HAQ- score. In the other 10 (25%) of cases, the treating rheumatologists made treatment changes because they considered patients as having active disease based on one tender or swollen joint or enthesitis, despite these patients actually meeting MDA criteria.

**Conclusions:** In our cohort, the T2T concept was implemented in 65.5% of the visits in accordance with other PsA studies. The main obstacle that we encountered in implementation of MDA concept was in physicians' overlooking the PRO components of the score. Efforts are needed to increase the accurate use of the MDA score and treat to target concept in daily practice.

### BURDEN OF PSORIATIC ARTHRITIS IN DIFFERENT DEFINITIONS OF DISEASE ACTIVITY: COMPARING MINIMAL DISEASE ACTIVITY AND DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS

<sup>1</sup>K. Wervers, M. Vis<sup>1</sup>, I. Tchetcherikov<sup>2</sup>, A.H. Gerards<sup>3</sup>, M.R. Kok<sup>4</sup>, C.W. Appels<sup>5</sup>, W. L. van der Graaff<sup>6</sup>, J.H. van Groenendaal<sup>7</sup>, L.A. Korswagen<sup>8</sup>, J.J. Veris-Van Dieren<sup>9</sup>, J.M. Hazes<sup>1</sup>, J.J. Luime<sup>1</sup>, on behalf of Cicero. <sup>1</sup>Rheumatology, ERASMUS MC, Rotterdam; <sup>2</sup>Rheumatology, Albert Schweitzer Hospital, Dordrecht; <sup>3</sup>Rheumatology, Sint Franciscus Vlietland Group, Schiedam; <sup>4</sup>Rheumatology, Maasstad Hospital, Rotterdam; <sup>5</sup>Rheumatology, Amphia Hospital, Breda; <sup>6</sup>Rheumatology, Rivas Hospital, Gorinchem; <sup>7</sup>Rheumatology, Reumazorg Zuid West Nederland, Roosendaal; <sup>8</sup>Rheumatology, Sint Franciscus Vlietland Group, Rotterdam; <sup>9</sup>Rheumatology, Reumazorg Zuid West Nederland, Goes, Netherlands

**Background:** Treat-to-target strategies have improved outcomes in rheumatic diseases. In psoriatic arthritis (PsA), the proposed targets are the multidimensional target Minimal Disease Activity (MDA) and the articular target Disease Activity index for PsA (DAPSA).

**Objectives:** We aimed to compare burden of PsA in patients with low disease activity according to the two definitions MDA and DAPSA-Low Disease Activity (DAPSA-LDA), one year after diagnosis.

**Methods:** We obtained data on MDA, DAPSA-LDA and disease burden one year after diagnosis from patients included in the Dutch southwest early PsA cohort. Disease burden was assessed in two domains: 'Body Functions', including Short Form 36 Bodily Pain (SF36-BP), and 'Activity', including Health Assessment Questionnaire (HAQ).

**Results:** Of the 292 patients included, 48% achieved MDA and 64% DAPSA-LDA. Average 'Body Functions' and 'Activity' were similar in patients in MDA and patients in DAPSA-LDA. However the scores were significantly better in the 44% of patients in both MDA and DAPSA-LDA than in the 20% of patients only in DAPSA-LDA. The average SF36-BP was higher in patients achieving both targets (74.7, 95% CI 72.0–77.4) than in patients only in DAPSA-LDA (58.7, 95% CI 54.8–62.6). Similarly, mean HAQ scores measuring 'Activity' were 0.19 (95%CI 0.14–0.25) and 0.61 (95%CI 0.48–0.73) respectively.

SF36-BP: Short Form 36 Bodily Pain, HAQ: Health Assessment Questionnaire, MDA: Minimal Disease Activity, DAPSA: Disease Activity Index for Psoriatic Arthritis, MDA - not in MDA, MDA + : in MDA, DAPSA - : not in DAPSA-Low Disease Activity (DAPSA-LDA), DAPSA + : in DAPSA-LDA

**Abstract THU0289 – Figure 1.** SF36-BP and HAQ scores in MDA and DAPSA subgroups.

**Conclusions:** Of patients newly diagnosed with PsA, 48% achieved MDA and 64% DAPSA-LDA after one year receiving usual care. Average disease burden was similar in patients in MDA and in patients in DAPSA-LDA. However, those that only achieved DAPSA-LDA reported worse outcomes than those also achieving MDA.

THU0290

### EFFECTS OF BIOLOGIC DMARDs ON PHYSICAL FUNCTION IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS OF NETWORK META-ANALYSES

<sup>1</sup>A. Ruysse-Witrand, C. Sapin<sup>2</sup>, S. Hartz<sup>3</sup>, S. Liu Leage<sup>2</sup>. <sup>1</sup>Rheumatology Center, Purpan Teaching Hospital, Toulouse; <sup>2</sup>Eli Lilly and Company, Paris, France; <sup>3</sup>Eli Lilly and Company, Erl Wood, UK

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory rheumatic disease associated with psoriasis and characterised by pain, stiffness, swelling of joints, joints ankylosing and low patient quality of life.<sup>1</sup> The economic burden of PsA is substantial<sup>2</sup>, and biologic treatments for PsA are increasingly scrutinised in health technology assessments. The most commonly used economic model framework for assessing biologics in PsA is the York Assessment Group model developed as part of a NICE appraisal (the "York model").<sup>3</sup> In this model improvement in Health Assessment Questionnaire- Disability Index (HAQ-DI) reflects physical function, and is linked to initial treatment response measured by joint improvement assessed by PsARC.

**Objectives:** To assess the effectiveness of biologic DMARDs on HAQ-DI among active biologic-naïve PsA patients through Bayesian network meta-analyses (NMAs) and to understand the relationship to PsARC response.

**Methods:** Data for the NMA was identified through a systematic literature review of published and grey literature (1990-May 2017) in EMBASE/MEDLINE. Bayesian NMAs were conducted in line with NICE guidelines<sup>4</sup> to assess the mean HAQ-DI scores change from baseline for ixekizumab, adalimumab, ustekinumab, etanercept, golimumab, infliximab, apremilast, secukinumab, certolizumab pegol, and placebo in the biologic-naïve overall population as well as in PsARC responders and non-responders. Results were expressed as absolute mean change from baseline and associated standard deviations, and 95% credibility intervals.

**Results:** Overall, 42 publications reporting 19 randomised clinical trials were included for the NMAs, most of these evaluated outcomes at 12 and 24 weeks. Mean changes in HAQ-DI score (overall and by PsARC response) from baseline are shown in figure 1. Among PsARC responders, the greatest mean changes were observed for infliximab, etanercept, ixekizumab, and secukinumab. Among PsARC non-responders, those values were greatest for infliximab, etanercept, ixekizumab Q2W, secukinumab, and adalimumab. The relatively wide 95% credibility intervals reflect the scarcity of available evidence.

**Abstract THU0290 – Figure 1.** Mean changes in HAQ-DI in patients on different biologic DMARD treatments

**Conclusions:** The results of the NMAs suggest that among the biologic DMARDs infliximab, etanercept, ixekizumab Q2W, secukinumab 150 mg, and certolizumab had the highest HAQ-DI improvements in biologic-naïve patients with active PsA. Changes in HAQ-DI were strongly associated with PsARC response for each treatment.

**Background:** Tildrakizumab, is a high-affinity, humanised, anti-IL-23p19 monoclonal antibody for the treatment of chronic plaque psoriasis.

**Objectives:** Here, we evaluated gastrointestinal (GI) adverse events (AE) and, specifically, cases of inflammatory bowel disease (IBD; ie, Crohn's disease or ulcerative colitis) in the clinical development program for tildrakizumab.

**Methods:** Patients with moderate to severe plaque psoriasis were randomised in 3 large, clinical trials: P05495 (phase 2; NCT01225731), reSURFACE 1 (phase 3; NCT01722331), and reSURFACE 2 (phase 3; NCT01729754).<sup>1,2</sup> In this analysis, we identified serious GI AEs and new-onset or exacerbation of pre-existing IBD from a pooled dataset of tildrakizumab-treated patients from these 3 studies. Doses of tildrakizumab included 5 mg, 25 mg, 100 mg, and 200 mg in P05495 and 100 mg and 200 mg in the reSURFACE studies.

**Results:** In this analysis, we pooled 1911 patients from the 3 trials who received either tildrakizumab 100 or 200 mg. There were no new cases of IBD reported; among 6 patients with a history of IBD randomised to tildrakizumab, none experienced an exacerbation. The numbers (rate per 100 patient-years) of patients with serious GI AEs in the pooled dataset were 8 (0.80) for tildrakizumab 100 mg and 4 (0.43) for tildrakizumab 200 mg. These serious GI AEs included abdominal pain, constipation, diverticulum, dyspepsia, gastritis, thrombosed haemorrhoids, esophageal polyp, pancreatitis (1 patient each) among tildrakizumab 100 mg patients and abdominal hernia, upper abdominal pain, acute pancreatitis, and salivary gland enlargement (1 patient each) among tildrakizumab 200 mg patients.

**Conclusions:** In this post-hoc analysis of patients from 3 large randomised clinical trials, serious GI AEs were infrequent and there were no new cases of IBD or exacerbations of IBD.

**THU0292** **DIAGNOSTIC EXPERIENCES OF PATIENTS WITH PSORIATIC ARTHRITIS: MISDIAGNOSIS IS COMMON**

<sup>1</sup>A. Ogdie, W.B. Nowell<sup>2</sup>, E. Applegate<sup>2</sup>, K. Gavigan<sup>2</sup>, S. Venkatachalam<sup>2</sup>, M. de la Cruz<sup>3</sup>, E. Flood<sup>3</sup>, E.J. Schwartz<sup>3</sup>, B. Romero<sup>3</sup>, P. Hur<sup>4</sup>. <sup>1</sup>*Perelman School of Medicine at the University of Pennsylvania, Philadelphia;* <sup>2</sup>*Global Healthy Living Foundation, Upper Nyack;* <sup>3</sup>*ICON, Gaithersburg;* <sup>4</sup>*Novartis Pharmaceuticals Corporation, East Hanover, USA*

**Background:** Psoriatic arthritis (PsA) is a heterogeneous, chronic, immune-mediated disease characterised by a range of musculoskeletal conditions including joint pain, swelling, enthesitis and dactylitis as well as skin and nail manifestations. Early diagnosis of PsA is important as shorter time to treatment may improve outcomes.<sup>1</sup> However, PsA is often undiagnosed or misdiagnosed.<sup>2</sup> There is limited information on the diagnostic experiences of patients with PsA, including medical care sought and potential barriers to diagnosis.

**Objectives:** To determine patients' experiences related to the diagnosis of PsA including initial symptoms experienced, medical care sought, and time to diagnosis.

**Methods:** US patients aged  $\geq 18$  years with a self-reported diagnosis of PsA were recruited through CreakyJoints ([www.Creakyjoints.org](http://www.Creakyjoints.org)), an online patient support community comprising patients with arthritis and arthritis-related diseases and their caregivers, and outreach through social media. Participants completed an online survey designed to collect data on socio-demographics, clinical symptoms, disease burden, and diagnosis history, including initial PsA symptoms experienced, types of health care providers seen, misdiagnoses received before a diagnosis of PsA, and time to PsA diagnosis. Survey questions were developed following analysis of qualitative interviews of patients with PsA and clinical experts, as well as a targeted literature review.

**Results:** Of the 203 patients included in the study, 172 (85%) were female, with a mean (SD) age of 51.6 (10.8) years; 132 patients (65%) had private insurance, 61 (30%) Medicare, and 25 (12%) Medicaid. The most common initial symptoms that led patients to seek medical attention were joint pain (142 patients [70%]), stiffness (109 [54%]), swollen joints (101 [50%]), skin rash/psoriasis (97 [48%]), and fatigue (96 [47%]). Most patients (153 [75%]) sought medical treatment within 2 years of symptom onset. During the diagnosis process, patients most commonly sought care from a general practitioner (162 [80%]), rheumatologist (135 [66%]), dermatologist (67 [33%]), orthopedist (44 [22%]), and/or podiatrist (25 [12%]). Only 8 patients (4%) reported that they had never received a misdiagnosis; common misdiagnoses were psychosomatic disease, osteoarthritis, and anxiety/depression (figure 1). Patients reported median (IQR) time since diagnosis of 6.0 (2–11.5) years. Many patients (94 [51%]) received a diagnosis of PsA  $\leq 1$  year after seeking medical attention; however, 25 (17%) and 31 (15%) patients received a PsA diagnosis  $\geq 5$  and  $> 10$  years after seeking medical attention for the first time, respectively.

**Abstract THU0292 – Figure 1.** Misdiagnoses Received Before Diagnosis of PsA (N=203). PsA, psoriatic arthritis

**Conclusions:** This study showed that patients often had substantial delays and misdiagnoses before they received a PsA diagnosis. Increased understanding of the diagnostic barriers may lead to earlier diagnosis and appropriate treatment that may improve outcomes.

#### THU0293 THE TRAJECTORY OF RADIOGRAPHIC PROGRESSION SLOWS AMONGST PATIENTS WITH PSORIATIC ARTHRITIS TREATED WITH ANTI-TNF

<sup>1</sup>A. Allard, A. Antony<sup>1</sup>, G. Shaddick<sup>2</sup>, D. Jason<sup>3</sup>, C. Cavill<sup>1,4</sup>, E. Korendowych<sup>1</sup>, N. McHugh<sup>1,4</sup>, W. Tillett<sup>1,4</sup>. <sup>1</sup>Rheumatology, Royal National Hospital for Rheumatic Diseases, Bath; <sup>2</sup>Mathematical Sciences, University of Exeter, Exeter; <sup>3</sup>Rheumatology, Cambridge University Hospitals, Cambridge; <sup>4</sup>Pharmacy and Pharmacology, University of Bath, Bath, UK

**Background:** Radiographic damage is an important outcome in psoriatic arthritis (PsA) but the natural history of radiographic progression has not been well described. Randomised Controlled Trials (RCTs) of treatment with anti-TNF have shown reduced damage progression in the short term but long term real world data is lacking.

**Objectives:** We set out to describe the long term radiographic progression amongst patients with PsA who transitioned from conventional synthetic Disease Modifying Drugs (csDMARDs) to anti-Tumour Necrosis Factor alpha inhibitors (anti-TNF) in routine care.

**Methods:** A retrospective sample of 28 patients (CASPAR criteria for PsA) was taken from the Bath longitudinal cohort. All patients had radiographs of the hands and feet taken at approximately 3 time points; 5 years before [T<sub>0</sub>], at the time of [T<sub>1</sub>] and 5 years post [T<sub>2</sub>] commencing anti-TNF treatment. 84 radiographs were scored using the Sharp-van der Heijde modified method (VDH) and osteoproliferation was scored using the psoriatic arthritis Rating score (PARS) method, by three assessors (AA, AA and WT). The assessors were blinded to the patient details and the order of the x-rays. Inter- and intra-rater reliability was assessed using intra-class correlation coefficients (ICC). Cumulative probability plots were used to describe radiographic progression on csDMARDs (T<sub>0</sub> to T<sub>1</sub>) compared with subsequent anti-TNF treatment (T<sub>1</sub> to T<sub>2</sub>). Change between probability plots was determined using the two-sample Kolmogorov-Smirnov test (K-S test). This sample size was calculated to ensure 90% power to determine the smallest detectable difference of the VDH (6.25) to 5% significance level.

**Results:** Of the 28 patients 15 were male, the mean age was 61 years (SD 13.4) and mean disease duration at T<sub>0</sub> was 11.2 years (SD 11.14). The mean study follow up period was 10.2 years (SD 2.76). Inter- and intra-rater reliability was >0.9. The median VDH score at baseline was 8.5 (IQR 1.75–27.5). The median scores for erosions, joint space narrowing and proliferation at baseline were 1.5 (IQR 0–8.5), 4.5 (IQR 1–15) and 7 (SD1–13.5) respectively.

The median change in VDH score on csDMARDs was 11.00 (IQR 3–19.5) and on anti-TNF was 4.00 (IQR 0.75–11.5). The median rate of change in VDH score per year was 2.29 (IQR 0.95–3.81) on csDMARDs and on anti-TNF was 1.04 (IQR 0.16) p=0.012 (figure 1). These scores correlate with observed improvements in clinical disease outcome measures including tender joint count, swollen joint count and nail score (data not shown).

**Abstract THU0293 – Figure 1.** mVDH rate of progression (per year). Δpre-TNF inhibition •post-TNF inhibition

**Conclusions:** In this real world observational cohort study the rate of radiographic progression slows following commencement of anti-TNF therapy. The overall rate of damage progression was low over long term follow up of more than ten years even amongst this group of more severe patients selected on the basis they progressed to anti-TNF therapy.

**Disclosure of Interest:** None declared

#### THU0294 5-YEAR EFFICACY AND SAFETY OF APREMILAST TREATMENT IN SUBJECTS WITH PSORIATIC ARTHRITIS: POOLED ANALYSIS OF THE PALACE STUDIES

<sup>1</sup>A. Kavanaugh<sup>2</sup>, D.D. Gladman<sup>3</sup>, C.J. Edwards<sup>3</sup>, G. Schett<sup>4</sup>, B. Guertte<sup>5</sup>, N. Delev<sup>2</sup>, L. Teng<sup>2</sup>, M. Paris<sup>2</sup>, P.J. Mease<sup>2</sup>. <sup>1</sup>University of California, San Diego, School of Medicine, La Jolla, USA; <sup>2</sup>Krembil Research Institute, Toronto Western Hospital, Toronto, Canada; <sup>3</sup>University of Southampton, Southampton, UK; <sup>4</sup>Friedrich-Alexander-Universität Erlangen, Nürnberg und Universitätsklinikum Erlangen, Erlangen, Germany; <sup>5</sup>Celgene Corporation, Summit, <sup>6</sup>Swedish Medical Center and University of Washington School of Medicine, Seattle, USA

**Background:** Apremilast (APR) is an oral phosphodiesterase 4 inhibitor for the treatment of adult patients with active psoriatic arthritis (PsA).

**Objectives:** The long-term efficacy and safety of APR treatment were evaluated for up to 5 years in subjects with active PsA from the phase 3 PALACE 1, 2, and 3 studies.

**Methods:** Subjects were randomised at baseline (BL) (1:1:1) to receive placebo (PBO), APR 30 mg BID (APR30), or APR 20 mg BID (APR20). PBO subjects were re-randomised (1:1) to APR30 or APR20 at Week 16 (early escape) or Week 24. Double-blind APR treatment continued to Week 52; subjects could continue APR during an open-label, long-term treatment phase for up to 5 years. Safety was assessed at each visit throughout the study.

**Results:** A total of 1493 subjects were randomised and received ≥1 dose of study medication (PBO: n=495; APR30: n=497; APR20: n=501). Of those randomised to APR30 at BL, 66.6% (331/497) completed 260 weeks of treatment. At Week 52, modified ACR20, ACR50, and ACR70 responses were achieved by 55.3%, 26.1%, and 11.9% of APR30 subjects, respectively, regardless of when APR was started (BL, Week 16, or Week 24). Sustained response rates were observed with continued APR30 treatment at Week 260 (table 1). Marked SJC improvements were seen, with mean percent reduction of 82.3% at Week 260; TJC reduction was 72.7%. At Week 260, 62.4% (136/218) of APR30 subjects with BL enthesitis achieved a MASES of 0; 80.9% (114/141) with BL dactylitis achieved a dactylitis count of 0. A total of 52.6% of APR30 subjects achieved HAQ-DI MCID ≥0.35 at Week 260, and low disease activity and remission, as defined by the cDAPSA (score ≤13), were achieved by 60.4% of APR30 subjects. Sustained responses in psoriatic skin involvement were observed with continued treatment at Week 260 in APR30 subjects who had ≥3% BL psoriasis body

surface area involvement, with PASI-50 and PASI-75 response rates of 65.8% (98/149) and 43.6% (65/149), respectively. Results were similar for subjects receiving APR20 (data not shown). Consistent efficacy results were seen across the 3 individual trials. No new safety concerns were identified with APR up to 260 weeks. For APR30 subjects entering the 5th year of APR exposure, adverse events (AEs) occurring in  $\geq 5\%$  were nasopharyngitis (6.6%) and upper respiratory tract infections (5.8%); most AEs were mild or moderate in severity. Among APR30-exposed subjects, serious AEs occurred in 5.8% in Weeks $>208$  to $\leq 260$ ; 5 subjects discontinued due to an AE.

**Table 1:**

	Outcomes at Week 260	
	APR30 n=329*	
ACR20, n/m <sup>†</sup> (%)	215/320 (67.2)	
ACR50, n/m <sup>†</sup> (%)	144/324 (44.4)	
ACR70, n/m <sup>†</sup> (%)	89/325 (27.4)	
SJC (0-76), mean % change from BL	-82.3	
TJC (0-78), mean % change from BL	-72.7	
MASES=0, n/m <sup>†</sup> (%)	136/218 (62.4)	
Dactylitis count=0, n/m <sup>†</sup> (%)	114/141 (80.9)	
cDAPSA (0-154) $\leq 13$ , n/m (%)	198/328 (60.4)	
HAQ-DI (0-3), mean change from BL	-0.42	
HAQ-DI MCID $\geq 0.35$ , n/m (%)	173/329 (52.6)	
PASI-50, n/m <sup>†</sup> (%)	98/149 (65.8)	
PASI-75, n/m <sup>†</sup> (%)	65/149 (43.6)	

Data as observed.  
\*The n reflects the number of subjects with data available at Week 260, regardless of when subjects started taking APR30 (BL, Week 16, or Week 24); actual number of subjects having data available for each end point may vary. †Denominators vary slightly due to availability of sufficient data for each level of ACR response assessment. ‡Examined among subjects with enthesitis at BL and having data at Week 260. §Examined among subjects with dactylitis at BL and having data at Week 260. ¶Examined among subjects with psoriasis involvement of the body surface area  $\geq 3\%$  at BL and data at Week 260. ACR20/50/70= $\geq 20\%/25\%/27\%$  improvement in American College of Rheumatology response criteria. n/m=number of responders/number of subjects with sufficient data for evaluation. SJC=swollen joint count. TJC=tender joint count. MASES=Maastricht Ankylosing Spondylitis Enthesitis Score. cDAPSA=Clinical Disease Activity in Psoriatic Arthritis. HAQ-DI=Health Assessment Questionnaire-Disability Index. MCID=minimal clinically important difference. PASI-50/75= $\geq 50\%/27\%$  reduction from BL Psoriasis Area and Severity Index score.

**Conclusions:** APR demonstrated sustained, clinically meaningful improvements in PsA signs and symptoms, physical function, and associated psoriasis in the population of subjects continuing treatment over 5 years. APR continued to demonstrate a favourable safety profile and was generally well tolerated at 5 years.

#### THU0295 FACTORS ASSOCIATED WITH PATIENT-PHYSICIAN DISCORDANCE IN A PROSPECTIVE COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS: AN ASIAN PERSPECTIVE

<sup>1</sup>C. Wang, Y.H. Kwan<sup>1,2</sup>, W. Fong<sup>1,2</sup>, S.Q. Xiong<sup>1</sup>, Y.Y. Leung<sup>1,2</sup>. <sup>1</sup>Rheumatology and Immunology, Singapore General Hospital, <sup>2</sup>Duke-NUS Medical School, Singapore, Singapore

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory articular disease with diverse clinical manifestations. Few biomarkers are available to assess disease activity in PsA. Hence, both the patient's and the physician's assessment of disease activity is vital in ensuring optimal treatment outcomes. Understanding factors associated with patient and physician discordance can facilitate shared decision making and treatment management between patient and physician. There is limited data on factors associated with patient and physician discordance in psoriatic arthritis; none of which exist in the Asian population.

**Objectives:** To identify the factors associated with patient-physician discordance in a multi-ethnic Asian cohort of Psoriatic arthritis (PsA) patients.

**Methods:** Data was obtained from a prospective cohort of consecutive patients with psoriatic arthritis, who fulfil the CASPAR criteria recruited from a single centre in Singapore. Sociodemographic, clinical data and patient reported outcomes

were collected using a standardised protocol at baseline, 4 months, 8 months, 1 year and 2 years. Patient-physician discordance was defined as patient global assessment minus physician global assessment (PGA - PhGA). We evaluated factors associated with patient-physician using generalised linear regression to control for within-subject effect.

**Results:** From 126 patients (50.4% male, 67.5% Chinese, age: 51 $\pm$ 13.8 years, duration of illness: 5.6 $\pm$ 6.1 years) recruited at baseline, paired data for patient and physician global assessments were available for 224 visits over a median follow up of 10 (range 0–15) months. In univariable analysis, gender, duration of illness, fatigue, pain score, number of tender joint/swollen joint/dactylitis, mental health subscale of SF36 and physical function by Health Assessment Questionnaire (HAQ) were significantly associated with patient-physician discordance. In multivariable analysis, higher level of fatigue, higher pain score, poorer mental health were associated with PGA-PhGA; while higher swollen joint and dactylitis count were negatively associated with PGA-PhGA (table 1).

**Abstract THU0295 – Table 1.** Multivariable analysis for factors associated with patient-physician discordance

Factors	$\beta$	95% Confidence Interval	p-value
Age	0.211	(-0.029, 0.452)	0.085
Gender	-3.687	(-8.830, 1.457)	0.160

#### THU0296 CLINICAL RESULTS OF PATIENTS WITH PERIPHERAL PSORIATIC ARTHRITIS NOT RECEIVING BIOLOGICAL THERAPY IN A MULTIDISCIPLINARY UNIT

<sup>1</sup>C.E. Pérez-Velásquez, M.L. García-Vivar<sup>1</sup>, S. Pérez-Barrio<sup>2</sup>, E. Galindez-Agirrekoia<sup>1</sup>, E. Ruiz-Lucea<sup>1</sup>, I. Torre-Salabern<sup>1</sup>, O. Fernandez-Berrizbeitia<sup>1</sup>, J. M. Blanco-Madrigal<sup>1</sup>, A.R. Intxaurre-Pellejero<sup>1</sup>, E. Guerrero-Basterretxea<sup>1</sup>, I. Calvo-Zorrilla<sup>1</sup>, O. Ibarquengoitia-Barrena<sup>1</sup>, D. Montero-Seisedos<sup>1</sup>, N. Rivera-García<sup>1</sup>, M.J. Allande<sup>1</sup>, I. Gorostiza-Hormaeche<sup>3</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Dermatology, <sup>3</sup>Research Unit, University Hospital of Basurto, Bilbao, Spain

**Background:** We consider multidisciplinary management necessary, especially in a subgroup of patients with Psoriatic Arthritis (PsA) for complexity, cutaneous and/or joint involvement. Despite the limited evidence of efficacy of methotrexate (MTX) and other classical synthetic DMARDs (csDMARDs) in these patients, they are commonly prescribed in our multidisciplinary unit (following the recommendations of experts, in peripheral PsA).

**Objectives:** To assess joint and cutaneous involvement in patients with peripheral psoriatic arthritis not receiving biologics in our multidisciplinary unit (visited for at least 6 months).

**Methods:** We review clinical the records of 199 PsA patients visited in our multidisciplinary unit and select 74 patients with the above mentioned criteria; we collect epidemiological and clinical data, and joint and skin activity evaluation by DAPSA, PASI, BSA and PGA (in plaque psoriasis) and proportion of patients that achieve MDA (minimum disease activity) as a therapeutic goal. Data were analysed using SPSSv23.

**Results:** 74 patients, 63.5% males, aged mean(SD) 54.8 (14.0) years. 56 peripheral PsA and 18 mixed (peripheral predominance); with mean 94.9 (92.4) months of disease; 35.1% with previous clinical enthesitis and 37.8% previous dactylitis. Cutaneous disease consisted mainly (82.4%) in plaque psoriasis, 9.5% affecting folds, 4.1% onychopathy. 52.7% have received a previous DMARD of (31.1% MTX, 9.5% leflunomide) and 23.0% PUVA; 4.1% have received previous biological treatment. Current treatment: 83.8% DMARDs (68.9% MTX and 5.4% leflunomide) with a mean follow-up of 60.6 (55.0) months.

**Disease activity:**

Skin plaque psoriasis was mainly controlled: 73.4% low PASI level (23.4% moderate) median PASI 3.0 [1.5–5.0]; 50.0% mild BSA, median BSA 3.0 [1.0–6.0]. 73.1% PGA of very mild or mild-moderate disease 87.0% of patients met DAPSA criteria of remission-low disease activity (DAPSA median 3.15 [1.34–6.71]; 55.9% achieved DAPSA<4); 75.7% were in low activity/remission according to medical judgement.

Overall 63.9% of patients achieved MDA.

15.3% (10 patients) had "relative contraindications" to biological therapy (6 cases of recent cancer, 2 HBV infection).

**Conclusions:** Over half of PsA patients from our multidisciplinary unit achieve low cutaneous and articular disease activity under csDMARDs, mainly Methotrexate. The use of targeted DMARDs such as apremilast in this scenario, before biological therapies, may improve disease outcomes in a subgroup of patients, corresponding with the efficacy shown in different domains of the psoriatic disease. Further research is needed to compare clinical results between csDMARDs and apremilast.

THU0297

#### EVALUATION OF CARDIOVASCULAR RISK FACTORS AMONG PATIENTS WITH PSORIASIS, PSORIATIC ARTHRITIS AND PERIPHERAL SPONDYLOARTHRITIS

M.R. Camacho-Sánchez<sup>1, 1,2</sup>, C. López-Medina, L. Bautista-Aguilar<sup>1,2</sup>, L. Ladehesa-Pineda<sup>1,2</sup>, L. Pérez-Sánchez<sup>1,2</sup>, I. Gómez-García<sup>1,2</sup>, A.J. Vélez García-Nieto<sup>1,3</sup>, E. Collantes-Estévez<sup>1,2</sup>, M.D. López-Montilla<sup>1,2</sup>. <sup>1</sup>Universidad de Córdoba; <sup>2</sup>Rheumatology; <sup>3</sup>Dermatology, Hospital Universitario Reina Sofía de Córdoba/IMBIC, Córdoba, Spain

**Background:** It is well known that the prevalence of Cardiovascular Risk Factors (CVRF) in patients with Psoriatic Arthritis (PsA) is higher than in the general population<sup>1</sup>. However, there is a lack of studies comparing PsA against Psoriasis without arthritis, and also against peripheral Spondyloarthritis (SpA).

**Objectives:** a) To compare the prevalence of CVRF among patients with PsA, Psoriasis without arthritis and peripheral SpA without Psoriasis; and b) to evaluate the association between CVRF and the presence of arthritis and/or Psoriasis.

**Methods:** A cross-sectional, observational and unicenter study in which clinical, analytical and demographic data from 300 patients were analysed. Patients were divided into four groups: PsA, Psoriasis without arthritis, peripheral SpA without Psoriasis and controls. Patients with PsA and peripheral SpA met CASPAR and peripheral ASAS criteria, respectively. Hypertension, Diabetes (T2DM) and Dyslipidemia were evaluated among the four groups by using the chi-square test. In order to evaluate whether CVRF could be explained by the presence of arthritis or Psoriasis, we divided patients (by excluding control groups) in arthritis/no arthritis and Psoriasis/no Psoriasis. Univariate and multivariate logistic regressions adjusted by sex and age were performed in order to determine variables independently associated with the presence of these three CVRF.

**Results:** Among the 300 patients included in the analysis, 89 (29.7%), 35 (11.7%) and 87 (29%) patients reported Hypertension, T2DM and Dyslipidemia, respectively. Regarding classification, 61 (20.3%) patients, 100 (33.3%), 100 (33.3%) and 39 (13.0%) patients were classified as control group, Peripheral SpA without Psoriasis, PsA and Psoriasis without arthritis, respectively. Patients from the control group showed significantly lower prevalence of Hypertension and Dyslipidemia against the other three groups (p<0.05); however, there were no differences between Peripheral SpA group, PsA and Psoriasis without arthritis regarding CVRF.

Patients with arthritis showed similar prevalence of CVRF than those without arthritis, as well as patients with Psoriasis vs. no Psoriasis.

Univariate analysis showed that Hypertension is significantly associated (p<0.05) to AINEs intake [OR 1.79 (95%CI 1.06–2.99)] as well as with disease duration [OR 1.02 (95%CI 1.01–1.05)]; however, the multivariate analysis adjusted by age and sex did not show significant differences. Regarding T2DM and dyslipidemia, the presence of arthritis or Psoriasis was not associated with the development of these comorbidities.

**Conclusions:** Our data suggest that the prevalence of CVRF among patients with Psoriasis, PsA and peripheral SpA are similar, although it is higher than in the general population. The presence of Hypertension in these patients is associated

with the use of NSAIDs; however, greater new studies would be necessary in order to determine specific associations.

#### PERITENON EXTENSOR TENDON INFLAMMATION, SYNOVITIS AND ENTHESOPATHY IN PSORIATIC ARTHRITIS: WHAT IS THE CONNEXION?

<sup>1</sup>C. Macía Villa, S. Falcao<sup>2</sup>, H.B. Hammer<sup>3</sup>, M. Gutierrez<sup>4</sup>, E. De Miguel<sup>5</sup>.

<sup>1</sup>Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain;

<sup>2</sup>Rheumatology, Chronic Diseases Study Center, NOVA Medical School, UNL, HEM. CHLO., Lisboa, Portugal; <sup>3</sup>Rheumatology, Diakonhjemmet Hospital, Oslo, Norway; <sup>4</sup>Division of Musculoskeletal and Rheumatic Disorders, Instituto Nacional de Rehabilitación, Mexico, Mexico; <sup>5</sup>Rheumatology, Hospital Universitario La Paz, Madrid, Spain

**Background:** Metacarpophalangeal joint (MCPJ) swelling in Psoriatic Arthritis (PsA) can be produced both by intra-articular synovitis (IAS) and peritenon extensor tendon inflammation (PTI). This last lesion has been reported as an enthesitis-like lesion.

**Objectives:** To evaluate if PTI is a synovitis or enthesitis related lesion using MASEI (Madrid Sonographic Enthesis Index) to analyse the existence of association with IAS and PTI.

**Methods:** 27 consecutive non selected PsA patients were included. An expert rheumatologist obtained the US images from the dorsal aspect of 2nd to 5th MCPJ of both hands evaluating IAS and PTI, and also performed the MASEI examination. In addition to the PD item of MASEI (defined as signal in bone profile or intra-tendon or bursa at the enthesitis), PD OMERACT was evaluated as present or absent (defined as signal in the enthesitis ≤2 mm to the bone profile). We used a MyLab 70 XVG machine, Esaote, Genova, Italy, with a greyscale (GS) 13 MHz probe and 7.1 MHz power Doppler (PD) frequency, PRF 750 Hz and 60 Gain. 3–5 s videos of each MCPJ and enthesitis were obtained in transverse and longitudinal views for further reliability analysis. Reliability of IAS and PTI was performed by 5 readers (true US result was the consensus of at least three) and MASEI's reliability was performed by 3 readers (true US result was the consensus of at least two). For reliability analysis, mean Cohen kappa was used for IAS and PTI, and intraclass correlation coefficient (ICC) for MASEI based on a mean-rating three readers, absolute-agreement, two-way mixed effect model. Statistical association between IAS, PTI and MASEI was analysed with T student test. SPSS statistical package version 20 (SPSS Inc, Chicago, IL) was used.

**Results:** Eighteen patients had PTI PD (66.7%), same for SIA PD. Inter-reader reliability for PTI and SIA was 0.685 and 0.680 kappa values respectively. Inter-reader reliability for MASEI was excellent ICC 0.922 (IC 95% 0.852–0.962), similar to PD MASEI ICC 0.921 (IC 95% 0.851–0.962) and PD OMERACT ICC 0.895 (IC 95% 0.802–0.949). Association data are shown in table 1.

**Abstract THU0298 – Table 1.** Association between IAS and PTI with MASEI and different PD subgroups.

	PTI		p value	IAS		p value
	Present	Absent		Present	Absent	
Mean MASEI±SD	32,44 ±15,62	27±9,33	0270	32±6,16	27,89 ±7,72	0380
Mean PD MASEI±SD	8±6	3,67 ±3,28	0023	6,83 ±6,15	6±4,5	0694
Mean PD OMERACT ±SD	1,61±1,33	0,56 ±1,01	0033	1,39 ±1,46	1±1	0426

**Conclusions:** In PsA, IAS at MCPJ didn't show any association with enthesitis. However, PTI showed a significant statistically association with active enthesitis (PD MASEI and PD OMERACT). This finding reinforces the idea that PTI at MCPJ level is related with the swelling of the functional enthesitis related to the retinaculum pulley structure.

THU0299

**AN INTEGRATED ANALYSIS OF CHANGES IN LIPID LEVELS AND INCIDENCE OF CARDIOVASCULAR EVENTS FOLLOWING TOFACITINIB TREATMENT IN PATIENTS WITH PSORIATIC ARTHRITIS ACROSS PHASE 3 AND LONG-TERM EXTENSION STUDIES**

<sup>1</sup>D.D. Gladman, C. Charles-Schoeman<sup>2</sup>, I.B. McInnes<sup>3</sup>, D.J. Veale<sup>4</sup>, B. Thiers<sup>5</sup>, D. Graham<sup>6</sup>, C. Wang<sup>6</sup>, T.V. Jones<sup>7</sup>, R. Wolk<sup>6</sup>, R. DeMasi<sup>7</sup>. <sup>1</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada; <sup>2</sup>University of California, Los Angeles, CA, USA; <sup>3</sup>University of Glasgow, Glasgow, UK; <sup>4</sup>St. Vincent's University Hospital and University College Dublin, Dublin, Ireland; <sup>5</sup>Medical University of South Carolina, Charleston, SC; <sup>6</sup>Pfizer Inc, Groton, CT; <sup>7</sup>Pfizer Inc, Collegeville, PA, USA

**Background:** Cardiovascular (CV) disease and cardiometabolic syndrome are common comorbidities/causes of mortality in patients (pts) with psoriatic arthritis (PsA). Tofacitinib is an oral JAK inhibitor for the treatment of PsA.

**Objectives:** To investigate changes in lipid levels and incidence of CV events in pts with PsA treated with tofacitinib in Phase (P) 3 and long-term extension (LTE) studies.

**Methods:** Data were analysed for pts who received  $\geq 1$  dose of tofacitinib 5 or 10 mg BID or placebo (PBO), integrated across 2 P3 studies (OPAL Broaden [12 months (m); NCT01877668, including adalimumab control]; OPAL Beyond [6 m; NCT01882439]) and 1 LTE study (OPAL Balance [data cut-off May 2016; ongoing, database not locked; NCT01976364]). Lipid levels were assessed throughout P3 and LTE studies; this analysis included data from the PBO-controlled period (M0–3) of P3 studies. Blood pressure, hypertension events (standardised MedDRA query [narrow]) and adjudicated (independent/blinded to treatment) major adverse cardiovascular events (MACE) are reported for all pts who received  $\geq 1$  dose of tofacitinib (pooled across doses for hypertension and MACE). Incidence rates (IR; pts with events/100 pt-years [PY]) and 95% CI are reported.

**Results:** Overall, 783 pts (776 PY of tofacitinib exposure) were included in P3 and LTE studies; treatment duration was 1–927 days. After 3 m of tofacitinib treatment in P3 studies, dose-dependent increases in lipid levels were observed with tofacitinib; minimal changes were observed with PBO, except for triglycerides (figure 1). Concurrent increases in high-density and low-density lipoprotein (HDL/LDL) and no change in the total cholesterol/HDL ratio were shown. Across P3 and LTE studies, no clinically significant changes in mean systolic or diastolic blood pressure were seen to 24 m. Hypertension events were reported in 38 (4.9%) pts: IR 4.93 [95% CI 3.49, 6.77]. Of these events, 4 led to pt discontinuation and 2 were serious adverse events. MACE were reported for 3 (0.4%) pts receiving tofacitinib (IR 0.38 [95% CI 0.08, 1.11]) and included sudden cardiac death (57 days of exposure at time of event), myocardial infarction (197 days) and ischaemic stroke (80 days). This is within the range reported in tofacitinib studies in pts with psoriasis (IR 0.24 [0.15, 0.37]; 8,759 PY of exposure) and rheumatoid arthritis (RA) (IR 0.38 [0.30, 0.47]; 21,286 PY of exposure). No dose-dependent effects on blood pressure were apparent.

**Figure.** Mean % change from baseline in lipid levels to Month 3 integrated across Phase 3 studies

BID, twice daily; SE, standard error

**Abstract THU0299 – Figure 1.** Mean% change from baseline in lipid levels to Month 3 integrated across Phase 3 studies. BID, twice daily; SE, standard error

**Conclusions:** In pts with PsA, the magnitude and dose dependency of increases in lipid levels to M3 were consistent with findings in tofacitinib studies in pts with psoriasis and RA. In P3 and LTE studies, no clinically significant changes were seen in blood pressure or incidence of hypertension. Incidence of MACE was within the range reported in prior tofacitinib studies in psoriasis and RA; however, the long latency of MACE requires longer-term observation.

**NETWORK META-ANALYSIS OF TOFACITINIB VS bDMARDS OR APREMILAST FOR THE TREATMENT OF TNF INHIBITOR-NAIVE PATIENTS WITH PSORIATIC ARTHRITIS**

<sup>1</sup>D.D. Gladman, A.-M. Orba<sup>2</sup>, J. Gomez-Reino<sup>3</sup>, S. Chang-Douglas<sup>4</sup>, E. Leoncini<sup>4</sup>, H.E. Burton<sup>4</sup>, K.S. Kanik<sup>5</sup>, T. Hendriks<sup>6</sup>, J.C. Cappellen<sup>5</sup>, M.-A. Hsu<sup>5</sup>. <sup>1</sup>University of Toronto, Toronto Western Hospital, Toronto, ON, Canada; <sup>2</sup>Johns Hopkins University School of Medicine, Baltimore, MD, USA; <sup>3</sup>Hospital Clinico Universitario, Santiago de Compostela, Spain; <sup>4</sup>Decision Resources Group, London, UK; <sup>5</sup>Pfizer Inc, Groton, CT; <sup>6</sup>Pfizer Inc, Collegeville, PA, USA

**Background:** Tofacitinib is an oral JAK inhibitor for the treatment of psoriatic arthritis (PsA).

**Objectives:** To perform a systematic literature review (SLR) and network meta-analysis (NMA) to evaluate the efficacy of tofacitinib 5 and 10 mg BID relative to biologic disease-modifying antirheumatic drugs (bDMARDs) or a targeted synthetic DMARD (apremilast [APR]) in tumour necrosis factor inhibitor-naïve (TNFi-N) patients with active PsA.

**Methods:** The SLR identified randomised controlled clinical trials (RCTs) evaluating tofacitinib, bDMARDs or APR to treat patients with active PsA who were TNFi-N. Outcomes included American College of Rheumatology (ACR)20 response and change from baseline in Health Assessment Questionnaire-Disability Index ( $\Delta$ HAQ-DI), Dactylitis Severity Score ( $\Delta$ DSS) and Leeds Enthesitis Index ( $\Delta$ LEI). Treatment effects were only evaluated during placebo (PBO)-controlled trial phases. The Bayesian NMA (with non-informative priors) was conducted using WinBUGS. The binomial logit model was used for ACR20.  $\Delta$ HAQ-DI,  $\Delta$ DSS and  $\Delta$ LEI were analysed using the normal identify link model. A fixed-effect model was fitted to the data. Median treatment rankings represent data from each iteration of the model from which inferences are based, following model convergence.

**Results:** The SLR identified 25 RCTs and 21 were included in the NMA (see treatments in table 1). All trials allowed methotrexate use. PBO-controlled treatment durations ranged from 12–24 weeks. In general, patient characteristics were similar across trials. All treatments were associated with improvements in ACR20 and  $\Delta$ HAQ-DI vs PBO. Tofacitinib 5 mg BID was associated with substantially decreased odds ratios (ORs) for ACR20 vs golimumab 50 and 100 mg Q4W, etanercept 25 mg BW, infliximab 5 mg/kg and secukinumab 150 mg QW-Q4W (table 1); ORs for all remaining comparators were not substantially different. Tofacitinib 10 mg BID was associated with a substantially increased OR for ACR20 vs APR 20 mg BID. Etanercept was associated with an improvement in  $\Delta$ HAQ-DI vs tofacitinib 5 and 10 mg BID. There was no difference in  $\Delta$ HAQ-DI for tofacitinib vs other bDMARDs. For ACR20, tofacitinib 5 and 10 mg BID were median ranked 14 (95% credible interval: 8, 17) and 9,<sup>5, 14</sup> respectively, among 18 comparators. For  $\Delta$ HAQ-DI, tofacitinib 5 and 10 mg BID were median ranked 11,<sup>4, 13</sup> and 8,<sup>2, 13</sup> respectively, among 14 comparators. Two studies evaluated  $\Delta$ DSS and  $\Delta$ LEI; there were no substantial differences in  $\Delta$ DSS and  $\Delta$ LEI for tofacitinib 5 and 10 mg BID vs adalimumab 40 mg Q2W and ixekizumab 80 mg Q2W and Q4W.

**Abstract THU0300 – Table 1.** Fixed-effect NMA data for ACR20 and ΔHAQ-DI in TNFi-N patients with PsA – comparison of bDMARDs or apremilast vs tofacitinib 5 and 10 mg BID<sup>a</sup>

**THU0301 A NOVEL ROLE FOR THE PSORIATIC ARTHRITIS IMPACT OF DISEASE QUESTIONNAIRE (PSAID)**

K. Johnson, J. Ye, V. Chandran, D. Gladman. *Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, Canada*

**Background:** Psoriatic arthritis (PsA) is an inflammatory arthritis that occurs in about 30% of patients with Psoriasis (Ps). Recently, a new Patient Reported Outcome Measure (PROM), Psoriatic Arthritis Impact of Disease (PsAID) was specifically developed for PsA Patients. The two versions of the PsAID, PsAID-9 and PsAID-12, are scored on a Numeric Rating Scale (NRS) of 0–10. The Minimal Disease Activity (MDA) is a composite outcome measure for PsA patients, which uses the Health Assessment Questionnaire (HAQ) as one criterion. However, the HAQ does not correlate well with measures of disease activity as PsA disease duration increases, and its use in the assessment of disease activity has been questioned.

**Objectives:** Our objectives were to 1) validate the PsAID within our patient cohort, 2) determine if the PsAID can replace any of the other PROMs administered in the clinic, and 3) determine if the PsAID can replace the HAQ in the MDA.

**Methods:** Patients were recruited from a large psoriatic arthritis clinic. All patients completed the PsAID and 10 other PROMs. Various measures of disease activity were recorded by a physician at each visit. Descriptive statistics (mean, median, SD, min, max) were calculated for all PROMs. PsAID cut-offs for use in the MDA were generated based on Remission (REM) and Low Disease Activity (LDA) disease states in the Clinical Disease Activity for Psoriatic Arthritis Index (cdAPSA).

**Results:** 115 patients completed the PsAID. There were 70 males, 45 females, with a mean PsA duration of 18.7 (±11.6) years. Mean scores of PsAID-9 and PsAID-12 were 3.4 (±2.4) and 3.2 (±2.3) respectively. The PsAID correlated moderately well with 9 of the PROMs administered in the clinic (R<sup>2</sup>=0.51–0.78). Four

PsAID cutoffs were generated for use in the MDA: REM PsAID-9, REM PsAID-12, LDA PsAID-9, and LDA PsAID-12. All four versions of the PsAID MDAs had a sensitivity greater than 85% with the HAQ MDA, and three versions of the PsAID MDA had a specificity greater than 85% with the HAQ MDA.

**Conclusions:** Our cohort had lower mean PsAID scores than previously reported series suggesting that our patients are monitored carefully. The only moderate correlations with other PROMs suggest that the PsAID cannot replace any of these PROMs. The high sensitivity and specificity of the PsAID MDA with the HAQ MDA suggest that the PsAID is an effective replacement for the HAQ in the MDA.

**THU0302 SURVIVAL OF DISEASE-MODIFYING DRUGS (DMARD) IN PATIENTS WITH RECENT DIAGNOSIS OF PSORIATIC ARTHRITIS IN DAILY CLINICAL PRACTICE**

<sup>1,2,3</sup>D. Freitas Nuñez, L. León<sup>2</sup>, Z. Rosales<sup>1,2</sup>, J. Font<sup>1</sup>, C. Lajas<sup>1</sup>, E. Pato<sup>1</sup>, L. Rodríguez<sup>1,2</sup>, B. Fernández<sup>1</sup>, J.-A. Jover<sup>1</sup>, L. Abasolo<sup>1,2</sup>. <sup>1</sup>Rheumatology, Hospital Clínico San Carlos; <sup>2</sup>Fundación para la Investigación Biomedica; <sup>3</sup>Complutense University, Madrid, Spain

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disease that benefits from DMARDs, in this regard knowing more about these therapies is a great step forward in the management of these patients in daily clinical practice.

**Objectives:** To evaluate the survival of DMARDs used in recent diagnose PsA patients as well as the causes of discontinuation and to analyse the possible associated factors.

**Methods:** Retrospective longitudinal observational study. **Subjects:** Inception cohort of patients from January 2010 to , December 2014 and followed up to December 2016, diagnosed with PsA according to ICD-10 code. **Main outcome:** discontinuation of conventional synthetic DMARDs (csDMARDs) and biological originator DMARDs (boDMARDs) due to: Adverse drug reactions (ADRs); Improvement or remission; Inefficacy; Patient's decision and Physician's decision. **Covariables:** sociodemographic and clinical. **Statistical analysis:** To estimate DMARDs discontinuation rates, survival techniques were used, expressing the incidence rate (IR) per 100 patients\*year with their respective CI at 95%. Multivariate Cox regression models were performed to analyse the factors associated with DMARDs discontinuation and the results were expressed in Hazard ratio (HR) and 95% CI.

**Results:** 191 patients with recent diagnosis of PsA were included, with a 379.70 Patients\*year follow-up. 50.3% were male, the mean age at diagnosis was 50 ±14.6 years old. 46.6% of the patients had a history of cutaneous psoriasis. The HLA-B27 was positive in 20% of patients. 50% of the patients started a DMARDs at the first visit. Throughout the follow-up, all patients received csDMARDs and 23 used boDMARDs. The median DMARD per patient was 2<sup>1-3</sup>. Methotrexate (MTX) was the most used drug 69.7%. According to the treatment regimen, 30% were on combination therapy, the most frequent was antiTNF +MTX (33%). 103 discontinuations were recorded with a IR 27.13 [22.36–32.90] within these, 44 were related with ADRs (IR 11.59 [8.62–15.57]), 24 (IR 6.32 [3.58–11.13]) were due to inefficiency, 9 (IR 2.37 [1.23–4.55]) were registered after remission, 12 (IR 3.16 [1.79–5.56]) by decision of the patient and 12 (IR 3.16 [1.79–5.56]) by doctor's decision. The DMARDs median survival was 1.8 years [1.4–2.7]. Table 1 shows the discontinuation rates for each type of DMARDs and the multivariate analysis for the factors associated with DMARDs discontinuation is in table 2.

**Table 1:**

Table 1	Patients*year	Events(n)	IR	95%CI
MTX orally	243.46	53	21.77	16.63–28.49
Sc MTX	49.90	18	36.07	22.73–57.25
Salazopyrine	84.80	30	35.37	24.73–50.59
Leflunomide	21.83	10	45.80	24.64–85.13
Antimalarials	25.34	8	31.56	15.78–63.12
boDMARDs	57.56	25	43.43	29.35–64.28

Table 2	HR	95% CI	P
Women	1.51	0.61–3.09	0.436
Age at diagnosis	0.97	0.97–1.01	0.267
Distress level	1.87	1.00–3.48	0.049
C Reactive protein≥1.05gr/dL	1.85	0.99–3.48	0.055
Combination therapy	2.36	1.46–3.80	0.000
boDMARDs	1.05	0.52–2.11	0.886
MTX vs rest DMARDs	0.53	0.31–0.91	0.021

**Conclusions:** In our study, the DMARD discontinuation rate was 27.13, mainly related with ADRs. We have also found some psychological, clinical and therapy regimen factors that can modify the DMARDs survival on PsA. We observed that MTX, presented the longest survival independent of the rest of the factors.

### THE EARLY PSORIATIC ARTHRITIS SCREENING QUESTIONNAIRE IDENTIFIES PATIENTS WITH PSORIATIC ARTHRITIS AMONGST TREATED PATIENTS WITH PSORIASIS

K. Nadeau<sup>1</sup>, F. Briggs<sup>2,3</sup>, S. O'Neill<sup>2,3</sup>, D. Sumpton<sup>2,3</sup>, G. Cains<sup>4</sup>, J. Woods<sup>4</sup>,  
<sup>2,3</sup>D. Chessman. <sup>1</sup>Université Laval, CHU de Québec, Québec, Canada;  
<sup>2</sup>Department of Rheumatology, Liverpool Hospital; <sup>3</sup>Ingham Research Institute,  
The University of New South UK; <sup>4</sup>Department of Dermatology, Liverpool Hospital,  
Sydney, Australia

**Background:** Studies suggest a high prevalence (approximately 15%) of undetected psoriatic arthritis (PsA) amongst patients with psoriasis<sup>1</sup>. A number of screening questionnaires have been designed to allow detection of such patients. This includes the Early Psoriatic Arthritis Screening Questionnaire (EARP) which detects early PsA in untreated patients with psoriasis, with a sensitivity of 85.2% and specificity of 91.6%<sup>2</sup>. Little is known about whether such questionnaires are also able to detect PsA in treated patients with psoriasis.

**Objectives:** To determine the case finding ability of EARP in a tertiary centre cohort of treated psoriasis patients.

**Methods:** All patients attending a tertiary centre psoriasis clinic were invited to complete the EARP. EARP comprises a 10 point patient reported questionnaire regarding symptoms of joint disease. Scores of 3 or more are considered positive. All patients who completed the questionnaire and received a positive score were assessed by a rheumatologist. Diagnosis of PsA was made by clinician impression and CASPAR criteria. Disease activity was assessed using psoriasis area severity index (PASI), 66/68 swollen and tender joint count, SPARCC enthesitis index, CRP and Health associated quality of life disability index (HAQ-DI). The composite disease activity measure DAPSA and the OMERACT definition of minimal disease activity were determined.

**Results:** 133 patients were invited to complete the EARP questionnaire and 119 participated. Fifty patients had a positive result (42%). Of these, 8 were known to have PsA and under rheumatologic care. A further 21 attended for formal rheumatologic assessment. Thirteen of the 21 patients (61.9%) were found to have psoriatic arthritis and were not under the care of a rheumatologist. This represents 10% of the initial 133 patients screened. Ten of those patients were further assessed. The average age was 52.8 and BMI 33.2. Seven patients were male. All 10 were on biologic agents but only 3 on concurrent conventional DMARDs. Average tender joint count was 16, swollen joint count 3.6, SPARCC 6.2 and PASI score 3.42. Only 1 patient was in minimal disease activity.

**Conclusions:** The EARP tool can identify patients with active PsA amongst patients with psoriasis, even those on treatment with biologic agents. Such a tool may be useful in identifying patients who may benefit from rheumatology care.

### ASSOCIATION OF ANXIETY, DEPRESSION AND FATIGUE WITH DISEASE ACTIVITY, JOINTS EROSION AND SKIN LESION SEVERITY IN EARLY PSORIATIC ARTHRITIS PATIENTS

E.E. Gubar, E.Y. Loginova, A.D. Koltakova, S.I. Glukhova, T.V. Korotaeva. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Depression is one of the precursors of psoriasis and psoriatic arthritis (PsA) development. It was found that depression and anxiety negatively affect the achievement of remission in PsA. B. Michelsen 2017] Interrelation of anxiety, depression and fatigue (according to patient-reported outcomes) with disease activity, erosive arthritis and skin lesion severity in early PsA hadn't been sufficiently studied.

**Objectives:** To study anxiety, depression and fatigue disorders (according to patient-reported outcomes) and their correlation with disease activity, erosive arthritis and severity of psoriasis in early PsA patients (pts).

**Methods:** 78 pts (M/F=39/39) with early PsA according to CASPAR criteria were included; all pts had peripheral arthritis for  $\leq 2$  years; mean age 36.5 $\pm$ 10.7 years, disease duration 12.2 $\pm$ 10.3 mo. It was a treatment naïve cohort. All pts underwent

standard clinical examination of PsA activity. Mean disease activity indexes (DAS)=4.0 $\pm$ 1.4, DAS28=4.2 $\pm$ 1.1. 78 patients were studied for fatigue (according to FACIT), patient global disease activity (PGA), patients pain measured by VAS, and Health Assessment Questionnaire (HAQ); 66 patients (M/F=33/33) were studied for anxiety and depression (according to HADS). At HADS score  $\geq 8$  patients had anxiety and depression disorders. Higher scores for FACIT scales indicate better quality of life (less fatigue). Skin lesion severity was evaluated in terms of body surface area (BSA) affected and Psoriasis Area Severity Index (PASI). When BSA was  $\geq 3\%$ , PASI was calculated. PASI $\geq 11$  indicates moderate and severe psoriasis. Descriptive statistics was used, M $\pm$ SD, Me [Q25;Q75], U-test were performed; p<0.05 was considered to indicate statistical significance.

**Results:** Mean FACIT score was low amounting to 35.3 $\pm$ 9.6, testifying increased fatigue; mean anxiety index was 5.7 $\pm$ 3.1, depression index was 3.8 $\pm$ 3.0. Anxiety disorders were detected in 16 out of 66 (24.2%) pts, depression disorders in 9 out of 66 (13.0%) pts. Negative correlation was found between FACIT score and DAS (r=-0.26), DAS28 (r=-0.26), CRP (r=-0.27), PGA (r=-0.35); and pain VAS (r=-0.25). Depression was more pronounced in pts with erosive arthritis in hands and/or feet (r=0.31). Negative correlation of FACIT score (r=-0.54), correlation of anxiety (r=0.26) and depression (r=0.33) indexes was found with health-related functional indexes according to HAQ. HADS indexes (anxiety and depression) are cross-correlating (r=0.51) and are negatively correlating with FACIT scores (r=-0.49 and r=-0.48, accordingly). An association was found of anxiety and depression indexes with the severity of psoriasis PASI index (r=0.38 and r=0.31, accordingly).

**Conclusions:** In early treatment-naïve PsA patients, increased fatigue and in a quarter of cases anxiety disorders, in 13% of patients depression disorders had been found. Psychological disorders are associated with PsA activity, the severity of psoriasis and joints erosion. Fatigue, anxiety and depression in early PsA patients result in the reduction of their functional capacity.

### MINIMAL DISEASE ACTIVITY (MDA) ATTAINMENT AFTER STARTING BIOLOGICAL (B) DMARDs AND NON-BDMARDs TREATMENT IN PSORIATIC ARTHRITIS PATIENTS (PTS) IN ROUTINE CARE: RUSSIAN PSORIATIC ARTHRITIS REGISTRY (RU-PSART) DATA

<sup>1</sup>E. Loginova, T. Korotaeva<sup>1</sup>, A. Koltakova<sup>1</sup>, E. Gubar<sup>1</sup>, Y. Korsakova<sup>1</sup>, E. Nasonov<sup>1</sup>, A. Lila<sup>1</sup>, M. Sedunova<sup>2</sup>, T. Salnikova<sup>3</sup>, I. Umnova<sup>4</sup>, I. Bondareva<sup>5</sup>, U. Zagidulina<sup>6</sup>, P. Zemtsova<sup>7</sup> on behalf of the RU-PsART study group. <sup>1</sup>Nasonova Research Institute of Rheumatology, Moscow; <sup>2</sup>St. Petersburg Clinical Rheumatology Hospital No.25, St. Petersburg; <sup>3</sup>Tula Regional Hospital, Tula; <sup>4</sup>Omsk Regional Hospital, Omsk; <sup>5</sup>Kemerovo Regional Hospital, Kemerovo; <sup>6</sup>Kazan City Hospital No.7, Kazan; <sup>7</sup>Nizhny Novgorod Regional Clinical Hospital n. a. Semashko, Nizhny Novgorod, Russian Federation

**Background:** MDA is a valid instrument for evaluating PsA treatment results. There is limited data about MDA attainment after starting bDMARDs and non-bDMARDs in routine care. RU-PsART collected data from 25 rheumatology clinics in the Russian Federation.

**Objectives:** evaluate MDA attainment after starting bDMARDs and non-bDMARDs treatment in PsA pts in routine care.

**Methods:** 294 (M/F=133/161) pts with PsA, diagnosed according to CASPAR criteria, mean age 41.2 $\pm$ 1.9 (Min 21 – Max 72) years (yrs.), PsA duration 6.1 $\pm$ 5.3 (Min 0 – Max 31) yrs., psoriasis duration 13.6 $\pm$ 10.7 (Min 0.2 – Max 54.8) yrs. were included in the RU-PsART after signing consent participation forms. The present analysis included 274 pts who have data concerning PsA activity, treatment and MDA. The number of pts who reached MDA at least once were calculated. At the time of evaluation 81 out of 274 pts (29.6%) were taking bDMARDs $\pm$ sDMARDs (Infliximab (25 pts), Etanercept (16 pts), Adalimumab (14pts), Ustekinumab (8pts), Golimumab (5pts), Sekukinumab (2pts)). 193 out of 274 pts (70.4%) were taking other types of treatment - sDMARDs $\pm$ NSAID, mostly methotrexate (74.2%), sulfasalazine (12%), leflunomide (3.6%), hydroxychloroquine (0.4%); steroids (9.8%). All pts underwent evaluation of PsA activity by DAS28, CRP, Pt/Physician GA, Pain GA by VAS (0–100 mm), swollen/tender joints count (SJC/TJC), DAPSA and considered REM $\leq 4$ /LDA $\leq 14$ . M $\pm$ SD, Me [Q25; Q75], Min-Max, %, U-test, ORs with 95% CI were performed. All CI >1, p $\leq$ 0.05 were considered to indicate statistical significance.

**Results:** At time of evaluation 60 out of 274 pts (21%) reached MDA at least once. Mean duration of sDMARDs and bDMARDs $\pm$ sDMARDs was 11<sup>6/17</sup>/Min 3 - Max 204 months and 9<sup>15</sup>/Min 2 - Max 82 months accordingly. 28 out of 193 pts (10.4%) taking sDMARDs achieved MDA. Among 81 pts taking bDMARDs  $\pm$ sDMARDs MDA was seen in significantly more cases - 32 pts (30.8%), OR=3.85 [CI 95% 2.11–7.01]. REM/LDA by DAPSA was found in significantly more cases compared to pts taking other therapies - in 50 out of 81 pts (61.7%) and in 56 out of 193 pts (29%) accordingly (p $\leq$ 0.05, U-test). Pts who had ever

taken bDMARDs±sDMARDs had significantly less PsA activity compared to those who had taken other types of treatment (table 1).

Abstract THU0305 – Table 1

Parameters	bDMARDs	other therapy
DAS28	1.8 [1.8;4.2]*	3.4 [2.8;5.1]
CRP	1.3 [0.9;7.9]*	6 [2.5;17.8]
Pain, VAS	20 [13;50]*	30 [30;60]
PGA, VAS	30 [17;60]*	40 [30;60]
PhGA, VAS	30 [10;50]*	38 [30;60]
SJC	1 [0;5]*	1 [0;8]
TJC	1 [0;2]*	1 [0;6]

\* p<0.05, U-test

**Conclusions:** MDA was seen in 21% of PsA pts in routine care but starting bDMARDs has a significantly higher probability of reaching MDA in most cases despite duration of treatment.

### CLINICAL SPECIALTY SETTING AS A DETERMINANT FOR DISEASE MANAGEMENT IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM LOOP, A CROSS-SECTIONAL, MULTI-COUNTRY, OBSERVATIONAL STUDY

W.-H. Boehncke<sup>1</sup>, R. Horváth<sup>2</sup>, E. Dalkılıç<sup>3</sup>, S.A.L. Lima<sup>4</sup>, M. Okada<sup>5</sup>, M. Hojnik<sup>6</sup>, F. Ganz<sup>7</sup>, <sup>8</sup>E. Lubrano. <sup>1</sup>Geneva Univ. Hospitals and Univ. of Geneva, Geneva, Switzerland; <sup>2</sup>Univ. Hospital Motol, Prague, Czech Republic; <sup>3</sup>Uludağ Univ. Sch. of Med., Gorukle, Bursa, Turkey; <sup>4</sup>ABC Med. Sch., Santo André, Brazil; <sup>5</sup>St. Luke's International Hospital, Tokyo, Japan; <sup>6</sup>AbbVie, Ljubljana, Slovenia; <sup>7</sup>AbbVie AG, Baar, Switzerland; <sup>8</sup>Univ. of Molise, Campobasso, Italy

**Background:** Evidence suggests that timely and effective management can improve long-term outcomes in patients (pts) with psoriatic arthritis (PsA); however factors influencing treatment management decisions are not well understood.

**Objectives:** To evaluate the association between the clinical specialty setting and time from inflammatory musculoskeletal symptom onset to PsA diagnosis and to different management steps in pts with a diagnosis of PsA.

**Methods:** LOOP is a large cross-sectional, multi-centre, observational study conducted in 17 countries across Western and Eastern Europe, Latin America, and Asia. Adult pts (≥18 years) with a suspected or an established diagnosis of PsA routinely visiting a rheumatologist (rheum), dermatologist (derm) or non-rheum/non-derm site were eligible to participate in this study. Each enrolled patient in the study was assessed by both rheum and derm. Main endpoints assessed were time from inflammatory musculoskeletal symptom onset to PsA diagnosis, time from PsA diagnosis to first csDMARD and to first bDMARD, and time from first csDMARD to first bDMARD.

**Results:** Of the 1483 pts enrolled in this study, 1273 pts with a confirmed diagnosis of PsA were included in this analysis. A majority of pts were recruited by rheums (671, 52.7%), followed by derms (541, 42.5%), physiatrists (36, 2.8%), and other specialties (25, 2.0%). PsA was first suspected by a rheum in 726 (57.0%) pts and by a derm in 541 pts (42.5%). Pt demographics and disease characteristics were mostly comparable between rheum and derm settings. Current disease activity and disease burden of patients with PsA categorised by clinical specialty are shown in **table 1**. Disease activity was higher in PsA pts in derm setting compared with rheum setting. The timing of different disease management steps by clinical specialty is reported in **table 2**. The mean time from symptom onset to PsA diagnosis was 24 months (mo) in rheum setting and 1 mo longer for derms. In rheum and derm settings, the mean time from PsA diagnosis to first csDMARD were 11 and 25 mo, respectively; whereas the mean time to first bDMARD were 52 and 55 mo, respectively. The mean time from first csDMARD to first bDMARD was 42 mo for rheums; while it was 3 months shorter for derms.

Abstract THU0306 – Table 1. Baseline Characteristics and Current Disease Activity and Disease Burden by Clinical Specialty in Patients with PsA from LOOP Study

Characteristic/Measure <sup>a</sup>	Rheum (N=726)	Derm (N=541)	P-value <sup>b</sup>
Age, years	51.1 (12.9)	50.7 (13.1)	.645
Gender, male, n (%)	375 (51.7)	270 (49.9)	.570
Weight, kg	77.3 (16.4)	77.7 (17.1)	.708
BMI, kg/m <sup>2</sup>	27.4 (5.5) <sup>c</sup>	27.4 (5.3)	.902
TJC66	6.0 (10.1) <sup>d</sup>	8.5 (12.6) <sup>e</sup>	<.001
SJC66	2.2 (4.3) <sup>f</sup>	3.2 (6.2) <sup>g</sup>	.001
Dactylitis count	0.4 (1.3) <sup>h</sup>	0.8 (2.6) <sup>i</sup>	<.001
Tender enthesal points	0.8 (1.7) <sup>j</sup>	1.5 (2.6) <sup>k</sup>	<.001
DAPSA	18.4 (24.0)	23.9 (30.9) <sup>l</sup>	.017

MDA, n (%)	309 (46.7) <sup>o</sup>	186 (39.2) <sup>p</sup>	.012
PGA	3.3 (2.6) <sup>q</sup>	4.4 (2.7) <sup>r</sup>	<.001
BSA (%)	6.6 (11.3) <sup>s</sup>	13.1 (19.7) <sup>t</sup>	<.001
Psoriatic nail count	4.0 (5.5) <sup>u</sup>	5.3 (6.3) <sup>v</sup>	<.001
HAQ-DI	0.7 (0.7) <sup>w</sup>	0.7 (0.7) <sup>x</sup>	.783
SF12-PCS	43.0 (10.6) <sup>y</sup>	42.6 (10.1) <sup>z</sup>	.544
SF12v2-MCS	44.9 (10.5) <sup>aa</sup>	44.6 (12.1) <sup>ab</sup>	.803
WPAI-PsA-TWPI (%)	30.1 (30.9) <sup>ac</sup>	29.5 (31.7) <sup>ad</sup>	.824
WPAI-PsA-TAI (%)	25.0 (29.8) <sup>ae</sup>	26.5 (31.4) <sup>af</sup>	.017
DLQI	5.3 (6.2) <sup>ag</sup>	7.6 (7.2) <sup>ah</sup>	<.001

<sup>a</sup>P-value from simple linear regression: Rheumatologist vs Dermatologist. All data are presented as mean (SD) unless otherwise specified. <sup>b</sup>WPAI-PsA-TWPI = work productivity and activity impairment questionnaire. <sup>c</sup>WPAI-PsA-TAI = total activity impairment. <sup>d</sup>TJC66 = tender joint count, 66 joints. <sup>e</sup>SJC66 = swollen joint count, 66 joints. <sup>f</sup>TJC = total active joint count. <sup>g</sup>SJC = swollen joint count. <sup>h</sup>HAQ-DI = health assessment questionnaire – disability index. <sup>i</sup>MCS = mental component score. <sup>j</sup>MDA = minimal disease activity. <sup>k</sup>PCS = physical component score. <sup>l</sup>PGA = physician global assessment. <sup>m</sup>PsA = psoriatic arthritis. <sup>n</sup>Rheum = rheumatologist. <sup>o</sup>SF12v2 = Short form 12-item health survey version 2. <sup>p</sup>SD = standard deviation. <sup>q</sup>SJC66 = swollen joint count, 66 joints. <sup>r</sup>TAI = total activity impairment. <sup>s</sup>TJC66 = tender joint count, 66 joints. <sup>t</sup>TWPI = total work productivity impairment. <sup>u</sup>WPAI-PsA = Work productivity and activity impairment questionnaire. <sup>v</sup>PsA = psoriatic arthritis. <sup>w</sup>Rheum = rheumatologist. <sup>x</sup>SD = standard deviation.

Abstract THU0306 – Table 2. Timing of Disease Management Steps by Clinical Specialty in Patients with PsA from LOOP Study

Duration in months, Mean (SD)	Rheum	Derm	P-value <sup>a</sup>
Time from inflammatory musculoskeletal symptom onset to PsA diagnosis <sup>b</sup>	23.6 (70.7)	24.9 (72.1)	.747
Time from PsA diagnosis to first csDMARD <sup>c</sup>	10.7 (59.4)	25.2 (33.9)	.004
Time from PsA diagnosis to first bDMARD <sup>d</sup>	52.3 (81.0)	54.7 (91.0)	.715
Time from first csDMARD to first bDMARD <sup>e</sup>	42.4 (82.7)	39.1 (83.5)	.556

<sup>a</sup>P-value from simple linear regression: Rheumatologist vs Dermatologist. <sup>b</sup>Rheum, N=631; Derm, N=527. <sup>c</sup>Rheum, N=428; Derm, N=264. <sup>d</sup>Rheum, N=372; Derm, N=178. <sup>e</sup>csDMARD = biologic disease modifying antirheumatic drug; csDMARD = nonbiologic synthetic disease modifying antirheumatic drug; Derm = dermatologist; PsA = psoriatic arthritis; Rheum = rheumatologist; SD = standard deviation.

**Conclusions:** Although the duration from symptom onset to PsA diagnosis was similar between rheum and derm setting, there were differences in the timing of introduction of different DMARD classes. Notably, mean time to first csDMARD was significantly shorter in rheum setting. PsA pts in derm setting had significantly higher disease activity. These data lend further support to the need for rheum-derm collaborative approach to optimise management of pts with PsA.

**Acknowledgements:** AbbVie funded the LOOP study, contributed to its design, and participated in data collection, analysis and interpretation of the data, and in writing, review, and approval of the publication. AbbVie and the authors thank all study investigators for their contributions and the patients who participated in this study. Medical writing was provided by Deepa Venkitaramani, PhD, of AbbVie.

THU0307

### QT INTERVAL AND ITS CORRELATIONS WITH TRADITIONAL RISK FACTORS OF DEVELOPMENT OF CARDIOVASCULAR DISEASES IN PATIENTS WITH ACTIVE EARLY PSORIATIC ARTHRITIS

E. Markelova, D. Novikova, T. Korotaeva, I. Kirillova, E. Loginova, V.A. Nasonova  
Research Institute Of Rheumatology, Moscow, Russian Federation

**Background:** Cardiovascular diseases (CVD) are leading cause of morbidity and mortality in patients (pts) with psoriatic arthritis (PsA). An abnormally prolonged and shorted QT interval are associate with an increased risk of ventricular arrhythmias and sudden cardiac death.

**Objectives:** to evaluate QT interval during Holter monitoring and cardiovascular (CV) risk assessment using SCORE (Systematic COronary Risk Evaluation) in early PsA (EPsA) pts.

**Methods:** We included data of 48 (F.-23) DMARD-naive EPsA pts (according to the CASPAR criteria) with no history of CVD: mean age - 36<sup>[26; 47]</sup> years, EPsA duration - 6,9<sup>[4; 12]</sup> months, DAS - 3.97 [3.27; 4.1], C-reactive protein - 19.4 [8.8; 37.6]mg/l. Controls subjects were matched by age, sex (n=48). All pts were assessed for traditional risk factors of CVD, ESC guidelines, 2016 24 hour (24 hour) ECG monitoring were analysed for QT interval corrected for heart rate (QTc). Prolonged QTc was defined as  $\geq 460$  ms in women and  $\geq 450$  ms in men, short QTc  $< 330$  ms. Ten-year risk of CV death was estimated using SCORE algorithms, ESC guidelines, 2016 categorised as low (<1%), intermediate (1% to <5%), high ( $\geq 5\%$  to <10%) or very high ( $\geq 10\%$ ). Intima-media thickness of the carotid artery (c-IMT) was measured using a high-resolution B-mode ultrasound machine.

**Results:** QTc interval during the 24 hours was significantly prolonged in EPsA pts when compared to the control group (table 1). We didn't find short or prolong QTc interval in EPsA pts and control group.

**Abstract THU0307 – Table 1.** QTc interval in EPsA pts and control group

Parameters	EPsA pts	Controls
QTc (ms), day	397[376; 404]	387.5[370.5; 396]*
QTc (ms), night	396[377; 408]	390[367; 396.5]*
QTc (ms), 24 hour	395[378; 406]	387[370; 396]*

Data are present in median values and interquartile range, \*p<0,05 (nonparametric paired Mann-Whitney U-test).

62.5% of patients with EPsA were classified as being at low risk 10 year risk of CV death using the SCORE algorithm, 6.25% pts - intermediate risk, 29.2% pts - high risk, 2.1% pts - very high risk. Increased cIMT was found in 11 (22.9%), atherosclerotic plaques - in 15 (31.3%). We found significant correlations between age and QTc duration during the 24 hours (R=0.48), as well as in both day (R=0.46) and night periods (R=0.45), for all p<0.05. We didn't find correlations between QTc duration and traditional risk factors of CVD, disease activity of EPsA. Significantly correlations were observed between SCORE level and abdominal obesity (R=0.43, p<0.05), BMI (R=0.41, p<0.0001), c-IMT (R=0.41, p<0.05).

**Conclusions:** QT interval was significantly prolonged in EPsA pts when compared to the control group. The age of pts was associated with increase of the QTc interval. 29.2% of patients were classified as being at high risk 10 year risk of CV death using the SCORE algorithm. The increase level of SCORE associated with a subclinical atherosclerosis. Combination of prolonged QT interval and carotid atherosclerosis confirms presence of high cardiovascular risk in EPsA pts.

THU0308

### CALPROTECTIN AS A MARKER OF DISEASE ACTIVITY IN PATIENTS WITH NEW ONSET PSORIATIC AND RHEUMATOID ARTHRITIS: CORRELATION WITH ULTRASONOGRAPHIC SYNOVITIS

<sup>1</sup>G. Sakellariou, G. Lombardi<sup>2</sup>, B. Vitolo<sup>1</sup>, M. Gomarasca<sup>2</sup>, M. Faraldi<sup>2</sup>, R. Caporali<sup>1</sup>, G. Banfi<sup>2,3</sup>, C. Montecucco<sup>1</sup>. <sup>1</sup>Chair And Division Of Rheumatology, IRCCS Policlinico San Matteo Foundation, Pavia; <sup>2</sup>Laboratory of Experimental Biochemistry and Molecular Biology, I.R.C.C.S. Istituto Ortopedico Galeazzi; <sup>3</sup>Vita-Salute San Raffaele University, Milano, Italy

**Background:** Serum Calprotectin has been tested as a marker of disease activity in psoriatic (PsA) and rheumatoid (RA) arthritis. In RA and in PsA on TNF inhibitors in remission calprotectin correlates with power-Doppler (PD) positive ultrasonographic (US) synovitis, while there is no data on untreated patients with new-onset PsA.

**Objectives:** To investigate the correlation and association between calprotectin and US synovitis in patients with new-onset PsA and in a control group of RA.

**Methods:** Consecutive patients with PsA and a group of age and gender-matched patients with RA, referred to an early arthritis clinic (2005–2014) were

included. Demographic and clinical features, including a 44 joint count for tenderness and swelling (TJC, SJC) and C-reactive protein (CRP) were recorded. US of wrists (radiocarpal, intracarpal and ulnocarpal) and MCP joints with grey scale (GS) and PD synovitis scored 0–3 at each site, with a total score from the sum of each site, was available at the same time, as well as serum samples to measure calprotectin concentration. Serum levels of calprotectin were compared by Mann Whitney test in PsA and RA. The correlation between calprotectin, TJC, SJC, CRP and US PD and GS was evaluated by Spearman's correlation coefficient, while the association of calprotectin concentrations and PD synovitis by regression analysis. Secondary analyses separating poliarticular and oligoarticular (SJC  $\leq 4$ ) PsA and using different definitions of synovitis (GS >1, PD >1) were performed.

**Results:** 156 patients (78 PsA and 78 RA) were included (RA: male 28.2%, mean (sd) age 51.9 (13.3); PsA male 32%; mean age 51.7 (13.5)). Patients with RA had significantly higher CRP (median, IQR) (0.6, 0.3–2.1 vs 0.36, 0.3–1, p 0.04), SJC (7, 5–12 vs 6, 3–9, p 0.008), GS (6, 4–11 vs 5, 2–7, p 0.01) and PD (2, 0–9 vs 1, 0–3, p 0.003) scores. Calprotectin (ng/ml, median, IQR) did not significantly differ in PsA (3123, 2063–4669) and RA (2556, 1615–4441), also when separating poliarticular and oligoarticular PsA. In patients with PsA, calprotectin significantly correlated with GS score (rho 0.340, p 0.007), PD score (rho 0.290, p 0.02) and with the presence of PD (categorical variable) (rho 0.263, p 0.04), while in RA there were no statistically significant correlations. When separating poliarticular and oligoarticular PsA, a significant correlation between calprotectin and GS score (rho 0.369, p 0.01) and PD score (rho 0.363, p 0.02) was confirmed in poliarticular but not oligoarticular disease. In both RA and PsA SJC and TJC did not significantly correlate with calprotectin. Calprotectin showed a statistically significant correlation with CRP in both PsA (rho 0.273, p 0.01) and RA (rho 0.27, p 0.01), showing concurrent validity. In regression analysis, calprotectin levels did not associate with the presence of PD in PsA also when using a more stringent cut-off. Similar results were achieved in RA.

**Conclusions:** In untreated patients with early onset PsA, but not in RA, calprotectin correlates with US PD-positive synovitis, especially in poliarticular disease. Prospective studies are needed to confirm the use of calprotectin as a biomarker in early inflammatory arthritis.

**Disclosure of Interest:** None declared

THU0309

### TEN YEARS FOLLOW-UP STUDY OF CLINICAL DISEASE STATUS AND TREATMENT IN PSORIATIC ARTHRITIS PATIENTS FROM AN OUTPATIENT CLINIC IN SOUTHERN NORWAY

<sup>1,2</sup>G. Haugeberg, S. Tengedal<sup>3</sup>, I.J.W. Hansen<sup>3</sup>, B. Michelsen<sup>3</sup>, A. Diamantopoulos<sup>1</sup>, A. Kavanaugh<sup>4</sup>. <sup>1</sup>Rheumatology, Martina Hansens Hospital, Bærum; <sup>2</sup>Research Unit; <sup>3</sup>Rheumatology, Hospital of Southern Norway Trust, Kristiansand, Norway; <sup>4</sup>Center for Innovative Therapy, UCSD, San Diego, USA

**Background:** In the new millennium remission has become an obtainable treatment goal for chronic inflammatory joint disorders, shown in particular for rheumatoid arthritis (RA). This has been attributed to new treatment strategies (early intervention and treat-to-target) and new drugs e.g. biologic Disease Modifying Anti-Rheumatic Drugs (bDMARDs).<sup>1</sup> For psoriatic arthritis (PsA) there is a lack of longitudinal long term clinical data illuminating potential changes that may have occurred over the years.

**Objectives:** To explore long term changes in clinical disease status and treatment in PsA patients monitored in an ordinary Norwegian outpatient clinic in the period 2008–2017.

**Methods:** For each year we collected data from last patient visit recorded in the hospital clinical computer system GoTreatIT Rheuma. Included patients had to fulfil the CASPAR criteria and have peripheral arthritis. Standard clinical data collection included demographic data, clinical measures of disease activity (Disease Activity Score with 28 joint counts [DAS28], Clinical Disease Activity Index [CDAI] and Assessors Global Assessments (AGA) on Visual Analogue Scale 0–100 mm (VAS)) laboratory measures of disease activity (Erythrocyte Sedimentation Rate (ESR), C-Reactive Protein (CRP) and Patient-Reported Outcomes Measures (PROMs) of physical function (MHAQ), morning stiffness and VAS scores for joint pain, fatigue and Patient Global Assessment (PGA). Treatment with prednisolone, synthetic DMARDs (sDMARDs) or bDMARDs, was recorded.

**Results:** Over the 10 years mean annual number of PsA patients monitored was 331, mean age 58.4 years, disease duration 9.6 years, BMI 27.6 kg/m<sup>2</sup>, females 49% and current smokers 17.6%. A statistically significant decrease for measures of disease activity for the period 2008–2017 was seen (all p<0.01): ESR 15.8–10.9 mm/hr, CRP 7.6–4.1 mg/dl, 28 swollen joints 1.5–0.6, 28 tender joints 3.3–1.6, DAS28 3.32–2.46, CDAI 10.1–6.8 and AGA 14.5–8.6 mm. No statistically significant changes in PROMs was seen. Mean values for the period was: MHAQ 0.46, joint pain 36.3 mm, fatigue 44.2 mm, PGA 38.8 mm and morning stiffness 0.95 hour. From 2008 to 2017 the percentage of patients treated with bDMARDs and/or sDMARDs and/or prednisolone increased from 72.6% to 80.9%. For the

10 year period the annual proportion of patients did not significantly change neither for treatment with prednisolone (14.9%), synthetic DMARDs (53.0%, Methotrexate 38.5%) or biologics (29.9%), this both for TNF (28.1%) and non-TNF inhibitors (1.8%).

**Conclusions:** Despite obvious limitations using disease activity measures (28 joint count, DAS28 and CDAI) designed for use in RA, our study indicate that disease activity decreased in our PsA outpatients over the 10 year period. This despite no significant change in proportions of patients treated with sDMARDs and bDMARDs. For PROMs no significant changes was seen. With new available outcome measures designed for use in PsA and more treatment options available e.g. secukinumab (IL17 inhibition) and ustekinumab (IL12/23) and tofacitinib (JAK inhibitor) further improvements in clinical outcomes both for disease activity and patient perception can be expected.

#### THU0310 BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN PSORIATIC ARTHRITIS: A REAL-WORLD COHORT OF 439 PATIENTS

<sup>1,2</sup>J.-G. Letauouilly, J.-H. Salmon<sup>3</sup>, P. Coquerelle<sup>4</sup>, V. Goeb<sup>5</sup>, M.-H. Guyot<sup>6</sup>, E. Houvenagel<sup>7</sup>, F. Maury<sup>8</sup>, L. Marguerie<sup>9</sup>, G. Morel<sup>10</sup>, G. Baudens<sup>11</sup>, E. Solau-Gervais<sup>12</sup>, N. Ramdane<sup>13</sup>, R.-M. Flipo<sup>1,2</sup>. <sup>1</sup>Rheumatology, Lille University Hospital; <sup>2</sup>Lille University, Lille; <sup>3</sup>Rheumatology, Maison Blanche Hospital, Reims University Hospitals, Reims; <sup>4</sup>Rheumatology, Hospital of Bethune, Bethune; <sup>5</sup>Rheumatology, Amiens University Hospital, Amiens; <sup>6</sup>Internal medicine, Hospital of Roubaix, Roubaix; <sup>7</sup>Rheumatology, Hospital of Saint Philibert, Lomme; <sup>8</sup>Rheumatology, Private Practice, Beuvry; <sup>9</sup>Rheumatology, Institut Calot, Berck; <sup>10</sup>Rheumatology, Hospital of Valenciennes; <sup>11</sup>Rheumatology, Private Practice, Valenciennes; <sup>12</sup>Rheumatology, Poitiers University Hospital, Poitiers; <sup>13</sup>Clinical Research and Methodology, Lille University Hospital, Lille, France

**Background:** For more than 15 years, severe psoriatic arthritis (PsA) has been treated only by TNF inhibitors. Two new Biologic Disease-modifying Antirheumatic Drugs (bDMARDs) have recently arrived on the market with different targets: IL12–23 for ustekinumab and IL 17 for secukinumab. Few studies exist with a large number of patients and with required hindsight.

**Objectives:** The objective was to assess drug survival in an observational cohort of 630 PsA depending on the line of treatment and to analyse the reasons of discontinuation.

**Methods:** This is a retrospective, multicentric observational study based on the data of the registry RIC Nord de France, from patients suffering from PsA (CASPAR criteria) and treated by bDMARDs from January 2000 to August 2017. Drug survival is defined as the time from initiation to discontinuation (stop/switch) of biologic therapy on the registry. The number of patients who discontinued each treatment and the duration of therapy were recorded. Using Kaplan-Meier survival curves and Cox-regression analyses [hazard ratios (HR) and 95% confidence intervals (CIs)], time to discontinuation was compared across cohorts undergoing first-, second- or third-line treatment.

Abstract THU0310 – Figure 1. Drug survival of biotherapies at first-line treatment

**Results:** Out of 630 PsA, 439 were included with a mean follow up greater than or equal to 6 months. The sex ratio was balanced with 47% of women. The mean age was 54.5 years old and the body mass index (BMI) was 28.7 kg/m<sup>2</sup>. The disease duration was 14.25 years. 51.6% of patients did not smoke. The DAS-28

CRP was 3.99 at the initiation of the biotherapy. The drug survival of the TNF inhibitors was similar at first-line treatment (n=439 patients) (figure 1) and at second-line treatment (n=238 patients). The drug survival of infliximab was statistically longer at third-line treatment (n=209) (p<0.0001), as the drug survival of TNF inhibitors compared to non TNF inhibitor biotherapies (ustekinumab and secukinumab) (p0.011). There was no impact of the age, the sex or the BMI on the drug survival. The discontinuation was mainly due to primary and secondary failure at first-line (respectively 33.33% and 33.71%) and to adverse events at second- and third-line (respectively 30.22% and 44.55%).

**Conclusions:** The results of the large observational study confirm those of the clinical trials, especially for the patients with failing initial TNF inhibitor therapy.

