### WINDOW OR NO WINDOW: EARLIER IS BETTER WHEN TREATING RHEUMATOID ARTHRITIS

J.A. van der Pol<sup>1</sup>, S.A. Bergstra<sup>1</sup>, N. Riyazi<sup>2</sup>, Y.P. Goekoop-Ruiterman<sup>2</sup>, A. Chopra<sup>3</sup>, P. Kerstens<sup>4</sup>, W.F. Lems<sup>5</sup>, R. Tsonaka<sup>6</sup>, T.W. Huizinga<sup>1</sup>, C.F. Allaart<sup>1</sup>. <sup>1</sup>Rheumatology, LUMC, Leiden; <sup>2</sup>HAGA Hospital, The Hague, Netherlands; <sup>3</sup>CRD, Pune, India; <sup>4</sup>Amsterdam Rheumatology and Immunology Center, Reade; <sup>5</sup>Rheumatology, VUMC, Amsterdam; <sup>6</sup>Medical Statistics and Bioinformatics, LUMC, Leiden, Netherlands

**Background:** Previous reports on a window of opportunity in rheumatoid arthritis (RA) may be related to the use of slow acting c(ontventional) s(ynthetic) DMARDs. We hypothesised that onset of action of therapy might influence whether there is a window of opportunity or whether 'earlier is just better'.

**Objectives:** To investigate the association between symptom duration at treatment onset and the achievement of sustained drug free remission (sDFR) in early RA patients initiating therapy including fast acting prednisone or infliximab, compared to patients initiating csDMARD monotherapy.

**Methods:** We analysed the shape (hyperbolic or linear) of the association between symptom duration and achievement of sDFR (DAS<1.6 and no DMARDs for  $\geq 1$  year) for patients initiating combination therapy in 3 cohorts: BeSt, IMPROVED study and METEOR. All patients had arthritis symptoms <2 years. In the BeSt study, early RA patients (1987 criteria) were randomised to 4 targeted treatment strategies: arm 1 and 2 started with csDMARD monotherapy, arm 3 with csDMARDs and tapered high dose prednisone and arm 4 with csDMARD and infliximab. Subsequent treatment adjustments aimed at DAS $\leq 2.4$ . In the IMPROVED study early RA patients (2010 criteria) were treated with csDMARD and tapered high dose prednisone. Subsequent treatment adjustments aimed at DFR. METEOR is an international observational cohort including daily practice data from patients with a diagnosis and treatment of RA according to the rheumatologist. We selected patients who started on csDMARD monotherapy or a combination of csDMARD with prednisone or anti-TNF and at least 1.5 year follow-up.

Missing DAS were imputed using last observation carried forward. We performed Cox regression analyses with as outcome sDFR and as predictor symptom duration and compared the likelihood ratio tests of a linear model and a model with inclusion of natural cubic spline functions (resulting in a hyperbola), to investigate which model was a better fit for the data.

**Results:** In BeSt (n=469), IMPROVED (n=421) and METEOR (n=1653) 54, 110 and 10 patients who started with csDMARD and prednisone or anti-TNF combination therapy, and 53 in BeSt and 15 in METEOR who started with csDMARD monotherapy (no monotherapy in IMPROVED) achieved sDFR. A hyperbolic model did not show a better fit for the data than a linear model (for combination therapy in BeSt  $p=0.743$ , IMPROVED  $p=0.337$ , METEOR  $p=0.608$ , for csDMARD monotherapy in BeSt  $p=0.609$ , in METEOR  $p=0.758$ ). Figure 1 shows the linear association between symptom duration and sDFR per study. These results indicate that the earlier treatment is started, the higher the likelihood of achieving sDFR. However, the data do not suggest that a hyperbolic relationship between treatment onset and outcome sDFR fit the data better.

**Conclusions:** Our data suggest that there is no evidence for a window of opportunity in early RA in 3 cohorts. This was not related to use of fast acting combination therapy including prednisone or anti-TNF instead of slow acting csDMARD monotherapy nor was it dependent on strict treatment to target in a clinical trial. It remains that earlier treatment initiation is better when aiming to achieve sDFR.

SAT0097

### RISK OF PREVENTABLE HOSPITALISATION BEFORE AND AFTER DIAGNOSIS AMONG RHEUMATOID ARTHRITIS PATIENTS COMPARED TO CONTROLS

C.-F. Kuo<sup>1,2</sup>, P.B. Burns<sup>3</sup>, J.-S. Chen<sup>2</sup>, L. Wang<sup>4</sup>, K.C. Chung<sup>3</sup>. <sup>1</sup>Academic Rheumatology, University Of Nottingham, Nottingham, UK; <sup>2</sup>Division of Rheumatology, allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China; <sup>3</sup>Section of Plastic Surgery, <sup>4</sup>Department of Biostatistics, School of Public Health, University of Michigan, Ann Arbor, USA

**Background:** Rheumatoid arthritis (RA) generally requires intensive medical intervention, which along with the progression of the disease itself, may lead to the occurrence of comorbidities and hospitalisation that can be prevented with a quality primary care. We assessed the risk of preventable hospitalizations in RA patients, for whom preventable hospitalizations have not been well studied. We compare the incidence rate of preventable hospitalizations in newly-diagnosed RA patients and non-RA patients using data from the Taiwan National Health Insurance (NHI) Database.

**Objectives:** To investigate the risk of preventable hospitalisation before and after diagnosis between RA and non RA patients.

**Methods:** 11 852 incident RA patients and 59 260 age-, sex-, and index year-matched controls were identified from the Taiwan National Health Insurance Database. Index date was defined as the initial diagnosis date for RA patients and this date was assigned to their matched controls. The incidence and incidence rate ratios (IRRs) of preventable hospitalisation between RA patients and controls were estimated using conditional Poisson regression adjusted for age, sex, Elixhauser Comorbidity Index, number of outpatient visits and hospitalizations 1 year prior to index date, residence urbanisation, income levels, occupation and the number of physicians practicing near the patients' residence.

**Results:** The overall incidence of preventable hospitalisation in RA patients and controls was 1.71 vs 0.95 events per 1000 person-months, corresponding to adjusted incidence rate ratio (IRR) of 1.43 (95% CI, 1.35–1.51). The crude IRR for preventable hospitalisation was 1.84 (1.61–2.11) one year prior to RA diagnosis. Adjusted IRRs (95% CI) for preventable hospitalisation categories were 1.43 (1.22–1.67) for chronic obstructive pulmonary disease, 1.28 (1.02–1.62) for asthma, 1.76 (1.62–1.91) for bacterial pneumonia, 1.47 (1.35–1.61) for urinary tract infection.

**Conclusions:** This population-based study indicates that RA is independently associated with a higher risk of preventable hospitalisation, and the risk was already greater prior to formal diagnosis of RA. These results signal gaps in the care and management of RA patients in this population.

SAT0098

### PATIENT AND DISEASE CHARACTERISTICS THAT PREDICT SWITCHING FROM A TNF INHIBITOR TO ANOTHER BIOLOGIC OR TARGETED SYNTHETIC DMARD IN PATIENTS WITH RA IN CLINICAL PRACTICE

L.R. Harrold<sup>1</sup>, H.J. Litman<sup>2</sup>, S.E. Connolly<sup>3</sup>, E. Alemao<sup>3</sup>, S. Kelly<sup>3</sup>, S. Rebello<sup>2</sup>, T. Blachley<sup>2</sup>, J.M. Kremer<sup>4</sup>. <sup>1</sup>University of Massachusetts Medical School, Worcester; <sup>2</sup>Corrona LLC, Waltham; <sup>3</sup>Bristol-Myers Squibb, Princeton; <sup>4</sup>Albany Medical College and The Center for Rheumatology, Albany, USA

**Background:** Specific patient demographics or disease characteristics may be associated with switching from one therapy to another for patients with RA. Identifying these predictive factors may help inform prospective treatment decisions.

**Objectives:** To examine factors predicting switching among patients with RA from a TNF inhibitor (TNFi) to a subsequent biologic (b)DMARD (TNFi or non-TNFi [abatacept, tocilizumab, rituximab]) or the targeted synthetic (ts)DMARD tofacitinib.

**Methods:** This analysis included patients aged  $\geq 18$  years, who were enrolled in a large sequential RA registry established in October 2001 and who initiated a TNFi on/after 1 January 2005 and had  $\geq 24$  months' follow-up. Switch was defined as discontinuation of a TNFi and initiation of another bDMARD or tofacitinib within 6 months. Of TNFi initiations, 67% were randomly selected as a prediction dataset and used to develop the final model; 33% were considered in the validation dataset. Logistic regression modelling was used to predict switching status; baseline demographics (age, sex, race), patient attributes (smoking status, BMI, work status) and clinical characteristics (RF and anti-cyclic citrullinated protein status, erosive disease, history of co-morbidities, prior and current treatment, disease activity, patient-reported pain, fatigue, morning stiffness) were considered. Goodness-of-fit statistics were used to assess model fit and receiver operating characteristic curves (area under the curve [AUC]) to validate the model.

**Results:** Among 6909 eligible TNFi initiations, there were 1343 switchers (prediction dataset: 4623 TNFi initiations, including 898 switchers). Compared with non-switchers, switchers were younger, had a shorter duration of RA and higher baseline mean CDAI score. Fewer switchers were positive for erosive disease or on combination therapy with MTX, but more were on monotherapy or combination therapy with a non-MTX DMARD. After investigation of several models, the best-fit model (Table) to predict switching from a TNFi yielded an AUC=0.705 (sensitivity=81%; false positive rate=49%).

Table 1. Predictive Model for TNFi Switching in Patients with RA

Covariate	Value	Odds ratio (95% CI)	p value
Age (10 year effect)		0.85 (0.79–0.92)	<0.0001
Duration of RA, years	0–2	Reference:	
	3–5	0.85 (0.67–1.07)	0.17
	6–10	0.65 (0.51–0.85)	0.001
	>10	0.52 (0.41–0.66)	<0.0001
History of diabetes		1.26 (0.94–1.68)	0.12
History of malignancy		0.66 (0.47–0.94)	0.02
History of serious infection		1.16 (0.82–1.64)	0.41
Prior number of conventional DMARDs		1.17 (1.08–1.27)	0.0002
Number of prior non-TNFi	0	Reference:	
	1	1.17 (0.88–1.55)	0.29
	$\geq 2$	1.36 (0.90–2.05)	0.15
CDAI score	Remission (0–2.8)	Reference:	
	Low (>2.8–10)	1.72 (1.11–2.66)	0.01
	Moderate (>10–22)	2.75 (1.82–4.16)	<0.0001
	High (>22)	2.75 (1.82–4.14)	<0.0001
Year of initiation		1.33 (1.28–1.37)	<0.0001

**Conclusions:** The model identified in this analysis revealed that factors including age, duration of RA, CDAI, history of co-morbid conditions, prior treatment and year of TNFi initiation predicted switching from a TNFi to another bDMARD or tsDMARD.

### SARCOPENIA IS ASSOCIATED WITH JOINT DAMAGE IN RHEUMATOID ARTHRITIS: A CROSS-SECTIONAL STUDY

J.-Z. Lin<sup>1</sup>, Y.-Y. Wang<sup>2</sup>, P.-J. Liu<sup>2</sup>, Y.-Q. Mo<sup>1</sup>, Q.-H. Li<sup>1</sup>, W.-M. Cheng<sup>3</sup>, X.-L. He<sup>3</sup>, L. Dai<sup>1</sup>. <sup>1</sup>Rheumatology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University; <sup>2</sup>Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou; <sup>3</sup>Shanghai Healthcare Co. Ltd, Zhangjiang Innopark, Shanghai, China

**Background:** The association of metabolic status with disease characteristics of rheumatoid arthritis (RA) remain controversial. Body composition (BC) instead of body mass index (BMI) has been more and more recommended to assess metabolic status.

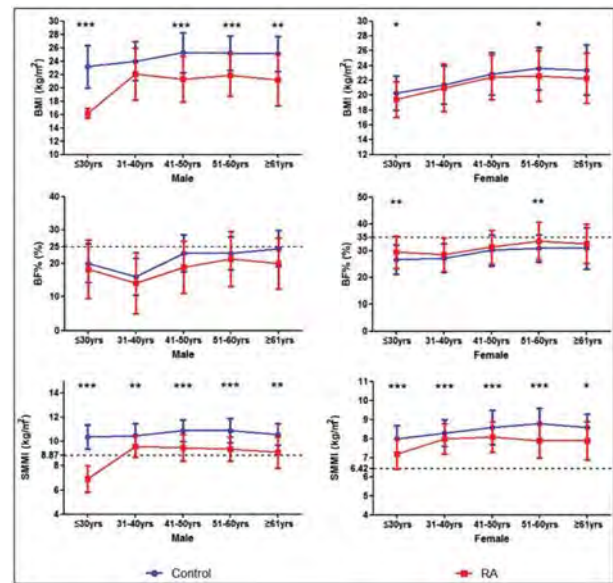

**Objectives:** To investigate the characteristics of BC in RA patients and their association with RA disease characteristics.

**Methods:** BC was assessed in RA patients and control subjects by bioelectric impedance analysis. Overfat was defined by body fat percentage (BF%) as  $\geq 25\%$  for men and  $\geq 35\%$  for women. Sarcopenia was defined by skeletal muscle mass

Characteristics	BF%		P	SMMI		P
	Normal fat (n=309)	Overfat (n=148)		Non-sarcopenia (n=405)	Sarcopenia (n=52)

**SAT0100 THE DETERMINANTS OF REFRACTORY RHEUMATOID ARTHRITIS**

M. Bécède, J. Smolen, D. Aletaha. Department of Medicine 3, Division of Rheumatology, Medical University of Vienna, Vienna, Austria

**Background:** It is an ongoing matter of research, whether the course of rheumatoid arthritis (RA) can be altered by an early intervention, a concept historically referred to as the “window of opportunity”.<sup>1</sup> With the inherent challenge of underlying self-limiting disease in early patients, it remains unclear, whether the ultimate disease course of definite RA is really affected by the timing of initial treatment.

**Objectives:** To explore whether the long-term course of RA is different according to the delay of initial treatment.

**Methods:** Patients were identified from a longitudinal clinical database, and patients with refractory RA (“reRA”) were compared with patients with treatment amenable RA (“taRA”). reRA was defined as ≥3 treatment courses (≥1 biological) over ≥18 months since diagnosis without reaching low disease activity (LDA) or remission (REM) defined by a Clinical Disease Activity Index (CDAI, ≥10); taRA patients reached at least LDA within their first 2 treatment courses. We performed both matched and adjusted logistic regression analysis to compare differences in timing of first treatment between these two groups.

**Abstract SAT0100 – Table 1.** Patient characteristics at first clinical visit.

Features Characteristics	Populations		Differences (p-value*)					
	reRA (n=70)	Other (n=240)	taRA (n=102)	reRA matched** (n=50)	taRA matched** (n=50)	Across all three unmatched groups	reRA vs taRA (unmatched)	reRA vs taRA (matched**)
First Visit (month/year)	12/2005 (03/2002; 03/2009) <sup>#</sup>	06/2006 (08/2001; 08/2010)	12/2009 (10/2005; 11/2012)	06/2007 (12/2003; 07/2010)	07/2007 (09/2004; 08/2010)	<0.001	<0.001	0.786
Time to First Treatment (years from onset of symptoms)	3.17 (4.10)	1.38 (2.61)	1.45 (2.80)	2.61 (3.76)	0.88 (0.97)	<0.001	0.001	0.003
Female (%)	92.9	75.4	70.6	94	70	0.002	<0.001	0.002
Age at Symptom Onset (years)	44.37 (14.44) <sup>†</sup>	46.88 (14.53)	51.14 (14.08)	46.73 (14.02)	53.42 (12.11)	0.006	0.002	0.012
CDAI (0-76)	26.06 (12.22)	17.94 (12.49)	15.39 (9.81)	25.36 (11.98)	16.93 (9.42)	<0.001	<0.001	<0.001

\* ANOVA, t-test, or Chi<sup>2</sup>, as appropriate; \*\* matched for date of first clinical visit;

† mean (SD)/% as applicable; # date: median (quartiles)

**Results:** We enrolled 412 patients, of whom 70 were reRA and 102 taRA; 240 patients fulfilled neither definition. As can be seen in table 1, reRA patients were more frequently female (92.9 vs. 70.6%,  $p<0.001$ ), younger (44.37 vs. 51.14 years,  $p=0.002$ ), and had higher CDAI levels at first presentation (26.06 vs. 15.39,  $p<0.001$ ); time to first DMARD treatment was significantly longer for reRA than taRA (3.17 vs. 1.45 years,  $p=0.001$ ). In a multivariate analysis, treatment delay also showed statistical significance ( $p=0.007$ ). After matching reRA with taRA patients for the date of their initial presentation at our clinic, treatment delay was significantly longer univariately ( $p=0.013$ ) and adjusted for other significant predictors ( $p=0.027$ ). As our matching allowance for calendar year was  $\pm 1$  year, we could only use 50 (of 70) identified reRA patients from the cohort study approach. Based on the significant predictors, a discriminative matrix model could be constructed (figure 1).

Characteristics	reRA n=70, non-reRA n=342			
	Univariate		Multivariate	
	OR (95% CI)	Sig. (p)	OR (95% CI)	Sig. (p)
Time to First Treatment	1.15 (1.07; 1.24)	<0.001	1.12 (1.03; 1.21)	0.007
Female gender	4.57 (1.78; 11.72)	0.002	3.07 (1.14; 8.23)	0.026
Age at Symptom Onset	0.98 (0.97; 1.00)	0.048	0.99 (0.99; 1.01)	0.381
CDAI	1.06 (1.03; 1.08)	<0.001	1.06 (1.03; 1.08)	0.001

Gender		reRA vs. non-reRA			Time to First Treatment
		REM/LDA ( $\leq 10$ )	MDA ( $>10, \leq 22$ )	HDA ( $>22$ )	
Female	>2 years	10.6 (2.8; 44.3)	36.6 (18.4; 69.7)	51.8 (29.9; 72.9)	>2 years
	>1; $\leq 2$ years	3.4 (0.8; 24.3)	15.2 (6.1; 33.3)	25.1 (11.2; 47.0)	>1; $\leq 2$ years
Male	>2 years	2.1 (0.5; 20.1)	10.8 (4.6; 27.3)	18.6 (9.0; 34.6)	>2 years
	>1; $\leq 2$ years	3.1 (0.5; 19.0)	13.2 (5.5; 45.9)	22.1 (6.6; 69.6)	>1; $\leq 2$ years
	<1 year	0.9 (0.1; 25.3)	4.6 (1.0; 24.8)	8.3 (2.0; 36.0)	<1 year
	<1 year	0.6 (0.1; 18.0)	3.0 (0.7; 18.4)	5.8 (1.5; 26.8)	<1 year

**Abstract SAT0100 – Figure 1.** Comparing reRA vs non-reRA in a cohort study (logistic regression model) and predicting the probability of reRA including all selected baseline risk factors\* in a matrix risk model

\*Colour scheme: blue: 0%–5%; green: 5.1%–15%; orange: 15.1%–25%; red: >25% predicted probability of reRA; results are estimated for patient presenting in the year 2010

**Conclusions:** Our data suggest that delay to initial treatment affects the long-term course of RA. Earlier treatment initiation thus may change the severity of RA.

#### SAT0101 ATLANTOEPITROPHIC MAGNETIC RESONANCE IMAGING INVOLVEMENT IN EARLY RHEUMATOID ARTHRITIS

M. Carotti<sup>1</sup>, F. Salaffi<sup>2</sup>, M. Di Carlo<sup>2</sup>, F. Sessa<sup>1</sup>, A. Giovagnoni<sup>1</sup>. <sup>1</sup>Clinic of Radiology, Università Politecnica delle Marche, Ancona; <sup>2</sup>Rheumatological Clinic, Università Politecnica delle Marche, Jesi, Italy

**Background:** The involvement of the cervical spine in rheumatoid arthritis (RA) can be essential regarding prognosis and mortality. The early detection of a cervical spine involvement in RA is essential to avoid possibly fatal complications.

**Objectives:** To assess the involvement of the atlantoaxial joint in patients with early rheumatoid arthritis (ERA) to evaluate the role of magnetic resonance imaging (MRI) in depicting this early joint involvement and to establish a risk-profile for the individual patient.

**Methods:** Fifty patients (13 men and 37 women), mean age of 58.2 years (range 36–79 years) with clinical and laboratory evidence of ERA (mean disease duration <12 months) were included in our study. MRI of the atlantoaxial joint was performed in all patients. The MRI features were correlated with clinical, radiological and biochemical variables. All patients underwent radiographic examination of the hands, wrists and feet. The assessment of the structural damage was carried out by two experienced readers, according to simple erosion narrowing scores (SENS).

**Results:** Twelve (24%) of the 50 patients with early ERA had positive MR findings. In all cases the MR showed pannus surrounded the dens, with additional erosions in 8 patients, bone marrow oedema at atlantoaxial in 9 patients and an abnormal cervico-medullary angle (<135°), in 2 patients. Compared with patients without cervical involvement, these 12 patients showed significantly higher anti-CCP antibodies (ACPA) titre [mean 200.25 UI (SD 262.44) vs. mean 22.05 (SD

40.21) ( $p<0.001$ ); higher swollen joint count (SJC) [mean 13.66 (SD 3.39) vs mean 8.65 (SD 3.38) ( $p<0.001$ ); higher Ritchie Articular Index (RAI) [mean 33.25 (SD 5.94) vs. mean 20.86 (SD 4.22) ( $p=0.047$ ); higher GH [mean 69.58 (SD 13.49) vs. mean 45.92 (SD 9.55) ( $p<0.001$ ); higher Disease Activity Score (DAS) in 44 joints level [mean 5.72 (SD 0.44) vs. mean 4.52 (SD 0.53) ( $p<0.001$ ); higher Health Assessment Questionnaire Disability Index (HAQ-DI) [mean 1.55 (SD 0.37) vs. mean 1.09 (SD 0.33) ( $p<0.001$ ), and higher simple erosion narrowing (SENS) scores [mean 15.83 (SD 4.52) vs mean 7.71 (SD 3.43) ( $p<0.001$ ). Multivariate analysis showed meaningful relationship between ACPAs, high level of DAS and the presence of hand and wrist erosive lesions (SENS) with cervical involvement.

**Conclusions:** Our results showed that ERA patients with higher disease activity and advanced peripheral erosiveness are indicators of higher risk of early involvement of the atlantoaxial inflammatory synovitis. In daily clinical practice the MRI of cervical spine it should be proposed in patients with prognostic factors of unfavourable disease evolution, even if asymptomatic.

#### SAT0102 PRISTANE-INDUCED ARTHRITIS IN DARK AGOUTI RAT: A NEW ANIMAL MODEL TO STUDY CARDIOVASCULAR DYSFUNCTION IN RHEUMATOID ARTHRITIS

M. Chouk<sup>1,2</sup>, R. Bordy<sup>2</sup>, J. Moretto<sup>2</sup>, M. Tournier-Nappey<sup>2</sup>, C. Prati<sup>1,2</sup>, D. Wendling<sup>1,3</sup>, P. Totoson<sup>2</sup>, C. Demougeot<sup>2</sup>. <sup>1</sup>CHRU Jean Minjoz, Besançon; <sup>2</sup>Pepite EA4267, Fhu Increase, Bourgogne Franche-Comté University; <sup>3</sup>EA 4266, Bourgogne Franche-Comté University, Besançon, France

**Background:** Rheumatoid arthritis (RA) is characterised by an increased cardiovascular (CV) mortality. Animal models provide the opportunity to study CV features in RA, however, most used animal models develop a “monophasic” arthritis, making those models inappropriate for long-term studies on CV impairments.

**Objectives:** The aim of this study was to characterise vascular function and cardio-metabolic parameters in the “chronic” model of pristane-induced arthritis (PIA) in Dark Agouti (DA) rats.

**Methods:** 80 rats DA received an intradermal injection of 150  $\mu$ L of pristane (PIA) or of saline solution (controls) at day 0. Arthritis score was daily followed. Acetylcholine (Ach) and sodium nitroprusside (SNP)-induced vasorelaxation were studied in macrovascular (aortic rings pre-contracted with serotonin) and in microvascular levels (mesenteric artery segments pre-contracted with phenylephrine) at day 28 (acute phase) and day 120 (chronic phase). Radiographic score, circulating markers of inflammation, lipid and glucose levels were also measured.

**Results:** PIA rats developed an acute arthritis phase from day 13 to day 50 followed by a remission phase, then by a chronic arthritis phase from day 70 to day 120. Radiographic score was higher in chronic than in acute phase in PIA ( $p<0.001$ ). Levels of IL-6, total cholesterol and triglycerides were higher in PIA than in controls at both phases ( $p<0.001$ ) whereas plasma myeloperoxidase activity and glycaemia were unchanged. Adiponectin levels were lower in PIA compared to controls in acute ( $p<0.001$ ) but not in chronic phase. Ach-induced vasorelaxation in macrovascular bed was significantly reduced in PIA compared to controls in acute ( $p<0.05$ ) but not in chronic phase. Furthermore, an altered Ach-induced vasorelaxation was shown in microvascular bed in PIA in chronic ( $p<0.001$ ) but not in acute phase. No altered SNP-induced vasorelaxation was observed between groups at both phases in both vascular beds. Endothelial function (EF) negatively correlated with arthritis score ( $p<0.001$ ), IL-6 ( $p<0.05$ ) and total cholesterol ( $p<0.05$ ) levels in macrovascular but not in microvascular bed. No correlation was found between EF and myeloperoxidase activity, adiponectin and triglycerides levels in both vascular beds.

**Conclusions:** PIA model shares several features of the CV alterations in RA: an endothelial dysfunction at the micro- and macrovascular level with independency of course among these vascular beds, a link between inflammation and macrovascular endothelial dysfunction, associated with low lipid levels. These data suggest that this model would be very useful for long-term pharmacological studies as well for deciphering the complex pathophysiology of increased CV risk in RA.

### THREE-MONTHLY ULTRASOUND MONITORING OF RHEUMATOID ARTHRITIS PATIENTS TAPERING THEIR MEDICATION HAS LIMITED VALUE IN PREDICTING DISEASE RELAPSE

M. van der Ven<sup>1</sup>, M. Kuijper<sup>2</sup>, A. Gerards<sup>3</sup>, I. Tcheterikov<sup>4</sup>, A. Weel<sup>1,2</sup>, D. van Zeben<sup>5</sup>, C. Bijkerk<sup>6</sup>, Y. de Man<sup>7</sup>, M. Hazes<sup>1</sup>, J. Luime<sup>1</sup>. <sup>1</sup>Rheumatology, Erasmus MC; <sup>2</sup>Rheumatology, Maastad Hospital, Rotterdam; <sup>3</sup>Rheumatology, Franciscus Vlieland, Schiedam; <sup>4</sup>Rheumatology, Albert Schweitzer Hospital, Dordrecht; <sup>5</sup>Rheumatology, Franciscus Gasthuis, Rotterdam; <sup>6</sup>Rheumatology, Reinier de Graaf Gasthuis, Delft; <sup>7</sup>Rheumatology, St. Antonius Hospital, Nieuwegein, Netherlands

**Background:** Prognostic factors that may guide tapering decisions for DMARDs and TNFi on individual patient level are not available. To improve successful tapering subclinical synovitis may play a role in maintaining the remission state. Studies using ultrasound suggest that the presence of subclinical synovitis may elicit early disease relapse in remission.

**Objectives:** Our aim is to determine if ultrasound synovitis precedes disease relapse while tapering synthetic DMARD (sDMARD) or TNFi in patients with RA who achieved clinical remission on sDMARD and TNFi.

**Methods:** We included 125 RA patients (aged >17 years) treated with an sDMARD and a TNF-inhibitor who were in remission (DAS44 ≤ 2.4 & SJC ≤ 1). Demographic characteristics, swollen and tender joints, laboratory variables and ultrasound synovitis (MCP2-5; PIP2-5; wrists; MTP2-5) were recorded at each visit (every three months) during one year follow-up. Patients were randomised to two tapering strategies: i) tapering sDMARD; ii) tapering TNFi. Disease relapse was defined as DAS44 > 2.4 or SJC > 1. Ultrasound synovitis was defined as GS ≤ 1 and/or PD ≤ 0. To estimate whether ultrasound is able to identify patients who will have a disease relapse within three months follow-up a Cox proportional regression model for time to event data was used.

**Results:** Ultrasound synovitis was found in 58% of RA patients in clinical remission. After one year follow-up 36% of RA patients had a disease relapse of whom 60% had ultrasound synovitis at baseline. Table 1 shows the distribution of relapse on ultrasound synovitis for every three months. In the multivariate Cox model increasing number of joints with ultrasound synovitis was not significantly associated with disease relapse within three months follow-up (HR 1.21; 95%CI: 0.97-1.51) [table 2].

### TREATMENT WITH METHOTREXATE IN RHEUMATOID ARTHRITIS PATIENTS ON STABLE BIOLOGICAL TREATMENT GIVES BETTER OUTCOMES OVER TIME

N. Boone<sup>1</sup>, A. Sepriano<sup>2,3</sup>, R. Janknegt<sup>1</sup>, H. van der Kuy<sup>4</sup>, R. Peeters<sup>5</sup>, R. Landewe<sup>5,6,1</sup>. <sup>1</sup>Clinical pharmacology and toxicology, Zuyderland Medical Centre, Sittard-Geleen; <sup>2</sup>Department of rheumatology, Leiden University Medical Center, Leiden, Netherlands; <sup>3</sup>Nova Medical School, Universidade Nova de Lisboa, Lisboa, Portugal; <sup>4</sup>Department of Clinical Pharmacy, Erasmus Medical Centre, Rotterdam; <sup>5</sup>Department of rheumatology, Zuyderland Medical Centre, Sittard-Geleen Heerlen; <sup>6</sup>Amsterdam Rheumatology & Immunology Centre, Amsterdam, Netherlands

**Background:** In patients with rheumatoid arthritis (RA) biological-Disease Modifying Anti-Rheumatic Drugs (bDMARDs) should be used preferentially in combination with methotrexate (MTX) as prescribed by EULAR<sup>[1]</sup>. The longitudinal treatment-effect of combination treatment compared to bDMARD monotherapy in daily clinical practice is not yet well known.

**Objectives:** To test in a registry of patients with RA the longitudinal effect of combination therapy (i.e. MTX and bDMARDs) compared to monotherapy (i.e. bDMARDs only) on the likelihood to be in clinical remission over time.

**Methods:** Adult RA patients on stable treatment with conventional synthetic disease modifying drugs (csDMARDs) and/or biologic DMARDs (bDMARDs) were followed in one centre. During clinical visits every 3 months up to 3 years rheumatologists/research nurses collected clinical- and medication data. The effect of a (time-varying) combination treatment strategy (i.e. MTX and bDMARDs) as compared to monotherapy with bDMARDs on the likelihood to be on DAS28 (≤ 2.6) and RAPID3 (0-30) (≤ 3) remission was tested in longitudinal binomial generalized estimating equations (GEE) models (one model per outcome). In addition, the effect of combination therapy compared to monotherapy on each individual component of DAS28 [tender joint count (TJC; 0-28); swollen joint count (SJC; 0-28); patient global assessment (PGA; 0-10) and ESR (mm/h)] was tested in separate longitudinal linear GEE models. All models were adjusted for possible confounders selected 'a priori' on clinical grounds: age, gender, drugs for comorbidities (yes/no), oral steroids (yes/no) and NSAID (yes/no).

**Results:** A total of 330 patients were included [mean (SD) age: 62 (12) years, 68% female, baseline mean (SD) DAS28: 3.3 (1.4) and RAPID3: 11.5 (6)]. The mean (SD) follow-up period and disease duration were 10.7 (9.7) months and 11.2 (9.6) years respectively. Combination treatment was significantly associated with a 55% higher likelihood to be in DAS28-remission (but not RAPID3-remission) over time compared with bDMARDs monotherapy (table 1). In addition, combination treatment resulted in a decrease on the SJC over time as compared to monotherapy [ $\beta = -0.91$  (95% CI: -1.77; -0.06)]. No significant differences between the two treatment strategies were seen for the other DAS28 components.

**Abstract SAT0104 Table 1.** Longitudinal effect of treatment with both MTX and bDMARDs compared to treatment with bDMARDs only (reference level)

aOR (95% CI) <sup>‡</sup>	
Outcome: DAS28 remission	
MTX + bDMARD vs bDMARD only	1.55 (1.04; 2.31)
Outcome: RAPID3 remission	
MTX+ bDMARD vs bDMARD only	1.16 (0.55; 2.42)

<sup>‡</sup> adjusted for treatment with NSAIDs, oral steroids, drugs for comorbidities, age and gender.

**Conclusions:** These results give support to the recommendation that continuing MTX in patients with RA under biological therapy increases the likelihood of clinical remission (especially when assessed with objective measures) and thus should be encouraged.

### PRELIMINARY ANALYSIS OF GENETIC VARIANTS IN THE IMMUNE SYSTEM RELATED TO THE BODY MASS INDEX IN EARLY ARTHRITIS PATIENTS

P. Moreno<sup>1</sup>, N. Montes<sup>1</sup>, J. Martín<sup>2</sup>, D. Carmona<sup>3</sup>, C. M. Mora<sup>4</sup>, R. P. Gomáriz<sup>5</sup>, A. Lamana<sup>1</sup>, A. Triguero<sup>1</sup>, A. M. Ortiz<sup>1</sup>, I. G. Álvaro<sup>1</sup> *Rheumatology, HU La Princesa, Madrid;* <sup>2</sup>Instituto López Neyra - CSIC; <sup>3</sup>Genetics Department, Universidad Granada, Granada; <sup>4</sup>Facultad de Medicina - UCM; <sup>5</sup>Facultad de Biología - UCM, Madrid, Spain

**Background:** We have observed in previous analyzes in our early arthritis (EA) cohort that patients with a higher body mass index (BMI) are, more frequently, ACPA negative and these patients carry, with a lower frequency, HLADRB1 alleles that encode for the shared epitope.

**Objectives:** To identify SNPs (Single Nucleotide Polymorphisms) of immune system genes related to BMI in EA patients.

**Methods:** The 257 patients of the PEARL (Princess Early Arthritis Register Longitudinal) cohort in which high density genotyping was available (using the Immunochip array of Illumina Inc) were included. As a previous step, those SNPs that did not meet the requirements of a genotyping call rate lower than 98%, being out of Hardy-Weinberg equilibrium ( $p < 10^{-4}$ ) and minor allele frequency lower than 1% were excluded. IMPUTE v.2 was used for the genotype imputation of the SNPs that failed in the immunochip, using as reference the data of phase III of the 1000 G project. The association analysis of the remaining SNPs was made by linear regression adjusted by sex, age and study level with PLINK v1.9. Of the 1384 SNPs associated with BMI with a value of  $p < 0.01$ , 250 SNPs were selected according to the lowest values of the division of  $p$  divided by the absolute value of its  $\beta$  coefficient. After analyzing and excluding the SNPs that were in linkage disequilibrium, the importance of the 186 resulting SNPs was quantified with the "Random Forest" and "Boosted Regression Tree" techniques using %IncMSE (Mean Decrease Accuracy).

**Results:** Table 1 shows the selection of the 15 SNPs that were more important in both "machine learning" techniques according to BMI. Although most of these SNPs are located in non-coding regions (intergenic or intronic), some of the genes where the SNPs belong or the neighboring genes have shown association in some GWAS (Genome-Wide Association) with a minor (BMP7) or a greater (RSPO3) BMI; and some of them have shown to have a regulatory role in the immune system in patients with RA (WDFY4, BMP7).

rs12722531	IL2RA	-3.544 [-5.713,-1.376]	1.535x10 <sup>-3</sup>

**Conclusions:** Our preliminary approach allowed us to select 15 SNPs that may have more relevance related to BMI in patients with early arthritis. However, this is a preliminary study and it is necessary to validate these results in other populations to ensure their involvement in the relationship between the BMI and EA.

SAT0106

### ADVANCES IN THERAPEUTIC MANAGEMENT WITH FIRST BIOLOGICAL THERAPY IN RHEUMATOID ARTHRITIS THROUGHOUT 15 YEARS

P. Bogas<sup>1</sup>, C. Plasencia<sup>1</sup>, V. Navarro-Colpán<sup>1</sup>, D. Benavente<sup>1</sup>, G. Bonilla<sup>1</sup>, L. Nuño<sup>1</sup>, I. Monjo<sup>1</sup>, G. González<sup>1</sup>, J. Molina<sup>1</sup>, A. Balsa<sup>1</sup>. *Rheumatology, Hospital Universitario La Paz, Madrid, Spain*

**Background:** In the last two decades the treatment in patients with rheumatoid arthritis (RA) has undergone major advances, especially due to the appearance of

new therapies, the use of the "treat to target" strategy and a better understanding of the "window of opportunity" concept. However, data from clinical practise confirming the benefits of using these strategies are scarce.

**Objectives:** To investigate whether the proportion of patients (pts) with RA in maintained remission (R) or low disease activity (LDA) after starting a first biological agent has increased over time and which factors are associated with this change.

**Methods:** Analysis of a database from a prospective cohort including 365 pts with RA starting a 1st biological agent (BA) (TNF inhibitor, abatacept or tocilizumab) in a tertiary hospital between 2000-2014. Demographic, clinical and analytical data were collected at the beginning of treatment and clinical activity (DAS28) was measured every 6 months. For this study, 3 groups were established according to BA initiation date: interval 1 (i1) (between 2000-2004), (i2) 2005-2009 and (i3) 2010-2014, with a minimum follow-up of 2 years at all pts. For each interval, the percentage of pts achieving maintained (at least 3 consecutive visits) R (DAS28 <2.6) or LDA (DAS28 <3.2) was determined. In addition, all variables collected were compared between groups by ANOVA and chi square test.

**Results:** Out of the 365 pts initiating a 1st BA, 133 started in i1, 122 in i2 and 110 in i3. Of these, 38% (n=137) achieved maintained R/LDA. This percentage increased significantly in successive intervals (31% in i1 vs, 38% in i2 vs 45% in i3,  $p=0.02$ ). Baseline characteristics of pts achieving R/LDA are shown in table 1A. For patients in i2 and i3, compared to the previous interval (i1 and i2 respectively), a significant higher frequency of use of BA with different mechanisms of action (0% in i1 vs 2.2% in i2 vs 34% in i3,  $p < 0.001$ ), women (56% in i1 vs 76% in i2 vs 84% in i3,  $p=0.01$ ) and concomitant methotrexate (56% in i1 vs 74% in i2 vs 81% in i3,  $p=0.03$ ) was found. On the other hand, the percentage of optimized pts increased significantly over time (13% in i1 vs 32% in i2 vs 56% in i3,  $p < 0.001$ ; table 1B).

	2000-2004 (n=41)	2005-2009 (n=46)	2010-2014 (n=58)	p value

- Methotrexate	76%	89%	98%	0.02
- Leflunomide	56%	74%	81%	0.03
- Sulfapyridine	7%	4%	8%	0.8
- Salicylic acid	27%	35%	35%	0.7
CPR	7.3 $\pm$ 10.6	12.1 $\pm$ 12.7	8.7 $\pm$ 11.4	0.001
ESR	33 $\pm$ 20.5	34 $\pm$ 20.5	19 $\pm$ 10.2	<0.001
DAS28	5.2 $\pm$ 1.4	4.8 $\pm$ 1.1	4.7 $\pm$ 1.1	0.2
HAQ	8.1 $\pm$ 5.6	7.9 $\pm$ 5.8	7.9 $\pm$ 4.5	0.9
Table 1B: Follow-up characteristics				
Follow-up time (years)	4.0 $\pm$ 2.9	4.7 $\pm$ 2.4	4.8 $\pm$ 2.6	0.06
Time under biologic (years)	3.8 $\pm$ 2.1	4.4 $\pm$ 2.6	4.1 $\pm$ 2.7	0.2
DAS28 < 3.2 at end of interval (%)	23%	30%	75%	0.1
Optimized at the end of interval (%)	13%	32%	56%	<0.001

**Conclusions:** The percentage of pts with RA achieving maintained R/LDA after initiating a 1st BA has progressively increased over time. This is probably related to a greater use of BAs with different mechanisms of action and concomitant methotrexate. The sustained control of disease activity may allow using more frequently optimized doses of BA.

### SEQUENTIAL ULTRASOUND SHOWS A LATE INCREASE IN INFLAMMATORY BURDEN IN ANTI-CCP POSITIVE PATIENTS WITH NON-SPECIFIC MUSCULOSKELETAL SYMPTOMS JUST BEFORE PROGRESSION TO INFLAMMATORY ARTHRITIS.

P. Pentony<sup>1,2,\*</sup>, K. Mankia<sup>1,2</sup>, E. M. Hensor<sup>1</sup>, J. L. Nam<sup>1,2</sup>, L. Hunt<sup>1,2</sup>, L. Garcia-Montoya<sup>2,3</sup>, L. Duquenne<sup>2,3</sup>, P. Emery<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>Leeds Biomedical Research Centre, National Institute of Health Research; <sup>3</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, Leeds University, Leeds, United Kingdom

**Background:** US abnormalities occur in patients with new rheumatoid arthritis (RA) and can also predict the development of clinical synovitis in anti-CCP positive patients with musculoskeletal symptoms (MSK) (CCP+) [1]. However, the timing of development of US synovitis in relation to clinical synovitis has not been longitudinally studied.

**Objectives:** To investigate whether US synovitis (grey scale (GS) and power doppler (PD)) changes in the period prior to the development of inflammatory arthritis (IA) in CCP+ individuals compared to those who do not develop IA.

**Methods:** CCP+ individuals were prospectively followed until the development of clinical synovitis in at least one joint (progressors). Progressors were compared to CCP+ individuals who did not develop clinical synovitis (non-progressors). For all subjects, US scans were performed at baseline, 6 and 12 months and then annually, and/or at the time of onset of clinical synovitis. A 22 paired joint US score was calculated for PD and GS >1 using the wrists, MCPJs (1-5) and PIPJs (1-5). Comparisons were made between baseline, the ultrasound prior to progression (or time equivalent in non-progressors)(scan 2) and progression scan (or time-equivalent) (scan 3).

**Results:** Patients with at least 3 serial US were included: 22 CCP+ progressors and 22 CCP+ non progressors. Age and gender was similar between groups.

The majority of patients in both groups showed no change in PD or GS >1 between baseline and scan 2 (table 1). All 22 non-progressors (100%) had a PD score of 0 at baseline, compared with 16/22 (72.7%) progressors. In contrast, between scan 2 and 3 (progression scan), the majority of patients in the progressor group increased total PD and GS scores, while non-progressors remained the same (table 1). Time between scan 2 and 3 was similar between groups.

**Table 1.** Direction of change in 22 paired joint PD and GS >1 scores between baseline and scan 1 and between interim scan and scan 3.

Between Baseline and Scan 1				
		DECREASED	REMAIN SAME	INCREASED
P	Progressor	13.6% (3/22)	68.2% (15/22)	18.5% (4/22)
D	Non-Progressor	All 0 at baseline	95.5% (21/22)	4.5% (1/22)
G	Progressor	27.3% (6/22)	54.5% (12/22)	18.5% (4/22)
S	Non-Progressor	18.2% (4/22)	77.3% (17/22)	4.5% (1/22)
Between Scan 2 and Scan 3/ Progression Scan				
		DECREASED	REMAIN SAME	INCREASED
P	Progressor	0	45.5% (10/22)	54.5% (12/22)
D	Non-Progressor	4.5% (1/22)	86.4% (19/22)	9.1% (2/22)
G	Progressor	0	31.8% (7/22)	68.2% (15/22)
S	Non-Progressor	4.5% (1/22)	63.6% (14/22)	31.8% (7/22)

**Conclusions:** After a period of stability the burden of US inflammation in CCP+ patients that progress to IA increases directly before the development of IA. This later increase in US inflammation may reflect a second hit in these at risk patients occurring prior to progression to IA. This may suggest that an intervention aiming to prevent the development of IA should target the subclinical phase prior to an escalation in US inflammation.

### EFFICACY OF ABATACEPT VERSUS ADALIMUMAB ON THE PROPORTION OF PATIENTS WITH SEROPOSITIVE, EROSION EARLY RA ACHIEVING DAS28 (CRP) <2.6 OR VALIDATED MEASURES OF REMISSION: A POST HOC ANALYSIS OF THE 2-YEAR AMPLE TRIAL

R. Fleischmann<sup>1</sup>, M. E. Weinblatt<sup>2</sup>, H. A. Ahmad<sup>3</sup>, M. A. Maldonado<sup>3</sup>, E. Alemao<sup>3</sup>, Y. Elbez<sup>4</sup>, M. Schiff<sup>5</sup>. <sup>1</sup>University of Texas Southwestern Medical Center, Dallas; <sup>2</sup>Brigham and Women's Hospital, Boston; <sup>3</sup>Bristol-Myers Squibb, Princeton, United States; <sup>4</sup>Excelya, Boulogne-Billancourt, France; <sup>5</sup>University of Colorado, Denver, United States

**Background:** Binary cut-offs for disease activity are frequently used in clinical decision-making for patients with RA because they are accurate reflections of disease activity, discriminate well between disease activity states and are feasible to perform in routine clinical practice.<sup>1</sup> Results from a previous *post hoc* analysis of the randomized, controlled, head-to-head AMPLE trial (NCT00929864) indicated a trend for increased efficacy, as assessed using DAS28 (CRP), for abatacept (ABA) compared with the TNF inhibitor adalimumab (ADA) in patients with seropositive, erosive early RA.<sup>2,3</sup>

**Objectives:** To evaluate *post hoc* the impact of treatment with either SC ABA or ADA on sustained validated definitions of remission and DAS28 (CRP) <2.6 in patients with seropositive, early, rapidly progressing RA with inadequate response to MTX.

**Methods:** This *post hoc* analysis of the AMPLE trial builds on previous work<sup>3</sup> to compare clinical outcomes between treatment groups in two subsets: patients with disease duration ≤6 months, RF or anti-citrullinated protein antibody seropositivity and >1 radiographic erosion (Cohort 1), and patients in whom ≥1 of these inclusion criteria were absent (Cohort 2). Disease activity and patient-reported outcomes were evaluated at Weeks 26, 52 and 104. Endpoints were defined as percentages of patients with DAS28 (CRP) <2.6, SDAI ≤3.3, CDAI <2.8 or Boolean remission. Endpoints were compared between ABA and ADA treatment groups using chi-square tests.

**Results:** Of 646 randomized patients, 83 were included in Cohort 1 (ABA, n=38; ADA, n=45) and 563 in Cohort 2 (ABA, n=280; ADA, n=283). At Week 52, significantly more ABA- than ADA-treated patients achieved DAS28 (CRP) <2.6 in Cohort 1 (p=0.03), a trend that was not seen at Week 104 or in Cohort 2 at either time point. At Weeks 52 and 104, more ABA- than ADA-treated patients achieved CDAI, SDAI and Boolean remission in Cohort 1, a trend not seen in Cohort 2.

**Figure 1.** Comparison of Treatments by Sustained Remission Outcomes and DAS28 (CRP) <2.6) Cohort 1: Pts with early (<6 months disease duration) seropositive erosive RA. B) Cohort 2: Pts with the absence of any 1 factor in Cohort 1. All p > 0.05 unless otherwise stated. \*Boolean remission is defined as tender joint count ≤1, swollen joint count ≤1, CRP ≤1 mg/dL and patient global assessment ≤1 (on a 0-10 scale).

**Conclusions:** This *post hoc* analysis indicates a trend towards increased efficacy for abatacept compared with adalimumab on measures of sustained remission and DAS28 (CRP) <2.6 in patients with seropositive, erosive early RA. These results, along with results from other studies,<sup>4,5</sup> support the pursuit of a clinically definable subset of patients who may respond differentially to targeted therapies.

**Conclusions:** US significantly reduced the need to switch treatment in this cohort of patients compared with DAS28. Longitudinal follow up supports the validity of US to determine those with active disease whilst on a biologic. The use of US may prevent over-treatment, and subsequently reduce morbidity and financial cost. Further work is needed to evaluate the clinical impact and cost effectiveness of routine US prior considering a change in biologic therapy.

**SAT0109** **ULTRASONIC EVALUATION OF JOINT INVOLVEMENT IN ESTABLISHED RA: ACTIVE SYNOVITIS PREDICTS SUSTAINED TREATMENT CHANGES IN SUSPECTED BIOLOGIC FAILURE**

R.L. Batten<sup>1,2</sup>, O. Mohammed<sup>2</sup>, L. Prober<sup>2</sup>, D. Wright<sup>2</sup>, I. Atchia<sup>3</sup>. <sup>1</sup>Rheumatology, Newcastle upon Tyne Hospitals NHS Foundation Trust, Newcastle; <sup>2</sup>Rheumatology, City Hospitals Sunderland, Sunderland; <sup>3</sup>Rheumatology, Northumbria Healthcare NHS Foundation Trust, Newcastle, United Kingdom

**Background:** EULAR guidelines recommend treatment of rheumatoid arthritis (RA) targeted to remission.<sup>1</sup> Biologic switching should be considered where there is at least moderate disease activity (DAS28 >3.2). The role of ultrasound (US) in guiding treatment is perhaps less clear. D'Agostino et al have proposed a novel algorithm based on current best evidence.<sup>2</sup>

**Objectives:** We present a case series of 30 RA patients with perceived biologic failure. By applying the algorithm to this group of patients we reviewed the impact of musculoskeletal ultrasound findings on treatment changes when compared to DAS28 assessment alone.

**Methods:** All patients had US of the Backhaus 7 joints on the most affected side, and any additional symptomatic joints. A global OMERACT-EULAR synovitis score (GLOESS) was calculated for each patient.<sup>3</sup> DAS28 was calculated at the time of US, and clinician opinion to continue or switch biologic was documented pre and post US. Patient notes were reviewed at 6 months to assess whether treatment changes were sustained.

**Results:** 26 patients had DAS28 >3.2. Of these, 10 were found to have GLOESS >6 and subsequently switched biologic therapy. 4 patients had DAS28 <3.2, despite clinical suspicion of persistent inflammatory disease. Of these patients, 2 were found to have GLOESS >6, and subsequently switched to an alternative biologic. At 6 months 20/24 patient's management remained consistent with previous US findings, 2 patients escalated treatment despite a previously negative US, 1 patient declined escalation (although US showed synovitis), 1 patient switched due to intolerance and 6 were lost to follow-up.

**Table 1.** Proposed treatment outcome (switch biologics) in symptomatic patients based on clinician opinion, DAS28 and US findings

	Clinician opinion pre-US	DAS28 at time of US	Clinician opinion post-US
Switch Biologics	23	26 (DAS28 >3.2)	12 (GLOESS>6) <sup>a</sup>
Don't Switch Biologics	7	4 (DAS28 <3.2)	18 (GLOESS<6)

**SAT0110** **TRAJECTORIES OF FUNCTIONAL DISABILITY IN PATIENTS WITH EARLY INFLAMMATORY POLYARTHRITIS AND MODERATE DISEASE ACTIVITY: RESULTS FROM THE EARLY RHEUMATOID ARTHRITIS NETWORK AND NORFOLK ARTHRITIS REGISTER**

S. Norton<sup>1,2</sup>, J. Gwinnutt<sup>3</sup>, Y. Pan<sup>3</sup>, D. Symmons<sup>3</sup>, A. MacGregor<sup>4</sup>, A. Young<sup>5</sup>, P. Kiely<sup>6</sup>, D. Walsh<sup>7</sup>, S. Verstappen<sup>3</sup>. <sup>1</sup>Psychology Department, <sup>2</sup>Academic Rheumatology, King's College London, London; <sup>3</sup>Arthritis Research UK Centre for Epidemiology, University of Manchester, Manchester; <sup>4</sup>Norwich Medical School, University of East Anglia, Norwich; <sup>5</sup>School of Life and Medical Sciences, University of Hertfordshire, Hatfield; <sup>6</sup>Rheumatology, St Georges University Hospitals NHS Foundation Trust, London; <sup>7</sup>Arthritis Research UK Pain Centre, University of Nottingham, Nottingham, United Kingdom

**Background:** A large group of patients with inflammatory polyarthritis (IP), and its subset rheumatoid arthritis (RA), have moderate disease activity, despite disease modifying therapy. Identifying patients with moderate disease who are likely to have subsequent high disability may prompt different treatment strategies for these patients.

**Objectives:** To identify common trajectories of disability progression in patients with moderate disease in two large prospective observational studies.

**Methods:** The Early Rheumatoid Arthritis Network (ERAN) recruited 1236 patients with RA (<36 months symptoms) from 23 centres in England from 2002-11. The Norfolk Arthritis Register (NOAR) recruited 1054 IP patients (<24 months symptoms) from Norfolk, England, from 2000-8. At baseline and subsequent follow-ups, functional disability was assessed using the Health Assessment Questionnaire (HAQ). Included patients scored ≥3.2 and <5.1 on the Disease Activity Score (DAS28) at either baseline, year 1 or year 2, and had previously received csDMARDs (N<sub>ERAN</sub>=605; N<sub>NOAR</sub>=407). Latent class growth models (LCGMs) were used to identify HAQ trajectories independently in each cohort. Age, sex, fulfilment of ACR RA criteria, symptom duration, DMARDs at baseline, and baseline

DAS28 were included as predictors of trajectory group membership using multinomial logistic regression.

**Results:** Baseline characteristics of the cohorts were similar (ERAN vs NOAR: mean age = 57 vs 56 years; female = 70% vs 69%; met ACR criteria = 88% vs 77%; mean DAS28 = 4.7 vs 4.2). For both cohorts, LCGM analysis indicated 4 subgroups provided best fit (Bayesian Information Criterion), with similar shaped trajectories (figure 1). Multinomial logistic regression indicated that older age (ERAN & NOAR,  $p < 0.005$ ), female gender (ERAN & NOAR,  $p < 0.01$ ), meeting ACR criteria (NOAR only,  $p < 0.05$ ), use of DMARD (ERAN & NOAR,  $p < 0.01$ ), and baseline DAS28 (ERAN & NOAR,  $p < 0.005$ ) were related to an increased likelihood of being in a subgroup with higher disability (vs. lowest disability subgroup).

**Conclusions:** Four disability trajectories were observed in both the ERAN and NOAR cohort of patients with moderate disease activity. Patients on a worse trajectory who may benefit from more intensive treatment could potentially be identified earlier in the disease the group of patients with moderate disease activity.

**SAT0111 EFFICACY OF TOFACITINIB IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS BY BASELINE C-REACTIVE PROTEIN LEVELS AND ERYTHROCYTE SEDIMENTATION RATES**

S. Schwartzman<sup>1</sup>, R. van Vollenhoven<sup>2</sup>, A. Matsumoto<sup>3</sup>, D. Orange<sup>4</sup>, S. Shah<sup>5</sup>, R. DeMasi<sup>6</sup>, H. Fan<sup>7</sup>, P. Dahl<sup>8</sup>, A. Wouters<sup>9</sup>, E. Keystone<sup>9</sup>. <sup>1</sup>Hospital for Special Surgery, New York, NY, United States; <sup>2</sup>Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands; <sup>3</sup>Arthritis & Rheumatism Associates, Wheaton, MD; <sup>4</sup>Rockefeller University; Hospital for Special Surgery; and New York Genome Center, New York, NY; <sup>5</sup>Pfizer Inc, Collegeville, PA, United States; <sup>6</sup>Pfizer Inc, Ballerup, Denmark; <sup>7</sup>Pfizer Inc, New York, NY, United States; <sup>8</sup>Mount Sinai Hospital, Toronto, ON, Canada

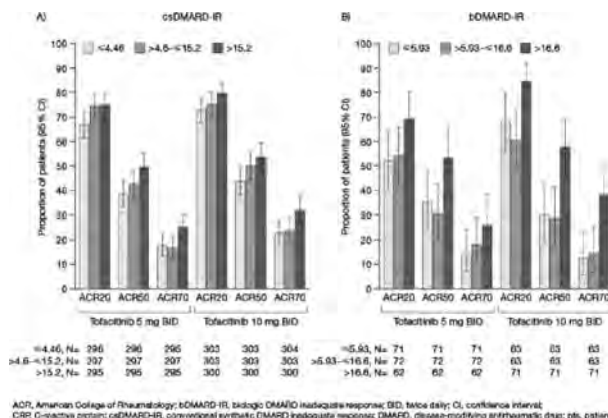

**Background:** C-reactive protein (CRP) and erythrocyte sedimentation rate (ESR) levels are serum markers of inflammation in rheumatoid arthritis (RA). Tofacitinib is an oral JAK inhibitor for the treatment of RA.

**Objectives:** To investigate the impact of baseline (BL) inflammation severity, measured by CRP and ESR levels, on tofacitinib efficacy and safety.

**Methods:** Data were analysed from tofacitinib studies in patients (pts) with RA and prior inadequate response (IR) to conventional synthetic (cs) or biologic (b) DMARDs, who initiated tofacitinib 5 or 10 mg BID as monotherapy or with csDMARDs, mainly methotrexate. Data were pooled from 4 Phase 2 trials (NCT00413660; NCT00550446; NCT00603512; NCT00687193) and 5 Phase 3

randomised, double-blind, placebo-controlled trials (ORAL Scan [NCT00847613]; ORAL Solo [NCT00814307]; ORAL Sync [NCT00856544]; ORAL Standard [NCT00853385]; ORAL Step [NCT00960440]). Analyses were stratified by BL CRP and ESR levels (tertiles) separately. Efficacy analyses at Month 6 (M6) included ACR20/50/70 response rates and changes from BL in CDAl, DAS28-4 (ESR) and SDAl. Summary/descriptive statistics were provided. Adverse events (AEs) to M6 were summarised. Results were not adjusted for multiplicity.

**Results:** A total of 2161 pts were included in the csDMARD-IR group (grp) and 512 pts in the bDMARD-IR grp. Pt BL characteristics were generally similar between grps and across CRP and ESR tertiles, except that a numerically higher proportion of csDMARD-IR pts were Asian and RA disease duration was numerically shorter for csDMARD-IR pts vs bDMARD-IR pts. In both dose grps, ACR20/50/70 response rates at M6 were generally numerically higher in the highest BL CRP grp for csDMARD-IR and bDMARD-IR pts (figure 1). Generally, a trend for greater improvement from BL in disease activity at M6 was observed with higher BL CRP. Trends across endpoints were less clear when stratified by BL ESR (data not shown). Proportions of pts with AEs, serious AEs, serious infections and discontinuations due to AEs to M6 were generally similar regardless of BL CRP or ESR.

**Figure 1.** ACR20/50/70 response rates at Month 6 for tofacitinib 5 and 10 mg BID by baseline CRP concentrations (mg/L) in A) csDMARD-IR and B) bDMARD-IR pts

**Conclusions:** While efficacy outcomes in csDMARD-IR and bDMARD-IR pts with RA were improved after 5 and 10 mg BID across all BL CRP/ESR tertiles, this post hoc analysis suggests that ACR response rates and disease activity improvements may be numerically greater in the highest BL CRP tertile, especially in bDMARD-IR RA pts. This trend was less clear with BL ESR. The tofacitinib safety profile was generally similar regardless of BL CRP or ESR, although changes in selected laboratory parameters have previously been associated with BL CRP following tofacitinib treatment.<sup>1</sup> These results suggest that subsets of pts with particularly good responses to therapy may be identified, but need further investigation.

### GUIDELINE-BASED CARE IMPROVES OUTCOMES THAT MATTER TO PATIENTS: TIGHTER CONTROL, LESS SUFFERING, AND GREATER WELL-BEING OVER THE PAST DECADE IN CANADIAN RA PATIENTS

S. J. Bartlett<sup>1,2</sup>, O. Schieir<sup>3</sup>, M.-F. Valois<sup>4</sup>, B. Haraoui<sup>5</sup>, G. Boire<sup>6</sup>, C. Thorne<sup>7</sup>, C. Hitchon<sup>8</sup>, D. Tin<sup>7</sup>, E. C. Keystone<sup>9,3</sup>, J. Pope<sup>10</sup>, V. P. Bykerk<sup>3,11</sup> on behalf of CATCH: Canadian Early Arthritis Cohort. <sup>1</sup>Medicine/ClinEpi & Rheumatology, McGill University, Montreal, QC, Canada; <sup>2</sup>Medicine/Rheumatology, Johns Hopkins, Baltimore, United States; <sup>3</sup>University of Toronto, Toronto, ON; <sup>4</sup>Clinical Epidemiology, McGill University; <sup>5</sup>Institute de Rheumatologie, Montreal, QC; <sup>6</sup>Rheumatologie, Université de Sherbrooke, Sherbrooke, QC; <sup>7</sup>Southlake Regional Health Centre, Newmarket, ON; <sup>8</sup>Rheumatology, University of Manitoba, Winnipeg, MB; <sup>9</sup>Sinai Health System, Toronto, ON; <sup>10</sup>Western University, London, ON, Canada; <sup>11</sup>Hospital for Special Surgery, New York, NY, United States

**Background:** Best practice recommendations can increase the quality of care and improve clinical outcomes, however, the impact of guideline-based care on outcomes that matter most to early RA patients before and after implementation of treat to target (T2T) recommendations has not been evaluated.

**Objectives:** We compared changes over the first year of treatment in outcomes valued most by RA patients: 1) in relation to disease activity; and 2) prior (2007-10) and subsequent (2011-16) to the release of T2T and Canadian RA Recommendations.

**Methods:** Data included early RA adults enrolled in CATCH (Canadian Early Arthritis Cohort) between 2007-16 who met 1987/2010 RA criteria with active disease at enrolment. Treatment was at the discretion of the rheumatologist and cohort investigators met annually to discuss ways to improve outcomes. We compared changes in DAS28, pain (0-10), fatigue (0-10), patient global (0-10), and HAQ-DI at 6 and 12 months prior to and after the release of guidelines using Cochran-Armitage trend tests and regression.

**Results:** The sample included 1942 adults who were mostly female (72%) with a mean (SD) age of 55 (15), 2 (2) comorbidities, and symptom duration of 6 (3) months. At enrollment, almost all (95%) were in DAS28 moderate disease activity [MDA; 42%] or high disease activity [HDA; 53%], and were initially treated with csDMARDs (92%) and MTX (75%). CDAI, DAS28 and PROs by DAS28 disease levels are shown in the Table.

Participant characteristics.

Mean (SD)	Total	LDA	MDA	HDA
<b>N (%)</b>	1942	93 (5%)	828 (42%)	1021 (53%)
<b>DAS28</b>	5.3 (1.3)	2.9 (0.2)	4.2 (0.5)	6.2 (0.8)
<b>CDAI</b>	28.1 (13.8)	10.8 (5.3)	19.4 (8.0)	36.9 (11.8)
<b>Patient Global (0-10)</b>	6.0 (2.8)	3.2 (2.2)	4.9 (2.7)	7.2 (2.4)
<b>Pain (0-10)</b>	5.7 (2.8)	3.3 (2.3)	4.6 (2.6)	6.8 (2.4)
<b>Fatigue (0-10)</b>	5.4 (3.0)	3.8 (2.8)	4.6 (2.9)	6.1 (2.9)
<b>HAQ-DI (0-3)</b>	1.1 (0.7)	0.6 (0.5)	0.8 (0.6)	1.4 (0.7)

As mean DAS28 decreased over the year, similar improvements in patient global, pain, HAQ, and fatigue were also evident (-3.0, -2.8, -2.3, -0.6; p's<0.001). When comparing change in PROs in the two time periods, there were more rapid improvements in patient global and pain at 6 and 12 months (p's<0.001; figure 1) and similar improvements in HAQ and fatigue.

**Conclusions:** Results from this large country-wide study suggest that T2T results in better disease control in the first year of RA with similar improvements in pain, fatigue, and disability—symptoms that patients identify as important—resulting in greater overall well-being. These data offer additional evidence supporting the importance of early identification and rapid control of RA to improve long-term outcomes and QOL.

SAT0113

### CLUSTERIN SERUM LEVELS ARE ELEVATED IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS AND PREDICT DISEASE ACTIVITY AND TREATMENT RESPONSE

T. Lennerová<sup>1,2</sup>, H. Mann<sup>1,2</sup>, O. Růžičková<sup>1,2</sup>, O. Šléglová<sup>1,2</sup>, L. Vernerová<sup>1</sup>, M. Tomčík<sup>1,2</sup>, K. Pavelka<sup>1,2</sup>, J. Vencovsky<sup>1,2</sup>, L. Šenolt<sup>1,2</sup>. <sup>1</sup>Institute of Rheumatology, Prague, Czech Republic; <sup>2</sup>Department of Rheumatology, 1st Faculty of Medicine, Charles University, Prague, Czech Republic

**Background:** Clusterin (also known as apolipoprotein J) is an extracellular chaperone that participates in a number of biological processes, including inflammation and apoptosis. Recent data suggest its possible protective role in the development of bone erosions and autoimmune disorders.

**Objectives:** The aim of our study was to analyze the serum levels of clusterin in patients with early rheumatoid arthritis (RA) and in healthy individuals, and to examine their potential association with disease activity and treatment response.

**Methods:** The serum levels of clusterin were determined by ELISA (BioVendor) in 56 patients with early RA before and three months after initiation of treatment, and in 56 age /sex-matched healthy subjects. Disease activity was evaluated by Clinical Disease Activity Index (CDAI), Simplified Disease Activity Index (SDAI) and 28-joint Disease Activity Score (DAS28). Response to therapy was assessed based on the SDAI/CDAI definition. Receiver operating characteristic (ROC) curve analysis of clusterin levels was performed to predict disease activity and treatment response after six months of treatment. The area under the curve (AUC) and the 95% confidence interval (CI) were calculated. Data are presented as mean±SD.

**Results:** Clusterin levels at baseline were significantly higher in patients with early RA than in healthy individuals (75.1±12.4 vs 56.7±9.7, p<0.001). After three months of therapy, the concentrations of clusterin decreased and reached levels comparable to those in healthy subjects (57.7±9.7 vs 56.7±9.7, p>0.05). Although there was no association between clusterin levels and disease activity at baseline, clusterin levels positively correlated with SDAI and CDAI at month 3 (r = 0.269, p=0.047 and r = 0.294, p=0.030, respectively) and at month 6 (r = 0.339, p=0.013 and r = 0.318, p=0.021, respectively) after treatment initiation. Using ROC analysis, clusterin baseline levels predicted remission and low disease activity according to SDAI (AUC = 0.709 (95% CI 0.548; 0.869), p=0.019) and CDAI (AUC = 0.829 (95% CI 0.721; 0.937), p<0.001), and major treatment response after 6 months of therapy (AUC = 0.696 (95% CI 0.549; 0.842), p=0.015 for both).

**Conclusions:** We demonstrate elevated serum concentrations of clusterin in patients with early rheumatoid arthritis and suggest clusterin as a biomarker for predicting disease activity and treatment response.

Guzmán-Illescas<sup>9</sup>, M. Galindo<sup>9</sup>, A. Herranz<sup>10</sup>, A. García-Vadillo<sup>11</sup>. <sup>1</sup>H.U. Móstoles, Madrid; <sup>2</sup>H.U. de Guadalajara, Guadalajara; <sup>3</sup>H.U.Fundación Alcorcón; <sup>4</sup>H.U. Severo Ochoa; <sup>5</sup>H.U. Puerta de Hierro; <sup>6</sup>H.U. Ramón y Cajal; <sup>7</sup>H.U. Clínico San Carlos; <sup>8</sup>C. S. La Rivotja; <sup>9</sup>H.U. 12 de Octubre; <sup>10</sup>H.U. del Henares; <sup>11</sup>H.U. La Princesa, Madrid, Spain

**Background:** During the last 20 years, the rheumatoid arthritis (RA) treatment has changed. Considering the increasing use of biological immunomodulators to treat this disease and the concern that immunomodulation may alter cancer risk, it's important to know the tumors incidence in RA.

**Objectives:** To analyze the incidence and trend of hospital admissions for solid tumors in patients with RA in Spain during the period between 1999 and 2015.

**Methods:** This is a retrospective population based study. We analyzed a national administrative database that includes a Minimum Basic Data Set (MBDS) of all hospital admissions of RA patients. Period: 1999 to 2015. We selected the MBDS for solid tumors. Cases were identified by the presence in primary and secondary diagnosis of ICD 9 codes. The population at risk was estimated through the

population census of the National Institute of Statistics, with an estimated prevalence of RA of 0,5% (women: 0,8%, men:0,2%). Crude and adjusted rates of the solid tumors were calculated. The trend was analyzed by Generalized Linear Model (GLM).

**Results:** 338.343 RA hospital admissions were detected in the study period, being 18.401 (5,4%) due to solid tumors. The main clinical-demographic characteristics are shown in the next table.

	Total	Women	Men	P value
N (%)	18.401 (5,4)	8689 (3,8)	9712 (8,6)	$P<0,001$
Age, mean (SD)	69,98 (11,21)	68,62 (12,3)	71,20 (9,99)	$P<0,001$
In-hospital exitus n (%)	2455 (13,34)	1035 (11,9)	1420 (14,62)	$P<0,001$
Charlson Index, mean (SD)	5,72 (2,95)	5,63 (2,95)	5,80 (2,95)	$P<0,001$
Stay, mean (SD)	10,94 (11,6)	10,76 (11,6)	11,1 (11,77)	$P=0,051$

The solid tumor adjusted rate during the study period was  $647,53/10^5$  inhabitants/yr ( $366,97/10^5$  in women and  $1792,99/10^5$  in men; relative risk men:women =4,8). This rate increased from  $305,65/10^5$  in 1999 to  $993,19/10^5$  inhabitants/yr in 2015 (from  $814,06/10^5$  in 1999 to  $2535,5/10^5$  in 2015 in men; from  $181,68/10^5$  in 1999 to  $607,71/10^5$  in 2015 in women). The annual age-adjusted rate increased significantly: 7,37% (6,52% in men and 8,02% in women;  $p<0,001$ ). figure 1

**Conclusions:** There was an increasing incidence of hospital admissions due to solid tumors in RA in Spain during the period 1999-2015. An annual rate increase of 7.37%, is estimated.

SAT0115

#### TRENDS IN THE ACTIVITY OF RHEUMATOID ARTHRITIS AS THE CONSEQUENCE OF TREAT-TO-TARGET STRATEGY: EIGHT-YEAR DATA FROM 2009 TO 2016

W. Xie<sup>1</sup>, J. Li<sup>1</sup>, X. Zhang<sup>1</sup>, G. Li<sup>1</sup>, Y. Hao<sup>1</sup>, J. Zhao<sup>1</sup>, L. Wang<sup>1</sup>, X. Sun<sup>1</sup>, Y. Fan<sup>1</sup>, Z. Zhang<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Peking University First Hospital, Beijing, China

**Background:** In past decades, treatment of rheumatoid arthritis (RA) has advanced greatly, driven largely by the advent of new medications and treat-to-target (T2T) strategy, but the secular trends in the activity and remission of RA over past years and the efficacy of T2T strategy are not fully validated in large population in real life practice.

**Objectives:** To investigate the trends in the activity of RA over past 8 years and evaluate the value of T2T strategy in daily practice.

**Methods:** All the medical records of RA patients from 2009 to 2016 were retrospectively reviewed. Disease activity scores at obtained visits were measured by DAS28-CRP, DAS28-ESR, SDAI and CDAI. To display trends over years, both mean and time-adjusted methods were applied in calculation of annual disease activity and remission rate. Disease activity and remission rate were also compared before and after the year of 2011 when application of T2T strategy was initiated in our center. Furthermore, a sub-cohort study including T2T and non-T2T period groups was conducted with outcome of cumulative percentage of remission and time to achieve first remission during the first year follow-up.

**Results:** In total, 1,001 patients with 6,944 clinical visits were included. Over eight-year period, significant improvements were witnessed in disease activity and remission rate, measured by all four indices ( $p<0.0001$ ). More patients achieved lower disease activity and higher remission rates after T2T adherence in 2011 compared to those in the years of 2009 and 2010 ( $P<0.0001$ ). Moreover, sub-cohort study revealed that more patients (49.3%>73.2% vs. 19.1%>34.5%,

OR=2.4-3.0) achieved remission with a shorter median time compared with the non-T2T period group ( $p<0.0001$ ), particularly in DAS28-CRP (21 vs. >52 weeks), DAS28-ESR (37 vs. >52 weeks).

**Figure 1.** Trends in disease activity scores over 8 years by four indices in mean and adjusted mean (AM) methods. (A) Trends based on DAS28-CRP and DAS28-ESR in two methods (B) Trends based on SDAI and CDAI in two methods

**Conclusions:** Over past 8 years, the RA activity has substantially decreased and T2T strategy was directly attributable to the favorable changes in clinical practice.

SAT0116

#### THE STUDY OF BASELINE SERUM sICAM-1 AND CXCL13 LEVELS IN PREDICTING RESPONSE TO TUMOR NECROSIS FACTOR-A INHIBITOR THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS

X. Ye<sup>1</sup>, J. Zhao<sup>1</sup>, Z. Zhang<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology Department, Peking University First Hospital, Beijing, China

**Background:** TNF- $\alpha$  inhibitors are not effective for each patient, leading to poor response as well as financial burden. There is an urgent need for biomarkers to assist us in individualized treatment. However, reliable biomarkers that predict therapeutic response to TNF- $\alpha$  inhibitors are still lacking.

**Objectives:** We aimed to investigate whether baseline serum soluble intercellular adhesion molecule-1 (sICAM-1) and C-X-C motif chemokine ligand 13 (CXCL13) could serve as biomarkers to predict therapeutic response to TNF- $\alpha$  inhibitor therapy in RA patients.

**Methods:** RA patients were enrolled from the 12-week TNF- $\alpha$  inhibitor clinical trial in our center between October 2014 and October 2017. 20 age- and gender-matched healthy controls were also recruited. Serum samples at baseline and week 12 were collected from RA patients, then serum levels of sICAM-1 and CXCL13 were measured by enzyme-linked immunosorbent assay. Clinical and laboratory data were recorded from baseline to week 12. RA patients were classified into responders and non-responders at week 12 according to EULAR response criteria.

**Results:** 51 RA patients were enrolled in this study. Serum levels of sICAM-1 and CXCL13 in RA patients were significantly higher than healthy controls ( $p<0.001$  and  $p<0.001$  respectively). Serum sICAM-1 and CXCL13 levels were higher in seropositive RA patients ( $p=0.012$  and  $p=0.005$  respectively). Baseline serum levels of sICAM-1 and CXCL13 were correlated with changes in ESR, DAS28-ESR, DAS28-CRP, SDAI and CDAI. Baseline serum sICAM-1 levels were higher in responders to TNF- $\alpha$  inhibitor therapy at week 12 by EULAR response criteria ( $p=0.010$ ). However, there was no significant difference in CXCL13 levels. In addition, serum sICAM-1 and CXCL13 levels were decreased after treatment in

responders ( $p < 0.001$  and  $p < 0.001$  respectively), nevertheless, non-responders showed a rising trend ( $p = 0.086$  and  $p = 0.051$  respectively). Binary logistic regression model revealed that baseline serum sICAM-1 levels had a positive effect on response to therapy. ROC curve analysis for predictive ability of baseline serum sICAM-1 showed an area under the curve (AUC) of 0.775 ( $p = 0.010$ ).

**Conclusions:** Serum sICAM-1 and CXCL13 levels were elevated in RA patients, and they were higher in seropositive patients than in seronegative patients. Elevated baseline serum sICAM-1 levels were associated with favorable response to TNF- $\alpha$  inhibitor therapy. The decrease of serum sICAM-1 levels after treatment in responders was consistent with their therapeutic response. Thus, baseline serum sICAM-1 could be a predictive biomarker for TNF- $\alpha$  inhibitor therapy in RA patients. There was a lack of reliable evidence that baseline serum CXCL13 had predictive ability, possibly due to different mechanisms of action or small sample size.

## Rheumatoid arthritis - comorbidity and clinical aspects

### SAT0117 HIGH URIC ACID AS A RISK FACTOR FOR CARDIOVASCULAR DISEASES IN RHEUMATOID ARTHRITIS PATIENTS

A. Al-Herz<sup>1</sup>, A. Aldeji<sup>1</sup>, K. Saleh<sup>2</sup>, A. Al-Awadhi<sup>1</sup>, W. Al-Kandari<sup>2</sup>, E. Hasan<sup>1</sup>, A. Ghanem<sup>3</sup>, M. Hussain<sup>1</sup>, E. Nahar<sup>3</sup>, F. Abutiban<sup>4</sup>, A. Alenizi<sup>4</sup>, Y. Ali<sup>3</sup>, H. Alhajer<sup>5</sup>, S. Hayat<sup>6</sup>, A. Khadrawy<sup>2</sup>, A. Fazaal<sup>2</sup>, K. Mokaddem<sup>1</sup>, A. Zaman<sup>3</sup>, G. Mazloum<sup>5</sup>, Y. Bartella<sup>1</sup>, S. Hamed<sup>1</sup>, R. Alsouk<sup>4</sup>, A. Al-Saber<sup>6</sup>. <sup>1</sup>Rheumatology, Amiri Hospital, Kuwait; <sup>2</sup>Farwania Hospital, Farwania; <sup>3</sup>Mubarak Al-Kabeer Hospital, Hawalli; <sup>4</sup>Jahra Hospital, Jahra; <sup>5</sup>Mubarak Al-Kabeer Hospital; <sup>6</sup>Department of Mathematics, Kuwait Technical College, Kuwait, Kuwait

**Background:** Rheumatoid arthritis (RA) patients have an increased risk of cardiovascular diseases (CVD). It is unclear whether an elevated serum uric acid (UA) further increases that risk.

**Objectives:** We study CVD and their risk factors in association with UA in RA patients.

**Methods:** Adult patients who satisfied the ACR classification criteria for RA from The Kuwait Registry for Rheumatic Diseases (KRRD) from four major hospitals were evaluated from February 2013 through May 2017. Patients with recorded UA were identified and CVD and their risk factors were studied in those patients. To optimize classifier number and prediction accuracy, hierarchical cluster analyses for multiple factors were performed, which indicated nine possible independent CVD risk factors. A binary logistic regression was conducted to examine their significant association with CVD and the independence of UA as a risk factor.

**Results:** A total of 564 RA patients with available UA were identified, 353(62.6%) females. Mean age was 50.8 $\pm$ 11.5 years and disease duration 10.5 $\pm$ 2.9 years. Mean UA was 271 $\pm$ 78  $\mu$ mol/L. Of those patients, 31 (5.5%) were reported to have CVD. UA was significantly correlated to the presence of CVD ( $\chi^2 = 6.49$ ,  $p = 0.011$ ). Logistic regression model indicated a 10% increase of CVD with every 10  $\mu$ mol/L increase in UA. A correlation matrix between UA and other risk factors showed a significant association between high uric acid and a younger age at RA diagnosis ( $r = -0.262$ ), hyperlipidemia ( $r = 0.191$ ) and diabetes mellitus ( $r = 0.244$ ).

**Conclusions:** Our study suggests that UA may be an independent risk factor for CVD and is associated with the presence of other risk factors. UA should be measured and carefully approached in RA patients.

**Disclosure of Interest:** None declared

### SAT0118 ASSOCIATION OF RENIN-ANGIOTENSIN SYSTEM IMBALANCE WITH SUBCLINICAL ATHEROSCLEROSIS AND DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS

N. F. T. Braz<sup>1</sup>, M. R. C. Pinto<sup>2</sup>, É. L. M. Vieira<sup>1</sup>, A. L. Teixeira<sup>1</sup>, A. C. S. Silva<sup>1</sup>, A. M. Kakehasi<sup>3</sup>. <sup>1</sup>Interdisciplinary Laboratory of Medical Investigation, Federal University Of Minas Gerais; <sup>2</sup>Rheumatology Unit, Clinic Hospital; <sup>3</sup>Locomotor System Department, Federal University of Minas Gerais, Belo Horizonte, Brazil

**Background:** Rheumatoid arthritis (RA) is an independent risk factor for cardiovascular disease (CVD). The renin-angiotensin system (RAS) is a hormonal cascade with important role in hydroelectrolytic homeostasis, blood pressure and regulation of cardiovascular remodeling. Angiotensin II (Ang II) acts as a proinflammatory mediator (1).

**Objectives:** To investigate the association of serum levels of RAS components with the presence of subclinical atherosclerosis using carotid ultrasonography in women with RA.

**Methods:** Women with RA according to ACR/EULAR 2010 or ACR 1987 criteria and without clinical ischemic CVD were included. Disease activity was assessed using the DAS28. The presence of atherosclerotic plaques and the thickness of the medium-intimal complex (EMI) of the arterial wall in the common carotid artery were evaluated by ultrasonography. Serum levels of angiotensin (Ang) II, Ang-(1-7), angiotensin converting enzyme (ECA) and ECA II were determined by enzyme immunoassay.

**Results:** 50 women with RA, mean age 48.2 years ( $\pm 7.32$ ), mean duration of disease of 15.35 years ( $\pm 8.56$ ), DAS28 of 4.02 ( $\pm 1.41$ ) and CDAI of 14.23 ( $\pm 11.53$ ) were included. Seven patients presented altered EMI, eight had atherosclerotic plaque. The prevalence of risk factors for CVD was: 12% of smoking, 12% of family history of premature CVD, 46% of arterial hypertension, 10% of diabetes, 62% of dyslipidemia, 94% of abdominal obesity and 46% of metabolic syndrome. The control group consisted of 30 healthy women, mean age of 46.3 years ( $\pm 7.72$ ). RA patients had a higher serum concentration of Ang II ( $p < 0.01$ ), Ang-(1-7) ( $p < 0.01$ ), and ACE ( $p < 0.01$ ) than the control group (table 1). There was a negative correlation between ECA II and EMI ( $p = 0.041$ ,  $\rho = -0.290$ ). EMI correlated positively with age ( $p = 0.022$ ,  $\rho = 0.324$ ), disease duration ( $p = 0.012$ ,  $\rho = 0.315$ ) and overall Framingham risk ( $p = 0.008$ ,  $\rho = 0.368$ ) and Ang II correlated positively with DAS28 ( $p = 0.034$ ,  $\rho = 0.301$ ) and CDAI ( $p = 0.040$ ,  $\rho = 0.291$ ).

**Table 1.** Comparison between plasma concentrations of SRA biomarkers in patients with rheumatoid arthritis (RA) and the control group (CG).

RAS Biomarkers (pg/mL)	RA (n = 50) Mean $\pm$ SD	CG (n = 30) Mean $\pm$ SD	p value
Ang II	407.60 $\pm$ 278.68	198.77 $\pm$ 105.48	<0.01 <sup>a</sup>
Ang-(1-7)	162.06 $\pm$ 234.58	36.94 $\pm$ 61.36	<0.01 <sup>a</sup>
ACE	266.21 $\pm$ 103.64	222.69 $\pm$ 147.61	<0.01 <sup>a</sup>
ACE II	71.86 $\pm$ 27.32	153.57 $\pm$ 225.04	0.17 <sup>a</sup>

RA = rheumatoid arthritis; CG= control group; SD= standard deviation; Ang = angiotensin, ACE =angiotensin converting enzyme. <sup>a</sup>Mann-Whitney Test.

**Conclusions:** Imbalance of RAS components, especially Ang II and ECA II, may be associated to CVD in RA patients. Ultrasonography of the carotid arteries can identify patients that could benefit from ECA blockade.

### SAT0119 PHYSICAL ACTIVITY IN TUNISIAN ADULTS WITH RHEUMATOID ARTHRITIS

A. feki<sup>1</sup>, A. fazaa<sup>1</sup>, S. miladi<sup>1</sup>, K. oueniche<sup>1</sup>, S. kassab<sup>1</sup>, S. chekili<sup>1</sup>, K. ben abdelghani<sup>1</sup>, A. laatar<sup>1</sup>. <sup>1</sup>Rheumatology, Mongi Slim Hospital - La Marsa, Tunis, Tunisia

**Background:** Physical activity (PA) is associated with multiple health-related benefits among the general population and adults with chronic diseases like

rheumatoid arthritis (RA) (1). As known, RA affects primarily synovial joints and can lead to loss of function and decreased mobility.

**Objectives:** The aim of this study was to explore the PA levels of adults with RA and to examine associations between PA and socio-demographic characteristics, immunological features, disease activity and treatment type.

**Methods:** This is a cross-sectional study including patients with RA (ACR/EULAR criteria). Disease activity was evaluated by Disease Activity Score erythrocyte sedimentation rate (DAS28 ESR). Physical activity was measured using IPAQ-SF (International Physical Activity Questionnaire-Short Form). Its items records the time spent on physical activity of three intensity levels (vigorous, moderate and walking) as well as the time spent on sitting in the past week. Both continuous [expressed as metabolic equivalent of task (MET-min/week)] and categorical (low, moderate and high level of PA) scores of IPAQ-SF were determined. Sedentary time (median) was reported in minutes/week. A p value <0.05 was considered significant.

**Results:** A total of 56 patients with RA were evaluated, 7 men and 47 women. The mean age was 54.9±9.8 years, the mean disease duration was 12.5±11.1 years and the mean DAS28 ESR was 4.3±1.3. The mean body mass index was 28.6 kg/m<sup>2</sup>. Eighty two point two percent of patients were on sDMARD, 17.9% were on Biologics and 64.3 were on prednisone. The mean sedentary time was 1777.5±729.6 minutes/week and the mean IPAQ-SF continuous score was 2962.2±3327.9 MET- min/week. Thirty point four percent of patients had low level PA, 46.4% had moderate level, and 23.2% of patients had high level PA. Patients with low level PA were significantly older (58.5 years for low level PA versus 55.3 years for moderate level PA versus 49.3 years for high level PA; p=0.035), and significantly more active (DAS28 ESR= 5.2 for low level PA versus 3.9 for moderate level PA versus 3.8 for high level PA; p=0.003). There were no significant differences in the other characteristics across the PA categories. Correlation analysis revealed a significant negative correlation between PA (Total MET-min/week) and both age (p=0.007; r = -0.354) and DAS28 ESR (p=0.023; r = -0.304). Moreover, there was a significant positive correlation between sedentary time and disease activity (p=0.021; r = 0.307).

**Conclusions:** Our study proved that PA in patients with RA decreased with age and activity disease with a concomitant increase in sedentary time. Given the risks of developing secondary chronic disease as a result of low levels of PA, physical exercise should be recommended as part of comprehensive RA care.

SAT0120

#### MULTIFOCAL RECURRENT PANCREATITIS CAUSED BY SYSTEMIC SECONDARY AA AMYLOIDOSIS IN RHEUMATOID ARTHRITIS - A POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 PATIENTS

Ápáthy<sup>1</sup>, M. Bély<sup>2</sup>. <sup>1</sup>Department of Rheumatology, St. Margaret Clinic; <sup>2</sup>Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest, Budapest, Hungary

**Objectives:** The aim of this study was to describe the prevalence and formal pathogenesis of multi (micro) focal liponecrotic pancreatitis (LnP) caused by systemic secondary AA amyloidosis (AAa) in rheumatoid arthritis (RA).

**Methods:** A randomized autopsy population of 161 in-patients with RA was studied. RA was confirmed clinically according to the criteria of the ACR. Tissue samples of pancreas were available for histologic evaluation in 111 of 161 patients. Pancreatitis and AAa were diagnosed histologically [1]. The possible role of AAa in the pathogenesis of LnP was analyzed by Pearson's chi-squared ( $\chi^2$ ) test.

**Results:** AAa complicated RA in 29 (26.12%) of 111 patients. Amyloid A deposition on different tissue structures of pancreas was detected in 25 (86.2 %) of 29 cases. Marked amyloid A deposition was found in the walls of arterioles, small and medium size arteries, and on different tissue structures of the pancreas.

Acute or chronic LnP with or without AAa was present in different stages of the pathological process (necrotic foci with or without inflammatory reaction, and/or consecutive focal accentuated fibrosis) in 15 (13.51%) of 111 patients. Seven (46.66 %) of these 15 were associated with massive AAa. The correlation between LnP and prevalence of AAa was significant ( $c^2=5.7939$ ,  $p<0.016$ ). Two (33.33%) of 15 LnP showed a special scattered multifocal appearance throughout the pancreas, characterized by necrotic foci of different size and stage of necrobiosis, without or with inflammation, and in association with severe AAa. The pancreatitis was basically not hemorrhagic, differing from hemorrhagic pancreatitis due to arterial erosions. Ductal changes were not present. The histological picture

was dominated by more or less pronounced atrophy of pancreatic glands. The link between this special type of LnP and AAa very strong and significant ( $c^2=16.2658$ ,  $p<0.0005$ ).

**Conclusions:** The close relationship between AAa and LnP suggests a relationship between amyloidosis and the prevalence of pancreatitis, that even may lead to a special multi (micro) focal pancreatitis. Amyloid A deposition in the walls of the pancreatic arterioles, small and medium size arteries (branches of splenic artery, upper and lower gastroduodenal arteries) can lead to local ischemia and to regressive changes in the pancreatic gland. This process is more or less widespread and multifocal, depending on the number of involved vessels. The size of necrobiotic areas is determined by the size of involved blood vessels. Multi (micro) focal necrosis of the pancreas caused by diminished blood supply is followed by reactive inflammation, and later fibrosis, depending on the stages of the pathological process.

AAa is a progressive cumulative process involving more and more blood vessels of different sizes, thus the regressive changes accumulate in the pancreas with time, and exist in different stages at death. Different size and stage of focal necrosis, and the co-existent marked AAa may identify this type of pancreatitis. The progressive and cumulative process of AAa with multi (micro) focal necrosis in the pancreas may cause recurrent abdominal symptoms. This form of pancreatitis may be regarded a special manifestation of AAa or a new vasculogenic entity caused by AAa in RA. Plausible similar changes of pancreas may be expected in other autoimmune diseases complicated with AAa.

#### PREVALENCE OF FIBROMYALGIA AMONG PATIENTS WITH RHEUMATOID ARTHRITIS IN DUBAI (WHAT IS THE CLINICAL RELEVANCE?)

A. A. Negm<sup>1,2</sup>, J. Al Saleh<sup>1</sup>. <sup>1</sup>Rheumatology Unit, Dubai Hospital, Dubai Health Authority, Dubai, United Arab Emirates; <sup>2</sup>Rheumatology, Faculty of Medicine, Al Azahar University, Cairo, Egypt

**Background:** Fibromyalgia (FM) is a multi-symptom syndrome characterized by chronic widespread pain, fatigue, and poor sleep quality. Some of these symptoms such as fatigue and disturb sleep seen in patients with rheumatoid arthritis (RA). Moreover, FM and RA can coexist creating a diagnostic challenge in rheumatology clinical practice and influence clinical decisions. Data on the prevalence of fibromyalgia in general population in Dubai 1.36%<sup>1</sup>. There is scarcity of data on the prevalence of FM in RA in the Middle East. We took the opportunity to study the prevalence of FM in our cohort of RA patients

**Objectives:** To assess the prevalence of fibromyalgia among RA patients in our practice.

**Methods:** We explored the prevalence of FM in 575 adult RA patients fulfilling the 2010 ACR/EULAR classification Criteria for RA<sup>2</sup>, attending the Rheumatology outpatient services in Dubai Hospital. Electronic Medical records (EMR) and medical files were reviewed for the occurrence of FM in the period from July 2017 to January 2018. We verified the documented diagnosis of FM using the 2016 revisions version of the 2010 ACR fibromyalgia classification criteria<sup>3</sup>. Grouping: Group 1 RA with FM, Group 2 RA without FM. A 2x2 contingency table (Fisher's exact test) was used to compare demographic, laboratory, drug use and biologics in both groups. Group 1 was further analyzed according to the drug used for FM.

**Results:** We identified fibromyalgia in 10.43% (60 out of 575) RA patient. FM in RA was predominately in females 58 (96.7%) versus male 2 (3.3%). Medications were used to control the symptoms of FM in 91.7% (55 of 60) and these were as follow Pregabalin (55%), Duloxetine (18.3%), Gabapentin (16.7%) and Amitriptyline (1.7%). Interesting, only 20% (12 out of 60) of patients had Vitamin D insufficiency. Five patients (8.3%) didn't use specific drug for Fibromyalgia.

On comparing the two groups there was no difference in regards to demographic data, and clinical parameters including treatment. However, RA patients with FM were twice likely to use more biologics than RA patients without FM Odds Ratio= 2, though it did not reach statistical significance (P-Value= 0.16).

**Conclusions:** The prevalence of fibromyalgia is 10.4% among RA patients in Dubai Hospital. Ten times higher than the general population (historical control). Females are the predominant gender affected. Pregabalin is the most commonly used medication in this group.

Odds ratio showed that RA patients with FM are twice likely to use biologic DMARDs than RA patients without FM, although this trend didn't reach statistical significance. Indeed, fibromyalgia can affect clinical decision in RA. Further prospective studies are recommended in different cohorts to clarify the true effect size.

SAT0122

### EXPERIENCE OF MUSCULOSKELETAL ULTRASOUND SCANNING IMPROVES SKILL OF PHYSICAL EXAMINATION IN ASSESSMENT OF SYNOVITIS

A. Saku<sup>1</sup>, S. Furuta<sup>1</sup>, H. Furuya<sup>1</sup>, K. Suzuki<sup>1</sup>, M. Fukuta<sup>1</sup>, S. Makita<sup>1</sup>, T. Ito<sup>1</sup>, K. Ikeda<sup>1</sup>, H. Nakajima<sup>1</sup>. <sup>1</sup>Allergy and Clinical Immunology, Chiba university, Chiba, Japan

**Background:** Assessment of presence/absence of joint swelling is one of the most essential factors in the management of rheumatoid arthritis (RA) patients. Although physical examination by touch is the basic assessment, it often varies among physicians. In contrast, it has been reported that musculoskeletal ultrasound (US) assessment is more objective and sensitive than physical examination in detecting synovitis.

**Objectives:** We hypothesized accumulation of experience of physical examination by touch with checking results of simultaneous US assessment as right answers could improve the accuracy of physicians' physical examination by touch. This study aimed to compare the accuracy of physicians' physical examination by touch according to physicians' US experience when considering the results of US assessment as right answers.

**Methods:** Seventy RA patients who planned to take US in daily clinical practice were enrolled. Twenty three physicians affiliated with Department of Allergy and Clinical Immunology at Chiba University Hospital were also participated in this study. Written informed consent was obtained from all the patients and physicians. At first plural physicians touched wrists, metacarpophalangeal (MCP) joints and proximal interphalangeal (PIP) joints and assessed swelling/non-swelling ("Ph swelling/non-swelling") of the joints. Subsequently, US assessment was performed by another physician blinded to the results of physical examination. In this study, "US swelling" and "US non-swelling" were defined as gray-scale imaging score (GS) 2 and GS 1. The positive predictive value (PPV) of physical examination by touch was calculated (= "Ph swelling" joint count/"US swelling" joint count). Negative predictive value (NPV) was also calculated (= "Ph non-swelling" joint count/"US non-swelling" joint count). The associated factors for PPV and NPV were identified by the univariate and multivariate logistic regression analysis.

**Results:** The patients were median 65 years old with median 5 year history of RA. A majority of the patients was rheumatoid factor positive (59/70) and median DAS28-CRP was 2.63.

A total of 6116 joints per physician were evaluated by touch, and the numbers of "Ph swelling" and "Ph non-swelling" joints were 990 and 5126. A total of 1540 joints were examined by US, the numbers of "US swelling" and "US non-swelling" joints were 172 and 1368. Overall PPV and NPV were 51.7% and 88.3%.

Regarding PPV, multivariate analysis identified duration of physicians' attending to rheumatology clinic, wrists, tender joints, patients' gender, patients' age and Steinbrocker Stage as significant factors increasing the accuracy and patients' disease duration as a significant factor decreasing the accuracy. Regarding NPV, multivariate analysis identified duration of physicians' US experience and patients' disease duration as significant factors increasing the accuracy and wrists, tender joints, presence of osteophytes and DAS28-CRP as significant factors decreasing the accuracy.

**Conclusions:** Experience of US improved accuracy of physicians' physical examination by touch in non-swelling joints and prevented overestimation, while experience of attending to rheumatology clinic rather than US improved the accuracy in swelling joints.

### THE EFFECTS OF TRIMETHOPRIM-SULFAMETHOXAZOLE ON DISEASE ACTIVITY IN PATIENTS WITH RHEUMATOID ARTHRITIS

A. Onishi<sup>1</sup>, K. Akashi<sup>1</sup>, M. Hashimoto<sup>2</sup>, W. Yamamoto<sup>2</sup>, K. Murata<sup>2</sup>, M. Katayama<sup>3</sup>, H. Amuro<sup>4</sup>, Y. Son<sup>4</sup>, S. Yoshida<sup>5</sup>, K. Nagai<sup>6</sup>, R. Hara<sup>7</sup>, K. Ebina<sup>8</sup>, T. Hirano<sup>9</sup>, Y. Yamamoto<sup>1</sup>, H. Yamada<sup>1</sup>, Y. Ichise<sup>1</sup>, I. Naka<sup>1</sup>, T. Okano<sup>1</sup>, S. Takahashi<sup>1</sup>, Y. Ueda<sup>1</sup>, S. Senda<sup>1</sup>, J. Saegusa<sup>1</sup>, A. Moriobu<sup>1</sup>, on behalf of ANSWER cohort study group. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Kobe University Graduate School of Medicine, Kobe; <sup>2</sup>Department of the Control for Rheumatic diseases, Graduate School of Medicine, Kyoto University, Kyoto; <sup>3</sup>Department of Rheumatology and Clinical Immunology, Osaka Red Cross Hospital; <sup>4</sup>First Department of Internal Medicine, Kansai Medical University; <sup>5</sup>Department of Internal Medicine (IV), Osaka Medical College; <sup>6</sup>Department of Internal Medicine (IV), Kansai Medical University, Osaka; <sup>7</sup>The Center for Rheumatic Diseases, Nara Medical University, Nara; <sup>8</sup>Department of Orthopaedic Surgery; <sup>9</sup>Department of Respiratory Medicine, Allergy and Rheumatic Disease, Graduate School of Medicine, Osaka University, Osaka, Japan

**Background:** Some experimental models suggested bacterial infection, such as periodontal disease and gut microbiota, might be an inciting and aggravating factor in rheumatoid arthritis (RA)<sup>1</sup>. Moreover, medications that have an antibacterial effect such as minocycline and sulfasalazine are used as DMARDs. However, the antibacterial effect itself on disease activity are unknown in patients with RA whereas trimethoprim-sulfamethoxazole (TMP-SMX) is often used for *Pneumocystis jirovecii* pneumonia (PCP) prophylaxis because PCP is a prevalent and potentially life-threatening opportunistic infection among patients with RA, especially in Japan<sup>2,3</sup>.

**Objectives:** To identify the effect of TMP-SMX on disease activity in patients with RA in a multi-center cohort study (ANSWER cohort study).

**Methods:** RA patients with a sampling interval of less than 1 year and at least two assessment of disease activity were enrolled. Disease activity was assessed using disease activity score 28-CRP (DAS28-CRP). Linear mixed effect models were used to evaluate the trajectories of disease activity in RA patients. Time from baseline, TMP-SMX administration, and their interaction were included as fixed effects while participant identification number and time from baseline were included as random factors. Age, sex, disease duration, RF, ACPA, HAQ, and DMARDs were included as covariates.

**Results:** A total of 49878 samples (mean sampling interval: 49 days) from 3255 patients was included. The median age at baseline was 64.0 years (interquartile range, 53.0 to 71.0 years) with 78.2 % of women (ACPA positivity, 79.2%; RF positivity, 70.8 %). The median DAS28-CRP was 2.83 with 33.8 % of patients taking TMP-SMX at baseline. Patients with taking TMP-SMX had a significantly but minimally better longitudinal trajectory on disease activity than patients without (-0.00012/month,  $P=0.009$ ). This result was similar even when patients taking sulfasalazine were excluded from analysis.

Evolution of disease activity over time based on ST use

**Conclusions:** TMP-SMX has minimal impact on disease activity, and therefore clinical utility of TMP-SMX for controlling disease besides PCP prophylaxis is limited. These results did not support a theoretical effect of bacterial infection on

disease activity in RA, although the effect of the other antibiotics on disease activity should be examined.

#### SAT0124 AORTIC STIFFNESS AND TIME TO WAVE REFLECTION ARE ASSOCIATED WITH LEFT VENTRICULAR DIASTOLIC DYSFUNCTION MEASURES IN RHEUMATOID ARTHRITIS

A. M. Millen<sup>1</sup>, L. Mokotedi<sup>1</sup>, S. Gunter<sup>1</sup>, C. Robinson<sup>1</sup>, F. Michel<sup>1</sup>, A. J. Woodiwiss<sup>1</sup>, L. Tsang<sup>1</sup>, G. R. Norton<sup>1</sup>, P. H. Dessein<sup>2</sup>. <sup>1</sup>School of Physiology, University of the Witwatersrand, Parktown, Johannesburg, South Africa; <sup>2</sup>Free University Brussels, Brussels, Belgium

**Background:** Patients with rheumatoid arthritis (RA) experience an increased frequency of heart failure with a preserved ejection fraction (HFpEF) (1). The treatment of HFpEF is currently suboptimal. Elucidation of the underlying pathophysiological mechanisms of HFpEF may provide potential targets for its management. Diastolic dysfunction often precedes the progression to HFpEF (2). Abnormalities in aortic function contribute to diastolic dysfunction in non-RA populations (3,4).

**Objectives:** The aim of this study was to determine whether impaired aortic function is associated with left ventricular diastolic dysfunction in RA.

**Methods:** Arterial function was determined by applanation tonometry using SphygmoCor software and left ventricular diastolic function was assessed by echocardiography in 176 patients with RA. Markers of arterial function included carotid femoral pulse wave velocity (PWV), central systolic and pulse pressure, pulse pressure amplification and the magnitude and timing of the forward and reflected waves. Markers of diastolic function included the ratio of early-to-late transmitral blood flow velocity (E/A), the ratio of E to the mean of the lateral and septal wall myocardial tissue lengthening at the mitral annulus (e')/(E/e') and the septal and lateral e'. Relationships of comprehensively evaluated arterial function with markers of LV diastolic function were determined in confounder adjusted multivariate regression models.

**Results:** The timing of the forward (Ft) and reflected (Rt) waves were each associated with E/A (Ft: partial r=0.20, p=0.02; Rt: partial r=0.30, p=0.001) and Rt was further associated with lateral e' (partial r=0.36, p<0.0001) and septal e' (partial r=0.36, p<0.0001); PWV was associated with E/e' (partial r=0.18; p=0.03). Reflected wave timing was associated with two indices of impaired relaxation (E/A<0.8: OR (95% CI)=0.51 (0.29-0.91), p=0.01; lateral e'<10: OR (95% CI)=0.43 (0.26-0.71), p=0.001); PWV was associated with an increased left ventricular filling pressure (E/e'>12: OR (95% CI)=1.58 (1.04-2.38), p=0.03).

**Conclusions:** Aortic stiffness and time to wave reflection are associated with increased filling pressure and impaired relaxation of the left ventricle, respectively. The development of diastolic dysfunction in RA may be partly mediated by changes in large artery function.