**Disclosure of Interest:** None declared

#### THU0311 IMPACT OF SECUKINUMAB TREATMENT ON PSORIATIC ARTHRITIS PATIENTS WITH OR WITHOUT ENTHESITIS AT BASELINE: POOLED DATA FROM TWO PHASE 3 STUDIES (FUTURE 2 AND FUTURE 3)

<sup>1</sup>J.K. Wallman, G. Schett<sup>2</sup>, I.B. McInnes<sup>3</sup>, E. Quebe-Fehling<sup>4</sup>, L. Rasouliyan<sup>5</sup>, L. Pricop<sup>6</sup>, A.E. Fasth<sup>7</sup>, C. Gallez<sup>4</sup>, on behalf of the FUTURE 2 and FUTURE 3 study groups. <sup>1</sup>Lund University, Lund, Sweden; <sup>2</sup>University of Erlangen-Nuremberg, Erlangen, Germany; <sup>3</sup>University of Glasgow, Glasgow, UK; <sup>4</sup>Novartis Pharma AG, Basel, Switzerland; <sup>5</sup>RTI Health Solutions, Barcelona, Spain; <sup>6</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA; <sup>7</sup>Novartis Sverige AB, Täby, Sweden

**Background:** Enthesitis is a common phenotypic manifestation of psoriatic arthritis (PsA) affecting approximately 70% of patients (pts) and may be associated with worse outcomes. <sup>1</sup>Secukinumab (SEC), a fully human monoclonal antibody that selectively neutralises IL-17A, provided significant and sustained improvement in the signs and symptoms of active PsA, with sustained resolution of enthesitis in Phase 3 studies.<sup>2,3</sup>

**Objectives:** To report the impact of SEC treatment on efficacy outcome measures in active PsA pts with or without baseline (BL) enthesitis (defined by Leeds Enthesitis Index) using pooled data from the FUTURE 2 (NCT01752634) and FUTURE 3 (NCT01989468) studies over 2 years.

**Methods:** SEC and placebo (PBO) were administered weekly during the first 4 weeks (wks) followed by subcutaneous maintenance dosing every 4 wks thereafter (PBO until Wk 16/24). The results are reported only for SEC 300 and 150 mg (approved doses). Efficacy outcomes (ACR20/50/70, PASI 90, HAQ-DI, SF-36 PCS and DAS28-CRP) were analysed *post-hoc* in pts with enthesitis at BL (BLE; n=466) or without enthesitis at BL (No BLE; n=246). Observed data are presented for binary variables and least-square (LS) means from analysis of covariance for continuous variables.

**Results:** A total of 65% of pts had BLE. BL demographics were balanced between the BLE and No BLE groups except for a higher proportion of females and numerically higher tender joint count, disability (HAQ-DI) and lower physical function (SF-36 PCS) in BLE pts than No BLE pts. At Wk 16, improvements in ACR and PASI responses, HAQ-DI, SF-36 PCS and DAS28-CRP were similar in both groups treated with SEC 300 mg, but were lower (except for PASI) in BLE pts treated with SEC 150 mg (table 1). Improvements in these outcomes followed a similar trend to Wk 104 in SEC-treated pts (table 1).

Abstract THU0311 – Table 1. Summary of Results with Secukinumab

	Wk	BLE			No BLE		
		300 mg	150 mg	PBO	300 mg	150 mg	
ACR20 <sup>a</sup>	16	53.5	46.5	19.6	53.7	64.6	18.1
	104	56.8	52.4	-	62.6	62.9	-
ACR50 <sup>a</sup>	16	31.3	21.4	6.7	35.8	35.4	5.6
	104	44.7	24.8	-	47.3	34.3	-
ACR70 <sup>a</sup>	16	16.0	8.2	1.8	21.1	16.5	1.4
	104	26.5	15.2	-	34.1	21.4	-
PASI 90 <sup>b,c</sup>	16	50.0	36.6	7.9	42.1	37.0	6.7
	104	67.9	59.7	-	73.5	44.4	-
HAQ-DI <sup>d</sup>	16	-0.5	-0.3	-0.2	-0.5	-0.5	-0.2
	104	-0.5	-0.4	-	-0.5	-0.6	-
SF-36 PCS <sup>d</sup>	16	6.4	3.7	2.5	6.5	7.4	2.6
	104	7.4	4.3	-	6.6	6.9	-
DAS28-CRP <sup>d</sup>	16	-1.5	-1.05	-0.5	-1.35	-1.6	-0.5
	104	-1.7	-1.6	-	-2.0	-1.9	-

<sup>a</sup>Response,%; <sup>b</sup>At Wk 16/104, n=144/132 (SEC 300), 159/145 (SEC 150) and 163 (PBO) with enthesitis and n=95/91 (SEC 300), 79/70 (SEC 150) and 72 (PBO) without enthesitis at BL; <sup>c</sup>At Wk 16/104, n=66/56 (SEC 300), 82/62 (SEC 150) and 63 (PBO) with enthesitis and n=38/34 (SEC 300), 46/36 (SEC 150) and 30 (PBO) without enthesitis at BL (psoriasis subset); <sup>d</sup>LS mean

**Conclusions:** Although pts with BLE had more severe BL clinical characteristics than pts with No BLE, SEC showed higher efficacy than PBO at Wk 16 and sustained efficacy over 104 wks in both groups with greater magnitude of improvement in pts treated with SEC 300 mg than 150 mg.

#### THU0312 RISK OF INFECTION IN PATIENTS WITH PSORIASIS/ PSORIATIC ARTHRITIS: A POPULATION-BASED STUDY IN THE PROVINCE OF BRITISH COLUMBIA

<sup>1,2</sup>J.A. Avina-Zubieta, A. Dominique<sup>3</sup>, T.A. Simon<sup>3</sup>, H. Tavakoli<sup>1</sup>. <sup>1</sup>Arthritis Research Canada, Richmond; <sup>2</sup>Faculty of Medicine, University of British Columbia, Vancouver, Canada; <sup>3</sup>Bristol-Myers Squibb, Princeton, USA

**Background:** Psoriasis (PsO) is a chronic autoimmune disease of the skin with a third of patients (pts) also developing inflammatory arthritis (PsA), which can lead to joint destruction. Research suggests that pts with PsA have an increased risk of complications (e.g. cardiovascular disease). There are limited data on the risk of infections among pts with PsO/PsA.

**Objectives:** To assess the risk of mild and severe infections in pts with newly diagnosed PsO/PsA in a general population.

**Methods:** Using administrative health data from British Columbia (Canada) we developed an incident cohort of pts diagnosed with PsO/PsA between 1996 and 2013, with equal control pts matched on sex, age and calendar year. PsO/PsA cases were determined by: a) one International Classification of Diseases code (696.X) for PsO/PsA assessed by a rheumatologist or dermatologist; b)  $\geq 2$  diagnostic codes for PsO/PsA,  $\geq 2$  months apart in a 2 year period assessed by a non-rheumatologist or dermatologist; c)  $\geq 1$  hospitalisation with a diagnostic code for

PsO/PsA. Individuals with a history of HIV or tuberculosis were excluded. Outcomes were mild infections (requiring a physician visit and antibiotics) or serious infections (requiring hospitalisation). Adjusted risks of these infections were estimated using generalised estimating equation extensions of multivariate Poisson regression models.

**Results:** We identified 84 616 newly diagnosed pts with PsO/PsA (51.6% female; mean age 49.5 years [SD: 18.2]) who were matched with an equal non-PsO/PsA cohort. Pts with PsO/PsA had a higher risk of developing mild infections during follow-up, including HIV (2.6-fold) and mycosis (2-fold), compared with the general population. PsO/PsA also increased the risk of severe infections including *Chlamydia* (1.7-fold) and viral diseases with exanthema (2.6-fold) (table 1).

P-Y=patient years

**Conclusions:** This large epidemiological study demonstrates that pts with PsO/PsA are at significantly higher risk of acquiring infections. The role of therapy for PsO/PsA on the risk of these infections needs to be evaluated.

**Acknowledgements:** This study received an unrestricted grant from Bristol-Myers Squibb for an investigator-initiated project in PsO/PsA.

#### THU0313 IXEKIZUMAB IMPROVES NAIL AND SKIN LESIONS THROUGH 52 WEEKS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND INADEQUATE RESPONSE TO TUMOUR NECROSIS FACTOR INHIBITORS

J.F. Merola<sup>1,2</sup>, P. Rich<sup>3</sup>, J.P. Dutz<sup>4</sup>, D. Adams<sup>5</sup>, L. Kerr<sup>5</sup>, L.E. Kristensen<sup>1</sup>. <sup>1</sup>Harvard Medical School; <sup>2</sup>Department of Dermatology and Medicine, Rheumatology, Brigham and Women's Hospital, Boston; <sup>3</sup>Dermatology and Clinical Research, Oregon Health Science University, Portland, USA; <sup>4</sup>Department of Dermatology and Skin Science, Faculty of Medicine, BC Children's Hospital Research Institute, The University of British Columbia, Vancouver, Canada; <sup>5</sup>Eli Lilly and Company, Indianapolis, USA; <sup>6</sup>The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen, Denmark

**Background:** Ixekizumab (IXE) is a high-affinity monoclonal antibody selectively targeting interleukin-17A. Compared to placebo (PBO), IXE resulted in significantly greater reduction and clearance of fingernail and skin lesions at Wk 24 in patients (pts) with active psoriatic arthritis (PsA) and inadequate response (IR) to tumour necrosis factor inhibitors (TNF-i).<sup>1</sup>

**Objectives:** This analysis examined the persistence of effect at 1 year.

**Methods:** In this Phase 3, double-blind trial (SPIRIT-P2; NCT02349295), pts with active PsA who were TNF-i-IR were randomised to PBO or 80 mg IXE SC every 2 or 4 Wks (IXEQ2W, IXEQ4W), after a 160 mg starting dose.<sup>2</sup> At Wk 16, pts with IR to treatment (ERB supplement defined) received rescue therapy and pts on PBO

**Abstract THU0312 – Table 1.** Incidence Rate (IR) and Rate Ratio (RR) of Mild and Severe Infections Among PsO/PsA Pts Compared With the General Population

were re-randomised to IXEQ2W or IXEQ4W. The primary objective was ACR20 at Wk 24, and an extension from Wks 24 to 156 is on-going. In this analysis, efficacy was assessed at Wk 52 for the intent-to-treat (ITT) population of pts randomised to IXE at Wk 0 by Nail Psoriasis Severity Index (NAPSI) scores in pts with baseline fingernail psoriasis (IXEQ4W, n=89; IXEQ2W, n=74), PASI 75/90/100 response rates in pts with baseline BSA  $\geq 3$  (IXEQ4W, n=68; IXEQ2W, n=68), and the rate of Static Physician Global Assessment (sPGA) of psoriasis scores of 0 or 1 (0=cleared, 1=minimal) in pts with baseline sPGA  $\geq 3$  (IXEQ4W, n=60, IXEQ2W, n=62). For categorical variables, nonresponder imputation was used for missing data. Percent change from baseline was calculated using modified baseline observation carried forward.

**Results:** At Wk 52, NAPSI total score (observed cases; mean (SD)) was 5.0 (12.7), 4.4 (7.6), IXEQ4W, IXEQ2W, respectively, with a mean percent change from baseline of -15.2 (19.7), -14.4 (19.0), IXEQ4W, IXEQ2W, respectively. The percentage of pts achieving a NAPSI score of 0 (0=cleared) was 46.1% (n=41), 32.4% (n=24), IXEQ4W, IXEQ2W, respectively. The percentage of pts achieving PASI responses was 60.3% (n=41), 54.4% (n=37) for PASI 75; 50.0% (n=34), 39.7% (n=27) for PASI 90; and 39.7% (n=27), 35.3% (n=24) for PASI 100, IXEQ4W, IXEQ2W, respectively. The percentage of pts achieving sPGA 0 or 1 was 61.7% (n=37), 66.1% (n=41), IXEQ4W, IXEQ2W, respectively. Safety was consistent with the larger study population.

**Conclusions:** In patients with active PsA, an inadequate response to TNF-inhibitors, and baseline fingernail or skin lesions, treatment with ixekizumab resulted in persistent<sup>1</sup> reduction and clearance of nail and skin lesions after 1 year.

**THU0314 IXEKIZUMAB MAKES VERY LOW DISEASE ACTIVITY AND REMISSION WITH PSORIATIC ARTHRITIS DISEASE ACTIVITY SCORE POSSIBLE IN ACTIVE PSORIATIC ARTHRITIS PATIENTS FOR UP TO 1 YEAR: SPIRIT-P1 AND SPIRIT-P2 TRIALS**

<sup>1</sup>L.C. Coates, M.E. Husni<sup>2</sup>, E. Lespessailles<sup>3</sup>, L. Kerr<sup>4</sup>, G. Gallo<sup>4</sup>, <sup>1</sup>Univ of Leeds, School of Medicine, Leeds, UK; <sup>2</sup>Cleveland Clinic, Cleveland, USA; <sup>3</sup>Orléans Hospital, Orléans, France; <sup>4</sup>Eli Lilly and Company, Indianapolis, USA

**Background:** Treatment goals in psoriatic arthritis (PsA) are moving toward attainment of absolute therapeutic thresholds rather than relative improvement. Minimal disease activity (MDA) and very low disease activity (VLDA); Disease Activity in Psoriatic Arthritis (DAPSA) LDA and DAPSA Remission; and Psoriatic Arthritis Disease Activity Score (PASDAS) LDA and PASDAS VLDA are validated composite indices used to measure disease activity states in PsA.

**Objectives:** The effect of ixekizumab (IXE), as assessed by composite endpoints that incorporate multiple disease domains, was explored up to 52 weeks for the SPIRIT-P1<sup>1</sup> and SPIRIT-P2<sup>2</sup> trials.

**Methods:** Data were analysed from 2 double-blind, phase III SPIRIT trials investigating the efficacy and safety of IXE, a high-affinity monoclonal antibody selectively targeting interleukin-17A, for patients with active PsA. For SPIRIT-1 (NCT01695239), patients who were biologic disease-modifying antirheumatic drug (DMARD)-naïve were randomised to placebo (n=106) or 80 mg IXE every 4 weeks (Q4W, n=107) or every 2 weeks (Q2W, n=103) after a 160 mg starting dose. For SPIRIT-2 (NCT02349295), patients who had an inadequate response or were intolerant to tumour necrosis factor inhibitors (TNFi) were randomised to placebo (n=118) or 80 mg IXE every 4 weeks (Q4W, n=122) or every 2 weeks (Q2W, n=123) after a 160 mg starting dose. MDA, MDA VLDA, DAPSA LDA, DAPSA Remission, PASDAS LDA, and PASDAS VLDA composite endpoints were evaluated. Imputation for categorical responses was non-responder

imputation. Treatment comparisons (with respect to placebo up to Week 24) based on the intent-to-treat population were made using a logistic regression model. Data up to Week 52 are summarised descriptively.

**Results:** The therapeutic threshold results are summarised in table 1. At Week 24, the percentage of patients achieving MDA, MDA VLDA, DAPSA LDA, DAPSA Remission, PASDAS LDA, and PASDAS VLDA was greater with IXE Q4W and IXE Q2W compared with placebo. In patients who continued treatment with IXE through Week 52, response rates of these therapeutic thresholds were either sustained or further improved.

in parentheses. <sup>100</sup>Patients from a logistic regression model using the unadjusted treatment effect estimates are presented in parentheses.

**Conclusions:** Regardless of previous TNFi exposure, in patients with active PsA, a higher proportion of IXE-treated compared with placebo-treated patients achieved MDA and MDA VLDA, DAPSA LDA and DAPSA Remission, and PASDAS LDA and PASDAS VLDA at Week 24. At Week 52, the extent of IXE clinical response was sustained or further improved.

**THU0315 PATIENT-PERCEIVED INVOLVEMENT IN DISEASE MANAGEMENT DRIVES PATIENT-PHYSICIAN ALIGNMENT IN SATISFACTION WITH DISEASE CONTROL IN PSORIATIC ARTHRITIS**

<sup>1</sup>L. Gossec, A.-M. Orbai<sup>2</sup>, S. Lobosco<sup>3</sup>, R. Moon<sup>3</sup>, O. Massey<sup>3</sup>, J. Piercy<sup>3</sup>, J. C. Cappelleri<sup>4</sup>, L. Fallon<sup>4</sup>, P. Young<sup>4</sup>, A.B. Romero<sup>4</sup>, M.-A. Hsu<sup>4</sup>, <sup>1</sup>Sorbonne Universités, Paris, France; <sup>2</sup>John Hopkins University, Baltimore, MD, USA; <sup>3</sup>Adelphi Real World, Bollington, UK; <sup>4</sup>Pfizer, Groton, CT, USA

**Background:** Previous analyses have indicated misalignment between Psoriatic Arthritis (PsA) patients and their physicians can be frequent, and can result in worse disease severity and health-related quality of life<sup>1,2</sup>. Factors associated with this misalignment have not been determined.

**Objectives:** To assess patient-physician misalignment regarding satisfaction with PsA disease control and identify factors associated with this misalignment.

**Methods:** Data were drawn from the Adelphi PsA Disease Specific Programme, a real-world survey conducted in 2015 across the US, France, Germany, Italy, Spain, UK. Patients had physician-confirmed PsA and had to have been receiving their current synthetic-DMARD (biologic naïve) or biologic therapy for at least 6 months.

Physicians and patients independently provided information on satisfaction with disease control on a 5-point scale (very satisfied/satisfied/neither/dissatisfied/very dissatisfied). Physician and patient reports of satisfaction were compared to assess levels of misalignment. Physicians also provided information on demographics and disease history/severity. Patients provided information on involvement in treatment decisions, EuroQol-5D Visual Analogue Scale (EQ-5D), Work Productivity and Activity Impairment (WPAI) and Health Assessment Questionnaire Disability Index (HAQ-DI). Factors associated with misalignment were analysed by a multivariate logistic regression modelled using predictors identified as significant in univariate logistic regression. Data entered in the analyses included demographics, time diagnosed, treatment history, disease severity, flaring, pain, patient-reported involvement in treatment decisions, EQ-5D, WPAI, HAQ-DI.

**Results:** 519 physicians (331 rheums, 188 derms) provided data for 2467 PsA patients, 656 meeting all inclusion criteria. Mean age was 49.9 (SD 12.1) years, mean disease duration 6.7 (6.2) years, 53.8% patients were male and 66.1% employed. Satisfaction with disease control was generally high amongst both patients (78.3%) and physicians (91.9%) with alignment in 79.4% of cases. In 16.8% of cases there was misalignment where patients were dissatisfied but physicians satisfied.

Multivariate logistic regression showed that worse HAQ-DI (OR [95% CI]: 0.54 [0.38–0.77],  $p=0.001$ ), worse EQ-VAS (OR 1.03 [1.02–1.04],  $p<0.001$ ), lack of involvement in treatment decisions (OR 1.26 [1.07–1.50],  $p=0.007$ ) and physician-reported severe disease as opposed to mild (OR 0.20 [0.05–0.78],  $p=0.020$ ) were all independently associated with misalignment.

**Conclusions:** Satisfaction with disease control was generally high for both patients and physicians; however, misalignment was not rare. Patients had higher levels of symptoms/increased impact on activities where there was misalignment. An independent factor associated with misalignment was patient-perceived involvement in condition management. Improving patient-physician engagement in overall disease management may lead to greater patient satisfaction and patient-physician alignment.

#### GENDER DIFFERENCES IN BIOLOGIC TREATMENT OUTCOMES – A STUDY OF 1750 PATIENTS WITH PSORIATIC ARTHRITIS USING DANISH HEALTH CARE REGISTERS

P. Højgaard<sup>1,2</sup>, C. Ballegaard<sup>1,2</sup>, R. Cordtz<sup>1</sup>, K. Zebbe<sup>1,2</sup>, M. Clausen<sup>1</sup>, L. E. Kristensen<sup>2</sup>, B. Glinthorg<sup>1,3</sup>, <sup>4,5</sup>L. Dreyer. <sup>1</sup>Center for Rheumatology and Spine diseases, Rigshospitalet Gentofte, Hellerup; <sup>2</sup>The Parker Institute, Bispebjerg and Frederiksberg Hospital, Frederiksberg; <sup>3</sup>Center for Arthritis Research COPECARE, Rigshospitalet Glostrup, Glostrup; <sup>4</sup>Center for Rheumatology and Spine diseases, Rigshospitalet Gentofte, Copenhagen; <sup>5</sup>Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark

**Background:** Previous studies have shown conflicting findings on the impact of gender on effectiveness of tumour necrosis factor alpha inhibitor (TNFi) treatment in patients with psoriatic arthritis (PsA).

**Objectives:** To investigate gender differences in disease manifestations, patient-reported outcomes, comorbidities and treatment effectiveness among patients with PsA treated with their first TNFi

**Methods:** In this observational cohort study, the nationwide DANBIO register provided prospectively collected data on disease activity and treatment outcomes for PsA patients who initiated their first TNFi in 2000–2015. Data on comorbidities, diagnosed in hospital departments, were obtained by cross-linkage to the Danish National Patient Register. Treatment response was evaluated according to EULAR and ACR criteria at 3- and 6 months. Cox- and logistic regression models analysed the impact of gender on TNFi persistence and response, respectively, while adjusting for a priori selected confounders including clinical-, laboratory- and patient-reported factors, comorbidities and lifestyle characteristics

**Results:** A total of 1750 PsA patients (53% females) were included. At baseline, women were older (49 years/47 years), more often smokers (32%/26%), had worse patient-reported scores (e.g. global score 71 mm/65 mm) and higher frequencies of hospital-diagnosed anxiety or depression (7%/4%) and chronic pulmonary disease (7%/3%), than men (all  $p<0.01$ ). Median TNFi persistence was 3.8 years (95% CI 3.0–5.7) in men versus 1.4 (1.1–1.8) in women ( $p<0.001$ ), figure 1. Men had higher odds of achieving response according to all response criteria, e.g. adjusted odds ratio=3.2 (1.6–6.1) for EULAR good/moderate response at 6 months (vs. women).

Abstract THU0316 – Figure 1. Kaplan meier plots

**Conclusions:** Male patients had better TNFi treatment outcomes. Adjustment for baseline risk factors including patient-reported outcomes, disease activity, comorbidities and lifestyle factors did not influence this relationship, which suggests a role of biological factors.

**Acknowledgements:** Thanks to patient-research partner Åse Stampe, to all patients and clinicians reporting to DANBIO, and to statistician Peder Frederiksen and biostatistician Robin Christensen for methodological and statistical advices. Thanks to the Oak Foundation, Danish Rheumatism Association, and Department of Rheumatology at Rigshospitalet, Gentofte.

Kvien, C. Codreanu, E.-M. Hauge, J. Asklng, F. Iannone, H. Mann, M.V. Hernandez, G. Macfarlane, M. van de Sande, L.H. Hyldstrup, N.S. Krogh, M. Hetland. *EuroSA Research Network Collaboration, Coordinating Centre, On behalf of the DANBIO, TURKBIO, biorx.si, ICEBIO, SCQM, ROB-FIN, Reuma.pt, NOR-DMARD, RRRB, ARTIS, GISEA, ATTRA, BIOBADASER, BSRBR-AS and ARC registries, Copenhagen, Denmark*

**Background:** A research network collaboration of 15 European registries collecting data on patients with spondyloarthritis (SpA), "EuroSpA", has recently been created to strengthen research capabilities in the real world setting<sup>1</sup>. Here we present initial findings from the collaboration.

**Objectives:** To investigate the feasibility of creating a common database within the EuroSpA collaboration and to conduct proof-of-concept analyses by investigation of baseline characteristics, disease activity at baseline and after 6 months and 12 months' TNFi retention rate in patients with psoriatic arthritis (PsA) initiating Tumour Necrosis Factor inhibitors (TNFi).

**Methods:** A common data model for PsA was agreed upon by the EuroSpA Scientific Committee. Virtual meetings between the EuroSpA and registry data managers clarified data availability and structure. This was followed by upload of anonymized data through the secure Virtual Private Network pipelines to the EuroSpA server. Baseline characteristics and disease activity at baseline and after 6 months were investigated with non-parametric descriptive statistics. Kaplan-Meier estimation was used to investigate TNFi retention rates.

**Results:** : By January 8th 2018, four of the 15 registries participating in EuroSpA had completed data upload to the EuroSpA database resulting in 3172 patients with PsA in a pooled dataset. Baseline characteristics of the participating registry populations at initiation of first TNFi are shown in table 1. Crude 12 month TNFi retention rates varied from 65%–80% for 1st TNFi and 57%–82% for 2nd TNFi (see figure 1). For the pooled dataset crude 12 months TNFi retention rates were 68% and 60% for the 1st and 2nd TNFi, respectively.

**Abstract THU0317 – Table 1.** Baseline demographic and disease characteristics of patients with PsA registered in four EuroSpA registries

+ TNFi	1955 (82)	181 (21)	63 (78)	107 (78)
+ 2017-2018	1630 (69)	239 (27)	11 (14)	108 (78)
	Baseline	6 months	Baseline	6 months
DMARD-CRP	1.6 (2.4-1.3)	2.7 (1.3-3.4)	1.4 (1.3-1.4)	2.7 (1.2-3.6)
CRP (mg/L)	1.7 (1.3)	2.1 (1.6)	1.8 (1.3)	2.1 (1.6)
CRP (mg/L) post	1.8 (1.3)	1.1 (0.7)	1.8 (1.3)	1.1 (0.7)
TNF post, n(%)	41 (1.7)	28 (3.2)	19 (23)	28 (20)

**Conclusions:** Preliminary analyses showed differences across European registries regarding baseline characteristics and crude retention rates in PsA patients initiating TNFi. These initial, preliminary analyses demonstrate that the creation of a large European database of PsA patients treated in routine care based on a common data model is feasible, offering important opportunities for future research.

**THU0318 TREATING PSORIATIC ARTHRITIS TO TARGET: COMORBIDITIES, NON-ADHERENCE AND FACTORS RELATED TO THE HEALTH SYSTEM PREVENT ESCALATION OF THERAPY IN REAL LIFE**

<sup>1</sup>M. Ferreira, R. Xavier<sup>1,2</sup>, E. Abegg<sup>2</sup>, O. Martins<sup>2</sup>, F. Menegat<sup>1</sup>, C. Kohem<sup>1,2</sup>, A. Gasparin<sup>1</sup>, N. Andrade<sup>1</sup>, V. Hax<sup>1</sup>, D. Vieccell<sup>1</sup>, C. Brenol<sup>1,2</sup>, J.C. Brenol<sup>1,2</sup>, P. Palominos<sup>1</sup>. <sup>1</sup>Hospital de Clinicas de Porto Alegre; <sup>2</sup>Universidade Federal do Rio Grande do Sul, Porto Alegre, Brazil

**Background:** Although the treat-to-target (T2T) strategy in psoriatic arthritis (PsA) clinical trials resulted in better outcomes in domains such as joints, skin, function and quality of life compared to standard care, in real life several factors affect such a strategy<sup>1</sup>.

**Objectives:** To determine the prevalence of patients achieving minimal disease activity (MDA) in our PsA clinic and the reasons why therapy in patients not achieving MDA was not optimised.

**Methods:** An observational, retrospective cross-sectional study nested in a cohort study was conducted; medical records of patients attending PsA clinic in a public university hospital were reviewed. Demographic data, current treatment and components of the MDA score were collected. When patients were not in MDA but the treatment was not optimised, the reasons for the non-escalation of therapy were recorded.

**Results:** MDA score was available in 113 visits, corresponding to 69 patients. Mean age of patients was 57.4±10.6, 53.6% (n=37) were females and 40.6% (n=28) were treated with biological drugs. MDA was reached in 31.0% (n=35) of visits; 36.2% (n=25) of the patients achieved MDA in at least one visit during the 8 months follow-up. There was no statistical difference in the proportion of patients achieving MDA according to treatment prescribed (biological DMARDs versus synthetic conventional DMARDs) (p=0.979). Although MDA was not achieved in 69.0% (n=78) of visits, optimisation of therapy was done in only 42.3% (n=33) of those visits. The main reasons which prevented treatment escalation were: physician impression of clinical remission and MDA overestimated by comorbidities and chronic deformities (57.7%, n=26), non-adherence to previous prescription (17.8%, n=8), delay to receive drugs from health insurance (17.8%, n=8), adverse events (11.1%, n=5), patient low cognitive level (6.7%, n=3) and patient refusal to escalate therapy (4.4%, n=2). In visits with impression of remission by rheumatologist, the skin and the swollen joint components of the MDA score were achieved in more than 80% of this visits (80.8%, n=21).

**Conclusions:** Rheumatologists are reluctant to escalate therapy in PsA even if patients are not in MDA if “objective” components of the MDA score such as skin and swollen joint counts are reached. Comorbid conditions, patients non-adherence to therapy and factors related to the health system influence a tight control strategy in the real life clinical practice.

**THU0319 OVERALL SAFETY OF 7-WEEK SECUKINUMAB EXPOSURE DURING PREGNANCY IN WOMEN WITH PSORIATIC ARTHRITIS**

<sup>1</sup>M. Meroni, E. Generali<sup>1</sup>, G.M. Guidelli<sup>1</sup>, M. Parodi<sup>2</sup>, M. Cutolo<sup>3</sup>, C. Selmi<sup>1,4</sup>. <sup>1</sup>Internal Medicine Dept., Rheumatology and Clinical Immunology, Humanitas Research Hospital, Rozzano (MI); <sup>2</sup>Internal Medicine Dept., Rheumatology Unit, A. O. S.S. Antonio e Biagio e Cesare Arrigo, Alessandria; <sup>3</sup>Internal Medicine Dept., Research Laboratory and Academic Division of Rheumatology, University of Genoa, Genoa; <sup>4</sup>BIOMETRA Department, University of Milan, Milan, Italy

**Background:** Psoriatic arthritis (PsA) often affects women of reproductive age. Secukinumab (SEC), a monoclonal antibody against interleukin-17A is effective in contrasting the progression of articular and cutaneous manifestations of PsA but has not been extensively studied in pregnancy, despite 84 cases of accidental exposure reported with reassuring safety outcomes.

**Objectives:** To evaluate the maternal and fetal outcomes in women with PsA exposed to SEC during pregnancy.

**Methods:** During a 10 months observational period, we enrolled 6 patients, treated by SEC 150 mg subcutaneously every month after weekly induction. All of them stopped the treatment by the time pregnancy test turned positive. All women had previously been counselled about contraceptive methods adoption and the potential risk of becoming pregnant during SEC administration, signing an informed consent. We collected demographic and clinical data of both patients

and babies, with a peculiar focus on maternal-fetal safety issues. APGAR scores at 1 min (APGAR1) and 5 min (APGAR5) from delivery were recorded.

**Results:** We observed 6 pregnancies from 6 mothers (4 of European, 1 Asian and 1 Latin-American ethnicity). Patient mean age at conception was 336±131 months; disease duration, 62±27 months; pre-conceptual exposure, 46±9 weeks; the (estimated) post-conceptual exposure 7±2 weeks. No major gestational complications were reported. One mother consulted the Emergency Department for a syncopal episode, but after a routine evaluation and an observation of 6 hours, was discharged; her pregnancy was otherwise unremarkable. Four girls (mean weight: 3170±200 g) and 2 boys (mean weight: 3460±60) were born. Mean gestational age was 38±2 weeks; 3 vaginal deliveries (1 oxytocine-induced for scarce dilation) and 3 caesarean sections were observed. The APGAR scores were above 8, excepting for an APGAR1 of 6 (born with caesarean section), then turned on 10 at APGAR5. Results are summarised on table 1. DAPSA, for the whole population, was under 4 (remission) at conception, and remained stable after delivery.

Abstract THU0319 – Table 1

Observed pregnancies	6					
Gestational age (weeks+days)	38±2					
Sex	M (4)			F (2)

APGAR, Appearance-Pulse-Grinace-Activity-Respiratory Score, SGA, Small for Gestational Age; IUGR, Intra-Uterine Growth Restriction; PsA, Psoriatic arthritis; DAPSA, Disease Activity in Psoriatic Arthritis; ED, Emergency Department (access).

**Conclusions:** The present study, despite the limited number of observations, represents the first report on pre-conceptual exposure to SEC. The available data, due to the lack of controlled studies, place the drug's use on FDA "B" category. Of note, SEC failed to cause teratogenicity, when administered throughout the whole pregnancy in a study conducted on primates (*Cynomolgus* monkeys). The limited knowledge on human beings suggests, nevertheless, not to administer SEC during pregnancy, unless a clear benefit overwhelm the potential risk. SEC, in conclusion, seems to have an acceptable safety profile, even when accidentally taken in the very first pregnancy phase. Reporting the cases of pregnancy exposures, as recommended by the ongoing Producer's policy, is the only way that would allow to confirm, or reject, this statement. A long-term follow-up of the mother and the offspring health, similarly, is needed.

#### THU0320 A SHORT, EASILY READABLE, ONLY 3-ITEM TOOL – BRISTOL RHEUMATOID ARTHRITIS FATIGUE SCALE (BRAFF) – IS VALID IN PATIENTS WITH PSORIATIC ARTHRITIS

<sup>1</sup>M. Haroon, K. Iqbal<sup>1</sup>, M. Ashraf<sup>1</sup>, P. Gallagher<sup>2</sup>, O. FitzGerald<sup>2</sup>. <sup>1</sup>Rheumatology, University Hospital Kerry, Tralee, County Kerry; <sup>2</sup>Rheumatology, St Vincent's University Hospital, Dublin, Ireland

**Background:** Fatigue in Psoriatic arthritis is very little studied. Recently, an instrument, the Functional Assessment of Chronic Illness Therapy (FACIT), has been validated in PsA, which is a relatively long, 13-item, instrument. An alternative instrument, the Bristol Rheumatoid Arthritis Fatigue Numerical Rating Scales (BRAFF-NRS), is an easily readable, much shorter, 3-item tool. The BRAFF-NRS

has been studied and validated in rheumatoid arthritis population; however, this has not been validated in patients with PsA.

**Objectives:** The purpose of this study was firstly to determine the internal consistency, test-retest reliability, criterion validity of the BRAFF-NRS in patients with PsA. Secondly, we also examined the potential clinical associations of worse fatigue in patients with established PsA.

**Methods:** Two independent cohorts fulfilling CASPAR criteria were enrolled.

STUDY PHASE 1: BRAFF-NRS SCALE VALIDATION COHORT (n=70)

A consecutive cohort of 70 PsA patients completed the 3-item BRAFF-NRS scale and 13 items of the FACIT-F scale, alongside laboratory testing and disease activity assessments. Moreover, all these patients completed BRAFF-NRS questionnaires twice, one day apart. Internal consistency was measured by Cronbach's alpha; test-retest reliability by the intra class correlation coefficient (ICC); and validity by the correlation of the BRAFF-NRS results with validated FACIT-F measures.

STUDY PHASE-2: IDENTIFYING THE POTENTIAL CLINICAL ASSOCIATIONS OF FATIGUE BY USING BRAFF-NRS (n=283)

Following informed consent, patients underwent a detailed skin and rheumatologic assessment including disease activity measures, and whether patient has achieved minimal disease activity (MDA). Moreover, we measured comorbidity using the Charlson Comorbidity Index (CCI). The factors predicting worse fatigue as measured by the BRAFF-NRS score were determined using univariate and multivariate linear regression analysis.

**Results:** STUDY PHASE 1: BRAFF-NRS SCALE VALIDATION COHORT (n=70): 67 patients had the complete assessments [mean age 52±9 years, 54% female, mean PsA duration of 5±3 years]. The internal consistency of the 3 items BRAFF-NRS questionnaire as measured by Cronbach's alpha was 0.92. Test-retest reliability as measured by the intraclass correlation coefficient between the first and repeat questionnaires was 0.98. The BRAFF-NRS scores were compared with the FACIT fatigue scores. There was an excellent correlation between the BRAFF-NRS and FACIT fatigue (r=-0.83 (p<0.001).

STUDY PHASE-2: IDENTIFYING THE POTENTIAL CLINICAL ASSOCIATIONS OF FATIGUE BY USING BRAFF-NRS (n=283)

On multiple linear regression analysis, the model predicted the significant association of low education status (p=0.03), number of deformed joints (p=0.01), not achieving MDA (p<0.001), higher CCI scores and worse HAQ (p<0.001) with worse fatigue scores.

**Conclusions:** BRAFF-NRS provides a reliable, reproducible and valid instrument of measuring fatigue in PsA. Fatigue is associated with low education status, higher number of deformed joints and comorbidities, not achieving remission and worse functional index. This short assessment tool can be especially valuable in the context of a busy clinic, and also in large epidemiological studies when other core domains warrant assessment.

#### THU0321 ACUTE PHASE MARKERS IN PSORIATIC ARTHRITIS IDENTIFY PATIENTS WITH A MORE SEVERE PHENOTYPE

<sup>1</sup>M. Haroon, M. Ahmad<sup>1</sup>, O. Mason<sup>2</sup>, O. FitzGerald<sup>3</sup>. <sup>1</sup>Rheumatology, University Hospital Kerry, Tralee, County Kerry; <sup>2</sup>STAR (Centre for Support and Training in Analysis and Research), University College Dublin; <sup>3</sup>Rheumatology, St Vincent's University Hospital, Dublin, Ireland

**Background:** CRP and ESR are the most commonly and probably the most studied inflammatory markers among patients with inflammatory arthritis. In contrast to rheumatoid arthritis, however, these markers are raised in less than 50% of people with psoriatic arthritis (PsA). Little is known about the long term significance of elevated inflammatory markers during the course of PsA disease.

**Objectives:** In a well characterised PsA cohort with a long term follow up, we examined the association of CRP and ESR over the disease course with demographics, clinical and radiographic features, patient reported outcome measures and the number of comorbid conditions.

**Methods:** A cohort of 283 PsA patients all meeting CASPAR criteria and attending rheumatology clinics were evaluated. All underwent detailed skin and rheumatologic assessments, along with cardiovascular risk factor evaluation. Moreover, we documented the presence/absence of comorbidities using the Charlson Comorbidity Index (CCI). All of these patients had CRP and ESR laboratory values assessed along with the other routine laboratory parameters during the disease course. For each patient, we documented CRP and ESR values at 3 different time points: firstly, at the time of the initial diagnosis; secondly, the highest value of CRP and ESR recorded during the disease course; and thirdly at the time of full assessment for this study. Cumulative inflammation over time was

represented by the cumulative averages of CRP (ca-CRP) and ESR (ca-ESR) which were calculated from the AUC (Area Under the Curve) of the 3 documented measurements divided by the total number of months of follow-up. Variables significantly associated at a Bonferroni-corrected p-value were included in the multiple linear regression modelling CRP and ESR.

**Results:** A total of 283 PsA patients [mean age 54.6±12 years; 52% female; mean PsA duration of 19±9 years; 25% with sacroiliitis; 44.5% with peripheral joint erosions; 60% of patients requiring TNFi for PsA] attended for detailed assessments. The median (IQR) and mean (SD) Ca-CRP was 8.8 (4.6–14.8) and 11.72 (10.52), respectively. The median (IQR) and mean (SD) Ca-ESR was 13.8 (7.8–20.1) and 15.78 (10.46). The variables were also checked for multicollinearity. On multiple linear regression, erosions, sacroiliitis, and the CCI were most significantly associated with Ca-CRP (unstandardised coefficient B=6.4, 2.9, 1.05, respectively, p<0.01), when controlled for all other variables in the model [(F=77.6, p<0.001), 72% (R-square)]. There was borderline significant association with the higher number of DMARDs and TNFi used (p=0.09, 0.08, respectively). Moreover, on multiple linear regression analysis, the erosions, extent of joint involvement (oligoarthritis/polyarthritis), number of TNFi used and the CCI were most significantly associated with Ca-ESR (unstandardised coefficient B=3.8, 1.8, 1.8, 0.76, respectively) when controlled for all other variables in the model [(F=130, p<0.001), 77% (R-square)].

**Conclusions:** PsA is a heterogeneous disease with <50% of patients developing radiographic damage. Elevated inflammatory markers, CRP and ESR, can help identify patients with a severe PsA phenotype. Such patients experience more radiographic damage, they have more comorbidities and their disease is more resistant to DMARDs and TNFi.

THU0322

#### SECUKINUMAB PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE PSORIATIC ARTHRITIS: 3-YEAR RESULTS FROM THE PHASE 3 FUTURE 2 STUDY

<sup>1</sup>P. Nash, I.B. McInnes<sup>2</sup>, P. Rahman<sup>3</sup>, A.B. Gottlieb<sup>4</sup>, B. Kirkham<sup>5</sup>, K. Ding<sup>6</sup>, L. Pricop<sup>7</sup>, on behalf of the FUTURE 2 study group. <sup>1</sup>University of Queensland, Brisbane, Australia; <sup>2</sup>University of Glasgow, Glasgow, UK; <sup>3</sup>Memorial University, St. John's, Canada; <sup>4</sup>New York Medical College, New York, USA; <sup>5</sup>Guy's and St Thomas' NHS Foundation Trust, London, UK; <sup>6</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA

**Background:** Secukinumab, a fully human monoclonal antibody that selectively neutralises IL-17A, provided significant and sustained improvement in the signs and symptoms of active psoriatic arthritis (PsA) over 2 years in the FUTURE 2 study (NCT01752634).<sup>1</sup>

**Objectives:** To report 3 year efficacy and safety results from the FUTURE 2 study.

**Methods:** Overall, 397 patients (pts) with active PsA were randomised to receive subcutaneous secukinumab (300, 150 or 75 mg) or placebo at baseline, Weeks (Wks) 1, 2, 3 and 4, and every 4 wks thereafter.<sup>1</sup> Assessments at Wk 156 are from pts originally randomised to secukinumab and included ACR20/50, PASI 75, HAQ-DI, and resolution of dactylitis and enthesitis. Analyses by prior anti-TNF use (naïve/inadequate response [IR]) and with/without concomitant methotrexate (MTX) were assessed. Data are reported as observed for secukinumab 300 and 150 mg (approved doses). Safety analysis included all pts who received ≥1 dose of secukinumab.

**Results:** In total, 73/100 (73.0%) and 72/100 (72.0%) pts in the secukinumab 300 and 150 mg groups, respectively, completed 156 wks of treatment. Sustained clinical improvements were observed in those continuing with secukinumab across all endpoints through Wk 156 (table 1). ACR20 response rates at Wk 156 in anti-TNF-naïve pts were 85.2% and 76.5% with secukinumab 300 and 150 mg respectively; corresponding rates in anti-TNF-IR pts were 55.6% and 54.5%. ACR20 response rates in pts receiving concomitant MTX were 73.0% and 77.1% with secukinumab 300 and 150 mg, respectively; rates in pts without concomitant MTX use were 77.3% and 63.2%. Over the study (mean secukinumab exposure of 991.3 days) the type, incidence and severity of adverse events (AEs) were consistent with that reported previously. Exposure adjusted incidence rates with secukinumab for selected AEs of interest were: serious infections (1.8), candida infections (1.8), inflammatory bowel disease (0.1), major adverse cardiovascular event (0.2) and malignant/unspecified tumours (1.2).

**Abstract THU0322 – Table 1.** Summary of Efficacy Results at Wk 156

Variable % responders (n), unless stated	Secukinumab 300 mg s.c. (n=100)	Secukinumab 150 mg s.c. (n=100) <sup>†</sup>
ACR20	75.3 (81)	69.9 (73)
ACR50	54.3 (81)	38.4 (73)
<sup>a</sup> PASI 75	74.3 (35)	81.8 (44)
HAQ-DI, mean change from BL (n)	-0.63 (81)	-0.47 (74)
<sup>b</sup> Resolution of enthesitis	68.9 (45)	70.8 (48)
<sup>c</sup> Resolution of dactylitis	82.1 (39)	80.0 (25)

<sup>a</sup>PASI responses assessed in pts with psoriasis affecting ≥3% body surface area at BL (300 mg: n=41; 150 mg: n=58)

<sup>b</sup>Assessed in pts (n=56 [300 mg] and 64 [150 mg]) with this symptom at BL

<sup>c</sup>Assessed in pts (n=46 [300 mg] and 32 [150 mg]) with this symptom at BL

<sup>†</sup>Secukinumab 150 mg arm includes 42 pts who were up-titrated to 300 mg starting at Wk 128

BL, baseline; HAQ-DI, health assessment questionnaire-disability index; PASI, psoriasis area and severity index

N, number of pts randomised; n, number of pts with evaluation

**Conclusions:** Secukinumab 300 and 150 mg provided sustained improvements in signs and symptoms of active PsA through 3 years. Secukinumab was well tolerated, with a safety profile consistent with that reported previously.<sup>1</sup>

THU0323

#### TOFACITINIB IMPROVES COMPOSITE ENDPOINT MEASURES OF DISEASE IN PATIENTS WITH PSORIATIC ARTHRITIS

<sup>1</sup>P. Helliwell<sup>1</sup>, L.C. Coates<sup>2</sup>, O. FitzGerald<sup>3</sup>, P. Nash<sup>4</sup>, E.R. Soriano<sup>5</sup>, M.E. Husni<sup>6</sup>, M.-A. Hsu<sup>7</sup>, K.S. Kanik<sup>7</sup>, T. Hendrikx<sup>8</sup>, J. Wu<sup>7</sup>, E. Kudlacz<sup>7</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds; <sup>2</sup>University of Oxford, Oxford, UK; <sup>3</sup>St Vincent's University Hospital, Dublin, Ireland; <sup>4</sup>University of Queensland, St Lucia, Brisbane, Australia; <sup>5</sup>Hospital Italiano de Buenos Aires, Buenos Aires, Argentina; <sup>6</sup>Cleveland Clinic Orthopedic and Rheumatologic Institute, Cleveland, OH; <sup>7</sup>Pfizer Inc, Groton, CT; <sup>8</sup>Pfizer Inc, Collegeville, PA, USA

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA). PsA is a heterogeneous disease and composite endpoints allow assessment of multiple clinical outcomes in one instrument.

**Objectives:** To examine the effects of tofacitinib treatment on several composite endpoints in patients (pts) with PsA.

**Methods:** In 2 placebo (PBO)-controlled, double-blind, multicentre, global Phase 3 studies, pts had active PsA and either had an inadequate response (IR) to ≥1 conventional synthetic disease-modifying antirheumatic drug (csDMARD) and were tumour necrosis factor inhibitor (TNFi)-naïve (OPAL Broaden [n=422;

12 months; NCT01877668]), or had an IR to  $\geq 1$  TNFi (OPAL Beyond [n=394; 6 months; NCT01882439]). Pts were randomised to receive tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks (OPAL Broaden only) or PBO (advancing to tofacitinib 5 or 10 mg BID at Month 3, OPAL Broaden and OPAL Beyond), in addition to continuing on a single, stable csDMARD. Composite endpoints assessed: Psoriatic Arthritis Disease Activity Score (PASDAS), Disease Activity Score using 28 joints with C-reactive protein, Disease Activity Index for Reactive Arthritis/Psoriatic Arthritis (DAREA/DAPSA) and Composite Psoriatic Disease Activity Index (CPDAI).

**Results:** Demographics and baseline disease characteristics were generally similar between treatment groups within the 2 studies, except for duration of PsA disease (longer in OPAL Beyond) and geographic distribution (OPAL Broaden having more Eastern EU pts). Baseline values for composite endpoints were generally similar across treatment groups and studies (table 1). Both doses of tofacitinib showed improvements in composite endpoints vs PBO at Month 3 in both studies (table 1). In OPAL Broaden, the effects of adalimumab were similar to both doses of tofacitinib across composite endpoints. Effect size for the composite endpoints (using a subpopulation of pts who had all available data for all endpoints) was highest for PASDAS and typically lowest for DAREA/DAPSA; this rank order of effect size was similar across treatment arms and studies. At Month 3, effect sizes in pts receiving active treatment ranged from 0.90 (DAREA/DAPSA for tofacitinib 5 mg BID) to 2.40 (PASDAS for tofacitinib 10 mg BID) in OPAL Broaden, and 0.81 (DAREA/DAPSA for tofacitinib 5 mg BID) to 1.84 (PASDAS for tofacitinib 10 mg BID) in OPAL Beyond (table 1). Standardised response means generally followed the same pattern as effect size across studies with both doses of tofacitinib (table 1).

**Abstract THU0323 – Table 1.** Summary of mean at baseline, LS mean change from baseline, effect size and standardised response mean at Month 3 for composite endpoints (PASDAS, DAS28-3(CRP), DAREA/DAPSA, CPDAI) in OPAL Broaden and OPAL Beyond studies

CPDAI	0.89	1.27	1.11	0.80	1.11	1.49	0.63

**Conclusions:** In 2 Phase 3 studies, tofacitinib 5 mg and 10 mg BID improved composite endpoint scores vs PBO over 3 months in pts with PsA. The largest effect size and standardised response means were observed for PASDAS. Effect sizes and standardised response means varied across endpoints but were consistent across studies.

**THU0324 DISEASE ACTIVITY AND PATIENT CHARACTERISTICS BY COMORBIDITY AMONG PSORIATIC ARTHRITIS (PSA) PATIENTS IN A US REGISTRY**

<sup>1</sup>P.J. Mease, H.J. Litman<sup>2</sup>, N.A. Accortt<sup>3</sup>, S. Rebello<sup>2</sup>, J.D. Greenberg<sup>4</sup>, H. Feng<sup>2</sup>, M.M. Gharaibeh<sup>3</sup>, G.A. Aras<sup>3</sup>, D.H. Collier<sup>3</sup>. <sup>1</sup>Swedish Medical Center and University of Washington, Seattle WA; <sup>2</sup>Corrona LLC, Waltham MA; <sup>3</sup>Amgen Inc., Thousand Oaks CA; <sup>4</sup>New York University, New York NY, USA

**Background:** PsA patients have greater prevalence of cardiovascular disease (CVD), metabolic syndrome (MetS), and cancer than patients without PsA.

**Objectives:** To examine patient characteristics and disease activity by comorbidity profile among PsA patients.

**Methods:** This analysis included adults with PsA enrolled in the US Corrona PsA/spondyloarthritis Registry from March 2013-March 2017 and followed for  $\geq 6$  months. Prevalence (at registry entry) and incidence rate (time to new events after registry entry) of CVD, MetS, and cancer were determined. Patient characteristics and disease activity were described by prevalent comorbidity, with t-tests for means despite skewed data and chi-squared tests for percentages.

**Results:** The analysis included 1493 patients and 3564 patient-years of follow-up. Incidences (95% confidence interval) per 1000 patient-years were 9.4 (6.5–13.5), 1.0 (0.3–3.1), and 11.4 (8.2–15.8) for CVD, MetS, and cancer (6.8 [4.5–10.2] nonmelanoma skin cancer), respectively. PsA patients with (vs without) prevalent CVD, MetS, or cancer were older, and fewer had full-time jobs or private insurance. Patients with (vs without) CVD had higher swollen joint count and mean body surface area, and tended to have higher rates of obesity. Patients with (vs without) MetS tended to have greater disease activity. Patients with (vs without) comorbidities reported less disease activity on patient global assessment. Data are mean or %

$\geq 3$  of 4 conditions: hypertension, hyperlipidemia, diabetes mellitus, or obesity  
<sup>b</sup>P value across all categories for employment or body mass index

**Conclusions:** PsA patients with (vs without) CVD had greater disease activity and those with (vs without) MetS tended to have greater disease activity by physician-derived measures, but PsA patients with (vs without) CVD or MetS reported lower global assessment of disease activity. Patient perception of PsA may mask the effect of comorbid CVD or MetS on disease activity.

THU0325

**SECUKINUMAB DEMONSTRATES A CONSISTENT SAFETY PROFILE WITH UP TO 5 YEARS TREATMENT IN PATIENTS WITH PSORIATIC ARTHRITIS AND MODERATE TO SEVERE PLAQUE PSORIASIS: UPDATED POOLED SAFETY ANALYSES**

<sup>1</sup>P.J. Mease, I.B. McInnes<sup>2</sup>, K. Reich<sup>3</sup>, P. Nash<sup>4</sup>, A. Widmer<sup>5</sup>, K. Abrams<sup>6</sup>, L. Pricop<sup>7</sup>, T. Fox<sup>5</sup>. <sup>1</sup>Swedish Medical Center and University of Washington, Seattle, USA; <sup>2</sup>University of Glasgow, Glasgow, UK; <sup>3</sup>Dermatologikum Hamburg and Georg-August-University Göttingen, Hamburg, Germany; <sup>4</sup>University of Queensland, St Lucia, Australia; <sup>5</sup>Novartis Pharma AG, Basel, Switzerland; <sup>6</sup>Novartis Pharmaceuticals Corp.; <sup>7</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA

**Background:** Pooled safety data from secukinumab (SEC) studies in psoriasis and psoriatic arthritis (PsA) have been reported previously.<sup>1</sup>

**Objectives:** To report updated longer-term safety data with up to 5 years of SEC treatment from psoriasis and PsA studies.

**Methods:** The moderate to severe plaque psoriasis and active PsA data pool consisted of 15 and 3 Phase III studies, respectively. Different SEC doses in the studies included intravenous (up to 10 mg/kg) or subcutaneous (s.c.; 75–300 mg) loading, followed by s.c. maintenance dosing (300, 150 or 75 mg). Placebo patients were re-randomised to SEC at 12–24 weeks depending on study design. Adverse events (AEs) were reported as exposure adjusted incident rates (EAIR) per 100 patient-years and analyses included all patients who received ≥1 dose of SEC.

**Results:** A total of 5181 and 1380 patients from psoriasis and PsA studies representing an exposure of 10416.9 and 3866.9 patient years, respectively, were included in this study. The most frequently reported AE was viral upper respiratory tract infection (table 1). EAIRs for serious infections, *Candida* infections, inflammatory bowel disease (IBD) and major adverse cardiac events (MACE) were low and similar in both psoriasis and PsA indications (table 1). No cases of tuberculosis were reported.

**Abstract THU0325 – Table 1.** Summary of Secukinumab Safety across Psoriasis and PsA studies: Entire Safety Period

	Psoriasis Any secukinumab n=5181	PsA Any secukinumab n=1380
Total exposure, patient-years	10416.9	3866.9
Min–max exposure (days)	1–1825	8–1827
Exposure (days), mean (SD)	734.4 (562.9)	1023.5 (472.3)
Death, n (%)	9 (0.2)	11 (0.8)
<b>EAIR per 100 Patient-years (95% CI)</b>		
Any AE	204.4 (198.4, 210.5)	147.0 (138.9, 155.5)
Any serious AE	6.9 (6.3, 7.4)	7.9 (7.0–8.9)
<b>Most Common AEs<sup>1</sup></b>		
Viral upper respiratory tract infection	21.0 (19.9–22.0)	12.1 (10.9–13.4)
Headache	6.2 (5.8, 6.8)	3.8 (3.2, 4.5)

Upper respiratory tract infection	5.4 (4.9, 5.9)	9.1 (8.1, 10.2)
<b>AEs of Selected Interest</b>		
Serious infections <sup>2</sup>	1.4 (1.2, 1.6)	1.9 (1.5, 2.4)
<i>Candida</i> infections <sup>3</sup>	2.2 (1.9, 2.5)	1.5 (1.1, 2.0)
IBD <sup>4</sup>	0.01 (0.0–0.05)	0.05 (0.01–0.19)
Crohn's disease <sup>4</sup>	0.05 (0.02–0.11)	0.08 (0.02–0.23)
Ulcerative colitis <sup>4</sup>	0.13 (0.07–0.23)	0.08 (0.02–0.23)
MACE <sup>5</sup>	0.3 (0.2, 0.5)	0.4 (0.3–0.7)

<sup>1</sup>AEs in the SEC group that occurred with an EAIR of ≥5 during the entire safety period in either of the pooled groups; <sup>2</sup>Rates are for system organ class; <sup>3</sup>Rates are for high level term; <sup>4</sup>Rates are for PT (IBD PT data are reported for unspecified IBD); <sup>5</sup>Rates are for Novartis MedDRA Query term; EAIR, exposure adjusted incidence rate per 100 patient-years; N, number of patients in the analysis; SD, standard deviation

**Conclusions:** SEC demonstrated a favourable safety profile during long-term treatment (up to 5 years) in patients with moderate to severe plaque psoriasis or PsA, hence, supporting long-term use. The safety profile was consistent with previous reports and comparable across psoriasis and PsA patients.

**THU0326 DISCONTINUATION AND SWITCHING PATTERNS OF TUMOUR NECROSIS FACTOR INHIBITOR (TNFI) THERAPY IN TNFI-NAIVE AND TNFI-EXPERIENCED PATIENTS WITH PSORIATIC ARTHRITIS IN THE US CORRONA PSORIATIC ARTHRITIS/ SPONDYLOARTHRTIS (PSA/SPA) REGISTRY**

<sup>1</sup>P. Mease, M. Liu<sup>2</sup>, B. Gershenson<sup>3</sup>, P. Hur<sup>4</sup>, J. Greenberg<sup>5</sup>. <sup>1</sup>Swedish Medical Center and University of Washington, Seattle; <sup>2</sup>Corrona, LLC, Waltham; <sup>3</sup>University of Massachusetts Medical School, Worcester; <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover; <sup>5</sup>New York University School of Medicine, New York, USA

**Background:** To better inform treatment decisions for patients with psoriatic arthritis (PsA), it is important to understand outcomes in patients who initiate a first line vs a subsequent line of TNFi therapy. Limited studies have evaluated persistence and switching of TNFi therapy in TNFi-naive vs TNFi-experienced US patients with PsA.

**Objectives:** To examine discontinuation and switching of TNFis in TNFi-naive and -experienced patients with PsA in the US Corrona PsA/SpA Registry.

**Methods:** All patients aged ≥18 years in the Corrona PsA/SpA Registry who were diagnosed with PsA, initiated a TNFi (index therapy) between March 2013 and , January 2017 and had ≥1 follow-up visit after TNFi initiation were included. Patients were stratified by prior TNFi use (TNFi naive: no prior TNFi or other biologic; TNFi experienced: ≥1 prior TNFi). Patient demographics and clinical and disease characteristics were assessed at the time of TNFi initiation (baseline). Time to discontinuation of the index TNFi (with or without switching) and time to switch to another biologic were assessed by Kaplan-Meier analysis. Log-rank tests were used to assess differences in persistence and switching between the TNFi-naive and -experienced cohorts. Provider-reported reasons for discontinuation of the index TNFi were summarised descriptively.

**Results:** 318 patients with PsA were included (TNFi naive, n=171; TNFi experienced, n=147), with a total follow-up of 579.2 person-years. Experienced patients had a longer mean (SD) disease duration (13.3 [10.0] vs 9.5 [9.7] years; p<0.01) and a higher proportion had a history of prednisone use (27.9% vs 17.5%; p=0.03) compared with naive patients. A total of 75 naive (43.9%) and 80 experienced patients (54.4%) discontinued their index TNFi, including 33 (19.3%) and 48 (32.7%), respectively, who switched to a new biologic. The median (95% CI) time to discontinuation of the index TNFi in naive vs experienced patients was 27 (22 to 33) vs 20 (18 to 28) months, respectively (figure 1). Among those who discontinued their TNFi, the mean (SD) time to discontinuation was 14.5 (8.0) months in naive patients vs 14.0 (8.9) months in experienced patients. Due to the low number of switching events, the median time to switch of the index TNFi could not be estimated. Among those who switched to a new biologic, the mean (SD) time to switch was 16.0 (8.1) vs 13.5 (7.5) months in naive and experienced patients, respectively. TNFi-naive patients had greater persistence with their index TNFi (p=0.03) and were less likely to switch to another biologic (p=0.002) compared with TNFi-experienced patients. Provider-reported reasons for discontinuation included lack of effect (naive, 71%; experienced, 62%), side effects (10%; 23%), social reasons (6%; 3%), doing well (3%; 0%), and other (10%; 12%).

**Abstract THU0326 – Figure 1.** Time to Discontinuation (With or Without Switching) and Time to Switch of Index TNFi in TNFi-Naive and TNFi-Experienced Patients With PsA. PsA, psoriatic arthritis; TNFi, tumour necrosis factor inhibitor.

**Conclusions:** In this real-world analysis of US patients with PsA, TNFi-experienced patients were more likely to discontinue and switch their index TNFi and had a shorter time to discontinuation compared with TNFi-naive patients. These results may help inform treatment decisions when selecting later lines of TNFi therapy in patients with PsA.

**THU0327 REAL WORLD (RW) EXPERIENCE WITH AN ANTI-IL-17A INHIBITOR IN BIOLOGIC NAÏVE AND BIOLOGIC EXPERIENCED PSORIATIC ARTHRITIS (PSA) PATIENTS**

<sup>1</sup>B. Moon, J. Hill<sup>2</sup>, N. Booth<sup>1</sup>, S. Lobosco<sup>1</sup>. <sup>1</sup>Adelphi Real World, Macclesfield, UK; <sup>2</sup>Eli Lilly and Company, Indianapolis, USA

**Background:** Two IL-17A inhibitors are approved for the treatment of PsA, ixekizumab and secukinumab. At the time of this survey, real world evidence was only available for secukinumab, which was approved for PsA in 2016 in EU, Australia and Switzerland. Secukinumab label dose for PsA patients with either concomitant moderate to severe plaque psoriasis or anti-TNFα inadequate responders is 300 mg. For other patients, the recommended dose is 150 mg. All patients receive a loading dose regimen by S.C. injection at Weeks 0, 1, 2, 3 and 4, followed by monthly maintenance dose. Little data are published on the RW utilisation of secukinumab in PsA.

**Objectives:** Describe RW dose utilisation of an anti-IL-17A inhibitor, among biologic naïve and biologic experienced PsA patients.

**Methods:** Data from a chart review study conducted in 2017 across France, Germany, Italy, Spain, UK, Australia and Switzerland where secukinumab is reimbursed were used. Specialists were recruited by field-based interviewers, and provided information on demographics, Body Surface Area (BSA), time since diagnosis and treatment for their adult PsA patients currently receiving secukinumab.

**Results:** 212 rheumatologists, 89 dermatologists, 1 orthopedist provided data for 1451 patients. Mean age 50.6 years, 47% female, mean time since PsA diagnosis 5.9 years and 86% had concomitant psoriasis. 96% received prior csDMARD(s) and 8% prior apremilast. 29% (425) were biologic naïve and 71% (1024) biologic experienced (limited differences between specialists: 74% rheumatologists; 63% dermatologists). 34%, 24%, and 13% received, 1, 2, and 3+prior biologics respectively.

Among biologic naïve patients on 150 mg, 36% (52/145) had a BSA ≥10%, where the recommended dose is 300 mg at secukinumab initiation. 29% (274/930) of biologic experienced patients received secukinumab at 150 mg, not the recommended 300 mg dose (figure 1)

**Abstract THU0327 – Figure 1.** Secukinumab Dosing: Current Dose (Loading or Maintenance). \*For this analysis, moderate to severe psoriasis was defined as BSA ≥10

**Conclusions:** In the RW, secukinumab is prescribed mainly in biologic experienced patients (71%) and is not universally prescribed at the recommended dose for PsA. Specifically, of those who are biologic naïve (29%), 36% of patients on 150 mg had moderate to severe psoriasis, which is outside the recommended dose. Further RW experience is needed for ixekizumab.

#### THU0328 MIR-499 POLYMORPHISM IS ASSOCIATED WITH SUSCEPTIBILITY TO PSORIATIC ARTHRITIS – PRELIMINARY STUDY

<sup>1</sup>R. Sokolik, J. Swierkot<sup>1</sup>, M. Iwaszko<sup>2</sup>, M. Kozłowski<sup>2</sup>, L. Korman<sup>1</sup>, P. Wiland<sup>1</sup>, K. Bogunia-Kubik<sup>2</sup>, <sup>1</sup>Department of Rheumatology and Internal Medicine, Medical University, <sup>2</sup>Laboratory of Clinical Immunogenetics and Pharmacogenetics, Hirsfeld Institute of Immunology and Experimental Therapy, Polish Academy of Sciences, Wrocław, Poland

**Background:** Polymorphism within the miR-499 has been reported to be associated with susceptibility to rheumatoid arthritis (RA) in various populations.

**Objectives:** Our study aimed to find out whether similar association could be observed also in Polish population in both RA and psoriatic arthritis (PsA) patients.

**Methods:** For this purpose 359 individuals were studied, including 111 RA patients, 86 patients with PsA and 162 healthy blood donors that served as a control group.

Genotyping for miR-499 rs3746444 T/C was performed using a LightSNIP assay. **Results:** Distribution of the miRNA-499 alleles and genotypes was similar in RA patients and controls. Among RA patients those carrying the CC homozygous genotype presented with lower DAS28 at diagnosis (0.027) but higher CRP levels after 12 weeks of anti-TNF treatment (p=0.042).

Interestingly, the TT genotype (rs3746444) was overexpressed in patients with PsA as compared to controls (OR=1.85, p=0.034) but its frequency was not significantly different when compared to RA cases. This polymorphism was also not found to be associated with clinical parameters in PsA patients.

**Conclusions:** These results show that miR-499 rs3746444 T/C polymorphism may constitute a risk factor for psoriatic arthritis development.

#### THU0329 AN ITALIAN OBSERVATIONAL PROSPECTIVE STUDY ON PREDICTORS OF CLINICAL RESPONSE TO GOLIMUMAB AT 6 MONTHS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

<sup>1</sup>B. Scrivero, A. Giardino<sup>2</sup>, C. Salvarani<sup>3</sup>, R. Foti<sup>4</sup>, A. Afeltra<sup>5</sup>, O. Viapiana<sup>6</sup>, F. Salaffi<sup>7</sup>, F. Iannone<sup>8</sup>, on behalf of the Predicting MDA in PsA Study Group. <sup>1</sup>Medicina Interna e Specialità Mediche, Sapienza Università di Roma; <sup>2</sup>MSD Italia S.r.l., Rome; <sup>3</sup>University of Modena and Reggio Emilia, Reggio Emilia; <sup>4</sup>A.O.U. Policlinico V. Emanuele, Catania; <sup>5</sup>Campus Bio-Medico, Rome; <sup>6</sup>University of Verona, Verona; <sup>7</sup>Politecnica University of Marche, Jesi; <sup>8</sup>University of Bari, Bari, Italy

**Background:** The identification of markers of response to biologic agents in the treatment of active psoriatic arthritis (PsA) may help in predicting the outcome and hence in optimising therapy.

**Objectives:** To evaluate the ability of a panel of candidate factors to predict the clinical response, defined as the achievement of minimal disease activity (MDA) following 6 month therapy with golimumab.

**Methods:** This Italian 6 month observational study included 149 PsA patients (53.7% males, mean age 49 years (SD 11) inadequate responders to conventional therapies who started the anti-tumour necrosis factor- $\alpha$  golimumab. Estimated factors included demographic data and baseline characteristics of the disease, measures of disease activity and functional disability, and biomarkers.

**Results:** At 6 months, a high rate of treatment persistency (80%) was observed. MDA was achieved in 44.3% of patients. Multivariate analysis showed Disease Activity in Psoriatic Arthritis (DAPSA) score, high-sensitivity C-reactive protein (hs-CRP), age, and disease duration as baseline factors correlating with MDA achievement at 6 months (table 1). A higher hs-CRP value and the absence of comorbidities were predictive factors for MDA at 6 months in biomarker-enhanced prediction models.

Golimumab was effective in improving disease and functional parameters and was well tolerated.

**Conclusions:** The availability of predictive factors of treatment response identified in this study may be helpful in driving the selection of PsA patients that are most likely to benefit of the therapy with golimumab.

#### THU0330 OBESITY IN PSORIATIC ARTHRITIS: COMPARATIVE PREVALENCE WITH SKIN PSORIASIS AND ASSOCIATED FACTORS

R. Queiro, A. Lorenzo, E. Pardo, A. Brandy, S. Alonso, M. Alperi, L. Arboleya, J. Ballina. Rheumatology, Hospital Universitario Central De Asturias, Oviedo, Spain

**Background:** Obesity (BMI  $\geq 30$  kg/m<sup>2</sup>) is a common cardiovascular risk factor in psoriatic disease<sup>1</sup>. Although the prevalence of obesity is high, the factors associated with it in psoriatic arthritis (PsA) are poorly understood.

**Objectives:** We aimed to evaluate the prevalence and obesity-associated factors in patients with PsA.

**Methods:** Retrospective cross-sectional study that included 205 consecutive patients with PsA according to CASPAR criteria. The prevalence of obesity was compared with that of 310 patients with skin psoriasis of similar age ( $\pm 3$  years). The factors associated with obesity were first analysed by a conditional logistic regression. The significant factors in this first model were then introduced in a multivariate model using a backward step approach (p-values < 0.05 were considered significant).

**Results:** One-hundred twelve men and 94 women were included, with a mean age of 53  $\pm$  13 years. Obesity was more prevalent among psoriatics (36.5%) compared to PsA patients (24%), OR 1.6 (1.1–2.3), p < 0.05. The factors associated with obesity in the univariate analysis (p < 0.05) were: onset of psoriasis > 40 years (OR 2.4), onset of arthritis > 40 years (OR 2.1), PsA family history (OR 3.1), polyarticular presentation (OR 1.9), axial presentation (OR 2.5), polyarticular evolution (OR 2.4), axial evolution (OR 4.2), diabetes (OR 3.6), HBP (OR 3.9), and dyslipidemia (OR 3.5). After correcting for age, sex, disease duration and other confounders, independent associations with obesity found in the multivariate model (p < 0.05) were: PsA family history (OR 3.6, IC95%: 1.1–14.4), axial evolution (OR 4.4, IC95%: 1.0–22.4) and dyslipidemia (OR 3.5, IC95%: 1.5–8.6).

Used model	Parameter	Item considered	Odds Ratio	95% confidence interval	P value
Univariate logistic model (ULM)	Gender	Female	0.3197	0.1531–0.6677	0.0024
		Continuous	0.9570	0.9252–0.9899	0.0109
	Baseline DAPSA score	Continuous	0.9287	0.8967–0.9618	<0.0001
	Baseline HAQ total score	Continuous	0.2937	0.1423–0.6063	0.0009
	Baseline Pain	Continuous	0.9833	0.9684–0.9984	0.0299
	Baseline BASDAI	Continuous	0.7036	0.5733–0.8635	0.0008
Multivariate logistic model (MLM)	Comorbidities	Presence	0.3258	0.1465–0.7241	0.0059
		Continuous	0.9542	0.9112–0.9993	0.0465
	Age	Continuous	1.0015	1.0002–1.0028	0.0241
	Baseline hs-CRP	Continuous	0.9255	0.8879–0.9647	0.0003
	Baseline DAPSA score	Continuous	1.0057	1.0007–1.0107	0.0260
	Disease duration	Continuous	1.0688	1.008–1.1334	0.0261
Biomarker-enhanced ULM	Baseline hs-CRP	Continuous	1.0688	1.008–1.1334	0.0261
Biomarker-enhanced MLM	Comorbidities	Presence	0.2645	0.0881–0.7941	0.0177
		Baseline DAPSA score	Continuous	0.9231	0.8850–0.9628

**Conclusions:** Obesity was more common among our patients with cutaneous psoriasis than in those with arthritis. The model that best explains obesity in this PsA series combines genetic factors (PsA family history), together with factors specific to the metabolic syndrome (dyslipidemia), with others owned to arthritis (axial evolution).

**THU0331 RELATIONSHIP BETWEEN THE NAIL ULTRASONOGRAPHIC EVALUATIONS AND CLINICAL FEATURES IN PATIENTS WITH PSORIATIC ARTHRITIS**

S. Acer, H.S. Baklacioğlu, D. Erdem, M.T. Duruöz. *Physical Treatment and Rehabilitation Department, Rheumatology Division, Marmara University, Istanbul, Turkey*

**Background:** Nail ultrasonography (US) is a favourable visualisation method to evaluate the subunits of the nail. Little is known about the relation between the properties of nail structures and the clinical characteristics of patients with psoriatic arthritis (PsA).<sup>1</sup>

**Objectives:** To show the relationship between the clinical features and ultrasonographic evaluations of the nail in patients with PsA.

**Methods:** Patients with PsA according to the CASPAR criteria were recruited into the study. All of the hand nails and toenails were examined by grayscale and power Doppler techniques. The relations between the characteristics of the patients and the sonographic findings of the nail structures were assessed. Concerning to patient characteristics, subtypes of PsA, gender, age, height, BMI, working status, smoking, PsA duration, psoriasis duration, history of dactylitis, history of uveitis, number of tender and swollen joints, Maastricht Ankylosing Spondylitis Enthesitis Score, CRP, disease activity, haemoglobin, sacroiliitis, inspectional nail involvement (INI), Nail Psoriasis Severity Index (NAPSI), PASI, HAQ, quality of life, and the biologic treatment were recorded. The nail plate thickness (NPT), number of nails with trilaminar irregularity (NTI), nail bed thickness (NBT), and the doppler activity score (DAS) were recorded as the sonographic nail findings. The Kruskal Wallis analysis, Spearman's correlation, and Man Whitney U tests were used in statistical analysis. p<0.05 was accepted as significant.

**Results:** 63 patients (756 nails) were evaluated. Among the PsA subtypes, 38% of patients were asymmetrical oligoarticular arthritis, 38% were symmetrical polyarthritis, 7.9% distal interphalangeal arthropathy, and 15.8% predominant spondylitis. All of the ultrasonographic nail parameters were independent of the PsA subtypes (p>0.05). The mean of NPT was higher in males and correlated with age, height, and the haemoglobin levels. The NTI score was higher in patients with INI and correlated with the NAPSI score. The mean of NBT was only correlated with the haemoglobin levels. The DAS was higher in workers and correlated with age and the NAPSI score. The other clinical parameters were not associated with the sonographic findings.

**Abstract THU0331 – Table 1.** Relationships between the patients' characteristics and the ultrasonographic parameters\*

US nail parameters	Gender	Worker	INI	Age	Height	NAPSI	Hemoglobin
NPT (mm)	p=0.002			p=0.001 rho:0.396	p=0.021 rho:0.290		p=0.021 rho:0.292
NTI (0-12)			p<0.0001			p<0.0001 rho:0.668	
NBT (mm)							p=0.012 rho:0.316
DAS (0-48)		p=0.042		p=0.001 rho:-0.407		p=0.006 rho:0.344	

(US: ultrasonography, INI: inspectional nail involvement, NAPSI: nail psoriasis severity index, NPT: nail plate thickness, NTI: nails with trilaminar irregularity, NBT: nail bed thickness, DAS: doppler activity score. \*Only parameters which have statistical significant relations by Mann Whitney U test and Spearman's correlation)

**Conclusions:** The ultrasonographic findings of the nail structures were determined in PsA. These findings did not differ among the subtypes of the disease. Although the sonographic nail findings were not associated with the most of the clinical parameters; they had significant relations with some demographics, inspectional nail involvements, and haemoglobin levels in PsA.

**THU0332 FATIGUE REMAINS A DOMINANT SYMPTOM DESPITE TUMOUR NECROSIS FACTOR INHIBITOR THERAPY IN PSORIATIC ARTHRITIS: A POPULATION-BASED COHORT STUDY**

T.S. Jørgensen, M. Skougaard<sup>1</sup>, C. Ballegaard<sup>1</sup>, P. Mease<sup>2</sup>, V. Strand<sup>3</sup>, L. Dreyer<sup>4</sup>, L.E. Kristensen<sup>1</sup>. <sup>1</sup>The Parker Institute, Copenhagen University Hospital, Bispebjerg and Frederiksberg, Copenhagen F, Denmark; <sup>2</sup>Swedish Medical Center and University of Washington, Seattle; <sup>3</sup>Division Immunology/Rheumatology, Stanford University, Palo Alto, USA; <sup>4</sup>Center for Rheumatology and Spine Diseases, Rigshospitalet-Genotofte, Copenhagen, Denmark

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disorder associated with fatigue, pain and impaired function. Tumour necrosis factor inhibitor (TNFi) therapy fails among half of patients with PsA treated in routine care.

**Objectives:** The objective of this population-based cohort study was to investigate the association of fatigue with disease activity and adherence to therapy in PsA patients receiving their first TNFi.

**Methods:** Data on patient characteristics, disease activity and treatment adherence were obtained from the DANBIO register. Information on comorbidities according to the Charlson Comorbidity Index (CCI) and psychiatric comorbidities was obtained through linkage with the Danish National Patient Register. We performed Kaplan-Meier plots and univariate Cox proportional hazard regression analysis. Percentages of patients achieving relevant clinical responses were calculated.

**Results:** From 2006 thru 2016, we identified 880 patients eligible for analyses. Patients with upper median fatigue scores had statistically significantly higher disease activity measures, higher pain and HAQ scores, more comorbidities and current smoking status at baseline compared with patients with lower median fatigue scores (table 1). After treatment initiation the mean VAS fatigue score decreased from 62 mm (SD 25) to 44 mm (SD 30) at six months (p<0.001). Kaplan-Meier curves showed shorter adherence to treatment in patients with higher baseline fatigue scores compared with patients with lower fatigue scores (HR 1.43 [1.2 to 1.7], p<0.001) (figure 1). ACR20, 50 and 70 responses at six months were 49%, 35% and 18% respectively. VASfatigue20, 50 and 70 responses were 57%, 39% and 20%, respectively. The kappa value between ACR20, 50, 70 and VASfatigue responses were 0.37, 0.40 and 0.48 (p<0.001), respectively.

**Abstract THU0332 – Table 1.** Baseline characteristics according to median fatigue stratification

	Lower median VAS fatigue (n=430)	Upper median VAS fatigue (n=450)	p value
Age, years	47.8 (39.4–57.3)	49.0 (40.0–56.1)	p=0.905
Male gender	51%	40%	p<0.001
DAS28-CRP (0–10)	4.0 (3.2–3.7)	4.8 (3.9–5.5)	p<0.001
HAQ score (0–3)	0.75 (0.38–1.13)	1.38 (0.88–1.75)	p<0.001
VAS patient pain (0–100)	45 (29–62)	74 (63–84)	p<0.001
BMI	26.8 (23.7–30.7)	27.7 (24.3–31.2)	p=0.118
Current smoking	28%	36%	p=0.034
Comorbidities (%)	66%	61%	p=0.049
CCI=0	27%	27%	
CCI=1	7%	12%	
CCI≥2			
Depression treated in hospital, n (%)	18 (4.2)	31 (6.8)	p=0.105

Values are the mean and SD except where stated otherwise. Comparisons were assessed by X<sup>2</sup>/Mann-Whitney test. Lower median fatigue <64 mm, higher median fatigue ≥64 mm

**Conclusions:** Fatigue remains a dominating symptom after TNFi treatment, and is associated with higher baseline disease activity, more comorbidities, smoking, higher pain and HAQ scores, and increased risk of TNFi treatment discontinuation in a cohort of Danish patients with PsA. The agreement between ACR responses and VASfatigue responses is weak to moderate suggesting heterogeneity between experienced fatigue and joint inflammation.

### THU0333 EFFICACY AND SAFETY OF IXEKIZUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: THREE YEAR RESULTS FROM A PHASE 3 STUDY (SPIRIT-P1)

<sup>1</sup>V. Chandran, R. Fleischmann<sup>2</sup>, E. Lespessailles<sup>3</sup>, P.S. Helliwell<sup>4</sup>, O. Benichou<sup>5</sup>, J. Erickson<sup>5</sup>, C. Shuler<sup>5</sup>. <sup>1</sup>Krembil Research Institute, Univ of Toronto, Toronto, Canada; <sup>2</sup>Metrex Clinical Research Center, Dallas, USA; <sup>3</sup>Univ Orléans, Orléans, France; <sup>4</sup>Univ of Leeds, Leeds, UK; <sup>5</sup>Eli Lilly and Company, Indianapolis, USA

**Background:** Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets interleukin-17A. IXE, every 4 (Q4W) or 2 (Q2W) weeks, was superior to placebo (PBO) in improving the signs and symptoms of psoriatic arthritis (PsA) at Week 24 in biologic-naïve patients (pts).

**Objectives:** To determine the efficacy and safety of IXE treatment up to 3 years in biologic-naïve pts with PsA.

**Methods:** In SPIRIT-P1 (NCT01695239), 381 pts entered the extension period (EP; Weeks 24–156). Pts failing to demonstrate  $\geq 20\%$  improvement in both tender and swollen joint counts at Week 32, or any subsequent visit, were discontinued (mandatory discontinuation criteria). Ad-hoc efficacy data are presented for intent-to-treat (ITT) pts initially randomised to IXE at Week 0. Modified non-responder imputation (mNRI; missing data treated as non-response for pts discontinued due to lack of efficacy or adverse events [AEs]; multiple imputation (MI) for all other missing data) was applied to categorical measures. Modified baseline observation carried forward (mBOCF) was applied to continuous efficacy measures. Safety assessments are presented for all pts who entered the EP; baseline was the first IXE dose during the EP.

**Results:** Of the 210 pts initially randomised to IXE at Week 0 (ITT), 125 (60%) pts completed 156 weeks of treatment; 27 pts discontinued due to AEs, and 26 pts met the mandatory discontinuation criteria. Efficacy results are summarised (table 1). Improvements in ACR (American College of Rheumatology) and PASI (Psoriasis Area and Severity Index) responses, resolution in enthesitis and dactylitis, and improvements from baseline HAQ-DI (Health Assessment Questionnaire Disability Index), enthesitis, and dactylitis persisted up to Week 156. Safety

assessments for all pts who entered the EP are summarised (table 2). Frequencies of treatment-emergent AEs (TEAEs) were similar between IXE Q4W and Q2W. The majority of TEAEs were mild or moderate in severity; serious AEs occurred in 47 pts.

Abstract THU0333 – Table 1. Efficacy Overview at Week 156 (ITT Population)

LDI-B <sup>c</sup>	-51.2 (91.0)	-55.4 (61.3)

LEI=Leeds Enthesitis Index; LDI-B=Leeds Dactylitis Index-Basic; Nx=pts with non-missing data; n=responders. With mNRI, missing data were treated as non-response for pts discontinued due to lack of efficacy or AEs. All other missing data were imputed with MI. With MI analysis, 32 patients were considered ACR20 responders. <sup>a</sup>Pts with psoriatic lesions  $\geq 3\%$  of body surface area at baseline. <sup>b</sup>Pts with LEI >0 at baseline. <sup>c</sup>Pts with LDI-B >0 at baseline.

Abstract THU0333 – Table 2. Safety Outcome Measures (Weeks 24–156)

	Total IXE Q4W (N=191)	Total IXE Q2W (N=190)
TEAEs	146 (76%)	144 (76%)
Serious AEs	28 (15%)	19 (10%)
Serious infections	5 (3%)	1 (<1%)
Discontinued due to AE	16 (8%)	21 (11%)
Death	1* (<1%)	0
Infections	92 (48%)	94 (49%)
Injection-Site Reactions	21 (11%)	23 (12%)
Hypersensitivities	8 (4%)	11 (6%)

n=pts with  $\geq 1$  designated AE. Data presented as n (%). For safety analyses, baseline was defined as the time of first study drug injection during the EP (Weeks 24–156). \*Pt experienced a cerebrocardiovascular accident.

**Conclusions:** In pts treated with IXE, improvements in the signs and symptoms of PsA persisted up to 3 years. No unexpected safety signals were observed, and the safety profile was consistent with previous studies of IXE.

THURSDAY, 14 JUNE 2018

### SLE, Sjögren's and APS – clinical aspects (other than treatment)

#### THU0334 PATTERNS OF ASPIRIN USE IN SLE PREGNANCIES WITHIN A MULTINATIONAL INCEPTION COHORT AND RELATIONSHIP TO PREECLAMPSIA RISK FACTORS

A. Mendel, S. Bematsky, E. Vinet, on behalf of SLICC Investigators. McGill University, Montreal, Canada

**Background:** Aspirin reduces the risk of preeclampsia in pregnancies at high risk, and is recommended in pregnant women with  $\geq 1$  risk factors for preeclampsia, including systemic lupus erythematosus (SLE).

**Objectives:** To assess the prevalence of aspirin use in SLE pregnancies within a multinational inception cohort and compare aspirin use among those with and without additional preeclampsia risk factors.

**Methods:** Premenopausal women aged 18–45 enrolled in the Systemic Lupus International Collaborating Clinics (SLICC) Registry (2000–2017) within 15

months of SLE onset were evaluated with yearly visits to update co-morbidities, pregnancy status, and medications. Study visits with a current pregnancy were assessed for aspirin use and preeclampsia risk factors. Aspirin use was compared over time and among those with and without traditional risk factors for preeclampsia (i.e. hypertension, renal disease, diabetes, nulliparity, BMI $\geq$ 35, age  $>$ 40), as well as known disease-specific risk factors (i.e. antiphospholipid antibodies [+aPL], nephritis).

**Results:** We identified 297 women who had 479 pregnancies over the study period. Mean age during pregnancy was 31 (SD 4.9) years and 30% were nulliparous. Half of the pregnancies experienced  $\geq$ 1 traditional preeclampsia risk factors in addition to SLE, while a third had +aPL. We observed aspirin use in 121/475 (25% of pregnancies (95% CI 22,29) versus 22% (95%CI 19,25) of visits before and after pregnancy among the same women. Aspirin use was similar among pregnancies with and without  $\geq$ 1 traditional risk factor for preeclampsia [25% (95%CI 20,31) versus 26% (95%CI 21,32)], while we observed a higher prevalence of aspirin use in those with +aPL (38%, 95% CI 24,55) versus those without (23%, 95% CI 15,34). There was a significant difference in aspirin use based on maternal race/ethnicity, with 67/205 (33%, 95% CI 26,39) aspirin use in Caucasians versus 9/88 (10%, 95% CI 5,18) for black women. Prevalence of aspirin use in pregnancy varied across regions (12% $>$ 37%), and did not increase over time.

**Abstract THU0334 – Table 1.** Prevalence of preeclampsia (PE) risk factors among pregnant SLE visits and prevalence of ASA use among women with and without PE risk factors

Risk factor	Overall prevalence n=475 n (%)	Prevalence of ASA use (%; 95% CI)	
		With risk factor	Without risk factor
Age $>$ 40	14 (3)	2/14 (14%, 4–40)	119/461 (26%, 22–30)
BMI $\geq$ 35	33/437 <sup>o</sup>	8/33 (24%, 13–41)	113/404 (28%, 24–33)
Nulliparous	136/461 <sup>oo</sup>	37/136 (27%, 20–35)	80/325 (25%, 20–30)
Renal disease	83 (17)	17/83 (20%, 13–30)	104/392 (27%, 22–31)
Nephritis	53 (11)	11/53 (21%, 12–23)	109/422 (26%, 22–30)
Hypertension	79 (17)	24/79 (30%, 21–41)	97/396 (24%, 21–29)
Diabetes	2 (0)	0/2 (0%, 0–1)	121/473 (26%, 22–30)
$\geq$ 1 traditional PE risk factor	234 (49)	58/234 (25%, 20–31)	63/241 (26%, 21–32)
aPL +	34/104 <sup>oo</sup>	13/34 (38%, 24–55)	16/70 (23%, 15–34)

**Conclusions:** In this cohort including 479 SLE pregnancies, most pregnant women were not on aspirin and half had preeclampsia risk factors in addition to SLE. It is possible that aspirin was introduced at/or following the study visit when the pregnancy was documented, highlighting the importance of the treating rheumatologist in reviewing aspirin use and initiating it in pregnant SLE women. Our findings suggest black SLE women as a potentially vulnerable group during pregnancy, having the lowest prevalence of aspirin use.

#### THU0335 FACTORS ASSOCIATED WITH DEVELOPMENT AND MORTALITY OF PULMONARY HYPERTENSION IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

<sup>1</sup>J.S. Kim, D. Kim<sup>1</sup>, Y.B. Joo<sup>2</sup>, S. Won<sup>3</sup>, J. Lee<sup>3</sup>, J. Shin<sup>4</sup>, S.-C. Bae<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Hanyang University Hospital for Rheumatic Diseases, Seoul; <sup>2</sup>Department of Rheumatology, St. Vincent's Hospital, The Catholic University of Korea, Suwon; <sup>3</sup>Clinical Research Center for Rheumatoid Arthritis (CRCRA); <sup>4</sup>Department of Cardiology, Hanyang University Hospital, Seoul, Korea, Republic of Ireland

**Background:** Pulmonary hypertension (PH) is a major cause of death in patients with systemic lupus erythematosus (SLE). In recent years, SLE with PH has become more common in the past few decades, and novel therapies has been developed to improve the prognosis of PH in SLE patients. Therefore, it is necessary to investigate further to identify serological and clinical factors for the development and mortality of PH in SLE patients.

**Objectives:** This study aims to estimate the prevalence of PH in SLE patients and identify the factors associated with the development of and mortality from PH in SLE patients.

**Methods:** We conducted a prospective study of SLE patients with fulfilling the American College of Rheumatology criteria (ACR) in a single tertiary centre from February 1998 to December 2013. PH was defined as a systolic pulmonary

arterial pressure (sPAP)  $\geq$ 30 mmHg at rest on transthoracic echocardiography (TTE). We assessed potential associated factors contributing to the development and mortality of PH in SLE patients using univariate and multivariable logistic regression models.

**Results:** Of 1110 patients with SLE, 48 patients were identified to have PH. Multivariable analysis indicated that pleuritis or pericarditis (odds ratio (OR)=4.62, 95% confidence interval (CI)=2.46 to 8.70, p<0.01), anti-RNP antibody (OR=2.42, 95% CI=1.21 to 4.82, p=0.01), interstitial lung disease (ILD) (OR=8.34, 95% CI=2.21 to 31.54, p<0.01), and cerebro-cardiovascular disease (OR=13.37, 95% CI=3.56 to 50.21, p<0.01) were independently associated with the development of PH in SLE. Subgroup analysis among patients with PH demonstrated that there were no statistically significant factors associated with PH mortality in SLE.

**Abstract THU0335 – Table 1.** Factors associated with pulmonary hypertension development in systemic lupus erythematosus

	Univariate		Multivariable	
	OR (95% CI)	p-value	OR (95% CI)	p-value
Sex: female	1.92 (0.46 to 8.07)	0.37	4.44 (0.54 to 36.76)	0.17
Age at diagnosis of SLE	0.99 (0.97 to 1.02)	0.59	0.99 (0.96 to 1.02)	0.49
Disease duration*	1.00 (1.00 to 1.00)	0.87	1.00 (0.99 to 1.00)	0.48
Ever smoker	0.52 (0.18 to 1.47)	0.23		
Pleuritis or pericarditis	4.62 (2.55 to 8.29)	<0.01	4.62 (2.46 to 8.70)	<0.01
Raynaud phenomenon	1.48 (0.79 to 2.77)	0.22		
Anti-Sm	1.65 (0.81 to 3.39)	0.17	0.89 (0.38 to 2.11)	0.79
Anti-RNP	2.48 (1.36 to 4.51)	<0.01	2.42 (1.21 to 4.82)	0.01
ACL	1.10 (0.55 to 2.19)	0.79		
LAC	0.83 (0.32 to 2.12)	0.69		
SLEDAI score at enrollment	1.03 (0.96 to 1.09)	0.42		
ILD (pulmonary, pleural fibrosis)	8.34 (2.89 to 31.69)	<0.01	8.34 (2.21 to 31.54)	<0.01
Cerebro-cardiovascular disease	13.37 (3.56 to 50.21)	<0.01	13.37 (3.56 to 50.21)	<0.01

OR: odds ratio; CI: confidence interval; SLE: systemic lupus erythematosus; Anti-Sm: Anti-Smith; Anti-RNP: Anti-ribonucleoprotein; ILD: interstitial lung disease.

\*From diagnosis of SLE to last follow-up.

**Conclusions:** The prevalence of PH was 4.3% in our cohort. There were significant associations with pleuritis or pericarditis, ILD, cerebro-cardiovascular disease, and anti-RNP antibody in SLE, which may contribute to the development of PH. However, there were no statistically significant factors correlating PH mortality in SLE.

#### THU0336 PREDICTORS OF SUBCLINICAL CAROTID ATHEROMATOSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RELEVANCE OF ACTIVITY, DAMAGE AND SEVERITY INDEXES

J.C. Quevedo<sup>1</sup>, H. Sánchez, I. Rúa-Figueroa<sup>1</sup>, B. Tejera<sup>3</sup>, A. de Vera<sup>4</sup>, A. González-Delgado<sup>4</sup>, C. Rodríguez-Lozano<sup>1</sup>, I. Ferraz-Amaro<sup>2</sup>. <sup>1</sup>Rheumatology Division, Hospital Universitario de Gran Canaria Dr Negrín, Las Palmas de Gran Canaria; <sup>2</sup>Rheumatology Division, Hospital Universitario de Canarias, Tenerife; <sup>3</sup>Rheumatology Division, Complejo Hospitalario Universitario Insular Materno Infantil, Las Palmas de Gran Canaria; <sup>4</sup>Laboratory Division, Hospital Universitario de Canarias, Tenerife, Spain

**Background:** The prevalence of subclinical atheromatosis in patients with systemic lupus erythematosus (SLE) is double that observed in the general population. The mechanisms of this accelerated atherosclerosis are unknown, but they may include factors related to the disease, as well as the interaction of these with classic cardiovascular risk factors (CVRF).

**Objectives:** We analyse wich predictors of subclinical carotid atheromatosis exist in a large series of patients with SLE, with special emphasis on the role of the activity, damage and severity indexes.

**Methods:** Cross-sectional study that included 276 patients with SLE. Lipid serum levels, autoimmunity profile and the activity (SLEDAI), severity (Katz) and damage (SLICC) indexes were determined. The thickness of the carotid intima-media (cIMT) and the presence of plaques were determined by radiofrequency US. The cardiovascular risk was estimated through SCORE. Multivariate regression analysis was performed to assess the relationship of the indexes with CVRF, cIMT and

carotid plaque. Predictive capacity for the presence of plaque by comparing the AUC of the different models was performed through the DeLong method

**Results:** 106 (38%), 85 (31%), 47 (17%) and 21 (8%) patients showed respectively SLEDAI null, low, moderate and high, 197 (71%) had a SLICC >1 and 104 (38%) a Katz>3. In 36% (99) of the patients carotid plaques were detected, with an average cIMT of 0.631±0.108 mm. SLEDAI showed a positive relationship with hypertension; the Katz with hypertension and dyslipidemia; and the SLICC with these and also with age, body mass index and abdominal waist. The relationship of the latter with the CVRF was maintained after subtracting its items related to cardiovascular risk. SLICC was univariately related to plaque (OR 1.29 [95% CI 1.13–1.48], p=0.000) and a SLICC >1 showed a tendency to be associated with a higher cIMT (beta coefficient 0.03 [95% CI 0.00–0.06], p=0.053). No univariate relationships were found between Katz or SLEDAI with subclinical atherosclerosis. The relationship of SLICC with plaque was maintained after adjusting for age, sex and CVRF (OR 1.19 [95% CI 1.00–1.42], p=0.047). Similarly, SLICC (even without its vascular damage items) (beta coefficient 0.26 [95% CI 0.12–0.41], p=0.000), but not Katz and SLEDAI, correlated significantly with SCORE. The predictive capacity of SCORE for the presence of plaque was AUC 0.788 (95% CI 0.735–0.842). Analogously SLICC showed an AUC 0.659 (95% CI 0.594–0.724) for plaque; the AUC of Katz and SLEDAI did not reach statistical significance. The AUC of the SCORE +SLICC versus SCORE did not show statistically significant differences (p=0.31). The statistical significance of the reclassification indexes were net reclassification index p=0.61, and integrated discrimination improvement p=0.01.

**Conclusions:** SLICC is independently related to the presence of plaque. SLE activity, severity and damage indexes are related to CVRF but they have little impact on the predictive capacity of SCORE for the presence of carotid plaque.

### THU0337 NONBACTERIAL THROMBOTIC ENDOCARDITIS (NBTE) IN SLE: PREVALENCE, CLINICAL CHARACTERISTICS AND SEROLOGICAL PROFILE

D.V. Tanna, M. Bindroo, D. Raval, W. Kazi, S. Bajad, R. Gupta. *Rheumatology and clinical immunology, MEDANTA THE MEDICITY, Gurgaon, India*

**Background:** SLE is characterised by excessive production of various autoantibodies and correlation of these antibodies with organ involvement may help to evaluate disease severity and long term prognosis. NBTE is a rare cardiac manifestation of SLE with prevalence rate varying from 6%–11%. Many, but no all, studies have shown association of NBTE with anti phospholipid antibodies, but, except this association, data regarding clinical, laboratory and serological characteristics of NBTE is sketchy. We designed this study to evaluate profile of patients having NBTE in SLE.

**Objectives:** 1. To study the prevalence of NBTE in SLE patients.

2. To study association of NBTE with clinical and laboratory characteristics and serological profile.

**Methods:** All consecutive SLE inpatients and outpatients attending the department of Rheumatology from September 2015 to December 2017 were enrolled. Patients subjected to 2D Echo were included and their demographic, clinical, laboratory and serological profile were recorded. Serological profile was studied with Blue diver kit which is an immunodot blot assay measuring autoantibodies against 25 ENA. Anti cardiolipin and anti beta 2 glycoprotein antibody were tested by ELISA. Study was approved by an independent ethics committee [ECR/282].

**Results:** Total number of patients enrolled in study were 355 out of which 213 had undergone 2DEcho. NBTE was found in 33 (15.49%) patients. Among all autoantibodies studied, we found that the presence of **anti-Nucleosome antibody, LAC, ACL and B2GP1** were significantly associated with NBTE (p<0.05). **Myocarditis, valvular lesions and Pulmonary Hypertension** were more common in NBTE group (p value: 0.012, <0.0001 and 0.013 respectively).

We also noticed that there is a statistically significant association between presence of NBTE with **APLA syndrome** and **Thrombotic events** (p value<0.0001 and 0.005 respectively).

Tab.1 Significant Serological association of SLE patients with NBTE.

Antibodies	SLE With NBTE-33 (15.49%)	SLE without NBTE- 180	P value
Anti-nucleosome	27 (81.8)	32 (17.7)	<0.0001
LAC	16/30 (53.3)	31/149 (20.8)	0.0002
ACL (Ig M and IgG)	9/30 <sup>ns</sup>	13/128 (10.1)	0.004
B2GP-1(Ig M and IgG)	6/22 <sup>ns</sup>	9/103 (8.73)	0.033

APLA profile was available in 30 patients of NBTE and 147 patients not having NBTE. Out of this, positivity for APLA antibodies were seen in 17 (56.6%) and 36 (24.4%) patients respectively [p:0.005]. 82.3% patients with Anti phospholipid antibodies had APLA syndrome in NBTE group while in NBTE group 48.5%

patients having Anti phospholipid antibodies had APLA syndrome. Thus, presence of NBTE increased the possibility of developing APLA syndrome in patients having positive serology for anti phospholipid antibodies

Tab.2 Significant Clinical and laboratory characteristic of SLE patients with NBTE.

Organ involvement	SLE with NBTE- 33	SLE without NBTE- 180	p- value
Myocarditis	11	27	0.012
Valvulopathy	10	4	<0.0001
PAH	9	21	0.013
Thrombotic events	8	16	0.005
APLA syndrome	14	17	<0.0001

**Conclusions:** Presence of Anti nucleosome antibody, LAC, Anti cardiolipin and anti beta 2 glycoprotein antibodies may predict presence or future development of NBTE in SLE patients. Presence of NBTE increases probability of developing APLA syndrome in patients with anti phospholipid antibodies. We have found association of NBTE with myocarditis, valvulopathy and PAH and thus propose that such patients with NBTE should be treated early and aggressively.

### THU0338 OUTCOME OF STROKE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A NESTED CASE-CONTROL STUDY

L.K. Tsoi, C.C. Mok, Y.P. Fu. *Medicine, Tuen Mun Hospital, HK, Hong Kong*

**Objectives:** To evaluate the outcome of stroke in patients with systemic lupus erythematosus (SLE) in comparison with matched non-SLE patients.

**Methods:** Patients who fulfilled ≥4 ACR criteria for SLE and had a history of stroke were identified from our SLE database. The outcome of stroke in these patients was evaluated retrospectively and compared with a group of randomly selected age/gender-matched non-SLE patients (in a 1:3 ratio) admitted to our stroke unit within the same time period. The type and extent of stroke, atherosclerotic risk factors (hypertension, smoking, diabetes mellitus, dyslipidemia, atrial fibrillation, valvular lesions) and previous stroke were compared between the two groups of patients. The primary outcome of interest was the 90 day functional outcome as assessed by the modified Rankin scale (mRS) (score 0–2: functional independence; score 3–6: functional dependence). Secondary outcomes included all-cause mortality, 30 day stroke mortality, stroke recurrence and stroke complications. Factors independently associated with a poor functional outcome was studied by logistic regression.

**Results:** A total of 40 SLE patients (age 53.7±11.5, 88% women) with stroke were identified from our database (stroke prevalence 0.39/100 patient-year). A control group of 120 non-SLE patients (age 52.8±14.8, 87.5% women) with stroke were randomly selected from our stroke database. All were ethnic Chinese. The prevalence of atherosclerotic risk factors was similar between the two groups, except SLE patients had a higher atherogenic index (Log serum [triglyceride/HDL-cholesterol]) (1.51±0.47 vs 1.32±0.31; p=0.005.) In SLE patients, the median time to stroke since diagnosis was 24 months. Ischaemic stroke was more common in SLE than non-SLE patients (90% vs 63%; p=0.001). Among patients with ischaemic stroke, SLE patients had more extensive infarction than controls on CAT scan (multiple infarct 65.7% vs 18.7%; p<0.001). The 90 day mRS score was significantly higher in SLE patients than controls (1.70±1.97 vs 0.88±1.36; p=0.004). Significantly more SLE patients had functional dependence (mRS score 3–6) at 90 days post-stroke than controls (32.5 vs 8.3%; p<0.001). Logistic regression showed that SLE was an independent risk factor for a poor stroke outcome after adjustment for age, sex, history of stroke, various atherosclerotic risk factors and the type of stroke (ischaemic vs haemorrhagic) (OR 12.2 [2.97–49.9]). Subgroup analysis of patients with ischaemic stroke showed that SLE was also independently associated with a poorer functional outcome after adjustment for the same confounding covariates and the extent of stroke (solitary vs multiple infarcts) (OR 12.4 [1.02–150]; p=0.048). There was no significant difference in the 30 day stroke mortality between SLE and non-SLE patients (5% vs 2.5%; p=0.43). However, SLE patients had a higher incidence of post-stroke epilepsy than controls (22.5% vs 3.3%; p=0.001). Upon a mean follow-up time of 7.5±5.2 years, SLE patients had a lower stroke recurrence free survival (59.5% vs 85.7%; p<0.001) and a higher rate of all-cause mortality (34.6% vs 15.1%; p<0.001).

**Conclusions:** Stroke in SLE patients is more likely to be ischaemic in origin and more extensive than matched controls. Short-term functional outcome of stroke is poorer in SLE patients. Over 7.5 years, stroke recurrence, post-stroke epilepsy and all-cause mortality is significantly more frequent in SLE than non-SLE patients.

THU0339 **IMPACT OF CAROTID ULTRASOUND ON THE CARDIOVASCULAR RISK STRATIFICATION OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

J.C. Quevedo Abeledo<sup>1</sup>, <sup>2</sup>H. Sánchez, I. Rúa-Figueroa<sup>1</sup>, B. Tejera<sup>3</sup>, A. Naranjo<sup>1</sup>, C. Rodríguez-Lozano<sup>1</sup>, I. Ferraz-Amaro<sup>2</sup>. <sup>1</sup>Rheumatology Division, Hospital Universitario de Gran Canaria Dr Negrín, Las Palmas de Gran Canaria; <sup>2</sup>Rheumatology Division, Hospital Universitario de Canarias, Tenerife; <sup>3</sup>Rheumatology Division, Complejo Hospitalario Universitario Insular, Las Palmas de Gran Canaria, Spain

**Background:** Autoimmune rheumatic diseases, including systemic lupus erythematosus (SLE), are associated with a significant increase in cardiovascular morbidity and mortality. The risk stratification instruments used in the general population underestimate the true risk of events in these patients. Carotid ultrasonography, through the detection of subclinical atherosclerosis, is a powerful predictor of future cardiovascular events. The available evidence, endorsed in the official Prevention Guidelines, supports the use of this technique for the adequate identification of those patients of "very high risk", candidates for preventive interventions of greater intensity.

**Objectives:** To analyse the cardiovascular risk profile, the prevalence of subclinical atherosclerosis detected by carotid echography, and its implications in the prevention strategy in patients with SLE.

**Methods:** A cross-sectional study of 276 patients diagnosed with SLE. The clinical characteristics and risk profile were analysed by SCORE. The presence of plaques and intima-media thickness (cIMT) was determined by carotid ultrasound and the cIMT percentiles were calculated according to tables adjusted for age and sex. Differences in risk stratification before and after carotid ultrasonography were determined by univariate regression analysis. The therapeutic implications after reclassification were evaluated according to the 2016 European Prevention Guides.

**Results:** Risk stratification using SCORE was: low in 187 (67%), moderate in 73 (26%), and high or very high in 16 (6%). The median percentiles for cIMT were not statistically different from the p50 of healthy general population ( $p=0.54$ ). Ultrasound showed the presence of plaque or cIMT  $>p75$  or cIMT  $>0.90$  mm in 60% (166) of the patients evaluated. The presence of this finding by risk categories was: low 102/187 (55%), moderate 55/73 (75%), high 7/9 (78%) and very high 6/7 (86%). According to the published guidelines, the detection of plaque carried out the re-stratification to a very high risk in 35% of patients. These patients whose reclassification was achieved showed a higher SLICC index compared to those that did not change of category (mean difference 0.9 points,  $p=0.000$ ). This difference remained statistically significant when the items related to cardiovascular risk that SLICC possesses were eliminated. SLEDAI and Katz were not statistically different between both groups. The SCORE of patients who were reclassified was also statistically higher (mean difference 0.7 points,  $p=0.021$ ). Ninety percent of patients were re-classified to a very high risk had out-of-target LDL cholesterol levels for their new risk category (LDL  $<70$  mg/dl). Similarly, only 46% of them were on statin therapy. Therefore, the indication or intensification of lipid-lowering treatment was followed only in 30% of the total evaluated.

**Conclusions:** The reclassification of cardiovascular risk through the use of ultrasonography in SLE occurs in one third of patients. Our data suggests that this may be consequence of the damage produced by the disease. One in three candidates needed preventive interventions of greater intensity that had not been taken.

THU0340 **PROLONGED REMISSION IS ASSOCIATED WITH A REDUCED RISK OF CARDIOVASCULAR DISEASE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

<sup>1</sup>S. Fasano, D.P. Margiotta<sup>2</sup>, L. Pierra<sup>1</sup>, A. Riccardi<sup>1</sup>, A. Afeltra<sup>2</sup>, G. Valentini<sup>1</sup>. <sup>1</sup>Rheumatology unit, Università degli studi della Campania Luigi Vanvitelli, Naples; <sup>2</sup>Clinical Medicine and Rheumatology Department, Campus Bio-Medico University of Rome, Rome, Italy

**Background:** Cardiovascular disease (CVD) has emerged as one of the most important causes of mortality in systemic lupus erythematosus (SLE)<sup>1</sup>. In previous studies, disease activity, as assessed by SLEDAI (at the first visit or as mean annual value registered during follow-up), did not result to have any predictive role on the subsequent occurrence of CVD<sup>2-3</sup>.

**Objectives:** To investigate the relationship between prolonged remission and the occurrence of a subsequent first CV event in patients with SLE.

**Methods:** Out of 452 patients consecutively admitted to two tertiary Italian centres from November 1st 2000 to December 31st 2016, the 409 patients, who, at admission, had not experienced any CV event, had not received any anticoagulation therapy and had been visited at least biannually during follow-up, were considered for the present study. Prolonged remission was defined as a 5 year consecutive period of no disease activity based on SLEDAI-2K<sup>3</sup>. Patients with

prolonged remission were furtherly subdivided according to Zen et al<sup>4</sup> into 3 groups: complete remission, clinical off-corticosteroids remission (offCR), clinical on-corticosteroids remission (onCR). Kaplan-Meier curves and the log-rank test were used to analyse differences in event-free survival between groups. Cox regression analysis was used to investigate disease and therapeutic features associated with the development of a first CV event.

**Results:** During 72 months median follow-up time, 29 (7.0%) CV events occurred (two events in patients who had undergone prolonged remission). Out of the 409 patients, 28 patients (6.8%) achieved a prolonged complete remission, 13 (3.1%) prolonged clinical offCR and 64 (15.5%) prolonged clinical onCR. Kaplan-Meier analysis revealed a greater overall CV event-free rate in patients achieving a prolonged remission compared to those in remission but for less than 5 years and patients not in remission (logrank test  $\chi^2=19.82$ ;  $p=0.0001$ ; figure 1). However, at Kaplan-Meier analysis, CV outcome was similar among patients in prolonged remission, irrespective of the type of remission achieved ( $p>0.05$ ). At multivariate analysis, treatment with hydroxychloroquine for more than 5 years and prolonged remission were protective (HR 0.38; 95% CI 0.16–0.90; HR 0.08, 95% CI 0.01–0.53) while antiphospholipid syndrome increased the risk of a first CV event (HR 3.80; 95% CI 1.68–8.61). No differences were found between patients treated or not with aspirin. Nevertheless, among patients from Rome cohort, aspirin was only prescribed to patients with high traditional CV risk score.

**Conclusions:** A prolonged remission, whichever the subtype, is associated with a better CV outcome and should be considered as a treat-to-target goal in the CV risk management of the lupus patient.

THU0341 **LOW VITAMIN D IS ASSOCIATED WITH THROMBOSIS IN SYSTEMIC LUPUS ERYTHEMATOSUS**

M. Petri, W. Fu, D.W. Goldman. *Medicine, Johns Hopkins University School of Medicine, Baltimore, USA*

**Background:** Low vitamin D is common in systemic lupus erythematosus (SLE). It is also found in antiphospholipid syndrome. Vitamin D has effects on tissue factor, PAI-1, thrombomodulin and platelet aggregation that suggest it has an anti-thrombotic role. We asked whether low vitamin D was associated with thrombosis in SLE, adjusting for lupus anticoagulant.

**Objectives:** We asked whether low vitamin D was associated with thrombosis in SLE, adjusting for lupus anticoagulant.

**Methods:** A total of 1,392 SLE patients were included in the analysis. At the first visit when vitamin D was measured, 76.7% had levels of 25-hydroxyvitamin D  $<40$  ng/mL. The SLE patients were: 92% female, mean age 42.9 years, and ethnicity 50% Caucasian, 41% African American. 27% patients had a history of thrombosis; 7% stroke, 4% MI and 14% DVT.

**Results:** Vitamin D, measured either as a continuous variable or as "low" ( $<40$  ng/mL) vs. normal, was associated with any thrombosis and with DVT.

**Abstract THU0341 – Table 1.** Associations of First Vitamin D Measurement with Thrombosis

	Positive for Thrombotic Event		No Thrombotic Event		P-value
	Mean (SD)	N (%)	Mean (SD)	N (%)	
<b>Any Thrombotic Event</b>					
Vitamin D (ng/ml) (Mean/SD)	27.6 (15.1)		30.6 (14.6)		0.0008
Vitamin D<40 ng/ml (N%)		299 (80.4)		759 (75.4)	0.064
<b>Stroke</b>					
Vitamin D (ng/ml) (Mean/SD)	28.9 (15.2)		29.9 (14.7)		0.5408
Vitamin D<40 ng/ml (N%)		79 (75.2)		988 (76.9)	0.7914
<b>Myocardial Infarction (MI)</b>					
Vitamin D (ng/ml) (Mean/SD)	30.2 (16.9)		29.8 (14.7)		0.883
Vitamin D<40 ng/ml (N%)		35(70)		1032(77)	0.3258
<b>DVT</b>					
Vitamin D (ng/ml) (Mean/SD)	25.9 (13.4)		30.4 (14.9)		<0.0001
Vitamin D<40 ng/ml (N%)		171 (87.2)		895(75)	0.0002

We next adjusted for race, age, sex and lupus anticoagulant. Low vitamin D remained associated with DVT.

**Abstract THU0341 – Table 2.** Summary of Adjusted Odds Ratio for Low Vitamin D (<40 ng/ml)

Dependent Variables	Unadjusted OR (95% CI)	Adjusted OR (95% CI)
Any Thrombosis	1.33 (0.99,1.79)	1.36 (0.99,1.86)
Stroke	0.91 (0.58,1.45)	0.92 (0.57,1.48)
MI	0.7 (0.38,1.29)	0.8 (0.42,1.53)
DVT	2.28 (1.47,3.54)	2.31 (1.47,3.65)

We next looked prospectively: this analysis excluded thrombotic events before the first vitamin D measurement. It allowed for vitamin D to be a time-varying variable, as replacement therapy was given if it was low. After adjustment for race, age and sex, the adjusted hazard ratio remained significant for any thrombosis: 1.75 (1.04,2.92).

**Conclusions:** Low vitamin D was significantly associated with any thrombosis and with DVT (even after adjustment for lupus anticoagulant). In prospective models it remained significantly associated with any thrombosis. As supplementation with vitamin D was proven to reduce thrombosis in an oncology randomised clinical trial, vitamin D replacement should become routine in SLE patients at risk for thrombosis.

### THU0342 THE LUPUS FOUNDATION OF AMERICA RAPID EVALUATION OF ACTIVITY IN LUPUS (LFA-REAL) PROVIDES A SIMPLE BUT RELIABLE MEASUREMENT OF SLE DISEASE ACTIVITY

<sup>1</sup>A. Thanou, C. Arriens<sup>1</sup>, T. Aberle<sup>1</sup>, J.A. James<sup>1</sup>, J.T. Merrill<sup>1</sup>, A.D. Askanase<sup>2</sup>.

<sup>1</sup>Oklahoma Medical Research Foundation, Oklahoma City; <sup>2</sup>Columbia University, New York, USA

**Background:** Clinical trial evaluations in SLE are problematic, in part due to glossary-based outcome measures with imperfect granular relevance. Visual analogue scales (VAS) allow real world scaling of disease severity, but may be inconsistent when used over time or by different raters. The SELENA SLEDAI Physician's Global Assessment (SSPGA) is a VAS with severity anchors and instructions to promote consistent, transitional scoring. The Rapid Evaluation of Activity in Lupus (LFA-REAL<sup>TM</sup>) extends the SSPGA by scoring each active feature separately, allowing additive impact of each manifestation within organs, and a global score with meaningful weighting of multiple symptoms. It differs from previous constructions that combine PGA with component scoring<sup>1</sup> by incorporating all manifestations of lupus and refining scaling of the SSPGA<sup>2</sup>.

**Objectives:** To compare performance of SSPGA and LFA-REAL<sup>TM</sup> to accepted SLE trial outcome measures during an ongoing trial in SLE, using a strict protocol for transitional scoring.

**Methods:** Disease activity, SLEDAI, BILAG 2004 CLASI, SSPGA and LFA-REAL<sup>TM</sup> was evaluated at monthly visits in an investigator-initiated, double-blind, placebo controlled study of abatacept (trial results pending). Validation of total scores and change in SSPGA and REAL vs SLEDAI and BILAG were examined by Spearman Correlation. ROC curve analysis compared changes in SSPGA and LFA-REAL<sup>TM</sup> to the dichotomous SLE trial endpoints, SRI-4 and BICLA.

**Results:** 50 adult SLE patients, 47 female, were assessed at 528 visits. Changes in disease activity compared to screening were examined in 478 visit pairs. Total SSPGA and REAL scores strongly correlated to each other (r=0.932), as well as to total SLEDAI and BILAG [SSPGA: r=0.742 (SLEDAI), r=0.776 (BILAG); REAL:

r=0.776 (SLEDAI), r=0.813 (BILAG); all p<0.0001]. Changes in SSPGA and LFA-REAL<sup>TM</sup> at each visit compared to screening correlated to each other (r=0.857) as well as to changes in SLEDAI and BILAG (all p<0.0001) (table 1). Changes in SSPGA and LFA-REAL<sup>TM</sup> were very strongly related to the dichotomous SRI-4 and BICLA endpoints by ROC analysis (all p<0.0001) (table 2). LFA-REAL<sup>TM</sup> musculoskeletal correlated to BILAG musculoskeletal, SLEDAI arthritis, and tender and swollen joint counts (r=0.842, 0.817, 0.634 and 0.784 respectively, all p<0.0001). LFA-REAL<sup>TM</sup> mucocutaneous also correlated to BILAG mucocutaneous, the sum of SLEDAI mucocutaneous features as well as CLASI activity (r=0.826, 0.798 and 0.789 respectively, all p<0.0001).

**Abstract THU0342 – Table 1.** Change in LFA-REAL<sup>TM</sup> and SSPGA in relation to change in SLEDAI and BILAG.

	ΔSLEDAI	ΔBILAG
ΔLFA-REAL <sup>TM</sup>	0.701	0.700
ΔSSPGA	0.681	0.624

**Abstract THU0342 – Table 2.** AUC of change in LFA-REAL<sup>TM</sup> and SSPGA in relation to SRI-4 and BICLA.

	SRI-4	BICLA
ΔLFA-REAL <sup>TM</sup>	0.876	0.852
ΔSSPGA	0.895	0.913

**Conclusions:** Both the SSPGA and LFA-REAL<sup>TM</sup> are reliable surrogates of commonly used endpoints in SLE trials. Both instruments are easy to score and understand, and could be employed as continuous or dichotomous endpoints. The LFA-REAL<sup>TM</sup> allows individualised scoring at the symptom or organ level, and each symptom contributes its exact severity to a global score. The simplicity of PGA scoring is accompanied by gains in versatility.

### THU0343 HOW PATIENTS ABILITY BELIEFS ABOUT MATH MATTER TO SLE PATIENTS DISEASE

<sup>1</sup>A.S. Meara, M.K. Tompkins<sup>2</sup>, K. Morris<sup>3</sup>, E. Sullivan<sup>4</sup>, S.P. Ardoin<sup>5</sup>, E. Peters<sup>6</sup>.

<sup>1</sup>Division of Immunology and Rheumatology, The Ohio State University;

<sup>2</sup>Department of Psychology, the Ohio State University; <sup>3</sup>Division Of Rheumatology, The Ohio State University; <sup>4</sup>Division of Rheumatology, The Ohio State University;

<sup>5</sup>Department of Medicine; <sup>6</sup>Department of Psychology, The Ohio State University, Columbus, USA

**Background:** Systemic lupus erythematosus (SLE) is a heterogeneous disease with high morbidity and mortality; requiring complex treatment plans which can be daunting especially to SLE patients with neuropsychiatric deficits. Numeracy is the "ability to use and understand numbers in daily life" and a key component for effective shared-decision making between physician and patient to ensure the best patient outcomes. Numeracy skills are needed for decisions about health care risk stratification when understanding treatments, understanding potential harm and benefits of therapy and for counting pills and taking medications as prescribed.

**Objectives:** As there is a lack of information within the lupus patient population, this proposal explores the relationship between patients' numeric ability (both actual and perceived ability) and clinical outcomes fulfilling a gap in our current knowledge of how to support physician communication with patients to ensure patient understanding.

**Methods:** Patients>18 recruited from IRB approved The Ohio State University Lupus, Vasculitis, Glomerulonephritis Registry. 112 patients had finished subjective numeracy (SNS) which measures patients' perception of their math ability, objective numeracy (ONS) which measures patients' actual math ability. We conducted regression analyses with ONS, SNS, and demographics as predictors of disease activity (measured by SLEDAI). We used backwards-stepwise regression, removing nonsignificant variables one at a time from the model.

**Results:** Logistic regression analysis revealed a significant interaction between ONS and SNS in predicting whether patients had the active disease or not (interaction b(SE)=-0.70 (0.33), p=0.03; ONS b(SE)=-0.13 (0.30), p=0.68; SNS b(SE)=-0.40 (0.32), p=0.21). Patients higher in both numeric competencies were least likely to have the active disease. Specifically, among those higher in ONS

(+1 SD), the predicted probability of having the active disease was 11% vs. 52% for those higher vs. lower in SNS ( $\pm 1$  SD), respectively. In comparison, among those lower in ONS ( $-1$  SD), the likelihood of active disease was 38% vs 25% for those higher vs. lower in SNS, respectively. Thus, among patients with greater math abilities, having greater beliefs in one's abilities appeared beneficial; however, among patients with lower math abilities, greater ability beliefs appeared harmful.

**Conclusions:** Patients with greater math ability, coupled with greater beliefs in one's numeric ability, were least likely to have the active disease. This is consistent with psychological theory about actual math ability and perceived math ability as an outcome predictor. Patients that are overconfident and more active in their health and numeric tasks may make decisions that lead them to worse outcomes. The SNS and ONS may be an efficient screening tool to identify high risk SLE patients that may require extra health care needs.

#### THU0344 ASSESSMENT OF THE PSYCHOMETRIC PROPERTIES OF PATIENT-REPORTED OUTCOMES OF DEPRESSION IN SLE

<sup>1</sup>A. Kwan, S. Marzouk<sup>2</sup>, H. Ghanean<sup>3</sup>, K. Ali<sup>4</sup>, N. Anderson<sup>4</sup>, J. Su<sup>4</sup>, Z. Touma<sup>5</sup>.

<sup>1</sup>Medicine, Queen's University, Kingston, Ontario; <sup>2</sup>Department of Psychiatry, <sup>3</sup>Psychiatry, University of Toronto; <sup>4</sup>Toronto Western Hospital; <sup>5</sup>Rheumatology, University of Toronto, Toronto, Canada

**Background:** Mood disorders, including depression, are amongst the most common manifestations of neuro-psychiatric SLE. Currently, the screening and diagnosis for depression in ambulatory settings are delayed and often missed due to the lack of standardised valid questionnaires for assessing depression in patients with SLE.

**Objectives:** This study aims to: 1) Determine the prevalence of depression in SLE patients using the Centre for Epidemiological Studies-Depression Scale [CES-D] and Hospital Anxiety and Depression Scale [HADS] questionnaires. 2) Study the criterion validity and interpretability of CES-D and HADS, and 3) evaluate their diagnostic accuracy when compared to the assessment of an independent psychiatric assessment using the Mini-International Neuropsychiatric Interview (MINI), based on the DSM-5, as the gold standard.

**Methods:** A cross-sectional study of consecutive consenting SLE patients (n=227), aged 18–65 and attending the Toronto Lupus Clinic between June 2017–September 2017, was performed. Participants were screened for depression using the CES-D and HADS, and underwent the MINI on the same date of their clinic visit. Conventional cut-off scores were used to indicate the prevalence of depression: CES-D  $\geq 16$  and HADS-D  $\geq 8$ . Sensitivity, specificity, positive predictive value (PPV), and negative predictive value (NPV) were evaluated against the MINI. Receiver operator characteristic (ROC) curves and the Youden Index were utilised to determine the optimal cut-off scores for CES-D and HADS-D.

**Results:** Among 227 patients, the prevalence of depression ranged from 27.8% (HADS-D) to 46.3% (CES-D). ROC curves showed that the CES-D (AUC 0.86, 95% CI: 0.78–0.95) slightly outperformed HADS-D (AUC 0.84, 95% CI: 0.75–0.93), when compared to the MINI. The sensitivity, specificity, PPV, and NPV for CES-D at the optimal cut-off of 26 was 80%, 82%, 43%, and 96%, respectively. The Youden index exhibited optimal cut-offs for CES-D at 26 and HADS-D at 8 that optimised their sensitivity and specificity as screening metrics for depression in SLE patients. The performance of the CES-D and HADS-D at various cut-offs are displayed in table 1 below.

**Abstract THU0344 – Table 1.** Cut-offs to predict depression by Youden Index

Cutoffs	Sensitivity	Specificity	PPV	NPV
<b>CES-D</b>				
26*	0.80	0.82	0.43	0.96
24	0.80	0.77	0.37	0.96
21†	0.85	0.71	0.34	0.97
16†	0.95	0.55	0.27	0.98
<b>HADS-D</b>				
8*†	0.80	0.79	0.40	0.96
7	0.85	0.72	0.35	0.97
6	0.95	0.62	0.30	0.99

\*Optimal cutoff as determined by the Youden Index

†Conventional cutoffs found in literature

**Abstract THU0344 – Figure 1.** ROC curves for comparisons

**Conclusions:** This study assessed the criterion validity and interpretability of patient-reported outcome tools HADS, and CES-D for depression screening in SLE patients. Compared to the gold standard, CES-D outperformed HADS-D. These results suggest that SLE-specific cut-offs may improve diagnostic accuracy of current screening metrics in lupus.

#### THU0345 SENSITIVITY AND SPECIFICITY OF ANTIBODIES AGAINST CARBAMYLATED PROTEINS IN A MONOCENTRIC COHORT OF PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND RHEUMATOID ARTHRITIS

<sup>1</sup>B. Özdemir, O. Kucuksahin<sup>2</sup>, T.H. Yeşil<sup>3</sup>, S. Akan<sup>4</sup>, S. Erten<sup>2</sup>. <sup>1</sup>Internal Medicine, Yıldırım Beyazıt University; <sup>2</sup>Rheumatology, Yıldırım Beyazıt University; <sup>3</sup>Rheumatology; <sup>4</sup>Internal Medicine, Atatürk Research and Educational Hospital, Ankara, Turkey

**Background:** Systemic lupus erythematosus (SLE) is a chronic systemic autoimmune disease characterised by numerous organ involvement. In SLE, autoantibody development against nucleic acids and their binding proteins plays an important role in disease pathogenesis.

**Objectives:** Purpose of this study is the determination of the diagnostic value of anti-carbamyl antibody in patients with Systemic Lupus Erythematosus and rheumatoid arthritis and the relationship with disease prognosis.

**Methods:** Fifty-seven SLE patients (F/M 50/7; median age 40.9 $\pm$ 13.7; median disease duration 2 years) were included in the study according to the 2012 SLICC SLE diagnostic criteria. 46 RA patients (F/M 38/8, median age 54.2 $\pm$ 12.4 years,

the median duration of disease 2 years) selected according to 2010 ACR/EULAR diagnostic criteria were included. 30 healthy control groups were selected. Anti carP antibody Anti-carbamylated Protein Human anti-carbamylated Protein Antibody (ACP-Ab) ELISA Kit (SunRedBio, China) was used for measurement of antibodies against carbamylated proteins.

**Results:** The study population consisted of 133 subjects, 30 controls, 57 SLEs and 46 RAs. The mean age of SLE patients was lower than that of RA patients. (40.9±13.7 versus 54.2±12.4;  $p<0.001$ ). The proportion of active smokers was found to be higher in RA patients compared to SLE patients (19.6% versus 5.3%,  $p=0.005$ ). The frequency of anti carP antibody positivity was 3.3% in the healthy control group. In contrast, the frequency of anti carP antibody positivity was found as high as 17.4% in patients with RA. ( $p<0.001$ ). And this frequency was 54.4% in the SLE patient group ( $p<0.001$ ). Anti carP antibody predicted SLE patients with 54.4% sensitivity and 96.7% specificity compared to the healthy control group. (AUC: 0.755,  $p<0.001$ ) Anti carP antibody predicted RA patients with 17.4% sensitivity and 96.7% specificity compared to the healthy control group (AUC: 0.570,  $p=0.032$ ). Anti carP antibody predicted SLE patients with 54.5% sensitivity and 82.6% specificity compared to healthy RA group (AUC: 0.685,  $p<0.001$ ). AnticarP antibodies were found to be positive in all of the SLE patient groups with anti-CCP positivity. There was no significant difference in terms of organ involvement between anti-carP antibody positive or negative SLE patients. Anti-carP antibody positivity was assessed by ROC Curve analysis for the prediction of diagnostic performance in SLE patients compared to RA patients. Accordingly, Anti carP antibody positivity, ANA positivity, were found to have similar diagnostic performance. (AUC: 0.639)

**Abstract THU0345 – Table 1.** Anti carbamylated protein antibody positivity distribution across groups

Variables	control n=30	SLE n=57	RA n=46	p
Anti carP antibody				
Negative	29(96.7)	26(45.6)	38(82.6)	$<0.001$
Positive	1(3.3)	31(54.4)	8(17.4)	

Categorical variables were expressed as number (%) (carP:carbamylated protein SLE:systemic lupus erythematosus RA: rheumatoid arthritis)

**Conclusions:** Antibody positivity was found to be 54.4% in SLE patient group. It is significantly higher in SLE compared to healthy control and RA patient group. In the SLE group, it is still a more significant diagnostic prognostic than the healthy control and RA group. Both SLE and RA patients have significant sensitivity and specificity compared to the healthy control group.

**DOI:** 10.1136/annrheumdis-2018-eular.4882

#### THU0346 DETERMINANTS OF SONOGRAPHIC GLANDULAR DAMAGE IN A LARGE COHORT OF PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME AND ITS IMPACT ON SALIVARY GLAND DYSFUNCTION

<sup>1</sup>C. Baldini, N. Luciano<sup>1</sup>, F. Ferro<sup>1</sup>, E. Calabresi<sup>1</sup>, E. Elefante<sup>1</sup>, V. Donati<sup>2</sup>, S. Bombardieri<sup>1</sup>, M. Mosca<sup>1</sup>. <sup>1</sup>Rheumatology Unit, University of Pisa; <sup>2</sup>Pathologic Anatomy II, AOUP, Pisa, Italy

**Background:** Salivary gland ultrasonography (SGUS) has increasingly appeared as a valid tool to characterise major salivary glands involvement in primary Sjögren's syndrome (pSS). An international score based on the number and location of the hypoechoic areas in the gland has been proposed for diagnostic purposes. Recently, a specific interest in using SGUS to estimate major salivary gland damage has also arisen in order to individualise patients treatment.

**Objectives:** a) to investigate frequency and severity of salivary gland damage in a large monocentric cohort of pSS patients; b) to explore determinants that could be associated with salivary gland damage accrual.

**Methods:** Sonographic data from a monocentric cohort of 311 pSS patients were collected from 2012 to 2017. SGUS had been performed according to a standard protocol that evaluated the echostructure of each gland graded on a 5-point scale (0–4). Salivary gland damage was defined by the presence of hyperechoic bands in more than 50% of the glandular parenchyma and on the basis of the size of the four glands.

**Results:** We included in the study 311 patients. The median age of the patients was 58 years (IQR, 49–68) and the median disease duration was 3 years (IQR, 0–9). Out of the cohort, 163 (52.4%) patients underwent SGUS examination within 3 years from the diagnosis, 91 (29.3%) within 4 to 10 years and 57 (18.3%) 10 years or more after the diagnosis. At SGUS evaluation 134/311 (43.1%) pSS patients did not present any findings of damage, whereas 177/311 (56.9%) presented at least one element of damage. SGUS damage inversely correlated with USFR ( $r=-0.382$ ,  $p$ -value=0.001). At the univariate analysis SGUS damage was associated to disease duration, number and location of the hypo-anechoic areas, focus score, ESSDAI score, hypergammaglobulinemia, and positivity for anti-Ro/SSA, anti-La/SSB, Rheumatoid Factor (RF) and cryoglobulins. In the linear

regression, duration of the follow-up, number and location of the hypo-anechoic areas and presence of cryoglobulins remained independently associated with SGUS damage. In 138/311 (44.4%) patients, SGUS was repeated prospectively at least twice during a median follow-up of 24 months (IQR, 12–36). Notably, 23/138 (16.7%) patients presented a damage progression. Presence of hyperechoic bands in the submandibular glands at the baseline evaluation was an independent risk factor for damage progression, whereas pSS low disease activity (ESSDAI <5) was protective against damage accrual.

**Conclusions:** Ultrasonographic damage resulted quite frequent in pSS patients and significantly associated with salivary gland dysfunction. Notably, pSS patients with normal echostructure of their glands were those less prone to develop SGUS damage during the disease course, whereas those presenting localised, diffuse or scattered hypo-anechoic areas were at higher risk of damage accrual.

#### THU0347 AQUAPORIN-4 IMMUNOGLOBULIN G ANTIBODY POSITIVE NEUROMYELITIS OPTICA SPECTRUM DISORDER AND SYSTEMIC AUTOIMMUNE DISEASES OVERLAP SYNDROME: A SINGLE CENTRE EXPERIENCE

E. Martín Nares, G. Hernández Molina, H. Fragoso Loyo. *Immunology and Rheumatology Department, Instituto Nacional de Ciencias Médicas y Nutrición Salvador Zubirán, Mexico City, Mexico*

**Background:** The coexistence of neuromyelitis optica spectrum disorder (NMOSD) with other systemic autoimmune diseases is well recognised, especially with systemic lupus erythematosus (SLE) and Sjögren syndrome (SS). However literature is scarce, limited to case reports and multicentric case series.

**Objectives:** To describe the clinical and radiological characteristics and outcomes of patients with AQP4-IgG seropositive NMOSD coexisting with SLE and SS in a single centre.

**Methods:** This was a retrospective study that included patients with concurrent diagnosis of AQP4-IgG seropositive NMOSD according to the 2015 International Consensus Diagnostic Criteria, and SLE according to the ACR revised criteria or SS according to the AECG criteria who regularly attended a tertiary referral centre in Mexico City (2003–2018). We collected demographics, clinical (neurological events, number of relapses, remission, treatment, follow-up [date of last visit to a rheumatologist and/or neurologist] and disability according to the Expanded Disability Status Scale [EDSS]), laboratory (cerebrospinal fluid (CSF) analysis) and imaging data of NMOSD, as well as clinical and serological data of the overlapping autoimmune disease. We assessed disease activity in SLE and SS using SLEDAI-2K and ESSDAI respectively, and accrual damage with the SLICC/ACR-DI and SSSDI respectively.

**Results:** We included 11 patients, 10 (90.9%) women with a mean age at diagnosis of 36±15 years. Seven (63.6%) had SLE and 4 (36.6%) primary SS. Five (45.5%) patients had also another systemic or organ-specific autoimmune disease. In 8 (72.7%) patients NMOSD followed SLE/SS onset, 3 (27.3%) had a simultaneous presentation, and in 1 (9.1%) NMOSD preceded SS diagnosis. The mean time from diagnosis of SLE/SS to the first neurological event was 54.6 months. The mean SLEDAI-2K and ESSDAI at first neurological event was 3.1 (mainly hypocomplementemia and high anti-dsDNA) and 14.3 points (mainly renal and peripheral nerve involvement) respectively. During follow-up, 10 patients (90.9%) experienced myelitis, 5 (45.5%) optic neuritis, 2 (18.2%) each experienced area postrema syndrome, acute brainstem syndrome and cerebral syndrome; being the median number of neurological events 4.<sup>1-8</sup> Three patients (27.3%) had antiphospholipid antibodies. None of the patients had pleocytosis or low CSF glucose and 3 had high CSF proteins. All patients had longitudinally extensive transverse myelitis on MRI, 3 (27.3%) optic nerve findings and 6 (54.5%) NMOSD-typical brain lesion patterns. Nine (81.8%) patients went into either total or partial NMOSD remission at a mean follow up of 6.5±5.3 years. At last follow up the median EDSS, SLICC/ACR-DI and SSSDI was 2.5 (1–10), 2 (0–7) and 2 (0–3) points respectively; 4 (36.4%) patients had sequelae and 1 patient was death.

**Conclusions:** Patients with SLE or SS with clinical features of NMOSD should be tested for AQP4-IgG. In our cohort, AQP4-IgG seropositive NMOSD arose in the context of low SLE activity and in the context of SS with extraglandular features, and the disability and accrual damage at last follow up appeared to be mild.

**THU0348 TIME ON DIALYSIS ADVERSELY AFFECTS RENAL TRANSPLANT OUTCOME IN LUPUS NEPHRITIS**

<sup>1,2</sup>E. Ntatsaki, V. Vassiliou<sup>3</sup>, A. Velo Garcia<sup>4</sup>, A.D. Salama<sup>5</sup>, D.A. Isenberg<sup>2</sup>.  
<sup>1</sup>Rheumatology, Ipswich Hospital NHS Trust, Ipswich; <sup>2</sup>Rheumatology, University College London, London; <sup>3</sup>Medical School, University of East Anglia, Norwich, UK; <sup>4</sup>Internal Medicine Department, University Hospital Complex of Pontevedra, Pontevedra, Spain; <sup>5</sup>Centre for Nephrology, University College London, London, UK

**Background:** Lupus nephritis (LN) is an important cause of morbidity and mortality in patients with systemic lupus erythematosus (SLE) often leading to end stage renal failure (ESRF) and necessitating renal transplantation. However, the optimal timing of transplantation in SLE patients with ESRF is uncertain and could potentially affect survival.

**Objectives:** We investigated time spent on dialysis before renal transplantation and survival following the transplantation in a cohort of SLE patients.

**Methods:** Retrospective analysis of all adult SLE patients undergoing renal transplantation over a 40 year period (1975–2015) in two tertiary UK centres followed up until 2017. Cox proportional hazard regression and receiver operator curves (ROC) were used to determine the risk associated with time on dialysis before the transplantation and other potential predictors.

**Results:** Forty patients (age 35±11 years, 34 female, 15 Caucasian, 15 Afro Caribbean and 10 South Asian) underwent transplantation. During a median follow up of 104 months (IQR 80,145), 8 (20%) patients died and the five year survival was 95%. Univariate analysis identified time on dialysis prior to transplantation as the only potentially modifiable risk predictor of survival with a Hazard Ratio of 1.013 for each additional month spent on dialysis (95% CI=1.001–1.026, p=0.03). ROC curve demonstrated that >24 months on dialysis had an adverse effect with sensitivity of 0.875 and specificity 0.500 for death. No other modifiable predictors were significantly associated with mortality, indicating that time on dialysis had an independent effect.

**Abstract THU0348 – Figure 1.** Kaplan-Meier estimator plot between patients who had less than 24 months of dialysis (blue line) or more than 24 months (green line), suggesting a trend of almost threefold risk of survival in those spending longer time on dialysis, HR 2.84 log rank p=0.15.

**Conclusions:** Increased time on dialysis pre-transplantation is an independent modifiable risk factor of mortality in this cohort of patients with lupus nephritis and should be one of the factors considered for patient selection to transplantation.

**THU0349 ANTIBODIES TO PHOSPHATIDYLSENERE-PROTHROMBIN COMPLEX AND ANNEXIN V AS RISK FACTORS FOR THE DEVELOPMENT OF THROMBOTIC COMPLICATIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

<sup>1</sup>E. Belolipetskaia, I. Beliaeva<sup>1</sup>, V. Mazurov<sup>1</sup>, S. Lapin<sup>2</sup>, O. Tkachenko<sup>2</sup>, V. Guseva<sup>2</sup>, O. Inamova<sup>3</sup>. <sup>1</sup>North-Western State Medical University named after I. Mechnikov; <sup>2</sup>St. Petersburg State Medical University named after I.P. Pavlov; <sup>3</sup>Clinical Rheumatological Hospital No 25, Saint-Petersburg, Russian Federation

**Background:** Seronegative antiphospholipid syndrome (APS) is a type of APS where the diagnostic levels of "classical" antiphospholipid antibodies (aPL) are not detected, though antibodies to the phosphatidylserine-prothrombin complex (aPS-PT) and anti-annexin V antibodies can be present. The role of these antibodies in the diagnosis of APS needs to be clarified.

**Objectives:** To study the prevalence of aPS-PT and anti-annexin V antibodies and their role in the development of thrombotic complications.

**Methods:** 79 SLE patients were enrolled in the study (M/F 7/72; mean age 11.0 years, range<sup>18,0,78,0</sup>). The main group consisted of 38 SLE patients with thrombotic complications and/or obstetric complications (mentioned in the classificational criteria for APS), a comparison group consisted of 41 SLE patients without thrombotic/obstetric complications. The groups were comparable in age, duration and SLE activity.

ELISA was used to test for aPL: anticardiolipin (aCL) IgG and IgM, anti-β<sub>2</sub>-glycoprotein-1 antibodies IgGAM (anti-β<sub>2</sub>GPI), antibodies to phosphatidylserine-prothrombin complex (anti-PS/PT) IgG/M, anti-annexin V antibodies IgG/IgM. Lupus anticoagulant (LA) was evaluated using the DRVV test method.

**Results:** In 11 patients (29%) of the main group "classical" aPL were not detected, although one SLE patient with thrombosis had elevated levels of antibodies to annexin V IgG (>5 U/ml).

Sensitivity and specificity of aPL for the diagnosis of APS in patients with SLE were 19% and 96% for anti-PS/PT, 11% and 94% for anti-annexin V antibodies IgG, 11% and 88% for anti-annexin V antibodies IgM respectively.

When comparing two groups using rank test, significant differences were revealed for aCL IgG, anti-β<sub>2</sub>GPI IgGAM levels (p<0.05); there were no significant differences between the main group and the comparison group (p>0.05) for levels of aCL IgM, aPS-PT and anti-annexin V antibodies. A positive correlation was revealed between the level of aPS-PT and the following aPL: LA (r=0.45, p=0.0006), aCL IgM and IgG (r=0.4 and r=0.45, p<0.001), anti-annexin V antibodies IgM and IgG (r=0.72 and r=0.47, p<0.001).

In a subgroup with elevated aPS-PT levels (>16 U/ml, 6 patients) thrombotic complications, venous thrombosis and its recurrence developed significantly more often than in a subgroup with a normal aPS-PT levels (OR=3.4, p=0.02, OR=4.1, p=0.02, OR=1.5, p=0.01, respectively).

**Conclusions:** 1. Anti-annexin V antibodies IgG and IgM have high specificity (94% and 88% respectively), but low sensitivity (11% and 11% respectively) for diagnosis of APS in SLE patients. 2. A level of aPS-PT has a positive correlation with both "classical" aPL and anti-annexin V antibodies, and has a sensitivity of 19% and a specificity of 96% for the diagnosis of APS in SLE patients. 3. Elevated levels of aPS-PT (>16 U/ml) increase the incidence of thrombotic complications in patients with SLE.

**Background:** Lupus nephritis (LN) is a common feature of systemic lupus erythematosus (SLE). While LN is considered a contributor to irreversible organ damage in SLE, the magnitude of impact of active renal disease relative to other contributors to damage accrual is unknown.

**Objectives:** To determine the time-dependent association of active lupus nephritis (LN) with organ damage accrual in SLE.

**Methods:** This study was performed on patients from the Asia Pacific Lupus Collaboration (APLC) cohort. SLE Disease Activity Index-2000 (SLEDAI-2k) is collected per-visit and SLICC-ACR Damage Index (SDI) annually. Analysis was restricted to patients with ≥2 SDI scores. Active LN was defined if patients had urinary casts, proteinuria, haematuria or pyuria as indicated in the SLEDAI-2k descriptor. Organ damage accrual was defined as a change of SDI (ΔSDI>0) between baseline and final visit. Glucocorticoid (GC) categories were defined according to cumulative GC exposure at each visit as either no GC (cum.GC=0); low GC (cum.GC ≤median) or high GC (cum.GC >median). Cox regression analyses were performed.

**Results:** 1735 patients and 5593 visits were included in the analysis. 93% of patients was female with a median ([inter-quartile range (IQR), (range)] age of 40 years.<sup>31, 51, 18, 77</sup> Median study observation period was 853 days [621, 1094].<sup>96, 1443</sup> 36% were Chinese; 20% Thai and 10% Caucasian ethnicity. 82% of patients were

**Abstract THU0348 – Table 1.** Univariate Cox proportional hazard modelling investigating the association of various parameters and mortality showing that only one modifiable risk factor associated with prognosis (time on dialysis, the longer on dialysis the worse the prognosis) and one non-modifiable (rTp taking place after 2000 associated with better survival). exposed to glucocorticoids. 40% had active renal disease at least once during the study period, and active renal disease was observed in 22% of visits (n=1238 visits). 41% of patients had organ damage at baseline and 14% accrued organ damage (272 damage accrual episodes in 250 patients). Active renal disease was significantly associated with damage accrual; after adjusting for confounders, patients with active renal disease were 66% more likely to accrue organ damage compared to those without active renal disease (adjusted hazard ratio=1.66 (95% CI: 1.26, 2.19), p-value<0.01 (table 1). High cumulative GC and age were also significantly associated with damage accrual.

	Univariable Cox regression analysis			Multivariable Cox regression analysis		
	HR	(95% CI)	p-value	HR	(95% CI)	p-value
Age at baseline (years)	1.02	(1.01,1.03)	<0.01	1.02	(1.01,1.03)	<0.01
Asian ethnicity	0.74	(0.52,1.05)	0.09	0.72	(0.50,1.04)	0.08
Cumulative glucocorticoid (GC) categories						
No GC	1.00	(1.00,1.00)		1.00	(1.00,1.00)	
Low GC (<median PNL)	1.42	(0.94,2.14)	0.1	1.47	(0.97,2.23)	0.07
High GC (>median PNL)	1.51	(1.04,2.18)	0.03	1.46	(0.99,2.16)	0.05
Baseline organ damage present	1.56	(1.22,2.00)	<0.01	1.27	(0.97,2.23)	0.09
Active lupus nephritis	1.66	(1.29,2.14)	<0.01	1.66	(1.26,2.19)	<0.01

**Conclusions:** Active LN is an independent risk factor for damage accrual in SLE. The concomitant independent association of GC exposure with damage accrual suggests non-GC treatments to reduce active LN are needed to reduce damage burden in SLE.

### SUSCEPTIBILITY TO CEREBRAL ISCHEMIA IN EARLY LUPUS PATIENTS: A PILOT STUDY OF CO-REGISTRATION WITH CONVENTIONAL BRAIN MRI, DIFFUSION- AND PERFUSION-WEIGHTED IMAGING

<sup>1</sup>E. Silvagni, A. Revenaz<sup>2</sup>, A. Bortoluzzi<sup>1</sup>, E. Groppo<sup>3</sup>, M. Padovan<sup>1</sup>, M. Borrelli<sup>2</sup>, S. Ceruti<sup>2</sup>, C.A. Scirè<sup>1</sup>, E. Fainardi<sup>4</sup>, M. Govoni<sup>1</sup>. <sup>1</sup>Department of Medical Sciences, Rheumatology Unit, University of Ferrara; <sup>2</sup>Neuroradiology Unit, Department of Neuroscience and Rehabilitation, Azienda Ospedaliero-Universitaria Sant'Anna, Cona; <sup>3</sup>Neurorehabilitation Unit, MS Center, Fondazione Don Gnocchi, Milan; <sup>4</sup>Neuroradiology Unit, Department of Experimental and Clinical Biomedical Sciences, University of Florence, Florence, Italy

**Background:** Conventional brain Magnetic Resonance Imaging (cMRI) has a limited usefulness in patients with early diagnosis of Systemic Lupus Erythematosus (SLE), showing not specific abnormalities in up to half of the patients. No data are available about cMRI combined with advanced MRI techniques in early SLE patients.

**Objectives:** To evaluate differences between early SLE patients, even without overt neuropsychiatric (NP) manifestations, and healthy controls (HCs) in a mono-centric cohort, using data derived from cMRI, diffusion-weighted imaging (DWI) and perfusion-imaging (PWI).

**Methods:** Patients referred to a single tertiary rheumatologic centre with early diagnosis of SLE (less than 24 months), aged less than 55, were consecutively enrolled (01/05/2013–31/12/2017) and imaged with cMRI, DWI and PWI (1.5 Tesla Philips "Signa Achieva" scanner). Data were analysed with a semi-automated measuring system (Diffusion/Perfusion Project Suite, developed in Multiple Sclerosis patients) to co-register apparent diffusion coefficient (ADC), cerebral blood flow (CBF) and volume (CBV), mean transit time (MTT) in normal appearing grey (NAGM) and white matter (NAWM), deep GM (putamen, pallidus, caudate, thalamus) and lesions. Demographic, clinical, serological and treatment information were collected as well as NP events at baseline attributed to SLE according to a validated algorithm. Statistical analysis were performed by comparing median (interquartile range, IQR) values for skewed variables between SLE and HCs and with quantile regression adjusted for cardiovascular comorbidities (hypertension, diabetes, previous coronary heart disease, hyperlipidaemia, obesity).

**Results:** 30 patients with early SLE (mean age 37.0 years, standard deviation SD 10.7, 27 females) and 8 HCs (mean age 40.6, SD 11.2, 6 females) were enrolled. MRI was performed after a mean period of 259 days from diagnosis; mean (SD) Systemic Lupus Erythematosus Disease Activity Index 2000 (SLEDAI-2k) was 8.87 (3.85) while mean (SD) Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index (SDI) was 0.40 (0.72); 3 patients were classified as NPSLE at diagnosis. Median (IQR) values of ADC in NAGM and NAWM were  $1.15 \times 10^{-3} \text{ mm}^2/\text{s}$  (1.12–1.16) and 0.86 (0.85–0.88) in SLE, 1.28 (1.16–1.33) and 0.97 (0.87–0.98) in HCs respectively (table 1). After adjusting for comorbidities, median differences between ADC values remained significant (p<0.001). SLE patients had lower median ADC values at bilateral putamen and pallidus. No differences were found in perfusion parameters in all the regions of interest (ROI) and lesions. A trend towards lower CBV and CBF and higher MTT values for NAGM-NAWM in NPSLE compared to non-NPSLE was found.

**Abstract THU0351 – Table 1.** Differences in diffusion and perfusion parameters at normal appearing GM and WM level in SLE patients and HCs.

ROI	NAGM ADC	NAWM ADC	NAGM CBF	NAWM CBF	NAGM CBV	NAWM CBV	NAGM MTT	NAWM MTT
SLE (30), median (IQR)	1.15 (1.12-1.16)	0.86 (0.85-0.88)	37.09 (30.97-47.21)	29.42 (26.00-37.48)	2.43 (2.20-2.58)	1.95 (1.80-2.26)	4.31 (3.80-5.23)	4.87 (4.12-5.85)
HCs (8), median (IQR)	1.28 (1.16-1.33)	0.97 (0.87-0.98)	33.89 (25.38-47.79)	26.54 (20.16-39.79)	2.57 (2.19-3.07)	2.11 (1.77-2.54)	5.11 (4.11-6.18)	5.78 (4.58-6.72)
p	0.004	0.009	0.591	0.519	0.283	0.452	0.123	0.124

Unit of measurement: ADC ( $\times 10^{-3} \text{ mm}^2/\text{s}$ ); CBF (ml/100g/min); CBV (ml/100g); MTT (s).

**Conclusions:** Lower ADC values in normal appearing GM and WM in early SLE patients could reflect susceptibility to cerebral ischemia, partially confirmed analysing perfusion data in NPSLE patients. Further prospective studies with higher sample size are necessary to confirm these findings.

### ASSOCIATION BETWEEN MEMORY B-CELLS AND PHENOTYPIC FEATURES OF SJÖGREN'S SYNDROME

<sup>1,2,3</sup>F. Barcelos, C. Martins<sup>1</sup>, A.L. Papoila<sup>4</sup>, C. Gerales<sup>4</sup>, J. Cardigos<sup>5</sup>, G. Nunes<sup>1</sup>, T. Lopes<sup>1</sup>, N. Alves<sup>5</sup>, J. Vaz-Patto<sup>2</sup>, J.C. Branco<sup>1,3</sup>, L.M. Borrego<sup>1</sup>. <sup>1</sup>CEDOC, Nova Medical School; <sup>2</sup>Rheumatology, Instituto Português de Reumatologia; <sup>3</sup>Rheumatology, Hospital Cuf Descobertas; <sup>4</sup>Nova Medical School; <sup>5</sup>Ophthalmology, CHLC, Hospital de Santo António dos Capuchos, Lisbon, Portugal

**Background:** B-cell disturbances are a hallmark of pSS and play a pivotal role in the disease pathogenesis and clinical evolution, and may as well have a potential role in diagnosis. In pSS, an increase of the naïve subset and a decrease of memory B-cells have been reported. A decreased frequency of memory cells has also been identified in patients with Sicca syndrome without criteria for pSS.

**Objectives:** Our study aims to evaluate the distribution of B-lymphocyte subpopulations in pSS and Sicca patients and to establish cut-off points for pSS classification in relation to healthy controls. Moreover, we aim to evaluate the relation between lymphocyte subpopulations and phenotypic features in pSS.

**Methods:** Fifty-seven pSS patients, 68 non-Sjögren Sicca patients and 24 healthy controls were included. Circulating B-cell frequencies were determined by flow cytometry, and the naïve and memory (switched and unswitched) subsets were characterised based on surface marker expression of the following monoclonal antibodies: CD19, CD24, CD27, Anti-IgD and Anti-IgM.

Kruskal-Wallis test was applied for groups' comparison. ROC curves were used to establish cut-off points in the B-cells subset levels and to estimate corresponding sensitivity and specificity. Data analysis was performed with R software.

**Results:** Absolute numbers of lymphocytes in pSS were lower compared to controls, with Sicca presenting intermediate levels.

Significant differences were found between pSS and controls in absolute counts of all memory populations: total memory (TMem) (CD19<sup>+</sup>CD27<sup>+</sup>), switched (SwM) (CD19<sup>+</sup>IgD<sup>+</sup>CD27<sup>+</sup>) and unswitched memory (UnSwM) (p<0.001 for all). Comparing pSS with controls, we found lower percentages of TMem in patients (p=0.078) and more significant differences in the UnSwM subset (p=0.043). Percentages of memory B-cells in Sicca were not significantly different from pSS and controls. Absolute memory B-cells numbers in Sicca were intermediate between those of pSS and controls.

Through ROC curves, the B-cell subsets that better discriminate between pSS and controls were TMem and SwM. A cut-off of equal to 58 TMem cells/μl yielded a specificity of 0.88 and a sensitivity of 0.60 for pSS, and was met by 59.6% of pSS, 12.5% of controls and 38.8% of Sicca, and a cut-off of equal to 23.5 SwM cells/μl yielded a specificity of 0.88 and a sensitivity of 0.54 and was met by 54.4% of pSS, 12.5% of controls and 37.3% of Sicca.

pSS patients with lower values than the established cut-off points had longer disease duration, higher disease activity (ESSDAI), and were more likely to present auto-antibodies and positive biopsy. Several Sicca patients also presented memory B-cell subsets counts lower than the pSS cut-off, but no consistent differences in clinical profile were identified.

**Conclusions:** Decreased numbers of memory B-cell subsets clearly discriminate pSS from healthy controls. Lower memory B-cells counts are associated with more active pSS disease profile. It remains to be clarified whether Sicca patients with decreased memory B-cells represent pSS and if B-cell profiling could help in the diagnosis of pSS.

### LUNG ULTRASOUND OF PLEURAL IRREGULARITIES (PI-US) IN PRIMARY SJÖGREN'S SYNDROME (PSS)-ASSOCIATED INTERSTITIAL LUNG DISEASE (ILD): CLINICAL, FUNCTIONAL, RADIOGRAPHIC AND ULTRASONOGRAPHIC SHORT-TERM FOLLOW-UP

<sup>1</sup>F. Ferro, A. Bulleri<sup>2</sup>, A. Delle Sedie<sup>1</sup>, S. Barsotti<sup>1</sup>, N. Luciano<sup>1</sup>, E. Elefante<sup>1</sup>, M. Mosca<sup>1</sup>, C. Baldini<sup>1</sup>. <sup>1</sup>Rheumatology Unit, University of Pisa; <sup>2</sup>Radiology Unit, University of Pisa, Pisa, Italy

**Background:** Ultrasound of Pleural Irregularities (PI-US) has recently been suggested as a useful tool for the diagnosis and the assessment of interstitial lung disease (ILD) in primary Sjögren's Syndrome (pSS). However, no data are available regarding its role in the post-therapy evaluation of pSS-ILD.

**Objectives:** Aim of this study was to describe the post-therapeutic changes of the pleural profile in a monocentric cohort of pSS-ILD patients analysing clinical, functional, US and radiographic features.

**Methods:** Eighteen patients with pSS-ILD were included in the study. PI-US, HRCT and pulmonary function test (PFT) were performed in each patient at baseline. In 15/18 patients who had been treated according to international guidelines for ILD, clinical assessment, PFT and PI-US were repeated after 6 months. PI-US was performed by a single operator using a MyLab-25 (Esaote), 10 MHz, 5 cm linear probe. PI was defined as the loss of normal hyperechoic linear pleural contour

(score 0–2: normal, minimal and major changes at each intercostal space). PI-US total score represented the sum of partial scores assigned to 6 lung fields (2 for the anterior, 2 for postero-superior and 2 for postero-inferior chest surface). HRCT- abnormal findings, distinguishing C-NSIP, F-NSIP and UIP pattern, were quantified using the Warrick score system.

**Results:** Eighteen pSS-ILD patients (14 F:4 M, mean age=68.8±9.9 years) were included in the study. The median PI-US score was 45 (range 25.5–73.5). Both PI-US total score and partial postero-inferior PI-US score strongly correlated with the Warrick HRCT score (r=0.813, p=0.000 and r=0.914, p=0.000) and inversely correlated with FVC (r=-0.849, p=0.000 and r=-0.836, p=0.000), TLC (r=-0.895, p=0.000 and r=-0.829, p=0.000), and DLCO (r=-0.953, p=0.000 and r=-0.883, p=0.001). Both PI-US score and PI-US of the poster-inferior field directly correlated with FEV1/SVC (r=0.701, p=0.004 and r=0.619, p=0.01) and with FEV1/FVC (r=0.600, p=0.02 and r=0.501, p=0.05). After 6 months of therapy, 15 patients (12F:3M, mean age 65.3 years) presenting at HRCT different ILD pattern distributions (4 C-NSIP, 7 F-NSIP, 4 UIP), were re-evaluated after appropriate medical treatment. Out of these 15 patients, 5 had been treated with glucocorticoids (GC) alone, 2 with azathioprine, 4 with hydroxychloroquine, 2 with Mycophenolate Mofetil, 1 with Rituximab and 1 with abatacept. Clinical, radiographic and functional evaluation showed stability of all parameters in the majority of the patients (13/15), maintaining unchanged the correlations with PI-US scores. Moreover, 2/15 patients with active C-NSIP pattern, showed a significant improvement in clinical, radiographic and functional parameters. In these patients a significant reduction of the PI-US scores was also observed (PI-US score from 22 to 10 and from 57 to 30).

**Conclusions:** This study confirms the usefulness of PI-US evaluation for the diagnosis and assessment of pSS-ILD, demonstrating a strong correlation between PI-US and both HRCT findings and PFT. Furthermore, the significant reduction of PI-US score in patients with clinical, radiographic and functional improvement suggests that this tool may play a role in the follow-up of treated patients with active pSS-ILD.

THU0354

### IMPACT OF BIOLOGIC THERAPY IN SJÖGREN'S SYNDROME PATIENTS WITH OVERLAPPING AUTOIMMUNE DISEASES OR EXTRAGLANDULAR MANIFESTATIONS. A SYSTEMATIC REVIEW OF LITERATURE

<sup>1</sup>G.E. Fragoulis, E. Nikiphorou<sup>2</sup>, A. Alunno<sup>3</sup>, F. Ng<sup>4</sup>, A.G. Tzioufas<sup>5</sup>. <sup>1</sup>Institute of Infection, Immunity and Inflammation, University of Glasgow, Glasgow; <sup>2</sup>Academic Rheumatology Department, King's College London, London, UK; <sup>3</sup>Rheumatology Unit, University of Perugia, Perugia, Italy; <sup>4</sup>Institute of Cellular Medicine, University of Newcastle, Newcastle, UK; <sup>5</sup>Pathophysiology Department, University of Athens, Athens, Greece

**Background:** Treatment of Sjögren's syndrome (SS) has traditionally focused on conventional synthetic DMARDs (csDMARDs), with encouraging evidence on the benefit of biologic therapies emerging, mainly for treatment of SS extraglandular manifestations. Overlapping autoimmune diseases in SS are poorly studied; yet evidence primarily from case reports suggest a beneficial effect with biologics.

**Objectives:** To systematically review the literature on the treatment of SS with biologics, taking a focus on case reports and overlapping autoimmune conditions or extraglandular manifestations (defined here as those described in the EULAR SS disease activity index - ESSDAI).

**Methods:** A literature review was performed independently by two reviewers, using Pubmed and the following search terms: "Sjogren" or "Sjogren's" AND any of the following: "biologics", "Etanercept", "Adalimumab", "Infliximab", "Golimumab", "Certolizumab", "Tocilizumab", "Abatacept", "Rituximab", "Belimumab", "Secukinumab", "Ustekinumab" and "Anakinra". Inclusion criteria were: articles in English; published until January 2018; case reports of patients with primary or secondary SS. Initial screening was based on title/abstract, followed by full-text review for articles fulfilling inclusion criteria. For articles written in a different language, information was obtained from abstract if available, otherwise excluded. Concordance in article screening was 95% across the two reviewers. Data extraction focused on reporting overlapping autoimmune diseases and extraglandular manifestations, treatment and response data.

**Results:** Out of 679 papers screened, 39 articles were included. 22 overlapping autoimmune conditions were reported in 22 SS patients (table 1). Most of the patients were treated with Rituximab (63.6%), while TNF-inhibitors (22.7%), Tocilizumab (9.1%) and Ustekinumab (4.5%) were also used. Concurrent treatment with csDMARDs and steroids was used in 28.6% and 42.9% of the cases, respectively. 61.9% and 13.6% of the patients were csDMARDs- and biologic- experienced, respectively. Good response of overlapping condition was seen in 86.4% of them, while in 13.6%, control or partial response was reported. Although, most of the studies do not mention the effect of biologic treatment on SS, general

'improvement' was mentioned in 4 cases, while arthritis was improved in 6 patients, 4 of which had secondary SS.

In terms of extraglandular manifestations (e.g cryoglobulinemic vasculitis, interstitial nephritis) 18 were reported. 16 (88.8%) patients received Rituximab (one of them in combination with Belimumab), while 2 (11.1%) were treated with TNF-inhibitors. 11.1% and 61.1% of them received concurrent treatment with csDMARDs and steroids, respectively. 55.5% and 11.1% of the patients were csDMARDs- and biologics- experienced, respectively. Extraglandular manifestations responded well in the majority (83.3%) of the patients, with the remaining having partial or late response. SS and arthritis 'improvement' was mentioned in 5 and 1 patients, respectively.

**Table 1** Biologic treatments used for overlapping autoimmune conditions in SS patients. csDMARDs: conventional synthetic Disease Modifying Antirheumatic Drugs, NA: Not Applicable, Joints: improvement of arthritis. ^SS response was defined as clinical improvement of sicca symptomatology or improvement in ESS-DAL. Improvement of arthritis was reported separately. † cases of secondary Sjogren's syndrome (3 cases co-existing with RA and one case with SLE)

Biologic Drug	Overlapping condition	Response of overlapping condition	SS-response <sup>†</sup>	csDMARDs (concurrent)	csDMARDs (past)	Steroids (concurrent)	First Biologic
Adalimumab	Crohn's disease	Good	Yes	No	Yes	No	Yes
Etanercept	Autoimmune hepatitis	Good	No (joints)	No	Yes	No	Yes
Infliximab	Psoriasis	Good	NA	Yes	Yes	No	Yes
Infliximab	gangrenous Sweet syndrome	Good	NA	No	Yes	Yes	Yes
Infliximab	Amphibias	Stable	NA (joints)	Yes	Yes	No	Yes
Tocilizumab <sup>†</sup>	Sarcoidosis	Good	NA (joints)	Yes	No	No	Yes
Tocilizumab	Organizing pneumonia	Good	Yes (joints)	Yes	No	Yes	No
Ustekinumab	Psoriasis	Good	NA (joints)	No	Yes	Yes	No
Rituximab	Psoriasis/dermatitis	Good	NA	No	Yes	No	Yes
Rituximab	Shrinking lung syndrome	Good	NA (joints)	Yes	Yes	Yes	Yes
Rituximab	Protein lung enteropathy	Good	NA	No	Yes	Yes	Yes
Rituximab	Angiodema	Partial	NA	No	No	Yes	Yes
Rituximab	Coeliac	Good	NA	No	Yes	No	Yes
Rituximab	Anterior scleritis	Good	NA	Yes	Yes	No	No
Rituximab	TTP	Good	NA	No	No	Yes	Yes
Rituximab	Acquired demyelinating neuropathy	Good	Yes	No	No	No	Yes
Rituximab	Werner's syndrome	Good	Yes	NA	NA	NA	Yes
Rituximab	Esophagitis	Good	NA	No	No	No	Yes
Rituximab	Acquired factor viii inhibitor	Good	NA	No	No	Yes	Yes
Rituximab	Anti-GAD ataxia	Stable	NA	No	No	No	Yes
Rituximab	ANCA-vasculitis	Good	NA	No	No	Yes	Yes
Rituximab	Shrinking lung syndrome	Good	NA	No	Yes	No	Yes

**Conclusions:** Treatment with biologic DMARDs, sometimes accompanied by steroids, appears to be beneficial also in treating overlapping autoimmune diseases as well as some extraglandular manifestations in SS patients.

**THU0355 DAMAGE ACCRUAL AND MORTALITY RATES AMONG DIFFERENT AGE GROUPS IN A COHORT OF PATIENTS WITH LUPUS**

G.A. Ramirez, B. Tejera-Segura, R. Lopez, A. Rahman, D.A. Isenberg. *Centre for Rheumatology, University College London (UCL) Hospital NHS Foundation Trust, London, UK, London, UK*

**Background:** Systemic lupus erythematosus (SLE) is a chronic, multi-system autoimmune disease, characterised by relapses and remissions, which eventually can lead to progressive, irreversible organ damage accrual. SLE-related damage implies increased morbidity and impaired quality of life. In addition, it constitutes itself a risk factor for the development of further damage and associates with early mortality. Age at disease onset has been postulated to affect the presenting clinical phenotype, the rate and likelihood of accruing damage and eventually mortality risk. Early-onset SLE patients have been reported to present with a more aggressive disease, especially in the first years after diagnosis. However, long-term data from large cohorts are scanty.

**Objectives:** To assess retrospectively the mortality and damage accrual rates in a large cohort of patients with SLE.

**Methods:** Demographic, clinical and laboratory data from 692 consecutive patients with SLE (631 females, 61 males), diagnosed according to the revised American College of Rheumatology (ACR) criteria in a single tertiary referral centre, were retrospectively analysed focusing on age of diagnosis. Damage accrual was assessed according to the Systemic Lupus Erythematosus

International Collaborating Clinics (SLICC)/ACR damage index (SDI). Cox's regression analysis, chi-square test, Kruskal-Wallis test and ANOVA were employed as appropriate.

**Results:** Thirty-three out of 692 patients were diagnosed with SLE before the age of 12, 172 between 12 and 20, 443 between 21 and 50 and 44 after 50 years of age. As previously reported, a female preponderance was more evident in the central part of the age spectrum (p=0.015). Nephritis and decreased complement were more frequent in patients with early-onset SLE (p=0.001 and p=0.033 respectively), serositis in the central age groups (p=0.025), and arthritis in late-onset patients (p=0.002). Neuropsychiatric manifestations were less frequent in patients aged >50 years (p=0.013; table 1). The global incidence rate for any damage was 48.36 per 1000 persons-years, whereas the death incidence rate was 8.54 per 1000 persons-years. Late-onset SLE associated with a higher risk of damage accrual (HR=1.63, p=0.024) and of death (HR=6.22, p<0.001). However, there were no significant differences in the time to first damage, to death after diagnosis and to death after the development of the first damage item, according to the age of diagnosis.

**Conclusions:** Younger patients with SLE show a distinct clinical phenotype, but share an accelerated accrual of morbidity and a higher risk of early mortality with patients of older age. Identifying age-specific predictors of disease severity will be of outstanding importance to improve long-term survival rates and patients' quality of life.

**THU0356 SYNERGISTIC EFFECT OF CUMULATIVE CORTICOSTEROID DOSE AND IMMUNOSUPPRESSANTS ON AVASCULAR NECROSIS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

H.-H. Kwon, S.-Y. Bang<sup>1</sup>, S. Won<sup>2</sup>, Y. Park<sup>2</sup>, J.-H. Yi<sup>3</sup>, Y.B. Joo<sup>1</sup>, H.-S. Lee<sup>1</sup>, S.-C. Bae<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Hanyang University Hospital For Rheumatic Diseases; <sup>2</sup>Clinical Research Center for Rheumatoid Arthritis (CRCRA), Seoul; <sup>3</sup>Department of Internal medicine, Hanyang University Guri Hospital, Guri, Korea, Republic of Ireland

**Background:** Avascular necrosis (AVN) is one of the most common organ damage in patients with systemic lupus erythematosus (SLE) and often causes serious physical disability.

**Objectives:** The aims of this study were to investigate clinical risk factors associated with symptomatic AVN and to analyse their synergistic effects in a large SLE cohort in Korea.

**Methods:** Patients with SLE were enrolled and followed from 1998 to 2014 in the Hanyang BAE Lupus cohort, in whom damage was measured annually according to the Systemic Lupus International Collaborating Clinics/American College of Rheumatology Damage Index. AVN was confirmed by imaging study if patients had symptoms. To determine risk factors for AVN, clinical, laboratory, and therapeutic variables were analysed by logistic regression. Relative excess risk due to interaction (RERI), attributable proportion (AP), and synergy index (S) were calculated to measure interactions between significant variables.

**Results:** Among 1,219 SLE patients, symptomatic AVN was the most common type of musculoskeletal damage (10.8%, n=132). SLE patients with AVN showed an earlier onset age, demonstrated AVN more commonly in conjunction with certain other clinical manifestations such as renal and neuropsychiatric disorders, and received significantly higher total cumulative corticosteroid dose and immunosuppressive agents than did patients without AVN. However, in multivariable analysis, only two variables including use of a cumulative corticosteroid dose greater than 20 g (odds ratio (OR) 3.08, p=0.005) and use of immunosuppressants including cyclophosphamide or mycophenolate mofetil (OR 4.34, p=0.002) remained as significant risk factors for AVN. Patients with cumulative corticosteroid dose >20 g and immunosuppressants use had a

Age group (years)	N	Females (%)	Nephritis (%)	Neurological inv. (%)	Arthritis (%)	Rash (%)	Photosensitivity (%)	Oral ulcers (%)	Serositis (%)	antiDNA (%)	Reduced complement (%)
<12	33	78.8	48.5	27.3	72.7	81.8	42.4	27.3	18.2	72.7	51.5
12-20	172	89.5	41.9	32.1	87.2	65.7	39.0	30.2	37.8	66.9	55.0
21-50	443	93.2	33.4	22.6	91.9	66.8	41.8	26.0	41.1	61.2	46.0
>50	44	86.4	11.4	6.8	93.2	54.5	27.3	22.7	27.3	63.6	31.8

15.44-fold increased risk for AVN, compared with patients without these risk factors ( $p < 0.001$ ). RERI, AP, and S, which define the strength of interactions between two risk factors, were 9.01 (95% confidence interval (CI) 1.30–16.73), 0.58 (95% CI 0.36–0.81), and 2.66 (95% CI 1.42–4.99), respectively, supporting the presence of synergistic interactions in the development of symptomatic AVN in our Korean lupus cohort.

**Abstract THU0356 – Table 1.** Synergistic effect of total cumulative steroid dose and use of immunosuppressants in development of AVN in SLE patients

	No. patients with AVN	No. patients without AVN	OR <sup>a</sup> (95% CI)	p-value
Total cumulative steroid dose $\leq 20$ g and immunosuppressants (-)	11	314	1.00	
Total cumulative steroid dose $> 20$ g and immunosuppressants (-)	17	168	3.08 (1.40–6.81)	0.005
Total cumulative steroid dose $\leq 20$ g and immunosuppressants (+)	18	121	4.34 (1.99–9.49)	$< 0.001$
Total cumulative steroid dose $> 20$ g and immunosuppressants (+)	64	134	15.44 (7.64–31.19)	$< 0.001$
RERI			9.01 (1.30–16.73)	
AP			0.58 (0.36–0.81)	
S			2.66 (1.42–4.99)	

AVN: avascular necrosis; SLE: systemic lupus erythematosus; OR: odds ratio; CI: confidence interval; RERI: relative excess risk due to interaction; AP: attributable proportion; S: synergy index

a. Odds ratios were adjusted for sex, age and disease duration.

**Conclusions:** An individual risk assessment for AVN development should be made prior to and during treatment for SLE, especially in patients with high-dose corticosteroid and immunosuppressant use regardless of clinical manifestations and disease activity.

#### THU0357 FEATURES ASSOCIATED WITH LOSS TO FOLLOW-UP IN THE YEAR PRIOR TO DEATH IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE ANALYSIS FROM A NATIONAL REFERRAL CENTRE

<sup>1</sup>L. Padjen, M. Erceg<sup>2</sup>, M. Cerovec<sup>1</sup>, M. Bakula<sup>1</sup>, M. Mayer<sup>1</sup>, R. Stevanovic<sup>2</sup>, B. Anic<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Clinical Immunology and Rheumatology, University Hospital Centre Zagreb and University of Zagreb, School of Medicine; <sup>2</sup>Croatian Institute of Public Health, Zagreb, Croatia

**Background:** Loss to follow-up in the year prior to death may lead to underrecognition and underreporting of systemic lupus erythematosus (SLE) as a cause of death of lupus patients.

**Objectives:** We aimed to assess the extent and features associated with loss to follow-up in the year prior to death in a group of 90 deceased SLE patients from our tertiary centre.

**Methods:** We retrospectively analysed 90 SLE patients (68 females) followed-up at our centre, deceased from 2002 to 2011. Patients were  $\geq 18$  years of age at death and fulfilled  $\geq 4$  classification criteria of the American College of Rheumatology (ACR). The cause and place of death were identified by matching patient data from our department's SLE registry with data from the National Death Database. Patients were considered lost to follow-up in the year prior to death (LTF) if the time span between the last visit to our centre and death exceeded 1 year. Other patients were considered to be under regular follow-up (RGF).

An extensive set of parameters was compared between the LTF and RGF groups: demographics, ACR classification criteria, cumulative damage according to the Systemic Lupus International Collaborative Clinics (SLICC)/ACR index, as well as causes of death. Frequencies were compared using the chi-square and Fisher's exact test, and continuous variables using the t-test and Mann-Whitney U-test.

**Results:** We identified 35/90 patients in the LTF group (29 females). The time span between the last visit to our centre and death of LTF patients ranged from  $> 1$  to 3 years. Compared to the RGF group, LTF patients were diagnosed at a later age (mean  $\pm$  SD:  $54 \pm 15$  vs.  $44 \pm 17$  years,  $p = 0.006$ ), while there was no difference in disease duration (median of 11 years, IQR of 5–15 years in the RGF group vs. median of 7 years, IQR of 5–15 years in the LTF group,  $p = 0.285$ ). The

LTF and RGF groups did not differ in the count of ACR criteria (median of 5, IQR of 4–6 vs. median of 6, IQR of 5–7,  $p = 0.053$ ) and cumulative damage (median damage of 3, IQR of 2–5 vs. median of 5, IQR of 3–8,  $p = 0.068$ ).

Compared to the RGF group, LTF patients had a lower cumulative proportion of pericarditis (1/35 vs. 16/55), proteinuria (10/35 vs. 30/55), hemolytic anaemia (1/35 vs. 10/55), thrombocytopenia (5/35 vs. 21/55) and Hughes syndrome (2/35 vs. 13/55) ( $p < 0.05$ ). Pulmonary damage and peripheral vascular damage were observed only in RGF patients (9/55 vs. 0/35,  $p = 0.011$ ; and 8/55 vs. 0/35,  $p = 0.021$ , respectively). LTF patients also had a lower proportion of cardiomyopathy (7/35 vs. 24/55,  $p = 0.021$ )

RGF patients died more frequently from active lupus compared to their LTF counterparts (24/55 vs. 2/35,  $p < 0.001$ ), while no difference was observed between the proportions of death from infections, cardiovascular diseases, malignancies and unknown causes (figure 1). SLE was reported in death certificates of 30/55 RGF patients compared to only 11/35 LTF patients ( $p = 0.032$ ). Compared to the RGF group, a lesser proportion of LTF patients died in the hospital (17/35 vs. 46/55,  $p = 0.004$ ).

**Abstract THU0357 – Figure 1.** Causes of death according to follow-up status

**Conclusions:** A lower proportion of LTF patients exhibited features of active SLE over their disease course. This may have led to underrecognition of SLE as a contributor to death.

#### THU0358 USEFULNESS OF 18F-FDG POSITRON EMISSION TOMOGRAPHY (PET) FOR LYMPHOMA DIAGNOSIS IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME

<sup>1</sup>J. Keraen, E. Blanc<sup>2</sup>, F. Besson<sup>3</sup>, M. Meyer<sup>3</sup>, V. Le Guem<sup>4</sup>, G. Nocturne<sup>1</sup>, J. Henry<sup>1</sup>, R. Belkhir<sup>1</sup>, X. Mariette<sup>1</sup>, R. Seror<sup>1</sup>. <sup>1</sup>Rheumatology, CHU du Kremlin Bicêtre, Kremlin Bicêtre; <sup>2</sup>Nuclear imaging, Centre Chirurgial Marie Lannelongue, Le Plessis Robinson; <sup>3</sup>Nuclear imaging, CHU du Kremlin Bicêtre, Kremlin Bicêtre; <sup>4</sup>Internal Medicine, Cochin, Paris, France

**Background:** Primary Sjögren's syndrome (pSS) is the autoimmune disease having the highest risk of lymphoma. The differential diagnosis between benign and malignant lymphoproliferation is sometimes difficult. Among imaging procedures, 18F-FDG PET could be useful for that purpose.

**Objectives:** To compare 18F-FDG PET results between patients with and without lymphoma to identify PET pattern associated with lymphomas in pSS

**Methods:** Retrospective study conducted in 2 centres including pSS patients (according to ACR/EULAR 2016 criteria) who undergo 18F-FDG PET. We compared PET abnormalities in patients with and without lymphoma, the PET having been done before any chemotherapy. Two independent readers analysed PET blind to lymphoma diagnosis. ESSDAI-PET score previously described by Cohen *et al.*<sup>1</sup> was calculated.

**Results:** 45 patients were included; 15 had lymphoma: MALT (n=12), nodal marginal zone with plasmacytic differentiation (n=2), diffuse large B-cell (n=1). Patients with lymphoma had more frequently parotid gland swelling (67% vs 20%,  $p = 0.003$ ) and higher ESSDAI score (24 [13.5–29] vs 9,  $p = 0.03$ ), even after exclusion of lymphoma item (19<sup>11–27</sup> vs 9,  $p = 0.03$ ).