SAT0125

#### THE IMPACT OF SELECTED COMORBIDITIES ON TREATMENT OUTCOME IN PATIENTS WITH RHEUMATOID ARTHRITIS: AN EXPLORATORY COHORT STUDY.

A. Emamiifar<sup>1</sup>, I. M. Jensen Hansen<sup>2</sup>. <sup>1</sup>Faculty of Health Sciences, University of Southern Denmark, Odense; <sup>2</sup>Rheumatology, OUH, Svendborg Hospital, Svendborg, Denmark

**Background:** Patients with Rheumatoid Arthritis (RA) may present with various comorbidities resulting in worse treatment response.[1-2]

**Objectives:** To investigate the impact of selected comorbid diseases on RA outcome with the aim of Disease Activity Score in 28 joints-C-Reactive Protein (DAS28-CRP).

**Methods:** All our RA patients were included in this study. Patients' demographics, serology results and DAS28-CRP at the time of diagnosis and after 4 months of treatment initiation were collected. Patients' electronic hospital records were evaluated for a positive history of thyroid diseases, Diabetes Mellitus (DM), primary hyperparathyroidism, vitamin B12 deficiency and presence of other diagnosed autoimmune diseases.

**Results:** 1035 RA patients were included. 63.4% were female, mean of age 67.1 years, mean of disease duration 9.6 years, 58.6% rheumatoid factor positive and 51.3% anti-cyclic citrullinated peptide positive. The observed prevalence of thyroid diseases was 11.8%, DM 10.4%, primary hyperparathyroidism 2.8%, vitamin B12 deficiency 5.8%, and other diagnosed autoimmune diseases 1.6%. There were significant associations between presence of thyroid diseases and female gender (p<0.001); DM and greater age (p<0.001); primary hyperparathyroidism and longer disease duration (p=0.002); other diagnosed autoimmune diseases and antinuclear antibody positivity (p<0.001). RA patients with thyroid diseases (p=0.001) and other comorbid autoimmune diseases (p<0.001) had significantly poorer initial response to the RA treatment compared to patients with isolated RA. Univariate analyses revealed that age, presence of thyroid diseases, presence of other diagnosed autoimmune diseases and DAS28-CRP at the time of diagnosis were significantly associated with ΔDAS28-CRP. Additionally, multivariate analysis demonstrated that ΔDAS28-CRP deterioration was significantly correlated to the presence of thyroid diseases (unstandardized regression coefficient (standard error); -0.188(0.088), p=0.030) and presence of other diagnosed autoimmune diseases (-0.537(0.208), p=0.010). (table 1)

**Table 1.** Univariate and multivariate analysis of risk factors for ΔDAS28-CRP.

**SAT0126 CHARACTERIZING HETEROGENEOUS CARE PATHWAYS OF INCIDENT RHEUMATOID ARTHRITIS PATIENTS**

A.A. Kawatkar<sup>1</sup>, J. An<sup>2</sup>, A. Marshall<sup>3</sup>, T. C. Cheetham<sup>2</sup>, E. Haupt<sup>1</sup>, G. Okano<sup>3</sup>, K. Gupta<sup>3</sup>, T. G. Curtice<sup>3</sup>. <sup>1</sup>Research and Evaluation, Kaiser Permanente Southern California, Pasadena, CA; <sup>2</sup>Pharmacy Practice and Administration, Western University of Health Sciences, Pomona, CA; <sup>3</sup>Health Economics & Outcomes Research, Bristol-Myers Squibb, Princeton, NJ, United States

**Background:** Clinical pathway analysis is the process of characterizing clinical activities in patients' (pts) care. Little is known about the clinical pathways that pts with rheumatoid arthritis (RA) follow after their diagnosis, and how treatment patterns differ between such pathways.

**Objectives:** To identify and characterize distinct clinical pathways in the management of incident RA pts and evaluate differences in treatment patterns.

**Methods:** A retrospective cohort study was conducted in RA pts identified using electronic medical records of the Kaiser Permanente Southern California health plan. Between 01/01/2007 and 31/12/2015, we identified adult pts (aged ≥18 years) who had at least two RA diagnoses within a 12-month period, a disease-modifying antirheumatic drug (DMARD) prescription and laboratory test for anti-citrullinated peptide antibody. Latent class analysis (LCA) method was applied to identify ≥2 heterogeneous care pathways. RA-specific healthcare utilization during the first year following the RA diagnosis was used as a marker of underlying latent classes. We characterized the latent classes based on the distribution of markers, co-morbidities and RA treatment patterns including switch, augmentation and discontinuation of DMARDs. Chi-square and F-tests were used to evaluate differences between the classes.

**Results:** We identified 2843 incident RA pts. LCA indicated five latent classes representing mutually exclusive pathways of managing pts with RA. Pts in Class 1 (low disease activity-low progression) had lowest RA office visits and labs to detect inflammation with the highest DMARD discontinuation. Pts in Class 2 (low-disease activity-moderate progression) were characterized by higher lab, imaging and DMARD augmentation. Class 3 (moderate disease activity with pain) was characterized by highest use of NSAIDs across any class. Pts in Class 4 (high disease activity-moderate progression) were characterized by above-average RA office visits and the highest corticosteroid use. Class 5 (high disease activity-high progression) had pts with the highest number of RA office visits, biologic DMARD use, DMARD augmentation, DMARD switching and the lowest initial treatment discontinuation.

Classification factors	Class 1 n=367	Class 2 n=1105	Class 3 n=516	Class 4 n=616	Class 5 n=239	Total N=2843

**SAT0127 THE EFFICACY OF TOFACITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS STRATIFIED BY BASELINE BODY MASS INDEX**

A. Dikranian<sup>1</sup>, M. A. Gonzalez-Gay<sup>2</sup>, F. Wellborne<sup>3</sup>, J. M. Alvaro-Gracia<sup>4</sup>, L. Takiya<sup>5</sup>, L. Stocker<sup>6</sup>, D. Chapman<sup>6</sup>, S. Tatulych<sup>7</sup>, P. Dahl<sup>8</sup>, J. R. Curtis<sup>9</sup>. <sup>1</sup>Cabrillo Center for Rheumatic Disease, San Diego, CA, United States; <sup>2</sup>Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, Spain; <sup>3</sup>Houston Institute for Clinical Research, Houston, TX, United States; <sup>4</sup>Hospital Universitario de La Princesa, IIS Princesa, Madrid, Spain; <sup>5</sup>Pfizer Inc, Collegeville, PA; <sup>6</sup>Pfizer Inc, New York, NY; <sup>7</sup>Pfizer Inc, Groton, CT, United States; <sup>8</sup>Pfizer Inc, Ballerup, Denmark; <sup>9</sup>University of Alabama at Birmingham, Birmingham, AL, United States

**Background:** Tofacitinib is anoral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).

**Objectives:** This post hoc analysis aims to explore the efficacy of tofacitinib in patients (pts) with RA based on their baseline (BL) body mass index (BMI).

\*p<0.05; \*\*p<0.001; \*\*\*p<0.0001 vs placebo  
 ACR, American College of Rheumatology; BID, twice daily; BMI, body mass index; CI, confidence interval; FAS, full analysis set; NRI, non-responder imputation

**Figure 1.** ACR20/50/70 response rates at Month 6 for each treatment group stratified by BMI category (FAS, NRI). \*p<0.05; \*\*p<0.001; \*\*\*p<0.0001 vs placebo. ACR, American

College of Rheumatology; BID, twice daily; BMI, body mass index; CI, confidence interval; FAS, full analysis set; NRI, non-responder imputation

**Methods:** Data were analysed from six Phase 3 studies for pts who were methotrexate-naïve (NCT01039688) or had an inadequate response to DMARDs (NCT00960440, NCT00847613, NCT00814307, NCT00856544, NCT00853385) and received  $\geq 1$  dose of tofacitinib 5 or 10 mg twice daily (BID) or placebo (PBO). Pts were stratified by BL BMI (<25, 25 to <30,  $\geq 30$ ). Efficacy endpoints (American College of Rheumatology [ACR]20/50/70 response rates at Month [M]6; changes from baseline [ $\Delta$ ] in Health Assessment Questionnaire-Disability Index [HAQ-DI], Disease Activity Score in 28 joints based on Erythrocyte Sedimentation Rate [DAS28-4(ESR)], DAS28 based on C-reactive protein [DAS28-4(CRP)] and Clinical Disease Activity Index [CDAI] at M3 and M6) were assessed. Non-responder imputation was used for the binary endpoints. No imputation was used for continuous endpoints. No multiplicity adjustment was performed in this post hoc analysis.

**Results:** Overall, 1589, 1611 and 681 pts received tofacitinib 5 and 10 mg BID and PBO, respectively, with 1690, 1173 and 1017 pts in the BMI <25, 25 to <30 and  $\geq 30$  categories, respectively. BL demographics were generally similar between BMI categories with the exception of higher rates of diabetes (12.9-14.2% vs 3.5-9.8%), hypertension (53.2-58.9% vs 22.0-39.8%), and use of prior TNFi (23.7-46.8% vs 15.0-26.9%), and numerically higher tender (28.8-29.9 vs 23.5-26.9) and swollen joint counts (16.5-17.1 vs 14.5-16.3) and HAQ-DI scores (1.6 vs 1.4-1.5) in the BMI  $\geq 30$  group vs BMI <25 or 25 to <30. ACR response rates were significantly higher ( $p < 0.05$ ) in the tofacitinib vs PBO groups, regardless of BMI category (figure 1). In general, there appeared to be a trend towards lower ACR20/50/70 response rates with increasing BMI at M6 in tofacitinib- and PBO-treated pts; however, confidence intervals (CI) overlapped. At M6,  $\Delta$ HAQ-DI was numerically smaller for pts receiving tofacitinib 5 mg BID with BMI  $\geq 30$  vs lower BMI categories, with overlapping CI. The  $\Delta$ DAS28-4(ESR),  $\Delta$ DAS28-4(CRP) and  $\Delta$ CDAI scores were similar within each treatment group regardless of BL BMI. Generally similar trends were observed when stratified by weight.

**Conclusions:** Results of this post hoc analysis suggest that tofacitinib is associated with improvements in RA outcomes compared with PBO regardless of BL BMI category. In both tofacitinib and PBO groups, similar trends in improvements were seen in most endpoints regardless of BMI category, implying that the effect of BL BMI is not specific to tofacitinib. Further investigation is needed to assess the degree of impact of BMI on tofacitinib efficacy.

### SAT0128 THE RISK FACTORS FOR SEVERE EXACERBATION OF INTERSTITIAL LUNG DISEASE IN RHEUMATOID ARTHRITIS DURING bDMARD THERAPY

A. Tanaka<sup>1</sup>, K. Kurasawa<sup>1</sup>, T. Miyao<sup>1</sup>, Y. Takamura<sup>1</sup>, R. Yamazaki<sup>1</sup>, S. Arai<sup>1</sup>, T. Owada<sup>1</sup>, R. Maezawa<sup>1</sup>, M. Arima<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Dokkyo Medical University, Tochigi, Japan

**Background:** Rheumatoid arthritis (RA) is a systemic inflammatory disease that affects joints and various organs. The lung is one of the most common site of extra-articular involvement. Interstitial lung disease (ILD) is one form of the lung involvement and influences prognosis of the patients. RA-ILD frequently developed acute exacerbation. Once acute exacerbation occurs, the prognosis of patients is poor. However, it is not fully elucidated what the risk factors for severe exacerbation of ILD are.

**Objectives:** The purpose of this study was to identify the risk factors for severe exacerbation of ILD in RA patients during bDMARDs therapy. The purpose of this study was to identify the risk factors for exacerbation of ILD in RA patients under the bDMARDs therapy.

**Methods:** A retrospective cohort study. Subjects were consecutive 208 RA patients who were treated with bDMARDs from 2004 to 2015 in our department and received HRCT scan before and during the therapy. Based on HR-CT imaging, pulmonary abnormalities were classified into 4 categories (ILD, nodular lesions, airway disease (AD) and others) and 20 lesions such as ground-glass opacity (GGO), reticular pattern, bronchiolitis and bronchiectasis. We recorded their existence and distribution before and during the therapy and examined their changes. Severe exacerbation of ILD was judged when patients revealed newly emerging/worsening of ILD lesions regardless of pre-existing pulmonary lesions and deceased or had to stop bDMARDs due to exacerbation of ILD. To identify risk factors, logistic regression analysis was conducted.

**Results:** Subjects were 208 RA patients, M/F; 64/144, mean age; 59.2 years old, disease duration; 7.9 years positive for RF in 84.1%. bDMARDs used for the longest period were TNFi in 79.8% of the subjects, abatacept in 15.4% and tocilizumab in 4.8%.

Pulmonary abnormalities were found in 146 (70.2%) of RA patients before bDMARDs (ILD 81, (38.9%); nodular lesions 45, (21.6%); and ADs, 115, (55.3%)). GGO, consolidation, reticular pattern and honeycombing was found in 14.8%, 19.8%, 51.9%, and 17.3% of ILD patients. Most of ILD lesions coexisted with ADs. During the observation period (3.26 $\pm$ 2.61 years), newly emerging/worsening pulmonary lesions were found in 42.3% of patients and the incidence of which was 13.7/100 person year. The incidence of newly development and worsening of ILD were 7.0/100 person years and 1.5/100 person years, respectively.

Severe exacerbation of ILD was developed in 13 patients (6.3%) and the incidence of which was 2.0/100 person year. Of 13 patients, 9 died of respiratory failure. All patients with severe exacerbation revealed GGO/consolidation. Interestingly, all these active ILD lesions were newly emerging lesions, however, most of the patients had pre-existing pulmonary lesions.

We identified risk factors for severe exacerbation of ILD (Table 1). The risk factors for severe exacerbation of ILD were older age and pre-existing pulmonary lesions of ILD and of ADs, particularly reticular pattern, honeycomb and bronchiectasis. Sero-positivity and choice of biologics were not identified as risk factors.

#### Risk factors for severe exacerbation of ILD

	Frequencies of an indicated factor in severe ILD exacerbation (-) vs (+)	Odds (95% CI) (ref: (-))	P
<b>Male</b>	55/195 (30.3%) vs 5/13 (38.0%)	1.44 (0.45-4.59)	0.54
Age of the entry	58.70 $\pm$ 13.20** vs 67.32 $\pm$ 10.36		0.022
Age of RA onset	50.71 $\pm$ 10.19 vs 60.80 $\pm$ 13.56		0.028
Disease duration (year)	8.00 $\pm$ 9.37 vs 7.01 $\pm$ 8.64		0.71
Smoking	65/144 (45.1%) vs 8/12 (66.7%)	2.43 (0.70-8.44)	0.16
RF positive	162/195 (83.1%) vs 12/13 (92.3%)	5.57 (0.32-95.9)	0.03
Anti-CCP antibody Positive	144/166 (86.7%) vs 8/10 (80.0%)	0.63 (0.13-3.20)	0.60
DAS28-ESR at the entry	4.36 $\pm$ 1.43 vs 3.66 $\pm$ 0.93		0.28
DAS28-ESR at following CT scan	3.26 $\pm$ 1.27 vs 3.73 $\pm$ 0.69		0.40
<b>TX</b>			
TNF vs non-TNF	156/209 (80.0%) vs 10/1 (76.9%)	0.83 (0.22-3.17)	0.79
Methotrexate	127/195 (65.1%) vs 9/13 (69.2%)	1.20 (0.36-4.00)	0.76
Glucocorticoid	147/195 (75.4%) vs 10/13 (76.9%)	1.09 (0.29-4.12)	0.90
<b>Pre-existing pulmonary abnormalities</b>			
Pulmonary abnormality	134/195 (68.7%) vs 12/13 (92.3%)	5.46 (0.69-42.96)	0.044
Interstitial lung disease	71/195 (36.4%) vs 10/13 (76.9%)	5.81 (1.55-21.80)	0.004
Reticular pattern	34/195 (17.4%) vs 8/13 (61.5%)	7.58 (2.34-24.58)	0.0007
Honeycomb	9/195 (4.6%) vs 5/13 (38.5%)	15.92 (3.51-71.50)	0.0004
Nodular lesions	43/195 (22.1%) vs 2/13 (15.4%)	0.64 (0.14-3.01)	0.56
Airway disease	104/195 (53.3%) vs 11/13 (84.6%)	4.81 (1.04-22.58)	0.050
Bronchiectasis	76/195 (38.9%) vs 11/13 (84.6%)	8.80 (1.00-80.80)	0.0009

\* Positive number/ number of live or dead cases. \*\* mean  $\pm$  SD

**Conclusions:** The incidence of severe exacerbation of ILD was 2.0/100 person years. The risk factors for severe exacerbation of ILD were older age and pre-existing reticular pattern, honeycomb and bronchiectasis.

Herranz<sup>10</sup>, C. Martinez Prada<sup>11</sup>, C. Morado Quiñoa<sup>11</sup>, V. Villaverde<sup>12</sup> on behalf of TREND-AR. <sup>1</sup>Rheumatology, Hospital Universitario Severo Ochoa; <sup>2</sup>Rheumatology; <sup>3</sup>Hospital Universitario Fundación Alcorcón; <sup>4</sup>Rheumatology, Hospital Universitario Ramón y Cajal; <sup>5</sup>C.S. La Rivota; <sup>6</sup>Rheumatology, Hospital Universitario Puerta de Hierro, Madrid; <sup>7</sup>Rheumatology, Hospital Universitario Guadalajara, Guadalajara; <sup>8</sup>Rheumatology, Hospital Universitario Doce de Octubre; <sup>9</sup>Rheumatology, Hospital Universitario La Princesa; <sup>10</sup>Rheumatology, Hospital del Henares; <sup>11</sup>Rheumatology, Hospital Universitario Clínico San Carlos; <sup>12</sup>Rheumatology, Hospital Universitario de Móstoles, Madrid, Spain

**Background:** Several changes have appeared in the last years in the management of Rheumatoid Arthritis (RA), and also a greater awareness about cardiovascular risk has emerged. However, the trend of CVDs in RA in Spain is unknown.

**Objectives:** To analyze the incidence and trend of hospital admissions for CVDs in patients with RA in Spain during the period between 1999 and 2015.

**Methods:** We performed an observational retrospective population study analyzing the spanish administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of patients with RA 1999-2015. We selected the MBDSs for CVDs, myocardial infarction (MI), ischemic heart disease (IHD), congestive heart failure (CHF), cerebrovascular disease (CeVD) and aortic aneurysm (AA). Cases were identified by the presence in primary and secondary diagnosis of ICD9 codes. The population at risk was estimated through the population census with an estimated prevalence of RA of 0,5% (0,8% women, 0,2% men). Crude and adjusted rates were calculated, and the trend was analyzed using the Generalized Linear Model (GLM) with the year as the analysis variable. SPSS statistical package version 20 (SPSS Inc, Chicago, IL) was used.

**Results:** 338.343 RA hospital admissions were detected in the period, being 207.597 (61,3%) due to CVDs. table1 summarizes the data of the six subgroups of CVDs.

**Conclusions:** CVDs were the first cause of hospital admissions in Spain in RA patients during the period 1999-2015. Moreover, in that period there was an increasing incidence of hospital admissions due to CVDs in all the studied subgroups, being strikingly higher in men after age-adjusted rates. An annual rate increase is estimated in all the different studied subgroups oscillating between 5 and 9% annual increasing.

	Cardiovascular disease	Myocardial infarction	Ischemic heart disease	Congestive heart failure	Cerebrovascular disease	Aortic aneurysm

**SAT0130 IMPROVEMENT OF NUTRITIONAL CONDITIONS IN PATIENTS WITH RHEUMATOID ARTHRITIS STARTING FIRST DISEASE MODIFYING ANTI-RHEUMATIC DRUGS**

D. Kobayashi<sup>1,2</sup>, S. Ito<sup>2</sup>, E. Hasegawa<sup>1,2</sup>, I. Narita<sup>1</sup>, K. Nakazono<sup>2</sup>. <sup>1</sup>Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata; <sup>2</sup>Rheumatology, Niigata Rheumatic Center, Shibata, Japan

**Background:** Rheumatoid arthritis (RA) is a chronic inflammatory condition, and has been associated with adreased life expectancy. Although life expectancy has improved in many RA patients recently, the reason for this is not entirely clear.

**Objectives:** We hypothesized that better disease activity control of RA led to relief from chronic inflammation, which resulted in better nutritional conditions, and contributed to a longer life expectancy. The aim of this analysis was to examine the relationship between RA disease control and the improvement of nutritional conditions.

**Methods:** We analyzed data obtained from 111 patients with RA (male 44, female 67) who were referred to our hospital and received first disease modifying anti-rheumatic drugs (DMARD) in 2016 and 2017, retrospectively. The patient data were obtained retrospectively from medical records for a 6-month period starting at the date DMARDs were initiated. We chose serum albumin (Alb), total lymphocyte count (TLC), and hemoglobin (Hb) concentration, as the indicators of the nutritional condition. Furthermore, D-values and nutrition index 40 (N.I.40), indicators of anastomotic leakage after gastrointestinal surgery were also analyzed. Comparisons between the two groups were performed using Mann-Whitney U test. Comparisons between the parameters at different time points were performed using Wilcoxon signed-rank test. The association among the ordered European League Against Rheumatism (EULAR) response rate and the magnitude of improvement in the nutritional condition were analyzed by using the Jonckheere-Terpstrat test. Data on each patient's age and duration of RA were calculated as median (IQR<sub>1/4-3/4</sub>) values.

**Results:** The patient age was 64.0 (54.0-74.5) years, and the duration of RA was 3.0 (1.0-7.0) months. Oral prednisolone (PSL) was used in 51 patients. Other drugs administered to patients over the 6-month period included: methotrexate (63 patients), iguratimod (42 patients), bucillamine (29 patients), sulfasalazine (25 patients), tacrolimus (6 patients), and bDMARD (13 patients). The level of C-reactive protein (CRP) and the disease activity score for 28 joints based on theory-thrombocytosis rate (DAS28-ESR) before and 6 months after the initiation of DMARD treatment improved from 0.50 (0.12-1.7) mg/dL to 0.10 (0.010-0.20), p<0.001, and from 4.62 (3.51-5.52) to 2.52 (1.53-3.13), p<0.001, respectively. The EULAR good response was achieved in 59 patients, and moderate response was

achieved in 31 patients. Serum Alb level, Hb concentration, D-value, and N.I.40 showed significant improvement 6 months after the starting of DMARD [3.9 (3.6-4.3) vs 4.2 (4.0-4.5) mg/dL, p<0.001; 12.5 (11.7-13.4) vs 12.6 (11.8-13.6) g/dL, p=0.0164; 0.155 (-0.47- 0.91) vs -0.26 (-0.72-0.18), p<0.001; 47.2 (41.8-51.1) vs 49.8(46.1-52.2), p<0.001, respectively]. Furthermore, we found a significant trend towards improvement of serum Alb level, Hb concentration, D-value, and N.I. 40 in patients with a better EULAR response (p value for trend=0.0124, 0.033, 0.0057, and 0.0040, respectively).

**Conclusions:** There was a statistically significant trend towards better nutritional improvement in patients with a better EULAR response. Control of RA may contribute not only to joint deterioration prevention, but may also help to improve the nutritional condition of patients.

**Disclosure of Interest:** None declared

**SAT0131 THE ROLE OF ULTRASOUND FOR THE ASSESSMENT OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS**

S. Farietta<sup>1</sup>, E. Castillo<sup>1</sup>, D. Buitrago-Garcia<sup>2</sup>, L. Villarreal<sup>3</sup>, P. Santos-Moreno<sup>4</sup>. <sup>1</sup>Ultrasound, Biomab, Center For Rheumatoid Arthritis, Bogota; <sup>2</sup>Epidemiology, SIIES; <sup>3</sup>Health services; <sup>4</sup>Rheumatology, Biomab, Center For Rheumatoid Arthritis, Bogota, Bogota, Colombia

**Background:** Rheumatoid arthritis (RA) a chronic systemic connective tissue disease, one of the main symptoms is inflammation that is mainly present in hands and feet. The evaluation and follow-up of disease activity relies on composite indexes with clinical outcomes. However, many studies have shown there are differences between disease activity measured by clinical examination and ultrasound findings (1).

**Objectives:** The aim of this study was to evaluate the utility of ultrasound in patients with RA stratified as moderate or severe disease activity based on DAS28.

**Methods:** We performed across-sectional study including patients with RA; patients were followed-up under T2T standards and a multidisciplinary approach. Clinical follow-up was designed by the authors according to DAS28 as follows: every 3-5 weeks (DAS28 >5.1), every 7-9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11-13 weeks (DAS28 <3.1). Additionally the patient was evaluated by a rheumatologist expert in ultrasound; US studies were carried out with a Esaote MyLab Seven® US equipment (Biomedica, Genoa, Italy) equipped with a 10-18 MHz linear transducer; PD was adjusted according to the following parameters: frequency, 8.0, PRF, 0.500, wall filter 3, gain between 50 and 70. The rheumatologist reported erosions, synovitis, osteophytes and power Doppler; we defined as active disease when patients had synovitis or positive power Doppler. We calculated means, and standard deviations for continuous variables and categorical variables were presented as rates. We performed a bivariate analysis using Pearson's Chi<sup>2</sup>

**Results:** 272 patients meet the inclusion criteria; most of patients were woman 87%, mean age were 57 years ± 11, mean DAS was 4.45 ± 1.1, 70% of patients were in moderate disease activity (MDA), and 30% in severe disease activity (SDA), 81% of patients were receiving conventional DMARDs therapy and 19% biological therapy. Regarding the findings of the ultrasound, the most prevalent elementary lesions in hands and feet were erosions, 75% and 6% see table 1. Active disease was found in 66% (11% of patients had only synovitis and 55% had synovitis plus Doppler) see table 2. Thus, in patients where we assumed that had MDA or SDA, by ultrasound we found that 34% did not have disease activity. We did not find statistical association between ultrasound and age, sex or type of pharmacological therapy.

VARIABLE	PRESENT		ABSENT	
	n	%	n	%
<b>HANDS</b>				
SYNOVITIS	181	67	91	33
POWER DOPPLER	152	56	120	44
<b>FEET</b>				
SYNOVITIS	9	4	263	96
POWER DOPPLER	5	2	267	98
EROSIONS	16	6	256	94
OSTEOPHYTES	19	7	253	7

**Conclusions:** In RA patients with moderate or severe disease activity ultrasonography can complement the clinical evaluation, since there are a third of patients without disease activity according to ultrasound findings; where by there is a need

for further research in order to identify the reasons of non-active disease activity in patients classified clinically as in moderate or severe disease activity.

### SAT0132 COMORBIDITIES AFFECT THE RETENTION RATE BUT NOT THE CLINICAL RESPONSE IN A COHORT OF RHEUMATOID ARTHRITIS PATIENTS TREATED WITH TUMOR NECROSIS FACTOR INHIBITORS.

E. G. Favalli<sup>1</sup>, M. Biggioggero<sup>1</sup>, A. Becciolini<sup>1</sup>, C. Crotti<sup>1</sup>, L. Sinigaglia<sup>1</sup>.

<sup>1</sup>Department of Rheumatology, Gaetano Pini Institute, Milano, Italy

**Background:** Rheumatoid arthritis (RA) is frequently complicated by other comorbid diseases that may drive therapeutic strategy or interfere with achieving clinical response.

**Objectives:** To retrospectively evaluate the impact of comorbidities on treatment choice, 12-month clinical response, and 24-month retention rate in a cohort of RA patients treated with a first-line subcutaneous tumor necrosis factor alpha inhibitor (TNFi).

**Methods:** Study population was extracted from a local registry which included all RA patients receiving adalimumab (ADA) or etanercept (ETN) as first-line biologic drug between January 2001 and December 2013. The prevalence of common RA comorbidities was computed and the study population was stratified according to Rheumatic Disease Comorbidity Index (RDCl) RDCl=0 vs RDCl≥1 for evaluating the role of comorbidities on the choice between ETN and ADA; the prescription of concomitant methotrexate (MTX); and the impact of comorbidities on 1-year Disease Activity Score 28 (DAS28-ESR) remission and EULAR good-moderate response rates. The 24-month retention rate was computed by the Kaplan-Meier method and a Cox proportional hazard model was developed to examine the role of RDCl and other baseline factors as predictors of TNFi persistence.

**Results:** 310 RA patients (153 ADA and 157 ETN) were included (female 82.1%, mean±standard deviation (SD) age 53.6±13.1 years, mean disease duration 11.6±9.2 years, mean baseline DAS 28.5±1.21, RF positivity 76.4%, mean HAQ 1.39±0.56). 41.2% of patients had at least one comorbidity (overall mean RDCl 0.73) and the prevalence of conditions is reported in table 1. The proportion of patients with RDCl≥1 was similar in the subgroup receiving or not concomitant MTX (55.1% versus 44.8%, respectively; p=0.57) and similar (p=0.22) in patients treated with ADA (44.8%) or ETN (37.8%). No individual comorbidity was associated with the prescription of MTX or the choice between the two TNFis. No difference was found in the rates of both EULAR good-moderate response (61.3% vs 53.7%, p=0.175) and DAS28-ESR remission (31.4% vs 27.2%, p=0.463) according to baseline RDCl score. On the other hand, elevated RDCl is a predictor of biologic drug discontinuation (Hazard Ratio [HR] 1.17, confidence interval [95% CI] 1.00-1.37; p=0.04), where as treatment with ETN (HR 0.50, 95% CI 0.35-0.71; p<0.001) and concomitant MTX (HR 0.57, 95% CI 0.40-0.81; p=0.002) were both associated with a lower risk of TNFi withdrawal.

COMORBIDITY	PREVALENCE (n=310)
Osteoporosis (no fractures)	24.5%
Hypertension	20.3%
Depression	11.8%
Cardiovascular disease	10.6%
Lung disease	7.9%
Fibromyalgia	7.6%
Autoimmune Thyroid disease	5.8%
Dyslipidemia	5.5%
Gastrointestinal disorders	5.1%
Diabetes	3.3%
Osteoporotic fractures	2.4%
Neurological disorders	1.8%
History of malignancy	0.3%

**Conclusions:** in our real-life experience, the baseline presence of comorbidity seemed to not influence the prescription of concomitant MTX and to not drive the choice between ADA and ETN. Comorbidities did not affect 1-year clinical response, but were associated with a higher risk of TNFi discontinuation over a 2-

year follow-up period. The use of ETN and concomitant treatment with MTX were both strong predictors of drug persistence.

### SAT0133 PREVALENCE OF TYPE 2 DIABETES AND EVALUATION OF PATIENT CHARACTERISTICS AMONG PATIENTS WITH AND WITHOUT RA FROM COMMUNITY RHEUMATOLOGY CLINICS

E. Alemao<sup>1</sup>, L. Ferri<sup>1</sup>, D. Paul<sup>1</sup>, A. Marshall<sup>1</sup>, L. McDonald<sup>2</sup>, A. Rao<sup>3</sup>, V. R. Anupindi<sup>4</sup>, G. Craig<sup>5</sup>, K. Knapp<sup>5</sup>. <sup>1</sup>Bristol-Myers Squibb, Princeton, United States; <sup>2</sup>Bristol-Myers Squibb, Uxbridge, United Kingdom; <sup>3</sup>MuSigma, Bangalore, India; <sup>4</sup>Mu Sigma, Princeton; <sup>5</sup>DiscusAnalytics LLC, Spokane, United States

**Background:** RA and type 2 diabetes (T2D) have common core pathophysiologic pathways, such as insulin resistance and increased glycated end products related to endothelial dysfunction, which may portend cardiovascular disease.<sup>1</sup> Currently there is limited real-world evidence of T2D prevalence among patients (pts) with RA.

**Objectives:** To estimate the prevalence of T2D and insulin resistance among pts with RA vs control (osteoarthritis [OA] pts). To evaluate characteristics among RA pts with/without T2D.

**Methods:** A retrospective study was conducted on a subset of the JointMan database (an electronic medical record of >6000 pts from >10 providers. At each visit, diagnosis, medications, test results, co-morbidities and demographic data were collected. Pts aged ≥18 years with ≥2 diagnoses of RA or satisfying ACR criteria from 1 Jan 2009 to 30 Nov 2017 were included with a control group (pts with ≥2 OA diagnoses in the same period). Pts were considered to have T2D if they had a diagnosis code, diabetic medications prescription, HbA1c ≥6.5%, random glucose test ≥200 mg/dL or prior report of T2D. Between-group prevalence was compared using a chi-squared test and characteristics of pts with/without T2D were compared using Fisher's exact, chi-squared and Mann-Whitney tests.

**Results:** Data were analysed from 4181, 1157 and 1626 pts in RA-only, OA-only and dual (RA plus OA) cohorts, respectively. The RA-only cohort was younger and had a lower proportion of white pts compared with other cohorts (Table). T2D prevalence was significantly higher in the dual cohort (24.3%, n=395) vs RA-only (16.2%, n=676; p<0.001) and OA-only cohorts (10.5%, n=121; p<0.001). T2D prevalence was significantly higher in the RA-only vs OA-only cohorts (p<0.001). Sicca and Sjögren's syndromes were more prevalent co-morbidities in pts with RA only with vs without T2D (16.3 vs 13.0%; p=0.023) and a similar trend was observed for thyroid disorder (6.4 vs 3.7%; p=0.001).

**Table 1.** Pt Characteristics by Cohort

	RA only (n=4181)		OA only (n=1157)		Dual (RA plus OA) (n=1626)	
	With T2D (n=676)	No T2D (n=3505)	With T2D (n=121)	No T2D (n=1036)	With T2D (n=395)	No T2D (n=1231)
<b>Age (years), mean (SD)</b>	59.6 (13.5)	59.6 (14.8)	68.6 (9.8)	65.4 (11.4)	64.7 (10.5)	64.5 (11.1)
<b>Female, n (%)</b>	504 (74.6)	2643 (75.4)	83 (68.8)	761 (73.5)	294 (74.4)	943 (76.6)
<b>Race, n (%)</b>						
American Indian or Alaska Native	29 (4.3)	71 (2.0)	6 (5.0)	9 (0.9)	12 (3.0)	27 (2.2)
White	521 (77.1)	2579 (73.6)	105 (86.8)	921 (88.9)	363 (91.9)	1127 (91.6)
<b>Co-morbidities, n (%)</b>						
Sicca/Sjögren's syndromes	110 (16.3)	456 (13.0)	20 (16.5)	117 (11.3)	92 (23.3)	356 (28.9)
Thyroid disorders	43 (6.4)	128 (3.7)	3 (2.5)	65 (6.3)	27 (6.8)	68 (5.5)
<b>Charlson Comorbidity Index, mean (SD)</b>	1.02 (0.15)	1.01 (0.18)	1.05 (0.34)	1.01 (0.12)	1.01 (0.14)	1 (0.09)

**Conclusions:** A higher prevalence of T2D was observed in pts with RA compared with controls. In addition, co-morbidities of Sjögren's syndrome and thyroid disorder were higher in T2D pts with RA but not for dual RA plus OA.

**SAT0134 MORTALITY AND MULTIPLE CAUSES OF DEATH IN RHEUMATOID ARTHRITIS PATIENTS. RESULTS FROM A LARGE POPULATION-BASED COHORT IN THE VENETO REGION, 2010-2015.**

F. Ometto<sup>1</sup>, U. Fedeli<sup>2</sup>, C. Botsios<sup>3</sup>, E. Schievano<sup>2</sup>, M. C. Corti<sup>2</sup>, L. Punzi<sup>1</sup>.  
<sup>1</sup>Department of Medicine - DIMED, University of Padova; <sup>2</sup>Epidemiological Department, Veneto Region; <sup>3</sup>Department of Medicine - DIMED, University of Padova, Padova, Italy

**Background:** Mortality rates in patients with rheumatoid arthritis (RA) are 1.5-1.6 fold higher than in the general population<sup>1,2</sup>. No recent data on mortality in large cohorts of RA patients in Italy are available.

**Objectives:** The aim of this study was to assess standardized mortality ratios (SMRs) and multiple causes of death in RA subjects living in the Veneto Region between 2010 and 2015.

**Methods:** We identified in the electronic archive of the Veneto Region a cohort of patients aged 20-89 years who were exempt from copayment for RA in January 2010, and linked them with the archive of causes of deaths of the period 2010-2015. The record-linkage was performed on previously anonymized records. In the Veneto Region a copy of all death certificates is transmitted to the Regional Epidemiology Service for coding of causes of death according to the International Classification of Diseases, 10th Edition. Each subject was followed from 1st January 2010 either until death, or 90 years of age, or 31st December 2015, whichever came first.

In the Veneto Region, the archive of causes of death include all diseases mentioned in the death certificate, and the selection of the underlying cause of death (UCOD) is performed by means of the Automated Classification of Medical Entities, a computer program developed by the US National Center for Health Statistics. SMRs with 95% confidence intervals, were computed as the ratios between deaths observed in the cohort, and those expected according to age- and gender-specific regional mortality rates.

Number of deaths and standardized mortality ratio (SMR) with 95% Confidence Interval (CI)	Deaths (n)	
	Deaths (n)	SMR (95% CI)
Certain infectious and parasitic diseases (A00-B99)	88	2.34 (1.89-2.89)
Septicemia (A40-A41)	66	3.07 (2.37-3.90)
Neoplasms (C00-D48)	519	0.98 (0.90-1.07)
Diseases of the blood and blood-forming organs (D50-D89)	23	3.22 (2.04-4.83)
Endocrine, nutritional and metabolic diseases (E00-E90)	57	0.86 (0.73-1.25)
Diabetes mellitus (E10-E14)	43	0.93 (0.67-1.26)
Mental and behavioural disorders (F00-F99)	50	0.90 (0.67-1.18)
Dementia (F00-F03)	44	0.86 (0.62-1.15)
Diseases of the nervous system (G00-G99)	61	0.89 (0.68-1.14)
Alzheimer's disease (G30)	27	0.90 (0.59-1.31)
Diseases of the circulatory system (I00-I99)	783	1.56 (1.45-1.67)
Hypertensive diseases (I10-I15)	101	1.51 (1.23-1.83)
Ischemic heart diseases (I20-I25)	247	1.51 (1.33-1.71)
Other heart diseases (I00-I09, I26-I51)	201	1.64 (1.42-1.88)
Cerebrovascular diseases (I60-I69)	182	1.43 (1.23-1.65)
Diseases of the respiratory system (J00-J99)	177	1.83 (1.57-2.12)
Pneumonia (J12-J18)	61	2.22 (1.70-2.86)
Chronic lower respiratory diseases (J40-J47)	54	1.47 (1.10-1.92)
Interstitial pulmonary diseases (J84)	20	3.47 (2.12-5.36)
Diseases of the digestive system (K00-K93)	117	1.93 (1.60-2.32)
Vascular disorders of intestine (K55)	21	2.40 (1.48-3.66)
Diseases of liver (K70-K76)	20	0.95 (0.58-1.47)
Diseases of the musculoskeletal system (M00-M99)	149	17.3 (14.7-20.4)
Rheumatoid arthritis (M05-M06)	130	63.3 (52.9-75.2)
Diseases of the genitourinary system (N00-N95)	27	1.29 (0.85-1.88)
External causes of mortality (V01-Y84)	70	1.65 (1.29-2.08)
Falls (W00-W19)	20	1.95 (1.19-3.01)
<b>All causes</b>	<b>2142</b>	<b>1.42 (1.36-1.48)</b>

**Results:** Overall 16,098 residents diagnosed with RA and aged 20-89 years were enrolled in the cohort. Follow-up was complete for above 99% of study subjects. The overall follow-up amounted to 88,599 person-years, with 2,142 registered decedents. The most common causes of death were circulatory diseases (36.6%), neoplasms (24.2%), and respiratory diseases (8.3%). SMR in RA

subjects was 1.42 (1.36-1.48). Mortality was significantly increased from circulatory, respiratory, digestive, infectious, hematological diseases and falls (figure 1). Mortality from neoplasms was similar to that expected based on rates from the general population. RA was selected as the underlying cause of death in 6.1% of all deaths in the cohort and was mentioned in 25.4% of death certificates.

**Conclusions:** Overall, a 42% excess risk of death could be observed among patients with RA in the Veneto Region. These data confirm results from previous studies in large cohorts of RA subjects [1,2].

**SAT0135 CYTOKINE ACTIVATION AND FORMATION OF NEPHROPATHY IN EARLY RHEUMATOID ARTHRITIS: CLINICAL AND PATHOPHYSIOLOGICAL PARALLELS**

D. Rekalov<sup>1</sup>, G. Prytkova<sup>1</sup>, R. Kulynych<sup>1</sup>. <sup>1</sup>Rheumatology, Zaporizhzhia Regional Clinical Hospital, Zaporizhzhia, Ukraine

**Background:** RA is characterized by not only joints destruction, but also of other organs and systems, particularly, lungs, heart, blood vessels, kidneys, etc. Nephropathy is currently the leading symptomatic complex of Rheumatoid Arthritis (RA), with upto 73% frequency, being identified as a prognostic criterion of disease severity and outcome. The development of renal insufficiency, as a rule, is the main cause of the fatal outcome of RA without possibility of regular hemodialysis to such patients.

**Objectives:** of the study are to determine pathophysiological relation between cell-mediated immunity (tumornecrosis factor-alpha (TNF-α) activation and renal dysfunction in the patients with early RA (eRA).

**Methods:** We analyzed the data from 35 early RA patients of average age of 50,71±2,25 years (ranged 18 - 76 years, 80% of women) with 9,21±0,43 months mean duration of the disease by the time of the study initiation. Urine and blood tests were performed to verify the main indicators of kidney function and inflammation cytokines significant interaction.

**Results:** All signs of renal dysfunction at the baseline in the patients with eRA were associated with glomerular filtration rate decrease and excretion of urine protein increase. Dynamics of albumin urine, according to the analysis of variance for one-factor scheme, were significantly determined by the state of disease activity, reflecting the severity of joint damage. High urine β-2-microglobulin level was significantly associated with the expression rate of main inflammatory cytokines as per binary regression analysis.

**Table 1.** Differences in the renal function features in the patients with early RA depending on the TNF-α expression (M±m (95%- confidence interval)).

Indicator, units of measure	Patients with RA (n=35)			The level of significance of differences between groups
	The TNF-α level less than the median 170 pg/ml (n = 18)	The TNF-α level higher than the median 170 pg/ml (n = 17)	In general, for the group (n = 35)	
GFR Cockcroft-Gault, ml/min	135,66±4,15	121,38±5,55	129,54±3,93	p<0,05
Albumin urine, mg/L	70,48±15,09 (40,3-100,67)	124,27±15,02 (94,22-154,32)	70,48±15,09 (40,3-100,67)	p<0,05
β <sub>2</sub> -microglobulin urine, μg/L	983,28±72,39 (758,5-1128,06)	1438,53±100,21 (1258,11-1639,95)	1283,28±72,39 (1138,5-1428,06)	p<0,05
The ratio of albumin: creatinine urine, mg/g creatinine	38,79±3,8 (31,2-56,39)	95,93±14,9 (71,13-110,73)	83,83±9,63 (64,38-103,09)	p<0,05
Glomerular permeation index, mg/l	0,42±0,04 (0,34-0,5)	1,23±0,24 (0,74-1,72)	0,81±0,14 (0,54-1,09)	p<0,05

**Conclusions:** The obtained dependence showed the dynamics of expression of tubular disorders in early RA with a progressive deterioration which did associate with the levels of TNF-α expression, and variety of the urine microglobulin rates in the interval 200-350 μg/L. Reliable correlation (r=0.51, p<0.05) between beta-2-microglobulinuria and TNF-α levels was clearly shown, revealing the relationship described by the formula MGU = - 481 + 937 × log<sub>10</sub> (TNF-α) as per regression analysis. The severity of tubular damage in early RA is associated with TNF-α expression, especially in the patients with TNF-α above 250 pg/mL, when microalbumin urine rates were significantly higher (p=0.00043). We identified robust data that in the early RA patients with high TNF-α, the number of reported cases of microalbumin urine was significantly higher than in those with low levels.

**Figure 1.** Differences in values of nephropathy markers in the patients with early RA, depending on TNF- $\alpha$  level.

#### SAT0136 THE INFLUENCE OF HDL-CHOLESTEROL AND CRP ON INCREASED INSULIN RESISTANCE AND IMPAIRED BETA-CELL FUNCTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. G. Ristić<sup>1</sup>, V. Subota<sup>2</sup>, D. Stanislavljević<sup>3</sup>, B. Glišić<sup>1</sup>, M. Petronijević<sup>1</sup>, D. Stefanović<sup>1</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology; <sup>2</sup>Institute of Medical Biochemistry, Military Medical Academy; <sup>3</sup>Institute of Medical Statistics, Faculty of Medicine, University of Belgrade, Belgrade, Serbia

**Background:** Increased CRP in RA pts is associated with lower levels HDL cholesterol. HDL cholesterol may enhance insulin secretion and stimulate glucose uptake into skeletal muscle, adipose tissue, and liver.

**Objectives:** To investigate whether low HDL, alone or in combination with CRP, could explain increased insulin resistance (IR) and impaired  $\beta$ -cell function in RA pts in comparison to healthy controls.

**Methods:** The study population included 127 nondiabetic subjects (90 RA pts and 37 matched controls). We determined body mass index, waist circumference (WC), and presence of metabolic syndrome (MetS). All pts were on disease modifying antirheumatic drugs, 65.6% on steroids (none on steroids >10 mg/day), and 27.8% on biologic therapy. Laboratory analyses included hsCRP, glucose, insulin, and C-peptide (as a marker of insulin secretion). Insulin resistance (IR) was calculated using the updated Homeostasis Model Assessment (HOMA2-IR), based on fasting plasma glucose and specific insulin concentrations. The output of the HOMA2 model was calibrated to give IR of 1 as normal. HOMA2-B indicates the potential of  $\beta$ -cells to compensate increased IR. Lack of compensatory rise of HOMA2-B implied impaired  $\beta$ -cell function.

**Results:** IR was detected in 74.4% of RA pts and in 54.2% controls,  $p=0.025$ . RA pts had significantly higher concentration of specific insulin, C peptide, and HOMA2-IR than controls, while HOMA2-B was not statistically different. Both groups were comparable regarding all other factors known to affect glucose metabolism (age, WC, presence of MetS). We found significant differences in inflammation markers between RA pts and controls: ESR 29.5 (14-44) vs. 16.0 (10.0-20.0); hsCRP 5.5 (2.8-15) vs. 3.0 (1.8-3.9);  $p<0.000$  for both, as well as in lipids, especially HDL concentration  $1.5\pm 0.4$  vs  $1.60\pm 0.3$ ,  $p=0.027$  and a number of the pts with low HDL (37.8 vs 13.5%,  $p=0.007$ ). Univariate regression analysis revealed significant positive effect of HDL on logHOMA2-B ( $\beta$  0.099, 95%CI 0.029-0.169,  $p=0.006$ ) and negative, but not significant effect on HOMA2-IR. In the logistic regression, after adjustment for HDL concentration, significant differences for HOMA2-IR and insulin became less important but still persisted (Table), while significance for C peptide became more prominent. When we added the influence of inflammation, this favourable effect of HDL-cholesterol on C-peptide disappeared.

**Conclusions:** RA pts had higher IR and impaired  $\beta$ -cell function in comparison to healthy controls. The augmentation of statistical significance for C peptide, as a marker of insulin secretion, after adjustment for low HDL-cholesterol and significant effect of HDL on logHOMA2-B implicate its important role in disturbances of glucose metabolism in RA.

SAT0137

### CAROTID INTIMA-MEDIA THICKNESS AND ATHEROSCLEROTIC PLAQUE IN PATIENTS WITH REACTIVE AND RHEUMATOID ARTHRITIS

H. Palhuyeva<sup>1</sup>, A. Litviakov<sup>1</sup>, N. Podolinskaya<sup>1</sup>. <sup>1</sup>Internal desiaases, Vitebsk state medical university, Vitebsk, Belarus

**Background:** It is well-known that the leading cause of premature mortality in patients with rheumatoid arthritis (RA) is cardiovascular disease, myocardial infarction, heart failure, stroke.<sup>1,2</sup> Another important group of rheumatic diseases that attract the attention in connection with possible proatherogenic effects are the seronegative spondyloarthropathies. Reactive arthritis (ReA) may involve the cardiovascular system, aortitis, myocarditis, pericarditis.<sup>3,4</sup>

**Objectives:** to estimate atherosclerotic changes of arteries in patients with RA and ReA, to confront the revealed changes with clinical features of joint pathology, activity of inflammatory process.

**Methods:** We included 75 patients with RA (age 38,7±7,4, disease duration 8,3±5,4), 41 patients with chronic ReA (age 35,8±7,2 disease duration 6,4±4,5) and 29 healthy subjects, matched for age and gender, without a history of CVD. An ultrasound investigation of the arterial vessel with measurement of the intima-media thickness (IMT) of carotids was performed.

**Results:** It has been determined, that in RA group IMT was 0,8 mm (0,7–0,9), compared with 0,6 mm (0,6–0,7) in ReA and 0,6 mm (0,6–0,7) in control group. In RA group IMT positively correlate with the age, duration of disease, Ritchie index, C-reactive protein level. In ReA group disease duration, C-reactive protein level, Ritchie index are not associated with IMT.

In 22 (29,3%) patients with RA we found atherosclerotic plaques lesion in carotids, aorta, and vessels of the lower extremities. Only in 1 (2,4%) patient with PeA we found atherosclerotic plaques. Presence of atherosclerotic plaques associated with RA ( $c^2=8,75$ ,  $p<0,05$ ). In RA detection of atherosclerotic plaques associated with disease durations (12 years (10–15) in group with plaques and 5 years (3–8) in group without plaques). The presence of atherosclerotic plaques is associated with rheumatoid factor ( $c^2=1,02$ ,  $p>0,05$ ), and systemic manifestations of RA ( $c^2=15,89$ ,  $p<0,001$ ).

**Conclusions:** Patients with RA had an increase thickness of IMT and atherosclerotic plaques, which appear in various vascular regions. Long-term duration of ReA is not associated with development atherosclerotic lesion.

### A DELAY TO DIAGNOSIS, BUT NOT TO TREATMENT INITIATION, IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) IS ASSOCIATED WITH ETHNIC GROUP AT ONE US ACADEMIC SITE

I. Castrejon<sup>1</sup>, T. Pincus<sup>1</sup>, J. Chua<sup>1</sup>, N. Shakoor<sup>1</sup>, S. Hassan<sup>1</sup>, J. A. Block<sup>1</sup>.

<sup>1</sup>Rheumatology, Rush University Medical Center, Chicago, United States

**Background:** Disparities in the initiation of disease modifying antirheumatic drugs (DMARDs) therapy in ethnic minorities have been described in rheumatoid arthritis (RA)(1). These disparities are of particular concern in view of the emergence of early diagnosis and aggressive treatment as a cornerstone of management. Delays in diagnosis and treatment have been ascribed in part to lack of awareness, insidious onset, and atypical clinical presentation, but patient-dependent factors may be as important.

**Objectives:** To evaluate disparities in referral and initiation of treatment in RA patients at a USA academic rheumatology site.

**Methods:** We conducted a retrospective study and reviewed the medical records of patients with a primary diagnosis of RA seen at one USA academic setting (2011–2016). Among 642 RA patients, 50 received their initial evaluation by a rheumatologist during the observation period, and were naïve to any DMARD. Data extraction included time between first symptoms and initial visit to our rheumatology facility, demographics, family history, and laboratory tests. In addition, a Multidimensional-Health Assessment Questionnaire (MDHAQ) allowed us to calculate a RAPID3 score as the sum of 0–10 scores for a pain visual analogue scale

(VAS), patient global VAS, and physical function. The time to initiation and type of DMARD prescribed after the first visit was also collected. Statistical analyses were performed using Kruskal-Wallis for differences between medians and chi-squared tests for comparisons between proportions according to ethnicity groups.

**Results:** Fifty new patients with RA were seen in the rheumatology outpatient clinic; 43% were White, 34% Black, and 23% Hispanic. The median delay to be seen by a rheumatologist was 7.2 months for White patients, 12 months for Black, and 11.9 months for Hispanic patients. There were no significant differences in time to initiation of DMARD according to ethnicity. Methotrexate was the DMARD most frequently prescribed, ranging from 86% in White patients to 60% in Hispanic patients. Disease severity according to RAPID3 scores was higher in Black and Hispanic groups, although laboratory tests did not differ between the 3 groups (Table).

**Table 1.** Patient characteristics by ethnicity

	White N=23	Black N=17	Hispanic N=10
Age, mean (SD)	55.5 (13.1)	52.6 (12.3)	49.7 (10.2)
Female, %	74%	88%	80%
Family History of RA, %	15%	9%	20%
Median disease duration (IQR) at the time of first rheumatology evaluation, months	<b>7.2</b> <b>(4.7, 23.9)</b>	<b>12.0</b> <b>(7.7, 22.9)</b>	<b>11.9</b> <b>(5.0, 47.9)*</b>
Time to initiate DMARDs, months, median (IQR)	1.0 (0.5,1.8)	0.8 (0.6,1.6)	0.5 (0,0.7)
Methotrexate	86%	75%	60%
Rheumatoid Factor, %	50%	64%	75%
Anti-CCP, %	69%	64%	80%
ESR, mean (IQR)	15 (10, 25)	23.5 (17, 41)	38 (19, 46)
CRP, mean (IQR)	5 (5, 15)	5 (5, 5.8)	5 (5, 7)
RAPID3, mean (IQR)	<b>12.9</b> <b>(8.2, 16.9)</b>	<b>18.8</b> <b>(14.6, 19.4)</b>	<b>18.5</b> <b>(10.2, 21.5)*</b>

Statistical significance in **bold \*p<0.05**.

**Conclusions:** There is a considerable delay in initial referral to a rheumatologist, which appears to be more pronounced among Black and Hispanic patients. However, once seen in the clinic, initiation of DMARDs occurred within 1-month, regardless of ethnicity. These findings suggest that ethnic minorities are at risk of deleterious outcomes as a consequence of delayed presentation to a rheumatology setting.

SAT0139

### SUBCLINICAL IMPAIRMENT OF MYOCARDIAL FUNCTIONALITY DURING THE VERY EARLY STAGE OF INFLAMMATORY JOINT DISEASES

A. Lo Gullo<sup>1</sup>, J. Rodríguez-Carrio<sup>2,3,\*</sup>, F. Savarino<sup>1</sup>, C. O. Aragona<sup>1</sup>, G. Dattilo<sup>1</sup>, C. Zito<sup>1</sup>, A. Suárez<sup>2,3</sup>, S. Loddo<sup>1</sup>, M. Atteritano<sup>1</sup>, A. Saitta<sup>1</sup>, G. Mandraffino<sup>1</sup>.

<sup>1</sup>Department of Clinical and Experimental Medicine, University of Messina, Messina, Italy, <sup>2</sup>Area of Immunology, University of Oviedo, <sup>3</sup>Instituto de Investigación Sanitaria del Principado de Asturias (ISPA), Oviedo, Spain

**Background:** cardiovascular (CV) disease morbidity is increased in inflammatory joint diseases (IJD), as rheumatoid (RA) and psoriatic arthritis (PsA). Whereas accelerated subclinical atherosclerosis and endothelial dysfunction have been widely studied, less attention has been paid to myocardial function. RA patients with established disease who develop heart failure often have impaired left ventricular (LV) diastolic functionality with preserved LV ejection fraction (EF) and present fewer signs than non-RA patients. Then, additional and more sensitive screening tools as myocardial strain imaging are needed. In this sense, speckle-tracking echocardiography (STE) has been demonstrated to be suitable for detecting impaired systolic function. Although CV risk is increased at disease onset, whether abnormal myocardial functionality could be found already in the early phase of IJD remains unknown.

**Objectives:** to evaluate the myocardial functionality by STE in recent onset RA and PsA patients and its associations with clinical features.

**Methods:** STE was used to assess the myocardial functionality in patients with very early RA (n=41) (2010 EULAR/ACR criteria) and PsA (n=35) (CASPAR criteria) without traditional CV risk factors, and 58 matched healthy controls (HC). Global longitudinal and circumferential strain (GLS and GCS) were estimated.

**Results:** RA patients exhibited impaired GLS ( $-18.13 \pm 1.36\%$ ) and GCS ( $-20.15 \pm 1.34\%$ ) compared to HC ( $-23.25 \pm 1.80\%$ ,  $p < 0.001$  and  $-24.50 \pm 0.70\%$ ,  $p < 0.001$ ; respectively), GLS being also altered in PsA ( $-21.57 \pm 2.59\%$ ,  $p = 0.020$  vs HC). No differences in LV mass index, posterior wall thickness, LV DD, E/A index or EF were found among groups (all  $p > 0.050$ ). DAS28 was correlated to GLS ( $r = 0.908$ ,  $p < 0.001$ ) and GCS ( $r = 0.868$ ,  $p < 0.001$ ) in RA. These findings were further confirmed by multivariate regression analyses adjusted for age, gender, BMI, CRP, ESR, SBP, DBP and duration of the symptoms, DAS28 being the only independent predictor of GLS ( $p < 0.001$ ) and GCS ( $p = 0.002$ ). Principal Component Analyses retrieved equivalent results. Although GCS was not significantly different in PsA compared to HC, a positive correlation with DAS28 ( $r = 0.438$ ,  $p = 0.008$ ) was observed. Consequently, GLS and GCS were impaired in PsA patients with high disease activity (DAS28 > 2.9) compared to HC (GLS:  $p = 0.066$  and GCS:  $p = 0.007$ ).

**Conclusions:** a subclinical myocardial dysfunction can be observed in IJD patients with preserved LV function and without traditional CV risk factors. The subclinical impairment of the myocardial function was found to be a very early event in IJD. Disease activity was the main predictor of myocardial strain impairment. Strain imaging by STE may detect early myocardial dysfunction in IJD.

SAT0140

#### RISK OF VENOUS THROMBOEMBOLISM IN RHEUMATOID ARTHRITIS PATIENTS TREATED WITH BIOLOGIC AND NON-BIOLOGIC DMARDS

J. C. Maro<sup>1</sup>, T. Menzin<sup>1</sup>, K. Hornbuckle<sup>2</sup>, J. T. Giles<sup>3</sup>, A. Kavanaugh<sup>4</sup>, T. Dörner<sup>5</sup>, D. Martin<sup>6</sup>, T. Huang<sup>1</sup>, C. A. Salinas<sup>2</sup>. <sup>1</sup>Harvard Medical School and Harvard Pilgrim Health Care Institute, Boston, <sup>2</sup>Eli Lilly and Company, Indianapolis, <sup>3</sup>Columbia University, New York, <sup>4</sup>UC San Diego School of Medicine, La Jolla, United States, <sup>5</sup>Charité Universitätsmedizin Berlin, Berlin, Germany, <sup>6</sup>U.S. Food and Drug Administration, Silver Spring, United States

**Background:** Individuals with rheumatoid arthritis (RA) have an increased risk of venous thromboembolism (VTE), including pulmonary embolism (PE) and deep vein thrombosis (DVT), compared with non-RA populations based on several recent studies<sup>1,2</sup>. However, information is sparse on the risk of VTE among patients receiving treatment with specific disease-modifying antirheumatic drugs (DMARDs) or categories of therapies.

**Objectives:** To estimate the incidence of VTE among patients receiving routine clinical care for RA, specifically during treatment with conventional (c) and biologic (b) DMARDs.

**Methods:** Incidence rates were estimated in a retrospective cohort study of patients with RA (defined as at least two International Classification of Disease, Ninth Revision, Clinical Modification [ICD-9-CM] Diagnostic codes) enrolled in US health insurance plans between October 1, 2010 to September 30, 2015 and participating in the Innovation in Medical Evidence Development and Surveillance (IMEDS) program. These data are formatted into the U.S. Food and Drug Administration's Sentinel Common Data Model and Sentinel's publicly available standardized analysis tools were used to estimate the incidence rates of VTE following initiation of cDMARDs or bDMARDs. Patients were required to be new users of the study drug class, with no evidence of use in the 365 days preceding initiation and were not allowed to re-enter the cohort. Patients were required to demonstrate continuous use of the study drug class to be considered at risk for VTE. VTE was defined based on ICD-9-CM codes, but patients diagnosed in outpatient settings were also required to have evidence of oral anticoagulant dispensing within 31 days of the event. PE and DVT ICD-9-CM codes were also disaggregated to produce separate incidence rates.

**Results:** During treatment with cDMARDs (i.e., methotrexate or leflunomide) or bDMARDs (i.e., abatacept, adalimumab, certolizumab pegol, etanercept, golimumab, infliximab, rituximab, and tocilizumab), patients experienced VTE at a crude incidence rate of 1.49 (95% CI 1.30, 1.71) per 100 person-years (PY) and 0.98 (95% CI 0.83, 1.14) per 100 PY, respectively. For each study drug class, age was an important risk factor for VTE, with increasing age associated with higher rates of VTE; for example, during treatment with bDMARDs incidence rate (IR)<sub>18-49 years</sub>=0.69, IR<sub>50-59 years</sub>=0.65, IR<sub>60-64 years</sub>=0.94, and IR<sub>65+ years</sub>=2.11 per 100 PY (figure 1). Men also had higher incidence rates of VTE than women. In the analyses of PE and DVT, DVT incidence rates were higher than PE incidence rates, and similar incidence rate trends overall and across age strata for cDMARD and bDMARD cohorts were noted.

Figure 1 Incidence of VTE among patients with RA treated with cDMARDs and bDMARDs, overall and by age. (Data displayed as incidence rates with 95% confidence intervals.)

**Conclusions:** Venous thromboembolism is an important clinical concern among patients with RA and incidence rates vary by age and sex during routine clinical treatment with DMARDs.

#### TRENDS IN THE INCIDENCE OF LYMPHOMAS AND LEUKEMIAS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SPAIN: AN OBSERVATIONAL COHORT STUDY OF HOSPITAL DISCHARGES FROM 1999 TO 2015 (TRENDR-AR STUDY)

J. L. Morell Hita<sup>1</sup>, R. Mazzucchelli<sup>2</sup>, E. Perez Fernandez<sup>3</sup>, J. Quiros<sup>2</sup>, C. Macía Villa<sup>4</sup>, N. Crespi<sup>5</sup>, M. Peña<sup>2</sup>, C. Herranz<sup>10</sup>, C. Martinez Prada<sup>11</sup>, C. Morado Quiñoa<sup>11</sup>, V. Villaverde<sup>12</sup>. <sup>1</sup>Rheumatology, Hospital Universitario Ramón y Cajal, <sup>2</sup>Rheumatology, <sup>3</sup>Hospital Universitario Fundación Alcorcón, <sup>4</sup>Rheumatology, Hospital Universitario Severo Ochoa, <sup>5</sup>CS La Rivota, <sup>6</sup>Rheumatology, Hospital Universitario Puerta de Hierro, Madrid, <sup>7</sup>Rheumatology, Hospital Universitario Guadalajara, Guadalajara, <sup>8</sup>Rheumatology, Hospital Universitario Doce de Octubre, <sup>9</sup>Rheumatology, Hospital Universitario La Princesa, <sup>10</sup>Rheumatology, Hospital del Henares, <sup>11</sup>Rheumatology, Hospital Universitario Clínico San Carlos, <sup>12</sup>Rheumatology, Hospital Universitario Móstoles, Madrid, Spain

**Background:** Oncohematological diseases have an increased incidence in Rheumatoid Arthritis (RA) patients. However, their trend in RA in Spain is unknown

**Objectives:** To analyze the incidence and trend of hospital admissions for lymphomas and leukemias in RA patients in Spain from 1999–2015

**Methods:** We performed an observational retrospective population study analyzing the Spanish administrative database that includes a Minimum Basic Data Set (MBDS) of hospital admissions of RA patients from 1999–2015. We selected MBDSs for lymphomas and leukemias. Cases were identified by the presence in primary/secondary diagnosis of ICD9 codes. The population at risk was estimated with a prevalence of RA of 0.5% (0.8% women and 0.2% men). Crude and adjusted rates were calculated, and the trend was analyzed using the Generalized Linear Model with the year as the analysis variable. SPSS version 20 (Chicago, IL) was used

**Results:** 338.343 RA hospital admissions were detected, being 3561 (1.1%) lymphomas (61.5% women, 38.5% men) and 1664 (0.5%) leukemias (52.3% women,

47.7% men). Mean age 68.94(SD 11.38) in lymphomas and 71.46(SD 11.24) in leukemias. Age-adjusted rate during the period for lymphoma was 152,19/10<sup>5</sup> inhab/year (92,05 women and 240,14 men). Lymphoma age-adjusted rate increased from 52,46/10<sup>5</sup> inha/year in 1999 to 187,57 in 2015, both women (from 42,74 to 142,95) and men (from 280,77 to 326,63). An annual increase in lymphoma rate of 6,9% is estimated (RRI 1,069; CI 95% 1,054–1,085). Age-adjusted rate during the period for leukemia was 90,87/10<sup>5</sup> inhab/year (37,09 women and 144,65 men). Leukemia age-adjusted rate increased from 18,86/10<sup>5</sup> inhab/year in 1999 to 94,05 in 2015, both women (13,80 in 1999 to 65,93 in 2015) and men (38,70 in 1999 to 204,84 in 2015). An annual increase in leukemia rate of 8,2% is estimated (RRI 1,083; CI 95% 1,069–1,097).

**Conclusions:** In Spain from 1999–2015 lymphoma and leukemia hospital admissions in RA patients increased, with an estimation of 6,9% and 8,2% annual increase respectively.

**Disclosure of Interest:** None declared

### SAT0142 PULMONARY HYPERTENSION AMONG HISPANIC PATIENTS WITH RHEUMATOID ARTHRITIS: A CASE-CONTROL STUDY

J. R. Azpiri-López<sup>1</sup>, D. A. Galarza-Delgado<sup>2</sup>, I. J. Colunga-Pedraza<sup>2</sup>, J. A. Dávila-Jiménez<sup>1</sup>, E. E. Abundis-Márquez<sup>2</sup>, A. H. Guillén-Lozoya<sup>2</sup>, F. J. Torres-Quintanilla<sup>1</sup>, R. E. Ramos-Cázares<sup>2</sup>, R. Vera-Pineda<sup>1</sup>, J. A. Cárdenas-de la Garza<sup>2</sup>. <sup>1</sup>Cardiology, <sup>2</sup>Rheumatology, Hospital Universitario "Dr José E. Gonzalez", UANL, Monterrey, Mexico

**Background:** Rheumatoid arthritis (RA) is a chronic, systemic, inflammatory, multifactorial disease that mainly affects synovial joints. Pulmonary artery hypertension (PAH) can appear as a complication of connective tissue diseases. It is possible that pulmonary artery systolic pressure (PASP) in RA may be elevated due to interstitial lung disease, pulmonary vasculitis, pulmonary veno-occlusive disease, or cardiac disease (1). Although right heart catheterization is the gold standard, Doppler echocardiography has proved to be a reliable non-invasive method for detecting PAH (2).

**Objectives:** To determine the prevalence of PAH in RA patients and compare it to matched controls.

**Methods:** A case-control study with RA patients aged 40 to 75 years that fulfilled the 2010 ACR/EULAR criteria and matching controls were included. Exclusion criteria: poor acoustic window, absence of tricuspid regurgitation (TR), prior atherosclerotic cardiovascular (CV) disease and overlap syndromes. Patients were matched using age, sex and comorbidities. Transthoracic echocardiogram was performed by a board-certified cardiologist. PASP was calculated using the Bernoulli equation: TR velocity<sup>2</sup> × 4 + right atrial pressure according to ASE's guidelines. We used Denton's definition of PAH on Doppler echocardiography as an estimated PASP ≥ 30 mmHg (3).

**Results:** A total of 76 RA patients and 52 matched controls were included. Demographic and clinical characteristics of both groups are shown on table 1. As shown on table 2, the mean PASP was higher RA patients (27.14±6.34 mmHg) than controls (24.68±5.44 mmHg) (*P*=0.024). PASP ≥ 30 mmHg prevalence was significantly higher in RA patients (34.2% vs 11.5%; *P*=0.004).

**Table 1** Demographic characteristics

	RA (n = 76)	Control (n = 52)	<i>P</i>
Women, n (%)	74 (97.4)	46 (88.5)	0.041
Age, mean±SD	55.71 ±8.84	53.86 ±6.14	0.195
BMI, mean±SD	29.11 ±5.42	28.31 ±4.37	0.343
Hypertension, n (%)	26 (34.2)	12 (23.1)	0.176
Type 2 Diabetes mellitus, n (%)	8 (10.5)	7 (13.5)	0.612
Active smoking, n (%)	6 (7.9)	6 (11.5)	0.487

**Table 2** Echocardiographic findings

	RA (n = 76)	Control (n = 52)	<i>P</i>
TR Vmax (m/s), mean±SD	2.27±0.32	2.18±0.33	0.157
PASP (mmHg), mean±SD	27.14 ±6.34	24.68 ±5.44	<b>0.024</b>
PASP ≥ 30 mmHg, n (%)	26 (34.2%)	6 (11.5%)	<b>0.004</b>

TR Vmax – Tricuspid regurgitation maximum velocity. **Conclusions:** Elevated PASP, suggesting PAH, was more prevalent on RA patients than controls. A higher number of CV events that cannot be explained by traditional risk factors have been reported in RA patients; and it is possible that the elevation in the PASP could contribute to the problem. Prospective studies are needed to evaluate the role of elevated PASP in morbidity and mortality of RA patients.

### SAT0143 THE ARREST OF BONE MINERAL DENSITY LOSS AT THE LUMBAR SPINE AND HIP IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS DURING RITUXIMAB THERAPY

K. Keywani<sup>1,2</sup>, H. G. Raterman<sup>1,2,3</sup>, M. M. ter Wee<sup>1,4</sup>, M. T. Nurmohamed<sup>1,2</sup>, A. E. Voskuyl<sup>1</sup>, I. E. Bultink<sup>1</sup>, W. F. Lems<sup>1,2</sup>. <sup>1</sup>Rheumatology and immunology Center, VU University Medical Center, <sup>2</sup>Rheumatology and immunology Center, Reade, Amsterdam, <sup>3</sup>Rheumatology, North West Clinics, Alkmaar, <sup>4</sup>Epidemiology and Biostatistics, VU University Medical Center, Amsterdam, Netherlands

**Background:** One of the well-known characteristics of rheumatoid arthritis (RA) is generalized bone loss.<sup>1–2</sup> Although rituximab is a frequently prescribed biologic disease-modifying anti-rheumatic drug (bDMARD) for the treatment of RA, data regarding changes in bone mineral density (BMD) in RA patients during rituximab therapy are limited.

**Objectives:** To study the extent of BMD loss at lumbar spine and hip in patients with active rheumatoid arthritis treated with rituximab.

**Methods:** Consecutive RA patients with an active disease status (DAS28 > 3.2) starting rituximab treatment were enrolled in a prospective cohort study. BMD of the lumbar spine and hip was measured before treatment and after one year using dual energy X-ray absorptiometry (DXA) to assess BMD changes. Clinical response was defined using the European League Against Rheumatism (EULAR) response criteria.

**Results:** A total of 43 subjects (18.6% men) with mean age of 53.6 (SD 10.7) years were included in the study. Median disease duration was 9.5 (IQR 0.7–40.2) years and baseline mean DAS28 was 5.6 (SD 1.3). In responders, the DAS28 decreased with 1.97 points (SD 0.78) 95% CI 1.67 – 2.28 *p* < 0.001; and in non-responders, the DAS28 decreased with 0.01 points (SD 0.67) 95% CI -0.35 – 0.37 *p* = 0.945. All changes in BMD were not statistically significant (table 1).

**Table 1** BMD change after one year categorized by EULAR response

	Mean (SD) baseline BMD	Mean (SD) follow-up BMD	Mean change	% change
LS total (n=43)	1.015 (0.182)	1.011 (0.186)	-0.004	-0.4
LS responders (n=27)	1.026 (0.169)	1.017 (0.182)	-0.009	-1.0
LS non-responders (n=16)	0.997 (0.206)	1.001 (0.198)	0.004	+0.7
Hip total (n=43)	0.845 (0.144)	0.849 (0.143)	0.003	+0.5
Hip Responders (n=27)	0.836 (0.126)	0.838 (0.129)	0.003	+0.3
Hip Non-responders (n=16)	0.862 (0.174)	0.867 (0.166)	0.005	+0.8

BMD is presented in g/cm<sup>2</sup>; BMD; bone mineral density; LS, lumbar spine.

**Conclusions:** The findings of this study indicate that patients with active RA treated with rituximab have arrest of bone loss at both the lumbar spine and hip. Moreover, these results suggest that rituximab has bone-saving abilities even in the absence of clinical response.

SAT0144

**EFFECT OF AGING ON BONE MASS AND SKELETAL MUSCLE MASS IN ELDERLY PATIENTS WITH RHEUMATOID ARTHRITIS: TOMORROW STUDY**

K. Inui<sup>1</sup>, T. Koike<sup>2,3</sup>, Y. Sugioka<sup>2</sup>, T. Okano<sup>1</sup>, K. Mamoto<sup>1</sup>, Y. Yamada<sup>1</sup>, K. Mandai<sup>4</sup>, M. Tada<sup>5</sup>, H. Nagata<sup>6</sup>, H. Nakamura<sup>1</sup>. <sup>1</sup>Department of Orthopaedic Surgery, <sup>2</sup>Center for Senile Degenerative Disorders (CSDD), Osaka City University Graduate School of Medicine, Osaka, <sup>3</sup>Search Institute for Bone and Arthritis Disease (SINBAD), Shirahama Hamayu Hospital, Wakayama, <sup>4</sup>Department of Orthopaedic Surgery, Osaka Social Medical Center Hospital, <sup>5</sup>Department of Orthopaedic Surgery, Osaka City General Hospital, Osaka, <sup>6</sup>Department of Orthopaedic Surgery, Shiraniwa Hospital, Nara, Japan

**Background:** Both osteoporosis and sarcopenia are common in patients with chronic inflammatory conditions such as rheumatoid arthritis (RA). Fragility fractures occur on osteoporotic bone on falling. Unstable gait caused by sarcopenia increases the frequency of such falls.

**Objectives:** To evaluate the relationship between bone mineral density (BMD) and appendicular skeletal muscle index (ASMI) in patients with RA and healthy controls.

**Methods:** We used data collected over a 7-year period from 2010 to 2016 as part of a prospective cohort study (TOMORROW Study: UMIN00003876) that included RA patients and age- and sex-matched volunteers recruited through mass media as controls. BMD of the lower leg and ASMI were determined using whole-body dual-energy X-ray absorptiometry. These were collected for all participants together with baseline characteristics including anthropometric data and blood test data related to lipid and sugar metabolism. Each parameter for the RA patients was compared with that for the healthy controls. Multiple regression analysis was carried out in the RA population only. In RA patients, treatment regimen and disease activity score 28 were recorded.

**Results:** Among 413 participants of the TOMORROW Study (208 RA patients; 349 women; mean age 58 years), 137 participants age 65 years or older (77 RA; 117 women) were enrolled in the present study. BMD and ASMI decreased significantly over the 7-year study period in RA patients and healthy controls from baseline. BMD and ASMI were lower in RA patients than in healthy controls at every time point through the 7-year study period. There was no interaction between time and RA ( $p=0.194, 0.089$ ; repeated measure ANOVA). The change of BMD at year 7 from baseline ( $\Delta$ BMD) and change of ASMI at year 7 from baseline ( $\Delta$ ASMI) did not correlate in health controls, however, in RA patients,  $\Delta$ BMD correlated positively with  $\Delta$ ASMI ( $r=0.331, p=0.023$ ) (Fig). Multiple regression analysis with  $\Delta$ BMD as the outcome variable and anti-citrullinated peptide antibody, Rheumatoid factor, ASMI, body mass index, disease activity score 28, homeostatic model assessment (HOMA)-R, Matrix metalloproteinase (MMP)-3 and sex as independent variables revealed that male sex ( $p=0.0036$ ) and ASMI ( $p=0.0020$ ) were independently related with  $\Delta$ BMD.

Figure 1 Correlation between change of ASMI and BMD for 7 years in elderly patients with RA. (pearson correlation coefficient;  $r=0.331, P=0.0229$ )

**Conclusions:** Decrease of BMD and ASMI were correlated with each other in elderly patients with RA.

**Disclosure of Interest:** None declared

SAT0145

**FEATURES OF PATIENTS WITH RHEUMATOID ARTHRITIS WHOSE DEBUT JOINT IS A FOOT OR ANKLE JOINT: A 5,479 CASES STUDY FROM THE IORRA COHORT**

K. Yano<sup>1</sup>, K. Ikari<sup>1</sup>, K. Okazaki<sup>2</sup>, A. Taniguchi<sup>1</sup>, H. Yamanaka<sup>1</sup>. <sup>1</sup>Institute of Rheumatology, <sup>2</sup>Orthopedic Surgery, Tokyo Women's Medical University, Tokyo, Japan

**Background:** Foot and ankle joint disorders are serious issues for patients with rheumatoid arthritis (RA). Rheumatoid foot is reported as the first symptom of the disease in 20–53% of RA patients<sup>1–3</sup>. However, there are few studies investigating the features of patients with RA whose debut joint is a foot or ankle joint.

**Objectives:** The aim of this study is to compare the differences between RA patients whose first symptom was a foot or ankle joint (FOOT group) and was other joints (OTHER group) by using the Institute of Rheumatology, Rheumatoid Arthritis (IORRA) cohort in our institute.

**Methods:** In the IORRA survey conducted in April 2016, patients were asked about first symptom at RA onset. Disease activities, clinical laboratory variables, functional disability, quality of life, and the use and ratio of anti-inflammation and anti-rheumatic drugs were compared between the FOOT group and OTHER group.

**Results:** Among 5,637 Japanese patients with RA who participated in the IORRA survey on April 2016, 5,479 patients (97.2%) responded to the questionnaire regarding debut joint. Of these 5,479 patients, 2,402 (43.8%) reported their first symptom of RA were a foot or ankle. Comparing the two groups, the FOOT group had higher disease activity, higher disabilities, lower quality of life, low activities of daily living, and poorer mental health and used higher dose and rate of anti-inflammatory drugs significantly than the OTHER group (all  $P<0.01$ ). On the other hand, medications to suppress the disease activity of RA have no statistical differences between the two groups (table 1).

Table 1 Comparison of clinical features and outcomes between the FOOT group and the OTHER group

	FOOT group (n=2,164)	OTHER group (n=2,164)	P
DAS28	2.82±1.1 (0.0–7.0)	2.51±0.95 (0.0–6.1)	<0.01
CRP, mg/dl	0.44±0.92 (0.0–9.7)	0.32±0.80 (0.0–18.3)	<0.01
RF, IU/ml	118.5±260.7 (3–7150)	97.2±217.1 (3–5544)	<0.01
J-HAQ	0.69±0.76 (0–3)	0.47±0.66 (0–3)	<0.01
EQ5D	0.78±0.18 (-0.1–1.0)	0.85±0.2 (0.1–1.0)	<0.01
NSAID use, no. (%)	1,162 (53.7)	972 (44.9)	<0.01
PSL use, no. (%)	659 (30.5)	569 (26.3)	<0.01
PSL dose, mg/day	1.17±2.3 (0–18)	0.9±2.0 (0–15)	<0.01
DMARD use, no. (%)	1,926 (89.0)	1,921 (88.8)	0.85
MTX use, no. (%)	1,671 (77.2)	1,656 (76.5)	0.61
MTX dose, mg/week	6.18±4.8 (0–17.5)	5.88±4.7 (0–20)	0.059
Biologic DMARD use, no. (%)	495 (22.9)	458 (21.2)	0.19

**Conclusions:** Patients whose debut joint was a foot or ankle had higher disease activity, higher dysfunction, lower quality of life, and used higher dose and rate of anti-inflammatory drugs than patients whose debut joint was the other joints on RA onset. Clinicians should have more attentions to foot and ankle joints in daily practice so as not to underestimate the disease activity of RA.

**SAT0146 AT DIAGNOSIS OF RHEUMATOID ARTHRITIS, AT-RISK PATIENTS FOLLOWED IN CCP+ CLINIC SHOWED Milder DISEASE ACTIVITY THAN CONVENTIONALLY REFERRED PATIENTS.**

L. Duquenne<sup>1,2\*</sup>, P. Pentony<sup>1,2</sup>, K. Mankia<sup>1,2</sup>, J. Nam<sup>1,2</sup>, L. Hunt<sup>1,2</sup>, A. L. Tan<sup>1,2</sup>, L. Garcia-Montoya<sup>1,2</sup>, P. Emery<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds, <sup>2</sup>NIHR Leeds Biomedical Research Centre, Chapel Allerton Hospital, Leeds, United Kingdom

**Background:** Early treatment of rheumatoid arthritis (RA) improves clinical and radiological outcomes<sup>1</sup>. Risk stratification models can identify patients at high risk of developing RA,<sup>2-5</sup> which may lead to an extension of the window of opportunity. Whether identifying and following at-risk individuals improves outcomes after the development of RA however is yet to be determined.

**Objectives:** The hypothesis is that patients followed in a specific at-risk clinic will have less severe disease at diagnosis than those referred via the conventional route if/when they develop RA.

**Methods:** In two single-centre prospective observational cohorts, patients fulfilling the 2010 EULAR classification criteria for RA were compared on a demographic and clinical approach. The first group was composed of 59 patients positive for anti-cyclic citrullinated protein antibodies (CCP) with non-specific musculoskeletal symptoms, considered to be "at-risk of RA", who were followed until RA diagnosis. The second group was composed of 92 CCP positive RA patients referred to a standard 'Early Arthritis' rheumatology clinic.

**Results:** Demographic data at RA development were consistent between both groups including smoking history and BMI. Immunological features were also similar. CCP titre: at risk median 193U/ml (IQR 41,300), standard care 300U/ml (IQR 81,300, p=0.176). Rheumatoid factor (RF) titre: at risk median 84iU/mL (IQR 15,223), standard care 87iU/mL (IQR18,161, p=0.850). RF positivity: at risk 75%, standard care 70% (p=0.544). High-titre CCP blood levels: at risk 95%, standard care 97% (p=0.566).

As shown in table 1, DAS28CRP score were significantly lower in the at risk group than in standard care, this was due to a difference in the general health Visual Analogue Scale score and the CRP levels. Patients in the at risk group also had fewer swollen large joints and reported significantly shorter time between onset of subjective joint swelling and diagnosis. There was no difference between the presence of erosions on ultrasound scans (at risk: 39%, standard care 38%, p=0.921).

	At Risk of RA*	Standard care*	P-value
Age mean (SD)	55.3 y (12.6)	56.4 y (19.1)	0.711
Women	73%	71%	0.815
BMI mean (SD)	28 (5.4)	27 (6.5)	0.299
Ever smoker	70%	55%	0.075
DAS28CRP	3.9 (3.2,4.6)	4.9 (3.4,5.6)	0.003
TJC28	5 (3,9)	7 (2,14)	0.447
SJC28	2 (1,5)	4 (2,9)	0.001
GH VAS	41 (18,64)	57 (37,75)	0.003
CRP	5.4 (0,11)	26 (18,49)	0.000
HAQ	10 (2,17)	12 (5,20)	0.197
Large joint swelling mean (SD)	0.14 (0.4)	0.39 (0.7)	0.014
Weeks before subjective swelling to RA diagnosis	6 (2,12)	29 (16,52)	0.00

\*Median (IQR) unless specified

**Conclusions:** Patients who were diagnosed with RA while being followed in an at-risk cohort had milder disease activity and less pain than those diagnosed through standard referral despite equivalent demographics and serology. This reflects an earlier diagnosis and hence shorter exposure to inflammation. Follow-up will be required to see if these differences convert to long-term benefits.

**SAT0147 PRESENCE OF HEPATITIS B VIRUS IN SYNOVIUM AND ITS CLINICAL SIGNIFICANCE IN RHEUMATOID ARTHRITIS**

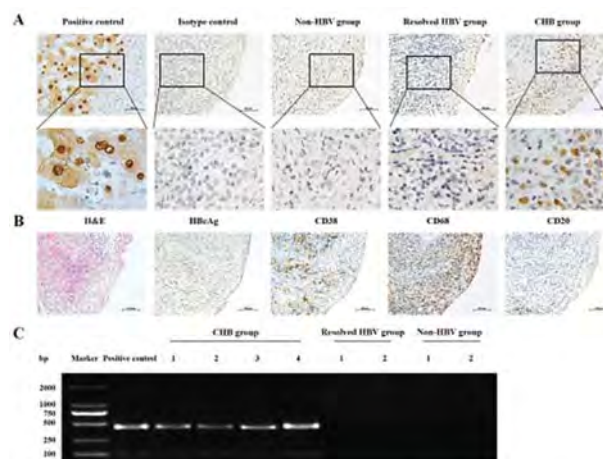

L.-J. Yang<sup>1</sup>, Y.-L. Chen<sup>1</sup>, J. Jing<sup>1</sup>, Y.-Q. Mo<sup>1</sup>, J.-D. Ma<sup>1</sup>, L.-F. Chen<sup>1</sup>, J.-Z. Lin<sup>1</sup>, Z.-H. Yang<sup>2</sup>, T. Yan<sup>3</sup>, D.-H. Zheng<sup>1</sup>, F. Pessler<sup>4,5</sup>, L. Dai<sup>1</sup>. <sup>1</sup>Department of Rheumatology, <sup>2</sup>Department of Radiology, Sun Yat-sen Memorial Hospital, Sun Yat-sen University, <sup>3</sup>Zhongshan School of Medicine, Sun Yat-sen University, Guangzhou, China, <sup>4</sup>TWINCORE Center for Experimental and Clinical Infection Research, Hannover, <sup>5</sup>Helmholtz Center for Infection Research, Braunschweig, Germany

**Background:** Previous studies have shown that hepatitis B virus (HBV) infection may be associated with rheumatoid arthritis (RA). However, no study regarding the presence of HBV in the synovial membrane from RA patients has been reported.

**Objectives:** To investigate the presence of HBV in RA synovium and determine its influence on histopathological characteristics of synovitis as well as clinical and radiographic outcomes in RA.

**Methods:** 57 consecutive patients with active RA (DAS28-CRP $\geq$ 2.6) and qualified synovium (at least 6 pieces of synovial tissues per patient, containing lining layer and sublining area) obtained by closed Parker-Pearson needle biopsy who had completed one year follow-up were retrospectively recruited from a prospective RA cohort (n=239). The patients were divided into chronic HBV infection (CHB, positive HBsAg and/or HBV DNA in serum persisting for over 6 months; n=11), resolved HBV (negative HBsAg and HBV DNA in serum, but positive anti-HBc; n=22), and non-HBV (negative HBsAg, HBeAg, anti-HBe, anti-HBc, and HBV DNA in serum, regardless of anti-HBs; n=24) groups according to baseline HBV infection status. Clinical data were collected at baseline and follow-up visits at months 1, 3, 6, and 12. Radiographic assessments of hand/wrist at baseline and month 12 were performed with the Sharp/van der Heijde-modified sharp score (mTSS). Serial tissue sections were stained immunohistochemically for HBsAg, HBeAg, CD3, CD15, CD20, CD34, CD38, and CD68. Nested PCR was used to detect HBV S gene DNA in synovium.

**Results:** Immunohistochemical staining and nested PCR revealed the presence of HBcAg and S gene DNA in the synovium from RA patients with CHB (figure 1). Compared with the non-CHB group (n=46), significantly more CD15-positive neutrophils, CD20-positive B cells, and CD68-positive macrophages infiltrated the CHB synovium (all p<0.05), together with smaller improvements from baseline in most disease activity indicators mainly at month 12. A significantly higher percentage of CHB patients experienced one-year radiographic progression ( $\Delta$ mTSS $\geq$ 0.5units/year, 64% vs. 26%, p=0.024). Multivariate logistic regression analysis showed that CHB status (OR: 14.230, 95%CI: 2.213–95.388; p=0.006) and the total count of CD68-positive macrophages (OR: 1.002, 95%CI: 1.001–1.003; p=0.003) were independently associated with one-year radiographic progression.

**Figure 1 Identification of HBV in RA synovium. (A) Representative immunohistochemical staining for HBcAg in RA synovium.** Representative images illustrated detection of HBcAg in a RA patient with CHB, but not in RA patients with resolved HBV or no infection. **(B) Representative staining of HBcAg in one RA patient with CHB compared to stains for CD38 and CD68.** Serial sections of synovium from one RA patient with CHB were stained with H&E and immunohistochemically. HBcAg immunoreactivity was

observed in the sublining inflammatory cells including plasma cells (CD38+) and macrophages (CD68+), mainly located in the cytoplasm. (C) **Detection of HBV S gene in RA synovium by nested PCR. Nested PCR showed HBV S gene only in all four CHB synovial tissues.** Liver tissue from a patient with HBV-related hepatocellular carcinoma was used as positive control.

**Conclusions:** Our results reveal definite presence of HBV in the synovium which may be involved in the pathogenesis of local lesion and exacerbate disease progression in RA patients with CHB.

#### SAT0148 ORAL CARE AND HEALTH IN RHEUMATOID ARTHRITIS PATIENTS BASED ON A SELF-ASSESSMENT QUESTIONNAIRE INVESTIGATION

L. L. Strandbygaard<sup>1</sup>, M. Radwan-Oczko<sup>2</sup>, I. Dus<sup>2</sup>, A. M. Thomsen<sup>1</sup>, K. Schmökel<sup>3</sup>, C. Rasmussen<sup>1</sup>. <sup>1</sup>Department of Rheumatology, North Jutland Regional Hospital, Hjørring, Hjørring, Denmark, <sup>2</sup>Department of Oral Pathology, Wrocław Medical University, Wrocław, Poland, <sup>3</sup>Municipal Pediatric Dental Care & Dental Care for the Impaired, Hjørring, Denmark

**Background:** Some investigations indicate a higher prevalence of periodontal disease (PD) in rheumatoid arthritis (RA) patients compared to healthy individuals without RA. Significant improvements in clinical parameters and laboratory tests were demonstrated in RA patients following periodontal therapy. Periodontal diseases – gingivitis and periodontitis are inflammatory, multifactorial pathologies of periodontal tissues, which support the teeth. The factor responsible for the inflammation is a plaque with specific bacteria.

In gingivitis, which is the first stage of PD, only gingiva is involved. Then in susceptible patients, periodontitis is developing and the deeper laying structures surrounding the teeth are involved and destroyed. The patients' own observation of gingival bleeding strongly indicates gingival disease.

The effectiveness of oral hygiene, including self-care, in controlling periodontal health is crucial and supported by several studies. RA patients frequently experience reduced function of fingers and wrists that makes oral hygiene troublesome.

**Objectives:** The purpose of this study was to assess RA patient's oral care and health based on a self-assessment questionnaire.

**Methods:** Questionnaires were mailed to 300 patients treated for RA in a Danish rheumatology outpatient clinic.

**Results:** A total of 164 patients completed the questionnaires. The mean age of patients was 65 years, and the average value of DAS28 was 2.31. Twelve percent were active smokers. The "dry mouth" syndrome, as a problem when chewing or swallowing, pointed out 4% of patients. Difficulties in biting or chewing revealed 10% of patients. As much as 87% stated they regularly visit a dentist, min. one time a year.

Regarding self-oral care 15% of patients answered, they brush teeth only once a day. Most of the patients (51%) used manual toothbrush vs electrical – which can be more convenient for patients with problems of the hands/wrists. Only 21% used mouth-rinsing liquid. Difficulties in performing home oral hygiene procedures were reported by 9% when brushing teeth, and by 17% using dental floss or interdental brushes. 11% of responders rated the status of their gingiva as poor. Gingival bleeding spontaneous or related to brushing was experienced by respectively 15% and 49% of patients. No patients stated knowledge of an association between oral health and RA.

**Conclusions:** The oral care in RA patients, including self-care, seems to require improvement. Providing important information to the patients about the relationship between the oral/periodontal health and RA disease activity should raise the patient's awareness, which may improve the course of the RA disease.

#### SAT0149 IS ESTABLISHED SERONEGATIVE RHEUMATOID ARTHRITIS EVEN A MILD FORM OF THE DISEASE?

L. D. Fajardo Hermosillo<sup>1</sup>. <sup>1</sup>Rheumatology, Internal Medicine Division, IMSS HGR110, Guadalajara, Mexico

**Background:** Established Seronegative Rheumatoid Arthritis (SNRA) was considered a mild form of the disease with a good response to therapy on the past<sup>1</sup>. Lately evidence indicates this form of arthritis in early stage is serious and should not be underestimated in terms of disease activity and radiographic damage<sup>2</sup>. By other hand early SNRA presents shorter symptoms duration and different response to therapy compare to seropositive (SP) patients<sup>3,4</sup>. At present, the influence of seronegative (SN) status of clinical course and treatment choice is still controversial. Data of this issue are scarce and often insufficiently powered.

**Objectives:** To determine demographical, clinical and treatment differences between established SN and SP Rheumatoid Arthritis (RA) in a Mexican cohort.

**Methods:** 511 patients with established RA (>2 years from time at onset of diagnosis) that fulfilled ACR/EULAR 2010 criteria ( $\geq 18$  years) from a Mexican cohort from 2012 to 2017 were examined. Patients without presence of rheumatoid factor (RF) and anti-citrullinated protein antibodies (ACPA) were considered SN. Demographic factors, clinical features, disease activity measured using DAS28, functional status, comorbidities and pharmacologic treatments were examined for patients with established SN and SP RA. Charlson's clinical co-morbidity index was used to analyze comorbidities. Chi-square and Student-t test was performed by univariate analysis and logistic regression was used by multivariate analysis, both were adjusted for age and gender. Standard deviation and mean of modified Charlson's index was obtained by ANOVA analysis. Statistical test were conducted at 5% level of significance.

**Results:** Of 511 patients with established RA 89% were women. The mean age [standard deviation (SD)] was 55.6 (11.8) years. The mean of time at onset of RA (SD) was 12.1 (8.7) years. A total of 77 (15.1%) patients had established SNRA. In the univariable analyses established SNRA patients were more likely to have shorter time at onset of RA, minor disease activity and radiographic progression, lesser extra-articular and sicca manifestations, reduced demand of hip and knee arthroplasty, also present lower comorbidities including osteoporosis and fibromyalgia, besides to use fewer methotrexate and corticosteroids. As expected, the modified Charlson's comorbidity index score was lower in established SNRA patients. No differences were found for use of biologic agents in both groups. In multivariable analyses, minor disease activity (OR 0.33, 95% CI 0.17–0.60,  $p \leq 0.001$ ), less frequently use of methotrexate (OR 0.38, 95% CI 0.17–0.82,  $p = 0.014$ ) and minor radiographic progression (OR 0.13, 95% CI 0.40–0.39,  $p \leq 0.001$ ), remained significant in established SNRA patients.

**Conclusions:** This study suggests that established SNRA present less disease activity and radiographic damage as well as fewer use of MTX than established SPRA. However differences in activity disease and response to treatment can be found in early stages of RA not included in this study. Therefore early SNRA cannot be considered to be a generally mild form of the disease like as established SNRA. These observations must be confirmed in larger studies including early stages of RA.

#### SAT0150 INADEQUATE CARDIOVASCULAR RISK MANAGEMENT IS NOT RHEUMATOID ARTHRITIS SPECIFIC AMONG PATIENTS WITH PREVALENT RHEUMATIC AND MUSCULOSKELETAL DISEASES

M. Reyskens<sup>1</sup>, L. Tsang<sup>1</sup>, M. Walschot<sup>1</sup>, F. Fleurinck<sup>1</sup>, A. O. Solomon<sup>2</sup>, A. Millen<sup>2</sup>, P. Desein<sup>1</sup>. <sup>1</sup>Free University Brussels, Brussels, Belgium, <sup>2</sup>Witwatersrand University, Johannesburg, South Africa

**Background:** Preventive pharmacotherapy for atherosclerotic cardiovascular disease (ACVD) is reportedly underused in patients with rheumatoid arthritis (RA). Whether this shortcoming is RA specific amongst patients with prevalent rheumatic and musculoskeletal diseases (RMD) is currently unknown.

**Objectives:** This study aimed to compare high ACVD risk profiles and statin use by indication between RA and non-RA patients with RMD.

**Methods:** We investigated 470 consecutive RMD patients of which 80 had RA, 92 undifferentiated inflammatory/early arthritis (UIA), 127 fibromyalgia and 171

osteoarthritis. High risk profiles comprised established ACVD (coronary artery disease, ischemic cerebrovascular disease or/and peripheral artery disease), diabetes (type 2 or type 1 aged >40 years), high LDL cholesterol concentration ( $\geq 190$  mg/dl), chronic kidney disease (CKD) (Chronic Kidney Disease Epidemiology Collaboration equation value  $< 60$  ml/min/1.73 m<sup>2</sup>), and a Systemic Coronary Risk Evaluation (SCORE) of  $\geq 5\%$  and Framingham score of  $\geq 20\%$  both before and after application of the recently reported European League Against Rheumatism (EULAR) multiplier (SCORE and Framingham score  $\times 1.5$  in the presence of RA) (1). The prevalence of high ACVD risk profiles and statin use by indication were compared between RA and non-RA patients in age, sex and race adjusted logistic regression models.

**Results:** RA patients were older (mean (SD) age=62.1 (15.8) versus 54.0 (15.4) years,  $p < 0.0001$ ) and less frequently women (66.3% versus 79.7%,  $p = 0.009$ ) than their non-RA counterparts; RA and fibromyalgia were the most frequent diseases in white and North-African patients, respectively. The prevalence of ACVD, diabetes, high LDL cholesterol, CKD, high SCORE and Framingham score did not differ between RA and non-RA patients. Only upon applying the EULAR multiplier (1) was RA associated with a high SCORE (OR (95% CI)=2.18 (1.01–4.72)) and Framingham score (OR (95% CI)=3.46 (1.63–7.36)). The prevalence of any high risk ACVD profile before (OR (95% CI)=1.02 (0.53–1.98)) and after application of the EULAR multiplier (OR (95% CI)=1.85 (0.93–3.69)) were similar in RA and non-RA patients. Statin use by indication was consistently similar in RA compared to non-RA patients. Overall, 38.3% of RA patients and 40.0% of non-RA patients that had any high risk ACVD profile used a statin (OR (95% CI)=0.79 (0.38–1.66)).

**Conclusions:** In this single center study, having one or more high ACVD risk profiles was equally prevalent in non-RA and RA patients. Circa 60% of patients with RMD and any high risk ACVD profile did not use statins and this finding did not differ in non-RA compared to RA patients. There is a vast and urgent need for improved ACVD risk management among patients with RMD irrespective of RA status.

### SAT0151 CARDIORESPIRATORY FITNESS IN PATIENTS WITH RHEUMATOID ARTHRITIS

M. H. Liff<sup>1,2</sup>, M. Hoff<sup>1,2</sup>, T. Fremo<sup>1</sup>, U. Wisloff<sup>1</sup>, R. Thomas<sup>3</sup>, V. Videm<sup>1,2</sup>. <sup>1</sup>NTNU – Norwegian University of Science and Technology, <sup>2</sup>St. Olavs University Hospital, Trondheim, Norway, <sup>3</sup>University of Queensland, Brisbane, Australia

**Background:** Mortality rates are higher in RA patients compared to the general population, mostly due to cardiovascular disease (CVD). Cardiorespiratory fitness (CRF) is inversely associated with CVD, but little is known about CRF levels in RA patients.

**Objectives:** To study the association between CRF in RA patients (measured as VO<sub>2</sub>peak), and CVD risk factors and RA-specific clinical variables.

**Methods:** 93 patients were recruited from a hospital rheumatology outpatient clinic. VO<sub>2</sub>peak was measured by ergospirometry during a treadmill test. Tender and swollen joint count, height, weight, waist circumference, resting heart rate, blood pressure and hsCRP were measured. RA characteristics and information on comorbidity were recorded from an interview and from medical records. Based on a previously published index weighting frequency, intensity and duration of self-reported physical activity (PA) (1), patients were categorized into four different PA categories (table 1). VO<sub>2</sub>peak was analyzed using multivariate linear regression, adjusting for age and gender. All participants signed an informed consent and the regional ethics committee approved the study.

**Results:** Table 1 Patient characteristics (n=93)

Gender, female, n(%)	68 (73)	Seropositivity (anti-CCP and/or RF pos.), n(%)	75 (81)
Age (yrs), median (IQR)	60 (52–66)	Disease duration (yrs), median (IQR)	10 (5–19)
BMI (kg/m <sup>2</sup> ), mean (SD)	26.7 (3.9)	VAS Global (0–100), median (IQR)	24 (10–37)
Smoking, present or previous, n(%)	58 (62)	DAS28CRP (%Remission/LowDA/IntermedDA/HighDA)	42/25/30/3
PA categories:		mHAQ, median (IQR)	0.13 (0–0.44)
Inactive, n(%)	25 (27)	Medications:	
Mod. active, n(%)	11 (12)	Biologics, n(%)	54 (58)
Active, n(%)	39 (42)	DMARDs, n(%)	74 (80)
Very active, n(%)	18 (19)	Corticosteroids, present or last year n(%)	39 (42)

In the multivariate regression model ( $R^2=0.79$ ), VO<sub>2</sub>peak was positively associated with the PA categories “Active” ( $p=0.018$ ) and “Very active” ( $p=0.008$ ), and negatively associated with BMI ( $p < 0.001$ ) and resting heart rate ( $p=0.017$ ). VO<sub>2</sub>peak was not associated with disease duration ( $p=0.47$ ), mHAQ ( $p=0.71$ ), DAS28 ( $p=0.43$ ), VAS Global ( $p=0.24$ ), hsCRP ( $p=0.14$ ), seropositivity ( $p=0.44$ ), use of biologics ( $p=0.91$ ), other DMARDs ( $p=0.66$ ) or corticosteroids ( $p=0.60$ ). There was a trend towards a negative association with smoking ( $p=0.096$ ).

**Conclusions:** We observed a strong association between common CVD risk factors (inactivity, high BMI, high resting heart rate) and lower CRF in RA patients, similar to published findings from the general population. Patients in the “Active” and “Very active” PA categories showed significantly higher VO<sub>2</sub>peak, whereas RA-specific variables such as seropositivity, disease activity, disease duration and medications had no impact on VO<sub>2</sub>peak. We cannot exclude a selection bias because more fit patients could be more likely to participate in the study.

### SAT0152 SYSTEMIC AND RENAL AA AMYLOIDOSIS IN RHEUMATOID ARTHRITIS – A COMPARATIVE POSTMORTEM CLINICOPATHOLOGIC STUDY OF 161 PATIENTS

M. Bély<sup>1</sup>, Á. Apáthy<sup>2</sup>. <sup>1</sup>Department of Pathology, Hospital of the Order of the Brothers of Saint John of God in Budapest, <sup>2</sup>Department of Rheumatology, St. Margaret Clinic, Budapest, Hungary

**Objectives:** The aim of our study was to determine the prevalence and severity of systemic AA amyloidosis (sAAa), to specify amyloid A deposits in different tissue structures of the kidneys, to outline the development of renal AA amyloidosis (rAAa), and to estimate the role of sAAa and rAAa in mortality.