Compared to non-lymphoma patients, mean size ( $45.5^{38–56}$  mm vs.  $40^{37–41}$  mm;  $p = 0.048$ ) and maximum standardised uptake value (SUVmax) of the parotid glands (5.6 [5–6.9] vs 3.8 [3.2–4.4];  $p = 0.001$ ) were higher in lymphoma patients. 53.3% of patients with lymphoma and 43.3% without lymphoma had lymph node FDG uptake, but neither their number nor their repartition or mean SUV differ between them.

Pulmonary uptake was observed in 6 (40%) patients with lymphoma and 6 (20%) without lymphoma ( $p=0.17$ ). But in lymphoma patients, this uptake was focal in 5 (33.3%) patients (nodules or condensation) and in only one (3.3%) patient without lymphoma ( $p=0.01$ ). Remaining patients had interstitial FDG uptake. Mean PET score ( $4^{-2}$  vs.  $2^{-3}$   $p=0.04$ ) and SUVmax at any site (6.3 [5.6–7.3] vs. 4.2 [3.7–5.9]  $p=0.02$ ) were significantly higher in lymphoma group. 20 patients had PET guided biopsy of a hypermetabolic lesion that conducted to lymphoma diagnosis in 7 cases (46.6%). After chemotherapy for lymphoma, PET was available for 10 patients: complete regression of hypermetabolic lesions was observed in 6 patients (60%), and decreased uptake intensity in the 4 remaining patients.

**Conclusions:** Some of the systemic manifestation of pSS (lung, lymph nodes and salivary glands) can be assessed by 18F-FDG PET. Lymph nodes hypermetabolism is frequent and not associated with lymphoma. The 18F-FDG PET abnormalities associated with lymphoma diagnosis are SUV max at any site  $>6$ , SUV max of parotid glands  $>5$  and focal nodular hypermetabolic lung lesions. Finally, PET can be helpful to guide biopsy toward the most hypermetabolic structure for diagnosing lymphoma.

#### THU0359 RELATIONSHIP BETWEEN DAMAGE CLUSTERING AND MORTALITY IN JUVENILE SYSTEMIC LUPUS ERYTHEMATOSUS: CLUSTER ANALYSES IN A LARGE COHORT FROM THE SPANISH SOCIETY OF RHEUMATOLOGY LUPUS REGISTRY

J.M. Pego-Reigosa, T.C. Salman-Monte<sup>2</sup>, I. Rua-Figueroa<sup>3</sup>, J. Calvo-Alén<sup>4</sup>, F. J. López-Longo<sup>5</sup>, M. Galindo<sup>6</sup>, A. Olivé<sup>7</sup>, V. Torrente-Segarra<sup>8</sup>, on behalf of RELESSER and EASSER groups. <sup>1</sup>Rheumatology, Hospital do Meixoeiro; IRIDIS (Investigation in Rheumatology and Immune-Mediated Diseases) Group, Instituto de Investigación Sanitaria Galicia Sur (IISGS), Vigo; <sup>2</sup>Rheumatology, Parc de Salut Mar-IMIM, Department of Medicine, Universitat Autònoma de Barcelona (UAB), Barcelona; <sup>3</sup>Rheumatology, Hospital Universitario Dr Negrín, Las Palmas; <sup>4</sup>Rheumatology, Hospital Araba, Vitoria; <sup>5</sup>Rheumatology, Hospital Gregorio Marañón; <sup>6</sup>Rheumatology, Instituto de Investigación Hospital 12 de Octubre (I+12), Madrid; <sup>7</sup>Rheumatology, Hospital Germans Trias i Pujol, Badalona; <sup>8</sup>Rheumatology, Hospital General Hospitalet-Moisès Broggi, Hospitalet Llobregat, Spain

**Objectives:** Identify patterns (clusters) of damage manifestations within a large cohort of patients with juvenile-onset SLE (jSLE) and evaluate their potential association with mortality.

**Methods:** Multicenter, descriptive and cross-sectional study of a cohort of 345 patients with jSLE (age at SLE diagnosis  $<18$  years) from the Lupus Registry of the Spanish Society of Rheumatology (RELESSER). Organ damage was determined by using the SLICC/ACR damage index (SDI). By using cluster analysis, groups of patients with similar patterns of damage manifestations were identified and compared among them.

**Results:** Mean age (years) $\pm$ S.D. at diagnosis was  $14.2\pm 2.89$ , 88.7% were female and 93.4% were Caucasian. Mean SLICC/ACR DI $\pm$ S.D. was  $1.27\pm 1.63$ . A total of 12 (3.5%) patients died. Three damage clusters were identified: Cluster 1 (72.7% of patients) presented a lower amount of individuals with damage (22.3% vs 100% in clusters 2 and 3,  $p<0.001$ ). Cluster 2 (14.5% of patients) was featured by renal damage in 60% of patients, significantly more frequent than clusters 1 and 3 ( $p<0.001$ ), alongside more ocular, cardiovascular and gonadal damage. Cluster 3 (12.7%) was the only group with musculoskeletal damage (100%), significantly higher than in clusters 1 and 2 ( $p<0.001$ ). The overall mortality rate in cluster 2 was 2.2 times higher than that in cluster 3 and 5 times higher than that in cluster 1 ( $p<0.017$  for both comparisons).

**Conclusions:** In a large cohort of jSLE patients, renal and musculoskeletal damage manifestations were the two dominant forms of damage to sort patients into clinically meaningful clusters. We found two clusters of jSLE with important clinical damage that were associated to higher rates of mortality, especially for the cluster of patients with predominant renal damage. Physicians should pay special attention to the early prevention of damage in this particular subset of jSLE patients with kidney involvement.

#### THU0360 A VALIDATION STUDY OF THE GLOBAL ANTIPHOSPHOLIPID SYNDROME SCORE (GAPSS) IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS AND PREGNANCY MORBIDITY

<sup>1,2</sup>K. Schreiber, M. Radin<sup>3,4</sup>, I. Cecchi<sup>3,4</sup>, M.J. Cuadrado<sup>5</sup>, L. Marozio<sup>6</sup>, D. Roccatello<sup>3,4</sup>, S. Sciascia<sup>3,4</sup>. <sup>1</sup>Department of Thrombosis and Haemophilia, Guy's and St Thomas' Hospital, London, UK; <sup>2</sup>Copenhagen Lupus and Vasculitis Clinic, Center for Rheumatology and Spine Diseases, Copenhagen University Hospital, Rigshospitalet, Copenhagen, Denmark; <sup>3</sup>Center of Research of Immunopathology and Rare Diseases- Coordinating Center of Piemonte; <sup>4</sup>Valle d'Aosta Network for Rare Diseases Department of Clinical and Biological Sciences, and SCU Nephrology and Dialysis, S. Giovanni Bosco Hospital, Turin, Italy; <sup>5</sup>Department of Rheumatology, Guy's and St Thomas' NHS Foundation Trust, London, UK; <sup>6</sup>Department of Gynaecology, S. Giovanni Bosco Hospital, Turin, Italy

**Background:** Systemic lupus erythematosus (SLE) and antiphospholipid antibodies (aPL) are associated with pregnancy complications.

**Objectives:** To validate the global antiphospholipid syndrome score (GAPSS) in a cohort of women with SLE.

**Methods:** 143 women ever pregnant with SLE who presented in our outpatient clinic were included (table 1). Data on cardiovascular risk factors and aPL positivity were retrospectively collected. The individual GAPSS was calculated for each patient by calculating the sum of each risk factor score, which is based on a linear transformation derived from the  $\beta$  regression coefficient as follows: 3 for hyperlipidaemia, 1 for arterial hypertension, 5 for aCL IgG/IgM, 4 for anti-b2 glycoprotein I IgG/IgM, 3 for aPS/PT IgG/M and 4 for lupus anticoagulant (LA)<sup>1</sup>.

**Results:** Significantly higher GAPSS values were seen in patients with a history of pregnancy complications compared to those without a history pregnancy complications. Results are outlined in table 1 and figure 1.

**Abstract THU0360 – Table 1.** Patient demographics

Patients Characteristics	All (n=143)	%
Age, mean (S.D.), years	43.6 (SD 10.8)	
Disease duration, mean (S.D.), years	13.4 (9.3)	
Ethnicity (White:Black:afro-carib:Columbian: Asian)	119:6:11:1:1:4	
Cardiovascular risk factor (any), n	84	58%
Smoking, n	39	27%
Arterial Hypertension	44	31%
Hyperlipidemia, n	31	22%
Diabetes, n	4	3%
Pregnancies, n	382	
Pregnancy morbidity (any), n	54	14%
Consecutive early miscarriages (>3), n	9	2%
Any miscarriage, n	39	10%
Fetal death, n	25	7%
Prematurity, n	15	4%
Pre-eclampsia, n	19	5%
Intrauterine death, n	10	3%
Placental infarction, n	5	1%

**Abstract THU0360 – Figure 1.** Graphic illustration of the global antiphospholipid syndrome scores (GAPSS) in women with and without pregnancy morbidity.

**Conclusions:** Higher GAPSS values are found in women with SLE and aPL with previous pregnancy complications compared to those without pregnancy complications. The clinical utility of the GAPSS score in pregnancy seem promising and should be validated in a prospective cohort.

#### THU0361 CHARACTERISATION OF NOVEL AUTOANTIBODIES TO AHNK1 SPECIFICALLY PRESENTED IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

K. Nozawa, Y. Matsushita, K. Doe, Y. Takasaki, K. Yamaji, N. Tamura. *Rheumatology, Juntendo University School of Medicine, Tokyo, Japan*

**Background:** Aberrant activation of T cells has been considered to play important roles for pathogenesis of SLE. In T cells activation, calcium signalling is essential for the process. Interestingly, T cells of SLE patients have been reported to show several abnormalities of calcium signalling. In the present study, we postulated that patients with SLE may target calcium signaling-related molecules as autoantigen as autoantibodies to these molecules are potentially capable of interfering with calcium signalling through binding to these molecules localised at the plasma membrane eventually resulting in abnormal T cells activation in SLE. Regarding to the calcium signaling-related molecules, recent studies have shown that AHNK1 is predominantly expressed in CD4 +T cells of cell membrane and cytoplasm. Moreover, AHNK1 is known to play significant roles for regulating of calcium signalling at T cells activation through its ability to localise calcium channels properly at the plasma membrane as scaffold protein. Therefore, we verify whether autoimmune response to AHNK1 is elicited in SLE.

**Objectives:** The present study was conducted to clarify whether autoantibodies to AHNK-1 are produced in SLE compared with other connective tissue diseases and normal healthy controls (NHCs).

**Methods:** The Patients sera consisting of SLE (n=59), other connective tissue diseases (PM/DM; n=40, SSc; n=40, SS; n=30, MCTD; n=30, and RA; n=30) and NHCs (n=115) were used in the present study. Immunoreactivity against AHNK1 recombinant antigens was evaluated by ELISA. AHNK1 mRNA expression in peripheral blood mononuclear cells (PBMCs) was evaluated by quantitative RT-PCR. Indirect immunofluorescence (IIF) staining using monoclonal anti-AHNK1 antibodies in combination with the patient's sera containing anti-AHNK1 antibodies was evaluated using HEp-2 substrate. The experimental data were statistically analysed using the Mann-Whitney U-test or Chi-square test, and differences with P-values<0.05 were considered to be significant.

**Results:** Immunoreactivity against AHNK1 was significantly elevated in SLE patients compared to both NHCs and other connective tissue diseases. Significant elevation of AHNK1 mRNA expression was observed in PBMC of SLE patients compared to NHCs. Among 17 SLE patients with anti AHNK1 antibodies positive sera, 4 patients revealed reduction of anti- AHNK1 antibodies level after the treatment like glucocorticoid or immune suppressive reagents, however, the remaining 13 patients did not show the reduction of serum level of anti-AHNK1 antibodies. In clinical profile, lymphopenia was frequently observed in these SLE patients. IIF analysis showed that AHNK-1 is localised at cell membrane and cytoplasm rather than nucleus.

**Conclusions:** In the present study, we found that autoantibodies to AHNK1 were significantly observed in sera with SLE compared to both NHCs and other connective tissue diseases. Furthermore, AHNK1 were enriched in PBMC of SLE patients suggesting antigen driven system may play an important role for this autoantibodies production. Anti-AHNK1 antibodies may be pathological and play an important role for pathogenesis of SLE because it may possibly alter physiological calcium signalling of T cells through binding to AHNK1 on cell membrane eventually resulting in aberrant T cells activation in SLE.

#### THU0362 INCIDENCE OF MAJOR INFECTIONS IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

<sup>1</sup>K. Yap, L. Kyi<sup>1</sup>, J. Chang<sup>2</sup>, P. Nguyen<sup>2</sup>, R. Kandane-Rathnayake<sup>2</sup>, A. Hoi<sup>1</sup>.

<sup>1</sup>Rheumatology, Monash Health; <sup>2</sup>Rheumatology, Monash University, Melbourne, Australia

**Background:** Major infections are one of the leading causes of morbidity and mortality in patients with systemic lupus erythematosus (SLE), and one of key concerns when considering the risk of immunosuppressive therapy. Previous studies have limited information on the relationship of infections and disease characteristics.

**Objectives:** To examine the incidence of major infections and describe the types of infections that occur in a cohort of well-characterised SLE patients

**Methods:** The study included 192 SLE patients who attended the Monash Lupus Clinic at Monash Health and enrolled in the Australian Lupus Registry and Bio-bank (ALRB) between 1st of July 2009 to 31st Dec 2016. Major infections were defined as any serious infections resulting in hospitalisation, reactivation of major viral infection, latent or active tuberculosis or any opportunistic infections. Patient and disease characteristics were examined in patients with or without major infections, and comparison was also made with 86 rheumatoid arthritis (RA) patients who are on similar level of immunosuppression. Associations between a number of patient and disease variables and infection were examined using Wilcoxon rank-sum tests (continuous variables) and Person's chi-squared tests (binary/categorical variables).

**Results:** 57 (30%) SLE patients reported 97 episodes of infection during the observation period (974 person-years). The median age of patients and observation period and other demographics were similar in patients who have experienced a major infection. In contrast, 15 (17%) RA patients reported 28 infection events during the study period. RA patients who reported infections were significantly older than SLE patients with infections events, median age (IQR) 68 years<sup>53</sup> vs 42 years<sup>33, 54</sup> (p<0.001) respectively. 61% of SLE patients and 54% of RA patients were on prednisolone. Comparing lupus with RA patients, the type of pathogens identified was significantly different (p<0.001), with no organism identified being the most common in lupus whereas in RA multiple pathogens are common (table 1). VZV reactivation causing shingles was the most common skin and soft tissue infection in lupus patients, and occurred more frequently than the RA patients. Among all of serious infections requiring hospitalisation, infection site did not differ between SLE and RA patients, and lower respiratory and urinary tracts were most commonly involved. In patients who experienced major infection they had a significantly higher SLEDAI (p 0.04), higher ESR (p 0.005) and lower haemoglobin (p 0.003).

Pathogen_type	SLE n=97	RA n=28	<0.001
CMV, EBV	4 (3.2%)	0 (0%)	
E coli, Salmonella	6 (5%)	7 (25%)	
HSV	9 (9%)	1 (4%)	
Influenza	2 (2%)	0 (0%)	
Multiple	7 (7%)	14 (50%)	
Unknown	30 (31%)	2 (7%)	
Pneumocystis jirovecii	1 (1%)	0 (0%)	
Staphylococcus,	12 (10%)	0 (0%)	
Streptococcus			
VZV	10 (10%)	2 (7%)	

**Conclusions:** Our data suggests that major infections occur commonly in SLE patients, and the likelihood of infection is higher in SLE, when compared to RA patients on a similar level of immunosuppression. Higher disease activity measures were associated with increased likelihood of infection. Medication exposure such as prednisolone use was similar in SLE and RA patients, suggesting other factors other than medication use plays an important role in driving infections.

#### THU0363 ASSOCIATION OF DEPRESSION WITH SOCIOECONOMIC STATUS, ANTICARDIOLIPIN ANTIBODIES, AND ORGAN DAMAGE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS FROM THE KORNET REGISTRY

K.-E. Lee, J.-H. Kang, D.-J. Park, S.-S. Lee. *Chonnam National University Medical School And Hospital, Gwangju, Korea, Republic of Ireland*

**Objectives:** Depression is more common in patients with systemic lupus erythematosus (SLE) compared to the general population. However, few studies have

investigated risk factors of depression in SLE patients, and the results are inconsistent. This study evaluated the prevalence of, and risk factors for, depression in ethnically homogeneous Korean SLE patients.

**Methods:** In this study, 505 consecutive SLE patients were enrolled from the Korean Lupus Network registry. Demographic variables, clinical manifestations, laboratory findings, physician global assessment, and SLEDAI-2000 and SLICC damage index were recorded at enrollment. Patients were identified as having depressive symptoms using the Korean version of the Beck Depression Inventory (BDI) with a cut-off  $\geq 16$ , and categorised into four groups. Multivariable logistic regression analyses were performed to identify independent risk factors for depression defined as a BDI score  $\geq 16$ .

**Results:** Of the 505 patients, 97 (19.2%) were diagnosed with depression. Patients with a higher BDI score were older, more likely to be a current smoker, and had a SLICC score  $>1$ . Conversely, they had lower income and educational levels. Regarding the serologic findings, patients with a higher BDI score had lower anti-double-stranded DNA positivity and higher anticholinergic (aCL) positivity. On multivariate analysis, the following factors were associated with depression: current smoking status (OR 2.533,  $p=0.049$ ), aCL-positivity (OR 2.009,  $p=0.035$ ), and a SLICC damage index score  $>1$  (OR 2.781,  $p=0.039$ ). On the other hand, high-level education (OR 0.253,  $p=0.024$ ) and a high income (OR 0.228,  $p=0.008$ ) were negatively associated with depression.

**Conclusions:** Our results show that depression is prevalent in patients with SLE and multiple factors are associated with depression in SLE. These data could help guide target programs for those at high risk of depression in SLE.

#### THU0364 RELATIONSHIP BETWEEN DISEASE ACTIVITY INDEX SCORES AND PHYSICIAN GLOBAL ASSESSMENT IN EARLY AND NON-EARLY SYSTEMIC LUPUS ERYTHEMATOSUS

<sup>1</sup>M. Garabaiju, V. Sadovici-Bobeica<sup>1</sup>, L. Mazur-Nicorici<sup>1</sup>, M. Cebanu<sup>2</sup>, V. Salaru<sup>3</sup>, M. Mazur<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Medical Emergencies; <sup>3</sup>Family Medicine, State University of Medicine and Pharmacy "Nicolaie Testemitanu", Chisinau, Moldova, Republic of Ireland

**Objectives:** To evaluate the disease activity and to compare it to physician's global assessment in patients with early (early SLE) and non-early systemic lupus erythematosus

**Methods:** Performed case-control study included SLE patients that fulfilled SLICC classification criteria, 2012. The research included two groups: patients with early SLE – first group (disease duration less than 24 months) and non-early SLE – second group (disease duration more than 24 months). The disease activity was assessed by SLEDAI-2K and SLAM. Physician global assessment (PhGA) was rated by 0–100 numeric score. We correlated disease activity indices with physician global assessment by Pearson coefficient.

**Results:** A total of 96 SLE patients were analysed. First group included 45 patients with female:male ratio 14:1. The second group included 51 patients, female:male ratio 1:49. The disease activity indices: SLEDAI and SLAM denoted high disease activity level in both groups. PhGA didn't correlate with SLEDAI ( $r=0.28$ ,  $p>0.05$ ) in the first group, while a statistically significant correlation was determined with SLAM index ( $r=0.39$ ,  $p=0.007$ ). In the second group we found a moderate statistical significant correlation of PhGA with SLAM ( $r=0.53$ ,  $p=0.0001$ ) and weak, but also statistical significant relationship with SLEDAI ( $r=0.35$ ,  $p=0.01$ ). There is a better correlation of PhGA assessment and SLAM in both study groups, which can be explained by the presence of subjective components in appreciation of this index. Patient's better appreciation of their condition in the group with longer disease duration (statistical significant correlation of PhGA and both indices:SLAM and SLEDAI), probably, is because this patients know better to appreciate their disease, and patients with early SLE tend to underestimate their general condition.

Parameters of the disease	Gr I, Nr 45	Gr II, Nr 51
Age at study entry $\pm$ SD (range), years	41.18 $\pm$ 14.0 (20–75)	43.51 $\pm$ 12.3 (22–67)
Disease duration $\pm$ SD (range), month	10.14 $\pm$ 9.10 (0.1–24)	159.71 $\pm$ 94.53 (31–432)
SLAM $\pm$ SD (range), points	9.31 $\pm$ 4.87 <sup>-24</sup>	8.08 $\pm$ 4.38 <sup>-22</sup>
SLEDAI $\pm$ SD (range), points	11.13 $\pm$ 7.58 <sup>-34</sup>	7.33 $\pm$ 5.54 (0–23)
PhGA $\pm$ SD (range), points	44.02 $\pm$ 18.75 <sup>10-80</sup>	47.73 $\pm$ 22.63 <sup>5-92</sup>

**Conclusions:** In patients with early SLE PhGA correlated with SLAM, while in patients with non-early lupus PhGA correlated with both indices - SLAM and SLEDAI-2K. A better correlation of PhGA with SLAM can be explained by the presence of multiple components in this tool and also subjective data as fatigue or cognitive dysfunction.

#### THU0365 POTENTIAL PREDICTIVE FACTORS INFLUENCING ESSDAI OF PRIMARY SJÖGREN'S SYNDROME PATIENTS

<sup>1</sup>M. Maślińska, J. Dmowska-Chalaba<sup>1</sup>, M. Mańczak<sup>2</sup>, B. Kwiatkowska<sup>3</sup>. <sup>1</sup>Early Arthritis Clinic; <sup>2</sup>Department of Gerontology, Public Health and Didactics; <sup>3</sup>Early Arthritis Clinic, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warsaw, Poland

**Background:** The useful tool to assessing disease activity in primary Sjögren's syndrome (pSS) is an EULAR Sjögren's syndrome disease activity index (ESSDAI)<sup>1,2</sup>.

**Objectives:** The aim of this study was indication of laboratory and clinical factors affecting the ESSDAI in pSS patients.

**Methods:** 75 pSS patients were included; 65 (87%) female, 10 (13%) men; mean age 50 years SD  $\pm 15$ . The tests included: basic laboratory tests, rheumatoid factor (RF), erythrocyte sedimentation rate, CRP, gammaglobulins serum concentration, C4 and C3 component of complement, antinuclear antibodies (ANA) - IF test HEp-2000, anti-SS-A and anti-SS-B antibodies evaluation with semi-quantitative immunoblotting, standard ELISA assays for serum cytokines levels (BAFF, APRIL, FLT-3L, TNF- $\beta$ , IL-21) and  $\beta 2$ -microglobulin. Biopsy of minor salivary gland with the histopathological evaluation (focus score-FS) and the immunocytochemistry was also performed with the CD3+, CD4+, CD19+, CD21+, CD35+ cells presence assessment. The Schirmer's test and ocular staining score (OSS) were performed. The Bioethics Committee approval was obtained. Statistics: U Mann-Whitney (continuous variables) tests, Spearman correlation coefficient (correlations between quantitative variables) with statistical significance set at  $p<0.05$ .

**Results:** ESSDAI depends on FS, the presence of CD4+, CD3+ cells in the minor salivary glands infiltrates, RF and cryoglobulins ( $p<0.05$ ). The division of pSS subjects into two subgroups (ESSDAI  $>5$ ;  $<5$ ) revealed, that the autoantibodies as anti-SS-A and anti-SS-B, influence the severity of the disease ( $p=0.046$ ;  $p=0.015$  respectively). ESSDAI positively correlated with OSS, but not with the Schirmer's test, other tested cytokines, ESR, CRP and gammaglobulins concentration - yet interestingly ESSDAI correlates negatively with IgG4 ( $\rho=-0.435$ ).

**Conclusions:** The results confirm, that organ-related complications are influenced by inflammatory activity. This activity is expressed by mononuclear cell infiltrates (FS), which consist primarily of T-lymphocytes (indicators of active and early stage inflammation). However, contrary to other observations,<sup>3</sup> no correlation between ESSDAI and cytokines or  $\beta 2$ -microglobulin was found. The correlation of ESSDAI with the presence of pSS marker autoantibodies (anti-SS-A, anti-SS-B antibodies), as well as with non-specific ones (RF or cryoglobulins), indicates the immunological disease activity and overactivity of B lymphocytes as suspected. The reduction of IgG4 concentration in pSS patients correlating with higher ESSDAI can be associated with breaking the autotolerance and lack of stimulation of IgG4 production. But the role and importance of IgG4 in immunological processes both as an activator of dependent autoimmune diseases and, on the other hand, the marker of induction of immune tolerance requires further research.

#### THU0366 STUDY OF THE ROLE OF MICRO-RNA 20A EXPRESSION IN SYSTEMIC LUPUS ERYTHEMATOSUS IN AN EGYPTIAN COHORT

<sup>1</sup>M.S. Elkhalfifa, M. Zehairy<sup>1</sup>, M. Tayel<sup>1</sup>, A. Elkeriaie<sup>2</sup>, D. Elkaffash<sup>3</sup>, N. Baddour<sup>4</sup>. <sup>1</sup>Rheumatology unit, Internal Medicine department; <sup>2</sup>Nephrology unit, Internal medicine department; <sup>3</sup>Clinical and Chemical Pathology; <sup>4</sup>pathology, Faculty of Medicine, Alexandria University, Egypt, Alexandria, Egypt

**Background:** Micro-RNAs are small noncoding RNAs that act as cytoplasmic post-transcriptional gene expression regulators by targeting their complementary messenger RNA. They regulate several inflammatory, immunologic and oncogenic pathways.<sup>(1)</sup> MicroRNAs are differentially expressed in patients with systemic lupus erythematosus (SLE), especially in association with lupus nephritis.<sup>(2,3)</sup> The positive miRNA list in SLE patients in different studies presents relatively

limited overlap. The heterogeneity of patient ethnicity and variety in detection method may in part explain some of the discrepancies.<sup>(4)</sup>

**Objectives:** to study the role of micro-RNA 20a expression in SLE in an Egyptian cohort and its role as a potential biomarker of lupus nephritis.

**Methods:** Expression levels of micro-RNA-20a extracted from peripheral blood mono-nuclear cells determined using quantitative reverse transcription-polymerase chain reaction assay. A total of 90 plasma samples were obtained from 30 SLE patients without clinical and laboratory evidence of lupus nephritis, 30 SLE patients with lupus nephritis and 30 healthy control subjects.

**Results:** The expression of micro-RNA-20a in SLE patients was significantly lower than the expression in normal healthy control,  $p < 0.001$ . In addition the Roc curve of micro-RNA-20a showed that micro-RNA-20a expression levels can significantly discriminate between lupus patients with and without lupus nephritis at a cut off level  $\leq 9.3 \times 10^{-6}$  with a specificity of 76.67% and sensitivity of 96.67%. We also found a significant correlation between micro-RNA-20a expression levels and the pathological activity index of renal biopsy, while there was no significant correlation between micro-RNA-20a expression level and the pathological chronicity index.

**Conclusions:** The expression level of micro-RNA-20a could be considered a diagnostic marker of SLE. Also, the expression level of micro-RNA-20a could be considered a potential biomarker for recognition of renal involvement in SLE patients.

THU0367

#### PREVALENCE AND SIGNIFICANCE OF ANTI-PHOSPHATIDYL SERINE ANTIBODIES: A POOLED ANALYSIS IN 5992 PATIENTS

<sup>1</sup>M. Radin, I. Cecchi<sup>1</sup>, E. Rubini<sup>1</sup>, S. Karen<sup>2</sup>, D. Roccatello<sup>1</sup>, M. Mahler<sup>3</sup>, S. Sciascia<sup>1</sup>. <sup>1</sup>Clinical and Biological Sciences, UNIVERSITÀ DEGLI STUDI DI TORINO, Turin, Italy; <sup>2</sup>Copenhagen University Hospital, Copenhagen, Denmark; <sup>3</sup>Inova Diagnostics, San Diego, USA

**Background:** The current classification criteria for antiphospholipid syndrome (APS) include three laboratory tests: lupus anticoagulant, anti-cardiolipin, and anti-b2 glycoprotein-I.<sup>1</sup>

Among the so-called 'extra-criteria' aPL tests, anti-phosphatidylserine (aPS) antibodies have been proposed as an additional tool to be considered when patient is suspected for having APS. However the exact prevalence of aPS antibodies, and their independent role as risk factor for developing clinical manifestations of APS, is uncertain.

**Objectives:** To estimate the prevalence of aPS antibodies in patients with clinical manifestations of APS, by systematically reviewing the literature.

**Methods:** A detailed literature search was applied *a priori* to Ovid MEDLINE, In-Process and Other Non-Indexed Citation 1989 to present and to abstracts from EULAR and ACR/ARHP Annual Meetings (2011–2017) (figure 1).

**Results:** Data from 5992 patients from 20 studies were analysed (table 1). In APS patients, we report an overall estimated median prevalence of aPS antibodies of 55% [S.D.±21.1, range 29%–87%] and 35% [S.D.±17.9, 16–65%] for IgG and IgM, respectively. aPS antibodies were more frequently found in patients with known APS, when compared to patients with thrombosis/pregnancy loss or SLE (IgG mean 55%±28.9, 30±19.6, 22±13; IgM 35±4.3, 1±2.8, 14±8.3, respectively,  $p < 0.05$ ). In detail, patients were distributed as follow: 366 APS patients in 7 studies [55% aPS IgG/37% aPS IgM-positive; in more detail, 78 primary APS in 2 studies (64% aPS IgG/48% aPS IgM-positive), 29 secondary APS in 2 studies (37% aPS IgG/24% aPS IgM-positive) and 259 not specified], 787 SLE patients in 7 studies (22% aPS IgG/14% aPS IgM-positive), 24 aPL asymptomatic carriers in one study (21% aPS IgG/25% aPS IgM-positive), 3565 patients with cardiovascular accidents in 4 studies (18% aPS IgG/7% aPS IgM-positive), 1250 patients with pregnancy morbidity in 6 studies (30% aPS IgG/1% aPS IgM-positive) and 952 healthy controls.

DIAGNOSIS	Number of patients included in the analysis	% of positive patients for anti aPS IgG antibodies	% of positive patients for anti aPS IgM antibodies	Studies included in the analysis
APS*	366	55	37	Roggenbuck et al. 2016 Khoger et al. 2014 Jaskowski et al. 2009 Lopes et al. 2004 Musial et al. 2003 Ware Branch et al. 1997

<sup>1</sup>M.M. Pham, G. Orsolini<sup>2</sup>, C.S. Crowson<sup>3</sup>, M.R. Snyder<sup>4</sup>, R.K. Pruthi<sup>5,6</sup>, K. G. Moder<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Mayo Clinic, Rochester, USA; <sup>2</sup>Department of Medicine, Rheumatology Unit, University of Verona, Verona, Italy; <sup>3</sup>Department of Health Sciences Research, Mayo Clinic College of Medicine and Science; <sup>4</sup>Department of Laboratory Medicine and Pathology; <sup>5</sup>Division of Hematology; <sup>6</sup>Special Coagulation Laboratory, Mayo Clinic, Rochester, USA

**Background:** Anti-phosphatidylserine prothrombin antibodies (PSPT) have been reported to be strongly associated with the lupus anticoagulant (LAC) in established antiphospholipid syndrome (APS) and autoimmune cohorts. However, there is a paucity of similar studies assessing clinical utility on an all-comer patient population undergoing evaluation for suspicions of APS.

**Objectives:** To determine the sensitivity and specificity of IgG and IgM PSPT to the LAC in patients undergoing evaluation for APS.

**Methods:** Patients from June 2017 to December 2017 undergoing evaluation for APS had blood draws for the LAC, anti-cardiolipin (aCL), anti-β2 glycoprotein-1 (β2GP1), and PSPT. Both IgG and IgM isotypes were tested for each antibody. Presence of the LAC was determined by trained haematologists interpreting a number of mixing and neutralisation studies. Demographic details were abstracted from the medical record and cases meeting the SLICC criteria for systemic lupus erythematosus (SLE) and the revised Sapporo criteria for APS were enumerated.

**Results:** Fifty six eligible patients were identified. Mean age was 50±18 years. 68% were female, 20% with SLE, and 20% with APS. At time of testing, 18% were on warfarin, 7% on direct factor Xa inhibitors and 2% on low-molecular weight heparin. The LAC was negative in 45% (25/56) of those tested. In LAC negative cases, the IgG and IgM PSPT were negative in 100% and 92% of cases, respectively. In LAC positive cases, IgG PSPT was positive in 35% and IgM PSPT was positive in 61%. Compared to the LAC, IgG PSPT was 100% (95% CI: 72%, 100%) sensitive but was only 56% (40%, 70%) specific. Similarly, the IgM isotype of PSPT showed 90% (70%, 99%) sensitivity but only 66% (48%, 81%) specificity. Overall, 38% (21/56) of the cases possessed an isolated, singly positive LAC with concurrent negative IgG/M aCL and β2GP1 antibodies. In this isolated LAC positive-only group, further testing with IgG and IgM PSPT was positive in 38% and 57% of the cases, respectively.

**Conclusions:** In this study, IgG and IgM PSPT were found to be highly sensitive to the LAC and may be a useful tool in the screening of and the interpretation of the LAC.

### CREATION OF A WEIGHTED SLICC SLE CLASSIFICATION CRITERIA AND COMPARISON WITH PROPOSED EULAR/ACR SLE CLASSIFICATION CRITERIA

<sup>1</sup>M. Petri, D.W. Goldman<sup>1</sup>, L.S. Magder<sup>2</sup>, on behalf of SLICC. <sup>1</sup>Medicine, Johns Hopkins University School of Medicine; <sup>2</sup>Biostatistics, University of Maryland, Baltimore, USA

**Background:** In previous validation work, the SLICC 2012 SLE classification criteria were more sensitive than the revised ACR-11 criteria, while both criteria had similar agreement with physician diagnoses. Both of these classification rules count each SLE manifestation equally.

**Objectives:** Our objective was to derive and test a classification rule which differentially weights the variable used in the SLICC classification rule. We also compared this rule to a recently proposed EULAR/ACR classification rule that also uses a weighted approach.

**Methods:** The physician-rated patient scenarios used to develop the 2012 SLICC classification criteria were re-employed to devise a weighted classification rule. A multiple linear regression model was constructed with the 2012 SLICC criteria variables as predictors and the binary outcome (physician classification of SLE) as the outcome. To generate the weights for each criteria, we then multiplied each criteria's coefficient by 100 and rounded to the nearest integer. The 'Direct Coombs' criteria (coefficient <1) was deleted for simplicity. The weights for the remaining manifestations were: acute cutaneous, 26 chronic cutaneous, 12 oral ulcers, 16 arthritis, 9 serositis, 16 renal without biopsy, 9 neurologic, 9 hemolytic anaemia, leukopenia or lymphopenia, 14 thrombocytopenia, 15 alopecia, 9 ANA, 11 anti-dsDNA, 19 anti-Sm, 16 antiphospholipid antibodies, 9 low complement. 11 A cutoff for classification was chosen as the score that maximised overall agreement (i.e., the sum of sensitivity and specificity) of the new weighted criteria with physician diagnosis. Patients with lupus nephritis or the new weighted classification rule of 56 or more with at least one clinical component and one immunologic component were classified as SLE. We evaluated the performance of this revised SLICC criteria, on an independent set of patient scenarios, and compared this to the performance of the older revised ACR criteria, the previous <sup>SLICC 2012</sup> criteria, and the newly proposed EULAR/ACR criteria.

**Results:** Table 1 shows the performance of the four classification rules. There was no statistically significant difference (at the 0.05-level) between any pair of rules with respect to overall agreement with the physician diagnosis.

**Abstract THU0369 – Table 1.** Sensitivity and specificity of four different SLE classification rules based on physician diagnoses of patient scenarios

Classification Rule	Sensitivity (n=349)	Specificity (n=341)	Overall Agreement (n=690)
Revised ACR-11	290 (83%)	326 (96%)	616 (89%)
SLICC 2012	340 (97%)	288 (84%)	628 (91%)
Proposed EULAR/ACR	317 (89%)	302 (90%)	619 (90%)
Weighted SLICC 2012 criteria	310 (88%)	304 (89%)	614 (89%)

**Conclusions:** The two newly derived weighted classification rules did not perform better than the existing list-based rules in terms of over-all agreement. Given that the list-based rules are easy to calculate, they may be preferred in most clinical settings.

**Disclosure of Interest:** None declared

THU0370

### THE SIGNIFICANCE OF NON-MYDRIATIC FUNDUS EXAMINATION OPERATED BY RHEUMATOLOGISTS IN SCREENING FOR RETINOPATHY OF SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

M. Yang, Q. Lv, Z. Lin, J. Qi, X. Guo, J. Gu. *Third Affiliated Hospital of Sun Yat-Sen University, Guangzhou, China*

**Background:** Retinopathy is a common fundus lesion in SLE patients. Non-mydriatic Fundus Camera images directly and objectively and avoids the mydriatic drug-induced glaucoma attack, which can not only reduce the suffering of patients but also save time and costs.

**Objectives:** To understand the significance of non-mydriatic fundus examination operated by rheumatologists in screening for retinopathy of SLE.

**Methods:** After professional training, rheumatologists use non-mydratric fundus camera to take fundus photography of inpatients in our department and record the clinical features and laboratory test results of the patients. The results of fundus photography are interpreted by both ophthalmologists and rheumatologists. The fundus results of SLE patients from July 2016 to June 2017 were analysed. 35 cases (62 eyes) of retinopathy were defined as experimental group, and 35 cases (70 eyes) without retinopathy were randomly selected as the control group.

**Results:** A total of 203 patients with SLE with an average age of 38.4±11.6 years acquired bilateral fundus results, including 28 males and 175 females (86.2%). Ocular lesions were found in 51 (25.1%) cases, of which 35 (62.6%) were common retinopathy. There were 5 cases of retinal atrophy and pigmented degeneration (4 binocular, 1 monocular), 9 cotton spots (6 binocular, 3 monocular), 7 flaming bleeding (7 binocular), 14 choroiditis with drusen (9 binocular, 5 monocular), arteries tortuous or occluded in 5 (3 binocular, 2 monocular). The SLEDAI score, anti-dsDNA level and C3 decline rate of the experimental group were significantly higher than those of the control group ( $p<0.05$  or  $p<0.01$ ), while the titer of antinuclear antibody, the positive rate of anti-SM antibody, the positive rate of anti-phospholipid antibodies, and the erythrocyte sedimentation rate had no significant difference ( $p>0.05$ ). Subsequently, we followed up 16 patients with retinopathy and SLEDAI score  $\geq 10$  and achieved remission (SLEDAI score  $\leq 4$ ) with glucocorticoid and immunosuppressive agents with an average duration of 6.5 ±4.5 months. The second examination showed that retinal lesions were improved in 9 cases (56.25%), 3 cases (18.75%) were unable to judge due to the appearance of optical media change which may caused by glucocorticoid, and 4 cases (25%) showed no obvious changes.

**Conclusions:** Non-mydratric fundus examination performed by rheumatologists may assist rheumatologists in screening for retinopathy in SLE patients, assessment of disease activity and treatment outcome.

#### THU0371 CORRELATION BETWEEN IRREGULAR MENSTRUATION AND DISEASE ACTIVITY OF SYSTEMIC LUPUS ERYTHEMATOSUS :1 YEAR COHORT STUDY

N. Oguro, N. Yajima, M. Saito. *Rheumatology, Showa University School of Medicine, Tokyo, Japan*

**Background:** Systemic lupus erythematosus (SLE) often occurs to young women of reproductive age. Not only the disease but the treatment itself could affect the capability of getting pregnant. In clinical scene, we often experience SLE patients having menstrual irregularity before their relapse. Reports about correlation between menstrual irregularity and disease activity of SLE was very limited.

**Objectives:** We started this study, that this study could be a suggestion for clinician to use the symptom as a warning sign for relapse.

**Methods:** The study design was prospective cohort. 67 patients who fulfilled  $\geq 4$  of the American College of Rheumatology (ACR) criteria for the classification of SLE whose age was 20 to 45 years old and treated as outpatient at Showa University Hospital from Feb 2016 to Jan 2017 were recruited. At the initial point, patients' disease were not active and were receiving maintenance therapy. Loss to follow up was eliminated. We set the main exposure as menstrual irregularity and the primary outcome as whether they would have relapse within 1 year from the registration. We defined the menstrual irregularity as deviation from the normal menstruation, which is 'flow occur every 25 to 35 days and last three to seven days'. We had questionnaire formed from each patient. Definition of relapse was the doctor's decision, to intensify the patients' treatment. We set the confounding as age, Japan Perceived Stress Scale (JPSS), current smoking, history of treatment with IVCY and logistic regression analysis was performed.

**Results:** The mean age was 35.7 years old. Irregular menstruation patients were 11 (16.4%). The relapse group was 12 (17.9%) and those of normal group was 59 (89%). There was no significant difference in patients' background between both groups. Adjusted with the cited confounding variable there was no significant difference between the both groups (Odds ratio 2.25; 95% Confidence Interval (CI) 0.24 to 20.7;  $p=0.47$ ).

**Abstract THU0371 – Table 1.** Abstract THU0371 – Table 2. Logistic regression analysis. Adjusted with age, history of treatment with IVCY, current smoking, and JPSS.

	Total	Normal menstruation group	Irregular menstruation group	p value
Number	67	36	11	
Age median [IQR]	35 [31-41]	38 [31-41]	37 [29-41]	0.26
0 month SLEDAI median [IQR]	32 [6]	30 [6]	42 [6]	0.04
JPSS median [IQR]	13 [11-18.8]	13 [11-18.5]	13 [9-29]	0.51
Current smoking (%)	8 (11.9)	6 (16.7)	2 (18.2)	0.4
History of IVCY (%)	10 (14.9)	6 (16.7)	4 (36.4)	0.74
0 month PSL dose median [IQR]	5.3 [4-10]	5.7 [4.3-9.6]	5 [3-11]	0.73
0 month Immune-Suppressing drug (%)	40 (59.7)	26 (72.2)	14 (127)	0.29

IQR: interquartile range; SLEDAI: Systemic Lupus Erythematosus Disease Activity Index; JPSS: Japan Perceived Stress Scale; IVCY: immunosuppressive drug; PSL: prednisolone.

	Coefficient ( $\beta$ )	SE	Wald $\chi^2$	p value	Odds ratio	95%CI
Irregular Menstruation Group	0.40	0.56	0.51	0.47	2.25	0.24-20.7

Adjusted with age, history of treatment with IVCY, current smoking, and JPSS

**Conclusions:** We investigate that whether menstrual irregularity could be the predictor for the disease relapse, but we could not prove the significant relation.

#### THU0372 ULTRASONOGRAPHIC SCORING OF THE MAJOR SALIVARY GLANDS: IS THERE A RELATIONSHIP WITH DISEASE ACTIVITY AND FUNCTIONAL STATUS OF THE GLANDS ?

<sup>1</sup>N. Inanc, Y. Yalcinkaya<sup>1</sup>, G. Mumcu<sup>2</sup>, Z. Erturk<sup>1</sup>, A.U. Unal<sup>1</sup>, P. Atagunduz<sup>1</sup>, H. Direskenli<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine; <sup>2</sup>University of Health Sciences, Istanbul, Turkey

**Background:** Ultrasonography (USG) of major salivary glands (SG-USG) is a non-invasive tool that has been used to evaluate salivary glands in primary and secondary Sjogren's syndrome (SjS).

**Objectives:** We aimed to investigate relation between the ultrasonographic scoring of major salivary glands and systemic disease activity or salivary secretion in patients with primary SjS.

**Methods:** Seventy-five SjS patients (F/M:73/2) with the mean age of 52±12 and duration of follow-up period of 58±54 months fulfilling ACR-EULAR classification criteria (2002) were included. Disease activity indexes (Sjögren's Syndrome Patients Reported Index (ESSPRI), Visual Analogue Scale (VAS), EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI)) were recorded. Simultaneously, sialometric evaluation of the salivary glands was performed. Major salivary glands (bilateral parotid and submandibular glands) were scored according to two different scoring systems [Hocevar A. (0–48) and Milic VD. (0–12)] and elastography was recorded as well.

**Results:** Demographics, clinical characteristics, disease activity indexes and SG-USG scores were summarised in table 1 and table 2. Forty-one (55%) and 45 (60%) patients had the cut-off values of  $\geq 17$  (Hocevar) and  $\geq 6$  (Milic USG). The patients with the scores of  $\geq 17$  (Hocevar) were found to have higher scores of ESSPRI-total (16±6 vs 13±7,  $p=0.045$ ) and lower sialometry (4.6±4.7 vs 8.4±4.6 ml,  $p=0.002$ ). Scores of Hocevar and Milic-USG were negatively correlated with sialometry ( $r=-.430$ ,  $p=0.001$  and  $r=-.430$ ,  $p=0.001$ ). Hocevar, Milic and

elastography-USG scores were shown to be higher in patients with sialometry of  $\leq 1.5$  ml ( $n=7$ ) ( $28\pm 3$  vs  $17\pm 10$ ,  $p=0.010$ ,  $8\pm 1$  vs  $5\pm 3$ ,  $p=0.006$  and  $9\pm 1$  vs  $5\pm 2$ ,  $p=0.028$ ) and anti-Ro positivity ( $n=24$ ) ( $24\pm 10$  vs  $13\pm 8$ ,  $7\pm 3$  vs  $4\pm 2$ ,  $p<0.001$  and  $7\pm 2$  vs  $3\pm 2$ ,  $p=0.003$ ). The patients with severe parotid involvement (inhomogeneity/hypoechoic areas  $\geq 2$ ) had more frequent anti-Ro and anti-La positivity (80 vs 42%,  $p=0.004$  and 48 vs 17%,  $p=0.011$ )

**Abstract THU0372 – Table 1.** Demographics and Clinical Characteristics of SjS patients.

	n=75
Sicca symptoms	69(92%)
Arthralgia/arthritis	62(83%)
Parotitis	20(27%)
Raynaud Phenomenon	12(16%)
Leucocytoclastic vasculitis	5(7%)
Peripheral neuropathy	7(9%)
Interstitial lung disease	3(4%)
Lymphadenopathy	12(16%)
Congenital heart block	2(3%)
ANA	62 (82%)
Anti-Ro/La	35(47%)
ESR(mm/h)	32±20
CRP(mg/l)	4,8±6,1

**Abstract THU0372 – Table 2.** Disease Activity Indexes and SG-USG Scores of SjS Patients

	n=75
ESSPRI-total	14,8±6,5
-dryness	5,4±2,5
-fatigue	4,8±2,8
-pain	4,6±3
VAS	50±22
ESSDAI-total	2,1±3,5
Hocevar-USG Score	19±5
Milic-USG Score	6±3
Sialometry (ml) (n=45)	6,4±5
Elastography (n=32)	5,3±2,6

**Conclusions:** Hocevar scoring system of major salivary glands was found to be related to patient reported activity in SjS. USG scores were associated with reduced saliva secretion and anti-Ro positivity. Severe parotid involvement was shown to be related to anti-Ro and La positivity. Evaluation of SG-USG including different scoring systems and elastography might reflect function of the salivary glands.

**Disclosure of Interest:** None declared

#### THU0373 THE MARKERS USEFUL IN PREDICTING LUPUS NEPHRITIS IN CLINICAL PRACTICE

<sup>1</sup>P. Dabrowski, K. Marczak<sup>1</sup>, A. Gala-Bładzińska<sup>2,3</sup>, K. Gargasza<sup>4</sup>, M. Dabrowska<sup>5</sup>.  
<sup>1</sup>Department of Rheumatology, Clinical Provincial Hospital No. 2, Lwowska 60 Street, 35–301 Rzeszów, Poland; <sup>2</sup>Faculty of Medicine, University of Rzeszów, Kopisto 2a Avenue, 35–359 Rzeszów, Poland; <sup>3</sup>Dialysis Center, Clinical Provincial Hospital No. 2, Lwowska 60 Street, 35–301 Rzeszów, Poland; <sup>4</sup>Data Analysis Laboratory, Centre for Innovative Research in Medical and Natural Sciences, Faculty of Medicine, University of Rzeszów, Kopisto 2a Avenue, 35–359 Rzeszów, Poland; <sup>5</sup>II Department of Pediatrics, Endocrinology and Diabetology, Clinical Provincial Hospital No. 2, Lwowska 60 Street, 35–301, Rzeszów, Poland

**Background:** Lupus nephritis (LN) is one of the most severe clinical manifestations of systemic lupus erythematosus (SLE). LN can be found in approximately 50% of SLE patients. The renal biopsy remains the gold diagnostic standard. However non-invasive and clinically practical laboratory markers of kidney damage in this disease are sought.

**Objectives:** The aim of the study was to assess the utility of biomarkers like inflammable indicators, complement system components and albuminuria in a single urine sample for prediction of kidney involvement and disease activity in patients with SLE.

**Methods:** A prospective study included 33 patients (81.8% women) with SLE criteria according to SLICC (Systemic Lupus International Collaborating Clinics) in age of  $39.0\pm 14.3$  years. Disease-duration ranged 6–60 months. We performed full physician examination and we excluded patients with active infection. The

disease activity based on the SELENA-SLEDAI scale was assessed and divided into groups: low activity (L) $<6$ , moderate (M) 7–12, high (H) $>12$  points.

In the blood samples complement components (C3, C4) (g/L), C-reactive protein CRP (mg/L), interleukin 6 (IL-6) (pg/mL), serum creatinine concentration (sCr) (mg/g), ESR (mm/h), glomerular filtration rate (eGFR) according to CKD-EPI (ml/min/1.73 m<sup>2</sup>) were determined. The concentration of albumin (uAlb) (mg/dl) and creatinine sCr (g/dL) from the morning urine sample was measured and the albumin/creatinine index (uACR) (mg/g) was calculated. Based on the obtained results, patients were divided into stages of chronic kidney disease (CKD) according to .KDIGO 2012. A daily proteinuria (DP) (g/24 hour) was performed. In the assessment of statistical significance, Kruskal-Wallis or Mann-Whitney U-tests were used.

**Results:** In our study the SLE activity was as follows (%): L-24 (72.7), M-6 (18.2), H-3 (9.1). The average values (range) of biomarkers of renal function were: Cr= $0.81\pm 0.27$  (0.55–1.65), eGFR= $99.6\pm 24.4$  (46–131), uAlb= $13.6\pm 34.4$  (0.04–161.0), uACR= $121.3\pm 356.3$  (4.8–1905.3), DP= $0.32\pm 0.92$  (0.015–5.3), and other biomarkers: OB= $26.1\pm 25.9$  (4.0–99.0); CRP= $10.3\pm 28.1$  (0.2–148.7); IL-6= $7.8\pm 14.7$  (0–78.3); C3= $1.08\pm 0.36$  (0.33–2.25); C4= $0.16\pm 0.09$  (0.02–0.43). The study group met the CKD criteria: G1 n=21 (63.6%), G2 n=9 (27.3%), G3 n=3 (9.1%); A1 n=26 (78.8%), A2 n=3 (9.1%), A3 n=4 (12.1%).

We showed a negative relationship between the eGFR and: CRP (R=–0.49,  $p=0.005$ ), IL-6 (R=–0.48,  $p=0.005$ ) and C4 (R=–0.43,  $p=0.01$ ). There was also a significant dependence of the SLEDAI SLE activity with: uAlb (L, H) ( $p=0.04$ ), DP (M, H) ( $p=0.03$ ), uACR in the whole study group ( $p=0.04$ ) and between uACR and DP ( $p=0.0003$ ).

**Conclusions:** Our studies showed that the risk of kidney damage in SLE may depend on the concentration of CRP, IL-6, C4. In addition albuminuria (uAlb, uACR) correlates with the value of DP and SLE activity, what indicates the dominant glomerular lesion in the etiopathogenesis of proteinuria in LN.

**Disclosure of Interest:** None declared

#### THU0374 FACTORS ASSOCIATED WITH HIGH-DOSE CORTICOSTEROID USE IN SLE PATIENTS POST INITIATION OF SLE THERAPY

K. Schroeder<sup>1</sup>, J. Paik<sup>1</sup>, R.W. Hoffman, S. Gelwicks<sup>2</sup>. <sup>1</sup>Eli Lilly and Company, <sup>2</sup>Former Eli Lilly and Company Employee, Indianapolis, USA

**Background:** Systemic lupus erythematosus (SLE) therapies include non-steroidal anti-inflammatory drugs, antimalarials, systemic immunosuppressants, and biologics with corticosteroids as necessary. The majority of these current therapies are only partially effective in disease control. Despite treatment, patients may experience flares of disease activity, which can lead to progressive end-organ damage. Severe flares may require intensive immunosuppression, including with high-dose corticosteroids, with risk including end-organ damage.

**Objectives:** To understand the unmet need in SLE by quantifying use of high-dose ( $\geq 40$  mg/day) corticosteroids and determining factors associated with its use.

**Methods:** This study utilized the Truven Marketscan commercial claims database. Patients were indexed on first use of antimalarial, oral immunosuppressant or biologic during 2012–2013 (first use determined based on no claims for the 3 drug classes during the 1 year pre-index). Included patients had 2 recorded SLE diagnoses, were 18–50 years of age and had continuous medical and prescription enrollment from baseline through the 2 year follow-up. Patients with other pre-specified autoimmune disorders or cancers during the study period (baseline through follow-up) were excluded. During follow-up, fill of at least 1 high-dose corticosteroid prescription was assessed and associative logistic regression modeling performed.

**Results:** 1401 patients (93% female; mean age 38.4 years) met the study criteria; 79% were indexed on an antimalarial, 15% on an oral immunosuppressive, 1% on a biologic and 5% on a combination of at least 2 of the aforementioned classes. 16% patients received a diagnosis code for nephritis or chronic kidney disease (CKD), 3% for myocarditis or pericarditis, and 13% for thrombocytopenia or leukopenia. During baseline, 56% of patients had at least 1 visit to a rheumatologist and 13% filled at least 1 high-dose corticosteroid prescription. During follow-up, 22% of patients had at least 1 high-dose corticosteroid prescription. Factors significantly associated ( $p<0.05$ ) with high-dose corticosteroids during follow-up included: baseline rheumatologist visit (OR=0.62; 95% CI=0.47–0.82), number of SLE medication classes received during follow-up (OR=1.85, 95% CI=1.36–2.51), receipt of high dose corticosteroid during baseline (OR=5.21, 95% CI=3.60–7.53), nephritis or CKD (OR=1.85, 95% CI=1.29–2.64), myocarditis/pericarditis (OR=3.38, 95% CI=1.75–6.55), and thrombocytopenia/leukopenia (OR=1.70, 95% CI=1.17–2.48).

**Conclusions:** A number of baseline factors were associated with high-dose corticosteroid treatment during the follow-up period; one notable factor is the high percentage of patients using high-dose corticosteroids ( $\geq 40$  mg/day). This indicates

that important subsets of patients experience inadequate disease control with current therapies. This study reveals high-dose corticosteroid use is prevalent in SLE management broadly, underscoring the unmet need in this population.

THU0375

### QUALITY OF LIFE IN INDIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN DURABLE REMISSION: PSYCHOSOCIAL AND DEMOGRAPHIC FACTORS

<sup>1</sup>R.P. Goswami, R. Chatterjee<sup>2</sup>, A. Mitra<sup>2</sup>, B. Bhattacharya<sup>2</sup>, A. Ghosh<sup>1</sup>, P. Ghosh<sup>1</sup>.  
<sup>1</sup>Department of Rheumatology, IPGMEER, Kolkata, India, Institute of Post Graduate Medical Education and Research; <sup>2</sup>Department of Clinical Psychology, Institute of Psychiatry, Kolkata, India

**Background:** Remission in systemic lupus erythematosus (SLE) is uncommon. Detrimental effect of disease activity on quality of life (QoL) is reported but literature on QoL in lupus patients in durable remission is scant.

**Objectives:** To study QoL in Indian SLE patients in durable remission

**Methods:** We retrospectively included female SLE patients fulfilling  $\geq 4$  SLICC Classification Criteria, followed regularly at our clinic, who were in durable remission as determined by European consensus criteria (complete/clinical remission  $\pm$  immunosuppressive drugs). QoL was assessed with Medical Outcomes Study Short-Form-12 (SF-12). We also collected data on demographics (age, duration of disease, years of education), duration and quality (complete versus clinical) of remission and patient reported fatigue through fatigue severity scale (FSS). A structured interview with a clinical psychologist using ICD-10 Diagnostic Criteria for Research (DCR) was performed to diagnose depression. Age matched female control subjects were also included and underwent similar exercises. Association of physical and mental component summary scores (PCS and MCS) of SF-12 with depression, quality and duration of remission, duration of disease, years of education and FSS were tested with generalised linear models using Gamma regression with log-link function.

**Results:** We included 106 female SLE patients (age:  $28.9 \pm 7.6$  years; duration of disease:  $45.1 \pm 34.8$  months; years of education:  $9.6 \pm 5.2$ ; depression present in 41 (38.7%) and 98 female controls (age:  $30.4 \pm 7$  years; years of education:  $10.8 \pm 6.2$ ; depression present in 32 (32.7%). At last visit, clinical remission was present in 68 (64.2%) and complete remission in 38 (35.2%). Duration of remission achieved were:  $<1$  year in 17 (16%), 1–2 years in 40 (37.7%), 2–3 years in 18 (17%) and  $>3$  years in 31 (29.2%). Steroid-free remission was present in 64 (60.37%) and the rest 42 (39.62%) were on  $\leq 5$  mg/d prednisolone. All were on hydroxychloroquine. A stable dose of 2nd immunosuppressive drug was present in 54 (50.94%) with 3 on stable dose of mycophenolate and 51 on azathioprine. SLE patients had comparable SF-12 PCS ( $48.4 \pm 8.1$  vs  $47.1 \pm 7$ ,  $p=0.098$ ) and MCS ( $57.7 \pm 3.4$  vs  $56.6 \pm 5.6$ ,  $p=0.199$ ) as compared to controls. Among lupus patients, both PCS ( $r=-0.616$ ,  $p<0.001$ ) and MCS ( $r=-0.298$ ,  $p<0.001$ ) were correlated with FSS and years of education (with PCS,  $r=-0.215$ ,  $p=0.027$ ; with MCS,  $r=-0.269$ ,  $p=0.005$ ). Independent predictors of PCS were: clinical remission (Odds ratio (OR) 0.95, 95% confidence interval (CI) 0.92–0.99,  $p=0.033$ ), FSS (OR 0.90, 95% CI 0.89–0.92,  $p<0.001$ ) and disease duration  $<5$  years (OR 0.92, 95% CI 0.86–0.97,  $p=0.006$ ). Independent predictors of MCS were: FSS (OR 0.991, 95% CI 0.983–0.999,  $p=0.025$ ), years of education (OR 0.998, 95% CI: 0.995–0.999,  $p=0.028$ ) and disease duration  $<5$  years (OR 1.053, 95% CI 1.018–1.089,  $p=0.003$ ). Estimated marginal means of PCS and MCS against quality of remission and duration of disease are plotted in figure 1.

**Abstract THU0375 – Figure 1.** Estimated marginal means for SF-12 PCS and MCS against quality of remission and duration of disease

**Conclusions:** Indian lupus patients in durable remission had similar physical and mental QoL compared to healthy controls. Physical QoL was better in patients with complete remission, longer disease duration and low fatigue. Mental QoL was better in patients with low fatigue, less education and longer disease duration.

### CHARACTERISTICS OF PRIMARY SJÖGREN'S SYNDROME PATIENTS WITH MORPHOLOGICAL CHANGES OF THE PAROTID GLANDS IN MR IMAGING

<sup>1</sup>S. Zhao, H. Zhang<sup>1</sup>, C. Chu<sup>2</sup>, X. Feng<sup>1</sup>, L. Sun<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Immunology; <sup>2</sup>Department of Radiology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China

**Background:** Primary Sjögren's syndrome (pSS) is a chronic autoimmune disease characterised by injury of exocrine glands, and a considerable proportion of pSS patients develop extraglandular involvement. The parotid glands are the most frequently involved glands in pSS. Conventional parotid examinations, such as X-Ray sialography and 99mTechnetium (<sup>99mTc</sup>) pertechnetate scintigraphy, played an important role in the diagnosis of pSS. However, X-Ray sialography only shows the abnormality of parotid ductal system and there is exposure to radionuclides with 99mTechnetium. Both examinations are invasive, while MR imaging is noninvasive, radiation-free, and sensitive to the morphological and signal changes of the parotid glands. MR sialography could be used to evaluate the parotid ductal system without the need for a contrast agent. But the clinical application value of parotid grand MR imaging in pSS patients has not been verified.

**Objectives:** The purpose of this study was to investigate the morphological changes of the parotid glands in MR imaging in patients with pSS and the correlations between morphological changes and the clinical manifestations.

**Methods:** Ninety-nine pSS patients who underwent parotid 3.0 Tesla MR imaging (T1, T2 and T2 STIR) were enrolled in this study. The morphological changes of the parotid glands (grades 0–3) and ducts (grades 0–4) were rated according to our previous studies.<sup>1</sup> Patients were divided into normal parotid MR group (both glands grade and ducts grade were 0) and abnormal parotid MR group. The correlations between morphological changes of the parotid glands and clinical or serological characteristics were analysed by chi-square test.

**Results:** There were 93 females (93.9%) and 6 males (6.1%) in this study. The mean age and median disease duration were 47.4 years and 24 months. There were 50 (50.5%) pSS patients in parotid grand grade 0, 27 (27.3%) in grade 1, 15 (15.2%) in grade 2 and 6 (6.1%) in grade 3 (Fig 1A), and there were 53 (53.5%) pSS patients in parotid duct grade 0, 15 (15.2%) in grade 1, 17 (17.2%) in grade 2, 4 (4.0%) in grade 3, and 10 (10.1%) in grade 4 (Fig 1B). We found that patients in abnormal parotid MR group presented lower positive rates of myasthenia and higher positive rates of xerostomia, Schimer's test, serum anti-SSA antibodies, anti-Ro-52 antibodies, antinuclear antibodies (ANA), rheumatoid factor (RF), plasma globulin, immunoglobulin G (IgG), and Hashimoto thyroiditis ( $p<0.05$ ). But no significant difference was observed between two groups in the incidence of salivary gland enlargement, articular involvement, dermatological involvement, interstitial lung disease, tubulointerstitial nephritis and primary biliary cirrhosis.

**Abstract THU0376 – Figure 1.** A: Axial T1-weighted image shows homogenous signal intensity of bilateral parotid glands with obvious hyperintense nodules (grade 3). B: MR sialography shows duct dilation of bilateral parotid glands (grade 4).

**Conclusions:** The results indicated that parotid MR imaging is a noninvasive, radiation-free examination with a potential role in diagnosing pSS. pSS patients with morphological changes of the parotid glands in MR imaging were more likely to have xerostomia, hyperglobulinemia and thyroid involvement.

### INFLUENCE OF UNDIAGNOSED VERTEBRAL FRACTURES ON ORGAN DAMAGE IN WOMEN WITH SYSTEMIC LUPUS ERYTHEMATOSUS

<sup>1,2</sup>S. Shkireeva, O.M. Lesnyak<sup>1</sup>, E.G. Zotkin<sup>2</sup>. <sup>1</sup>North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg; <sup>2</sup>Research Institute of Rheumatology named after V.A. Nasonova, Moscow, Russian Federation

**Objectives:** To investigate the influence of asymptomatic vertebral fractures on organ damage and to identify risk factors associated with critical organ damage in women with systemic lupus erythematosus (SLE).

**Methods:** 197 women with SLE were included in this study. Bone mineral density (BMD) measurements of the hip and spine were performed using the dual energy X-ray absorptiometry (DXA). Vertebral fracture assessment (VFA) was done for detection vertebral fractures using a method described by Genant. Accumulated damage was scored using the SLICC/ACR damage index (SDI). Critical organ damage was defined as SDI>3.

**Results:** Vertebral fractures were developed in 55 (27.9%) women with SLE. Half of all women with SLE (n=31, 15.7%) had asymptomatic vertebral fractures which were diagnosed for the first time in this study. 131 (66.5%) women with SLE had critical organ damage (SDI>3). Average SDI before and after morphometry was 4.4±2.2 and 5.3±2.6 respectively. Multivariate analysis showed age (p=0.01), cumulative dose of glucocorticoids (p=0.00005), previous therapy with cyclophosphamide (p=0.04) were significantly associated with critical damage in women with SLE.

**Conclusions:** Detection of vertebral fractures helps in counting accumulated organ damage correctly. VFA in the combination with DXA in women with SLE is an effective method for diagnostic asymptomatic vertebral fractures.

THU0378

### WIRE-LOOP LESION IS ASSOCIATED WITH SEROLOGICAL IMMUNE ABNORMALITY, BUT NOT RENAL PROGNOSIS IN LUPUS NEPHRITIS

T. Zoshima, S. Hara, M. Kawano. *Division of Rheumatology, Kanazawa University Hospital, Kanazawa, Japan*

**Background:** International Society of Nephrology/Renal Pathology Society (ISN/RPS) 2003 Classification of Lupus Nephritis (LN) defines wire-loop lesion (WL) as an active lesion (AL). In it, LN patients with WL are classified as class III or IV, which are associated with a poor prognosis and recommended to be treated by intense immunosuppressive therapy including corticosteroid, cyclophosphamide, mycophenolate mofetil and other immunosuppressants.<sup>1</sup> However, among AL, few reports have focused on the clinicopathological impact of WL on serological immune abnormality and renal prognosis.

**Objectives:** To identify clinicopathological characteristics associated with WL, and to clarify whether WL predicts renal prognosis of LN.

**Methods:** We enrolled 117 Japanese LN patients subjected to renal biopsy in 11 hospitals from 2000 to 2017. We measured clinical findings at the time of renal biopsy, including creatinine (Cr), estimated glomerular filtration rate (eGFR), total protein (TP), IgG, IgA, IgM, C3, C4, CH50, anti-nuclear antibodies (Abs), anti-double strand DNA (dsDNA) Abs, anti-Sm Abs, anti-RNP Abs in the sera, urinalysis, and presence of comorbidities (antiphospholipid antibody syndrome, hypertension, hyperlipidemia, diabetes mellitus, and hyperuricemia). Renal biopsy findings were classified by ISN/RPS classification including AL and chronic lesions (CL). Immune deposit was evaluated by immunofluorescence. We also measured Cr and eGFR at the last patient visit, and recorded medications prescribed for LN. Chronic kidney disease (CKD) was defined as eGFR <60 ml/min/1.73 m<sup>2</sup>. In class III or IV patients, we retrospectively compared these clinical and histological findings between those with WL (WL +group) and without WL (WL- group).

**Results:** Of 117 patients, 94 (81.2%) were classified as class III or IV (78 females; mean age 41.3 years; observational period 5.8±5.2 years). WL was found in 27 of them (28.7%). Although there was no significant difference in renal function (eGFR; 81.1±31.4 vs 80.6±34.4 ml/min/1.73 m<sup>2</sup>, p=0.91), WL +group had higher

titer of serum anti-dsDNA Abs (median values; 205 vs 67 IU/ml, p=0.011) and lower level of TP (5.7±1.2 vs 6.3±1.0 g/dl, p=0.025) than WL- group. There were no significant differences in any other clinical findings. In histological findings, most WL (96.3%) were accompanied by other ALs such as endocapillary proliferation and/or crescent formation. WL +group had a higher frequency of class IV, AL and IgM deposit, while CL did not differ between the two groups. Linear regression analysis revealed associations between anti-dsDNA Abs and IgM deposit and WL (β=0.48, p<0.01; β=0.26, p=0.016, respectively). There was no difference in the latest renal function (eGFR; 76.9±27.5 vs 74.0±29.5 ml/min/1.73 m<sup>2</sup>, p=0.72) between the two groups. Cox regression analysis revealed significant associations between AL such as necrosis, CL, initial eGFR, HT, HL and medication for LN with CKD at the last visit, but not with WL (p=0.13).

**Conclusions:** WL was associated with serum anti-dsDNA Abs, but not with renal prognosis, suggesting that WL reflects immune abnormality, but is not an independent factor predictive of the renal prognosis of LN. Although WL is defined as an AL in the present classification, this may need to be revised to better reflect its clinical impact.

### CORONARY ARTERY DISEASE IN SLE: A CASE-CONTROLLED ANGIOGRAPHIC STUDY

<sup>1</sup>T. Chazal, M. Kerneis<sup>2</sup>, P. Guedeney<sup>2</sup>, J. Haroche<sup>1,3</sup>, A. Mathian<sup>1</sup>, P. Ruffat<sup>4</sup>, F. Cohen-Aubart<sup>1,3</sup>, G. Montalescot<sup>2,3</sup>, Z. Amoura<sup>1,3</sup>. <sup>1</sup>Service de Médecine interne 2; <sup>2</sup>Service de Cardiologie, Hôpital Pitié Salpêtrière; <sup>3</sup>Sorbonne Université – Université Pierre et Marie Curie Paris VI; <sup>4</sup>Département d'information médicale, Hôpital Pitié Salpêtrière, PARIS, France

**Background:** Coronary artery disease (CAD) is a major cause of morbidity and mortality in systemic lupus erythematosus (SLE) patients.<sup>1</sup> Whether SLE is a cardiovascular risk factor *per se* remains controversial.

**Objectives:** This study was conducted to determine the clinical and angiographic characteristics of SLE patients with CAD and to compare them to those of control non-SLE patients with CAD.

**Methods:** All SLE patients who underwent a coronary angiography procedure in our tertiary centre between 2005 and 2016 were enrolled in the study. Those without significant atherosclerosis (stenosis >50%) were excluded. Each SLE patient was matched by sex and age at catheterization with seven non-SLE controls with significant CAD. Angiographic characteristics were reviewed by two independent cardiologists.

**Results:** Among the 73 SLE patients who underwent coronary angiography, 28 patients had at least one significant coronary atherosclerotic lesion. The SLE patients were predominantly female (75%, median age of 55.7 years) with a long-standing disease duration (median SLE duration of 20.5 years). Ten patients (35%) had renal involvement, and 9 patients (32%) had antiphospholipid syndrome. The patients with SLE had fewer cardiovascular risk factors (1.6 vs 2.1, p=0.01) than the controls, including lower body mass index (23.8 kg/m<sup>2</sup> vs 24.98 kg/m<sup>2</sup>, p=0.03), less frequent family history of coronary artery disease (3.5% vs 18%, p=0.049) and less diabetes (7% vs 22%, p=0.07) than controls. However, SLE patients were more likely to have chronic kidney failure (35% vs 20%, p=0.07) and to need hemodialysis (17% vs 2%, p=0.001). The SLE patients more often had multivessel disease (50%).

**Conclusions:** While they have fewer cardiovascular risk factors, patients with SLE experience more severe CAD than non-SLE patients, suggesting that SLE, associated conditions or the treatments themselves play key roles in the development of atherosclerosis.<sup>2</sup>

**THU0380** **DIAGNOSTIC UTILITY OF ANTI-DFS-70 AUTOANTIBODIES IN A UNIVERSITY RHEUMATOLOGY CENTRE**

U. Salzer, A.C. Venhoff, I. Jandova, R.E. Voll, J. Thiel, N. Venhoff. *Department of Rheumatology and Clinical Immunology, University Medical Center Freiburg, Freiburg, Germany*

**Background:** The detection of antinuclear autoantibodies by immunofluorescence (ANA-IFT) supports the diagnosis of many different autoimmune and rheumatological diseases (ARE). In combination with the detection of specific autoantibodies against known extracted nuclear antigens (ENA) ANAs have high diagnostic sensitivity and specificity. However, positive ANA-IFT may also occur in disease states not related to ARE and even in healthy individuals. Especially in the latter group this may lead to unnecessary and repeated hospital visits, as well as avoidable diagnostic and therapeutic interventions. Anti-DFS70 autoantibodies were introduced as a biomarker for the exclusion of ARE in ANA-IFT +patients without additional ENAs and non-specific clinical history.

**Objectives:** To evaluate if the diagnostic pathway for suspected or established ARE patients in our centre benefits from the addition of anti-DFS70 autoantibodies to an existing ENA test profile.

**Methods:** Serum from patients was tested for anti-DFS70 autoantibodies by the ANA-Profil 3 plus DFS70 line blot (Euroimmun, Lübeck Germany).

**Results:** In 2017 the Freiburg university rheumatology centre tested 671 patients, referred to for diagnosis or follow up of ARE, for anti-DFS70 and 126 patients were found positive. Descriptive statistics of the anti-DFS70 positive vs negative cohorts are summarised in table 1. Of the 126 anti-DFS70 positive patients, 53 (42%) had one or more additional ENAs positively tested (4 snRNP/Sm, 1 Sm, 15 SS-A/Ro, 15 Ro-52, 2 SS-B/La, 4 Scl-70, 8 PM-Scl, 2 PM-Scl75, 1 SRP, 2 Ku, 1 Jo-1, 4 Centromer, 2 PCNA, 2 Nucleosomes, 9 Histones, 1 ribos-P-Prot, 2 AMA-M2, 6 ds-DNA) and 3 (2%) patients had anti-DFS70 in conjunction with anti CCP autoantibodies. 70 (56%) patients were tested single positive for anti-DFS70. 81 (64%) of anti-DFS70 positive patients either had an established diagnosis of ARE or were newly diagnosed with ARE based on clinical criteria and laboratory results. The majority of these patients had additional ENAs or other autoantibodies tested positive, as described above. A diagnosis of ARE was excluded or revised with help of the anti-DFS70 result in 45 (36%) patients, all of these were anti-DFS70 positive only. In 10 of these patients (20%) preexisting therapies were discontinued (9 Hydroxychloroquin, 1 MTX/sulfasalazine).

	Anti-DFS70 positive (n=126)	Anti-DFS70 negative (n=544)	p-value
Male, n (%)	19 (15.1)	111 (20.4)	n.s.
Mean age, years (min-max)	47 (18–77)	52 (14–88)	n.s.
DFS70 +++, n (%)	82 (65.1)	NA	NA
DFS70 ++, n (%)	13 (10.3)	NA	NA
DFS70 +, n (%)	10 (7.9)	NA	NA
DFS70 (+), n (%)	21 (16.7)	NA	NA

**Abstract THU0380 – Table 1.** Descriptive statistics of the patient cohorts tested for anti-DFS70-antibodies

**Conclusions:** We found a high added diagnostical value of anti-DFS70 autoantibodies testing, since they were helpful to rule out or revise a previously suspected diagnosis of ARE in more than a third all patients tested anti-DFS70 positive at our centre. However, patients referred to a university rheumatology centre are a highly selected cohort and have a higher probability being finally diagnosed with ARE, and thus consideration of clinical criteria and thorough testing for additional autoantibodies is recommended in such a setting since also many patients with confirmed ARE will test positive for anti-DFS70.

**THU0381** **HIGH LEVELS OF CIRCULATING TYPE I, II AND III INTERFERONS DEFINE DISTINCT PATIENT SUBSETS WITH ACTIVE SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)**

<sup>1</sup>V. Oke, I. Gunnarsson<sup>1</sup>, J.M. Dorschner<sup>2</sup>, A. Zickert<sup>1</sup>, T.B. Niewold<sup>3</sup>, E. Svenungsson<sup>1</sup>. <sup>1</sup>Rheumatology Unit, Department of Medicine, Karolinska Institutet, Stockholm, Sweden; <sup>2</sup>Division of Rheumatology and Department of Immunology, Mayo Clinic, Rochester, MN; <sup>3</sup>Colton Center for Autoimmunity, New York University, New York, NY, USA

**Background:** Interferons (IFN) play a major role in SLE pathogenesis.<sup>1</sup> IFNs type I (predominately IFN- $\alpha$ s) are of major importance,<sup>2</sup> but IFN type II (IFN- $\gamma$ ) and IFNs type III ( $\lambda$ ) have also important roles.<sup>3,4</sup> How the levels of circulating IFNs type I, type II and type III relate to each other, and if they associate with any particular SLE disease manifestations is not known.

**Objectives:** We investigated serum levels of type I, type II, and type III IFNs and explored how these measurements relate to each other and to specific organ manifestations in patients with SLE.

**Methods:** We studied 497 well-characterised SLE patients and 322 controls. Functional type I IFN-activity (IFN-activity) was measured by WISH cell assay. IFN- $\alpha$  and IFN- $\lambda$ 1 were measured by ELISA, and IFN- $\gamma$  by MSD 30-plex assay. High IFN-activity/levels were defined as value over 3rd quartile of the measurement.

**Results:** SLE patients had higher levels of all investigated IFNs. IFN-activity correlated with IFN- $\alpha$  and IFN- $\gamma$ . High functional IFN-activity associated with active SLE in most domains: weight loss, fatigue, fever, rash, lymphadenopathy, arthritis and nephritis. The IFN- $\gamma$  high group had active disease with higher rates of nephritis, arthritis, leuko-, lymphopenia and Sm, SmRNP, RNP68, Ro52 and Ro60 autoantibodies. A higher proportion of the IFN- $\alpha$  high group had active rash, lymphadenopathy, Ro52 and La autoantibodies, while rates of antiphospholipid antibodies/syndrome, vascular events and renal affection were lower. High IFN- $\lambda$ 1 associated with anti-nucleosome autoantibodies and lymphopenia.

**Conclusions:** High type I IFN functional activity is associated with active SLE in the majority domains. A severe SLE phenotype, including active nephritis, arthritis and anti-Sm/SmRNP autoantibodies is associated with high IFN- $\gamma$ , while rash and a benign cardiovascular profile are linked to high serum IFN- $\alpha$ . Isolated increase in IFN- $\lambda$ 1 is only coupled to lymphopenia and antinucleosome antibodies. Our findings demonstrate that several IFNs can be elevated at the same time in SLE and the importance of IFN- $\gamma$  has so far been underscored. Sub-setting of SLE patients might be important when planning future clinical trials.

**THU0382** **FATIGUE IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: CONTRIBUTING FACTORS AND EFFECTS ON THE QUALITY OF LIFE**

<sup>1</sup>X. Du, Y. Zhuang<sup>1</sup>, Q. Zhao<sup>1</sup>, H. Chen<sup>2</sup>, B. Shen<sup>1</sup>. <sup>1</sup>The Second Affiliated Hospital of Nantong University, Nursing College of Nantong University; <sup>2</sup>The Second Affiliated Hospital of Nantong University, Nantong, China

**Background:** Fatigue is a very common symptom in Systemic Lupus Erythematosus (SLE), affecting more than 90% of patients<sup>1</sup>. Fatigue can lead to a decline in the quality of life<sup>2</sup>. Fatigue in SLE patients is associated with adverse demographic, clinical, and psychological characteristics<sup>3,4</sup>. However, there is no systematic study of SLE fatigue in China.

**Objectives:** This cross-sectional study aims to evaluate the contributors of fatigue and the effects of fatigue on the quality of life in Chinese SLE patients.

**Methods:** A self-report survey was administered to 119 SLE patients and 105 healthy individuals using the Fatigue Severity Scale (FSS) to assess the severity of fatigue. SLE patients completed the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI) for disease activity, the Hospital Anxiety and Depression Scale (HADS) for anxiety and depression, the Pittsburgh Sleep Quality Index (PSQI) for sleep quality and the Short Form 36 health survey for the quality of life. Meanwhile, healthy individuals completed the Hospital Anxiety and Depression Scale (HADS) and the Pittsburgh Sleep Quality Index (PSQI). We used independent samples t-tests, Chi square analysis and logistic regression modelling to analyse these data.

**Results:** Our results found that the FSS score of patients with SLE was higher than that of the controls ( $4.33 \pm 1.66$  versus  $3.41 \pm 1.39$ ;  $p < 0.001$ ). The SLE patients were significantly different from the control group in terms of anxiety, depression and quality of life. There were significant correlations among course of disease, anxiety, depression, subjective sleep quality, sleep disorders and fatigue in SLE patients. Meanwhile, logistic regression models identified depression and

sleep disorders as predictors of fatigue. In SLE patients, fatigued patients had lower quality of life than those who were non-fatigued.

**Conclusions:** This is the first known evaluation of the contributors of fatigue and the effects of fatigue on SLE patients' quality of life in China. The majority of Chinese SLE patients suffer from fatigue, which significantly impairs their quality of life. The results emphasise the need for holistic assessment and targeted intervention/management of SLE patients to relieve the symptoms of fatigue and finally improve their quality of life.

#### THU0383 PERFORMANCE OF MUSCULOSKELETAL INVOLVEMENT OF SYSTEMIC LUPUS ERYTHEMATOSIS: AN ULTRASOUND STUDY IN 114 PATIENTS

*Y. Geng. Department of Rheumatology, Peking University First Hospital, Peking, China*

**Background:** Joints are commonly involved in systemic lupus erythematosus (SLE). Ultrasound (US) has been widely used in rheumatoid arthritis (RA), however rarely applied and studied in SLE.

**Objectives:** To investigate the ultrasonic changes of the symptomatic joints and their correlations with clinical manifestations in SLE patients.

**Methods:** 114 SLE patients who complained of arthralgia or arthritis from May 2014 to Aug 2017 and 15 Rhupus patients due to overlapping with RA were recruited for ultrasound evaluation. Ultrasound scan of the symptomatic joint areas was completed. The correlation between ultrasonographic changes and clinical characteristics was analysed. Besides that, US changes of bilateral wrists and hands of Rhupus patients were compared with those of the SLE patients.

**Results:** In a total of 1866 joints scanned, synovial hyperplasia, tenosynovitis, erosion and osteophytes were all observed. Synovial hyperplasia was more often observed in knees in 28.6% patients (12/42), ankles in 25% patients (7/28), wrists in 23.3% patients (23/69) and elbows in 20% patients (5/25). Tenosynovitis and erosion were most commonly found in shoulders in 35% (7/20) and 65% (13/20) patients. Osteophytes were more common in proximal interphalangeal (PIP) joints, elbows and knees. Among 69 patients with 22 joints (bilateral wrists and hands) scanned, synovial hyperplasia was observed in 25 patients (36.2%) and erosion in 22 patients (31.8%). The agreement between synovial hyperplasia and swollen joints in PIP was fair ( $\kappa=0.633$ ,  $p<0.01$ ), however poor in wrists ( $\kappa=0.089$ ,  $p=0.584$ ). 18.4% patients with synovial hyperplasia had no tenderness or swollen clinically, while 15.7% patients with tenderness or swollen had no synovial hyperplasia on ultrasound. No correlation was found between ultrasound changes with SLE disease activity index. Both synovial hyperplasia and erosion were more common in Rhupus patients (73.3% vs. 36.2%,  $p=0.08$ ; 66.7% vs. 26.0%,  $p=0.03$ ) with significantly higher GS score ( $7.4\pm 6.4$  vs.  $1.6\pm 4.1$ ,  $p=0.04$ ) than SLE alone patients.

**Conclusions:** Variety of changes can be observed by ultrasound at different joints in SLE patients. The ultrasonographic changes and clinical manifestations did not always correspond to each other. Synovial hyperplasia and erosion was more common in Rhupus patients.

#### THU0384 SALIVARY GLAND ULTRASONOGRAPHY AND STIMULATED SALIVARY FLOW CORRELATED WITH SALIVARY GLAND BIOPSY AMONG PATIENTS WITH SJÖGREN SYNDROME AND SICCA SYMPTOMS: EXPERIENCE FROM A SINGLE MEDICAL CENTRE IN TAIWAN

*<sup>1,2</sup>Y.P. Tsao, M.H. Chen<sup>1,2</sup>, S.Y. Wu<sup>3,4</sup>, C.Y. Wu<sup>3,4</sup>, W.S. Chen<sup>1,2</sup>, C.C. Lai<sup>1,2</sup>, C. Y. Tsai<sup>1,2</sup>. <sup>1</sup>Medicine, Taipei Veterans General Hospital, Division of Allergy, Immunology, Rheumatology (AIR); <sup>2</sup>Faculty of Medicine, National Yang Ming University; <sup>3</sup>Stomatology, Taipei Veterans General Hospital; <sup>4</sup>School of Dentistry, National Yang Ming University, Taipei, Taiwan, Province of China*

**Background:** Sjögren's syndrome is an autoimmune disease that involves several organs. In the latest classification criteria, salivary minor gland is one of the major factor contributing to the diagnosis. Ultrasonography is a non-invasive, easy accessible tool in evaluation the contour and structure of salivary glands, which have been shown to have efficacy in monitoring the disease status of Sjögren's syndrome as well as in diagnosis the disease. Otherwise, salivary flow rate is another component of classification criteria, and its association with disease activity remains to be elucidated.

**Objectives:** To investigate the efficacy of salivary gland ultrasonography and salivary flow rate in patients with Sjögren's syndrome and Sicca symptoms.

**Methods:** Total 97 patients of primary or secondary Sjögren's syndrome, and patients with sicca symptoms were enrolled. Ultrasonography was performed at parotid and submandibular glands with 13–16MHz linear probe. Each gland was scored from 0 to 4. Minor salivary gland biopsy results were examined by pathologist with Chisholm-Mason grade. Unstimulated salivary flow rate was recorded first, and stimulated salivary flow rate was tested after 5 min of sugar-free chewing gum stimulation. Patients' symptoms were recorded by ESSPRI questionnaires.

**Results:** Total 56 primary Sjögren's Syndrome, 10 secondary Sjögren's Syndrome, and 31 patients with sicca symptoms were enrolled. Significant correlations were noted between unstimulated salivary flow rate and minor gland biopsy ( $p=0.029$ ), stimulated salivary flow rate and biopsy ( $p=0.006$ ), salivary gland ultrasonography and minor gland biopsy ( $p<0.001$ ), and minor gland biopsy with serum anti-SSB (La) level ( $p=0.009$ ). The correlations between minor gland biopsy and serum anti-SSA (Ro) level was not significant. The stimulated salivary flow rate also correlated with self-reported dryness in ESSPRI questionnaires ( $p=0.018$ ). The salivary gland ultrasonography also correlated with ESSPRI ( $p<0.001$ ) and the three factors in ESSPRI (dryness,  $p<0.001$ ; pain,  $p=0.039$ ; fatigue,  $p=0.002$ ).

**Conclusions:** Both salivary gland ultrasonography and salivary flow rate correlated with the severity of salivary minor gland biopsy. The stimulated salivary flow rate had better correlations with the biopsy result than unstimulated flow, and it also correlated with patients' self-reported dryness symptoms. Salivary gland ultrasonography had correlations with symptoms of patient. These non-invasive methods may play roles in evaluation of the disease activity.

#### THU0385 URINARY INFLAMMATORY CELLS REFLECT HISTOPATHOLOGICAL KIDNEY INJURY IN PATIENTS WITH LUPUS NEPHRITIS

*Y. Wada, M. Sudo, M. Sakatsume, T. Kuroda, M. Nakano, I. Narita. Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan*

**Background:** Lupus nephritis (LN) is one of the common manifestations of systemic lupus erythematosus (SLE), and is considered to be a very important factor influencing the course of the disease. Although kidney biopsy is the gold standard for defining the histopathologic class of LN, it is an invasive procedure sometimes associated with a risk of bleeding and thrombotic events; furthermore, repeated biopsies are not always applicable in clinical practice. We have already reported that, in patients with glomerulonephritis, inflammatory cells such as T cells and macrophages appear in the urine when there are accompanying signs of active cellular infiltration such as cellular crescent formation and diffuse interstitial cell infiltration, but not when active inflammatory lesions are absent.

**Objectives:** To assess the utility of urinary inflammatory cell analysis in patients with LN by examining the correlations between the numbers of urinary inflammatory cells and renal histopathological findings.

**Methods:** Twenty-six patients with SLE, who had been referred to Niigata University Hospital between 2004 and 2017 and diagnosed as having LN by percutaneous kidney biopsy, were recruited for this study. Flow-cytometric analysis of urinary inflammatory cells was performed for each subject at the time of admission for kidney biopsy. Numbers of urinary T cells or macrophages were determined by multiplying the number of viable cells in the gated mononuclear cell region in each sample by the percentage of urinary CD3-positive or CD14-positive cells in the population, respectively. The histopathological findings of kidney biopsy specimens for each subject were classified according to the 2003 International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification of LN. In addition, they were also evaluated for glomerular and interstitial lesions such as mesangial cell/matrix proliferation, endocapillary hypercellularity, crescent formation, and interstitial cell infiltration and fibrosis. The severity of each lesion was scored from 0 to 4, and the numbers of urinary inflammatory cells were analysed by Spearman's rank correlation coefficient to determine the relationships among these scores. Next, the patients were divided into two groups according to whether the total number of urinary inflammatory cells was significantly increased (more than 120 cells/ml; positive group, n=12) or not (negative group, n=14), and the severities of the histopathological lesions were compared between the two groups.