**Methods:** At the National Institute of Rheumatology 9475 patients died between 1969 and 1992; among them 161 with RA (females 116, average age: 64.95 years, range 87–16, onset of RA: 50.19, average disease duration: 14.79 years; males 45, average age: 66.29 years, range 88–19, onset of RA: 52.57, average disease duration: 13.46 years at death); who were autopsied.

RA was confirmed clinically according to the criteria of the ACF.

sAAa was specified histologically, based on evaluation of 5 organs (heart, lung, liver, kidney and pancreas) in each of 161 patients. Amyloid A deposition was diagnosed histologically according to Romhányi by a modified (more sensitive) Congo red staining. Amyloid A deposits were identified in serial sections by immunohistochemical and histochemical methods. The prevalence (existence) and severity (extent) of amyloid A deposition were evaluated microscopically with an Olympus BX51 polarizing microscope.

**Results:** sAAa complicated RA in 34 (21.12 %) of 161 patients; in 127 (78.88 %) of 161 patients amyloid A deposits were not found.

Amyloid A deposits were found in 29 (87.88 %) kidneys of 33 patients with sAAa; kidneys were negative for amyloid in 4 (12.12 %) of 33 cases (in 1 of 34 patients with sAAa tissue blocks of kidneys were not available).

sAAa was lethal in 17 (50.0 % of 34) patients due to massive amyloid A deposition in the kidneys, leading to renal insufficiency and uremia. Cardiac amyloid A deposition led to death in 3 (8.82 % of 34) patients with sAAa (and contributed to the lethal outcome in further 5). Fourteen (41.18 % of 34) patients with sAAa died of other causes such as peritonitis, lethal septic infection, etc.

sAAa was clinically diagnosed in 9 (26.47 %) and missed in 25 (73.52 %) of 34 patients, and only cases with massive renal amyloid A deposits were recognized. Cardiac AAa or its pathogenic role in mortality was not diagnosed.

**Conclusions:** sAAa is one of the main and the most insidious complications of RA affecting the kidneys with high prevalence and severity. sAAa is related to the cardiovascular system, and rAAa is associated with it. sAAa and rAAa may be developed in both sexes, and at any time in the course of the disease.

Systemic and renal amyloid A deposition is a progressive and cumulative process, involving in its early stage only a few structures in various organs, and increasingly more in the later stages of the disease.

In sAAa the renal amyloid A deposition starts after a latent stage. This latency may be caused by a not specified local protective mechanism, e.g. great excretion capacity of the kidneys.

Amyloid A deposition starts in the most frequently involved structures of the kidneys with more massive deposits. The chronology of amyloid A deposition allows

an indirect assessment of the stage of renal amyloidosis, which may have a prognostic value in everyday surgical pathology.

Half of the patients with **sAA** died of uremia caused by massive **rAA** and only 9 of these were clinically recognized. Renal amyloid A deposition should be considered a very serious, life-threatening complication of **RA**.

### ANALYSIS OF CLINICAL-ANALYTICAL CHARACTERISTICS IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA) AND INTERSTITIAL LUNG DISEASE (ILD): CASE-CONTROL STUDY

N. Mena-Vázquez<sup>1</sup>, S. Manrique-Arija<sup>1</sup>, C. Romero-Barco<sup>2</sup>, I. Ureña-Garnica<sup>1</sup>, M. Ordóñez-Cañizares<sup>1</sup>, F. Jiménez-Núñez<sup>1</sup>, G. Díaz-Cordovés<sup>1</sup>, M. Rojas-Giménez<sup>1</sup>, C. Fuego<sup>1</sup>, R. Caparrós-Ruiz<sup>1</sup>, L. Cano-García<sup>1</sup>, A. Belmonte<sup>1</sup>, M. Irigoyen-Oyarzábal<sup>1</sup>, A. Fernández-Nebro<sup>3</sup>. <sup>1</sup>UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA) Hospital Regional Universitario de Málaga, Universidad de Málaga, Málaga, Spain., <sup>2</sup>UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA), Hospital Clínico Virgen de la Victoria, Universidad de Málaga, Málaga, Spain., <sup>3</sup>UGC de Reumatología, Instituto de Investigación Biomédica de Málaga (IBIMA) Hospital Regional Universitario de Málaga, Departamento de Medicina y Dermatología, Universidad de Málaga., Málaga, Spain

**Objectives:** To study the differences in severity marker and disease activity in patients with RA and ILD and patients with RA without DILD, and to identify factors associated with ILD in RA patients.

**Methods:** Design: Observational case-control study. Patients: consecutive RA-patients (ACR/EULAR 2010 criteria) with ILD (American Thoracic Society) selected from a prospective cohort from Regional Hospital and Virgen Victoria Hospital of Málaga were included. Controls: RA-patients without ILD. Sex-age matched controls were collected from a prospective cohort of Regional Hospital. Protocol: RA Patients are reviewed every six months in general clinic and patients with biological therapy every three months. All patients are reviewed according to a protocol with systematic data collection. The data of patients with RA and ILD are also collected in a database according to a specific protocol for these patients. The day that was reviewed the last time in consultation will be marked as inclusion date. Data will be collected on the date of inclusion and their clinical records. Outcomes: Difference in severity marker in both groups on the date of inclusion (RF, ACPA, erosive arthritis); in disease Activity Score (DAS28-ESR) and Health Assessment Questionnaire (HAQ); description of modifying antirheumatic drugs (DMARDs); Variables: Demographic, clinical-analytical variables: number of tender joints (TJ), number of swollen joints (SJ), CRP, ESR, general evaluation, DAS28-ESR, HAQ and adverse effects (description, severity and number). Statistical analysis: Descriptive and paired T-test or Chi-square test followed by binary logistic regression (RLB) (Vd:ILD in patients with RA).

VARIABLE	RA-ILD (n=29)	RA (n=24)	P- value
Age (years), mean (SD)	67.7 (8.0)	66.9 (7.2)	0.682
Sex (female), n (%)	18 (55.2)	13 (54.2)	0.942
Sex (male), n (%)	11 (44.8)	11 (45.8)	
Smoker			0.003
Non-smoker, n (%)	13 (44.8)	16 (66.7)	
Ex-smoker, n (%)	11 (37.9)	9 (40.0)	
Smoker, n (%)	5 (17.2)	8 (33.3)	
Disease duration RA, median (p75-p25)	130.9 (93.4-208.2)	99.9 (73.4-121.8)	0.002
Socio Economic Status			0.500
No income, n (%)	9 (31.0)	8 (33.3)	
<1500 €/month, n (%)	17 (58.6)	11 (45.8)	
>1500 €/month, n (%)	3 (10.3)	5 (20.8)	
Educational level			0.345
None, n (%)	12 (41.4)	9 (25.0)	
Primary and secondary school, n (%)	12 (41.4)	14 (58.3)	
University, n (%)	8 (11.3)	4 (16.7)	
Rheumatoid factor, n (%)	27 (93.1)	20 (83.3)	0.264
Anti-cyclic citrullinated peptide, n (%)	27 (93.1)	20 (83.3)	0.264
Anti-cyclic citrullinated peptide elevated (>340), n (%)	22 (75.9)	10 (43.5)	0.008
Erosions, n (%)	24 (82.8)	12 (50.0)	0.013

**Results:** Fifty-three patients were included, 29 RA with ILD and 24 RA controls. The differences between clinical and epidemiological characteristics to cases and controls are shown in table 1. RA patients with ILD showed more months with RA duration (p=0.002), more number of exsmokers (p=0.003), erosive arthritis (p=0.011) and ACPA positive (P=0.008). No significant differences in the mean of

DAS28 in cases and controls were observed (2.61 vs 2.68; p=0.789), but RA patients with ILD presented worse in physical function parameters by HAQ (1.12 VS 0.63; P=0.032). All patients were treated with disease modifying antirheumatic drugs (DMARDs). RA patients with ILD had: 5 (17.2%) monotherapy with bDMARDs, 17 (58.62) monotherapy with sDMARD and 7 (24.1) sDMARDs with a bDMARDs. In multivariate analysis, the independent variables that were associated with ILD in RA patients were: ACPA elevated (OR [IC95%] =5.0 [1.2-9.9]; p=0.023) and RA duration (months) (OR [IC95%]=1.1 [1.0-1.2]; p=0.037). This model would explain 28% of the variability of the ILD in RA (R<sup>2</sup>=0.28).

**Conclusions:** The evolution time of arthritis and the presence of ACPA to high titres (>340) were the predictors of ILD in patients with RA in our study. More prospective studies with a greater number of patients are necessary to identify the possible association.

**Disclosure of Interest:** None declared

SAT0154

### ASSESSMENT OF BONE TURNOVER MARKERS IN PRE- AND POSTMENOPAUSAL WOMEN WITH RHEUMATOID ARTHRITIS

O. Garmish<sup>1</sup>, T. Orlyk<sup>1</sup>, A. Romanovsky<sup>1</sup>, T. Gavrylenko<sup>2</sup>. <sup>1</sup>rheumatology, <sup>2</sup>immunology, Institute of Cardiology, Kyiv, Ukraine

**Background:** To compare bone metabolism in pre- and postmenopausal women with RA

**Objectives:** GCs and inflammation lead to BMD loss through increase the expression of RANK-ligand and decrease the expression of osteoprotegerin in stromal and osteoblastic cells. Determination of indicators relevant for clinical practice for identification a high-risk BMD loss group of RA patients is needed.

**Methods:** The bone turnover markers were analyzed in 58 women with RA: 36 premenopausal (PreM) and 22 postmenopausal (PM). The two groups were significantly different in age (35.9±8.7 PreM vs 57.1±4.1 PM) and BMI (23.8±4.3 PreM vs 28.6±5.0 PM). By disease duration (8.9±5.7 years vs 10.0±6.1 years), disease activity by DAS28, x-ray changes, GC, MTX and biologic therapy both group were comparable. BMD was measured in 3 part of the skeleton: hip, lumbar spine, distal part of forearm. Serum levels of 25 (OH) vitamin D (Vit D), parathormone (PTH), osteoprotegerin (OPG), RANKL were analyzed.

**Results:** Low level of Vit D (25(OH)D<30 ng/ml) was observed in 46.6% of patient and was preferable in PreM women. Vit D deficiency was associated with age (R=-0.31, p<0.05) and positive anti-CCP (R=-0.46, p<0.05). The mean level of PTH was normal in 74.1%. Serum OPG level was significantly higher in more than 50% of patients. It was associated with presence of erosion (R=0.97, p<0.05), decreased cortical index (R=-0.28, p<0.05) in PreM patient and DAS28 (R=-0.44, p<0.05) in all patients. High level of RANKL was preferable in PM women (47.6%), decreased level more often was observed in PreM patient (38.9%). In PM patients increased level of RANKL was correlated with BMI, duration of menopause and DAS28, in PreM – only with DAS28. In PreM women the changes in serum levels of PTH and vitamin D was negatively correlated with levels of RANKL and C-TP, low level of vitamin D had negative correlation with OPG (R -0.47). According to lineal regression analysis positive correlation between disease duration, Sharp van der Heijde erosion score and PTH (r=0.31; p=0.01, r<sup>2</sup>=0.11) was observed in all patients, more often in PreM women. Low spine BMD in PreM associated with high PTH (R=0.82, p<0.05), in PM – with high PTH, OPG/RANKL and low level of RANKL. Low hip neck BMD correlated with decreased level of vit D in PM patients. Low levels of vit D, C-TP and high levels of OPG and OPG/RANKL index was significantly associated with forearm low BMD in all patients. In PreM women strong association between low vit D (R=-0.60, p<0.05), high OPG (R=0.89, p<0.05) and BMD in medium part of forearm was observed.

**Conclusions:** In premenopausal women vitamin D deficiency had high predictive value for decrease BMD in the medium part of forearm, high level of PTH – for decrease BMD in the spine. In PreM RA patients low Vit D, low cortical index and high PTH can be considered as an indication for BMD assessment. PM women with high BMI, longstanding postmenopausal period and high disease activity may be candidate for bone markers assessment.

### TRADITIONAL AND NONTRADITIONAL CARDIOVASCULAR RISK FACTORS IN PATIENTS WITH EARLY ONSET ARTHRITIS OF THE PANLAR-EOA

I. Acosta Colman<sup>1</sup>, P. Delgado<sup>2</sup>, G. Avila-Pedretti<sup>3</sup>, S. Cabrera-Villalba<sup>4</sup>, P. Melgarejo<sup>4</sup>, G. Elizaur<sup>4</sup>, M. Franco<sup>4</sup>, A. Ramagli<sup>5</sup>, J. Mazzoleni<sup>4</sup>, P. Abreu<sup>6</sup>.

<sup>1</sup>Departamento de Reumatología, Hospital de Clínicas de la Facultad de Medicina de la Universidad Nacional de Asunción, <sup>2</sup>Departamento del IPS, <sup>3</sup>Departamento de Reumatología, <sup>4</sup>Departamento de Reumatología, Instituto de Previsión Social, Asunción, Paraguay, <sup>5</sup>Departamento de Reumatología, Presidente del grupo de estudio PANLAR-EOA, Montevideo, Uruguay, <sup>6</sup>Sociedad Paraguaya de Reumatología, Asunción, Paraguay

**Background:** Inflammation plays a significant role in atherosclerosis and cardiovascular disease (CVD). Patients with chronic inflammatory diseases are at increased risk of CVD, but it is debated whether this association is causal or dependent on shared risk factors or inflammatory pathways.

**Objectives:** Identify the mScore value and the association between traditional and nontraditional cardiovascular risks factors (CVRF) in an early onset arthritis (PANLAR-EOA)

**Methods:** Prospective, longitudinal cohort study. Patients were protocolled according to the PANLAR-EOA project. For this analysis only patients with 12 and 24 months follow up were included. Patients were registered in REPANARC (www.panlareoa.org) database. The mScore evolution and the nontraditional CVRF linked to the disease (i.e. DAS28) association with the traditional CVRF (i.e. obesity) were studied. The Wilcoxon Test and the Spearman correlation test, depending on whether the variables were categorical or numerical, were utilized.

**Results:** Initially 136 patients with early onset arthritis were included, out of which 88 completed the 12 months follow up and 58 the 24 months one. There was a female predominance 86% (117/136) of patients, with a median age of 44.80 ±14.47 years. When comparing the change ratio of the values obtained with the mScore on the initial, the 12 months and 24 months visit, the results were not statistically significant (p=0.106 at 12 months and p=0.175 at 24 months). An association between the elevated erythrocyte sedimentation rate and obesity (p=5.807e-03) and diabetes (p=3.739e-02) was found in the initial visit. An association between elevated prednisone doses and high levels of total cholesterol (2.084e-02), high levels of diastolic blood pressure (p=1.967e-02) and low HDL values were observed (7.706e-03). At 12 months a significant association between obesity and high CRP (p=3.649e-02) and between high glycaemia levels with elevated prednisone doses and high CRP levels (p=2.549e-02). In the 24 months visit analysis, an association between elevated HDL-cholesterol with high prednisone doses (p=5.016e-03) and elevated CRP levels (3.492e-02).

**Conclusions:** An increment in Cardiovascular Risk (CVR) was not found at 12 and 24 months follow up according to the mScore. We have observed that there is an association between traditional and nontraditional CVRF. Therefore, the prevention strategies should be aimed not only towards the control of traditional CVRF, but also against the nontraditional CVRF associated with disease activity, which in a certain way could influence over the previous ones and modify the global CVR of patients with EOA

SAT0156

### ASSOCIATION BETWEEN CUMULATIVE METHOTREXATE DOSE, NON-INVASIVE SCORING SYSTEM AND HEPATIC FIBROSIS DETECTED BY FIBROSCAN IN RHEUMATOID ARTHRITIS PATIENTS RECEIVING METHOTREXATE.

R. Lertnawapan<sup>1</sup>, S. Chonprasertsuk<sup>1</sup>, S. Siramolpiwat<sup>1</sup>. <sup>1</sup>Dept.Medicine, Faculty of Medicine, Thammasat University, Bangkok, Thailand

**Background:** Methotrexate (MTX) is recommended by recent ACR and EULAR guideline as a first-line drug for RA. Liver fibrosis, which occurs as long-term side effect is one of the most concerns.

**Objectives:** To find the association between clinical parameters, cumulative MTX dosage, liver fibrosis scoring systems and the presence of liver fibrosis assessed by transient elastography (TE; Fibroscan<sup>®</sup>).

**Methods:** Rheumatoid arthritis, prescribed MTX, patients had been evaluated of liver fibrosis with TE. Two subgroups of patients were compared: non-fibrosis and fibrosis (TE >7 kPa). Univariate and multivariate logistic regression analysis were performed to identify factors associated with liver fibrosis.

**Results:** One hundred and eight patients were recruited. Twenty-nine patients (26.8%) were classified by transient elastography as liver fibrosis cases. The multivariate analysis demonstrated only the statistically significant of the association in BMI (OR=1.217; 95%CI 1.048–1.414; P=0.010); fatty liver (OR=2.318; 95%CI 0.584–9.189; P=0.232); ALT (OR=1.044; 95%CI=1.003–1.087; P=0.036) and cumulative MTX dosage (OR 1.001; 95%CI 1.000–1.001; P=0.001).

**Conclusions:** Liver fibrosis measured with Fibroscan was associated with cumulative MTX. RA patients with metabolic syndrome including high BMI, IFG, fatty liver had higher risk of MTX-induced hepatic fibrosis. RA patients with high cumulative MTX dose, especially patients with concurrent metabolic syndrome should be cautiously monitored for liver fibrosis.

### THE PREVALENCE OF DYSLIPIDEMIA AND DAILY NUTRITIONAL INTAKE IN RHEUMATOID ARTHRITIS PATIENTS: A STUDY OF THE KOREAN NATIONAL HEALTH AND NUTRITION EXAMINATION SURVEY (KNHANES)

S. H. Joo<sup>1</sup>, Y. W. Song<sup>2,3</sup>. <sup>1</sup>Division of Rheumatology Department of Internal Medicine, Jungang Medical Foundation, Jeju-si, <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, <sup>3</sup>Department of Molecular Medicine and Biopharmaceutical Sciences, Graduate School of Convergence Science and Technology, and College of Medicine, Medical Research Center, Seoul National University, Seoul, Korea, Republic Of

**Background:** Lipid metabolism appear to be changed in rheumatoid arthritis (RA) patients because of disease activity and inflammation.

**Objectives:** It was not clear in the previous studies that lipid profiles status is associated with nutritional intake in RA patients.

**Methods:** We analyzed RA, dyslipidemia, serum lipid profiles (total cholesterol, TG, HDL, and LDL) and nutritional intake data related lipid from the data of

**Abstract Sat0156 – Table 1.** The univariate and multivariate logistic regression analysis of factors associated with significant liver fibrosis.

KNHANES (N=22,948, estimated population size=48,402,221). We analyzed the prevalence of RA and abnormal status of lipid profiles using general linear model and logistic regression with complex sample design method adjusted by age and sex and evaluated the association between RA and dyslipidemia including nutritional intake data.

**Results:** The prevalence of RA was 1.21% [95% CI: 1.07–1.38]. The prevalence of dyslipidemia with RA (3.31% [95% CI: 2.63–4.17]) was significantly increased compared with that of dyslipidemia without RA (1.37% [95% CI: 1.17–1.59],  $p < 0.001$ ).

LDL (RA vs. control:  $117.77 \pm 3.87$  mg/dL vs.  $114.47 \pm 0.51$  mg/dL,  $p < 0.001$ ) was significantly increased, whereas TG (RA vs. control:  $129.21 \pm 6.38$  mg/dL vs.  $136.72 \pm 1.20$  mg/dL,  $p < 0.001$ ) was significantly decreased in RA. Total cholesterol tended to be higher in RA (RA vs. control:  $198.12 \pm 3.09$  mg/dL vs.  $188.11 \pm 0.39$  mg/dL,  $p = 0.051$ ), but HDL (RA vs. control:  $54.16 \pm 1.42$  mg/dL vs.  $52.46 \pm 0.15$  mg/dL,  $p = 0.98$ ) was not different between two groups.

There were no differences in nutritional intake volume including total diet volume, energy intake, water, carbohydrate, protein, fat, other fatty acids and dietary fiber (Table).

Table 1 Nutritional intake difference between RA and control

	RA	control	p
Total diet (g/day)	1447.96 ± 55.81	1658.24 ± 11.50	0.40
Energy intake (kcal/day)	1826.19 ± 61.89	2121.24 ± 12.16	0.87
Water (g/day)	1027.92 ± 46.74	1182.23 ± 9.66	0.38
Protein (g/day)	61.06 ± 2.88	74.71 ± 0.58	0.85
Carbohydrate (g/day)	298.90 ± 8.76	318.72 ± 1.64	0.45
Fat (g/day)	36.66 ± 2.46	47.71 ± 0.49	0.72
Cholesterol (mg/day)	207.17 ± 33.49	278.72 ± 6.63	0.62
Saturated fatty acid (g/day)	10.05 ± 0.77	13.75 ± 0.15	0.95
Monounsaturated fatty acid (g/day)	10.97 ± 0.77	15.17 ± 0.18	0.86
Polysaturated fatty acid (g/day)	10.08 ± 0.76	11.94 ± 0.14	0.88
n-3 fatty acid (g/day)	1.59 ± 0.19	1.70 ± 0.03	0.46
n-6 fatty acid (g/day)	8.56 ± 0.67	10.31 ± 0.12	0.77
Crude fiber (g/day)	8.53 ± 0.71	7.71 ± 0.09	0.74
Dietary fiber (g/day)	23.85 ± 1.62	24.53 ± 0.30	0.25

Adjusted by age, sex and body mass index

**Conclusions:** We showed increased prevalence of dyslipidemia patients in the individuals with RA than those without RA. Serum LDL levels was increased and TG was decreased in RA patients of the Korean population survey.

**Disclosure of Interest:** None declared

#### SAT0158 THE ASSESSMENT OF SAFETY AND EFFICACY OF USING SELF-MONITORING OF DISEASE ACTIVITY VIA WEB PORTAL IN THE MANAGEMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS

G. Bagirova<sup>1</sup>, E. Lygina<sup>1</sup>, S. Lakushin<sup>1</sup>, A. Vorobyev<sup>1</sup>. <sup>1</sup>Ryazan State Medical University, Ryazan, Russian Federation

**Background:** According to the Treat-to-Target guidelines for the RA, the main goal of treatment is remission or, alternatively, a lower activity of the disease. However, persistent remissions and preservation of working capacity are observed in no more than 5–6% of cases. As a result of the analysis of possible causes of the strategy's lack of efficacy, it seemed to us urgent to create and approve the method of managing RA patients via the "Web portal for self-monitoring of rheumatoid arthritis activity".

**Objectives:** Maximally quickly identify the exacerbation of the disease and timely strengthen the therapy, for more rapid achievement of remission or low disease activity.

**Methods:** The authors created an interactive web portal for self-monitoring of RA activity. The patient management model using this method is that a patient conducts a monthly self-evaluation of the disease activity and transmits this information to his treating doctor in a remote manner via the web portal. The doctor receives information about the patient's health as quickly as possible. In case of worsening and in the absence of any dynamics, according to the patient, he was invited to the center, where this information was verified by a doctor and, if necessary, correction of therapy was made. If, in the patient's opinion, there was an improvement, he did not come to clinic, but continued therapy. During the management of patients with RA using this method (1 year) initially and further regularly clinical, laboratory and radiological monitoring of efficacy and safety was conducted. Currently, 30 women with RA, age 57 (38; 71), who completed the 6-month treatment period, are included in the study. All patients underwent a clinical examination, hand and feet X-ray, laboratory tests and assessment of the RA activity by DAS28 index. Initially, all patients were trained by a rheumatologist to carry out a self-assessment of tender and swollen joints according to the original

author's technique "Structured curriculum for teaching RA patients self-monitoring of disease activity".

**Results:** During 6 months, there was a positive dynamics of the course of the disease, the activity of the RA by DAS 28 decreased. Initially, 5 patients (16.7%) had high DAS activity, 24 – moderate (80%), 1 – low (3.3%). After 6 months of treatment 8 patients (26.7%) had low activity, 22 (73.3%) achieved remission. The mean value of the DAS 28 index at the time of inclusion was 3.99 (2.46; 5.78) and after 6 months of management 2.175 (0.79; 4.31), a statistically significant decrease (Wilcoxon T-test = 5). Initially, all patients received methotrexate at an average dose of 12.9 mg (10 mg; 30 mg), at 6 months of follow-up, the average dose was 14.6 mg (10 mg; 25 mg). An increasing the dose of methotrexate was required in 11 (36.6%) patients. Analysis of clinical and laboratory parameters did not reveal statistically significant deviations.

**Conclusions:** The 6-month period of patient management via the "web portal for self-monitoring of rheumatoid arthritis activity" proved the possibility of achieving remission and low disease activity in all patients.

#### SAT0159 THYROID FUNCTION IN EARLY VERSUS ESTABLISHED RHEUMATOID ARTHRITIS

S. Hannawi<sup>1</sup>, H. Hannawi<sup>2</sup>, I. Al Salmi<sup>3</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Ministry of Health and Prevention of UAE, Dubai, United Arab Emirates, <sup>3</sup>The Royal Hospital, Muscat, Oman

**Background:** Thyroid dysfunction is common in rheumatoid arthritis (RA). Sub-clinical hypothyroidism is the first most common, followed by clinical hypothyroidism. Thyroid dysfunction in RA had been found to increase the risk of cardiovascular disease. Subclinical hypothyroidism is defined as increased serum TSH concentration with normal serum free thyroxine (T4) level.

**Objectives:** The aim of this study was to compare the thyroid function in early RA patients (of less than one-year duration of RA symptoms) versus established RA patients (of more than or equal to one-year duration of RA symptoms)

**Methods:** We recruited 35 early RA patients (ERA) and 52 established RA patients attending specialized rheumatology clinic. All the patients had no clinical evidence of thyroid dysfunction. Patients with diabetes, pregnancy, renal and liver impairment were excluded. Fasting Free thyroxine (FT4), Free triiodothyronine (FT3), and thyroid stimulating hormone (TSH) were assessed in all the participants. t-test was used to compare the RA disease characteristics and the thyroid function between early and established RA. P value of <0.05 was considered significant.

**Results:** Rheumatoid arthritis patients had been recruited through a specialized rheumatology clinic, 35 were with new onset rheumatoid arthritis (early RA; ERA of less than a year of RA symptoms onset) and 52 were with established RA (of more than a year of RA symptoms onset). The mean RA duration was  $7.4 \pm 2.0$  months for ERA and  $96 \pm 92$  months for the established RA group. There were no significant differences in age ( $45.76 \pm 2.45$  years for ERA vs. established RA respectively,  $p = 0.49$ ), or in gender distribution (31 F and 4 M in ERA vs. 46 F and 6 M in established RA,  $p = 0.9$ ) between the two groups.

ERA compared to the established RA group had more active RA as manifested by more swollen 28- joints (5.7 vs 1.7, respectively,  $p = 0.001$ ), more tender 28-joints (17 vs 11, respectively,  $p = 0.01$ ), higher DAS-28-ESR score (5.8 vs 4.5, respectively,  $p = 0.0001$ ), higher DAS 28-CRP score (5.1 vs. 3.9, respectively,  $p = 0.001$ ), and longer morning stiffness duration ( $p = 0.04$ ). As well, ERA had lower HDL level (1.4 vs 1.2, respectively,  $p = 0.04$ ). On the other hand, established-RA patients had RA disease onset at an earlier age than the EAR group (36.5 vs 44 years, respectively,  $p = 0.02$ )

While the mean TSH, T3 and T4 were within normal range in both groups, there were significant differences in the mean values between ERA and established RA. TSH was  $2.12 \pm 1.52$  in ERA vs.  $5.8 \pm 8.3$  in established RA (NR:  $0.27 - 4.2$  mIU/L),  $p = 0.04$ . Mean FT3 was  $4.54 \pm 0.53$  in ERA vs.  $3.61 \pm 1.13$  in the established RA (NR:  $4 - 6.8$  pmol/L),  $p = 0.04$ . Average FT4 was  $17.7 \pm 4.77$  in ERA vs.  $15.3 \pm 2.51$  in the established RA (NR:  $12 - 22$  pmol/L),  $p = 0.01$ .

**Conclusions:** RA patients with more than a year of RA symptoms are at a higher risk of silent autoimmune thyroid disease than their age sex matched RA patients with new onset RA; of less than a year of RA symptoms onset. Regular assessment of thyroid function might be an important part in the routine biochemical and immunological profile screening of RA.

### SAT0160 EFFECT OF PERIODONTAL TREATMENT ON E-SELECTIN LEVEL IN RHEUMATOID ARTHRITIS PATIENTS

S. A. Kusumo<sup>1</sup>, H. Isbagio<sup>1</sup>, S. Marhamah<sup>2</sup>, C. Intan<sup>2</sup>, D. Antono<sup>1</sup>, K. Harimurti<sup>1</sup>.

<sup>1</sup>Department of Internal Medicine, Cipto Mangunkusumo Hospital/Faculty of Medicine, Universitas Indonesia, <sup>2</sup>Department of Oral Medicine, Cipto Mangunkusumo Hospital, Jakarta, Indonesia

**Background:** Cardiovascular (CV) disease is the main cause of mortality in rheumatoid arthritis (RA).<sup>1</sup> Studies showed that periodontitis is associated with RA and CV diseases.<sup>2-4</sup> Endothelial dysfunction is the first step in the pathogenesis of atherosclerosis. E-selectin is a marker of endothelial dysfunction and was expressed specifically in endothelial cells. To date, there is no study on the effect of periodontal treatment on endothelial dysfunction in RA patients.

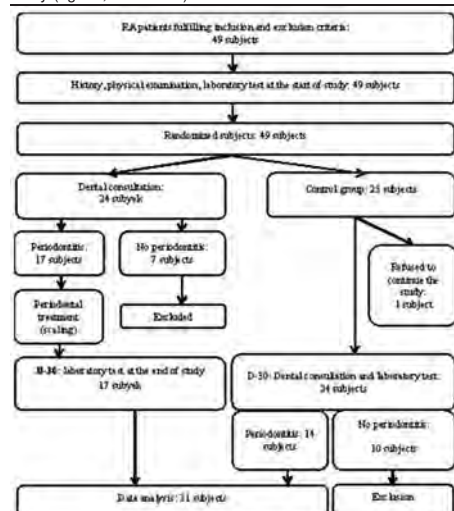

**Objectives:** To determine the effect of periodontal treatment on E-selectin level in RA patients.

**Methods:** This was a clinical trial in RA patients visiting Rheumatology Clinic in our hospital between March-May 2017. Inclusion criteria: adult RA patients, has periodontitis, low-high RA disease activity, RA duration of 10 years or less, has received DMARD. Exclusion criteria: subjects who smoke, have diabetes, underwent dental treatment for the past 3 months, have other autoimmune diseases, and patients who refused to join the study. Subjects was randomized into intervention group (periodontal scaling for 1 month) and control group. Study flow is visualized in figure 1. E-selectin level was measured at the start and at the end of the study. T-test was used to measure the difference of E-selectin level changes before-after study between groups.

**Results:** There were 31 subjects who completed the study. The prevalence of periodontitis was 64.5%. There was no statistically significant difference on delta E-selectin before-after treatment between both groups (table 1). We further divided the subjects based on disease activity and lipid profile at the end of the study. Subjects on the treatment group who was on remission and has normal lipid profile (normal LDL and decreased total cholesterol/HDL ratio) has decreased E-selectin level compared to other subjects.

Table 1 Study subjects and intervention

Characteristics	Total (n = 31)	Intervention group (n = 17)	Control group (n = 14)
Age (years, mean±SD)	55,4±8,8	52,6±9,6	58,9±6,4
RA duration (months, mean±SD)	68,8±36,5	57,8±36,5	83,5±32,3
Disease activity (n, %)	16	10 (58,3%)	6 (37,5%)
- Low	(53,3%)	6 (35,3%)	8 (53,8%)
- Moderate	14	1 (3,3%)	0 (0%)
- High	(43,3%)		
	1 (3,3%)		
Taking glucocorticoid (n, %)	20	12 (70,6%)	8 (57,1%)
	(64,5%)		
BMI (kg/m <sup>2</sup> , mean±SD)	24,9±3,17	24,89±3,47	24,92±2,86
Oral Hygiene Index (median, min-max)	0,85 (0,14 - 3,2)	0,8 (0,14 - 2)	0,82 (0,2 - 3,2)
Delta of E-selectin level start-end of study (ng/mL, mean±SD)	-	-6,3±9,3	-2,7±9,7 (p value 0,303)

**Conclusions:** Periodontal treatment for a month has no effect on E-selectin level in RA patients. Further studies on the effect of periodontal treatment on endothelial dysfunction in RA patient needs to be done on patients on remission, without dyslipidemia, and with longer treatment period.

### SAT0161 INFLUENCE OF DISEASE ACTIVITY IN RHEUMATOID ARTHRITIS ON RADIOGRAPHIC PROGRESSION OF CONCOMITANT INTERPHALANGEAL JOINT OSTEOARTHRITIS

C. Lechtenboehmer<sup>1</sup>, V. Jaeger<sup>2</sup>, D. Kyburz<sup>2</sup>, U. A. Walker<sup>2</sup>, T. Hügle<sup>3</sup>. <sup>1</sup>Radiology, <sup>2</sup>Rheumatology, University Hospital Basel, Basel, <sup>3</sup>Rheumatology, University Hospital Lausanne, Lausanne, Switzerland

**Background:** The role of inflammation in distal interphalangeal (DIP) osteoarthritis (OA) is not clear. Unlike the situation in psoriatic arthritis, DIP joints are considered not to be affected in rheumatoid arthritis (RA). Despite synovitis and bone marrow edema are also associated with radiographic progression of hand OA, the radiological course of DIP-OA and joints affected from RA differ substantially.

**Objectives:** To clarify the influence of RA disease activity and bone erosions on radiologic progression of DIP joint OA.

**Methods:** In sequential radiographs of 1988 RA patients available within the Swiss rheumatic disease registry (SCQM), we scored 15904 DIP joints for the presence of erosions as well as the severity of osteophytes, subchondral sclerosis and joint space narrowing according to the modified Kellgren Lawrence Grade (KLG). Progression was defined as an increase of KLG.

**Results:** The mean patient age was 56.1 years (SD 11.1). The median follow-up time was 4.5 years (IQR 3.1 – 7.0). DIP-OA was present in 60% of patients at baseline. Age, female sex and higher body mass index but not anti-citrullinated protein antibodies or rheumatoid factors were associated with the presence of DIP-OA. Preexisting DIP-OA (odds ratio [OR] 4.7, p<0.001) and female sex (OR 1.4, p=0.009) were predictors for radiologic progression, whilst metacarpophalangeal joint erosions or DAS28-ESR had no influence on the radiological course of DIP-OA.

**Conclusions:** Known risk factors for DIP-OA are replicated in patients with RA. RA disease activity, autoantibody status or metacarpophalangeal joint erosions were not associated with DIP-OA presence or progression, indicating distinct roles of inflammation in the pathogenesis of RA and OA.

### SAT0162 WHERE SHOULD WE SEEK FOR SUBCLINICAL SYNOVITIS USING ULTRASOUND IN RHEUMATOID ARTHRITIS?

W. Hamdi<sup>1</sup>, M. Sellami<sup>1</sup>, H. Riahi<sup>2</sup>, D. Kaffel<sup>1</sup>, K. Maatallah<sup>1</sup>, M. Chelli-Bouaziz<sup>2</sup>, M. F. Ladeb<sup>2</sup>, M. M. Kchir<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Radiology, Kassab Orthopedics Institute, Manouba, Tunisia

**Background:** The role of ultrasound imaging (US) in rheumatoid arthritis (RA) management is fundamental by sharpen diagnosis, predicting prognosis, monitoring disease activity and identifying remission. The detection of subclinical synovitis and articular inflammatory changes represent the real advantages of this technology. However, joint US is time-consuming, thus identifying the area of sub-clinical synovitis should be useful to overcome this difficulty.

**Objectives:** We aimed to assess the most profitable joint locations in detecting subclinical synovitis in RA.

**Methods:** We performed a cross-sectional study of one hundred patients with inflammatory joint pain or synovitis for more than 6 weeks and less than 2 years. All patients were free of conventional or biological DMARD's at inclusion. An experienced radiologist performed the MSUS scan of 22 joints (2 wrists, 10 metacarpophalangeal joints MCP and 10 proximal interphalangeal joints PIP) unaware of clinical and biological findings. MSUS was performed using a Philips HD11. The used frequency ranged from 15 to 17 MHz and we used a Power Doppler (PD). After US assessment, patients were classified as having RA according to ACR/EULAR 2010 criteria.

**Results:** We enrolled 100 patients (77 women and 23 men) with a mean age of 51.8 years [16-77]. Fifty-five patients (55%) fulfilled the ACR/EULAR 2010 criteria for the diagnosis of RA. The mean disease duration was 10.96 months [2-24]. Rheumatoid factor and ACPA were positive in 53% and 25% cases respectively. The mean disease activity score at the time of study was 5.36 [1.36-8.61]. A clinical wrist synovitis was found in 92 cases (46%). In the 54 wrists with no clinical

synovitis, a total number of US wrist synovitis was detected at 30 (15%) radioulnar (of which half was Doppler +), 91 (45.5%) radiocarpal (of which 60% was Doppler +) and 105 (52.5%) intercarpal joints (of which 67% was Doppler +). Concerning the MCP and PIP joints, the most frequent location of subclinical synovitis were 1st MCP in 51 cases (25.5%), 4th MCP in 49 cases (24.5%), 5th MCP in 50 of cases (25%), 1st PIP in 24 cases (12%) and 5th PIP in 22 cases (11%).

**Conclusions:** Our study highlighted the low sensitivity of physical examination of synovitis in hand and wrist joints, especially in some locations. We showed the most frequent location for detecting subclinical synovitis were radiocarpal and intercarpal joint, 1st-4th -5th MCP and 1st-5th PIP. About half of those subclinical synovitis were Doppler +.

**SAT0163 ABSOLUTE NUMBER OF PERIPHERAL CD4-CD25+FOXP3+ T CELLS DECREASES AND RESTORES AFTER LOW-DOSE INTERLEUKIN-2 TREATMENT IN RHEUMATOID ARTHRITIS**

X. Jia<sup>1</sup>, H. An<sup>1</sup>, K. Fan<sup>1</sup>, F. Li<sup>1</sup>, C. Gao<sup>2</sup>, X. Li<sup>1</sup>. <sup>1</sup>Rheumatology, The Second Hospital Of Shanxi Medical University, Taiyuan, China, <sup>2</sup>Pathology, Brigham and Women's Hospital, Boston, United States

**Background:** Recently, several studies have suggested that abnormal quantity and function of regulatory T cells (Tregs) may play a vital role in the development of rheumatoid arthritis (RA). CD25<sup>+</sup>FOXP3<sup>+</sup> T cells include CD4<sup>+</sup> (CD4<sup>+</sup> Tregs) and CD8<sup>+</sup> cells (CD8<sup>+</sup> Tregs). Recently studies have shown that CD8<sup>+</sup> Tregs also have immunosuppressive function, similar to even stronger than CD4<sup>+</sup> Tregs, and are more sensitive to IL-2 in vivo. However, the status of CD8<sup>+</sup>Treg cells in RA is unknown.

**Objectives:** Our study was designed to clarify the level of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells in RA patients, and to investigate the role of low-dose interleukin-2 (IL-2) therapy in the regulation of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells in RA patients to provide another theoretical basis besides CD4<sup>+</sup> Tregs to IL-2 therapy.

**Methods:** Three hundred and four RA patients (diagnosis according to the 2010 ACR criteria) were enrolled; no treatment group (N = 75), DMARDs treatment group (N = 73), low dose IL-2 treatment group (50WU/day × 5 days, subcutaneous injection) (N = 156), and healthy control group (N = 90). The absolute numbers of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells in peripheral blood were detected by flow cytometry. We assumed that CD4<sup>+</sup> T cells with CD25<sup>+</sup> and FOXP3<sup>+</sup> were mostly CD8<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> Treg cells, which was CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells in this study. The levels of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells among these groups were compared with that of health group or each other respectively, and then the statistical software SPSS 20.0 was used for analysis; p<0.05 was considered significant.

**Results:** As compared with the healthy group, the absolute number of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells decreased significantly in the untreated RA patients [0.94(0.41,1.61) vs 1.31(0.72,2.52), P<0.001] and more dramatically in DMARDs treatment patients [0.86(0.36,1.83) vs 1.31(0.72,2.52), P<0.01]. After treatment with IL-2, the absolute count of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells increased significantly compared with that before treatment [0.91(0.48,1.54) vs 2.10(1.12,3.56), P<0.001].

**Conclusions:** The absolute number of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells in untreated RA patients were lower than those health, implying that CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells deficiency was caused by disease itself but not immunosuppressive therapy, which may be an important factor in the pathogenesis of RA. The traditional DMARDs therapy did not improve this reduction. Low dose IL-2 can increase the absolute number of CD4<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> T cells in peripheral blood. We are about to detect the number of CD8<sup>+</sup>CD25<sup>+</sup>FOXP3<sup>+</sup> Treg cells accurately to verify this theory.

**SAT0164 ADVERSE DRUG REACTIONS DUE TO DISEASE MODIFYING DRUGS IN PATIENTS WITH INCIDENT RHEUMATOID ARTHRITIS**

Z. Rosales Rosado<sup>1,2</sup>, D. D. Freitas NÚÑEZ<sup>2</sup>, C. Lajas Petisco<sup>1</sup>, E. Pato Cour<sup>1</sup>, L. León Mateos<sup>2</sup>, L. Abásolo Alcázar<sup>2</sup>. <sup>1</sup>Rheumatology, hospital clínico san carlos, <sup>2</sup>Instituto De Investigación Sanitaria San Carlos, Madrid, Spain

**Background:** There is a well-known risk of developing adverse drug reactions (ADR) in rheumatology due, mainly, to the Disease Modifying Antirheumatic Drugs (DMARD) used. There is no doubt about their efficacy in Rheumatoid Arthritis (RA), but it is necessary to increase our knowledge of their ADR, especially those that lead to discontinuation

**Objectives:** To describe the incidence and characteristics of ADR related with DMARD in patients with incident RA as well as the factors involved in their development

**Methods:** Observational retrospective longitudinal study between April 15th 2007 and December 31st 2016. **Inclusion criteria:** patients diagnosed with RA between April 15th 2007 and June 31st 2011 followed until December 31st 2016 whom started any DMARD. **Primary endpoint:** development of an ADR that required discontinuation of the DMARD (moderate: discontinuation; severe: discontinuation with hospitalization or death). **Co-variables:** sociodemographic; clinical and therapy. **Statistical analysis:** incidence rates of discontinuation (IR) per 100 patient-years were estimated using survival techniques with their respective 95% confidence interval [CI]. Comparisons between associated factors were run by Cox bivariate and multivariate regression models. Results were expressed by hazard ratio (HR) and [CI]

**Results:** We included 1054 courses of DMARD treatment in 405 patients (2277.9 patient-years). 78.3% were women with a mean age at diagnosis of 57 ±15 years. During follow-up, 16.3% of patients were taking biological DMARD, 73.3% were using monotherapy and 89% were taking corticoids. There were 369 ADR in 212 patients, 88.9% moderate. Gastrointestinal was the most frequent cause of ADR (26.3%), followed by infections (12.2%). IR are shown in table 1 and the multivariate analysis in table 2. Regarding type of DMARD, Abatacept had the highest risk of ADR development (HR:4.9[2.1–11.2]) compared to the other drugs followed by Gold (HR:1.6[1–2.6]) and Leflunomide (HR:1.4[1.1–1.9]). Methotrexate was the safest drug compared with the others (0.6[0.5–0.8])

Liver disease	2	1.2–	0.012
		3.3	

**Conclusions:** The IR of ADR was 16.2%, being similar in all age categories. Gastrointestinal was the main cause of ADR followed by infections. We have found differences in discontinuation rates among DMARD due to ADR, being Abatacept, Gold and Leflunomide the drugs with the highest risk. Methotrexate had a lower risk of ADR compared to other DMARD. Caution should be taken in patients receiving combined therapy and with certain comorbidities

Rheumatoid arthritis - biological DMARDs

**SAT0165 REASONS FOR bDMARD CESSATION AND SUBSEQUENT PERSISTENCE OF SECOND LINE TREATMENT IN A LARGE REAL WORLD RHEUMATOID ARTHRITIS REGISTRY**

P. Youssef<sup>1</sup>, B. Marcal<sup>2</sup>, P. Button<sup>3</sup>, M. Truman<sup>3</sup>, P. Bird<sup>4</sup>, H. Griffiths<sup>5</sup>, L. Roberts<sup>6</sup>, K. Tymms<sup>7</sup>, G. Littlejohn<sup>8</sup>. <sup>1</sup>Royal Prince Alfred Hospital, Camperdown, <sup>2</sup>Roche Products, Pty. Limited, <sup>3</sup>OzBiostat Pty. Ltd., <sup>4</sup>University of New South Wales, Sydney, <sup>5</sup>Barwon Rheumatology Service, Geelong, <sup>6</sup>Monash Rheumatology, Clayton, <sup>7</sup>Canberra Rheumatology, Canberra, <sup>8</sup>Monash University, Clayton, Australia

**Background:** The current recommendations for treating Rheumatoid Arthritis (RA) patients (pts) who fail on conventional disease modifying anti-rheumatic drugs (DMARDs) is to use biologic (b) or targeted synthetic (ts) DMARDs. Pts who fail first (1st) line b/tsDMARDs are recommended to go on other b/tsDMARDs; however, reasons for stopping or switching between bDMARDs according to mode of action and the persistence on treatment are not well characterized in real world patient populations.

**Objectives:** The primary objective was to identify the reasons for stopping 1st line b/tsDMARDs in RA pts treated in the clinical practice setting. The secondary objectives were to identify second (2nd) line b/tsDMARDs choices in pts who stop TNF inhibitors (TNFis) within 6 months (mo) due to lack of efficacy and the persistence on these treatments.

**Methods:** Pts  $\geq 18$  years with confirmed RA who were treated with 1st line b/tsDMARDs, from 1 August 2010 to 30 June 2017, by physicians participating in the OPAL-QUMI database, were included in the analyses. Reasons for stopping b/tsDMARDs were recorded by the treating physician during routine visits. The following b/tsDMARDs were included abatacept (ABA), adalimumab, certolizumab pegol, etanercept, golimumab, infliximab and tocilizumab (TCZ), rituximab (RTX) and tofacitinib (TFB). Data were analysed using descriptive statistics for continuous variables and frequency counts for categorical variables. Persistence on treatment was summarised using Kaplan-Meier (K-M) methodology. Individual TNFis were combined for simplicity.

**Abstract Sat0165 – Table 1.** Patients receiving 1st line treatment by mechanism of action.

First-line Treatment	RTX	TCZ	TFB	ABA	TNFis
Started, n	230	555	518	609	5002
Stopped, n(%)	51(22)	238(43)	105(20)	233(38)	2029(41)
Stopped within 6 months: n(%) <sup>a</sup>	11(22) <sup>a</sup>	41(17) <sup>a*</sup>	57(54)	72(31) <sup>b</sup>	733(36) <sup>a*</sup>

percentage relative to subset stopped treatment  
<sup>a</sup>p<0.001: RTX vs TFB; TCZ vs ABA; TNFis vs TFB  
<sup>b</sup>p<0.0001: TCZ vs TFB; TNFis/ABA vs TFB

**Abstract Sat0165 – Table 2 K-M.** estimates of persistence on 2nd line b/tsDMARDs after discontinuation of 1st line TNFis due to lack of efficacy.

	RTX	TCZ	TFB	ABA	TNFis
N	13	49	25	92	130
6 months, %	75	78	71	61	60
12 months, %	75	57	ND	49	40

ND=not determined

**Results:** A total of 6914 pts received 1st line b/tsDMARDs. Median age was 61 years, median disease duration (RA onset to last visit) was 10 years. The majority

(75%) were females. Treatment was stopped in 2656 pts (38%); 914 (34%) of these stopped within 6 mo of treatment initiation. The highest and lowest percentage of pts stopping treatment within 6 mo was in pts receiving TFB (54%) and TCZ (17%), respectively (table 1). The most common reasons for stopping therapy within 6 mo were lack of efficacy (45%>ABA, 44%>TNFis, 33%>TFB and 27%>TCZ) and adverse reactions (21%>TFB, 20%>TCZ, 15%>TNFis, 13%>ABA). Stopping due to lack of efficacy-primary failure was highest for TFB (23%). The percentage of pts remaining on 2nd line b/tsDMARD treatment after stopping 1st line TNFis due to lack of efficacy was the highest for TCZ (78%) at 6 mo and RTX (75%) at 12 mo (table 2). Median time to stopping 2nd line treatment was 48 mo (95% CI:17–74) for RTX, 21 mo (95% CI:11–62) for TCZ, 21 mo (95% CI:6–21) for TFB; 11 mo (95% CI:8–22) for ABA and 9 mo (95% CI:7–12) TNFis.

**Conclusions:** The primary failure rate is lower than previously reported. In pts who failed 1st line TNFis within 6 mo of commencement due to lack of efficacy, 2nd line TNFis resulted in the lowest treatment persistence. These real world data will assist clinicians with treatment choices post primary TNFis failure.

**SAT0166 WHICH BIOLOGIC AGENT IS MOST SUITABLE FOR AN EXTENDED-INTERVAL TREATMENT FOR RHEUMATOID ARTHRITIS ? RESULTS FROM A MULTICENTER STUDY**

K. Katayama<sup>1</sup>, H. Matsuno<sup>2</sup>, T. Matsubara<sup>3</sup>. <sup>1</sup>Orthopedic Surgery, Katayama Orthopedic Rheumatology Clinic, Asahikawa, <sup>2</sup>Orthopedic Surgery, Matsuno Clinic for Rheumatic Diseases, Toyama, <sup>3</sup>Orthopedic Surgery, Matsubara Mayflower Hospital, Kobe, Japan

**Background:** Biological disease-modifying antirheumatic drugs (bDMARDs) have made apparent development of treating rheumatoid arthritis (RA). However, prescription of them appeared to be relatively difficult due to high cost. The newest EULAR recommendation advocates tapering of bDMARDs when RA activity is controlled.

**Objectives:** A multicenter clinical study on a longer interval treatment with three bDMARDs, Golimumab (GOL), which is one of TNF inhibitors, and two of non-TNF inhibitor, Tocilizumab (TCZ) and Abatacept (ABT) was investigated.

**Methods:** Patients, who were maintained at low disease activity by DAS28 score for more than 3 months treated with GLM, TCZ, ABT, were enrolled. These selected patients were treated with these drugs with 1.5 fold longer interval of standard schedule for 60 weeks, and the rate of patients, who preserved low disease activity were determined. The patients who were not tolerated these drugs because of the side effects or adverse events, were withdrawn from this study.

**Results:** One hundred thirty-one patients treated with GLM, 149 with ABT (S.C. 61, I.V. 88) and 299 with TCZ (S.C. 87, I.V. 212) were enrolled. Among these, 57 patients treated with GLM (43%), 40 with ABT (26%, S.C. 18, I.V. 22), 93 with TCZ (31%, S.C. 21, I.V. 72) were successfully maintained at low disease activity with

this 1.5 folds longer interval treatment, respectively. The age of patients in ABT group was 73.5±10.6, and significantly higher than those in TCZ (58.8±13.9) and GOL (58.1±14.7) groups. At 60 weeks, DAS28 in ABT group was 3.1±0.5, and significantly higher than those in TCZ (2.6±0.7) and GLM (2.6±0.7) groups. On the other hand, CDAI in GOL was 6.6±3.4, and was significantly higher than those in TCZ (4.4±2.6) or ABT (4.6±2.3) groups. Accordingly, successive rate at 60th week in ABT group was 52% and significantly lower than those in TCZ (69%) or in GOL (73%) groups as shown in figure. Finally, no significant difference in successive rate was observed between s.c. and i.v.

**Conclusions:** This study clarified that TCZ and GLM had higher successive rate than ABT for maintaining low disease activity for 60 weeks by longer interval treatment. This effectiveness might relate to the high therapeutic efficacy of TCZ and low antigenicity of GOL.

SAT0167

### COMPARISON OF THE EFFICACY AND TOLERABILITY OF TOCILIZUMAB, SARILUMAB, AND SIRUKUMAB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS: A BAYESIAN NETWORK META-ANALYSIS OF RANDOMIZED CONTROLLED TRIALS

Y. H. Lee<sup>1</sup>, Y. H. Seo<sup>1</sup>. <sup>1</sup>Rheumatology, Korea University Medical Center, Seoul, Korea, Republic Of

**Background:** A humanized, anti-human IL-6 receptor monoclonal antibody, tocilizumab, was developed to block IL-6 signaling and has been used as an effective therapeutic agent for patients that do not respond to methotrexate (MTX) or tumor necrosis factor (TNF) inhibitor. The successful use of tocilizumab in RA stimulated the development of other biologics targeted to the IL-6 pathway, such as anti-IL-6R (sarilumab) or anti-IL-6 (sirukumab) antibodies.

**Objectives:** The relative efficacy and tolerability of tocilizumab, sarilumab, and sirukumab were assessed in patients with rheumatoid arthritis (RA) and an inadequate response to MTX or TNF inhibitors.

**Methods:** We performed a Bayesian network meta-analysis to combine direct and indirect evidence from randomized controlled trials (RCTs) to examine the efficacy and safety of tocilizumab, sarilumab, and sirukumab in RA patients and an inadequate MTX or TNF inhibitor response.

**Results:** Fourteen RCTs, comprising 9,753 patients, met the inclusion criteria. Tocilizumab 8 mg combined with MTX or as monotherapy was the most effective treatment for active RA with an inadequate MTX or TNF antagonist response, followed by sarilumab and sirukumab, regardless of MTX combination. The ranking probability based on the surface under the cumulative ranking curve (SUCRA) indicated that tocilizumab 8 mg+MTX had the highest probability of being the best treatment to achieve the ACR50 response rate, followed by tocilizumab 8 mg, sarilumab 200 mg, sarilumab 200 mg+MTX, sirukumab 100 mg, tocilizumab 4 mg +MTX, sirukumab 100 mg+MTX, sirukumab 50 mg+MTX, sarilumab 150 mg +MTX, adalimumab 40 mg, and sirukumab 50 mg, and placebo+MTX. No significant differences were observed in withdrawals owing to adverse events after treatment with tocilizumab 8 mg+MTX, sirukumab 100 mg+MTX, or sarilumab 200 mg+MTX.

**Conclusions:** In RA patients with an inadequate MTX or anti-TNF therapy response, tocilizumab 8 mg as monotherapy and combined with MTX showed acceptable tolerability and the highest performance based on the ACR50 response rate, followed by sarilumab and sirukumab.

### MRI RESULTS FOLLOWING DISCONTINUATION OF METHOTREXATE IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH SUBCUTANEOUS TOCILIZUMAB: RESULTS FROM A RANDOMIZED CONTROLLED TRIAL

C. Paterly<sup>1</sup>, J. Kremer<sup>2</sup>, W. Rigby<sup>3</sup>, N. Singer<sup>4</sup>, C. Birchwood<sup>5</sup>, D. Gill<sup>5</sup>, W. Reiss<sup>5</sup>, J. Peji<sup>5</sup>, M. Michalska<sup>5</sup>. <sup>1</sup>Spire Sciences, Inc., Boca Raton, <sup>2</sup>Albany Medical College and The Center for Rheumatology, Albany, <sup>3</sup>Geisel School of Medicine, Dartmouth College, Lebanon, <sup>4</sup>Case Western Reserve University and the MetroHealth System, Cleveland, <sup>5</sup>Genentech, Inc., South San Francisco, United States

**Background:** Although previous studies have established the efficacy of tocilizumab (TCZ) initiated as monotherapy (MONO) for the treatment of rheumatoid arthritis (RA),<sup>1,2</sup> changes in active intra-articular inflammation after discontinuation of methotrexate (MTX) in patients achieving good clinical control with TCZ + MTX have not been evaluated. Magnetic resonance imaging (MRI) effectively images synovitis and osteitis and can detect changes in bone erosion with greater sensitivity than radiography.<sup>3</sup>

**Objectives:** This study used MRI to assess differences in joint damage between patients with RA who achieved low disease activity with TCZ + MTX and then continued or discontinued MTX in the COMP-ACT trial (NCT01855789).

**Methods:** US patients with RA who were inadequate responders to MTX were enrolled; initial combination therapy included MTX (≥15 mg/week orally) plus TCZ 162 mg subcutaneous (SC) either weekly or every 2 weeks. Patients who achieved DAS28-ESR ≤3.2 at week 24 were randomized 1:1 to receive TCZ-MONO or continue TCZ + MTX until week 52 (double blind). A subset of these patients was included in this MRI substudy; 1.5 Tesla MRI was used to obtain images of bilateral hands and wrists at Weeks 24 and 40. Two independent radiologists evaluated images at a central reading facility using RAMRIS (synovitis, osteitis, erosion) and CARLOS (cartilage loss). Outcomes included changes in MRI scores from Week 24 to 40 and the proportion of patients with progression of each score.

**Results:** Of the 296 patients who achieved DAS28 ≤3.2 at Week 24 and were randomized to TCZ + MTX or TCZ-MONO, 79 were enrolled in the MRI substudy (n = 41 and 38, respectively); 74.7% were women, and the mean (SD) age was 56.3 (12.8) years. Patient demographics in the MRI substudy were similar to overall study demographics. Mean changes from Week 24 to 40 in bone erosion, synovitis, osteitis and cartilage loss scores were not significantly different between the TCZ + MTX and TCZ-MONO groups for both bilateral hands and the dominant hand (table 1). There were no significant differences between the groups in the proportion of patients with no progression in each outcome measure (range, 89.7% to 97.4% with TCZ + MTX and 87.9% to 100.0% with TCZ-MONO).

**Table 1** MRI Changes in Patients Receiving TCZ in Combination With MTX or TCZ as Monotherapy

	Both Hands			Dominant Hand		
	TCZ + MTX (n = 41)	TCZ-MONO (n = 38)	Difference (95% CI) (TCZ-MONO minus TCZ + MTX)	TCZ + MTX (n = 41)	TCZ-MONO (n = 38)	Difference (95% CI) (TCZ-MONO minus TCZ + MTX)
Bone erosion score (0-250) mean (SE)	-0.06 (0.18)	0.18 (0.19)	0.24 (-0.21 to 0.60)	0.06 (0.24)	0.49 (0.25)	0.43 (-0.14 to 1.01)
Synovitis score (0-24) mean (SE)	-0.24 (0.15)	-0.10 (0.15)	0.06 (-0.30 to 0.41)	-0.22 (0.12)	-0.11 (0.12)	0.11 (-0.16 to 0.40)
Osteitis score (0-75) mean (SE)	-0.16 (0.34)	0.37 (0.36)	0.53 (-0.36 to 1.36)	-0.39 (0.52)	0.69 (0.54)	1.07 (-0.16 to 2.33)
Cartilage loss score (0-100) mean (SE)	0.20 (0.14)	-0.03 (0.15)	-0.23 (-0.58 to 0.11)	0.11 (0.10)	-0.05 (0.19)	-0.16 (-0.59 to 0.27)

MTX, methotrexate; TCZ, tocilizumab; TCZ-MONO, TCZ monotherapy

\* ANCOVA model for estimated means includes Week 24 bone erosion as a covariate, treatment group and the randomization stratification factors: DAS28 remission status at Week 24 (< 2.6, ≥ 2.6 to < 3.2), patient anti-TNF exposure (Yes or No) and baseline weight-by-dosing group (< 80 kg q2w, 80 to < 100 kg q2w, 80 to < 100 kg qw, ≥ 100 kg qw)

**Conclusions:** In patients who achieved low disease activity with TCZ + MTX, MRI changes were minimal and showed no difference in the response of active intra-articular inflammation in patients who discontinued MTX vs those who continued TCZ + MTX within the period of observation, consistent with the result of similar mean change in DAS28 between the groups in the primary analysis.

**SAT0169 NO EVIDENCE THAT CONCOMITANT GLUCOCORTICOID THERAPY AFFECTS EFFICACY AND SAFETY OF TOCILIZUMAB MONOTHERAPY IN RHEUMATOID ARTHRITIS CLINICAL TRIALS**

M. Safy<sup>1</sup>, J. W. G. Jacobs<sup>1</sup>, M. Edwardes<sup>2</sup>, J. Pei<sup>3</sup>, M. De Hair<sup>4</sup>, X. Teitsma<sup>1</sup>, P. Welsing<sup>1</sup>, M. Borm<sup>5</sup>, Y. Luder<sup>6</sup>, J. Van Laar<sup>1</sup>, A. Pethö-Schramm<sup>6</sup>, J. W. J. Bijlsma<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, University Medical Center Utrecht, Utrecht, Netherlands, <sup>2</sup>Everest Clinical Research, Markham, Canada, <sup>3</sup>Genentech, San Francisco, United States, <sup>4</sup>University Medical Center Utrecht, Utrecht, <sup>5</sup>Roche, Woerden, Netherlands, <sup>6</sup>Roche, Basel, Switzerland

**Background:** For rheumatoid arthritis (RA) patients included in clinical trials, background treatment with glucocorticoids (GCs) is quite common (40–60%), but their potential contribution to efficacy and safety of the disease modifying anti-rheumatic drug (DMARD) tested in that trial has rarely been evaluated.

**Objectives:** To establish whether a stable GC dose at baseline and during the study contributed to the efficacy and safety of TCZ monotherapy initiated in RA patients in 4 TCZ RCTs. In addition, to investigate the same issue in the comparator arms of these trials, in which adalimumab (ADA) or methotrexate (MTX) was initiated.

**Methods:** Data from 4 randomized controlled double-blind trials (AMBITION, ACT-RAY, ADACTA and FUNCTION) with TCZ monotherapy arms was analysed in this post hoc analysis [1–4]. Study participants were MTX-naïve, intolerant or had an inadequate response to conventional synthetic DMARDs (csDMARD-IR). Because of differences between the studies in region, and baseline RA duration and disease severity, analyses were done separately for each study. Stable GC dose at baseline was allowed and was to be continued unchanged during the first 24 weeks. Analyses of covariance (ANCOVA) of change from baseline to Week 24 in CDAI and DAS28 and logistic regression analyses at Week 24 for CDAI remission and ACR50 were performed. Repeated measures analyses using all visits up to week 24 were also done. Incidence rates of serious adverse events (SAEs) were assessed by GC use.

Table 1 Disease Activities at week 24 of GC Users versus non-GC Users per Treatment per Study

**Results:** Baseline characteristics were mostly comparable between GC users and non-GC users in each treatment arm for each study. The adjusted differences (95% CIs) of CDAI change at week 24 between GC and non-GC users in TCZ arms of AMBITION, FUNCTION, ACT-RAY and ADACTA were -1.4 (-4.8, 2.1), 0.8 (-2.5, 4.1), 1.2 (-4.0, 6.3) and -4.2 (-9.7, 1.4), respectively (table 1). CDAI remission rates, ACR50 response rates and DAS28 score changes at 24 weeks neither were significantly different between GC users and non-GC users in the TCZ arms, nor in the MTX and ADA arms (table 1). Repeated measures analyses to week 24 showed no significant differences in DAS28 or CDAI. Statistically significant predictors for the various clinical outcomes included baseline CDAI, baseline DAS28, age, sex, RA duration and region. A numerically higher but not significantly different SAE rate was seen in the GC-arms of all four trials, compared to the non-GC-arms.

**Conclusions:** No evidence was found that GC treatment at baseline and continued at a stable dose affects either clinical efficacy or safety over 24 weeks of TCZ, MTX, or ADA monotherapy initiated at baseline in RA clinical trials.

González-Gay<sup>1,5,6</sup>. <sup>1</sup>Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, Rheumatology Division, Hospital Universitario Marqués de Valdecilla, IDIVAL, Santander, <sup>2</sup>Rheumatology Department, Hospital Universitario Araba, Vitoria, <sup>3</sup>Epidemiology and Computational Biology Department, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, <sup>4</sup>Rheumatology Department, Hospital Universitario La Princesa, IIS-IPrincesa, Madrid, <sup>5</sup>School of Medicine, University of Cantabria, Santander, Spain, <sup>6</sup>Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

**Background:** Leptin is an adipocytokine that plays an important role in the regulation of body weight and also participates both in immune homeostasis and inflammatory processes [1,2]. Chronic systemic inflammation is of major importance in the development of atherosclerosis in rheumatoid arthritis (RA) [3]. IL-6 blocker yields a rapid improvement of endothelial function [4].

**Objectives:** To determine whether the infusion of IL-6 blockade improves the endothelial function by altering circulating Leptin concentrations in patients with RA.

**Methods:** 50 Spanish patients on treatment with anti-IL-6 monoclonal antibody-Tocilizumab who fulfilled the 2010 classification criteria for RA [5] were recruited. Patients with diabetes mellitus or plasma glucose >110 mg/dl were excluded. Leptin serum levels were determined immediately prior to (time 0) and after (time 60 minutes) Tocilizumab infusion by Enzyme-Linked ImmunoSorbent Assay (ELISA).

**Results:** A significant reduction in Leptin concentration was observed following Tocilizumab infusion (mean±standard deviation (SD): 9.24±7.98 ng/ml versus 7.91±7.36 ng/ml, p<0.0011). In addition, a significant positive correlation between Leptin concentration and insulin resistance (HOMA at the time of the study) was found (r= 0.40; p=0.0046). Furthermore, a significant negative correlation between Leptin levels and insulin sensitivity (QUICKI) was disclosed (r= -0.46; p=0.0009).

**Conclusions:** Our study confirms that circulating Leptin concentrations are modulated by anti-IL-6 treatment. In addition, Leptin concentration correlates with insulin resistance and sensitivity. The beneficial effect of anti-IL-6 blockage on cardiovascular mortality in RA may be mediated by reduction in serum levels of leptin.

SAT0171

### REVERSIBLE DECREASES IN ABSOLUTE NEUTROPHIL COUNT (ANC) IN RHEUMATOID ARTHRITIS (RA) PATIENTS (PTS) ON SARILUMAB: COMPARISON OF DOSE DELAY AND DOSE DECREASE VS CONTINUED TREATMENT

J. R. Curtis<sup>1</sup>, G. St John<sup>2</sup>, M. Panucci<sup>2</sup>, J. A. Maldonado-Cocco<sup>3</sup>. <sup>1</sup>Division of Clinical Immunology and Rheumatology, University of Alabama at Birmingham, Birmingham, United States, <sup>2</sup>Regeneron Pharmaceuticals, Inc, Tarrytown, United States, <sup>3</sup>Universidad de Buenos Aires, Buenos Aires, Argentina

**Background:** In randomized studies (RCTs: MOBILITY, TARGET and MONARCH), and open-label [OLE] EXTEND, for those patients who experienced decreases in ANC this typically occurred early after initiating sarilumab. For sarilumab patients with decreased ANC in the RCTs and the OLE, we assessed the outcomes associated with either continuing treatment, decreasing the sarilumab dose or delaying the dose.

**Objectives:** The effects of a dose decrease (200 to 150 mg), dose delay (>17 days), vs no change in treatment were evaluated in RA patients who experienced decreased ANC while on sarilumab 150 or 200 mg q2w. Outcomes data from patients in MONARCH, MOBILITY and TARGET, and MOBILITY and TARGET patients entering EXTEND were analyzed to compare the three strategies. In MONARCH, patients received sarilumab 200 mg q2w. In MOBILITY and TARGET, patients received sarilumab 150 or 200 mg q2w. In EXTEND, patients were switched to, or initiated on, 200 mg q2w.

Table 1 Outcomes following dose delay, dose decrease, or continued treatment with sarilumab among pts who experienced ANC <1000/mm<sup>3</sup> at any time

Table: Outcomes following dose delay, dose decrease, or continued treatment with sarilumab among pts who experienced ANC <1000/mm <sup>3</sup> at any time	RCTs		OLE		
	Continued without change (n=88)	Dose delay (n=43)	Continued without change (n=31)	Dose delay (n=82)	Dose decrease (n=62)
Total treated (n)	1346	1351	105 (8)	147 (11)	
ANC <1000/mm <sup>3</sup> at any time (n, %)	105 (8)	147 (11)	24 (23)	15 (19)	
Pts who did not continue* (n, %)	24 (23)	15 (19)	81 (77)	132 (90)	
Normalized on treatment after 21 episodes of ANC <1000/mm <sup>3</sup> (n, %)	31 (35)	27 (63)	29 (94)	66 (80)	51 (82)
Median time to normalization for patients with 1 episode (days)	9	15	27	17	28
Pts with >1 episode of ANC <1000/mm <sup>3</sup> who normalized on treatment** (n, %)	6 (7)	6 (14)	3 (10)	33 (40)	22 (35)
Renormalized after treatment discontinuation (n, %)	2 (3)	9 (21)	1 (3)	7 (9)	5 (8)
Did not normalize after 31 episode of ANC <1000/mm <sup>3</sup> (n, %)	11* (13)	7* (16)	1 (3)	9 (11)	8 (13)
Discontinued treatment due to abnormal ANC after last episode (n)	1	1	1	9	6
ANC at last episode: (<2000/<1500/<1000/mm <sup>3</sup> )	10/1/0	0/0/1	1/0/0	2/6/1	1/4/1

\*10 and % pts enrolled into EXTEND  
 \*\*ANC <500/mm<sup>3</sup> confirmed or had evidence of an infection or had ANC 500 to 1000/mm<sup>3</sup> and were discontinued at the investigator's discretion.  
 \*\*\*pts >1 episode of ANC <1000/mm<sup>3</sup> was defined as pts who, at least once, experienced ANC <1000/mm<sup>3</sup>, then displayed normalized ANC levels and were able to resume treatment, but later experienced ANC <1000/mm<sup>3</sup> again.

**Methods:** In RCTs, patients were required to have baseline neutrophil levels  $\geq 2000/\text{mm}^3$ . In RCTs and EXTEND, patients who experienced ANC <500/mm<sup>3</sup> (grade 4 [G4] neutropenia) or  $\geq 500$  to <1000/mm<sup>3</sup> (grade 3 [G3] neutropenia) and signs of infection were required to permanently discontinue treatment. Patients with G3 neutropenia (no signs of infection) temporarily discontinued treatment (or permanently discontinued at the investigators discretion); patients were retested  $\leq 48$  hrs after identifying decreased ANC and before the next scheduled dose, and could resume if ANC  $\geq 1000/\text{mm}^3$ . In RCTs, patients restarted sarilumab at their randomized dose. In OLE, patients restarted sarilumab at 150 mg q2w, as per the protocol, or otherwise were able to restart at 200 mg q2w at the investigators discretion. In OLE, patients who required a dose decrease to 150 mg q2w sarilumab

received the reduced dose for the remainder of the treatment period. ANC normalization was defined as a return to the patient's baseline or within normal ranges.

**Results:** Of the 8–11% of patients who experienced ANC <1000/mm<sup>3</sup> at any time, 81/105 (RCTs) and 132/147 (OLE) were able to continue or reinstate sarilumab; the majority of patients who experienced ANC <1000/mm<sup>3</sup> one or more times displayed normalized ANC levels and continued treatment when ANC  $\geq 1000/\text{mm}^3$  (25/38 in RCTs; 29/31 in OLE). The majority of patients who dose delayed (27/43 in RCTs; 66/82 in OLE) or dose decreased (51/62, OLE) before ANC normalized resumed treatment.

**Conclusions:** More than three-quarters of patients who discontinued treatment until ANC normalized were able to reinstate at their randomized dose (RCT), or at the open-label study dose (200 mg q2w; OLE) or were able to resume at the lower dose (150 mg q2w; OLE).

### LONG-TERM EFFICACY WITH 5-YEAR-RADIOGRAPHIC RESULTS AND SAFETY OF SARILUMAB IN COMBINATION WITH csDMARDs IN PATIENTS WITH RHEUMATOID ARTHRITIS

G. R. Burmester<sup>1</sup>, Y. Lin<sup>2</sup>, G. St John<sup>3</sup>, S. Wang<sup>2</sup>, J. J. Gomez-Reino<sup>4</sup>, J. A. Maldonado-Cocco<sup>5</sup>, J. C. Salazar<sup>6</sup>, D. van der Heijde<sup>7</sup>, M. C. Genovese<sup>8</sup>.

<sup>1</sup>Charité – University Medicine Berlin, Berlin, Germany, <sup>2</sup>Sanofi Genzyme, Bridgewater, NJ, <sup>3</sup>Regeneron Pharmaceuticals, Inc, Tarrytown, NY, United States, <sup>4</sup>IDIS, Complejo Hospitalario Universitario de Santiago, Santiago, Spain, <sup>5</sup>School of Medicine, Buenos Aires University, Buenos Aires, Argentina, <sup>6</sup>Clinical Research at Riesgo de Fractura S.A, CAYRE, Bogotá, Colombia, <sup>7</sup>Leiden University Medical Center, Leiden, Netherlands, <sup>8</sup>Stanford University Medical Center, Palo Alto, CA, United States

**Background:** Long-term data are being collected on sarilumab in combination with csDMARDs in patients with RA originally enrolled in six trials (TARGET, NCT01709578; MOBILITY, NCT01061736; NCT01764997; NCT01768572; NCT02057250; NCT01217814) including those who continued into extension trials.

**Objectives:** To assess efficacy and safety of long-term treatment with sarilumab plus csDMARDs in patients with RA.

**Methods:** Long-term efficacy and safety data were available in patients enrolled in placebo-controlled trials of sarilumab 150 or 200 mg sc q2w who continued into the open-label EXTEND trial of sarilumab 200 or 150 mg sc q2w (NCT01146652). Safety data were evaluated in 2887 patients who received  $\geq 1$  dose of sarilumab sc in combination with csDMARDs.

**Results:** Clinical and radiographic efficacy of sarilumab plus csDMARDs was maintained over 5 years' follow-up (table 1; figure 1). Initial treatment with either dose of sarilumab was associated with significantly better radiographic outcome than placebo. Initial treatment with sarilumab 200 mg portended better radiographic outcome than sarilumab 150 mg or placebo. Mean duration of sarilumab treatment in the safety population was 2.6 years (max 6.8), representing 7412 cumulative patient-years of exposure. Incidence rate of adverse events of special interest (AESIs; table 2) was generally stable over >5 years' treatment, with no signal for increased rate of any AESI (including serious AEs and serious infection) over time. Incidences of injection site reaction, ANC <1 Giga/L, & elevated ALT declined over time.

Table 1 Clinical response, % (number of patients assessed)

Initial treatment	DAS28-CRP<2.6 (remission)			CDAI ≤2.8 (remission)		
	MOBILITY (52 weeks)→EXTEND					
Week	148	196	244	148	196	244

**SAT0173 EFFECTS OF DENOSUMAB, A SUBCUTANEOUS RANKL INHIBITOR, ON THE PROGRESSION OF STRUCTURAL DAMAGE IN JAPANESE PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH csDMARDs: RESULT FROM THE LONG-TERM TREATMENT OF PHASE 3, DESIRABLE STUDY**

T. Takeuchi<sup>1</sup>, Y. Tanaka<sup>2</sup>, S. Soen<sup>3</sup>, H. Yamanaka<sup>4</sup>, T. Yoneda<sup>5</sup>, S. Tanaka<sup>6</sup>, T. Nitta<sup>7</sup>, N. Okubo<sup>7</sup>, H. Genant<sup>8</sup>, D. van der Heijde<sup>9</sup>. <sup>1</sup>Keio University School of Medicine, Tokyo, <sup>2</sup>University of Occupational and Environmental Health, Kitakyushu, <sup>3</sup>Kindai University Nara Hospital, Ikoma, <sup>4</sup>Institute of Rheumatology Tokyo Women's Medical University, Tokyo, <sup>5</sup>Osaka University Graduate School of Dentistry, Osaka, <sup>6</sup>The University of Tokyo, <sup>7</sup>Daiichi Sankyo, Tokyo, Japan, <sup>8</sup>University of California, San Francisco, United States, <sup>9</sup>Leiden University Medical Center, Leiden, Netherlands

**Background:** Denosumab is a fully human monoclonal antibody (IgG<sub>2</sub> subclass) that inhibits bone resorption by inhibiting RANKL, a key mediator of osteoclast formation, function, and survival. The effect of denosumab on the progression of joint damage in patients with RA on csDMARDs background treatment from the first 12 months (double-blind, placebo-controlled) of the Phase 3 DESIRABLE study has previously been reported.<sup>1</sup>

**Objectives:** To evaluate the safety and efficacy of long-term treatment with denosumab 60 mg every 6 months (Q6M) or every 3 months (Q3M) with RA patients in long term treatment phase of the DESIRABLE study.

**Methods:** Upon completion of the 12-month, double-blind phase, all patients were to receive denosumab 60 mg/Q6M or 60 mg/Q3M and calcium and vitamin D daily during the 36-month, open-label extension phase. Patients were randomized in a 1:1:2:2 ratio to receive one of four treatments (figure 1). In this analysis, the continuous administration group received 36 months of denosumab treatment, and the cross-over group received 24 months of denosumab treatment (12 month of placebo in DB phase and 24 months of denosumab treatment phase). The radiographic evaluation was the change from baseline to 12, 24 and 36 months in the van der Heijde modified total Sharp score (mTSS). Radiographs of hands and feet at baseline, 12, 24 and 36 months were scored with blinded time order by 2 readers independently. Average score of the 2 readers is used for the analysis. Missing scores were imputed using linear extrapolation/interpolation.

Figure 1 Study design

Characteristic	Visit	Cross-over group		Continuous administration group	
		Placebo/denosumab 60mg Q6M N = 105	Placebo/denosumab 60mg Q3M N = 101	Denosumab 60mg Q6M N = 191	Denosumab 60mg Q3M N = 195
mTSS	12 months	1.29 ± 2.86	1.60 ± 3.62	1.25 ± 4.16	0.98 ± 3.01
	24 months	2.33 ± 4.73	2.05 ± 4.35	2.12 ± 9.10	1.42 ± 4.02
	36 months	2.93 ± 6.56	2.49 ± 4.70	2.26 ± 6.66	1.71 ± 4.59
ES	12 months	0.79 ± 1.76	0.87 ± 2.48	0.70 ± 2.39	0.27 ± 0.98
	24 months	1.23 ± 2.36	1.01 ± 2.48	1.09 ± 3.55	0.36 ± 1.35
	36 months	1.54 ± 3.39	1.18 ± 2.96	0.96 ± 3.36	0.40 ± 1.51
JSN score	12 months	0.51 ± 1.44	0.63 ± 1.75	0.59 ± 2.13	0.71 ± 2.42
	24 months	1.10 ± 2.87	1.04 ± 2.27	1.03 ± 3.13	1.07 ± 3.20
	36 months	1.39 ± 3.83	1.31 ± 2.87	1.30 ± 4.04	1.31 ± 3.67

Table 1 Change from baseline in mTSS, ES and JSN score in DB and long-term treatment phase. Data presented are mean ± SD

**Results:** 667 (placebo/Q6M (P/Q6M), n=113; placebo/Q3M (P/Q3M), n=110; Q6M, n=222; Q3M, n=222) received at least one dose of study drug, and 607 (P/Q6M, n=105; P/Q3M, n=103; Q6M, n=199; Q3M, n=200) completed the DB period and entered the long-term extension. In both continuous administration and

cross-over group, sustained inhibition of mTSS and erosion score (ES) progression was observed during long-term treatment phase (table 1). No effect on joint space narrowing (JSN) was observed (table 1). Overall proportions of patients with no progression (ie, mTSS change  $\leq 0.5$ ) at 36 months were 56.8% in P/Q6M, 53.3% in P/Q3M, 66.3% in Q6M group, and 65.7% in Q3M group. Incidence of adverse events (AEs), serious AEs and AEs leading to discontinuation of study drug were similar across treatment groups. No events of atypical femoral fracture were observed.

**Conclusions:** Denosumab treatment was associated with sustained inhibition of progression of joint destruction for up to 36 months and was generally well tolerated in Japanese patients with RA on csDMARDs. Denosumab has the potential to be a new therapeutic option to inhibit the progression of structural damage for patients with RA.

**Background:** Abatacept (ABT) is clinically used as the only T-cell modifier available for rheumatoid arthritis treatment and has shown similar efficacy as tumour necrosis factor inhibitors and a safer profile, especially a lower infection ratio in registry data. Latourte et al. recently published the results of perioperative complications of orthopaedic and other types of surgery in patients using ABT. However, they did not compare the complication rates with those in patients who received

csDMARDs. It remains unknown whether ABT is associated with more postoperative complications than conventional synthetic DMARDs (csDMARDs).

**Objectives:** The aims of this study were to investigate whether ABT is associated with more adverse events after orthopaedic surgery compared with csDMARDs and, if so, to identify significant risk factors for those events.

**Methods:** A retrospective multicenter nested case-control study was performed in 18 institutions. Patients receiving ABT were matched individually with patients receiving csDMARDs and/or steroid. Serious adverse events were defined as surgical site infection, delayed wound healing, deep vein thrombosis or pulmonary embolism, flare-up, serious infection in other organs. The incidence rates of serious adverse events in both groups were compared with Mantel-Haenszel test. Risk factors for serious adverse events in the ABT group were analyzed by logistic regression model.

**Results:** A total of 3358 cases were collected. After inclusion and exclusion, 2651 patients were selected for matching, and 194 patients in 97 pairs were chosen for subsequent comparative analyses between the ABT and control groups. No between-group differences were detected in the incidence rates of each adverse event or in the combined incidence rate of adverse events. The odds ratio of the history of serious infection for serious adverse events was 12.6 (95%CI 1.12-141, P=0.04) in patients who received ABT and underwent orthopaedic surgery.

**Conclusions:** Compared with csDMARDs and/or steroid without ABT, adding ABT to the treatment does not appear to increase the incidence rates of postoperative adverse events in rheumatoid arthritis patients undergoing orthopaedic surgery. A history of serious infection is a significant risk factor for both infection and other serious adverse events, and such patients should be treated with particular caution.

#### SAT0175 RESPONSE TO BIOLOGIC TREATMENT IMPROVES SEXUAL HEALTH ASSESSED BY THE QUALISEX SCORE IN RA

A. Perdriger<sup>1</sup>, C. Lucas<sup>1</sup>, J. Sibilia<sup>2</sup>, J.-E. Gotteberg<sup>2</sup>. <sup>1</sup>rheumatology, rheumatology Department, Rennes university, Rennes Cedex 2, <sup>2</sup>rheumatology, strasbourg University, strasbourg, France

**Background:** Sexual health of RA patients is an aspect of the care often neglected and about which little is known. Qualisex is a simple (10 questions) and valid tool investigating impact of RA on sexuality. This tool can be useful to assess this important aspect of quality of life. (Gossec and al, *Clin Exp Rheum*, 2012).

**Objectives:** Qualisex questionnaire was used in active RA patients of the ROC (Rotation or change) study (Gotteberg et al, *JAMA* 2016) in order to investigate the association between disease activity and response to a biologic treatment and sexual health.

**Methods:** Among 153 patients of the randomized controlled trial "ROC", which compared a second anti-TNF to a non-TNF biologic in RA patients with inadequate response to a first anti-TNF. Qualisex questionnaire was proposed to 83 RA patients, and 57 of them filled the questionnaire before and after 6 months of their allocated biologic. Changes in the qualisex score was analyzed according to the variation of the clinical and biological parameters.

**Results:** The mean age of the 57 RA patients studied was 50.2 (9.6) years. The mean duration of disease was 11.2 (9.5) years, and 43 (75.4%) were female. After 6 months of treatments, 19 were considered with a good response to the treatment according to EULAR response (DAS 28 VS  $< 3.2$  and a variation of 0.6 of the DAS from the base line).

The mean value of qualisex score was 4.05 (+/- 2.53) at V0 and 3.91 (+/- 2.45) after 6 months of treatment. The variation of the qualisex score was more important among the 19 responder patients than among the 43 patients with a persistently active disease. Changes in the qualisex score was significantly correlated to the changes in DAS28, in asthenia, and in SF36 mental score, but not with changes in pain, or in SF36 physical score.

Variables correlation with qualisex score P value

Variation of DAS 28 CRP 0.33 0.01

Variation of DAS 28 VS 0.27 0.04

Variations of asthenia 0.31 0.03

Variation of pain 0.13 NS

Variations of SF 36 physical score -0.21 NS

Variation of SF36 mental score -0.3 0.03

**Conclusions:** This first study of sexual health of RA patients in a randomized trial demonstrates an improvement in sexual health in patients responders to a biologic treatment. Improvement of sexual health was associated with a decrease in disease activity and asthenia.

#### SAT0176 CONTRIBUTION OF CD4+ T CELLS DECREASE ON CLINICAL RESPONSE TO RITUXIMAB IN RHEUMATOID ARTHRITIS

A. Bensalem<sup>1</sup>, D. Mulleman<sup>1,2</sup>, G. Thibault<sup>1,3,4</sup>, N. Azzopardi<sup>3</sup>, G. Paintaud<sup>1,5</sup>, P. Goupille<sup>1,2</sup>, D. Ternant<sup>1,5</sup>. <sup>1</sup>EA GICC, University of Tours, <sup>2</sup>Rheumatology, CHRU de Tours, <sup>3</sup>CNRS ERL 7001, University of Tours, <sup>4</sup>Immunology, <sup>5</sup>Pharmacology-Toxicology, CHRU de Tours, Tours, France

**Background:** Rituximab (RTX) is approved for the treatment of rheumatoid arthritis (RA), but there is a large inter-individual variability in clinical response. A better response was previously associated with a decrease in CD4+ T cell counts [1, 2].

**Objectives:** This study aimed at analyzing the contribution of CD4+ T cell decrease in the clinical response in RA patients treated with RTX.

**Methods:** In this retrospective monocentric observational study, 52 patients were assessed. All patients had received 2 infusions of 1000 mg of RTX 2 weeks apart. Disease activity score in 28 joints (DAS28) was used as clinical endpoint. RTX serum concentrations, peripheral blood CD4+ counts, and DAS28 were measured before and after each RTX infusion and at 3, 6 and 9 months after last infusion. A population PK-PD model, including a physiological turnover and direct response model, was developed to estimate the probability of CD4+ counts decrease. The turnover model was used to describe the effect of RTX on CD4+ T-cell counts, and the direct model was used to describe both RTX and CD4+ T cell count effect on DAS28.

**Results:** The probability of CD4+ counts decrease was estimated at 0.75. Patients with a CD4+ decrease had a higher  $\Delta$ DAS28 than the patients without CD4+ decrease, with a maximal  $\Delta$ DAS28 of -1.34 and -0.64 in patients with and without CD4+ cell decrease, respectively. Moreover, at M6, patients with CD4+

cell decrease had a median DAS28 of 3.5 (IQR: 2.7 – 4.4), among them 39.5 % with low disease activity (DAS28 $\leq$ 3.2) and 22.3 % in remission (DAS28<2.6). At the same time point, median DAS28 of patients without CD4+ cell decrease was 4.3 (IQR: 3.5 – 5.1), among them 17.7 % with low disease activity, and 8.6 % in remission (see Figure 1 Box plot of DAS28 in patients with and patients without CD4+ decrease.).

**Conclusions:** This is the first study to quantify the contribution of CD4+ T cell decrease to the clinical response in RA patients treated with RTX.

#### SAT0177 REAL-WORLD INTERRUPTIONS IN JANUS KINASE INHIBITOR THERAPY OBSERVED AMONG BIOLOGIC-NAÏVE AND BIOLOGIC-EXPERIENCED RHEUMATOID ARTHRITIS PATIENTS

B. Chastek<sup>1</sup>, E. Koep<sup>1</sup>, U. G. Mallya<sup>2</sup>, A. Cockerham<sup>2</sup>, J. Choi<sup>2</sup>, S. Boklage<sup>3</sup>, D. E. Furst<sup>4,5,6</sup>. <sup>1</sup>Optum, Eden Prairie, <sup>2</sup>Sanofi, Bridgewater, <sup>3</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, <sup>4</sup>University of California Los Angeles, Los Angeles, <sup>5</sup>University of Washington, Seattle, United States, <sup>6</sup>University of Florence, Florence, Italy

**Background:** Orally administered janus kinase inhibitors (JAKi) can be used to treat moderate-to-severe rheumatoid arthritis (RA).

**Objectives:** Examine real-world patterns of use, including interruptions in therapy and switching, in biologic-naïve and biologic-experienced patients with RA newly prescribed a JAKi.

**Methods:** A retrospective analysis was performed using healthcare claims data from the Optum Research Database. Commercial and Medicare Advantage patients aged  $\geq$ 18 years were included with:  $\geq$ 1 pharmacy claim for a JAKi 01 January 2012–29 February 2016 (index date = date of first claim); continuous enrollment in health plan for  $\geq$ 12 months before and 13 months post-index; and  $\geq$ 1 claim with a RA diagnosis (ICD-9 = 714.0x; ICD-10 = M05\* or M06\*) during baseline or on the index date. A variable length pre-index period to 01 January 2006 was implemented to capture certain measures. Persistence was defined as the time from index prescription fill to earliest gap in fills  $\geq$ 30 days (interruption) or switching to a biologic disease-modifying antirheumatic drug (bDMARD). Patients were classified as being: persistent with the index therapy for the full year, switching before interruption, switching after interruption, interruption with restart, and interruption without restart (discontinuation). Patients were assigned to two groups: those with and without  $\geq$ 1 claim for bDMARD treatment during the variable length pre-index period (biologic-experienced and biologic-naïve). Data were expressed as % or mean (SD). Sensitivity analyses assessed prescription fill gaps  $\geq$ 90 days.

**Results:** Of 1059 patients who met the inclusion criteria, 80.2% were biologic-experienced, 81.8% female, mean age 56.2 (11.8) years. More biologic-naïve patients (48.6%) had Medicare Advantage coverage than biologic-experienced (22.3%). For the primary analysis, 72.4% of patients were not persistent for the 1-year following initiation of a JAKi, with 39.1% not persistent beyond 90 days (figure 1). Among non-persistent patients, 42.4% interrupted and restarted a JAKi (time from index to restart, 168.9 [83.8] days), 16.8% switched to a bDMARD before interruption, 13.3% switched after interruption and 27.5% discontinued bDMARD and JAKi therapy (time to discontinuation, 148.4 [117.6] days). More biologic-naïve than biologic-experienced patients neither initiated a bDMARD nor restarted a JAKi after interruption (44.2% vs 23.3%, respectively;  $P<0.001$ ). For the sensitivity analysis, 52.6% were non-persistent for the full year.

**Figure 1** Kaplan-Meier curve of persistence with JAKi therapy

**Conclusions:** Most patients (80.2%) newly initiating JAKi therapy had prior bDMARD experience. Over 70% were non-persistent with JAKi treatment for 1 year, with 39% non-persistent beyond 90 days. For non-persistent patients, the pattern of JAKi use was characterized most as interrupting with restart (42%), followed by switching (30%), and then discontinuation (28%). Reasons for the high non-persistence rate are unknown but may include suboptimal efficacy or intolerance. Further research is needed to elucidate these points.

## SAT0178 PREDICTORS OF DRUG SURVIVAL OF ABATACEPT IN RHEUMATOID ARTHRITIS – RESULTS FROM A LARGE NATIONAL QUALITY REGISTER COHORT STUDY

G. Cagnotto<sup>1,2</sup>, M. Willim<sup>2,3</sup>, J.-Å. Nilsson<sup>1,2</sup>, S. Saevarsdottir<sup>4</sup>, C. Turesson<sup>1,2</sup>.

<sup>1</sup>Rheumatology, Department of Clinical Sciences, Malmö, Lund University,

<sup>2</sup>Department of Rheumatology, SKÅNE UNIVERSITY HOSPITAL, Malmö,

<sup>3</sup>Rheumatology, Department of Clinical Sciences, Lund, Lund University, Lund,

<sup>4</sup>Rheumatology Unit, Department of Medicine, Solna, Karolinska Institutet, Stockholm, Sweden

**Background:** Abatacept is a biologic disease modifying anti-rheumatic drug (bDMARD) used to treat rheumatoid arthritis (RA). There is growing experience with abatacept in many countries. National registers are useful resources for investigation of long term real world outcomes.

**Objectives:** To compare the effectiveness of abatacept in the treatment of RA between bionative patients and patients with previous bDMARD treatment, and to investigate predictors of remaining on treatment with abatacept.

**Methods:** This was an observational cohort study, based on a national quality register database. Patients with a diagnosis of RA who initiated treatment with abatacept between April 1, 2006 and November 20, 2017, were included. Patients were censored at abatacept discontinuation, death, migration, or the end of the study period. Analyses were stratified by previous exposure to bDMARDs. Survival on drug was estimated using the Kaplan-Meier method. Predictors of discontinuation of abatacept were investigated in Cox Proportional Hazards analyses, with significance-based backwards stepwise selection of variables for the final multivariate model.

**Results:** A total of 2716 patients with RA (80 % females, mean age 59 years, mean duration of RA 14 years) started abatacept during the study period. Of these, 17 % had no previous bDMARD treatment (bionative patients), 27 % had received 1 bDMARD previously, and 56 % had been treated with  $\geq 2$  bDMARDs.

Fifty percent each of the patients received intravenous and subcutaneous therapy. At the time of abatacept initiation, 57 % were on methotrexate (MTX), and 48 % were treated with glucocorticosteroids. There were significant differences in drug survival across categories of previous bDMARD exposure ( $p=0.002$ ). The median survival time on treatment was 2.23 years for bionative patients (95 % confidence interval (CI) 1.69–2.79), 1.68 years for those with 1 previous bDMARD (95 % CI 1.34–2.01) and 1.56 years for those with  $\geq 2$  previous bDMARDs (95 % CI 1.35–1.76). At 6 months, 88 % of bionative patients remained on abatacept, compared to 74 % at 12 months. The corresponding figures for those with 1 or  $\geq 2$  previous bDMARDs were 78 % and 61 %, and 76 % and 59 %, respectively. In bivariate analyses, bionative patients were less likely to discontinue treatment compared to those treated with  $\geq 2$  previous bDMARDs previously (Table). Bionative patients were more often male (28 % vs 18 %) and had lower pain scores (mean Visual analogue scale score 58 vs 62) compared to those previously exposed to  $\geq 2$  bDMARDs. Measures of disease severity were associated with reduced drug survival (Table), but age, RA duration and method of administration had no significant impact on discontinuation. In the final multivariate model, pain increased the risk of abatacept discontinuation, whereas male patients and those on concurrent MTX had a reduced risk of stopping abatacept (Table).

### Significant predictors for abatacept discontinuation. Cox regression analysis

		Unadjusted analysis HR (95 % CI)	Multivariate analysis = final model HR (95 % CI)
Sex	Male	0.85 (0.75-0.96)	0.86 (0.74-0.98)
No of previous bDMARDs	$\geq 2$ bDMARDs	reference (1.0)	*
	Bionative	0.78 (0.68-0.90)	*
	1 bDMARD	0.94 (0.84-1.05)	*
Baseline clinical characteristics	DAS28-CRP (per SD)	1.11 (1.04-1.17)	*
	VAS pain (per SD)	1.14 (1.08-1.21)	1.14 (1.07-1.20)
	Current Methotrexate	0.86 (0.78-0.96)	0.85 (0.76-0.95)
	HAQ-DI (per SD)	1.10 (1.04-1.17)	*

\*Not included in the final model

**Figure 1.** Significant predictors for abatacept discontinuation. Cox regression analysis\*Not included in the final model

**Conclusions:** Survival on abatacept was significantly longer in bionative RA patients compared to those previously exposed to bDMARDs. In the bionative subset, 50 % of the patients remained on treatment after 2.2 years. Concomitant MTX therapy, male sex and low pain scores were associated with longer drug survival for abatacept.

## SAT0179 THE BLOOD B-CELL SUBSETS AND EFFECT OF TOCILIZUMAB THERAPY ON THEM IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Gerasimova<sup>1</sup>, T. Popkova<sup>2</sup>, A. Aleksankin<sup>2</sup>, S. Davidyan<sup>3</sup>, A. Martinova<sup>2</sup>, E. Aleksandrova<sup>2</sup>. <sup>1</sup>34A, Kashirskoe Shosse, Gerasimova Elena, <sup>2</sup>34A, Kashirskoe Shosse, <sup>3</sup>V.A.Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** The use of the IL-6 receptor antagonist, tocilizumab (TCZ), in rheumatoid arthritis (RA) produce pleiotropic effects that also involve circulating B-cells. Preliminary reports have suggested that B cell function and humoral immune responses might be modulated by TCZ treatments in RA pts.

**Objectives:** To assess the effect of 12 months (mo) TCZ therapy on B-cell phenotype and gene expression in RA and to analyze the association between B-cell subsets and RA activity.

**Methods:** 24 active RA pts (20 F/4 M); median age 55[49; 64] years; disease duration 72[24; 108]m; DAS28 score 5,8[5,3;6,3]; RF+100%, ACCP+ 87% were treated in an open-label study with tocilizumab (8 mg/kg every 4 weeks). Immunophenotyping was performed at baseline and 12 mo. Pts were assessed for B-cell subpopulations and laboratory data: ESR, RF, ACCP, CRP. CD19+B cells, memory B cells (CD19+CD27+), non-switched memory B cells (CD19+CD27+ IgD-), switched memory B cells (CD19+ CD27+IgD-), naive (CD19+CD27-IgD+), double-negative (CD19+CD27-IgD-), transitional (CD19+CD38++CD10+IgD+CD27-) B cells, and plasmablasts (CD19+CD38+++CD27+IgD-CD20-) were analyzed using multicolor flow cytometry.

**Results:** At baseline, the absolute counts of memory B cells (CD19+CD27+) and switched memory B cells (CD19+CD27+IgD-) were lower in RA pts compared to

healthy donors: 0,0015(0,001–0,003) vs 0,003(0,001–0,007) and 0,01(0,005–0,02) vs 0,02(0,01–0,04), respectively,  $p < 0,01$  for both cases. At baseline, a significant correlation was found in RA pts between absolute counts of memory B cells (CD19+CD27+) and CRP ( $r = 0,50$ ,  $p < 0,05$ ); the percentage and absolute counts of plasmablasts (CD19+CD38+++CD27+IgD-CD20-) and RF ( $r = 0,41$  and  $r = 0,52$ ,  $p < 0,05$ ). After 12 mo of TCZ therapy, 54% of pts were categorized as good responders, 46% of pts – as moderate responders according to the EULAR response criteria. Reductions in the percentages and absolute counts of plasmablasts (CD19+CD38+++CD27+IgD-CD20-) were documented after 12 mo of TCZ therapy: 0,15%(0,1–0,3) vs 0,1%(0,01–0,1) and 0,0003(0,00007–0,004) vs 0,0001(0–0,0003), respectively,  $p < 0,05$ . The median percentages/absolute counts of switched memory B cells (CD19+CD27+IgD-) were 6,8%(3,6–11,6)/0,01(0,005–0,02) at baseline; and 3,1%(1,1–4,2)/0,003(0,002–0,006) after 12 mo of TCZ therapy,  $p > 0,05$ . After 12 mo of TCZ therapy, the median percentages and absolute counts of memory B cells (CD19+CD27+) and switched memory B cells (CD19+CD27+IgD-) became lower in RA pts than in the controls: 1,0%(0,7–1,2) vs 2,2%(1,1–3,0); 0,001(0,006–0,003) vs 0,003(0,001–0,007); 3,1%(1,1–4,2) vs 12,8%(9,3–17,0); 0,003(0,002–0,006) vs 0,02(0,01–0,04), respectively,  $p < 0,05$ , respectively, for all cases. Other B-cell subpopulations did not changed after 12 mo of TCZ therapy as compared to baseline values.

**Conclusions:** Immunophenotyping in pts with active RA showed the decrease in the absolute counts of memory B cells (CD19+CD27+), switched memory B cells (CD19+CD27+IgD-) as compared to healthy subjects. Positive correlation between the counts of memory B cells and plasmablasts and values of laboratory indicators of RA (CRP, RF) suggests that B-lymphocytes may be involved in RA pathogenesis. The reduction in the levels of plasmablasts after 12 mo of TCZ therapy was observed.

**Disclosure of Interest:** None declared

#### SAT0180 TWO-YEAR CONSOLIDATED SAFETY DATA FOR ABP 501 IN PATIENTS WITH MODERATE TO SEVERE RHEUMATOID ARTHRITIS

E. Krishnan<sup>1</sup>, N. Zhang<sup>1</sup>, H. Wang<sup>1</sup>. <sup>1</sup>Biosimilars Development, Amgen Inc., Thousand Oaks, United States

**Background:** Biosimilars are expected to have similar long-term safety profiles as originator products.

**Objectives:** To describe the consolidated, 2-year safety data on ABP 501, an approved biosimilar to adalimumab.

**Methods:** We combined individual patient data from a 26-week randomized controlled head-to-head study (parent study) comparing ABP 501 with adalimumab (NCT01970475) and its 72-week open-label extension (OLE) study (NCT02114931) in which all patients received only ABP 501. Safety data were reported by exposure-adjusted incidence rate as the number of subjects with the specified adverse events \*(AEs) per 100 person-years. AEs from the parent and OLE studies were summarized; for each category, patients were included only once based on the 1st event in that AE category. All comparisons were performed descriptively.

**Results:** In the parent study, 264 patients received ABP 501 and 262 patients received adalimumab reference product (RP). Of these, 229 in the ABP 501 arm and 237 in the RP arm entered and were treated in the open-label extension study. The exposure-adjusted incidence rate for treatment-emergent AEs by treatment group are shown in the Table.

Adverse Event Category	ABP 501/ABP 501 (N = 264)	Adalimumab RP/ABP 501 (N = 262)
Exposure-adjusted incidence rate n/E (r)		
Any AE	187/187.6 (99.7)	197/192.2 (102.5)
Any grade $\geq 3$ AE	32/405.2 (7.9)	30/410.6 (7.3)
Any treatment-related AE	72/345.3 (20.9)	79/344.3 (22.9)
Any grade $\geq 3$ treatment-related AE	6/427.2 (1.4)	5/433.6 (1.2)
Any serious AE	34/407.6 (8.3)	32/410.1 (7.8)
Any treatment-related serious AE	6/427.9 (1.4)	2/434.3 (0.5)
Any events of interest	141/261.5 (53.9)	154/254.7 (60.5)
Infections and infestations	125/289.9 (43.1)	130/287.4 (45.2)
Liver enzyme elevations	25/401.4 (6.2)	20/415.6 (4.8)
Hypersensitivity	19/407.7 (4.7)	22/412.2 (5.3)
Injection site reactions	6/417.9 (1.4)	13/418.3 (3.1)
Hematological reactions	6/421.8 (1.4)	7/426.1 (1.6)
Malignancies	6/423.9 (1.4)	3/433.6 (0.7)
Heart failure	1/428.4 (0.2)	2/435.6 (0.5)

n = number of subjects with the specified AE; E = total subjects exposure-time (patient-years); r = exposure-adjusted incidence rate per 100 patient-years ( $100 * n/E$ ).