**Results:** Disease severity in terms of the ISN/RPS classifications was positively correlated with the severity of mesangial cell and matrix proliferation, cellular crescent formation, and duplication of the glomerular basement membrane. In addition to these four factors, the numbers of CD3-positive and CD14-positive cells were also positively correlated with adhesion, endocapillary hypercellularity, interstitial inflammatory cell infiltration, and interstitial fibrosis. The severity scores for adhesion, endocapillary hypercellularity, cellular and fibrous crescent formation, duplication, and interstitial cell infiltration were significantly higher in the positive group than in the negative group.

**Conclusions:** Analysis of urinary immune cells reflects the histopathological features of kidney biopsy specimens from patients with LN.

THU0386

#### DIFFERENCE OF IMAGE FEATURES ON COMPUTED TOMOGRAPHY BETWEEN LUPUS ENTERITIS AND MESENTERIC VASCULITIS OF OTHER CONNECTIVE TISSUE DISEASES

Y. Yoshida, T. Kondo, K. Yukawa, T. Tokunaga, T. Kuranobu, K. Oi, T. Nojima, S. Hirata, E. Sugiyama. *Department of Clinical Immunology and Rheumatology, Hiroshima University Hospital, Hiroshima, Japan*

**Background:** Lupus enteritis (LE), lupus mesenteric vasculitis, occurs occasionally in systemic lupus erythematosus (SLE). Not only LE but also other mesenteric vasculitis can lead to bowel haemorrhage or perforation and will be fatal, but it is difficult to demonstrate histologically-proven vasculitis on endoscopic biopsy.<sup>1</sup> Although several computed tomography (CT) features of LE are reported, we have little knowledge about whether they differ from those of other mesenteric vasculitis.

**Objectives:** To clarify the imaging pattern on CT which can distinguish LE from other mesenteric vasculitis.

**Methods:** Patients diagnosed with LE and non-LE at our hospital were consecutively registered from January 2009 to August 2017. The diagnosis of LE was made by the criteria of <sup>BILAG</sup> 2004 which is defined as either vasculitis or inflammation of small or large bowel with supportive imaging and/or biopsy findings.<sup>2</sup> Non-LE was defined as mesenteric vasculitis of other connective tissue diseases (CTDs). We compared the contrast-enhanced CT patterns of LE with non-LE. Statistical analyses were performed using XLSTAT.

**Results:** A total of 8 patients were diagnosed with LE and enrolled in this study. The mean age was 41.1 years old, range 23–53, and 7 were females. CT exams of all 8 patients demonstrated small bowel wall thickening, dilatation of intestine and comb sign (indicating engorgement of mesenteric vessels). Severe bowel wall thickening (>8 mm) was observed in 87.5% (n=7), ascites in 75.0% (n=6) and target sign (indicating abnormal bowel wall enhancement) in 62.5% (n=5). 5 patients were enrolled in non-LE (1 eosinophilic granulomatosis with polyangiitis, 1 IgA vasculitis and 3 Behcet's disease). Comparison of CT findings between LE patients and non-LE patients were summarised on table 1. Bowel wall thickness and comb sign were common in both groups, however the prevalence of dilatation of intestine in LE patients was significantly higher than in non-LE patients. Although not significant, complication of large bowel involvement was shown only in LE patients.

Abstract THU0386 – Table 1

	LE (n=8)	non-LE* (n=5)	p-value
Thickening bowel wall	100%	100%	—
Large bowel involvement	50.0%	0%	0.10
Asymmetrical patterns of involvement	12.5%	60.0%	0.21
Dilatation of intestine	100%	20.0%	0.0070
Ascites	75.0%	40.0%	0.29
Target sign	62.5%	40.0%	0.59
Comb sign	100%	100%	—

\*non-LE : 1 Eosinophilic granulomatosis with polyangiitis, 1 IgA-vasculitis, 3 Behcet's disease

\*non-LE : 1 Eosinophilic granulomatosis with polyangiitis, 1 IgA-vasculitis, 3 Behcet's disease

**Conclusions:** Dilatation of intestine on CT is significant to distinguish LE from mesenteric vasculitis of other CTDs.

THU0387

#### HIGH-THROUGHPUT QUANTITATIVE HISTOLOGY IN SYSTEMIC SCLEROSIS SKIN DISEASE USING COMPUTER VISION

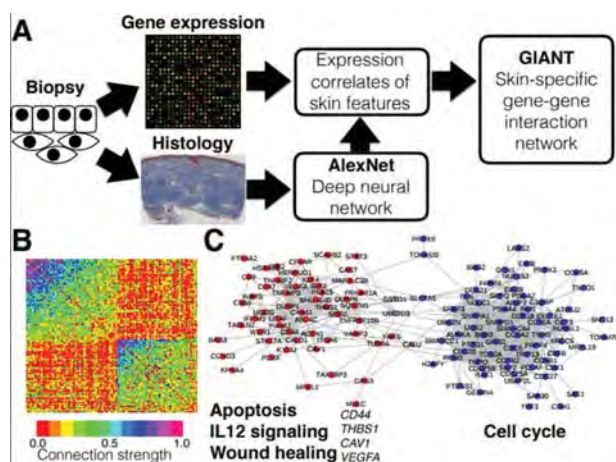

<sup>1</sup>C. Correia, M. Hinchcliff<sup>1</sup>, M. Mahoney<sup>2</sup>. <sup>1</sup>*Rheumatology, Northwestern University Feinberg School of Medicine, Chicago;* <sup>2</sup>*Neurological Sciences, University of Vermont, Burlington, USA*

**Background:** There are no validated systems to quantify dermal architecture of skin biopsy sections in systemic sclerosis (SSc). Significant advances in computer vision, called deep neural networks (DNNs), have demonstrated human-level pattern recognition abilities using mathematical transformations of images into millions of quantitative features.<sup>1</sup> Publicly available DNN algorithms have the potential to radically augment current histological analyses via robust, reproducible, and high-throughput image quantification.

**Objectives:** Apply publicly available DNN algorithms to trichrome-stained sections of dermal biopsies from patients with SSc to identify quantitative features of images that correlate with clinical skin fibrosis assessment via the validated modified Rodnan skin score (mRSS) and skin gene expression.<sup>2</sup>

**Methods:** One rheumatologist performed local mRSS (lmRSS) assessments (0–3) and two dermal punch biopsies for 7 patients with SSc and one healthy control at baseline and 6, 12, 24, and 36 months. One biopsy was paraffin embedded, sectioned, stained with trichrome, and photomicrographed. Images were transformed into high-level quantitative features using AlexNet and the Matlab Neural Network Toolbox.<sup>3</sup> Correlations between quantitative features and lmRSS were determined with Bonferroni-Holm correction. One biopsy underwent gene expression profiling by DNA microarray. The degree of correlation between each gene and lmRSS was assessed and a functional gene network was determined using the GIANT database.<sup>4</sup>

**Results:** We identified 90 quantitative features that correlated significantly with local skin score (p<0.05, Bonferroni-Holm correction). Using these features, biopsies sorted into three clusters corresponding to low (mean=0.13), intermediate (mean=0.91), and high (mean=1.7) lmRSS. Gene expression for 488 genes in the biopsies correlated significantly with quantitative features (p<0.05, Bonferroni-Holm correction). Among these 488 genes, 185 genes formed a large functional network in the GIANT database including genes associated with the cell cycle, apoptosis, IL12 signalling, and wound healing such as CD44, THBS1, CAV1, and VEGFA.

**Conclusions:** This proof-of-principal study demonstrates that DNN processing of stained dermal biopsy sections are sensitive to clinically relevant features of SSc skin. These results suggest that DNNs dramatically expand the quantifiable SSc phenome and that histological samples can now be incorporated into models of SSc. Moreover, our results indicate that the gene expression underlying SSc may be driving histological differences in SSc skin.

#### THU0388 DIFFERENCES IN CLINICAL COURSES AND SERUM MARKERS OF INTERSTITIAL LUNG DISEASE ASSOCIATED WITH ANTI-AMINOACYL-TRANSFER RNA SYNTHETASE ANTIBODY AND ANTI-MELANOMA DIFFERENTIATION-ASSOCIATED GENE 5 ANTIBODY-POSITIVE POLYMYOSITIS/DERMATOMYOSITIS

K. Akashi, Y. Nose, T. Shirai, Y. Fujikawa, T. Nagamoto, T. Okano, S. Takahashi, S. Sendo, A. Onishi, J. Saegusa, A. Morinobu. *Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe, Japan*

**Background:** Polymyositis/dermatomyositis (PM/DM) is a chronic autoimmune disease that is often complicated by interstitial lung disease (ILD). Anti-aminoacyl-transfer RNA synthetase antibody (ARS-Ab) and anti-melanoma differentiation-associated gene 5 antibody (MDA5-Ab) are highly detected in PM/DM with ILD. It was reported that ARS-Ab-positive-ILD (ARS-ILD) is often recurrent<sup>1</sup>, and patients with MDA5-Ab-positive-ILD (MDA5-ILD) develop fatal rapidly progressive ILD<sup>2</sup>.

**Objectives:** To evaluate the differences in clinical courses between ARS-ILD and MDA5-ILD, including the changes in serum ILD markers.

**Methods:** We retrospectively investigated 25 patients with ARS-ILD and 26 patients with MDA5-ILD who received induction therapy between April 2002 and September 2017 at Kobe University Hospital. The survival rate and relapse-free survival rate were analysed with Kaplan-Meier estimation and the log-rank test. The differences in serum ILD markers between patients with ARS-ILD and MDA5-ILD were evaluated with the Student's t-test.

**Results:** Disease subtypes at diagnosis with PM/DM-associated ILD were as follows: Eleven ARS-ILD and no MDA5-ILD patients had PM, 10 ARS-ILD and 5 MDA5-ILD patients had DM, and 4 ARS and 21 MDA5 patients had amyopathic DM. The survival rate for MDA5-ILD was significantly lower than that for ARS-ILD ( $p < 0.01$ , figure 1A). On the other hand, there was no significant difference in the relapse-free survival rate between ARS-ILD and MDA5-ILD ( $p = 0.25$ , figure 1B). The serum level of Krebs von den Lungen-6 was not significantly different between ARS-ILD and MDA5-ILD (1044.3 ± 768.1 U/ml in ARS-ILD vs 1044.863.1 ± 566.5 U/ml in MDA5-ILD,  $p = 0.33$ ), but the serum level of ferritin was significantly higher in MDA5-ILD than in ARS-ILD (286.4 ± 422.3 ng/ml in ARS-ILD vs 696.2 ± 839.5 ng/ml in MDA5-ILD,  $p = 0.04$ ). Although the serum level of surfactant protein D (SP-D) in ARS-ILD was high, the SP-D level in MDA5-ILD was normal (158.9 ± 82.1 ng/ml in ARS-ILD vs 46.3 ± 22.1 ng/ml,  $p < 0.01$ ).

**Conclusions:** MDA5-ILD patients should be monitored for both rapidly progressive disease and relapsing disease. A normal SP-D level is a feature of MDA5-ILD.

#### THU0389 BORDERLINE PULMONARY HYPERTENSION WAS ASSOCIATED WITH REDUCED CARDIAC OUTPUT DURING EXERCISE IN PATIENTS WITH CONNECTIVE TISSUE DISEASES

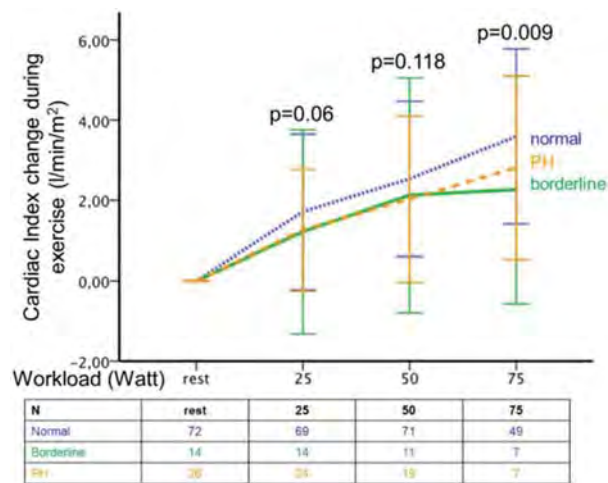

A. Marra<sup>1</sup>, C. Nagel<sup>1</sup>, B. Egenlauf<sup>1</sup>, P. Xanthouli, S. Harutyunova<sup>1</sup>, N. Blank<sup>2</sup>, H.-M. Lorenz<sup>2</sup>, C. Fiehn<sup>3</sup>, N. Benjamin<sup>1</sup>, C. Fischer<sup>4</sup>, E. Bossone<sup>5</sup>, A. Cittadini<sup>6</sup>, E. Grünig<sup>1</sup>. <sup>1</sup>*Pneumology, Thoraxklinik Heidelberg*; <sup>2</sup>*Rheumatology, University Hospital, Heidelberg*; <sup>3</sup>*Rheumatology, Practice for Rheumatology and clinical Immunology, Baden-Baden*; <sup>4</sup>*Department of Human Genetics, University Heidelberg, Heidelberg, Germany*; <sup>5</sup>*Kardiologie, University Hospital, Salerno*; <sup>6</sup>*Department of Translational medical Science, University Federico II, Naples, Italy*

**Background:** In patients with systemic sclerosis (SSc) borderline mean pulmonary arterial pressures (mPAP; 21–24 mmHg at rest) are a frequent finding and could represent an intermediate stage between normal pulmonary pressures and manifest pulmonary hypertension (PH).<sup>1</sup>

**Objectives:** The objective of this prospective study was to compare right ventricular function and pulmonary arterial compliance (PAC) at rest and during exercise between systemic sclerosis (SSc)-patients with normal and borderline mean pulmonary artery pressures, respectively.

**Methods:** SSc-patients (n=112) underwent clinical assessment, including right heart catheterization at rest and during exercise and were divided in three groups according to their resting mPAP values: normal mPAP (≤20 mmHg), borderline mPAP (21–24 mmHg) and manifest pulmonary hypertension (PH, mPAP ≥25 mmHg). Results were compared between groups by ANOVA followed by post-hoc student's t-test.

**Results:** SSc Patients with borderline PAP showed significantly lower cardiac index (CI) increase during exercise and higher PVR values than SSc patients with normal PAP at rest. Six-Minute-walking distance (6MWD) and PAC (stroke volume/(systolicPAP-diastolicPAP)) were significantly lower in the borderline PAP group compared to patients with normal PAP.

**Conclusions:** The results of this study suggest that impaired 6MWD in SSc patients with borderline PAP (and normal RV function at rest) might be caused by reduced RV contractile reserve (reduced RV output) and reduced PAC during exercise rather than by elevated pressures in the borderline range alone. These findings give further evidence for borderline PAP being an early stage of pulmonary vascular disease.

#### THU0390 PATIENTS WITH SYSTEMIC SCLEROSIS DEVELOP FOCAL FIBROSIS OVER TIME, AND INCREASED ECV DIFFUSE FIBROSIS SEEN IN POOR PROGNOSTIC GROUP – A FIRST LONGITUDINAL CARDIAC MRI STUDY

<sup>1</sup>R.B. Dumitru, L.-A. Bissell<sup>1</sup>, B. Erhayiem<sup>2</sup>, G. Fent<sup>2</sup>, E.M. Hensor<sup>1</sup>, A. Giollo<sup>1</sup>, A. Kidambi<sup>2</sup>, J. Greenwood<sup>2</sup>, F. Del Galdo<sup>1</sup>, S. Plein<sup>2</sup>, M.H. Buch<sup>1</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine; <sup>2</sup>Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, Leeds, UK

**Background:** Subclinical SSc-cardiomyopathy is described in up to 2/3 of the patients when sensitive methods such as cardiac MRI (CMR) are used. The prognostic implications and the natural history of these findings is unknown.

**Objectives:** To evaluate in SSc patients, free of cardiovascular (CV) risk factors and CV disease (CVD) the prevalence, clinical association and natural history of CMR abnormalities over 3 years.

**Methods:** 35 SSc patients, fulfilling the ACR/EULAR criteria, with no CVD, diabetes and  $\leq 1$  CV risk factor had 2 CMRs, 3 years apart. A 3T CMR with late gadolinium enhancement (LGE), T1 mapping for extracellular volume (ECV) quantification and stress perfusion (data available later) was undertaken. Initial CMR was compared with CMR results of 30 healthy controls (HC).

**Results:** 35 pts had an initial CMR: 26 (74%) female, mean (SD) age 55 (15) (43%) dcSSc, 11 (31%) ACA+, 12 (34%) Scl70+, 15 with (43%) interstitial lung disease (ILD) and 13 (37%) with history of digital ulcers (DU). 21 (60%) received any DMARD over the 3 year period and 10 (29%) prior treatment with cyclophosphamide. The first CMR (CMR1) of SSc pts vs HC showed higher ECV% values and comparable left ventricle (LV) volumes (table 1). LGE was present in 9/22 pts vs 1/30 HC. 22/35 pts had a second CMR (CMR2) at year 3 (Y3). A further 5 pts had evidence of LGE, total of 14 (40%): 7/14 had dcSSc, 6/14 males, 2 ACA positive, 6 Scl70 positive. LGE distributed in the basal and mid segments, mainly in a linear or patchy pattern. Of those with LGE at CMR1 (5/9 pts with LGE on CMR1 had CMR2) no change in the LGE pattern at CMR2 was observed. None of the initial CMR measures associated with LGE development at Y3 ( $p > 0.05$ ). Whilst ECV had an overall decrease, ECV increased in patients with ILD [mean diff. (CI) 3 (-

1,6),  $p = 0.14$ ] and in those with higher mRSS at baseline ( $r = 0.455$ ,  $p = 0.04$ ). A significant decrease over the 3 years was observed in LV end-diastolic volume (LVEDV/BSA), LV end-systolic volume (LVESV/BSA) and left ventricular stroke volume (LVSV/BSA) (table 1). A decrease in LVEDV/BSA was noticed for those with a history of DU [mean diff. (CI)  $-5$  (-12.2),  $p = 0.1$ ], ILD [mean diff. (CI)  $-6$  (-12.0, 5),  $p = 0.07$ ] and shorter disease duration ( $r = -0.504$ ,  $p = 0.02$ ).

**Abstract THU0390 – Table 1**

CMR variable	HC Mean (SD)	SSc patients Mean (SD)	SSc patients Mean (SD)	Change (95% CI) in CMR between SSc patients	P value

Distensibility (10-3mmHg <sup>-1</sup> )	5 (2)	4 (2)	5 (3)	0 (-1, 2)	0.491
Torsion	15(4)	13(4)	13(5)	0 (-2, 3)	0.828

**Conclusions:** This longitudinal CMR study in SSc demonstrates that CMR is sensitive to change over time. More individuals developed LGE (of focal fibrosis) despite immunosuppressive treatment, and ECV% (diffuse fibrosis) appeared to worsen in a poor prognostic group. Functional changes were also observed. These data justify larger studies to inform stratification strategy for CMR in SSc, and also provide new insights for further investigation.

#### THU0391 CLINICAL VALUE OF COMPUTED TOMOGRAPHY FOR THE DIAGNOSIS OF ESOPHAGEAL DYSMOTILITY IN SYSTEMIC SCLEROSIS

<sup>1</sup>C. Sobrino Grande, C. Pijuan Moratalla<sup>1</sup>, N. Almeida Arostegui<sup>2</sup>, L. Sarasúa<sup>2</sup>, C. de la Puente Bujidos<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Ramón y Cajal University Hospital, Madrid, Spain

**Background:** Esophageal dysmotility is common in Systemic Sclerosis (SSc), affecting 50%–80% of patients, usually associated with poor prognosis. SSc leads to atrophy and fibrosis of the smooth muscle of the oesophagus, modifying peristaltic contractions and motility. Manometry is considered the gold standard for the diagnosis of esophageal motility disorders, but dilatation can also be observed with computed tomography (CT), even if its diagnostic validity is still unknown.

**Objectives:** To compare esophageal dilatation observed with CT to manometry, in patients with SSc and to confirm whether CT can be used in the assessment of esophageal dysmotility.

**Methods:** Forty six patients meeting the 2013 ACR/EULAR Classification Criteria for SSc, and 53 healthy controls were included and retrospectively studied. Patients with overlapping syndromes, active infections or with longstanding diabetes were excluded. Epidemiological and clinical data were collected from medical records. All patients and controls had undergone at least one manometry and one CT, requested in daily clinical practice for another purpose. The most recent exams were selected for the study. Esophageal involvement was assessed using manometry (aperistalsis, inefficient peristalsis, nonspecific dysmotility and normal peristalsis) and compared with the largest coronal esophageal luminal diameters proximally, near the carina, and distally observed by CT. Data analysis was performed by STATA. All patients signed written informed consent, approved by the Research Ethics Committee.

**Results:** The sample included 76 women (10 dcSSc, 28 lcSSc, 3 MCTD, 35 controls) and 23 men (3 dcSSc, 2 lcSSc, 18 controls). Esophageal dysmotility was seen in 40/46 patients with SSc (87%) by manometry (defined as inefficient peristalsis or aperistalsis). Esophageal dilatation ( $\geq 10$  mm) was present proximally in 23/44 patients (52.3%), distally in 35/46 patients (76.1%), and near the carina in 26/44 patients (59.1%). Esophageal dilatation at any level was statistically associated with esophageal dysmotility ( $p < 0.05$ ). The areas under the ROC curves (figure 1) suggest that the esophageal proximal diameter in the coronal plane is good for detecting esophageal dysmotility (0.798, 95% CI 0.705–0.890), with the distal diameter (0.759, 95% CI 0.661–0.857) and the carinal diameter (0.712, 95% CI

0.607–0.816), being slightly lower. A proximal diameter  $\geq 7.5$  mm provides a specificity of 87.2% (95% CI: 76.7–96.7) and a sensitivity of 65.3% (95% CI: 51.9–78.6) for esophageal dysmotility, enabling correct classification of 75% of the patients. A distal diameter  $\geq 12.9$  mm provides a specificity of 76.6% (95% CI: 64.5–88.7) and a sensitivity of 71.2% (95% CI: 58.8–83.5), correctly classifying 73% of the patients.

**Abstract THU0391 – Figure 1.** ROC curves of the diameters for esophageal dysmotility detected by manometry.

**Conclusions:** CT, a less invasive technique than manometry, can be an acceptable diagnostic tool for esophageal dysmotility in SSc, when the maximum proximal or distal esophageal diameter are  $\geq 7.5$  mm and 12.9 mm, respectively. CT done in the daily clinical practice could be exploited when manometry is not preferred in selected patients with SSc. More studies need to be carried out to confirm this results.

#### SYSTEMIC SCLEROSIS AND PRIMARY BILIARY CHOLANGITIS: AN OVERLAP SYNDROME? PRELIMINARY DATA FROM A MULTICENTRE EUSTAR STUDY

<sup>1</sup>G. Lepri, P. Airo<sup>2</sup>, O. Distler<sup>3</sup>, K. Andréasson<sup>4</sup>, Y. Braun-Moscovici<sup>5</sup>, E. De Langhe<sup>6</sup>, C. Bruni<sup>1</sup>, M. Matucci-Cerinic<sup>1</sup>, Y. Allanore<sup>7</sup>, on behalf of EUSTAR co-authors. <sup>1</sup>Rheumatology, University of Florence, Florence; <sup>2</sup>Rheumatology and Clinical Immunology, Spedali Civili, Brescia, Brescia, Italy; <sup>3</sup>Rheumatology, University Hospital Zurich, Zurich, Switzerland; <sup>4</sup>Clinical Sciences, Lund University, Lund, Sweden; <sup>5</sup>Rheumatology Department, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion, Haifa, Haifa, Israel; <sup>6</sup>Rheumatology, University Hospitals Leuven, Leuven, Belgium; <sup>7</sup>Rheumatology A, Paris Descartes University, Paris, France

**Background:** The association between systemic sclerosis (SSc) and primary biliary cholangitis (PBC) is well known. However, classifications criteria of the 2 diseases have been recently revised and may change the relationships. Furthermore, the specific outcomes with regards to organ involvement and also of liver aspects have been only scarcely investigated.

**Objectives:** To describe clinical characteristics of SSc-PBC patients compared to SSc using a large series

**Methods:** A multicentre EUSTAR study collection data of SSc patients with known PBC or with PBC-specific antibodies (abs) and of SSc controls matched for disease duration and cutaneous subset. Data were recorded at baseline and at the last available visit.

**Results:** 229 patients were enrolled (85 SSc-PBC and 144 SSc). The mean age of the population at the SSc diagnosis was of  $53 \pm 12.8$ . **Baseline characteristics.** The limited cutaneous subset was the most common. Anticentromere abs (ACA) were present in 82.9% of SSc-PBC patients (vs 68.5% in SSc,  $p$ -value=0.01) while anti-topoisomerase I abs were less frequently (1.2% vs 9.7%),  $p$ -value=0.02. Out of 85 SSc-PBC patients, antimitochondrial abs (AMA) were present in 80%, only 9.4% presented anti-gp210 abs and 7.1% anti-sp100 abs. The two populations did not differ for fibrosis at HRCT, lung function tests, the value of creatinine and for pulmonary arterial hypertension. A trend towards statistical significance was found in the prevalence of digital ulcers (DUs) as patients that have never suffered from past or current DUs were greater in the SSc-PBC group (78.6% vs 66%,  $p$ -value=0.051). Regarding other autoimmune associated diseases, a greater prevalence of Hashimoto thyroiditis was found in SSc-PBC ( $p$ -value=0.03). At baseline, transaminase, alkaline phosphatase and  $\gamma$ GT levels were all higher in PBC-SSc ( $p$ -value<0.001) (see Fig 1). **Outcomes of organ**

**involvements.** The mean follow-up was of  $10.5 \pm 6.8$  years. During the follow-up the percentage of patients presenting ILD (defined as new appearance of fibrosis at control HRCT scan) was greater in SSc vs SSc-PBC (12.9% vs 2.8%,  $p$ -value=0.02) and PAH percentage of new cases was of 9.9% in SSc while it was not present in SSc-PBC ( $p$ -value=0.003).

	SSc-PBC population	SSc controls	p-value
Cutaneous subset			
Limited cutaneous subset	77 (30.6%)	132 (91.7%)	0.73
Diffuse cutaneous subset	2 (2.4%)	5 (3.5%)

Aspartate transaminase [median(IQ)]	38 (26-54.25)	21 (19-27)	<0.001
Alkaline phosphatase (AP) [median(IQ)]	147 (94-296)	71 (56-90)	<0.001
vGT [median(IQ)]	143 (59.5-251.5)	18 (11-31.25)	<0.001

**Abstract THU0392 – Figure 1.** Clinical features at baseline

**Conclusions:** PBC is more present in ACA positive IcSSc; SSc-PBC patients have a higher risk of polyautoimmunity. Of the most interest, SSc-PBC patients seem to have a milder SSc phenotype with less severe organ involvement and progression. Regarding PBC phenotype, only 4 patients presented portal hypertension and nobody was subjected to liver transplantation. At baseline, the SSc-PBC group had higher cholestatic liver enzymes and more than 60% were treated with deoxycholic acid. In the future, it will be useful to evaluate the PBC phenotype during the follow-up enrolling a greater number of patients.

#### THE PREDICTOR OF MALNUTRITION IN SYSTEMIC SCLEROSIS (PREMASS) SCORE: A VALIDATED COMBINED INDEX PREDICTIVE OF FUTURE WEIGHT LOSS IN SYSTEMIC SCLEROSIS

<sup>1</sup>G. Bagnato, E. Pigatto<sup>2</sup>, A. Bitto<sup>3</sup>, N. Irrera<sup>3</sup>, C.G. Pizzino<sup>3</sup>, G. Abignano<sup>1</sup>, A. Ferrera<sup>4</sup>, D. Sciortino<sup>4</sup>, M. Hutchinson<sup>5</sup>, F. Squadrino<sup>3</sup>, M. Buch<sup>1</sup>, P. Emery<sup>1</sup>, E. Zanutta<sup>2</sup>, S. Gangemi<sup>6</sup>, W.N. Roberts<sup>7</sup>, A. Saitta<sup>8</sup>, F. Cozzi<sup>2</sup>, F. Del Galdo<sup>1</sup>.

<sup>1</sup>NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust and Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, Leeds, UK; <sup>2</sup>Rheumatology, University of Padova, Padova; <sup>3</sup>Pharmacology, <sup>4</sup>Rheumatology, University of Messina, Messina, Italy; <sup>5</sup>Statistics, University of Leeds, Leeds, UK; <sup>6</sup>Allergy and Clinical Immunology, University of Messina, Messina, Italy; <sup>7</sup>Rheumatology, University of Louisville, Louisville, USA; <sup>8</sup>Internal Medicine, University of Messina, Messina, Italy

**Background:** Malnutrition and severe gastrointestinal dysfunction are the cause of mortality in 4%–15% of systemic sclerosis (SSc) patients whereas overall gastrointestinal involvement is observed in 75%–90% of cases.<sup>1</sup> Hence, a reliable tool for stratification of risk for malnutrition would be of great value in the clinical management of SSc.

**Objectives:** Here we set out to identify a combined index predictive of significant weight loss at 12 months employing Malnutrition Universal Screening Tool (MUST) and serum adiponectin to leptin ratio (A/L) already used in other conditions.

**Methods:** This was an international, multicentre, longitudinal study employing 180 SSc patients in two independent cohorts: a study cohort (110 consecutive SSc patients) enrolled from University of Messina (60) and University of Padova,<sup>50</sup> and a validation cohort (70) at the University of Leeds. Serum A/L ratio was measured by ELISA. MUST score, which includes BMI and weight loss reported by the patient in the last 3–6 months, was calculated as described: 0=no, 1=mild, >2= moderate/severe risk of malnutrition. End point of the study was weight loss >10% of baseline weight at 12 months.

**Results:** The two cohorts showed no significant differences in demographic and clinical features. Overall, median BMI decreased over time in both study and validation cohorts (23.5 vs 22.35 and 23.44 vs 22.49, respectively;  $p$ <0.0001). A/L

ratio correlated significantly with BMI in both cohorts ( $r^2=0.19$  for study cohort,  $r^2=0.25$  for validation cohort;  $p<0.0001$ ). MUST score had only moderate value in predicting weight loss in the study cohort (AUC 0.7; 95% CI: 0.58–0.82). Specifically, 46.5% of SSc patients lost >10% wt despite having “no” or “mild” MUST scores. Logistic regression analysis identified the combination of BMI and A/L as the best PREDICTOR of MAInutrition in Systemic Sclerosis (PREMASS). The formula  $12.18-(0.63 \times \text{BMI})+(1.51 \times \text{A/L})$  predicted the end point with AUC=0.91 (95% CI: 0.77–0.84). A PREMASS score >0.23 showed 91.3% sensitivity (95% CI: 79.79–100) and 80.46% specificity (95% CI: 72.13–88.79) for >10% wt loss with an overall 55.26% positive predictive value (PPV) (95% CI: 39.45–71.07) and 97.22% negative predictive value (NPV) (95% CI: 93.43–100) and a relative risk (RR) of 19.90 (95% CI: 4.93–80.37). In the validation cohort, PREMASS showed 76.47% sensitivity (95% CI: 56.31–96.63) and 75.47% specificity (95% CI: 63.89–87.06) with an overall 50% PPV (95% CI: 30.78–69.22) and 90.91% NPV (95% CI: 82.41–99.4) and a RR of 5.5 (95% CI: 2–15.10).

**Conclusions:** PREMASS is the first validated index for weight loss risk stratification in the following 12 months in SSc. Prediction of future weight loss in SSc could aid both in clinical management and stratification/enrichment in clinical trials.

### THU0394 ENTHESTITIS IN SYSTEMIC SCLEROSIS (SSC): AN ULTRASOUND (US) PILOT STUDY

<sup>1</sup>R. Terenzi, R. Karalilova<sup>2</sup>, S. Bellando-Randone<sup>1</sup>, S. Guiducci<sup>1</sup>, M. Manetti<sup>3</sup>, E. Romano<sup>1</sup>, D.E. Furst<sup>1,4,5</sup>, G. Pacini<sup>1</sup>, A. Batalov<sup>2</sup>, M. Maticci-Cerinic<sup>1</sup>. <sup>1</sup>Department Of Medicine, Division Of Rheumatology, UNIVERSITÀ DEGLI STUDI DI FIRENZE, Firenze, Italy; <sup>2</sup>Clinic of Rheumatology, Medical University of Plovdiv, Plovdiv, Bulgaria; <sup>3</sup>Department Of Medicine, Division Of Anatomy and Histology, UNIVERSITÀ DEGLI STUDI DI FIRENZE, Firenze, Italy; <sup>4</sup>Department Of Medicine, Division Of Rheumatology, University of California, Los Angeles, California; <sup>5</sup>University of Washington, Seattle, Washington, USA

**Background:** Articular involvement is frequently encountered in SSc and previous US studies suggest that synovitis is the commonest manifestation. Recently, it has been reported that SSc patients may show typical “hall-marks” of spondyloarthritis (SpA). Apart from tendon involvement which is a common event, sacroiliitis has been estimated to have a prevalence of 23%.

**Objectives:** To estimate the prevalence of enthesal and Synovio-Enthesal Complex (SEC) modifications in SSc

**Methods:** 30 SSc patients (2013 ACR/EULAR classification criteria) without a history of articular involvement (4 male, 26 female, mean age 53.3±16.6 years) were included in this pilot cross sectional US study. 12 healthy subjects (2 male, 10 female, mean age 46.9±5.8 years) were used as controls. The enthesal sites were the lateral epicondylar common extensor tendons (CET), and sites of the Glasgow Ultrasound Enthesis Scoring System. The GUESS score was also calculated as a soft tissue score (GUESS soft tissue) and as a bone score (GUESS bone). US assessment was performed with a MyLab 70XVG scanner equipped with a 6–18 MHz linear transducer (Esaote). Only the epicondylar region was evaluated with PowerDoppler US (PDUS), using semi-quantitative graded from 0 to 3. Involvement of SEC was evaluated at the epicondylar region in SSc patients who presented a PDUS signals  $\geq 1$  in the CET closer than 2 mm from the bony surface. SEC involvement was defined as the presence of a PDUS signal  $\geq 2$  in the elbow epicondylar synovial fold proximal to the annular ligament (AL), inferior to the bone insertion of CET and to the radial collateral ligament (RCL). Statistical analyses were carried out using Mann-Whitney U, Spearman correlation and Chi-square tests. Results were considered significant if  $p<0.05$

**Results:** In SSc, the GUESS and GUESS soft tissue scores were significantly higher ( $5.67 \pm 0.87$  and  $3.43 \pm 0.44$ , respectively) than in controls ( $1.25 \pm 0.41$  and  $0.92 \pm 0.29$ , respectively) ( $p<0.0001$ ) as was the GUESS bone score (SSc  $2.23 \pm 0.55$  vs controls  $0.33 \pm 0.22$ ;  $p<0.05$ ). The CET entheses of SSc patients showed significantly more US B-mode alterations than controls (hypoechoogenicity  $\chi^2=5.95$ ,  $p=0.015$ , cortical irregularity  $\chi^2=7.90$ ,  $p=0.005$ , calcification/enthesophytes  $\chi^2=3.78$ ,  $p=0.05$ ). A PD signal in the CET enthesis was found in 18/60 sites in SSc and in 1/24 in controls. The PD signal of the CET enthesis was significantly higher in SSc patients than in healthy controls ( $0.47 \pm 0.10$  and  $0.08 \pm 0.08$  respectively,  $p=0.018$ ) as was the presence of SEC inflammation ( $\chi^2=4.54$ ,  $p=0.033$ ). In SSc, there was a strong correlation between the presence of PD signal at CET entheses and concomitant SEC inflammation ( $\rho=0.655$ ,  $p<0.0001$ ) but there were no correlations between GUESS score or CET enthesitis and disease subset, disease duration, antibodies, DLCO, FVC, DLCO/VA.

**Conclusions:** Our data show that SSc patients frequently present the usual US features of enthesitis. Moreover, CET enthesitis were correlated with SEC inflammation suggesting that enthesal inflammation in SSc may share same microanatomical targets as SpA.

### THU0395 INFLUENCE OF SETTING AN UPPER LIMIT OF THE MRSS AS AN INCLUSION CRITERION IN SSC CLINICAL TRIALS ON THE RATIO OF SKIN FIBROSIS PROGRESSION VS. IMPROVEMENT – AN ANALYSIS OF THE GENISOS COHORT

<sup>1,2</sup>C. Mihai, R. Dobrota<sup>1,2</sup>, S. Assassi<sup>3</sup>, M. Mayes<sup>3</sup>, O. Distler<sup>1</sup>, on behalf of GENISOS COLLABORATION. <sup>1</sup>Department of Rheumatology, Zurich University Hospital, Zurich, Switzerland; <sup>2</sup>Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; <sup>3</sup>Division of Rheumatology, The University of Texas Health Science Center at Houston, Houston, TX, USA

**Background:** Skin involvement is a main domain in the assessment of patients with systemic sclerosis (SSc), and the modified Rodnan skin score (mRSS) is a primary outcome measurement in SSc clinical trials. Recent studies on large SSc cohorts have shown that lowering the upper threshold of mRSS as a study inclusion criterion leads to cohort enrichment with patients with progressive skin disease. Limitations of these studies were lack of racial diversity and low proportion of patients with anti-RNA-Polymerase III (Pol3) antibodies.

**Objectives:** As the Texas-based GENISOS is an ethnically diverse cohort and includes a large proportion of Pol3-positive patients, this study aimed to assess the effect of different mRSS cut-off values at baseline on progression of skin fibrosis after one year of follow-up.

**Methods:** We extracted data from GENISOS for patients fulfilling the 1980 ACR criteria for SSc and the Le Roy criteria for diffuse cutaneous SSc, who had a mRSS  $\geq 7$  at inclusion and a follow-up visit with documented mRSS at 12±2 months. Progressors were defined as having an increase in mRSS >5 points and  $\geq 25\%$  from the baseline to 2nd visit, while regressors were defined as having a decrease in mRSS of >5 points and  $\geq 25\%$ . To identify the optimal cut-off of baseline mRSS that yields the highest sensitivity for progressive skin fibrosis, we developed ROC curves and logistic regression models with “progression” as outcome variable and a binary variable of baseline mRSS cut-off point as predictor.

**Results:** We identified 152 patients (age and disease duration [median, Q1-Q3, years] 49.5, 40.2–57.3 and 2.2, 1.1–3.3 respectively, 22.4% males) who matched the inclusion criteria. The proportion of patients of African American ethnicity was 31/152 and 50/152 were Pol3-positive patients, both substantially higher than in European cohorts.

After one year, 17 patients (11.2%) classified as progressors and 51 (33.6%) as regressors. Progressors were more frequently positive for anti-topoisomerase antibodies (37.5% vs. 15.3%,  $p=0.028$ ), negative for anti-Pol3 antibodies (93.8% vs. 62.3%,  $p<0.012$ ), had a shorter disease duration (median, Q1-Q3: 1.3, 0.5–2.2 vs. 2.4, 1.1–3.5 years,  $p<0.005$ ) and lower mRSS (median, Q1-Q3: 21, 11–25 vs. 24, 16–31,  $p<0.012$ ) than non-progressors.

Sixteen of 17 progressors, but only 33 of 51 regressors had a baseline mRSS  $\leq 27$ . The mRSS cut-off of  $\leq 27$  had the highest probability of progression (odds ratio 9.1, 95% confidence interval 1.2–70.9,  $p<0.035$ , area under the curve 0.652). Using this cut-off as an inclusion criterion (vs. no cut-off) would have included 94% of all progressors, but only 65% of all regressors and 67% of all patients. The figure 1 displays absolute numbers of progressors and regressors at 1 year for each mRSS cut-off.

**Conclusions:** This analysis reconfirmed, in a population rich in patients of African American origin and with high prevalence of Pol3 antibodies, that setting a lower upper threshold of mRSS at study inclusion increases the proportion of progressors and reduces the absolute number of regressors. This confirms that this recruitment strategy should be used for clinical trial design in early diffuse SSc.

### THU0396 COMBINED POSITRON EMISSION TOMOGRAPHY AND MAGNETIC RESONANCE IMAGING FOR THE ASSESSMENT OF SYSTEMIC SCLEROSIS GASTROINTESTINAL INVOLVEMENT

<sup>1,2</sup>S.-A. Ng, S. Marcheseau<sup>3</sup>, Y. Wang<sup>4</sup>, J. Schaefferkoetter<sup>3</sup>, W. Xie<sup>5</sup>, D. Ng<sup>5</sup>, J. Totman<sup>3</sup>, A.H. Low<sup>1,2</sup>. <sup>1</sup>Rheumatology and Immunology, Singapore General Hospital; <sup>2</sup>Duke-National University of Singapore; <sup>3</sup>Clinical Imaging Research Center, A\*STAR and National University of Singapore; <sup>4</sup>Gastroenterology and Hepatology; <sup>5</sup>Nuclear Medicine and PET, Singapore General Hospital, Singapore, Singapore

**Background:** The gastrointestinal (GI) tract is affected in 90% of patients with systemic sclerosis (SSc), a disease characterised by excessive fibrosis. Baseline GI involvement is an independent predictor of 2 year mortality in patients with early diffuse cutaneous SSc. There is an urgent need to develop non-invasive methods of assessing SSc GI involvement for early diagnosis and monitoring. Novel non-invasive tools such as fluorodeoxyglucose-positron emission tomography (FDG-PET) and magnetic resonance imaging (MRI) have been used in oncology. Development of a new MRI sequence, T1 MOLLI (modified look-locker inversion recovery) mapping, has been used in cardiac imaging for detection and quantification of diffuse fibrosis.

**Objectives:** In this pilot study comparing SSc patients with healthy controls, we investigated whether FDG-PET-MRI is able to detect fibrosis and inflammation associated with SSc GI tract involvement.

**Methods:** We recruited 16 patients fulfilling the 2013 ACR/EULAR criteria for SSc and 15 healthy age-matched (within 5 years) controls. Severity of GI involvement was determined by the total Gastrointestinal Tract score (GIT, from University of California Los Angeles Scleroderma Clinical Trials Consortium).

All subjects fasted 6 hours prior and had non-spicy low-residue diet 3 days prior. Subjects were injected with FDG (6mCi) 1 hour prior and 10 mg hyoscine butylbromide (to reduce peristalsis) immediately before scanning. Breath-hold native T1 MOLLI mapping was acquired. FDG uptake was quantified by specific uptake value (SUV). All SSc patients and 5 controls underwent PET-MRI protocol. The remaining 10 controls only had MRI scanning. Student t-test was performed and statistical significance was taken to be  $p < 0.05$ .

**Results:** Demographics and clinical features of our study cohort are shown in table 1. Mean T1 values on MRI for the large and small bowels were significantly higher in SSc patients than healthy controls (large bowel:  $1113 \pm 189$  ms vs  $856 \pm 182$  ms respectively,  $p = 0.0006$ ; small bowel:  $1331 \pm 246$  ms vs  $1169 \pm 123$  ms respectively,  $p = 0.0296$ ), indicating the presence of GI fibrosis.

Mean PET SUV values for the large bowels were also higher in SSc patients than healthy controls ( $1.12 \pm 0.23$  vs  $0.82 \pm 0.23$  respectively,  $p = 0.0217$ ).

Abstract THU0396 – Table 1. Demographics and clinical features

	SSc patients (n=16)	Controls (n=15)
Limited/Diffuse SSc, n	11/5	Not applicable
Female, n (%)	14 (87.5%)	11 (73.3%)
Age, years	49.2±13.9	45.3±14.4
Mean disease duration from Raynaud's phenomenon onset, years	6.1±7.3	Not applicable
Mean disease duration from non-Raynaud's phenomenon onset, years	6.6±7.4	Not applicable
Mean GIT score	0.43±0.31	0

**Conclusions:** MRI T1-MOLLI mapping demonstrated evidence of bowel fibrosis in SSc patients. FDG-PET showed increased large bowel inflammation in patients. FDG-PET-MRI may potentially be a useful diagnostic and monitoring tool for SSc GIT disease.

### THU0397 THE PROGNOSTIC VALUE OF AUTOANTIBODIES IN SYSTEMIC SCLEROSIS AND A TWO-YEAR FOLLOW-UP OF FORCED VITAL CAPACITY

A.A.A. Mohamed, M. Hassanien. *Rheumatology and Rehabilitation, Assiut University, Assiut, Egypt*

**Background:** Systemic sclerosis (SSc) is a connective tissue disease involving the skin and internal organs of the body. Affection of the lungs and the vascular system significantly increases the morbidity and mortality. Controlling disease progression represents a challenge in clinical practice.

**Objectives:** We aimed to address prognostic factors of disease activity and study the progress of interstitial lung disease (ILD) under conventional disease modifying anti-rheumatic drugs (DMARDs) therapy.

**Methods:** Data of SSc patients (limited or diffuse) followed up in the Rheumatology Department Clinics throughout the past 2 years were collected for a retrospective study. The positivity of Antinuclear (ANA), Anti-centromere (ACA) and Anti-Scl70 antibodies was gathered from patients' data. Disease activity was assessed by the European Scleroderma Study Group (EScSG) activity index. Forced vital capacity (FVC) was used to mark the progress of ILD. Friedman and Wilcoxon signed rank tests were used for comparison of paired data as appropriated. Mann-Whitney U test, Kruskal-Wallis test and Chi-Square test were used to compare between two or more groups.

**Results:** The data of 42 SSc patients (59.5% limited SSc and 40.5% diffuse SSc) with a mean age  $40 \pm 12$  years were enrolled. 83.3% of the patients showed ANA positivity. ACA was positive in 28.6% of the patients and Anti-Scl70 in 23.8% while 47.6% of the patients were negative for both. DMARDs were indicated according to organ involvement, and changes were made according to breakthrough events. Low scores of EScSG were noticed in the ACA +ve group compared to intermediate scores in the Scl70 +ve group and high scores in the negative group at baseline ( $p = 0.082$ ) and 24 month follow-up ( $p = 0.045$ ). The frequency of pitting digital ulcers at baseline was lowest in the ACA +ve group compared to the highest frequency in the negative group ( $p = 0.026$ ), however, there was no difference between the groups at the 24 month follow-up. ANA did not affect the activity throughout the studied period. Follow up of FVC in the two years with different DMARDs is illustrated in figure 1. Patients followed on methotrexate (MTX) after cyclophosphamide (CYC) or mycophenolate (MMF) had raised FVC ( $p = 0.033$  and  $p = 0.054$  respectively) comparable to azathioprine (AZA) after CYC or MMF ( $p = 0.031$  and  $p = 0.27$  respectively).

**Conclusions:** ACA is proposed to be a marker of low disease activity and good response to therapy. Despite the risk of inducing ILD, MTX maintained a favourable effect on FVC throughout a follow-up period.

### THU0398 UNEXPLAINED IRON DEFICIENCY IS FREQUENT IN SYSTEMIC SCLEROSIS

A. Sari, A. Gill, S.I. Nihtyanova, V.H. Ong, C.P. Denton. *Rheumatology, Royal Free Hospital, University College London, London, UK*

**Background:** Prevalence of iron deficiency (ID) in systemic sclerosis (SSc) is unclear and can occur related to several causes.

**Objectives:** This cross sectional study aims to analyse association between ID and disease characteristics in SSc patients who does not have an overt cause for ID.

**Methods:** We identified 227 consecutive SSc patients who had iron laboratory studies (serum iron, total iron binding capacity and ferritin) with concurrent full blood count and serum C-reactive protein (CRP) measurement between May

2015 and November 2017. Exclusion criteria were as follows: not having serum CRP levels within 1 month of iron studies, chronic kidney disease (eGFR <60 ml/min), haemoglobinopathies, major surgery within one year, overt gastrointestinal (GI) or genitourinary blood loss, active GI cancer and vascular lesions of GI (GAVE, intestinal telangiectasia). Patients who have ferritin levels below cut-off values or were already on iron replacement were considered as iron deficient. To define iron deficient status, threshold levels of serum ferritin 30 ng/mL and 100 ng/mL were used to denote those with normal and high CRP levels (>5 mg/L) respectively. WHO classification system was used to determine the presence and severity of anaemia. Relationship between demographic and disease characteristics and serum iron status was analysed using Fisher's exact and Mann-Whitney U test.

**Results:** 178 patients (76.4% female) were eligible for final analysis. Clinical characteristics are reported in table 1. Median age and disease duration (interquartile range, IQR) were 54.6 (44.8–66.1) and 4.9 (2.1–4.8) years, respectively. ID was present in 43.2% of the patients and 41.6% of these patients was not anaemic. Iron deficient patients were more frequently female and had longer disease duration. Among female patients, ID was significantly more prevalent before the age of 50 (77.6% vs 0%,  $p < 0.001$ ).

**Abstract THU0398 – Table 1.** Comparison of demographics and disease characteristics between iron deficient and iron replete patients

	Iron replete (n=101)	Iron deficient (n=77)	p
Age, years, median (min-max)	58.8 (48.9–66.2)	52.9 (35.7–65.9)	0.06
Female, n (%)	70 (69.3)	66 (85.7)	0.01
Disease duration, years, median (min-max)	3.6 (1.7–8.1)	6.1 (3.0–24.6)	<0.01
Diffuse disease, n (%)	87 (86.3)	46 (59.7)	0.06
Anaemia, n (%) <sup>1</sup>	39 (38.6)	45 (58.4)	0.01
Moderate/severe anaemia, n (%) <sup>2</sup>	11 (10.9)	24 (31.2)	<0.01
* GI involvement, n (%) <sup>3</sup>	8 (8.0)	3 (3.9)	0.73
* Digital ulcer (DU), n (%)	23 (22.8)	20 (26.0)	0.62
* Severe DU, n (%) <sup>4</sup>	14 (13.9)	12 (15.6)	0.74
* PAH, n (%)	2 (2.0)	3 (4.5)	0.85
ILO, n (%)	29 (28.7)	28 (36.3)	0.43
Proton pump inhibitor use, n (%)	51 (50.5)	64 (83.0)	0.34
Antibody specificity			
Scl-70, n (%)	11 (10.9)	11 (14.3)	0.25
Centromere, n (%)	20 (19.8)	13 (16.9)	0.67
RNA polymerase III, n (%)	16 (15.8)	9 (11.6)	0.48

\* Diagnosed between May 2015 and November 2017  
<sup>1</sup> Serum haemoglobin level of <13 mg/dL for men and <12 mg/dL for women  
<sup>2</sup> Serum haemoglobin level of <11 mg/dL for both sexes  
<sup>3</sup> Required antibiotics or bosentan, critical digital ischaemia, gangrene  
<sup>4</sup> Intestinal pseudo-obstruction requiring hospitalisation, >2 courses of small bacterial overgrowth, PEG insertion or parenteral nutrition

**Conclusions:** Unexplained iron deficiency is frequent in scleroderma patients and a significant number of these patients do not have frank anaemia. Female sex and longer disease duration is associated with iron deficiency. Increased frequency in young female patients can be related to menstrual blood loss and further study to evaluate this association is required.

#### THU0399 FEMALE SEXUAL DYSFUNCTION IN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

<sup>1,2</sup>B. Hermankova, M. Spiritovic<sup>1,2</sup>, H. Smucrova<sup>1</sup>, S. Oreska<sup>1</sup>, H. Storkanova<sup>1</sup>, K. Pavelka<sup>1</sup>, L. Senolt<sup>1</sup>, H. Mann<sup>1</sup>, J. Vencovsky<sup>1</sup>, M. Tomcik<sup>1</sup>. <sup>1</sup>Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology, <sup>2</sup>Department of Physiotherapy, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic

**Background:** Idiopathic inflammatory myopathies (IIM) are characterised by inflammation and atrophy of skeletal muscles, pulmonary and articular involvement, which leads to functional impairment, reduced quality of life including sexual life.

**Objectives:** To assess sexual functions/quality of life and pelvic floor function in female IIM patients compared to age-/sex-matched healthy controls (HC).

**Methods:** In total, 22 women with IIM [mean age: 55.1, disease duration: 7.9 years, dermatomyositis (DM, 8)/polymyositis (PM, 10)/necrotizing myopathy (IMNM, 3)/inclusion body myositis (IBM, 1)], who fulfilled the Bohan/Peter 1975 criteria for DM/PM, and 22 healthy controls (mean age: 55.1 years) without rheumatic diseases filled in 12 well-established and validated questionnaires assessing sexual function/quality of life, pelvic floor function, fatigue, physical activity and depression. Data are presented as mean  $\pm$  SEM.

**Results:** Compared to HC, patients with IIM had significantly higher prevalence and greater severity of sexual dysfunction (FSFI, BISF-W: in all subscales as well as total scores), dysfunction of pelvic floor (PISQ-12), and worse sexual quality of life (SQoL-F) (table 1). Worse scores in IIM patients were associated with elevated muscle enzyme levels [lactate dehydrogenase: FSFI ( $r = -0.524, p = 0.0123$ ), BISFW ( $r = -0.528, p = 0.0115$ )], greater fatigue [FIS: FSFI ( $r = -0.434, p = 0.0438$ ), BISF-W ( $r = 0.488, p = 0.0211$ ), SQoL-F ( $r = -0.488, p = 0.0070$ ), PISQ-12 ( $r = 0.643, p = 0.0013$ )], more severe depression [BDI-II: PISQ-12 ( $r = 0.474, p = 0.0258$ )], deteriorated quality of life [HAQ: PISQ-12 ( $r = 0.476, p = 0.0252$ )], and worse ability to perform physical activities [HAP: FSFI ( $r = 0.437, p = 0.0417$ ), BISF-W ( $r = 0.451, p = 0.0351$ ), PISQ-12 ( $r = -0.494, p = 0.0195$ )].

Questionnaire: score range	Idiopathic inflammatory myopathies (n=22)	Healthy controls (n=22)	p-value
FSFI: Female Sexual Function Index: 2 (worst)–36(best)	14.2 $\pm$ 2.7	23.5 $\pm$ 2.5	$p = 0.0146$
BISF-W: Brief Index of Sexual Function for Women: –16(worst)–75(best)	15.5 $\pm$ 3.9	28.9 $\pm$ 3.8	$p = 0.0193$
PISQ-12: Pelvic Organ Prolapse/Urinary Incontinence Sexual Questionnaire short form: 0(best)–48(worst)	13.8 $\pm$ 1.1	8.0 $\pm$ 1.0	$p = 0.0003$
PFIQ7: Pelvic Floor Distress Inventory Questionnaire – short form 7: 0(best)–300(worst)	15.8 $\pm$ 4.5	5.6 $\pm$ 2.3	$p = 0.1450$
SQoL-F: Sexual Quality of Life Questionnaire – Female: 0(worst)–100 (best)	54.9 $\pm$ 6.0	83.1 $\pm$ 3.4	$p = 0.0006$
FSS: Fatigue Severity Scale: 9(best)–63 (worst)	46.9 $\pm$ 2.8	26.7 $\pm$ 2.5	$p < 0.0001$
FIS: Fatigue Impact Scale: 0(best)–160 (worst)	60.6 $\pm$ 6.9	29.0 $\pm$ 4.2	$p = 0.0003$
MAF: Multidimensional Assessment of Fatigue Scale: 1(best)–50(worst)	26.1 $\pm$ 2.3	17.8 $\pm$ 1.4	$p = 0.0129$
BDI-II: Beck's Depression Inventory II: 0 (best)–63(worst)	14.5 $\pm$ 2.2	5.3 $\pm$ 1.1	$p = 0.0003$
HAP: Human Activity Profile – adjusted activity score: 0(worst)–94(best)	53.7 $\pm$ 4.3	81.1 $\pm$ 1.5	$p < 0.0001$
HAQ: Health Assessment Questionnaire: 0 (best)–3(worst)	1.0 $\pm$ 0.2	0.0 $\pm$ 0.0	$p < 0.0001$

**Conclusions:** Women with IIM reported significantly impaired sexual function, sexual quality of life and pelvic floor function than age-matched healthy controls. Worse scores in IIM were associated with disease activity, physical activity, fatigue, depression and quality of life.

Allanore<sup>11</sup>, on behalf of EUSTAR. <sup>1</sup>Department of Rheumatology, Zurich University Hospital, Zurich, Switzerland; <sup>2</sup>Internal Medicine and Rheumatology, Cantacuzino Hospital, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania; <sup>3</sup>Department of Rheumatology, Ghent University Hospital; <sup>4</sup>Department of Internal Medicine, Ghent University, Ghent, Belgium; <sup>5</sup>Department of Internal Medicine and Clinical Immunology, Referral Centre for Rare Systemic Auto-immune Diseases North and North-West of France, University of Lille, Huriez Hospital, Lille, France; <sup>6</sup>Department of Rheumatology, Tübingen University Hospital, Tübingen; <sup>7</sup>Department of Rheumatology, Charité University Hospital, Berlin, Germany; <sup>8</sup>Rheumatology Unit, Internal and Experimental Medicine, Second University of Naples, II Policlinico, Naples, Italy; <sup>9</sup>Department of Rheumatology and Clinical Immunology, Justus-Liebig University Giessen, Campus Kerckhoff, Bad Nauheim, Germany; <sup>10</sup>Department of Experimental and Clinical Medicine, University of Florence, Florence, Italy; <sup>11</sup>Department of Rheumatology, Cochin Hospital, Paris Descartes University, Paris, France

**Background:** Digital ulcers (DUs) affect about half of systemic sclerosis (SSc) patients during disease course. In some patients, peripheral vasculopathy can promote critical ischemia and gangrene, severe complications with potential life threatening consequences. Recently the DUO registry suggested a 18% prevalence of gangrene in DU-SSc patients, with smoking and a high number of DUs being predictive factors. However, little is known about gangrene in unselected SSc patients.

**Objectives:** To investigate the prevalence, incidence and risk factors for gangrene in the EUSTAR cohort.

**Methods:** We included patients from the EUSTAR database satisfying the <sup>ACR</sup> 1980 or the ACR/EULAR 2013 classification criteria for SSc, with at least one visit recording data on gangrene. We extracted from this database data regarding the reporting of DUs, DUs history and digital gangrene. Centres were asked for supplementary data on traditional cardiovascular (CV) risk factors. We analysed by uni- and multivariable logistic regression the cross-sectional relationship between gangrene and its potential risk factors such as history of DUs, cutaneous subset, disease duration, autoantibodies, traditional CV risk factors. Furthermore, longitudinal data were analysed by Cox proportional hazards regression.

**Results:** 1757 patients matched the inclusion criteria (age at inclusion 55.9±14.5 years, disease duration since first non-Raynaud's symptom 7.9±10.3 years and from onset of Raynaud's phenomenon (RP) 11.1±11.0 years, male sex 16.7%, 24.6% diffuse cutaneous subset (DcSSc). At inclusion, 8.9% of patients had either current or previous digital gangrene, 15.7% had current DUs and a further 25.8% had previously had DUs. Among the potential risk factors, older age, a history of DUs and the DcSSc subset were statistically significant risk factors in the cross-sectional multivariable model.

For the longitudinal part, during the entire follow-up (median [Q1,Q3] 13.1 [9.6, 19.3] months), 16/771 patients had incident gangrene (2.1%), accounting for an incidence of 1.73/100 patient-years. All 16 patients who developed incident gangrene had previously had DUs and gangrene. Further risk factors for incident gangrene were the DcSSc subset and longer disease duration: hazard ratio [95% confidence interval]: 8.97 [2.90–27.71] and 1.08 [1.04–1.13] respectively, both p<0.001.

**Conclusions:** In unselected SSc patients, gangrene still occurs in about 9% of SSc patients. Of the most importance, a history of DUs and, to a lesser extent, the DcSSc subset are strongly and independently associated with gangrene, while traditional CV risk factors were not identified as risk factors. Our results confirm that gangrene is still a concern in SSc. They emphasise the importance of microvascular SSc-associated disease in the pathogenesis of gangrene and suggest that the DcSSc subset should be prioritised for risk-stratification of the patients.

**THU0401** **GLOBAL LONGITUDINAL STRAIN AS EARLY PREDICTOR OF SYSTOLIC DYSFUNCTION IN SYSTEMIC SCLEROSIS**

<sup>1</sup>C. Fischetti, F. Guerra<sup>2</sup>, A. Ferrarini<sup>3</sup>, L. Zuliani<sup>3</sup>, G. Stronati<sup>2</sup>, P. Fraticelli<sup>3</sup>, M. G. Danieli<sup>3</sup>, A. Capucci<sup>2</sup>, A. Gabrielli<sup>1</sup>. <sup>1</sup>Dipartimento di Scienze Cliniche e Molecolari, Università Politecnica delle Marche; <sup>2</sup>Department of Cardiology; <sup>3</sup>Department of Internal Medicine, Azienda Ospedaliera Universitaria Ospedali Riuniti "Umberto I- Lancisi- Salesi" Ancona, Ancona, Italy

**Background:** Systemic sclerosis (SSc) is a chronic autoimmune disease of unknown etiology, characterised by microvascular abnormalities, immune abnormalities and progressive cutaneous and internal organs fibrosis. Subclinical heart disease in SSc patients is common but difficult to detect through conventional imaging.

**Objectives:** We sought to evaluate speckle-tracking derived global longitudinal strain (GLS) as an early marker of subclinical systolic dysfunction in patients with SSc.

**Methods:** We enrolled 52 patients with SSc and 52 age and gender matched controls. Patients with structural heart disease, heart failure, atrial fibrillation or pulmonary hypertension were excluded. An echocardiographic exam was performed for all patients, and standard and speckle-tracking derived variables for the systolic and diastolic function of the left ventricle (LV) and right ventricle (RV) were acquired. SSc variant, antibodies pattern, cardiovascular risk factors and involvement of other organ systems were recorded.

**Results:** Common parameters of left and right systolic function did not differ between SSc patients and controls and were on average well above the cut-off for normality (all p=NS). LV and RV GLS were significantly impaired in patients with SSc when compared to healthy controls (-19.2% vs. -21.1%; p=0.009 and -18.2% vs. -22.3%; p=0.012 respectively). In patients with SSc, GLS impairment was greater in basal segments when compared to midventricular and apical ones and homogeneous between the endo-, meso-, or epicardial layers of the RV, while LV showed an eccentric pattern with the epicardial layers mostly impaired. Using -20% as a cut-off for GLS, SSc patients had a 2.5-fold increased risk of subclinical LV systolic impairment (OR 2.5; 95% CI 1.1–5.5; p=0.027) and a 3.3-fold increased risk of subclinical RV systolic impairment when compared to age and gender matched controls (OR 3.3; 95% CI 1.4–7.7; p=0.004).

**Conclusions:** While traditional parameters are ineffective in detecting subclinical systolic impairment, a reduced GLS is common in patients with SSc and is significant for both LV and RV. While GLS impairment recognises a basal-apical gradient, transmural heart involvement seems different between RV and LV, suggesting a different mechanism of disease between the two ventricles.

### THU0402 DO WE HAVE GOOD INSTRUMENTS TO PREDICT MAJOR CARDIOVASCULAR EVENTS IN SYSTEMIC SCLEROSIS PATIENTS?

C. Radu, L. Groseanu, T. Gudu, A. Balanescu, D. Predeteanu, V. Bojinca, D. Opris-Belinski, A. Borangiu, I. Saulescu, S. Daia-Iliescu, C. Constantinescu, D. Mazilu, F. Berghia, M.M. Negru, V. Vlad, M. Abobului, R. Ionescu. *Internal Medicine and Rheumatology, "Sfanta Maria" Clinical Hospital Bucharest, Carol Davila University of Medicine and Pharmacy, Bucharest, Romania*

**Background:** While macrovascular disease and higher cardiovascular (CV) risk are well documented in other systemic rheumatic diseases, the risk for major cardiovascular events for patients with systemic sclerosis (SSc) is yet to be established.

**Objectives:** The aim of the study was to determine the ability of different cardiovascular risk indices to predict major cardiovascular events (MACE) in systemic sclerosis.

**Methods:** The study included 144 patients followed in EUSTAR centre 096, but only patients with a follow-up for more than 10 years were selected for statistical analyses. Cardiovascular risk was estimated using QRiskII, systemic coronary risk evaluation (SCORE) and ACC/AHA risk indices. MACE were defined as: myocardial infarctions, strokes, peripheral vascular disease and cardiovascular related death. Data were compared by non-parametric tests.

**Results:** 32 patients, 31 females, 12 diffuse SSc subsets were included. The control group included 30 age and sex matched patients without autoimmune diseases. Mean age of the group was 52 years±SD 9.7, mean disease duration was 8 years±SD 9. The prevalence of traditional risk factors was: 13% smokers, significant family history 38%, obesity 16%, dyslipidemia 32%, older age 13%, hypertension 16%. There were no significant differences from the control group.

Major cardiovascular events were: 13% myocardial infarction, 9% peripheral vascular disease, 9% CV related deaths. Concerning CV risk indices of the 32 SSc patients, 4 (13%) were classified as having high CV risk according to QRiskII/SCORE/ACC risk.

In SSc patients, we could not identify any correlation between the above mentioned risk indices and MACE, including death of cardiovascular causes, except for a slight correlation between the SCORE and cardiovascular related death ( $p=0.04$ ).

**Conclusions:** In our study, the main prediction indices were not correlated with the 10 year risk for CV events in SSc patients suggesting that we need better risk prediction tools. Both traditional risk factors and endothelial dysfunction have been proposed to participate at the onset and progression of vascular disease in SSc. Special attention should be paid to correct the traditional risk factors in combination with specific treatment for SSc.

### THU0403 SERUM LEVELS OF MACROPHAGE MIGRATION INHIBITORY FACTOR AND INTERLEUKIN-1 FAMILY CYTOKINES ARE ELEVATED IN SYSTEMIC SCLEROSIS

<sup>1</sup>E. Lin, F. Vincent<sup>1</sup>, J. Harris<sup>1</sup>, R. Kandane-Rathnayake<sup>1</sup>, G.-S. Ngian<sup>1,2</sup>, J. Sahhar<sup>1,2</sup>, E. Morand<sup>1,2</sup>, T. Lang<sup>1</sup>. <sup>1</sup>School of Clinical Sciences, Monash University, <sup>2</sup>Rheumatology, Monash Health, Melbourne, Australia

**Background:** Systemic sclerosis (SSc) is an autoimmune connective tissue disorder, the pathogenesis of which remains unknown. Recent evidence suggests dysregulation of the innate immune system, particularly interleukin-(IL)-1 family cytokines. Given the emerging role of macrophage migration inhibitory factor (MIF) in pathways of IL-1 family cytokine secretion, the role of MIF, IL-1 $\alpha$ , IL-1 $\beta$  and IL-18 in SSc is of interest.

**Objectives:** To examine associations between MIF and IL-1 cytokines (IL-1 $\alpha$ , IL-1 $\beta$ , IL-18), in SSc, and associations with clinical features.

**Methods:** 115 SSc patients (2013 ACR/EULAR criteria) attending Monash Scleroderma Clinic and 52 healthy controls were recruited between August 2015 and August 2017. Serum MIF, IL-1 $\alpha$ , IL-1 $\beta$  and IL-18 levels were quantified using ELISA and analysed alongside concurrent clinical and laboratory data from the Australian Scleroderma Cohort Study database

**Results:** Compared to controls, SSc patients had significantly elevated serum MIF and IL-18 (figure 1). A weak positive correlation was observed between MIF

and SScHAQ score ( $R=0.2107$ ,  $p=0.0437$ ) which was stronger in the diffuse cutaneous (dcSSc) subgroup ( $R=0.457$ ,  $p=0.0373$ ). Patients with elevated IL-18 levels were more likely to have active disease (EUSTAR score  $\geq 3$ ) however IL-18 was lower in patients with pulp atrophy and sclerodactyly. IL-1 $\beta$  was elevated in dcSSc patients with pulmonary fibrosis and correlated with mRSS ( $R=0.213$ ,  $p=0.0254$ ) in all SSc patients. IL-1 $\alpha$  was elevated in patients with joint contractures and pulp atrophy. Positive correlations were found between concentrations of MIF and both IL-1 $\alpha$  and IL-1 $\beta$ . However, there was no significant correlation between MIF and IL-18.

**Abstract THU0403 – Figure 1.** Serum cytokines in SSc patients and healthy controls. Serum cytokines (A) MIF and (B) IL-18 were measured by ELISA in healthy controls ( $n=52$ ) and SSc patients ( $n=115$ ). Data is presented as median  $\pm$  interquartile range. Analysis was performed in Prism using the Mann-Whitney test.

**Conclusions:** MIF and IL-18 were significantly elevated in SSc compared to health controls, and IL-1 family cytokines were variably associated with clinical manifestations of SSc. A relationship between MIF and IL-1 $\beta$  was confirmed. Further investigation into the roles of MIF and IL-1 family cytokines in SSc is justified.

### THU0404 ESOPHAGEAL INVOLVEMENT PREDICTS PULMONARY FUNCTION DETERIORATION IN PATIENTS WITH SYSTEMIC SCLEROSIS

E. De Lorenzis<sup>1</sup>, G. Natalello<sup>1</sup>, L. Berardini<sup>2</sup>, G. Canestrari<sup>1</sup>, L. Verardi<sup>1</sup>, L. Gigante<sup>1</sup>, S. Bosello<sup>1</sup>, L. Richeldi<sup>2</sup>, G. Ferraccioli<sup>1</sup>, E. Gremese<sup>1</sup>. <sup>1</sup>Rheumatology Unit, <sup>2</sup>Respiratory Medicine Unit – Institute of Internal Medicine, Fondazione Policlinico Universitario A. Gemelli – Catholic University of the Sacred Heart, Rome, Italy

**Background:** Interstitial lung disease (ILD) is the leading cause of death in systemic sclerosis (SSc) but its pathogenesis and the risk factors of pulmonary function deterioration are not fully understood. Esophageal disease is high frequent in SSc and motor activity abnormalities with occult micro-aspiration of both acid and non-acid gastro oesophageal reflux has been implicated in the pathogenesis of ILD. DLCO reduction is considered the earliest sign of microaspiration-induced lung damage<sup>1</sup>. Cross-sectional studies have demonstrated an association of SSc-ILD and esophageal abnormalities on 24 hours intraoesophageal pH-monitoring and esophageal manometry but prospective evaluation of lung deterioration is lacking<sup>2,3</sup>. Esophagogram was proposed as a useful tool to evaluate disease severity of upper gastrointestinal tract involvement in SSc<sup>4</sup>.

**Objectives:** To assess the role of esophagogram in predicting pulmonary function test deterioration in SSc-patients.

**Methods:** We retrospectively evaluated 160 consecutive SSc patients who underwent esophagogram because of suspected upper gastro-intestinal involvement. All patients underwent baseline pulmonary function tests and global clinical evaluation. Eighty-five patients underwent a High Resolution CT within 3 months from esophagogram because of suspected lung involvement. One hundred twenty three patients underwent pulmonary function test every 6 months up to 24 months.

**Results:** Seventy five patients (46.9%) presented abnormalities of peristaltic waves, 50 patients (31.2%) showed structural changes (hypotonic oesophagus or dilatation) while indirect signs of cardiac incontinence (patent cardia or gastro-esophageal reflux) were present in 36 patients (22.5%). A reduced peristaltic activity with a prolongation of transit time was associated to reduced DLCO (50.16% $\pm$ 19.80% vs 60.36% $\pm$ 22.69%,  $p=0.002$ ) and TLC (87.05% $\pm$ 20.43% vs 95.09% $\pm$ 20.59%,  $p=0.017$ ). An hypotonic oesophagus was reported in 25.2% of patients and it was associated to ILD on CT (72.0% vs 28.0%,  $p=0.033$ ). Patients

with hypotonic oesophagus presented a reduced FVC (84.63%±22.86% vs 102.93±21.40%,  $p<0.0001$ ), TLC (79.85%±19.62% vs 95.29±19.80,  $p<0.0001$ ) and DLCO (42.88%±20.00% vs 59.89±20.78%,  $p<0.0001$ ) at baseline and to a faster deterioration of DLCO median values (5.10%±20.61% vs -4.77±14.23%,  $p=0.012$ ) at follow-up. Patients with hypotonic oesophagus have a higher prevalence of diffuse skin disease and ongoing immunosuppressive treatment, but were comparable in term of age, sex, BMI, smoking habits, disease duration and prevalence of autoantibodies to the patients without this alteration.

**Conclusions:** The esophagogram is wide available, well tolerated and inexpensive tool to assess upper gastro-intestinal tract involvement and its abnormalities are associated to SSc-ILD severity. Because of a faster deterioration of lung function is associated to esophagogram abnormalities, a complete gastro-intestinal evaluation in ILD-SSc patients is mandatory.

THU0405

#### THE ASSOCIATION BETWEEN BASELINE SERUM RESISTIN LEVELS AND THE DEVELOPMENT OF NEW DIGITAL ULCERS IN PATIENTS AFFECTED BY SYSTEMIC SCLEROSIS

F. Pignataro<sup>1</sup>, D.P.E. Margiotta<sup>1</sup>, G. Sambataro<sup>1</sup>, L. Navarini<sup>1</sup>, A. Gigante<sup>2</sup>, E. Rosato<sup>2</sup>, A. Afeltra<sup>1</sup>. <sup>1</sup>Unit of Allergology, Clinical Immunology and Rheumatology, Campus Bio-Medico University; <sup>2</sup>Department of Clinical Medicine, Sapienza University, Rome, Italy

**Background:** Resistin is a soluble factor produced by adipose tissue, implicated in the regulation of inflammatory processes and in microvascular damage.<sup>1</sup> When incubated with resistin, endothelial cells respond by a greater production of endothelin-1, a potent endothelium-derived vasoactive factor that engenders endothelial dysfunction (ED) in many cardiovascular and autoimmune diseases, such as Systemic Sclerosis (SSc).<sup>2</sup> SSc is a complex connective tissue disease, whose pathogenesis results from the variable interaction of three main processes: microvascular damage, autoimmunity-mediated inflammation and fibroblast activation.<sup>3</sup> ED is at the base of the development of painful ischaemic events due to chronic hypoxia, namely digital ulcers (DUs),<sup>4</sup> considered a prognostic marker of disease severity.<sup>5</sup>

**Objectives:** To evaluate the association between baseline serum resistin levels and the development of new DUs in a cohort of patients with SSc.

**Methods:** We conducted a one-year prospective cohort study. Patients with SSc and healthy controls (HC) were consecutively enrolled. Baseline serum resistin was assessed by commercial ELISA kit. The development of new DUs was prospectively evaluated during the follow-up after the cross-sectional point in which the resistin levels were measured.

**Results:** We enrolled 70 SSc patients and 26 HC matched by gender and vital parameters. Mean basal resistin levels were increased in SSc patients compared to HC (6.58±5.48 vs 2.56±0.95,  $p=0.0004$ ). In SSc group, resistin was higher among patients with active DUs ( $p=0.0007$ ), infected DUs ( $p=0.0009$ ) and active pattern at nailfold videocapillaroscopy ( $p=0.01$ ). During one-year follow-up, 27 (38%) SSc patients presented new skin ulcers. Baseline resistin was increased in patients who developed new DUs (8.4±6.4 vs 5.4±4.5,  $p=0.026$ ). In multiple logistic regression, the development of new DUs was associated to basal serum resistin concentration (OR 2.1, 95% CI 1.1–3.9), to the presence of active DUs at

baseline (OR 3.4, 95% CI 1.0–11.9), and to basal Disease Activity Score (DAI) according to European Scleroderma Study Group<sup>6</sup> (OR 1.3, 95% CI 1.0–1.6). In proportional Cox regression, the time to new DUs was associated to basal resistin concentration (HR 1.7, 95% CI 1.1–2.8) and DAI (HR 1.2, 95% CI 1.0–1.4).

**Conclusions:** Serum resistin seems to be associated to the presence and to the development of DUs, suggesting a possible involvement in micro-vascular dysfunction in patients affected by SSc.

THU0406

#### IV CYCLOPHOSPHAMIDE VS. RITUXIMAB FOR THE TREATMENT OF EARLY DIFFUSE SCLERODERMA LUNG DISEASE: OPEN LABEL, RANDOMISED, CONTROLLED TRIAL

G. Sircar<sup>1</sup>, R.P. Goswami<sup>2</sup>, D. Sircar<sup>3</sup>, D. Rath<sup>1</sup>, S. Mondal<sup>2</sup>, P.S. Mahapatra<sup>1</sup>, A. Ghosh<sup>2</sup>, P. Ghosh<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>IPGME and R, Kolkata, India; <sup>3</sup>Nephrology, IPGME and R, Kolkata, India

**Background:** Systemic sclerosis is characterised by fibrotic changes in the skin and lung, and the mainstay of treatment has been cyclophosphamide. B cell involvement suggests that rituximab may also be of therapeutic benefit. In this study, we compared the safety and efficacy of rituximab compared to cyclophosphamide in the treatment of skin and lung manifestations of systemic sclerosis.

**Objectives:** The aims of the study were to assess the efficacy and safety of IV Rituximab compared to IV cyclophosphamide in the primary therapy of systemic sclerosis, with particular emphasis on pulmonary and dermatological manifestations.

**Methods:** We randomly assigned 60 patients of systemic sclerosis, age 18–70 years with skin and lung involvement, to monthly pulses of cyclophosphamide 500 mg/sq. m or rituximab 1000 mg x 2 doses at 0, 15 days. Primary outcomes were forced vital capacity (FVC) percent predicted at six months. Secondary outcomes were: absolute change in litres (FVC-L) at 6 months; modified Rodnan Skin Scores at 6 months, six-minute walk test (6MWT), and Medsger's score

**Results:** The FVC (%mean ±SD) in Rituximab group improved from 61.30 (±11.28) to 67.52 (±13.59) while in Cyclophosphamide group, it declined from 59.25 (±12.96) to 58.06 (±11.23) at 6 months ( $p=0.003$ ). The change of FVC was 1.51 (±0.45) L to 1.65 (±0.47) L in Rituximab group compared to 1.42 (±0.49) to 1.42 (±0.46) L in Cyclophosphamide group. The mRSS changed from 21.77 (±9.86) to 12.10 (±10.14) in RTX group and 23.83 (±9.28) to 18.33 (±7.69) in Cyclophosphamide group after 6 months. Serious adverse events were more common in the cyclophosphamide group.

	Rituximab (n=30)			Cyclophosphamide (n=30)			Difference at 6 months Mean (95% CI)	p-value
	Baseline (mean (SD))	6 months (mean (SD))	p-value	Baseline (mean (SD))	6 months (mean (SD))	p-value

#### THU0407 EVALUATION OF SOLUBLE AND MEMBRANE HLA-G IN PATIENTS WITH SYSTEMIC SCLEROSIS AND ROLE OF THESE MOLECULES IN THE PATHOGENESIS OF THE DISEASE

G. Murdaca, P. Contini, S. Negrini, M. Borro, F. Puppo. *Internal Medicine, University of Genova, Genova, Italy*

**Background:** Systemic sclerosis (SSc) is a complex disease characterised by immune abnormalities, vascular damage and fibrosis. Human leukocyte antigen-G (HLA-G) is a non-classic class I major histocompatibility complex (MHC) molecule expressed on different cell lineages in both physiological and pathological conditions and detectable in soluble forms (sHLA-G1 and HLA-G5 shed and secreted isoform, respectively). Several immunomodulatory functions have been attributed to both membrane-bound and soluble HLA-G molecules. HLA-G is expressed on extravillous cytotrophoblast, in placenta but also in a few normal tissues, solid tumours, transplanted organs and virally infected cells. Soluble form (sHLA-G) derives from shedding of cleaved surface isoforms (sHLA-G1) or secretion of soluble isoforms (HLA-G5). Immunosuppressive functions have been attributed to both membrane HLA-G (mHLA-G) and sHLA-G.

**Objectives:** The aims of the present study were: 1) to determine the serum levels of sHLA-G molecules in a cohort of SSc patients with the limited or diffuse form of the disease; 2) to correlate sHLA-G levels with TGF- $\beta$ ; 3) to evaluate the expression of HLA-G in peripheral blood mononuclear cells (PBMC).

**Methods:** Thirtyfive patients (28 females/7 males, age 40–89 years) with diffuse SSc (dSSc, n. 12) or limited SSc (lSSc, n. 23) and 40 healthy sex and age matched controls were enrolled. Plasma sHLA-G, sHLA-G1 and HLA-G5 levels were determined by immunoenzymatic assays. mHLA-G expression in peripheral blood mononuclear cells (PBMC) was evaluated by flow cytometry.

**Results:** The plasma levels of sHLA-G were higher in SSc patients (444.27  $\pm$  304.84 U/ml) compared to controls (16.74  $\pm$  20.58 U/ml) ( $p < 0.0001$ ). The plasma levels of TGF- $\beta$  were higher in SSc patients (18937  $\pm$  15217 pg/ml) compared to controls (11099  $\pm$  6081 pg/ml);  $p = 0.003$  and a significant correlation was found between TGF- $\beta$  and the plasma levels of total sHLA-G ( $r: 0.65$ ;  $p < 0.01$ ), sHLA-G1 ( $r: 0.60$ ;  $p = 0.003$ ) and HLA-G5 ( $r: 0.47$ ;  $p = 0.02$ ). The percentage of HLA-G-positive monocytes (0.98  $\pm$  1.72), CD4+ (0.37  $\pm$  0.68), CD8+ (2.05  $\pm$  3.74) and CD4+CD8+ double positive cells (14.53  $\pm$  16.88) was higher in SSc patients than in controls (0.11  $\pm$  0.08, 0.01  $\pm$  0.01, 0.01  $\pm$  0.01 and 0.39  $\pm$  0.40, respectively) ( $p < 0.0001$ ). A high percentage of HLA-G+ cells (30.47  $\pm$  26.75) was detectable on CD4<sup>dim</sup>CD8<sup>high</sup> cells from SSc patients only.

**Conclusions:** These data indicate that in SSc secretion and/or shedding of sHLA-G and mHLA-G are clearly elevated and involved in immune dysregulation.

#### THU0408 CHARACTERISTICS OF MILD TO MODERATE LUNG DISEASE IN SYSTEMIC SCLEROSIS AND IMPACT OF SURVIVAL; DATA FROM THE POPULATION-BASED, NATIONWIDE NORWEGIAN COHORT

H. Fretheim<sup>1</sup>, M. Seip<sup>2</sup>, A.-K. Halse<sup>3</sup>, H. Bitter<sup>4</sup>, M. Wallenius<sup>5</sup>, M. Aaløkken<sup>1</sup>, T. Garen<sup>1</sup>, Ø. Midtvedt<sup>1</sup>, Ø. Molberg<sup>1</sup>, A.-M. Hoffmann-Vold<sup>1</sup>. <sup>1</sup>Oslo University Hospital, Oslo; <sup>2</sup>University Hospital of North Norway, Tromsø; <sup>3</sup>Haukeland University Hospital, Bergen; <sup>4</sup>Hospital of Southern Norway, Kristiansand; <sup>5</sup>St. Olav's University Hospital, Trondheim, Norway

**Background:** In systemic sclerosis (SSc) it is well-documented that severe interstitial lung disease (ILD), defined as an extent of lung fibrosis >20% on high resolution computed tomography (HRCT) is strongly associated with male gender, anti-topoisomerase antibody (ATA), diffuse cutaneous (dc) form of disease and decreased survival. Much less is, however, known about the disease characteristics and impact of less lung involvement. A possible explanation might be the selected nature of many hitherto investigated SSc cohorts. In an era with novel treatment options, and multiple ongoing clinical trials, it is important to gain natural history knowledge on the whole spectre of lung involvement in systemic sclerosis.

**Objectives:** Characterise the SSc patients with mild to moderate ILD, defined as 1%–10% extent of lung fibrosis on HRCT in the population based nationwide Norwegian SSc cohort and assess the impact of this ILD form on survival.

**Methods:** The Norwegian, nationwide SSc (Nor-SSc) study cohort included all adult SSc patients who were resident in Norway between 01.01.2000–01.01.2013 and met the classification criteria for SSc. Detailed electronic patient journal review was performed in all patients to assess demographic, clinical and ILD features at baseline. Pulmonary function tests (PFTs) and lung HRCT images were analysed and the extent of lung fibrosis was expressed as percentage of total lung volumes. We defined mild-moderate ILD as 1%–10% fibrosis on HRCT and severe disease as >20% fibrosis. Ground glass opacities, bronchiectasis and honeycombing were registered if present. Vital status and causes of deaths were available in all patients at study end (January 2018). Descriptive statistics and regression analysis were applied.

**Results:** The Nor-SSc cohort included 815 patients. Baseline lung HRCT images were available in 416 patients (51%), whereof 226 (54.3%) had signs compatible with ILD. Mild to moderate ILD, defined as 1%–10% lung fibrosis were present in 149 (65.9%), while 48 (21.2%) had extensive lung fibrosis defined as >20%. Patients with mild-moderate ILD were 55.2 years at SSc onset and characterised by female gender (81.9%) and limited cutaneous SSc (70.5%). Their antibody profile was dominated by anti-centromere Ab (ACA) in 48.3%, followed by anti-polymerase III, ATA, and anti-RNP, in 14.1%, 13.4% and 5.4%, respectively. The mean modified Rodnan skin score (mRSS) was 9.3 (9.3%), baseline FVC was 93.4% and DLCO 66.5%. Univariable associations of clinical characteristics and mild-moderate ILD are shown in figure 1. After a mean observation time of 8.2 years, 49 (32.9%) of patients with mild-moderate ILD had died. The 5- and 10 year survival was 76% and 62% compared to 83% and 76% in patients with no ILD ( $p = 0.03$ ). In univariable cox regression analyses, mild-moderate ILD was associated with mortality (HR 1.6, 95% CI 1.03–2.40,  $p = 0.034$ ).

**Abstract THU0408 – Figure 1.** Associations of clinical characteristics and mild-moderate ILD at baseline

**Conclusions:** In this population based, nationwide study, mild-moderate ILD was frequent and had a considerably impact on survival in SSc patients.

**Background:** In SSC, the management of DU is a real clinical challenge. It includes the use of vasoactive and vasodilating drugs, but no comparative studies between agents are available. DeSScipher was the first European multicentre observational study with the aim to decipher the optimal management of SSC.

**Objectives:** To assess in expert centres the current therapeutic strategy for the management of SSC related DU.

**Methods:** Baseline demographic and clinical characteristics of patients enrolled in the DeSScipher/EUSTAR ulcer study and detailed data regarding DU were analysed.

**Results:** There were 1823 patients enrolled in this study. 277 (15.2%) presented DU at the enrolment visit, 628 (34.4%) had previous DU and 918 (50.4%) had never experienced DU. Patients with DU (current or previous) were more frequently anti-Scl70 positive, had more frequently the diffuse cutaneous subset (40.8% vs 26.7% ( $p<0.000$ )), gastro-esophageal symptoms (70% vs 63.4% ( $p=0.002$ )) and lung fibrosis on lung Rx or HRCT (65.7% vs 54% ( $p=0.001$ )) compared to patients without DU. There were no significant differences in the prevalence of pulmonary hypertension (7.3% patients with DU vs 5.3% patients without DU,  $p=0.87$ ). Treatment of patients with and without DU is shown in table 1.

**Abstract THU0409 – Table 1.** Treatment of patients with and without DU

	Patients with DU (current or previous) 905 patients	Patients without DU (never developed) 918 patients
Calcium channel blockers	601 (66.4%)	704 (76.9%)* ( $p<0.000$ )
Bosentan	199 (22%)	41 (4.5%)* ( $p<0.000$ )
Sildenafil	120 (13.3%)	57 (6.2%)* ( $p<0.000$ )
Bosentan+Sildenafil	85 (9.4%)	15 (1.6%)* ( $p<0.000$ )
Iloprost iv in the last 3 months	306 (33.8%)	74 (8.1%)* ( $p<0.000$ )
No vasodilating therapy	48 (5.3%)	97 (10.6%)* ( $p<0.000$ )
Immunosuppressants	482 (53.3%)	560 (61%)

Information on recurrent DU were available for 779 (86.1%) of patients with DU. Treatment of patients with and without recurrent DU is shown in table 2.

**Abstract THU0409 – Table 2.** Treatment of patients with and without recurrent DU

	Patients with recurrent DU (428)	Patients without recurrent DU (351)
Calcium channel blockers	258 (60.3%)	255 (72.7%)* ( $p<0.000$ )
Bosentan	105 (24.5%)	70 (19.9%)
Sildenafil	58 (13.6%)	45 (12.8%)
Bosentan+Sildenafil	323 (75.5%)	87 (24.7%)* ( $p<0.000$ )
Iloprost iv in the last 3 months	212 (49.5%)	77 (22%)* ( $p<0.000$ )
No vasodilating therapy <sup>a</sup>	27 (6.3%)	14 (3.9%)
Immunosuppressants	222 (51.9%)	226 (64.3%)

**Conclusions:** 90% of SSC patients were on vasodilating and/or vasoactive treatment regardless of the history/presence of DU. Recurrent DU were treated

aggressively, using in 75% of cases Bosentan and Sildenafil combination therapy. Our data indicate frequent use of Sildenafil and Bosentan for DU management in specialised centres, especially for recurrent DU.