**Conclusions:** Over the 2-year observation period, there were no meaningful differences in AEs between adalimumab reference product and ABP 501.

#### SAT0181 EFFECT OF ANTI-IL-6 THERAPY ON SERUM LEVELS OF METABOLIC SYNDROME-RELATED BIOMARKERS IN RHEUMATOID ARTHRITIS PATIENTS

F. Genre<sup>1</sup>, S. Remuzgo-Martínez<sup>1</sup>, R. López-Mejías<sup>1</sup>, V. Mijares<sup>1</sup>, J. Calvo-Alen<sup>2</sup>, R. Blanco<sup>1,3</sup>, J. Llorca<sup>4</sup>, S. Castañeda<sup>5</sup>, M. Á. González-Gay<sup>1,3,6,7</sup>. <sup>1</sup>Epidemiology, Genetics and Atherosclerosis Research Group on Systemic Inflammatory Diseases, IDIVAL, Santander, <sup>2</sup>Rheumatology Department, Hospital Universitario Araba, Vitoria, <sup>3</sup>Rheumatology Department, Hospital Universitario Marqués de Valdecilla, <sup>4</sup>Epidemiology and Computational Biology Department, School of Medicine, University of Cantabria, and CIBER Epidemiología y Salud Pública (CIBERESP), IDIVAL, Santander, <sup>5</sup>Rheumatology Department, Hospital Universitario La Princesa, IIS-IPrincesa, Madrid, <sup>6</sup>School of Medicine, University of Cantabria, Santander, Spain, <sup>7</sup>Cardiovascular Pathophysiology and Genomics Research Unit, School of Physiology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

**Background:** Metabolic syndrome (MeS) is a pathologic state that encompasses metabolic anomalies such as hyperglycemia, dyslipidemia, obesity and hypertension and that, apart from being a cardiovascular risk factor, it has been associated with chronic inflammatory diseases such as rheumatoid arthritis (RA)<sup>1,2</sup>. Ghrelin and retinol binding protein-4 (RBP-4) are two biomarkers associated with MeS, and are also linked to different cardiometabolic risk factors. In this regard, it is known that ghrelin exerts an anti-inflammatory role<sup>2</sup>.

**Objectives:** Since a beneficial effect on endothelial function has been reported for anti-IL-6 therapy<sup>3</sup>, we aimed to evaluate the effect of a single infusion of anti-IL-6 on the serum levels of ghrelin and RBP-4 in patients with RA.

**Methods:** Ghrelin and RBP-4 levels were measured in serum samples from 50 Spanish individuals with RA that fulfilled the 2010 classification criteria<sup>4</sup>, and that were under treatment with the anti-IL-6 monoclonal antibody Tocilizumab. Patients with diabetes mellitus or plasma glucose levels  $>110$  mg/dL were excluded. Blood samples were taken in the fasting state, immediately before (time 0) and after (time 60 minutes) Tocilizumab infusion.

**Results:** A significant increase in serum levels of ghrelin was observed after a single infusion of Tocilizumab (mean  $\pm$  standard deviation: 72.99  $\pm$  58.43 pg/mL versus 134.02  $\pm$  225.93 pg/mL, before and after Tocilizumab infusion,  $p = 0.04$ ). Serum levels of RBP-4 were not affected by the administration of Tocilizumab (mean  $\pm$  standard deviation: 23.48  $\pm$  13.99  $\mu$ g/mL versus 20.90  $\pm$  15.54  $\mu$ g/mL, before and after Tocilizumab infusion,  $p = 0.42$ ).

**Conclusions:** Our results show that ghrelin levels increase after a single infusion of Tocilizumab, supporting the hypothesis that IL-6 blockade has a rapid beneficial effect on factors associated with MeS and cardiovascular risk in RA patients. Hence, long-term treatment with anti-IL-6 may reduce the risk of developing cardiovascular disease in RA.

**Background:** The non-interventional ARATA study (NCT02251860) observes the clinical effectiveness and safety of subcutaneous Tocilizumab [TCZ] s.c. treatment under routine conditions over a 2-year period.

**Objectives:** In this interim analysis, the treatment with TCZ s.c., in particular with respect to patient-reported outcomes regarding depression, fatigue and pain, was evaluated.

**Methods:** TCZ-naïve patients (Pts) (>18 years) with RA, who receive TCZ s.c. treatment, could be included in the study since 2014. Demographic and disease-specific characteristics, the progression of the disease under treatment, concomitant medications, adverse events (AE) and patient questionnaires were documented.

**Results:** This interim analysis (reporting date 01-FEB-2017) included 912 Pts. 75% of the Pts were female, the average age at baseline (BL) was 57 years, the median disease duration was 8 years. 319 Pts (35%) were pretreated exclusively with sDMARD and 585 Pts (64%) were also pretreated with bDMARD. For the readjustment, TCZ s.c. was applied for 69% without sDMARD, 31% in combination with MTX and for 66% with glucocorticoids.

In the course of the study, 65% of the Pts achieved a DAS28-BSG remission. Furthermore, the functional restrictions in day-to-day life (HAQ-DI D from BL: -0.3) improved. No new safety signals were observed.

By means of the Beck Depression Inventory (BDI-II) score (Englbrecht et al., Arthritis Care Res 2017; 69:58–66), validated for RA, the depressive symptoms could be documented. At baseline, 186 Pts (50%) showed no, 70 (19%) minor, 67 (18%) moderate and 47 (13%) severe depression. Under the treatment with TCZ, the depressive symptoms improved (compare figure 1).

The patients reported a significant improvement of the pain (VAS: average change from BL to week 52 by -21 points and to week 104 by -24 points) as well as the fatigue (VAS: average change from BL to week 52 by -11 points and 104 by -12 points).

**Conclusions:** In the ARATA study, TCZ s.c. demonstrated an effective and persistent reduction in the disease activity of the treated RA patients. The patients confirmed improved physical functionality as well as less fatigue and pain. Depression plays an important role in RA, as the results of BDI-II highlight, whereby the depressive symptoms also improved distinctively under treatment with TCZ s.c.

**SAT0183 SWITCHING FROM ADALIMUMAB TO SARILUMAB IS ASSOCIATED WITH COMPARABLE EFFICACY BUT LOWER FUNCTIONAL IMPROVEMENT VERSUS CONTINUOUS SARILUMAB MONOTHERAPY THROUGH 48-WEEK OPEN-LABEL EXTENSION (OLE) OF THE PHASE 3 MONARCH TRIAL**

G. R. Burmester<sup>1</sup>, G. St John<sup>2</sup>, M. Iglesias-Rodriguez<sup>3</sup>, C.-C. Hu<sup>3</sup>, T. Raskina<sup>4</sup>, H. Amital<sup>5</sup>, A. Gomez Centeno<sup>6</sup>, A. Rubbert-Roth<sup>7</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology, Charité – University Medicine Berlin, Free University and Humboldt University Berlin, Berlin, Germany, <sup>2</sup>Regeneron Pharmaceuticals, Inc, Tarrytown, NY, United States, <sup>3</sup>Sanofi Genzyme, Bridgewater, NJ, United States, <sup>4</sup>Kemerov State Medical Academy of Roszdrav, Kemerovo, Russian Federation, <sup>5</sup>Sheba Medical Center, Tel-Hashomer, Israel, <sup>6</sup>Corporació Sanitària Parc Taulí, Barcelona, Spain, <sup>7</sup>Klinik fuer Rheumatologie, Kantonsspital St. Gallen, St. Gallen, Switzerland

**Background:** Sarilumab is a human mAb blocking IL-6R $\alpha$ . In Phase 3 MONARCH (NCT02332590), sarilumab (200 mg subcutaneously [SC] every 2 wks [q2w] for 24 wks) was superior to adalimumab monotherapy (40 mg SC q2w) in reducing disease activity and improving physical function in RA patients (pts) with an inadequate response or intolerance to methotrexate.

**Objectives:** To assess whether pts who achieved clinical response on sarilumab during MONARCH sustained this response in the OLE and to evaluate efficacy and safety of switching from adalimumab to sarilumab vs continuous sarilumab treatment.

**Methods:** Pts completing the double-blind phase of MONARCH were eligible for the ongoing OLE, in which all pts receive sarilumab (200 mg SC q2w) for a maximum duration of 276 wks. Disease activity, physical function, and safety were assessed regularly.

**Results:** 320/369 Pts enrolled in MONARCH entered the OLE; pts either switched from adalimumab to sarilumab (n=155) or continued on sarilumab (n=165). At OLE entry (Wk 24 of the double-blind phase), the mean  $\Delta$  from baseline DAS28-ESR was -2.28 in the switch group vs -3.36 in the continuation group, and by Wk 48 was -4.06 vs -4.18, respectively. By Wk 48 of the OLE, the proportion of pts in the switch and continuation groups who achieved DAS28-ESR $\leq$ 3.2 was 61.3% vs 61.2%, DAS28-ESR $<$ 2.6 was 43.9% vs 49.7%, and DAS28-CRP $<$ 2.6 was 52.9% vs 52.1%, respectively. From OLE entry to Wk 48, mean HAQ-DI improved in the switch group from 1.21 to 0.91, but did not reach the level of improvements in the continuation group (1.01 to 0.84). See table 1 for ACR responses. After 166 vs 182 cumulative patient-years exposure in the switch vs continuation groups, treatment-emergent adverse events (TEAEs) were observed in 76.1% vs 70.9%, serious TEAEs in 11.0% vs 3.6%, and infections in 41.9% vs 35.8%, respectively, with 2 deaths in the switch group (malignancy; cerebrovascular accident) and 1 death (subarachnoid hemorrhage) in the continuation group. No GI related AEs (ulcerations, perforations or diverticulitis) were observed in either group.

**ACR responses & mean HAQ-DI in the OLE of MONARCH (OLE ITT Popn)**

**Figure 1** Mean V from baseline in DAS28-ESR (OLE population; as observed). **Conclusions:** Switching from adalimumab (40 mg q2w) to sarilumab monotherapy (200 mg q2w) improved the signs and symptoms of RA to a similar level as continuous sarilumab treatment, and was associated with a lower HAQ-DI score, which may have resulted in numerical differences in ACR responses between the two groups.

the analysis. Treatment response was evaluated as achievement of “BASDAI50” or “ASDAS Clinically important improvement (CII)” at the 3-months’ and 6 months’ visits. Clinical and demographic parameters were compared between current/never and current/previous smoker groups. Demographic and descriptive data are presented by medians/interquartile ranges (IQRs). Groups were compared by non-parametric tests ( $\chi^2$ , Kruskal Wallis and Mann Whitney tests). Kaplan Meier plots, Cox and logistic regression analyses were calculated for treatment adherence and treatment response.

**Results:** Among 561 AS patients included in the study, 506 (90%) had known smoking status (37% current, 35% never, 17% previous smokers). The median follow-up time was 1.9 years (IQR 0.85–3.5) and disease duration was 3.1 years (0.6–7.7). At baseline, current smokers were younger (34, IQR 29–41) compared with never (38, IQR 30–46  $p=0.007$ ) and previous smokers (42, IQR 34–49  $p<0.001$ ). Current smokers had male predominance ( $n=148$ , 43.9%;  $n=85$ , 25.2%); lower erythrocyte sedimentation rate (28 mm/h (13–42); 34 mm/h, (20–49) and higher change in BASMI (40, IQR 10–57.5; 10, IQR 4–30) compared with never smokers (all  $p<0.005$ ). HLA status, body mass index, CRP, baseline disease indexes (BASDAI, BASFI, BASMI, HAQ, ASDAS) and treatment response was not found to be different between current and never smoker patients in our population (table 1). In multivariate analysis, male (OR:1.98; 95% CI (1.39–2.82),  $p<0.01$ ), HLA positive (OR:1.54; 95%CI (1.08–2.18),  $p=0.016$ ) and active DMARD user (OR:1.84; (95%CI 1.12–3.01)  $p=0.015$ ) patients had better treatment response and treatment adherence (HR:1.93; 95% CI (1.36–2.73); HR:1.60; 95% CI (1.13–2.27); HR:1.80; 95% CI (1.10–2.95) all  $p<0.005$ ) but smoking status were not significant ( $p>0.05$ ).

**Background:** Although there is good evidence that smoking has a dose-dependent impact on structural damage progression in ankylosing spondylitis (AS) the evidence is poor for its impact on disease activity, physical mobility, life quality and treatment response.

**Objectives:** We aimed to investigate the impact of smoking on disease activity, treatment adherence and treatment response in Turkish patients with AS treated with their first tumour necrosis factor-alpha inhibitor (TNFi) therapy in a real-life cohort.

**Methods:** 561 patients fulfilling the modified New York criteria for AS and treated with their first TNFi therapy since 2011 from 8 centers in Turkey were included in

**Background:** Measurement of serum drug levels can help clinicians tailor treatment with TNF-inhibitors. An association between certolizumab pegol (CP) serum levels and treatment response in rheumatoid arthritis (RA) patients (pts) has previously been demonstrated in a prospective observational study (1). These results need to be confirmed in other studies, with particular focus on finding an optimal therapeutic serum level for CP.

**Objectives:** To examine the association between serum CP drug levels and treatment response in RA pts and to identify a therapeutic target level.

**Methods:** Patients with a clinical diagnosis of RA starting standard treatment with CP included in the NOR-DMARD registry with biobank sample at 3 months follow-up, were included in the present analyses. Serum drug levels (non-trough) were analysed with an in-house immunofluorometric assay automated on the AutoDELFA immunoassay platform. We studied association between serum CP level and ΔDAS28 and EULAR good/moderate response at 3 months by multi-variable linear and logistic regression analyses, respectively, adjusting for age, sex and prior bDMARD (Y/N).

**Results:** In 91 included patients, median serum drug level at 3 months follow up was 34.7 mg/L (17.6–44.6). Response data were available in 81/91 patients. Serum CP level ≥20 mg/L was associated with greater improvement in DAS28 at

3 months ( $\beta=0.89$  (95% CI 0.03–1.74),  $P=0.04$ . 44.4 % of pts with CP level <20 mg/L achieved EULAR response after 3 months treatment, while 73.5 % of pts with CP level 20–40 mg/L and 55.2 % with  $\geq 40$  mg/L were responders. However, the difference in EULAR response between pts with CP level  $\geq 20$  vs. <20 mg/L did not reach statistical significance (OR 1.5 (95% CI 0.5–5.1),  $P=0.48$ ).

**Conclusions:** Certolizumab serum levels  $\geq 20$  mg/L were associated with DAS28 improvement, but not significantly with EULAR response after 3 months treatment in RA pts. We suggest 20 mg/L as a lower target limit for non-trough CP samples in RA-patients. No additional benefit of having a certolizumab level over 40 mg/L was observed.

SAT0186

#### TREATMENT RESPONSE OF INTRAVENOUS TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS BASED ON THE LEVEL OF PRIOR EXPOSURE TO BIOLOGIC THERAPY: RESULTS FROM THE KOBIO

K. Shin<sup>1</sup>, S.-K. Lee<sup>1</sup>, S. Oh<sup>2</sup>, H.-A. Kim<sup>3</sup>, Y. W. Song<sup>4</sup>. <sup>1</sup>Division of Rheumatology, <sup>2</sup>Department of Biostatistics, Seoul Metropolitan Government-Seoul National University Hospital Boramae Medical Center, Seoul, <sup>3</sup>Division of Rheumatology, Ajou University School of Medicine, Suwon, <sup>4</sup>Division of Rheumatology, Seoul National University Hospital, Seoul, Korea, Republic Of

**Background:** Previous studies have showed that response rate to biologic therapy in patients with rheumatoid arthritis (RA) are lower in those who had prior exposure to multiple biologic agents compared with first-time users. However, most of these studies targeted on patients undergoing anti-TNF therapy.

**Objectives:** To investigate the treatment response of RA patients using intravenous tocilizumab (TOC) as the first biologic agent, comparing with those who had prior exposure to other biologic agents

**Methods:** Data of RA patients treated with TOC were obtained from the Korean College of Rheumatology Biologics Registry (KOBIO). Patients were grouped as first (1st)-line, second (2nd)-line, and third or more ( $\geq 3$ rd)-line users. Clinical outcomes including SDAI changes at the first year and second year of TOC therapy were evaluated, and subsequent switching to another biologic agent and its associated factors were analyzed using the Cox proportional hazard model.

**Results:** A total of 408 patients were included in the study; 1st-line ( $n=258$ ), 2nd-line ( $n=95$ ),  $\geq 3$ rd-line ( $n=55$ ) users. The mean age was 54.0 years, and mean disease duration of 8.2 years. At baseline, mean SDAI was 30.0, and 7.1% of patients were treated without a concomitant conventional DMARD, which increased to 21.6% at the end of the second year. The clinical response of related parameters in 1st-line TOC users were more robust than the 2nd-line or  $\geq 3$ rd-line users, and greater proportion of 1st-line users achieved remission or low disease activity at the second year ( $p=0.00291$ ) (figure). In addition, switching to another agent was more frequent in the 2nd-line or  $\geq 3$ rd-line users within 2 years (1st, 2nd,  $\geq 3$ rd-line users, 4.7%, 15.1%, 11.1%, respectively). A multivariate analysis revealed that higher baseline SDAI (HR 1.1018,  $p=0.00680$ ) and multiple prior exposure to biologics (HR 2.5751,  $p=0.0139$ ) were predictors of subjects switching to other agents.

**Conclusions:** Amongst RA patients with high disease activity who receive TOC, patients naïve to biologics have better treatment response and lower switch rates after two years.

SAT0187

#### GOLIMUMAB IMPROVES WORK PRODUCTIVITY AND ACTIVITY IMPAIRMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA), ANKYLOSING SPONDYLITIS (AS) AND PSORIATIC ARTHRITIS (PSA): 1-YEAR RESULTS FROM A NON-INTERVENTIONAL TRIAL IN GERMANY

I. Klaudius<sup>1</sup>, K. Krueger<sup>2</sup>, S. Remstedt<sup>3</sup>, A. Thiele<sup>4</sup>. <sup>1</sup>MSD Sharp & Dohme GmbH, <sup>2</sup>Praxiszentrum St. Bonifatius, Munich, <sup>3</sup>Rheuma Praxis, Berlin, <sup>4</sup>Krankenhaus St. Josef, Wuppertal, Germany

**Background:** Non-interventional studies (NIS) are essential instruments in pharmaceutical research not only for pharmaceutical companies but also for regulatory authorities or reimbursement bodies in Germany.

Aside from direct costs by a disease, German sick funds as well as health authorities have a keen interest in indirect costs, such as costs derived from loss of work productivity.

**Objectives:** It is the aim of this study to show the benefit of Golimumab (GLM) in work productivity and activity for RA, AS and PsA patients in Germany. The analysis was performed using the validated indication-specific Work Productivity Activity Impairment (WPAI) Questionnaire as primary endpoint. The WPAI is rated to be the most psychometrically validated and frequently used instrument for measuring of health-related work-productivity.

**Methods:** As primary endpoint, the change of work productivity impairment and ability for daily activities in month 3 (V1) versus baseline visit (V0) was evaluated.

All 4 subscores of the WPAI were analysed: disease related absence from work (absenteeism), working while sick (presenteeism), total work productivity impairment (TWPI) and activity impairment with TWPI as primary score.

In addition, an evaluation of the activity impairment in the mITT population (modified-Intention-To-Treat) was performed.

As exploratory endpoint, the change in work productivity/activity impairment after 6 months and 12 months versus baseline as measured by WPAI for PsA, RA and AS patients treated with Golimumab in German clinical practice was evaluated.

**Results:** Of 748 patients (100%) who started treatment with Golimumab at V0 (baseline), 666 (89.0%), 634 (84.8%) and 552 patients (73.8%) continued treatment until V1 (Month 3), V2 (Month 6), and V3 (Month 12/end of observation period), respectively.

Efficacy analyses were performed on the mITT population which included 700 patients (RA=237, PsA=235, AS=228) who had at least 2 documented visits.

The statistically significant improvements (all  $p$ -values  $<0.05$ ) in the mean WPAI domain scores were maintained over the 12-month observation period in all 3 indications with a higher treatment effect regarding “activity impairment” and “presenteeism” than with “absenteeism”. The magnitude of improvements in the 4 WPAI domains and the time course of improvements varied between the underlying disease (RA, PsA, AS).

In general, the improvements in the 4 WPAI domains were greater in patients with AS and PsA compared to RA patients. A continuous improvement over time was seen in AS patients regarding the domain “activity impairment”. A positive effect of pre-treatment with biologics (i.e. better improvement in WPAI) was seen in RA

patients for 3 domains (TWPI<sup>®</sup>, absenteeism, presenteeism), and in PsA patients for 2 domains (absenteeism, activity impairment).

**Conclusions:** Golimumab s.c. 1 x monthly is an effective treatment in patients with RA, AS and PsA.

All scores of the WPAI showed a significant ( $p < 0.05$ ) reduction in mean score values in each indication.

Golimumab leads to an improvement of work productivity and daily activities in all patients already within the first 3 months of treatment and provided sustained improvement in WPAI in patients with RA, PsA and AS.

### SAT0188 TOCILIZUMAB IN EARLY RHEUMATOID ARTHRITIS DELIVERS CLINICAL AND ULTRASOUND-CONFIRMED RAPID AND DEEP REMISSION WITH ABOLITION OF PD – TREMERA STUDY

L. Hunt<sup>1</sup>, E. Hensor<sup>1,2</sup>, K. Naraghi<sup>1</sup>, R. J. Wakefield<sup>1,2</sup>, P. Emery<sup>1,2</sup>, M. H. Buch<sup>1,2</sup>.  
<sup>1</sup>Leeds Institute of Rheumatic & Musculoskeletal Medicine, University of Leeds,  
<sup>2</sup>NIHR Leeds Biomedical Research Centre, Leeds Teaching Hospitals NHS Trust, Leeds, UK

**Background:** Tocilizumab (TCZ) has shown impressive outcomes in early RA (ERA) with clinical remission rates of up to 80%<sup>1</sup>. The speed and depth of remission of TCZ in treatment-naïve ERA have not been specifically evaluated.

**Objectives:** To evaluate the rate and depth of clinical and imaging response and remission, and timing of optimal response in ERA.

**Methods:** A prospective, open-label, RCT of active (DAS28  $\geq 3.2$ ), new-onset (symptom duration  $\leq 12$  months) treatment-naïve RA (2010 ACR/EULAR RA classification criteria), randomised 1:1, and treated with either TCZ 8 mg/kg (4-wkly) monotherapy or TCZ 8 mg/kg (4-wkly) and methotrexate (MTX) combination for 48 weeks.

Clinical response/remission rates, and patient reported outcomes (PRO) were evaluated at early (wks 4 and 12) timepoints, and wks 24 and 48. High resolution US dominant hand (together baseline active joints) was performed at baseline, wks 12, 24 and 48. Odds ratios were calculated using Firth logistic regression.

**Results:** 20 pt [16 female; 13 RF+, 15 ACPA+; mean(SD) age 55.25(12) years] were recruited; baseline mean(SD) DAS28-ESR 5.98(1.21), HAQ 1.64(0.67). High-hurdle endpoints: at wk4, 30%, 95% and 35% achieved DAS28-ESR rem, EULAR and ACR50 response respectively; and continued to increase, peaking at wk48 with 67%, 93% and 63% respectively [OR wk4 1.0, 0.3, 0.7 and wk48 1.4, 3.0, 4.0 respectively]. Sustained DAS28-ESR remission (8 successive weeks) was observed in 40%;  $\text{chisq}=0.5$ ,  $p=0.462$ ; mean (90% CI) time to remission 38.3 (33.2, 43.3) wks.

PRO: Baseline median(IQR) VASGH 56.5(29,71.5) improved by wk4 to 24 (14,54), maintained wk48 24.5(3.5,46.5); VASDA from 62(54,77.5) to wk4 22 (12.5,49.5), further improved by wk48 14.5(3.5,44.5); VASPain from 63.5(42,77) to wk4 19.5(4,53), maintained wk48 17.5(2.5,49.5). Similarly, median(IQR) HAQ at baseline 1.63(1.25,2.13) decreased by wk4 1.13(0.19,2.0) and wk48 0.75 (0.19,1.38).

**Ultrasound:** Baseline mean grey scale (GS) and power Doppler (PD) (as well as DAS28-ESR) are shown in the figure below, illustrating rapid reduction by wk4 that continued through the study period to all achieving PD=0 by wk48. Baseline median (IQR) erosions 0 (0, 0) remained unchanged throughout study. Baseline GS and PD appeared to associate with achievement of DAS44ESR remission ( $p=0.038$  and  $p=0.043$  respectively).

No meaningful numerical differences between the two treatment arms was recorded.

**Conclusions:** Conclusion TCZ in ERA (both monotherapy and TCZ/MTX combination) was associated with rapid clinical and imaging improvements, strikingly abolishing PD; with sustained remission in almost half the patients. The peak imaging response was noted at 48 weeks. Impressively, rapid PRO improvement

was also observed. These data indicate convincing patient-relevant, imaging-determined depth of remission in a new-onset, treatment-naïve RA cohort.

### SAT0189 DYNAMICS OF CIRCULATING TNF DURING ADALIMUMAB TREATMENT OF RHEUMATOID ARTHRITIS USING A NOVEL DRUG-TOLERANT TNF ASSAY

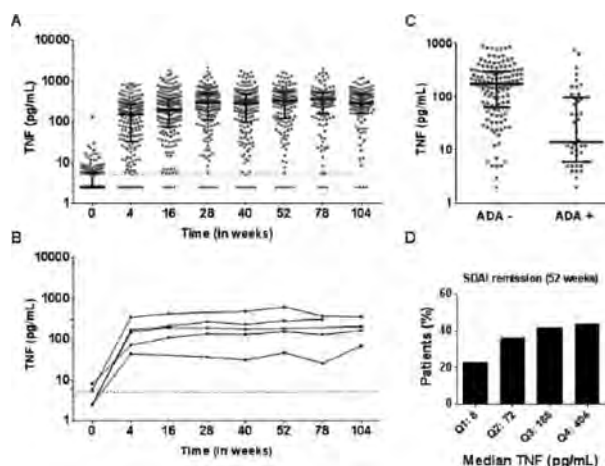

L. C. Berkhout<sup>1</sup>, M. J. l'Ami<sup>2</sup>, J. Ruwaard<sup>2</sup>, M. H. Hart<sup>1</sup>, P. Ooijevaar-de Heer<sup>1</sup>, K. Bloem<sup>1</sup>, M. T. Nurmohamed<sup>2,3,4</sup>, R. F. van Vollenhoven<sup>2,3,4</sup>, M. Boers<sup>3,5</sup>, C. Smith<sup>1</sup>, G. Wolbink<sup>1,2</sup>, T. Rispens<sup>1</sup>.  
<sup>1</sup>Department of Immunopathology, Sanquin Research, <sup>2</sup>Amsterdam Rheumatology and immunology Center, Reade, <sup>3</sup>Amsterdam Rheumatology and immunology Center, VU University Medical Center, <sup>4</sup>Amsterdam Rheumatology and immunology Center, Academic Medical Center, <sup>5</sup>Department of Epidemiology & Biostatistics, VU University Medical Center, Amsterdam, Netherlands, <sup>6</sup>St. John's Institute of Dermatology, Division of Genetics and Molecular Medicine, Kings College London, London, UK

**Background:** Tumor necrosis factor- (TNF) inhibitors are effective in the treatment of rheumatoid arthritis (RA); these include adalimumab, which binds TNF to form inactive complexes. Once in remission, a proportion of patients can successfully discontinue adalimumab treatment, indicating that blocking TNF is no longer necessary for disease control. We developed a novel assay that can quantify TNF in the presence of large amounts of TNF-inhibitor, i.e. a 'drug-tolerant' assay.

**Objectives:** To investigate, for the first time, the relationship between TNF levels and disease course during adalimumab treatment.

**Methods:** The new drug-tolerant competition enzyme-linked immunosorbent (ELISA) assay was used to quantify TNF levels on initiation and during 2 years of adalimumab treatment in 206 consecutive RA patients. The relationship between TNF levels and clinical response was evaluated.

**Results:** Circulating TNF levels were close to the detection limit at baseline, but TNF levels increased on average >50-fold upon adalimumab treatment (**figure 1A**; black lines show median (IQR)), and reached a stable level in time in the majority of patients (**figure 1B**; representatives of n=206), regardless of disease activity. During treatment, TNF was in complex with adalimumab, and recovered as inactive 3:1 adalimumab:TNF complexes. Low TNF levels at week four were associated with a higher frequency of anti-drug antibodies (ADAs) at subsequent time points (**figure 1C**) and significantly less methotrexate (MTX) use at baseline. Furthermore, week four TNF levels were significantly correlated with SDAI score, with significantly lower TNF levels in patients who did not reach remission (Spearman  $r = -0.18$ ;  $p=0.015$ ; **figure 1D**)

**Conclusions:** TNF levels, mostly in complexed form, do not appear to decline in patients that reach remission, and may therefore not be predictive for treatment

discontinuation. However, low complexed TNF levels in the early phase of treatment (wk 4) are strongly associated with ADA formation and can be used to identify non-responders in the early phase of treatment.

### SAT0190 RISK FOR OPPORTUNISTIC INFECTIONS IN RHEUMATOID ARTHRITIS TREATED WITH bDMARDs IN CLINICAL PRACTICE, 10 YEARS OF FOLLOW UP

L. Leon<sup>1,2\*</sup>, M. Peñuela<sup>3</sup>, F. J. Candel<sup>3</sup>, D. Freites<sup>1</sup>, L. Rodriguez-Rodriguez<sup>1</sup>, L. Abasolo<sup>1</sup>. <sup>1</sup>Rheumatology and Idiss, Hospital Clinico San Carlos, <sup>2</sup>Health Sciences, Universidad Camilo Jose Cela, <sup>3</sup>Microbiology, Hospital Clinico San Carlos, Madrid, Spain

**Background:** Biologic disease-modifying anti-rheumatic drugs (bDMARDs) may be associated with opportunistic infections (OI).

**Objectives:** Our purposes were to describe the incidence of OI in Rheumatoid Arthritis (RA) taking bDMARDs, and compare the risk of OI between TNF-targeted and non-TNF-targeted biologics.

**Methods:** Retrospective longitudinal observational study from 2007 to 2017. We included RA patients, diagnosed and followed in our outpatient clinic, whom started treatment with a TNF-targeted bDMARD [etanercept (ETN), golimumab (GOLI), certolizumab (CTZ), infliximab (IFX), adalimumab (ADA)], or non-TNF-targeted bDMARD [rituximab (RTX), abatacept (ABA), or tocilizumab (TCZ)]. According to microbiologist criteria, we consider OI when there was a positive culture (virus, fungus, bacterial, parasitary) or compatible symptoms that respond to specific treatment. The independent variable was the Type of targeted bDMARD: TNF-targeted vs non-TNF-targeted. Secondary variables: sociodemographic; clinical and other therapies. We used survival techniques to estimate the incidence of OI, expressed per 1000 patient-year [CI 95 %]. The exposure time was defined from the start date of each bDMARD to the development of an OI, loss of follow up or end of study (01/02/2017). We performed Cox multivariate regression models to compare the risk of OI between the types of bDMARD used. Results were expressed in Hazard ratio (HR).

**Results:** 441 RA patients were included, starting 761 different courses of bDMARD treatment. 81% were women with a mean age at first bDMARD of 57.3 ± 14 years. The median time from onset of bDMARD until onset of OI was 3.1 years [0.5–4.6]. More than 90% of patients were on steroids. 71.3% of the courses were TNF-targeted bDMARD (ADA 39%, ETN 33%, CTZ 15%, IFX 9%, GOLI 2%), and 28.7% non-TNF-targeted bDMARD (RTX 60%, ABA 21%, TCZ 18%). There were 38 OI [26 Virus (18 Herpes Zoster, 2 virus B reactivation, 3 virus C reactivation, 1 Epstein Barr, 1 Avian flu, 1 CMV), 6 Fungus (5 Candida, 1 Trichophyton), 5 Bacterian (1 Legionella, 1 Salmonella, 3 TB)] and 1 parasitary (Leishmania)]. 9 of them required hospitalization and one died (Candida). The global incidence of OI was 23.1 [16.8–31.8]. TNF-targeted bDMARD had 26 OI, with an incidence of 20.8 [14.1–30.6], and non-TNF-targeted bDMARD with 12 OI, incidence 30.4 [17.3–53.6]. We not find statistical differences in the rate of OI between TNF-targeted vs non-TNF-targeted in the multivariate model, adjusted by age, sex and calendar-time (HR 1.37, p=0.4). Male sex was found a predictor of OI in the multivariate analysis (HR 2.17, p=0.04). Age (HR 1.02, p=0.08), concomitant treatment with corticosteroids (HR 6.61, p=0.05) and leukopenia (HR 2.7, p=0.08) showed a tendency to increase the risk of OI.

**Conclusions:** Incidence of OI due to bDMARDs was near 23 cases per 1000 patients-year. Crude incidence was higher for non-TNF-targeted bDMARD compared to TNF-targeted bDMARD. Nevertheless this difference was not maintained in the multivariate model, reflecting that many of the variability in patients' risk of OI development were driven by factors other than biological agent exposure. Close monitoring should be taken in those RA patients taking bDMARD, corticosteroids, and with leukopenia.

### SAT0191 THE PATIENT PERSPECTIVE ON bDMARD DOSE REDUCTION: A MIXED METHODS STUDY

L. M. Verhoef<sup>1</sup>, E. M. Selten<sup>1</sup>, J. E. Vriezolk<sup>1</sup>, A. J. de Jong<sup>2</sup>, F. H. van den Hoogen<sup>1,3</sup>, A. A. den Broeder<sup>1,3</sup>, M. E. Hulscher<sup>4</sup>. <sup>1</sup>Rheumatology, Sint Maartenskliniek, Nijmegen, <sup>2</sup>Rheumatology, Rijnstate, Arnhem, <sup>3</sup>Rheumatology, <sup>4</sup>IQ healthcare, RIHS, Radboudumc, Nijmegen, Netherlands

**Background:** Dose reduction of bDMARDs, after low disease activity is reached, is safe and effective.(1) To date, few studies have focused on bDMARD dose reduction from the patient perspective.

**Objectives:** The aim of this study was to identify the factors that play a role for patients with RA when considering bDMARD dose reduction, and to determine their relative importance.

**Methods:** A mixed methods design was used in which we 1) identified influencing factors with interviews and 2) ranked these factors using a Maximum Difference Scaling (MaxDiff) survey.

**Sub study 1:** We performed semi-structured interviews with 22 RA patients. Interviews were transcribed verbatim and two researchers analyzed the transcriptions by inductive thematic analysis.

**Sub study 2:** The influencing factors were derived from the interviews and used in a MaxDiff survey with RA patients from 3 different centers in the Netherlands (N=192; an academic hospital, a specialized hospital and a large general hospital). Besides questions about patient characteristics, the survey included 18 MaxDiff questions in which patients were asked to choose the most and least important factor from a subset of 5 factors. A relative importance score for each factor was calculated using hierarchical Bayes modeling.

**Results:** Thirty factors were identified from the interviews and used in the survey. Most respondents had a positive attitude towards bDMARD dose reduction (table 1). The top-10 of factors (table 2) shows that patients are concerned that dose reduction will lead to a disease flare that affects their daily life (pain, function). It is important for them to know that it is possible to increase the dose if (further) reduction is not possible and that the bDMARD will be effective again. Patients value the opinion of their rheumatologist, and being involved in the decision to start tapering is highly ranked as well.

Table 1 Patient characteristics (mean (sd) or n (%))

Characteristic	Sub study 1 (n=22)	Sub study 2 (n=192)
Female	15 (68%)	125 (65%)
Age (years)	62 (7.6)	59 (12.1)
Disease duration (years)	13 (9.4)	16 (10.0)
Experience with bDMARD dose reduction	Yes: 16 (73%) No: 6 (27%)	Yes: 117 (61%) No: 71 (37%) I don't know: 4 (2%)
Attitude towards bDMARD dose reduction	Not applicable	Very positive: 64 (33%) Positive: 78 (41%) Neutral: 27 (14%) Negative: 11 (6%) Very negative: 2 (1%) I don't know: 10 (5%)

Table 2 Top-10 factors

Rank	Factor
1	The possibility to increase the dose when disease symptoms worsen
2	The risk that my disease activity will increase
3	My current disease activity
4	The risk that my physical function will deteriorate (e.g. I won't be able to work)
5	The confidence I have in my rheumatologist
6	To what extent I'm involved in the decision on bDMARD dose reduction
7	Whether the bDMARD is (still) necessary for the RA
8	The advice of my rheumatologist regarding bDMARD dose reduction
9	The risk that I will experience more pain
10	The efficacy of the bDMARD after increasing the dose

**Conclusions:** The results from this study could facilitate implementation of bDMARD dose reduction by informing care providers on what is important for patients and providing a basis for shared decision making.

SAT0192

### COMPETITIVE ELISA AND BRIDGING ELISA WITH ACID DISSOCIATION DETECT ANTI-DRUG ANTIBODIES IN A GREATER PROPORTION OF PATIENTS TREATED WITH TNF-ALPHA INHIBITORS THAN CLASSICAL BRIDGING ELISA

M. Ogrič<sup>1</sup>, P. Žigon<sup>1</sup>, K. Lakota<sup>1,2</sup>, S. Praprotnik<sup>1</sup>, D. Drobne<sup>3,4</sup>, B. Štabuc<sup>3,4</sup>, S. Sodin-Semrl<sup>1,2</sup>, S. Čučnik<sup>1,5</sup>, <sup>1</sup>Department of Rheumatology, University Medical Centre Ljubljana, Ljubljana, <sup>2</sup>FAMNIT, University of Primorska, Koper, <sup>3</sup>Department of Gastroenterology, University Medical Centre Ljubljana, <sup>4</sup>Faculty of Medicine, <sup>5</sup>Faculty of Pharmacy, University of Ljubljana, Ljubljana, Slovenia

**Background:** Therapeutic drug monitoring is used to guide treatment in patients treated with TNF- $\alpha$  inhibitors. Current bridging ELISA (bELISA), mostly used in routine analysis, cannot detect anti-drug antibodies (ADA) in immune complexes and differentiate between neutralizing and non-neutralizing ADA. Reporter Gene Assay (RGA), which detects only neutralizing ADA, is both costly and labour-intensive. Therefore, alternative assays are warranted to obviate these limitations.

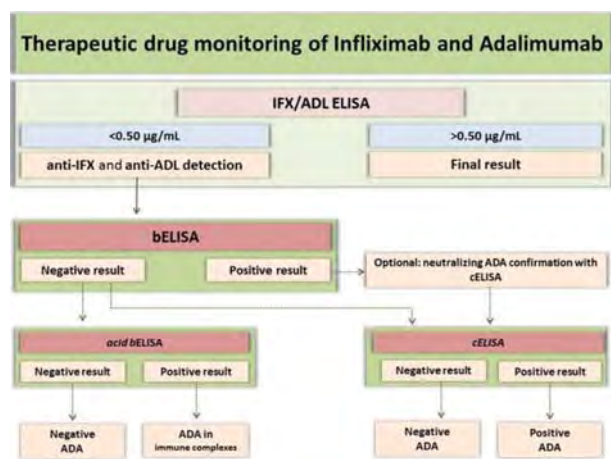

**Objectives:** To develop an *in-house* competitive ELISA (cELISA) for detection of neutralizing ADA, to compare results between four different assays for ADA detection and to propose an algorithm to assist clinicians in personalized therapeutic drug monitoring of Infliximab (IFX) and Adalimumab (ADL).

**Methods:** Samples from 105 patients on IFX or ADL therapy ( $n_{IFX}=61$ ,  $n_{ADL}=44$ ) from the Departments of Rheumatology and Gastroenterology, University Medical Centre Ljubljana, with undetectable drug levels, were tested with *in-house* cELISA, *in-house* bELISA, *in-house* bELISA with acetic acid dissociation (acid bELISA (1)) and RGA. cELISA was developed following the principles of RGA, briefly, diluted samples were pre-incubated with a fixed amount of IFX or ADL, linked to horseradish peroxidase. After incubation on a TNF- $\alpha$  plate, the reaction was detected using TMB substrate. Within and between-run imprecisions for cELISA were determined. Correlation coefficient and agreement between results from different assays were calculated.

**Results:** Within and between-run imprecisions in cELISA met the validation criteria (<20%). We found high correlation between cELISA and RGA (anti-IFX  $r=0.932$  ( $p<0.0001$ ) and anti-ADL  $r=0.948$  ( $p<0.0001$ )) and 100% agreement between results. cELISA also correlated with bELISA (anti-IFX  $r=0.663$  ( $p=0.0002$ ) and anti-ADL  $r=0.896$  ( $p<0.0001$ )). Agreement between bELISA and cELISA was 79% for anti-IFX and 82% for anti-ADL samples.

The more sensitive cELISA and functional RGA detect 13% (8/61) more positive samples in anti-IFX group and 18% (8/44) more samples in anti-ADL group. Acid bELISA found 3% (2/61) more positive samples in anti-IFX group and 14% (6/44) of samples in the anti-ADL group.

In total, 16% (10/61) more samples in anti-IFX and 30% (13/44) more samples in anti-ADL group were confirmed having ADA. Based on our results we propose a sequential algorithm, which enables reliable, affordable and increased detection of ADA (figure 1).

**Figure 1.** Algorithm for therapeutic drug monitoring of IFX and ADL. IFX – Infliximab, ADL – Adalimumab, ADA – anti-drug antibodies, bELISA – bridging ELISA, acid bELISA – bELISA with acid dissociation, cELISA – competitive ELISA;

**Conclusions:** cELISA and acid bELISA, together, can detect ADA in 16% more samples in anti-IFX and 30% in anti-ADL group than classical bELISA used in current practice. The proposed algorithm can assist in everyday practice and enables better evaluation of patients treated with TNF- $\alpha$  inhibitors.

**Background:** Tumor necrosis factor- $\alpha$  inhibitors (TNFi) are usually the first biologic drugs employed in rheumatoid arthritis (RA) after failure of conventional disease-modifying antirheumatic drugs (DMARDs). Retention rate is a useful surrogate marker of effectiveness and safety in real life, but few studies investigated the causes of early discontinuation of these drugs.

**Objectives:** Aim of the study was to investigate the possible predictors of early discontinuation (within 1 year of treatment) of etanercept (ETA) in RA patients enrolled into the GISEA (Italian Group for the Study of Early Arthritis) registry.

**Methods:** RA patients who began etanercept as first biologic DMARD were included in the study. For all patients age, sex, disease duration, smoking status, the intake of glucocorticoids and DMARD, clinical and serological data, comorbidities and extra-articular manifestations were collected.

**Results:** We analyzed 477 RA patients (females/males 382/95, mean age 51.3  $\pm$  14.1 years; mean DAS28 5.4  $\pm$  1.5); rheumatoid factor (RF) and anti-citrullinated peptide antibodies (ACPA) were positive in 66% and 62.3%, respectively. Comorbidities were observed in 16.6% of patients, mainly cardiovascular diseases, while extra-articular RA manifestations were recorded in 6.3%. Concurrent DMARDs therapies were reported in 54.3% of patients, mainly methotrexate (40.5%), while 52.4% of subjects taken low doses of steroids.

Seventy patients (14.7%) discontinued ETA during the first year (for inefficacy in 43 patients, adverse events in 22, and other reasons in 5). The presence of comorbidities and a combination therapy with DMARDs different by MTX were independent predictors of early discontinuation of ETA at multivariate analysis (see table 1). The association with MTX didn't increase the 1-year retention rate of ETA. No significant associations were observed with steroids, presence of RF or ACPA or the disease activity at baseline.

**Table 1.** Multivariate analysis. Factors associated to early discontinuation of etanercept

Parameter	Standard Error	Odds ratio	95% Confidence Interval	p
Comorbidities	0,28	1,86	1.07–3.25	0,029
DMARDs different by MTX	0,35	2,01	1.014–3.982	0,045
ETA monotherapy	0,297	0,701	0.392–1.256	0,232

**Conclusions:** ETA demonstrated a high persistence in RA patients and after 12 months more than 85% of patients continued the treatment. The presence of comorbidities and a combination therapy with DMARDs different by MTX were associated to an early withdrawal of the drug.

SAT0194

**SIGNIFICANT OVERTREATMENT WITH BIOLOGICAL DRUGS IS COMMON IN ROUTINE CARE FOR PATIENTS WHERE SERUM DRUG LEVELS ARE MONITORED**M. E. Perry<sup>1</sup>. <sup>1</sup>Rheumatology, Royal Alexandra Hospital, Paisley, United Kingdom

**Background:** Current challenges in treating rheumatic disease include using the right drug at right dose for the right length of time. Measuring serum drug levels can help prevent over-treatment, inform regarding secondary drug failure on account of immunogenicity and improve confidence to extend the interval of drug dosing.<sup>1</sup> This pilot work was a prelude to the implementation of the first national monitoring service worldwide within the relatively endogenous Scottish population.

**Objectives:** 1. To develop skill and familiarity with TDM at a Scottish laboratory prior to a business case for a national service  
2. To understand the reasons why a clinician would use the service as part of clinical practice  
3. To understand the current extent of over and undertreatment in an endogenous population

**Methods:** ELISA assays (Promonitor) were supplied by GRIFOLS (Barcelona) for the detection of serum levels of adalimumab (ADA), infliximab (IFX), Golimumab (GOL), Etanercept (ETA) and Rituximab (RIX). A single laboratory site was selected and laboratory training was provided. A bespoke clinical request form was developed. Adult & paediatric rheumatologists across Scotland were invited to send serum biological drug trough samples for analysis. The clinical indication for testing was also captured.

Reference ranges for free drug levels and anti-drug antibody levels: Analyte: Lower limit of measurement-Upper limit of measurement. Units ug/mL: Adalimumab 0.024–12, Infliximab 0.2–14.4, Etanercept 0.035–40, Golimumab 0.036–12.8, Rituximab 0.75–204.

**Results:** Internal calibration and quality control for the assays were established. A total of 39 IFX, 26 ADA, 14 ETA, 3 RIX, 14 GOL samples were received (total n=96). Only 4 (4%) of patients had serum levels below the reference range and of these just one had anti drug antibodies, suggesting that immunogenicity was not a significant clinical factor in this population. Overtreatment was common: 19 patients (20%) had drug levels greater than the maximum value in the reference range. 12 patients had anti-drug antibodies, but only one of these had poor disease control, suggesting a high proportion had non-neutralising antibodies. Based on this study, if all overtreated patients had dosing interval extended by 33%, this would produce a drug budget reduction of 6–7%, easily dwarfing the setup and running costs of a biological drug monitoring service.

Clinicians requested samples to help assess flaring patients to determine if immunogenicity had occurred or drug levels were too low (n=36) confidence around tapering drug (n=28), switching to biosimilar (n=6) and miscellaneous other reasons (n=15)

**Conclusions:** In this population, immunogenicity was not clinically relevant. Overtreatment with biological drugs was common, highlighting potential longer term safety risk and opportunity for cost reduction by dose interval prolongation. Clinicians primarily indicate the usefulness of serum biological drug testing in determining if secondary failure has occurred or to aid decisions about drug dose tapering.

**OPTIMIZATION OF BIOLOGIC THERAPIES IN RHEUMATOID AND PSORIASIS ARTHRITIS: A SINGLE-CENTRE EXPERIENCE**

M. Sgrulletti<sup>1</sup>, S. Salemi<sup>1</sup>, R. Di Rosa<sup>1</sup>, R. Petruccelli<sup>1</sup>, B. Laganà<sup>1</sup>, M. L. Sorgi<sup>1</sup>, G. Meneguzzi<sup>1</sup>, S. Quarta<sup>1</sup>, M. Catoni<sup>2</sup>, A. Picchianti Diamanti<sup>1</sup>, S. Caporuscio<sup>1</sup>, G. Salerno<sup>1</sup>, R. D'Amelio<sup>1</sup>. <sup>1</sup>Dipartimento di Medicina Clinica e Molecolare, Sapienza Università di Roma, Azienda Ospedaliera S. Andrea, ROME, <sup>2</sup>Policlinico Universitario di Monserrato, Università degli Studi di Cagliari, CAGLIARI, Italy

**Background:** A timely diagnosis and a suitable therapy allow a better control of disease activity and limit joint damage in autoimmune arthritis. Biological therapies played a key role, modifying disease natural history. However, the use of these drugs implies several risks and increases health-care costs [1]. This has

raised a question: could be possible, in patients in a state of sustained remission or low disease activity (LDA), choose an optimized regimen of treatment? Recommendations provided by EULAR in 2013 includes this possibility, especially if biologic therapy is in association with DMARDs [2]. While optimized regimen has been attempted in different clinical trials with good results, strong evidences are currently lacking [3].

**Objectives:** The aim of our study was to analyse the effectiveness of optimization of biologic therapies in a cohort of patients with Rheumatoid and Psoriasis Arthritis (RA and PA).

**Methods:** We retrospectively included patients undergoing optimized therapy in a cohort of 328 outpatients (190 RA, 128 PA) treated with first-line biologic therapy from 2006 to 2017. Optimization was considered as predefined dose downtitration and/or expansion of dose interval in patients with a sustained remission or LDA (DAS 28 -ESR <2.6 or 2.6–3.2 respectively, for at least 24 months). Relapse was defined by an increase in DAS28-ESR >20% over baseline or by the onset of at least one tender and swollen joint. Our principal end-points were: (I) estimate the proportion of subjects able to optimize therapy (II) define the rate of relapse at 6–12 and 24 months follow-up (FU) in patients undergoing optimization (III) compare the effectiveness of optimized therapy in RA and PA patients and value the rate of optimization in relation to different biologic drugs. Survival analysis (Kaplan-Meier Curves) and Chi Square test were used and a p value <0.05 was considered as statistically significant.

**Results:** During FU, 15/190 (8%) RA patients and 16/138 (12%) PA patients reached a persistent LDA or remission and started the optimized biologic therapy. In survival analysis, rates of relapse at 6 months were 10% and 0% in RA ad PA respectively, increasing to 21% and 8% at 12 months and finally to 48% and 34% at 24 months. No significant differences emerged between the two groups. The use of Etanercept was associated with higher possibility to optimize biologic treatment (p=0.007).

**Conclusions:** Biologic therapy optimization is a workable option in RA ad PA patients who reached persistent remission or LDA. In our cohort Etanercept seems to be the most promising drug. Further studies are needed to better define the predictive factors of response in order to identify eligible patients.

SAT0196

**TIME TO DISCONTINUATION OF BIOLOGIC THERAPY BY MECHANISM OF ACTION IN RHEUMATOID ARTHRITIS: RESULTS FROM THE ONTARIO BEST PRACTICE RESEARCH INITIATIVE (OBRI) COHORT**

M. Movahedi<sup>1</sup>, S. Couta<sup>1</sup>, A. Cesta<sup>1</sup>, C. Bombardier<sup>1</sup> on behalf of Other OBRI Investigators. <sup>1</sup>Ontario Best Practices Research Initiative, Toronto General Research Institute, University Health Network, Toronto, Canada

**Background:** Patients with rheumatoid arthritis (RA) may discontinue their biologic disease modifying antirheumatic drug (bDMARDs) due to non-response, loss of response or adverse events. However, time to discontinuation may be related to mechanism of action.

**Objectives:** We aimed to compare drug survival of tumor necrosis factor inhibitors (TNFi) versus non-TNFi in patients initiating bDMARD treatment in a Canadian (Ontario) observational cohort.

**Methods:** Patients enrolled in the Ontario Best Practice Research Initiative (OBRI) who started bDMARD therapy within 30 days before or any time after OBRI enrolment were included in the primary analysis. Patients were followed from bDMARD start until discontinuation/switching, death, lost to follow-up, or last visit, whichever came first. Time to discontinuation/switching of bDMARD due to (i) any reason, (ii) non-response or loss of response, and (iii) adverse events (AEs), were assessed using Kaplan-Meier survival analysis for TNFi versus non-TNFi users.

**Results:** Among the 943 patients included in the primary analysis, 187 (19.8%) received non-TNFi and 756 (80.2%) TNFi. Mean (SD) age and disease duration were 56.4 (12.7) years and 9.6 (9.8) years, respectively, and the majority were females (79.1%) and biologic naïve (84.4%). TNFi included Etanercept,

Adalimumab, Certolizumab, Golimumab, and Infliximab; and non-TNFi included Abatacept, Rituximab, Tocilizumab, and Tofacitinib.

Over a mean (SD) follow-up of 2.4 (2.0) years, bDMARD discontinuation/switching was reported for 37.6% of patients, with significant difference in time to discontinuation between TNFi and non-TNFi users (Logrank  $p=0.01$ ). However, there was no significant difference due to non-response or loss of response (Logrank  $p=0.67$ ) between the two groups. At 2 years, more patients remained on TNFi (71.0%) compared to non-TNFi (57.0%). At 5 years, 51.0% and 44.0% of patients still remained on TNFi and non-TNFi, respectively.

**Conclusions:** The overall retention rate for biologics was comparable to finding in European registries. We found that patients stay on TNFi longer compared to non-TNFi. However, no significant difference was found between the two groups, for discontinuation or switching of bDMARDs due to non-response or loss of response. Further analyses are required to adjust for the effect of potential confounders (e.g. age, sex, disease activity, and other treatment regimens) on biologic discontinuation.

#### SAT0197 ADHERENCE TO BIOLOGIC THERAPY OF RHEUMATOID ARTHRITIS PATIENTS – IS THERE ANY RELATION WITH DISEASE ACTIVITY?

N. Madeira<sup>1</sup>, A. Cardoso<sup>2</sup>, R. Trinca<sup>3</sup>, C. Silva<sup>1</sup>, H. Santos<sup>1</sup>, C. Miguel<sup>1</sup>, F. Barcelos<sup>1</sup>, D. Medeiros<sup>1</sup>, R. Campanilho Marques<sup>1</sup>, L. Cunha Miranda<sup>1</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Nutrition, <sup>3</sup>Nursing, Instituto Português de Reumatologia, Lisbon, Portugal

**Background:** In the last years, there has been an increase interest in using Patient Reported Outcomes (PROs) in clinical trials and daily clinical practice in Rheumatology to provide patient-centered care. The most frequently reported PROs are patient's pain, patient's global assessment (PGA) of disease activity and reports of functional capacity, fatigue, anxiety and depression. To date, studies that explore patient adherence to rheumatic medications are scarce.

**Objectives:** To study the level of adherence to biologic therapy of Rheumatoid Arthritis (RA) patients, followed at a day care hospital of Rheumatology.

**Methods:** Observational and cross-sectional study which took place in two months of consultation of day care hospital (5 periods per week). Patients with a diagnosis of RA according to 1987 American College of Rheumatology (ACR) and/or 2010 ACR/European League Against Rheumatism criteria, on biologic therapy, able to complete a questionnaire autonomously and who agreed to participate were included. Demographic and clinical data (DAS28, CDAI and SDAI to assess RA disease activity, HADS-A for anxiety, HADS-D for depression, FACIT-F for fatigue) were collected. To assess adherence, a Portuguese version of the Morisky Medication Adherence Scale (MMAS-8) was used and the patients were asked to apply it only to biologic therapy. Three levels of adherence were considered based on the following scores: 0 to <6 (low); 6 to <8 (medium); 8 (high). Statistics: Kruskal-Wallis and Mann-Whitney tests,  $p<0.05$ , SPSS<sup>®</sup> v.23.

**Results:** In total, 61 patients were included, 91.8% female, 82.0% on anti-Tumor Necrosis Factor (anti-TNF), the others on Tocilizumab (16.4%) or Abatacept (1.6%). Table 1 reports the means and medians of demographic and clinical variables included. The mean MMAS-8 score was  $7.0\pm 1.2$ , the median 7.0 (6.8–8.0), with a minimum of 2.5 and a maximum of 8. The adherence was medium in 50.8%, high in 36.1% and low in 13.1% patients. The median of current age was significantly higher for patients with high and medium levels of adherence compared to those with low levels ( $p=0.030$ ). The time on treatment with the current biologic therapy was significantly different between the levels of adherence ( $p=0.028$ ); the median of time on treatment for patients with medium levels of

adherence was significantly higher comparatively to the other patients ( $p=0.009$ ). No other significant difference was found among the levels of adherence for the studied variables.

**Conclusions:** The adherence to biologic therapy was at least medium for 86.9% of patients. Differences between levels of adherence were found only for current age and time on treatment. Disease activity of RA does not seem to influence the levels of adherence.

Table 1 Means and medians of demographic and clinical variables.

	Mean ±SD	Median (IQR)
Current age – years	56.1 ±11.1	58.1 (48.1– 62.8)
Disease duration – years	15.0±7.5	13.1 (10.1– 18.2)
Time on treatment with the current biologic therapy – years	3.5±2.7	2.8 (1.0–5.6)
DAS28–4V	3.4±1.2	3.3 (2.6–4.2)
CDAI	9.7±7.8	7.0 (3.6–15.1)
SDAI	10.1±8.0	7.0 (4.0–15.7)
HAQ	0.9±0.6	0.9 (0.4–1.4)

#### SAT0198 DRUG SURVIVAL AND EFFICACY OF ABATACEPT IN RHEUMATOID ARTHRITIS PATIENTS IN ROUTINE CARE – 7 YEAR EXPERIENCE FROM A SINGLE CENTRE IN THE UNITED KINGDOM

N. Nolkha<sup>1</sup>, T. Sheeran<sup>1</sup>, S. Venkatchalam<sup>1</sup>. <sup>1</sup>The Rheumatology Centre – Cannock, Wolverhampton, The Royal Wolverhampton NHS Trust, Cannock, United Kingdom

**Background:** Even after the advent of multiple biologic drugs, optimum treatment of rheumatoid arthritis (RA) in a real-world situation continues to be challenging. The data on long-term drug survival of biologic drugs in routine clinical practice is lacking. We extended our earlier analysis of abatacept use in RA patients<sup>1,2</sup> from a single centre in the United Kingdom over 7 years.

**Objectives:** To assess the efficacy, tolerability and drug survival of abatacept use in RA patients in a routine clinical setting like ours.

**Methods:** From November 2010 to December 2017, all RA patients with at least 6 months of follow up after abatacept initiation were included in the analysis. Data on demographics, disease duration, previous biologics, mode of administration, reasons for discontinuation and length of abatacept therapy were retrospectively collected from biologics database and medical records. Effectiveness was assessed by change in Disease activity scores (DAS 28) and European League Against Rheumatism response criteria (EULAR) after 6 months of therapy.

**Results:** 220 patients had received abatacept with at least 6 months follow up until December 2017. 176 were females and 44 males with mean age of 67.83 years (SD = 10.32). Mean disease duration in these patients was 14.42 years (SD = 8.11). 152 (69%) patients were seropositive (Rheumatoid factor and/or anti-CCP antibody). 207 (94%) patients had received a prior biologic and only 13 (6%) patients were biologic naïve. 193 (87.7%) patients were initiated on intravenous (iv) abatacept and 27 (12.2%) patients on subcutaneous (s/c) abatacept. 90 (40.9%) patients were successfully switched from iv to s/c abatacept.

The mean number of prior biologic drugs use per patient was 1.70 (SD = 1.03). 83.6% patients were co-prescribed DMARDs at the initiation of abatacept therapy. Mean baseline DAS 28 score was 6.02 (SD = 3.11). Average DAS 28 change at 6 months was -1.5 (95% CI -1.27, -1.33). 75% patients had a positive EULAR response (38% good, 37% moderate) and 25% had no response at 6 months.

Overall 57 (25.9%) patients discontinued treatment. 43 (19.5%) patients discontinued abatacept early (<9 months) due to primary inefficacy (10.9%) and adverse reactions (8.6%). 24 (10.9%) patients discontinued abatacept later, after a mean 27.46 (SD = 12.9) months of use, due to secondary loss of efficacy (6.3%) and adverse reactions (4.5%).

82% (180/220) of RA patients continued taking abatacept beyond 6 months. 61.5% (91/148) patients were still adherent at 2 years, 51.3% (39/76) retained the drug beyond 48 months.

**Conclusions:** Abatacept continues to be a safe and effective treatment option for patients with RA who are biologic naïve or after discontinuation of prior biologic due to failure or intolerance. A significant number of patients continue on abatacept even after 4 years.

SAT0199

#### SWITCH FROM INNOVATOR ETANERCEPT TO BIOSIMILAR ETANERCEPT IN INFLAMMATORY RHEUMATIC DISEASES: THE EXPERIENCE OF COCHIN UNIVERSITY HOSPITAL PARIS-FRANCE.

O. Al Tabaa<sup>1</sup>, A. Etcheto<sup>1</sup>, C. Miceli-Richard<sup>1</sup>, M. Anna<sup>1</sup>, M. Dougados<sup>1</sup>.  
<sup>1</sup>Rheumatology, Cochin University Hospital, Paris, France

**Background:** Etanercept biosimilar (bETN) is available for treatment of spondyloarthritis (SpA) and rheumatoid arthritis (RA) since 2016 in France. Data showing effectiveness and safety of bETN are still limited.

**Objectives:** 1/To evaluate the RA and SpA patients' and treating rheumatologists' characteristics associated with the switch 2/To evaluate the safety and efficiency of bETN.

**Methods:** Patients: All the patients receiving innovator etanercept for at least 3 months on October 2016 and monitored in the department of rheumatology B of Cochin hospital. Physicians: All the 9 physicians in charge of at least one patient. Study design: After information (one hour session) on the biosimilars, all the physicians were invited to propose a switch from innovator etanercept to bETN. Data collected: physicians' characteristics, patients' characteristics (demographics, diagnosis of the rheumatic disease, disease activity parameters).

**Results:** Of the 435 outpatients who had received etanercept; 304 were receiving etanercept in 2016 and 183 were eligible for a potential switch (the remaining 121 patients did not attend any out-patient-clinic between October 1st 2016 and April 1st 2017).

The percentage of patients who switched to bETN was 51.6% (94 patients).

This switch was more frequently performed in patients monitored by older physicians (mean age: 50.4±14.3 vs 44.8±11.3, p=0.005) and by physicians with a full-time academical position (56.4% vs 13.5%, p<0.001)

The patients' characteristics were similar: % RA (51.1% vs 44.9%), age (52.1±15 vs 50.5±15), female gender (57.4% vs 51.6%), disease duration (16.8±11.9 vs 14.8±11.3) except for the NSAID intake (28.3% vs 12.3%, p=0.014) and the global evaluation (25.2±19.4 vs 19.1±21.8, p=0.02) in the switchers vs non-switchers, respectively. However, no independent factors were associated with the switch in the multivariate analysis.

The bETN retention rate was 83% [0.76–0.92] after a 6 month follow-up period. The bETN was discontinued in 26 patients with the following reasons: inefficiency 13 patients, adverse event 13 patients (painful injection site n = 4, fatigue = 2, pruritus n = 2, "allergic reaction" n = 1, headache n = 1, pollakiuria n = 1, dizziness n = 1, supply problem n = 1).

The univariate analysis aimed at evaluating the baseline predisposing factors of bETN discontinuation overtime picked up the baseline objective sign of inflammation (defined by CRP≥6 mg/L or ESA ≥28 mm) (OR=4.18 [1.19 – 14.66] p=0.0256), p=0.002) and global disease activity score (OR = 1.57 [1.04 – 2.36], p=0.03). Nevertheless, no independent factors were associated with the switch in the multivariate analysis.

There was no difference in the changes in the disease activity parameters in both the completer and ITT population.

**Conclusions:** This study suggests that:

- 1/The probability to switch from etanercept innovator to bETN was mainly related to physicians' behavior
- 2/Using an open design, the percentage of patients complaining of a lower efficiency and/or a worse safety profile of the biosimilar was high
- 3/There was no objective parameter permitting to conclude at a lower efficiency and/or a worse safety profile of the bETN in comparison to the innovator etanercept.

**Background:** Filgotinib (FIL) is an orally administered, selective inhibitor of Janus Kinase 1 (JAK1) in Phase 3 development for the treatment of rheumatoid arthritis (RA).

**Objectives:** Assess the long-term safety and efficacy of FIL in the DARWIN 3 open-label extension study.

**Methods:** Two 24-week Phase 2b studies were completed in patients (pts) with moderately to severely active RA (DARWIN 1, DARWIN 2; Ref 1, 2). Following study completion, pts were offered FIL in the ongoing DARWIN 3 extension study: 100 mg QD (US males), 200 mg QD, or 100 mg BID. This report summarizes safety data from the first dose of FIL in the DARWIN program to 11 Oct 2017 and efficacy data from the DARWIN 3 baseline visit to Week 108, which all ongoing pts have completed.

**Results:** Of 877 pts, 790 (90%) completed DARWIN 1/2, and 739 (84%) enrolled in DARWIN 3; 603 (82%) were female, mean age 53 years. At analysis, 491/739 (66%) were on study. Cumulative patient years of exposure (PYE) was 1931, median time on study drug was 1072 days. Key data are summarized in table 1. 87%, 68%, and 48% of pts achieved ACR20/50/70, respectively, and 72% achieved DAS28-CRP≤3.2 (by observed case analysis).

### REAL WORLD EVIDENCE ON SWITCHING BETWEEN ETANERCEPT AND ITS BIOSIMILAR IN RHEUMATIC DISEASES

R. Alten<sup>1</sup>, H. Jones<sup>2</sup>, C. Curiale<sup>3</sup>, T. Meng<sup>4</sup>, L. Lucchese<sup>5</sup>, C. Miglio<sup>5</sup>. <sup>1</sup>Schlosspark-Klinik, University Medicine Berlin, Berlin, Germany, <sup>2</sup>Pfizer Inc., Collegeville, PA, United States, <sup>3</sup>Pfizer, Rome, Italy, <sup>4</sup>Pfizer Pharma GmbH, Berlin, Germany, <sup>5</sup>IQVIA, London, United Kingdom

**Background:** Etanercept (Etn) is a biologic agent (BA) that has been proved to be successful in the treatment of rheumatic diseases, by acting as tumour necrosis factor inhibitor, but it is costly. In February 2016, the first etanercept biosimilar (EtnBS) was launched in Germany as a relatively cheaper alternative.

**Objectives:** In a recent study using the German Longitudinal Prescriptions database IQVIA® (LRx) we showed that despite many patients (approximately 50%) were moved from EtnBA to EtnBS treatment over the year following its launch, some (10%) switched back to the original product after few months<sup>1</sup>. As new data are available from the database, the objective of this second analysis was to evaluate switching-back dynamics over longer follow-up durations.

**Methods:** The German LRx covers prescription data from January 2008, representing approximately 60% of the German statutory health insurance market. The study period was from February 2016, date of EtnBS launch in Germany, to August 2017 (last available data). Patients receiving first EtnBS prescription (index date) during the study period were retrospectively identified and separated into two groups based on treatment received in the 12 months prior to index date: treatment-naïve patients (no prior biologic treatment) and patients previously treated with EtnBA or other anti-TNF biologics. For the latter group, the cumulative proportion of patients switching back from EtnBS to EtnBA and the median time to the switch-back were evaluated over 3 time periods corresponding to dates of new data availability within the data source: February 2016-September 2016 (1), February 2016-March 2017 (2), and February 2016-August 2017 (3). The results were compared using the chi square test with significance set at p<0.05. Data on the market share for biologic agents and their biosimilars in rheumatic diseases are also shown on a monthly basis, between January 2015 and August 2017.

**Results:** A total of 707, 1,607 and 2,229 patients were identified who received prior EtnBA treatment before switching to EtnBS in time periods 1, 2 and 3 respectively. Of these patients, the proportion of those who switched back to EtnBA significantly (p<0.05) increased over time: 53 (7%) in time period 1, 153 (10%) in time period 2 and 320 (14%) in time period 3. Patients generally switched back to the biologic agent within 3–4 months of starting EtnBS treatment. The use of EtnBS by rheumatologists has constantly grown since February 2016, with a market share of 6% in Dec 2016 increased to 12% in August 2017.

**Conclusions:** This study confirmed previous findings on switching dynamics between EtnBA and its biosimilar. In addition, the study shows that despite a constant increase in the use of EtnBS since its launch, from September 2016 to August 2017, the proportion of patients who switch back to EtnBA after 3–4 months of initiating EtnBS has doubled.

SAT0202

### COMPARISON OF THE BIOAVAILABILITY OF A SINGLE DOSE OF CERTOLIZUMAB PEGOL INJECTED BY PRE-FILLED SYRINGE OR BY ELECTRO-MECHANICAL AUTO-INJECTION E-DEVICE: A PHASE 1, OPEN-LABEL, RANDOMISED, PARALLEL GROUP, SINGLE-CENTRE BIOEQUIVALENCE STUDY

R. Oliver<sup>1</sup>, B. VanLunen<sup>2</sup>, I. Mountian<sup>3</sup>, E. Brown<sup>2</sup>, D. Tatla<sup>2</sup>. <sup>1</sup>UCB Pharma, Slough, United Kingdom, <sup>2</sup>UCB Pharma, Raleigh, NC, United States, <sup>3</sup>UCB Pharma, Brussels, Belgium

**Background:** When administered subcutaneously (SC) using a pre-filled syringe (PFS), the anti-TNF certolizumab pegol (CZP) has a half-life of ~14 days and has shown good bioavailability (~80%) at all tested doses in healthy volunteers and patients with rheumatoid arthritis.<sup>1,2</sup> A reusable electro-mechanical auto-injection device (e-Device), ava<sup>®</sup>, was recently approved in the EU,<sup>1</sup> providing an alternative SC-delivered CZP option in addition to the PFS and autoinjector device (AutoClicks<sup>®</sup>).<sup>1,3</sup>

**Objectives:** To determine if a single 200 mg CZP dose is bioequivalent when delivered SC by PFS or e-Device, and to assess the safety and tolerability of both administration methods.

**Methods:** NCT02806219 was a phase 1, open-label, randomized, parallel group, single-center bioequivalence study. Healthy volunteers were randomized 1:1 to receive CZP via either the PFS or e-Device. Primary outcomes were assessed using the pharmacokinetic per-protocol set (PK-PPS): maximum CZP plasma concentration (C<sub>max</sub>), area under the plasma concentration vs time curve (AUC), and AUC from baseline (BL) to final data point (AUC<sub>(0-t)</sub>). At BL (Day 1), volunteers received a single 200 mg CZP dose. CZP plasma concentrations were measured on Day 1 prior to CZP administration, at 12 hours (h) post-dose, and on Days 2–7, 10, 14, 21, 28, 42, 56, and 70. Safety and tolerability were assessed using the safety set (all receiving a CZP dose) via reported treatment-emergent adverse events (TEAEs), serious AEs, and adverse device events (ADEs: AEs considered by the investigator to be related to/caused by the device). An injection site pain visual analog scale (VAS; 0–100 mm) was completed immediately post-injection (0 h) and 1 h post-injection.

**Results:** 100 healthy volunteers were randomized to receive CZP either via PFS (n=50) or e-Device (n=50). The mean plasma CZP concentration vs time profiles for the e-Device and PFS were comparable. Point estimates and 90% confidence intervals (CIs) for test/reference geometric mean ratios in C<sub>max</sub> and AUC were contained within bioequivalence limits of 80–125% (table 1). Both administration methods were equally well tolerated; all reported TEAEs were mild or moderate, with no ADEs or injection site reaction TEAEs. Mean VAS pain scores were low at 0 h (PFS: 10.7 [SD 14.3], e-Device: 18.0 [24.4]) and 1 h (1.4 [2.9] vs 2.7 [7.0]).

Table 1 Results of the bioequivalence analysis comparing the PFS and e-Device

	Reference		Test		Test/Reference		ANCOVA CV (%)
	CZP 200mg PFS	CZP 200mg e-Device	CZP 200mg PFS	CZP 200mg e-Device	Point estimate	90% CI	
C <sub>max</sub> (µg/mL)	48	50	28.8 (27.1, 30.5)	28.7 (27.1, 30.4)	1.00	0.93, 1.07	20.6
AUC <sub>0-t</sub> (µg·d/mL)	47	50	670.8 (623.7, 721.5)	668.7 (623.1, 717.7)	1.00	0.92, 1.09	25.6
AUC (µg·d/mL)	45	49	701.8 (653.3, 754.0)	688.6 (643.0, 737.6)	0.98	0.90, 1.07	24.8

PK-PPS: ANCOVA: analysis of covariance; AUC: area under the curve; AUC<sub>(0-t)</sub>: AUC from baseline to final data point; CI: confidence interval; C<sub>max</sub>: maximum plasma concentration; CV: coefficient of variation; d: day; CZP: certolizumab pegol; LS: least squares; PFS: pre-filled syringe; PK-PPS: pharmacokinetic per-protocol set.

**Conclusions:** CZP 200 mg doses were bioequivalent whether administered by PFS or e-Device. The SC-delivered CZP injections were well tolerated in healthy volunteers when using either method.

**SAT0203 OPTIMIZATION OF BIOLOGIC TAPERING USING ULTRASOUND IN RA PATIENTS**

S. Bawa<sup>1</sup>, M. Todd<sup>1</sup>, J. France<sup>1</sup>. <sup>1</sup>Dept of Rheumatology, Gartnavel General Hospital, Glasgow, United Kingdom

**Background:** Optimal treatment using Treat 2 Target regimen has reduced morbidity and mortality rates in RA patients. However the use of biological therapies is expensive and a huge financial burden on Health budgets.

Current guidelines suggest to consider tapering biological therapies in patients with sustained low disease activity<sup>1</sup>.

There is a risk of overtreatment in this cohort, with potential risks from sustained immunosuppression of increased infection rates and the chance of malignancy.

**Objectives:** Studies have shown biologic tapering is possible. Some studies have performed progressive tapering using DAS28 scores, others with ultrasonography assessment<sup>2</sup>.

We used a progressive tapering strategy in tapering biological DMARDs in a selected RA cohort in a busy UK University Teaching Hospital, using ultrasound to guide the tapering process throughout and for detecting early recurrence during longer term followup.

**Methods: Inclusion Criteria:** Patients identified from routine clinic appointments as being either in clinical remission (DAS 28<2.6), or with low disease activity (DAS 28<3.2 and no swollen joints), and with no flares of their RA for at least 12 months.

**Assessment:** At each clinic visit the patients' joints were examined, a DAS 28 and HAQ completed. Ultrasound was performed on hand and wrist joints (MCPJ's, PIPJ's, Wrists) in both Grey scale and Power Doppler to assess for inflammation. Biologic medication was progressively tapered according to results. Adalimumab was tapered to '3 weekly – 4 weekly – stop' and Etanercept to '2 weekly – 3 weekly – stop'. Patients were given 3 monthly appointments. If patient flared or Ultrasound showed active synovitis, tapering was stopped and medication adjusted according to the findings. Patients were followed up for a year at 3 monthly intervals, a year at 6 monthly intervals and then referred back to routine outpatient clinic.

**Results:** 28 patients were identified on Adalimumab and 8 on Etanercept. Adalimumab: 17 patients (61%) stopped completely. At the time of writing, 16 (94%) remained off at 6 months. 12 (71%) at 12 months and 5 (29%) for >23 months. 6/17 flared and had to restart medication – 3 returned to a 4 weekly dose, 1 to 3 weekly and 2 to 2 weekly. 11/17 (65%) remain off medication.

At present 7 patients (25%) are on a 4 weekly dose, 1 (4%) patient is on a 3 weekly dose and 9 (32%) remain on 2 weekly.

Etanercept: 4 patients (50%) stopped completely. 1 of these has remained off for over 12 months and 1 over 24 months. 1 of these patients returned to weekly injections within 4 months

1 patient (12.5%) is on a 2 weekly dose and 4 (50%) remain on weekly

The management of 72% of patients was optimised using Ultrasonography. Ongoing cost savings as a result of tapering were in the region of £250,000.

**Conclusions:** Our study shows Ultrasound significantly aided in successful biologic tapering. It helped in selection of appropriate patients, as well as in monitoring during/after tapering. It also resulted in significant cost savings in the region of £250,000

**SAT0204 NAÏVE AND RECENT THYMIC EMIGRANT CD4+ T CELLS INCREASE IN RHEUMATOID PATIENTS TREATED WITH ABATACEPT.**

S. Piantoni<sup>1,2</sup>, F. Regola<sup>1</sup>, A. Tincani<sup>1</sup>, P. Airò<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology Unit, Spedali Civili and University of Brescia, <sup>2</sup>Department of Molecular and Translational Medicine, University of Brescia, Brescia, Italy

**Background:** CD4+ T cells in rheumatoid arthritis (RA) display a peculiar restriction of the T-cell receptor (TCR) repertoire which compromises their ability to react to novel antigens (1). We demonstrated that this process could be partially reverted by abatacept (ABA), which is a blocker of T lymphocyte co-stimulation, used in the treatment of RA (2). This effect could be at least in part due to a reduced generation of oligoclonal effector T cells, such as CD4+CD28-T cells (2). To better understand the mechanisms underlying this phenomenon, we speculated that ABA could influence the frequency of other peripheral T cell subpopulations, even at early stages of maturation. The homeostasis of the naïve T cell pool is maintained not only by thymus production, but also by mechanisms of peripheral replication involving TCR activation, which can be revealed by CD31 (PECAM-1) down-modulation (3). Indeed, CD4+CD45RA+CD31+ T cells have been described as recent thymic emigrants (RTE) newly produced by the thymus and CD4+CD45RA+CD31- T cells as central naïve, involved in a self-renewal peripheral process. This latter population may have a restriction of TCR repertoire and was shown to be involved in mechanisms of cardiovascular damage in patients with coronary syndrome (4).

**Objectives:** We aimed at profiling circulating naïve CD4+CD45RA+ T cells, by assessing their expression of CD31.

**Methods:** Thirty-one RA patients (median age [10<sup>th</sup>-90<sup>th</sup> percentile] 42 [25–64] years) were evaluated before and after 6 months of ABA therapy. The response to treatment was evaluated with the EULAR criteria. Phenotypic analysis of peripheral blood T lymphocytes was made by flow-cytometry.

**Results:** After ABA therapy, the absolute number of total T CD4+ increased from 780 [423–1351] to 1000 [658–1566] cells/mm<sup>3</sup> (p=0.01). Total naïve CD4+ increased in percentage (33 [18–56] vs 40 [20–61] % of CD4+; p=0.02) and in absolute number (257 [82–568] vs 344 [62–689] cells/mm<sup>3</sup>; p=0.03). In parallel, the number of RTE increased in percentage (10.6 [2–26] vs 11.6 [3–25] % of CD4+; p=0.04) and in absolute number (51 [15–194] vs 110 [23–271] cells/mm<sup>3</sup>; p=0.01). The central naïve counterpart did not show significant variations in percentage (29 [23–40] vs 27 [20–38] % of CD4+; p=0.20) nor in absolute number (191 [41–404] vs 242 [76–526] cells/mm<sup>3</sup>; p=0.20). The modifications of T cell number were not significantly different when good and moderate responder (n=22) and no responder (n=9) patients were compared, at baseline and after therapy. No correlation was found between age of patients, clinical features of the disease and RTE number at baseline and after 6 months.

**Conclusions:** The number of total naïve T cells increases after therapy with ABA together with the number of RTE, suggesting a thymic output boost. Besides the peripheral effect in reducing the number of effector T cells which was showed by previous studies (5), ABA could have a role in promoting the immune reconstitution at the early stage of T cell development. Furthermore, a consequent favorable effect on possible cardiovascular damage mechanisms mediated by CD31-T cells might be hypothesized.

**SAT0205 COMPARISON OF DISEASE STATUS IN UK PATIENTS WITH RA RECEIVING TNFI VS CDMARD**

J. Addison<sup>1</sup>, S. Lobosco<sup>2</sup>, B. Hoskin<sup>2</sup>, E. Sullivan<sup>2</sup>, J. Pike<sup>2</sup>, S. Fenwick<sup>1</sup>. <sup>1</sup>Biogen Idec, Maidenhead, <sup>2</sup>Adelphi Real World, Bollington, United Kingdom

**Background:** UK NICE guidance recommends initiation of tumour necrosis factor-alpha inhibitor (TNFi) for patients with severe RA unresponsive to intensive

therapy with conventional disease-modifying anti-rheumatic drugs (cDMARD). Data comparing cDMARD and TNFi in clinical trial settings are common, but there is limited published real-world evidence on their comparative effectiveness.

**Objectives:** Compare disease status and outcomes in UK patients with RA receiving cDMARD vs TNFi.

**Methods:** Data derive from Adelphi's RA Disease Specific Programme 2017, a cross-sectional survey of 49 UK rheumatologists providing information on demographics, disease history, disease status and treatment of patients with RA. All patients (n=640) were included in the RA treatment analysis; patients were included in the comparative analysis if at the time of survey they had been receiving current treatment for at least 3 months, with either cDMARD (and had never received biologic(b)DMARD), or a TNFi (and had never received prior bDMARD). A propensity score based on BMI, duration on current therapy, RA severity and disease duration at initiation of current therapy was used to match treatment groups. Using Abadie-Imbens standard errors, clinical characteristics and measures of disease activity were compared between the matched groups.

**Results:** Current therapy of 640 patients: 379 (59.2%) bDMARD, of which 253 (66.8%) were receiving TNFi; 212 (33%) cDMARD; 18 (2.8%) had never received any DMARD, 15 (2.3%) had discontinued bDMARD. Mean DAS28 at initiation of therapy was 4.94 in overall cDMARD and 5.77 in TNFi groups. Table 1 shows the comparative analysis of cDMARD vs TNFi matched treatment groups. The cDMARD group had a higher proportion of moderate/severe and active/very active disease at time of survey, a higher proportion of patients in this group had no improvement in disease severity or activity since initiation of current therapy, and they were less likely to have achieved a EULAR response. A higher proportion of cDMARD patients and physicians were not satisfied with their disease control. Mean DAS28 scores at time of survey had declined from time of initiation of therapy to time of survey in matched cDMARD vs TNFi groups, from 5.27 to 3.1 vs 5.77 to 2.7 respectively.

Table 1

	%	%	P=
<b>Physician reported current disease status</b>			
Moderate or severe	43.5	22.4	0.02
'Active' or 'very active' disease	58.8	44.1	0.10
<b>Change in disease status since initiation of current treatment</b>			
'No improvement' in severity	25.3	7.7	0.04
'No improvement' in disease activity <sup>1</sup>	22.0	7.7	0.08
Not achieved EULAR response (based on DAS28) <sup>2</sup>	16.0	6.9	0.08
<b>Satisfaction with current disease control</b>			
Physicians 'not satisfied'	39.4	8.2	<0.01
Patients 'not satisfied' <sup>3</sup>	31.7	16.7	0.35

Lower sample size due to missing values: <sup>1</sup> cDMARD 147, TNFi 168; <sup>2</sup> cDMARD 75, TNFi 131; <sup>3</sup> cDMARD 54, TNFi 60

**Conclusions:** UK patients with RA receiving cDMARD have poorer outcomes, in terms of measured disease status and control, than their matched counterparts receiving TNFi. Despite having a higher mean DAS score at initiation, patients in the TNFi group had a lower mean score at time of survey than patients receiving cDMARD. This real-world evidence highlights the continued utility of TNFi as effective treatments for patients with RA. Potential benefit of early TNFi initiation merits further research.

#### RESULTS OF THE ALTERRA CLINICAL TRIAL – THE EFFICACY OF THE ALTERNATIVE DOSING REGIMEN FOR RITUXIMAB BIOSIMILAR IN bDMARDS NAIVE PATIENTS WITH RHEUMATOID ARTHRITIS

V. Mazurov<sup>1</sup>, L. Denisov<sup>2</sup>, I. Gordeev<sup>3</sup>, O. Nesmeyanova<sup>4</sup>, T. Plaksina<sup>5</sup>, E. Ilivanova<sup>6</sup>, D. Krechikova<sup>7</sup>, E. Zonova<sup>8</sup>, L. Knyazeva<sup>9</sup>, A. Artemeva<sup>10</sup>, E. Dokukina<sup>10</sup>, E. Chernyaeva<sup>10</sup>, R. Ivanov<sup>10</sup>. <sup>1</sup>North-Western State Medical University named after I.I. Mechnikov, Saint-Petersburg, <sup>2</sup>V.A. Nasonova Research Institute of Rheumatology, <sup>3</sup>O.M. Filatov City Clinical Hospital №15, Moscow, <sup>4</sup>Chelyabinsk Regional Clinical Hospital, Chelyabinsk, <sup>5</sup>N.A. Semashko Nizhniy Novgorod Regional Clinical Hospital, Nizhniy Novgorod, <sup>6</sup>Leningrad Regional Clinical Hospital, Saint-Petersburg, <sup>7</sup>The Department Hospital at Smolensk Station of the open JSC "Russian Railways", Smolensk, <sup>8</sup>Novosibirsk State Medical University, Novosibirsk, <sup>9</sup>Kursk Regional Clinical Hospital, Kursk, <sup>10</sup>JSC BIOCAD, Saint-Petersburg, Russian Federation

**Background:** Rituximab (RTX) is successfully used in patients with active rheumatoid arthritis (RA) who previously received biological disease-modifying

antirheumatic drugs (bDMARDs) at a dose of 1000 mg. Previous preclinical and clinical studies showed that BCD-020 is highly similar to innovator RTX. ALTERRA study demonstrated that first-line use of 600 mg BCD-020 is very effective in bDMARDs naive patients with RA.

**Objectives:** The goal of ALTERRA study was to evaluate the efficacy and safety of the alternative dosing regimen (600 mg) of BCD-020 in bDMARDs naive patients with RA.

**Methods:** ALTERRA study was conducted as multicenter randomized double-blind placebo-controlled phase 3 study. After the screening patients were stratified by age, anti-CCP level and DAS28 score, randomized (2:1) into 2 arms and received BCD-020 (in combination with methotrexate (MTX)) in a dose 600 mg IV or placebo (in combination with MTX) on day 1 and day 15, then, if the activity of arthritis persisted after 24 wks of study, a second course was provided. Patients were observed up to 52 wks.

**Results:** A total of 159 patients were enrolled in ALTERRA study, 107 patients in BCD-020 arm and 52 patients in placebo arm.

**Efficacy:** ACR20 at wk 24 was reached by 65.69% of patients in BCD-020 arm and 29.41% in placebo arm (p=0.00005, the difference in proportion of registration ACR20 with 95%CI was 29.41 [19.27%; 53.28%], margin 10.5%) in per protocol population, so hypothesis of superiority was confirmed. The performed analysis showed a much more pronounced decrease in the DAS28-4 (ESR) index in BCD-020 arm compared with placebo arm (p=0.0006) at wk 24. A much more significant decrease in change of the HAQ-DI index was also shown in the BCD-020 arm (p=0.008). Analysis of efficacy at wk 52 showed the preservation of the response after 2 courses of therapy with BCD-020, 600 mg (in combination with MTX): ACR20 reached by 84.5%, ACR50 – by 54.6%, ACR70 – by 29.9 % of patients.

**Safety:** BCD-020 showed a favorable safety profile with no significant difference with placebo use (in combination with MTX). After 24 wks patients of both groups developed high similar level of related adverse events: 16.8% of patients in BCD-020 arm and 11.76% in placebo arm (p=0.555). There were only 3 cases of severe adverse events (2.8%) in BCD-020 arm and 2 cases (3.92%) in placebo group. From wk 24 to wk 52: 13.08% of patients (who received 2 courses of BCD-020) and 19.61% of patients (who received one course of BCD-020 after 24 wk) developed related adverse events.

Figure 1 ACR 20/50/70 in bDMARDs naive patients with RA after 24-wk treatment of BCD-020/placebo (in combination with MTX).

**Conclusions:** ALTERRA study showed high efficacy and favorable safety profile of RTX biosimilar BCD-020 at a dose of 600 mg in combination with MTX in bDMARDs naive patients with RA.

SAT0207

### DEPRESSIVE SYMPTOMS IN PATIENTS WITH RHEUMATOID ARTHRITIS IN SARILUMAB TARGET AND MOBILITY TRIALS AND IMPACT OF TREATMENT

V. Strand<sup>1</sup>, O. Hagino<sup>2</sup>, S. Guillonnet<sup>3</sup>, S. Boklage<sup>4</sup>, M. Reaney<sup>5</sup>, J. Sadeh<sup>2</sup>, N. Narcisse<sup>6</sup>, E. Mangan<sup>4</sup>, T. Kimura<sup>4</sup>. <sup>1</sup>Stanford University, Palo Alto, <sup>2</sup>Sanofi, Bridgewater, United States, <sup>3</sup>Sanofi, Chilly-Mazarin, France, <sup>4</sup>Regeneron Pharmaceuticals, Inc., Tarrytown, United States, <sup>5</sup>Sanofi, Guildford, United Kingdom, <sup>6</sup>AIXAL, Boulogne-Billancourt, France

**Background:** In patients with clinical depression, elevated interleukin-6 (IL-6) levels have been associated with higher symptom severity and greater resistance to standard antidepressant treatments. Depression and IL-6 elevation are highly prevalent in patients with rheumatoid arthritis (RA), and their co-occurrence may have an impact on health-related quality of life (HRQoL). Sarilumab is a human immunoglobulin G1 anti IL-6 receptor  $\alpha$  (anti-IL-6R $\alpha$ ) monoclonal antibody for treatment of moderately-to-severely active RA.

**Objectives:** To explore the effect of sarilumab on HRQoL in patients with moderate-to-severely active RA with co-existing symptoms of depression.

**Methods:** *Post-hoc* statistical analyses were performed on the Medical Outcomes Study Short Form 36 (SF-36) in 2 randomized controlled trials, MOBILITY (NCT01061736) and TARGET (NCT01709578), of sarilumab subcutaneous 150 mg or 200 mg every 2 weeks vs placebo, each combined with conventional synthetic disease modifying anti-rheumatic drugs. Patients were classified at baseline for probable major depressive disorder<sup>1</sup> (PMDD; SF-36 mental health (MH) domain score  $\leq 56$ ) or probable depressed mood and anhedonia<sup>2</sup> (PDMA; score  $\leq 10$  on both items of the MH domain: "Have You Felt Downhearted and Depressed" and "Have You Felt So down in the Dumps that nothing could cheer you up"). Analyses of least squares mean differences in changes from baseline in SF-36 domain scores for sarilumab versus placebo in the PMDD and PDMA subgroups were performed at Weeks 4, 12 and 24 for TARGET and Weeks 24 and 52 for MOBILITY. Sensitivity analysis adjusted for baseline Disease Activity Score 28 C-reactive protein (DAS28-CRP).

**Results:** Of the 546 patients from TARGET and 1197 from MOBILITY, 59.5% and 60.2% were classified as PMDD respectively, and 50.4% and 51.6% as PDMA. In both RCTs disease duration and baseline DAS-28 CRP, tender and swollen joint count (table 1) and SF-36 domain scores (figure 1) were similar between sarilumab and placebo within the PMDD and PDMA subpopulations. TARGET: MH scores for PMDD and PDMA subgroups were nominally higher ( $p < 0.05$ ) for sarilumab 200 mg versus placebo at all assessments. Both subgroups also scored nominally higher ( $p < 0.05$ ) in the domains of physical functioning (PF), role-physical (RP), bodily pain (BP), general health (GH), vitality (VT) and social functioning (SF) but not role-emotional (RE) in the PMDD subgroup at Week 24 (figure 1). MOBILITY: all scores except PF and RE were nominally higher ( $p < 0.05$ ) for sarilumab 200 mg versus placebo for Weeks 24 (figure 1). Sensitivity analysis provided similar results. Exploratory results also suggested reduced prevalence of depressive symptoms over the course of the trial.

Figure 1. PMDD: SF-36 MH domain score  $\leq 56$ ; PDMA:  $\leq 10$  on both items of SF-36 MH domain

**Conclusions:** In patients with RA and depressive symptoms, sarilumab provided clinically meaningful improvements in most domains of health status/HRQoL compared with placebo, which may be a function of targeting the IL-6R $\alpha$  and subsequent reduction in disease activity.

### HOW GOOD ELDERLY RHEUMATOID ARTHRITIS PATIENTS RESPOND AT FIRST YEAR OF TREATMENT WITH CERTOLIZUMAB PEGOL?

V. Torrente-Segarra<sup>1</sup>, M. Fernandez Prada<sup>2</sup>, R. Expósito<sup>3</sup>, N. Garrido Puñal<sup>4</sup>, A. Sánchez-Andrade<sup>5</sup>, J. R. Lamúa-Riazuelo<sup>6</sup>, A. Olivé<sup>7</sup>, J. V. Tovar<sup>8</sup> on behalf of RENACER Study Group (Registro Nacional Certolizumab). <sup>1</sup>Rheumatology, Hospital General Hospitalet-Moisès Brogg, Hospitalet Llobregat, <sup>2</sup>Hospital Universitario de Guadalajara, Guadalajara, <sup>3</sup>Hospital Comarcal de Laredo, Laredo, <sup>4</sup>Hospital Universitario Virgen del Rocío, Sevilla, <sup>5</sup>Complejo Hospital Universitario Lucus Augusti, Alicante, <sup>6</sup>Hospital Universitario del Henares, Alcalá Henares, <sup>7</sup>Hospital Germans Trias i Pujol, Badalona, <sup>8</sup>Hospital General Universitario de Elche, Elche, Spain

**Background:** In rheumatoid arthritis (RA), the efficacy and safety of Certolizumab pegol (CZP) is well established, as reported in randomized clinical trials (RCT)<sup>1</sup> and some registries<sup>2</sup>. Only the 30% of RA patients are within the age range of 65 years or older. However, they are usually excluded from the RCT. Aging is associated with declining immune cell function and age-related comorbidities<sup>3,4</sup>.

**Objectives:** The aim of this study was to determine the effectiveness and safety of CZP in elderly patients in a real world setting at 12 months follow-up.

**Methods:** Observational longitudinal prospective study of RA patients from 40 sites in Spain. Variables (baseline, 3- and 12-month assessment): socio-demographics, smoking status, previous synthetic DMARD (sDMARD) and biological DMARD (bDMARD) use; TJC, SJC, ESR, CRP, DAS28. Response variables EULAR Moderate/Good Response and DAS28 remission and Safety were assessed. Low Disease Activity as DAS28 remission or mild DAS28. Descriptive, comparative and Logistic regression analyses were performed comparing  $< 65$  vs.  $> 65$  yr population. Kaplan-Meier survival curve was performed.

**Results:** A total of 501 RA patients were included, 23% were aged  $\geq 65$  yr (mean age 70.8 ( $\pm 4.5$  SD)yr). Sociodemographics and baseline features are shown in table 1.

Table 1.

	$< 65$	$> 65$	P
Women	77.7%	80.7%	NS
Disease evolution (yr)	6.7 ( $\pm 6.5$ SD)	10.4 ( $\pm 9.1$ SD)	$< 0.001$
- $\leq 2$ yr	-30.5%	-18.3%	-0.012
Smoking status:			0.024
Current	19.9%	9.1%	
Exsmoker never	13.6%	11.1%	
Bio-naïve	66.5%	79.8%	
	56%	53.1%	NS
		*previous Abatacept use was higher in $> 65$ yr ( $p = 0.017$ )	

Efficacy variables are shown in table 2.

Variable	$< 65$ years	$\geq 65$ years	p value
DAS28 Remission (yes)	43%	31.3%	0.026
DAS28 Low Disease Activity	57.5%	47.3%	NS
DAS28 $> 1.2$ score reduction	55.4%	60.7%	NS
EULAR Response	67.7%	75%	NS
CZP Retention rate	74.6%	67.5%	NS
Adverse Events	11.3%	19.3%	0.026

**Comorbidities (yes)** 34.8% 46.5% 0.024

The only associated factors to a better response in patients  $\geq 65$  yr were: higher DAS28 score, lower HAQ score and bio-naïve ( $p < 0.05$ ).

**Conclusions:** The effectiveness of CZP among  $\geq 65$  yr only differed from their younger counterparts from DAS28 remission rate, with a lower percentage, and side-effects (higher percentage, with higher comorbidities percentage too). However, after one year of real-life data CZP seemed as both safety and effective enough as younger RA patients in real-life scenario.

#### SAT0209 A COMPARATIVE REAL-WORLD UTILIZATION PATTERNS OF INNOVATOR AND BIOSIMILAR INFlixIMAB IN A TREATMENT NAÏVE AND SWITCH POPULATION FROM GERMANY: A PRESCRIPTION CLAIMS ANALYSIS

E. M. Ewara<sup>1</sup>, L. Ellis<sup>2</sup>, K. Goyal<sup>2</sup>, V. Jairath<sup>3</sup>, A. M. Marrache<sup>4</sup>, X. Baraliakos<sup>5</sup>.  
<sup>1</sup>Government Affairs and Market Access, Janssen Inc., Toronto, Canada, <sup>2</sup>Janssen Scientific Affairs, Horsham, United States, <sup>3</sup>Western University & London Health Sciences Centre, London, <sup>4</sup>Medical Affairs, Janssen Inc., Toronto, Canada, <sup>5</sup>Rheumazentrum Ruhrgebiet, Ruhr-University Bochum, Herne, Germany

**Background:** Data on treatment utilization patterns for innovator infliximab (IFX) and biosimilar infliximab (CT-P13) in IBD are scarce. Given low uptake of biosimilars in Canada to date, evaluation of treatment initiation and discontinuation was undertaken in a proxy country, Germany, which has similar demographic factors and neither have a mandated biosimilar switch policy.

**Objectives:** Retrospective prescription claims analysis comparing utilization patterns of innovator (IFX) and biosimilar (CT-P13) infliximab in treatment naïve population at 12 months and in patients continuing IFX vs switching to CT-P13 at 6 months.

**Methods:** QuintilesIMS™ longitudinal health insurance prescription data from Germany identified patients with an index claim of IFX or CT-P13 in all indications between Feb 2015-Oct 2016. Twelve-month post-drug initiation and 6-month post innovator-to-biosimilar switch retention analyses were conducted. All patients had sufficient claims history post-index and  $\geq 2$  claims of IFX or CT-P13 within the analysis period. Six-month analyses included: 1) matched analysis where each CT-P13 switch patient was matched to 5 IFX patients for IFX exposure prior to switch; 2) unmatched analysis where CT-P13 switch patients were compared to the first 6 months of the IFX treatment naïve population. Log-binomial regression analyses were conducted to determine the relative risk (RR) of being retained on treatment at 6 or 12 months adjusted for age, sex, biologic treatment history and prescriber specialty.

**Results:** 6,491 patients had a claim of IFX or CT-P13. Of these, 1,160 and 1,324 patients had follow up time for inclusion in the 12-month naïve and 6-month post-switch analyses, respectively. Only IFX to CT-P13 switch utilization ( $n=101$ ) was investigated. The risk adjusted probability of being retained on treatment after 12 months was 23% greater in the IFX group than in the CT-P13 group (RR IFX=1.23, 95% Confidence Interval [CI]: 1.12–1.36,  $p < 0.0001$ ). The probability of being retained was also greater in men, those who were bio-naïve and those prescribed drug by a rheumatologist. In the matched 6 months post-switch analysis the risk adjusted probability of being retained on treatment was 26% greater in the IFX maintenance group than in the CT-P13 switch group (RR IFX=1.26, 95%CI: 1.10–1.45,  $p=0.0007$ ). The probability of being retained was also greater in those prescribed drug by a rheumatologist. Similar results were found in the unmatched analysis (RR IFX =1.32, 95%CI: 1.16–1.51,  $p < 0.0001$ ), where the probability of being retained was also greater in men and in those who were bio-naïve.

**Conclusions:** The findings from Germany demonstrate significant differences in the real-world utilization patterns of patients treated with IFX or CT-P13 in all labelled indications. Limitations of this study include a heterogeneous population, disease severity and reasons for staying on treatment or switching could not be determined. Future analyses should capture clinical outcomes to better understand observed utilization patterns.

#### SAT0210 TREATMENT RETENTION RATE OF BIOLOGICAL TREATMENT IN ELDERLY RHEUMATOID ARTHRITIS PATIENTS COMPARED WITH YOUNGER RHEUMATOID ARTHRITIS PATIENTS – A SINGLE CENTER COHORT STUDY -

Y. Hirano<sup>1</sup>, K. Hattori<sup>1</sup>, R. Yamada<sup>1</sup>, Y. Oishi<sup>1</sup>. <sup>1</sup>Rheumatology, Toyohashi Municipal Hospital, Toyohashi, Japan

**Background:** Biological (BIO) therapy has become a standard therapy in the treatment of rheumatoid arthritis (RA) and long-term outcomes has increasingly evaluated. Elderly people has increased in Japan and 27.3% of whole people in Japan was 65 years of age or older in 2016. We reported treatment retention rate of BIO therapy in RA patients in EULAR2015 annual meeting as mixed data of elderly RA patients (ERA) and younger RA patients (YRA) <sup>1</sup>.

**Objectives:** This observational cohort study investigated the treatment retention rate in ERA compared with YRA.

**Methods:** Toyohashi RA Database (TRAD) was used. 330 RA patients who initiated any of BIO agents (infliximab, etanercept, adalimumab, tocilizumab, abatacept, golimumab, infliximab-BS) as first Bio in our institute from 2003 to 2016 were included in this study. Switching from one Bio agent to another was defined as continuation of Bio therapy in this study. Stopping of BIO therapy was defined as non-administration for longer than 3 months for any reasons other than remission and pregnancy related. We divided whole patients into two categories using age at initiation of BIO therapy such as YRA (64 years of age or younger) and ERA (65 years of age or older). ERA was further subdivided into two categories such as yERA (65–74 years of age) and oERA (75 years of age or older). We investigated patients' characteristics, treatment retention rate by Kaplan-Meier method and reasons of stopping BIO therapy and compared them between categories.

**Results:** Baseline characteristics at the initiation of BIO treatment: %female was 82.4%. Mean age was 58.1 years old (210 YRA, 98 yERA and 22 oERA). Mean RA duration was 10.9 years. % methotrexate (MTX) concomitant was 82.1% and mean used dose was 8.9 mg/weeks (MTX dose was restricted up to 8 mg/weeks until 2011 in Japan and 16 mg/w after 2011). % prednisolone (PSL) concomitant was 50.9%. % Bio monotherapy was 9.1%. Mean baseline DAS28-CRP and SDAI was 4.6 and 24.4, respectively. % high disease activity measured using DAS28 and SDAI at baseline was 44.4% and 42.2%, respectively (Fig1). Baseline disease activity were getting lower year by year. Continuation rate of BIO treatment in whole patients is 88.4% at 1 year, 82.0% at 3 years, 72.2% at 5 year and 57.1% at 10 years. There were significant differences in continuation rate of BIO treatment between YRA and ERA (Fig2), between yERA and oERA and between YRA and oERA, but not between yERA and oERA. Major reasons (over 10%) of stopping BIO therapy in YRA were infection other than respiratory system (15.7%), infection of respiratory systems (11.8%), ineffectiveness (11.8%) and malignancy (11.8%). Major reasons in ERA were infection of respiratory systems (21.3%) and infection other than respiratory systems (10.6%).