### SURVIVAL OF PATIENTS WITH MUSCLE BIOPSY PROVEN IDIOPATHIC INFLAMMATORY MYOPATHY BASED ON A STUDY IN A TERTIARY UNIVERSITY CENTRE

K. Gulyás<sup>1</sup>, E. Pál<sup>2</sup>, T. Minier<sup>1</sup>, T. Berki<sup>3</sup>, L. Czirjak<sup>1</sup>, C. Varjú<sup>1</sup>. <sup>1</sup>UP MS Department of Rheumatology and Immunology; <sup>2</sup>UP MS Department of Neurology; <sup>3</sup>UP MS Department of Immunology and Biotechnology, Pécs, Hungary

**Background:** Idiopathic inflammatory myopathies (IIM) are characterised by muscle weakness due to muscle inflammation, various organ involvements and the presence of certain specific autoantibodies.

**Objectives:** To assess survival and characterise subsets based on muscle biopsy and myositis specific autoantibodies.

**Methods:** Eighty-two patients with muscle biopsy proven IIM were included in the study. Muscle biopsy was reevaluated and categorized by the same investigator (EP). All cases had myositis specific (MSA) and myositis associated (MAA) antibody tests. The MSAs and MAAs (Jo-1, PL-7, PL-12, Mi-2, SRP, Pm-Scl, Ku, ribosomal, AMA-M2) were tested with Western-blot.

Dermatomyositis/DM/, polymyositis/PM/, juvenile PM/DM, inclusion body myositis/IBM/, overlap myositis/OM/ and immune mediated necrotizing myopathy/IMNM/were identified based on clinical data, immunoserology and muscle biopsy. Patients were treated with glucocorticoids/cytostatics, interstitial lung disease was treated with pulse cyclophosphamide in 15/43 cases. Survival analysis was performed by Kaplan Meier test.

**Results:** Fifty-nine women and 23 men with a mean age of 49.3±14.6 years were included. Mean follow-up of the patients was 7.5±4.5 years. Interstitial lung disease (ILD) (51.2%), arthritis (51.2%), Raynaud's phenomenon (42.7%), skin symptoms (45.1%), dysphagia (24.4%) and significant cardiac involvement (15.9%) were the most prevalent disease manifestations. 15 cases were associated with malignancies.

The distribution of myositis subsets is as follows: 26.8% (n=22) PM, 30.5% (n=25) DM, 1.2% (n=1) juvenile PM/DM, 8.5% (n=7) IBM, 22% (n=18) OM, and 11% (n=9) IMNM.

Malignancy was most frequently associated with IMNM (7 out of 9 patients).

Altogether 18 patients died from which 15 deaths can be connected to myositis related events. Eight patients died of malignancies (4 in the IMNM, 2 in the PM and 2 in the DM group), 5 patients due to cardiac events (heart failure, arrhythmia), 2 due to lung fibrosis and 3 by unknown causes. The worst prognosis with a 10 year survival of 31% was in the IMNM subgroup ( $p<0.01$ ), followed by patients with PM (68%), IBM (84%) OM (85.1%) and DM (85.3%). Mi-2 positive patients had a favourable prognosis with a 10 year survival of 100. Patients with muscle histology corresponding with IMNM had the worst prognosis (10 year survival of 31.1%), followed by PM (76%), DM and IBM (85.7% each). Non specific muscle changes unclassifiable to any of the previous groups were associated with a relatively favourable prognosis (5 year survival of 80%) ( $p<0.01$ ).

Patients with antisynthetase antibody-positivity had worse prognosis compared with patients with other antibodies or no identifiable antibodies (10 year survival of 55%, n=16) ( $p<0.05$ ). When comparing patients with MSA or MAA, the worst prognosis was seen in patients with both MSA and MAA positivity (10 year survival of 35.6%, n=10).

**Conclusions:** The worst survivals were seen in the IMNM and PM groups, due to the high frequency of the underlying malignancies and cardiac manifestations. Although ILD was the most frequent involvement, it was not a major determinant of outcome.

### MYASTHENIA GRAVIS WITHOUT THYMIC PATHOLOGY AND POLYMYOSITIS: A RARE ASSOCIATION

L. Castelnovo<sup>1</sup>, P. Faggioli<sup>1</sup>, A. Tamburello<sup>1</sup>, A.G. Gilardi<sup>1</sup>, A. Laria<sup>2</sup>, A.M. Lurati<sup>2</sup>, K.A. Re<sup>2</sup>, D. Mazzocchi<sup>2</sup>, M.G. Marrazza<sup>2</sup>, A. Mazzone<sup>1</sup>. <sup>1</sup>Medicina Interna, Asst Ovest Milanese – Ospedale Civile Di Legnano E Cuggiono, Legnano; <sup>2</sup>Reumatologia, Asst Ovest Milanese – Ospedale Civile Di Legnano E Cuggiono, Magenta, Italy

**Background:** Myasthenia gravis(MG) is an autoimmune disease frequently associated with antibodies against the acetyl-choline receptor. These antibodies contribute to the characteristic defects in neuromuscular transmission. Inflammatory myopathies, as polymyositis(PM), are immune-mediated neuromuscular

diseases. PM and MG present both with muscle weakness and other similar features; electrophysiological and laboratory features of each of them are distinct. In Literature there are only few reports about PM and MG association

**Objectives:** To evaluate the prevalence of MG in patients with PM in our case series

**Methods:** We enrolled patients with PM/DM visited in our Centre in past 10 years; diagnoses of PM/DM were based on Bohan and Peter criteria. The follow-up was conducted until December 2017

**Results:** We made 17 PM/DM diagnosis:14 F and only 3 M aged 41–85 years (mean 65 y). We found 6 patients (42,8%) with association of PM and MG. They are all F, aged 51–78 years (mean 61 y) who developed inflammatory myositis confirmed by increasing of CK, EMG, autoantibodies pattern positivity and deltoid biopsy. Paraneoplastic, post-infectious or post-vaccinal syndromes was excluded. At the onset all presented progressive proximal muscle weakness and pain and asthenia. After initial treatment with oral corticosteroids (0.5–1 mg/kg/day methylprednisolone) a minimal response was observed only as improvement of asthenia and decreasing of CK levels. After one month of therapy 2 patients developed a bilateral palpebral ptosis, one dysphagia and mild dyspnea, one a severe intestinal pseudo-obstruction, 2 a mild dysarthria, ipovision and a worsening of muscular tone. Pyridostigmine test was positive in all patients; antiAChR antibodies levels were high. We started high doses corticosteroids (methylprednisolone 500–1000 mg/day for 5 days) and pyridostigmine (180–240 mg/day) with smart improvement. After this we introduced an immunosuppressant: azathioprine in 3 patients, mycophenolate mofetil in 4 patients. At the same time, because of the severity of the disease, monthly cycles of high doses IgV (20 g/kg in 5 days) were performed in 5 patients. A stable remission was achieved and maintained in all patients

**Conclusions:** This is one of the largest case series of patients with PM/DM-MG overlap. Our findings suggest that this association is not so rare and that patients affected by PM presenting palpebral ptosis, diplopia, gastrointestinal or oral symptoms, bulbar symptoms, weakness, asthenia, should be evaluated to exclude a concomitant MG, despite the absence of thymic pathology. A patient with PM-MG overlap should allow us for proper management of both conditions. This may include a more adequate therapy providing simultaneous association between immunosuppressant, pyridostigmine and, if necessary, a short time of high doses IgV therapy

#### ABSOLUTE REDUCTION OF PERIPHERAL CD4 + REGULATORY T CELL SUBSET OF PATIENTS WITH SYSTEMIC SCLEROSIS AND ITS RESTORATION BY SHORT-TERM AND LOW DOSE IL-2 TREATMENT

L. Shang<sup>1</sup>, J. Yuan<sup>1</sup>, Q. Li<sup>1</sup>, X. Liu<sup>1</sup>, J. Luo<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>, H. Gao<sup>1</sup>.

<sup>1</sup>Rheumatology, THE SECOND HOSPITAL OF SHANXI MEDICAL UNIVERSITY, Taiyuan, China; <sup>2</sup>Pathology, Brigham and Women's Hospital, Boston, USA

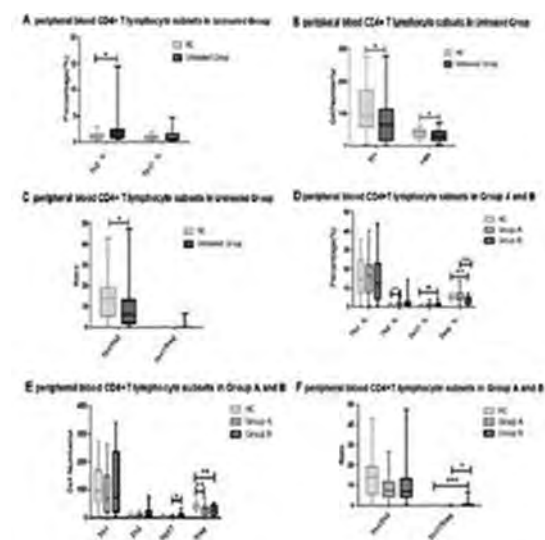

**Background:** Systemic sclerosis (SSc) is a chronic inflammatory disease with complex pathogenesis. The role of regulatory T cells (Tregs) in the development of SSc has started being studied during the last decade with new aspects being disclosed continuously. Although there is a general agreement in the medical literature regarding the decreased functional capacity of circulating Tregs in SSc, the alteration of absolute number of Treg cells as well as other CD4 + T lymphocyte subsets in SSc is still unclear.

**Objectives:** The aim of the present study was to explore the absolute number status of CD4 + T subsets in peripheral blood of patients with SSc using our modified flow cytometric method and investigate whether the imbalance of Th17 and Treg cells can be corrected by supplementing low dose interleukin -2 (IL-2).

**Methods:** The peripheral CD4 + T subsets from 54 patients with SSc and 30 healthy control subjects were analysed. The patients were divided into the untreated group (n=29) and treated group (n=25). The patients were also divided into group A (n=28) who only used low-dose glucocorticoids (GCS), and group B (n=26) who also used immunosuppressant cyclophosphamide (CYC), methotrexate (MTX), leflunomide (LEF) or mycophenolate mofetil (MMF). In addition, 21 patients from 54 patients, given a small dose of IL-2 (50WIU) treatment for a 5 day

course, divided into pre-treatment group and post-treatment group. Directly using the results from flow cytometry combined with internal standard beads, absolute number of peripheral CD4 + T subsets from the subjects in each group were calculated.

**Results:** Although there were some changes among CD4 + T cell subsets in peripheral blood from these SSc patients, the major alteration was the reductions of Treg cell absolute number. Compared with the normal controls, the number of CD4 + CD25 + FOXP3 + Treg cells were significantly decreased in all patients (p=0.001), in untreated group (p=0.029), in treated group (p=0.029), in group A (p=0.006) and in group B (p=0.004). The ratio of Th17/Treg in total patients (p=0.008) and group B (p=0.001) were significantly higher than that in normal control group, and the group B was significantly higher than the group A (p=0.032). Moreover, the number of Th17 cells in group B was significantly higher than that in group A (p=0.023). After IL-2 treatment, the absolute number of CD4 + CD25 + FOXP3 + Treg cells (p<0.001) were significantly increased, while the number of Th1, Th2 and Th17 cells were slightly higher than those before treatment with IL-2 (p>0.05). Since Th17 cells increases significantly lower than Treg cells, so their ratio decreases significantly (p=0.001) to get re-balance.

**Abstract THU0412 – Figure 1.** Comparison of the levels of CD4+ T lymphocyte subgroups among different groups. (A and D) The percentage of Th2 cells were significantly increased in untreated group and Group A compared with healthy controls. (B and E) The number of CD4+CD25+FOXP3+Treg cells decreased in patients with SSc, whether or not they use immunosuppressive agents. (C and F) The ratio of Th17/Treg cells was found to be significantly increased in Group A, as well as between Group B and Group A. \*P<0.05; \*\*P<0.01; \*\*\*P<0.001.

**Abstract THU0412 – Figure 2.** Comparison of the levels of CD4+ T lymphocyte subgroups among different groups as well as before and after IL-2 treatments. (A) The percentage of Th2 cell were significantly increased before and after IL-2 treatment compared with healthy controls, and the percentage of Treg cells significantly increased after IL-2 treatment. (B) The number of CD4+CD25+FOXP3+Treg cells decreased in patients before IL-2 treatment, but increased significantly after IL-2 treatment (p<0.05); while Th1, Th2 and Th17 cells after IL-2 treatment were slightly higher than those before treatment (p>0.05). (C) The ratio of Th17/Treg cells were found to be significantly increased after IL-2 treatment. \*P<0.05, \*\*P<0.01, \*\*\*P<0.001.

**Conclusions:** The absolute number of peripheral CD4 +CD25+FOXP3+Treg cells decreased in untreated patients, indicating that this reduction arising from the disease itself. Our findings suggest that SSc progression is associated with the absolute decrease of peripheral Treg cells. Although there was no statistically

significant different, absolute number of the Treg cells trended to decrease in patients treated with immunosuppressive agents. The use of IL-2 can effectively up-regulate Treg cells as well as increase Th17 to a certain extent, which restores the balance of Th17/Treg cells, but the long-term effect needs further investigation.

#### THU0413 NORMALISATION OF NAILFOLD MICROVASCULATURE AFTER HEMATOPOIETIC STEM CELL TRANSPLANTATION IN SEVERE SYSTEMIC SCLEROSIS

M. Boonstra, D.C. Noordhoek, L.J. Beart-van de Voorde, T.W. Huizinga, J.K. de Vries-Bouwstra. *department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands*

**Background:** Microangiopathy in Systemic Sclerosis (SSc), as visualised by nailfold capillary microscopy (NCM), is a dynamic and sequential process. Uncontrolled case-reports and a case-series report possible improvement of nailfold microangiopathy after hematopoietic stem cell transplantation (HSCT).

**Objectives:** To evaluate differences in nailfold microvasculature in patients with severe SSc treated with HSCT and those treated otherwise.

**Methods:** Severe SSc was defined as fulfilling criteria of the ASTIS trial.<sup>1</sup> For included patients two treatment groups were defined: 1. Patients treated with HSCT, 2. Patients treated otherwise (including cyclophosphamide, methotrexate, mycophenolate mofetil and rituximab). All available capillaroscopy images collected prior to and after treatment were scored independently by two trained observers, blinded for treatment. Scoring included categorical scores (0=no changes to 3≥66% alterations per millimetre) for capillary loss, neoangiogenesis, haemorrhages, dilatations, giants, disorganisation, together with a qualitative pattern and a VAS score for overall severity of microangiopathy.

**Results:** In total 55 patients were included, of whom 33 were female, mean age was 50±13 years and median mRSS of 20.<sup>15-28</sup> Twenty-nine patients were treated with HSCT. After treatment categorical score of capillary loss was lower with HSCT (median score 1.0 vs. 2.0, p=0.04) and VAS scores for severity of microangiopathy were better with HSCT (50.0 vs. 67.3, p=0.03). Compared to controls, a typical SSc pattern was less frequent in patients treated with HSCT (n=12/22, 55%, vs. n=18/20, 90% p=0.01).

In 25 patients (HSCT n=11, control n=14) images prior to treatment were available. Improvement in capillary loss (HSCT -0.5 [IQR -1 to 0] vs. control +0.3 [IQR -1.0 to 1.0] p=0.01;), dilatation (HSCT -1.5 [IQR -2.0 to -1.0] vs. control 0.0 [IQR -1.0 to 0.5] p<0.01) and VAS scores (HSCT median -32.5 [IQR -80.5 to -4.5] vs. - controls +2.0 [IQR -35.5 to +46.0] p<0.01;) improved significantly more in the HSCT group.

**Conclusions:** In patients with severe SSc, microangiopathy as reflected by nailfold capillaroscopy images, is less severe after treatment with HSCT and shows more improvement over time compared to patients with severe SSc treated otherwise. In specific, improvement seems to be characterised by normalisation of the capillary diameter and capillary density. To our knowledge, this is the first study to report on changes in microangiopathy after HSCT in a controlled study design.

#### THU0414 ASSOCIATION OF THE ESOPHAGEAL DILATION AND INTERSTITIAL LUNG DISEASE ON CHEST HIGH-RESOLUTION COMPUTED TOMOGRAPHY IN PATIENTS WITH IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY

F. Salaffi<sup>1</sup>, M. Di Carlo<sup>1</sup>, M. Carotti<sup>2</sup>, P. Fraticelli<sup>3</sup>, A. Gabrielli<sup>3</sup>, A. Giovagnoni<sup>2</sup>. <sup>1</sup>Rheumatological Clinic, Università Politecnica delle Marche, Jesi; <sup>2</sup>Clinic of Radiology; <sup>3</sup>Medical Clinic, Università Politecnica delle Marche, Ancona, Italy

**Background:** Esophageal dilation and dysfunction has been implicated in the pathogenesis of interstitial lung disease (ILD) in systemic sclerosis (SSc).

**Objectives:** The aims of this were to explore the association of the esophageal dilation and ILD on chest high-resolution computed tomography (HRCT) in patients with SSc and to establish a cut-off point for the esophageal dilation suggestive for the presence of a significant SSc-ILD.

**Methods:** The widest esophageal diameter (WED) was obtained on axial HRCT images. The parenchymal abnormalities on HRCT were coded and scored according to Warrick method. Patient-centred measures, pulmonary function tests (PFTs) and the single breath carbon monoxide diffusing capacity of the lung (DLco) were also obtained. Multivariate regression analyses were performed to identify factors associated with esophageal diameter on HRCT.

**Results:** 126 subjects with SSc were included in the analysis. The mean (±SD) WED was 13.5 (±4.2) mm, and in 76 (60.3%) participants WED was ≥11 mm. ILD was diagnosed in 86 SSc patients (Warrick score ≥7), while in 40 subjects the lung findings were normal. SSc patients with ILD had larger mean esophageal diameter than those without lung disease (19.4 mm vs. 14.1 mm, p<0.001). We observed a high correlation between WED and Gastroesophageal reflux disease questionnaire (GerdQ) (r=0.886, p<0.001), Borg score (r=0.705, p<0.001), Warrick score (r=0.614, p<0.001). WED negatively correlated with DLco (r=-0.508, p<0.001). Multivariate analysis demonstrated positive associations between mean esophageal diameter and GerdQ (p<0.0001), Borg index (p<0.0005), and total Warrick score (p=0.019).

**Conclusions:** In patients with SSc, an increased esophageal diameter (>11 mm) on chest HRCT is associated with pulmonary and esophageal symptoms, more severe ILD, and lower DLco.

#### THU0415 ANTI-PM/SCL ANTIBODY CLINICAL ASSOCIATIONS IN PATIENTS WITH SYSTEMIC SCLEROSIS. ANALYSIS OF THE MULTICENTER EUSTAR COHORT

M.G. Lazzaroni<sup>1</sup>, A. Furloni<sup>1</sup>, I. Cavazzana<sup>1</sup>, S. Zingarelli<sup>1</sup>, F. Franceschini<sup>1</sup>, A. Tincani<sup>1</sup>, S. Bellando-Randone<sup>2</sup>, C. Caimmi<sup>3</sup>, E. Hachulla<sup>4</sup>, Y. Allanore<sup>5</sup>, P. Airo<sup>1</sup>, on behalf of EUSTAR co-authors. <sup>1</sup>University and Spedali Civili of Brescia, Brescia; <sup>2</sup>University of Florence and Division of Rheumatology AOUC, Firenze; <sup>3</sup>Azienda Ospedaliera Universitaria Integrata, Verona, Italy; <sup>4</sup>University Lille Nord-de-France, Lille; <sup>5</sup>University Paris Descartes and Cochin Hospital, Paris, France

**Background:** Antibodies to the PM/ScI complex are found in patients with Systemic Sclerosis (SSc), but also with Polymyositis, Dermatomyositis and overlap syndromes. Historically, the main clinical association of anti-PM/ScI antibodies in SSc, which include calcinosis, articular and muscle involvement, and interstitial lung diseases, were described by some large single-centre studies, or by multicenter studies which recruited a relatively small number of positive patients. Therefore, some unresolved issue deserves further research. In particular, scleroderma renal crisis was recently identified in a sizeable number of anti-PM/ScI +SSc patients in a large monocentric British cohort (4 out of 70; 5.7%), a somewhat unexpected finding since this antibody type is generally considered not to be associated with renal crisis.<sup>1</sup>

**Objectives:** To evaluate clinical associations of anti-PM/ScI in patients with SSc in the large multicenter EUSTAR database, with specific focus on scleroderma renal crisis.

**Methods:** Patients from the EUSTAR database were included when the item anti-PM/ScI was fulfilled in at least one visit; clinical data were collected from the last visit available.

**Results:** Anti-PM/ScI status was available in 8,287 SSc patients from EUSTAR database: 295 were anti-PM/ScI +. After exclusion of 145 patients with multiple autoantibody positivity, 150 anti-PM/ScI+ patients were compared with 7992 anti-PM/ScI -negative patients. Among these, 2530 were positive for anticentromere, 1933 for anti-topoisomerase I, 186 for anti-RNA polymerase III, and 220 for anti-U1Rnp antibodies.

Renal crisis was identified in 8 of 150 anti-PM/ScI+SSc patients (5.3%), and was significantly more frequent than in anti-PM/ScI-negative SSc patients (1.6%; p=0.0015). Positivity for anti-PM/ScI was also associated with male sex, diffuse cutaneous subsets, joint and muscle involvement, lung fibrosis at chest X-rays, heart conduction blocks, stomach and intestinal symptoms (table 1). However, in multivariate analysis, adjusted for age at disease onset, sex, and disease duration, the association of anti-PM/ScI with renal crisis was not significant, whereas

the associations with joint and muscle involvement, lung fibrosis, and intestinal symptoms were confirmed (table 1).

**Table 1** Results of the univariable and multivariable analysis adjusted on sex, age at disease onset and disease duration (n=8142 patients). Results are presented as number/number available data (%) unless stated otherwise.

Characteristics	Univariable analysis			Multivariable analysis		
	Anti-PM/Scl -	Anti-PM/Scl +	p Value	N available data (%)	OR (95% CI)	p Value
Age at disease onset (years, mean (SD) (n available))	46.7 (14.5) (6883)	44.7 (15.1) (1461)	0.081	7025 (86.3)	0.98 (0.90 to 0.99)	0.0015

Elevated sPAP (ECHO)	376/8882 (4.2)	18/137 (13.9)	0.33	5729 (70.4)		
Lung fibrosis on plain X-rays	64/117 (54.7)	1342/4537 (29.6)	10.0001	4664 (57.0)	2.812 (1.429 to 5.872)	<0.0001

**Conclusions:** In the largest series of anti-PM-Scl positive patients so far reported, well-known clinical associations were confirmed. Moreover, scleroderma renal crisis was more frequent than in the antibody-negative patient controls (which included a majority of anticentromere-positive patients, and a relatively small number of anti-RNA polymerase III-positive patients). However, this association was probably explained by covariates, such as joint and muscle involvement, or lung fibrosis. A possible role of corticosteroid therapy might therefore be suspected.

#### VERTEBRAL FRACTURE PREVALENCE AND MEASUREMENT OF THE SCANOGRAPHIC BONE ATTENUATION COEFFICIENT ON CT SCAN IN 70 PATIENTS WITH SYSTEMIC SCLERODERMA

M. Fauny<sup>1</sup>, E. Bauer<sup>1</sup>, E. Albuissou<sup>2</sup>, J. Perrier-cornet<sup>1</sup>, J. Deibene<sup>2</sup>, F. Chabot<sup>2</sup>, D. Mandry<sup>2</sup>, O. Huttin<sup>2</sup>, I. Chary-valckenaere<sup>1</sup>, D. Loeuille<sup>1</sup>. <sup>1</sup>*Rheumatology*; <sup>2</sup>*CHU Nancy, Vandoeuvre Les Nancy, France*

**Background:** Osteoporosis screening is not systematic in scleroderma patients but some studies demonstrated a similar risk between rheumatoid arthritis and systemic scleroderma.<sup>1,2,3</sup> Thoracic and/or TAP (thoraco-abdomino-pelvic) CT (Computed Tomography) scans are classically performed in the follow-up of scleroderma, mainly to evaluate lung involvement.

**Objectives:** To study vertebral fracture (VF) prevalence and the scanographic bone attenuation coefficient of the first lumbar vertebra (SBAC-L1) on CT scans in systemic scleroderma patients. Secondary objectives are to study specific risk factors of SBAC-L1 ≤145 Hounsfield Units (HU) and to evaluate SBAC-L1 measurements reliability.

**Methods:** This monocentric retrospective study included patients followed from 2000 to 2014 and fulfilling ACR/EULAR 2013 criteria for systemic scleroderma and who underwent a thoracic or TAP CT scan. Osteoporotic risk factors, Dual Energy X-ray Absorptiometry (DXA) measurements and clinical characteristics were collected. For CT scan, the VFs were determined according to Genant's

classification on sagittal sections. The SBAC-L1 was measured in Hounsfield Units (HU) on axial section of L1 in a Region of Interest drawn in trabecular bone. Intra- and inter-reader reliabilities for SBAC-L1 were calculated. An SBAC-L1 ≤145 HU (fracture threshold) was used to define patients at risk of VF.<sup>4</sup> Predictive factors for VF or SBAC-L1 ≤145 HU were studied.

**Results:** A total of 70 patients were included (mean age: 62.3 (±15.6) years, women 88.5%, diffuse scleroderma 22.9% (n=16)) in the study. Sixty patients (85.7%) presented with at least one clinical risk factor for osteoporosis. Eighteen patients (25.7%) received vitaminocalcic supplementation and 10 (14.3%) received antiresorptive therapy. DXA was only performed on 30 patients (42.8%), and 5 (16.7%) of them presented a T-score ≤ -2.5 DS. 3 VFs were detected in 3 patients (4.3%). The mean SBAC-L1 was 157.26 HU (±52.1), and 35 patients (50%) presented a SBAC-L1 ≤145 HU. SBAC-L1 measurements were highly reliable (Kappa >0.9 for both intra- and inter-reader reliability). For the univariate analysis, a SBAC-L1 ≤145 HU was significantly associated with age (OR=1.09, CI 95%: 1.04–1.13), calcinosis (OR=6.3, CI 95%: 1.61–24.75) and periarticular calcifications (OR=3.22, CI 95%: 1.06–9.77). For the multivariate analysis, age (especially patients older than 63 years), calcinosis and acro-osteolysis were independently associated with a SBAC-L1 ≤145 HU.

**Conclusions:** On a large sample of scleroderma patients with clinical risks of osteoporosis, only 42.8% were screened for DXA and 16.7% of them were osteoporotic. The VF prevalence on CT scan was 4.3% and the SBAC-L1 measurement identified 50% of the population at the fracture threshold. The presence of calcinosis, periarticular calcifications or acro-osteolysis should lead to an osteoporosis screening, especially for patients under 63 years old.

#### WHOLE BODY DISTRIBUTION AND CLINICAL ASSOCIATIONS OF TELANGIECTASIA IN SYSTEMIC SCLEROSIS: A CROSS-SECTIONAL STUDY

M. Jouvray<sup>1</sup>, D. Launay<sup>1</sup>, S. Dubucquois<sup>2</sup>, V. Sobanski<sup>1</sup>, C. Podevin<sup>3</sup>, M. Lambert<sup>1</sup>, S. Morell-Dubois<sup>1</sup>, H. Maillard<sup>1</sup>, P.-Y. Hatron<sup>1</sup>, E. Hachulla<sup>1</sup>, J. Giovannelli<sup>3</sup>. <sup>1</sup>*département de médecine interne et immunologie clinique*; <sup>2</sup>*Institut d'Immunologie*; <sup>3</sup>*Centre de Référence des Maladies Autoimmunes et Systémiques Rares du Nord et Nord-Ouest de France (CeRAINO), CHU Lille, Lille, France*

**Background:** Telangiectasia (TA), one of the diagnostic criteria for systemic sclerosis (SSc), could be a clinical marker for the severity of vasculopathy, including pulmonary hypertension (PH).

**Objectives:** We designed a cross-sectional study: (i) to describe the whole-body distribution of TA, (ii) to assess the associations between the whole-body number of TA and the characteristics of patients, (iii) to determine whether the number of TA may be useful to discriminate SSc-PH patients.

**Methods:** Patients were included in the National Referral Centre for Rare Systemic And Autoimmune Diseases if they fulfilled the 2013 ACR/EULAR criteria for SSc. They were excluded if they had received laser treatment. The whole-body number and distribution of TA were recorded at inclusion. The associations were studied using univariate, adjusted and multiple linear regressions.

**Results:** 106 patients were enrolled, including 12 with PH. The median (interquartile range) number of TA was 30 (82.7). Their distribution was: 37.2% on the face, 33.2% on the upper limbs including 26.4% on the hands, 28.1% on the trunk including 17.1% for the upper part of the trunk, and 1.5% on the lower limbs. Using multivariate linear regression model, the whole-body telangiectasia number was independently associated with male gender (percentage change (95% CI)= +144.4% (7.5; 455.9), p=0.033), pulmonary hypertension (+162.8% (5.6; 553.8), p=0.038), history of pulmonary embolism (+336.4% (39.0; 1270.1), p=0.012), glomerular filtration rate (-1.6% (-3.2; -0.1) per 1 ml/min/1.73m<sup>2</sup> increase, p=0.038) and soluble endoglin (+28.2% (1.2; 62.5) per 1 ng/ml increase, p=0.039). The ROC analyses assessing the ability of telangiectasia to discriminate the presence of pulmonary hypertension revealed that the area under the curve was significant for the telangiectasia number on the whole body (0.77 (0.57; 0.88)), on the hands and face (0.81 (0.57; 0.91)) and on the hands (0.77 (0.57; 0.89)).

**Conclusions:** In SSc-patients, TA were predominantly located on the face, hands and the upper part of the trunk. They may reflect the vasculopathy of SSc and could represent a clinical biomarker for vascular disease, particularly for PH, one of the most severe vascular complications of the disease.

#### LONG-TERM EFFICACY AND SAFETY OF MONOTHERAPY VERSUS COMBINATION THERAPY IN SYSTEMIC SCLEROSIS-ASSOCIATED PULMONARY ARTERIAL HYPERTENSION (PAH): A RETROSPECTIVE COHORT STUDY FROM THE NATIONWIDE SPANISH SCLERODERMA REGISTRY (RESCLE)

M. Pestaña-Fernández<sup>1</sup>, M. Rubio-Rivas<sup>1</sup>, N. Villalba-Jiménez<sup>1</sup>, B. Mari-Alfonso<sup>2</sup>, A. Guillén-Del-Castillo<sup>3</sup>, M. Freire<sup>4</sup>, J.A. Vargas-Hitos<sup>5</sup>, J.A. Todolí-Parra<sup>6</sup>, M. Rodríguez-Carballeira<sup>7</sup>, G. Espinosa-Garriga<sup>8</sup>, X. Corbella Virós<sup>1</sup>, V. Fonollosa-Pla<sup>3</sup>, C.P. Simeón-Aznar<sup>3</sup> on behalf of RESCLE. <sup>1</sup>Internal Medicine, Hospital Universitario Bellvitge, Barcelona; <sup>2</sup>Internal Medicine, Corporació Sanitària Parc Taulí, Sabadell; <sup>3</sup>Internal Medicine, Hospital Universitario Vall d'Hebron, Barcelona; <sup>4</sup>Internal Medicine, Complejo Hospitalario Universitario de Vigo, Vigo; <sup>5</sup>Internal Medicine, Hospital Universitario Virgen de las Nieves, Granada; <sup>6</sup>Internal Medicine, Hospital Universitario y Politécnico La Fe, Valencia; <sup>7</sup>Internal Medicine, Hospital Universitario Mútua Terrassa, Terrassa; <sup>8</sup>Internal Medicine, Instituto Clínic de Medicina y Dermatología, Hospital Universitario Clínic, Barcelona, Spain

**Background:** Monotherapy with endotelin antagonist receptors (ERA) an phosphodiesterase 5 (PDE5) inhibitors is a first choice treatment for PAH in functional class (FC) II-III, with the same grade of evidence and recommendation than combination therapy. Recently, studies have proven superiority of combination therapy against monotherapy in combined morbi-mortality endpoints.

**Objectives:** To demonstrate superiority of combination therapy against monotherapy in a single mortality endpoint in SSc-associated PAH.

**Methods:** Retrospective cohort study including patients from the Spanish Scleroderma Registry (RESCLE) diagnosed with SSc-associated-PAH by right heart catheterization (RHC). Patients were divided in 3 groups: monotherapy vs. sequential combination therapy (>12 weeks between first and second treatment)

vs. upfront combination therapy (<12 weeks between treatments). Primary endpoint was mortality from any cause.

**Results:** Seventy-six patients with PAH out of 1817 participants were included. Thirty-four (45%) were receiving monotherapy [with ERA (22 patients, 29%) or PDE5 inhibitors (12 patients, 16%)], 25 patients (33%) sequential combination therapy and 17 patients (22%) upfront combination therapy.

Baseline demographic, clinical and complementary tests were similar among groups. ILD (mainly moderate) was more frequent in both combination groups in 58% vs. 80% vs. 76.4%, without statistical significance. A worse FVC/DLco in the sequential combination group was reported (2.9±1.1 vs. 1.8±0.4 vs. 2.3±0.8, global p=0.085 but p=0.043 comparing monotherapy with sequential combination) and also a worse mPAP in both sequential and upfront combination groups (37.2±8.7 mmHg vs. 40.8±8.8 vs. 46±15.9, p=0.026).

The treatment regimen prescribed (p=0.017) and FC at baseline (p=0.007) were found predictors of mortality. Sequential combination therapy was found a protective factor [HR=0.11 (95%CI 0.03–0.51), p=0.004] and the upfront combination therapy showed a tendency of protection [HR=0.68 (95%CI 0.23–1.97), p=0.476]. Survival rates from diagnosis of PAH among groups were: 78% vs. 95.8% vs. 94.1% at 1 year, 40.7% vs. 81.5% vs. 51.8% at 3 years and 31.6% vs. 56.5% vs. 34.5% at 5 years (p=0.007).

Side effects were not significantly different among groups.

**Conclusions:** Combined sequential therapy improves survival in SSc-PAH patients, even with moderate ILD.

Upfront combination therapy may improve survival, but did not reach statistical significance due to study limitations.

Treatment regimen and FC were found as prognostic factors for survival: sequential combination therapy was a protective factor and FC was a risk factor.

THU0419

#### ASSOCIATION OF INFLAMMATORY MARKERS C-REACTIVE PROTEIN AND ERYTHROCYTE SEDIMENTATION RATE WITH PULMONARY FUNCTION TESTS AND EUROPEAN SCLERODERMA STUDY GROUP ACTIVITY INDEX (ESCSG-AI) IN SYSTEMIC SCLEROSIS – ASSOCIATED INTERSTITIAL LUNG DISEASE IN FOLLOW UP STUDY

O.B. Ovsyannikova, O. Koneva, L. Ananieva. Department Of Vascular Pathology, Nasonova Research Institute of Rheumatology, Moscow, Russian Federation, Москва, Russian Federation

**Background:** inflammatory markers are very important to assess severity and activity of SSc-ILD, but it's role needs further investigation.

**Objectives:** to assess inflammatory markers of SSc such as hsCRP and ESR and compare with lung function test and ESCSG-AI in the long-term follow up study.

**Methods:** It was a longitudinal study involving 77 pts with SSc-ILD (mean age was 46,2±13,4; 69% have limited subset of the disease; 93% were female). The mean duration of follow up was 58,9±11,4 months. Pts. were investigated with HRCT twice (at first visit and at the end of the study) and according the CT-changes were divided into 3 groups: the 1st group (16 pts) with improvement; 2nd group (39 pts) without any changes and 3rd group (22 pts) with worsening of fibrosis. Other data collected including biological results (high-sensitivity C-reactive protein (hsCRP) and erythrocyte sedimentation rate (ESR)), PFT (forced vital capacity (FVC,% of predicted) and diffusing capacity of the lung for carbon monoxide (DLCO,% of predicted), composite score (ESCSG-AI).

**Results:** there were no significant differences between groups related to sex, frequency of diffuse form and duration disease. Mean levels of hsCRP and ESR didn't change significantly during the follow up. In all pts the mean levels of hsCRP and ESR correlated directly with each other at first visit and at the end of the study (R=0,45 and R=0,4 (p<0,001) accordingly). We compared the mean levels of hsCRP and ESR with mean dates of FVC, DLCO and ESCSG-AI score in first visit and the end of follow up. Mean levels of hsCRP inversely correlated with mean dates of DLCO at the first visit and at the end of the study (R=-0,39 and R=-0,42 (p<0,05) accordingly); in groups 2 and 3 (R=-0,34 and R=-0,47 (p<0,05) accordingly) at the end of the study; with mean dates of FVC in all pts and group 2 (R=-0,42 and R=-0,47 (p<0,05) accordingly) only at the end of the study; correlated directly with ESCSG-AI score in all pts and groups 2,3 (R=0,58 (p<0,0001), R=0,46 (p<0,01) and R=0,77 (p<0,001) accordingly) at the end of the study. While mean levels of ESR inversely correlated with mean dates of DLCO only in all pts and groups 1,2 (R=-0,43, R=-0,66 and R=-0,39 (p<0,05) accordingly) at first visit; correlated directly with ESCSG-AI score in all pts. (R=0,309 (p<0,01) at the end of the study. Mean levels of hsCRP inversely correlated with DLCO, FVC and directly correlated with ESCSG-AI and these correlations were more evident than with mean levels of ESR.

**Conclusions:** In our group of pts. the hsCRP has proven to be an accurate reflection of disease severity especially in pts with progression of ILD.

### AN EXTENT OF INTERSTITIAL LUNG DISEASE IS A POTENTIAL PREDICTOR OF RESPONSE TO A-B-CELL THERAPY IN THE PATIENTS WITH SSC

O. Koneva, O. Desinova, O. Ovasyannikova, L. Garzanova, M. Starovoytova, L. Ananieva. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Systemic sclerosis (SSc) is a connective tissue disease associated with chronic polyclonal B-lymphocytic activation and immunological tolerance disturbance. Several research and clinical studies showed that B-cell depletion is potentially efficacious in SSc treatment. However, neither strong evidence of RTX efficacy for treatment of interstitial lung disease (ILD) associated with SSc, no potential predictor of response to a-B-cell therapy.

**Objectives:** To evaluate rituximab (RTX) therapy efficacy in the patients with systemic sclerosis (SSc) differing in extent of interstitial lung disease (ILD) based on multispiral computed tomography (MSCT) findings.

**Methods:** 42 patients (average age 48±2 years; male/female 1/6, diffuse/limited disease 15/1 (25 and 17), disease duration since the first non-Raynaud syndrome – 6.6±5.9 years) with definitely diagnosed SSc and ILD signs evidenced by MSCT were enrolled into the study. During the observation period 29±15.3 months the patients received rituximab (RTX) total dose of 2.5±1.3 grams in combination with glucocorticoids at average dose of 11.7±3.9 mg. 10 (24%) patients concurrently took immunosuppressants. The therapy efficacy was evaluated both in the general study population and in the patient subgroups with interstitial lesion extent up to 20% (Group A, n=13) and greater than 20% (Group B, n=29) of total pulmonary tissue area.<sup>1</sup>

**Results:** In the general patient population significant FVC increase from 73.2±18.8% to 82±21.8% (p=0.000031) and stabilisation of DLCO (42.6%±15.7% vs 44.7±14.6%. p=0.2) were observed. Median FVC increment was 6% (25th% >3.3%; 75th%>16%). FVC-based parameters increased by ≥10% in 16 (38%) patients and decreased in 3 (7%) patients.

Average FVC values in Group A were significantly higher compared with Group B both at the baseline (88.8%±18.6% vs 65.4±14.5%, p=0.0002) and after the treatment (103.3%±15.9% vs 74.1±18.5%, p=0.0009) with statistically significant FVC increase in both groups during the treatment period (p=0.016 and p=0.0014, respectively). Median FVC increment in Group A and Group B was 10.2% (25th% >4.7%; 75th%>21.9%) and 5.9% (25th%>2.75%; 75th%>14.7%), p>0.05, respectively. FVC-based parameters increased by ≥10% in 6 (46%) patients in Group A, and in 10 (34%) patients in Group B, and decreased in 1 (8%) and 2 (7%) patients, respectively.

Average DLCO values were also significantly higher in Group A compared to Group B both before and after treatment (58.4%±16.4% vs 36.3±10.1%. p=0.025; 59.3±15.2% vs 38.9±9.7%. p=0.005); DLCO values did not change over time during RTX therapy.

**Conclusions:** RTX therapy resulted in significant FVC increase. FVC increment in the patient group with ILD extent up to 20% achieved clinical significance level in contrast to the patients with ILD extent greater than 20%, where FVC increment was 5.9%. Obtained data suggest that initial lung lesion area is a potential predictor of response to a-B-cell therapy in the patients with SSc.

### PREVALENCE AND CLINICAL CORRELATES OF SMALL AIRWAY OBSTRUCTION IN PATIENTS WITH SYSTEMIC SCLEROSIS

P. Ostojic<sup>1,2</sup>, M. Vujovic<sup>2</sup>, A. Blanka Protic<sup>3</sup>. <sup>1</sup>*Institute of Rheumatology*, <sup>2</sup>*School of Medicine, University of Belgrade*; <sup>3</sup>*Clinical Center of Serbia, Clinic for Pulmonary, Belgrade, Serbia*

**Background:** Small airways are usually defined as non-cartilaginous airways with an internal diameter <2 mm. Small airway obstruction (SAO) may be result of a primary bronchiolar disorder, or secondary to a disease that also affects large airways (like asthma or chronic obstructive pulmonary disease - COPD), or related to an interstitial lung disease with bronchiolar involvement.

**Objectives:** To assess prevalence and clinical correlates of SAO in patients with systemic sclerosis (SSc).

**Methods:** 69 consecutive patients with SSc (63 women and 6 men) were included in this study. Patients with previously diagnosed bronchiectasis, COPD or asthma were excluded. Forty two (60.9%) patients had limited cutaneous SSc, whilst 27 (39.1%) of patients had diffuse form of the disease. Seventeen patients (24.6%) were tobacco-smokers, 52 (75.4%) were nonsmokers. Lung function tests, including assessment of lung diffusing capacity, were performed in all patients. Patients were considered to have small airway obstruction (SAO) when Maximum Expiratory Flow at 25% of the forced vital capacity (MEF<sub>25</sub>) was lower than 60% as predicted. We assessed the relationship of SAO in our patients with large airway obstruction, decreased lung diffusing capacity, disease duration, disease subtype, scleroderma-specific antibodies and smoking.

**Results:** SAO was noticed in 46/69 (66.6%) of patients with SSc. Restrictive lung disease was found in 4/69 (5.8%), obstruction of large airways in 18/69 (26.1%) and decreased lung diffusing capacity in 47/69 (68.1%) of patients. No difference in gender, age, disease duration, disease form and scleroderma-specific antibodies was found between patients with and without SAO. 18/46 (39.1%) patients with SAO had decreased FEV<sub>1</sub> and FEV<sub>1</sub>/FVC, indicating presence of coexistent large airway obstruction. Indeed, all patients with signs of obstructive lung disease on spirometry, had associated SAO. Moreover, MEF<sub>25</sub> correlated significantly with FEV<sub>1</sub> (ρ=0.54, p<0.001), FEV<sub>1</sub>/FVC (ρ=0.74, p<0.001), PEF (ρ=0.29, p=0.02) and MEF<sub>50</sub> (ρ=0.80, p<0.001) in our patients with SSc. However, 28/46 (60.9%) SSc patients with SAO did not have signs of concomitant large airway obstruction. 20/46 (43.5%) patients had associated decreased lung diffusing capacity, whilst 8/46 (17.4%) of patients had isolated SAO. We have found that tobacco-smokers among SSc patients with SAO have more common associated obstructive lung disease on spirometry (58.8% vs 15.4%, p=0.004), and have a significantly lower mean value of MEF<sub>25</sub> compared to non-smokers (32.1%±7.1% vs. 45.4±11.6%, p=0.001). On the other hand, isolated SAO, and SAO associated with impaired diffusing capacity was equally frequent among smokers and non-smokers.

**Conclusions:** Patients with SSc have commonly SAO. It can be considered as clinical feature of undiagnosed asthma or COPD, if associated with large airway obstruction, especially in tobacco-smokers. On the other hand, isolated SAO or associated with decreased lung diffusing capacity was found to be not related to smoking, and may indicate a possible prominent bronchiolar involvement within SSc related interstitial lung disease.

### PERFORMANCE OF EULAR/ACR 2017 IDIOPATHIC INFLAMMATORY MYOPATHIES CLASIFICATION CRITERIA IN A REAL WORLD COHORT

R.A. Gómez, A. Brailard Pocard, M. Pino, G. Medina, D. Dubinsky. *HTAL DE CLÍNICAS, Ciudad Autónoma de Buenos Aires, Argentina*

**Background:** Idiopathic Inflammatory Myopathies (IIM) are a heterogeneous group of multisystemic diseases. It includes Polymyositis (PM), Dermatomyositis (DM) with its clinically amioopathic variant (CADM), the antisynthetase syndrome (ASS), the inclusion body myositis (IBM), Immune-mediated necrotising myopathy (IMNM), the juvenile variants of DM/PM and the connective tissue disease-myositis overlap (CTD-OM).

Distinction between subtypes is made on grounds of clinical features, histologic findings at muscle biopsy and presence of certain autoantibodies.

Multiple classification criteria had been proposed through time, EULAR/ACR been the most recent. However, their performance in patients from common practice in Latin America had not been widely evaluated.

In our practice, access to muscle biopsy and electromyogram (EMG) is not always available

**Objectives:** To evaluate the performance of the EULAR/ACR 2017 IIM classification criteria in a real world cohort and compare it with the performance of other classification criteria

**Methods:** Retrospective study. IIM patients defined by expert opinion followed in our centre between October 2007 and November 2017 were included.

The patients were classified clinically in DM, CADM, PM, ASS and CTD-OM. Patients with positive antisynthetase antibodies were reclassified as ASS.

Availability of EMG, muscle biopsy and anti Jo-1 antibodies was evaluated. Bohan & Peter (1975) Tanimoto (1995) y EULAR/ACR (2017) criteria were applied to the population

**Results:** 60 patients were included. DM 20 (33.3%), CADM 4 (6.66%), PM 4 (6.66%), ASS 10 (16.66%) y CTD-OM 22 (36.66%). Muscle biopsy available 14/60 (23.33%), EMG available 33/60 (55%) and anti Jo-1 determination available in 57/60 (95%).

In general, 12/60 (20%) classified as defined disease by Bohan and Peter criteria, 29/60 (48.3%) by Tanimoto criteria and 34/60 (56.6%) by EULAR/ACR 2017 criteria.

Extending the classification to probable besides defined, 38/60 (63.3%) met Bohan and Peter criteria and 51/60 (85%) met EULAR/ACR criteria.

Table 1 shows percentage of patients meeting each criteria set by clinical subtype.

Patients with available muscle biopsy (n=14) were subanalyzed: 11/14 (78.6%) muscle biopsy were compatible with IIM (3 not compatible, but previously treated). DM 3/11 (28.6%), ASS 1/11 (7.14%) y CTD-OM 7/11 (50%). 7/11 (50%) met Bohan and Peter criteria, 8/11 (78.6%) met Tanimoto criteria and 8/11 met EULAR/ACR criteria. If extended to probable cases, 11/11 (100%) met Bohan and Peter criteria and 10/11 (91%) EULAR/ACR criteria.

Table 1 Fulfillment of different criteria set by IIM subtype

	Bohan & Peter (%)			Tanimoto (%)	EULAR/ACR (%)		
	Probable	Definite	Total		Probable	Definite	Total
DM (n=20)	60	25	85	35	10	85	95
CADM (n=4)	0	0	0	0	25	75	100
PM (n=4)	75	0	75	50	50	0	50
ASS (n=10)	50	10	60	80	30	70	100
CTD-OM (n=22)	27,3	27,3	54,6	54,50%	41	31,8	72,8
DM/CTD-OM (n=4)	25	50	75	75	0	100	100
PM/CTD-OM (n=18)	27,8	22,2	50	55,5	50	18,6	66,6

**Conclusions:** EULAR/ACR<sup>2017</sup> performed especially well for DM, and were the only criteria set met by CADM patients.

PM patients failed to meet Bohan and Peter and EULAR/ACR criteria for definite disease, probably due to low availability of EMG and muscle biopsy. This was similar for pure PM and PM/CTD-OM.

Tanimoto criteria were the most sensitive for classification of ASS patients, which could be explained because they consider arthritis among clinical features.

When considering probable and defined cases, EULAR/ACR criteria were highly sensitive in this real world cohort

#### THU0423 EPIDEMIOLOGY AND SURVIVAL OF SYSTEMIC SCLEROSIS-SYSTEMIC LUPUS ERYTHEMATOSUS OVERLAP SYNDROME

S. Alharbi<sup>1,2,3,\*</sup>, Z. Ahmad<sup>2</sup>, A. Bookman<sup>1</sup>, Z. Touma<sup>1,4</sup>, J. Sanchez-Guerrero<sup>1,2</sup>, N. Mitsakakis<sup>4,5</sup>, S.R. Johnson<sup>1,2,4</sup>. <sup>1</sup>Toronto Scleroderma Program, Division of Rheumatology, Toronto Western Hospital, University Health Network; <sup>2</sup>Division of Rheumatology, Mount Sinai Hospital, University of Toronto, Toronto, Canada; <sup>3</sup>Taibah University, Medina, Saudi Arabia; <sup>4</sup>Institute of Health Policy, Management and Evaluation; <sup>5</sup>Toronto Health Economics and Technology Assessment Collaborative, University of Toronto, Toronto, Canada

**Background:** Systemic sclerosis (SSc) is an immune disorder characterised by vasculopathy and fibrosis that may overlap with another disease such as systemic lupus erythematosus (SLE). Little is known about the epidemiology, clinical characteristics, and survival of SSc-SLE overlap (also called lupoderma). We evaluated the prevalence of SSc-SLE overlap syndrome, differences in SSc clinical characteristics and survival compared with SSc without SLE.

**Methods:** A cohort study was conducted including subjects who fulfilled the ACR-EULAR classification criteria for SSc and/or the ACR criteria for SLE. The primary outcome was the time from diagnosis to death from all causes. Survival was evaluated using Kaplan Meier curves and Cox Proportional Hazard models.

**Results:** We identified 1252 subjects (SSc n=1166, SSc-SLE n=86) with a SSc-SLE prevalence of 6.8%. SSc-SLE were younger at diagnosis (37.9 years versus 47.9 years, p<0.001), more frequently had lupus anticoagulant (6% versus 0.3%, p<0.001), anticardiolipin antibody (6% versus 0.9%, p<0.001), and pulmonary arterial hypertension (PAH) (52% versus 31%, p<0.001). SSc-SLE less frequently had calcinosis (13% versus 27%, p=0.007), telangiectasia (49% versus 75%, p<0.001) and diffuse subtype (12% versus 35%, p<0.001). There were no significant differences in the occurrence of renal crisis (7% versus 7%), interstitial lung disease (40% versus 34%), and digital ulcers (38% versus 32%). SSc-SLE had better survival (median 26.1 versus 22.4 years), but this was not statistically significant (log rank p=0.06). Female sex and diffuse subtype attenuated survival differences between groups (Hazard Ratio 0.70, 95% CI 0.45, 1.11).

**Conclusions:** SSc-SLE are younger at diagnosis, more frequently have PAH, and less frequently have cutaneous manifestations of SSc. SSc-SLE patients should be monitored for pulmonary hypertension, interstitial lung disease, renal crisis and digital ulcers.

**Disclosure of Interest:** None declared

#### THU0424 ARTICULAR INVOLVEMENT IN SYSTEMIC SCLEROSIS: COMPARISON OF CLINICAL, RADIOGRAPHIC AND SONOGRAPHIC FINDINGS

S. Thietart<sup>1</sup>, K. Louati<sup>2</sup>, E. Gaigneux<sup>2</sup>, M. Gafosse<sup>1</sup>, S. Riviere<sup>1</sup>, J. Sellam<sup>2</sup>, F. Berenbaum<sup>2</sup>, O. Fain<sup>1</sup>, A. Mekinian<sup>1</sup>. <sup>1</sup>Internal medicine; <sup>2</sup>Rheumatology, Hôpital Saint Antoine, AP-HP, Université Paris 6, 75012 Paris, France., Paris, France

**Background:** Joint involvement in Systemic Sclerosis (SSc) is frequent and varied.<sup>1,2</sup>

**Objectives:** We study US synovitis and its correlation with clinical synovitis, radiological erosions and organ involvement.

**Methods:** In a prospective cohort of SSc patients, tender and swollen joint counts, DAS28-CRP, hand US sonographies, X-ray hand views, as well as respiratory, cardiac, cutaneous and renal characteristics were assessed.

**Results:** 54 patients were included with a median age of 59 years,<sup>27-81</sup> 45 women (83%), with a diffuse cutaneous subtype in 13 patients (24%). 23 patients (52%) presented with arthralgia, 9 had clinical synovitis (16%) and DAS28-CRP of 3.7 (2.98-5.90). US sonography (34 patients) found at least one synovitis in 23 patients: 14 patients with grade 1 (66%), 6 patients grade 2 (29%), 1 patient grade 3 (5%), with a positive power Doppler signal in one case (3%). Among the patients having US-synovitis, 4 had clinical synovitis (17%), and 4 had X-ray erosions (17%). Radiological erosions were present in 8 patients (15%), without any correlation with clinical or US synovitis. Articular involvement (defined as clinical synovitis, US-synovitis and/or articular erosions) were found more frequently in limited SSc (n=28, 72%) than in diffuse SSc (n=4, 31%) (p<0.001), with a more frequent positivity of anti-centromere antibodies (n=23, 60% versus n=3, 20%). No correlation was found with disease severity or other organ impairment.

**Conclusions:** US synovitis were found more frequently than clinical synovitis, which are merely active, and did not correlate with articular destruction.

**Background:** At early stages, SSc lung involvement is characterised by Ground Glass Opacities (GGO) at High Resolution Computed Tomography (HRCT). However, HRCT scan is not able to provide functional information and to discriminate between an "active inflammatory" and an "established fibrotic" GGO. 18Fluoro-Deoxy-d-Glucose (18F-FDG) Positron Emission Tomography/Computed Tomography (PET/CT) is able to detect metabolic activity picking up inflammation and provides both morphologic and metabolic data.

**Objectives:** The aim of this study was to evaluate, if 18F-FDG PET/CT scan may identify the inflammatory component of GGO in SSc interstitial lung disease.

**Methods:** Seven patients with SSc (1 male and 6 females; mean age 59.56 y ±9.15 SD; median disease duration 5 years,<sup>2-11</sup> who underwent 18F-FDG PET/CT scan because of cancer screening, were retrospectively analysed. HRCT

images analysis led to classification of pulmonary segments as "negative" (normal morphology) and "positive" (GGO). Furthermore, the "Warrick score" was used as a staging tool for SSc-ILD. Mean Standardised Uptake Value (mSUV) of segmental parenchyma was normalised (nmSUV) by comparison with the values of selected control subjects.

**Results:** No SSc patient was affected by cancer. Three patients had a Warrick Score >0, while 4 patients did not have any lung involvement (Warrick Score=0). The 3 patients with a Warrick Score >0 had also skin involvement with a median mRSS 6 (2–7) and pathological lung FDG uptake. In "positive" segments of SSc patients, nmSUV was significantly higher than in the lung segments of the control population (mean estimation 1.53; C.I. 1.42–1.65,  $p<0.0001$ ). In "negative" segments of SSc patients, with a Warrick score >0, the nmSUV was significantly higher than in segments of the control population (mean estimation 1.29; C.I. 1.22–1.37,  $p<0.0001$ ). Lung segments with GGO showed an nmSUV higher (21%) than "negative" segments (C.I. 0.13–0.28,  $p<0.0001$ ) of patients with Warrick score >0. "Negative" lung segments of patients with Warrick Score >0 showed a 32% higher 18F-FDG uptake than "negative" lung segments of patients with Warrick Score=0. (C.I. 0.17–0.48,  $p<0.0001$ ). (figure 1)

**Abstract THU0425 – Figure 1.** a) Differences in 18F-FDG uptake between "positive" segments of Warrick score >0 SSc patients, "negative" segments of Warrick score >0 SSc patients and "negative" segments of Warrick score=0 SSc patients vs attended normalised control value (=1); b) Differences in 18F-FDG uptake between "positive" lung segments of SSc patients with Warrick score>0 vs "negative" segments of the same patients; c) Differences in 18F-FDG uptake "negative" lung segments of patients with Warrick Score>0 vs "negative" lung segments of patients with Warrick Score=0

**Conclusions:** Morphologically "positive" GGO segments show an increased 18F-FDG uptake suggesting the existence of a metabolically active (inflammatory) GGO. However, in patients with GGO, negative lung segments showed a higher nmSUV than negative lung segments in patients without GGO. This may suggest that PET/CT may disclose an underlying inflammatory process, which cannot yet be evidenced by HRCT. Further studies on a larger population are warranted to confirm these data and possibly provide a prognostic significance of PET/CT positivity in SSc patients.

#### THU0426 ETHNIC VARIATION IN SYSTEMIC SCLEROSIS MORBIDITY AND MORTALITY

H. Al-Sheikh, Z. Ahmad, S.R. Johnson. Toronto Scleroderma Program, Division of Rheumatology, Department of Medicine, Sinai Health Systems, University Health Network, University of Toronto, Toronto, Canada

**Background:** Systemic sclerosis (SSc) is an uncommon connective tissue disease characterised by pathological skin thickening and can involve multiple internal organs. Ethnic variations in SSc have been reported in clinical manifestations, severity of the disease as well as survival.

**Objectives:** Our aim was to compare the survival and disease manifestations across ethnicity among SSc patients.

**Methods:** The Toronto Scleroderma Program is the largest single-centre, multi-ethnic, longitudinal SSc cohort in Canada. Patients are followed every 6 to 12 months using a standardised protocol. Patients who fulfilled the American College of Rheumatology-European League Against Rheumatism classification criteria for SSc and are 16 years of age or older were included in our retrospective cohort study. The study period was 1970–2017. Ethnicity was self-reported and was categorised as: Caucasian, African-American, Hispanic, Arab, East-Asian, First Nations or Persian. The primary outcome was the time from diagnosis to death from all causes. Secondary outcomes were differences in disease duration, SSc subtype, clinical manifestations, and serology. Survival probabilities and median survival times were determined using Kaplan-Meier survival curves. Cox proportional hazard models were used to estimate adjusted survival.

**Results:** 1005 subjects were evaluated, the majority of whom were Caucasian ( $n=745$  (74%), African-American  $n=58$  (6%), South Asian ( $n=69$  (7%)), and East Asian ( $n=80$  (8%)). Compared to Caucasians, East Asians less frequently had calcinosis (29% versus 9%,  $p=0.002$ ), and esophageal dysmotility (88% versus 69%,  $p=0.002$ ); African-Americans more frequently had interstitial lung disease (31% versus 53%,  $p=0.007$ ); and First Nation subjects more frequently had diffuse cutaneous disease (35% versus 56%,  $p=0.02$ ) and diabetes (5% versus 33%,  $p=0.03$ ). There were no differences across ethnicities in the prevalence of pulmonary hypertension, renal crisis, or digital ulcers.

We found no difference in the short-term survival across ethnicities. However, in the long-term, there was trend for Hispanic subject to have better survival (81.3% (95%CI 63, 100), while First Nations (58.3% (95%CI 25, 100) and South Asian subjects (52.6% (95%CI 32, 87) had worst survival at 15 years and 20 years, respectively. East Asians appear to have the longest median survival time 43.3 years.

**Conclusions:** Ethnic variations in disease SSc disease manifestations are observed. However, in the setting of a universal health care system, this does not result in significant differences in survival.

**Disclosure of Interest:** None declared

#### THU0427 COMPARABLE CARDIOVASCULAR DISEASE AND NEOPLASM RATES BUT HIGHER FREQUENCY OF DEPRESSION IN SYSTEMIC SCLEROSIS VERSUS RHEUMATOID ARTHRITIS: A MULTICENTRE COMPARATIVE STUDY OF COMORBIDITIES

S. Panopoulos<sup>1</sup>, M.G. Tektonidou<sup>1</sup>, A. Drosos<sup>2</sup>, S.-N. Lioussis<sup>3</sup>, T. Dimitroulas<sup>4</sup>, L. Sakkas<sup>5</sup>, D. Boumpas<sup>1</sup>, P. Voulgari<sup>2</sup>, D. Daoussis<sup>3</sup>, K. Thomas<sup>1</sup>, G. Georgiopoulos<sup>1</sup>, G. Vosvotekas<sup>4</sup>, D. Vassilopoulos<sup>1</sup>, P.P. Sfikakis<sup>1</sup>. <sup>1</sup>Joint Rheumatology Program, School of Medicine, National and Kapodistrian University of Athens, Athens; <sup>2</sup>Rheumatology Clinic, Department of Internal Medicine, Medical School, University of Ioannina, Ioannina; <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, Faculty of Medicine, University of Patras, Patras; <sup>4</sup>4th Department of Internal Medicine, School of Medicine, Hippokraton Hospital, Aristotle University of Thessaloniki, Thessaloniki; <sup>5</sup>Department of Rheumatology and Clinical Immunology, Faculty of Medicine, School of Health Sciences, University of Thessaly, Larissa, Greece

**Background:** An increased burden of comorbid conditions negatively impacts patients' outcomes, leads to increased mortality and seems to characterise all chronic systemic connective tissue diseases. Systemic Sclerosis (SSc) is associated with the highest mortality rate comparing to other diseases, whereas data regarding epidemiology and clinical expression of SSc comorbidities is limited. In contrast, comorbidities of rheumatoid arthritis (RA), and especially the increased rate of cardiovascular disease, are better established.

**Objectives:** To compare the prevalence of common comorbidities in SSc versus RA in a large multicentre case-control study from 5 academic centres in Greece.

**Methods:** Between 2016 and 2017 consecutive SSc patients ( $n=408$ , mean age: 58.6 years, 88% women) were matched 1:1 for age and gender with 408 RA patients. Evaluated comorbidities were dyslipidemia, diabetes mellitus, arterial hypertension, coronary artery disease, stroke, chronic obstructive pulmonary disease, osteoporosis, neoplasms and depression. Differences were examined by  $\chi^2$  test.

**Results:** The prevalence of dyslipidemia (18.4% vs 30.1%,  $p=0.001$ ) and diabetes mellitus (5.6% vs 11.8%,  $p=0.007$ ) was lower in SSc than RA patients and there was no difference regarding arterial hypertension (31.8% vs 30.6%, respectively,  $p=0.742$ ) between the two groups. Disease duration, smoking and alcohol consumption were comparable between SSc and RA groups. While there was a trend for lower prevalence of ischaemic strokes in SSc than RA (0.4% vs 2.2%,  $p=0.085$ ), comparable rates of coronary artery disease were noted (2.7% vs 3.7%,  $p=0.445$ ). No differences were found between SSc and RA patients regarding chronic obstructive pulmonary disease (5.2% vs 3.7%, respectively,  $p=0.326$ ), osteoporosis (24% vs 22%,  $p=0.668$ ) and neoplasms (1.1% vs 1.7%,  $p=0.534$ ). Depression requiring treatment was more prevalent in SSc compared to RA patients (22% vs 12%,  $p=0.001$ ).

**Conclusions:** Despite almost half prevalence of dyslipidemia and diabetes mellitus in SSc versus RA patients, the cardiovascular comorbidity burden appears to be similar between the two diseases. SSc has no higher prevalence of neoplasms than RA but a greater negative impact on quality of life, as clearly more SSc patients develop depression compared to RA patients. Acquisition of prospective data is currently underway.

**Disclosure of Interest:** None declared

#### THU0428 SKIN SCORE CHANGES IN EARLY DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS (dcSSc) PATIENTS ARE ASSOCIATED WITH OVERALL DISEASE SEVERITY

T. Nevskaya<sup>1</sup>, M. Baron<sup>2</sup>, B. Zheng<sup>2</sup>, C.A. Baxter<sup>2</sup>, D.R. Ramey<sup>4</sup>, J.E. Pope<sup>1</sup>, on behalf of Canadian Scleroderma Research Group. <sup>1</sup>Department of Medicine, Division of Rheumatology, University of Western Ontario, Schulich School of Medicine And Dentistry, London; <sup>2</sup>Division of Rheumatology, Jewish General Hospital, McGill University, Montreal, Canada; <sup>3</sup>MSD Ltd, Hoddesdon, UK; <sup>4</sup>Merck and Co., Inc., Kenilworth, NJ, USA

**Objectives:** To determine if skin changes over 2 years are associated with changes in organ involvement in early diffuse cutaneous systemic sclerosis (dcSSc).

**Methods:** dcSSc with  $\leq 5$  years disease duration followed for 2 years from the Canadian Scleroderma Research Group (CSRG) registry were studied for organ involvement using the Medsger Disease Severity Score (DSS) with  $\geq 1$  point changes (decrease or increase) considered improvement or progression, correspondingly. Other disease measures were assessed including pulmonary function, patient and physician globals, functional disability and quality of life. Modified Rodnan Skin Score (mRSS) improvement was defined as a decrease of  $\geq 5$  points and/or  $\geq 25\%$  reduction. Adjusted regression analysis, ANOVA, chi-square, t-test and Pearson's tests were used.

**Results:** Of the 128 patients, mRSS improved for 50% from 22.6 to 18.1 ( $p=0.0001$ ). More skin-improvers improved in severity of lung (39% vs 17%,  $p=0.006$ ), joint/tendon (50% vs 21%,  $p=0.017$ ), and any visceral organ involvement (renal, cardiac, pulmonary or gastrointestinal) (60% vs 27%,  $p=0.031$ ) compared to mRSS non-improvers. Skin-improvers less often developed new skin ulcers (0% vs 11%,  $p=0.015$ ) and GI disease (5% vs 18%,  $p=0.023$ ), as well as progression of joint/tendon involvement (7% vs 29%,  $p=0.02$ ). Improving mRSS correlated with changes in total Medsger's severity score (without skin domain), severity of lung, GI, and peripheral vascular disease (table 1). FVC% stabilised in skin-improvers vs. worsened by 6.5% in non-improvers,  $p=0.026$ . Physician global assessments (severity, activity, damage) HAQ-DI, and SF-36 PCS improved more with improved mRSS ( $p<0.003$ ,  $p=0.001$ ,  $p=0.005$  respectively). Improvement in Forced Vital Capacity% predicted correlated with skin improvement ( $r=0.33$ ,  $p=0.004$ ).

**Abstract THU0428 – Table 1.** Relationship between change in disease measures and change in skin score

Outcome measure	Skin-improver (n=64)	Skin non-improver (n=64)	P-value Improvers vs. Non-improvers
Total Medsger's severity score without skin domain (negative is improvement)	-2.57 $\pm$ 3.11	0.42 $\pm$ 2.98	0.002
Patient global score	-0.70 $\pm$ 2.69	0.15 $\pm$ 2.61	0.088
Physician global score:	-1.97 $\pm$ 2.50	-0.61 $\pm$ 2.63	0.003
Activity	-1.33 $\pm$ 2.54	-0.03 $\pm$ 2.04	0.002
Severity	-0.72 $\pm$ 1.87	0.77 $\pm$ 1.98	0.000
Damage			
HAQ-DI	-0.19 $\pm$ 0.64	0.18 $\pm$ 0.47	0.001

SHAQ Numeric Rating Scales:	-0.29 $\pm$ 2.59	0.00 $\pm$ 2.55	0.552
Pain	0.29 $\pm$ 2.93	0.66 $\pm$ 2.30	0.445
RP	0.32 $\pm$ 1.96	0.16 $\pm$ 2.32	0.681
Finger ulcers	-0.21 $\pm$ 3.02	0.54 $\pm$ 2.97	0.178
Gastrointestinal	0.02 $\pm$ 2.32	0.05 $\pm$ 3.34	0.950
Breathing	-0.70 $\pm$ 2.70	-0.22 $\pm$ 2.62	0.340
Overall			
SF-36 PCS	3.08 $\pm$ 9.03	-1.55 $\pm$ 8.33	0.005

**Conclusions:** Over two years, improving skin scores in dcSSc were associated with an improvement in lung disease, joint/tendon, physician global assessments, HAQ-DI, SF-36 PCS, and overall visceral organ improvement. Improvement in mRSS as a primary outcome in drug trials is likely to be concordant with improvement in organ involvement and several other disease measurement domains in early dcSSc.

#### THU0429 NAILFOLD VIDEO CAPILLAROSCOPY AND DETERIORATION OF SKIN INVOLVEMENT AND LUNG FUNCTION TESTS IN SYSTEMIC SCLEROSIS: A 3-YEAR PROSPECTIVE STUDY

V.-K. Bournia<sup>1</sup>, K. Kottas<sup>1</sup>, A. Iliopoulos<sup>2</sup>, P.P. Sfikakis<sup>1</sup>, P. Vlachoyiannopoulos<sup>1</sup>. <sup>1</sup>Joint Rheumatology Program, School of Medicine, National and Kapodistrian University of Athens; <sup>2</sup>Department of Rheumatology, Veterans Administration Hospital (NIMTS), Athens, Greece

**Background:** Nailfold video-capillaroscopy(NVC) is a non-invasive method to assess peripheral microangiopathy. Abnormal capillaroscopic patterns are almost universally found in patients with Systemic Sclerosis (SSc) and assist the diagnosis of SSc. However, little is known about the prognostic value of NVC in skin and lung involvement progression in these patients.

**Objectives:** To test the hypothesis that baseline capillaroscopic indices, as well as possible changes in capillaroscopic indices over time, correlate with deterioration in skin thickening and lung function tests in a prospective SSc cohort.

**Methods:** Fifty-five consecutive SSc patients from a tertiary care university centre (49 women, 29 limited cutaneous SSc, mean age: 50.84 $\pm$ 14.88 years, mean disease duration 6.74 $\pm$ 6.25 years) were evaluated by NVC at baseline and after a median of 3.1 years. Qualitative assessment of NVC findings permitted categorization of patients to a predominantly normal, early, active or late capillaroscopic pattern. Capillary loss, capillary dilatation, giant or ramified capillaries and microhemorrhages were further assessed using a semi-quantitative rating scale (score 0–3), derived as the mean of three fields in each of the 2nd, 3rd, 4th and 5th finger of both hands. Scoring was performed by two different assessors. Skin thickening was measured using the modified Rodnan Skin Score (mRSS). FVC and DLCO were performed within 6 months from the NVC. Deterioration in FVC and DLCO was considered clinically significant when  $>10\%$ . Between baseline and follow-up evaluation 36% of patients had been receiving both major antiproliferative and vasodilator therapy, while 15% and 29% had been receiving only antiproliferative or vasodilator therapy, respectively.

**Results:** Intraclass correlation coefficient (ICC) for interrater reliability analyses was very good for all semi-quantitative capillaroscopy scores [ICC: 0.97 (0.74–0.99) for capillary loss score, 0.94 (0.85–0.98) for dilatation score, 0.98 (0.97–0.99) for giant score, 0.94 (0.84–0.97) for microhemorrhages score], except for the ramification score [ICC: 0.52 (-0.2, -0.81)] which was excluded from all analyses. Linear regression, adjusted for age and gender, showed no association between either baseline capillaroscopy scores or of their changes and changes in mRSS over time. FVC and DLCO deteriorated in 13 and 11 patients, respectively. Binary logistic regression analysis adjusted for age and gender showed no association either baseline capillaroscopy scores or of their changes with deterioration in FVC or DLCO, with the exception of the change in microhemorrhages score, which correlated inversely with deterioration in FVC [ $p=0.013$ , Odds Ratio=0.051 (CI: 0.005–0.534)]. Regarding qualitative analysis of capillaroscopic findings, the baseline capillaroscopy pattern remained unchanged in 35, deteriorated in 15 and improved in 5 patients. No difference was found between these 3 groups regarding change in mRSS (ANOVA,  $p=0.634$ ), deterioration in FVC ( $\chi^2$  test,  $p=0.502$ ) or deterioration in DLCO ( $\chi^2$  test,  $p=1.00$ ).

**Conclusions:** Although a possible confounding effect of treatment cannot be excluded, NVC seems to have poor prognostic value for the progression of skin thickening and interstitial lung disease in rigorously treated SSc patients.

**THU0430 DESCRIPTION AND PROGNOSIS FACTORS OF SYSTEMIC SCLEROSIS-ASSOCIATED INTERSTITIAL LUNG DISEASE OUTCOME ON SERIAL HRCT**

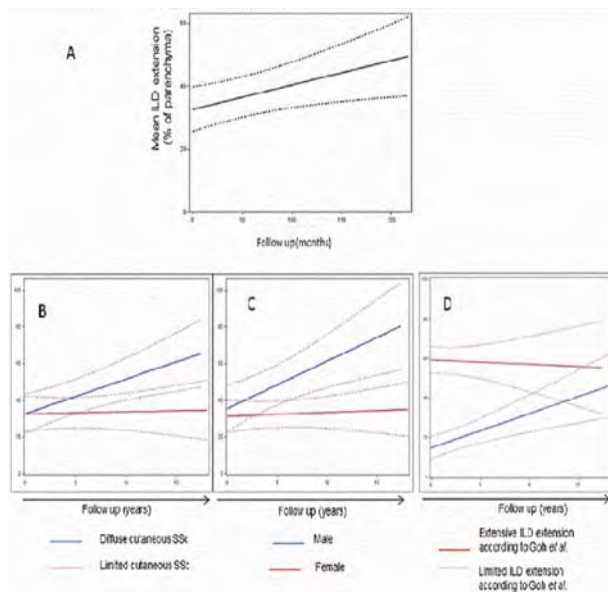

A. Forestier<sup>1</sup>, N. le gouellec<sup>2</sup>, A. duhamel<sup>3</sup>, G. kramer<sup>4</sup>, T. perez<sup>5</sup>, V. sobanski<sup>1</sup>, S. morell dubois<sup>1</sup>, M. lambert<sup>1</sup>, P.-Y. hatron<sup>1</sup>, E. hachulla<sup>1</sup>, H. behal<sup>3</sup>, R. matran<sup>5</sup>, D. launay<sup>6</sup>, M. remy jardin<sup>4</sup>. <sup>1</sup>medecine interne et immunologie clinique, chru lille, lille; <sup>2</sup>internal medicine, CH valencienne, valencienne; <sup>3</sup>UDSL, EA2694; <sup>4</sup>imagerie thoracique; <sup>5</sup>explorations fonctionnelles respiratoires; <sup>6</sup>internal medicine, chru lille, lille, France

**Background:** Interstitial lung disease (ILD) is a leading cause of morbidity and mortality in systemic sclerosis (SSc). While factors associated with the presence of ILD in SSc (SSc-ILD) are identified, those associated with ILD outcome are still debated and studies assessing the evolution of SSc-ILD on HRCT are scarce. Yet, it is important to identify patients at risk of SSc-ILD worsening because those patients are thought to benefit the most from immunosuppressants.

**Objectives:** Thus, the aims of our study were: to describe the evolution of HRCT extension and patterns of SSc-ILD, to identify baseline prognosis factors of ILD outcome on serial HRCT and to investigate whether the evolution of pulmonary function tests (PFTs) parameters correlated with the evolution on HRCT.

**Methods:** We included 58 SSc patients with HRCT proven ILD, with at least two available HRCT, and collected clinical, biological data and PFT at baseline. We collected all HRCT and PFTs available during follow-up. We modeled PFTs and HRCT evolution using linear mixed model with random coefficients.

**Results:** Mean ILD extension at baseline was 32.3%±28.7%. During a mean follow-up of 5.3±4.9 years, we found a significant mean progression of ILD extension of 0.92%±0.36% per year (p=0.018). Male sex, anti-topoisomerase 1 antibodies, diffuse cutaneous SSc were associated with faster progression of ILD extension. Limited ILD according to Goh *et al.* staging system, and a coarseness score at zero (meaning 100% of ground glass opacification) were associated with a faster progression of ILD extension. We also found a significant decline of DLCO, FVC and TLC during follow-up. There was a significant correlation between the progression of ILD extension on HRCT and the decline of DLCO, but not with the evolution of FVC.

**Conclusions:** Male patients, patients with diffuse SSc/antitopoisomerase 1, patients with less severe and less extensive ILD at baseline were more likely to experience a faster progression of ILD extension on serial HRCT. To our knowledge, this is the first study that clearly highlighted the diffuse form of SSc/presence of antitopoisomerase 1 as a worsening factor of SSc-ILD on HRCT. FVC might not be the best mirror of ILD progression while DLCO significantly correlated with change in ILD extension. Our study helps to define the profile of patients who are going to experience a progression of ILD on HRCT during follow up.

**THU0431 ARE EXTREMITY TELANGIECTASES RELATED TO SEVERE DISEASE IN SYSTEMIC SCLEROSIS ?**

Y. Yalcinkaya<sup>1</sup>, O. Pehlivan<sup>2</sup>, Z. Ertürk<sup>1</sup>, U. Gazel<sup>3</sup>, A. Aksoy<sup>1</sup>, F. Alibaz-Oner<sup>1</sup>, P. Atagunduz<sup>1</sup>, H. Direskeneli<sup>1</sup>, N. Inanc<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology, Marmara University, School of Medicine; <sup>2</sup>Department of Internal Medicine, Division of Rheumatology, Umraniye Education and Research Hospital; <sup>3</sup>Marmara University, School of Medicine, Istanbul, Turkey

**Background:** The number and morphology of telangiectases (T) have been studied in terms of severity and organ involvement in systemic sclerosis (SSc). T are located more frequently on face and trunk than extremities.

**Objectives:** We aimed to evaluate the impact of the localisation of T on different skin areas in addition to number on disease severity of SSc.

**Methods:** SSc patients fulfilling ACR/EULAR classification criteria (2013) who had the manifestation T were included. The number of T were calculated by using telangiectasia score (TS) (Shah A, et al) and localisation was classified according to presence of T on extremities or not. Simultaneously; early, active and late scleroderma patterns (Cutolo et al.) were determined qualitatively and capillary number (CN) was calculated per linear mm at distal row quantitatively by using nail fold video-capillaroscopy (NVC) in all patients.

**Results:** In 113 (106 female) SSc patients with T; the mean age was 52±12, the duration of follow-up 57±62 months, Raynaud and non-Raynaud symptom 10 ±8 and 7±7 years. Limited cutaneous form was found to be in 77 (%68), ANA positivity in 102 (%90) ve anti-Scl70 positivity in 33 (%29) patients. In SSc patients with TS score ≥6 or extremity T; the duration of non-Raynaud symptom was found to be longer (p=0010 or 0,009), MRSS and activity scores were higher (p=0004 or 0012 and p=0010 or 0,009) and severity scores of general, peripheral vascular involvement and skin were higher (p=0022 or 0,014, p=0030 or 0025 and p=0006 or 0,02), digital ulcers and flexion contractures were more frequent (p=0008 or 0035 and p=0027 or 0,032), late NVC pattern was more frequent and CN was lower (p=0001 or 0003 and p=0001 or 0,007). When patients were classified in 3 groups according to TS and presence of extremity T, differences in terms of organ involvement, disease activity and severity scores and NVC findings were summarised in table 1.

**Abstract THU0431 – Table 1.** The scores of disease activity, severity and capillaroscopy in SSc patients grouped according to TS and localisation of T.

	All patients N=113	TS ≤ 6 Extremity T(-) N=77	TS ≤ 6 Extremity T(+) N=11	TS > 6 Extremity T(-) N=25	P*
Duration of non-Raynaud's (year)	6±7	6±6	8±5	10±9	P=0,008
MRSS	7,7±6,5	6±6	9±6	11±9	P=0,013
Disease activity score (Valentin)	1,4±1,2	0,7±0,9	1,2±1,0	1,6±1,4	P=0,015
Disease severity score (Medinger)	5,6±3,7	5,3±4,1	5,9±2,6	6,4±2,7	P=0,024
severity-general	0,6±0,7	0,5±0,6	0,7±0,7	1±0,8	P=0,050
severity-PVI	1,5±0,8	1,4±0,8	1,6±0,5	1,8±0,8	P=0,023
severity-skin	1,1±0,5	1±0,5	1,2±0,4	1,3±0,6	P=0,012
Clinical findings					
digital ulcer	52(%46)	29(%38)	7(%64)	16(%64)	P=0,033
Flex contr.	16(%14)	7(%9)	2(%18)	7(%28)	NS
renal crisis	1(%1)	0(%0)	1(%9)	0(%0)	P=0,010
Low DLCO	55(%49)	33(%44)	7(%70)	15(%60)	NS
Fibrosis	48(%43)	28(%38)	7(%70)	13(%52)	P=0,028
high PAB	20(%18)	10(%13)	2(%20)	8(%32)	P=0,034
IS receivers	64(%57)	39(%54)	8(%80)	17(%68)	NS
ERA receivers	30(%27)	15(%21)	3(%33)	12(%50)	P=0,028
NVC					
Normal	7(%6)	6(%9)	0(%0)	0(%0)	NS
Early	23 (%20)	19(%25)	2(%18)	2(%8)	NS
Active	22(%19)	19(%25)	1(%9)	2(%8)	NS
Late	62(%54)	33(%43)	9(%82)	21(%84)	P<0,001
Capillary number	5,8±2,0	6,4±2,1	5±2	4,9±1,8	P<0,001

NS=not significant, MRSS=modified Rodnan skin score, PVI=peripheral involvement, IS=Immunosuppressives, ERA=endothelin receptor antagonists, \*Kruskal-Wallis H/Chi-Square tests

**Conclusions:** Disease duration was shown to be long, disease activity and severity were high and NVC findings were severe in patients with high scores of TS and extremity T. In patients with lower TS the presence of T on extremities was found to be related to severe disease. The number and localisation of T was emphasised as they are easy to evaluate in clinical practice and may be useful in determining severe patients with SSc.

**THU0432 PERICARDIAL EFFUSION IS AN INDEPENDENT FACTOR PREDICTIVE OF SCLERODERMA RENAL CRISIS**

Y. Fujisawa, S. Hara, T. Zoshima, K. Ito, I. Mizushima, H. Fuji, K. Yamada, M. Kawano. Rheumatology, Kanazawa University Hospital, Kanazawa City, Ishikawa, Japan

**Background:** Scleroderma renal crisis (SRC) adversely affects renal and patient survival in systemic sclerosis (SSc).<sup>1, 2</sup> The survival rate of SRC has been

improved dramatically by angiotensin-converting enzyme inhibitor therapy, but SRC still has a poor prognosis.<sup>3</sup> Factors predictive of SRC include early diffuse skin involvement, rapid skin thickening, anti-RNA polymerase (RNAP) III antibodies, arthralgia/synovitis, and high glucocorticoid dosage.<sup>4</sup> Although classical data have implicated pericardial effusion as another predictive factor of SRC,<sup>5</sup> its role in SRC has not been well established.

**Objectives:** To clarify the clinical impact of pericardial effusion as a predictor of SRC.

**Methods:** Ninety-five patients diagnosed with SSc at our hospital between January 2003 and December 2017 were enrolled in the study. They were divided into a pericardial effusion group (n=21) and non-pericardial effusion group (n=74), and their clinical features retrospectively compared. Cox-regression analysis was performed to identify factors predictive of SRC.

**Results:** The patients comprised 14 men and 81 women with an average age of 57.4 years (range, 14 to 82) and the mean observation period was 65 months (range, 1 to 125). Pericardial effusion was detected in 21 of 95 (22.1%) cases. In the pericardial effusion group, SRC, modified Rodnan's total skin thickness score (mRSS), C-reactive protein, maximum glucocorticoid dose, proteinuria, finger apex ulcers, and interstitial pneumonia were significantly more prevalent compared to the non-pericardial effusion group. Cox regression analysis indicated that pericardial effusion (hazard ratio; HR 11.8 [95% CI 1.6–84.6], p=0.014) and anti-RNAP III antibodies (HR 11.1 [95% CI 2.0–59.6], p=0.005) were independent risk factors for SRC, while mRSS (HR 1.0 [95% CI 0.9–1.1], p=0.12), finger apex ulcers (HR 0.57 [95% CI 0.073–4.2], p=0.57), max glucocorticoid dose (HR 1.0 [95% CI 0.9–1.0, p=0.89]), and interstitial pneumonia (HR 0.9 [95% CI 0.2–3.7], p=0.96) were not. In the Kaplan-Meier method, SRC was significantly increased in the pericardial effusion group compared to non-pericardial effusion group (p<0.0001 by log rank test).

**Conclusions:** Pericardial effusion is another independent factor predictive of SRC in addition to anti-RNAP III antibodies.

### THU0433 THE PREVALENCE OF SPONDYLOARTHROPATHY IN PATIENTS WITH TAKAYASU ARTERITIS

S. Güzel<sup>1</sup>, B. Armağan<sup>2</sup>, Ö. Varan<sup>3</sup>, A. Erden<sup>2</sup>, H. Küçük<sup>4</sup>, H. Babaoğlu<sup>3</sup>, N. Atas<sup>3</sup>, L. Kılıç<sup>2</sup>, B. Göker<sup>3</sup>, S. Haznedaroğlu<sup>3</sup>, M. A. Öztürk<sup>3</sup>, U. Kalyoncu<sup>2</sup>, A. Akdoğan<sup>2</sup>, A. Tufan<sup>3</sup>. <sup>1</sup>Internal Medicine, Gazi University, <sup>2</sup>Rheumatology, Hacettepe University, <sup>3</sup>Rheumatology, Gazi University, Ankara, <sup>4</sup>Rheumatology, Education and Training Hospital, Erzurum, Turkey

**Background:** Takayasu arteritis (TA) is characterised by inflammation of large arteries causing stenosis, occlusion, dilatation and/or aneurysm of affected vessels. TA is most commonly seen in younger women between 20–30 ages. Etiopathogenesis of TA is largely unknown although evidence suggest complex interplay between environmental and genetic factors such as HLA (human leukocyte antigen) groups. The coexistence of TA with spondyloarthropathies (SPA) has been reported in limited case series, raising hypotheses about shared pathogenetic mechanisms.

**Objectives:** To determine prevalence of spondyloarthropathy in patients with TA.

**Methods:** Detailed clinical and demographic features of TA patients were recorded and all were screened for the presence of SPA following recommendations of (ASAS). Patients were questioned for inflammatory back pain, enthesitis, uveitis, inflammatory bowel disease, peripheral arthritis, and investigated accordingly with HLA-B27, plain X-rays of pelvis and sacroiliac magnetic resonance imaging. Radiographic spondyloarthritis was reported in case of bilateral grade  $\geq 2$  or unilateral grade  $\geq 3$  sacroiliitis.

**Results:** There were 65 patients (61 female, 4 male) in the cohort. Mean age was 43±13 years and age at the diagnosis of TA was 35±13 years. Inflammatory bowel disease, psoriasis and psoriatic arthritis were observed in four, three and one patients. Chronic axial pain was reported by 26 (40%) patients but inflammatory back pain was evident in 13 (20%) patients. Chronic arthritis was observed in 4 patients. HLA-B27 was positive in three patients. Six patients were diagnosed as radiographic SPA and 3 were diagnosed as non-radiographic SPA. In sum nine patients were diagnosed as SPA (14.2%).

**Conclusions:** Our study demonstrated that SPA is common in patients with Takayasu arteritis suggesting shared pathogenetic mechanisms.

### THU0434 PREDICTORS OF LONG-TERM GLUCOCORTICOID THERAPY IN POLYMYALGIA RHEUMATICA: DISCONTINUATION IS MORE COMMON FOR PATIENTS TREATED WITH AMINOBISPHOSPHONATES

A. Giollo, F. Bettini, F. Ghellere, O. Viapiana, L. Idolazzi, D. Gatti, M. Rossini. *Rheumatology Unit, Department of Medicine, University of Verona, Verona, Italy*

**Background:** Glucocorticoids (GCs) are the cornerstone of polymyalgia rheumatica (PMR) therapy. Although guidelines for PMR generally recommend tapering GCs after 12–24 months, most patients are unable to discontinue GCs within the recommended time-frame. However, glucocorticoid-related adverse events can occur in up to 85% of treated cases. Patients treated with GCs should receive aminobisphosphonates (N-BPs) for the prevention of GCs-induced osteoporosis.

**Objectives:** In this retrospective observational study, we aimed to establish: 1) the proportion of patients with PMR who do not discontinue GCs, and 2) whether the use of N-BPs may be associated with a discontinuation of GCs.

**Methods:** Data were collected from electronic medical records of Rheumatology Unit at Azienda Ospedaliera Universitaria Integrata (AOUI) Verona, Italy. Patients were eligible for inclusion if they fulfilled the 2012 EULAR/ACR classification criteria for PMR. The following exclusion criteria were applied: a history of large vessel vasculitis and other diagnoses that could explain the symptoms. The main outcome was the long-term use of GCs, defined as a patient still receiving active treatment with GCs at the last evaluation available. Putative predictors included age, sex, dosage of prednisone, inflammatory markers (ESR and CRP), haemoglobin, peripheral joint involvement, use of DMARDs, number of relapses, osteoporosis and use of N-BPs. Univariable and multivariable Cox regression analyses were used to examine the association between several predictors and the outcome.

**Results:** 385/467 patients screened were eligible (median age 72 years [IQR 66–78], 64% females). Peripheral joint involvement was detected in 29%; 22% received DMARDs. The initial prednisone dose (median daily dose 20 mg<sup>13–25</sup>) was correlated with age, haemoglobin, CRP and ESR. More than 60% of patients were treated with N-BPs, of whom only 26% were diagnosed with osteoporosis. The median follow up time was 38 months [IQR 9–57]. Disease relapse occurred in 307/467 patients (80%). GCs were discontinued in 47% after a median time of 20 months [IQR 14–27], but were restarted in 39%. At the last evaluation, 276 patients (72%) were still receiving active treatment with GCs (median daily dose 5 mg [IQR 0–8]). Multiple Cox regression analysis showed that older age (HR 1.02, 95% CI 1.00–1.04, p=0.006) and higher CRP at baseline (HR 1.24, 95% CI 1.10–1.40, p=0.001) were associated with the long-term use of GCs, whereas significant predictors of a shorter treatment duration were the use of N-BPs (HR 0.66, 95% CI 0.50–0.88, p=0.004; figure 1) and a higher initial prednisone dose (HR 0.98, 95% CI 0.96–0.99, p=0.002).

**Abstract THU0434 – Figure 1.** Risk function of long-term GC use for the use of antiresorptive medications.

Adjusted HR 0.66 (95% CI: 0.50, 0.88), p=0.004.

**Conclusions:** Unlike current guidelines, in clinical practice a long-term treatment with GCs is often necessary in PMR. There is need to investigate novel treatments for PMR. This preliminary data suggests that aminobisphosphonates may have a role in the management of PMR.

**THU0435** **LONG-TERM OUTCOME AND PROGNOSIS FACTORS OF COMPLICATIONS IN THROMBOANGIITIS OBLITERANS (BUERGER'S DISEASE): A MULTICENTER STUDY OF 224 PATIENTS**

A. Le Joncour<sup>1</sup>, S. Soudet<sup>2</sup>, A. Dupont<sup>3</sup>, O. Espitia<sup>4</sup>, F. Koskas<sup>5</sup>, P. Cluzel<sup>6</sup>, P.-Y. Hatron<sup>2</sup>, P. Cacoub<sup>1</sup>, M. Resche-Rigon<sup>3</sup>, M. Lambert<sup>2</sup>, D. Saadoun<sup>1</sup>.

<sup>1</sup>Département de médecine interne et immunologie clinique, Hôpital de la Pitié Salpêtrière, Paris; <sup>2</sup>Département de Médecine Interne et Immunologie Clinique, CHU Lille, Lille; <sup>3</sup>Département de Biostatistiques, CHU Saint Louis, Paris; <sup>4</sup>Département de Médecine interne, CHU Hôtel Dieu, Nantes; <sup>5</sup>Département de chirurgie vasculaire; <sup>6</sup>Département d'imagerie cardio vasculaire et interventionnelle, Hôpital de la Pitié Salpêtrière, Paris, France

**Background:** Buerger's disease or thromboangiitis obliterans (TAO) is a non-atherosclerotic arteritis of distal extremities. Data regarding long term outcome of patients with Buerger's disease or thromboangiitis obliterans (TAO) are lacking and most series come from Middle-East and Far-East.

**Objectives:** We aim report clinical presentation and assess long-term outcome and prognosis factors in a large cohort of TAO.

**Methods:** Retrospective multicenter study of characteristics and outcomes of 224 TAO patients fulfilling Papa's and/or 5 Shinoya's criteria were analysed. Factors associated with vascular event free survival and amputation free survival were identified.

**Results:** The median age at diagnosis was 38.5<sup>32-46</sup> years, 51 (28.5%) patients were female and 81.5% were Caucasians. All but 3 were smokers with a median of 22 pack-year and 22.8% were also addict to cannabis. At diagnosis, 53% had claudication, 73% trophic disorders and 8.8% an infection. Lower extremities and upper extremities were affected in 54% and 28% respectively. Superficial vein thrombosis, Raynaud's phenomenon and arthralgia occurred in 18%, 41% and 8%, respectively.

Ethnic group (non-Caucasian) and ischaemic ulcers or necrosis were independent factors of vascular events HR=7.67 [3.1-19.2] p=0.005 and 2.28 [1.3-4] p<0.001. At 15 years, amputation-free survival and major amputation-free survival were 66% and 91%, respectively. Infection was the only independent predictive factor of amputation HR=4.6[1.9-11], p<0.001. Age, sex and cannabis addiction were not associated with events or amputation. Patient who stopped their tobacco consumption had lower vascular event (p=0.029) and amputation rate (p=0.001) than those who continued. Three patients died during follow-up.

**Conclusions:** This nationwide study shows that 34% of TAO patients will experience an amputation within 15 years from diagnosis. We identified specific characteristics that identified those at highest risk for subsequent vascular complications.

**Disclosure of Interest:** None declared

**THU0436** **INCIDENCE, PREVALENCE, MORTALITY AND CHRONIC RENAL DAMAGE OF ANCA-ASSOCIATED GLOMERULONEPHRITIS IN A 20 YEAR POPULATION-BASED COHORT**

A. Berti<sup>1,2</sup>, E. Cornec-Le Gall<sup>3</sup>, D. Cornec<sup>4</sup>, E. Matteson<sup>5</sup>, C.S. Crowson<sup>6</sup>, S. Sethi<sup>3</sup>, F. Fervenza<sup>3</sup>, U. Specks<sup>4</sup>. <sup>1</sup>Unit of Immunology, Rheumatology, Allergy and Rare Diseases, IRCCS San Raffaele Scientific Institute, Milan; <sup>2</sup>Rheumatology Clinic, Santa Chiara Hospital, Trento, Italy; <sup>3</sup>Nephrology Department; <sup>4</sup>Pulmonary and Critical Care Medicine; <sup>5</sup>Rheumatology Department; <sup>6</sup>Division of Biomedical Statistics and Informatics, Mayo Clinic, Rochester, USA

**Background:** True population-based incidence rates of ANCA-associated glomerulonephritis (AAGN) are lacking.

**Objectives:** We aimed to estimate incidence, prevalence and mortality of AAGN, and to assess if the grade of chronic renal damage at presentation predicts renal and non-renal outcomes.

**Methods:** A population-based incident cohort of 57 Olmsted County residents diagnosed with ANCA-associated vasculitis (AAV) in 1996-2015 was identified

by medical record review. AAGN was defined as an increase in creatinine >30% and/or a decrease in estimated glomerular filtration rate >25%, and/or the presence of urine red cell casts or hematuria and/or biopsy-proven necrotizing and/or crescentic glomerulonephritis. Incidence rates were age- and sex-adjusted to the 2010 US white population. Age- and sex-adjusted prevalence was calculated for January 1, 2015. Survival rates were compared with expected rates in Minnesota population. Chronic renal damage was assessed by chronicity score (CS) on biopsies performed at diagnosis.

**Results:** Thirty-four (60%) patients had AAGN. Of these, 65% had microscopic polyangiitis (MPA), and 74% were myeloperoxidase (MPO)-ANCA-positive. The annual incidence of AAGN was 2.0/100,000 population (95% CI:1.3-2.7), the overall prevalence was 35/100,000 (95%CI:24-47). Mortality for AAGN was increased (p<0.001), whereas mortality for AAV without glomerulonephritis did not differ from the general population. Minimal/mild CS predicted recovery of renal function at 1 year (p=0.035; **figure 1A**); clinical diagnosis (granulomatosis with polyangiitis (GPA) versus MPA) and ANCA-specificity (proteinase 3(PR3)-AAV versus MPO-AAV) did not (**figure 1B-C**).

**Conclusions:** Annual incidence and prevalence of AAGN in Minnesota are 2.0/100,000 and 35/100,000, respectively. Mortality is worse compared to AAV patients without glomerulonephritis. More advanced renal damage at diagnosis predicts less renal recovery.

**ILLNESS PERCEPTION AND ITS CORRELATES IN PATIENTS WITH IN ANCA-ASSOCIATED VASCULITIS – PRELIMINARY REPORT**

A. Masiak<sup>1</sup>, K. Nowicka-Sauer<sup>2</sup>, D. Banaszekiewicz<sup>3</sup>, B. Grygiel-Gómiak<sup>4</sup>, M. Komomiczak<sup>5</sup>, A. Hajduk<sup>1</sup>, Z. Zdrojewski<sup>1</sup>. <sup>1</sup>Clinic of Internal Medicine, Connective Tissue Diseases and Geriatrics, Medical University of Gdansk; <sup>2</sup>Department of Family Medicine, Medical University of Gdansk; <sup>3</sup>Department of Statistics, Faculty of Management, Gdansk University, Gdansk; <sup>4</sup>Department of Rheumatology and Internal Medicine, Medical University of Karol Marcinkowski, Poznan; <sup>5</sup>Department of Nephrology, Transplantology and Internal Diseases, Medical University of Gdansk, Gdansk, Poland

**Background:** Illness perception (IP) is one of the most important factors related to health related quality of life, psychological and physical functioning and medical adherence.<sup>1,2</sup>

**Objectives:** To explore illness perception and its relationship with chosen clinical, socio-demographic and psychological variables in patients with granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA).

**Methods:** 38 patients (57.9% women; median age 57 years; range 18–85; median disease duration: 11.5, range: 1–248 months) with GPA (28 patients) and MPA (10 patients). Inpatients recruited in 3 clinical centres were asked to complete Brief-Illness Perception Questionnaire (B-IPQ),<sup>3</sup> Hospital Anxiety and Depression Scale-Modified (HADS-M) and Multidimensional Fatigue Inventory-20 (MFI-20). Socio-demographic variables included age, sex, education and marital status. Medical files were reviewed to gather data on disease duration and its activity (assessed using Birmingham Vasculitis Activity Score version 3, BVASv3). p<0.05 was considered significant.

**Results:** 63% of patients had active disease as defined by BVASv3. Median total score of B-IPQ was 48.5 points (range 24–64). There were no significant differences in illness perception (B-IPQ total score) between groups according to sex, education and marital status. No significant relationships between IP and age, disease duration and its activity were noted. Significant positive correlations were observed between B-IPQ total score and MFI-20 total score, general, physical and mental fatigue as well as depression, anxiety and irritability (table 1).

**Abstract THU0437 – Table 1.** Correlation coefficients between studied variables and B-IPQ results.

Variable	Spearman's r correlations
Age	0.06
Disease duration	-0.02
BVASv3	0.00
MFI-20 total	0.48*
General fatigue	0.48*
Physical fatigue	0.38*
Reduced activity	0.26
Reduced motivation	0.25
Mental fatigue	0.34*
Depression	0.54*
Anxiety	0.53*
Irritability	0.35*

\* statistically significant p<0,05

**Conclusions:** In the studied group illness perception was not related to clinical and socio-demographic factors. More negative illness perception was related to higher levels of fatigue, depression, anxiety and irritability. The results suggest that psychotherapeutic interventions seem vital for improving illness perception in this population.

**Objectives:** To compare the efficacy of infliximab (IFX) versus adalimumab (ADA) as first biologic drug in refractory uveitis with cystoid macular oedema (CME) associated to BD.

**Methods:** Multicenter study of 40 patients with BD-associated uveitis with CME refractory or intolerant to standard treatment (corticosteroids and at least one conventional immunosuppressive agent). CME was considered if macular thickness was greater than 300 µm. Comparative outcome measures were macular thickness, improvement of visual acuity (VA), activity of anterior chamber inflammation and vitritis. Results were expressed as mean ±SD for variables with a normal distribution, or as median [25th-75th interquartile range- IQR] when not normally distributed. The comparison of continuous variables among time-periods was performed with the Wilcoxon signed rank test.

**Results:** We selected patients with CME from a cohort of 177 patients with refractory BD-related uveitis (n=40). IFX was used in 15 cases and ADA in 25. No significant differences at baseline were observed between IFX vs ADA groups in sex (♂/♀ 8/7 vs 13/12, p=0.93), mean age (38±9 vs 41±10 years, p=0.53), HLA-B51 + (10 vs 19, p=0.87), uveitis pattern (panuveitis 67% vs 80%, posterior uveitis 33% vs 20%, p=0.34), previous conventional treatment (intravenous pulses of methylprednisolone 60% vs 52%, p=0.62, oral corticosteroids 93% vs 72%, p=0.1, methotrexate 53% vs 52%, p=0.93, cyclosporin A 73% vs 88%, p=0.23, azathioprine 53% vs 56%, p=0.86, other drugs 47% vs 68%, p=0.18), and combined treatment (67% vs 64%, p=0.86). After 1 year of therapy, ocular remission was achieved in 60% of cases with IFX and in 76% of cases with ADA (p=0.28). Regarding CME, 65% of patients with IFX reached a macular thickness <250 µm vs 87% of patients with ADA, with no statistically significant differences (p=0.07). Evolution of ocular parameters is shown in the table 1. Only 2 adverse effects were observed, both in ADA group (local rash and bacteremia).

**TABLE 1.** Rapid and maintained improvement following the onset of anti-TNF agents. Data are expressed as mean±SD or median [IQR].

**Background:** Giant cell arteritis (GCA) can be refractory to corticosteroids<sup>1-3</sup>. Tocilizumab (TCZ) demonstrated to be effective in two short-term clinical trials.

**Objectives:** To assess efficacy of TCZ in refractory GCA or with side effects to corticosteroids in clinical practice.

**Methods:** Multicenter study on 134 patients with GCA in treatment with TCZ due to lack of efficacy and/or unacceptable adverse events of previous therapy.

**Results:** 134 patients (101 w/33 m); mean age of 73.0±8.8 years. Main clinical features at TCZ onset were: PMR (n=73), constitutional syndrome (n=31), headache (n=70), visual (n=28) and jaw (n=14) affection. Besides steroids, 98 patients also received immunosuppressive agents. table 1 shows evolution during follow-up period. After a median follow-up of 12 [3.7–24] months, it was observed a decrease in: **a)**CRP from 1.7 [0.4–3.2] to 0.1 [0.0–0.3] mg/dL **b)**ESR from 33 [14.5–61] to 4<sup>2-9</sup> mm/1st hour and **c)** Prednisone dose from 15<sup>10-30</sup> to 5 [0–7.5] mg/day. Outcome of patients was: **a)**discontinuation of TCZ (n=15) due to sustained remission, **b)**dose reduction due to improvement (n=17) or side effects (n=11), **c)**withdrawal of TCZ because of side effects (n=12) and **d)**same dose that at onset (n=73). TCZ had to be discontinued due to: infections, haematological and cardiovascular alterations, neoplasms and hepatic toxicity among the most frequent.

Table 1:

	Baseline n=134	Month 1 n=132	Month 3 n=122	Month 6 n=99	Month 12 n=71	Month 24 n=39
Clinical improvement % (n#)		93.9% (124/132)	94.2% (115/122)	94.9% (94/99)	92.9% (66/71)	100% (38/39)
Laboratory markers, median [IQR]						
ESR (mm/1 <sup>st</sup> h)	33 [14.5-61]**	8 [2-12]** (102)	4 [2-7]** (116)	4 [2-6]** (98)	4 [2-6]** (71)	5 [2-16]** (39)
CRP (mg/dl)	1.7 [0.4-3.2]**	0.1 [0.0-0.3]** (98)	0.1 [0.0-0.3]** (116)	0.1 [0.0-0.2]** (92)	0.1 [0.0-0.2]** (67)	0.1 [0.0-0.1]** (38)
Hemoglobin (g/dl)	12.3 [11.4-13.2]**	11.2 [12.3-14]** (104)	13.5 [12.5-14.2]** (107)	13.8 [12.8-14.1]** (88)	13.3 [12.6-14]** (64)	13.1 [12.3-13.8]** (36)
Dose of corticosteroids (mg/day), median [IQR]	15 [10-30]** (134)	8.7 [7.5-20]** (116)	6.1 [5-12.8]** (120)	5 [2.5-7.8]** (97)	2.9 [2.6]** (71)	0 [0-5]** (38)

# Improvement in at least one of the clinical features. \* p<0.001 \*\* p<0.0001 (test de Wilcoxon).

**Conclusions:** TCZ leads to a rapid and maintained improvement in patients with refractory GCA and/or with unacceptable side effects related to corticosteroids. However, the risk of neutropenia and infection should be kept in mind.

**THU0440** SOLUBLE CTLA-4 IS ELEVATED IN PATIENTS WITH POLYMYALGIA RHEUMATICA AND CORRELATES WITH VASCULAR INFLAMMATION DETECTED BY PET/CT

D. Camellino<sup>1,2</sup>, M. Marchiano<sup>2</sup>, G. Pesce<sup>2</sup>, G. Bianchi<sup>1</sup>, M. Bagnasco<sup>2</sup>, M. A. Cimmino<sup>3</sup>, D. Saverino<sup>4</sup>. <sup>1</sup>Division of Rheumatology, Musculoskeletal System Department, Azienda Sanitaria Locale 3 Genovese, Arenzano; <sup>2</sup>Autoimmunology Laboratory, Department of Internal Medicine; <sup>3</sup>Rheumatology Clinic, Department of Internal Medicine; <sup>4</sup>Autoimmunology Laboratory, Department of Experimental Medicine, University of Genoa, Genoa, Italy

**Background:** Positron emission tomography has shown the presence of large vessel vasculitis (LVV) in 30%–40% of patients with apparently isolated polymyalgia rheumatica (PMR)<sup>[1]</sup>, but biomarkers associated with the presence of LVV in PMR patients are still lacking. Anti-cytotoxic T lymphocyte antigen-4 (CTLA-4) and its soluble (s) form, resulting from alternative splicing, are well-known immune checkpoint receptors<sup>[2]</sup> and have shown to play a role both in neoplastic<sup>[3]</sup> and autoimmune diseases<sup>[4]</sup>. The rationale for studying the involvement of CTLA-4 in PMR is provided by the evidence of drug-induced PMR/giant cell arteritis (GCA) in patients treated with ipilimumab, an anti-CTLA-4 antibody<sup>[5]</sup>.

**Objectives:** To evaluate the concentration of sCTLA-4 in PMR patients and to correlate it with vascular and joint inflammation.

**Methods:** Forty consecutive patients with of PMR, of whom 9 also had also GCA, underwent a standardised clinical examination and a PET/CT scan. Arterial and joint uptake of FDG were scored relative to liver and then summed up to obtain a total vascular score (TVS) and a total joint score (TJS). Patients were further subdivided into three groups for the analysis of the correlation with joint and vascular uptake: "vasculitic patients" (with grade-3 uptake in at least one vascular district), patients with intermediate uptake (excluded from this set of analyses), and patients without vasculitis. sCTLA-4, was evaluated by ELISA. Patients without autoimmune diseases served as controls.

**Results:** sCTLA-4 serum levels were significantly higher in PMR patients than in controls (p<0.001, figure 1), although their concentrations did not significantly differ between patients with and without vasculitis. However, sCTLA-4 showed a positive correlation with TVS (r=0.35, p=0.025), figure 1. Panel A: comparison of serum level of sCTLA-4 in patients with PMR and controls (HD: healthy donors). Panel B: correlation between sCTLA-4 and total vascular score.

**Conclusions:** The present study provides the first evidence that serum sCTLA-4 concentration is elevated in PMR patients, and that it correlates with TVS. Although the exact mechanisms underlying the upregulation of sCTLA-4 remain

elusive, we feel that aberrant production of cytokines, or abnormal activation of intercellular signalling pathways can be involved.

#### THU0441 ENDOTHELIAL DYSFUNCTION IN POLYMYALGIA RHEUMATICA

D. Birra<sup>1</sup>, L. Santoro<sup>2</sup>, S. Bosello<sup>1</sup>, A. Nesci<sup>2</sup>, G. Peluso<sup>1</sup>, G. Ferraccioli<sup>1</sup>, E. Gremese<sup>1</sup>, A. Santoliquido<sup>2</sup>, A. Zoli<sup>1</sup>. <sup>1</sup>UOC of Rheumatology, Fondazione Policlinico Universitario A. Gemelli Catholic University of the Sacred Heart; <sup>2</sup>Dipartimento di Medicina Interna, Università Cattolica del sacro cuore, Fondazione Policlinico Gemelli, Roma, Italy

**Background:** Polymyalgia Rheumatica (PMR) is an inflammatory disease that affects people over 50 years old, characterised by pain and functional limitation of shoulder and hip, acute phase reactant elevation and a dramatic response to low doses of steroids.

Atherosclerosis is a chronic inflammatory process that affects the arterial vessels of multiple districts. Endothelial dysfunction is an early event of the atherogenic process. Chronic inflammatory diseases have an increased risk of accelerated atherosclerosis and cardiovascular disease.

A study on 41 subjects with giant cell arteritis with and without PMR showed an increased mean-intimal thickness, suggesting a pro-atherogenic role of PMR. However there are no studies that evaluated endothelial dysfunction which is a more precocious marker of subclinical atherosclerosis in PMR patients

**Objectives:** Aim of the study was to compare endothelial function among PMR patients to a control population. Moreover, the trend of endothelial dysfunction was evaluated over time in relationship to the improvement of clinical, laboratory and instrumental parameters.

**Methods:** The study involved 16 treatment-naive patients with a new PMR diagnosis.

Every 3 months routine visits were performed; at each visit laboratory and clinical data and the endothelial function at the brachial artery were evaluated.

The endothelial function was evaluated at the brachial artery level after 15 min of rest; the brachial artery diameter and the basal flow was measured at baseline and after the positioning of sphygmomanometer for 5 min to induce the forearm ischemia. The flow was measured again 15 s after deflation of the sleeve and 60–90 s after the diameter of the artery reassessed to obtain flow-mediated dilatation (FMD). The FMD, which represents endothelium-dependent vasodilatation was expressed as percentage increase to the starting diameter after stimulation

**Results:** 16 PMR patients (mean age 73.9±5.8, 7 Female) were compared with a population of 16 healthy controls age-matched (70.8±8.1, p=ns).

The two groups differed for the values of Erythrocyte Sedimentation Rate (ESR) (61.1±28 vs 19.3±16 mm/h, p<0.001) and C-Reactive Protein (CRP) (35.6±28.1 mg/L vs 2.4±0.4 mg/L, p<0.001).

At the sixth month of follow-up ESR was 31.2±29.9 mm/h while CRP was 8±5.9 mg/L; at the twelve month of follow-up ESR was 22.7±13.6 and CRP was 9.1±8.2 mg/L

In PMR patients group 11 patients had hypertension, 5 dyslipidemia, 1 diabetes and 5 patients were smokers, while in control group 9 had hypertension, 10 dyslipidemia, 6 were smokers and no one had diabetes. Healthy subjects matched by age, sex and comorbidity were chosen as controls.

At baseline FMD of patients was lower than controls (6.6±3.4 vs 10.7±2.3, p<0.001). After 6 months of steroid therapy the difference between the two groups remained significant (6.1±2.7 vs 10.7±2.3 p=0.001), while at the twelfth month the two groups achieved comparable FMD values (8.7±3.6 vs 10.7±2.3, p=0.067). The FMD values show an inverse correlation with values of ESR (R=-0.42 p=0.019) and CRP (R=-0.56 p=0.001) at baseline.

**Conclusions:** Endothelial dysfunction in patients with PMR appears early during the course of the disease and is related to levels of acute phase reactant; steroid therapy gradually improves these values; only after a year of therapy comparable values are observed between patients and healthy controls.

#### THU0442 IS BEHCET'S SYNDROME GETTING Milder? A RETROSPECTIVE ANALYSIS OF INITIAL PRESENTATION FINDINGS THROUGHOUT 4 DECADES

E. Dincses<sup>1</sup>, Y. Ozguler<sup>1</sup>, D. Ucar<sup>2</sup>, Y. Ozyazgan<sup>2</sup>, S. Ugurlu<sup>1</sup>, G. Hatemi<sup>1</sup>, M. Melikoglu<sup>1</sup>, S. Yurdakul<sup>1</sup>, H. Yazici<sup>1</sup>, E. Seyahi<sup>1</sup>. <sup>1</sup>Cerrahpasa Rheumatology; <sup>2</sup>Cerrahpasa Ophthalmology, Istanbul, Turkey

**Background:** There is some evidence that incident Behcet's syndrome (BS) might be becoming less severe.<sup>1</sup>

**Objectives:** We compared clinical findings at presentation of BS patients registered in a large, long standing dedicated multidisciplinary outpatient clinic at 4 time points during a 40 years period.

**Methods:** There were 4 groups. Group 1 included patients registered in 1979–1981, Group 2 those registered in 1990, Group 3 in 2000 and Group 4 in 2010. Only demographic and clinical findings at initial presentation were recorded.

**Results:** As shown in table 1, over 4 decades, male/female ratio decreases gradually. While mean age at presentation does not change, the median disease duration got shorter. Almost all clinical manifestations except genital ulcers and neurological involvement tended to decrease in frequency. This was also true when genders were separately analysed. Importantly the severity of vascular and eye disease decreased (table 1,2). The slope of vascular disease was more obvious.

**Abstract THU0442 – Table 1.** Initial demographic and clinical characteristics of cohorts

**Conclusions:** Our observations support the notion that incident BS might be getting milder. There might be a list of explanations for this observation. 1. It might be a biological phenomenon due to changing environmental causes. In this line the significant decrease in papulopustular lesions could be due to a more sanitary environment while the rather unchanging frequency of neurologic involvement might be its possible independence from the environment. 2. It might be that the awareness of BS is increasing and we are recognising less severe cases. 3. Another explanation might be the more effective treatment these patients received before they were referred which was not specifically sought in this survey.

#### THU0443 A PROBABILITY SCORE FROM A FAST TRACK CLINIC TO AID THE MANAGEMENT OF SUSPECTED GIANT CELL ARTERITIS

F. Laskou<sup>1</sup>, F. Coath<sup>1</sup>, S. Mackie<sup>2</sup>, S. Banerjee<sup>1</sup>, T. Aung<sup>1</sup>, B. Dasgupta<sup>1</sup>.

<sup>1</sup>Rheumatology, Southend University NHS Trust, Westcliff-On-Sea;

<sup>2</sup>Rheumatology, The Leeds Teaching hospitals NHS Trust, Leeds, UK

**Background:** Diagnosis of Giant Cell Arteritis(GCA) is difficult since its manifestations are protean<sup>1</sup>. Under-diagnosis is associated with ischaemic complications whereas over diagnosis is associated with inappropriate glucocorticoids (GC)<sup>2</sup>. GCA is diagnosed by different specialties, including family physicians, who would benefit from a clinical prediction score. A fast track pathway also requires clinical triage in terms of probability of disease. We evaluated all referred patients (08/16–08/17) to develop a pre-test probability score(PTBS) to support a diagnostic pathway and decision-making.

**Methods:** The PTBS was generated from long standing clinical experience. Information collected at initial assessment was given varying positive weightage. This included baseline demographics (age-gender), symptomatology at presentation (onset, headache and scalp tenderness, ischaemic symptoms, constitutional symptoms, polymyalgia), C-Reactive protein(CRP) and examination findings (ischaemic ophthalmic complications, temporal artery abnormalities, extra-cranial abnormalities, cranial nerve palsies). Negative weightage was given for competing diagnoses (infection, cancer, head and neck pathology, systemic rheumatological diseases). The PTBS was compared with the final diagnosis as GCA or non-GCA 6 months after the initial assessment. Analysis was performed in Stata SE, version 13.1.

**Results:** 122 PTBS were collected of which CRP was missing in 1 case which was excluded from the analysis. 23 had a final diagnosis of GCA at 6 months follow up. The rest consist our control group(99 patients). The area under the ROC curve for the 121 cases was 0.953 (figure 1). Using the bootstrap method gave an estimated area under the ROC curve (95% confidence interval) of 0.953 (0.911, 0.994). At the point of inflection, corresponding to a cut point of 9.5, sensitivity was 95.7%, and specificity was 86.7%; the likelihood ratio for a positive test was 7.2 and the likelihood ratio for a negative test, 0.050. At this cut point, 88.4% cases were correctly classified.

**Conclusions:** This single centre retrospective study suggests that PTBS is a useful standardised assessment tool for rating pre-test probability for GCA with high levels of sensitivity and specificity. PTBS may reduce variation in clinical assessment and aid decision making. A patient with low probability score(<9.5) can be managed with colour doppler ultrasound examination(US) which if

negative will exclude the disease and the clinician can reassure patient. A patient with high PTBS and positive US can safely have the diagnosis confirmed and treated with GC. With intermediate scores, conflicting PTBS and US findings, equivocal US, additional investigations including TA biopsy and/or other imaging scans may be needed. Our results need validation in a prospective study and in internal and external validation cohorts. PTBS has the potential for forming the basis for education programme for the correct and early diagnosis of GCA and limit inappropriate GC in non GCA mimics.

#### THU0444 AORTIC DILATATION IN PATIENTS WITH LARGE VESSEL VASCULITIS: A LONGITUDINAL CASE CONTROL STUDY USING POSITRON EMISSION TOMOGRAPHY/COMPUTED TOMOGRAPHY

F. Crescentini<sup>1</sup>, F. Muratore<sup>1</sup>, L. Spaggiari<sup>2</sup>, G. Pazzola<sup>1</sup>, L. Boiardi<sup>1</sup>, N. Pipitone<sup>1</sup>, C. Salvarani<sup>1</sup>. <sup>1</sup>Rheumatology Unit; <sup>2</sup>Radiology Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

**Objectives:** To evaluate aortic diameter and predictors of aortic dilatation using FDG-PET/CT in a longitudinally followed cohort of patients with large vessel vasculitis (LVV) compared with controls.

**Methods:** All consecutive patients with LVV who underwent at least 2 PET/CT scans between January 2008 and May 2015 were included. The first and last PET/CT study of each patient was independently evaluated by a radiologist and a nuclear medicine physician. The diameter of the aorta was measured at 3 different levels: ascending, descending thoracic and infrarenal aorta. Aortic dilatation was defined as a diameter of >4 cm in the ascending, ≥4 cm in the descending thoracic and ≥3 cm in the infrarenal aorta. Aortic FDG uptake was graded at the same levels using a 0–3 semiquantitative scale and was reported as negative (score 0 or 1) or positive (score 2 and 3). Patients younger than 50 years at symptoms' onset were classified as Takayasu arteritis (TAK), while those older than 50 years as giant cell arteritis (GCA). 29 age- and sex-matched patients with lymphoma who underwent at least 2 PET/CT in the same time interval without evidence of aortic FDG uptake were selected as controls.

**Results:** 93 patients with LVV were included in the study. 53% of patients were newly-diagnosed; the remaining 47% had a median disease duration of 34 months. At first PET/CT, the mean (SD) diameter of descending thoracic aorta was significantly higher in LVV patients compared with controls [28.07 (4.40) vs 25.60 (3.59) mm, p=0.012]. At last PET/CT, after a median time of 31 months, patients with LVV compared with controls had higher diameter of ascending [35.41 (5.54) vs 32.97 (4.11) mm, p=0.029] and descending thoracic aorta [28.42 (4.82) vs 25.72 (3.55) mm, p=0.007] and more frequently had aortic dilatation [19% vs 3%, p=0.023]. Significant predictors of aortic dilatation were male sex [OR 7.27, p=0.001], and the diameter of ascending [OR 2.03, p<0.001], descending thoracic [OR 1.57, p<0.001] and infrarenal [OR 1.25, p=0.005] aorta at first PET/CT study. Positive aortic FDG uptake, disease activity and elevated inflammatory markers at first PET/CT were not associated with an increased risk of aortic dilatation. The results remained unchanged when the analysis were restricted to the 48 newly-diagnosed LVV patients.

According to age at symptoms onset, 56% of patients were classified as GCA and 44% as TAK. Compared with TAK, GCA patients had higher aortic diameter at all 3 levels evaluated in both first and last PET/CT study. However there were no differences in the proportion of patients with aortic dilatation (at last PET/CT 23% in GCA vs 15% in TAK, p=0.306). The results remained unchanged when the analysis were restricted to the newly-diagnosed patients.

**Conclusions:** Patients with large vessel vasculitis are at increased risk of aortic dilatation compared with age- and sex-matched controls. Significant predictors of aortic dilatation are male sex and aortic diameter at first imaging study. Positive aortic FDG uptake at first PET/CT is not associated with increased risk of aortic dilatation.

THU0445

### PRIMARY DIAGNOSIS OF LARGE VESSEL VASCULITIS BY TISSUE HISTOLOGY AFTER SURGERY OF AORTIC VALVE AND ASCENDING AORTA

G. Assmann<sup>1</sup>, I. Karlova<sup>2</sup>, F. Langer<sup>2</sup>, M. Schreiber<sup>3</sup>, M. Pfreundschuh<sup>1</sup>, H.-J. Schaefers<sup>2</sup>. <sup>1</sup>Rheumatology and Oncology; <sup>2</sup>Thoracic Surgery; <sup>3</sup>Radiology Imaging, University Medical School of Saarland, Homburg, Germany

**Background:** Large vessel vasculitis showed different histological patterns, ranging from well-formed granulomas and lymphoplasmacytic pattern to giant cell pattern. Most of entities of large vessel vasculitis belong to rheumatic diseases such as the giant cell arteritis (GCA). The clinical feature is very variable depending on the GCA manifestations.

**Objectives:** Here we present an observation study of non-vasculitis patients, which had to undergo surgery of aortic valve and/or ascending aorta with a tissue histology of aortic inflammation.

**Methods:** In the department of thoracic surgery of the University Medical School of Saarland, Germany, 1474 patients (in 2014 n=806, in 2015 n=668) underwent thoracic surgery of aortic valve or ascending aorta due to different indications such as any entity of aortic aneurysm, dissection, aortic stenosis and/or insufficiency. Patients with bacterial endocarditis were excluded from analysis. All surgical specimens were pathologically analysed according standard procedure. All specimens (n=19 in 2014, n=17 in 2015) with histological inflammation signs of aortitis being negative for tbc, mycosis, or lues were underwent further investigation searching for IgG4 +plasmacells, giant cells, and granuloma; all patients (n=36) were re-evaluated by a rheumatologist (immediately during the hospitalisation or within 3 weeks with outpatient presentation) including laboratory tests for RF, ANA, ANCA, ACCP, IgG subclasses, complement, ESR, CRP. Furthermore, all aortitis patients were investigated with MRI of aorta (n=15) or PET scan (n=17) or both (n=4) between 4 to 12 weeks after surgery to exclude persistent aortitis in native vessels. All patients which were diagnosed for aortitis through MRI and/or PET received immunosuppressive treatment containing glucocorticosteroids with or without synthetic or biological DMARDs.

**Results:** Patients after thoracic surgery of aortic valve and/or ascending aorta were positive tested for aortitis in 2014 with the frequency of 2.36% (n=19/806) and in 2015 2.54% (n=17/668). The mean age of the 36 cases were 61 (range 39–80), of them were male 55.5% (n=20). The pathologic findings described 14 cases typical for GCA, 6 with granuloma, one with IgG4 +plasmacells, and one with predominant lymphocytic infiltration, 14 with unspecific inflammation. Rheumatologic consultation in all 36 cases could evaluated in 6 patients a preexisting rheumatologic disorder (RA n=2, polymyalgia rheumatica (PMR) n=4) without treatment. One patient were positive for significant elevated serum levels of IgG4. MRI and/or PET scan documented aortitis spots in the native aorta with or without concerning iliac arteries and/or supra-aortic vessels. All imaging-positive aortitis patients (n=12) were treated with glucocorticosteroids according to the protocol for giant cell arteritis (prednisolone 1 mg/Kg/body weight), six patients additionally with methotrexate, one with tocilizumab and one with rituximab.

**Conclusions:** Only a small fraction of thoracic surgery patients with aortic aneurysm, dissection, aortic stenosis and/or insufficiency show histologic signs of aortitis. However, a third of them could be diagnosed via histological findings for active large vessel vasculitis after surgery.

THU0446

### USEFULNESS OF COLOUR DOPPLER ULTRASONOGRAPHY IN FOLLOW UP OF GIANT CELL ARTERITIS

H. Mukoyama, K. Nishimura, K. Kadoba, R. Saito, D. Waki, T. Yokota. *Department of Endocrinology and Rheumatology, Kurashiki Central Hospital, Kurashiki-shi, Okayama, Japan*

**Background:** Colour doppler ultrasonography (CDU) in temporal arteries (TA) is useful for diagnosis and follow-up of giant cell arteritis (GCA).<sup>1</sup> However, the usefulness of CDU in carotid arteries (CA) for follow-up of GCA is not fully understood.<sup>2</sup>

**Objectives:** We investigated retrospectively relationship between clinical features and vessel wall thickness of TA and CA on CDU at baseline and during follow-up.

**Methods:** We recruited patients with newly diagnosed GCA in our hospital from January in 2004 to July in 2017. Among 35 patients, both of TA and CA were evaluated by CDU before and after treatment in 14 patients (four male and 10 female). Trained ultrasonographers and rheumatologists evaluated the CDU findings. Vessel wall thickness was evaluated at thickest portion of parietal or frontal ramus of TA, where biopsy was often performed. Intima-media thickness (IMT) of CA was also evaluated at thickest portion in each carotid artery.

**Results:** Average age was 73.2±11.3 years old. Follow-up periods after starting treatment were 244±149 weeks. All patients were diagnosed as GCA according to ACR criteria (1990) or temporal artery biopsy. Twelve patients were complicated with polymyalgia rheumatica (PMR) meeting EULAR/ACR classification criteria

(2012). All patients were treated with oral glucocorticoids (0.2 to 1.0 mg/kg prednisolone, 0.886 mg/kg on average). Immunosuppressants were added in four patients (methotrexate; n=3, tacrolimus; n=1). Aspirin was prescribed in nine patients.

Eleven patients (78.6%) had circumferential hypoechoic vessel wall thickness (halo sign) of TA at baseline, and halo signs disappeared in eight patients during follow-up. Average of vessel wall thickness significantly decreased from 0.665 mm to 0.311 mm (p=0.0016). The vessel wall thickness apparently increased in two patients out of three on clinical relapse, but it didn't increase in those who kept remission.

Graphical changes consistent with vasculitis in CA were observed in six patients, who showed hypoechoic thick intima and media on ultrasound or integration of FDG on PET/CT. Average of IMT in CA decreased from 1.167 mm to 0.883 mm (p=0.090) during follow-up in patients with vasculitis on CA. IMT changed little in patients without vasculitis on CA. Improvement rate was significantly higher in CA-involved patients than in CA-non-involved patients (p=0.043). IMT increased during follow-up in two CA-non-involved patients.

**Abstract THU0446 – Table 1.** Time-dependent change in vessel wall thickness of TA (mm)

	Baseline	Follow-up	Relapse
Patient 1	0.30	0.30	0.30
Patient 2	0.63	0.30	0.60
Patient 3	0.63	0.10	0.60

**Abstract THU0446 – Table 2.** Improvement rate of IMT in CA involved and non-involved patients

	IMT (mm)		Rate(B/A)	Median follow-up period (months)
	Baseline [A]	Follow-up [B]		
All (n=14)	0.964	0.843	0.874	30.0
CA involved (n=6)	1.167	0.883	0.757	34.0
CA non-involved (n=8)	0.813	0.813	1.000	27.6

Difference in B/A between CA involved and non-involved: p=0.043 (Mann-Whitney U test)

**Conclusions:** CDU of temporal arteries is useful for follow-up of GCA. CDU of carotid arteries has limited usefulness only in CA-involved patients.

### NO ADVANTAGE OF METHOTREXATE IN THE TREATMENT OF GIANT CELL ARTERITIS

I. Monjo Henry<sup>1</sup>, on behalf of Luis Coronel<sup>2</sup>, Ignacio Castaño<sup>3</sup>, Diana Peiteado<sup>1</sup>, Sara García-Carazo<sup>1</sup>, Alejandro Balsa<sup>1</sup>, Eugenio de Migue<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Universitario La Paz, Madrid, Spain.; <sup>2</sup>Rheumatology, Hospital Universitario Nuestra Señora de la Candelaria, Santa Cruz de

**Background:** The high-dose glucocorticoids (GCs) are the mainstay of treatment in Giant Cell Arteritis (GCA). Patients treated with greater GCs dosages are at the greatest risk of morbidity. Immunosuppressive agents have been trialled in an effort to reduce toxicity from GCs and to improve efficacy of treatment. The results of one meta-analysis with the three trials that included methotrexate (MTX) showed a weak benefit in those patients receiving MTX, but the results were heterogeneous, with one trial showing significant benefit, while the other two did not.<sup>1</sup>

**Objectives:** To study the efficacy and safety of MTX adjunct to GCs in the treatment of GCA.

**Methods:** New-onset giant-cell arteritis initiating treatment of the disease was included in a retrospective observational study to compare treatment efficacy and safety. According to the treatment received the patients were divided two groups: GCs alone (group 1) and MTX and GCs (group 2). To avoid bias, we defined a subgroup of patients in which only patients who started MTX in the first trimester of treatment were included (group 3). As efficacy outcome the number of relapses and the cumulative dose of GCs at 6, 12 and 24 months were collected. For safety,

the number of emergency room visits, hospitalisation admissions and infections were investigated in the follow-up.

**Results:** One hundred twenty-three patients were included, 74 (60.2%) women, the mean age was 79.41 years old. Fifty-six (45.53%) received GCs alone (group 1) and 67 (54.48%) received GCs and MTX as an adjuvant treatment at some time during follow-up (group 2). 30 of these 83 patients (24.39% of total patients) received MTX in the first trimester after diagnosis (group 3). The cumulative doses of GCs, number of patients with relapses, visits to the emergency room and hospitalisation admissions are shown in the table 1. In none of these variables there were statistically significant differences among the three groups, except for the number of patients with relapses, which was greater in group 2 than in group 1 ( $p=0.03$ ). The number of relapses in patients who received MTX early (group 3) was 56.7%, in the rest of patients (who only received GCs and those who started MTX after the first trimester) was 52.69%–33.3% of the patients in group 3% and 21.5% of the rest of the patients presented infections.

	Group 1: GCs alone	Grupo 2: GCs+MTX at some moment during the follow-up	Group 3: GCs and MTX since 1st trimester	P group 3 vs (1 +2)	P group 1 vs 2
Cumulative GCs doses at 6 month (mg±SD)	6193 ±6820	7028±11 230	5942,50±1827	0.629	0.646
Cumulative GCs doses at 12 months (mg ±SD)	7772 ±7154	8976±11 148	7987±2360	0.759	0.897
Cumulative GCs doses at 24 months (mg ±SD)	9340 ±7886	10814±11 150	9383±2522	0.608	0.903
N° of patients with relapses (35.71%)	20/56	42/67 (62.69%)	17/30 (56.7%)	0.430	0.003
N° of patients with emergency room visits	20 (35%)	22 (32.8%)	12 (24%)	0.508	0.849
N° of patients hospitalisation admissions	16 (28.57%)	21 (31.34%)	11 (36.7%)	0.370	0.844

**Conclusions:** Whilst MTX have been used in an effort to reduce toxicity from GCs and to improve efficacy of treatment our observational study shows that there is no benefit from adjunct MTX in GCA either in terms of efficacy or toxicity.

#### THU0448 IS THERE AN ASSOCIATION BETWEEN ADULT IGA VASCULITIS AND CANCER?

J. Ostrovšnik, Ž. Rotar, R. Ješe, M. Tomšič, A. Hočevar. *Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, Slovenia*

**Background:** An increased incidence rate of cancer has been reported in adult patients with IgA vasculitis (IgAV). These conclusions are mostly based on observations in severely ill, hospitalised subgroup of patients. Most of the studies allowed for a wide time interval between IgAV and cancer appearance, not necessarily reflecting a causative link.

**Objectives:** The aim of our study was to look for the potential association between IgAV and cancer in an unselected adult IgAV population.

**Methods:** We analysed medical records of prospectively followed, histologically proven adult IgAV cases at our secondary/tertiary rheumatology centre between 1 January 2010 and 30 June 2017, who were followed until 31 December 2017 and lived in a well-defined referral region. We identified cancer as concurrent with IgAV, if the patients had afferent cancer or a relapse of cancer or newly-diagnosed cancer diagnosed up to 6 months prior or 6 months after IgAV diagnosis. Cancers developing after 6 months of follow up were labelled as unrelated to IgAV. We used appropriate descriptive statistical methods, and the Fisher's exact and Mann-Whitney U tests to assess differences of clinical characteristics in acute phase of IgAV, between the cancer and non-cancer groups. The national prevalence and age adjusted incidence rates of cancer from a well-defined referral region were obtained from National cancer registry (NCR).

**Results:** During the 90 months of observation we identified 196 new IgAV cases. 2 patients died in the acute disease phase due to vasculitis, and 8 during the first 6 months of follow-up for reasons other than IgAV or cancer. 20 patients were lost to

follow-up. The remaining 166 patients (55% male, median (IQR) age 63<sup>43–76</sup> years) were followed for a median (IQR) of 20<sup>11–32</sup> months. At the time of IgAV diagnosis, 6/166 (3.6%) had active, previously diagnosed malignant disease (prostatic cancer in 4, among which one also had cancer of urinary bladder, and sarcoma in 2 patients). In 2/166 patients (1.2%) a new cancer was diagnosed at presentation and in 2/166 (1.2%) during follow-up. One of the patients with an active cancer of urinary bladder, was treated with antibiotics for urinary tract infection prior to IgAV diagnosis, and was also on chemotherapy. The patients with cancer were older (median age (IQR) 80<sup>77–83</sup> vs. 64<sup>44–77</sup> years;  $p=0.002$ ) but their presenting features of IgAV, and the initial IgAV treatment did not significantly differ from those without cancer. At the end of the observation period, the prevalence of cancer in our cohort was 6.0%, compared to the 4.8% prevalence of cancer in our general population and the relative risk of cancer in our IgAV cohort was 1.25 (95% CI 0.687–2.29;  $p=0.461$ ). The age adjusted incidence rate of cancer was 11.4 per 1000 patients per year. The annual age adjusted incidence rate of cancer in our citizens, acquired from NCR, was 8.9 per 1000 adults and the standardised incidence ratio for our IgAV cohort was 1.62 (CI 0.441–4.15;  $p=0.472$ ).

**Conclusions:** In our cohort of unselected adult IgAV cases, we did not confirm the previous observations of the association of IgAV, and cancer.

**Disclosure of Interest:** None declared

#### THU0449 DIAGNOSTIC PERFORMANCE OF ANTINEUTROPHIL CYTOPLASMIC ANTIBODIES IN A COHORT OF UNSELECTED SPANISH PATIENTS

J. Loureiro-Amigo<sup>1</sup>, J. Mestre Torres<sup>2</sup>, C.L. Franco Jarava<sup>3</sup>, A. Marín Sánchez<sup>3</sup>, R. Solans Laqué<sup>1</sup>. <sup>1</sup>Internal Medicine – Autoimmune Diseases Division; <sup>2</sup>Internal Medicine – Autoimmune Division; <sup>3</sup>Immunology Division, Vall d'Hebron University Hospital, Barcelona, Spain

**Background:** Antineutrophil cytoplasmic antibodies (ANCA) are the serological marker of some idiopathic systemic vasculitides, predominantly involving small and medium-sized blood vessels, such as granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), which are known as the ANCA-associated vasculitis (AAV). Nevertheless, ANCA have been reported in a number of other conditions.

**Objectives:** To retrospectively evaluate ANCA diagnostic accuracy in a cohort of unselected patients.

**Methods:** From January 2014 to December 2016 a total of 6781 serum samples with a test request for ANCA were submitted to the Immunology Department of a 1.000-bed tertiary teaching hospital from Barcelona (Spain), from both inpatients and outpatients.

Indirect immunofluorescence (IIF) was performed for all requests using a commercially available "Granulocyte Mosaic 13" (EUROIMMUN). IIF allowed recognition of three staining patterns: cytoplasmic (cANCA), perinuclear (pANCA) and atypical (xANCA). For the detection of antibodies against myeloperoxidase (MPO) and proteinase 3 (PR3) a chemiluminescent immuno-assay (CLIA) using commercially available "QUANTA Flash MPO/PR3" (INOVA diagnostics) was performed in patients with positive IIF.

We reviewed the clinical charts of patients that underwent ANCA testing and collected patients' diagnoses, as established by their treating physician one year after sampling. In the event of multiple ANCA test in a single patient we include only the first test request (we excluded 1323 tests performed in 661 patients). We also excluded 184 patients with insufficient information and 306 ANCA tests with no diagnostic purpose. Therefore the study population includes 4968 patients.

Statistical analysis was performed with Stata 14.2 (College Station, TX, USA). Diagnostic performance was assessed using sensitivity, specificity, positive likelihood ratio (LR+), positive and negative predictive values (PPV and NPV) and global efficiency. Confidence Intervals (CI) were calculated using Wilson method.

**Results:** Only 34 patients (0.68%) received a diagnosis of AAV: 25 MPA, 6 GPA and 3 EGPA.

	Sensitivity [CI 95%]	Specificity [CI 95%]	LR+ [CI 95%]	PPV [CI 95%]	NPV [CI 95%]	Efficiency [CI 95%]
<b>Positive IIF</b>	94.1% [80.9– 98.4]	87.6% [86.7– 88.5]	7.6 [6.8– 8.5]	5% [3.5– 6.9]	99.95% [99.83– 99.99]	87.7% [86.7– 88.5]
<b>IIF Typical pattern</b>	91.2% [77–97]	96.9% [96.3– 97.3]	29 [24.1– 35]	16.7% [12– 22.7]	99.94% [99.82– 99.98]	96.8% [96.3– 97.3]
<b>cANCA/PR3 or pANCA/MPO</b>	76.5% [60–87.6]	99.1% [98.8– 99.3]	83.8 [59.3– 118.4]	36.6% [26.4– 48.2]	99.84% [99.68– 99.92]	98.9% [98.6– 99.2]

The majority (87.1%) of patients had a negative ANCA test and only 12.9% were found positive by IIF. Among 643 positive patients IIF pattern distribution was: 457 (71.1%) atypical, 108 (16.8%) perinuclear and 78 (12.1%) cytoplasmic pattern.

Among patients with positive ANCA 32 (5%) had an AAV. Two patients with AAV had negative ANCA (one GPA and one EGPA).

Data of diagnostic accuracy of ANCA for AAV are showed in table 1:

**Conclusions:** ANCA testing with commonly commercially available methods has an excellent diagnostic performance for AAV in routine clinical practice, especially if a typical pattern is associated with proper antigenic specificity (cANCA with PR3 or pANCA with MPO).

#### THU0450 DIAGNOSTIC RELEVANCE OF ORGAN BIOPSIES IN ANCA ASSOCIATED VASCULITIS

J. Kronfeldner<sup>1</sup>, J. Eifer<sup>1</sup>, S. Quickert<sup>1</sup>, P. Oelzner<sup>1</sup>, M. Busch<sup>1</sup>, C. Kroegel<sup>2</sup>, G. Wolf<sup>1</sup>, T. Neumann<sup>1,3</sup>. <sup>1</sup>Department of Internal Medicine III; <sup>2</sup>Department of Internal Medicine I, Jena University Hospital, Jena, Germany; <sup>3</sup>Division of Rheumatology, Immunology and Rehabilitation, Kantonsspital St. Gallen, St. Gallen, Switzerland

**Background:** The diagnostic workup of ANCA-associated vasculitis (AAV) is a challenge due to the possible multi-organ involvement and the wide range of differential diagnosis. Before classification, vasculitis needs to be proofed by clinical or histopathologic signs.

**Objectives:** We aimed to evaluate specific histopathologic features of organ biopsies and their contribution to the diagnosis of vasculitis and to the classification of specific AAV subgroups.

**Methods:** Retrospective, single-centre cohort study in patients with granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA), classified by ACR-criteria, who have received at least one organ biopsy. Characteristic histopathologic features were analysed and compared between AAV subgroups, organ systems and ANCA-status (Chi-square-test).

**Results:** 306 patients (GPA n=154, MPA n=58, EGPA n=94) diagnosed between 1990–2017 were included. All biopsies were taken at active stage of GPA, MPA or EGPA at initial diagnosis (n=415) or during flair of the disease (n=36). 168 patients had a renal biopsy, 185 patients had 283 non-renal biopsies (1 biopsy in 102 pts, 2 different organ biopsies in 68 pts, >2 in 15 pts). In kidney biopsies glomerulonephritis was described in 78.6%, unspecific inflammation in 26.8% and normal tissue in 1.2%. In non-renal biopsies vasculitis, granuloma, tissue eosinophilia, unspecific inflammation or normal tissue were reported in patients with GPA 32.9/29.4/21.2/71.8/9.4%, MPA 27.3/9.1/27.3/90.9/9.1% and EGPA 20.2/10.1/67.4/73.0/20.2%; p<0.0001 (lung n=103, 13.6/13.6/37.9/71.8/3.9%; skin n=35, 42.8/11.4/40.0/51.4/1.4%; upper respiratory tract n=98, 19.3/16.3/37.7/72.4/8.2%; peripheral nerves n=7, 14.3/14.3/0/14.3/42.8%; p<0.0001). According to the ANCA status the distribution was 31.1/25.2/28.3/68.9/10.7% in ANCA+patients and 20.8/11.1/62.5/79.2/19.4% in ANCA- patients (p<0.0001). Diagnosis of vasculitis was based on biopsy result in 2% of GPA, none of MPA and 8% of EGPA patients, but ACR criteria were only fulfilled including a characteristic biopsy in 6.6% of GPA and 35.5% of EGPA patients. Assignment to GPA, MPA and EGPA by application of the EMA algorithm were only possible in consideration of a characteristic non-renal biopsy in 2.8/0/21.9% and of a characteristic non-renal and/or renal biopsy in 4.7/14.6/28.1% of all patients.

**Conclusions:** Histologic proof of vasculitis remains the gold standard of AAV diagnostic, however the diagnostic value is most prominent for renal biopsies. Distribution of various histopathologic features is different among AAV subgroups (GPA, MPA, EGPA) and varies between different organ biopsies. While classification of GPA and MPA is only in a few cases based on histopathology, in EGPA a characteristic histopathology is necessary for classification in almost one third of patients.

#### THU0451 CAUSE OF DEATH IN PATIENTS DIAGNOSED WITH GIANT CELL ARTERITIS IN WESTERN NORWAY 1972–2012

L.K. Brekke<sup>1</sup>, A.P. Diamantopoulos<sup>2</sup>, B.-T. Fevang<sup>3</sup>, J. Assmus<sup>4</sup>, C.G. Gjesdal<sup>3</sup>. <sup>1</sup>Haugesund Hospital for Rheumatic Diseases, Haugesund; <sup>2</sup>Martina Hansens Hospital, Bærum; <sup>3</sup>Dept. of Rheumatology; <sup>4</sup>Centre for Clinical Research, Haukeland University Hospital, Bergen, Norway

**Background:** Giant cell arteritis (GCA) is the most common systemic vasculitis in adults.

**Objectives:** To determine the causes of death in GCA patients during a 41 year period.

**Methods:** Hospital-based retrospective cohort study including patients diagnosed with GCA in Bergen Health Area during 1972–2012. Patients were

identified through computerised hospital records using the International Classification of Diseases (ICD)-coding system. Clinical information was extracted from patients' medical journals. We excluded patients if data were unavailable, if the reviewing rheumatologist found GCA to be an implausible diagnosis or if the American College of Rheumatology (ACR) 1990 classification criteria for GCA were not fulfilled. Information on cause of death was obtained from the Norwegian Cause of Death Registry (NCoDR). We grouped causes of death according to the European Shortlist for Causes of Death 2012-version (COD-SL-2012). Statistics Norway (www.ssb.no) provided background population data (all deaths during 1972–2012 in the Norwegian population ≥50 years of age). Statistical comparison was performed using mid-p values.

**Results:** The patient inclusion process and patient characteristics have been published previously.<sup>1</sup> A total of 792 patients were included, 566 (71.5%) females (mean age 73.5 years, SD 8) and 226 (28.5%) males (mean age 72.1, SD 9). 432 patients (54.5%) died during the study period (1 January 1972 – 31 December 2012). NCoDR had data on the cause of death for 431 of these. During the study period (1972–2012) there were 1635979 registered deaths in the general Norwegian population aged ≥50 years. The most frequent underlying causes of death in the overall study population were diseases of the circulatory system (53.4%), cancer (11.6%) and diseases of the respiratory system (10.0%). The most frequent causes of death in the general population were also diseases of the circulatory system (46.0%), cancer (22.8%) and diseases of the respiratory system (10.0%). The distribution of causes of death differed significantly between GCA-patients and the general Norwegian population (mid-p-value<0.001 both overall and stratified by sex). Absolute numbers of deaths and corresponding percentages of all causes of death stratified by sex are presented in figure 1.

**Conclusions:** The most frequent causes of death in our cohort of GCA-patients were diseases of the circulatory system, cancer and diseases of the respiratory system (including influenza and pneumonia). These were also the most frequent causes of death in the general Norwegian population aged ≥50 years, but the distribution of death causes differed significantly between GCA-patients and the general population. However, this might reflect differences in the composition of the populations that we were not able to adjust for. We aim to analyse this further by comparing our GCA-cohort with randomly selected age-, sex- and geographically matched control subjects.

#### THU0452 ANTI-INTERLEUKIN-6 (TOCILIZUMAB) EXPERIENCE IN TAKAYASU'S ARTERITIS PATIENTS

L. Kilic<sup>1</sup>, O. Karadag<sup>1</sup>, A. Erden<sup>1</sup>, A. Sari<sup>1</sup>, B. Armagan<sup>1</sup>, E. Firat<sup>2</sup>, U. Kalyoncu<sup>1</sup>, S. Apras Bilgen<sup>1</sup>, S. Kiraz<sup>1</sup>, I. Ertenli<sup>1</sup>, A. Akdogan<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine; <sup>2</sup>Department of Internal Medicine, HACETTEPE UNIVERSITY, ANKARA, Turkey

**Background:** Targeted therapies such as tumour necrosis factor inhibitors (TNFi) and anti-interleukin 6 (anti-IL-6) are increasingly being used in Takayasu's Arteritis (TA) patients who are unresponsive to corticosteroids±conventional immunosuppressives.

**Objectives:** The aim of this study was to evaluate the indications and efficacy of anti-IL-6 (tocilizumab) therapy in a case series of TA patients.

**Methods:** In the prospective database of the Hacettepe University Vasculitis Centre (HUVAM), 105 TA patients meeting the 1990 modified American College of Rheumatology (ACR) criteria were registered at the end of July 2017. Total 28

(26.7%) patients were treated with biological therapy and 22 (21.0%) of them were taking tocilizumab. Patients were assessed using a combination of clinical, laboratory and radiological evaluation before and after Tocilizumab therapy. The demographic and clinical characteristics of the patients, the pre-tocilizumab and end of the follow-up acute phase values (Erythrocyte sedimentation rate (ESR), C-reactive protein (CRP)), visual analogue scales (VAS) (Pain, Fatigue, Patient Global), and concomitant therapies were recorded. Other clinical, imaging and laboratory results of the TA patients were obtained from hospital files. The comparative imaging (Computed Tomography and Magnetic Resonance Imaging) results of the patients just before the Tocilizumab therapy and during follow-up were recorded from the hospital data system.

**Results:** Twenty-two patients (86.4% female) were included in to the analysis. The median (minimum-maximum) age of the patients was 40<sup>24-63</sup> years and the median disease duration (from diagnosis) was 48<sup>12-168</sup> months. Before tocilizumab therapy; cyclophosphamide (8 patients (36.4%), conventional immunosuppressives (21 patients, 95.4%) and TNFi (7 patients, 31.8%) were used in addition to corticosteroid therapy. Main indications for tocilizumab therapy was as follows; radiological progression in 9 patients (acute phase was normal in 2 of them), acute phase elevation in 8 patients (4 of them radiologically stable, 4 of them had no radiologic evaluation), physician's decision and clinical symptoms in 3 patients (acute phase normal; 2 of them radiologically stable, one had no radiologic evaluation), in two patients tocilizumab therapy was started out of our centre and data before tocilizumab was not available. Fifteen patients (median follow-up time 15<sup>3-42</sup> months) were evaluated for response to tocilizumab treatment. There was a significant decrease in ESR, CRP, and VAS-patient-global of patients after tocilizumab therapy; median (min-max) ESR (26<sup>5-119</sup> vs. 3 (2-49) mm/s, p=0.02), CRP (39.8 (2.4-149.0) vs. 7.9 (0-92.9) mg/L, p=0.017), VAS-patient-global (50 (0-90) vs. 30 (0-60), p=0.027), respectively. Total of 9 patients had follow-up imaging; 8 of them was radiologically stable and regression was seen in one patient (figure 1).

**Table 1:**

Patient No	Age/Sex	Age at diagnosis	Disease Duration (months)	Previous treatments	Before Tocilizumab Therapy Steroid dosage	ESR mm/h	CRP mg/L	VAS (Pain/Fatigue/Patient Global)	Imaging
1	52F	35	43	MTX	Pred. 15 mg/day	36	42.8	8/2/20	Stable
2	44MF	31	72	CYC, MTX, SGC, P.E., ADA	Pred. 18 mg/day	75	81.7	8/2/20	Stable
3	47F	37	96	CYC, SGC, MTX, P.E., ETH	Mpred. 32 mg/day	24	19.8	8/7/30	Progression

7	50F	37	12	MTX, P.E., PFC	Pred. 40 mg/day	119	188.5	7/5/27	Progression
8	43F	61	12	MTX	-	-	-	-	Tocilizumab was started out of our center
9	78F	23	48	MTX, P.E.	P.E. 500 mg/month	103	85.1	8/8	-
10	43F	30	168	CYC, MTX	Pred. 40 mg/day	25	62.7	10/2/18	-
11	43F	40	38	CYC, MTX	-	12	18.7	8/8/30	Progression
12	34F	26	72	MTX, PFC	Pred. 50 mg/day	30	3.2	8/2/24	Progression
13	55F	39	36	AZT, MTX	Pred. 10 mg/day	7	1.8	8/8/37	Stable
14	54MF	13	72	MTX, P.E.	Pred. 5 mg/day	-	-	-	Tocilizumab was started out of our center
15	51F	23	84	CYC, MTX	Pred. 20 mg/day	6	2.7	8/8/28	Progression
16	51F	29	34	AZT, MTX	Pred. 30 mg/day	7	2.4	8/7/30	Stable
17	58F	38	13	CYC	Pred. 5 mg/day	42	28.8	7/9/27	Stable
18	68F	48	12	MMF	Mpred. 18 mg/day	2	8.8	8/8/20	Progression
19	52MF	20	24	CYC, MTX	Pred. 40 mg/day	18	31.7	8/10	Progression
20	53F	23	12	-	Mpred. 4 mg/day	14	3.5	8/8/30	Progression
21	68F	58	132	AZT	-	2	2.7	8/9/30	-
22	43F	34	60	MTX	Pred. 10 mg/day	10	1.8	8/7/30	Progression

**Conclusions:** The use of biological therapies in more than a quarter of TA patients suggests that the role of conventional therapies in TA is limited. Although imaging modalities and acute phase elevations are the main factors in the decision of change in treatment, presence of symptoms and physician opinion are also important. Significant response was obtained with the treatment of tocilizumab.

**THU0453 EFFICACY OF AB INITIO OR VERY EARLY INTRODUCTION OF IMMUNOSUPPRESSIVE THERAPY IN GIANT CELL ARTERITIS: A MULTICENTER RETROSPECTIVE OBSERVATIONAL STUDY**

L. Quartuccio<sup>1</sup>, E. Cavallaro<sup>1</sup>, F. Angelotti<sup>2</sup>, R. Capecechi<sup>2</sup>, G. Vitiello<sup>3</sup>, D. Cammelli<sup>3</sup>, A. Tavoni<sup>2</sup>, S. De Vita<sup>1</sup>. <sup>1</sup>Department of Medical Area, Rheumatology Clinic, Udine Academic Hospital "Santa Maria della Misericordia", Udine; <sup>2</sup>Department of Internal Medicine, Clinic of Immunology, Pisa; <sup>3</sup>Experimental and Clinical Medicine Department, School of Allergy and Clinical Immunology, University of Florence, Florence, Italy

**Background:** Glucocorticoids (GC) remain the mainstay of treatment of giant cell arteritis (GCA). However, relapses occur in up to 50% of patients when GC are tapered and prolonged courses of GC are associated with serious side effects. In this setting, the outcome is frequently determined by GC-related adverse events

(AEs). Thus, several studies have been conducted on the effectiveness of a GC-sparing immunosuppressive therapy (IT), with conflicting results.

**Objectives:** To evaluate the effectiveness of IT in a series of GCA patients, in: 1) reducing the risk of GCA relapse; 2) lowering the exposure to GC therapy; 3) minimising the occurrence of steroid-induced AEs.

**Methods:** We performed a multicenter retrospective observational study including 69 patients (75.4% females; mean age  $\pm$ SD 68,7 $\pm$ 7,8 y; median follow-up time 40 months [range 26-65]) diagnosed with GCA, all receiving an adjunctive IT given ab initio (71%) or within 3 months from the start of GC. All but 17 patients (with extracranial involvement) fulfilled the GCA ACR classification criteria. Risk of first relapse of GCA, GC exposure and main AEs were retrospectively analysed. Results were compared with those reported in other studies, all characterised by a lower use of IT.

**Results:** all patients received GC plus IT: methotrexate up to 20 mg/week in 63 patients, cyclophosphamide in 22, tocilizumab in 12. In the follow-up, a first relapse of GCA occurred in 14 (20.3%) of patients. The rates of first relapse at 12, 24, 36 and 48 weeks were 4.3%, 11.6%, 15.9% and 15.9%, respectively, in comparison with rates of 24.3%, 41.6%, 61%, 64.9%, respectively, in the GC monotherapy arm in the meta-analysis by Mahr,<sup>1</sup> where similar data were available. The median daily prednisone dose at beginning was 50 mg, and decreased to 10 mg at 3 months and to 5 mg at 6 months. The median time required to reduce prednisone to 7.5 mg/day and 5 mg/ was 3 and 5 months respectively (vs. 6.5 and 7.5 months in series by Proven,<sup>2</sup> where similar data were available). In our cohort, lower cumulative GC use was accompanied by a reduction of AEs, without further toxicity (tab.1).

	Present work	Proven 20032	Mahr 20071	Souza 20143	Alba 20144	Labarca 20165
Number of patients	69	120	77	45	106	286
% use of IT	100%	2%	0%	55.6%	14.2%	0%
Follow up, months	40	120	13,7	54,9	93,6	61,2
Fragility fractures	11,6%	38%	8%	NA	NA	27%
Diabetes	4,3%	9%	12%	33,4%	8,5%	NA
Hypertension	8,7%	22%	NA	66,7%	51%	1,7%
Infections	10,1% (2,9% hospitalisation)	31%	NA	23%	NA	17% (all needing hospitalisation)

**Conclusions:** The use of IT ab initio or very early in the treatment of GCA appears to be effective and safe, lowering the risk of relapses, reducing GC dose and the rate of GC-related AEs. Therefore, the present data support the early introduction of IT in the treatment of GCA.

**THU0454 INCREASED FDG UPTAKE OF THE MUSCLES IN POLYMYALGIA RHEUMATICA (PMR)**

M.A. Cimmino<sup>1</sup>, N. Vecchiola<sup>1</sup>, M. Bauckneht<sup>2</sup>, D. Camellino<sup>3</sup>, S. Morbelli<sup>2</sup>, S. Paulino<sup>1</sup>, M. Cutolo<sup>1</sup>, G. Sambucetti<sup>2</sup>. <sup>1</sup>Department of Internal Medicine, University of Genova; <sup>2</sup>Division of Nuclear Medicine, Università di Genova; <sup>3</sup>Autoimmunology Laboratory, University of Genova, Genova, Italy

**Background:** PMR is an inflammatory disease affecting the shoulder and pelvic girdles of elderly patients. Its causes, development mechanisms and anatomical targets of inflammatory damage are still elusive. Synovitis, vasculitis, and bursitis have all been demonstrated in PMR but data on muscles are scanty.

**Objectives:** Our study evaluated muscular uptake at FDG-PET/CT in patients with PMR.

**Methods:** Fifty patients with PMR diagnosed according to Bird et al criteria and 50 age- and sex-matched control patients without inflammatory disorders, who underwent FDG-PET/CT to rule out malignancy, were studied. Standard FDG-

PET/CT examination was performed and its results were evaluated by both qualitative scoring, on a 5-grade scale from 0 (no uptake) to 4 (clearly higher than liver uptake), and analysis of the standardised uptake value (SUV max and mean) in a ROI placed on the deltoid, biceps, gluteus and quadriceps muscles. A ROI of the joints and bursae was also designed and the SUV calculated. The muscle ROIs were positioned distant from the corresponding joints to avoid interference from possible articular or periarticular uptake. Demographic, clinical and laboratory data were collected.

**Results:** PMR patients showed an uptake higher than that of controls in the deltoid ( $p=0.0004$ ), gluteus ( $p=0.015$ ), and quadriceps ( $p=0.009$ ), but not in the biceps ( $p=0.06$ ) muscles. The semiquantitative SUV evaluation was consistent for the deltoid (SUV mean,  $p=0.047$ ) and gluteus (SUV mean,  $p=0.01$ ; SUV max,  $p=0.006$ ) muscles. There was no correlation between muscle uptake and that of the adjoining joint. Similarly, no correlation was found between muscle uptake and demographic, clinical and laboratory (CRP, ESR) findings.

**Conclusions:** PMR show muscular inflammation at FDG-PET/CT, which does not derive from the nearby joints or periarticular tissues. A clearly defined myositis is not probable, because creatine kinase concentrations are normal in PMR. However, muscle inflammation may contribute to the global inflammatory burden and symptoms of patients with PMR.

#### THU0455 AGE IS MORE CLOSELY ASSOCIATED WITH POSITIVE TEMPORAL ARTERY BIOPSY OVER BIOPSY LENGTH IN LARGE VETERANS ADMINISTRATION DATABASE STUDY

M.B. Morcos<sup>1</sup>, S. Chung<sup>1</sup>, B. Ng<sup>1,2</sup>. <sup>1</sup>Rheumatology, University of Washington; <sup>2</sup>Rheumatology, Veterans Administration, Seattle, USA

**Background:** Giant cell arteritis (GCA) is a granulomatous vasculitis with a predilection for older women. While American College of Rheumatology (ACR) diagnostic guidelines exist, temporal artery biopsy (TAB) remains an essential tool often used independently to substantiate long-term steroid use and/or immunosuppression. No consensus exists regarding the ideal length of biopsy to optimise pathological yield. The influence of demographic factors such as age, race, and gender on the yield of biopsies is not defined.

**Objectives:** To determine if length of TAB and patient's race, gender, or age at biopsy influenced TAB results using the Veteran's Administration (VA) national database.

**Methods:** Patients with a procedure code for TAB between 1999–2017 were queried through the VA national database. The biopsy length and result (positive, negative, or indeterminate) were recorded. Demographic information including subject age, gender, and race was also extracted. Logistic regression models were run using Stata to identify independent determinants of a positive TAB.

**Results:** 2136 biopsies have been randomly reviewed to date. The average length of TAB was 12.15 mm. TAB results were 9% positive, 89% negative, and 2% indeterminate. There was no statistically significant association between biopsy length and a positive result; however, when compared to the reference group (>10 mm–<15 mm), the odds ratio for positive results increased with specimen length >20 mm to 30 mm in length. Conversely, there was a trend towards negative biopsy results for samples <10 mm in length when compared to the reference length group. There was no correlation between TAB result and race or gender; however, age correlated with a positive biopsy which was statistically significant. None of the subjects <50 years of age had a positive TAB. Younger age groups (age categories 50–59 and 60–69) were less likely to have a positive TAB (OR of 0.32 CI 0.17–0.61 and OR 0.53 CI 0.38–0.74, respectively) when compared to the reference age group (age 70–79). Conversely, older populations aged 90 and above demonstrated a statistically significant increased likelihood of a positive biopsy result with an OR of 2.25, CI 1.05–4.85.

**Conclusions:** The incidence of positive TAB among patients with suspected temporal arteritis in the VA national database was surprisingly low. The effect of other factors, such as the referring specialty or pre-biopsy steroid use, on TAB result may be insightful in understanding the low yield. Age remains a helpful tool given its association with increased likelihood of a positive biopsy, and the decision to pursue TAB in patients <50 years old should be approached judiciously. Length of biopsy was not associated with a positive result; however, the trends we note suggest a biopsy between 10 mm and 25 mm could optimise the yield. Gender and race were not helpful predictors for biopsy yield in this population.

#### THU0456 THE CLINICO-HISTOPATHOLOGICAL ALGORITHM FOR DIFFERENTIAL DIAGNOSIS OF BUERGER'S DISEASE, TAKAYASU ARTERITIS AND ATHEROSCLEROTIC OCCLUSIVE DISEASE

M. Bagriy<sup>1</sup>, O. Zimba<sup>2</sup>. <sup>1</sup>Department of Pathomorphology and Legal Medicine, Ivano-Frankivsk National Medical University, Ivano-Frankivsk; <sup>2</sup>Department of Internal Medicine, Danylo Halytsky Lviv National Medical University, Lviv, Ukraine

**Background:** Arterial occlusive disease is a significant cause of the disability due to lower limbs amputations. In addition to atherosclerosis, systemic vasculitides can present with progressive critical limb ischemia and could be misdiagnosed as atherosclerotic occlusive disease.

**Objectives:** To investigate the pathological findings in vessels of the lower limbs amputated due to Takayasu arteritis (TAK), Buerger's disease (BD) in comparison to atherosclerotic occlusive disease (AOD) and diabetic angiopathy (DA). Additionally, to develop an algorithm for clinico-histopathological differential diagnosis.

**Methods:** The specimens of vessels segments were obtained from the nine anatomical levels of amputated lower extremities in 132 patients, of which 30 were with TAK, 42 with BD, 30 with AOD and 30 with DA.

**Results:** In cases of BD, the exudative-productive endo-mesoarteritis with intimal hyperplasia from stenosis to complete obliteration have been found in the lower leg and foot arteries. No morphological abnormalities were observed in proximal arteries above knee. The pathologic hallmark of BD was panphlebitis with intimal hyperplasia, most often in anterior and posterior tibial veins, vena dorsalis pedis and superficial vein. The most remarkable finding in cases of TAK was mesoarteritis and luminal narrowing due to the reactive intimal hyperplasia in proximal arterial segments. In approximately half of the cases, TAK was not diagnosed clinically and identified only based on the pathological examination. The most common incorrect clinical diagnosis was atherosclerotic occlusive disease. In seven cases of TAK, concomitant premature atherosclerosis of varying severity was observed. Interestingly, in our series of cases of TAK, males were most frequently affected. The correct clinical diagnosis of TAK was made in all females' cases. It seems to be a trend to miss the clinical diagnosis of TAK in men. In cases of AOD, pathological examination revealed stenotic atherosclerotic plaques occurred most prominently in the tunica intima of femoral and popliteal arteries. The most common morphologic features in cases of DA were media calcinosis and fibrous lipid plaques both distal and proximal arterial segments. The algorithm for clinico-histopathological differential diagnosis of TAK, BD, AOD and DA consists of the following: a) the best diagnostic performance can be obtained with four-five specimens of the magistral vessels from the proximal and distal parts of the amputated limb and the superficial vein at the level of the upper third of the shin; b) using routine and special staining techniques (H and E, Masson's trichrome stain for collagen fibres, Hart's elastin stain); c) analysis of the demographic and clinical data; d) interpretation of pathologic changes in vessels of the lower limbs; e) making a pathologic diagnosis.

**Conclusions:** The current findings could contribute to the improving the differential diagnosis of Takayasu arteritis, Buerger's disease, atherosclerotic occlusive disease and diabetic angiopathy.

#### THU0457 INTERLEUKIN-6 EXPRESSION IN INFLAMED AND NON-INFLAMED TEMPORAL ARTERIES FROM PATIENTS WITH GIANT CELL ARTERITIS

N. Pipitone<sup>1</sup>, F. Muratore<sup>1</sup>, I. Tamagnini<sup>2</sup>, A. Cavazza<sup>2</sup>, L. Cimino<sup>3</sup>, L. Boiardi<sup>1</sup>, G. Restuccia<sup>1</sup>, M. Bonacini<sup>4</sup>, S. Croci<sup>4</sup>, C. Salvarani<sup>1</sup>. <sup>1</sup>Rheumatology Unit, <sup>2</sup>Pathology Unit, <sup>3</sup>Ophthalmology Unit, <sup>4</sup>Clinical Immunology, Allergy and Advanced Biotechnologies Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

**Objectives:** To evaluate if interleukin-6 (IL-6) expression in the temporal artery biopsy (TAB) specimens may differentiate patients with giant cell arteritis (GCA) from those without.

**Methods:** 63 consecutive formalin-fixed, paraffin-embedded (FFPE) TABs performed between 2009 and 2012 from 32 patients with transmural biopsy-proven GCA, 8 patients with biopsy-negative GCA and 23 controls were retrieved. Demographic, clinical, and laboratory data at presentation and at each follow-up visit were collected. A pathologist reviewed all TABs. Immunohistochemistry was performed on 4 µm FFPE tissue sections with a 1:400 dilution of rabbit polyclonal anti-human IL-6 antibody (NOVUS Biologicals Littleton, Co.) for 60' at 37°. Slides of TAB specimens were independently assessed by five readers. IL-6 expression was graded as 0 (absent), 1 (mild), 2 (moderate) and 3 (marked). Inter-reader differences were resolved by consensus. Anti-IL6 staining was considered positive if staining was grade 2 or 3, since grade 1 was faint, sometimes difficult to differentiate from background, and showed the least degree of agreement between readers.

**Results:** TAB specimens from patients with biopsy-proven GCA, biopsy-negative GCA and controls were positive for anti-IL-6 staining in 59%, 13% and 48% of cases, respectively, the difference between biopsy-proven and biopsy-negative GCA patients being significant ( $p=0.04$ ). In non-inflamed TABs, IL-6 was mainly expressed by mesenchymal cells in media and intima layers, while in inflamed TABs IL-6 was mainly expressed by mononuclear inflammatory infiltrating cells. IL-6 grade 2–3 expression was observed in all 6 patients with visual loss compared to 25 (43.9%) of 57 patients without ( $p=0.011$ ). Blindness was recorded in 2 patients with biopsy-proven GCA and 4 controls (all with a final diagnosis of non-arteritic ischaemic optic neuropathy). No associations were found between IL-6 expression and demographic characteristics, GCA signs/symptoms, laboratory and histopathological TAB findings. However, there was a statistical trend ( $p=0.055$ ) of increased frequency of the halo sign at temporal artery CDS in patients with IL-6 expression grade 2–3 compared to those with IL-6 expression grade 0–1. No significant differences for the expression of IL-6 were observed between patients with and without PMR (5/8%–62.5% - versus 6/15%–40% -,  $p=0.400$ ) and between patients with isolated PMR and those with TAB positive GCA (62.5% vs 59%,  $p=1.000$ ).

**Conclusions:** Our study provides evidence that IL-6 expression does not increase the sensitivity of TAB in patients with morphologically uninfamed arteries. A search for further markers that may increase the sensitivity of TAB is warranted.

**THU0458 INVESTIGATION OF THE ROLE OF M-TOR PATHWAY IN KIDNEY NEEDLE BIOPSIES OF PATIENTS WITH ANTINEUTROPHIL CYTOPLASMIC AUTOANTIBODY-ASSOCIATED VASCULITIS**

Z. Soyupaci<sup>1</sup>, O. Cakmak<sup>2</sup>, F. Cakalagaoglu<sup>3</sup>, O. Gercik<sup>4</sup>, I. Ertekin<sup>5</sup>, A. Uzum<sup>1</sup>, R. Ersoy<sup>1</sup>, S. Akar<sup>4</sup>. <sup>1</sup>Nephrology; <sup>2</sup>Internal Medicine, Izmir Katip Celebi University School of Medicine; <sup>3</sup>Pathology, Izmir Katip Celebi University School of Medicine Ataturk Research Hospital; <sup>4</sup>Rheumatology, Izmir Katip Celebi University School of Medicine; <sup>5</sup>Nephrology, Izmir Katip Celebi University School of Medicine Ataturk Research Hospital, Izmir, Turkey

**Background:** Anti-neutrophil cytoplasmic antibody (ANCA)-associated vasculitis (AAV) frequently affect the kidneys and renal involvement is an important factor regarding morbidity and mortality. Kidney lesion in AAV is characterised by necrotizing and crescentic glomerulonephritis by little or no immune deposition, and hence it was called pauci-immune glomerulonephritis (PIGN). The underlying mechanisms in the formation or progression of crescent formation need further investigations. Mammalian target of rapamycin (mTOR) is a serine/threonine kinase and plays role in the regulation of cell growth and proliferation.

**Objectives:** We aimed to evaluate the role of mTOR, which might be a potential therapeutic target, in kidney biopsies of patients with AAV.

**Methods:** The patients diagnosed as PIGN at an outpatient nephrology clinics of a tertiary hospital, between May 2009 and June 2016, were retrospectively reviewed and those patients who had a renal biopsy before receiving an immunosuppressive treatment were included in the study. Renal biopsy specimens were immunohistochemically stained with antibodies of mTOR, phosphatase and tensin homolog (PTEN) and transforming growth factor- $\beta$  (TGF- $\beta$ ) and scored by an experienced renal pathologist.

**Results:** In total 54 patients with AAV (52% female) were included in the study. Twenty-five (46%) patients were diagnosed as granulomatosis with polyangiitis, 6 (11%) patients as microscopic polyangiitis, 16 (30%) patients as renal-limited disease, one (2%) patient as eosinophilic granulomatosis with polyangiitis. Six (11%) patients with PIGN could not be classified definitely. According to the histopathologic examination; 22% of the biopsies were classified as focal, 33% crescentic, 22% mixed and 22% as sclerotic. The mTOR was expressed in substantial percentages of glomeruli of patients with PIGN. However we observed PTEN expression in all samples and mTOR in all tubulointerstitial areas. mTOR expression was found to be related with the presence of crescentic and sclerotic changes observed in glomeruli and the degree of fibrosis in interstitial areas. In our study serum creatinine level or response to treatment were not found to be associated with mTOR pathway expression

**Conclusions:** Our study showed that glomerular or interstitial expression of PI3K/Akt/mTOR pathway may play a role in the pathogenesis of PIGN and mTORC1 inhibitors might provide a viable alternative for this disease.

**Disclosure of Interest:** None declared

**THU0459 SURVIVAL OF BIOPSY PROVEN GIANT CELL ARTERITIS IN NORTHERN ITALY: CORRELATION WITH CLINICAL, LABORATORY AND HISTOPATHOLOGICAL FINDINGS**

P. Macchioni<sup>1</sup>, L. Boiardi<sup>1</sup>, F. Muratore<sup>1</sup>, M. Catanoso<sup>1</sup>, A. Cavazza<sup>2</sup>, P. Mancuso<sup>3</sup>, L. Cimino<sup>4</sup>, G. Restuccia<sup>1</sup>, C. Salvarani<sup>1</sup>. <sup>1</sup>Rheumatology Unit; <sup>2</sup>Pathology Unit; <sup>3</sup>Epidemiology Service; <sup>4</sup>Ophthalmology Unit, Azienda USL-IRCCS di Reggio Emilia, Reggio Emilia, Italy

**Objectives:** To correlate survival with clinical, laboratory and histopathological findings in a population based cohort of patients with biopsy-proven giant cell arteritis (GCA) living in the Reggio Emilia area during a 26 years period.

**Methods:** In this population-based study, all patients living in the Reggio Emilia area who underwent temporal artery biopsy (TAB) for suspected GCA from January 1, 1986 to December 31, 2012 were identified. A pathologist with expertise in vasculitis and blinded to clinical data and final diagnosis reviewed all TABs. Based on the localization of the inflammation, positive TABs were classified into 4 categories: small vessel vasculitis (SVV), with inflammation limited to small periadventitial vessels devoid of muscular coat; vasa vasorum vasculitis (VVV), with inflammation surrounding the adventitial vasa vasorum; inflammation limited to adventitia (ILA), with inflammation spreading from vasa vasorum to the adventitia without extension to the media; transmural inflammation (TMI), with external elastic lamina disruption and extension of the inflammation to the media. Histopathologic features evaluated were: the severity of inflammation and intimal hyperplasia, both graded on a semiquantitative scale (mild=1, moderate=2 severe=3), the presence of intraluminal acute thrombosis, calcifications, giant cells, fibrinoid necrosis and laminar necrosis. Information about clinical manifestations, laboratory findings, treatment and disease course were collected. Patients were followed from GCA diagnosis to death, migration or December 2013.

**Results:** 281 patients (206 female, 73.3%) with biopsy-proven GCA were identified in the study period. 120 patients (84 female, 70%) died during a median follow-up period of 96 (IQR 55, 143) months. At univariate analysis, the presence of polymyalgia rheumatica (PMR) (HR 0.54, 95% CI 0.37–0.79,  $p=0.002$ ), higher level of haemoglobin (HR 0.84, 95% CI 0.74–0.96,  $p=0.011$ ) at disease onset, long-term remission (HR 0.47, 95% CI 0.26–0.86,  $p=0.015$ ) and ILA or VVV at TAB (HR 0.48, 95% CI 0.24–0.97,  $p=0.041$ ) were associated with lower mortality, while the evidence of large vessel involvement at imaging studies performed at diagnosis was associated with increased mortality (HR 5.84, 95% CI 1.57–21.8,  $p=0.009$ ). Multivariate analysis confirmed the association between lower mortality and PMR (HR 0.54, 95% CI 0.36–0.81,  $p=0.003$ ), higher level of haemoglobin (HR 0.83, 95% CI 0.69–0.99,  $p=0.049$ ) at disease onset, and ILA or VVV at TAB (HR 0.38, 95% CI 0.17–0.82,  $p=0.014$ ), and between increased mortality and large vessel involvement at imaging studies performed at diagnosis (HR 5.31, 95% CI 1.39–20.26,  $p=0.014$ ).

**Conclusions:** PMR at diagnosis and only adventitial inflammation at TAB seem to identify subsets of biopsy-proven GCA patients with more benign disease, while large vessel involvement at diagnosis a subset with reduced survival.

**Disclosure of Interest:** None declared

**THU0460 FULLY INTEGRATED 18F-FDG PET/MR IN LARGE VESSEL VASCULITIS**

R. Padoan<sup>1</sup>, F. Crimi<sup>2</sup>, M. Felicetti<sup>1</sup>, F. Padovano<sup>3</sup>, L. Punzi<sup>1</sup>, C. Lacognata<sup>2</sup>, R. Stramare<sup>2</sup>, D. Cecchin<sup>3</sup>, F. Bui<sup>3</sup>, P. Zucchetta<sup>3</sup>, F. Schiavon<sup>1</sup>. <sup>1</sup>Operative Unit of Rheumatology, Department of Medicine DIMED; <sup>2</sup>Operative Unit of Radiology, Department of Medicine DIMED; <sup>3</sup>Operative Unit of Nuclear Medicine, Department of Medicine DIMED, University of Padova, Italy

**Background:** Positron emission tomography (PET) is a non-invasive imaging method that detects <sup>18</sup>F-fluorodeoxyglucose (FDG) uptake in vessel's walls. Its simultaneous combination with magnetic resonance (MR) would offer not only a more detailed morphological analysis of the vessels but also a reduction of the radiation, simplifying the clinical workflow and being logistically easier for the patient.

**Objectives:** To evaluate, for the first time up to now, the usefulness of a fully integrated 18F-FDG PET/MR in a series of large vessels vasculitides (LVV) patients.

**Methods:** We performed a controlled non-randomised prospective study. Images were acquired on a fully integrated PET/MR scanner (Siemens Biograph mMR), consisting in a complete MR protocol and FDG-PET whole body imaging. We evaluated vessel's standard uptake value (SUV) maximum and wall thickness (WT), defined as the mean of 4 measures (at 12, 3, 6 and 9 o'clock) at the inferior margin of D5, D9, D12, L3 and at thickest point (max WT).