Figure 1 Continuation rate of biological therapy in whole patients

Figure 2 Continuation rate of biological therapy in YRA and ERA

YRA: younger RA patients, ERA: elderly RA patients

**Conclusions:** Although continuation rate of BIO treatment in ERA was inferior to that in YRA, that in yERA was not significantly different from that in oERA. Serious infection, especially in respiratory systems, was most frequent reason for stopping BIO therapy in ERA. These results suggested that BIO therapy in ERA demands close attention to infection and special strategies might need in the treatment of ERA people.

SAT0211

#### IS THERE A POTENTIAL FOR THERAPEUTIC DRUG MONITORING OF SUBCUTANEOUS TOCILIZUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS IN DAILY PRACTICE?

Z. Layegh<sup>1</sup>, M. J. L. 'Ami<sup>1</sup>, C. Bastida<sup>2</sup>, A. D. Huitema<sup>2,3</sup>, C. Kriekkaert<sup>1</sup>, M. T. Nurmohamed<sup>1,4</sup>, T. Rispens<sup>5</sup>, G. Wolbink<sup>1,5</sup>. <sup>1</sup>Amsterdam Rheumatology and immunology Center | Reade, <sup>2</sup>Pharmacy & Pharmacology, Cancer Institute-Antoni van Leeuwenhoek, Amsterdam, <sup>3</sup>University Medical Center Utrecht, Utrecht, <sup>4</sup>Amsterdam Rheumatology and Immunology Center | Vumc, university medical center, <sup>5</sup>Immunopathology, Sanquin Research and Landsteiner Laboratory, Amsterdam, Netherlands

**Background:** Tocilizumab (TCZ), is a humanized antibody that competitively inhibits membrane-bound and soluble IL-6 receptors. Subcutaneous (sc) TCZ might be a potential candidate for therapeutic drug monitoring (TDM) since a high variability in serum concentrations has been reported. Considering that TCZ concentrations above 1 µg/mL have been claimed to be sufficient for normalizing CRP production (1), there might be an overexposure in a substantial proportion of patients. We expect that patients can at least reduce to a dose aiming for a trough concentration of 5 µg/mL. Insights in serum concentrations of sc TCZ with clinical efficacy are lacking, but are necessary to reduce overexposure, potential dose-dependent adverse effects and at the same time reduce costs.

**Objectives:** To describe TCZ trough serum concentrations in patients with rheumatoid arthritis (RA) treated with sc TCZ.

**Methods:** Prospective study with consecutive RA patients starting treatment with sc TCZ between June 2015 to October 2017 who had previously failed treatment with at least two DMARDs, including MTX. TCZ was administered at a dose of 162 mg every week and patients were followed for 28 weeks. The study was conducted at the Amsterdam Rheumatology and Immunology Center | Reade. Serum trough samples were collected at baseline and at 4, 16, 28 weeks thereafter. An enzyme-linked immunosorbent assay (ELISA) was used for TCZ measurement. To analyze the concentration variability among patients at 28 weeks, a last observation carried forward approach was used.

**Results:** In total, 26 patients were included in the study and 94 TCZ serum concentrations were measured. Median and interquartile range (IQR) of the follow-up period was 28 (16-28) weeks and 54% of the patients accomplished week 28. Drug concentrations ranged from 0.2 to 63 µg/mL, with an overall median (IQR) of 26.0 (10.5-42.0) µg/mL. In the majority of patients, TCZ concentrations stabilized after 4 weeks of treatment. Variability in drug concentrations at 28 weeks is shown in figure 1. Median (IQR) TCZ serum concentrations at 28 weeks was 24.0 (6.4-43.0) µg/mL, 92% of the patients achieved a concentration above 1 µg/mL and 88% had a concentration > 5 µg/mL.

#### [TCZ] at 28 weeks with LOCF

**Conclusions:** The Interindividual variability among patients on sc TCZ is remarkably high. The majority of the patients achieved serum concentrations far above 5 µg/mL, suggesting overexposure in those patients. Therefore, TDM might be useful to optimize treatment, reduce (potential) side effects and achieve cost-effectiveness.

Chernykh<sup>2</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Cellular immunotherapy laboratory, Federal State Budgetary Scientific Institution Research Institute Of Fundamental And Clinical Immunology, Novosibirsk, Russian Federation

**Background:** Dendritic cells (DCs) are known to contribute to the pathogenesis of rheumatoid arthritis (RA) through the presentation of cartilage glycoprotein, production of proinflammatory cytokines and activation of Th1/Th17 responses. Along with stimulating activity, DCs may exhibit suppressive functions via capacity to induce T cell apoptosis/anergy and to generate regulatory T cells. Since these DCs have potential to control autoreactive T-lymphocytes, utilization of tolerogenic DCs seems to be a promising immunotherapeutic tool to treat RA.

**Objectives:** The aim of our study is to evaluate the safety and tolerability of a single intra-articular injection (into the knee joint) of autologous monocyte-derived dendritic cells generated in the presence of IFN-α/GM-CSF and tolerated with Dexamethasone in RA patients.

**Methods:** DCs were generated by culturing blood monocytes for 5 days with GM-CSF and IFN-α in the presence dexamethasone, applied on third day. Azoximer bromide as maturation stimuli was added on fourth day. Ten RA patients with moderate and high disease activity and ultrasound-defined knee synovitis were recruited in this study. All patients fulfilled ACR/EULAR criteria (2010) and received methotrexate, leflunomide, sulfasalazine or their combination. The patients received intra-articular injections of 1\*10<sup>6</sup>, 3\*10<sup>6</sup>, 5\*10<sup>6</sup>, 8\*10<sup>6</sup> DCs in knee joints. Safety was assessed by evaluation of adverse events (AE). Acceptability was assessed by questionnaire. DAS28 and HAQ were used for assessment of treatment efficiency. This trial registered on clinicaltrials.gov (ID: NCT03337165).

**Results:** DCs injections were safe and well tolerated. No one participants showed worsening of symptoms in targeting knee, fever, elevation of blood pressure or other AE within 7 days after injection. After one month the median pain VAS score decreased from 45 (40–65) mm to 40 (15–40) mm;  $p=0.03$ . Ultrasound and clinical examination did not detect synovitis. At 3 month no patients demonstrated recurrence of synovitis and median DAS28-ESR improved from baseline 5.1 to 4.4 ( $p=0.008$ ;  $n=10$ ). Five patients, evaluated at 6 months follow-up showed a good EULAR response (improvement of DAS28-ESR  $>1.2$ ). The median DAS28-ESR in this group decreased from 5.1 to 3.3 ( $p=0.04$ ). In addition, we detected median HAQ improvement (from 1.45 to 1.0;  $p=0.04$ ).

**Conclusions:** The data obtained suggest that single intra-articular injection of autologous tolerogenic dendritic cells is safe, well tolerated, and according to preliminary data have a potential efficiency. However, the final conclusion should be done after the completion of the trial.

### TIGHT TREATMENT OF PATIENTS WITH RHEUMATOID ARTHRITIS IN THE EARLY STAGES OF DISEASE LEADS TO HIGH LEVELS OF REMISSION AND REDUCED USE OF BIOLOGICS

K. Levasseur<sup>1</sup>, S. Raizada<sup>1</sup>. <sup>1</sup>Royal Wolverhampton NHS Trust, Wolverhampton, United Kingdom

**Background:** Early treatment with synthetic DMARDs has demonstrated favourable outcomes in patients with Rheumatoid Arthritis (RA). It leads to a reduction in inflammation, limits articular and extra-articular manifestations of RA, enables earlier functional improvement and causes less radiographic damage.<sup>1</sup> Treat to target (TTT) approaches have been used to adapt therapy according to disease activity in order to achieve clinical remission, providing a standardised treatment algorithm that allows for rapid treatment escalation when needed.

**Objectives:** To evaluate the remission rate of patients in a real life TTT clinic at a district general hospital in the United Kingdom and to compare our local data to the United Kingdom 2015–2016 Healthcare Quality Improvement Partnership (HQIP) audit. To evaluate the proportion of patients starting biological therapy post follow up in a TTT clinic.

**Methods:** The electronic records of patients referred to the TTT clinic between September 2012 and December 2015 were accessed retrospectively and data collected. All patients with a diagnosis of RA were included in data analysis. Patient demographics and clinical data were collected. Statistical analysis was performed using GraphPad Prism. Comparisons of outcomes for antibody status and smoking status were made using Fisher's exact test.

**Results:** 242 patients were seen at least once in the TTT clinic. Follow-up data was available for 216 patients. 65% were female with a median age of 62 years (range 19–90). 69% patients were either rheumatoid factor or anti-CCP positive and 80% were started on combination therapy (Methotrexate and Hydroxychloroquine) at their first clinic appointment. Overall 46% of patients entered remission (disease activity score (DAS) of  $<2.6$ ). 49% of seropositive patients achieved remission compared to 39% of seronegative patients although this was not statistically significant ( $P=0.249$ , Fisher's exact test). A statistically significant fewer number of people who were current smokers achieved remission ( $p=0.005$ , Fisher's exact test). Only 9 patients (4.2%) required the addition of biologic drugs within the first year of treatment.

**Conclusions:** Our TTT clinic was successful in starting a significant proportion (80%) of patients on combination DMARDs (compared to an estimated national average of 46% based on HQIP data).<sup>2</sup> This approach also resulted in a higher proportion of patients entering DAS remission (46%, national average 31%), though understandably this was lower than the remission rate achieved in clinical trials.<sup>3</sup> Only 4.2% of patients went onto biological DMARDs within the first year, which is far less than the proportion commencing biologics prior to TTT. This data demonstrates that TTT approaches in a real life clinical setting are important in achieving remission in patients with RA and reducing the need for expensive biologic treatment.

### EFFECTIVENESS OF A RANDOMIZED STEP-DOWN TO METHOTREXATE OR LEFLUNOMIDE MAINTENANCE THERAPY IN PATIENTS WITH LOW DISEASE ACTIVITY, 40 WEEKS AFTER STARTING COMBINED METHOTREXATE-LEFLUNOMIDE REMISSION INDUCTION THERAPY IN EARLY RHEUMATOID ARTHRITIS: RESULTS FROM THE CARERA TRIAL

V. Stouten<sup>1</sup>, S. Michiels<sup>2</sup>, A. Belba<sup>2</sup>, R. Westhovens<sup>1,2</sup>, P. Verschuere<sup>1,2</sup> on behalf of the CareRA study group. <sup>1</sup>Skeletal Biology and Engineering Research Centre, KU Leuven, <sup>2</sup>Rheumatology, University Hospitals Leuven, Belgium

**Background:** Combination of methotrexate, leflunomide and a short-term course of glucocorticoids is an effective initial treatment strategy for early rheumatoid arthritis (ERA) (1). However, evidence concerning further maintenance or step-down strategies after achieving remission or low disease activity is lacking.

**Objectives:** To evaluate efficacy and tolerability of a step-down to methotrexate versus leflunomide monotherapy in ERA patients achieving low disease activity (LDA) after induction therapy with a combination of both.

**Methods:** The care in ERA (CareRA) trial is a 2-year randomized pragmatic superiority trial comparing different remission induction strategies in ERA. For the purpose of the current sub-study, DMARD-naïve ERA patients initially randomized into the COBRA Avant-Garde arm (methotrexate 15 mg weekly + leflunomide 10 mg daily + prednisone step-down from 30 mg) were re-randomized, after a period of 40 to 52 weeks, to a methotrexate 15 mg weekly or leflunomide 20 mg daily maintenance therapy when achieving LDA (DAS28-CRP  $\leq 3.2$ ). Disease activity, functionality and X-ray damage were registered. Efficacy of both regimens was compared at week 65 after re-randomization as well as their safety profiles and drug retention rates (ITT analysis).

**Table 1** Clinical and radiological outcomes at week 65 per treatment arm Data are presented as mean  $\pm$  SD or number of patients and percentages; LDA, low disease activity; SvdH, Sharp van der Heijde score.

**Table 2** Effectiveness analysis after re-randomization AE, adverse event; SAE, serious adverse event; other AEs include all other AEs less likely to be related to methotrexate or leflunomide.

	Methotrexate N=32	Leflunomide N=26	p-value
Remission DAS28-CRP $<2.6$	30 (93.8%)	19 (73.1%)	0.031
LDA DAS28-CRP $\leq 3.2$	32 (100%)	23 (88.5%)	0.048
$\Delta$ DAS28-CRP from re-randomization	0.2 $\pm$ 0.7	-0.2 $\pm$ 1.0	0.214
Remission CDAI $\leq 2.8$	21 (65.6%)	14 (53.8%)	0.362
LDA CDAI $\leq 10$	32 (100%)	21 (80.8%)	0.009
$\Delta$ CDAI change from re-randomization	0.6 $\pm$ 2.7	-2.8 $\pm$ 8.1	0.462
Remission SDAI $\leq 3.3$	20 (62.5%)	14 (53.8%)	0.506
LDA SDAI $\leq 11$	32 (100%)	22 (84.6%)	0.021
$\Delta$ SDAI change from re-randomization	0.8 $\pm$ 3.1	-3.1 $\pm$ 8.2	0.244
HAQ (0-3)	0.3 $\pm$ 0.5	0.3 $\pm$ 0.4	0.968
Change in SvdH from baseline CareRA	0.7 $\pm$ 0.9	0.9 $\pm$ 1.8	0.702

Data are presented as mean  $\pm$  SD or number of patients and percentages; LDA, low disease activity; SvdH, Sharp van der Heijde score.

	Methotrexate	Leflunomide
Patients still on monotherapy on w65	23 (71.9%)	14 (53.4%)
Patients with AE related to study therapy	10 (31.2%)	9 (34.6%)
Total number of AEs	80	79
Infection	14	16
Gastrointestinal discomfort	7	13
Liver function disturbances	3	1
Other AEs	56	49
Total number of SAEs	7	4
Number of SAEs related to study therapy	0	0

AE, adverse event; SAE, serious adverse event; other AEs include all other AEs less likely to be related to methotrexate or leflunomide.

**Results:** We re-randomized 58 patients to either methotrexate ( $n=32$ ) or leflunomide ( $n=26$ ) monotherapy. At re-randomization 81.2% of patients in the methotrexate group (26/32) was in remission (DAS28-CRP  $<2.6$ ), versus 92.3% (24/26) in the leflunomide group ( $p=0.225$ ). At 65 weeks post re-randomization significantly more patients achieved DAS28-CRP remission in the methotrexate group (93.8%) than in the leflunomide group (73.1%) ( $p=0.031$ ). Patients re-randomized to methotrexate also achieved more frequently a state of LDA measured by DAS28-CRP, CDAI and SDAI in comparison to patients re-randomized to leflunomide (table 1). Safety analysis after re-randomization did not show differences between groups with regards to number or type of adverse events (AEs). Numbers of patients with AEs related to study medication were comparable (31.2% in the methotrexate and 34.6% in the leflunomide group). Throughout these 65 weeks 71.9% of patients in the methotrexate and 53.8% ( $p=0.098$ ) in the leflunomide arm remained on the assigned DMARD monotherapy. At the end of the study, in patients remaining on methotrexate monotherapy the mean dose was 15.3 mg weekly versus a mean dose of 17.1 mg daily in patients remaining on leflunomide monotherapy.

**Conclusions:** Step-down to methotrexate monotherapy instead of leflunomide monotherapy seems more efficacious, is well tolerated and has a good drug retention rate in ERA patients in LDA after combination therapy with methotrexate and leflunomide.

SAT0215

### LIVER BLOOD TEST ABNORMALITIES ARE RARE IN PATIENTS ON METHOTREXATE: EVIDENCE FROM A LARGE COHORT OF INFLAMMATORY ARTHRITIS PATIENTS

T. Malley<sup>1</sup>, G. Corfield<sup>1</sup>, D. Heneghan<sup>1</sup>, J. Kitchen<sup>1</sup>. <sup>1</sup>Royal Berkshire Hospital, Reading, United Kingdom

**Background:** National British Society of Rheumatology guidelines for monitoring non-biologic disease-modifying anti-rheumatic drugs (DMARDs) suggest reducing the frequency of blood monitoring for patients on stable doses of methotrexate to 12 week intervals.<sup>1</sup> Implementation of this recommendation would reduce pressure on services, reduce costs and enhance patient experience. However, it remains unclear whether patient safety would be compromised with 12 week interval blood monitoring in a real world setting.

**Objectives:** The primary objective was to establish whether reducing blood monitoring frequency from monthly to 12 week intervals would compromise the safety of patients on methotrexate by either late detection or missing signs of transaminitis on blood results.

**Methods:** Between June 2016 and July 2017, monthly liver function test results were monitored in 1,964 patients on methotrexate. Demographic data were collected and abnormal results were reviewed. Patients with raised alanine aminotransferase (ALT) (>34 U/l) were categorised as either: isolated (only one abnormal result), persistent (at least two consecutive abnormal results) or intermittent (more than one abnormal result separated by at least one normal result). For those with an ALT>100 U/l, medical records were reviewed to determine causality.

**Results:** ALT results for 1,964 patients were reviewed (F=1288, M=676). 775 were on one concomitant DMARD, 82 were on triple DMARD therapy (hydroxychloroquine and sulfasalazine) and 396 were on biologic therapy. Indications for methotrexate were rheumatoid arthritis (n=1262), psoriatic arthritis (n=611) and spondyloarthritis (n=91). Ten patients (0.51%) had an ALT>100 U/l over 13 months: 8 were persistent, 1 was intermittent and 1 was isolated. Further investigations revealed fatty liver in one patient (necessitating methotrexate discontinuation) and a weakly positive anti-smooth muscle antibody in another (both with persistent ALT>100), but were unremarkable in the other 8. A further 48 patients had at least one ALT rise of 35–100 U/l which did not alter therapy.

**Conclusions:** Over 13 months monitoring 1,964 patients on methotrexate, only 0.51% developed an ALT>100 U/l of whom only one patient discontinued methotrexate. In this patient the ALT rise was persistent for more than 12 weeks. Therefore 12 week interval blood monitoring would have reliably detected this abnormality. In those with intermittent and isolated ALT rises >100 U/l, there were no concerning features requiring cessation of methotrexate. This suggests that although a proportion of ALT rises would not be captured on 12 week blood monitoring intervals, isolated or intermittent rises are unlikely to pose harm to patients. Reducing the frequency of blood monitoring to 12 week intervals would be an efficient use of resources whilst being safe for patients. Furthermore this study provides evidence that less frequent blood monitoring may be feasible in patients on combination DMARDs, particularly relevant in an era where combination treatment is the standard of care in inflammatory arthritis.

### THE ADDITION OF COLCHICINE TO METOTREXATE MIGHT HELP ACHIEVE LOW DISEASE ACTIVITY IN PATIENTS WITH EARLY RHEUMATOID ARTHRITIS BY DOWNREGULATING THE ACTIVITY OF CASPASE-1.

D. Ramos-Bello<sup>1</sup>, A. J. Pedro-Martínez<sup>2</sup>, G. Aguilera Barragán-Pickens<sup>2</sup>, E. S. Acevedo-Castañeda<sup>2</sup>, H. López-Ferretis<sup>2</sup>, G. Martínez-Flores<sup>2</sup>, T. A. Luna-Zúñiga<sup>2</sup>, E. Santillán-Guerrero<sup>2</sup>, R. Moreno-Valdés<sup>2</sup>, M. Saldaña-Baard<sup>2</sup>, E. Cuevas-Orta<sup>2</sup>, C. Álvares-Quiroga<sup>2</sup>, R. González-Amaro<sup>2</sup>, C. Abud-Mendoza<sup>2</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>UASLP, San Luis Potosí, Mexico

**Background:** NLRP3 inflammasome is an intracellular protein complex involved in the production of pro-inflammatory cytokines as IL-1 $\beta$  and IL-18, which has been reported to have a role in the pathogenesis of RA<sup>1,2</sup>. Since colchicine (CCH) is a potent inhibitor of NLRP3<sup>3</sup>, we hypothesized that it may significantly modify the expression and function of this molecular complex, reducing the inflammatory phenomenon in early rheumatoid arthritis (eRA).

**Objectives:** To evaluate the possible effect of CCH administration on the expression and activity of NLRP3 in patients with eRA and evaluate if it has an effect on disease activity.

**Methods:** Inflammasome expression by monocytes was assessed by two-color flow cytometry (CD14<sup>+</sup>NLRP3<sup>+</sup> cells), and its function was estimated through the analysis of caspase-1 activity (colorimetric assay). Clinical activity was assessed by HAQ-DI, CDAI, SDAI and DAS28ESR at 0, 4 and 12 weeks.

**Results:** Twenty DMARD naive patients were recruited, 18 women, mean age 47.55 (30–72), mean time with symptoms 20 months and seropositive (RF/ACCP) in 60% of patients; all described in table 1. All patients had increased levels of caspase-1 activity and NLRP3 in week 0. At week 12, MTX+CCH patients showed decreased activity of caspase-1 and numerical difference in the expression of NLRP3. Patients with MTX+CCH at week 12 had significant clinical improvement, with low disease activity in 6/10 patients vs 2/10 patients with MTX (p<0.05). Mean change in HAQ was -0.64 in patients with MTX compared with -1.5 in patients with MTX+CCH (p<0.05).

Table 1 Demographic characteristics

	$\pm 0.59$	$\pm 0.53$				
CD14+NLRP3+ Cells – %	30.63	27.06	0.47	26.12	17.48 +	0.1
	$\pm 11.5$	$\pm 7.85$		$\pm 14.7$	4.34	
Immunofluorescence CD14 +NLRP3+	576.8	514.9	0.62	402.6	319.8	0.3
	$\pm 267.35$	$\pm 252.44$		$\pm 236.99$	$\pm 201.7$	
Caspase-1 activity- nm	0.572	0.463	0.27	0.300	0.120 +	<b>0.005</b>
	$\pm 0.159$	$\pm 0.243$		$\pm 0.176$	0.07	

**Conclusions:** The data suggest that CCH administration is associated with decrease in the expression NLRP3 inflammasome and activity of caspase-1. This phenomenon contributes to decrease inflammation and may help to achieve low disease activity. The administration of CCH might block additional targets in patients with eRA.

**SAT0217 IDENTIFICATION OF DISTINCT DISEASE ACTIVITY TRAJECTORIES IN PATIENTS WITH RHEUMATOID ARTHRITIS RECEIVING TOFACITINIB OVER 12 MONTHS**

V. P. Bykerk<sup>1</sup>, R. van Vollenhoven<sup>2</sup>, C. Connell<sup>3</sup>, D. Gruben<sup>3</sup>, L. Fallon<sup>4</sup>, J. Woolcott<sup>5</sup>, E. Keystone<sup>6</sup>. <sup>1</sup>Weill Cornell Medical College, New York, NY, United States, <sup>2</sup>Amsterdam Rheumatology and Immunology Center, Amsterdam, Netherlands, <sup>3</sup>Pfizer Inc, Groton, CT, United States, <sup>4</sup>Pfizer Canada, Montreal, QC, Canada, <sup>5</sup>Pfizer Inc, Collegeville, PA, United States, <sup>6</sup>Mount Sinai Hospital, Toronto, ON, Canada

**Background:** Persistence of active disease in patients (pts) with rheumatoid arthritis (RA) is highly variable following treatment initiation. One possible explanation is the existence of distinct disease activity/response trajectories influenced by baseline variables, such as sociodemographics, disease characteristics and health status.<sup>1</sup>

**Objectives:** To identify distinct disease activity trajectories over 12 months and distinguishing baseline factors using pooled data from 3 randomised, controlled Phase 3 (P3) studies of tofacitinib 5 mg twice daily (BID) in pts with active RA who were inadequate responders (IR) to conventional synthetic (cs)DMARDs, with or without prior biologic (b)DMARDs (NCT00847613, NCT00856544 and NCT00853385).

**Methods:** Disease Activity Score in 28 joints, erythrocyte sedimentation rate (DAS28-4[ESR]) data from 3 P3 studies were pooled. A group-based trajectory modelling strategy was applied to find unique longitudinal groups of pts with similar disease activity over time.<sup>2</sup> Trajectories were latent models, fit as polynomials. The number of groups and polynomial degree of each group were specified and fit for all combinations of up to 6 groups and up to a 4th degree polynomial; a best-fit model was chosen using Bayesian information criteria.

**Results:** csDMARD-IR/bDMARD-naïve pts (n=677) were separated into 5 unique disease activity trajectories (figure 1); csDMARD-IR pts who received prior bDMARDs (n=149) were separated into 4 trajectories (not shown). In the bDMARD-naïve pts, Group 5 (3.8%) had the highest predicted baseline DAS (7.3) with minimal improvement (6.4) at Month 12; Group 4 (26.7%) had baseline DAS 7.0, improving to DAS 5.0 at Month 12; Groups 2 (30.4%) and 3 (36.6%) had baseline DAS 5.9 and 6.2, respectively, leading to low DAS (2.9) and moderate DAS (3.9), respectively, at Month 12; Group 1 (2.4%) had the lowest baseline DAS of 4.3, improving to remission (DAS 2.1) at Month 12 (figure 1). The 4 trajectories in csDMARD-IR pts who received prior bDMARDs were similar to Groups 2–5 in bDMARD-naïve pts. While baseline demographics were generally similar between bDMARD-naïve groups, there were statistically significant differences in baseline disease activity measures and pt-relevant outcomes between groups.

n = sample size of trajectory; d = degree of polynomial of trajectory  
 Solid lines represent predicted values, with 95% CI indicated by shading. Percentages reflect the proportion of subjects in each group  
 csDMARD, Conventional synthetic DMARD; BID, twice daily; CI, confidence interval; csDMARD, conventional synthetic DMARD; DAS28-4(ESR), Disease Activity Score in 28 joints, erythrocyte sedimentation rate; DMARD, disease-modifying antirheumatic drug; HDA, high disease activity; IR, inadequate responder; LDA, low disease activity; RA, rheumatoid arthritis

**Figure 1.** Predicted group trajectories based on DAS28-4(ESR) with 95% CI identified using group-based trajectory modeling in patients with active RA who were csDMARD-IR and bDMARD-naïve and receiving tofacitinib 5 mg BID = sample size of trajectory; d = degree of polynomial of trajectory

**Conclusions:** It was possible to identify heterogeneous phenotypic subgroups as distinct disease activity trajectories in csDMARD-IR pts treated with tofacitinib.

The groups were characterised by differences in disease activity and pt-relevant outcomes, including baseline pain and physical function. Very high disease activity may limit pts' ability to achieve low disease activity. The identification of distinct trajectory groups could be used to develop personalised treatment optimisation algorithms incorporating clinical and molecular phenotypes.

**Background:** Baricitinib (BARI) is an oral selective inhibitor of Janus kinase 1 (JAK1) and JAK2. In the EU and some other countries, baricitinib has been approved for the treatment of moderately to severely active rheumatoid arthritis (RA) in adult patients. This abstract reports efficacy and safety results from a phase 3, double-blinded, 52-week study (RA-BALANCE) that enrolled patients (pts) in China, Argentina and Brazil (NCT02265705).

**Objectives:** To assess the efficacy and safety of BARI vs placebo (PBO) in the treatment of RA.

**Methods:** Patients with moderately to severely active RA (tender joint counts  $\geq 6$  & swollen joint counts  $\geq 6$  & hsCRP  $\geq 6$  mg/L) despite stable background methotrexate (MTX), were randomized 1:1 to PBO (n=145) or BARI 4-mg (n=145) once daily (QD), stratified by country and baseline joint erosion status. Background MTX was continued. Non-responders were rescued from Week 16. At Week 24, pts receiving PBO were switched to BARI 4-mg QD. ACR20 at Week 12 was the primary endpoint and there were multiple secondary endpoints e.g., assessing physical function, low disease activity and pain.

**Results:** The primary ACR20 response was significantly greater for BARI than PBO (58.6% vs 28.3%,  $p \leq 0.001$ , Table). At Weeks 12 and 24, significant improvements were seen in pts receiving BARI vs PBO for ACR20/50/70, DAS28-hsCRP, CDAL low disease activity and SDAL low disease activity, many as early as by Week 1. At Week 16, significantly less radiographic progression was seen in pts receiving BARI vs PBO and numerical improvement was observed at Week 24. At Week 12, significant improvement in HAQ-DI minimum clinically important difference  $\geq 0.3$  (physical function), duration of morning joint stiffness, severity of morning joint stiffness numeric rating scale (NRS), worst tiredness NRS and reduced pain (0–100 mm VAS) were seen in pts receiving BARI vs PBO.

During Weeks 0–24, treatment emergent adverse events and infections were reported in 74.5% and 42.1% of BARI pts and 62.1% and 28.3% of PBO pts, respectively. Serious adverse events were reported in 2.8% of pts in both groups. There was 1 nonserious esophageal candidiasis in the BARI group for Week 0–24. Four herpes zoster events (1 PBO, 3 BARI) were reported for Week 0–24. No major cardiovascular events, deaths, tuberculosis, venous thromboembolic

events or malignancies were reported in the study through Week 24 for PBO and through Week 52 for BARI group. No unexpected safety signals were observed.

**Table 1.** Study RA-BALANCE efficacy measures

	Week 12		Week 24		Week 52 <sup>†</sup>

SAT0219

**UPADACITINIB IN PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE OR INTOLERANCE TO BIOLOGICAL DMARDs: A PHASE 3 RANDOMIZED, PLACEBO-CONTROLLED, DOUBLE-BLIND STUDY OF A SELECTIVE JAK1 INHIBITOR**

M. C. Genovese<sup>1</sup>, R. Fleischmann<sup>2</sup>, B. Combe<sup>3</sup>, S. Hall<sup>4</sup>, Y. Zhang<sup>5</sup>, Y. Zhou<sup>5</sup>, M. F. Mohamed<sup>5</sup>, S. Meerwein<sup>6</sup>, A. L. Pangan<sup>5</sup>. <sup>1</sup>Stanford Univ, Palo Alto, <sup>2</sup>Univ of Texas Southwestern, Dallas, United States, <sup>3</sup>Montpellier Univ, Montpellier, France, <sup>4</sup>Monash Univ, Cabrini Health & Emeritus Res, Malvern, Australia, <sup>5</sup>AbbVie, N Chicago, United States, <sup>6</sup>AbbVie Deutschland, Ludwigshafen, Germany

**Background:** Upadacitinib (UPA), an oral, selective JAK1 inhibitor was effective in ph 2 trials in rheumatoid arthritis (RA) pts with inadequate response (IR)/intolerance to csDMARDs and bDMARDs.

**Objectives:** To evaluate safety and efficacy of UPA in bDMARD-IR pts on stable background csDMARDs.

**Methods:** Pts with active RA (TJC≥6, SJC≥6; hsCRP≥3 mg/L) were randomized 2:2:1:1 to receive UPA 15 mg or 30 mg once daily (QD) or PBO for 12 wks followed by UPA 15 mg or 30 mg QD starting at Wk 12. The primary endpoints were the proportion of pts achieving ACR20 (for FDA) and the proportion achieving DAS28CRP≤3.2 (for EMA) at Wk 12 (NRI).

**Results:** Of 499 randomized pts, 498 received study drug; 451 (90.6%) and 419 (84.1%) completed Wks 12 and 24 respectively. BL disease characteristics

indicated long-standing severe, refractory disease: (means) duration since diagnosis 13 yrs; DAS28CRP, 5.8; TJC68, 27.9; SJC66, 16.8; 53% experienced ≥2 prior bDMARDs. At Wk 12, more pts (p<0.001) on UPA 15 and 30 vs PBO achieved the primary endpoints (ACR20: 64.6% and 56.4% vs 28.4%; DAS28CRP≤3.2: 43.3% and 42.4% vs 14.2%) and other secondary endpoints (Table). Among pts with IR to multiple bDMARDs/MOAs, and pts with lack of efficacy for α-IL-6, the proportions achieving ACR20 on UPA vs PBO were comparable to the overall treated population. By Wk 1, more pts achieved ACR20 on UPA 15 and 30 vs PBO (27.4% and 24.8% vs 10.7%, p<0.001). At Wk 12, significant improvements were observed on UPA 15 and 30 vs PBO for HAQ-DI (LSM change -0.39 and -0.42 vs -0.17, p<0.001). At Wk 24, responses were similar or greater for pts originally on UPA and comparable for pts who switched to UPA after 12 wks of PBO.

Up to wk 12, the frequency of AEs was comparable for PBO and UPA 15, but higher for UPA 30 (table 1). Overall AE rates (E/100 PY) through Wk 24 for UPA 30 were similar or slightly higher vs UPA 15; more AEs led to study drug discontinuation in UPA 30. Occurrence of infections was similar in all arms, but there were more serious infections and herpes zoster cases in UPA 30. Malignancies were reported in 3 pts over 12 wks with 1 additional case through Wk 24. Through Wk 12, pulmonary embolism (PE) was reported in 2 pts (1 each on UPA 15 and 30), none with DVT; through Wk 24, PE were reported in 4 more pts (UPA 15: 3, 1 of whom also had a DVT; UPA 30:1). All had risk factors for DVT/PE. 2 deaths were reported (UPA30: 1 before Wk 12; UPA 15:1 after Wk12).

CV Events adjudicated <sup>‡</sup>	0	1 (0.6)	0	0	1 (0.6)	2 (1.2)	0
Deaths <sup>¶</sup>	0	0	1 (0.6)	0	0	1 (0.6)	0

D/C, discontinuation; LoE, lack of efficacy; NMISCI, non-melanoma skin cancer; PE, pulmonary embolism; GI, gastrointestinal; CV, cardiovascular.

<sup>†</sup>Opportunistic infections: oral candidiasis, one case of mucocutaneous candidiasis.

<sup>‡</sup>Herpes Zoster: most were mild and all but one were single dermatome; 2 serious cases.

<sup>§</sup>Malignancies: through Wk 12-UPA 15: 1 malignant melanoma; UPA 30: 2 pts with prostate cancer; Wk 12-24, UPA 15: 1 pt with bladder cancer.

<sup>¶</sup>1 pt also had DVT; <sup>‡</sup>adjudicated CV events: through Wk 12-UPA 15 mg: 1 pt with ischemic stroke; Wk 12-24, UPA 15: 1 pt with CV procedure, 1 pt with cardiac arrest adjudicated to undetermined/unknown cause of death; UPA 30: 1 pt with myocardial infarction; <sup>‡</sup>Deaths: through Wk 12-UPA 30: 1 due to cardiac failure & PE; Wk12-24, UPA 15:1 unwhimpered death adjudicated as undetermined/unknown cause of death.

**Conclusions:** In this treatment-refractory, bDMARD-IR RA population, rapid, significant improvements were observed with UPA at both doses vs PBO during 12 wks of treatment, and maintained through 24 wks. Overall safety was consistent with ph2 and other ph3 studies with UPA. The rates of PE and DVT observed in this study have not been reported for the other ph3 studies that have been unblinded to date. Overall data from the ph3 program will allow a comprehensive evaluation of the benefit:risk profile of UPA in RA.

### EVALUATION OF LIVE ZOSTER VACCINE IN A SUBSET OF PATIENTS WITH RHEUMATOID ARTHRITIS TREATED WITH TOFACITINIB WITH OR WITHOUT METHOTREXATE, AND ADALIMUMAB WITH METHOTREXATE: RESULTS FROM A PHASE 3B/4 RANDOMISED TRIAL

L. H. Calabrese<sup>1</sup>, C. Abud-Mendoza<sup>2</sup>, S. Lindsey<sup>3</sup>, S.-H. Lee<sup>4</sup>, L. Takiya<sup>5</sup>, N. Iikuni<sup>6</sup>, K. Soma<sup>7</sup>, Z. Luo<sup>8</sup>, R. Fleischmann<sup>9</sup>. <sup>1</sup>Cleveland Clinic Foundation, Cleveland, OH, United States, <sup>2</sup>Hospital Central, San Luis Potosí, Mexico, <sup>3</sup>Ochsner Medical Center, Baton Rouge, LA, United States, <sup>4</sup>Konkuk University School of Medicine, Seoul, Korea, Republic Of, <sup>5</sup>Pfizer Inc, Collegeville, PA, <sup>6</sup>Pfizer Inc, New York, NY, <sup>7</sup>Pfizer Inc, Groton, CT, United States, <sup>8</sup>Pfizer Inc, Shanghai, China, <sup>9</sup>Metrolplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, United States

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Patients (pts) with RA are at increased risk for herpes zoster (HZ) and this risk is further increased with tofacitinib treatment.<sup>1</sup>

**Objectives:** To evaluate the effect of live zoster vaccination (LZV) on HZ rates in a subset of methotrexate inadequate responder (MTX-IR) pts with RA who received tofacitinib with or without MTX, or adalimumab (ADA) with MTX in the ORAL Strategy randomised controlled trial (RCT).<sup>2</sup>

**Methods:** ORAL Strategy (NCT02187055) was a Phase 3b/4, 1-year, triple-dummy active-comparator-controlled RCT. Pts were randomised 1:1:1 to receive tofacitinib 5 mg twice daily (BID; tofa mono), tofacitinib 5 mg BID+MTX (tofa +MTX), or subcutaneous ADA 40 mg every other week + MTX (ADA+MTX); target MTX dose was 15–25 mg/week. In countries where LZV was available, pts aged ≥50 years received LZV at the investigator's discretion, 28 days before the first dose of study drug. HZ incidence rates (IR; pts with events per 100 pt-years) and 95% confidence intervals (CI) were calculated for each treatment arm and for vaccinated vs non-vaccinated pts.

**Table 1.** IRs and 95% CIs of HZ (serious and non-serious), and demographic characteristics among patients vaccinated and not vaccinated against HZ in the ORAL Strategy RCT

<sup>a</sup>From LZV sites not available in Canada, Israel or Thailand at the beginning of ORAL Strategy. In some instances, the other countries did not allow the vaccine to be given. <sup>b</sup>USA, n=7; Mexico, n=2; Latin America, n=1; Poland, n=3; Russia, n=1; Bosnia and Herzegovina, n=1; UK, n=1; Taiwan, n=1. <sup>c</sup>HZ cases requiring hospitalization or parental HZ treatment. <sup>d</sup>Defined as disseminated or multifocal/monoclonal (monoclonal or >2 adjacent dermatomes) HZ. <sup>e</sup>One case of varicella adjudicated as an OI was included as an HZ case. ADA, adalimumab; BID, twice daily; CI, confidence interval; EQW, every other week; HZ, herpes zoster; IR, incidence rate; patients with events per 100 pt-years; LZV, live zoster vaccination; MTX, methotrexate; OI, opportunistic infection; RCT, randomised controlled trial.

**Results:** Of 1146 pts who received study drug (mean age: 50.1 years), 216 received LZV (proportion of pts who received LZV by treatment group: tofa mono: 18.0%; tofa+MTX: 19.9%; ADA+MTX: 18.7%) 28 days before randomisation in this RCT; 30 pts self-reported prior vaccination (Table). No pts had zoster-like lesions within 42 days of vaccination; 1 pt had vaccination site erythema. In the overall study population, HZ IR was similar between tofa mono and ADA+MTX and numerically higher (overlapping CI) with tofa+MTX. IRs were generally similar for pts who received LZV (18.8% of pts were vaccinated) vs those who did not (81.2%) (Table). Overall, 18/1146 pts had HZ. Among vaccinated pts, 3 (1.4%) had HZ: no events were serious and 1 (0.5%) event was multidermatomal (tofa mono). Among pts not vaccinated, 15 (1.6%) had HZ: there were 2 (0.2%) serious HZ events (tofa+MTX: n=1; ADA+MTX: n=1), 2 (0.2%) multidermatomal events (tofa mono: n=1; ADA+MTX: n=1) and 1 (0.1%) disseminated event (ADA+MTX).

**Conclusions:** In MTX-IR pts with RA, LZV was well-tolerated. HZ IR was numerically similar between tofa mono and ADA+MTX and higher with tofa+MTX. HZ rates were generally similar in pts who received LZV vs those not vaccinated. LZV has shown efficacy in prevention of HZ in 51% (pts ≥60 years old) and 70% (50–59 years old) of immunocompetent adults.<sup>3</sup> Efficacy of LZV could not be fully evaluated as a minority (<20%) of pts received LZV and not all geographic regions studied in other tofacitinib studies were represented.

### EFFECT OF TOFACITINIB ON REDUCING PAIN IN PATIENTS WITH RHEUMATOID ARTHRITIS, PSORIATIC ARTHRITIS AND ANKYLOSING SPONDYLITIS

A. Ogdie<sup>1</sup>, K. de Vlam<sup>2</sup>, I. B. McInnes<sup>3</sup>, P. J. Mease<sup>4</sup>, P. Baer<sup>5</sup>, T. Lukic<sup>6</sup>, K. Kwok<sup>6</sup>, C. Wang<sup>7</sup>, M.-A. Hsu<sup>7</sup>, A. Maniccia<sup>8</sup>. <sup>1</sup>Perelman School of Medicine at the University of Pennsylvania, Philadelphia, PA, United States, <sup>2</sup>UZ Leuven, Leuven, Belgium, <sup>3</sup>University of Glasgow, Glasgow, United Kingdom, <sup>4</sup>Swedish Medical Center and University of Washington, Seattle, WA, United States, <sup>5</sup>Baer Weinberg MPC, Scarborough, ON, Canada, <sup>6</sup>Pfizer Inc, New York, NY, <sup>7</sup>Pfizer Inc, Groton, CT, United States

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA) and psoriatic arthritis (PsA), which has also been evaluated in other inflammatory rheumatic diseases (IRD) including ankylosing spondylitis (AS). Pain contributes substantial morbidity in patients (pts) with IRD and directly impacts treatment adherence, assessment of disease improvement and health-related quality of life.

**Objectives:** To evaluate the effectiveness of tofacitinib in reducing pain in randomised controlled clinical trials in pts with RA, PsA and AS.

**Methods:** Five pt populations treated with tofacitinib 5 mg twice daily (BID), 10 mg BID or placebo (PBO) were evaluated: [1] conventional synthetic disease-modifying antirheumatic drug (csDMARD)-inadequate response (IR) RA pts pooled from ORAL Scan (NCT00847613), ORAL Sync (NCT00856544) and ORAL Standard (NCT00853385), [2] tumour necrosis factor inhibitor (TNFi)-IR RA pts from ORAL Step (NCT00960440), [3] csDMARD-IR PsA pts from OPAL Broaden (NCT01877668), [4] TNFi-IR PsA pts from OPAL Beyond (NCT01882439) and [5] AS pts from a Phase 2 study (NCT01786668). Pain outcomes evaluated from baseline to Month (M)6 (Week [W]12 in the AS population) included Pt's Assessment of Arthritis Pain (PAAP) (RA and PsA populations only), Short-Form Health Survey (SF)-36v2 Q7 (bodily pain in the past week), SF-36v2 Bodily Pain Domain (BP), EuroQol Five Dimensions Questionnaire Pain/Discomfort Domain (EQ-5D PD; all populations) and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI) Q2 (level of AS neck, back or hip pain) and Q3 (other pain) score (PsA and AS populations only; PsA pts had presence of spondylitis at screening and baseline BASDAI total score >0 in the full analysis set [FAS]). Data were analysed descriptively.

**Results:** The csDMARD-IR RA, TNFi-IR RA, csDMARD-IR PsA, TNFi-IR PsA and AS populations comprised a total of 2066, 399, 316, 394 and 155 pts in the FAS, respectively. In each RA or PsA csDMARD-IR and TNFi-IR population treated with tofacitinib, mean PAAP at baseline (5 mg BID, range 55.7–65.7 mm; 10 mg BID, 54.4–60.1 mm) decreased as early as W2 (1st post-baseline assessment; 45.8–49.8 mm; 38.9–44.8 mm) and continued to decrease through M6 (30.9–34.4 mm; 28.2–36.7 mm); decreases were numerically greater vs PBO and the magnitude of change in RA and PsA populations was similar (Table). Improvements in SF-36v2 Q7 (Table), SF-36v2 BP (Table) and EQ-5D PD were observed in all 4 RA and PsA csDMARD-IR and TNFi-IR populations, and in BASDAI Q2 and Q3 in the csDMARD-IR PsA and TNFi-IR PsA populations. In the AS population, improvements from baseline in mean SF-36v2 Q7 (Table), SF-36v2 BP (Table), EQ-5D PD and BASDAI Q2 were reported at W12 and were numerically greater vs PBO.

**Table 1.** Mean (SE) PAAP score,<sup>a</sup> SF-36v2Q7 score<sup>b</sup> and SF-36v2 BP<sup>c</sup> at baseline through M6(FAS) in RA and PsA csDMARD-IR or TNFi-IR population, and SF-36v2Q7 score,<sup>b</sup> and SF-36v2 BP<sup>c</sup> at baseline and W12 (FAS) in the AS population

Time point	Subpopulation 1: RA				Subpopulation 2: PsA				Subpopulation 3: AS			
	Mean	SE	95% CI	n	Mean	SE	95% CI	n	Mean	SE	95% CI	n
Baseline	4.2 (0.1)	0.1	3.9-4.5	100	4.1 (0.1)	0.1	3.8-4.4	100	4.3 (0.1)	0.1	4.0-4.6	100
W6	4.5 (0.1)	0.1	4.2-4.8	100	4.4 (0.1)	0.1	4.1-4.7	100	4.6 (0.1)	0.1	4.3-4.9	100
W12	4.8 (0.1)	0.1	4.5-5.1	100	4.7 (0.1)	0.1	4.4-5.0	100	4.9 (0.1)	0.1	4.6-5.2	100

**Conclusions:** Treatment with tofacitinib is associated with a rapid improvement and sustained reduction of pain in pts with RA and PsA who are csDMARD-IR or TNFi-IR, and in pts with AS.

**Acknowledgements:** Study sponsored by Pfizer Inc. Medical writing support was provided by P Scutt of CMC and funded by Pfizer Inc.

**SAT0222 CLINICAL RISK STRATIFICATION FOR HYDROXYCHLOROQUINE PRESCRIBING IN A LARGE URBAN DISTRICT GENERAL HOSPITAL**

A. Saravanan<sup>1</sup>, T. Ahmed<sup>1</sup>. <sup>1</sup>Rheumatology Department, Croydon University Hospital, LONDON, United Kingdom

**Background:** New 2017 British Society of Rheumatology guidelines have recommended baseline formal ophthalmic examination, ideally including objective retinal assessment for example using optical coherence tomography, within 1 year of commencing an antimalarial drug. While the feasibility and costing of this recommendation is being assessed, we audited the current risk assessment for hydroxychloroquine prescriptions (HCQ) against the American College of Ophthalmology (ACO) guidelines for HCQ published in 2016. Table 1 shows the clinical criteria for assessment.

**Methods:** We identified all prescriptions of HCQ documented on the electronic patient records (EPR) from January to September 2017 by the Rheumatology department of Croydon University Hospital. This generated 237 records of which 114 were new prescriptions and 117 were continuation prescriptions. 8 records were excluded due to inadequate patient compliance. Cumulative doses were estimated from dates in the EPR going back to 2013

**Results:** New patient records were assessed for compliance with the ACO guidelines. Patients were assessed for kidney function, pre-existing renal disease, pre-existing eye disease. 74.6% patients were counselled regarding side effects and were advised to have optician retinal screening and 3.5% who had pre-existing eye disease were referred to ophthalmologists. 50.0% of patients had their weight documented prior to prescription. There was no documentation of dose calculated by weight. The commonest indication for HCQ were Systemic Lupus Erythematosis, Inflammatory Arthritis and Sjogren's Syndrome. 13.2% discontinued HCQ due to side effects. The commonest side effects were diarrhoea, dizziness, rashes, and mood swings.

Long-term patient records were assessed for cumulative dose of HCQ estimated from documentation. The average cumulative dose for these patients was with a maximum of 810,000 mg and a minimum of 49,600 mg. Overall, 3.0% percentage of patients did not have cumulative doses calculated due to documented compliance issues and 64.0% of patients had tightly monitored renal function.

Table 1 Clinical criteria for HCQ risk assessment based on American College of Ophthalmology guidelines (2016)

TABLE 1. Clinical criteria for HCQ risk assessment based on American College of Ophthalmology guidelines (2016)	
Factors Assessed	Explanation
Cumulative dose <5mg/kg daily dose for 5years	Guidelines recommend a daily dose of <5mg/kg. Any higher can incrementally increase the risk of retinopathy
Duration of Use	Decades of use can increase the risk, even in patients on the recommended daily dose.
Renal Disease Screening	HCQ is cleared by the kidneys, any drop in GFR can increase circulating drug doses therefore increase risk of toxicity.
Retinal Baseline Screening	Retinal screening is recommended for all patients to monitor the Retinal Pigment Epithelium damage therefore preserve central vision
Tamoxifen Use	Use of tamoxifen alongside HCQ can increase the risk of toxicity approximately 5-fold.
Pre-existing Retinal OR Macular disease	Eye sight can worsen on initiating HCQ.

**Conclusions:** 50% of patients had weight documented prior to prescription and this was not used to determine dosage. The majority of patients were well informed regarding side-effects of HCQ, had tightly monitored renal function and advised to have baseline retinal screening.

**Disclosure of Interest:** None declared

**Background:** Methotrexate (MTX) is generally recommended as first-line treatment of rheumatoid arthritis (RA). Despite its efficacy is well established, a percentage of patients fails the treatment. Few studies investigated the causes of early discontinuation of MTX; a two-year retention rate of about 66% is described for RA patients with lower age and longer disease duration as independent predictors for discontinuation.

**Objectives:** Aim of this study was to detect possible predictive factors for early discontinuation of MTX prescribed as first line treatment in RA patients enrolled in the GISEA (Italian Group for the Study of Early Arthritis) registry.

**Methods:** RA patients who began MTX as first line treatment were included in the study. For all patients age, sex, disease duration, smoking status, the intake of glucocorticoids, clinical and serological data, comorbidities and extra-articular manifestations were collected.

**Results:** We analyzed 612 RA patients (females/males 477/132, mean age 55.73±14.5 years; mean DAS28 5.35±1.5); rheumatoid factor (RF) was positive in 64.9%, anti-citrullinated peptide antibodies (ACPA) in 42.7%. Comorbidities were observed in 17.5% of patients, while extra-articular RA manifestations were recorded in 1.5%; 68.3% of subjects taken low doses of steroids. One hundred and forty-nine (24.3%) patients discontinued MTX during the first year (for inefficacy in 66/149 (44.3%) patients, adverse events in 51/149 (34.2%), and other reasons in 32/149 (21.5)). At univariate analysis early discontinuation of MTX was associated to a lower mean age (p=0.041) and a higher mean tender

and swollen joints count ( $p=0.001$  and  $p=0.024$ , respectively). Age and tender joints count were confirmed at multivariate analysis (OR 1.014, CI95% 1.001–1.027 and OR 0.951, CI95% 0.923–0.981, respectively) as independent predictors of early withdrawal of MTX.

**Conclusions:** More than 75% of RA patients treated with MTX as first-line therapy remained in treatment after 12 months. Age was directly correlated and tender joints count was inversely correlated with early withdrawal of MTX in RA patients.

**Disclosure of Interest:** None declared

SAT0224

#### AMELIORATION OF INFLAMMATORY DISEASE ACTIVITY AND VASCULAR INFLAMMATION WITH HMG-CoA REDUCTASE INHIBITION AND ANGIOTENSIN RECEPTOR BLOCKADE IN RHEUMATOID ARTHRITIS

A. Syngle<sup>1,2</sup>, N. Garg<sup>3</sup>, P. Krishan<sup>3</sup>. <sup>1</sup>Cardio Rheuma, Healing Touch City Clinic, Chandigarh, <sup>2</sup>Internal Medicine & Rheumatology, Fortis Hospital, Mohali, <sup>3</sup>Department of Pharmaceutical Sciences & Drug Research, Punjabi Univ., Patiala, India

**Background:** Rheumatoid Arthritis (RA) has 50% increased risk of cardiovascular (CV) mortality<sup>1</sup>. Similarities between atherosclerosis and RA and proven benefit of Angiotensin receptor Blockers and HMG-CoA reductase inhibitors in atherosclerotic vascular disease provide strong rationale to investigate the impact of Rosuvastatin, HMG-CoA reductase inhibitor and Olmesartan, an angiotensin receptor blocker on inflammatory disease activity and vascular inflammation in RA.

**Objectives:** To investigate the impact of Rosuvastatin and Olmesartan on inflammatory disease activity and vascular inflammation in RA

**Methods:** 84 RA patients randomized to 3 groups to receive 24 weeks of treatment with Rosuvastatin (Rvs) (10 mg/day, n=28), Olmesartan (OLME) (10 mg/day, n=28) and placebo (PL) (n=28) as an adjunct to existing stable antirheumatic drugs. 2 patients from the OLME group were lost to follow up. FMD was assessed by AngioDefender. EPCs were estimated by flow cytometry. Measures of vascular inflammation: serum nitrite, TBARS, adhesion molecules (ICAM-1 and VCAM-1) and lipids were measured at baseline and after treatment. Inflammatory measures included DAS28, SDAI, CRP and ESR, pro-inflammatory cytokines (TNF- $\alpha$ , IL-6 and IL-1). SCORE system estimated the 10 year risk of a first fatal atherosclerotic event. Quality of life was assessed with HAQ-DI and SF-36.

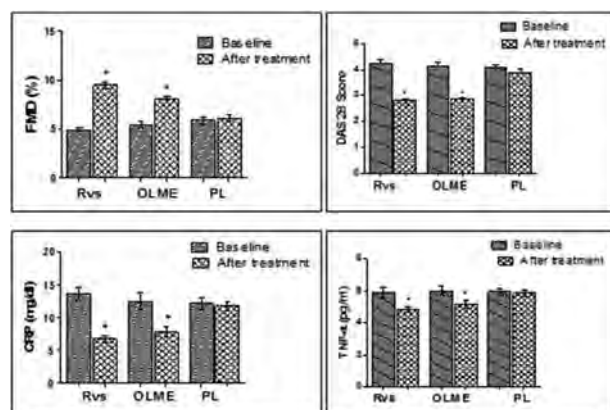

Figure 1A Effect on Flow Mediated Dilation (FMD).Rvs vs. OLME vs. PL (Rvs vs. PL ( $p<0.01$ ), OLME vs. PL ( $p\leq 0.01$ ), Rvs vs. OLME ( $p=0.03$ ) after 24 weeks. Figure 1B Effect on Disease Activity Score of 28 joints (DA S28). Rvs vs. OLME vs. PL (Rvs vs. PL ( $p<0.01$ ), OLME vs. PL. ( $p\leq 0.01$ ), Rvs vs. OLME ( $p=0.08$ ) after 24 weeks. Figure 1C Effect on C-Reactive Protein (CRP).Rvs vs. OLME vs. PL (Rvs vs. PL ( $p<0.01$ ), OLME vs. PL ( $p\leq 0.01$ ), Rvs vs. OLME ( $p=0.05$ ) after 24 weeks. Figure 1D Effect on Tumour Necrosis Factor- $\alpha$  (TNF- $\alpha$ ). Rvs vs. OLME vs. PL (Rvs vs. PL ( $p<0.01$ ), OLME vs. PL ( $p\leq 0.01$ ), Rvs vs. OLME ( $p=0.86$ ) after 24 weeks.

**Results:** At baseline, FMD correlated inversely with DAS28 ( $r = -0.42$ ,  $p<0.05$ ) and TNF- $\alpha$  ( $r = -0.50$ ,  $p<0.05$ ) and positively correlated with EPCs ( $r = 0.44$ ,  $p<0.05$ ) in all three groups indicating high inflammatory disease activity and decreased EPCs population associated with endothelial dysfunction. FMD also correlated inversely with CRP in both Rvs ( $r = -0.46$ ,  $p<0.05$ ) and OLME ( $r = -0.40$ ,  $p<0.05$ ) groups. After treatment, FMD improved significantly in the Rvs vs. OLME

vs. PL group from their baseline levels, respectively {Rvs vs. PL ( $p<0.01$ ), OLME vs. PL ( $p\leq 0.01$ ), Rvs vs. OLME ( $p=0.03$ )} (Fig.1A). The improvement in FMD after treatment with Rvs was significantly greater than OLME [Rvs vs. OLME ( $p=0.03$ )]. EPCs and nitrite levels were improved significantly in both Rvs and OLME groups. A significant reduction was found in ICAM-1 after Rvs treatment ( $p<0.01$ ) where as OLME significantly decreased VCAM-1 and TBARs ( $p=0.04$ ), ( $p=0.01$ ) respectively. Both Rvs and OLME resulted in significant reductions of DAS28 (figure 1B), SDAI, ESR, CRP (figure 1C), IL-6 and TNF- $\alpha$  (figure 1D) vs. PL. There was a significant reduction in the SCORE, HAQ-DI and SF-36 score after treatment with Rvs and OLME.

**Conclusions:** Rvs and OLME ameliorate inflammatory disease activity and vascular inflammation in RA. Both Rvs and OLME lowers the TNF- $\alpha$  & IL-6 which down regulates the production of CRP and NO and improved EPC population and FMD. However, Rvs also favourably impacted ICAM-1 and lipid abnormalities while OLME has beneficial effect on VCAM-1, TBARs and blood pressure. Thus, both Rvs and OLME ameliorate inflammatory disease activity, reduce cardiovascular risk in context of vascular inflammation, endothelial dysfunction and EPCs biology.

SAT0225

#### COMPARATIVE EFFECTIVENESS IN PAIN AND HAQ-DI IMPROVEMENT FOR BARICITINIB VERSUS ADALIMUMAB, TOCILIZUMAB, AND TOFACITINIB MONOTHERAPIES IN csDMARD-NAÏVE RHEUMATOID ARTHRITIS PATIENTS: A MATCHING-ADJUSTED INDIRECT COMPARISON (MAIC)

B. Fautrel<sup>1</sup>, B. Zhu<sup>2</sup>, P. C. Taylor<sup>3</sup>, M. van de Laar<sup>4</sup>, P. Emery<sup>5</sup>, F. De Leonardi<sup>2</sup>, C. Gaich<sup>2</sup>, C. Nicolay<sup>2</sup>, Z. Kadziola<sup>2</sup>, I. De La Torre<sup>2</sup>, R. Fleischmann<sup>6</sup>. <sup>1</sup>University Pierre et Marie Curie, Paris, France, <sup>2</sup>Eli Lilly and Company, Indianapolis, United States, <sup>3</sup>Botnar Research Centre, Univ of Oxford, Headington, United Kingdom, <sup>4</sup>Arthritis Center Twente, Enschede, Netherlands, <sup>5</sup>Leeds MSK Biomed/Chapel Allerton Hosp, Leeds, United Kingdom, <sup>6</sup>Univ of Texas Southwestern Med Ctr, Dallas, United States

**Background:** In Phase 3 trial, RA-BEGIN, baricitinib (BARI) monotherapy demonstrated superiority to MTX in pain reduction and HAQ-DI improvement in treatment of csDMARD-naïve active RA patients.<sup>1</sup> No prospective head-to-head (H2H) trial data are available comparing BARI monotherapy vs. bDMARD monotherapy in csDMARD-naïve RA patients.

**Objectives:** To assess pain and HAQ-DI for BARI monotherapy from a randomized, MTX-controlled trial vs adalimumab (ADA), tocilizumab (TCZ), and tofacitinib (TOFA) monotherapy from similar randomized, MTX-controlled trials in csDMARD/bDMARD naïve RA patients using matching-adjusted indirect comparison (MAIC).

**Methods:** Individual patient data from the RA-BEGIN BARI 4 mg arm were weighted to match baseline characteristics of the ADA arm from PREMIER,<sup>2</sup> TOFA 5 mg arm from ORAL-START,<sup>3</sup> and TCZ 8 mg/kg arm from combination of AMBITION and FUNCTION,<sup>4,5</sup> respectively; MTX arms were also matched between trials. Method of moments was used to determine weights for age, gender, baseline disease scores, and baseline values of the outcome variable. Mean change on pain VAS and HAQ-DI at Week 24 for BARI were adjusted for the above baseline characteristics with the weighted linear model, and then indirectly compared vs. respective published results for Week 24 TCZ and TOFA and for Week 26 ADA data. Statistical significance of the weighted treatment effect was assessed with the bootstrap method. Sensitivity analyses included MAIC with study level matching<sup>6</sup>, Bucher's method without matching adjustment<sup>7</sup>, and inclusion of disease duration as an additional matching variable.

**Results:** Across trials, the mean baseline pain VAS ranged from 58.7 to 65.2 with a 6-month mean change in pain of -28.3 to -33.5 for the MTX arm, indicating comparability between trials. Similar HAQ-DI and changes in HAQ-DI for the MTX arm were observed. At Week 24, BARI showed numerically greater improvement over MTX in pain than that for TCZ, ADA, and TOFA; statistically significant pain improvement were observed for BARI vs ADA and TCZ with all 3 matching methods but only with the Bucher method for TOFA (figure 1). BARI-treated patients showed significantly greater improvement in HAQ-DI at Week 24 than TCZ and ADA but not TOFA (figure 1). Sensitivity analyses showed consistent results.

**Conclusions:** This indirect comparison of different studies in cs/bDMARD-naïve RA patients, after adjusting for differences in baseline characteristics, suggest a greater pain reduction and improved physical function for BARI monotherapy vs. TCZ and ADA monotherapy. There is suggestion of greater pain reduction for BARI monotherapy vs. TOFA monotherapy, but no differences in improved physical function between the JAK inhibitors. A H2H clinical trial would be needed to confirm these results.

SAT0226

#### A PHASE 1, RANDOMIZED, DOUBLE-BLIND, PLACEBO-CONTROLLED, SINGLE- AND MULTIPLE-RISING DOSE STUDY OF THE BTK INHIBITOR TAK-020 IN HEALTHY VOLUNTEERS

E. Esfandiari<sup>1</sup>, H. Gevorkyan<sup>2</sup>, H. Faessel<sup>3</sup>, Z. Zhao<sup>4</sup>, K. Hanna<sup>5</sup>, G. Smithson<sup>3</sup>, J. Wagner<sup>3</sup>, E. R. Fedyk<sup>3</sup>, L. Mclean<sup>6</sup>. <sup>1</sup>Takeda, London, United Kingdom, <sup>2</sup>Parexel, Glendale CA, <sup>3</sup>Takeda, Boston, <sup>4</sup>Takeda, <sup>5</sup>PRA, Deerfield IL, <sup>6</sup>Takeda, San Diego, United States

**Background:** TAK-020 is a highly selective covalent inhibitor of the Btk enzyme. Btk is involved both in B cell receptor and FcR signaling. TAK-020 showed anti-inflammatory and disease-modifying efficacy in a rat collagen-induced arthritis model and is in clinical development, with potential for immune disorders including RA and SLE.

**Objectives:** To assess the safety, tolerability, pharmacokinetic (PK) and pharmacodynamic (PD) properties of TAK-020.

**Methods:** The study population comprised healthy volunteers aged 18 to 55 years. The SRD had 9 cohorts and the MRD 6, each randomized 6 active- to 2 placebo-treated subjects. 72 subjects were enrolled in the SRD, with 6 each receiving 0.1 mg, 0.5 mg, 2.5 mg, 4.4 mg, 8.8 mg, 17.5 mg, 35 mg, 70 mg, or 105 mg of TAK-020; and 18 subjects received placebo. 48 subjects were in the MRD, six

each receiving 7 once-daily (OD) doses of 3.75 mg, 5.75 mg, 13 mg, 25 mg, 45 mg, or 60 mg. A total of 30 subjects received placebo.

The PD effects of TAK-020 were assessed by measuring Btk occupancy and the inhibition of FcεR1-mediated activation of basophils, a Btk-dependent process resulting in increased CD63 expression.

**Results:** In the SRD the same percentage of subjects (11.1%) in the pooled placebo group and the overall TAK-020 group experienced treatment-emergent adverse events (TEAE). All TEAEs were of mild intensity. Abdominal distension, upper abdominal pain, nausea, and headache were reported as drug-related TEAEs in 3 subjects in the TAK-020 group. In the MRD a lower percentage of subjects receiving TAK-020 had TEAEs than with placebo (30.6 vs 41.7%). In 4 subjects (11.1%) these were considered drug-related and included nausea, diarrhea, dizziness and headache.

There were no serious AEs or AEs leading to study drug discontinuation. No subject had clinically significant changes in laboratory tests, vital signs, or ECGs.

TAK-020 was rapidly absorbed (median Tmax 45- 60 min), and had a mean elimination half-life of approximately 3- 9 hr after single and multiple dosing. Plasma exposure was in general proportional to dose up to 70 mg administered as a single dose and up to 60 mg after 7d of OD dosing.

Single doses of TAK-020 were associated with rapid binding of Btk, with occupancy >80% and maintained for 72 hours. Sustained binding of Btk was associated with >80% reduction from baseline in the proportion of CD63-positive basophils. This PD effect was sustained throughout the entire 24 hr dosing interval after administration of the 2 highest repeat doses of TAK-020 (45 and 60 mg) but fully reversed 1 week after the last dose.

**Conclusions:** TAK-020 was well tolerated in healthy volunteers after single and multiple doses, and demonstrated target engagement and biological activity. The PD effects outlasted PK exposures, as expected for a covalent inhibitor.

SAT0227

#### RHEUMATOID ARTHRITIS PATIENTS TREATED WITH A LOW-DOSE AND SHORT-TERM GLUCOCORTICOID WERE SATISFIED WITH EARLIER IMPROVEMENT AND REPORTED DECREASED ANXIETY REGARDING ADVERSE EVENTS.

E. Torikai<sup>1</sup>, D. Suzuki<sup>1</sup>, M. Suzuki<sup>2</sup>, Y. Matsuyama<sup>2</sup>. <sup>1</sup>Department of Rheumatology, Iwata city hospital, Iwata, <sup>2</sup>Department of Orthopaedic surgery, Hamamatsu university school of medicine, Hamamatsu, Japan

**Background:** At EULAR 2017, we reported that the treatment of early rheumatoid arthritis (RA) patients by a low-dose and short-term glucocorticoid therapy (low and short GC) enabled earlier improvement and didn't worsen the rate of new complications. Currently, in RA treatment, subjective assessment of patients as well as objective assessment of doctors is gaining more importance<sup>(1)</sup>. What do patients think about the risks of low and short GC? Does low and short GC improve patients' satisfaction?

**Objectives:** In this study, we investigated the change in each factor of the disease activity index (DAI) and patients' expectation of and anxiety regarding low and short GC through a questionnaire.

**Methods:** We include 96 Japanese patients with RA and <2-years disease duration. Patients were treated with a T2T strategy; if the disease activity was not improved within 3 months, their DMARDs were replaced with alternatives or additional DMARDs were added. We classified patients into two groups: those treated with DMARDs alone (N group; 35 females, 10 males) and those treated with ≤5 mg/day GC for a maximum of 1 year along with DMARDs (GC group; 40 females, 11 males). The mean ages of the N and GC groups were 56.3 and 60.9 years, respectively. In the GC group, the mean GC dose was 2.46 mg/day. No significant differences were observed between the groups regarding MTX or Biologics agent use rates. We evaluated changes in the number of swollen joints and tender joints, DAS28-CRP score, CRP and VAS of pain for 3 years and compared each factor of DAI between both groups. We then asked them by a questionnaire what was beneficial from the therapies and how much paid attention to the adverse events.

**Results:** There were no significant differences in all factors of DAI at baseline between the groups. At 1 month after treatment, there were significant differences in the improvement rate of VAS, CRP and DAS28-CRP score in the GC group compared with the N group. However, no significant difference was observed between the groups at ≥3 months after treatment (figure 1). In the questionnaire (figure 2), pain improvement was the most expected effect from the treatment (89%), and early therapeutic effect was the second (80%) in the GC group. The pain improvement and the early therapeutic effect were significantly higher in the

GC group than in the N group. The patients in both groups equally recognized the reduction in arthritis, morning stiffness, fatigue and the recovery of activities of daily living (ADL). Anxiety regarding adverse events was eliminated in the GC group as GC administration was restricted to a low dose for a short term. Almost identical results were obtained from the two groups.

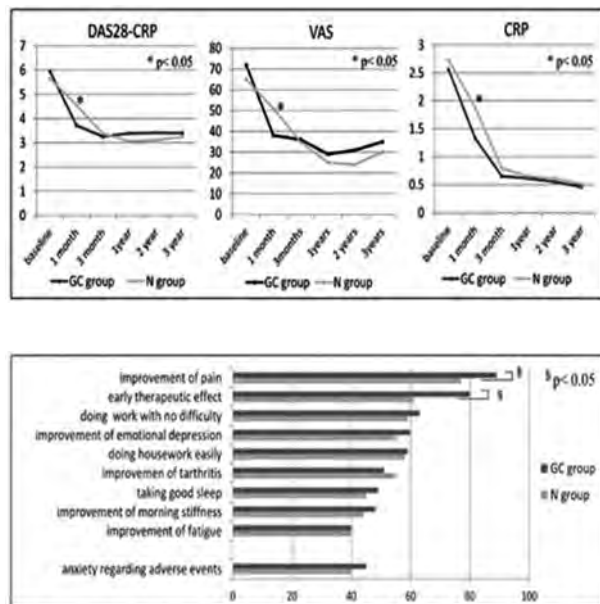

Figure 2. questionnaire results

**Conclusions:** The treatment of early RA patients with low and short GC enables earlier improvement of disease activity, particularly VAS and CRP. Patients also reported that low and short GC were an improvement effect from the early stage, particularly regarding pain and anxiety about adverse events. These data confirm that the treatment with low and short GC in RA patients leads to improved patient satisfaction.

#### STEP-DOWN METHOTREXATE THERAPY IN RHEUMATOID ARTHRITIS (STEMETRA): A PILOT STUDY TO ASSESS THE SAFETY AND THE TOLERABILITY OF HIGH-DOSE METHOTREXATE.

G. Bianchi<sup>1</sup>, D. Camellino<sup>1</sup>, A. Locaputo<sup>1</sup>, P. Diana<sup>1</sup>, A. Giusti<sup>1</sup>, G. Girasole<sup>1</sup>, J. Kremer<sup>2</sup>, M. Weinblatt<sup>3</sup>. <sup>1</sup>Division of Rheumatology, Musculoskeletal System Department, Azienda Sanitaria Locale 3 Genovese, Arenzano, Italy, <sup>2</sup>The Center For Rheumatology, Albany, New York, <sup>3</sup>Division of Rheumatology, Brigham and Women's Hospital, Boston, United States

**Background:** Methotrexate (MTX) remains the cornerstone of the treatment of rheumatoid arthritis (RA). However, MTX is frequently underutilized in terms of suboptimal dosage, insufficient duration of treatment, and route of administration.

**Objectives:** To evaluate the tolerability and the safety of higher-dose, subcutaneous methotrexate (MTX) in patients with rheumatoid arthritis (RA).

**Methods:** The STEP-down METHotrexate Therapy in Rheumatoid Arthritis (STEMETRA) was an open-label, monocentric, pilot study of 12-week duration. The protocol treatment schedule consisted of subcutaneous (SC) MTX 50 mg/week for 4 consecutive weeks, followed by 25 mg/week for 4 weeks and then 15 mg/week for 4 weeks. All patients received oral supplementation of folic acid (leucovorin) 12 mg, administered twelve hours after the injection of SC-MTX.

**Results:** Ten patients (7 females and 3 males), with a mean age of 58.1 (±12.1), were enrolled in this study; one of them withdrew consent before taking study drug. Therefore, nine patients were treated. MTX was well tolerated: a total of 5 adverse events (AEs) occurred in 4 patients, none of which was severe. AEs consisted in: transient elevation of alanine aminotransferase (<2 ULN), which resolved spontaneously, and vertigo, in the same patient; moderate fatigue in one patient; one case of urinary tract infection; low back pain in one patient. At week 12, four patients (44.4%) achieved DAS28(ESR) remission, two (22.2%) reached

low disease activity, one (11.1%) patient showed moderate disease activity, and two (22.2%) had still had high disease activity. Overall, 8 out of 9 patients (88.8%) showed a reduction in DAS28>1.2 from baseline.

Table 1 Adverse events in patients who received study drug. MTX: methotrexate; ALT: alanine aminotransferase; ULN: upper limit of normal; UTI: urinary tract infection. \*: this adverse event resolved by the time of the next visit. +: at week 12, this patient decided to withdraw MTX. §: this patient was taking MTX 20 mg/week instead of 15 mg/week as an escape treatment for insufficient disease control (see main text).

	Baseline	Week 2	Week 4	Week 8	Week 12
MTX dose	-	50 mg/week	50 mg/week	25 mg/week	15 mg/week
Patient #1	none	none	none	none	none
Patient #2	none	none	none	none	none
Patient #3	none	none	none	none	none
Patient #4	none	none	none	none	none
Patient #5	none	none	none	none	none
Patient #6	none	none	Increased ALT (<2 ULN)*	Vertigo	Vertigo+
Patient #7	none	none	none	Fatigue*	none
Patient #8	none	none	none	none	UTI <sup>§</sup>
Patient #9	none	none	none	Low back pain*	none

**Conclusions:** In this study, short-term higher dose MTX was well tolerated. Based on the tolerability observed in this preliminary study, a randomized controlled study of higher dose induction therapy versus traditional dosing will be conducted.

**Disclosure of Interest:** None declared

SAT0229

#### RHEUMATOID ARTHRITIS TREATMENT WITH COMBINATION OF THREE CONVENTIONAL SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS (csDMARDs) AND ITS EFFECTIVENESS ON DISEASE CONTROL IN A SHORT TERM COMPARED TO BIOLOGIC DMARDs TREATMENT AFTER PROPENSITY SCORE MATCHING PROCEDURE IMPLEMENTED

I. Yoshii<sup>1</sup>, T. Chijiwa<sup>2</sup>. <sup>1</sup>Rheumatology and Musculoskeletal Medicine, Yoshii Hospital, Shimanto City, <sup>2</sup>Rheumatology, Kochi Memorial Hospital, Kochi, Japan

**Background:** Rheumatoid arthritis (RA) treatment has now many variations with use of biologic or targeted synthetic disease modifying anti-rheumatic drugs (b/tsDMARDs) and conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs). In these, triple csDMARD combination therapy (tri-TX), that has comparable disease activity control effectiveness compared to anti-TNF therapy is one of alternative [1].

**Objectives:** Aim of this study is to evaluate the effectiveness of tri-TX compared to bDMARD with methotrexate treatment (bm-TX) for RA statistically, with the use of propensity score matching (PSM) technique.

**Methods:** Five hundred and fifty RA patient had been treated for more than one year in our clinic. In these, 74 patients had been treated with tri-TX and 135 had been treated with bm-TX, were recruited. Their sex distribution (Sex), anti-cyclic citrullinated peptide antibodies (ACPA), age, 28-joints disease activity score with C-reactive protein (DAS28-CRP), Health Assessment Questionnaire Disability Index (HAQ-DI), Sharp/van der Heijde Score (SvdHS), and pain score measured with visual analog scale (PS-VAS) at start of the treatment were measured for each patient, and their values were compared for each group. Thus, sample selection was performed with PSM technique in order to reduce bias on each of treatment groups. After selection, change of DAS28-CRP, HAQ-DI, PS-VAS for every three months until one year since start, and SvdHS at one year after were compared statistically with Mann-Whitney U test.

**Results:** After selection, twenty-three patients for each treatment group were harvested, and there demonstrated no significant difference in Sex, ACPA, DAS28-CRP, HAQ-DI, PS-VAS, and SvdHS at start of the treatment (table 1). Average DAS28-CRP demonstrated 2.76, 1.88, 1.91, 1.77, and 1.67 in bm-TX, while 2.71, 2.03, 2.41, 2.56, and 2.39 in tri-TX, at start, 3 month, 6 month, 9 month, and 1 year, respectively. There is no statistical significant difference between the two groups, but bm-TX demonstrated more significant improvement at every time after six month than tri-TX (<0.05), while no significant difference demonstrated in PS-VAS. Average HAQ-DI demonstrated 0.603, 0.579, 0.598, 0.609, and 0.625 in bm-TX, while 0.707, 0.654, 0.619, 0.594, and 0.567 in tri-TX, respectively. HAQ-DI showed tendency that improved more in tri-TX compared to bm-TX, whereas significant more improvement for tri-TX than for bm-TX had demonstrated at one-year (<0.05), however until then there demonstrated no statistical significance for both of absolute value and improvement. SvdHS demonstrated 62.4 to 61.6 from

start to one year in bm-TX, while 75.6 to 78.7 in tri-TX. Improvement of SvdHS demonstrated better result in bm-TX than in tri-TX significantly ( $p < 0.05$ ).

**Table 1.** Average values of each parameter and their  $p$ -values

	bm-TX	tri-TX	$p$ -value
Women	17 (73.9%)	16 (69.6%)	0.75
age	65.7	70.3	0.16
ACPA	171.1	452.6	0.14
GCs use	26.1%	21.7%	0.85
MTX use	100%	100%	1.00
DAS28-CRP	2.76	2.71	0.70
HAQ-DI	0.603	0.706	0.94
SvdHS	62.39	75.61	0.37
PS-VAS	41	39.7	0.79

bm-TX, a group of rheumatoid arthritis (RA) patient who is undertaken with biologic disease modifying anti-rheumatic drug (bDMARD) and methotrexate (MTX) therapy ; tri-TX, a group of RA patient who is undertaken with combination of three conventional synthetic DMARDs therapy ;  $p$ -value, statistical level of significance used with Mann-Whitney U test. Women express number and percentage in parenthesis. ACPA, anti-cyclic citrullinated peptide antibodies ; GCs, glucocorticoid steroid ; DAS28-CRP, 28-joints disease activity score with C-reactive protein ; HAQ-DI, Health Assessment Questionnaire Disability Index ; SvdHS, Sharp/van der Heijde Score ; PS-VAS, pain score measured with visual analog scale.

**Conclusions:** PSM is useful technique to diminish artificial bias. tri-TX is one choice for RA patient, but not superior for clinical results compared to bm-TX.

#### COMPARISON OF EFFICACY OF TOFACITINIB VS. ETANERCEPT TREATMENT IN RHEUMATOID ARTHRITIS PATIENTS WITH HIGH ACTIVITY DISEASE BY ULTRASOUND EVALUATION WITH POWER DOPPLER (1 YEAR TREATMENT PERIOD).

I. Menshikova<sup>1</sup>, N. Dzhenezhera<sup>2</sup>, Y. Pak<sup>1</sup>, I. Kolosova<sup>1</sup>. <sup>1</sup>*Rheumatology, <sup>2</sup>Ultrasound, First Moscow State Medical University, Moscow, Russian Federation*

**Background:** Modern clinical recommendations rule us to timely and rational treatment of rheumatoid arthritis (RA) patients with biologics or tofacitinib when traditional DMARDs failed in achievement of remission or low disease activity (LDA). Ultrasound power Doppler (PD) was recently recommended by some investigators for accuracy of evaluation of local inflammation in small joints to predict the possible flares of RA.

**Objectives:** To compare the efficacy of tofacitinib vs. etanercept in real clinical practice by complex evaluation including PD during 1-year treatment of RA patients with high disease activity.

**Methods:** In this randomized open study, we assign 30 patients to receive either etanercept 50 mg subcutaneous weekly (10 pts) or tofacitinib 5 mg BID orally (20 pts). There are 21 females and 9 males with severe RA (average DAS 28 >5,8) with inadequate response to methotrexate in effective dose enrolled into the study. Average age was 48.2±5.6 (42,1 for etanercept group and 51,9 for tofacitinib group), average disease history was 5,3 (1,5-25) years. Patients evaluated at baseline, after 3, 6 and 12 months of treatment: number of painful and swollen joints, ESR, C-protein, RF, anti-MCV, DAS 28, SDAI, ultrasound examination of hands and feet (German US7 score) by grey scale (GS) and power Doppler (PD).

**Results:** Patients in both groups had statistically significant decrease of disease activity. In etanercept group median DAS 28 decreased from 6.05 to 2.5

( $p < 0.001$ ), 5 pts achieved remission, 3 - LDA. In tofacitinib group median DAS 28 decreased from 5.86 to 3.23 ( $p < 0.001$ ), 5 pts achieved remission, 3 - LDA. Number of painful and swollen joints decreased to 3-8 times, ESR and C-protein normalized in 8 patients in etanercept group and 12 pts in tofacitinib group. SDAI evaluation showed lowering down the score of activity from range 37,10 to range 6,50 in etanercept group and from 40,78 to 14,25 in tofacitinib group. US dynamics: median GS score decreased from 6.5 to 2,5 ( $p < 0.01$ ) in etanercept group and from 8 to 3 ( $p < 0.01$ ) in tofacitinib group. Number of bone erosions still unchanged. In PD mode number of joints with hypervascularized synovium decreased from 3 to 0 ( $p < 0.001$ ) in both groups.

Also it was noticed that by 3rd month of the treatment LDA was achieved for 2 patients (out of 10) in etanercept group and 5 (out of 15) in tofacitinib one, and relatively by 12 month - 8 in etanercept group and 8 in tofacitinib. The most significant decrease of SDAI (more than 2 times) was achieved by 3rd month and go further with the same dynamics in etanercept group and slightly less in tofacitinib group.

**Conclusions:** Integrated evaluation of efficacy of treatment of patients with severe RA showed that both etanercept and tofacitinib have good effect in achieving of remission or LDA (DAS28 and SDAI). Tofacitinib acts similar to etanercept in 3 months of therapy, but then its effect progressed more slowly. PD is additional method of monitoring of sinovial inflammation and shows us the significant regression of tissue hypervascularisation (activity of inflammation) by 6 months of treatment both etanercept and tofacitinib. Follow up of patients within the year and later on helps to adjust therapy.

#### EFFECTS OF THE JAK1-SELECTIVE INHIBITOR FILGOTINIB ON GENE EXPRESSION PROFILE IN BLOOD OF PATIENTS WITH ACTIVE RHEUMATOID ARTHRITIS

P. C. Taylor<sup>1</sup>, J. Tarrant<sup>2</sup>, L. Zhao<sup>2</sup>, Y. Gindin<sup>2</sup>, A. Mirza<sup>2</sup>, P. Harrison<sup>3</sup>, C. Tasset<sup>3</sup>, R. Galien<sup>4</sup>, A. Van der Aa<sup>3</sup>, B. Downie<sup>2</sup>. <sup>1</sup>*Botnar Research Centre, Nuffield Dept Orthopaedics, Rheumatology and Musculoskeletal Sciences, University of Oxford, Oxford, United Kingdom, <sup>2</sup>Gilead Sciences, Inc., Foster City, United States, <sup>3</sup>Galapagos NV, Mechelen, Belgium, <sup>4</sup>Galapagos SASU, Romainville, France*

**Background:** Filgotinib (FIL), an oral selective JAK1 inhibitor, has shown good safety and efficacy in two phase 2b studies (background methotrexate (MTX, DARWIN 1) and as monotherapy (DARWIN 2)) in active rheumatoid arthritis (RA) patients with inadequate response to MTX<sup>1,2</sup>. We conducted a large-scale RNA sequencing study of genes expressed in blood samples from these studies.

**Objectives:** Identify RA-associated gene transcripts that are altered in response to FIL treatment.

**Methods:** PAXgene blood samples from 242 RA patients receiving either a stable dose of MTX and placebo (PBO) or FIL 200 mg once daily (QD, DARWIN 1); or PBO, FIL 100 mg, or 200 mg monotherapy QD (DARWIN 2), were collected and analyzed at baseline, week 1 and/or week 12. RNA in whole blood was sequenced (Illumina HiSeq 2500) after globin depletion. Differential gene expression analysis was performed on all time-paired data after subtracting gene expression changes in the PBO group. Spearman's rank correlation of gene expression to time, dose, and disease activity score (DAS28) were calculated on samples without missing values. A false-discovery rate (FDR) of 10% was applied for all analyses

**Results:** Top-ranked gene sets positively associated with DAS28 disease activity at baseline over both studies included interferon alpha (IFN- $\alpha$ ) and IFN gamma (IFN- $\gamma$ ) response, IL6/JAK/STAT3 signaling, and toll-like receptor signaling pathways (FDR<10%). Of 197 genes that positively correlated with disease score (increased gene expression with increased DAS28, FDR<10%), 117 (59%) trended toward reduced expression at 12 weeks with FIL in both studies. These genes were enriched in pathways which included granulocyte and macrophage activation. Conversely, of 256 genes negatively correlated with disease score (FDR<10%), 169 (66%) trended toward increased expression post-FIL (figure 1). Of 14724 genes expressed at >1CPM in at least 5% of the samples, 607 were differentially expressed following FIL treatment in either DARWIN1 or DARWIN2 with 48 genes significant in both studies (FDR<10%). Genes reaching significance in at least one study showed consistent magnitude and direction of change in both studies and were enriched in JAK/STAT, innate and adaptive immunity, and autoimmune associated pathways. CISH, SOCS2, SOCS3, VWA5a,

APCCD1, DNASE1L3, and PIM3 correlated with both duration of treatment and FIL dose (FDR<10%). CISH and SOCS confirm JAK pathway modulation.

**Figure 1** Heatmap of 453 DAS28-correlated genes and the corresponding change in gene expression with 12 wk FIL in Phase2b RA studies

**Conclusions:** RA patients treated with FIL show reproducible changes in gene expression consistent with modulation of JAK/STAT signaling and innate and adaptive immunity. FIL was shown to partially reverse the dysregulated gene expression profile associated with baseline DAS28 score, consistent with the efficacy observed in RA patients.

#### SAT0232 REACTIVATION OF IMMUNE CHECKPOINTS BY AN EPITOPE-SPECIFIC VACCINE REINSTATES TOLERANT PATHWAYS AND INDUCES CLINICAL AMELIORATION IN PATIENTS WITH RHEUMATOID ARTHRITIS

J. H. S. Chan<sup>1</sup>, T. van den Broek<sup>2</sup>, J. Y. Leong<sup>1</sup>, M. Rossetti<sup>1</sup>, R. Spreafico<sup>3</sup>, S. Albani<sup>4</sup>. <sup>1</sup>Translational Immunology Institute (TII)/Singapore Health Services Pte Ltd, Singapore, Singapore, <sup>2</sup>Harvard Medical School, Boston, <sup>3</sup>University of California, California, United States, <sup>4</sup>Translational Immunology Institute (TII)/Singapore Health Services Pte. Ltd, Singapore, Singapore

**Background:** Immune checkpoints like PD-1 that govern immune tolerance are attractive therapeutic targets in diseases driven by the dysregulation of tolerogenic pathways. We have previously reported that the induction of immune tolerance by epitope-specific immunotherapy with dnaJP1, a peptide sharing sequence homology to the HLA alleles implicated in the pathogenesis of rheumatoid arthritis (RA), results in clinical improvement in RA and represents a promising therapeutic intervention.

**Objectives:** In the present work, we adopt a holistic approach in deciphering the tolerogenic immune mechanisms underlying the efficacy of epitope-specific immunotherapy with dnaJP1 in a fully human context. We hypothesize that clinical amelioration of RA by dnaJP1 immunotherapy is attributed to the reactivation of immune checkpoints that triggers immune mechanisms modulating immune tolerance and clinical control.

**Methods:** Peripheral Blood Mononuclear Cells (PBMCs) were obtained at the end of the Phase II trial (Day168), from clinical responders treated with dnaJP1 (n=6) and clinical non-responders treated with placebo (n=10). Gene expression analysis was performed by quantitative PCR. The T cell compartment was studied by multi-coloured flow cytometry using specifically designed antibody panels. Flow cytometry results were then analysed by clustering with Multi-Dimensional Automated Reduction and Visualization (MARVis).

**Results:** Analysis of the T cell immunomes of dnaJP1 responders and placebo non-responders revealed a subset of CD4+FoxP3+ regulatory T (Treg) cells exclusively in dnaJP1 responders that displayed a higher expression of the

inhibitory immune checkpoint receptor, PD-1. The expression of PD-1 contributes to an enhancement of the tolerogenicity of this Treg cell subset by upregulating the production of signature anti-inflammatory cytokines such as TGFβ. In addition, we observed a corresponding reshaping of the effector T (Teff) cell compartment in which the expression of pro-inflammatory cytokines such as IL-17A and IFNγ was downregulated. Importantly, epitope-specific immunotherapy also induced a subset of active antigen-experienced memory T cells (CD4+CD45RO+CD69+) which sustains the tolerogenic immune response by secreting TGFβ. Lastly, our preliminary findings demonstrate that the concurrent use of Hydroxychloroquine (HCQ) exerts a synergistic effect in reinstating immune homeostasis by promoting the immunomodulatory capacity of antigen-presenting cells (APCs). The switch to a tolerogenic DC phenotype in the presence of HCQ in turn skews effector T cells towards a functionally protective phenotype by upregulating the expression of PD-1.

**Conclusions:** Our data exemplifies that the toggle between inflammation and tolerance is delicately controlled by a unique subset of Treg cells in which the immune checkpoint protein, PD-1 is switched on. We have also provided mechanistic knowledge on the synergistic relationship between HCQ and the clinical effectiveness of dnaJP1. Taken together, we demonstrate a vaccine-like therapeutic strategy that modifies the multitudinous perturbations in the auto-reactive immune system by reactivating immune checkpoints governing tolerogenic pathways.

#### SAT0233 METHOTREXATE TREATMENT IN RHEUMATOID ARTHRITIS AND ELEVATED LIVER ENZYMES: A LONG-TERM FOLLOW-UP OF OCCURRENCE, PREDICTORS, SURVEILLANCE, AND OUTCOME IN CLINICAL PRACTICE

J. Sundbäum<sup>1,2</sup>, N. Ericsson<sup>3</sup>, P. Hallberg<sup>3</sup>, N. Lehto<sup>2</sup>, M. Wadelius<sup>3</sup>, E. Baecklund<sup>1</sup>. <sup>1</sup>Department of Medical Sciences, Rheumatology, Uppsala University, Uppsala, <sup>2</sup>Dept of Health Science, Luleå University of Technology, Luleå, <sup>3</sup>Department of Medical Sciences, Clinical Pharmacology, Uppsala University, Uppsala, Sweden

**Background:** Hepatotoxicity is an important safety issue in long-term methotrexate (MTX) treatment. Guidelines, including the widely used American College of Rheumatology guidelines, therefore recommend testing of liver enzymes at intervals of 8–12 weeks in all MTX-treated patients with rheumatoid arthritis (RA), making this one of the most frequent screening tests in rheumatology care. Although a number of potential risk factors for liver toxicity have been identified, individual risk stratification is still not part of guidelines. Besides, it is unclear what proportion of all monitoring tests that captures liver enzyme elevations and what happens after an alanine aminotransferase (ALT) elevation in clinical practice.

**Objectives:** To assess predictors of ALT elevation in an unselected population of MTX-treated RA patients, describe monitoring of liver enzymes in clinical practice, including the handling and outcome of elevated ALT levels.

**Methods:** All RA patients starting MTX treatment January, 2005–April, 2013 at a rheumatology clinic, (Uppsala university hospital, Sweden) were identified. Clinical and laboratory data from onset of RA until MTX treatment stopped or the end of the study period September, 2013, were obtained from medical records and supplemented by a telephone interview. Predictors for ALT>1.5 the upper limit of normal (ULN) were identified by multiple regression analysis.

**Results:** The study comprised 213 RA patients starting MTX therapy. During a mean follow-up (MTX-treatment period) of 4.3 years, 6288 ALT tests were performed. ALT >ULN was observed in 84 (39%) of the patients and 7% of all tests. The strongest predictor for ALT >1.5 x ULN was a pre-treatment ALT elevation (mean observation period 1.5 years before MTX start) (adjusted OR=6.8, 95% CI 2.2–20.5). In the patients with pre-treatment ALT elevation, the mean time to first ALT elevation was shorter than in those without pre-treatment elevation (p<0.001), and all had recurrent elevations during MTX treatment. In all patients with ALT >ULN, re-elevations occurred in 70%, with similar proportions in those without active interventions and in those where e.g. MTX dose reduction was performed (73% vs. 67%, p=0.43). In patients who permanently stopped MTX due to ALT elevation (n=7), ALT >ULN recurred in 5 (71%) after stopping MTX. Two patients were eventually diagnosed with nonalcoholic fatty liver disease. No patient developed signs of hepatic failure.

**Conclusions:** Pre-treatment ALT elevation is a strong predictor for early and recurrent ALT elevations during therapy. Overall, re-elevations are common, but only a minority of performed ALT tests captures elevations. More individualized or alternative means to follow these patients could be considered to more effectively identify those with MTX-related liver toxicity, and those who despite recurrent ALT elevations could continue MTX treatment without risk for deleterious liver damage.

### TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, IN THE TREATMENT OF RHEUMATOID ARTHRITIS: SAFETY AND EFFICACY IN OPEN-LABEL, LONG-TERM EXTENSION STUDIES OVER 9 YEARS

J. Wollenhaupt<sup>1</sup>, J. Silverfield<sup>2</sup>, E. B. Lee<sup>3</sup>, K. Terry<sup>4</sup>, K. Kwok<sup>5</sup>, S. Strengholt<sup>6</sup>, R. DeMasi<sup>7</sup>, L. Wang<sup>8</sup>. <sup>1</sup>Schön-Klinik Hamburg-Eilbek Teaching Hospital of the University of Hamburg, Hamburg, Germany, <sup>2</sup>Healthpoint Medical Group, Tampa, FL, United States, <sup>3</sup>Seoul National University, Seoul, Korea, Republic Of, <sup>4</sup>Pfizer Inc, Groton, CT, <sup>5</sup>Pfizer Inc, New York, NY, United States, <sup>6</sup>Pfizer Inc, Capelle aan den IJssel, Netherlands, <sup>7</sup>Pfizer Inc, Collegeville, PA, United States

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).

**Objectives:** To report tofacitinib safety and tolerability up to 114 months and clinical efficacy up to 96 months in long-term extension (LTE) studies.

**Methods:** Data were pooled from 2 open-label studies (NCT00413699 [database locked as of March 2017]; and NCT00661661) of patients with RA who had participated in qualifying Phase 1/2/3 studies of tofacitinib. Patients received tofacitinib 5 or 10 mg twice daily (BID) as monotherapy or with background conventional synthetic (cs)DMARDs. As patients in the LTE studies were allowed to switch doses, they were assigned to the 5 mg BID group if the total daily dose (TDD) was <15 mg/day, and to the 10 mg BID group if TDD was ≥15 mg/day. Primary endpoints were adverse events (AEs) and confirmed laboratory safety data. Other endpoints included clinical efficacy measures (ACR20/50/70 response rates, mean DAS28-4[ESR] score, mean HAQ-DI score and mean change from baseline in Clinical Disease Activity Index score). Safety data were included up to Month 114 and completer-analyzed efficacy data up to Month 96 (n<100 post-Month 96).

Table 1 Safety data (Month 114) and clinical efficacy outcomes (up to Month 96; as observed) in LTE studies of tofacitinib in patients with RA

Table. Safety data (Month 114) and clinical efficacy outcomes (up to Month 96; as observed) in LTE studies of tofacitinib in patients with RA	Tofacitinib (5 and 10 mg BID) ± background csDMARDs, N=4967		
		IR per 100 py (95% CI)	
<b>AEs of interest</b>			
Serious adverse events		9.13 (8.67, 9.61)	
Serious infections		2.46 (2.23, 2.70)	
Malignancies (excluding NMSC)		0.83 (0.71, 0.98)	
<b>Confirmed laboratory abnormalities</b>	n (%)	IR per 100 py (95% CI)

<b>CDAI score, mean change from baseline (SE)</b>	NA	N=4802	N=161
		24.5 (0.21)	10.7 (1.05)

ACR20/50/70, American College of Rheumatology 20%/50%/70% improvement; AE, adverse event; ALC, absolute lymphocyte count; ALT, alanine aminotransferase; ANC, absolute neutrophil count; AST, aspartate aminotransferase; BID, twice daily; CDAI, Clinical Disease Activity Index; CI, confidence interval; csDMARD, conventional synthetic disease-modifying antirheumatic drug; DAS28-4[ESR], Disease Activity Score in 28 joints; erythrocyte sedimentation rate; HAQ-DI, Health Assessment Questionnaire-Disability Index; IR, incidence rate; LTE, long-term extension; N, number of evaluable patients; NA, not applicable; NMSC, non-melanoma skin cancer; py, patient-years; RA, rheumatoid arthritis; SE, standard error; ULN, upper limit of normal

**Results:** Overall, 4967 patients were treated (mean [max] duration: 3.5 [9.4] years). Total tofacitinib exposure was 17,738.5 patient-years (py); 76.4% of patients maintained their initial dose. In total, 2518 patients (50.7%) discontinued (AEs: 1189 [23.9%]; insufficient clinical response: 179 [3.6%]). The most common classes of AE were infections and infestations (69.6%; exposure adjusted event rate [EAER; events per 100 py], 19.71) and musculoskeletal/connective tissue disorders (40.3%; EAER, 11.40). The most common AEs were nasopharyngitis (19.1%; EAER, 5.41), upper respiratory tract infection (17.9%; EAER, 5.07), bronchitis (12.6%; EAER, 3.58) and urinary tract infection (12.5%; EAER, 3.55). Serious AEs occurred in 29.4% of patients and serious infections (SIEs) in 8.9% of patients. Malignancies, excluding non-melanoma skin cancer, were reported in 3.0% of patients. Incidence rates (IR; patients with events per 100 py) for AEs of interest, with 95% confidence intervals, are provided in the table 1. IRs for SAEs, SIEs and malignancies through Month 114 did not increase vs reported data through Month 105.<sup>1</sup> Confirmed laboratory data are provided in the table 1. No new safety risks were identified. Clinical responses were sustained from Month 1 to Month 96 (table 1).

**Conclusions:** In patients with RA who remained in the LTE studies, tofacitinib (5 or 10 mg BID), with or without background csDMARDs, was associated with consistent safety through Month 114 and sustained clinical efficacy through Month 96.

SAT0235

### SUBCUTANEOUS METHOTREXATE IS SAFER AND MORE EFFECTIVE THAN ORAL METHOTREXATE ALONE AND IN COMBINATION

K. H. C. Li<sup>1</sup>, T. Jones<sup>2</sup>, M. Grove<sup>3</sup>, A. Roberts<sup>4</sup>, F. Birrell<sup>1</sup>. <sup>1</sup>Newcastle University, Newcastle Upon Tyne, <sup>2</sup>Sunderland University, Sunderland, <sup>3</sup>Northumbria Healthcare NHS Foundation Trust, Newcastle Upon Tyne, <sup>4</sup>Therapy Audit Ltd, Shrewsbury, United Kingdom

**Background:** Methotrexate (MTX) is established as both first line therapy and combination therapy anchor drug for Rheumatoid Arthritis (RA) and other peripheral inflammatory arthritis such as Psoriatic Arthritis (PsA). There is evidence subcutaneous (sc) MTX is more effective than oral MTX, with fewer treatment failures<sup>1-3</sup>, but it is not known if this holds true in routine practice and in combination.

**Objectives:** To show the safety & efficacy of sc MTX therapy in routine practice, compared to oral MTX, alternate monotherapy and combination therapies.

**Methods:** The Therapy Audit Monitoring System (TAMS, www.therapyaudit.com/tamonitor) was installed Jan 2014. Since then all new patients starting disease modifying therapy and existing patients are entered. The database was queried for diagnosis, dose and response, together with adverse events (defined as ALT>80U/l or neutrophils<2.0x10<sup>9</sup>/l). Statistical comparisons used the two proportion Z test, T-test or exact rate ratio test, as appropriate: significance threshold p<0.05.

### Results:

Patient groups	Oral MTX only	sc MTX only	Biologics only	Conventional Combination	Biologic Combination
Total patients ever exposed – n	2093	949	570	1596	552
Patients affected by abnormal LFTs n (%)	198 (10%)	100 (10%)	47 (8%)	154 (10%)	72 (13%)
Patients affected by low neutrophils n (%)	140 (7%)	64 (7%)	66 (12%)	219 (14%)	115 (21%)
Current patients	920	425	345	921	384

8394 patients had received one or more therapies with 4109 current patients identified. Including combinations, 2650 started oral MTX (1463 current) and 1343 sc MTX (911 current). Mean (range) oral MTX dose was 17 (2.5–30) mg and sc MTX was 21 (5–40) mg (p<0.0001). 4356 adverse events were observed over follow-up in 2382 patients, with 1710 (39%) due to ALT>80U/l and 2646 (61%) to neutrophils<2.0x10<sup>9</sup>/l. Abnormal ALT events by drug: oral MTX 486, sc MTX 222 (p=0.92 sc vs. oral). Similarly, low neutrophil count (<2.0x10<sup>9</sup>/l): oral MTX 491, sc MTX 151 (p<0.00001 sc vs. oral). Rate ratios (RR) for low neutrophils for oral MTX-only vs. sc MTX-only showed highly significant differences (RR=1.40, 95% CI: 1.17–1.70; p=0.0002). 14% (1197/8294) of all patients had post-treatment DAS28 scores. Of these 59% (67/113) patients on sc MTX only, and 72% (273/377) on conventional combination achieved DAS<5.1 compared to 69% (69/98) biologic-only and 78% (102/131) biologic-combination. Sensitivity analyses examined response & toxicity by group (data not included).

**Conclusions:** sc MTX is safe and effective in routine practice at doses up to 40 mg. It has lower toxicity than oral MTX in monotherapy and combination, despite a higher mean dose with highly significant reduction in neutropenia rate and the same rate of liver problems compared to oral. This is the largest study of sc MTX yet reported and supports use of higher doses in selected patients and aggregation or replication of data like this may support license extension for sc MTX beyond 30 mg. If patients are usually switched to sc MTX when oral MTX is ineffective or not tolerated, many do not progress to biologic therapy: delivering good care at lower cost.

**SAT0236 LONG-TERM SAFETY AND EFFICACY OF UPADACITINIB (ABT-494), AN ORAL JAK-1 INHIBITOR IN PATIENTS WITH RHEUMATOID ARTHRITIS IN AN OPEN LABEL EXTENSION STUDY**

M. C. Genovese<sup>1</sup>, J. Kremer<sup>2</sup>, S. Zhong<sup>3</sup>, A. Friedman<sup>3</sup>, <sup>1</sup>Stanford Univ, Palo Alto, <sup>2</sup>Albany Medical College, Albany, <sup>3</sup>AbbVie Inc., North Chicago, United States

**Background:** Upadacitinib (UPA, ABT-494) is a selective, oral JAK-1 inhibitor studied in two phase 2 randomized controlled trials (RCTs) in patients (pts) with rheumatoid arthritis (RA).

**Objectives:** We assessed UPA safety and efficacy in BALANCE-EXTEND, an ongoing, combined open-label extension (OLE) of the phase 2 RCTs.