	All (n 23)	GCA (n 13)	TAK (n 8)	p
Female, n (%)	19 (82.6)	12 (92.3)	6 (75)	ns
Age at diagnosis	63 (51–68)	68 (63–73)	43.5 (30.5–57)	0.003
Diagnostic latency (months)	4.5 (2–12)	3 (2–10)	8 (3.5–12)	ns
ESR at disease onset (mm/h)	49 (38–68)	52.5 (45.5–59.7)	42 (40–61.5)	ns
CRP at disease onset (mg/L)	61.8 (13–132.5)	89 (32.5–106)	60.5 (9.3–132.5)	ns
Disease duration at PET/MR (months)	27 (18–36)	24 (13–29.5)	36.5 (14.75–129.3)	ns
ESR at examination (mm/h)	18 (9–35)	16 (7–31)	20.5 (11–44.5)	ns
CRP at examination (mg/L)	4.5 (2.55–8.9)	3.9 (3.48–4.72)	4.55 (2.05–10.4)	ns

**Results:** 23 LVV patients were included, 56.5% GCA, 34.8% TAK and 8.7% isolated aortitis, all Caucasian, mostly females (82%). We considered 55 PET scans, 32/55 in LVV group (from min. 1 to max. 3 scans/patient) mainly during follow-up (29/32 scans), and 23/55 in control group. Considering patients with abdominal aorta involvement, we found higher SUV max compared to controls, in all sites, regardless of disease activity. Mean WT resulted higher in patients than controls, but did not significantly differ between PET active or inactive patients (figure 1). Mean WT positively correlated with age in both cohorts, inversely correlated to disease duration in LVV patients, while no correlation with SUV max was observed. Despite clinical assessment was suggestive of remission in 24 (75%) cases before PET/MR acquisition, a normal uptake was present only in 12 (50%) of them. On the contrary, all patient with active disease at clinical examination (8, 25%) had also a positive PET/MR. Cohen's K coefficient between clinical assessment and imaging was poor (K Cohen=0, 33, 0.11–0.55). Finally, we found no significant correlation between SUV max and acute phase reactants.

Demographic and clinical data of LVV patients.

**Conclusions:** PET/MR is a safe imaging technique capable of detecting vasculitic inflammation, similar to PET/CT, but with a greater anatomical definition. The low radiological exposure represents a valid alternative to PET/CT for disease monitoring, especially in young women.

THU0461

#### COMPARISON BETWEEN CLINICAL PROFILE AND OUTCOME OF PATIENTS WITH JUVENILE ONSET AND ADULT ONSET TAKAYASU ARTERITIS

R.A. Goel<sup>1</sup>, D. Danda<sup>1</sup>, G. Joseph<sup>2</sup>, A. Nair<sup>1</sup>, R. Ravindran<sup>1</sup>, V. Jeyaseelan<sup>3</sup>.  
<sup>1</sup>Clinical Immunology and Rheumatology; <sup>2</sup>Cardiology; <sup>3</sup>Biostatistics, Christian Medical College, Vellore, Tamil Nadu, Vellore, India

**Background:** There is a paucity of data comparing juvenile onset Takayasu arteritis (jTA) and adult onset TA (aTA).

**Objectives:** We aimed to compare differences in clinical profile and outcome of patients with jTA and aTA attending our centre during 1998–2017.

**Methods:** Details of demography, clinical presentation, laboratory results, angiography and treatment response were collected prospectively for 252 and retrospectively for the rest of patients with TA. Disease activity was defined by Indian Takayasu Activity Score- A (ITAS-A)(CRP).<sup>1</sup> Complete remission (CR) was defined as ITAS-A=0 with no angiographic progression. Patients with onset of disease at ≤16 years of age were classified as jTA while the rest as aTA.

**Results:** Among 602 patients with TA during this period, 119 (19.8%) were jTA, while 483 were aTA. Female predominance was less striking in jTA (71.4%) than aTA (79%), p=0.047. Patients with jTA had presented more commonly with fever (29% vs 17.4%, p=0.002), headache (31% vs 18%, p=0.002), pain abdomen (11% vs 5.6%, p=0.031), systolic hypertension (66.4% vs 48.4%, p<0.001), cardiomyopathy (15.1% vs 5.4%, p<0.001) and raised creatinine (16% vs 4.7%, p<0.001) while claudication as presenting symptom was less common in jTA (39%) as compared to aTA (55%), p=0.003. Pulse abnormality tended to be commoner in aTA. Angiographically, type-I disease (5.1% vs 22.6%, p<0.001) and coronary involvement (8.3% vs 20.6%, p=0.016) was less common while type-IV disease occurred more frequently (25% vs 14.3%, p=0.004) in jTA than in aTA. Logistic regression showed similar results after adjustment for gender. Median ITAS<sup>2010</sup> score was higher in jTA [7 (2–14)] than aTA [5 (2–11)].

Follow up was available for 77 and 287 patients with jTA and aTA respectively. Median follow up duration was 32<sup>10–61</sup> months for jTA and 27<sup>10–59</sup> months for aTA. CR was attained more frequently in jTA (n=67; 87%) than aTA (n=190; 66.2%), p=0.001. Another, 7 (9%) and 55 (19.2%) of patients with jTA and aTA respectively achieved partial response with immunosuppression. Among patients with initial CR, relapse of active disease during further follow up was observed more frequently in jTA [n=20, (29.9%)] as compared to aTA [n=50, (26.6%)], p=0.029. Altogether, persistently stable disease course was more common in jTA (62.3%) than aTA (47.5%), p=0.029.

**Conclusions:** In our large cohort of TA treated with uniform immunosuppression protocol, systemic features, hypertension, cardiomyopathy, renal dysfunction and type IV disease are more commonly observed in jTA while claudication, pulse abnormality, coronary involvement and type I disease are more frequent in aTA. Patients with jTA respond better to immunosuppression but relapse more frequently than aTA. Persistent stable disease course is commoner in jTA patients.

#### LONG TERM FOLLOW-UP RESULTS OF TAKAYASU ARTERITIS COHORT: A TERTIARY-SINGLE CENTRE STUDY

S. Kaymaz Tahra, F. Alibaz-Oner, H. Direskeneli. *Department of Rheumatology, Marmara University, Istanbul, Turkey*

**Objectives:** To assess the clinical characteristics and long term follow-up outcomes of patients with Takayasu's arteritis (TAK) in a tertiary referral centre.

**Methods:** In this retrospective study, 107 (F/M: 96/11) patients fulfilling ACR<sup>1990</sup> criteria for Takayasu Arteritis and referred to our centre between 2004 and 2017 were investigated. All clinical and demographic data during first diagnosis and longitudinal follow-up were abstracted from medical records. Relapse was defined according to the physician's global assessment (PGA).

**Results:** The median age was 30<sup>14–67</sup> years at symptom onset and 33<sup>14–68</sup> years at diagnosis. Median follow-up duration was 72 (6–264) months. According to Hata Angiographic Classification, Type 5 (51.8%) and Type 1 (38.8%) were the most common patterns with the most frequently affected vessel subclavian artery (82.2%). At diagnosis 0.5–1 mg/kg/day corticosteroid treatment was started in 94.6% patients and a steroid-sparing immunosuppressive (IS) agent in 96.3% of the patients. An initial pulse steroid (1 g/day) therapy was chosen for 8 patients. Before diagnosis 24% patients had a history of a revascularisation procedure. After IS treatments, 24% of the patients were undergone a new revascularisation procedure. During follow-up, biologic agents were chosen for 13.8% of the

patients (5 infliximab and certolizumab each, 2 adalimumab and 2 tocilizumab). Remission was observed in 84% of the patients. At least one relapse was occurred in 43% and >1 relapse in 14 patients. At the last visit 26% were determined to have an active disease. A >4 mg of methylprednisolone dose was required in only 8.4%. Mortality rate was 3.7% (4 patients).

**Conclusions:** We have defined the long-term follow-up results of our Takayasu's arteritis cohort. Comparing with European and Asia series published recently, requirement for a surgical intervention was lower under immunosuppressive treatments in our series. However, disease activity and relapse rate were still high under conventional ISS, suggesting a need for better therapeutic options.

#### THU0463 COMPLEMENT FACTORS OF THE ALTERNATIVE PATHWAY IN GPA AND MPA

S. Fukui<sup>1</sup>, K. Ichinose<sup>1</sup>, K.-E. Sada<sup>2</sup>, M. Harigai<sup>3</sup>, A. Kawakami<sup>1</sup>, on behalf of Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS). <sup>1</sup>Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki; <sup>2</sup>Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama; <sup>3</sup>Department of Epidemiology and Pharmacoepidemiology, Tokyo Women's Medical University, Tokyo, Japan

**Background:** In antineutrophil cytoplasm autoantibody (ANCA)-associated vasculitis (AAV), involvement of complements, especially alternative pathway of complement, has been reported in researches using mouse models. In human, while some studies have identified levels of C3 as a renal prognostic factor, entire complement factors in alternative pathway have not been evaluated.

**Objectives:** To evaluate complement profiles of AAV patients at diagnosis and at 6 months after treatments (Month 6).

**Methods:** In total, 91 incident cases of granulomatosis with polyangiitis (GPA) and microscopic polyangiitis (MPA) based on the European Medicines Agency algorithm were enrolled. They are a part of participants of the Japanese nationwide, prospective, inception cohort study from 22 tertiary Japanese institutions (RemIT-JAV-RPGN). Multiplex complement bead assays to measure levels of C1q, C2, C3, C3b/iC3b, C4, C4b, C5, C5a, C9, Factor D, Factor I, MBL, factor B, factor H, and properdin were performed using preserved sera at diagnosis and at Month 6. We compared complement levels at diagnosis of AAV patients with those of age- and sex-matched healthy donors, and compared those of the AAV patients at diagnosis and Month 6.

**Results:** Seventy-two of 91 patients had serum both at baseline and Month 6. Compared with healthy donors, GPA patients had significantly higher levels of C2, C5a, and Factor B, and significantly lower levels of C3b/iC3b, C4b, and properdin. MPA patients had significantly higher levels of C2 and Factor D, and significantly

lower levels of C3b/iC3b, C4, C5, Factor H, and properdin (table 1). At baseline, GPA had significantly higher levels of C4, Factor B and Factor H, and had significantly lower levels of C4b and Factor D compared to MPA. There are no significant differences in levels of C3, C5, Factor D, MBL, and properdin using Wilcoxon signed-rank test between at diagnosis and Month 6 both in GPA and MPA. Factor I significantly decreased at Month 6 only in GPA. Other complement factors significantly decreased at Month 6 both in GPA and MPA.

**Abstract THU0463 – Table 1.** Complement profiles of patients with AAV at baseline and healthy donors

GPA, granulomatosis with polyangiitis; MPA, microscopic polyangiitis; HD, healthy donor.

**Conclusions:** We found some differences in complement factors among GPA, MPA, and healthy donors. There were no differences of levels of C3, C5, Factor D, and properdin, which suggested involvements of alternative pathway, both in GPA and MPA between at diagnosis and Month 6.

#### THU0464 INCREASED FREQUENCY OF OBSTRUCTIVE SLEEP APNEA SYNDROME IN BEHÇET'S SYNDROME PATIENTS WITH VENA CAVA SUPERIOR THROMBOSIS

A. Gokturk<sup>1</sup>, S.N. Esatoglu<sup>1</sup>, Y. Ozguler<sup>1</sup>, E. Atahan<sup>2</sup>, B. Musellim<sup>2</sup>, V. Hamuryudan<sup>1</sup>, H. Yazici<sup>1</sup>, E. Seyahi<sup>1</sup>. <sup>1</sup>Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology; <sup>2</sup>Istanbul University, Cerrahpasa Medical School, Department of Chest Diseases, Istanbul, Turkey

**Background:** Superior vena cava syndrome (SVCS), is a medical emergency and can also be seen in Behçet's syndrome (BS). Contrary to the severe outcome seen in malign conditions, SVCS in BS usually has a benign course, complicated rarely by hemoptysis, pleural effusion, and a chylothorax. We had noted that BS patients with SVCS frequently complained of sleep disturbances, snoring and sleep apnea, suggesting an obstructive sleep apnea (OSA) disorder.

**Objectives:** We formally surveyed the degree of risk for OSA among BS patients with SVCS and suitable controls using the Berlin questionnaire, a screening questionnaire for OSA with a high sensitivity and modest specificity.<sup>1</sup>

**Methods:** Because of the lower frequency of female patients with VCSS (n=2), only males were included. We studied 28 BS patients with SVCS (Group 1), 80 BS patients with vascular involvement without a SVCS (Group 2), and 59 BS patients with no vascular involvement (Group 3). Also, 80 apparently healthy individuals (Group 4) of similar age and gender to BS patients were studied. Polysomnography was performed in patients at high risk for OSA according to the Berlin questionnaire.

**Results:** There were no differences regarding demographic characteristics, disease duration, and variables associated with OSA among the groups (table 1). The Berlin questionnaire categorised 57.1% (16/28) of the BS patients with SVCS (Group 1) as having a high risk for OSA and this was significantly higher compared to that found in the control groups. The frequency of those at high risk for OSA was 15%, 8.5%, 11.3% in Group 2, 3 and 4, respectively (p>0.05). Until now, polysomnography was performed in 12 subjects (5 patients with SVCS, 1 patient with vascular involvement without a SVCS and 6 healthy controls). OSA was detected

in 3/5 patients with SVCS and 1/1 patient with vascular involvement without a SVCS and 4/6 healthy controls.

**Abstract THU0464 – Table 1.** Demographic characteristics and variables associated with obstructive sleep apnea

	Group 1 (BS patients with SVCS) (n=28)	Group 2 (BS patients with vascular involvement without SVCS) (n=80)	Group 3 (BS patients with no vascular involvement) (n=59)	Group 4 (Healthy controls) (n=80)	<i>p</i> value
Age, mean ±SD, years	44.3±9.7	42.1±7.8	41.9±5.9	42.7±9.7	0.051
Disease duration, mean±SD, years	18.7±9.4	14.6±7.7	12.5±6.5		<b>0.001</b>
Hypertension, n (%)	4 (14.3)	6 (7.5)	2 (3.4)	4 (5)	NS
BMI, mean ±SD	26.8±4.7	26.4±3.9	26.2±3.3	27.0±3.5	NS
High risk for OSA, n (%)	16 (57.1)	12 (15)	5 (8.5)	9 (11.3)	<0001

**Conclusions:** This study shows that BS patients with a history of VCSS are at high risk of OSA. This is probably due to the external pressure of the significant venous collaterals on the upper airways.

#### THU0465 A LONGITUDINAL STUDY OF NEUTROPHIL PHENOTYPE CHANGES IN GIANT CELL ARTERITIS

T. Kuret<sup>1</sup>, K. Lakota<sup>1,2</sup>, P. Žigon<sup>1</sup>, M. Ogrič<sup>1</sup>, S. Sodin-Šemrl<sup>1,2</sup>, S. Čučnik<sup>1,3</sup>, M. Tomšič<sup>1,4</sup>, A. Hočevar<sup>1</sup>. <sup>1</sup>Department of Rheumatology, University Medical Center Ljubljana, Ljubljana; <sup>2</sup>FAMNIT, University of Primorska, Koper; <sup>3</sup>Faculty of Pharmacy; <sup>4</sup>Faculty of Medicine, University of Ljubljana, Ljubljana, Slovenia

**Background:** Neutrophils with differential surface protein expression were recently implicated in pathogenesis of Giant Cell Arteritis (GCA)<sup>1</sup>. However, data are lacking with regard to treatment-naïve GCA and their long-term follow-up.

**Objectives:** To determine the expression of I-selectin (CD62L) and integrin  $\alpha$ M (CD11b) on CD16<sup>+</sup> neutrophils in peripheral blood of newly diagnosed, treatment-naïve GCA cases, at the time of diagnosis (time 0) and during follow-up - at week 1, 4, 12, 24 and 48. In parallel, we aimed to measure also sera levels of serum amyloid A (SAA) and interleukin-6 (IL-6).

**Methods:** Peripheral blood from 33 treatment-naïve GCA patients and 16 healthy blood donors (HBD) was stained, lysed, fixed and analysed by flow cytometry (Miltenyi). SAA and IL-6 were measured by nephelometry and ELISA, respectively. 3/33 GCA patients experienced relapse and were analysed separately during follow-up, at the time of relapse and 12 weeks after relapse. At the time of diagnosis, all patients received steroid treatment and therapy tapering started after 4 weeks. At week 12, some of the patients (14/22) received leflunomide, in addition to steroid therapy.

**Results:** Expression of CD62L, but not CD11b, was significantly higher on CD16<sup>+</sup> neutrophils in treatment-naïve GCA patients (median; IQR: 72.5; 56.2–100.7), as compared to HBD (55.9; 44.5–70.6,  $p=0.017$ ). Longitudinally, the expression of CD62L significantly decreased in GCA patients from day 0 to week 4 ( $p=0.005$ ). At week 12 there was an elevation in CD62L which escalated also at week 24. Patients receiving steroids only showed a marked increase at week 48, while patients receiving also leflunomide exhibited a decrease (Fig 1). Expression of CD11b declined from day 0 to week 4, but substantially increased throughout week 12, 24 and 48, regardless of therapy used. SAA and IL-6 declined sharply from day 0 to week 1 and 4, with gradual elevation of both at week 12. There was a decline in SAA levels observed in all patients at week 24, while IL-6 increased in patients receiving only steroids. These patients exhibited further elevation of both markers at week 48, while patients receiving steroids, in combination with leflunomide, showed a decrease. In 2/3 patients who experienced a relapse, we could observe an increase in the expression of CD62L at the time of relapse, which was found to be decreased again 12 weeks later. A similar trend was observed for IL-6.

**Conclusions:** Neutrophil CD62L could represent a good surface marker for detection of relapse in GCA. A distinct dichotomy was found for CD62L, as well as SAA and IL-6 in GCA during long term follow-up, with the combination of steroids with leflunomide showing more optimal results.

#### THU0466 SEXUAL DYSFUNCTION AND DEPRESSION IN BEHCET'S DISEASE – ARE THERE DIFFERENCES REGARDING PATIENT'S ORIGIN

T. Xenitidis<sup>1</sup>, A.-C. Pecher<sup>1</sup>, T. Schmalen<sup>2</sup>, M. Henes<sup>3</sup>, J.C. Henes<sup>1</sup>. <sup>1</sup>Centre for Interdisciplinary Clinical Immunology, Rheumatology and Auto-inflammatory Diseases and Department of Internal Medicine II (Oncology, Haematology, Immunology, Rheumatology, Pulmology); <sup>2</sup>University Hospital Tuebingen, Tuebingen, Germany; <sup>3</sup>Department of Women's Health, Women's University Hospital, University Hospital Tuebingen, Tuebingen, Germany

**Background:** Behcet's disease (BD) is a systemic vasculitis of veins and arteries characterised by oral and genital ulcers (aphthae), skin lesions and uveitis. BD is more common in Middle Eastern countries and Asia but also occurs in Caucasian people.

**Objectives:** Aim of this study was to evaluate the prevalence of sexual dysfunction (SD) in patients with BD as well as analysing differences between patients from different origins. Additionally we investigated the prevalence of depression in both ethnic groups.

**Methods:** This prospective, monocentric study included 106 patients with BD. The International Index of Erectile Function (IIEF) and the Female Sexual Function Index (FSFI) were used for assessing sexual dysfunction and the Beck Depression Inventory (BDI) was used for depression assessment.

**Results:** The mean age of our group was 40.5 years. Half of the patients had Middle Eastern and half Caucasian origin. SD was found in 24.5% of all subjects. Only 6.9% of the male patient's group showed signs of SD, while half of the women's group was suffering from SD ( $p<0.001$ ). The prevalence for SD was significantly higher in women with Middle Eastern origin compared to women with Caucasian origin (75% vs. 33.3%,  $p=0.024$ ). Genital ulcers affected 73.6% of all patients. Depression was found in 36.7% of all subjects. Both SD and depression correlated positively in males ( $p=0.017$ ) and females ( $p=0.013$ ).

**Conclusions:** SD and depression are very common problems in BD and should be addressed by the treating physician. Both manifestations are intensifying each other.

#### THU0467 EFFICACY AND PATENCY OF REVASCULARISATION IN PATIENTS WITH THROMBOANGIITIS OBLITERANS (BUERGER'S DISEASE)

T. Mirault<sup>1</sup>, M. Delahaye<sup>1</sup>, A. Galloula<sup>1</sup>, M. Guillet<sup>1</sup>, S. Zarka<sup>1</sup>, M.-C. Courtois<sup>1</sup>, M. Sapoval<sup>2</sup>, G. Goudot<sup>1</sup>, E. Messas<sup>1</sup>. <sup>1</sup>National reference center for Rare Vascular Diseases; <sup>2</sup>Interventional Vascular Radiology unit, Georges-Pompidou European Hospital, APHP, Paris Descartes University, Sorbonne Paris Cite, PARIS, France

**Background:** The cornerstone of therapy in thromboangiitis obliterans (TAO) is complete abstinence from tobacco. In addition to discontinuation of cigarette smoking, very few pharmacological and surgical options of controversial efficacy are available to date. TAO is associated with a high amputation rate because of tobacco continuation, medical therapy failure, and desert foot with no revascularisation option. Endovascular or bypass revascularisation patency and efficacy are poorly described in the literature.

**Objectives:** To describe the results of the French National Reference Centre on TAO on revascularisation modalities, their patency and efficacy.

**Methods:** Among the 198 patients followed in our centre, we retrieved data from 19 patients for who a revascularisation procedure has been attempted. Patency was assessed on angioCT scan and Duplex ultrasounds performed during follow-up. Efficacy was assessed according to clinicians in charge of the patient, and if

an amputation had been performed or not despite a primary successful procedure.

**Results:** In this cohort of 19 patients, 16 were male (84%), all were tobacco active users, and 21% cannabis users. Median follow-up was 19.9 months [11.0–36.9]. Iloprost infusion had been tested for 84.2% of the patients before revascularisation, and 63.2% had a dihydropyridine, 73.3% a statin and 100% at least aspirin. Endovascular procedure was exclusive for 14 patients, and bypass surgery for 1 patient. Four patients had combined procedures. Globally, 44 procedures including 7 bypasses (15.9%) and 37 endovascular surgeries (84.1%), due to multiple procedures for some patients. Primary patency of endovascular procedures was 89.4% and their patency duration was  $221 \pm 173$  days. For bypass surgery, the patency duration was higher  $827 \pm 408$  days ( $p=0.273$ ). Looking at the territory, aorto-iliac revascularizations gave better results on long term 1830 days followed by upper limb  $751 \pm 402$  days, femoro-popliteal procedures  $347 \pm 196$  days and finally infra-popliteal ones with  $178 \pm 134$  days.

Stability or improvement was observed after 52.3% of the revascularizations. Among the failures, 21.2% were associated with a minor amputation, and 11.3% with a major amputation. No predicting factors of failure could have been determined.

**Conclusions:** We report the largest series of revascularization in TAO. As expected, proximal artery revascularisation of lower limbs were associated with a higher and a longer patency rate than femoro-popliteal procedures and even more than infra-popliteal revascularisations. Surprisingly, upper limb revascularisation had a better outcome than for lower limbs. Efficacy of revascularizations are difficult to assess because such procedures are often proposed as a salvage option. However, it is worth to note that more than 50% of the patients had a benefit from the revascularisation.

#### THU0468 SERUM ANGIOGENESIS BIOMARKERS PREDICT DISEASE OUTCOME IN GIANT CELL ARTERITIS

Y. van Sleen, M. Sandovici, W. Abdulhad, J. Bijzet, A. Boots, E. Brouwer. *Rheumatology and Clinical Immunology, University Medical Center Groningen, Groningen, Netherlands*

**Background:** Giant cell arteritis (GCA) is characterised by inflammation of the medium and large vessels. Two forms of GCA are described, C(cranial)-GCA and LV(large vessel)-GCA, which can be present either separately or co-exist in a patient. Clinical features, erythrocyte sedimentation rate (ESR) and C-reactive protein (CRP) levels are used for disease diagnosis and monitoring, but are not disease specific. Relapses are common during and after treatment, therefore new biomarkers are needed for diagnosis and disease course prediction.

**Objectives:** As the majority of infiltrating cells in the vessels of GCA patients are macrophages the aim of this project was to identify and compare levels of macrophage products in the serum of GCA patients as potential biomarkers.

**Methods:** Forty-one newly diagnosed GCA patients (temporal artery biopsy proven C-GCA and FDG-PET scan-positive LV-GCA) were recruited before start of glucocorticoids. Disease course was monitored and time to glucocorticoid treatment free remission was documented. Thirty age- and sex matched healthy controls (HCs) and 13 infection controls (bladder or lung infection) were also included. Serum concentrations of interleukin (IL)-6, serum amyloid A (SAA), soluble CD163 (sCD163), calprotectin, YKL-40 (human cartilage glycoprotein-39), vascular endothelial growth factor (VEGF), and angiopoietin-1 and 2 were determined by ELISA or Luminex assay.

**Results:** IL-6, SAA, sCD163, calprotectin, YKL-40, VEGF and angiopoietin-2 levels are increased in GCA and infection controls compared to HCs. IL-6 levels correlated strongly with CRP, ESR and SAA, all markers of the Acute Phase Response (APR), in GCA. Interestingly, YKL-40, angiopoietin-2 and calprotectin levels showed only weak or no correlation with APR biomarkers, while they were strongly correlated with the APR in infection controls. Monocytes in peripheral blood correlated with APR biomarkers in GCA, whereas neutrophils correlated with the APR in infection controls. Patients with overlapping C-GCA and LV-GCA displayed a significantly stronger APR than patients with C-GCA or LV-GCA alone. High VEGF and angiopoietin-1, but low angiopoietin-2 levels at baseline predicted a shorter time to treatment free remission. This is in contrast to markers of the APR, which did not significantly predict time to treatment free remission.

**Conclusions:** In this study, we show that markers of angiogenesis are better predictors of disease outcome than APR biomarkers. It appears that levels of calprotectin, YKL40 and angiopoietin-2 are increased through other than APR pathways during GCA compared to acute infection. Monocytes rather than neutrophils appear to drive the APR in GCA. This response is stronger in GCA patients with both cranial and systemic symptoms.

## Osteoporosis

#### THU0469 QUANTIFYING THE TREATMENT WITH GLUCOCORTICOID AS A RISK FACTOR FOR THE OCCURRENCE OF OSTEOPOROSIS AND FRACTURES IN PATIENTS WITH RA

E. Wiebe, R. Biesen, K.N. Zeiner, D.C. Freier, S. Hermann, G.-R. Burmester, F. Buttgerit. *Department of Rheumatology and Clinical Immunology, Charité – University Medicine Berlin, Berlin, Germany*

**Background:** Rheumatoid arthritis (RA) is associated with increased systemic bone loss, leading to a high risk for fragility fractures. The etiology of increased fracture risk in RA is multifactorial and comprises next to general risk factors also RA-specific risks, most prominently chronic inflammation, seropositivity and glucocorticoid (GC) use<sup>1</sup>. Yet, there is evidence that GCs may, by adequately suppressing systemic inflammation, also have a positive effect on BMD and fracture risk in RA<sup>2</sup>.

**Objectives:** The purpose of this study was to investigate the prevalence of osteoporosis and fragility fractures in RA patients and to characterise, among other risk factors, the role of GC dose, cumulative dose (GCCD) and duration as well DMARD treatment on bone health.

**Methods:** Rh-GIOP is an ongoing prospective observational study collecting and analysing disease- and bone-related data from patients with chronic rheumatic diseases treated with GCs. In this cross-sectional analysis, we evaluated the initial visit of 238 patients with RA. Descriptive analyses were performed, with values displayed as mean/standard deviation and median/range for continuous variables. For subgroup analyses, non-parametric tests were used.

**Results:** Of 238 patients with RA (79.4% women, mean age:  $63.6 \pm 12.5$  years), 155 were seropositive and 83 seronegative. Seronegative patients were numerically older ( $66.8 \pm 12.1$  vs  $61.8 \pm 12.1$  years) and more often in menopause (78.3% vs 61.8%, ns) than seropositive, while the latter had longer disease duration (median:  $4.0 \pm 20$  vs  $11.0$  years,  $p=0.03$ ). Overall, osteoporotic BMD was more frequent at femoral sites, with 21% of patients having T-Scores  $< -2.5$ . Osteoporotic BMD was more common in seronegative patients (ns), although no difference in the frequency of fragility fractures ( $n=18; 24.1\%$  vs  $n=28; 23.2\%$ ) was found.

All patients received GCs (mean dose:  $5.0 \pm 6.8$  mg, mean GCCD  $15.1 \pm 19.3$  g, mean duration  $7.7 \pm 8.2$  years) with seropositive patients having numerically higher GCCD, longer duration of GC therapy and more often current GC doses above  $>10$  g/day. Biological DMARDs were more frequently used in seropositive patients ( $n=20; 24.1\%$  vs  $n=67; 43.2\%$ ,  $p=0.02$ ). Anti-osteoporotic therapies between both groups did not differ.

Neither current GC doses nor GCCD nor DMARD therapy had a statistically significant and independent effect on BMD or fragility fractures in either RA group.

**Conclusions:** Osteoporosis and fragility fractures remain a challenge in the management of RA, being determined by multiple interacting factors. Our data confirm that GCs may not *per se* increase fracture risk and decrease BMD in RA but rather, that optimal management of disease activity with or without GCs may be beneficial to bone health. Interestingly however, despite higher cumulative GC doses and duration, seropositive RA patients did not have lower BMD or higher prevalence of fragility fractures compared to seronegative patients. Further prospective data is warranted to better characterise the role of GCs and DMARDs in regard to osteoporosis and fracture risk in RA patients.

**THU0470 NON-CLONAL ELEVATION OF SERUM IMMUNOGLOBULIN FREE LIGHT CHAINS IS PREDICTIVE OF HIP FRACTURE IN BOTH WOMEN AND MEN**

S. Amin, E.J. Atkinson, S.J. Achenbach, A. Dispenzieri, R.A. Kyle, S.V. Rajkumar. MAYO CLINIC, Rochester, USA

**Background:** Proinflammatory cytokines favour uncoupling of bone turnover and decreased bone density and strength, leading to increased fracture risk. Non-clonal elevation of serum immunoglobulin free light chains (sum of kappa and lambda chains) ( $\Sigma$ FLC) may be a global marker of generalised immune stimulation, and has been associated with chronic co-morbidities<sup>1</sup> as well as increased mortality<sup>2</sup>.

**Objectives:** We examined whether elevated  $\Sigma$ FLC is associated with an increased risk for hip fractures in a population-based cohort.

**Methods:** We studied Olmsted County, Minnesota, USA residents, age  $\geq 50$  years, in whom  $\Sigma$ FLC was measured between March 1995 and November 2003 and research authorisation was available. Anyone with a known plasma cell disorder was excluded. Using the Rochester Epidemiology Project, a unique medical records linkage system that allows access to all (inpatient and outpatient) community medical records for Olmsted County residents, we identified all hip fractures that occurred in subjects following their  $\Sigma$ FLC measurement to their last available follow-up or the end of 2015. All available medical records were reviewed by trained nurse abstractors to validate hip fractures identified and to determine their antecedent cause (pathological process [e.g., malignancy], severe trauma [e.g., motor vehicle accidents] and those due to no more than moderate trauma [by convention, equivalent to a fall from standing height or less]). Charlson comorbidity index (CCI) was determined at the time of baseline  $\Sigma$ FLC measurement. We used a Cox proportional hazards model, stratified by sex, adjusting for age, serum creatinine and CCI, to examine whether a  $\Sigma$ FLC  $\geq 4.72$  mg/dl (levels previously associated with increased mortality in this population<sup>1</sup>) is associated with an increased risk for hip fracture.

**Results:** We studied 15 814 residents [mean age (SD), 64<sup>10</sup> yrs; 8722 women, 7092 men] of whom 796 (9.1%) women and 781 (11.0%) men had a  $\Sigma$ FLC  $\geq 4.72$  mg/dl. Women and men with an elevated  $\Sigma$ FLC  $\geq 4.72$  mg/dl had higher CCI [median (IQR) 2 (0,4) vs 0 (0,2); same results for both sexes]. We identified 687 women and 255 men with a hip fracture from any cause (628 women and 220 men had a moderate trauma hip fracture), over 1 12 171 person-years (p-y) and 89 269 p-y of follow-up, respectively. We found that both women and men with  $\Sigma$ FLC  $\geq 4.72$  mg/dl had an increased risk for hip fracture due to any cause: hazard ratio (HR) [95% CI] 1.31 [1.00, 1.73] in women, HR 1.97 [1.37, 2.83] in men; as well as for moderate trauma hip fractures: HR 1.39 [1.05, 1.84] in women, HR 2.12 [1.46, 3.09] in men.

**Conclusions:** We found that  $\Sigma$ FLC  $\geq 4.72$  mg/dl is associated with an increased risk for hip fracture in both women and men, independent of age and chronic co-morbidities. Elevated  $\Sigma$ FLC may be a marker of proinflammatory cytokines detrimental to bone health and warrants further study.

Shumnalieva<sup>1</sup>. <sup>1</sup>Department of Rheumatic Diseases, Medical University – Sofia; <sup>2</sup>Department of Internal Medicine, Medical University – Sofia, Medical Institute; <sup>3</sup>Department of Internal Medicine, Medical Institute – Ministry of Interior, Sofia, Bulgaria

**Background:** Systemic sclerosis (SSc) is a multisystem autoimmune disease, characterised by diffuse fibrosis, degenerative changes, and vascular

abnormalities in the skin, joints, and internal organs. The effect of systemic sclerosis on bone density is not well understood.

**Objectives:** The aim of this study is to evaluate the risk factors of low bone mineral density (BMD) and occurrence of fracture and fracture-related mortality in patients with SSc.

**Methods:** Demographics, disease manifestations of SSc, biological inflammatory parameters, functional disability, scleroderma health assessment questionnaire, immunological status, BMD (lumbar spine and femoral neck), risk factors for low BMD, fractures, and fracture-related mortality were collected in patients with SSc. BMD was measured by using a dual-energy X-ray absorptiometry in lumbar spine (L1-L4) and femoral neck. Fisher's Exact and Student's t-tests were used to evaluate differences between women with and without low BMD. Logistic regression was used for multivariate analysis.

**Results:** Forty eight consecutive unselected SSc women were approached. The mean age of women was 48,32 $\pm$ 15,56 years, the mean disease duration was 10,12 $\pm$ 4,78 years. Twenty-nine women (60,42%) had low BMD, of those 11 (37,93%) had osteoporosis, mean BMD in lumbar spine was  $-2,86\pm 0,38$  and in femoral neck was  $-2,22\pm 0,26$ . Twenty three (47,92%) women with SSc were postmenopausal. In correlation analysis and in multiple regression models, there were correlations between BMD and longer duration of SSc (p<0,01), family history of osteoporosis (p<0,05), age (p<0,01), menopause (p<0,01), low body mass index (p<0,02), presence of internal organ involvement (p<0,05), malabsorption syndrome (p<0,05), joint involvement (severe joint pain and erosive arthropathy) (p<0,05), and immunological status (positivity of anti-DNA topoisomerase I antibodies) (p<0,05). 4 women (4/29) with low BMD had a fracture, compared to 2 without low BMD. Fracture-related mortality did not occur in any patients.

**Conclusions:** Our data suggest that women with SSc are at risk of low BMD and fracture, especially when other risk factors for osteoporosis are present. A number of clinically relevant factors (longer duration of SSc, presence of internal organ involvement, joint involvement, immunological status) are associated with low BMD.

**Disclosure of Interest:** None declared

Meneses<sup>1</sup>, J.R. Curtis<sup>1</sup>, K.G. Saag<sup>1</sup>.

<sup>1</sup>University of Alabama at Birmingham, Birmingham; <sup>2</sup>University of Massachusetts Medical School, Worcester; <sup>3</sup>University of Pittsburgh, Pittsburgh; <sup>4</sup>Group Health Cooperative, Seattle; <sup>5</sup>Helen Hayes Hospital, West Haverstraw; <sup>6</sup>Cedars-Sinai Medical Center, Los Angeles; <sup>7</sup>Columbia University Medical Center, New York; <sup>8</sup>Mercy Health Osteoporosis and Bone Health Services, Cincinnati, USA

**Background:** Understanding factors associated with the readiness for adopting osteoporosis treatment change may inform the design of behavioural interventions to improve osteoporosis treatment uptake in women at high risk for fracture.

**Objectives:** To examine the factors associated with the readiness for adopting osteoporosis treatment change among US women with prior fractures.

**Methods:** US women in the Global Longitudinal Study of Osteoporosis (GLOW) with prior self-reported fractures who were not currently using osteoporosis therapy were eligible to participate in the Activating Patients at Risk for Osteoporosis (APROPOS) Study. Participants' readiness for behaviour change was assessed using a modified form of the Weinstein Precaution Adoption Process Model (PAPM). We defined pre-contemplative participants as those who self-classified in the unaware and unengaged stages of PAPM. Contemplative participants were defined by the undecided, decided not to act, and decided to act stages of PAPM. Bivariate tests and stepwise multivariable logistic regression evaluated the following factors associated with these two levels of readiness for behaviour change: sociodemographic characteristics, health literacy, self-reported history of depression and dementia, previous treatment for osteoporosis, whether participants had been told they had osteoporosis/osteopenia, and whether they had concerns about osteoporosis.

**Results:** A total of 2684 women were enrolled in APROPOS. Participants were 95% Caucasian, with a mean (SD) age 74.9 (8.0) years and 77% had some college education. Overall, 25% (n=544) self-classified in the contemplative stage of behaviour change. Compared to women who self-classified as pre-contemplative, contemplative women were more likely to be concerned about osteoporosis (adjusted OR [aOR]=3.2, 95% CI 2.3-4.4) and to report prior osteoporosis treatment (aOR 4.3, 95% CI 3.1-6.0). Participants who were told they had osteoporosis had a 12.4 fold odds to be in the contemplative group (95% CI 8.5-18.1), while those who were told they had osteopenia had 4.1 fold odds to be in the contemplative group (95% CI 2.9-5.9).

	Age>75	Sex M vs F	Residence	Hepatic Disease	CRF	OCFA	Dementia	CHF	Diabetes mellitus	Charlson i. >2
HR	1.05	1.32	1.48	3.25	1.87	1.46	1.46	2.50	1.11	1.98
IC	(1.04–1.06)	(1.21–1.44)	(1.36–1.60)	(2.17–4.86)	(1.60–2.18)	(1.30–1.62)	(1.30–1.62)	(2.07–3.00)	(1.02–1.22)	(1.73–2.26)

**Conclusions:** Among women with high risk of future fracture, having been told by a health care provider that they had osteoporosis/osteopenia was independently associated with considering taking medications for osteoporosis. Our results suggest that in considering osteoporosis intervention design efficiency and effectiveness, women's recognition of a diagnosis of osteoporosis/osteopenia are critical components to be considered when attempting to influence stage of behaviour transitions.

#### THU0473 TREND OF MORTALITY AFTER OSTEOPOROTIC HIP FRACTURE IN A PERIOD OF 17 YEARS

R. Mazzucchelli<sup>1</sup>, O. Guzón-Illescas<sup>2</sup>, E. Pérez-Fernandez<sup>2</sup>, M. Peña<sup>2</sup>, J. Quirós<sup>2</sup>, N. Crespi Villarias<sup>3</sup>, A. García-Vadillo<sup>4</sup>, <sup>1</sup>Rheumatology, <sup>2</sup>Hospital U. Función Alcorcón; <sup>3</sup>C.S La Rivota, Alcorcón; <sup>4</sup>H. U. La Princesa, Madrid, Spain

**Background:** It is known that the mortality after a hip fracture is increased with respect to the general population. However, the trend of mortality is a controversial issue.

**Objectives:** The objective of this study is to analyse the incidence, trend and factors associated with mortality in patients with osteoporotic hip fracture.

**Methods:** This is a retrospective cohort study using the Minimum Basic Data Set (MBDS) of our hospital that collects a minimum data set at hospital discharge. We identified patients older than 45 years who suffered an osteoporotic hip fracture during the period from 1999 to 2015. (3992 hip fractures). The demographic data and comorbidities were obtained from the exploitation of the MBDS and the Income Nursing Assessment Form (subgroup of 810 patients). The identification of the deceased was obtained by consulting the MBDS and the INDEF (National Death Index facilitated by the Ministry of Health). A survival analysis was performed (regression of Cox and Kaplan-Meier). The incidence rate, standardised mortality index (SMI) was calculated with respect to the mortality of the general population of Madrid (mortality data of the general population obtained INE), trend (Poisson regression) and risk (Hazard Ratio) for the different clinical and demographic variables.

**Results:** The cumulative incidence of mortality was 72.69% in the study period. The crude mortality rate at 1, 3, 6 months and 1 and 3 years was 9.2%, 17.4%, 24.6%, 33% and 56%, respectively. In men it was 13.7%, 25%, 32.7%, 43.3% and 65.6% and in women 7.9%, 15.7%, 22.3%, 30%, 53.2%. The median overall survival was 886 days (95% CI: 836–951), with 576 for men and 998 for women. A statistically significant reduction in median survival was observed throughout the study period. The IME was 8.3 (95% CI: 7.98–8.59); (similar values in men and women). The clinical-demographic variables that showed a statistically significant association with mortality are shown in the following table 1 (HR and p-value):

Other variables that showed statistical association were: presence of auditory and visual alterations, incontinence (urinary and faecal) and the total score on the Norton scale and the Downton scale.

**Conclusions:** We found an increase in mortality (or decrease in median survival) of patients with hip fracture during the last 17 years. An increase in mortality has been observed in patients with hip fracture related to age, male sex, diabetes, hepatic disease and living in a nursing home.

**Disclosure of Interest:** None declared

#### THU0474 UTILISATION OF ANTI-OSTEOPOROTIC DRUGS IN REAL-WORLD DATA: AN ANALYSIS OF PERSISTENCE TO THERAPY AND RISK OF FRACTURE

V. Orlando<sup>1</sup>, V.M. Monetti<sup>1</sup>, F. Guerriero<sup>1</sup>, A. Moretti<sup>2</sup>, V. Russo<sup>1</sup>, A. Piscitelli<sup>1</sup>, G. Iolascon<sup>2</sup>, E. Menditto<sup>1</sup>. <sup>1</sup>CIRFF Center of Pharmacoeconomics, University of Naples Federico II; <sup>2</sup>Department of Medical and Surgical Specialties and Dentistry, University of Campania "Luigi Vanvitelli", Naples, Italy

**Background:** Osteoporosis is a chronic progressive disease characterised by low bone mass and deterioration of bone structure, leading to an increase risk of fractures. It is a major public health problem, affecting hundreds of millions of people worldwide. The primary aim of pharmaceutical therapy is to reduce the risk of osteoporotic fractures. However, long-term adherence to therapy is requisite for optimal therapeutic benefit for patients with osteoporosis. Poor adherence is considered to be one primary reason for suboptimal clinical benefit.

**Objectives:** The aim of this study was to investigate the determinants of non-persistence and impact of persistence on the risk of fractures by using administrative databases.

**Methods:** We conducted a retrospective cohort study using administrative data from four local health authorities in the Abruzzo Region (Central Italy), which comprise about 9 000 000 inhabitants (68% of the overall regional population). The final cohort consisted of a total of 7862 patients, aged ≥60 years, identified through records of filled prescriptions for an antiosteoporotic drug between January 1, 2006 to December 31, 2006. The primary outcome of this study was persistence at one year. Persistence was defined as the length of time (in days) from the date of the index prescription to the date of discontinuation therapy.

**Results:** Kaplan – Meier analysis showed that 3733 patients (47.5%) were persistent with antiosteoporotic drugs after 1 year. An adjusted analysis showed that there is a big difference in persistence between women and men: women are more likely to be non-persistent than men (HR:1.94). Switcher patients were more likely to be non-persistent (HR:1.22). The odds of fracture were significantly higher for patients with previous fractures in comparison with those without previous fractures [OR, 1.70, (95% CI, 1.12–2.59)] (table 1)

**Table 1** Logistic regression model: impact of persistence and other factors on the risk fracture

Characteristics	Unadjusted OR (95%CI)	p-value	Adjusted OR (95%CI)	p-value
<b>Gender</b>				
Male	Reference			
Female	1.31 (0.93-1.85)	0.119	1.28 (0.91-1.82)	0.159
<b>Age</b>				
60-69	Reference			
70-79	1.54 (1.14-2.06)	0.005	1.52 (1.13-2.06)	0.006
≥80	2.56 (1.89-3.45)	< 0.001	2.49 (1.83-3.39)	< 0.001
<b>Previous fractures</b>				
No	Reference			
Yes	1.71 (1.58-1.84)	< 0.01	1.70 (1.12-2.59)	0.013
<b>Persistence</b>				
No	Reference			
Yes	0.78 (0.63-0.97)	0.022	0.79 (0.63-0.97)	0.026
<b>ACCI</b>				
Zero score [0]	Reference			
Mild score [1-4]	0.86 (0.32-2.36)	0.772	1.35 (0.49-3.78)	0.562
Severe score [≥5]	1.50 (1.06-2.12)	0.022	1.33 (0.94-1.90)	0.112

**Conclusions:** Persistence with antiosteoporotic drugs is a significant predictor of incurring a fracture. For these reason, improving osteoporosis treatment compliance and persistence represents one of a major challenge for the future.

THU0475

### INCIDENCE AND DETERMINANTS OF VERTEBRAL AND PERIPHERAL FRACTURES IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A PROSPECTIVE LONGITUDINAL COHORT STUDY

F. El Hadiyen<sup>1</sup>, M. Tsang-A-Sjoe<sup>1</sup>, M. ter Wee<sup>1,2</sup>, A. Voskuyl<sup>1</sup>, W. Lems<sup>1</sup>, I. Bultink<sup>1</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands

**Background:** Systemic lupus erythematosus (SLE) is associated with an increased risk of fractures<sup>1</sup>. However, data on the incidence of vertebral and peripheral fractures are limited. In particular, data on (morphometric) vertebral fracture incidence and determinants of such fractures are scarce and show conflicting results.

**Objectives:** To assess the incidence of fractures in a population of patients with SLE, and to identify determinants that predict incident vertebral and peripheral fractures.

**Methods:** A prospective longitudinal cohort study in 145 patients with SLE was performed. Serial bone mineral density (BMD) measurements using dual x-ray absorptiometry, and radiographs of the thoracic and lumbar spine were performed at inclusion and after a median of 5 years (IQR 3–5) follow-up. Demographic and clinical data were also collected. Vertebral fractures were scored according to the semi-quantitative method by Genant *et al.* Reported peripheral fractures were confirmed by x-rays. Analyses were performed with logistic regression (forward selection procedure, p-value of 0.05 as cut-off level). The outcome measures were incident fracture in general (yes/no), vertebral fracture (yes/no), and peripheral fracture (yes/no).

**Results:** Of the 145 included patients, 131 (90%) were females and 100 (69%) Caucasian. The mean age was 41 years (SD 12) at baseline, and median follow-up was 7.2 years (IQR 6–12). A total of 42 incident fractures (vertebral and peripheral) occurred during 998 patient years. The incidence rate of vertebral and peripheral fractures was 2.0 per 100 patient years (95% CI 1.30–3.13), and 2.20 per 100 patient years (95% CI 1.45–3.35), respectively.

Any fracture (both vertebral and peripheral) was predicted by postmenopausal status and Caucasian ethnicity. Vertebral fractures were predicted by age, in which the older the SLE patient, the higher the odds of getting vertebral fractures. Peripheral fractures were predicted by history of stroke, postmenopausal status and moderate alcohol use (1–12 units per week). Use of higher dosages of alcohol (>13 units per week) did not reduce peripheral fracture occurrence. Table 1 shows the final prediction models.

**Conclusions:** The results of our study suggest a twofold increased risk of both vertebral and peripheral fractures in SLE patients compared to the general population<sup>1,2</sup>. Age, Caucasian ethnicity and postmenopausal status are important risk factors for incident fractures in SLE. In addition, special attention should be paid to SLE patients with a history of stroke since this subgroup of patients is at high risk of peripheral fractures.

THU0476

### SPONTANEOUS VERTEBRAL FRACTURES AFTER DENOSUMAB DISCONTINUATION: A REPORT OF 6 CASES

H. Florez, J. Ramirez, A. Monegal, N. Guañabens, P. Peris. *Department of Rheumatology, Hospital Clínic, Barcelona, Spain*

**Background:** Denosumab (Dmab) is an antiresorptive treatment with demonstrated efficacy in osteoporosis. However, discontinuation of Dmab has been associated with rapid bone loss, and recently, the development of vertebral fractures (VF) in some patients. It is essential to identify the risk factors for these adverse events and follow its evolution.

**Objectives:** To analyse the clinical characteristics, parameters of bone metabolism and evolution of patients developing VF after Dmab discontinuation.

**Methods:** Six women with spontaneous VF after Dmab discontinuation were included (median age 66 years<sup>56–75</sup>). The clinical history, cause of osteoporosis, treatments received, fractures, Dmab treatment duration and discontinuation period were reviewed. Additionally, the clinical and densitometric evolution, and bone mineral parameters were also analysed after Dmab discontinuation.

**Results:** All the patients had postmenopausal osteoporosis, and one was receiving glucocorticoid treatment; 3/6 patients had previous fractures (2 VF and 1 calcaneus); 4/6 had previously received antiosteoporotic treatment (hormone replacement therapy, risedronate, alendronate, zoledronate [once or consecutively]) during 1–23 years. All had received Dmab for 24–53 months (median 37). The reasons for treatment discontinuation were: dental indication (1 patient), BMD improvement (T-score –1.2) (1 patient), poor adherence,<sup>1</sup> prescription problems and/or delay in administration.<sup>3</sup> The median bone mineral density T-scores prior to VF were –2.6 (–1.2/–4) at the lumbar spine and –3.0 (–0.6/–3.7) at the femoral neck. The mean time between the last Dmab dose and VF was 9.5 months,<sup>8–20</sup> with a median of 5 VFs/patient.<sup>2–8</sup> No patient showed 25-OH vitamin D <20 ng/ml. After Dmab discontinuation, bone turnover markers increased (median increase +364% in PINP and +287% in NTx); one patient presented hypercalcaemia (Ca 11.3 mg/dL); and BMD decreased 1%–21% in the lumbar spine and 2%–6% in total hip at 8–19 months. After VF, 3 patients restarted Dmab, 1 received zoledronate and 2 alendronate. No new fractures occurred during follow-up.

**Conclusions:** Discontinuation of Dmab is associated with an increase in bone turnover markers and bone loss which can be associated with the development of spontaneous VF. Previous bisphosphonate therapy does not seem to decrease this risk. Further studies are needed to assess the optimal antiresorptive treatment and its duration after Dmab discontinuation.

**Disclosure of Interest:** None declared

THU0477

### FACTORS ASSOCIATED WITH THE INITIATION OF TREATMENT AFTER FRAGILITY FRACTURE IN A FRACTURE LIAISON SERVICE

A. Saavedra<sup>1</sup>, A. Naranjo<sup>1</sup>, S. Ojeda<sup>1</sup>, R. Lopez<sup>1</sup>, A. Molina<sup>1</sup>, C. Alonso<sup>2</sup>, I. Bernardos<sup>1</sup>, C. Rodriguez-Lozano<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology, Hospital Univ. Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain

**Background:** Adherence to treatment in osteoporosis (OP) is not adequate, so that in the first year the percentage of suspensions is between 30% and 50%, up to an adherence of 20% at 3 years. In 2012, we started in Gran Canaria a Fracture Liaison Service (FLS).

**Abstract THU0475 – Table 1.** Multivariate logistic regression analyses of independent explanatory variables that predict incident fracture, showing OR and 95% CI

Variables	Any fracture			Vertebral fractures			Peripheral fractures		
	OR	95% CI	P	OR	95% CI	P	OR	95% CI	P
Age				1.0	1.0–1.1	0.017			
Caucasian ethnicity	13.3	1.7–104.3	0.014						
Postmenopausal status	4.0	1.6–10.1	0.004				3.2	0.86–11.6	0.084
Past stroke							15.5	1.1–212.2	0.040
Alcohol use							Ref	Ref	Ref
- No							0.06	0.01–	0.019
- Moderate							1.9	0.62	0.634
- Heavy								0.14–24.9	

**Objectives:** To describe the factors associated to an effective initiation of treatment after the baseline visit to our FLS.

**Methods:** Prospective observational study that consists of: 1) training of primary care physicians (GP), 2) capture of patients; 3) baseline visit: questionnaire including FRAX; 4) Bone densitometry; 5) patient education by a Nurse with special attention to adherence; 6) referral to GP with a report with management recommendations; those with multiple fractures or who require parenteral therapy were referred to rheumatology; and 7) follow-up by telephone survey to check whether the treatment was taking and confirmation of the prescription in the electronic records (both of which are necessary to consider an effective start of treatment). The variables included were: sex, age, type of fracture, use of previous bisphosphonate, type of prescribed treatment, prescribing physician and causes of non-adherence.

**Results:** Up to December 2017, the adherence of 887 patients with fragility fractures to whom a bisphosphonate or equivalent was prescribed, was recorded. Treatment was initiated in the following 3 months by 74% (n=656) of patients. The following variables were associated with the initiation of treatment: female sex, previous treatment with antiresorptives, prescription of denosumab vs bisphosphonate and treatment prescribed by a rheumatologist vs GP (table 1). The causes of not initiating or withdrawing the treatment at 3 months are shown in table 2. In the regression analysis, we found a significant association with the effective initiation of treatment with a previous treatment with bisphosphonate (p<0.01), initiation of treatment by the rheumatologist (p=0.01) and prescription of denosumab vs bisphosphonate (p<0.01)

**Abstract THU0477 – Table 1.** Factors associated to start of treatment at 3 months \*p<0,01

	Patients that initiate treatment (n=656)	Patients who did not initiate or stop treatment (n=231)
Female/Male, n(%)	577 (76)/79 (63)*	185 (24)/46 <sup>37</sup>
Age, mean (SD)	76 (9)	76 (9)
Type of fracture, n (%) Wrist/Hip	191 (29)/213 <sup>32</sup>	71 (31)/68 <sup>29</sup>
Previous treatment with	178 (91)/478 (69)*	18 (9)/213 <sup>31</sup>
Bisphosphonate, n (%) Yes/No		
Prescription of Bisphosphonate/denosumab n (%)	446 (70,5)/203 (80)*	186 (29,5)/
Prescription by Primary Care/Rheumatology, n (%)	412 (69,5)/230 (82)*	180 (30,5)/51 <sup>18</sup>

**Abstract THU0477 – Table 2.** Causes of no start or stop treatment, N (%)

No prescription/suspension by GP	115 (50)
Patient related causes	93 (40)
Patient does not want the treatment	39 (17)
Polipharmacy	20 (9)
Don't know/Did not visit the GP	20 (9)
Drug intolerance	14 (6)
Other causes	23 (10)

**Conclusions:** 74% of patients seen in the FLS start treatment within 3 months of the baseline visit. The factors associated with the initiation of therapy were prior antiresorptive treatment, denosumab prescription and initial prescription by the rheumatologist. The reason of non adherence in half of the cases is the GP's refusal to initiate or continue the FLS recommendation.

**Disclosure of Interest:** None declared

#### THU0478 BEFORE AND AFTER MENOPAUSE, OSTEOPOROSIS RISK FACTORS ARE DIFFERENT IN WOMEN WITH RHEUMATOID ARTHRITIS

J.-F. Chen, T.-T. Cheng, S.-F. Yu, Y.-C. Chen, C.-Y. Hsu, H.-M. Lai, F.-M. Su, B. Y.-J. Su, W.-C. Chiu. *Division of Rheumatology, Allergy, and Immunology, Department of Internal Medicine, Kaohsiung Chang Gung Memorial Hospital and Chang Gung University College of Medicine, Kaohsiung, Taiwan, Province of China*

**Background:** Rheumatoid arthritis (RA) is an autoimmune disease characterised by systemic inflammation, involving not only the juxta-articular bone erosion, but generalised bone loss.<sup>1</sup> Sex hormone activates RA disease activity and induced bone resorption, but hormone replacement therapy increases bone mass and density. The ambiguous role of sex hormone on bone remodelling is confusing in RA patients. Under the impact of sex hormone, risk factors for osteoporosis might be different at pre- and post-menopausal stage.

**Objectives:** To investigate the different clinical risk factors of osteoporosis in pre- and post-menopausal women with RA.

**Methods:** A cross-sectional study was performed during 2014 to 2017, enrolling female participants fulfilled 2010 RA criteria.<sup>2</sup> We recorded demographic data,

risk factors for osteoporosis and blood test. Osteoporosis is defined if one of hip, distal forearm, and lumbar spine bone mineral density less than -2.5 by T-score for post-menopausal women, or less than -2.0 by Z-score for pre-menopausal women. Data was analysed by Student's t test and Chi-square test for continuous and categorical variables, respectively. Multivariate logistic regression was applied to detect association of osteoporosis and selected variables.

**Results:** A total of 451 participants were enrolled in the study, including 89 pre- and 362 post-menopausal women. The prevalence of osteoporosis is 14.6% and 36.7% for pre- and post-menopausal women with RA, respectively. At pre-menopause, low body weight is the only significant risk factors for osteoporosis, while old age, low body height, low body weight, positive anti-cyclic citrullinated peptide antibody (anti-CCP), previous fracture history, elevated white blood cell and platelet count, and lower calcium level are potential risk factors for post-menopausal women developing osteoporosis (table 1). Multivariate stepwise logistic regression analysis (table 2) showed body weight remains the leading risk factors in pre-menopausal women (Odds ratio[OR]=0.84, 95% confidence interval [CI]=0.76-0.94, P-value=0.002), while body weight and previous fracture history are significant risk factors in post-menopausal women (body weight OR=0.91, 95% CI=0.88-0.94, P-value<0.001, previous fracture OR=2.03, 95% CI 1.13-3.64, P-value 0.02).

**Conclusions:** Risk factors of osteoporosis are different in pre- and post-menopausal women with RA. For pre-menopausal women, Low body weight is a leading risk factor, while low body weight and previous fracture history are important for post-menopausal women. Without protection of sex hormone, there are Potential roles of anti-CCP and white blood cell participating in osteoporosis pathogenesis and need more survey for confirmation.

**Background:** A relevant number of patients with vertebral fracture (VF) do not receive specific treatment for osteoporosis and remain as invisible fractures. The objective of the Fracture Units-FLS is to detect patients with fracture, to perform an adequate diagnostic evaluation, initiate treatment and try to prevent new fractures.

**Objectives:** To know the characteristics of the patients and attitude of the referring service, in which the radiological report identifies the presence of VF.

**Methods:** Observational study carried out from January 1 to June 30, 2017, of consecutive patients in which the radiological report after performing simple radiology or CT, reflects the presence of dorsal, lumbar or both VF. The attitude of the service requesting the radiological test was reviewed 3 months after the radiological report.

The following variables were collected: general data of the patients (age, gender), the service requesting the imaging test (specialty, request from hospitalisation or ambulant, diagnosis and/or previous treatment for osteoporosis, attitude towards the VF) and the radiological test (type of test and location of the VF).

**Results:** 91 patients were included, of which 62% were women, with a mean age of 72±11.56 years. In 46% of the patients, the image test was requested by one of the Internal Medicine Services (gastroenterology: 31%, oncology-haematology: 17%, rheumatology: 14%, neumology: 12%, cardiology: 10%), 36% by Primary Care Physicians, 15% from the Emergency Department of the Hospital and the remaining 2% from a Surgical Service.

In 77%, the radiological test was given to ambulatory patients. In 56%, the imaging test was simple radiology (chest X-ray: 56%, dorsal-lumbar spine: 41% and the

remaining 4% bone series study) and 44% CT. In 61%, the fracture was located in dorsal spine, in 28% in lumbar spine and the remaining 11% in the dorsal and lumbar spine. Previously, 44% were diagnosed with osteoporosis and 38% were undergoing specific treatment (oral bisphosphonate: 23%, bisphosphonate iv: 20%, denosumab: 20%, SERM: 8%, PTH: 6% and only calcium +vitamin supplements D: 23%).

Three months after the identification of the VF, 66% did not receive specific treatment for osteoporosis, 11% were referred to Rheumatology (initiating treatment in all) and 3% to Traumatology. Three (3%) of the patients had died and 2 (2%) had moved away.

**Conclusions:** Despite being reflected in the radiological report, a significant number of patients with vertebral fracture do not receive antiosteoporotic treatment, 3 months later.

**Acknowledgements:** The study was supported with a research grant from the Association for Research in Rheumatology of Marina Baixa (AIRE-MB).

Rodríguez-Lozano<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Gerontology, Hospital Univ. Gran Canaria Dr. Negrin; <sup>3</sup>Primary Care, Gerencia Gran Canaria; <sup>4</sup>Rehabilitation; <sup>5</sup>Analisis Clinicos; <sup>6</sup>Orthopedic Surgery; <sup>7</sup>Radiology, Hospital Univ. Gran Canaria Dr. Negrin, Las Palmas de Gran Canaria, Spain

**Background:** in March 2012 was implemented a FLS Unit coordinated by Rheumatology

**Objectives:** communicate the results of the unit in the 2012–2017 period.

**Methods:** Patients >50 years with fragility fracture. The program consists of: 1) training of primary care doctors (GP), 2) recruitment from the emergency room or admitted with hip fracture; 3) Bone densitometry; 4) patient education by a nurse; 6) report to GP with recommendations of managing; and 7) follow-up of persistence of treatment (telephonic survey plus prescription in the electronic records) at 3, 6, 12 and 24 months.

**Results:** The FLS has attended 1739 patients: mean age 73 y, 81% women. The location of fractures was forearm (32%), hip (24%), humerus (21%), vertebra (10%) and other locations (12%). Previous treatment with bisphosphonate 17%, 10% of them at baseline.

After the baseline visit, 75% of patients were sent to GP and 25% to rheumatology. Treatment with bisphosphonate or equivalent was recommended to 1264 patients (72%). Persistence of treatment (analysed at 3, 6, 12 and 24 months in 1,051, 823, 622 and 351 patients, respectively) was 74%, 72%, 75% and 69%, respectively.

#### THU0481 PHYSICAL PERFORMANCE FACTORS INFLUENCING GAIT SPEED IN PATIENTS SURGICALLY TREATED FOR OSTEOPOROTIC HIP FRACTURES

B.R. Kim. JEJU NATIONAL UNIVERSITY HOSPITAL, Jeju, Korea, Republic of Ireland

**Objectives:** This study was undertaken to determine physical performance factors associative of gait speed in patients surgically treated for hip fractures.

**Methods:** Fifty eight patients (16 males and 42 females; average age 79.1±9.1 years) who underwent a hip surgery due to hip fractures participated in this study. Patients completed 10 metre walk test (10MWT) to assess gait speed. Additional physical performance tests included Timed up and go test (TUG), Berg balance scale (BBS), one repetitive maximum (1RM) of leg extension, leg curl, hip abduction of surgical and nonsurgical sides, and instrumental gait analysis for spatio-temporal parameters.

**Results:** In the bivariate analyses, postoperative 10MWT had a significant positive correlation with the postoperative TUG ( $r=0.85$ ,  $p<0.01$ ), age ( $r=0.57$ ,  $p<0.01$ ), swing phase duration ( $r=0.35$ ,  $p<0.01$ ), gait cycle duration ( $r=0.49$ ,  $p<0.01$ ) and significant negative correlation with the postoperative BBS ( $r=-0.69$ ,  $p<0.01$ ), 1RM of surgical leg extension ( $r=-0.35$ ,  $p=0.01$ ), 1RM of nonsurgical leg extension ( $r=-0.40$ ,  $p<0.01$ ), 1RM of surgical leg curl ( $r=-0.44$ ,  $p<0.01$ ), 1RM of nonsurgical leg curl ( $r=-0.41$ ,  $p<0.01$ ), 1RM of hip abduction ( $r=-0.32$ ,  $p=0.02$ ), cadence ( $r=-0.53$ ,  $p<0.01$ ), stance phase duration ( $r=-0.26$ ,  $p=0.04$ ). In addition, a presence of dementia was significantly correlated with 10MWT (44.2 s vs 22.4 s,  $p=0.02$ ). In the linear regression analyses, the postoperative TUG ( $\beta=0.85$ ,  $p<0.01$ ) was a factor associative of the postoperative 10MWT.

**Conclusions:** This study revealed that the presence of dementia, the postoperative balance ability, muscle strength of surgical and nonsurgical legs were significantly associated with postoperative gait speed 1 month after hip surgery due to hip fractures. Therefore, these results could be importance in planning various postoperative rehabilitative programs to improve gait speed early after hip surgery due to hip fractures.

#### THU0482 RELATIONSHIP BETWEEN MILD VERTEBRAL BODY DEFORMITY AND KELLGREN-LAWRENCE'S OSTEOARTHRITIS LEVEL WITH THE PREVALENCE OF NON-TRAUMATIC DORSAL AND LUMBAR BACK PAIN IN FEMALE PATIENTS WITH RISK OF OSTEOPOROTIC VERTEBRAL COLLAPSE

C.A. Guillen-Astete, C. Ijoán, J.R. Quiñones-Torres, M. Vázquez Díaz. Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain

**Background:** There is a lack of information about the meaning of mild vertebral body deformities and its relationship with back pain. Many patients with this kind of wedges are sent to rheumatology clinics to assess the possibility to start treatment for secondary prevention of osteoporosis fractures.

**Objectives:** The present study aims to determine the relationship of the number of medical consultations due to dorsal or lumbar pain and two categorical variables: Presence or absence of mild vertebral wedge (Genant's first level of classification) and Kellgren-Lawrence's osteoarthritis classification levels I-II and III-IV.

**Methods:** We conducted a retrospective follow-up of 1131 patients with and without mild vertebral body deformities along three years to compare the frequency of axial pain episodes assessed in emergency units and their chance to evolve to moderate or severe wedges.

**Results:** In the group without deformities, the cumulative incidence of dorsal or lumbar pain episodes was 7.2% per year, and the incidence density was 7805 cases per 100 patients-year. In the group with mild deformities, the cumulative incidence of dorsal or lumbar pain episodes was 7.0% per year, and the incidence density was 7318 cases per 100 patient-year ( $p=0.77$  and  $0.58$ , respectively). We grouped patients according to their osteoarthritis severity. The cumulative incidence of dorsal and lumbar pain episodes along the period of observation, in patients with a spinal Kellgren-Lawrence's osteoarthritis degree I-II and III-IV were 19.8% (CI95% 12.10%>27.49%) and 31.5% (CI95% 18.27%>44.72%), respectively ( $p<0.0001$ ). The density of incidence for both groups was 6.18 cases per 100 patients-year and 11.3 cases per 100 patients-year, respectively ( $p<0.0001$ ). The difference in proportions of patients who developed a moderate or severe Genant's vertebral deformities was not statistically significant among patients with or without mild vertebral wedges.

**Conclusions:** Our results point that back pain incidence is not related to the presence of mild vertebral wedges but the severity of axial osteoarthritis. Also, the behaviour of starting a secondary osteoporosis prevention treatment after the detection of a mild vertebral wedge is not supported by our results.

THU0483

### BONE MINERAL DENSITY AND PREVALENCE OF OSTEOPOROSIS IN HIV-INFECTED PATIENTS IN COMPARISON WITH A REFERENCE SPANISH POPULATION: THE IMPORTANCE OF LOCAL NORMATIVE RANGES

C. Sobrino<sup>1</sup>, J. Loarce<sup>1</sup>, F. López<sup>1</sup>, J. Gallego<sup>2</sup>, M.J. Vivancos<sup>2</sup>, M. Pérez Elías<sup>2</sup>, J. L. Casado<sup>2</sup>, M. Vazquez<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Infectious Diseases, Hospital Universitario Ramón y Cajal, Madrid, Spain

**Background:** HIV-infected patients have less bone mineral density (BMD) than non-HIV population. According to current guidelines, the normal BMD reference range is that derived from the US NHANES III (National Health and Nutrition Examination Survey) and from BMDCS-Hologic. However, local variations of BMD could change the interpretation of bone loss and the prevalence of osteoporosis (OP) in this population.

**Objectives:** To compare the BMD in HIVinfected Spanish patients with values from healthy Spanish population and to estimate the prevalence of OP in this patients, based on the local data.

**Methods:** This was a cross-sectional study in a homogenous cohort of HIV-infected patients (RyC cohort, EC 009/17). Data of femoral neck and spine BMD were obtained by DXA (Dual-Energy X-ray Absorptiometry) from 949 patients (241 women, 25%) and compared with the results of a nationally representative Spanish cohort (14 centres) including 2442 subjects (1305 women, 53%) aged 20–80 years.

**Results:** Overall, mean age was 45.4 years (women, 46.5 years). The Spanish reference cohort showed a reduced BMD (–7%, 3%–12%) in comparison with NHANES, especially in middle aged women. HIVinfected patients had a lower BMD than Spanish cohort in both spine and femoral neck localizations for the different age strata ( $p < 0.001$ ), not significant in femoral neck for males aged 30–39 ( $n = 152$  patients, 0.848 vs 0.869 gr/cm<sup>2</sup>;  $p = 0.07$ ). Using NHANES data, the prevalence of OP was 26% in women in the Spanish cohort and 41% in our HIV population. By contrast, if the Spanish data are used as normative range, the prevalence of OP decreased in HIV females, significant between 40–60 years (from 26.5% to 23.5% in spine,  $p < 0.01$ ). Although OP in spine was less frequent in males by using Spanish data ( $p < 0.01$ , OP decrease from 17.8% to 6.5%), there was more OP in femoral neck in males older than 40 years (from 13.5% to 21% in 60–69;  $p < 0.01$ ).

**Conclusions:** Our data demonstrate that HIV-infected patients had a significantly reduced BMD in comparison with both US and Spanish reference data for all the age strata. However, the prevalence of osteoporosis could change if local representative cohorts are used as normative data, with almost 30% of patients being reclassified.

THU0484

### REBOUND-ASSOCIATED MULTIPLE VERTEBRAL FRACTURES AFTER DISCONTINUATION OF DENOSUMAB: NINE CASES REPORT

E. Fernández, D. Benavent, G. Bonilla, I. Monjo, S. García, M. Bernad, A. Balsa, P. Aguado. Rheumatology, Hospital Universitario La Paz, Madrid, Spain

**Background:** Denosumab (DNB) is an IgG monoclonal antibody with high affinity for RANKL that transiently decreases bone resorption. It increases bone mineral density (BMD) and decreases turnover markers, reducing fracture risk in patients with osteoporosis (OP). Several cases of rapid loss of BMD, severe bone turnover rebound (BTR) and associated fractures have been reported after DNB discontinuation. A clinical alert has been generated from these findings.

**Objectives:** To evaluate the clinical and demographic features in a case series of patients with multiple vertebral fractures after discontinuation of denosumab.

**Methods:** An observational descriptive study analysing data from nine patients with multiple vertebral fractures after DNB discontinuation that were admitted to our Rheumatology service between 2015 and 2017.

**Results:** Nine women with postmenopausal OP that received treatment with DNB were included (table 1). Mean age at treatment onset was 66.9±8.0 SD years. Four of them had previous fragility fractures, and one of them had risk factors for secondary OP (treatment with aromatase inhibitors, case 8). Eight patients (88.9%) had already received treatment other than DNB. Mean DNB received doses was 6±1.6 SD. Mean T-score before treatment was –2.6±0.6 SD for femoral neck (FN) and –3.0±1.3 SD for lumbar spine. Mean T-score ±SD after 6 months or more of DNB discontinuation was –3.5±0.8 and –3.3±1.8, respectively. Bone turnover markers (BTM) remained elevated (CTX mean 0.143 ±0.663 SD ng/ml and P1NP 152.1±122.4 SD ng/ml). There were a total of 47 fractures, and all occurred spontaneously. Most affected vertebrae were D9, D12, L3 y L5. Two patients underwent vertebroplasty, suffering both of them vertebral fractures after surgery.

### PREDICTING 1-YEAR MORTALITY AFTER A FRAGILITY HIP FRACTURE – THE EXPERIENCE OF A FRACTURE LIAISON SERVICE

F. Aguiar<sup>1,2</sup>, M. Guerra<sup>3</sup>, S. Ganhão<sup>1,2</sup>, D. Gonçalves<sup>4</sup>, T. Martins-Rocha<sup>1,2</sup>, R. M. Ferreira<sup>1,2</sup>, A. Águeda<sup>2,5</sup>, R. Vieira<sup>3</sup>, G. Terroso<sup>1</sup>, C. Vaz<sup>1,2</sup>, L. Costa<sup>1</sup>.

<sup>1</sup>Rheumatology, Centro Hospitalar São João, Porto; <sup>2</sup>Faculty of Medicine of Porto University, Oporto; <sup>3</sup>Rheumatology, Centro Hospitalar Gaia/Espinho, Gaia; <sup>4</sup>Rheumatology, Centro Hospitalar Trás-os-Montes e Alto Douro, Vila Real; <sup>5</sup>Rheumatology, Centro Hospitalar Baixo Vouga, Aveiro, Portugal

**Background:** Hip fractures are the most serious outcome of osteoporosis and are a leading public health concern due to the associated increase in morbidity and mortality, loss of independence and financial burden.

**Objectives:** The aim of this study was to investigate possible predictive factors of 1 year mortality in patients with fragility proximal femur fracture referred to a fracture liaison service (FLS).

**Methods:** Patients aged ≥65 years admitted in Orthopaedics department with a fragility hip fracture were evaluated and referred to the Rheumatology outpatient clinic. In this setting patients were evaluated with laboratory and imagiological workup and afterwards anti-osteoporotic therapy was started. We retrospectively collected information regarding patients hospitalised from March 2015 to March 2017 and conducted univariate and multivariate analysis to determine possible predictive factors of 1 year mortality.

**Results:** 522 patients were included, with a median age of 84 years (range 65–104), 416 (79.7%) females. The median time to intervention was 2 days (range 0–44) and median hospital stay 10 days (range 0–175). Median Charlson Comorbidity Index (CCI) score was 5 (range 2–13). In-hospital mortality was 6.3% and overall 1 year mortality was 16.7%.

In the univariate analysis, the factors significantly associated with death in one year time were male gender, CCI score >5, previous physical limitation in daily activities, walking disability previously and 2 months after the fracture, longer time to surgery (>48 hour), conservative treatment and previous osteoporosis diagnosis. In multivariate analysis previous physical limitation in daily activities (OR 2.1, CI 1.22–3.62;  $p = 0.007$ ) and walking disability 2 months after the fracture (OR 4.23, CI 1.73–10.37;  $p = 0.002$ ) were independent predictors of 1 year mortality.

**Conclusions:** In this study, in-hospital mortality was similar to what has been described in literature but 1 year mortality was slightly lower. Previous physical limitation and walking disability 2 months after the fracture were independent risk factors for 1 year mortality. These findings should be confirmed in larger, prospective studies with a control group.

**THU0486 THE VITAMIN D RECEPTOR EXPRESSION IN SKELETAL MUSCLE OF WOMEN WITH DISTAL RADIUS FRACTURE**

H.S. Gong<sup>1</sup>, K. Kim<sup>2</sup>. <sup>1</sup>Department of Orthopaedic Surgery, Seoul National University Bundang Hospital, Seongnam; <sup>2</sup>Department of Orthopaedic Surgery, Hallym University College of Medicine, Chuncheon, Korea, Republic of Ireland

**Background:** A distal radius fracture (DRF) is the most common upper extremity fracture in old women. Since DRFs typically occur earlier than hip fractures by an average of 15 years, they can reflect early changes of bone such as osteoporosis and muscle frailty for instance, the loss of muscle mass.

**Objectives:** We aimed to evaluate the relationship between the vitamin D receptor (VDR) expression in the muscle cell and the muscle mass in women with a DRF.

**Methods:** This research was conducted as a part of the Study on Ageing Radial fracture Cohort (SARCO) which is an ongoing longitudinal, population-based cohort investigation of patients with a DRF which began in November 2015. For the current study, we prospectively recruited 45 women over 50 years of age (mean age, 66 years) with DRF and acquired biopsy of the forearm flexor muscle. The muscle cross-sectional area (CSA) and VDR expression were measured using immunohistochemistry staining. The clinical parameters including grip strength, gait speed, body mass index (BMI), bone mineral density (BMD), and serum vitamin D levels were compared between patients grouped by appendicular lean mass index and were correlated with the VDR expression.

**Results:** Twelve patients (27%) showed a decreased appendicular lean mass index, less than the cut-off value of 5.4 kg/m<sup>2</sup> which was suggested by the Asian Working Group for Sarcopenia. Patients with a low appendicular lean mass index had significantly lower muscle CSA ( $p=0.037$ ), but a higher VDR expression ( $p=0.045$ ) than those with higher indices. VDR expression was negatively correlated with BMI ( $r=-0.417$ ,  $p=0.004$ ) and appendicular lean mass index ( $r=-0.316$ ,  $p=0.044$ ).

**Conclusions:** DRF patients with low appendicular lean mass index presented high VDR expression and low CSA in forearm muscle cells. This suggests that the VDR expression might be up-regulated in the attempt to compensate for the decreasing muscle mass. Further studies are necessary to explore the role of VDR in the progression of sarcopenia.

**THU0487 AN AUDIT OF THE USE OF PERCUTANEOUS VERTEBROPLASTY FOR OSTEOPOROTIC VERTEBRAL FRACTURES IN A UK RHEUMATOLOGY CLINIC**

J. Pinnell<sup>1</sup>, H. Merris<sup>1</sup>, M. Dhillon<sup>2</sup>, K. Chaudhuri<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Interventional Radiology, University Hospitals Coventry and Warwickshire NHS Trust, Coventry, UK

**Background:** University Hospital, Coventry, UK (UHCW), offers percutaneous vertebroplasty (PVP) to patients with painful osteoporotic vertebral fractures. The National Institute for Health and Care Excellence (NICE) Technology Appraisal 279 (TA279) (2013) restricts the use of PVP to patients with severe ongoing pain despite optimal pain management, where the pain corresponds to the level of fracture on examination and imaging.<sup>1</sup>

**Objectives:** To audit the use of PVP by Rheumatology at UHCW against NICE TA279.<sup>1</sup>

To assess the clinical outcomes of PVP for our patients.

**Methods:** The records of all UHCW Rheumatology patients who received PVP from MD<sup>3</sup> (Interventional Radiologist) between September 2007 and August 2014 were retrospectively assessed against NICE TA279.<sup>1</sup>

We defined a 'recent' fracture as occurring 6–12 weeks prior to PVP as this allows time for natural bone healing whilst minimising therapeutic delay.<sup>1</sup> 'Optimal pain

management' was defined as analgesia in addition to, or stronger than, paracetamol.

**Results:** 57 of the 221 PVP performed by MD were for Rheumatology patients. 38 patients were female and 19 were male. They were aged 42–95 years (median 73), and 95% were Caucasian. 26 had taken corticosteroids for more than 6 months.

7 patients received PVP 6–12 weeks after their fracture. 10 patients had PVP within 6 weeks. 39 patients waited 12 weeks or longer due to late patient presentation, slow referral processes, and the time taken to optimise analgesia.

38 (67%) patients received optimal analgesia before PVP.

46 (81%) patients had pain that correlated with the level of vertebral fracture.<sup>1</sup>

Following PVP back pain was gone for 9 (16%) patients, improved for 38 (66%), not changed for 4 (7%), and worse for 1 (2%) patient.

Complications included leakage of cement locally (57%) or into local veins (5%). 2 patients had pulmonary cement emboli. One presented with breathlessness and the second was found incidentally. Both recovered with conservative therapy.

**Conclusions:** In line with NICE TA279, most patients had pain at the level of their fracture and received optimal pain management prior to receiving PVP.

10 patients received PVP earlier than our standard of 6 weeks. However, recent randomised trials suggest that PVP may be beneficial in this group.<sup>2</sup>

Most (68%) patients received PVP later than 12 weeks but they often found benefit. The VERTOS V trial may help determine the role of PVP for chronic fractures.<sup>3</sup>

Introducing an osteoporotic vertebral fracture pathway at UHCW will help ensure appropriate management, timely review and, when necessary, prompt PVP.

**THU0488 AGE AT THE TIME OF HIP FRACTURE IN PATIENTS WITH RHEUMATOID ARTHRITIS IS GREATER THAN IT WAS 10 YEARS AGO, BUT IS STILL YOUNGER THAN THAT OF THE GENERAL POPULATION**

K. Arai<sup>1</sup>, J. Ajiro<sup>2</sup>. <sup>1</sup>Department of Orthopaedics; <sup>2</sup>Department of Internal Medicine, Niigata Prefectural Central Hospital, Joetsu, Japan

**Background:** Niigata Prefectural Central Hospital (NPCH) is the principal hospital of Joetsu and Myoko cities in Niigata Prefecture, Japan. It serves a population of 230,186, of whom 70,205 (30.5%) were aged  $\geq 65$  years in 2015. About 90% of patients with hip fractures underwent surgery within 48 working hours after admission in NPCH. Between 50% and 60% of all hip fractures in our region are treated at the NPCH, which employs two rheumatologists and treats 500 rheumatoid arthritis (RA) patients.

**Objectives:** We sought to identify the characteristics of RA patients with hip fractures, as compared to those of the general population and of RA patients treated 10 years previously.<sup>1</sup>

**Methods:** Between 2012 and 2015, 789 hip fractures were treated at the NPCH. The mean age of these patients was 84 $\pm$ 8.0 years. RA patients with such fractures were compared with fracture patients from the general population. We recorded the neck/trochanter (n/t) ratio, age at fracture, disease duration, steroid and anti-osteoporosis drug-use rates, secondary fracture rate, walking capacity after operation, 1 year and 30 day mortality rates, and infection rate, in both current RA patients and those treated 10 years previously.

**Results:** Eleven RA cases had hip fractures (mean age: 76 $\pm$ 7.0 years; all females); 8 had been treated for RA at NPCH. RA patients constitute 1.4% of the general population, and 1.6% of all RA patients treated at the NPCH. Mean RA duration was 23 $\pm$ 20 years. The n/t ratio was 1.2. Three cases aged 60–69 years were of the mutilated type and mean RA duration was 35 $\pm$ 18 years. Five cases

aged 70–79 years featured amyloidosis associated with hemodialysis (1 case), severe interstitial pneumonia,<sup>1</sup> Parkinson's disease,<sup>1</sup> total knee arthroplasty triggered by RA,<sup>2</sup> and mean RA duration was 17±11 years. Of 3 cases aged 80–89 years, RA onset was after age 80 years in two. At the time of fracture, 7 were receiving anti-osteoporosis treatment; 2 were on teriparatide, 4 on bisphosphonate, and 3 on activated vitamin D. Some patients discontinued anti-osteoporotic medication because of renal failure or side effects; 84% of patients had taken anti-osteoporotic medications prior to fracture. Seven patients were taking steroids (mean prednisolone dose 3.9±2.1 mg/day). Secondary fractures occurred in 2 cases; one had RA of the mutilated type with renal failure; a secondary fracture occurred 4 months later. The 2nd case was taking anti-osteoporotic medication but the secondary fracture occurred 32 months later. At 3 months after surgery, the walking abilities of all patients were the same as prior to fracture. No mortality was recorded at either 30 days or 1 year. No infective complication was noted.

**Conclusions:** Hip fracture in patients with RA occurs in 1.4% of the general population in Joetsu and Myoko, Japan, ranging from 0.93% in Taiwan<sup>2</sup> to 1.6% in Sweden<sup>3</sup>, and 1.6% of all RA patients, ranging 3.3% in Taiwan<sup>2</sup> to 6.5% in Sweden<sup>3</sup>. The mean age at hip fracture was 76±7.0 years, thus about 8 years younger than that of fracture patients from the general population, but was 72±4.5 years 10 years ago<sup>1</sup>. Among all patients, 64% were on steroids (83% 10 years ago<sup>1</sup>), 84% were on anti-osteoporosis drugs (31% 10 years ago<sup>1</sup>) and the n/ratio was 1.2 (3.2 10 years ago<sup>1</sup>).

#### THU0489 THE IMPACT OF CALCIUM INTAKE AND PHYSICAL EXERCISE ON PEAK BONE MINERAL DENSITY

L. Brites, M.L. Marques, A. Marques, A. Daniel, M. Santiago, J. Pereira da Silva. *Rheumatology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal*

**Background:** Regular exercise and adequate nutrition are frequently prescribed as strategies to optimise peak bone mass and maintain bone and muscle health throughout life.

**Objectives:** The aim of our work was to determine the relationship of clinically assessed milk intake and physical exercise with bone mineral density (BMD) in young adults.

**Methods:** This cross-sectional study included members of the general population aged between 20 and 30 years from the Portuguese cohort SAOL (individuals aged 18+years randomly selected from a local county of Coimbra, Portugal). No exclusion criteria were applied. Individuals were asked to describe their milk intake (up to 2 glass/day and 2+glass/day, corresponding to up to and more than 480 mg/day), regular physical activity (categorised as none-to-moderate and at least intense physical activity) and strenuous sports practice (up to 2 hour/week and 2+hour/week) from the age of 10 to 25. They underwent a Dual-energy x-ray absorptiometry (DEXA) of the lumbar spine (LS) and proximal femur (PF). Categorical data is presented as proportions/percentages and continuous variable as median ±standard deviation. Differences between groups were assessed by Mann–Whitney U test. Potential predictors of a higher BMD of PF and LS were identified using multiple linear regression analysis. P-values<0.05 were considered statistically significant.

**Results:** We included 259 individuals (mean age of 24.7±2.7 years, 60.6% being female). The majority (82.6%), described having a moderate regular physical activity (equivalent to working as a mailman), practicing strenuous sports at least 2 hours per week (81.1%) and ingesting at least two glasses of milk per day (83.4%). The current BMD of the PF and LS were 0.8±0.13 and 0.99±0.11, respectively. On univariate analysis, the only significant association related the PF BMD and milk intake (p=0.008). Multiple linear regression analysis showed that while physical activity and sports practice did not predict BMD values, milk intake persisted as a predictor of a higher BMD of PF (p=0.022), even after including other explanatory variables. No statistically significant predictors were found for BMD of the LS.

**Conclusions:** Our study showed that clinically assessed milk intake between the ages of 10 and 25 years, but not physical exercise, is a significant predictor of higher bone mineral density assessed by DEXA at the PF. These results do not exclude a positive impact of exercise upon peak bone mass, but suggest that its retrospective evaluation in a clinical setting should not be taken as reassurance that a good peak bone mass was achieved in early adulthood.

#### THU0490 TEMPORAL INCREASES IN SIDE EFFECT CONCERNS OF OSTEOPOROSIS MEDICATIONS AMONG WOMEN WITH PREVIOUS FRACTURES

Meneses<sup>1</sup>, J.R. Curtis<sup>1</sup>, K.G. Saag<sup>1</sup>.

<sup>1</sup>University of Alabama at Birmingham, Birmingham; <sup>2</sup>University of Massachusetts Medical School, Worcester; <sup>3</sup>University of Pittsburgh, Pittsburgh; <sup>4</sup>Group Health Cooperative, Seattle; <sup>5</sup>Helen Hayes Hospital, West Haverstraw; <sup>6</sup>Cedars-Sinai Medical Center, Los Angeles; <sup>7</sup>Columbia University Medical Center, New York; <sup>8</sup>Mercy Health Osteoporosis and Bone Health Services, Cincinnati, USA

**Background:** High-consequence, albeit rare, adverse side effects of osteoporosis medication raise patients' risk perceptions and contribute to non-adherence. In the past decade, fears of osteonecrosis of the jaw (ONJ) and atypical femoral fractures (AFF) have been increasingly reported as barriers to both the initiation of and adherence to osteoporosis medications.

**Objectives:** To examine the temporal prevalence of self-reported concern about ONJ and AFF as reason for discontinuation of osteoporosis medication.

**Methods:** Activating Patients at Risk for Osteoporosis (APROPOS) enrolled US women from the Global Longitudinal Study of Osteoporosis (GLOW) with previous self-reported fractures and no current use of osteoporosis medication. Using mailed surveys in 2010 (T1), 2012 (T2) and 2013 (T3), women were asked whether they discontinued osteoporosis medication in the prior year because of concerns about ONJ at three time points (T1, T2, T3) and AFF at two time points (T2, T3). We calculated the proportion of women reporting fears of ONJ and AFF among those who discontinued osteoporosis medication, and compared the proportions using chi-square tests.

**Results:** A total of 833 women discontinued osteoporosis treatment at three time points, T1 (n=255), T2 (n=471), and T3 (n=107), respectively. There were no differences in the demographic characteristics between groups. The proportion of women reporting concerns of ONJ was 18.4% (T1), 26.7% (T2) and 64.5% (T3), while 23.5% (T2) and 60.7% (T3) reported fear of AFF as reason to discontinue osteoporosis treatment. These differences were statistically significant (p<0.0001) for all comparisons.

**Conclusions:** The proportion of women reporting concerns of ONJ and AFF increased over time among those women who discontinue osteoporosis medications. Strategies are needed to help patients balance risks and benefits given a significant and temporally growing concern of rare bisphosphonate side effects.