**Methods:** Pts completing the two 12-week RCTs (in TNF-IR and (MTX-IR pts)<sup>1,2</sup> could enter the OLE. Pts switched to 6 mg UPA from their RCT dose of UPA 3, 6, 12, 18 mg twice daily (BID), 24 mg once daily (QD) or Placebo. A dose increase to 12 mg BID was required for pts with <20% improvement in both SJC and TJC on 6 mg BID (at wk 6 or 12), and permitted for pts not meeting CDAI LDA. Pts without 20% improvement in SJC and TJC 6 wks after escalation, or at any 2 consecutive visits, were discontinued. The dose was decreased to 6 mg BID only in pts with a safety concern or intolerability. Pts are grouped as: Never-titrated (on 6 mg BID throughout); Titrated-up (from 6 to 12 mg BID); Titrated-up and back down (to 6 mg BID). After Jan 2017, the 6 and 12 mg BID doses were replaced by 15 and 30 mg QD extended-release equivalents currently being studied in phase 3. Data up to Jan 13 2017 are reported. Adverse events (AE) per 100 yrs of pt exposure (PY) are summarized starting from day 1 of OLE. Efficacy is assessed by ACR20/50/70 and LDA (by DAS28-CRP and CDAI), and observed data are presented up to Wk 72 of OLE due to sample size consideration.

**Results:** Out of 516 pts who completed the 2 RCTs, 494 entered the OLE, 493 were dosed, 328 (66.5 %) were never-titrated, 150 (30.4%) were titrated-up, and 15 (3%) were titrated-up and back down; 150 pts (30.4%) were discontinued [42 (8.5%) withdrew consent, 37 (7.5%) due to AE and 24 (4.9%) due to lack of efficacy]. Mean exposure to UPA was 525.4±221.4 days (range 1-961 days), and cumulative exposure was 725.1 PY (Table). The E/100PY for any AE in the OLE (170.5) were lower than for the RCTs in the TNF-IR (697.9, 48 PY) and MTX-IR (408.4, 54.6 PY) study populations. The E/100PY were 2.3 for serious infection, 3.7 for herpes zoster, 0.8 for malignancies excluding non-melanoma skin cancer, and 0.7 for adjudicated cardiovascular events. There were 2 deaths: one sudden death (adjudicated as undetermined or unknown cause of death) and one death due to Hodgkin's lymphoma. Changes from baseline in laboratory parameters were consistent with observations from phase 2 RCTs. For those pts completing Wk 72, efficacy was maintained in pts on 6 mg BID UPA from day 1 of OLE (never-titrated); 55% pts met ACR70 and 83% were in LDA by DAS28-CRP and CDAI based on as observed data (Table).

Summary of Adverse Events in Patients who Entered the OLE	Efficacy Measures at Week 72 in Patients who Entered the OLE			
	Never-titrated	Titrated-up	Discontinued	Overall (n/N)
Any AE	1226 (170.5)	1062 (111.90)	769 (17.9)	2997 (217.1)
AE leading to discontinuation	42 (5.8)	37 (3.5)	22 (2.1)	101 (7.4)
AE leading to death	5 (0.7)	4 (0.4)	1 (0.1)	10 (0.7)
Infections	427 (58.9)	344 (35.8)	245 (5.6)	1016 (74.3)
Serious infections	11 (1.5)	9 (0.9)	3 (0.3)	23 (1.7)
Opportunistic infections	3 (0.4)	2 (0.2)	1 (0.1)	6 (0.4)
Herpes zoster	17 (2.3)	13 (1.4)	8 (0.8)	38 (2.8)
Aspergillus	1 (0.1)	1 (0.1)	0	2 (0.1)
Lymphomas	17 (2.3)	13 (1.4)	8 (0.8)	38 (2.8)
CD performance	0	0	0	0
MACE <sup>†</sup>	3 (0.4)	2 (0.2)	1 (0.1)	6 (0.4)
Malignancy other than MACE	9 (1.2)	7 (0.7)	4 (0.4)	20 (1.5)
CYP inhibition	26 (3.6)	22 (2.3)	14 (1.6)	62 (4.5)
Drug-drug interaction	33 (4.5)	28 (2.9)	17 (1.9)	78 (5.7)
VTE	5 (0.7)	4 (0.4)	2 (0.2)	11 (0.8)
Serious VTE	2 (0.3)	2 (0.2)	1 (0.1)	5 (0.4)
Adjudicated cardiovascular events	6 (0.8)	5 (0.5)	3 (0.3)	14 (1.0)
MACE	3 (0.4)	2 (0.2)	1 (0.1)	6 (0.4)
Other cardiovascular events	3 (0.4)	3 (0.3)	2 (0.2)	8 (0.6)

**Conclusions:** The safety profile of UPA remained consistent with that expected for an RA population treated with JAKi. Efficacy responses were maintained up to 72 wks in pts on 6 mg BID UPA in the OLE.

**SAT0237 EFFICACY OF BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS WHO FAILED 2 OR MORE DMARDS**

M. C. Genovese<sup>1</sup>, M. Dougados<sup>2</sup>, S. Schwartzman<sup>3</sup>, D. Schlichting<sup>4</sup>, S. Beattie<sup>4</sup>, L. Xie<sup>4</sup>, A. Cardoso<sup>4</sup>, J. S. Smolen<sup>5</sup>. <sup>1</sup>Stanford University, Palo Alto, United States, <sup>2</sup>Rene Descartes Univ/Cochin Hospital, Paris, France, <sup>3</sup>Hospital for Special Surgery (HSS), New York, <sup>4</sup>Eli Lilly and Company, Indianapolis, United States, <sup>5</sup>Medical University of Vienna, Vienna, Austria

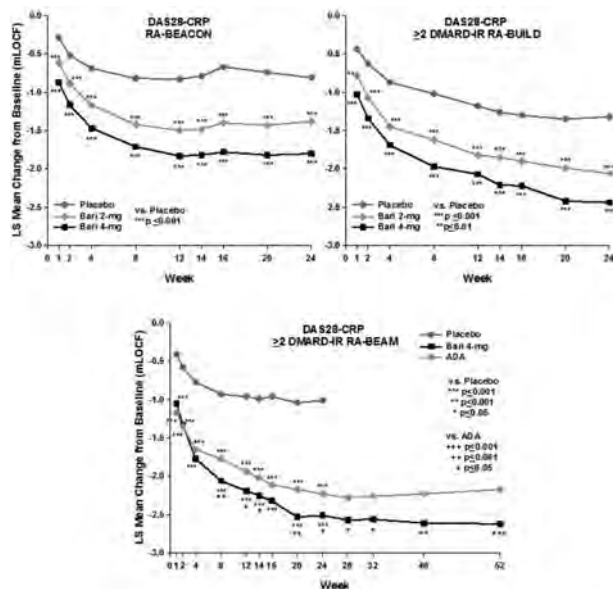

**Background:** Baricitinib (Bari) is an oral Janus Kinase (JAK)1/JAK2 inhibitor in development for patients with active rheumatoid arthritis (RA). In Phase 3 studies, Bari has demonstrated clinical efficacy and has a favorable safety profile.

**Objectives:** To evaluate Bari 2- and 4-mg in patients who have failed multiple DMARDs, across several studies.

**Methods:** Data from the subgroup of patients who had failed  $\geq 2$  DMARDs, including approx. one-half of patients in RA-BUILD (csDMARD-IR) and RA-BEAM (MTX-IR) and all patients from RA-BEACON (bDMARD-IR) were assessed, post hoc, for comparison of Bari 2-mg and 4-mg to placebo across time points using the following measures: ACR20, ACR50, ACR70, SDAI, CDAI, DAS28-CRP, HAQ-DI, and radiographic assessment of structural damage (mTSS), as well as safety. For patients who had failed  $\geq 2$  DMARDs from RA-BEAM, a comparison was also made between Bari 4-mg and adalimumab.

**Results:** In the  $\geq 2$  DMARD-IR populations from RA-BEACON, RA-BUILD, and RA-BEAM, >95% had failed MTX as one of the DMARDs. Compared to PBO in this population, Bari resulted in statistically significantly greater improvement in efficacy measures at Week 24, including physical function (Table). In the  $\geq 2$  DMARD-IR population from RA-BEAM (all patients received background MTX), Bari 4-mg was associated with greater improvements compared to adalimumab (table 1 and figure 1). Compared to PBO, Bari 4-mg statistically significantly inhibited structural progression at Week 24 in the  $\geq 2$  DMARD-IR subsets of RA-BEAM and RA-BUILD. The overall safety profile of Bari 4-mg in the  $\geq 2$  DMARD-IR population was consistent with findings from the overall baricitinib-treated population.

<sup>v</sup>Data are the proportion (%) of pts who achieved the response at Week 24 (non-responder imputation), unless otherwise indicated. <sup>s</sup>Approximately 56% of patients in RA-BUILD and 54% of patients in RA-BEAM failed  $\geq 2$  DMARDs. <sup>Δ</sup>least squares mean change from baseline (modified last observation carried forward). <sup>¶</sup>mTSS data are as randomized using last observation carried forward. \*p $\leq$ 0.05, \*\*p $\leq$ 0.01, \*\*\*p $\leq$ 0.001 for Bari 4-mg or Bari 2-mg vs. PBO; <sup>†</sup>p $\leq$ 0.05 Bari 4-mg vs. ADA

**Conclusions:** These data demonstrate that a dose response is present between Bari 2-mg and Bari 4-mg, with both doses providing benefit in the patients who failed multiple DMARDs in the phase 3 program by improving signs and symptoms, physical function, and structure.

**SAT0238 RAPID ELEVATION OF ERYTHROCYTE METHOTREXATE-POLYGLUTAMATE3 (MTX-PG3) LEVELS RELATED TO THE EFFICACY OF MTX IN PATIENTS WITH RHEUMATOID ARTHRITIS (RA).**

M. Nishida<sup>1</sup>, G. Tsuji<sup>1,2</sup>, M. Takahashi<sup>2</sup>, T. Saitou<sup>2</sup>, Y. Noda<sup>1</sup>, K. Yoneda<sup>1</sup>, N. Amano<sup>1,3</sup>, S. Senda<sup>1,3</sup>, A. Onishi<sup>3</sup>, A. Morinobu<sup>3</sup>, M. Shinohara<sup>4,5</sup>, S. Kumagai<sup>1,2</sup>. <sup>1</sup>Center for Rheumatic Diseases, Shinko Hospital, <sup>2</sup>Shinko Institute for Medical Research, <sup>3</sup>Department of Rheumatology and Clinical Immunology, <sup>4</sup>Division of Epidemiology, <sup>5</sup>The Integrated Center for Mass Spectrometry, Kobe University Graduate School of Medicine, Kobe, Japan

**Background:** MTX is transported into cells and retained long after polyglutamation. Recently, it has been described that the response to MTX treatment is related to the intracellular MTX-polyglutamate (MTX-PG) levels, but little is known about its details and determinants<sup>1</sup>.

**Objectives:** To clarify the association of erythrocyte concentrations of MTX-PGs (PG1 to PG4) with the efficacy of MTX in 35 MTX naïve patients with RA.

**Methods:** We measured erythrocyte MTX-PGs at 4, 12, 24, and 48 weeks after administration of MTX using liquid chromatography (LC)-mass spectrometry (MS)/MS assay. The associations of MTX-PG concentrations with disease activity and the 9 SNPs including 5 SNPs reported for associations with MTX-efficacy were analyzed.

**Results:** As shown in the figure, MTX-PG1 and PG2 elevated at week 4, and total MTX-PGs as well as MTX-PG3 and MTX-PG4 increased until week 12. The MTX-PG2 fraction (as percentage of total) was 26% to 29% and almost constant throughout the course. MTX-PG3 and MTX-PG4 fractions were gradually elevated over time, although MTX-PG1 fraction was decreased. A negative association of Disease Activity Score in 28 joints (DAS28) at week 4, 12 and 24 was observed with levels of MTX-PG2 (p=0.008), MTX-PG3 (p=0.0045), MTX-PG4 (p=0.0142) and total MTX-PG (p=0.023). On the other hand,  $\Delta$ DAS28 (change in DAS28 scores from baseline) was positively correlated to fraction of MTX-PG3 (p=0.011) but negatively correlated to that of MTX-PG1 (p=0.0071). At week 12 and 24, MTX-PG2 fraction was higher (p=0.0783) in the patients who achieved the EULAR good response criteria than in those who did not. MTX-PG3 levels were associated with SLC19A1c.80G>A and FMO2\_c.585A>G, and the fraction of MTX-PG2 in total MTX-PGs was associated with GGH c.452C>T and with FMO2\_c.585A>G.

**Conclusions:** This study suggests that rapid elevation of erythrocyte MTX-PG3 levels from MTX-PG1 through MTX-PG2 and higher distribution of MTX-PG3 is

important to exert certain efficacy of MTX. We previously reported in retrospective study that MTX-PG concentration in RA patients keeping remission for long time was associated with several SNPs<sup>2</sup>, and some of the results were confirmed in this prospective study.

**SAT0239 RAPID RESPONSE WITH UPADACITINIB TREATMENT IN PATIENTS WITH RHEUMATOID ARTHRITIS AND AN INADEQUATE RESPONSE TO CSDMARDS OR bDMARDS**

O. FitzGerald<sup>1</sup>, A. Rubbert-Roth<sup>2</sup>, K. Chen<sup>3</sup>, S. Meerwein<sup>4</sup>, J. Enejosa<sup>3</sup>, T. Shaw<sup>3</sup>, A. F. Wells<sup>5</sup>. <sup>1</sup>St. Vincent's Univ Hospital and Conway Inst Univ College Dublin, Dublin, Ireland, <sup>2</sup>Kantonsspital St. Gallen, St Gallen, Switzerland, <sup>3</sup>AbbVie, N Chicago, United States, <sup>4</sup>AbbVie Deutschland, Ludwigshafen, Germany, <sup>5</sup>Rheum and Immunotherapy Ctr, Franklin, United States

**Background:** Upadacitinib (UPA), an oral JAK inhibitor selective for JAK1, demonstrated efficacy in patients (pts) with moderate to severe rheumatoid arthritis (RA) with an inadequate response (IR) to csDMARDs or bDMARDs in the SELECT-NEXT<sup>1</sup> and SELECT-BEYOND<sup>2</sup> trials, respectively.

**Objectives:** To investigate the speed of response to UPA across disease measures in csDMARD- and bDMARD-IR pts.

**Methods:** 661 pts in NEXT and 498 in BEYOND received UPA 15 mg or UPA 30 mg once daily (QD) or placebo (PBO) for 12 weeks (wks)<sup>1,2</sup>. Time to first achievement of clinically meaningful outcomes, including ACR20/50, DAS28-CRP≤3.2 and Low Disease Activity (LDA) measures of CDAI (≤10) and SDAI (≤11) was evaluated. The cumulative incidences of ACR20/50, DAS28-CRP≤3.2 and LDA by CDAI and SDAI over 12 wks were estimated. Hazard ratios between UPA and PBO were obtained using Cox proportional hazards model with treatment group, corresponding baseline values and main stratification factors, without control for multiple comparisons. All analyses were based on observed data without imputation.

Table 1. Summary of Median Time (in Weeks) to Achieve First Response Over 12 Weeks

		csDMARD-IR			bDMARD-IR		
		N	Median (Q1, Q3)	HR	N	Median (Q1, Q3)	HR
ACR20	PBO	221	12.1 (9.9, NE)		169	11.9 (2.9, NE)

HR, Hazard ratio; NE (not estimable) indicates that the response was not reached within the 12-week period. \*\*\*p<0.001

HR, hazard ratio, NE (not estimable) indicates that the response was not reached within the 12-week period. \*\*\*p<0.001

**Results:** Pts had a disease duration of 7 and 13 years in NEXT and BEYOND respectively.<sup>1,2</sup> In BEYOND, pts were treatment-refractory as evidenced by 53% having received ≥2 prior bDMARDs<sup>2</sup>. Median times to achieve ACR20 were similar, irrespective of pt population, being 4 wks for UPA 15 mg QD and 2–3 wks for

UPA 30 mg QD vs 12 wks on PBO (p<0.001). In general, the median times to achieve ACR50 and DAS28-CRP≤3.2 for UPA 15 mg and 30 mg QD were ~12 wks and ~8 wks for both csDMARD-IR and bDMARD-IR pts, whereas the median was not reached for pts on PBO during the first 12 wks (p<0.001, table 1). The median time to LDA by CDAI and SDAI was ~12 wks across UPA doses and populations, but was not reached for pts receiving PBO within that time. Pts receiving UPA were 2–4 times more likely to achieve clinical responses vs pts receiving PBO. In general, both UPA doses performed similarly across pt populations, with numerically quicker responses observed in pts receiving UPA 30 mg vs UPA 15 mg QD. Median times to achieve 20% and 50% improvements in tender and swollen joint counts were 1–2 wks and 2–4 wks respectively, for both UPA doses, irrespective of pt population. Median times to achieve 20% improvements in morning stiffness duration and severity were approximately 2 wks in each of the UPA arms vs 4 wks on PBO (p<0.001).

**Conclusions:** Pts receiving UPA at either 15 mg or 30 mg QD were more likely to achieve clinical responses at significantly earlier time points when compared with pts receiving PBO. Irrespective of being csDMARD-IR or bDMARD-IR, times to achieve various clinical responses were consistent between pt populations.

**SAT0240 VAGUS NERVE STIMULATION IN PATIENTS WITH RHEUMATOID ARTHRITIS: TWO-YEAR SAFETY AND EFFICACY**

F. A. Koopman<sup>1</sup>, A. Musters<sup>1</sup>, M. J. Backer<sup>1</sup>, D. Gerlag<sup>1</sup>, S. Miljko<sup>2</sup>, S. Grazio<sup>3</sup>, S. Sokolovic<sup>4</sup>, Y. A. Levine<sup>5</sup>, D. Chernoff<sup>5</sup>, N. de Vries<sup>1</sup>, P.-P. Tak<sup>1</sup>. <sup>1</sup>Academic Medical Center/University of Amsterdam, Amsterdam, Netherlands, <sup>2</sup>University Clinical Hospital, Mostar, Bosnia and Herzegovina, <sup>3</sup>Clinical Hospital Center Sestre Milosrdnice, Zagreb, Croatia, <sup>4</sup>Sarajevo University Clinical Center, Sarajevo, Bosnia and Herzegovina, <sup>5</sup>SetPoint Medical, Inc, Valencia, United States

**Background:** Rheumatoid arthritis (RA) is a debilitating chronic disease with an unmet need for additional therapeutic approaches. Activating neuro-immune reflex pathways by stimulation of the vagus nerve (VNS) could represent a novel means of treating RA [1] and other immune-mediated inflammatory diseases. Last year we reported a 12-week proof-of-concept study using a VNS device, approved for drug-resistant epilepsy, showing reduction in the DAS28-CRP clinical disease activity score, with concomitant reductions in TNF and IL-6 levels [2].

**Objectives:** To understand the long term safety and efficacy of this novel treatment approach, we followed the patients in a 24 months long-term extension study and report on the safety and clinical efficacy data.

**Methods:** VNS devices were implanted into 17 RA patients, mostly with insufficient response to multiple conventional and biologic disease-modifying antirheumatic drugs (DMARDs), on stable background of methotrexate (≤25 mg weekly) therapy. The devices electrically stimulated the vagus nerve, 1–4 min/day, over a 12 week open label period. On completion, subjects were offered to enroll into a follow-up study, where the study physicians were given flexibility to alter VNS dosing parameters and/or to add a biologic DMARD to the treatment regimen. DAS28-CRP and Health Assessment Questionnaire-Disability Index (HAQ-DI) were collected over 2 years.

**Results:** All subjects electively continued on VNS treatment through 24 months of the long term follow-up study. Biologic DMARDs were started in 1 and restarted in 8 of 17 subjects; of these, 4 were non-responders to VNS, and 5 had stable improvement but had not yet achieved disease remission on VNS alone (table 1). At the start of the follow-up study, the mean DAS28–28 and HAQ-DI were significantly reduced compared to the pre-implant baseline (mean difference±SE in DAS28-CRP=-1.60±0.37, p<0.0001; mean difference±SE in HAQ-DI = -0.44 ±0.21, p<0.037), and the depth of effect was retained through 24 months. At 24 months, there was no significant difference in DAS28-CRP between the subjects using VNS monotherapy or those using a combination of VNS and biologic

DMARDs (VNS monotherapy= 3.76±1.77 vs. VNS and biologic DMARD= 3.21±1.44,  $p<0.54$ ). No difference in the adverse events profile between the two groups was seen.

**Table 1** Two Year Efficacy of VNS Treatment. Mean DAS28-CRP at primary study baseline (month -3-5) and at visits over 2 years of long term follow up (months 0-24). **Conclusions:** The data presented here demonstrate that VNS in subjects with RA is associated with a substantial reduction in disease activity that is sustained for 24 months without untoward safety signals. In addition, the data suggest that biological DMARDs can be initiated safely in combination with VNS treatment, though this requires further study in larger cohorts. These results support further development of VNS devices as an alternative therapeutic approach for RA treatment, which potentially can safely be combined with biologic DMARDs.

#### SAT0241 PATIENTS' PERSPECTIVE ON THE EFFICACY AND RISKS OF GLUCOCORTICOIDS IN RA – AN INITIATIVE UNDER THE GLORIA PROJECT

P.D. Carvalho<sup>1</sup>, N. Goef<sup>2</sup>, M. Voshhaar<sup>3</sup>, M. Boers<sup>4,5</sup>, J.A.P. D. Silva<sup>6</sup>. <sup>1</sup>*Serviço de Reumatologia, Centro Hospitalar e Universitário do Algarve, Faro, Portugal*, <sup>2</sup>*QVIA, Duke University School of Medicine, Durham, NC, United States*, <sup>3</sup>*Department Psychology, Health and Technology, University of Twente, Twente*, <sup>4</sup>*Department of Epidemiology and Biostatistics*, <sup>5</sup>*Amsterdam Rheumatology and Immunology Center, VU University Medical Center, Amsterdam, Netherlands*, <sup>6</sup>*Faculty of Medicine and University Hospital, Coimbra, Portugal*

**Background:** The Glucocorticoid Low-dose Outcome in Rheumatoid Arthritis Study (GLORIA) is an international investigator-initiated pragmatic randomised trial designed to study the effects of low dose glucocorticoids (GC) in elderly patients with Rheumatoid Arthritis (RA). The research team is also committed to promote a better understanding of the risks and benefits of these drugs among health professionals and patients. In order to achieve these goals, it is important to assess the current concepts and concerns of patients regarding GC.

**Objectives:** In this study, we evaluated the beliefs about GC in RA patients who are, or have been treated with GC.

**Methods:** Patients with RA from three different countries (United States (US), Portugal, and the Netherlands) completed an online survey which was presented in their native language.

Members of People with Arthritis and Rheumatism, and national associations were involved in the development of the questionnaire. In Europe, patients were invited to participate through national patients' organizations, and SurveyMonkey<sup>®</sup> was used to disseminate the online surveys. In the US, patients were invited to participate and surveyed through MediGuard.org.

Patients with RA from three different countries (United States (US), Portugal, and the Netherlands) completed an online survey which was presented in their native language.

Members of People with Arthritis and Rheumatism, and national associations were involved in the development of the questionnaire. Participants were asked to agree or disagree with statements on a 5-point scale. In Europe, patients were invited to participate through national patients' organizations, and SurveyMonkey<sup>®</sup> was used to disseminate the online surveys. In the US, patients were invited to participate and surveyed through MediGuard.org.

**Results:** Data was collected from 314 RA patients with exposure to GCs (table 1). Mean education level was around 15 years and duration of GC exposure was

skewed (median 48 months [inner quartiles 8, 120]). The majority of US patients had received prednisone and in Europe, prednisolone. The majority of participants in all three regions had already read articles or pamphlets on the benefits or harms related to GC therapy.

Regarding GC risk, about half of the European patients stated that they had already suffered a serious adverse event (SAE) due to GC. US patients were not asked if they suffered GC-related SAE due to regulatory reporting rules, but 82% showed concern about experiencing an SAE from GC use.

Regarding GC efficacy, high levels of endorsement were found for the three questions asked: more than 78% of patients considered that GC were very useful in their case, more than 61% considered that GC were effective even in low doses, and more than 60% agreed that GC improved RA symptoms within days.

**Table 1** Patient beliefs about GC from surveys in USA, Portugal and The Netherlands.

	USA	Portugal	Netherlands
Number of patients	139	131	44
Education, mean ± SD (years)	14 ± 3	15 ± 5	16 ± 4
GC prescribed (%)			
Prednisone	78	18	33
Prednisolone	11	73	62
Methylprednisolone	9	10	5
Other	1	0	0
Treatment duration, median (inner quartiles, months)	24 (5-84)	120 (36-180)	36 (4-108)
Have you read any articles or pamphlets on the benefit or harm of GC therapy? (%)	72	64	75
Level of agreement for statements (%)*			
If I take GC, I am concerned that I may suffer a serious adverse event	82 (55)	NA	NA
I have suffered serious adverse events due to GC	NA	48 (18)	51 (23)
GC are or have been very useful to me	79 (56)	86 (55)	85 (69)
At a dose of less than or equal to 7.5 mg of prednisolone/day, GC:			
- are very effective in the control of signs and symptoms of RA	61 (38)	78 (41)	69 (44)
- improve RA symptoms within days	60 (41)	74 (45)	69 (49)

\* Total of 'slightly agree' and 'agree' in parentheses the percentage of 'agree'; SD: Standard Deviation; GC: Glucocorticoid; RA: Rheumatoid Arthritis; NA: Not Asked.

**Conclusions:** Patients with RA exposed to long-term GC report a high prevalence of SAE or fear thereof. This is accompanied by a strong conviction that GC are very useful and effective for the treatment of their RA, even at low dosages.

#### SAT0242 EFFECTIVENESS OF CONVENTIONAL DMARD THERAPY IN PATIENTS WITH RHEUMATOID ARTHRITIS TREATED UNDER A TREAT TO TARGET MODEL – LESSONS FROM A REAL-LIFE COHORT

P. Santos-Moreno<sup>1</sup>, D. Buitrago-Garcia<sup>2</sup>, L. Villarreal<sup>3</sup>, M. Cabrera<sup>3</sup>, E. Castillo<sup>1</sup>, E. Cardozo<sup>1</sup>, S. Farietta<sup>1</sup>, R. Giraldo<sup>1</sup>, D. Gomez<sup>1</sup>. <sup>1</sup>*Rheumatology, Biomab, Center For Rheumatoid Arthritis, Bogota, Bogota, Colombia*, <sup>2</sup>*Epidemiology, SILES, Health services, Biomab, Center For Rheumatoid Arthritis, Bogota, Bogota, Colombia*

**Background:** Rheumatoid arthritis (RA) is a common chronic inflammatory disease. It is characterized by progressive, joint damage, impaired joint function and pain, the disease causes disability and reduces quality of life. Treat-to-target (T2T) is an acknowledged management strategy for RA; it proposes that the therapeutic target in RA should be a state of remission or low disease activity. There are two types of pharmacological therapy available: biological DMARDs that are considered highly expensive for our countries and conventional DMARDs which have demonstrated effectiveness and is a low-cost treatment (1,2).

**Objectives:** The aim of this study was to describe global change in Disease Activity Score 28 (DAS28) using a T2T strategy during three years in a cohort of patients receiving conventional DMARDs.

**Methods:** A descriptive cohort study was conducted. Medical records of patients from specialized in RA center were reviewed during 2015–2017; those patients were followed-up under T2T standards and a multidisciplinary approach. Clinical follow-up was according to DAS28: every 3–5 weeks (DAS28 >5.1), every 7–9 weeks (DAS28 ≥3.1 and ≤5.1), and every 11–13 weeks (DAS28 <3.1). Therapy had to be adjusted with DAS28 >3.2 unless patient's conditions don't permit it; We divided patients in four groups: remission (REM), low disease activity (LDA), moderate disease activity (MDA) and severe disease activity (SDA) patients and the aim of the study was to look at what percentage of patients reached LDA or REM. Descriptive epidemiology was done, we calculated means, and standard deviations for continuous variables and categorical variables were presented as rates.

We analyzed normality for DAS28, in order to compare disease activity at beginning and the end of follow-up.

**Results:** During 3 years we included 1953 patients were 39% were in low disease activity, 47% in moderate disease activity and 14% were in severe disease activity, 84% were female, mean age was 60 years±12. At baseline mean DAS28 was 4.45±0.90 with a median of 4.3 at three years the mean DAS28 was 3.83 ±1.08 with a median of 3.60. At the end of follow-up 46% of population achieved remission and 25% achieved low disease activity; at overall 71% improved disease activity, see table 1. In our study DAS28 was not normally distributed, thus we performed a Wilcoxon test in order to compare the mean DAS28 at baseline/36 months showing statistical significance (P<0.05).

ACTIVITY LEVEL	BASELINE		3 YEARS FOLLOW-UP	
	n	%	n	%
REM			898	46
LDA	759	39	488	25
MDA	912	47	528	27
SDA	282	14	39	2

**Conclusions:** Patients treated with conventional DMARD therapy and under a T2T model achieve favorable results in regards of disease activity. This is real life evidence that can support the advantages of treating RA patients with a multidisciplinary team under a T2T model with a low-cost treatment.

**Background:** Tofacitinib is an oral Janus kinase (JAK) inhibitor that preferentially inhibits signalling by JAK3 and JAK1, with functional selectivity over JAK2. Potential increased risk of venous thromboembolic events (VTE) in patients (pts) with rheumatoid arthritis (RA) has been reported for a JAK 1/2 inhibitor.<sup>1</sup>

**Objectives:** To assess VTE risk with tofacitinib in pts with RA, psoriasis (PsO), psoriatic arthritis (PsA) and ulcerative colitis (UC).

**Methods:** Data from Phase (P)2 (RA, PsO, UC) and P3 (RA, PsO, PsA, UC) randomised clinical studies of tofacitinib as monotherapy or in combination with conventional synthetic (cs)DMARDs were reviewed. Two cohorts were defined; 1) the placebo (PBO)-controlled cohort: pts randomised to tofacitinib 5 or 10 mg BID, or PBO up to Month (M)3 in RA, PsO and PsA studies, and pts randomised to tofacitinib 10 mg BID or PBO for the 9-week induction period in UC studies; 2) the dose-comparison cohort: pts randomised to tofacitinib 5 or 10 mg BID, adalimumab (ADA) 40 mg SC Q2W (RA and PsA only) or methotrexate (MTX) 20 mg QW (RA only) throughout the P2/3 studies for RA (up to M24), PsO (up to M12) and PsA (up to M12), and for the 12-month P3 UC maintenance study. First deep vein thrombosis (DVT) and pulmonary embolism (PE) events were identified using the MedDRA embolic and thrombotic SMQ preferred terms restricted to the respiratory, thoracic, mediastinal and vascular disorder System Organ Classes; incidence rates (IRs; pts with events/100 pt-years) were based on single events occurring during treatment or ≤28 days after the last dose or up to the cohort cut-off date. IRs for PE in RA pts were compared with Corrona Registry data (May 2017 cut-off).

**Results:** Up to M3 in the PBO-controlled cohort, DVT and PE each occurred in 2 pts receiving PBO (1 RA pt and 1 UC pt per event); no tofacitinib-treated pts had DVT or PE events (Table). In the dose-comparison cohort 2 DVT events occurred in tofacitinib-treated pts with RA (5 mg BID, n=1; 10 mg BID, n=1) and 1 DVT event in a pt with PsA (tofacitinib 10 mg BID) (Table). IRs (95% CI) were 0.1 (0.0, 0.3) for both tofacitinib doses in RA and 0.5 (0.0, 2.8) for tofacitinib 10 mg BID in PsA. Two DVT events occurred with MTX; none with ADA. Five PE events occurred in the dose comparison cohort, all in RA (5 mg BID, n=2; 10 mg BID, n=3). IRs were 0.1 (0.0, 0.4) for tofacitinib 5 mg BID and 0.2 (0.0, 0.4) for 10 mg BID. IRs for PE with tofacitinib in RA were similar to those reported by the Corrona Registry in RA pts treated with tofacitinib (0.1 [0.0, 0.4]), biologic DMARDs (0.2 [0.1, 0.3]) and csDMARDs (0.2 [0.0, 0.5]).

**Table 1** Incidence rates for deep vein thrombosis and pulmonary embolism from randomised controlled studies across the tofacitinib clinical development programme

SAT0244

### IMPACT OF 12 WEEKS OF UPADACITINIB TREATMENT ON INDIVIDUAL AND COMPOSITE DISEASE MEASURES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC OR BIOLOGIC DMARDS

R. van Vollenhoven<sup>1</sup>, R. Dore<sup>2</sup>, K. Chen<sup>3</sup>, H. S. Camp<sup>3</sup>, J. Enejosa<sup>3</sup>, T. Shaw<sup>3</sup>, J. L. Suboticki<sup>3</sup>, S. Hall<sup>4</sup>. <sup>1</sup>Amsterdam Rheumatology and Immunology Center ARC, Amsterdam, Netherlands, <sup>2</sup>Univ of California, Los Angeles, Los Angeles, <sup>3</sup>AbbVie, N Chicago, United States, <sup>4</sup>Dept of Medicine, Monash Univ, Cabrini Health and Emeritus Research, Malvern, Australia

**Background:** Upadacitinib (UPA), an oral, JAK1-selective inhibitor, demonstrated efficacy through 12 and 24 weeks (wks) in phase 3 trials of patients (pts) with active rheumatoid arthritis (RA) and inadequate response (IR) to csDMARDs and bDMARDs, respectively.<sup>1,2</sup> Efficacy evaluations at Wk 12 are an important assessment point according to T2T recommendations.<sup>3</sup>

**Objectives:** To assess the impact of UPA at 12 wks on individual and composite measures of RA disease activity.

**Methods:** Pts received UPA 15 mg or 30 mg once daily (QD) or PBO for 12 wks in two phase 3 trials. SELECT NEXT<sup>1</sup> and SELECT BEYOND<sup>2</sup> enrolled csDMARD- and bDMARD-IR pts, respectively. For this investigation, responses at Wk 12, were defined as  $\geq 50\%$  improvement in ACR components. Among ACR50 responders, the proportions of pts achieving  $\geq 50\%$  improvement in all 7 components of the ACR response criteria [Tender Joint Count (TJC68), Swollen Joint Count (SJC66), Pt Global Assessment (PtGA), Physician Global Assessment (PhGA), Pt Pain, Health Assessment Questionnaire-Disability Index (HAQ-DI), and high sensitive C-reactive protein (hsCRP)] were assessed. Differences in the cumulative distributions of CDAI, DAS28-CRP, and SDAI between baseline (BL) and Wk 12 were assessed. All analyses were based on observed data without imputation.

**Results:** Pts in both studies, on average, had established, moderate to severe RA at BL, with (mean) disease durations of 7.3 and 13.2 years, CDAI of 38.2 and 40.9, in csDMARD-IR and bDMARD-IR pts, respectively; 53% of bDMARD-IR pts had exposure to  $\geq 2$  bDMARDs.<sup>1,2</sup> In both populations, significantly more pts on UPA vs PBO achieved  $\geq 50\%$  improvement in each ACR component at Wk 12 (Table). Among pts who achieved ACR50 at Wk 12, approximately one-half of the csDMARD-IR and one-third of the bDMARD-IR pts achieved  $\geq 50\%$  improvement in all 7 ACR components. While there were no differences at BL, cumulative distributions of CDAI, DAS28-CRP, and SDAI separated by treatment at Wk 12 ( $p < 0.001$ ); for the lowest quartiles for UPA 15 mg and 30 mg vs PBO, CDAI levels dropped to 6.2 and 5.1 vs 12.5 in csDMARD-IR; and 7.2 and 8.2 vs 13.1 in bDMARD-IR.

	UPA 30	94	59 (62.8)***	35.2***	59	39 (65.9)***	22.6*

\* \*\* \*\*\* p < .05, .01 and .001 respectively for comparisons of UPA vs PBO; delta ( $\Delta$ ) = difference

**Conclusions:** In pts with an insufficient response to either csDMARDs or bDMARDs, treatment responses at 12 wks were observed in significantly higher proportions with UPA vs PBO. Favorable effects with UPA were seen in the composite scores and the individual parameters, including PROs and acute-phase reactants.

### AZD9567: A NOVEL ORAL SELECTIVE GLUCOCORTICOID RECEPTOR MODULATOR, DEMONSTRATED TO HAVE AN IMPROVED THERAPEUTIC RATIO COMPARED TO PREDNISOLONE IN PRE-CLINICAL STUDIES, IS SAFE AND WELL TOLERATED IN FIRST CLINICAL STUDY.

R. Hendrickx<sup>1</sup>, T. Hegelund-Myrbäck<sup>2</sup>, M. Dearman<sup>1</sup>, S. Prothon<sup>2</sup>, G. Edenro<sup>1</sup>, J. Leander<sup>3</sup>, R. Fuhr<sup>3</sup>, T. Körnicke<sup>3</sup>, P. Svanberg<sup>1</sup>, A. R. Berggren<sup>4</sup>, T. Drmota<sup>1</sup>, C. Keen<sup>1</sup>, U. G. Eriksson<sup>2</sup>. <sup>1</sup>Respiratory Inflammation & Autoimmunity, <sup>2</sup>Early Clinical Development, IMED Biotech Unit, AstraZeneca, Gothenburg, Sweden, <sup>3</sup>Early Phase Clinical Unit, Parexel, Berlin, Germany, <sup>4</sup>Global Medicines Development, AstraZeneca, Gothenburg, Sweden

**Background:** Glucocorticoids (GC) are highly effective in the treatment of inflammatory diseases but chronic treatment is limited by severe adverse effects including hyperglycemia and bone re-modelling. AZD9567 is a novel, orally delivered, non-steroidal Selective Glucocorticoid Receptor Modulator (SGRM) with the potential to demonstrate an improved therapeutic ratio (TR) compared to steroidal GC such as prednisolone.

**Objectives:** To investigate the effects of AZD9567 and prednisolone on biomarkers of inflammation, glucose metabolism and bone re-modelling in pre-clinical models. To confirm the inhibition of inflammatory biomarker production and to evaluate safety and pharmacokinetics (PK) of AZD9567 in a first clinical study.

**Methods:** The effects on biomarkers of gluconeogenesis (tyrosine aminotransferase, TAT mRNA), bone re-modelling (osteoprotegerin, OPG mRNA) and anti-inflammatory activity (TNF $\alpha$ ) were evaluated *in vitro* using human hepatocytes, an osteoblast cell line and whole blood, respectively. *In vivo*, effects on plasma insulin and osteocalcin levels were compared with inhibition of whole blood TNF $\alpha$  release in rats. Efficacy was evaluated in an adjuvant-induced rat arthritis model. In a human single ascending dose study the effect of AZD9567 on TNF $\alpha$  inhibition was investigated, together with assessment of safety profile and PK.

**Results:** Potent *in vitro* anti-inflammatory activity (IC<sub>50</sub>, 6.2 nM, 7-fold more potent than prednisolone) was observed, whilst no effect on TAT mRNA expression in human hepatocytes was detected for AZD9567 (prednisolone EC<sub>50</sub> 92 nM). This resulted in a substantially better TR compared to prednisolone. Furthermore, AZD9567 showed a 7-fold superior TR compared to prednisolone based on OPG mRNA expression in human osteoblasts. An improved profile for AZD9567 was also demonstrated *in vivo* in the rat (TR of 7.5 for osteocalcin and 3.6 for insulin). Efficacy was demonstrated in the rat arthritis model where an inhibition of joint inflammation was observed (ED<sub>50</sub> 0.1 mg/kg). In human, AZD9567 was safe and well tolerated after single doses (2–155 mg). The PK properties showed a fast absorption with a median t<sub>max</sub> of 0.50 to 1.25 hour and a dose-dependent increase in exposure, with a mean terminal half-life of 3.9 to 6.4 hours, suitable for a once daily dosing regimen. TNF $\alpha$  release was inhibited in a concentration-dependent manner (IC<sub>50</sub>, 5.2 nM), consistent with pre-clinical findings.

**Conclusions:** In pre-clinical models, AZD9567 demonstrated anti-inflammatory activity with a reduced effect on gluconeogenesis and biomarkers of bone re-modelling compared to prednisolone. Single oral dosing of AZD9567 was well tolerated and showed good PK properties in healthy subjects. These results support that AZD9567 has the potential to improve the treatment of several inflammatory diseases with a better TR compared to prednisolone. AZD9567 is currently in clinical evaluation in rheumatoid arthritis.

### AT WHICH POINT AND FOR WHICH REASONS ARE ORAL MTX FORMULATIONS SWITCHED TO INJECTABLE ONES IN RA PATIENTS? COMBINED RESULTS FROM 3 INDEPENDENT OBSERVATIONAL AND CLINICAL TRIALS

R.-M. Flipo<sup>1,2</sup>, A. Saraux<sup>3</sup>, C. Hudry<sup>4,5</sup>, C. Gaujoux-Viala<sup>6</sup>, E. Senbel<sup>7</sup>, S. Tropé<sup>8</sup>, E. Zinovieva<sup>9</sup>, H. Herman-Demars<sup>9</sup>. <sup>1</sup>Rheumatology department, CHRU Roger Salengro, <sup>2</sup>University, Lille, <sup>3</sup>Rheumatology department, CHU La Cavale Blanche, Brest, <sup>4</sup>Rheumatology Department, Cochin Hospital, <sup>5</sup>Institut de Rhumatologie Paris 8, Paris, <sup>6</sup>Rheumatology department, CHU Carêmeau, Nîmes, <sup>7</sup>Rheumatology office, Marseille, <sup>8</sup>ANDAR Patients' association, Montpellier, <sup>9</sup>Medical Department, Nordic Pharma, Paris, France

**Background:** MTX is considered as a cornerstone in RA treatment since the 1990s and its injectable forms have proven their enhanced clinical and pharmacological efficacy and safety in case of insufficient response or poor tolerance of oral formulations. Few data are available considering the timepoint at which the route of administration is changed in current practice.

**Objectives:** The objective of this work was to investigate across 3 independent trials if there was a consistency in patterns of MTX oral ->injectable switches in terms of RA characteristics, MTX dosages (before and after the switch) and reasons of passage.

**Methods:** Three trials were considered for this work: 1/STRATEGIE (observational study designed to investigate the therapeutic strategies used in current practice in RA patients insufficiently responding to initial MTX monotherapy), 2/APRIM (observational study aimed to investigate the treatment adherence of RA patients switching from oral to injectable MTX or between two different MTX prefilled syringes) and 3/SELFI (phase III randomized trial aiming to compare a new MTX autoinjector to the historical MTX prefilled syringe in terms of treatment adherence and functional capacity in RA patients at 6 months). In all three studies we selected baseline data concerning patients switching from oral to injectable MTX at the inclusion visit.

#### Results:

	STRATEGIE N = 151	APRIM N = 270	SELFI N = 98
RA duration, years (mean±SD) (median (min;max))	4.9±6.1 2.8 (0.0; 29.0)	6.6±8.1 3.0 (0.0; 40.0)	4.5±5.9 2.0 (0.2; 30.5)
MTX treatment duration, years (mean±SD) (median (min;max))	3.6±4.5 1.9 (0.0; 24.3)	3.3±4.2 1.4 (0.0; 23.6)	2.5±2.8 1.4 (0.1; 15.4)
DAS28 (mean±SD)	4.4±0.9	3.9±0.9	3.5±1.2
MTX oral dosage at V0, mg/wk (mean±SD)	15.3±3.7	15.0±4.1	14.8±3.8
MTX injectable dosage at the end of V0, mg/wk (mean±SD)	17.0±4.0	16.3±3.8	17.0±4.0
Distribution MTX dosage unchanged/raised/ reduced	50%/45%/ 5%	62%/34%/ 4%	51%/42%/ 7%

Consistent data were observed across the three considered trials concerning the oral/injectable MTX switch. It occurs after about 3 years of treatment, at a DAS28 of 4 and at an average dose of 15 mg/wk (which is consistent with bioavailability data shown before). In most situations, MTX dosage is unchanged or very slightly raised at the switch timepoint. The main switch reasons were "non-achievement of treatment target" and "RA worsening", the safety reasons were mentioned only in 5% of cases.

**Conclusions:** Our work showed a consistent pattern across 3 independent trials concerning the oral/injectable MTX switch. It generally occurs at 15 mg/wk, the new injectable dosage being either unchanged or very slightly raised as compared to the last oral one. Surprisingly, the MTX route of administration seems to be modified mostly for efficacy reasons, safety issues being anecdotal.

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). Glucocorticoids (GC) are an established therapy in RA that are often used to rapidly reduce pain and inflammation while awaiting the effects of disease-modifying antirheumatic drugs.

**Objectives:** A post hoc analysis to describe the impact of background GC on the efficacy and safety of tofacitinib with and without methotrexate (MTX) and adalimumab (ADA) with MTX in ORAL Strategy.

**Methods:** ORAL Strategy (NCT02187055) was a 1-year, double-blind, Phase 3b/4, head-to-head, non-inferiority randomised controlled trial in adult patients (pts) with active RA despite MTX therapy. Pts were randomised 1:1:1 to receive tofacitinib 5 mg twice daily (BID; tofa mono), tofacitinib 5 mg BID + MTX (tofa+MTX) or subcutaneous ADA 40 mg every other week + MTX (ADA+MTX). Pts receiving low-dose GC (≤10 mg/day prednisone or equivalent) before enrolment maintained a stable dose throughout the study period. The following efficacy endpoints were assessed through Month 12 for pts receiving tofa mono, tofa+MTX and ADA+MTX with/without GC: ACR20, ACR50 and ACR70 response rates, proportions of patients achieving low disease activity (LDA; DAS28-4[ESR]≤3.2) and remission (DAS28-4[ESR]<2.6) and change from baseline (BL) in HAQ-DI (ΔHAQ-DI). Safety endpoints were evaluated throughout the study and included adverse events (AEs), serious AEs (SAEs), discontinuations due to AEs and serious infection events (SIEs).

**Results:** 1146 patients were randomised and treated; low-dose BL GC were received by 228/384 (59.4%) pts receiving tofa mono (mean [SD] BL GC dose: 7.5 [13.7] mg/day), 215/376 (57.2%) pts receiving tofa+MTX (mean [SD] BL GC dose: 6.5 [2.5] mg/day) and 223/386 (57.8%) pts receiving ADA+MTX (mean [SD] BL GC dose: 6.4 [2.6] mg/day). BL demographics and disease characteristics were generally similar across treatment groups, regardless of BL GC use. Efficacy endpoints (ACR50 response rate, LDA and remission rates, ΔHAQ-DI) were generally similar for each treatment group when stratified by GC use (figure 1, table 1; similar results were seen for ACR20/70 response rates – data not shown). GC use did not appear to be associated with higher rates of AEs, discontinuations due to AEs, SIEs and SAEs; some AE rates were higher with MTX than without MTX (table 2). SIEs in pts using GC included herpes zoster (HZ; tofa mono, n=2) and tuberculous meningitis (tofa+MTX, n=1); in pts not using GC, there was 1 event each of cytomegalovirus chorioretinitis (tofa+MTX), pulmonary TB (tofa+MTX), HZ (ADA+MTX) and varicella (ADA+MTX).

Figure 1. Proportion of patients achieving ACR50 response according to treatment group and GC use (FAS, with imputation\*)

naive T-, B-cells and CD16<sup>+</sup> NK-cells along with a relative increase in memory lymphocytes and CD16<sup>+</sup> NK-cells. These effects were also observed but less pronounced in controls.

**Conclusions:** Bowel cleanse and fasting in RA induces a reduction of inflammation related to monocyte activation and turnover immediately within few days. Changes in the monocyte compartment were specific for RA compared to controls and dominated the immunological changes, suggesting that innate triggering mechanisms from gut and its microbiota are etiologically relevant in RA.

#### SAT0250 THE DOSING OF INTRA-ARTICULAR TRIAMCINOLONE HEXACETONIDE FOR KNEE SYNOVITIS IN CHRONIC POLYARTHRITIS – A RANDOMIZED CONTROLLED STUDY

T. Weitoff<sup>1</sup>, K. Öberg<sup>2</sup>. <sup>1</sup>Section for Rheumatology, Center for Research and Development Uppsala University/Region of Gävleborg, Gävle, <sup>2</sup>Rheumatology clinic, Falun Hospital, Falun, Sweden

**Background:** Intra-articular glucocorticoid (IAGC) injection treatment is an easy and effective way to treat signs and symptoms of arthritis and it has been used for decades. Serious adverse reactions are rare, but IAGC therapy has impact on endocrine balances. There is limited knowledge of the adequate dosing for different joints and dosing traditions vary all over world.

**Objectives:** To compare the relapse rate during 6 months after IAGC for knee synovitis, between two common doses (20 mg vs 40 mg) of triamcinolone hexacetonide (THA).

**Methods:** A total of 159 adult patients with rheumatoid arthritis (RA) or psoriatic arthritis (Psoa) and active knee synovitis were randomized to IAGC injection with either 20 mg or 40 mg THA blinded to the participants. The primary endpoint was relapse of arthritis. When symptoms from the treated joint recurred and signs of arthritis could be confirmed on a following clinical examination a relapse was recorded and days from injection to relapse was calculated. At the end of the observation period those without relapse had a phone call to verify persistence of good treatment response.

**Results:** In this material there was no significant difference in patient characteristics at baseline and the proportion of relapse after 6 months were equal in the treatment arms (30% versus 32%, p=0.822). Additionally no significant differences were found in the subgroups with RA and Psoa patients.

**Conclusions:** To reduce the risk for endocrine side effects and as no difference in treatment outcome between the compared doses was found the lower 20 mg THA dose should be preferred in IAGC treatment for knee synovitis in chronic polyarthritis.

**Disclosure of Interest:** None declared

Fuhr<sup>4</sup>, T. Körmicke<sup>4</sup>, Z. Tahib<sup>1</sup>, E.-M. Andersson<sup>5</sup>, P. Svanberg<sup>2</sup>, K. Edman<sup>6</sup>, R. Hendrickx<sup>2</sup>, C. Keen<sup>2</sup>, M. Kraan<sup>2</sup>, K. Johansson<sup>2</sup>, U. G. Eriksson<sup>1</sup>, B. Carlsson<sup>1</sup>, O. Vaarala<sup>2</sup>. <sup>1</sup>Early Clinical Development, IMED Biotech Unit, <sup>2</sup>Respiratory Inflammation & Autoimmunity IMED Biotech Unit, <sup>3</sup>Global Medicines Development, AstraZeneca, Gothenburg, Sweden, <sup>4</sup>Early Phase Clinical Unit Berlin, PAREXEL International GmbH, Berlin, Germany, <sup>5</sup>Cardiovascular & Metabolic Disease IMED Biotech Unit, <sup>6</sup>Discovery Science, AstraZeneca, Gothenburg, Sweden

**Background:** AZD9567 is a novel oral selective glucocorticoid receptor modulator (SGRM) developed to have an improved safety profile versus prednisolone while maintaining efficacy.

**Objectives:** To show clinical evidence of safety differentiation for AZD9567 compared to prednisolone with respect to glucose homeostasis and to investigate the underlying effects on the glucose metabolism in human cell systems *in vitro*.

**Methods:** In a dose escalation study (NCT02760316), healthy volunteers were randomized to a 5-day once-daily treatment with AZD9567 (20, 40, 80, 125 mg) or prednisolone (5, 20, 40 mg). We monitored the anti-inflammatory effect by TNF $\alpha$  release from *ex vivo* LPS stimulated whole blood and modelled the relationship with pharmacokinetics (PKPD). Plasma glucose was measured (AUC<sub>0-4h</sub>) during an oral glucose tolerance test (OGTT) before and after four days of treatment.

We also studied the effects of AZD9567 and prednisolone on mRNA expression of key gluconeogenesis enzymes (tyrosine aminotransferase (TAT), phosphoenolpyruvate carboxykinase (PEPCK) and glucose 6-phosphatase (G6Pase)) in primary human hepatocytes as well as on insulin secretion in human islets microtissues.

**Results:** The inhibition of TNF $\alpha$  release increased with the plasma concentrations of AZD9567. PKPD modeling of TNF $\alpha$  inhibition data showed that 40 mg AZD9567 results in an anti-inflammatory activity similar to that predicted for 20 mg prednisolone.

A significantly smaller increase of the glucose AUC was observed following treatment with 20 to 125 mg AZD9567 compared to 20 mg prednisolone (p<0.05). Mean (95% CI) changes from baseline for 20, 40, 80 and 125 mg AZD9567 were 16% (6.5–26, n=7), 19% (9.3–30, n=7), 19% (9.8–30, n=7) and 34% (24–46, n=7), respectively. The corresponding values for 5, 20 and 40 mg prednisolone were 17% (10–24, n=13), 53% (43–62, n=13), and 68% (58–79, n=12), respectively.

We found significant induction of TAT, PEPCK, and G6Pase mRNA in hepatocytes after prednisolone treatment. In contrast, AZD9567 did not change the expression of these enzymes and inhibited the effect of prednisolone when co-administered. Furthermore, AZD9567 showed less suppression of insulin secretion in human islets microtissues compared to prednisolone at concentrations with comparable inhibition of TNF $\alpha$  release, resulting in a 12-fold better therapeutic ratio.

**Conclusions:** In healthy individuals, AZD9567 showed significantly reduced effect on glucose homeostasis versus prednisolone at doses with similar anti-inflammatory activity. Thus, AZD9567 shows potential as an anti-inflammatory treatment with an improved metabolic safety profile compared to prednisolone.

#### SAT0252 CLINICAL AND FUNCTIONAL RESPONSE TO TOFACITINIB AND ADALIMUMAB IN PATIENTS WITH RHEUMATOID ARTHRITIS: PROBABILITY PLOT ANALYSIS OF RESULTS FROM THE ORAL STRATEGY TRIAL

T. Takeuchi<sup>1</sup>, J. S. Smolen<sup>2</sup>, R. Fleischmann<sup>3</sup>, N. Iikuni<sup>4</sup>, H. Fan<sup>5</sup>, K. Soma<sup>6</sup>, E. Akyilbekova<sup>7</sup>, T. Hirose<sup>8</sup>. <sup>1</sup>Keio University, Tokyo, Japan, <sup>2</sup>Medical University of Vienna and Heitzing Hospital, Vienna, Austria, <sup>3</sup>Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, <sup>4</sup>Pfizer Inc, New York, NY, <sup>5</sup>Pfizer Inc, Collegeville, PA, <sup>6</sup>Pfizer Inc, Groton, CT, <sup>7</sup>IQVIA, Durham, NC, United States, <sup>8</sup>Pfizer Japan Inc, Tokyo, Japan

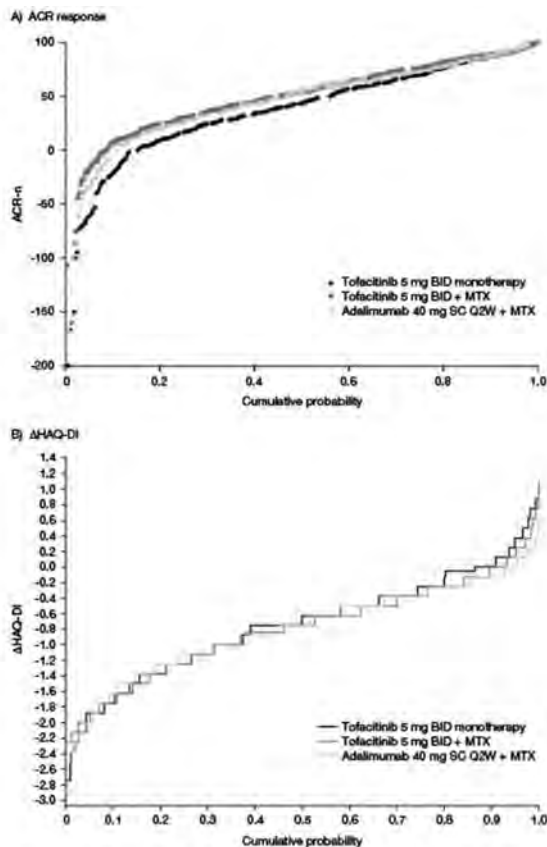

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA). ORAL Strategy (NCT02187055), a 12-month, global, Phase 3b/4 study, demonstrated that in patients with RA and an inadequate response to methotrexate (MTX), tofacitinib + MTX was non-inferior to adalimumab + MTX, while tofacitinib monotherapy was not non-inferior to either combination based on American College of Rheumatology (ACR)50 response rates at Month 6.<sup>1</sup>

**Objectives:** To assess clinical and functional efficacy across treatments in the ORAL Strategy trial using cumulative probability plots.

**Methods:** Efficacy was evaluated between patients who received tofacitinib 5 mg twice daily (BID) as monotherapy (N=384), tofacitinib 5 mg BID + MTX (N=376) and adalimumab 40 mg subcutaneously once every 2 weeks + MTX (N=386) based on ACR responses and changes from baseline in Health Assessment Questionnaire-Disability Index ( $\Delta$ HAQ-DI) score at Month 12. Cumulative probability plots for ACR-n (where ACR is the % improvement from baseline in ACR components, and n represents the minimum % achieved by each patient)

and  $\Delta$ HAQ-DI are presented. The area under the curve (AUC) was calculated for ACR-n up to Month 12 (in months), and an analysis of covariance model was used to assess treatment effects in terms of the AUC of ACR-n at Month 12; there was no adjustment for multiplicity for this post hoc analysis.

**Results:** The cumulative probability plots of ACR responses at Month 12 indicated that the proportion of patients who achieved responses of ACR20, ACR50 and ACR70 was similar for tofacitinib + MTX and adalimumab + MTX, but was numerically smaller for tofacitinib monotherapy (figure, A). Responses of approximately  $\geq$ ACR80 were achieved by a similar proportion of patients in each treatment group. Least squares mean (standard error) AUC of ACR-n up to Month 12 (in months) was similar for tofacitinib + MTX (437 [35]) and adalimumab + MTX (402 [35]), but was smaller for tofacitinib monotherapy (319 [35];  $p < 0.05$ ). The cumulative probability plots of  $\Delta$ HAQ-DI suggested that, in general, reductions from baseline in HAQ-DI were similar across treatment groups (figure, B), although a slightly higher proportion of patients who received tofacitinib monotherapy reported an increase in HAQ-DI vs other treatments.

ACR-n, American College of Rheumatology response, where n represents the minimum % response achieved by each patient; BID, twice daily;  $\Delta$ HAQ-DI, change from baseline in Health Assessment Questionnaire-Disability Index; MTX, methotrexate; Q2W, once every 2 weeks; SC, subcutaneous

Figure 1 Cumulative probability plot of A) ACR response and B)  $\Delta$ HAQ-DI at Month 12. Two outlets for ACR response are not shown: tofacitinib 5 mg BID monotherapy, ACR-n-1700, cumulative probability-0.0003; adalimumab 40 mg SC Q2W + MTX, ACR-n-463, cumulative probability-0.003

**Conclusions:** These data support the primary ORAL Strategy findings,<sup>1</sup> indicating that in patients with RA, clinical efficacy, based on ACR response, was generally similar for tofacitinib + MTX and adalimumab + MTX, while a smaller proportion of patients who received tofacitinib monotherapy achieved ACR response in general, and particularly for  $<$ ACR80. Functional efficacy, based on  $\Delta$ HAQ-DI, was generally similar across all treatment groups. Cumulative probability analyses for CDAI will be further evaluated.

SAT0253

#### DOSE REDUCTION OF BARICITINIB IN PATIENTS WITH RHEUMATOID ARTHRITIS ACHIEVING SUSTAINED DISEASE CONTROL: RESULTS OF A PROSPECTIVE STUDY

T. Takeuchi<sup>1</sup>, M. C. Genovese<sup>2</sup>, B. Haraoui<sup>3</sup>, Z. Li<sup>4</sup>, L. Xie<sup>5</sup>, R. Klar<sup>6</sup>, A. P. Correia<sup>5</sup>, S. Otawa<sup>5</sup>, P. Lopez-Romero<sup>5</sup>, I. De La Torre<sup>5</sup>, T. Rooney<sup>5</sup>, J. S. Smolen<sup>7</sup>. <sup>1</sup>Keio Univ. School of Medicine, Tokyo, Japan, <sup>2</sup>Stanford Univ., Palo Alto, United States, <sup>3</sup>Centre Hospitalier de l'Université de Montréal, Montreal, Canada, <sup>4</sup>Peking Univ. People's Hospital, Beijing, China, <sup>5</sup>Eli Lilly and Company, Indianapolis, <sup>6</sup>IQVIA, Durham, United States, <sup>7</sup>Medical Univ. of Vienna, Vienna, Austria

**Background:** In patients with rheumatoid arthritis (RA) and inadequate response (IR) to DMARDs, ph3 studies demonstrated efficacy of baricitinib (Bari) (2-mg and 4-mg).

**Objectives:** To investigate the effects of Bari dose step-down in patients who achieved sustained disease control with Bari 4-mg.

**Methods:** Patients with RA participating in the Bari ph3 long-term extension study who received Bari 4-mg for  $\geq 15$  months and who achieved sustained low disease activity (LDA) – CDAI score  $\leq 10$  or remission (REM) – CDAI  $\leq 2.8$   $\geq 3$  months apart were re-randomised in a blinded manner to continue Bari 4-mg or step down to 2-mg. Patients could rescue to Bari 4-mg. Efficacy and safety were assessed through 48 weeks (wks) following re-randomisation.

	Patients Originating from RA-BEAM, RA-BUILD, RA-BEACON Combined <sup>†</sup>

SAE	27 [7.96]			26 [8.17]		
Serious infection	10 [2.95]			4 [1.26]		
AE	9 [2.64]			12 [3.74]		
	—discontinuation					

Efficacy and safety data are n/N (%), and n [EAIR], respectively. <sup>†</sup>RA-BEAM=MTX-IR patients; RA-BUILD=csDMARD-IR patients; RA-BEACON=bDMARD-IR patients; EAIR=exposure-adjusted incidence rate; NRI=nonresponder imputation; SDEAE=step-down emergent adverse event; \*  $p \leq 0.05$ , \*\*  $p \leq 0.01$ , \*\*\*  $p \leq 0.001$  vs. continued Bari 4-mg

**Figure 1.** Data represent patients who have completed 48 weeks in the step-down period, or would have completed 48 weeks if not discontinued prior to the data cut-off date (April 1, 2017). Relapse defined as loss of step-down eligibility criteria, CDAI >10 for patients originating from RA-BUILD, RA-BEAM, or RA-BEACON. The p-value was computed using the Wilcoxon test.

**Results:** The majority of patients in both groups maintained the state of LDA or REM over the 48 wks. However, dose reduction to 2-mg resulted in significant increases in disease activity at 12, 24, and 48 wks (Table). Dose reduction also resulted in a shorter time to relapse (defined as loss of step-down eligibility criteria); significantly more patients relapsed over 48 wks compared to the 4-mg group (figure 1). Rescue rates were 8.3% for Bari 4-mg, 16.6% for Bari 2-mg. Most rescued patients could regain LDA or REM. Dose reduction was associated with a lower rate of infections; rates of SAEs and AEs leading to discontinuation were similar across groups.

**Conclusions:** These data indicate that disease control was better maintained with Bari 4-mg than 2-mg. However, most stepped-down patients could maintain LDA or REM, or recapture control with re-introduction of the 4-mg dose. Stepping down to a dose of 2-mg daily may be a viable option for many patients who have achieved sustained LDA or REM on the 4-mg dose.

**SAT0254 UPADACITINIB IMPROVES PATIENT-REPORTED OUTCOMES IN PATIENTS WITH RHEUMATOID ARTHRITIS AND INADEQUATE RESPONSE TO CONVENTIONAL SYNTHETIC DISEASE-MODIFYING ANTI-RHEUMATIC DRUGS: RESULTS FROM SELECT-NEXT**

V. Strand<sup>1</sup>, J. Pope<sup>2</sup>, N. Tundia<sup>3</sup>, A. Friedman<sup>3</sup>, H. S. Camp<sup>3</sup>, A. Pangan<sup>3</sup>, A. Ganguli<sup>3</sup>, M. Fuldeore<sup>3</sup>, D. Goldschmidt<sup>4</sup>, M. Schiff<sup>5</sup>. <sup>1</sup>Stanford University, Palo Alto, United States, <sup>2</sup>University of Western Ontario, London, Canada, <sup>3</sup>AbbVie Inc., North Chicago, <sup>4</sup>Analysis Group, Inc, New York, <sup>5</sup>University of Colorado, Denver, United States

**Background:** Upadacitinib (UPA), a selective JAK-1 inhibitor, has demonstrated efficacy in active RA among patients with an inadequate response to conventional synthetic disease-modifying anti-rheumatic drugs (csDMARD-IR).<sup>1</sup> To understand treatment effectiveness from the patients' perspective we examined the impact of UPA on patient-reported outcomes (PROs).

**Objectives:** To evaluate the effect of UPA vs placebo (PBO) on PROs in SELECT-NEXT (NCT02675426), a randomized controlled trial assessing the efficacy and safety of UPA in csDMARD-IR RA patients.

**Methods:** Patients in SELECT-NEXT received UPA 15 mg or 30 mg daily or PBO for 12 weeks followed by a 5-year extension phase. PROs included physical function (Health Assessment Questionnaire Disability Index [HAQ-DI]), Patient's Global Assessment of Disease Activity (PtGA) by visual analog scale (VAS), pain by VAS, fatigue by FACIT-F, duration and severity of morning (AM) stiffness, quality of life (QoL) by Short Form 36 Health Survey [SF-36], and Work Instability Scale for RA (RA-WIS). Changes in least square means (LSMs) from baseline (BL) to week 12 were based on mixed effect repeated measures models. Percentages of patients reporting changes in PRO scores from BL to week 12 ≥ minimum clinically important differences (MCIDs) or scores ≥ normative values (age- and gender-matched for SF-36 only) were determined for UPA and PBO arms; comparisons between groups used chi-square tests. For each PRO, the incremental number needed to treat (NNT) to achieve clinically meaningful improvement from BL (≥MCID) was calculated.

**Results:** Data from 661 patients (221 in UPA 15 mg; 219 in UPA 30 mg; 221 in PBO) were analysed. Mean age was 56 years, 79% were female; 45% had RA for ≥5 years. Statistically significant LSM changes from BL to week 12 were reported with both UPA doses vs PBO for HAQ-DI, PtGA, pain, FACIT-F, duration and severity of AM stiffness, SF-36 (PCS; 6 or 7/8 domains), and RA-WIS (Table). Compared with PBO at week 12, significantly more UPA-treated (both doses) patients reported improvement ≥MCID in HAQ-DI, PtGA, pain, FACIT-F, duration and severity of AM stiffness, SF-36 (PCS; 4 or 7/8 domains), and RA-WIS as well as scores ≥ normative values in HAQ-DI, PtGA, FACIT-F, SF-36 (PCS; 4 or 5/8 domains). For most PROs, NNTs with UPA ranged from 4 to 8 patients.

Table 1 LSM changes from baseline and percentage of responders at week 12 after UPA initiation

PRO	Change from Baseline			% Responders

\*P<0.05 for UPA vs PBO. <sup>a</sup>Duration in minutes. % responders reporting scores ≥ minimal important difference. <sup>b</sup>Assessed on a numeric scale of 1-10, 10 being the worst level.

**Conclusions:** Treatment with UPA 15 mg or 30 mg daily for 12 weeks resulted in significant and clinically meaningful improvements in physical function, pain, fatigue, AM stiffness, QoL, and less work instability among csDMARD-IR RA patients. The NNTs to achieve these improvements were favourable.

**SAT0255 PATIENT REPORTED OUTCOMES OF UPADACITINIB: RESULTS FROM BIOLOGIC INADEQUATE RESPONDERS (SELECT BEYOND PHASE III TRIAL)**

V. Strand<sup>1</sup>, M. Schiff<sup>2</sup>, N. Tundia<sup>3</sup>, A. Friedman<sup>3</sup>, S. Meerwein<sup>3</sup>, A. Pangan<sup>3</sup>, A. Ganguli<sup>3</sup>, M. Fuldeore<sup>3</sup>, Y. Song<sup>4</sup>, J. Pope<sup>5</sup>. <sup>1</sup>Stanford University, Palo Alto; <sup>2</sup>University of Colorado, Denver; <sup>3</sup>AbbVie Inc., North Chicago; <sup>4</sup>Analysis Group, Inc., Boston, USA; <sup>5</sup>University of Western Ontario, London, Canada

**Background:** Patient reported outcomes (PROs) were studied in patients with active rheumatoid arthritis (RA) who had an inadequate response to biologic disease modifying anti-rheumatic drugs (bDMARD-IR) in a trial of upadacitinib (UPA), a selective JAK-1 inhibitor. Improvements in PROs are important when evaluating comprehensive efficacy of treatments for RA.

**Objectives:** The objective of this post-hoc analysis was to compare PRO responses and numbers needed to treat (NNT) in order to assess clinically meaningful improvements in bDMARD-IR patients with RA receiving UPA.

**Methods:** Data from the SELECT BEYOND randomised controlled trial (RCT) (NCT02706847) were used to compare PRO responses between UPA (15 mg QD and 30 mg QD) and PBO. PROs included physical function by Health Assessment Questionnaire Disability Index (HAQ-DI), Patient's Global Assessment of Disease Activity (PtGA) by visual analogue scale (VAS), pain by VAS, duration and severity of morning (AM) stiffness, health-related quality of life by Short Form 36 Health Survey (SF-36), and severity of insomnia by Insomnia Severity Index (ISI). Changes in least squares means (LSM) from baseline to week 12 were based on mixed effect repeated measures models. Percentages of patients reporting changes in PRO scores from baseline to week 12 ≥ minimum clinically important difference (MCID) values or scores ≥ normative values (age- and gender-matched for SF-36 only) were determined; comparisons between groups used chi-square tests. For each PRO measure, the incremental NNT to achieve clinically meaningful improvements from baseline (≥ MCID) was calculated.

Abstract SAT0255 – Table 1. LSM Changes From Baseline and Percentage of Responders at Week 12

\*P<0.05 for UPA vs PBO.  
 \*Quotient in minutes. \*% Incidence reporting across 2 minimal important differences. \*Assessed on a numeric scale of 1-20 with 10 being the worst level.  
 RP, bodily pain; GH, general health; MCS, Mental Component Summary; MH, mental health; PCS, Physical Component Summary; PF, physical functioning; RE, role emotional; RP, role physical; SF, social functioning; VT, vitality.

**Results:** Data from 498 patients (169 in PBO, 164 in UPA 15 mg, 165 in 30 mg UPA) were analysed. Mean age was 57 years, 84% were females, and 55% had RA for ≥10 years. Both UPA doses resulted in statistically significant LSM

changes from baseline vs PBO in HAQ-DI, PtGA, pain, duration and severity of AM stiffness, SF-36 Physical Component Summary (PCS), 7/8 domains (15 mg), and 6/8 domains (30 mg) (Table). Compared with PBO at week 12, UPA-treated patients reported higher responses that were statistically significant and clinically meaningful for HAQ-DI, PtGA, pain, duration and severity of AM stiffness, SF-36 PCS, 7/8 domains (15 mg), 5/8 domains (30 mg), and ISI (30 mg). The Table presents the proportion of patients reporting scores that were ≥ normative values at week 12. Across most PROs, the NNTs with UPA ranged from 4 to 7 patients.

**Conclusions:** This RCT demonstrated that even in difficult-to-treat bDMARD-IR patients with active RA, treatment with UPA resulted in significantly more patients with clinically meaningful improvements in PROs or responses that approached normative values. The NNT to achieve a meaningful response was favourable.

**SAT0256 TOFACITINIB WITH AND WITHOUT METHOTREXATE VERSUS ADALIMUMAB WITH METHOTREXATE FOR THE TREATMENT OF RHEUMATOID ARTHRITIS: PATIENT-REPORTED OUTCOMES FROM A PHASE 3B/4 RANDOMISED TRIAL**

V. Strand<sup>1</sup>, E. Mysler<sup>2</sup>, R.J. Moots<sup>3</sup>, G. Wallenstein<sup>4</sup>, R. DeMasi<sup>5</sup>, D. Gruben<sup>4</sup>, K. Soma<sup>4</sup>, N. Iikuni<sup>6</sup>, R. Fleischmann<sup>7</sup>. <sup>1</sup>Division of Immunology/Rheumatology, Stanford University, Palo Alto, CA, USA; <sup>2</sup>Organización Médica de Investigación, Buenos Aires, Argentina; <sup>3</sup>Institute of Ageing and Chronic Disease, University of Liverpool, Liverpool, UK; <sup>4</sup>Pfizer Inc, Groton, CT; <sup>5</sup>Pfizer Inc, Collegeville, PA; <sup>6</sup>Pfizer Inc, New York, NY; <sup>7</sup>Metroplex Clinical Research Center and University of Texas Southwestern Medical Center, Dallas, TX, USA

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of rheumatoid arthritis (RA).

**Objectives:** To compare patient-reported outcomes (PROs) among patients receiving tofacitinib monotherapy, tofacitinib +methotrexate (MTX) and adalimumab (ADA) +MTX, in a head-to-head trial of patients with RA and inadequate responses to MTX (MTX-IR).

**Methods:** ORAL Strategy (NCT02187055) was a Phase 3b/4, 1 year, triple dummy, active randomised controlled trial (RCT). Patients were randomised 1:1:1 to receive tofacitinib 5 mg twice daily (BID; tofa mono), tofacitinib 5 mg BID+MTX (tofa +MTX) or subcutaneous ADA 40 mg every other week +MTX (ADA +MTX); MTX doses were 15–25 mg/wk. PROs (secondary endpoints in this RCT) assessed at Months (Mos) 6 and 12 included mean changes from baseline in: patient global assessment of disease activity (visual analogue scale [VAS]); arthritis pain (VAS); Health Assessment Questionnaire-Disability Index (HAQ-DI); Short Form-36 Health Survey; EuroQol 5-dimensions Questionnaire; Work Productivity and Activity Impairment Questionnaire; Functional Assessment of Chronic Illness Therapy-Fatigue; and the proportion of patients reporting improvements in HAQ-DI ≥ minimum clinically important difference (MCID; -0.22). Nominal p values were calculated with no adjustment for multiple comparisons.

**Results:** Among 1146 patients treated (tofa mono: n=384; tofa +MTX: n=376; ADA+MTX: n=386), baseline demographics and disease characteristics were comparable. At Mos 6 and 12, improvements in all PROs were similar for tofa +MTX and ADA+MTX (there were essentially no differences based on nominal p values) and numerically greater than with tofa mono (Table). Mean changes from baseline in HAQ-DI scores were similar in each treatment group at Mos 6 and 12; similar proportions reported improvements ≥ MCID.

**Abstract SAT0256 – Table 1.** LSM (SE) changes from baseline in patient-reported outcomes and proportion of patients reporting improvements in HAQ-DI ≥MCID at Month 6 and Month 12 in ORAL Strategy

**Background:** Upadacitinib (UPA) is an oral, JAK1-selective inhibitor found to be effective in Phase 2 and 3 studies in rheumatoid arthritis (RA) patients with inadequate response or intolerance to csDMARDs and bDMARDs.<sup>1-4</sup>  
**Objectives:** To evaluate the efficacy and safety of UPA in Japanese active RA patients with inadequate response to csDMARDs (csDMARD-IR).  
**Methods:** During the 12 week double-blind period, patients on stable csDMARDs were randomised to receive UPA 7.5, 15 or 30 mg once daily or PBO (1:1:1:1). The primary endpoint was proportion of patients achieving ACR20 at Wk 12 (NRI).  
**Results:** Of 197 patients treated, 187 completed the double-blind period. At Week 12, more patients receiving UPA 7.5, 15 and 30 mg vs PBO met ACR20 (75.5%, 83.7%, 80% vs 42.9%, p<0.001). A significant difference in ACR20 was observed as early as Week 1 (table 1). The more stringent responses, such as ACR50/70, DAS28-CRP≤3.2, were achieved by significantly higher proportions of patients on UPA vs PBO with more patients on UPA 15 mg and 30 mg achieving

these responses vs UPA 7.5 mg (Table). At Week 12, patients receiving UPA vs PBO had greater improvements from baseline (p<0.001) in DAS28-CRP (-2.08,-2.39, -2.41 vs -0.79) and HAQ-DI (-0.41,-0.45, -0.49 vs -0.10).

Overall adverse events (AE), serious AEs, infections (including serious infections, opportunistic infections and herpes zoster) were numerically higher in UPA 30 mg. There were no events of pulmonary embolism, deep vein thrombosis, tuberculosis or malignancy and there were no deaths. Mean haemoglobin levels improved with UPA 7.5 (+0.35 g/dL) and remained stable with UPA 15 (-0.03 g/dL) vs UPA 30 (-0.54 g/dL) and PBO (-0.17 g/dL). CPK elevations and lymphopenia occurred more frequently in UPA 30 mg.

Efficacy Endpoints at Week 12 <sup>1</sup>				
Endpoint	PBO, N=49	UPA 7.5 MG, N=49	UPA15 MG, N=49	UPA 30 MG, N=50
ACR20 (%)	42.9%	75.5%***	83.7%***	80.0%***
ACR50 (%)	16.3%**	40.8%**	65.3%***	68.0%***
ACR70 (%)	2.0%	20.4%**	34.7%***	28.0%***
DAS28 (CRP), mean change	-0.79	-2.08***	-2.39***	-2.41***
HAQ-DI, mean change	-0.10	-0.41***	-0.45***	-0.49***
SE-36 PCS, mean change	-2.09	7.21***	6.38***	8.81***
DAS28 (CRP) ≤ 3.2	16.4%	63.1%***	89.4%***	87.0%***

ACR20 at Week 1%	6.2%	30.6%**	24.5%**	34.0%**

Adverse Events (AE) Summary, n (%)				
AE	PBO, N=49	UPA 7.5 MG, N=49	UPA 15 MG, N=49	UPA 30 MG, N=50
Any AE	23 (46.9)	29 (59.2)	28 (57.1)	37 (74.0)
Serious AE	0	1 (2.0)	1 (2.0)	8 (16.0)
AE leading to Study Drug Dis.	0	0	1 (2.0)	7 (14.0)
Severe AE	0	2 (4.1)	2 (4.1)	4 (8.0)

AE of Special Interest, n (%)				
Infection	PBO, N=49	UPA 7.5 MG, N=49	UPA 15 MG, N=49	UPA 30 MG, N=50
Infection	11 (22.4)	18 (36.7)	16 (32.7)	22 (44.0)
Serious Infection <sup>2</sup>	0	0	1 (2.0)	3 (6.0)
Opportunistic Infection <sup>3</sup>	0	0	0	2 (4.0)
Herpes Zoster <sup>4</sup>	1 (2.0)	1 (2.0)	0	3 (6.0)
Tuberculosis	0	0	0	0
Malignancy	0	0	0	0
Haemoglobin	2 (4.1)	0	1 (2.0)	1 (2.0)
GI Perforation	0	0	0	0
PE/VT	0	0	0	0
Cardiovascular event ( adjudicated)	0	1 (2.0) <sup>5</sup>	0	0
Death	0	0	0	0

<sup>1</sup>Results for binary endpoints are based on NRI analysis. Results for continuous endpoints are based on MMRM (Mixed Effect Model Repeat Measures) analysis. \*\* p<0.01 and p<0.001, respectively.  
<sup>2</sup>Serious infections: UPA 15 mg, Cellulitis; UPA 30 mg, 1 case each of HZ, hand, foot and mouth disease and pneumocystis pneumonia.  
<sup>3</sup>Opportunistic infections: UPA 30 mg, 1 case each of oral candidiasis and pneumocystis pneumonia (counted also under serious infections).  
<sup>4</sup>Herpes zoster: all cases were non-serious, except one in UPA 30 which was single dermatome and considered by the investigator as possibly related to study drug.  
<sup>5</sup>Cardiovascular event ( adjudicated): Non-MACE (transient ischaemic attack).

**Conclusions:** In this Japanese RA csDMARD-IR population, the efficacy of UPA was demonstrated, with better responses for more stringent endpoints on UPA 15 mg and 30 mg vs 7.5 mg. The frequency of overall AEs was numerically higher in UPA 30 mg. Overall, safety and tolerability were consistent with Phase 2 and 3 studies to date.

SAT0258

### WEEKLY SPLIT DOSE COMPARED WITH SINGLE DOSE ORAL METHOTREXATE REDUCED POLYGLUTAMYLATION IN RED BLOOD CELLS AND INCREASED THE RISK OF ADVERSE EVENTS IN PATIENTS WITH RHEUMATOID ARTHRITIS

Y. Yoshioka<sup>1</sup>, K. Katayama<sup>2</sup>, T. Kasama<sup>3</sup>, M. Sato<sup>4</sup>, S. Ohno<sup>5</sup>, Y. Amasaki<sup>6</sup>, H. Kataoka<sup>7</sup>, D. Kanai<sup>1</sup>, A. Suda<sup>1</sup>, M. Okamoto<sup>8</sup>, M. Sasano<sup>9</sup>, S. Nagaoka<sup>1</sup>, A. Sagawa<sup>9</sup> on behalf of ADDMe trial Group. <sup>1</sup>Yokohama Minami Kyosai Hospital, Yokohama; <sup>2</sup>Katayama Orthopedic Rheumatology Clinic, Asahikawa; <sup>3</sup>Showa University Koto-Toyosu Hospital, Tokyo; <sup>4</sup>Ohashi Tani Orthopedic Hospital, Gifu; <sup>5</sup>Yokohama City University Medical Center, Yokohama; <sup>6</sup>KKR Sapporo Medical Center, Sapporo City General Hospital, Sapporo; <sup>7</sup>AYUMI pharmaceutical Corporation, Kyoto; <sup>8</sup>Sagawa Akira Rheumatology Clinic, Sapporo, Japan

**Background:** Methotrexate (MTX) is a well-known anchor drug for rheumatoid arthritis (RA); however, dose regimens vary. We previously reported in EULAR2015 that split dose weekly oral methotrexate induced elevation of AST and ALT in association with elevation of MTX with 2 glutamates (MTX-PG2) in a single-centre trial.

**Objectives:** We performed a multi-centre randomised controlled trial to compare the incidence of adverse events using single and split dose regimens.

**Methods:** Six hospitals and 2 rheumatology clinics participated in this study. Seventy-eight patients with insufficient control on MTX 8 mg/week were randomly assigned to 2 groups, i.e., a single weekly dose regimen with 39 patients and a 3 dose per week regimen with 39 patients. The MTX dose in all patients was gradually increased to 16 mg/week. The primary endpoint was the occurrence of liver dysfunction during the observation period (20 weeks). Other endpoints included the incidence of adverse events and the changes from baseline in the disease activity score (DAS28) based on ESR or CRP, the Simplified Disease Activity Index (SDAI), and MTX-PG at week 20.

**Results:** There were no differences between the groups in baseline data and MTX dose at 20 weeks (single dose: 10.2±0.8 vs. 3-dose: 10.2±0.9 mg/week). Liver dysfunction occurred in 3 patients (7.7%) receiving the single dose regimen and in 5 patients (13.2%) receiving the 3-dose regimen, but there was no significant difference in the incidence in both groups (p=0.455). There was a significant difference in the incidence of adverse events (gastrointestinal disorder was most common) between single dose (11 patients, 28.9%) and 3-dose (20 patients, 52.6%) regimens (p=0.036). There was no significant difference in the changes from baseline in DAS28-ESR (-1.55 vs. -1.36), DAS28-CRP (-1.31 vs. -1.26), or SDAI (-9.45 vs. -10.11). Compared to the single dose regimen, MTX-PG2 was significantly increased in the 3-dose regimen, and MTX-PG3, -PG4, and -PG5 were significantly increased in the single dose regimen (table 1).

**Abstract SAT0258 – Table 1.** MTX-PG changes from baseline in red blood cells at week 20.

	Single dose Mean (n=28) (nmol/L) (1)	3-dose Mean (n=27) (nmol/L) (2)	Difference (2) – (1) Mean (95% CI)	P (Wilcoxon)
MTX-PG1	22.95	57.9	34.95 (-56.99, 126.89)	0.448
MTX-PG2	-1.14	17.36	18.50 (12.73–24.27)	<0.001
MTX-PG3	39.24	27.83	-11.41 (-21.51, -1.32)	0.032
MTX-PG4	15.43	5.10	-10.33 (-15.03, -5.63)	<0.001
MTX-PG5	3.36	0.15	-3.22 (-4.73, 1.69)	<0.001

**Conclusions:** There were no differences in the incidence of liver dysfunction and efficacy according to the oral MTX dose regimen; however, split weekly dosing

compared with single weekly dosing reduced polyglutamylation and increased the risk of adverse events.

### Spondyloarthritis - treatment

SAT0259

### LOW RATE OF SPINAL RADIOGRAPHIC PROGRESSION OVER 2 YEARS IN ANKYLOSING SPONDYLITIS PATIENTS TREATED WITH SECUKINUMAB: A HISTORICAL COHORT COMPARISON

J. Braun<sup>1</sup>, H. Haibel<sup>2</sup>, M. de Hooge<sup>3,4</sup>, R. Landewé<sup>5</sup>, M. Rudwaleit<sup>6</sup>, T. Fox<sup>7</sup>, A. Reade<sup>8</sup>, H.B. Richards<sup>7</sup>, B. Porter<sup>8</sup>, R. Martin<sup>9</sup>, D. Poddubny<sup>2</sup>, J. Sieper<sup>2</sup>, D. van der Heijde<sup>3</sup>. <sup>1</sup>Rheumazentrum Ruhrgebiet, Herne; <sup>2</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>3</sup>Leiden University Medical Centre, Leiden, Netherlands; <sup>4</sup>VIB Inflammation Research Center, Ghent, Belgium; <sup>5</sup>Maastricht University Medical Center, Maastricht, Netherlands; <sup>6</sup>Klinikum Bielefeld, Bielefeld, Germany; <sup>7</sup>Novartis Pharma AG, Basel, Switzerland; <sup>8</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA

**Background:** Secukinumab, a fully human interleukin 17A (IL-17A) inhibitor, improved signs and symptoms of ankylosing spondylitis (AS) in patients (pts) in the MEASURE 1 core trial at 2 years and through 4 years in the extension study.<sup>1,2</sup> A low radiographic progression rate was reported for the modified Stoke Ankylosing Spondylitis Spinal Score ( $\Delta$  mSASSS at Yr 2=0.3).<sup>1</sup> Comparison of anti-TNF agents with historical NSAID-treated cohorts have not shown a significant benefit at 2 years in reducing radiographic progression.<sup>3,4</sup>

**Objectives:** This retrospective analysis compared spinal radiographic progression over 2 years in the MEASURE 1 cohort of secukinumab-treated AS patients (C1; NCT01358175) vs a historical cohort of biologic-naïve AS pts (ENRADAS [C2; NCT00715091]).<sup>5</sup>

**Methods:** Baseline (BL) and 2 year X-ray data from the 2 cohorts were compared. Only data from pts with X-rays at BL and Yr 2 (data capture window for Yr 2 X-rays: 31–744 days) were included (n=168 [C1], n=69 [C2]). X-rays were independently re-evaluated using the mSASSS by 2 reviewers and an adjudicator blinded to the timing and cohorts; averaged values were analysed. Cases with the highest difference in  $\Delta$  mSASSS between readers (top 10%) were adjudicated. The primary outcome was to compare the % pts with no radiographic progression ( $\Delta$  mSASSS at Year 2 $\leq$ 0) in C1 vs C2. The difference between C1 and C2 was analysed using a logistic regression with cohort as a factor and BL mSASSS as a covariate.

**Results:** BL demographics were comparable across cohorts, with mean age 40.9 vs 42.6 years, and gender 72.8% vs 66.7% male in C1 vs C2, respectively. Over 2 years, least squares (LS) mean  $\Delta$  mSASSS was 0.55 for C1 vs 0.89 for C2 (p=0.185) and % pts with no radiographic progression ( $\Delta$  mSASSS at Year 2 $\leq$ 0) was slightly higher in C1 vs C2 (table 1).

**Abstract SAT0259 – Table 1.** Radiographic status at Yr 2

	C1 (MEASURE 1) n=168	C2 (ENRADAS) n=69	Odds ratio/difference of LS mean (95% CI), p-value
BL mSASSS (SD)	9.55 (14.14)	9.95 (13.76)	
mSASSS at Yr 2 (SD)	10.10 (14.70)	10.85 (14.66)	
$\Delta$ mSASSS over 2 years, LS mean (SE)	0.55 (0.14)	0.89 (0.22)	p=0.185
No progression ( $\Delta$ mSASSS $\leq$ 0), %	61%	52%	1.43 (0.79, 2.60), p=0.243
No progression ( $\Delta$ mSASSS $<$ 2), %	82%	73%	1.84 (0.90; 3.77), p=0.093

CI, confidence interval; SD, standard deviation; SE, standard error

**Conclusions:** Over 2 years, a numerically lower rate of progression was seen in secukinumab-treated pts vs a control cohort of biologic-naïve AS pts. Further research is needed to understand the impact of IL-17A inhibition with secukinumab on spinal disease progression in AS pts; SURPASS (NCT03259074), an ongoing H2H study powered to compare differences in spinal radiographic progression with secukinumab vs biosimilar adalimumab, will help answer these questions.

**SAT0260 ELIGIBILITY CRITERIA FOR TNFI THERAPY IN AXSPA: GOING BEYOND BASDAI**

J.A. Marona<sup>1,2</sup>, A. Sepriano<sup>2,3</sup>, S. Rodrigues-Manica<sup>1,2</sup>, F. Pimentel-Santos<sup>1,2</sup>, A. F. Mourão<sup>1,2</sup>, N. Gouveia<sup>2</sup>, J.C. Branco<sup>1,2</sup>, F. Vinagre<sup>4</sup>, R. Roque<sup>4</sup>, J. Rovisco<sup>5</sup>, M. L. Marques<sup>5</sup>, J. Tavares-Costa<sup>6</sup>, J. Silva<sup>6</sup>, H. Santos<sup>7</sup>, N. Madeira<sup>7</sup>, E. Vieira-Sousa<sup>8,9</sup>, R. Machado<sup>8</sup>, M. Bernardes<sup>10</sup>, R. Ferreira<sup>10</sup>, S. Ramiro<sup>2,3</sup>. <sup>1</sup>CHLO; <sup>2</sup>CEDOC, NMS, Lisbon, Portugal; <sup>3</sup>LUMC, Leiden, Netherlands; <sup>4</sup>HGO, Almada; <sup>5</sup>CHUC, Coimbra; <sup>6</sup>ULSAM, Ponte de Lima; <sup>7</sup>IPR; <sup>8</sup>CHLN; <sup>9</sup>IMM, FMUL, Lisbon; <sup>10</sup>CHSJ, Porto, Portugal

**Background:** A BASDAI  $\geq 4$  has been often used to start TNFi therapy in patients with axSpA. However, this cut-off of high disease activity (HDA) is largely arbitrary. Unlike BASDAI, ASDAS incorporates objective measures (e.g. CRP) and has a validated definition of HDA ( $\geq 2.1$ ). It has thus been suggested that ASDAS could also be used to guide treatment decisions, but evidence to support this is still scarce.

**Objectives:** To compare the impact of applying the ASDAS and BASDAI definitions of HDA in selecting patients for TNFi-treatment in daily clinical practice

**Methods:** Patients from Reuma.pt (Rheumatoid Diseases Portuguese Register), with diagnosis of axSpA according to their rheumatologists (both treated and not treated with their first TNFi), with complete baseline BASDAI and ASDAS data, and complete 6 month of follow-up (i.e. baseline, 3 and 6 months visits available) were included. Four subgroups [cross-tabulation between ASDAS ( $\geq 2.1$ ) and BASDAI ( $\geq 4$ ) definitions of HDA], were compared according to baseline demographic and clinical characteristics in the 'eligible population' (i.e. irrespective of TNFi-treatment). In addition, for patients starting TNFi and with complete follow-up BASDAI/ASDAS data ('efficacy population'), the subgroups were also compared according to different response criteria (see table 1), at 3 and 6 months.

**Results:** In total, 466 patients were included (59% males and 66% HLA-B27 positive). The large majority (n=382; 82%) fulfilled the definition of HDA according to both BASDAI and ASDAS at baseline (i.e. BASDAI  $\geq 4$  and ASDAS  $\geq 2.1$ ). The frequency of ASDAS  $\geq 2.1$ , if BASDAI  $< 4$ , was much higher than the opposite condition (i.e. ASDAS  $< 2.1$ , if BASDAI  $\geq 4$ ) (70% vs 0.5%). Compared to patients fulfilling both definitions, those who were ASDAS  $\geq 2.1$  only, were more likely to be male (82.5% vs 54%), HLA-B27 positive (79% vs 54%), to show higher levels of CRP ( $2.6 \pm 2.5$  vs  $2.2 \pm 2.8$  mg/dL) and lower BASFI ( $3.1 \pm 2.6$  vs  $5.6 \pm 2.3$ ). In the 'efficacy population' (n=296), better responses were observed among patients with ASDAS  $\geq 2.1$  only, especially for the most 'stringent' outcomes [e.g. ASDAS inactive disease (ASDAS ID): 59% and 50%, at 3 and 6 months respectively], compared to patients fulfilling both definitions (ASDAS ID: 26% and 25% at 3 and 6 months respectively) (table 1).

**Abstract SAT0260 – Table 1.** TNFi response criteria across subgroups according to BASDAI/ASDAS category ('efficacy population')

Variables	Overall (N=296) *	ASDAS $\geq 2.1$		ASDAS $< 2.1$		p-value **

\* ASDAS patients treated with TNFi with complete 3 months of follow-up and data for BASDAI/ASDAI at every timepoint \*\* comparison between subgroups according to BASDAI/ASDAI category of disease activity (ASDAI) for continuous variables and Chi for categorical variables. ASDAS CR, ASDAS clinically important improvement; ASDAS MI, ASDAS major improvement; ASDAS ID, ASDAS inactive disease.

**Conclusions:** Our results show that the ASDAS-HDA definition (ASDAS  $\geq 2.1$ ) is more inclusive than the BASDAI-HDA definition ( $\geq 4$ ) in selecting axSpA patients for TNFi treatment. Importantly, the additionally 'captured' patients respond better and have higher likelihood of predictors thereof. These results support the use of ASDAS  $\geq 2.1$  as a selection criterion for treatment decisions.

SAT0261

### CERTOLIZUMAB PEGOL SERUM LEVELS $\geq 20$ MG/L ARE ASSOCIATED WITH TREATMENT RESPONSE IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS. DATA FROM THE NOR-DMARD STUDY

J.E. Gehin<sup>1,1</sup>, S.W. Syversen<sup>2</sup>, D.J. Warren<sup>1</sup>, G.L. Goll<sup>2</sup>, J. Sexton<sup>2</sup>, E.K. Strand<sup>3</sup>, T.K. Kvien<sup>2</sup>, N. Bolstad<sup>1</sup>, E. Lie<sup>2</sup>. <sup>1</sup>Department of Medical Biochemistry, Oslo University Hospital; <sup>2</sup>Department of Rheumatology, Diakonhjemmet Hospital, Oslo; <sup>3</sup>Lillehammer Hospital for Rheumatic Diseases, Lillehammer, Norway

**Background:** Measurement of serum drug levels can help clinicians tailor treatment with TNF-inhibitors. An association between certolizumab pegol (CP) serum levels and response has previously been found in patients (pts) with rheumatoid arthritis. <sup>1</sup>Data for pts with axial spondyloarthritis (axSpA) are lacking.

**Objectives:** To examine the association between serum CP levels and treatment response in pts with axSpA and to identify a therapeutic target level.

**Methods:** Patients with a clinical diagnosis of axSpA starting standard treatment with CP included in the NOR-DMARD study with biobank sample at 3 months follow-up, were included in the present analyses. Serum drug levels (non-trough) were analysed with an in-house immunofluorometric assay automated on the AutoDELFI immunassay platform. Associations between CP level and improvement in ASDAS-CRP and response (defined as ASDAS clinically important improvement (CII)) were assessed by multivariable linear and logistic regression (adjusting for age, sex and prior bDMARD (Y/N)), respectively.

**Results:** Median serum drug level at 3 month follow up was 35.0 mg/L (IQR 21.3–45.3) in 116 pts. Response data were available in 110/116 patients. Serum CP level  $\geq 20$  mg/L was associated with improvement in ASDAS at 3 months ( $\beta=0.55$ , (95% CI 0.12–1.98),  $p=0.01$ ). Serum CP level  $\geq 20$  mg/L was associated with ASDAS CII at 3 months (OR 3.4 (95% CI 1.0–11.1,  $p=0.045$ )). Only 18.2% of pts with CP level  $< 20$  mg/L achieved ASDAS CII at 3 months, while 53.2% of pts with CP level 20–40 mg/L and 36.6% with  $\geq 40$  mg/L were responders.

**Conclusions:** Serum CP level was associated with clinical response after 3 months of treatment in pts with axSpA. We suggest 20 mg/L as a lower target level for non-trough samples. No additional benefit of having a certolizumab level over 40 mg/L was observed. These results suggest that a therapeutic level of 20–40 mg/L can be implemented in clinical practice for non-trough serum samples in pts with axSpA.

### 3-YEAR FOLLOW-UP OF A DOSE TAPERING PROTOCOL OF ANTI-TNF THERAPY IN A COHORT OF PATIENTS WITH SPONDYLOARTHRITIS (SPA) IN CLINICAL REMISSION UNDER CONDITIONS OF CLINICAL PRACTICE

M.D.C. Castro Villegas<sup>1</sup>, E.-L. Saldarriaga<sup>2</sup>, P. Font Ugalde<sup>3</sup>, M. Romero Gómez<sup>1</sup>, J. Calvo Gutierrez<sup>1</sup>, R. Ortega Castro<sup>1</sup>, E.C. López-Medina<sup>1</sup>, R.A. Altamirano<sup>4</sup>, A. Escudero-Contreras<sup>3</sup>, E. Collantes Estévez<sup>3</sup>. <sup>1</sup>Department of Rheumatology, Hospital Reina Sofia. IMIBIC., Cordoba, Spain; <sup>2</sup>Department of Rheumatology, Universidad de La Sabana, bogota, Colombia; <sup>3</sup>Department of Rheumatology, Hospital Reina Sofia. IMIBIC. Medicine Faculty Cordoba University; <sup>4</sup>Department of Rheumatology, Medicine Faculty Cordoba University, Cordoba, Spain

**Background:** The dose tapering of biological therapy in patients in clinical remission is a strategy used in recent years in Rheumatology, consists in the reduction of the dose administered or in the extension of the interval between two doses, some studies suggest the possibility that patients with sustained remission could obtain the same benefit with a lower dose.

**Objectives:** Evaluate the effectiveness of 3 year follow-up of a dose tapering in patients with SpA in maintained clinical remission and detect possible predictors of maintenance of the response.

**Methods:** Retrospective observational study, all patients with SpA were included, according to ASAS criteria, treated with antiTNF, with dose tapering, from October 2014-December 2017. Clinical remission defined by BASDAI  $\leq 2$  and/or CRP  $\leq 5$  mg/L for at least 6 months, establishing dose tapering as lower doses or longer intervals (according to the guidelines of the Spanish Society of Rheumatology and Pharmacy). Those patients who relapsed (BASDAI  $> 2$  and/or CRP  $> 5$  mg/L) at any time during the study returned to the standard dose. Clinical and analytical parameters were collected (baseline and at the time of optimisation), as well as the survival of the drug and the efficacy parameters until the time of relapse and who continued in dose tapering.

**Results:** 149 patients with SpA in treatment with antiTNF, 38/149 (25.5%) included in the dose tapering protocol, 84.4% men and the mean age  $47.2 \pm 10.6$  years. The antecedents 25% uveitis, 6.3% psoriasis and 6.3% inflammatory bowel disease. Regarding the type of optimisation strategy, 32 patients (84.37%) followed the protocol for increasing the interval between doses, compared to the rest (15.62%) who used reduced doses. We found 27/38 patients (71.05%, CI: 55.2–83) maintained clinical remission with tapering, 9 (33.3%) infliximab, 7 (25.9%) golimumab, 6 (22.2%) etanercept and 5 (18.5%) adalimumab, at a time of drug follow-up of  $57.9 \pm 29.7$  months. The demographic factors analysed sex, age, time of evolution and clinical remission, were not found as possible predictors of greater survival in the dose tapering.

	PATIENTS RELAPSE (n=11)			PATIENTS REMISSION (n=27)		
	Basal	Start tapering	Relapse	Basal	Start tapering	Last visit
BASDAI (0–10)	3.8 $\pm$ 2.4	2 $\pm$ 1.8	3.18 $\pm$ 2.27	4.4 $\pm$ 2.8	2.1 $\pm$ 2.5	1.5 $\pm$ 1.6
BASFI (0–10)	4.3 $\pm$ 2.8	2.8 $\pm$ 2.8	2.9 $\pm$ 2.37	3.7 $\pm$ 2.6	2.8 $\pm$ 3.1	2.0 $\pm$ 2.4
ESR (mm/1 <sup>h</sup> )	17.1 $\pm$ 22.5	9.3 $\pm$ 11.1	11.84 $\pm$ 11.29	20.4 $\pm$ 18.8	7.8 $\pm$ 6.1	8.4 $\pm$ 7.6
CPR	10.9 $\pm$ 12.2	9.7 $\pm$ 12.4	3.84 $\pm$ 4.54	14.6 $\pm$ 22.5	3.7 $\pm$ 6.1	2.69 $\pm$ 3.0

	n=38	
	Age (years, mean $\pm$ SD)	47.2 $\pm$ 10.6
Sex (%) Man/woman	84.4/15.6	
Time of evolution disease (years, mean $\pm$ SD)	12.2 $\pm$ 10.4	
Start biological therapy (months, mean $\pm$ SD)	22.84 $\pm$ 12.68	
	Start antiTNF	Start tapering
BASDAI(0-10)	4.2 $\pm$ 2.6	2.07 $\pm$ 1.96
BASFI(0-10)	4 $\pm$ 2.7	2.8 $\pm$ 2.9
CPR(mg/L)	13.1 $\pm$ 18.7	6.4 $\pm$ 9.7
ESR(mm/1 <sup>h</sup> )	19 $\pm$ 20.1	8.5 $\pm$ 8.5

**Conclusions:** The monitoring of dose tapering of biological therapy in patients with SpA is possible and allows more than 70% of patients to maintain the clinical remission of the disease. However, a greater number of patients and longer follow-up are necessary for a solid conclusion. Additionally, our results do not show possible predictors of a longer survival in tapering protocol.

**SAT0263 PREDICTORS OF REMISSION MAINTENANCE AND SUCCESSFUL THERAPY DISCONTINUATION IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS (NR-AXSPA) WHO ACHIEVED SUSTAINED REMISSION ON OPEN-LABEL ADALIMUMAB (ADA) TREATMENT**

J. Sieper<sup>1</sup>, R. Landewé<sup>2</sup>, M. Magrey<sup>3</sup>, J. Anderson<sup>4</sup>, S. Zhong<sup>4</sup>, X. Wang<sup>4</sup>, A. Lertratanakul<sup>4</sup>. <sup>1</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>2</sup>University of Amsterdam, Amsterdam, Netherlands; <sup>3</sup>Case Western Reserve University School of Medicine at MetroHealth Medical Center, Cleveland; <sup>4</sup>AbbVie Inc., North Chicago, USA

**Background:** Sustained remission is an important treatment goal in patients (pts) with non-radiographic axial SpA (nr-axSpA). Factors predicting successful remission maintenance are unknown.

**Objectives:** We sought to identify predictors of remission maintenance in nr-axSpA pts who achieved remission after open-label (OL) adalimumab (ADA) treatment in the ABILITY-3 trial (NCT01808118) and were subsequently randomised to continuation or withdrawal of ADA therapy.

**Methods:** ABILITY-3 enrolled adult pts with nr-axSpA with objective evidence of active MRI inflammation in the SI joints or spine or elevated high-sensitivity CRP at screening, active disease at baseline (ASDAS<sub>2.1</sub>≥2.1, BASDAI<sub>4</sub>≥4, and Patient's Assessment of Total Back Pain score ≥4), and inadequate response to ≥2 NSAIDs (table 1). Pts received ADA 40 mg every other wk during a 28-wk OL lead-in period. Pts who achieved sustained remission, defined as ASDAS inactive disease [ID] score <1.3 at wks 16, 20, 24, and 28, were randomised to double-blind withdrawal (placebo; PBO) or continued ADA for 40 wks during period 2 (study wk 68). Stepwise logistic regression was used to identify predictors of sustained remission in those in the continued ADA and withdrawal (PBO) groups. Remission maintenance in period 2 was assessed with the following: ASAS partial remission (PR; score ≤2.0) and ASDAS ID at wk 68, ASAS PR and ASDAS ID at every visit, and ASDAS ID for ≥5 of 10 visits.

**Abstract SAT0263 – Table 1. Characteristics at Baseline and Wk 28**

Variable	ADA (40 mg EOW) n=152	PBO n=153	P Value	Wk 28, mean (SD)	ADA (40 mg EOW) n=152	PBO n=153	P Value
Age, y	54.7 (10.3)	55.3 (10.2)	0.611	ASDAS	0.7 (0.4)	0.6 (0.4)	0.355
Female, n (%)	56 (37)	60 (39)	0.724	BASDAI	0.8 (0.8)	0.7 (0.7)	0.145
SpA symptom duration, y	6.4 (6.9)	7.1 (6.8)	0.358	BASFI	0.7 (1.0)	0.7 (1.2)	0.994
HLA-B27 positive, n (%)	132 (87)	134 (88)	0.866	Hi-CRP, mg/L	1.5 (2.4)	1.4 (1.8)	0.617
ASDAS	3.5 (0.9)	3.5 (0.8)	0.851	Pt total back pain	1.1 (1.4)	1.0 (1.4)	0.565
BASDAI	6.8 (1.4)	6.8 (1.5)	0.851	PGA	0.8 (1.0)	0.9 (1.1)	0.386
BASFI	5.1 (2.3)	5.0 (2.3)	0.776	SPARCC SI joint score*	2.6 (6.1)	2.5 (4.0)	0.755
Hi-CRP, mg/L	9.9 (11.1)	9.1 (13.3)	0.576	SPARCC spine score*	1.2 (3.8)	1.2 (3.8)	0.809
Pt total back pain	7.0 (1.7)	7.0 (1.8)	0.946				
PGA	6.6 (1.5)	6.4 (1.4)	0.150				
SPARCC SI joint score*	8.5 (12.8)	10.3 (13.4)	0.226				
SPARCC spine score*	3.3 (7.5)	3.6 (7.2)	0.671				

**Results:** By wk 68, 100/145 (69%) ADA pts had not flared, 41% achieved ASAS PR and 56% ASDAS ID at wk 68; 23% achieved ASAS PR and 29% ASDAS ID at every visit, while 70% achieved ASDAS ID for ≥5 of 10 visits. By wk 68, 70/148 (47%) PBO pts had not flared, 28% achieved ASAS PR and 33% ASDAS ID at wk 68; 14% achieved ASAS PR and 15% ASDAS ID at every visit, while 52% achieved ASDAS ID for ≥5 of 10 visits. Shorter symptom duration, lower wk 28 BASDAI, and male sex were associated with absence of flare in the continued ADA group. Lower wk 28 ASDAS was associated with absence of flare with ADA withdrawal. Lower wk 28 ASDAS consistently predicted ASAS PR and ASDAS ID

at wk 68, ASAS PR and ASDAS ID at every visit, and ASDAS ID for ≥5 of 10 visits in pts who continued or withdrew ADA.

**Conclusions:** In nr-axSpA pts who achieved remission after 28-wk OL ADA therapy, lower wk 28 ASDAS is a consistent predictor of remission maintenance using all definitions in both the adalimumab continuation and withdrawal groups, except absence of flare in the adalimumab continuation group, suggesting early aggressive treatment may be beneficial in achieving sustained remission.

**SAT0264 DOES BIOLOGICAL DISEASE-MODIFYING ANTI-RHEUMATIC DRUG NAÏVE VERSUS NON-NAÏVE PATIENTS WITH INFLAMMATORY JOINT DISEASES HAVE SIMILAR GOLIMUMAB DRUG SURVIVAL AND EFFICACY? DATA FROM THE PROSPECTIVE OBSERVATIONAL NOR-DMARD STUDY**

B. Michelsen<sup>1,2</sup>, J. Sexton<sup>1</sup>, T.K. Kvien<sup>1</sup>. <sup>1</sup>Dept. of Rheumatology, Diakonhjemmet Hospital, Vinderen, Oslo; <sup>2</sup>Hospital of Southern Norway Trust, Kristiansand, Norway

**Background:** Knowledge is limited regarding the impact of previously used biological disease modifying anti-rheumatic drugs (bDMARD) on golimumab drug survival and efficacy in inflammatory joint diseases (IJD).

**Objectives:** To explore golimumab drug survival and efficacy in bDMARD naïve vs. non-naïve IJD patients, as well as predictors of golimumab discontinuation.

**Methods:** From the observational prospective multicenter Norwegian-DMARD (NOR-DMARD) study rheumatoid arthritis (RA), psoriatic arthritis (PsA) and axial spondyloarthritis (ax-SpA) patients starting golimumab were included. Drug survival was explored by Kaplan-Meier analyses with comparison of bDMARD naïve vs. non-naïve patients with log rank test, stratified by diagnosis. 3 month responses were compared with independent t-test, and with ANCOVA adjusted for age, gender, disease duration and baseline values of the respective composite scores. Univariable and multivariable Cox regression analyses including age, gender, disease duration, smoking, concomitant synthetic DMARDs (sDMARDs) and previous bDMARD use were performed to identify predictors of golimumab discontinuation.

**Results:** Mean (SD) age of the 163 RA, 267 PsA and 382 ax-SpA patients was 51.2 (14.1)/48.1 (11.7)/41.8 (11.1) years, disease duration 11.3 (10.0)/8.7 (9.0)/10.6 (11.2) years, %females 76.1/55.1/44.1%, respectively. Golimumab drug

Diagnosis	Composite score	Changes (baseline minus 3 months)			
		Unadjusted analyses		Adjusted analyses	
		Mean (SD)	p-value	Estimated marginal means (95% CI)	p-value
	bDMARD naïve patients	Previous bDMARD users	bDMARD naïve patients	Previous bDMARD users	
RA	Δ DAS28	-1.1 (1.3)	0.39	-1.7 (-2.6,-0.7)	0.08
	Δ CDAI	-9.0 (10.8)	0.99	-11.7 (-14.5,-8.9)	0.10
PsA	Δ DAS28	-1.2 (1.1)	<0.001	-1.0 (-1.3,-0.8)	0.01
	Δ CDAI	-7.1 (7.8)	0.005	-6.2 (-7.6,-4.8)	0.18
	Δ BASDAI	-1.4 (2.1)	0.08	-1.2 (-1.6,-0.8)	0.38
Ax-SpA	Δ BASDAI	-1.9 (2.4)	<0.001	-1.9 (-2.3,-1.6)	<0.001
	Δ ASDAS	-1.2 (1.3)	<0.001	-1.1 (-1.3,-0.9)	<0.001

Identified predictors for golimumab discontinuation were [Hazard Ratio (95% CI)]: RA, None; PsA, female gender [1.63 (1.18–2.25), p=0.003] and no concomitant sDMARDs [1.39 (1.01–1.90), p=0.04]; ax-SpA, female gender [1.97 (1.50–2.60), p<0.001].

survival for bDMARD naïve vs. non-naïve patients was similar for all diagnoses (RA,  $p=0.15$ ; PsA,  $p=0.23$ ; ax-SpA  $p=0.71$ ), with trend towards better drug survival in bDMARD naïve RA and PsA patients (figure). 4 year drug survival in bDMARD naïve/non-naïve patients were: RA, 54/48%; PsA, 47/43%; ax-SpA, 48/46%, respectively. Subgroup analyses of patients with and without concomitant sDMARDs showed similar findings. A trend was seen towards better 3 month responses in bDMARD naïve vs. non-naïve patients, with statistically significant better responses for DAS28 in PsA and BASDAI and ASDAS in ax-SpA (table 1).

**Conclusions:** Golimumab drug survival was similar in bDMARD naïve vs. non-naïve RA, PsA and ax-SpA patients. A trend was seen towards better responses for bDMARD naïve patients. Identified predictors for golimumab drug discontinuation was female gender and no concomitant sDMARDs in PsA and female gender in ax-SpA.

#### SAT0265 THE RESPONSE TO TNF-BLOCKERS TREATMENT OF SPA PATIENTS IS INFLUENCED BY THE INTERPLAY BETWEEN HLA-B27 AND GUT MICROBIOTA COMPOSITION AT BASELINE

M. Vallier<sup>1</sup>, M. Chamailard<sup>1</sup>, S. Ferreira<sup>2</sup>, S. Menegatti<sup>3</sup>, E. Bianchi<sup>3</sup>, L. Rogge<sup>3</sup>, M. Dougados<sup>4,5</sup>, C. Miceli-Richard<sup>3,4</sup>. <sup>1</sup>NLR/II, Institut Pasteur; <sup>2</sup>Genoscreen, Lille; <sup>3</sup>Immunoregulation Unit 25, Institut Pasteur; <sup>4</sup>Service de Rhumatologie, Hôpital Cochin; <sup>5</sup>Inserm U1153, Clinical Epidemiology and Biostatistics, PRES Sorbonne Paris-Cité, Paris, France

**Background:** The response to TNF-blockers in axial spondyloarthritis (AxSpA) is at least partially influenced by HLA-B27 through a still poorly understood mechanism.

**Objectives:** Given that HLA-B27 regulates the gut microbiota composition in rats<sup>1,2</sup>, we seek to evaluate the predictive value of the gut microbiota composition in AxSpA patients on their responsiveness to TNF-blockers.

**Methods:** A total of 58 patients was monocentrically recruited between October 2014 and May 2015. At baseline, these patients had an active disease despite NSAIDs intake and were eligible for treatment with a TNF-blocker, while having no history of inflammatory bowel disease (IBD). The mean BASDAI ( $\pm$ SD) was  $45.6 \pm 21.4$ ; ASDAS  $2.8 \pm 0.9$  and CRP  $9.7 \pm 11.4$  mg/L. Among these patients, 56 fulfilled the ASAS classification criteria (imaging arm) with sacro-iliitis on X-rays ( $n=37$ ) or objective signs of inflammation on MRI ( $n=48$ ). Two patients fulfilled the clinical arm. These patients were not subjected to antibiotics within 3 months before stool sample collection. Bacterial 16S rRNA gene sequencing of the V3-V4 region was performed on stools samples before and 3 months after TNF-blocker

treatment. Beta diversity metrics were calculated on the abundance of operational taxonomic units (OTU) after their taxonomic assignment on quality-filtered sequences.

**Results:** Principal component analysis (PCA) ordination of Bray-Curtis similarity revealed that current smoking (compared with never or ever smokers) and HLA-B27 genotype were significantly associated with the overall composition of the microbiota at baseline. Meanwhile, the abundance of eleven bacterial OTUs was influenced by HLA-B27 genotype at baseline but not after 3 month of treatment. In contrast, we identified a bacterial signature that was linked to the smoking behaviour independently of TNF-blocker treatment, whereas the BASDAI and ASDAS indices were significantly associated to the general composition of the gut microbiota after the 3 month treatment. In line with a previous report<sup>3</sup>, the abundance of *Ruminococcus gnavus* was not associated with disease activity in the absence of IBD. Interestingly, the abundance of 5 and 7 bacterial OTUs at baseline was associated with the response to TNF-blockers assessed by BASDAI and ASDAS, respectively. Among these candidates, the abundance of one bacterial OTUs belonging to the *Clostridiales* order was associated with a better response to the treatment and with the HLA-B27 genotype.

**Conclusions:** Anti-TNF treatment was found to modulate the HLA-B27-induced variations of the intestinal microbiota of AxSpA patients. Moreover, the abundance of a subset of OTUs at baseline was found to predict the responsiveness to TNF-blockers. Further functional studies will be conducted to assess how these taxa can be used as predictors of the treatment outcome.

#### SAT0266 USE OF CONVENTIONAL SYNTHETIC DMARDS AND BIOLOGICAL DMARDS IN PATIENTS WITH ENTEROPATHIC SPONDYLOARTHRITIS: A COMBINED GASTRO-RHEUMATOLOGICAL APPROACH

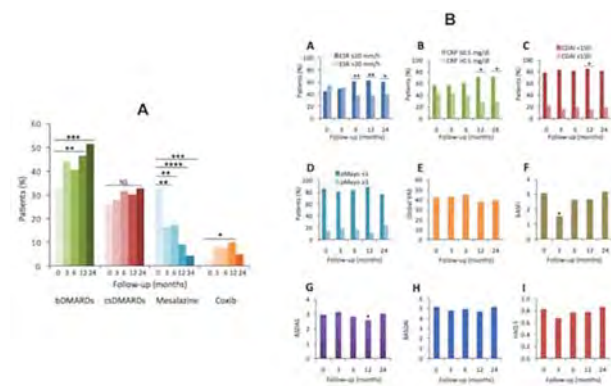

M.S. Chimenti<sup>1</sup>, P. Conigliaro<sup>1</sup>, P. Triggianese<sup>1</sup>, C. Canofari<sup>1</sup>, F. Cedola<sup>1</sup>, S. Onali<sup>1</sup>, E. Calabrese<sup>1</sup>, C. Petruzzello<sup>1</sup>, A. Ruffa<sup>1</sup>, G. Monteleone<sup>2</sup>, L. Biancone<sup>2</sup>, R. Perricone<sup>1</sup>. <sup>1</sup>Department of system medicine, Rheumatology, Allergology and Clinical Immunology; <sup>2</sup>Department of systems medicine, Unit of Gastroenterology, University of Rome Tor Vergata, Roma, Italy

**Background:** Enteropathic spondyloarthritis (eSpA) is a chronic autoimmune disease associated with inflammatory bowel disease (IBD) that is poorly diagnosed and managed.

**Objectives:** To assess the diagnostic and therapeutic effect of a combined gastro-rheumatological approach in eSpA patients.

**Methods:** IBD-patients with joint pain referred to a dedicated rheumatologist by gastroenterologist were enrolled. Clinical and biochemical variables, SpA and intestinal disease activity measures, and treatment (biologic; bDMARDs and conventional synthetic; csDMARDs) were recorded at baseline, 3, 6, 12 and 24 months. The association between treatment on demographic and clinical characteristics was evaluated by logistic regression.

**Results:** From a total of 229 IBD patients, 147 (64.2%) were diagnosed with eSpA; 96 (65.3%) showing peripheral involvement and 51 (34.7%) with axial involvement. The majority (67.3%) of eSpA patients were female ( $n=99$ ), median age and disease duration of 46 and 14.6 years. bDMARD treatment increased over the follow-up period (baseline-24 months: 32.6% $\rightarrow$ 60%; AOR:3.45, 95% CI: 1.93–6.2,  $p<0.001$ ), however, their use was less frequent in elderly patients (AOR: 0.73, 95% CI: 0.56–0.96,  $p=0.023$ ), in ulcerative colitis patients (AOR:0.43, 95% CI:0.2–0.94,  $p=0.034$ ) and in patients with peripheral involvement (AOR:0.53, 95% CI:0.3–1.04,  $p=0.067$ ). csDMARD use was increased in patients with peripheral involvement (AOR: 4.65, 95% CI:2.09–10.33,  $p<0.001$ ) and in patient with ulcerative colitis (AOR:2.30, 95% CI:1.13–4.67,  $p=0.021$ ) (figure 1). CRP, ESR, ASDAS-ESR levels and BASFI were significantly decreased over the follow-up period whereas pMayo score, BASDAI and HAQ-S were unchanged (figure 2).

**Conclusions:** A multidisciplinary approach can improve in the therapeutic management and outcome (e.g. disease activity measures) of eSpA patients. bDMARD use paralleled an improvement in disease measures and confirmed a good safety profile.

**SAT0267 EFFICACY AND SAFETY OF BCD-055, PROPOSED INFLIXIMAB BIOSIMILAR, COMPARED TO INFLIXIMAB: 54-WEEK RESULTS FROM ASART-2 PHASE 3 CLINICAL STUDY**

L. Denisov<sup>1</sup>, P. Shesternya<sup>2</sup>, T. Plaksina<sup>3</sup>, T. Kropotina<sup>4</sup>, N. Soroka<sup>5</sup>, E. Kunder<sup>5</sup>, A. Lutskii<sup>6</sup>, A. Ereemeva<sup>6</sup>, E. Dokukina<sup>6</sup>, E. Chernyaeva<sup>6</sup>, R. Ivanov<sup>6</sup>, V. Mazurov<sup>7</sup>. <sup>1</sup>V.A.Nasonova Research Institute of Rheumatology, Moscow; <sup>2</sup>Professor V.F. Voyno-Yasenetskiy Krasnoyarsk State Medical University, Krasnoyarsk; <sup>3</sup>Regional Clinical Hospital, Nizhniy Novgorod; <sup>4</sup>Regional Clinical Hospital, Omsk, Russian Federation; <sup>5</sup>Clinical Hospital №9, Minsk, Belarus; <sup>6</sup>JCS BIOCAD, Saint-Petersburg; <sup>7</sup>North-Western State Medical University named after I.I. Mechnikov, Moscow, Russian Federation

**Background:** Non-inferiority of BCD-055 in direct comparison to infliximab originator after 30 weeks of treatment in patients with ankylosing spondylitis (AS) was shown previously<sup>1</sup>. Here we present 54 week safety and efficacy data in ITT population from international double-blind randomised ASART-2 clinical trial.

**Objectives:** To compare BCD-055, proposed infliximab biosimilar and infliximab originator in terms of efficacy and safety in patients with AS.

**Methods:** Adult patients (n=199) aged 18–65 years, with active AS (BASDAI>4) received 5 mg/kg of BCD-055 (n=132) or infliximab (n=67) IV on w0, w2 and w6 and then every 8 w until w54. The results of the primary endpoint assessment (ASAS20 at w30) were presented earlier<sup>1</sup>. Secondary endpoints were proportion of patients, achieved ASAS20/40, and mean change from baseline in BASDAI, BASMI, BASFI, MASES, SF36 scores, chest excursion and TJC<sup>44</sup> at w54. Rate of AEs and proportion of patient with ADA to infliximab in both groups were also evaluated.

**Results:** The proportions of patients achieved ASAS20/ASAS40 were similar in both study groups at w54 (Abstract SAT0267 – figure 1). Improvement in AS symptoms showed similar dynamics in both groups: significant decrease in AS activity (BASDAI) and improvement in other secondary endpoints has developed within the first 14 weeks of treatment in both study groups and remained at achieved level until w54. The magnitude of changes of all evaluated parameters did not differ between groups.

No statistically significant differences in rates of AEs were found between study groups (table 1). Most common reported AEs were infections, hematologic and vascular disorders, hypersensitivity reactions. Formation of ADA to infliximab was detected with similar frequency in both groups.

**Abstract SAT0267 – Table 1.** 54 w safety data

	BCD-055, n (%)	Infliximab, n (%)	p value
Any AE/SAE	82 (62.12)	43 (64.18)	0.898
Any SAE	7 (5.30)	5 (7.46)	0.376
Therapy-related AE/SAE	40 (30.30)	26 (38.81)	0.296
Therapy-related SAE	5 (3.79)	4 (5.97)	0.489
Any SAE/AE grade 3–5	18 (13.64)	11 (16.42)	0.754
Therapy-related AE grade 3–5	11 (8.33)	7 (10.45)	0.818
Treatment withdrawal due to SAE/AE	11 (8.33)	7 (10.45)	0.818
Deaths	1 (0.76)	0 (0)	1.000
ADA positive	27 (21.26)	13 (20.63)	0.920
ADA positive, confirmed by neutralisation assay	4 (3.15)	4 (6.35)	0.443

**Abstract SAT0267 – Figure 1.** Proportion of patients achieved ASAS20 at weeks 14, 30 and 54 (%; 95%CI).

**Conclusions:** The 54 week results supports previously confirmed similar efficacy and safety of BCD-055, proposed infliximab biosimilar, and infliximab originator in patients with active AS. At all evaluated time points the efficacy as well as rate of AEs/SAEs did not differ between BCD-055 and infliximab originator groups.

**SAT0268 SECUKINUMAB DEMONSTRATES LOW RADIOGRAPHIC PROGRESSION AND SUSTAINED EFFICACY THROUGH 4 YEARS IN PATIENTS WITH ACTIVE ANKYLOSING SPONDYLITIS**

X. Baraliakos<sup>1,2</sup>, J. Braun<sup>1,2</sup>, A. Deodhar<sup>3</sup>, D. Poddubny<sup>4</sup>, P. Emery<sup>5</sup>, E. M. Delicha<sup>6</sup>, Z. Talloczy<sup>7</sup>, B. Porter<sup>8</sup>. <sup>1</sup>Rheumazentrum Ruhrgebiet, Herne; <sup>2</sup>Ruhr University, Bochum, Germany; <sup>3</sup>Oregon Health and Science University, Portland, USA; <sup>4</sup>Charité Universitätsmedizin Berlin, Berlin, Germany; <sup>5</sup>University of Leeds, Leeds, UK; <sup>6</sup>Novartis Pharma AG, Basel, Switzerland; <sup>7</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA; <sup>8</sup>Novartis Pharmaceuticals Corporation, East Hanover, Switzerland

**Background:** The MEASURE 1 core trial reported improved signs and symptoms of ankylosing spondylitis (AS) with secukinumab, a fully human anti-interleukin-17A monoclonal antibody.<sup>1</sup>

**Objectives:** To assess efficacy, including imaging outcomes, and safety from the MEASURE 1 extension trial (NCT01863732) up to 4 years.

**Methods:** Patients (pts) had completed 104 wks (2 years) in the core study with SC secukinumab 150 (IV→150 mg) or 75 mg (IV→75 mg) every 4 wks, following IV loading to Wk4, or placebo to Wk16/24. Efficacy data at Wk208 are reported for pts originally randomised to secukinumab 150 mg (approved dose). Lateral cervical and lumbar spine radiographs were assessed with the modified Stoke Ankylosing Spondylitis Spinal Score (mSASSS), and MRIs with the Berlin SI joint total oedema score and Berlin spine score (derived from ASspi-MRI-a results). Images were evaluated by 2 central readers blinded to treatment/visit; mean scores were used. Descriptive statistics on observed/imputed data are provided.

**Results:** Of the 274 pts enrolled in this extension study, 89.7% (78/87) originally assigned to secukinumab 150 mg completed 208 wks. Δ mSASSS (mean ±SD) from baseline (BL) to Wk208 was numerically lower with secukinumab 150 mg (1.2±3.91) vs 75 mg (1.7±4.70). No definite radiographic progression (Δ mSASSS from BL <2) was seen in 79% of pts on secukinumab 150 mg over 208 wks (figure 1). Mean Δ mSASSS at Wk208 was numerically higher in males, and in pts with

BL syndesmophytes or elevated BL hsCRP. Reductions from BL in the Berlin SI joint oedema and Berlin spine scores were seen with secukinumab 150 mg. Sustained efficacy in signs/symptoms was seen through 208 wks (Table). Exposure-adjusted incidence rates per 100 pt-yrs (total exposure [mean  $\pm$ SD]=3.4  $\pm$ 1.44 years) were: serious infections (1.0), IBD (0.7), uveitis (1.8) and malignant/unspecified tumours (0.5).

Abstract SAT0268 – Table 1. Efficacy at Wk208

	Secukinumab IV $\rightarrow$ 150 mg (n=87)
<b>mSASSS<sup>a,b</sup></b>	
BL (n=71 with X-rays at BL and Wk208)	8.8 $\pm$ 16.23
$\Delta$ BL to Wk208	1.2 $\pm$ 3.91
$\Delta$ BL to Wk104/ $\Delta$ Wk104 to 208 <sup>d</sup>	0.5 $\pm$ 1.69/0.8 $\pm$ 3.34
<b>MRI<sup>a,b</sup></b>	
Berlin SI joint total oedema score, $\Delta$ BL to Wk104/ $\Delta$ BL to Wk208	-2.3 $\pm$ 3.06 <sup>18</sup> / $-1.6\pm 3.03$ <sup>22</sup>
Berlin spine score, $\Delta$ BL to Wk104/ $\Delta$ BL to Wk208	-0.9 $\pm$ 2.17 <sup>18</sup> / $-0.6\pm 2.01$ <sup>22</sup>
<b>Clinical efficacy</b>	
ASAS20/40 <sup>e</sup>	76.4/58.0
BASDAI, <sup>f</sup> $\Delta$ from BL	-3.3 $\pm$ 0.23
ASDAS inactive disease <sup>g</sup>	27.6
BASFI/BASMI, <sup>h</sup> $\Delta$ from BL	-2.9 $\pm$ 2.39 (80)/-0.5 $\pm$ 1.12 (76)

n, no. of pts assessed; N, total no. of pts in extension trial

<sup>a</sup>Radiographs/MRIs taken at BL and Wk104 were re-read for pts completing Wk208 of treatment; <sup>b</sup>Mean $\pm$ SD (n) for observed data; <sup>c</sup>Based on n=67 pts with X-rays at BL, Wk104 and Wk208 and BL mSASSS of 8.01 $\pm$ 15.29 and 9.01 $\pm$ 16.77, calculated from matched vertebral edges at BL and Wk104, and BL and Wk208, respectively; <sup>d</sup>% pts estimated using multiple imputation; <sup>e</sup>Least-squares mean $\pm$ standard error for MMRM estimates

**Conclusions:** Secukinumab 150 mg showed numerically lower radiographic progression vs 75 mg at 4 years. Secukinumab also demonstrated sustained efficacy on signs and symptoms, and MRI outcomes and a consistent safety profile.<sup>1</sup>

SAT0269

### THE EFFECT OF BIOLOGIC DISEASE-MODIFYING ANTIRHEUMATIC DRUGS IN TARGETING DISEASE REMISSION IN AXIAL SPONDYLOARTHRITIS (AXSPA): A SYSTEMATIC LITERATURE REVIEW

A.R. Cruz-Machado<sup>1,2</sup>, S.R. Manica<sup>3,4</sup>, J.L. Silva<sup>5</sup>, F.M. Pimentel-Santos<sup>3,4</sup>, J. Tavares-Costa<sup>5</sup>, E. Vieira-Sousa<sup>1,2</sup>. <sup>1</sup>Rheumatology and Metabolic Bone Diseases Department, Hospital de Santa Maria, CHLN, Lisbon Academic Medical Centre; <sup>2</sup>Rheumatology Research Unit, Instituto de Medicina Molecular, Faculty of Medicine, University of Lisbon; <sup>3</sup>Rheumatology Department, Hospital Egas Moniz, Centro Hospitalar de Lisboa Ocidental; <sup>4</sup>CEDOC, NOVA Medical School, Lisbon; <sup>5</sup>Rheumatology Department, Unidade Local de Saúde do Alto Minho, Ponte de Lima, Portugal

**Background:** The treat-to-target concept is currently recommended in axSpA management and remission is the main objective of treatment. Although consensual definitions of remission are lacking, most authors assume remission as a state of inactive disease or, alternatively, of low disease activity, as a near concept. In current practice, ASAS-Partial Remission (ASAS-PR) and ASDAS-Inactive Disease (ASDAS-ID) scores have gained wide acceptance as clinical remission-like definitions.

**Objectives:** In this review we assessed the efficacy of different biologic disease-modifying anti-rheumatic drugs (bDMARD) in achieving ASAS-PR or/and ASDAS-ID as remission-like primary outcomes. Data from randomised controlled trials (RCT) conducted in radiographic axSpA (r-axSpA) and non-radiographic axSpA (nr-axSpA) patients were included.

**Methods:** A systematic literature review was performed using the MEDLINE database (August 17 2017) with the filters “published in the last 10 years” and “humans”. The PICO (P, population; I, intervention; C, comparison; O, outcome) concept was used to perform the analysis according to: Patients – adults (>18 years old) with r-axSpA or nr-axSpA; Intervention – any bDMARD regardless of formulation or duration; Comparison – placebo and/or any different drug; Outcomes: ASAS-PR and ASDAS-ID.

**Results:** After screening 557 references (after de-duplication), 7 RCTs fulfilled the inclusion criteria, all concerning tumour necrosis factor inhibitors (TNFi) bDMARDs – table 1. ASAS-PR was the most commonly used remission-like definition in 6 of the 7 trials, 1 of those as a composed measure with a magnetic resonance score. Despite different baseline populations (including r-axSpA and nr-axSpA), all these trials provide evidence of TNFi efficacy in achieving remission. The proportion of patients achieving ASAS-PR and ASDAS-ID varied between 33%–61.9% and 27.3%–55%, respectively, with a minimum and maximum follow-up periods of 28 to 254 weeks for ASAS-PR and 24 weeks to 5 years for ASDAS-ID.

Abstract SAT0269 – Table 1. bDMARD trials addressing ASAS-PR or ASDAS-ID as primary outcomes

Reference	Phenotype	Study design and duration	Drug (number of patients enrolled)	Primary Outcome	Results
Braun, 2008	r-axSpA	Extension 254 weeks	IFX/IFX vs PBO/IFX (38)	ASAS-PR	34.2% of patients achieved ASAS-PR
Sieper, 2012	r-axSpA and nr-axSpA	RCT 28 weeks	NPX + PBO (51) vs NPX + IFX (105)	ASAS-PR	ASAS-PR in 61.9% NPX+IFX vs 35.3% NPX+PBO (p<0.05)
Sieper, 2013	r-axSpA and nr-axSpA	Extension 52 weeks	NPX (40) vs no treatment (40) after partial remission under IFX+NPX or NPX+PBO	ASAS-PR	No statistically significant differences between the groups
Davis, 2008	r-axSpA	Extension 192 weeks	ETN/ETN (128) vs PBO/ETN (129)	ASAS-PR	44% of patients achieved ASAS-PR
Song, 2012	nr-axSpA	RCT (first part) 48 weeks	ETN (40) vs SSZ (36)	ASAS-PR plus MRI remission	ASAS-PR+MRI remission in 33% ETN vs 11% SSZ (p<0.05)
Sieper, 2011	r-axSpA	RCT and Extension 5 years	ADA/ADA vs PBO/ADA (311)	ASAS-PR and ASDAS-ID	ASAS-PR in 45% ASDAS-ID in 55%
van Heijde, 2014	r-axSpA	RCT (first part) 24 weeks	GOL (278) vs PBO (78)	ASDAS-ID	ASDAS-ID in 27.3% GOL vs 2.8% PBO (p<0.001)

Legend : ADA: adalimumab; ASAS-PR: ASAS-Partial Remission; ASDAS-ID: ASDAS Inactive Disease; ETN: etanercept; GOL: golimumab; IFX: infliximab; MRI: magnetic resonance image; NPX: naproxen; nr-axSpA: non-radiographic axial spondyloarthritis; PBO: placebo; r-axSpA: radiographic spondyloarthritis; RCT: randomised controlled trial; SSZ: sulfasalazine, vs – versus

**Conclusions:** Clinical trials addressing remission-like concepts as primary outcomes are scarce. ASAS-PR score was the most commonly used remission outcome. Depending on the studies, between one third to one half of patients treated with TNFi achieved ASAS-PR or ASDAS-ID. Considering nowadays aimed treatment targets, these data raise the unmet need for improved treatment options and strategies, that favour optimised remissions rates in axSpA patients.

SAT0270

**LOW INCIDENCE OF BOTH NEW-ONSET AND FLARES OF UVEITIS IN SECUKINUMAB-TREATED PATIENTS WITH ANKYLOSING SPONDYLITIS: CLINICAL TRIAL AND POST-MARKETING SAFETY ANALYSIS**

A. Deodhar<sup>1</sup>, C. Miceli-Richard<sup>2</sup>, X. Baraliakos<sup>3</sup>, H. Marzo-Ortega<sup>4</sup>, D. D. Gladman<sup>5</sup>, R. Martin<sup>6</sup>, J. Safi Jr<sup>6</sup>, B. Porter<sup>6</sup>, A. Shete<sup>7</sup>. <sup>1</sup>Oregon Health and Science University, Portland, USA; <sup>2</sup>Hôpital Cochin, Paris, France; <sup>3</sup>Rheumazentrum Ruhrgebiet, Herne, Germany; <sup>4</sup>IHR LBRC, LTHT and LIRMM, University of Leeds, Leeds, UK; <sup>5</sup>Toronto Western Hospital, Toronto, Canada; <sup>6</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA; <sup>7</sup>Novartis Pharma AG, Basel, Switzerland

**Background:** Uveitis, a common extra-articular manifestation of SpA, has an estimated prevalence in patients (pts) with ankylosing spondylitis (AS) of 33.2%, which increases with disease duration and positive HLA-B27 status.<sup>1</sup> Uveitis occurs in 10%–50% of SpA pts.<sup>1</sup> The exposure-adjusted incidence rate [EAIR] of uveitis (combined new-onset and flares) reported in AS pts treated with TNF inhibitors is 2.6–3.5 per 100 patient-years (pt-yrs).<sup>2–5</sup>

**Objectives:** To assess the incidence of uveitis in secukinumab-treated AS pts in long-term pooled clinical data from three phase 3 trials (MEASURE 1–3 [NCT01358175, NCT01649375, NCT02008916]) and from post-marketing analyses.

**Methods:** Analysis included pooled pt-level data from all pts in MEASURE 1 who received any dose ( $\geq 1$ ) of secukinumab up to the last pt attending Week 156 study visit, and up to visit Week 156 in MEASURE 2 and visit Week 104 in MEASURE 3 for each patient, respectively. Post-marketing data were from the most recent periodic safety surveillance report. Incidence of uveitis is reported as EAIR per 100 pt-yrs of secukinumab exposure.

**Results:** In the phase 3 AS clinical trials, 135 (17%) pts reported pre-existing (but not active or ongoing) uveitis at baseline and 589 (74.2%) pts were HLA-B27 positive. The EAIR for uveitis was 1.4 per 100 pt-yrs over the entire treatment period (n=794). Among all cases of uveitis (n=26), 14 (54%) were flares in pts with a history of uveitis at baseline (Table). The EAIR of uveitis in the post-marketing data (based on cumulative secukinumab exposure of 96 054 pt-yrs) was 0.03 per 100 pt-yrs.

**Abstract SAT0270 – Table 1.** Safety Analysis for Uveitis with Secukinumab in AS

**Data from Clinical Studies**

Number of clinical studies/pts included	3/794
Uveitis cases reported, n (%)	
Total	26 (3.3%)
New onset cases	14 (1.8%)
Treatment discontinuation	2 (0.3%)
Treatment interruption	1 (0.1%)
EAIR (95% confidence interval) per 100 pt-yrs <sup>a</sup>	1.4 (0.9–2.0)
<b>Post-Marketing Data<sup>b</sup></b>	
Cumulative estimated market experience (pt-treatment yrs) <sup>c</sup>	96 054
Cumulative number of cases reported	29
Crude incidence rate per 100 pt-yrs	0.03

<sup>a</sup>Rates are for uveitis MedDRA preferred term

<sup>b</sup>Data from the periodic safety update report (PSUR) dated 10th August 2017 – includes all indications

<sup>c</sup>Estimated based on cumulative worldwide sales volume and the average maintenance dose

**Conclusions:**

In secukinumab-treated pts with active AS, a low incidence of uveitis was observed, including new-onset cases and flares, in both clinical trials and post-marketing analyses.

**Background:** Secukinumab (SEC), a fully human monoclonal antibody (mAb) that selectively targets IL-17A, is highly efficacious for the treatment of psoriatic arthritis (PsA) and ankylosing spondylitis (AS). mAb therapies may be associated with immunogenicity (IG) and production of anti-drug antibodies (ADAs) that may cause adverse events (AEs), and affect drug pharmacokinetics (PK) and clinical response.

**Abstract SAT0271 – Table 1.** Overview of pts with TE-ADA<sup>1</sup>

	F2314	PBO-300 mg	0	W52 (1.02)/N	N	None	Normal
	F2320	150 mg	0	W16 (6.35)/N	N	None	Normal
		150 mg	0	W52/ (2.96)/N	N	None	Normal
		No Load	0	W16 (2.70)/N	N	None	Normal
		150 mg	0	W24/ (2.80)/N	N	None	Normal
		PBO–150 mg	0	W52/ (2.89)/N	N	None	Normal

Neut-Ab=neutralising antibodies; PBO, placebo; Y, yes; N, No. <sup>1</sup>Only positive ADA results at the respective study week are shown; <sup>2</sup>Impact on efficacy is defined as: PsA, failure to achieve >20% reduction, compared to baseline, in both tender and swollen joint counts; AS, failure to achieve ASAS20, after previously achieving such improvement for at least 2 consecutive visits prior to the first detection of ADA; <sup>3</sup>Normal PK: Concentrations in ADA-positive pts within observed range for all pts without ADA

**Objectives:** To assess the IG of SEC in PsA and AS patients (pts) treated with SEC for up to 52 weeks (W).

**Methods:** IG in pts with PsA (FUTURE 1–3 studies, n=1414) and AS (MEASURE 1–4 studies, n=1163) exposed to SEC was evaluated at baseline (BL) and at W 12, 16 (AS only), 24 and 52. Treatment emergent (TE)-ADA were defined as a positive ADA signal in  $\geq 1$  post-treatment sample in pts negative at BL. TE-ADA positive samples were analysed for drug-neutralising potential, SEC impact on PK, IG-related AEs and TE-ADA impact on efficacy through W52.

**Results:** Of 1414 treated PsA and 1163 treated AS pts with samples for IG evaluation, 5 (0.35%) and 8 (0.68%) developed TE-ADAs respectively, over 52 weeks (Table). All but 1 PsA pt were biologic naïve; 2/5 PsA and 1/8 AS pts received concomitant methotrexate, 2/8 AS pts received concomitant sulfasalazine. Associations between TE-ADAs and SEC dose, frequency or mode of administration were not observed. Other than 1 PsA pt, all TE-ADAs were non-neutralising and none were associated with any IG-related AE. All TE-ADAs were associated with normal PK and none were associated with loss of SEC efficacy over 52 weeks.

**Conclusions:** SEC treatment was associated with a low incidence of IG in PsA and AS pts, as shown by TE-ADA detection in only 0.35% PsA pts and 0.68% AS pts over 52 weeks in a database of >2500 pts, which is consistent with the low incidence of IG (0.4%) seen with SEC in pts with plaque psoriasis.<sup>1</sup>

SAT0272

#### DO TNF INHIBITORS IMPACT THE COMORBIDITIES AND EXTRA-ARTICULAR MANIFESTATIONS, AND THEREBY ALTER THE NATURAL HISTORY OF ANKYLOSING SPONDYLITIS?

A. Deodhar<sup>1</sup>, K.L. Winthrop<sup>1</sup>, R.L. Bohn<sup>2</sup>, B.K. Chan<sup>1</sup>, R.Y. Suruki<sup>2</sup>, J.L. Stark<sup>3</sup>, H. Yun<sup>4</sup>, S.A.R. Siegel<sup>1</sup>, L. Chen<sup>4</sup>, M. Yassine<sup>3</sup>, J.R. Curtis<sup>4</sup>. <sup>1</sup>Oregon Health and Science University, Portland, OR; <sup>2</sup>UCB Pharma, Raleigh, NC; <sup>3</sup>UCB Pharma, Smyrna, GA; <sup>4</sup>University of Alabama at Birmingham, Birmingham, AL, USA

**Background:** Anti-tumour necrosis factor (anti-TNF) treatment has led to reduction in signs and symptoms, and improvements in physical function and quality of life in ankylosing spondylitis (AS) patients (pts). Whether anti-TNFs impact the incidence of AS-related comorbidities and extra-articular manifestations (EAMs) is not known.

**Objectives:** To evaluate the incidence and prevalence of AS-related comorbidities and EAMs in AS pts in the US.

**Methods:** This was a retrospective cohort study of 3 commercial insurance claims databases (Multi-Payer Claims Database [MPCD 2007–2010], Truven MarketScan [2010–2014], and US Medicare Fee-for-Service Claims [2006–2014]) to evaluate EAMs (uveitis, psoriasis, inflammatory bowel disease) and physician-diagnosed comorbidities (cardiac, renal, pulmonary, neurologic) in AS pts diagnosed by a rheumatologist (index date), having 6 months' baseline data prior to the index date, and drug-specific exposures after AS diagnosis (ICD-9 720.0). Three mutually exclusive hierarchical exposure groups were examined (low to high):<sup>1</sup> no therapy or prescription NSAIDs;<sup>2</sup> conventional DMARDs;<sup>3</sup> anti-

TNFs. Prevalence of comorbidities was ascertained in a 12 month period (6 months pre- and post-index date). Incidence of comorbidities and EAMs was assessed during the period between treatment initiation and the earliest of death, loss of medical coverage, end of study, first outcome occurrence, treatment discontinuation or initiation of therapy at a higher level in exposure hierarchy. Pts with a history of prior events (except infections) were excluded from the incidence assessment for that event. Hazard ratios comparing anti-TNFs vs DMARDs and NSAIDs/no therapy were estimated using inverse probability treatment weighted Cox proportional hazards models.

**Results:** A total of 37,566 AS pts were included. Prevalence of AS in the MPCD population was 0.26% and in the Medicare population was 1.21%. As expected, comorbidities were more common in Medicare AS pts vs those in MPCD or MarketScan databases in all exposure groups. The propensity score-weighted incidences of solid cancers, myocardial infarction, conduction block, cord compression and vertebral fractures were lower in anti-TNF treated pts vs those treated with NSAIDs or DMARDs alone, although anti-TNF treated Medicare pts had a higher incidence of EAMs such as psoriatic arthritis, uveitis and ulcerative colitis (figure 1).

Abstract SAT0272 – Figure 1. Propensity score-weighted hazard ratios of physician-diagnosed outcomes and EAMs by treatment exposures

**Conclusions:** This investigation of the prevalence and incidence of comorbidities and EAMs of AS in US pts suggests that anti-TNF use is associated with a lower incidence of some comorbidities, and a trend of higher incidence of EAMs, which may reflect channelling of more severe AS pts to anti-TNFs. Although results vary somewhat by data source and may be explained by different baseline characteristics (e.g. Medicare pts were older), our results suggest that anti-TNF use is associated with lower incidence of those comorbidities that confer substantial morbidity in AS.

### GOLIMUMAB RETENTION RATE IN PATIENTS WITH SPONDYLOARTHRITIS. DIFFERENCES BETWEEN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS

B. Serrano-Benavente<sup>1,2</sup>, C.M. González Fernández<sup>1,2</sup>, L. Valor<sup>1</sup>, J.C. Nieto-González<sup>1</sup>, R.D. González-Benítez<sup>1</sup>, I. Janta<sup>1</sup>, C. Sáenz Tenorio<sup>1</sup>, J.G. Ovalles-Bonilla<sup>1</sup>, J. Martínez-Barrio<sup>1</sup>, M. Correyero Plaza<sup>1</sup>, L. García-Montoya<sup>1</sup>, F.J. López-Longo<sup>1,2</sup>, I. Monteagudo Saez<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital General Universitario Gregorio Marañón; <sup>2</sup>Faculty of Medicine, Universidad Complutense de Madrid, Madrid, Spain

**Background:** The efficacy of Golimumab treatment in spondyloarthritis (SpA) has been widely documented.

**Objectives:** The aim of this study was to analyze the long-term retention rate of Golimumab and to identify independent predictors of retention in patients with SpA.

**Methods:** Prospective monocentric cohort of SpA patients treated with Golimumab according with clinical practice. Study was approved by local Ethics Committee. Demographic and clinical variables were analysed with Cox proportional hazard regression model.

**Results:** 105 patients were included, 49 (46.7%) Ankylosing Spondylitis (AS), 40 (38.1%) non-radiographic axial SpA (nr-AxSpA) and 16 (15.2%) peripheral SpA. The baseline characteristics of the patients are shown in table 1. Follow-up time was 206.6 patients-year. Mean survival time was 47.2 months (95% CI: 39.4–54.9). Age, gender, HLA-B27, radiographic or nr-AxSpA and previous biological use were significant in the univariate analysis. Concomitant DMARD had no influence on Golimumab retention rate (HR: 1.2; 95% CI: 0.6–2.4; p: 0.6).

**Abstract SAT0273 – Table 1.** Baseline demographic and clinical characteristics of the patients.

	All (axial and peripheral SpA)	AS	nr-AxSpA
Age -mean (SD)-years	45.1 (13.2)	51.1 (10.8)	39,8 (10.1)
Male gender (%)	52 (49.5%)	30 (61.2%)	19 (47.5%)
Mean evolution time (SD)- years	11.8 (12.3)	18.8 (10.1)	7.3 (10.3)
Positive HLA-B27 (%)	73 (69.6%)	44 (90.7%)	21 (52.6%)
Uveitis (%)	17 (16.2%)	12 (24.5%)	4 (10.0%)
Back pain -mean (SD)	7.5 (7.0)	6.5 (2.4)	9.1 (10.7)
BASDAI -mean (SD)	6.2 (1.6)	6.3 (2.1)	6.2 (1.2)
BASFI -mean (SD)	5.8 (2.3)	6.0 (2.4)	5.4 (2.1)
CRP mg/dl – mean (SD)	1.1 (1.7)	1.5 (2.1)	0.65 (1.4)
Concomitant DMARD (%)	31 (29.8%)	15 (31.3%)	3 (7.5%)
Biological Therapy naive (%)	48 (45.7%)	15 (30.6%)	24 (60%)

Golimumab retention rate of patients with nr-AxSpA and objective inflammation (positive MRI or CRP) was not different compared to AS patients (p=0.19). Patients with nr-AxSpA without objective inflammation (negative MRI and CRP) had worse retention rate compared to AS patients (HR: 2.47; 95% CI: 1.09–5.57; p<0.03), figure 1. There was a numerically better Golimumab retention rate in patients treated previously with less number of biologicals, but did not reach statistical significance. 39/105 patients (37%) withdrew Golimumab treatment. 26/39 (66.7%) due to lack of efficacy, 6/39 (15.4%) due to adverse events and 7/39 (17.5%) due to other reasons.

**Abstract SAT0273 – Figure 1.** retention rate

**Conclusions:** Real-world Golimumab retention rate in patients with Spondyloarthritis was good and did not depend on concomitant treatment with DMARD. Patients with Ankylosing Spondylitis and non-radiographic axial SpA with objective inflammation had a better Golimumab retention rate than patients with non-radiographic axial SpA without objective inflammation. A better retention rate was expected in patients who had previously used less biological, but was not found.

SAT0274

### RETENTION RATES OF CERTOLIZUMAB PEGOL IN ANKYLOSING SPONDYLITIS AND NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS PATIENTS: HUR-BIO REAL LIFE RESULTS

B. Armagan, A. Sari, A. Erden, G.K. Yardimci, L. Kilic, U. Kalyoncu, O. Karadag, S. Apras Bilgen, S. Kiraz, A. Akdogan, I. Ertenli. Hacettepe University, Department of Internal Medicine, Division of Rheumatology, Ankara, Turkey

**Background:** Drug survival rate is generally accepted as a reliable indicator of both efficacy and safety profile of a biological DMARD.

**Objectives:** To evaluate survival rates of certolizumab-pegol (CZP) in ankylosing spondylitis (AS) and non-radiographic axial spondyloarthritis (nrAxSpA) patients registered in HUR-BIO (Hacettepe University Rheumatology Biologic Registry).

**Methods:** HUR-BIO is a monocentric database of biologics including 2058 SpA patients (226 were prescribed CZP) by June 2017. All AS (n=142) and nrAxSpA (n=54) patients in HUR-BIO prescribed CZP at least once were enrolled in the study. Twenty-three patients who was already on CZP before admitting Hacettepe University were excluded. Patients prescribed CZP within 6 months period before analysis defined as drug continuing. Demographic, clinical and laboratory data of AS and nrAxSpa patients were evaluated. Kaplan-Meier analysis was used to estimate CZP survival rates.

**Results:** In total, 124 AS and 49 nrAxSpA patients were analysed. Baseline characteristics of patients were shown in Table. Median duration of CZP usage was 7.54 (3–26.5) months in AS and 6.27 (3–26.7) months in nrAxSpA group (p=0.53). CZP survival was similar between AS and nrAxSpA patients (figure 1). Forty-nine (27.2%) patients had used at least one TNFi and 38 (21.9%) patients had used more than one TNFi before CZP. There was no difference in drug survival between those who used TNFi and those who did not use TNFi before CZP (figure 2). BASDAI 50 response was reached in 27.6% of AS and 36.0% of nrAxSpA patients and at the last control visit (p=0.44).

**Abstract SAT0274 – Table 1.** Baseline demographic and clinical characteristics of patients.

	AS	nrAxSpA	p
Age, years (min-max)	36.5 (18–60)	32 (18–54)	0.041
Male, n (%)	58 (46.8)	21 (42.9)	0.641
Female, n (%)	66 (53.2)	28 (57.1)	
Disease duration, months (min-max)	48 (3–312)	24 (3–144)	0.011
Disease duration ≥ 5 years, n (%)	59 (47.6)	16 (32.7)	0.07
History of smoking, n (%)	79 (63.7)	26 (53.1)	0.196
History of uveitis, n (%)	9 (7.3)	3 (6.1)	0.791
Previous biological use, n (%)	59 (47.6)	26 (53.1)	0.516
Baseline BASDAI	57 (4–100)	57 (0–94)	0.495
Baseline BASFI	41 (0–100)	42 (0–94)	0.422
Baseline back pain VAS	70 (0–100)	70 (10–100)	0.961
ESR, mm/h (min-max)	15 (2–105)	13 (2–97)	0.177
CRP, mg/dL (min-max)	0.83 (0.1–18.2)	0.91 (0.1–8.32)	0.810
ESR > UL, n (%)	48 (39.7)	14 (29.8)	0.286
CRP > UL, n (%)	64 (52.9)	25 (54.39)	0.866
Syndesmophytes on X-ray, n (%)	21 (16.9)	3 (6.1)	0.064

Abstract SAT0274 – Figure 1. CZP survival in AS and nrAxSpA patients

Abstract SAT0274 – Figure 2. CZP survival in patients with and without history of TNFi use before CZP

**Conclusions:** In this single centre biological SpA cohort, adherence to CZP therapy seems to be high with a first year survival rate of 83% and there was no difference between AS and nrAxSpA patients.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.4649

#### SAT0275 VITAMIN D INSUFFICIENCY IS ASSOCIATED WITH VERTEBRAL FRACTURES IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS

C. Romera-Lopez<sup>1</sup>, C. Fernández-Carballido<sup>2</sup>, M.P. Martínez-Vidal<sup>3</sup>, T. Pedraz<sup>2</sup>.

<sup>1</sup>Reumatología, Hospital Vinalopo, Elche, Alicante; <sup>2</sup>Reumatología, Hospital General Universitario de Elda, Elda, Alicante; <sup>3</sup>Reumatología, Hospital General Universitario de Alicante, Alicante, Spain

**Background:** Vitamin D insufficiency is common in general population, and it has been associated with the development and activity of several diseases, such as cardiovascular and autoimmune diseases. In patients with axial spondyloarthritis (axSpA) vitamin D (25(OH)D) insufficiency has been associated with disease activity, but studies in these patients that associate 25(OH)D insufficiency with vertebral fractures (VF) are scarce.

**Objectives:** To evaluate the associations between 25(OH)D levels and VF, as well as the 10 year-estimated risk (FRAX) and low bone mineral density (BMD), in patients with axSpA.

**Methods:** Cross-sectional study of patients with axSpA (ASAS criteria); 25(OH)D insufficiency when <30 ng/mL and BMD measured by Lumbar spine (LS) and femoral neck (FN) Dual X-ray absorptiometry (DXA). Evaluation of VF with semi-quantitative method (Genant) in thoracolumbar X-rays. Bivariate and multivariate analyses performed, and p values <0.05 considered significant.

**Results:** We included 206 axSpA patients (70% male; 86% AS714% nr-axSpA); age 52±14 and disease duration 12.9±10.3 years; ASDAS-CRP 2.2±0.9, ASDAS-ESR 2.5±0.9; total mSASSS 20.5±19.1 and 25(OH)D levels 19.8±9.3 ng/mL (all values are mean ±SD); with 85.7% of the patients having insufficiency; VF were observed in 34% of the patients. The prevalence of low BMD was higher in FN 45.2% (z-score) and 28.9% (t-score) than in LS 25.7% (z-score) and 29.9% (t-score).

These differences were even higher when 25(OH)D insufficiency was also present (table).

In multivariate analysis, 25(OH)D was associated with FN BMD (p=0.001); without association with LS BMD. Vitamin D insufficiency was directly associated with the presence of VF [OR 0.95 (95%CI 0.86–0.98); p=0.029] and a higher 10 year-estimated risk of fracture (major FRAX [OR 0.92 (95%CI 0.81–0.96); (p=0.036)].

Differences between axSpA patients with/without 25(OH)D insufficiency			
	Insufficiency	No insufficiency	p value
Patients (%)	85.7%	14.3%	
Vertebral fractures (%)	38.7%	32.48%	p=0.049
FRAX major	8.7±6.7	7.5±6.4	p=0.036
BASDAI	4.2±2.2	3.1±1.3	p=0.003
BASFI	3.8±2.5	3.0±2.4	p=0.000
ASDAS-CRP	2.21±0.15	1.89±0.16	p=0.003
ASDAS-ESR	2.72±0.21	2.19±0.25	p=0.002
Low FN BMD (%)	56.4%	44.6%	p=0.014
FN t-score	0.80±0.31	0.92±0.44	p=0.002
FN z-score	0.84±0.28	0.9±0.31	p=0.002

Values are mean ±standard deviation (SD) unless otherwise specified.

**Conclusions:** In patients with axSpA, vitamin D insufficiency is even more generalised than in general population. Low 25(OH)D is associated with lower FN BMD and more vertebral fractures, as well as increased disease activity and disability. Vertebral fractures are a serious complication of axSpA, so 25(OH)D insufficiency should be taken into account in the management of the comorbidities of the patients with axial spondyloarthritis.

#### SAT0276 UVEITIS DURING ANTI-TNF THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS: A PARADOXICAL EVENT OR DISEASE MANIFESTATION?

C. Ancuta<sup>1,2</sup>, C. Pomirleanu<sup>2,3</sup>, R. Paiu<sup>1</sup>, G. Strugariu<sup>1</sup>, L. Petriariu<sup>1</sup>, C. Bran<sup>4</sup>, E. Ancuta<sup>5</sup>, R. Chiriac<sup>6</sup>. <sup>1</sup>Clinical Rehabilitation Hospital; <sup>2</sup>University of Medicine and Pharmacy Grigore T Popa Iasi; <sup>3</sup>Clinica Rehabilitation Hospital, Iasi; <sup>4</sup>Stantur Ioan Emergency Hospital, Suceava; <sup>5</sup>Elene Doamna Clinical Hospital; <sup>6</sup>SANOCARE Medical and Research Center, Iasi, Romania

**Background:** Although widely recognised as extra-articular manifestations of axial spondyloarthritis (axSpA), uveitis developing throughout anti-TNFα treatment is difficult to be classified as disease related or paradoxical event.

**Objectives:** We aimed to evaluate the incidence of new onset or relapsing uveitis in patients with axSpA receiving TNF inhibitors.

**Methods:** We performed a cross-sectional retrospective study evaluating 126 consecutive active axSpA exposed to TNFα inhibitors according to the local recommendations, followed-up in a single rheumatology department. Patients identified with uveitis were systematically assessed based on a predefined protocol comprising (i) *data about uveitis* (de novo or flare; unique episode or recurrence; acute or chronic; anterior, posterior, intermediary or panuveitis; uni or bilateral; outcomes), (ii) *responsible medication* (drug exposure prior to uveitis, biologic-naïve or experimented axSpA, continuation or switching to another biologic) and (iii) *rheumatic condition* (activity, response to treatment, extra-articular manifestations, disease duration).

**Results:** 91 biologic naïve axSpA and 35 receiving more than one anti-TNFα were recruited; among them, 318 patient-years exposed to etanercept, 225.37 patient-years to adalimumab, 113.52 patient-years to infliximab, 30.49 patient-years on golimumab. A history of uveitis was found in 27.77% (35 cases).

We reported 12 patients developing at least one episode of uveitis during biologic treatment (7 de novo, 10 recurrent uveitis); etanercept was mostly associated with uveitis (8 episodes, 2.51 per 100 patient-years), but also monoclonal antibodies, 3 with golimumab (9.83 per 100 patient-years), 2 under infliximab (1.76 per 100 patient-years), surprisingly, 3 with adalimumab (1.33 per 100 patient-years). Only 3 axSpA had uveitis before starting anti-TNFs.

Uveitis was described irrespective of the prior exposure to biologics, mainly in biologic-naïve patients, aged between 26 and 72, with disease duration of 6 to 38 years, occurring any-time during biologics (2–116 months). Acute anterior uveitis was commonly reported, only one case of complicated panuveitis.

3 cases (one infliximab, two golimumab) had benefit with switching to another TNF blocker, but in most reported cases uveitis was solved without anti-TNFα

interruption. Further, continuation of the same anti-TNF $\alpha$  did not cause relapse in some cases.

The underlying SpA was well controlled (ASDAS-CRP) when uveitis, patients being classified as responders compared to previous visit, suggesting paradoxical uveitis.

**Conclusions:** Although rare, new onset or flare of uveitis may occur during anti-TNF therapy in axSpA. Surprisingly, not only TNF receptor but also monoclonal antibodies were responsible, etanercept being involved mainly in new onset uveitis.

**Disclosure of Interest:** None declared

### SAT0277 IMMUNOGENICITY AND LOSS OF RESPONSE TO TNF INHIBITORS IN AXIAL SPONDYLOARTHRITIS: RESULTS FROM AN OBSERVATIONAL COHORT STUDY

C.I. Ancuta<sup>1</sup>, C. Pomirleanu<sup>2</sup>, R. Paiu<sup>2</sup>, G. Strugariu<sup>2</sup>, L. Petrariu<sup>2</sup>, E. Ancuta<sup>3</sup>, C. Iordache<sup>1</sup>, R. Chiriac<sup>4</sup>. <sup>1</sup>University of Medicine and Pharmacy Grigore T Popa Iasi; <sup>2</sup>Clinical Rehabilitation Hospital; <sup>3</sup>Elene Doamna Clinical Hospital; <sup>4</sup>Sanocare Medical Center, Iasi, Romania

**Objectives:** We aimed to evaluate the immunogenicity of TNF- $\alpha$  inhibitors and to assess potential influence on serum drug levels and clinical efficacy in patients with axial spondyloarthritis (axSpA).

**Methods:** We performed a cross sectional observational cohort study in 87 consecutive axSpA receiving anti-TNFs (either for the first time or switched), followed-up in a single outpatient rheumatology department. Treatment with anti-TNF agents was recommended in accordance with the local regulations on the initiation and continuation of biologics, as well as ASAS/EULAR guidelines.

Disease activity scores were assessed at baseline (V1) and study visit (V2), while drug trough levels and anti-drug antibodies were measured in serum samples (ELISA, Progenika) and collected before the next administration as a single-point data. Serum drug levels were considered positive if >0.035  $\mu$ g/mL IFX, >0.024  $\mu$ g/mL ADL and >0.035  $\mu$ g/mL ETN, while the cut-offs for anti-IFX was 5AU/mL, anti-ADL 10AU/mL, anti-ETN 142 AU/mL. Statistical analysis was performed using SPSS version 19.0, p<0.05.

**Results:** Among 150 axSpA treated with TNF inhibitors in our centre, 28 (32.18%) receiving adalimumab (ADL), 19 (21.83%) infliximab (IFX) and 40 (45.97%) etanercept (ETN) were included in the immunogenicity analysis. Only 11 patients (12.64%) developed anti-drug antibodies, 8 under ADL (28.57%) and 3 under IFX (15.78%), with significant decrease in drug levels (3.97  $\mu$ g/mL vs. 0.07  $\mu$ g/mL ADL, p<0.05; 1.82  $\mu$ g/mL vs. 0.05  $\mu$ g/mL IFX, p<0.05) and impact on disease outcomes (p<0.05).

Higher disease activity scores (BASDAI, ASDAS-CRP) were reported in anti-drug positive axSpA irrespective of the background therapy (p<0.05), with more patients classified as being in a high or very high disease activity status at V2. Furthermore, a relation between clinical improvement (change in ASDAS) and immunogenicity was reported: positive anti-drug antibodies axSpA achieved worse clinical response than negative anti-drug antibodies cases, with a significant association between ADL respectively IFX levels and ASDAS (p<0.05).

No anti-drug antibodies were found in patients treated with ETN; significant higher persistence on ETA than under monoclonal antibodies was registered in our axSpA (p<0.05).

**Conclusions:** Immunogenicity may impact disease outcomes and drug survival, particularly in the adalimumab and infliximab treated axSpA. Measuring anti-drug antibodies and serum drug levels may help to optimise therapeutic strategies in selected patients.

### SAT0278 NSAIDS REDUCES RADIOGRAPHIC PROGRESSION IN SACILOIAC JOINTS IN EARLY AXIAL SPONDYLOARTHRITIS

D. Rumiantseva<sup>1</sup>, T. Dubinina<sup>2</sup>, O. Rumyantseva<sup>1</sup>, A. Demina<sup>2</sup>, S. Erdes<sup>1</sup>. <sup>1</sup>Laboratory of spondyloarthritis; <sup>2</sup>Laboratory of scientific and organizational problems in rheumatology, V. A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

**Background:** According to the ASAS-EULAR management recommendations for axial spondyloarthritis (axSpA) patients (pts) suffering from pain and stiffness should use an NSAIDs as first-line drug and for pts who respond well to NSAIDs continuous use is preferred if symptomatic otherwise. Two studies have suggested that the continuous use of NSAIDs in patients with an elevated CRP results in reduced progression of structural damage in the spine in comparison to on-demand use.<sup>1,2</sup> But up-to-date the question of the effect of NSAIDs on radiographic progression in early axSpA remains open.

**Objectives:** To compare continuous and on-demand treatment groups on radiographic progression sacroiliac joints (SIJ) in axSpA.

**Methods:** The research included 68 pts with early axSpA<sup>ASAS criteria, 2009</sup> from Moscow CORSAR cohort with disease duration <5 years, age onset <45 years and at least 2 years follow up (FUP). 33 (48,5%) males, pts mean age was 28,5 (5,8) y., average disease duration – 24,1 (15,4) mo, 63 (92,6%) pts were HLA-B27 positive. Pts were randomised into two treatment groups: group 1 – continuous uses of NSAIDs; group 2 – on-demand uses of NSAIDs. The dosages of NSAIDs accounted by the ASAS NSAID index. At baseline 6 pts received TNF inhibitors, after 2 y. FUP 14 pts receives TNF inhibitors.

**Results:** No significantly differences in axSpA disease activity between two groups at baseline (table 1) and after 2 y. FUP (table 2). At group №1 8,2% pts had radiographic progression in SIJ (from nr-axSpA to AS), at group №2%–13,3% pts (p=0,000).

**Abstract SAT0278 – Table 1.** Outcome parameters at baseline.

	Group №1 (n=31)	Group №2 (n=31)	p
Ankylosing spondylitis, n,%	22 (70,9%)	15 (50,0%)	0088
Non-radiographic axSpA, n,%	9 (29,1%)	17 (50,0%)	0257

### SAT0279 COMPARISON OF RETENTION RATES BETWEEN TUMOUR NECROSIS FACTOR-A INHIBITORS IN ANKYLOSING SPONDYLITIS PATIENTS: DATA FROM THE KOREAN COLLEGE OF RHEUMATOLOGY BIOLOGICS REGISTRY

E.H. Park<sup>1</sup>, S. Oh<sup>2</sup>, H.-A. Kim<sup>3</sup>, Y.-B. Park<sup>4</sup>, K. Shin<sup>2</sup>. <sup>1</sup>Department of Internal Medicine (Division of Rheumatology), Seoul National University Hospital; <sup>2</sup>Department of Internal Medicine (Division of Rheumatology), SMG-SNU Boramae Medical Center, Seoul; <sup>3</sup>Department of Internal Medicine (Division of Rheumatology), Ajou University Hospital, Suwon; <sup>4</sup>Department of Internal Medicine (Division of Rheumatology), Yonsei University College of Medicine, Severance Hospital, Seoul, Korea, Republic Of

**Background:** Drug persistence of tumour necrosis factor-a inhibitors (TNFi) tends to be higher in patients with ankylosing spondylitis (AS) than rheumatoid arthritis but there are few studies of Asian AS patients in the literature.

**Objectives:** To investigate drug retention rates of various TNFi used in Korean AS patients.

**Methods:** Subjects were AS patients enrolled in the Korean College of Rheumatology Biologics registry<sup>KOBIO, Dec 2012 -</sup>). All approved and commonly prescribed TNFi were included in the analysis. Discontinuation was defined as switching or stopping the biologic agent. Kaplan-Meier curve and Cox proportional hazard model were used for further analysis. Reason of TNFi discontinuation was also assessed. Univariate and multivariate analyses were used to identify possible predictors of discontinuation.

**Results:** Data of total of 1005 AS patients were analysed (median follow-up period: 14 months). The mean age of patients was 40.7, and 77.4% were males. The mean disease duration was 7.1 years, HLA-B27 were positive in 82.4%, and 33.2% of patients had lesion(s) of syndesmophytes. Seventy-six percent of patients were first-time biologic users. Discontinuation of TNFi occurred in 24.2% (switching in 9.6%) of patients during follow-up. The drug survival function estimate showed that the adjusted hazard ratio (HR) of golimumab (compared with etanercept) was 0.441 (95% CI 0.277–0.703,  $p < 0.001$ ). The reason of discontinuation was inefficacy (32.6%), adverse events (23.6%), clinical improvement (11.2%), and others (32.6%). A multivariate analysis indicated predictors of discontinuation to be shorter disease duration (HR 0.973,  $p = 0.044$ ), and negative HLA-B27 (HR 1.623,  $p = 0.0093$ ).

**Conclusions:** Our study demonstrates that few AS patients switched to other TNFi during their course of treatment. The drug retention rate of golimumab was higher compared with other agents prescribed in Korean AS patients.

SAT0280

### RAPAMYCIN RESTORES THE BALANCE BETWEEN TH17 AND REGULATORY T CELLS IN USPA PATIENTS

F. Jinnan<sup>1</sup>, X. Dan<sup>1</sup>, G. Chong<sup>2</sup>, L. Xiaofeng<sup>1</sup>. <sup>1</sup>The Second hospital of Shanxi Medical University, Taiyuan, China; <sup>2</sup>Brigham and Women's Hospital, Boston, USA

**Background:** The association of undifferentiated spondyloarthritis (uSpA) with the imbalance of Th17/Treg cells is still unclear. By inhibiting mTOR, rapamycin promotes the proliferation of Treg cells and inhibits the growth of Th17 cells.

**Objectives:** Therefore, we aimed to investigate the status of Treg and Th17 cells in uSpA patients and explore the therapeutic effect of Rapamycin on uSpA patients with imbalanced of Th17 and Treg cells.

**Methods:** Two hundred thirty-seven new onset uSpA patients and 93 healthy controls were enrolled. These patients fulfilled ESSG criteria for SpA but did not fulfill the criteria for any established disease of the group. Both absolute numbers and proportions of Treg (CD4 +CD25+Foxp3+T) and Th17 (CD4 +IL-17+T) cells in peripheral blood were analysed by flow cytometry. The 21 new onset Patients with imbalance of Th17/Treg cells were treated with rapamycin at a dose of 0.5 mg twice for a weeks or every 2 days for 6 weeks combined with conventional treatment (salazosulfapyridine 500 mg three times per day; etoricoxib 60 mg once per day or other NSAIDs drugs).

**Results:** Increase in absolute number and percentage of Th17 (Th17% 1.11 ±0.66 vs 2.43±1.21,  $p < 0.05$ ; Th17 cells/μl 7.54±4.07 vs 19.54±18.45,  $p < 0.05$ ) and decrease in those of Tregs (Treg% 4.8±1.60 vs 3.35±1.76,  $p < 0.05$ ; Treg cells/μl (33.77±13.67 vs 27.79±28.62,  $p < 0.05$ ) were found in 18.6% (44/237) of patients with uSpA as compared with that of healthy controls. The patients with imbalance of Th17/Treg cells displayed higher BASDAI scores and ESR as compared with other uSpA patients [BASDAI (3.27±1.06 vs 1.13±0.91  $P < 0.05$ ); ESR (29.27±19.32 vs 21.80±18.34  $P < 0.05$ )]. The absolute count of Th17 in 21 patients received rapamycin reduced after 6 weeks (12.35±11.00 vs 6.69±5.54,  $p < 0.05$ ) whereas that of Treg cells showed increase trend but the difference did not reach statistical significance.

**Conclusions:** Absolute number of Treg decreased and that of Th17 cells increased in the peripheral blood of uSpA patients, suggesting that imbalance of the two subsets contributes to the pathogenesis of uSpA. Rapamycin recovered the balance between Th17 and Treg cells in uSpA patients by reducing Th17 cells.

### BIOLOGICS IN SAPHO SYNDROME. A SYSTEMATIC REVIEW

D. Daoussis, G. Konstantopoulou, I. Antonopoulos, S.-N. Lioussis. *Rheumatology, University of Patras Medical School, Rio, Patras, Greece*

**Background:** The SAPHO (Synovitis, Acne, Pustulosis, Hyperostosis, Osteitis) syndrome is a relatively rare clinical entity characterised by a wide range of dermatological and musculoskeletal manifestations. Treatment is largely empiric since guidelines do not exist. Biologics have been used in cases refractory to conventional treatment.

**Objectives:** To systematically review all cases of patients with SAPHO syndrome treated with biologics to date.

**Methods:** We performed a systematic electronic search (PubMed) using the key words SAPHO combined with any of the following: treatment, biologics, anti-TNF, infliximab, adalimumab, etanercept, certolizumab, golimumab, IL-1, anakinra, canakinumab, IL-17, secukinumab, IL-23, ustekinumab, IL-6, tocilizumab, abatacept, rituximab. The only limit set was English language. The computerised search was supplemented by a manual one on the reference lists of the retrieved articles.

The search identified 461 articles; the abstracts of these articles were assessed in order to identify studies related to the therapeutic use of biologics in patients with SAPHO syndrome. Only 36 articles fulfilled the search criteria and were included in the analysis.

**Results:** We identified 64 cases treated with biologics (44 with TNF blockers, 7 with IL-1 blockers, 12 with biologics targeting the IL-23/IL-17 axis and 1 with tocilizumab). Data support a positive effect of anti-TNF treatment in SAPHO with a response rate in bone and joint manifestations of 95.4%. Skin disease also improved in 21/29 cases (response rate 72.4%). Data related to IL-1 inhibition in SAPHO are encouraging with most patients (6/7) exhibiting a significant response in musculoskeletal manifestations (response rate 85.7%). However, IL-1 inhibition is not effective in skin manifestations. Ustekinumab seems to have some efficacy with 2/4 patients responding in skin and 3/5 in bone/joint manifestations. Data related to IL-17 blockade indicate efficacy in skin disease with 4/7 patients responding (response rate 57.1%). Joint/bone manifestations improved in 2/7 patients (response rate 28.6%).

**Conclusions:** In SAPHO patients not responding to conventional treatment, TNF blockers should be the first choice. In patients failing TNF blockers, IL-1 inhibitors and biologics targeting the IL-17/IL-23 axis could be used.

SAT0282

### OCCURRENCE OF ANTERIOR UVEITIS IN PATIENTS WITH SPONDYLOARTHRITIS AND PSORIATIC ARTHRITIS TREATED WITH TUMOUR NECROSIS FACTOR INHIBITORS: A RESTROSPECTIVE MONOCENTRIC STUDY COMPARING THE SOLUBLE RECEPTOR TO THE MONOCLONAL ANTIBODIES

G. Khoury<sup>1</sup>, B. Combe<sup>1</sup>, J. Morel<sup>1</sup>, C. Lukas<sup>2</sup>. <sup>1</sup>Rheumatology, Hopital Lapeyronie; <sup>2</sup>Rheumatology, Hop Lapeyronie, Montpellier Cedex 5, France

**Background:** The efficacy of tumour necrosis factor inhibitors against anterior uveitis has been shown, but discrepancies remain as to the difference in efficacy between soluble receptor and monoclonal antibodies.

**Objectives:** The objective of this study was to compare the occurrence of anterior uveitis with soluble receptor and monoclonal antibodies in patients with spondyloarthritis (SPA) and psoriatic arthritis (PA).

**Methods:** This was an observational, retrospective, monocentric study. Patients attending the rheumatology department of the Montpellier University Hospital for a SPA or a PA and who were prescribed anti-TNF agents between 2000 and 2014 were included in our cohort. Data on the diagnosis of rheumatism, the history of the disease and the extra-articular symptoms were collected from medical records. The risk of uveitis has been interpreted qualitatively (number of subjects with at least one flare of uveitis) and quantitatively (number of uveitis flares for each patient). Logistic regression models were used for qualitative analyses and Poisson models for quantitative analyses.

**Results:** 429 patients were included (302 with SPA and 127 with PA, 203 were treated with a monoclonal antibody as first TNF alpha inhibitor and 226 with the soluble receptor). No difference between monoclonal antibodies and soluble receptor was found in the risk of uveitis occurring during the first year of treatment (OR=0.94 [0.35; 2.54],  $p = 0.90$  in qualitative analysis and RR=0.62 [0.26; 1.46];  $p = 0.27$  in quantitative analysis). The risk of uveitis was higher with the soluble receptor for the first-line TNF inhibitors, as well as for all therapeutic lines, but this difference was not statistically significant ( $p = 0.09$  and  $0.08$  respectively in quantitative analysis and  $0.68$  and  $0.53$  in quantitative analysis).

**Conclusions:** In view of our observations, the risk of uveitis does not appear to be significantly higher with the soluble receptor than with the monoclonal

antibodies in SPA and PA, to recommend systematically the eviction of etanercept in subjects with a moderate risk of developing anterior uveitis.

**Disclosure of Interest:** None declared

SAT0283

**SECUKINUMAB 150 MG PROVIDES SUSTAINED IMPROVEMENTS IN THE SIGNS AND SYMPTOMS OF ACTIVE ANKYLOSING SPONDYLITIS WITH HIGH RETENTION RATE: 4-YEAR RESULTS FROM THE PHASE III TRIAL, MEASURE 2**

H. Marzo-Ortega<sup>1</sup>, J. Sieper<sup>2</sup>, A. Kivitz<sup>3</sup>, R. Blanco<sup>4</sup>, M. Cohen<sup>5</sup>, E.M. Delicha<sup>6</sup>, S. Rohrer<sup>6</sup>, H. Richards<sup>6</sup> on behalf of MEASURE 2 Study Group. <sup>1</sup>NIHR LMBRU, LTH and LIRMM, UoL, Leeds, UK; <sup>2</sup>University Clinic Benjamin Franklin, Berlin, Germany; <sup>3</sup>Altoona Center for Clinical Research, Duncansville, USA; <sup>4</sup>Hospital Universitario Marqués de Valdecilla, Santander, Spain; <sup>5</sup>McGill University, Montreal, Canada; <sup>6</sup>Novartis Pharma AG, Basel, Switzerland

**Background:** Secukinumab, a fully human monoclonal antibody that neutralises IL-17A, has shown significant and sustained improvement in the signs and symptoms of active ankylosing spondylitis (AS) through 3 years in the MEASURE 2 study (NCT01649375).<sup>1</sup>

**Objectives:** To report the longer-term (4 year) efficacy and safety of subcutaneous (s.c.) secukinumab 150 mg in the MEASURE 2 study.

**Methods:** AS patients (pts; n=219) were randomised to receive s.c. secukinumab 150 mg, 75 mg or placebo at baseline, Weeks (Wks) 1, 2 and 3 and every 4 weeks from Wk 4. At Wk 16, placebo-treated pts were re-randomised to receive secukinumab 150/75 mg. Efficacy results are reported for pts initially randomised to secukinumab 150 mg and those who switched from placebo to secukinumab 150 mg at Wk 16. Safety analyses included all pts who received  $\geq 1$  dose of secukinumab. Results are reported as observed.

**Results:** The retention rate from Wk 16 to 208 was 85% (85/100) for secukinumab 150 mg. Sustained improvements were observed with secukinumab 150 mg across all endpoints through 4 years (Table). These improvements were maintained regardless of prior exposure to anti-TNF therapy; greater responses were demonstrated in anti-TNF-naïve pts. Over the entire study period, the mean exposure ( $\pm$ SD) to secukinumab was 1189.3 $\pm$ 452.9 days. Exposure-adjusted incidence rates (per 100 pt-years) with any secukinumab dose for selected adverse events were: serious infections/infestations (1.5), *Candida* infections (1.2), Crohn's disease (0.6), major adverse cardiovascular events (0.6), uveitis (0.6), and malignant/unspecified tumours (0.4).

**Abstract SAT0283 – Table 1.** Clinical improvements with secukinumab 150 mg at Weeks 52 and 208

Variable	Week	Secukinumab 150 mg <sup>a</sup>		
		Total	Anti-TNF-naïve	Anti-TNF-IR
ASAS20,% responders (n)	52	74.2 (93)	80.0 (60)	63.6 (33)
	208	73.3 (86)	74.6 (59)	70.4 (27)

**AN ADD-ON TRAINING PROGRAM INVOLVING BREATHING EXERCISES, COLD EXPOSURE, AND MEDITATION ATTENUATES INFLAMMATION AND DISEASE ACTIVITY IN AXIAL SPONDYLOARTHRITIS**

G.A. Buijze<sup>1</sup>, H.M.Y. De Jong<sup>2</sup>, M. Kox<sup>3</sup>, D. van Schaardenburg<sup>2</sup>, R.M. van Vugt<sup>4</sup>, C. Popa<sup>5</sup>, P. Picckers<sup>3</sup>, D.L. Baeten<sup>2</sup>. <sup>1</sup>Orthopaedic Surgery, <sup>2</sup>Clinical immunology and rheumatology, Academic Medical Center, Amsterdam; <sup>3</sup>Intensive Care Medicine, Radboud University Medical Centre, Nijmegen; <sup>4</sup>Rheumatology, VU medical center, Amsterdam; <sup>5</sup>Rheumatology, Sint Maartenskliniek, Nijmegen, Netherlands

**Background:** A training program involving breathing exercises, cold exposure, and meditation (further referred to as: 'add-on training program') was shown to exert immunomodulating properties in healthy individuals undergoing experimental endotoxemia.

**Objectives:** Assessment of safety and anti-inflammatory effects of the add-on training program in patients with axial spondyloarthritis (axSpA).

Primary objectives: safety (24 weeks) and change in serum CRP levels (week 8). Secondary objectives: changes in erythrocyte sedimentation rate (ESR), serum calprotectin levels, disease activity as measured by the ASDAS-CRP and Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), quality of life measures (SF-36, EQ-5D), and hospital anxiety and depression scale (HADS).

**Methods:** 24 patients with moderately active axSpA (ASDAS >2.1 and CRP >5 mg/L) were included in this trial. The intervention consisted of an 8 weeks add-on training program comprising three elements: breathing exercises (cyclic hyperventilation followed by breath retention), gradual cold exposure (immersions in ice cold water), and meditation (third eye meditation). An open-label randomised one-way crossover design was used to rule out regression to the mean by comparing an intervention group with a control group.

**Results:** There was no significant difference in adverse events between groups, with one serious adverse event (hypertensive crisis) occurring 8 weeks after end of the intervention and judged 'unrelated'. The study met its primary efficacy endpoint, with a significant decline in serum CRP at week 8 in the intervention group

(median [interquartile range] from 10.2 [6.5–17.1] to 6.0 [3.9–15.6] mg/L;  $p=0.02$ ), but not in the control group (from 8.7 [5.2–17.2] to 13.2 [7.9–20.1] mg/L;  $p=0.70$ ). A similar trend was seen for serum calprotectin ( $p=0.065$  in intervention versus  $p=0.31$  in control), but not for ESR. In addition, ASDAS-CRP ( $p=0.02$ ), BASDAI ( $p=0.04$ ), SF-36 physical component score ( $p=0.01$ ), EQ-5D ( $p=0.049$ ), and EQ-5D VAS ( $p=0.02$ ) decreased significantly in the intervention group, but not the control group.

**Conclusions:** This proof-of-concept study in axSpA revealed a significant decrease in serum CRP levels upon add-on training program, in the absence of safety signals. Together with the significant improvement in disease activity and quality of life, these findings warrant full-scale randomised controlled trials of this novel therapeutic approach in patients with axSpA and other inflammatory conditions.

#### EFFICACY OF EARLY VERSUS DELAYED INITIATION OF ANTI-TNF-ALPHA TREATMENT IN AXIAL SPONDYLOARTHRITIS. DATA FROM THE CZECH REGISTRY ATTRA

H. Mann<sup>1</sup>, K. Bubová<sup>1</sup>, J. Závada<sup>1</sup>, Š. Forejtová<sup>1</sup>, Z. Křístková<sup>2</sup>, L. Szczuková<sup>2</sup>, P. Horák<sup>3</sup>, J. Vencovsky<sup>1</sup>, K. Pavelka<sup>1</sup> on behalf of ATTRA registry. <sup>1</sup>Institute of Rheumatology, Prague 2; <sup>2</sup>Institute of Biostatistics and Analyses, Faculty of Medicine, Masaryk University, Brno; <sup>3</sup>III Department of internal Medicine, Faculty of Medicine and Dentistry, Palacký University Olomouc, Olomouc, Czech Republic

**Background:** Anti-TNF- $\alpha$  agents are the mainstay of pharmacotherapy for patients with axial spondyloarthritis (AxSpA) who failed treatment with NSAIDs. A little is known about the influence of early versus delayed treatment initiation on their clinical efficacy.

**Objectives:** To compare change of disease activity in AxSpA patients on anti-TNF- $\alpha$  therapy based on symptom duration prior to treatment initiation.

**Methods:** Baseline demographic data and efficacy parameters of patients starting their first anti-TNF- $\alpha$  treatment  $\leq 10$  years (EARLY) or  $> 10$  years (DEALYED) after first symptoms of AxSpA from the Czech national registry ATTRA were compared. Mean  $\pm$ SD and absolute/relative frequencies were used to describe continuous and categorical variables, respectively. P-value of Fisher's exact test and Mann-Whitney test is given when assessing difference between groups in categorical and continuous variables. ATTRA is a centralised prospective computerised registry of patients receiving bDMARD therapy for rheumatic diseases collecting data on efficacy, safety and quality of life of all patients treated in the Czech Republic. Anti-TNF- $\alpha$  therapy was indicated for patients with AxSpA who have failed treatment with NSAIDs with CRP  $\geq 1$  mg/dl and BASDAI score  $\geq 4$ .

**Results:** Data from 1290 axSpA patients were available for analysis. 618 patients started treatment  $\leq 10$  years (EARLY) and 672  $> 10$  years (DEALYED) after the onset of AxSpA symptoms. There was no significant difference in gender distribution (71.4 vs 72.5% males;  $p=0.67$ ) or age at AxSpA diagnosis ( $33.3 \pm 10.4$  vs  $33.5 \pm 10.4$ ;  $p=0.68$ ) between the two groups. At the time of anti-TNF- $\alpha$  initiation EARLY patients were significantly younger ( $36.4 \pm 10.6$  vs  $44.0 \pm 11.2$  years;  $p < 0.001$ ) with shorter symptom duration ( $5.5 \pm 2.7$  vs  $18.9 \pm 8.1$ ;  $p < 0.001$ ), but disease activity assessed by BASDAI ( $6.3 \pm 1.8$  vs  $6.3 \pm 1.6$ ;  $p=0.81$ ) and serum CRP levels ( $2.6 \pm 2.5$  vs  $2.4 \pm 2.0$  mg/dL;  $p=0.34$ ) were comparable in both groups. Mean change of BASDAI scores from baseline during anti-TNF- $\alpha$  therapy was significantly greater in the EARLY group at all time-points ( $3.7 \pm 2.5$  vs  $3.4 \pm 2.2$  at month 3,  $4.2 \pm 2.5$  vs  $3.8 \pm 2.3$  at month 6,  $4.4 \pm 2.5$  vs  $4.0 \pm 2.3$  at month 12 and  $4.4 \pm 2.5$  vs  $4.0 \pm 2.4$  at month 24;  $p < 0.05$  for all) suggesting better treatment response. The difference in survival on therapy between the two groups was not statistically significant.

**Conclusions:** AxSpA patients starting anti-TNF- $\alpha$  therapy more than 10 years after onset of symptoms have significantly worse response to treatment compared to patients with earlier treatment initiation.

#### RETENTION RATE AND SAFETY DATA OF BIOSIMILAR CT-P13 IN ANKYLOSING SPONDYLITIS PATIENTS: DATA FROM THE KOREAN COLLEGE OF RHEUMATOLOGY BIOLOGICS REGISTRY

H.-A. Kim<sup>1</sup>, E.-Y. Lee<sup>2</sup>, S.-K. Lee<sup>3</sup>, Y.-B. Park<sup>4</sup>, K. Shin<sup>3</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Medical Informatics, Ajou University School of Medicine, Suwon; <sup>3</sup>Department of Internal Medicine (Division of Rheumatology), Seoul Metropolitan Government-Seoul National University Hospital Boramae Medical Center; <sup>4</sup>Department of Internal Medicine (Division of Rheumatology), Yonsei University College of Medicine, Severance Hospital, Seoul, Korea, Republic Of

**Background:** CT-P13 is a biosimilar prescribed in a number of countries for indications approved for the reference infliximab (RINF), including ankylosing spondylitis (AS), rheumatoid arthritis, and inflammatory bowel diseases. Clinical data of CT-P13 have been analysed in previous clinical trials, demonstrating equivalence of efficacy and pharmacokinetic profile to RINF. However, there are few studies showing long-term data of its drug survival or safety.

**Objectives:** To investigate the drug retention rate and safety data of biosimilar CT-P13 in Korean AS patients.

**Methods:** Subjects were AS patients enrolled in the Korean College of Rheumatology biologics registry (KOBIO). Data from patients who received RINF and CT-P13 were included in the analysis<sup>Dec 2012 ~ Dec 2017</sup>. Discontinuation was defined as switching or stopping the biologic agent. Kaplan-Meier curve and Cox proportional hazard model were used for further analysis. Reason for RINF or CT-P13 discontinuation was also assessed.

**Results:** Data from 399 AS patients (CT-P13; 256, RINF; 143) were analysed. The mean age of patients was 39.0 in the CT-P13 group, and 73% were males. The mean disease duration was 4.1 years. Eighty percent of patients were first-time biologic users. Discontinuation of CT-P13 occurred in 30.9% (switching in 17.6%) of patients during follow-up. The drug retention rate of first-line users of CT-P13 was marginally higher compared with second or more ( $\geq 2$ )-line users of CT-P13, first-line users of RINF, and  $\geq 2$  line users of CT-P13 in Korean AS patients ( $p=0.0518$ ). The reason of discontinuation was inefficacy (42.7%), adverse events (20.2%), clinical improvement (7.9%), and others (18.0%) in the CT-P13 group. The incidence of adverse events of CT-P13, including infusion reaction ( $n=10$ ), mycobacterial infection ( $n=2$ ), and skin eruption ( $n=1$ ) was comparable to that of RINF.

**Conclusions:** Our study demonstrates that the drug retention rate of CT-P13, especially in first-line users was relatively higher than that of RINF, [H1] and CT-P13 showed a reasonable long-term safety profile in Korean AS patients.

SAT0287

### WHAT ARE THE ECONOMIC IMPLICATIONS OF ANTI-TNF THERAPY IN PATIENTS WITH AXIAL SPONDYLOARTHRITIS? – RESULTS OF A HEALTH INSURANCE CLAIMS DATA ANALYSIS

J. Redeker<sup>1</sup>, F. Hoffmann<sup>2</sup>, J. Callhoff<sup>1</sup>, H. Haibel<sup>3</sup>, J. Sieper<sup>3</sup>, A. Zink<sup>1,4</sup>, D. Poddubnyy<sup>1,3</sup>. <sup>1</sup>Epidemiology Unit, German Rheumatism Research Centre, Berlin; <sup>2</sup>Department of Health Services Research, Carl von Ossietzky University, Oldenburg; <sup>3</sup>Department of Gastroenterology, Infectiology and Rheumatology; <sup>4</sup>Department of Rheumatology and Clinical Immunology, Charité – Universitätsmedizin Berlin, Berlin, Germany

**Background:** Tumour necrosis factor (TNF)- $\alpha$  inhibitors are an effective but rather expensive treatment option in axial spondyloarthritis (axSpA) patients who fail conventional treatment.

**Objectives:** The aim of this study was to analyse the changes in healthcare costs and resource utilisation after initiation of TNF- $\alpha$  inhibitors in patients with axSpA.

**Methods:** Data of patients with axSpA newly exposed to TNF- $\alpha$  inhibitors between January 1, 2011 and December 31, 2015 were studied by using health insurance claims data in Germany. Resource utilisation, direct healthcare costs and productivity costs were assessed. Direct healthcare costs comprised costs for outpatient care (i.e., visits to physicians, laboratory visits, non-physician visits [e.g., visits to physical therapists], emergency department visits, outpatient hospital services, and aids [e.g., walkers]), costs for inpatient care (i.e., inpatient admissions) and costs for pharmacotherapy. Productivity costs comprised costs due to absence from paid work and were calculated using the friction cost method (FCM) and the human capital approach (HCA). Costs and resource utilisation were analysed the year before (baseline period) and the year after (follow-up period) initiation of TNF- $\alpha$  inhibitors.

**Results:** Data from 1452 persons were included in the analyses; mean age was 44.6 years and 47.9% were female. AxSpA-related pharmacotherapy use (non-steroidal anti-inflammatory drugs [NSAIDs], non-opioid analgesics, opioid analgesics, systemic steroids, local steroids and conventional synthetic disease-modifying anti-rheumatic drugs [csDMARDs]) and admissions to hospital decreased significantly in the follow-up period compared to the baseline period. However, due to anti TNF- $\alpha$  therapy, mean direct healthcare costs increased from € 4494 per patient in the baseline period to € 26 473 per patient in the follow-up period. Mean total costs increased from € 8072 to € 29 959 using the HCA and from € 6377 to € 28 162 using the FCM (Table). Excluding costs for anti-TNF therapy, total costs decreased by 15% to € 6876 or by 20% to € 5080 based on whether the HCA or the FCA was used.

**Abstract SAT0287 – Table 1.** Mean costs per patient before and after initiation of TNF- $\alpha$  inhibitors in axial spondyloarthritis (n=1,452).

	Baseline period mean $\pm$ SD	Follow-up period mean $\pm$ SD	P-value
Outpatient care*, €	1,402 $\pm$ 1,008	1,381 $\pm$ 1,054	0.0285
Hospital admissions*, €	1,890 $\pm$ 3,681	1,134 $\pm$ 3,558	<0.0001
with diagnosis of axSpA*	612 $\pm$ 1582	136 $\pm$ 714	<0.0001
Pharmacotherapy, €	1,201 $\pm$ 2,939	23,957 $\pm$ 5,480	<0.0001
excluding anti-TNF therapy	1,201 $\pm$ 2,939	875 $\pm$ 1,721	<0.0001
NSAIDs	130 $\pm$ 159	83 $\pm$ 151	<0.0001
non-opioid analgesics	21 $\pm$ 77	12 $\pm$ 46	<0.0001
opioid analgesics	118 $\pm$ 517	123 $\pm$ 564	0.3352
systemic steroids	23 $\pm$ 52	17 $\pm$ 54	<0.0001
local steroids	1 $\pm$ 4	1 $\pm$ 4	0.0091
csDMARDs	159 $\pm$ 366	97 $\pm$ 278	<0.0001
Absence at work, HCA, €	3,578 $\pm$ 7,211	3,486 $\pm$ 7,896	0.0458
Absence at work, FCM, €	1,883 $\pm$ 2,943	1,690 $\pm$ 2,934	0.0021
Total costs, HCA, €	8,072 $\pm$ 9,734	29,959 $\pm$ 10,679	<0.0001
excluding anti-TNF therapy	8,072 $\pm$ 9,734	6,876 $\pm$ 9,626	<0.0001
Total costs, FCM, €	6,377 $\pm$ 6,401	28,162 $\pm$ 7,609	<0.0001
excluding anti-TNF therapy	6,377 $\pm$ 6,401	5,080 $\pm$ 5,813	<0.0001

Values are presented as mean  $\pm$  standard deviation. P-values were assessed using Wilcoxon signed-rank tests. Total costs per patient were calculated as the sum of the domains outpatient care, hospital admissions, pharmacotherapy and absence at work.

TNF, Tumour Necrosis Factor; NSAIDs, Nonsteroidal Anti-inflammatory Drugs; csDMARDs, conventional synthetic Disease-Modifying Anti-Rheumatic Drugs; HCA, Human Capital Approach; FCM, Friction Cost Method; SD, standard deviation.

\* excluding costs for pharmacotherapy.

**Conclusions:** Overall resource utilisation decreased after initiation of TNF- $\alpha$  inhibitors. The rise in pharmacotherapy costs driven by anti-TNF agents is accompanied by significantly lower costs for outpatient and inpatient care, as well as significantly lower productivity costs. However, the effect of TNF-blocker therapy on

the patient's disease activity, function or quality of life could not be assessed in this analysis.

### SECUKINUMAB DEMONSTRATES RAPID AND SUSTAINED EFFICACY IN ANKYLOSING SPONDYLITIS PATIENTS WITH NORMAL OR ELEVATED BASELINE CRP LEVELS: POOLED ANALYSIS OF TWO PHASE 3 STUDIES

J. Braun<sup>1</sup>, J. Sieper<sup>2</sup>, R. Landewé<sup>3</sup>, X. Baraliakos<sup>1</sup>, C. Miceli-Richard<sup>4</sup>, E. Quebe-Fehling<sup>5</sup>, B. Porter<sup>6</sup>, K. Gandhi<sup>6</sup>, D. van der Heijde<sup>7</sup>. <sup>1</sup>Rheumazentrum Ruhrgebiet Herne, Ruhr-University Bochum, Herne; <sup>2</sup>Charité University Medicine Berlin, Berlin, Germany; <sup>3</sup>University of Amsterdam and Atrium Medical Center, Amsterdam, Netherlands; <sup>4</sup>Department of Rheumatology, Hôpital Bicêtre, Paris, France; <sup>5</sup>Novartis Pharma AG, Basel, Switzerland; <sup>6</sup>Novartis Pharmaceuticals Corporation, East Hanover, USA; <sup>7</sup>Leiden University Medical Center, Leiden, Netherlands

**Background:** Elevated baseline (BL) CRP levels is one of the predictors of treatment response in patients (pts) with active AS.<sup>1</sup> The relationship between BL CRP levels and the treatment response to IL-17A inhibition has not been assessed in AS pts thus far.

**Objectives:** This *post-hoc* analysis assessed the response to secukinumab (SEC) treatment in AS pts with normal or elevated BL CRP from the phase 3 MEASURE 1 and MEASURE 2 studies over 3 years.

**Methods:** The study designs of MEASURE 1 and 2 have been reported.<sup>2</sup> This analysis pooled data from all pts with available BL CRP levels who received subcutaneous (s.c.) SEC 150 mg (approved dose; n=197) or placebo (PBO; n=195). Efficacy endpoints included ASAS20/40, BASDAI, BASDAI50, ASDAS inactive disease, and ASAS partial remission (PR) stratified by normal (<5 mg/L) and elevated ( $\geq$ 5 mg/L) BL CRP; elevated BL CRP group was further subdivided into a range of elevated CRP levels: >5–10, >10–15, >15 mg/L. Data are presented as non-responder imputation (NRI) at Week (Wk)16 and multiple imputation (MI) at Wk156 for binary variables and mixed-effect model repeated measure (MMRM) at Wks 16 and 156 for continuous variables.

**Results:** Overall, 36.5% (143/392) of pts with normal CRP and 63.5% (249/392) of pts with elevated BL CRP were included in the pooled analysis. BL characteristics were balanced across normal and elevated BL CRP groups.<sup>3</sup> At Wk16, efficacy endpoints were improved with SEC 150 mg vs PBO in pts with normal or elevated BL CRP.<sup>3</sup> Results were consistent across all levels of elevated BL CRP with a trend for greater improvement in pts with more elevated CRP (Table). Improvements were sustained or further improved at Wk156 in all groups (Table).

**Abstract SAT0288 – Table 1.** Summary of Clinical Efficacy

Clinical outcomes	Wk	Normal BL CRP (<5mg/L)		Elevated BL CRP					
		SEC (N=72)	PBO (N=71)	>5–10mg/L	>10–15mg/L	>15mg/L

	156	40.4	–	56.1	–	75.5	–	68.5	–
ASDAS inactive disease, %	16	19.4 <sup>c</sup>	4.2	21.1	6.5	26.3	0	8.8	1.8
	156	28.9	–	28.5	–	16.9	–	15.1	–
ASAS PR, %	16	12.5	2.8	23.7 <sup>a</sup>	3.2	15.8	3.2	11.8	4.8
	156	14.4	–	34.6	–	33.4	–	30.2	–

<sup>a</sup>P<0.0001, <sup>b</sup>P<0.001, <sup>c</sup>P<0.01, <sup>d</sup>P<0.05 vs PBO; NRI/MMRM data presented at Wk16. MI and MMRM presented at Wk156 included n=56 in normal and n=32, 18, and 53 in >5 to 10, >10 to 15, and >15mg/L elevated CRP groups, respectively. Data included pts (87/125) continuing in the extension trial for MEASURE 1 and all pts for MEASURE 2 at Wk156. LS, least squares; N, number of pts with available BL CRP at Wk16; n, number of pts at Wk156.

**Conclusions:** SEC 150 mg demonstrated sustained efficacy through 3 years in AS patients with both normal and elevated CRP levels, with an increased effect in elevated CRP patients.

#### LONG-TERM EFFECTS OF TNF-ALPHA INHIBITORS ON BONE MINERAL DENSITY AND THE INCIDENCE OF VERTEBRAL FRACTURES IN PATIENTS WITH ANKYLOSING SPONDYLITIS

K. Beek<sup>1</sup>, M. van der Weijden<sup>1</sup>, T. Rusman<sup>1</sup>, W. Lems<sup>1</sup>, C. van Denderen<sup>2</sup>, M. Nurmohamed<sup>1</sup>, I. van der Horst-Bruinsma<sup>1</sup>. <sup>1</sup>Rheumatology, Amsterdam Rheumatology immunology Centre/VUmc and Reade; <sup>2</sup>Rheumatology, Amsterdam Rheumatology immunology Centre/Reade, Amsterdam, Netherlands

**Background:** Ankylosing Spondylitis (AS) is not only characterised by pathological bone formation leading to ankylosis, but also by bone loss which may lead to vertebral fractures (VFX). TNF-alpha inhibitors (TNFi) have proven to be effective in blocking the inflammatory process. A few studies also showed an increase of Bone Mineral Density (BMD) in AS patients treated with TNFi<sup>1-3</sup>; however, the incidence of VFX after two years of treatment was increased.<sup>3-4</sup>

**Objectives:** To evaluate the long-term effect of TNFi on BMD and the incidence of VFX in patients with AS.

**Methods:** Consecutive TNFi naive AS patients (who fulfilled the Modified New York criteria) were included. Patients were recruited from the VUmc and Reade and were treated with TNFi for 4 years. BMD at hip and lumbar spine (LS) were measured at baseline and after 4 years. T-scores were categorised as 'normal BMD', 'osteopenia' and 'osteoporosis', based on the WHO osteoporosis criteria.<sup>5</sup> The incidence of VFX was determined by two observers using the Genant method.<sup>6</sup>

**Results:** In total, 107 AS patients with complete datasets (68.2% male) were included. The mean age was 42.6 years and the disease duration (time since diagnosis) was 11.0 years. The use of steroids or osteoporosis prophylaxis varied respectively between 0.9% and 2.8%. At baseline 40.1% of the patients had a decreased BMD of the hip and 40.2% of the spine, of whom 27 patients (26%) had both a decreased hip BMD as well as a decreased lumbar BMD. The BMD of spine and hip improved after 4 years of TNFi treatment (table 1). In 13 patients (12.1%), 14 VFX were observed both at baseline and after 4 years of TNFi-treatment, 26 VFX were observed in 21 patients.

After 4 years, 4 out of 21 patients with  $\geq 1$  VFX had a decreased BMD at hip and lumbar spine whereas the other 17 patients had a normal BMD. The majority of VFX was localised in the mid or lower thoracic spine.

Table 1 BMD measurement in spine and hip of 107 AS patients treated with TNFi.

	Baseline*	After 4 years of TNFi**
Osteopenia LS	34 (31.8)	25 (23.4)
Osteoporosis LS	9 (8.4)	2 (1.9)
Abnormal BMD LS	43 (40.2)	27 (25.3)
Osteopenia total hip	39 (36.4)	31 (29.0)
Osteoporosis total hip	4 (3.7)	3 (2.8)
Abnormal BMD total hip	43 (40.1)	34 (31.8)
Patients with VFX	13 (12.1)	21 (19.5)
Total number of VFX	14	26

\* 1 patient with spondylolysis; 4 patients with a total hip replacement

\*\* 2 patients with spondylolysis; 5 patients with a total hip replacement

LS: lumbar spine, Abnormal BMD = osteopenia and/or osteoporosis according to WHO guideline<sup>6</sup>

Vertebral fractures (VFX) are presented in number of patients with a VFX and the actual prevalence of VFX. Outcomes are presented in n (%)

\* p < 0.05, \*\* p < 0.001

**Conclusions:** The percentage of relatively young AS patients with a decreased BMD at baseline of the hip and lumbar spine was high (40%). After 4 years of TNFi-treatment, the BMD of the lumbar spine improved in 14.9% of the patients and of the hip in 8.3% of the patients. At baseline, 12% of the patients had vertebral fractures which increased to 21% after 4 years of treatment. A normal population of 1984 individuals above 50 years showed a prevalence of 8.9% osteoporotic spinal fractures.<sup>7</sup> Probably, the start of treatment with TNFi at an earlier stage of the disease might prevent the onset of fractures in AS.

#### CANADIAN ADALIMUMAB POST-MARKETING OBSERVATIONAL EPIDEMIOLOGICAL STUDY ASSESSING THE EFFECTIVENESS OF ADALIMUMAB VS. NON-BIOLOGIC DMARDS IN ANKYLOSING SPONDYLITIS (COMPLETE-AS): 12-MONTH EFFECTIVENESS DATA

L. Bessette<sup>1</sup>, M. Khraishi<sup>2</sup>, A. Chow<sup>3</sup>, V. Pavlova<sup>4</sup>, S. Silverberg<sup>5</sup>, J. Stewart<sup>6</sup>, V. Remple<sup>7</sup>. <sup>1</sup>Laval University, Centre Hospitalier de l'Université Laval, Quebec; <sup>2</sup>Memorial University of Newfoundland, St. John's; <sup>3</sup>University of Toronto, Toronto; <sup>4</sup>McMaster University, Hamilton; <sup>5</sup>Etobicoke General Hospital, Toronto; <sup>6</sup>University of British Columbia, Penticton; <sup>7</sup>AbbVie Corporation, Montreal, Canada

**Background:** COMPLETE-AS is an ongoing Canadian observational study of anti-TNF $\alpha$  naive adults with active AS per the judgment of the treating physician, who require change in current AS treatment to either<sup>1</sup> a subsequent NSAID or non-biologic disease modifying antirheumatic drug (nbDMARD group), or<sup>2</sup> to adalimumab (ADA group).

**Objectives:** The aim of this analysis was to describe and compare the baseline demographic and disease parameters of patients in the nbDMARD and ADA groups and to compare the 12 month effectiveness of the two treatment methods.

**Methods:** In the current analysis patients enrolled between July/2011 – Jun/2016 were included. Outcome measures analysed were extra articular manifestations (EAM 1: IBD, psoriasis, uveitis, enthesitis; EAM 2: IBD, uveitis, enthesitis), disease activity (BASDAI), functional status (BASFI), and quality of life (QoL; SF-12). Between-group differences in baseline parameters were assessed with the Chi-square test for categorical variables and the independent samples t-test for continuous variables. Baseline-adjusted changes in BASDAI and BASFI over time were compared between the two groups using linear mixed models.

**Results:** A total of 609 patients (nbDMARD n=177, ADA n=432) were included in the current analysis. No significant differences in baseline demographics were observed between the two groups. However, at baseline, patients initiating ADA were more likely to be unemployed (38% ADA vs. 27.1% nbDMARD, p=0.009), had higher mean BASDAI (6.4 vs. 5.0; p<0.001) and BASFI (5.5 vs. 3.7; p<0.001) scores, and worse QoL (SF-12 PCS: 24.4 vs. 24.7, p=0.002) at baseline. The baseline prevalence of EAMs was comparable between the two groups (EAM 1: 34.7% vs. 31.6%, p=0.454; EAM 2: 25.9% vs. 22.6%, p=0.381). However, IBD was more common among patients initiating ADA treatment (9% vs. 4.5%, p=0.062).

After 12 months of treatment the prevalence of EAMs decreased significantly in the ADA group (EAM 1: p=0.004; EAM 2: p=0.033) but not in the nbDMARD group. After adjusting for baseline values, patients treated with ADA had numerically lower BASDAI score (least square means – LSM: 3.7 vs. 4.3, p=0.171) significantly lower BASFI score (2.9 vs. 3.6, p=0.031) scores, and comparable SF12-

PCS (24.9 vs. 24.7, p=0.210) and SF12-MCS (19.1 vs. 18.9, p=0.532) scores at 12 months.

During follow-up, 7.4% of ADA patients initiated another biologic and 23.7% of patients in the nbdMARD group initiated biologic treatment (p<0.001).

**Conclusions:** AS patients initiating ADA in Canadian routine clinical care have significantly greater disease severity and impaired quality of life at baseline compared with those initiating non-biologic treatment. Treatment with ADA for 12 months resulted in greater reduction in the prevalence of EAMs and a greater reduction in disease severity scores compared to treatment with non-biologic agents.

SAT0291

**CREATION OF A EUROPEAN DATABASE OF PATIENTS WITH AXIAL SPONDYLOARTHRITIS TREATED IN CLINICAL PRACTICE– INITIAL, PRELIMINARY FINDINGS FROM THE EUROSPA RESEARCH NETWORK COLLABORATION**

L.M. Ørnberg, M. Østergaard, F. Onen, G. Can, Z. Rotar, M. Tomsic, B. Gudbjornsson, A.J. Geirsson, M.J. Santos, A. Barcelos, D. Nordström, K. Aaltonen, M.J. Nissen, A. Ciurea, E.K. Kristianslund, T. Kvien, C. Codreanu, E.-M. Hauge, L. Jacobsson, H. Mann, G. Jones, F. Iannone, M.V. Hernandez, I. van der Horst-Bruinsma, L.H. Hyldstrup, N.S. Krogh, M.L. Hetland. *EuroSpA Research Collaboration Network, Coordinating Centre, On behalf of the DANBIO, TURKBIO, biorx.si, ICEBIO, Reuma.pt, ROB-FIN, SCQM, NOR-DMARD, RRRB, ARTIS, ATTRA, BSRBR-AS, GISEA, BIOBADASER and ARC registries, Copenhagen, Denmark*

**Background:** A research network collaboration of 15 European registries sharing data on patients with spondyloarthritis (SpA), “EuroSpA”, has recently been created to strengthen research capabilities in the real world setting<sup>1</sup>. Here we present the first results from the collaboration.

**Objectives:** To investigate the feasibility of creating a common database for axial SpA (axSpA), including non-radiographic SpA and ankylosing spondylitis, within the EuroSpA collaboration and to conduct proof-of-concept analyses by investigation of baseline characteristics, disease activity at baseline and after 6 months, and crude 12 months’ Tumour Necrosis Factor inhibitor (TNFi) retention rate in patients with axSpA initiating TNFi.

**Methods:** A common data model was agreed upon by the EuroSpA Scientific Committee. Virtual meetings between the EuroSpA and registry data managers clarified data availability and structure. This was followed by upload of anonymized data through the secure Virtual Private Network pipelines to the EuroSpA server. Baseline characteristics and disease activity at baseline and after 6 months were investigated with non-parametric descriptive statistics. Kaplan-Meier estimation was used to investigate TNFi retention rates.

**Results:** By January 8th 2018, four of the 15 registries participating in EuroSpA had completed data upload to the EuroSpA database resulting in 6756 patients with AxSpA in a pooled dataset. Baseline characteristics of the participating registry populations at initiation of first TNFi are shown in Table I. Crude 12 months’ TNFi retention rate varied from 66%–85% for 1 st TNFi and 61%–78% for 2nd TNFi (see figure 1). For the pooled dataset crude 12 months’ TNFi retention rates were 73% and 66% for the 1 st and 2nd TNFi, respectively.

**Abstract SAT0291 – Table 1.** Baseline demographic and disease characteristics of patients with social spondyloarthritis registered in four registries participating in the EuroSpA Research Network Collaboration.

VAS Pain, mm	64 (49-70)	25 (10-50)	70 (50-80)	30 (16-50)	72 (50-80)	28 (16-50)	65 (46-77)	14 (6-33)

**Conclusions:** Preliminary analyses showed differences across European registries regarding baseline characteristics and crude retention rates in axSpA patients initiating TNFi. These initial, preliminary analyses demonstrate that the creation of a large European database of axSpA patients treated in routine care based on a common data model is feasible, offering important opportunities for future research.

SAT0292

### EVALUATION OF RADIOGRAPHIC PROGRESSION AFTER 4 YEARS OF ETANERCEPT (ETN) IN ANKYLOSING SPONDYLITIS (AS): RESULTS FROM THE OPEN-LABEL EXTENSION (OLE) OF THE PHASE 3 CLINICAL TRIAL

N. Haroon<sup>1</sup>, R.D. Inman<sup>1</sup>, M. Fairbairn<sup>2</sup>. <sup>1</sup>University Health Network, University of Toronto, Toronto; <sup>2</sup>Amgen Canada Inc., Mississauga, Ontario, Canada

**Background:** ETN was well tolerated and showed clinical efficacy (ASAS 20: ETN 59%, placebo 28%,  $p < 0.0001$ ) through 24 wks in a phase 3 AS trial;<sup>1</sup> efficacy was sustained up to 2 years in pts who completed the study and continued ETN in an OLE.<sup>2</sup> No significant difference was found in change in modified Stoke AS Spine Score (mSASSS) from baseline (BL) to yr 2 of the OLE among ETN-treated pts vs a historic cohort not treated with tumour necrosis factor inhibitors (TNFi).<sup>3</sup>

**Objectives:** Report radiographic progression through 4 years in ETN-treated pts with AS.

**Methods:** In the double-blind, placebo-controlled phase 3 study, pts with active AS were randomised to ETN 25 mg BIW or placebo for 24 wks. Pts who completed the study could enrol in a 168-wk OLE and were treated with ETN 25 mg BIW (amended after 17 months to 50 mg QW). The primary radiographic endpoint was change in mSASSS from BL to yr 2 vs change in mSASSS from yr 2 to yr 4.

**Results:** 257 pts were treated in the OLE, of whom 126 (49.0%) completed the study and 131 (51.0%) withdrew prior to 168 wks (most common reasons [ $>5\%$ ]: pt refusal [10.1%]; adverse event, infection, or injection-site reaction [8.2%]; lack of efficacy [7.8%]). ETN resulted in sustained improvement in signs and symptoms of active disease for up to 168 wks beyond the 24-wk double-blind study. Of 267 pts who received  $\geq 1$  dose of ETN in the phase 3 study or OLE, 124 were included in the 4 year primary radiographic endpoint analysis (8 received a prohibited TNFi and were excluded). BL characteristics were similar between these pts and all pts who received  $\geq 1$  dose of ETN in the phase 3 study. Mean change in mSASSS among completers was 1.96 from BL to yr 4 ( $n=110$ ) while change in mean mSASSS between yr 2 and yr 4 was 0.66 ( $n=109$ ). The nominal  $p$ -value for change in mSASSS from BL to yr 2 vs change from yr 2 to yr 4 was 0.0536. Radiographic data suggest disease progression continued in pts receiving ETN continuously over 4 years; however, mean mSASSS increased from BL to year 2 and not from yr 2 to yr 4 (figure 1) due to a few outlier patients with large mSASSS values at yr 2 but missing 4 year data.

Abstract SAT0292 – Table 1. Baseline Demographic and Disease Characteristics

	Pts Who Received $\geq 1$ Dose of ETN in the Phase 3 Study or Its Extension and Had Baseline, 2 year, and 4 year X-rays ( $n=127$ )
Mean (SD) age, yrs	42.43 (9.63)
Male, n (%)	89 (70.1)
HLA-B27 positive, n (%)	100 (78.7)
Used NSAIDs, n (%)	115 (90.6)
Used DMARDs, n (%)	43 (33.9)
Used corticosteroids, n (%)	16 (12.6)
Mean (SD) mSASSS	16.7 (16.3)
Mean (SD) disease duration, yrs	10.61 (8.67)

Abstract SAT0292 – Figure 1. Mean mSASSS

**Conclusions:** This is the first report of 4 year radiographic ETN data in AS, and these data suggest that disease progression continued in pts who received ETN continuously throughout, but that disease progression may be slower after longer-term treatment with ETN vs shorter term. This adds to the already-existing data that demonstrate TNFi seem to reduce radiographic progression in pts with AS.

SAT0293

### SAFETY AND EFFICACY OF TOFACITINIB, AN ORAL JANUS KINASE INHIBITOR, UP TO 36 MONTHS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: DATA FROM THE THIRD INTERIM ANALYSIS OF OPAL BALANCE, AN OPEN-LABEL, LONG-TERM EXTENSION STUDY

P. Nash<sup>1</sup>, L.C. Coates<sup>2</sup>, A.J. Kivitz<sup>3</sup>, P.J. Mease<sup>4</sup>, D.D. Gladman<sup>5</sup>, J. A. Covarrubias-Cobos<sup>6</sup>, D. Fleishaker<sup>7</sup>, C. Wang<sup>7</sup>, E. Kudlacz<sup>7</sup>, S. Menon<sup>7</sup>, L. Fallon<sup>8</sup>, T. Hendrikx<sup>9</sup>, K.S. Kanik<sup>7</sup>. <sup>1</sup>University of Queensland, Brisbane, Australia; <sup>2</sup>University of Oxford, Oxford, UK; <sup>3</sup>Altoona Center for Clinical Research, Duncansville; <sup>4</sup>Swedish Medical Center and University of Washington, Seattle, USA; <sup>5</sup>University of Toronto, Toronto Western Hospital, Toronto, Canada; <sup>6</sup>Unidad Reumatologica Las Americas S.C.P, Mérida, Mexico; <sup>7</sup>Pfizer Inc, Groton, USA; <sup>8</sup>Pfizer Canada, Montreal, Canada; <sup>9</sup>Pfizer Inc, Collegetown, USA

**Background:** Tofacitinib is an oral Janus kinase inhibitor for the treatment of psoriatic arthritis (PsA).

**Objectives:** To report the safety, tolerability and efficacy of tofacitinib in patients (pts) with active PsA from an ongoing, open-label, long-term extension (LTE) study (OPAL Balance, NCT01976364; November 2017 data-cut; database not locked).

**Methods:** Eligible pts from 2 Phase (P)3 tofacitinib PsA studies (OPAL Broaden, NCT01877668; OPAL Beyond, NCT01882439) entered a 3 year LTE  $\leq 3$  months after completing the P3 study or discontinuing for reasons unrelated to study drug. Pts received tofacitinib 5 mg BID to Month (M)1, after which dose adjustments between 5 and 10 mg BID were permitted to improve efficacy, or for safety reasons. Pts receiving a csDMARD at P3 study entry continued the same csDMARD in the LTE. Primary endpoints were incidence and severity of adverse events (AEs) and changes from baseline ( $\Delta$ ) in laboratory values. Safety data are reported up to M36. Efficacy was evaluated up to M30 (when  $n > 50$ ) as a secondary endpoint.

**Results:** 686 pts were treated in OPAL Balance; 468 (68.2%) remained in the study at data cut-off. Mean (range) LTE tofacitinib exposure was 614 (1–1032) days. On Day 1, 675 pts (98.4%) received a csDMARD, which was discontinued in 86 pts (12.7%). To M36, 2189 AEs were reported in 546 pts (79.6%), 95 pts (13.8%) had serious AEs and 59 pts (8.6%) discontinued due to AEs. Serious infections occurred in 12 pts (1.7%), herpes zoster (HZ) in 20 pts (2.9%; 1 serious event), major adverse cardiovascular events in 5 pts (0.7%), malignancies in 24 pts (3.5%; including 12 pts with NMSC) and uveitis in 2 pts (0.3%). No AEs of gastrointestinal perforation or inflammatory bowel disease were reported. There were 5 deaths (not attributed to treatment, as assessed by the investigator) due to metastatic pancreatic carcinoma, acute cardiac failure/hypertensive heart disease, chronic obstructive pulmonary disease, pulmonary embolism and cardiovascular insufficiency. Four AEs of latent tuberculosis were reported in pts whose previously negative QuantiFERON response became positive. ALT was elevated  $\geq 3 \times$  ULN in 27 pts (4.0%), and AST  $\geq 3 \times$  ULN in 15 pts (2.2%). Changes in laboratory values observed in P3 studies were generally stable in the LTE, except for a modest decrease in absolute lymphocyte count over time. Eight pts (1.2%) discontinued (protocol-mandated) due to laboratory value changes. ACR responses,  $\Delta$ HAQ-DI, PASI75 response,  $\Delta$ Leeds Enthesitis Index,  $\Delta$ Dactylitis Severity Score and  $\Delta$ Pain were maintained up to M30.

**Conclusions:** Over 36 months in the LTE, the safety profile of tofacitinib in active PsA pts was generally similar to that of the P3 studies. No new safety risks were identified. Efficacy across various PsA disease domains was maintained over time.

SAT0294

### ASSOCIATION OF ENTHESITIS WITH ACHIEVEMENT OF NORMAL QUALITY OF LIFE AND CLINICAL RESPONSE IN PATIENTS WITH NON-RADIOGRAPHIC AXIAL SPONDYLOARTHRITIS TREATED WITH ADALIMUMAB

P.J. Mease<sup>1</sup>, F. Van den Bosch<sup>2</sup>, U. Kiltz<sup>3</sup>, P. Zueger<sup>4</sup>, K. Chen<sup>4</sup>, M. Wu<sup>4</sup>, J. K. Anderson<sup>4</sup>. <sup>1</sup>Swedish Medical Center and University of Washington, Seattle, USA; <sup>2</sup>Ghent University, Ghent, Belgium; <sup>3</sup>Rheumazentrum Ruhrgebiet, Herne, Germany; <sup>4</sup>AbbVie, North Chicago, USA

**Background:** Enthesitis, a key pathology in axial spondyloarthritis (axSpA), has been difficult to treat with conventional therapies and may take longer to resolve than other disease manifestations. It is unknown if failure to attain resolution of enthesitis affects achievement of normal quality of life (QoL) and clinical response.

**Objectives:** To assess if enthesitis at baseline (BL) and after 12 wks of adalimumab (ADA) treatment in the ABILITY-3 study associates with achieving normal QoL and clinical response in patients (pts) with non-radiographic axSpA (nr-axSpA).

**Methods:** ABILITY-3 enrolled adult pts with nr-axSpA with objective evidence of inflammation (MRI positive or elevated hsCRP), active disease at BL (ASDAS  $\geq 2.1$ , BASDAI $\geq 4$ , and Patient's Assessment of Total Back Pain score  $\geq 4$ ), and an inadequate response to  $\geq 2$  NSAIDs. Pts received ADA 40 mg every other wk during a 28-wk open-label lead-in. Pearson's correlation coefficients were used to assess the relationship between total enthesitis count (sum of Maastricht Ankylosing Spondylitis Enthesitis Score [MASES] and plantar fascia enthesitis score) and QoL and disease activity at BL. Multivariable stepwise logistic regression was used to evaluate the relationship between total enthesitis count or enthesitis location and normal QoL (EQ-5D $\geq 0.898$  or SF36 MCS/PCS $\geq 50$ ) and clinical response (ASDAS-ID [ASDAS  $< 1.3$ ], ASAS40, or BASDAI50) at wk 12.

**Results:** At BL, 74% (501/673) of pts had enthesitis, and mean (95% CI) total enthesitis count was 3.7 (3.42, 3.98). Enthesitis resolved in 39% (196/501) of pts, and total enthesitis count was 1.9 (1.68, 2.12) at wk 12 of ADA treatment. At BL, total enthesitis count significantly correlated with all QoL and disease activity measures (Table). Each 1-unit increase in BL total enthesitis count was associated with 7% lower odds of ASDAS-ID (OR [95% CI]: 0.93 [0.88, 0.99],  $p=0.018$ ) and 6% lower odds of BASDAI50 (0.94 [0.89, 0.99],  $p=0.024$ ) at wk 12 and was not associated with normal QoL or ASAS40 at wk 12. Total enthesitis count at wk 12 was associated with lower odds of normal QoL and clinical response at wk 12 (Table). Achievement of normal QoL at wk 12 was less likely if pts had BL enthesitis at the posterior (EQ-5D $\geq 0.898$ ) or anterior superior iliac spine (SF36 PCS  $\geq 50$ ), and pts with BL enthesitis at the 7th costochondral joint were less likely to achieve clinical response at wk 12 (Table).

**Abstract SAT0294 – Table 1.** Association of Total Enthesitis Count With QoL and Disease Activity at BL and Clinical Response at Wk 12

Locations evaluated included 1st costochondral joint L/R, 7th costochondral joint L/R, anterior superior iliac spine L/R, posterior superior iliac spine L/R, iliac crest L/R, 5th lumbar spinous process, proximal insertion of Achilles tendon L/R, and plantar fascia L/R. ASAS40, Assessment of SpondyloArthritis international Society 40% improvement; ASDAS-ID, Assessment of SpondyloArthritis international Society inactive disease; BASDAI, Bath Ankylosing Spondylitis Disease Activity Index; EQ-5D, EuroQol 5 dimension; MCS, mental component summary; PCS, physical component summary; QoL, quality of life; SF-36, short form health survey.

\* $P < 0.001$ ; † $P < 0.01$ ; ‡ $P < 0.05$ .

**Conclusions:** 39% of pts achieved complete resolution of enthesitis after 12 wks of ADA treatment. Total enthesitis count at BL was not associated with normal QoL and inversely associated with clinical response at wk 12. Total enthesitis count at wk 12 was negatively associated with normal QoL and clinical response. Our exploratory analysis suggested possible inverse associations of specific BL enthesitis sites with achievement of normal QoL and clinical response; however, additional research is needed to further define these relationships.

SAT0295

### TOOL FOR THE PRESCRIPTION OF EXERCISE IN SPONDYLOARTHRITIS WITH MULTIMEDIA ANIMATIONS (EJES-3D): PILOT STUDY

R. Almodovar<sup>1</sup>, M.T. Florez<sup>2</sup>, P. Zarco<sup>1</sup>, L. Carmona<sup>3</sup> on behalf of EJES -3D GROUP. <sup>1</sup>Rheumatology Unit; <sup>2</sup>Rehabilitation Unit, Hospital Universitario Fundación Alcorcón; <sup>3</sup>Instituto de Salud Musculoesquelética, MADRID, Spain

**Background:** Exercise is a basic pillar in the management of axial spondyloarthritis (SpA-axe), together with pharmacological treatment<sup>1,2</sup>. Since it has been shown to improve pain, inflammation, mobility, physical and respiratory function. The information provided to the patient on paper on exercises has limitations of understanding. To this must be added the barriers to exercise that patients perceive, such as the lack of adaptation of the exercises according to the SpA phases

and the contradictory messages among professionals. Therefore we decided to develop an electronic tool to facilitate and encourage the prescription of exercise.

**Objectives:** To evaluate the usefulness of a computer tool and a training workshop to improve the prescription of physical exercise in SpA by rheumatologists.

**Methods:** An online platform was developed for the individualised prescription of exercise to patients with SpA according to stage and with 3D animations (EJES-3D), which was presented in a training workshop. Tests were conducted before and after the workshop to assess the change in knowledge. Six months after the workshop, the degree of use and acceptance of the tool was evaluated through a survey aimed at rheumatologists and the fulfilment of the concepts learned through a survey of 100 consecutive patients attended in the centres of the attendees.

**Results:** The level of knowledge improved with the workshop (6.8/10 to 7.7). After 6 months 77.8% indicated that the contents of the workshop were useful and adapted to their expectations and all applied the knowledge. 22% stated that they prescribed exercise more regularly and 44% with greater confidence. 67% of rheumatologists considered the tool EJES-3D useful. The 82 patients who completed the survey agreed in their majority that they had been prescribed exercise, they had been informed and the messages received had been positive and coherent. 50% of the patients were prescribed specific exercises, which were qualified by them as simple, adaptable and attractive. And 64% were satisfied with the degree of exercise they performed. On the other hand, aspects to be improved at the tool and training level were identified.

**Conclusions:** The specialised training in the prescription of the exercise directed to the professionals who are in charge of the management of patients with SpA can be very beneficial to homogenise the type of exercise in each phase of the disease and help to gain confidence. In addition to having a specific tool (EJES-3D) to perform individualised prescription, it can be very useful.

#### PATIENTS WITH DIFFUSE IDIOPATHIC SKELETAL HYPEROSTOSIS AND LOW BACK PAIN – EVALUATION AND REHABILITATION

R. Traistaru<sup>1</sup>, D. Kama<sup>2</sup>, A.M. Bumbea<sup>1</sup>, C. Kamal<sup>1</sup>, O. Rogoceanu<sup>1</sup>. <sup>1</sup>University of Medicine and Pharmacy of Craiova; <sup>2</sup>Elga CLINIC, CRAIOVA, Romania

**Background:** Diffuse Idiopathic Skeletal Hyperostosis (DISH) generally occurs in people between the ages of 50 and 60, more often in men than women. Physical therapy and kinetic program may help delay the loss of motion in affected joints and control the low back pain (LBP). In most cases of DISH with LBP, certain muscles of the back that stabilise the spine are reflexively inhibited and do not spontaneously recover even if patients are pain free with a return to normal activity levels.

**Objectives:** In our observational study we evaluated the role of rehabilitation program in quality of life and assessed the thickness of the erector spinae (ES) muscle in these patients and to evaluate the correlation between thickness difference in three different trunk postures and functional parameters.

**Methods:** 38 male patients (61.5 years mean age) with DISH and LBP were enrolled in this study. Frontal (AP) and lateral lumbosacral regions were radiologically evaluated. Clinical and functional parameters were collected by a physiotherapist, that applied rehabilitation program (12 sessions of TENS, interferential current, ultrasound, aerobic training) and an US examination was performed by a physiatrist within 72 hours of the clinical examination. We performed ultrasonography to measure the thickness of the ES muscle at L4 and L5 level in maximum flexion, neutral posture, and maximum extension. All collected clinical and imaging data were statistical analysed, pre-post rehabilitation.

**Results:** Multivariate analysis showed that thickness differences between flexed and neutral, and flexed and extended maximally positions were correlated statistically with functional parameters (VAS and The Roland-Morris Disability Questionnaire score). We obtained a significant improvement in VAS ( $p < 0.01$ ) and Disability Questionnaire score ( $p < 0.05$ ) after supervised rehabilitation program.

**Conclusions:** Although ossification in DISH generally affects the ligament of the spine, pain is more likely to arise in correlation with the erector vertebral muscle status. Visual observation of the image during contraction indicates that US may

be a valuable biofeedback tool. Kinetic program (regular exercises that strengthen spine, walking and global stretching), avoiding sitting position for long periods of time, sleep on a correct mattress and optimal daily activities are the most important recommendations for all patients with DISH.

#### THE ROLE OF BASELINE CONCOMITANT USE OF CONVENTIONAL SYNTHETIC DISEASE MODIFYING ANTI-RHEUMATIC DRUGS WITH TNF INHIBITORS IN SPONDYLOARTHRITIS PATIENTS

S. Akar<sup>1</sup>, S. Kiraz<sup>2</sup>, O. Gercik<sup>1</sup>, I. Ertenli<sup>2</sup>, O. Kucuksahin<sup>2</sup>, E. Dalkilic<sup>3</sup>, C. Bes<sup>4</sup>, T. Kasifoglu<sup>5</sup>, H. Emmungil<sup>6</sup>, S.S. Koca<sup>7</sup>, M. Cinar<sup>2</sup>, V. Yazisiz<sup>8</sup>, B. Kelesoglu Dincer<sup>2</sup>, A. Ates<sup>2</sup>, N. Alpay Kanitez<sup>4</sup>, S. Erten<sup>2</sup>, S. Turan<sup>6</sup>, Y. Pehlivan<sup>3</sup>, B. Oz<sup>7</sup>, S. Yasar Bilge<sup>5</sup>, A. Erden<sup>2</sup>, B. Armagan<sup>2</sup>, B.N. Coşkun<sup>3</sup>, U. Kalyoncu<sup>2</sup>. <sup>1</sup>TURKBIO biological registry, Izmir; <sup>2</sup>TReasure biological registry, Ankara; <sup>3</sup>TReasure biological registry, Bursa; <sup>4</sup>TReasure biological registry, Istanbul; <sup>5</sup>TReasure biological registry, Eskisehir; <sup>6</sup>TReasure biological registry, Edirne; <sup>7</sup>TReasure biological registry, Elazig; <sup>8</sup>TReasure biological registry, Antalya, Turkey

**Background:** Conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) are drugs of choice in the treatment of rheumatoid arthritis and their concomitant use with TNFi is also of unequivocal importance. On the other hand there is limited evidence regarding the efficacy of csDMARD in axial spondyloarthritis (SpA) and concomitant use with TNFi are not recommended. However recently there is conflicting results about the comedication with csDMARD on the TNFi drug survival in patients with AS.

**Objectives:** To evaluate the effect of concomitant csDMARD use on first TNFi drug survival in patients with spondyloarthritis.

**Methods:** The data of patients that have been included in two Turkish registries (TURKBIO (n=356) and TReasure (n=1382)) with the diagnosis of ankylosing spondylitis (AS) or SpA obtained. Drug survival was calculated from the date of first TNFi prescription to the last visit or until the stop date of first biologic agent. For drug survival analysis Kaplan-Meier method with log-rank test. Cox proportional hazard method was used to evaluate the relative effects of each covariate on the drug survival.

**Results:** In total 1738 patients (1040 [59.1%] male, median [range] age 39<sup>16–81</sup> years) with SpA initiating first TNFi were included in the analysis. Median disease duration was 116 months. 690 (39.7%) patients received adalimumab and 135 (22.3%) etanercept, 324 (18.6%) infliximab, 202 (11.6%) golimumab and 135 (7.8%) certolizumab. At the time of first biologic prescription 794 (45.7%) were using sulfasalazine or methotrexate. Baseline median BASDAI score was 60 (0–100), BASFI score was 46 (0–100), patient global assessment of disease activity was 70 (0–100), ESR was 23<sup>1–140</sup> mm/h and median CRP value was 13 (0–659) mg/L. In our study group median drug survival time was 12 (0–205) months. In total 585 (33.7%) of our patients stop their first TNFi. 323 (55.2) patients discontinued the medication due to inefficacy, 133 (22.7) due to adverse effect. Drug survival was significantly better in patients using concomitant csDMARDs at baseline (with a median survival 104 vs 30 months;  $p < 0.001$ ; figure). In Cox regression model baseline age (HR 0.978,  $p = 0.028$ ), and concomitant csDMARD usage (HR 0.341,  $p < 0.001$ ) were found to be as the predictors for better drug survival, female sex (HR 1.546,  $p = 0.039$ ), presence of psoriasis (HR 3.803,  $p = 0.015$ ), enthesitis

(HR 1.619,  $p=0.018$ ) and uveitis (HR 1.732,  $p=0.025$ ) as predictors for worse drug survival. At the time of censoring only 202 (11.6%) patients were using csDMARDs with TNFi agent. When we repeat the analysis with patients continuing csDMARDs we showed that there is no significant differences regarding TNFi survival.

**Conclusions:** The results of present study showed that considerable amount of SpA patients were using csDMARDs at time of first TNFi initiating and drug survival was significantly better in those patients.

### SAT0298 TRANSCUTANEOUS VAGUS NERVE STIMULATION IN PATIENTS WITH PSORIATIC ARTHRITIS OR ANKYLOSING SPONDYLITIS

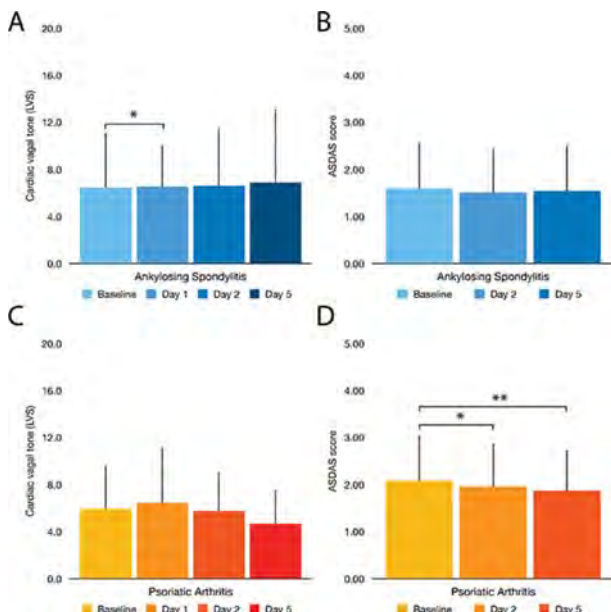

S.E. Rasmussen<sup>1</sup>, C. Brock<sup>1,2</sup>, A. Mohr Drewes<sup>1</sup>, M. Pfeiffer Jensen<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Aarhus University Hospital, Aarhus C; <sup>2</sup>Mech-Sense, Department of Medical Gastroenterology, Aalborg University Hospital, Aalborg, Denmark

**Background:** Psoriatic arthritis and ankylosing spondylitis are chronic autoimmune diseases characterised by inflammation of both peripheral and spinal joints. The chronic inflammation may lead to impaired functionality and absenteeism from work. It has become increasingly accepted that the vagus nerve plays a pivotal role as a communicator between the immune and nervous systems<sup>1</sup>. Recent studies in similar immune-mediated inflammatory diseases have demonstrated promising anti-inflammatory effect of vagus nerve stimulation<sup>2,3</sup>.

**Objectives:** We hypothesised that transcutaneous vagus nerve stimulation (t-VNS) would increase the activity of the vagus nerve, and that this enhanced parasympathetic tone would reduce inflammation and disease activity. The aims of this study were to investigate the effects of t-VNS on cardiac vagal tone and disease activity in patients with psoriatic arthritis or ankylosing spondylitis.

**Methods:** Twenty patients diagnosed with psoriatic arthritis (median disease duration 7.0 years) and 17 patients diagnosed with ankylosing spondylitis (median disease duration 4.5 years) were included in the study. Transcutaneous vagus nerve stimulation for 120 s was performed bilaterally, thrice daily for four days, using a non-invasive handheld device. Cardiac vagal tone, measured on a linear vagal scale (LVS), and disease activity scores were assessed on the 1st, 2nd and 5th day.

**Results:** In the ankylosing spondylitis group, cardiac vagal tone was significantly increased 30 min after t-VNS in comparison to baseline (6.46 vs. 6.57. LVS,  $p<0.05$ ) (figure 1A), accompanied by a significant reduction in heart rate (68.44 vs. 65.37,  $p<0.01$ ). Transcutaneous vagus nerve stimulation did not change cardiac vagal tone in the psoriatic arthritis group (figure 1C), however, a significant reduction in heart rate 30 min after t-VNS in comparison to baseline was observed (71.26 vs. 68.04,  $p<0.01$ ). A significant reduction in ASDAS score was demonstrated in the psoriatic arthritis group on both day 2 (2.09 vs. 1.96,  $p<0.05$ ) and day 5 (2.09 vs. 1.88,  $p<0.01$ ) (figure 1D).

**Abstract SAT0298 – Figure 1.** Cardiac vagal tone and ASDAS score. \* $p<0.05$ , \*\* $p<0.01$

**Conclusions:** Transcutaneous vagus nerve stimulation may have an acute effect on cardiac vagal tone and heart rate in patients with ankylosing spondylitis and psoriatic arthritis. The observed effect of t-VNS on ASDAS scores in patients with psoriatic arthritis was not associated with a modulation of cardiac vagal tone.

### SAT0299 REAL WORLD SECUKINUMAB STUDY IN AS AND PSA – COMORBIDITIES AND EXTRAARTICULAR MANIFESTATIONS: INCIDENCE AND STATUS THROUGHOUT NON-INTERVENTIONAL AQUILA STUDY IN GERMANY

U. Kiltz<sup>1</sup>, P. Kästner<sup>2</sup>, H. Krauel<sup>2</sup>, I. Schwarze<sup>3</sup>, J. Brandt-Jürgens<sup>4</sup>, M. Maier-Peuschel<sup>5</sup>, C. Legeler<sup>5</sup>, J. Veit<sup>5</sup>, H.-P. Tony<sup>6</sup> on behalf of the AQUILA Study Group. <sup>1</sup>Rheumazentrum Ruhrgebiet, Herne; <sup>2</sup>Ambulantes Rheumazentrum, Erfurt; <sup>3</sup>Praxis für internistische Rheumatologie, Leipzig; <sup>4</sup>Rheumatologische Schwerpunktpraxis, Berlin; <sup>5</sup>Novartis Pharma GmbH, Nürnberg; <sup>6</sup>Medizinische Klinik II – Rheumatologie/Immunologie, Universitätsklinikum Würzburg, Würzburg, Germany

**Background:** Patients with psoriatic arthritis (PsA) or ankylosing spondylitis (AS) may suffer from extraarticular manifestations (EAM) (uveitis, psoriasis) and have higher rates of comorbidities like cardiovascular diseases (CVD) or depression than the normal population. Comorbidities should be kept in mind when managing pts with PsA and AS, as they can contribute to increased mortality and influence disease activity<sup>1</sup>.

**Objectives:** The aim of this interim analysis is to evaluate the incidence of selected EAM and comorbidities at baseline and the impact of secukinumab on the status of these attributes compared to baseline.

**Methods:** The presence and severity of uveitis and psoriasis (assessed by PASI) as well as diagnosis of coronary heart disease (CHD), stroke, heart insufficiency, and depression (assessed by Becks Depression Inventory (BDI-II)) were documented according to clinical routine at baseline and at week 4, 16, 24 and 52 after initiation of secukinumab. At baseline 486 patients were included and observed up to 52 weeks, at the time of analysis not all patients have already reached the end of the study, therefore the results are presented as observed.

**Results:** As expected, current plaque psoriasis was very frequent in PsA pts (63.3%), but also present in AS pts (11.5%) at baseline. For PsA pts, median PASI improved from 5.0 at baseline to 0.0 at wk 52. Half of pts with available PASI achieved clear skin at wk 52 (Tab 1).

Uveitis was more frequent in AS pts than in PsA pts (6.2% vs 0.9%). Only 1 AS pt and 2 PsA pts experienced new onset of uveitis.

CVD were more frequent in PsA than in AS patients at baseline: CHD (PsA 8.9%, AS 3.5%), heart failure (PsA 3.3%, AS 0.7%) and stroke (PsA 2.4%, AS 0.0%). During 52 wks study duration none comorbidity worsened with secukinumab treatment. Two patients with PsA were newly diagnosed with CHD and heart insufficiency throughout wk 52. No new stroke occurred.

Depression was common in both populations (PsA 15.4%, AS 12.2%) at baseline. Up to wk 52 median BDI-II improved from 12.0 to 6.0 (AS pts) and from 9.0 to 6.0 (PsA pts [Tab 1]).

**Abstract SAT0299 – Table 1.** PASI and BDI response under secukinumab

	Baseline	Wk 4	Wk 16	Wk 28	Wk 40	Wk 52
PASI 100 n(%)	0 (0.0)	7 (13.0)	23 (34.3)	28 (47.5)	18 (41.9)	15 (50.0)
PASI 75 n(%)	0 (0.0)	9 (16.7)	26 (38.8)	33 (55.9)	21 (48.8)	18 (60.0)
BDI-II (AS pts)	12.0	9.0	8.0	8.0	7.5	6.0
BDI-II (PsA pts)	9.0	8.0	7.5	8.0	7.0	6.0

**Conclusions:** Incidence of CVD and depression in PsA and AS pts is generally comparable to the published literature<sup>2,3</sup>. However, in contrast to other studies<sup>4</sup>, previous uveitis was less frequently reported in SpA pts selected for treatment with a IL-17 inhibitor, particularly in the AS group. Cardiovascular comorbidities remained overall stable under secukinumab up to wk 52. Plaque psoriasis and depressive mood improved with Secukinumab treatment.

SAT0300

#### TREATMENT EXPERIENCE AND SATISFACTION IN ANKYLOSING SPONDYLITIS PATIENTS TREATED WITH SECUKINUMAB: RESULTS FROM A US WEB-BASED SURVEY

M. Magrey<sup>1</sup>, M. Bozyczko<sup>2</sup>, D. Wolin<sup>3</sup>, M. Mordin<sup>3</sup>, L. Mcleod<sup>3</sup>, E. Davenport<sup>3</sup>, Y. Park<sup>4</sup>. <sup>1</sup>Case Western Reserve University, Cleveland, OH; <sup>2</sup>National Psoriasis Foundation, Portland, OR; <sup>3</sup>RTI Health Solutions, Research Triangle Park, NC; <sup>4</sup>Novartis Pharmaceuticals Corporation, East Hanover, NJ, USA

**Background:** Secukinumab is the only interleukin-17A inhibitor approved for the treatment of ankylosing spondylitis (AS). There are limited real-world data about treatment experience and patient satisfaction with secukinumab among patients with AS.

**Objectives:** To evaluate real-world treatment experience and satisfaction with secukinumab in US patients with AS.

**Methods:** Data on demographics, AS symptoms, treatment history, and treatment satisfaction were collected from a cross-sectional, web-based panel survey from July 10 to August 3, 2017. A random sample of US patients were invited to participate in the survey by Survey Sampling International via their patient panels. Eligibility criteria included patients aged  $\geq 18$  years with a self-reported diagnosis of AS who initiated secukinumab  $\geq 3$  months before participation and received secukinumab continuously since initiation. The outcomes evaluated were AS patient experience and satisfaction with effectiveness and symptom improvement with secukinumab, both overall and when compared to their previous treatment. Outcomes were summarised descriptively.

**Results:** Of 2755 patients screened, 200 patients with AS were eligible for the analysis. The mean (SD) age of survey participants was 34.4 (10.6) years; 60.0% were male and 66.0% were white. Equal proportions of patients (86.5%) had a history of biologic and nonbiologic use, and 98.5% of patients had previously received treatment for AS; the primary reason for discontinuation of their previous treatment was lack of efficacy (25.4%). Most patients (74.0%) reported overall improvement in AS symptoms compared with their previous treatment before secukinumab initiation (“a little better,” 34.5%; “moderately better,” 21.0%; “much better,” 18.5%). Overall, the majority of patients were satisfied with secukinumab treatment (Abstract SAT0300 – figure 1), and expressed better treatment experience with secukinumab compared with their previous treatment (Abstract SAT0300 – figure 2).

**Abstract SAT0300 – Figure 1.** Overall satisfaction with secukinumab treatment reported by patients with AS

**Abstract SAT0300 – Figure 2.** Treatment satisfaction with secukinumab for AS compared with previous treatment

**Conclusions:** Overall, >90% of patients with AS who were treated with secukinumab expressed overall satisfaction with their treatment experience, even when compared with their previous treatment. These data provide early insight into the secukinumab treatment experience and satisfaction of US patients with AS.

SAT0301

#### SIMILAR EFFICACY OF RHU-TNFR-FC TEPERING AND MAINTENANCE FOR HIP ARTHRITIS IN PATIENTS WITH ANKYLOSING SPONDYLITIS

Z. Huang, X. Huang, W. Deng, X. Guo, Y. Huang, T. Li. *Department of Rheumatology and Immunology, Guangdong Second Provincial General Hospital, Guangzhou, China*

**Background:** Hip involvement is common in patients with ankylosing spondylitis (AS) and eventually leads to functional impairment. Recent studies indicated tumour necrosis factor inhibitors (TNFi) might be an effective therapy for hip arthritis in AS patients. However, the conventional dose of TNFi associates with high cost and increasing risk for adverse effects, so dose reduction is necessary.

**Objectives:** We compared the efficacy between recombinant human soluble tumour necrosis factor receptor II: IgG Fc fusion protein (Rhu-TNFR-Fc) dose reduction and maintenance in terms of disease activity, function and change of imaging examination.

**Methods:** Fifty-one AS patients (102 hips) who admitted to our hospital from January 2015 to December 2017 were involved in this retrospective cohort study. Patients who had previously received disease modifying anti-rheumatic drugs or systemic glucocorticoid therapy were excluded. After being treated by Rhu-TNFR-Fc (YISAIPU) 50 mg/week for 12 weeks, subcutaneous injections were performed every other week for patients in the tapering group, while the control group maintained the same therapy till the 24th week. AS disease activity score-C reactive protein (ASDAS-CRP), Bath AS function index (BASFI) and Harris hip score were recorded at every follow-up. Pelvic X-ray and MRI examinations for hips were conducted before treatment and in the 24th week. Bath AS radiology index-hip (BASRI-h) was employed to assess the change in X-ray, and definition of hip MRI finding was described by Huang et al. Bone marrow oedema, enthesitis and synovitis was thought to be a marker for active inflammatory changes. Chronic inflammatory changes included bone erosion, fat accumulation and ankylosis.

**Results:** After markedly descending to the minimum at week 12 ( $p<0.05$ ), ASDAS-CRP, BASFI and Harris hip score kept stable till the end in both groups (table 1). BASRI-h of these groups unchanged during 24 weeks ( $p>0.05$ , figure 1). Nevertheless, active inflammatory changes improved dramatically in the second MRI examination ( $p<0.05$ , table 2). No statistical significant was existed between groups ( $p>0.05$ ).

**Abstract SAT0301 – Table 1.** Changes in the variables of patients with ankylosing spondylitis at follow-ups (Mean±SD)

Variables	Tapering group (n=31)			Control group (n=20)		
	Week 0	Week 12	Week 24	Week 0	Week 12	Week 24
ASDAS-CRP	3.9±0.8	1.0±0.6*	1.1±0.7*	4.0±0.6	1.0±0.6*	1.1±0.7*
BASFI	3.5±1.4	1.2±0.9*	1.5±1.2*	3.7±1.2	1.2±0.8*	1.2±1.1*
Harris hip score	51.7±12.5	75.9±11.1*	72.0±10.4*	51.9±11.0	76.0±9.6*	75.9±8.8*

\* $P<0.05$  compared with week 0 in the same group. ASDAS-CRP, ankylosing spondylitis disease activity score-C reactive protein; BASFI, Bath ankylosing spondylitis function index

**Abstract SAT0301 – Table 2.** Changes in the MR features of hips in patients with ankylosing spondylitis at week 0 and week 24 (n,%)

Variables	Tapering group (n=62)		Control group (n=40)	
	Week 0	Week 24	Week 0	Week 24
Active inflammatory change	49 (79.0)	14 (22.6)*	32 (82.5)	5 (12.5)*
Chronic inflammatory change	17 (27.4)	17 (27.4)	10 (25.0)	10 (25.0)

\* $P<0.05$  compared with week 0 in the same group

**Abstract SAT0301 – Figure 1.** Changes of Bath AS radiology index-hip

**Conclusions:** Rhu-TNFR-Fc tapering might maintain remission of hip arthritis in patients with AS, and it shares similar therapeutic effect of full-dose Rhu-TNFR-Fc. Therefore, dose reduction of TNFi tends to be an acceptable therapy for AS-related hip arthritis.

## Psoriatic arthritis

### SAT0302 EVALUATION OF SUBCLINICAL GUT INFLAMMATION USING FAECAL CALPROTECTIN LEVEL AND COLONIC MUCOSAL BIOPSY IN PATIENTS WITH PSORIASIS AND PSORIATIC ARTHRITIS

M. B. adarsh<sup>1</sup>, S. K. sinha<sup>2</sup>, S. dogra<sup>3</sup>, K. vaiphei<sup>4</sup>, C. vaishnavi<sup>2</sup>, A. sharma<sup>1</sup>.  
<sup>1</sup>Internal Medicine, <sup>2</sup>gastroenterology, <sup>3</sup>dermatology, <sup>4</sup>histopathology, Post Graduate Institute of Medical Education and Research, Chandigarh, India

**Background:** The association between gut inflammation and ankylosing spondylitis is well established, while it is not so in psoriatic arthritis (PsA).

**Objectives:** To study the prevalence of subclinical gut inflammation in PsA and Psoriasis (PsO) patients using faecal calprotectin levels and colonic mucosal biopsies and its correlation with disease phenotypes and activity scores.

**Methods:** Fifty patients with active PsA and hundred with active PsO were recruited. Faecal calprotectin levels of more than 43.2 µg/gm by ELISA was considered positive. Sigmoidoscopy and multiple colonic mucosal biopsies were done in twenty PsA patients and eight PsO patients. Thirty consecutive patients with irritable bowel syndrome (IBS) according to ROME III criteria were disease control population. Mann Whitney u test and Kruskal Wallis H test were used.

**Results:** Baseline characteristics are given in table 1. Faecal calprotectin level was elevated in 29 (58%) PsA patients and 26 (26%) PsO patients ( $p=0.000$ ). The mean value of faecal calprotectin was higher in PsA patients than PsO (86.6±81.5 µg/gm vs 32.9±48.1 µg/gm,  $p=0.000$ ). The Odds for a positive faecal calprotectin level in PsA was 3.9 (95% CI 1.9–8.0) in comparison to PsO. Faecal calprotectin levels were significantly higher in PsA patients with high body surface area (BSA) and psoriasis area and severity index (PASI) scores. Those with axial phenotype had higher calprotectin levels and the levels correlated with BASDAI. Mean faecal calprotectin level was 22.0±18.5 µg/gm in IBS patients which was significantly lower than PsA patients (0.002) but was comparable with that of PsO patients ( $p=0.8$ ). Sigmoidoscopy was normal in all PsO patients while two PsA patients had mucosal erythema. Fifteen PsA and all PsO patients showed increased lymphoplasmocytic infiltration of lamina propria. Evidence of active colitis with cryptitis was seen in two and collagenous colitis was seen in seven PsA patients (figure 1). No PsO patient had active or collagenous colitis.

**Abstract SAT0302 – Table 1.** Baseline characteristics (TJC Tender Joint Count, SJC Swollen Joint Count, BASDAI Bath Ankylosing Spondylitis Disease Activity Index, LEI Leeds enthesitis index, BSA Body Surface Area, PASI Psoriasis Area And Severity Index, DLQI Dermatology Life Quality Index, CPDAI Composite Psoriatic Disease Activity Index)

Variable	Psoriatic Arthritis (n=50)	Psoriasis (n=100)
Mean age (years)	44.4±12.0	41.5±14.6
Male: Female	26:24	70:30
Duration of skin involvement (yrs)	9.3±9.0	8.6±8.4
Mean duration of joint involvement (yrs)	3.5±4.8 (0.25–30)	
Mean TJC	4.8±4.0 (0–20)	
Mean SJC	4.5±4.0 (0–19)	
BASDAI	1.8±2.3 (0–7.4)	
LEI	0.3±0.7 (0–3)	
BSA	5.7±13.2 (0–90)	13.6±19.3 (1–90)
PASI	3.5±7.0 (0–48)	8.1±9.1 (0.3–44)
DLQI	4.9±5.3 (0–25)	8.8±6.1 (1–29)
CPDAI	3.8±2.0 (1–10)	1.7±0.8 (1–3)
Nail involvement	21 (42%)	45 (45%)

**Figure 1.** Photomicrograph of A showing mild to moderate increased intra-epithelial lymphocytes with thickened basement membrane B. shows the thickened basement membrane highlighted better in Masson's trichrome staining

**Conclusions:** Subclinical gut inflammation was significantly higher in PsA patients in comparison to PsO patients and is more prevalent among those with axial phenotype.

SAT0303

**PAIN MECHANISMS AND ULTRASONIC INFLAMMATORY ACTIVITY AS PROGNOSTIC FACTORS IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS OF A DANISH PROSPECTIVE, EXPLORATORY COHORT STUDY**

P. Højgaard<sup>1,2</sup>, K. Ellegaard<sup>1</sup>, S.M. Nielsen<sup>1</sup>, R. Christensen<sup>1</sup>, J. Guldborg-Møller<sup>1</sup>, C. Ballegaard<sup>1,2</sup>, L. Dreyer<sup>1,2</sup>, P. Mease<sup>3</sup>, M. de Wit<sup>4</sup>, L. Skov<sup>5</sup>, B. Glinthorg<sup>2,6</sup>, H. Bliddal<sup>1</sup>, E.M. Bartels<sup>1</sup>, K. Amris<sup>1</sup>, L.E. Kristensen<sup>1</sup>. <sup>1</sup>The Parker Institute, Bispebjerg and Frederiksberg Hospital, Frederiksberg, Denmark; <sup>2</sup>Center for Rheumatology and Spine diseases, Rigshospitalet Gentofte, Hellerup, Denmark; <sup>3</sup>Swedish Medical Center, University of Washington, Seattle, USA; <sup>4</sup>Department of Medical Humanities, Vrije University, Amsterdam, Netherlands; <sup>5</sup>Department of Dermatology and Allergology, Herlev and Gentofte Hospital, Hellerup, Denmark; <sup>6</sup>Center for Arthritis Research COPECARE, Rigshospitalet Glostrup, Glostrup, Denmark

**Background:** Pain is a major concern for patients with psoriatic arthritis (PsA) in spite of treatment with biologic/conventional disease modifying drugs (b/cDMARDs). Studies on the prognostic role of pain mechanisms in PsA, are scarce.

**Objectives:** To investigate the presence of widespread non-arthritis pain (WP) in patients with PsA, and determine its relation to patient-reported, clinical- and ultrasound (US) disease measures, as well as to achievement of 4 months response to b/cDMARD therapy. Secondly, to study if US Colour Doppler activity (CD) at baseline is associated to treatment response.

**Methods:** A prospective cohort study was performed following a protocol.<sup>1</sup> Patients initiating b/cDMARDs for PsA were recruited from rheumatology clinics in Copenhagen. Clinical- and US examinations and patient-reported outcomes (PROs) were performed at baseline and after 4 months. WP was defined as a Widespread Pain Index  $\geq 4$ , and pain in  $\geq 4/5$  regions. CD activity in selected joints, entheses and tendons (73 projections) was summed. Response was assessed by American College of Rheumatology 20% (ACR20), Disease Activity in Psoriatic Arthritis 50% (DAPSA 50) and Minimal Disease Activity (MDA). Main response analyses were based on intention to treat with non-responder imputation, and consisted of logistic regressions adjusting for gender and age.

**Results:** Of 123 screened patients, 69 were included. Of these, 24 (35%) fulfilled the WP definition. At baseline (Table), WP was associated with worse PROs and composite scores, while CD activity and clinical measures were similar to those without WP. WP profile was significantly related to achievement of MDA at follow-up but not to other response criteria (table 1). Presence of CD activity at baseline was not significantly associated to 4 months response by any criteria, e.g. 19%/31% with CD=0/CD >0, reached ACR20, (p=0.262).

**Abstract SAT0303 – Table 1.** Baseline characteristics

Females, n (%)	15 (63)	24 (53)	0.634
PsA impact of Disease (PsAID)	6.2 (1.7)	4.2 (2.2)	<0.001
HAQ-DI (0–3)	1.2 [0.9 to 1.5]	0.6 [0.3 to 1.0]	<0.001
VAS Pain (0–100)	68.8 (19.2)	44.5 (27.6)	<0.001
DAPSA (0–164)	49.3 (18.1)	29.8 (18.5)	<0.001
SPARCC enthesitis (0–16)	7.5 (3.4)	4.2 (3.0)	<0.001
CD score (0–200)	1.0 [0.0 to 4.3]	1.0 [0.0 to 5.0]	0.686
Swollen Joints (0–66)	3.0 [1.0 to 6.3]	4.0 [2.0 to 8.0]	0.352
Tender Joints (0–68)	26.5 [24.5 to 37.0]	11.0 [6.0 to 20.0]	<0.001
<b>4 months responses</b>			
ACR20, n (%)	6 (25)	12 (28)	0.779
DAPSA 50, n (%)	7 (29)	15 (33)	0.724
MDA, n (%)	0 (0)	9 (20)	0.022

Data as mean(SD) or median[IQR] P-value from T test/Mann Whitney U-test/ $\chi^2$  test,

**Conclusions:** WP was present in 1/3 of patients, and associated with worse PROs, composite measures, and failure to achieve MDA at follow-up. Neither WP nor CD at baseline was related to other response measures.

**PRECLINICAL PHASES OF PSORIATIC ARTHRITIS: A CROSS-SECTIONAL ULTRASONOGRAPHIC STUDY ON PSORIASIS AND PSORIATIC ARTHRALGIA PATIENTS**

A. Zabotti<sup>1</sup>, F. Zuliani<sup>1</sup>, E. Errichetti<sup>1</sup>, I. Tinazzi<sup>2</sup>, S. Sacco<sup>1</sup>, L. Quartuccio<sup>1</sup>, A. Zanetti<sup>3</sup>, A. Batticciotto<sup>4</sup>, O. De Lucia<sup>5</sup>, L. Idolazzi<sup>6</sup>, G. Stinco<sup>1</sup>, A. Iagnocco<sup>7</sup>, S. De Vita<sup>1</sup>. <sup>1</sup>Rheumatology Clinic, "Santa Maria della Misericordia" University Hospital, Udine, Italy, Udine; <sup>2</sup>Rheumatology Clinic, Ospedale Sacro Cuore Don Calabria, Verona; <sup>3</sup>Epidemiology Unit, Italian Society of Rheumatology; <sup>4</sup>Rheumatology Unit, Sacco University Hospital; <sup>5</sup>Department of Rheumatology, ASST Centro traumatologico ortopedico G. Pini – CTO, Milan; <sup>6</sup>Rheumatology Unit, University of Verona, Ospedale Civile Maggiore, Verona; <sup>7</sup>Dipartimento di Scienze Cliniche e Biologiche, University of Turin, Turin, Italy

**Background:** Identify the preclinical phase of arthritis could be clinically relevant. In this scenario, musculoskeletal ultrasonography (US) may play an important role, since it may detect subclinical disease. Psoriatic Arthritis (PsA) is a perfect disease to identify risk factors, since the risk pool group [i.e. patients with only cutaneous Psoriasis (Pso)] is known.

**Objectives:** To evaluate in Pso patients, with and without clinical arthralgia (CA), defined by the presence of joint pain without other clinical evidence of musculoskeletal inflammation: I) the prevalence of subclinical US inflammation in joints, entheses, tendons and bursae; II) the prevalence of US structural damage; III) the relationship between US lesions and clinical data.

**Methods:** Cross-sectional prevalence study of US abnormalities in Pso patients with or without CA and healthy controls (HCs). Inclusion and exclusion criteria (e.g. osteoarthritis and fibromyalgia) are pre-defined. Forty-four joints (MCP, PIP and DIP joints, wrists, knees, MTP joints) and 12 entheses (achilles, quadriceps, proximal and distal patellar, plantar aponeurosis and common extensor tendon entheses) were scanned in each patient. US scans were performed using a ESAOTE MyLabClassC equipped with a high frequency linear probe. Active synovitis was defined by the presence of a grade  $\geq 2$  for grey scale (GS) and  $\geq 1$  for PD, while active enthesitis if there was hypoechogenicity in GS and an enthesial PD signal ( $\leq 2$  mm from bone insertion).

**Results:** Sixty-four Pso patients and 21 HCs were included; globally 2816 joints and 768 entheses were scanned. Twenty-three out of 64 (35.9%) Pso patients displayed CA. Baseline characteristics are reported in table 1. Active synovitis was found, in at least one joint, in 20/64 (31.3%) Pso patients and 0/21 HCs (p=0.002), while active enthesitis in 14/64 (21.9%) Pso patients and 0/21 HCs (p=0.017). No significant differences were found for active synovitis or enthesitis between the two subgroups of Pso, with or without CA. In the Pso cohort, 5/23 (23.8%) patients with CA and 2/41 (5%) without CA displayed tenosynovitis or paratenonitis (p=0.042). Furthermore, active synovitis, as well as GS-synovitis  $\geq 2$ , was associated with higher NAPSI (9.7 $\pm$ 8.0 vs 4.6 $\pm$ 7.1, p=0.04 for GS  $\geq 2$ ),

whereas active enthesitis was associated with higher PASI (5.4±3.0 vs 3.7±2.9, p=0.02). No significant differences were found between Pso patients and HCs for the structural damage (i.e. osteoproliferation and erosions), both for joints and entheses.

**Abstract SAT0304 – Table 1.** \* p significant Pso with CA vs HCs; \*\* p significant Pso with CA vs Pso without CA

Baseline data	Pso without CA (n=41)	Pso with CA (n=23)	Healthy controls (n=21)
Age mean (±SD)	51.37 (±15.88)	49.91 (±14.23)	45.76 (±15.89)
Female n. (%)	23 (56.1%)	10 (43.5%)	12 (57.1%)
Smoking n. (%)	12 (29.3%)	2 (9.0%)	6 (28.6%)
BMI mean (±SD)	25 (4.0%)	27 (±4.3%)	24 (±4.2)
Clinimetric data	Pso without CA (n=41)	Pso with CA (n=23)	Healthy controls (n=21)
VAS pain (0-10) mean (±SD)	2 (±2.4)	4 (±2.4) * **	2 (±2.35)
HACQ mean (±SD)	0 (±0.31)	0 (±0.45) * **	0 (±0.21)
Joints tenderness mean	0.34 per patient	2.56 per patient * **	0.17 per patient
Comorbidities	Pso without CA (n=41)	Pso with CA (n=23)	Healthy controls (n=21)
Obesity n. (%)	4 (9.8%)	0 (0%)	1 (4.8%)
Diabetes Mellitus n. (%)	3 (7.3%)	0 (0%)	2 (9.5%)
Hypertension n. (%)	7 (17.0%)	7 (30.4%)	5 (23.8%)
Metabolic syndrome n. (%)	5 (12.2%)	3 (13.4%)	4 (19.0%)
Fatty liver disease n. (%)	5 (12.2%)	4 (17.4%)	1 (4.8%)
Uveitis n. (%)	2 (4.9%)	0 (0%)	0 (0%)
Depression n. (%)	2 (4.9%)	3 (13.0%)	0 (0%)
CV disease n. (%)	3 (7.3%)	0 (0%)	1 (4.8%)

**Conclusions:** In Psoriasis subclinical US active synovitis and/or enthesitis are present in 20%–30% of patients. In Pso the comparison between groups, with or without CA, show no significant difference in active subclinical synovitis or enthesitis, but Pso patients with CA present more frequently US tenosynovitis or paratenonitis. In Pso subclinical US synovitis or enthesitis are significantly associated with higher NAPSI and PASI. The relevance of these results, to possibly identify a subgroup of Pso more prone to develop PsA, deserve further investigation and prospective evaluation.

### SAT0305 ASSESSMENT OF SUB CLINICAL HAND JOINT SYNOVITIS IN PATIENTS WITH PSORIATIC ARTHRITIS AND PSORIASIS BY ULTRASOUND AND ITS RELATIONSHIP WITH CLINICAL DISEASE ACTIVITY

S. Mondal<sup>1</sup>, R.P. Goswami<sup>1</sup>, D. Sinha<sup>1</sup>, G.B. Sircar<sup>1</sup>, A.K. Das<sup>2</sup>, P. Ghosh<sup>1</sup>, A. Ghosh<sup>1</sup>. <sup>1</sup>Rheumatology, IPGIMER; <sup>2</sup>Orthopaedics, West Bengal Health Service, Kolkata, India

**Background:** Articular involvement in Psoriatic arthritis (PsA) can have diverse presentations; oligoarticular involvement is predominant in early disease. Ultrasound (US) detected subclinical synovitis can be present in early PsA and a substantial portion of oligoarthritic PsA patients are being reclassified as having polyarthritides.<sup>1</sup> Asymptomatic US synovitis and enthesopathy can be present in Psoriasis (Pso) patients which probably indicate subclinical musculoskeletal involvement.<sup>2</sup>

#### Objectives:

- To evaluate sub-clinical synovitis of hand joints in patients with PsA and Pso by B-mode and Power Doppler US.
- Correlation of PsA and Pso disease activity with US detected synovitis.

**Methods:** 27 patients of PsA (disease duration <2 years, no clinical evidence of hand joint involvement), 36 Pso patients and 30 controls were recruited. PASI and DAPSA score used for assessment of cutaneous and articular disease activity respectively. US [grey scale (GS) and power Doppler (PD)] used to assess synovitis of hand joints. A GS score ≥2 and/or a PD score ≥1 were used to identify US detected synovitis.

**Results:** Significantly more patients with PsA had sub-clinical hand joint synovitis than controls (62.96% versus 20%, p value=0.001, relative risk: 3.148, 95% C.I.: 1.455 to 6.814), and Pso patients [(27.78%), p value=0.0095, relative risk=2.267, 95% C.I.: 1.243 to 4.135]. Median number of joints involved in PsA group was 4 (inter quartile range: 2–5). Among 810 hand joints scanned in PsA group, 59 (7.28%) joints showed evidence of sub-clinical synovitis. Wrist joint was most commonly involved (28.81%), followed by DIP3 (13.56%) and MCP3 (10.17%). Less involvement noted in MCP4, MCP5, PIP1, PIP5 and DIP5 (1.69%). In Pso patients, evidence of sub-clinical synovitis was not significantly different from control. (p value=0.5689, relative risk=1.389, 95% C.I.: 0.5710 to 3.378). However, wrist and DIP involvement was significantly more in Pso than control. No correlation noted between numbers of joints with subclinical synovitis with DAPSA or PASI score.

#### Conclusions:

- Almost two third patients with early PsA had PDUS evidence of sub-clinical synovitis in hand joints, most commonly in wrist joint followed by DIP3 and MCP3.
- No significant increase of sub-clinical synovitis in Pso compared to control group. However, wrist and DIP joint involvement was significantly more in Psoriasis.
- There was no correlation between number of joints with sub-clinical synovitis and disease activity indices.

### SAT0306 FINGER FLEXOR TENDON PULLEY COMPLEX INVOLVEMENT IN PSA DACTYLITIS: AN ULTRASONOGRAPHY STUDY

L. Tinazzi<sup>1</sup>, D. Mc Gonagle<sup>2</sup>, A. Zabotti<sup>3</sup>, P. Macchioni<sup>4</sup>, S.Z. Aydin<sup>5</sup>. <sup>1</sup>Rheumatology, Ospedale Sacro Cuore Negrar (Verona), Negrar Verona, Italy; <sup>2</sup>NIHR Leeds Musculoskeletal Biomedical Research Unit, Leeds, UK; <sup>3</sup>AOU "Santa Maria della Misericordia", Udine; <sup>4</sup>Rheumatology, Ospedale S.Maria Nuova, Reggio Emilia, Italy; <sup>5</sup>The Ottawa Hospital Research Institute, Ottawa, Canada

**Background:** Dactylitis is a hallmark of psoriatic arthritis (PsA) occurring in around 40% of cases at some point in the disease course. At the micro anatomical level PsA is strongly linked to disease localisation to entheses and other sites of high mechanical stress. Recently high resolution MRI has shown prominent abnormalities at the mini-entheses of the flexor tendon pulleys may be common

**Objectives:** . In this study we aimed to understand the changes within the pulleys for patients with PsA, with or without dactylitis to explore the role of the pulley disease in the dactylitis.

**Methods:** Consecutive 20 cases of PsA with dactylitis were recruited and had an US scan of the A1, A2 and A4 pulleys of the digit with dactylitis and the contralateral side. A high resolution probe (22 MHz) was used to explore a) the thickness of the pulleys, b) the presence of Doppler signals. A comparison was made within digits with or without dactylitis

	Dactylitis (-)	Dactylitis (+)	p
A1- longitudinal	0.69 (0.10)	1.00 (0.34)	0.001
A2- longitudinal	0.77 (1.11)	0.75 (0.15)	<0.001
A4- longitudinal	0.50 (0.09)	0.65 (0.15)	<0.001
A1- transverse	0.68 (0.10)	1.01 (0.33)	<0.001
A2- transverse	0.51 (0.09)	0.73 (0.16)	<0.001
A4- transverse	0.50 (0.08)	0.71 (0.27)	<0.001

**Abstract SAT0306 – Figure 1.** The increased thickness and the presence of Doppler signals in the A1 pulley in a digit with dactylitis in longitudinal (A and B) and transverse (C and D)

**Results:** Half of the A1 pulleys with dactylitic digits had Doppler signals (10/20, 50%), which was less common in A2 (6/20 (30%)) and A4 pulleys (6/20 (30%)) (figure). The digits without dactylitis had Doppler signals less frequently (A1: 1/19 (5%); A2: 1/19 (5%); A4: 1/19 (5%))

A1, A2 and A4 pulleys were significantly thicker in dactylitis fingers compared to fingers without dactylitis, both in longitudinal and transverse planes (table 1).

**Conclusions:** This study demonstrates that pulleys contribute to the pathogenesis of dactylitis with increased vascularity and thickening, probably due to the micro-enthesitis at the level where the flexor tendons are exposed to high mechanical stress. This is important to understand the anatomical basis of a complex disease feature in PsA, dactylitis

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.7258

SAT0307

#### IMPACT OF THE MODIFIED RHEUMATIC DISEASE COMORBIDITY INDEX (mRDCI) ON DRUG SURVIVAL OF FIRST LINE ANTI-TNF $\alpha$ DRUGS IN PATIENTS AFFECTED WITH PSORIATIC ARTHRITIS IN REAL LIFE SETTING

M. Fornaro<sup>1</sup>, V. Venerito<sup>1</sup>, L. Cantarini<sup>2</sup>, M.G. Anelli<sup>1</sup>, F. Cacciapaglia<sup>1</sup>, G. Lopalco<sup>1</sup>, G. Lapadula<sup>1</sup>, F. Iannone<sup>1</sup>. <sup>1</sup>Rheumatology Unit, Department of Emergency and Organ Transplantation (DETO), University of Bari (Italy), BARI; <sup>2</sup>Research Center of Systemic Autoinflammatory Diseases and Behçet's Disease Clinic, Department of Medical Sciences, Surgery and Neurosciences, Università di Siena, Siena, Italy

**Background:** Psoriatic Arthritis (PsA) is a chronic condition resulting in significant physical disability and, in many cases, accelerated mortality. Studies have shown that patients with PsA suffer also from associated comorbidities, including cardiovascular diseases, obesity and metabolic syndrome, diabetes, osteoporosis, malignancy and depression; these could also play a role in determining discontinuation from therapy, especially if anti-TNF $\alpha$  drugs are prescribed.

**Objectives:** Our study's goal is to demonstrate the impact of comorbidities on drug survival of first line anti-TNF $\alpha$  treatment in a cohort of patients affected with PsA.

**Methods:** We retrospectively assessed 208 patients, (136 female, 72 male) mean age ( $\pm$ SD) 51.35 $\pm$ 12.34 years, fulfilling the CASPAR criteria for PsA who underwent first line anti-TNF $\alpha$  therapy in two centres for a mean duration of 23.34  $\pm$ 15.50, from 2011 to 2016. Disease characteristics were registered at first entry. To evaluate the burden of comorbidities we used the modified Rheumatic Disease Comorbidity Index (mRDCI),<sup>1</sup> a validated score including lung illnesses, cardiovascular diseases, stroke, hypertension, gastrointestinal disorders, diabetes, fractures, depression, obesity, kidney diseases and cancer. The mRDCI was scored at baseline as well. Drug retention was analysed using Kaplan-Meier curves. Cox regression models were used to estimate the inference of mRDCI and several disease characteristics on drug discontinuation. Goodness of fit of the final model was assessed comparing Cox-Snell residuals to Nelson-Alen cumulative hazard function.

**Results:** Drug persistence in first line therapy was significantly higher in patients with mRDCI <4 (70.43%) than in those with mRDCI  $\geq$ 4 (45.45%). Compared to mRDCI  $\geq$ 4, those with mRDCI <4 showed significantly higher drug survival rate (p=0.018). Multivariate Cox model showed that mRDCI  $\geq$ 4 (HR 1.94) and female gender (HR 2.39) were strong predictors of drug discontinuation. Nelson-Alen hazard function followed very closely Cox-Snell residuals showed final model fitted well the data except for large values of time.

**Abstract SAT0307 – Figure 1.** Drug survival in first-line anti-TNF $\alpha$  treatment assessed by Kaplan-Meier and comparison among patients with mRDCI <4 and mRDCI  $\geq$ 4.

**Abstract SAT0307 – Figure 2.** Nelson-Alen Hazard function and Cox-Snell residual

**Conclusions:** This study shows that a high mRDCI at baseline negatively impacts the persistence on first line anti-TNF $\alpha$  treatment in patients affected with PsA in real life setting; hence Rheumatologists should take into account comorbidities in the management of PsA and in administering anti-TNF $\alpha$  therapy as these may condition the persistence on therapy.

Salandri<sup>2</sup>, M. Cesareo<sup>2</sup>, R. Perricone<sup>1</sup>. <sup>1</sup>Department of System Medicine, Rheumatology, allergology and clinical immunology; <sup>2</sup>Ophthalmology Unit, Department of Experimental Medicine and Surgery, University of Rome Tor Vergata, Rome, Italy

**Background:** Psoriatic Arthritis (PsA) is a chronic inflammatory arthritis typically often associated to several comorbidities. The presence of eye involvement in terms of uveitis is well known in PsA patients while retinal abnormalities and dry eye need to be characterised

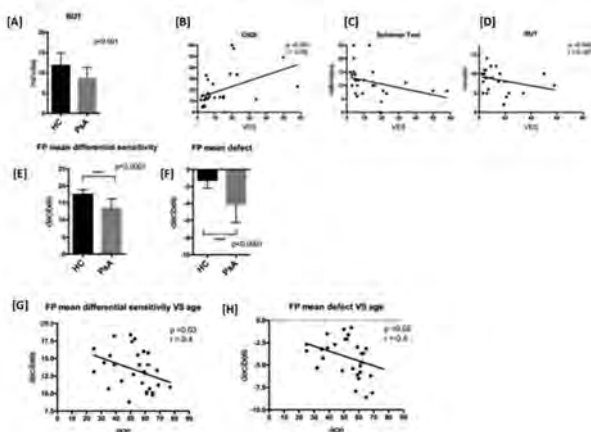

**Objectives:** The aim of the study was to analyse subclinical retinal abnormalities and dry eye in a cohort of PsA patients who were naïve to biologic treatments

**Methods:** In a prospective cross-sectional study, consecutive PsA patients without clinical eye involvement were enrolled (time frame January 2017-December 2017). Joint disease activity and ESR and CRP were measured. Functional and morphological eye assessment included: complete ophthalmological examination, ocular surface disease index (OSDI), Schirmer test, BUT, spectral-domain optical coherence tomography (SD-OCT), standard automated perimetry (SAP, measured as mean defect – MD – and pattern standard deviation – PSD), and fundus perimetry (FP). Data were compared to findings from the eyes of 24 age/sex matched healthy controls (HC).

**Results:** A total of 58 eyes from 29 PsA patients (21 women and 8 men; age 52.7  $\pm$ 13.3 years) and 48 eyes from HC (14 women and 10 men; age 47.6 $\pm$ 15 years) were evaluated.

Overall, most of the PsA patients showed a normal Schirmer test, with the exclusion of three patients (10.3%). PsA patients showed abnormal OSDI in 55.2% and lower BUT in compared to HC (p<0.001, Fig.1A). ESR resulted positively correlated with OSDI (p<0.001, r=0.6, Fig.1B), and negatively related with Schirmer test (p=0.005, r=-0.5, Fig.1C) and BUT (p=0.04, r=-0.4, Fig.1D). In the PsA group, SAP tests showed a lower MD (p<0.0001) and a higher PSD (p=0.0043) in

comparison with the HC. The latter PSD analysis resulted positively correlated with ESR ( $p=0.01$ ;  $r=0.5$ ) and CRP values ( $p=0.001$ ;  $r=0.4$ ). FP mean differential sensitivity and FP mean defect values were lower in PsA patients with respect to HC ( $p<0.0001$  for both the comparisons, figure 1E-F) and resulted negatively correlated with the age ( $p=0.03$   $r=-0.4$  for both the correlations, figure 1G-H). SD-OCT in the posterior pole (superior and inferior hemifields) did not reveal differences for the mean retinal thickness between PsA patients and HC.

**Conclusions:** Intriguingly, an impairment in quality of tear film in PsA patients was observed compared to HC. The correlation between ESR and dry eye tests may be explained with a potential relationship between systemic inflammation and sicca syndrome.

Interestingly, PsA patients showed a retinal functional impairment by reduced retinal sensitivity measured by MD, FP mean differential sensitivity and FP mean defect values.

To our knowledge this is the first study investigating eye function and morphology in PsA patients. Further studies are needed to confirm and explain these results.

### SAT0309 UNDERESTIMATION OF CARDIOVASCULAR EVENTS BY CARDIOVASCULAR RISK SCORES IN PSORIATIC ARTHRITIS PATIENTS

H.M. Lam<sup>1</sup>, S.H.O. Ngai<sup>1</sup>, S.H. Cho<sup>1</sup>, T.K. Chun<sup>1</sup>, K.L. Kot<sup>1</sup>, C.T. Yim<sup>1</sup>, E.F. Yu<sup>1</sup>, E. W.L. Kun<sup>2</sup>, L.S. Tam<sup>1</sup>. <sup>1</sup>Department of Medicine and Therapeutics, THE CHINESE UNIVERSITY OF HONG KONG, Sha Tin; <sup>2</sup>Department of Medicine, Alice Ho Miu Ling Nethersole Hospital, Tai Po, Hong Kong

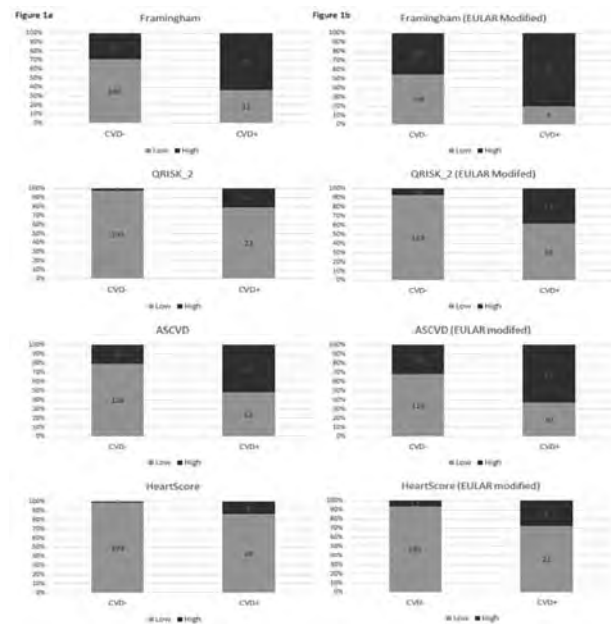

**Background:** Compared with the general population, patients with Psoriatic Arthritis (PsA) have elevated risks of developing cardiovascular diseases (CVD). The performances of established CVD risk scores in PsA patients have not been fully evaluated yet. European League Against Rheumatism (EULAR) recommends a 1.5 multiplication factor to these CVD risk scores when it is applied in rheumatoid arthritis patients. Whether the same multiplication factor could improve the performance of the risk scores in PsA patients is unknown.

**Objectives:** To investigate the performances of various CVD risk scores and their EULAR modified versions for predicting CVD events in PsA patients

**Methods:** Prospectively collected data from the two Hong Kong PsA cohort was used. Discriminatory ability for CV risk prediction was estimated by the area under the receiver operating characteristic curve (AUC). Four different CVD risk scores namely Framingham risk score (FRS), QRISK II, HeartScore and American College of Cardiology and American Heart Association (ACC/AHA) 10 year atherosclerotic cardiovascular disease (ASCVD) and their EULAR modified versions were calculated at baseline. The primary outcome was first CVD events, including stable and unstable angina, myocardial infarction, ischaemic and haemorrhagic stroke, transient ischaemic attack, heart failure, coronary insufficiency, pericardial disease, peripheral arterial disease, thrombosis, percutaneous coronary intervention (angioplasty), coronary artery bypass graft, implantation of pacemaker or defibrillator and CVD death.

**Results:** 228 patients [48.9±11.8 years, male: 124 (54.4%)] were recruited between 2006 to 2016. Baseline data were available from 227, 226, 226 and 188 patients to calculate the FRS, QRISKII, HeartScore and ASCVD, respectively. After a mean follow up of 6.7±4.7 years, 30 patients (13.2%) experienced a CVD event (CVD +group). At baseline, the CVD +group was significantly older (57.8±12.0 vs 47.6±11.2 years;  $p<0.001$ ), with a higher prevalence of diabetes (26% vs 12%;  $p<0.021$ ), had higher systolic blood pressure (SBP: 142±22.0 vs 128

±19.6 mmHg;  $p<0.001$ ) and higher triglycerides (TG: 1.9±1.3 vs 1.4±0.8 mmol/L,  $p=0.027$ ). All CVD risk scores were significantly higher in the CVD +group (FRS: 18.3±13.1 vs 8.9±8.7,  $p<0.001$ ; QRISKII: 11.9±8.6 vs 4.9±5.0,  $p<0.001$ ; HeartScore: 2.3±2.1 vs 0.9±1.3,  $p=0.001$ ; ASCVD: 14.5±12.8 vs 4.8±5.2,  $p=0.001$ ). AUC for FRS, QRISKII, HeartScore and ASCVD were 0.74 (0.64–0.83,  $p<0.001$ ), 0.76 (0.66–0.86,  $p<0.001$ ), 0.72 (0.62–0.83,  $p<0.001$ ), and 0.77 (0.67–0.86,  $p<0.001$ ), respectively. In total, 76 (33.5%), 9(4.0%), 7 (3.1%) and 47 (25.0%) patients were classified as high CVD risk according to FRS >10%, QRISK II>20%, HeartScore >5% and ASCVD >7.5% respectively. In the CVD +group, those identified as high risk were only 63% (by FRS), 20% (by QRISK2), 13.3% (by HeartScore) and 46% (by ASCVD) (figure 1a). By applying the EULAR multiplication factor, 80%, 36%, 26.67% and 56.7% of the patients with CVD +were reclassified as high risk (figure 1b).

**Abstract SAT0309 – Figure 1**

**Conclusions:** All CVD risk scores significantly underestimated CVD risks among PsA patients. This study demonstrated for the first time that adaptation of the EULAR recommendation only improved the accuracy of FRS to a moderate level.

### SAT0310 THE ASSOCIATIONS OF SERUM IL18 AND OSTEOPROTEGERIN (OPG) LEVELS WITH THE LIPID PROFILE IN PSORIATIC ARTHRITIS (PSA) PATIENTS

K. Bonek<sup>1</sup>, P. Gluszczo<sup>1</sup>, E. Kontny<sup>2</sup>. <sup>1</sup>Department of Rheumatology; <sup>2</sup>Department of Pathophysiology and Immunology, National Institute of Geriatrics, Rheumatology and Rehabilitation, Warszawa, Poland

**Background:** We have previously found that IL-18 and OPG serum concentrations are correlated with cardiovascular (CV) risk in psoriatic arthritis but not in ankylosing spondylitis (AS) patients.<sup>1</sup>

**Objectives:** To investigate whether in PsA patients the association of OPG and IL-18 with CV risk is mediated by an impact of these cytokines on lipid profile changes.

**Methods:** 49 patients with PsA (25 M/24 F) with (n=10) and without (n=39) coronary heart disease (CHD), and 25 sex and age matched (mean age 44,4 vs 43,4 years) patients with AS were enrolled. Disease activity was measured by DAPSA (25,17±19,9) in PsA group and by BASDAI (5,37±2) and ASDAS- CRP (3,18±1) in AS group. The lipid profile (triglycerides – TG, total cholesterol – tChol, low- and high-density lipoprotein – LDL and HDL, respectively), systemic inflammation markers and cytokines (OPG, IL-18) were measured in patients serum samples. Atherogenic index (AI=tChol/HDL) was calculated. Statistical analysis was performed using Mann-Whitney U-test and Spearman's Rank test. Data are expressed as mean values.

**Results:** Patients with PsA presented more atherogenic lipid profile than AS patients because of their higher TG levels (153 vs 126,6 mg/dl;  $p=0,05$ ) and AI values (3,83 vs 3,24;  $p=0,05$ ) while lower HDL concentrations (51,6 vs 61,4 mg/

dl;  $p=0,04$ ). Compared to AS group, PsA patients were characterised by higher IL-18 (235 vs 208 pg/ml;  $p<0,05$ ) but lower OPG (815 vs 1660 pg/ml;  $p<0,05$ ) serum levels. In PsA patients without CHD, serum OPG positively but moderately correlated with LDL ( $r=0,3$ ;  $p=0,05$ ), TG ( $r=0,43$ ;  $p=0,007$ ) and AI ( $r=0,45$   $p=0,004$ ). Moreover, in this PsA patients subgroup we confirmed previously observed<sup>1</sup> inverse correlation of IL-18 with HDL levels ( $r=-0,34$ ;  $p=0,05$ ) and positive correlation of this cytokine with both TG levels ( $r=0,37$ ;  $p=0,04$ ) and AI values ( $r=0,53$ ;  $p=0,002$ ). Interestingly, similar but stronger associations of IL-18 with HDL levels ( $r=-0,88$ ;  $p=0,004$ ) and AI values ( $r=0,88$ ;  $p=0,004$ ) were presently found in PsA patients with accompanied CHD. Consistently with our previous report,<sup>1</sup> we failed to find any correlations between CV risk, lipid profile, and tested cytokines serum concentrations in patients with AS.

**Conclusions:** We report that in PsA, but not AS, patients serum IL-18 and OPG concentrations are correlated with an altered and pro-atherogenic lipid profile. These associations are stronger in patients with concomitant CHD. Thus, present results explain partially the way by which these cytokine contribute to CV complications in PsA.

SAT0311

#### PREVALENCE AND FACTORS RELATED TO INAPPROPRIATELY HIGH LEFT VENTRICULAR MASS IN PATIENTS WITH PSORIATIC ARTHRITIS WITHOUT OVERT CARDIAC DISEASE

A. Giollo<sup>1</sup>, N. Farina<sup>1</sup>, G. Orsolini<sup>1</sup>, G. Cioffi<sup>2</sup>, F. Ognibeni<sup>1</sup>, L. Idolazzi<sup>1</sup>, D. Gatti<sup>1</sup>, M. Rossini<sup>1</sup>, O. Viapiana<sup>1</sup>. <sup>1</sup>Rheumatology Unit, Department of Medicine, University of Verona, Verona; <sup>2</sup>Department of Cardiology, Villa Bianca Hospital, Trento, Italy

**Background:** Early cardiovascular (CV) involvement has been found in patients with psoriatic arthritis (PsA). These patients may have a high prevalence of subclinical left ventricular (LV) dysfunction, even without established CV disease and in the absence of traditional CV risk factors. However, currently, the factors associated with LV dysfunction in PsA are unknown. Patients with inflammatory disorders are exposed to the development of excessive left ventricular mass disproportionate to the need to compensate left ventricular load, a condition named 'inappropriately high left ventricular mass' (iLVM). Previously, we have shown that iLVM is associated with unfavourable prognosis in patients with rheumatoid arthritis independent of traditional CV risk factors.

**Objectives:** In this cross-sectional study, we assessed the prevalence and factors associated with iLVM in a cohort of patients with PsA and tested the hypothesis that PsA is *per se* related to iLVM.

**Methods:** We evaluated 101 non-institutionalised patients >18 years of age diagnosed with PsA according to CASPAR criteria and consecutively recruited between March 2014 and December 2016. All PsA patients were free of symptoms or signs of cardiovascular disease. Patients with PsA were compared with 101 controls matched for age, sex, BMI, prevalence of hypertension and diabetes. Left ventricular chamber dimensions and wall thicknesses were measured according to the American Society of Echocardiography guidelines and predicted LVM was calculated using a validated equation considering height, sex and left ventricular work. iLVM was defined as measured/predicted LVM ratio above the 95% percentile of a reference population of healthy controls.<sup>1</sup>

**Abstract SAT0311 – Table 1.** Variables significantly related to iLVM in the entire study population (101 patients with PsA and 101 matched controls).

Predictors	OR	95% CI	P value
Psoriatic arthritis	6.91	2.80–17.06	<0.001
Waist circumference	1.04	1.00–1.07	0.047
Dyslipidemia	0.85	0.39–1.89	0.696
Hypertension	1.29	0.56–2.96	0.547
Diabetes mellitus	2.42	0.60–9.79	0.214
Age	1.02	0.98–1.07	0.291
Sex (male)	1.27	0.57–2.84	0.559

**Results:** iLVM was detected in 58% of patients with PsA and 18% of controls ( $p<0,001$ ). In multivariable logistic regression analysis considering only patients with PsA, the variables independently associated with iLVM were left ventricular

systolic dysfunction (LVSD) measured as mid-wall shortening and concentric left ventricular geometry. In multiple regression analyses considering the entire study population (patients with PsA and matched controls), the diagnosis of PsA was significantly associated with iLVM independent of traditional cardiovascular risk factors (OR 6.91, 95% CI 2.80–17.06,  $p<0,001$ ; table 1).

**Conclusions:** More than 50% of patients with PsA have a disproportionate increase in their LVM. An inappropriately high LVM in PsA is associated with LV systolic dysfunction and LV concentric geometry.

#### INCIDENCE OF INFECTIONS IN CLINICAL TRIALS OF TILDRAKIZUMAB FOR MODERATE TO SEVERE CHRONIC PLAQUE PSORIASIS

J. Crowley<sup>1</sup>, C. Leonardi<sup>2</sup>, S. Sturgill-Koszycki<sup>3</sup>, A. Menter<sup>4</sup>, A.M. Mendelsohn<sup>5</sup>, Q. Li<sup>5</sup>, N. Cichanowitz<sup>5</sup>, C. La Rosa<sup>5</sup>. <sup>1</sup>Bakersfield Dermatology, Bakersfield, CA; <sup>2</sup>Central Dermatology, St Louis, MO; <sup>3</sup>Sun Pharmaceutical Industries, Inc., Princeton, NJ; <sup>4</sup>Division of Dermatology, Baylor Scott and White and Texas AandM College of Medicine, Dallas, TX; <sup>5</sup>Merck and Co., Inc., Kenilworth, NJ, USA

**Background:** Risk of infections is a concern with cytokine inhibitor treatments.

**Objectives:** This analysis assessed infections during phase 2 and 3 trials of tildrakizumab (TIL), a high-affinity, humanised, immunoglobulin G1/κ monoclonal antibody against IL-23p19 under development for moderate to severe chronic plaque psoriasis.

**Methods:** Patients were randomised in P05495 (phase 2; NCT01225731), reSURFACE 1 (phase 3; NCT01722331), and reSURFACE 2 (phase 3; NCT01729754). In Part 1 (Weeks 1–16) of P05495, patients received subcutaneous (SC) TIL 5, 25, 100, or 200 mg or placebo (PBO) at Weeks 0 and 4 and were rerandomized to various TIL doses in Part 2 (Weeks 16–52). In Part 1 (Weeks 1–12) of reSURFACE 1 and 2, patients received SC TIL 200 mg, TIL 100 mg, or PBO at Weeks 0 and 4. Patients were rerandomized in Part 2 (Weeks 12–28) and Part 3 (Weeks 28–64 or –52 in reSURFACE 1 and 2, respectively). Etanercept (ETN) 50 mg was an active control in Parts 1–2 of reSURFACE 2. Treatment-emergent adverse event (AE) data pools (n=2081) for the PBO-controlled and full trial periods (52 weeks for P05495/reSURFACE 2; 64 weeks for reSURFACE 1) were analysed. Severe infections met the regulatory definition of a serious AE or required intravenous antibiotics.

**Results:** In the PBO-controlled period, incidences of infections were comparable for TIL 100 mg and 200 mg (23% and 22%, respectively) and PBO (23%); all were comparable with ETN (24%). Incidences of severe infections were low for all treatment groups (range, 0.0%–0.3%; TIL  $p \geq 0.6$  vs PBO). In the full trial period, exposure-adjusted rates (patients/100 patient-years) for infections with TIL 100 mg and 200 mg (48.9 and 52.6, respectively) were lower than with PBO and ETN (79.5 and 86.0, respectively). Exposure adjusted rates for severe infections were 1.10, 1.61, 1.96, and 0.91 for TIL 100 mg, TIL 200 mg, ETN, and PBO, respectively. In total, 33 severe infections were identified (respiratory: TIL 100 mg, 4 events; TIL 200 mg, 2 events; ETN and PBO, 0 events; skin: TIL 100 mg, 3 events; TIL 200 mg, 6 events; ETN, 2 events; PBO, 3 events; gastrointestinal: TIL 100 mg, 4 events; TIL 200 mg, 5 events; ETN and PBO, 0 events; urinary tract: TIL 200 mg, 1 event; ETN, 1 event; TIL 100 mg and PBO, 0 events). One patient had bone tuberculosis (TIL 200 mg; original purified protein derivative test was negative); 1 sepsis event (TIL 200 mg) occurred months after ending TIL treatment.

**Conclusions:** Infection rates with TIL treatment were low and comparable to PBO and ETN during the PBO-controlled period. By Weeks 52/64, exposure-adjusted rates remained low for all groups.

### LIPID PROFILE OF PSORIATIC ARTHRITIS PATIENTS. A FIVE-YEAR STUDY

M. Migkos, E. Kaltsonoudis, T.E. Markatseli, A.A. Drosos, P.V. Voulgari. *Rheumatology Clinic, Department Of Internal Medicine, Medical School, University Of Ioannina, Ioannina, Greece*

**Background:** Psoriatic arthritis (PsA) is an inflammatory arthritis associated with psoriasis. Many studies have shown alterations in lipid profile of PsA patients and an association with increased cardiovascular risk.

**Objectives:** To evaluate the changes of lipid profile in PsA patients treated with conventional synthetic disease modifying anti-rheumatic drugs (csDMARDs) and/or with biological DMARDs (bDMARDs) in a five-year period.

**Methods:** We studied 254 patients diagnosed with PsA according to CASPAR and ASAS (for those with axial disease) criteria. Patients were followed up at pre-defined time points [baseline, 24 weeks (wks), 48 and 240 wks after initiation of treatment. We recorded levels of Total Cholesterol (CHOL), Low Density Lipoproteins (LDL), High Density Lipoproteins (HDL) and Triglycerides (TGL). The disease activity was assessed by using Bath Ankylosing Spondylitis Disease Activity Index (BASDAI), Bath Ankylosing Spondylitis Functional Index (BASFI), disease activity score-28 (DAS) -C-Reactive Protein (CRP), DAS28-erythrocyte sedimentation rate (ESR), Health Assessment Questionnaire (HAQ), and inflammatory marker CRP and ESR. Patients were categorised in three treatment groups: patients treated with bDMARDs: anti-tumour necrosis factor alpha (TNF $\alpha$ ) agents, patients treated with csDMARDs and combined therapy (bDMARDs and csDMARDs). Disease Phenotype and epidemiological features of PsA patients were also recorded.

**Results:** There were 137 male and 117 female patients. The (Mean  $\pm$ SD) age of the patients was 56,11 $\pm$ 14,64 years and the body mass index (BMI) was 27,86  $\pm$ 5,12. Thirty-nine per cent of the patients presented as asymmetric oligoarthritis, 25,6% as symmetric polyarthritis while 27,6% had axial involvement with or without peripheral arthritis. Total CHOL and LDL levels were significantly associated with disease duration ( $p < 0,05$ ) while TGL and HDL were not significantly correlated. We found that HDL levels were significantly correlated with disease activity through time. More specific lower disease activity was associated with higher HDL levels for all disease activity scores and CRP at all time points ( $p < 0,05$ ). The significance was lost only for ESR. No association was found between the HDL levels and the different therapeutic option used. The rest of lipid profile levels did not show statistical significant association with disease activity at any time point for all disease activity indexes, including CRP and ESR.

**Conclusions:** Lipid profile of PsA patients seems to improve with better control of disease activity. More specifically high HDL levels are associated with low disease activity and these changes appear to be independent of the therapeutic choices.

SAT0314

### TO DESCRIBE AND CHARACTERISE THE PATIENT GROUP DEFINED AS COMPLEX IN A JOINT RHEUMATOLOGY/DERMATOLOGY CLINIC (PAIDER)

A. Garcia-Guillen<sup>1</sup>, A. Laiz<sup>1</sup>, A. Lopez-Ferrer<sup>2</sup>, P. Moya<sup>1</sup>, I. Castellvi<sup>1</sup>, B. Magallares<sup>1</sup>, C. Diaz-Torné<sup>1</sup>, H. Corominas<sup>1</sup>, H. Park<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Dermatology, Hospital de la Santa Creu i Sant Pau, Barcelona, Spain

**Objectives:** To describe and characterise the patient group defined as complex in a joint Rheumatology/Dermatology clinic (PAIDER).

**Methods:** We performed a retrospective chart review of patients evaluated between May 2012 and November 2017 at a weekly joint Rheumatology/Dermatology clinic at Hospital de Sant Pau (Autonomous University of Barcelona), Spain. We reviewed the medical records for demographic information, source of referral, complexity, cardiovascular risk factors and the number of visits. Complexity or complex patient was defined by at least one of the following characteristics: liver disease, neoplastic disease, psychiatric disorders, communication difficulties, adverse drug reactions to previous treatment, or paradoxical effects of biological therapy. The degree of complexity was a number (from 1 to 6) resulting from the sum of the previous characteristics. A descriptive analysis was carried out and the correlation between variables was studied through the application of nonparametric tests. The statistical package SPSS v. 21 was used to analyse the data.

**Results:** 494 patients were evaluated (52% women) with a total of 1110 visits. The mean age was 53 years. Patients were referred from Rheumatology, Dermatology, primary care physicians and other specialties in 47%, 40%, 6.5% and 5.5% of cases, respectively. The average number of visits per patient was 2.25.

164 patients (33%) were defined as complex with a total of 546 visits. 48.8% were women. The mean age was 55 years. They were referred from Rheumatology, Dermatology, primary care physicians and other specialties in 50.6%, 35.4%, 7.3% and 6.7% of cases, respectively. The mean number of following-up visits for the complex patients was 3.33.

The features that defined complexity and the number of visits required are shown in table 1.

Complexity features	Number of patients	Visits Mean $\pm$ SD
Liver disease	47/164 (28.7%)	3.6 $\pm$ 3.7
Psychiatric disorder	47/164 (28.7%)	3.4 $\pm$ 4.7
Adverse drug reactions	46/164 (28%)	4.7 $\pm$ 5.2
Paradoxical effects of biological therapy	37/164 (22.6%)	5.2 $\pm$ 5.7
Neoplastic disease	27/164 (16.5%)	1.8 $\pm$ 1.5
Communication difficulties	19/164 (11.6%)	4.1 $\pm$ 4.9

The number of visits according to the degree of complexity is shown in table 2.

Degree of complexity	Number of patients	Visits Mean $\pm$ SD
1	120/164 (73.2%)	2.8 $\pm$ 2.9
2	32/164 (19.5%)	4.1 $\pm$ 4.1
3	10/164 (6.1%)	6.4 $\pm$ 7.3
4	1/164 (0.6%)	1
5	1/164 (0.6%)	1
6	0/164 (0%)	0

The complexity features that had a significant correlation with the number of visits were liver disease ( $p < 0.001$ ), serious adverse effects to previous treatments ( $p < 0.001$ ) and paradoxical effects of biological therapy ( $p < 0.001$ ). The degree of complexity was also correlated with the number of visits (Spearman's Rho=0.262,  $p < 0.001$ ).

**Conclusions:** A third of the patients visited in our joint clinic were defined as complex, although the great majority showed a low level of complexity. Of all the features used to define complexity, only a few were associated with a greater number of visits. However, the degree of complexity of the patients was associated with an increased number of visits.

SAT0315

### ABATACEPT IN PSORIATIC ARTHRITIS: A SINGLE CENTRE, PLACEBO-CONTROLLED, CROSSOVER STUDY IN 20 PATIENTS; A PILOT PROTEOMIC FEASIBILITY STUDY

A. Kwasnik<sup>1</sup>, S. Pennington<sup>1</sup>, O. FitzGerald<sup>2</sup>. <sup>1</sup>Conway Institute of Biomolecular and Biomedical Research, University College Dublin; <sup>2</sup>Department of Rheumatology, St. Vincent's University Hospital, Dublin, Ireland

**Background:** Psoriatic arthritis (PsA) is a multifaceted inflammatory disease that affects approximately 0.25% of the global population<sup>1</sup>. A range of disease modifying drugs has been used to treat PsA including Abatacept. Unfortunately, not all PsA patients respond to Abatacept treatment and some patients may be intolerant, thus there is an urgent need for the improved selection of patients who are likely to respond Abatacept treatment.

**Objectives:** This pilot project seeks to demonstrate the potential with which MS based proteomics strategies might be used to discover proteins that may discriminate responders from non-responders to treatment with Abatacept. Using synovial samples collected at baseline and a label-free nLC-MS/MS strategy, candidate proteins were identified. These proteins together with other proteins identified in previous studies were further evaluated by developing multiplexed MRM assays to quantify the proteins both before and during Abatacept treatment (at 2 and 6 months).

**Methods:** Baseline samples from 6 patients were prepared according to the FASP protocol and analysed by Q-Exactive. MS data was analysed using MaxQuant (v. 1.4.1.2.) and Perseus (v. 1.5.0.8). For the evaluation of candidate proteins Skyline (v. 3.7.0.11317) was used to develop multiplexed MRM assays for these newly identified proteins and to analyse the MRM data acquired on high sensitivity triple quadrupole mass spectrometer (Agilent 6495).

**Results:** 41 proteins were shown to be differentially expressed at baseline between responders (n=5) and the non-responder (n=1). Of these proteins, 15 were elevated and 26 were reduced in the non-responder. A sub-set of the candidate proteins identified here (n=41) and some proteins identified in our previous PsA related studies<sup>2</sup> was used to develop an MRM assay targeting total 114 proteins. The MRM assay was developed using our stringent MRM assay standards. Six candidate proteins, ANXA1, ANXA2, S100A10, LMNA, CADH5 and MYL6 have been shown to be differentially expressed in synovial samples collected at 2 months when compared to 6 months. A further 5 proteins, ANXA5, RS18, TAGL, TRFL and HPT were differentially expressed between responders and non-responder at the 2 month time point but most importantly, these five proteins have shown a similar pattern of expression following four months of Abatacept treatment.

**Conclusions:** Although the small number of patient samples in this pilot study limits the biological significance of these findings, the data highlights some of the significant advantages of unbiased LC-MS/MS protein discovery and of multiplexed MRM assays. These advantages include reproducible and robust coverage of a large number of proteins in small synovial tissue samples and a workflow that supports rapid development of optimised multiplexed assays targeted to proteins of interest.

### RAPID AND SUSTAINED IMPROVEMENTS IN BOTH SKIN AND MUSCULOSKELETAL SYMPTOMS CORRELATES WITH IMPROVED QUALITY OF LIFE IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS

A.F. Kavanaugh<sup>1</sup>, J. Birt<sup>2</sup>, C.-Y. Lin<sup>2</sup>, O. Benichou<sup>3</sup>, M. Hufford<sup>2</sup>, A.B. Gottlieb<sup>4</sup>.  
<sup>1</sup>Univ of CA San Diego Health System, La Jolla; <sup>2</sup>Eli Lilly and Company, Indianapolis, USA; <sup>3</sup>Eli Lilly and Company, Paris, France; <sup>4</sup>New York Medical College, New York, USA

**Background:** Psoriatic arthritis (PsA) is a chronic, systemic, autoimmune, inflammatory arthritis condition commonly associated with psoriasis. Several biologic

therapies exist for the treatment of PsA, with varying degrees of efficacy and onset of action.

**Objectives:** The objective of this analysis was to examine whether there is additional value to a patient's overall quality of life if efficacy is achieved early during treatment and sustained.

**Methods:** Data were analysed from an integrated database of 2 double-blind, phase III SPIRIT trials investigating the efficacy and safety of ixekizumab (IXE), a high-affinity monoclonal antibody selectively targeting interleukin-17A, for patients with active PsA. The integrated database consisted of patients who were biologic-naïve (SPIRIT-P1, NCT01695239) or who had an inadequate response or were intolerant to tumour necrosis factor inhibitors (SPIRIT-P2; NCT02349295). Patients were randomised to placebo (n=224) or 80 mg IXE every 4 (n=229) or 2 weeks (n=226) after a 160 mg starting dose. Patients included in this post-hoc analysis had baseline  $\geq 3\%$  body surface area (BSA) and at least one visit with a Psoriasis Area and Severity Index (PASI) 75 and American College of Rheumatology (ACR) 20 response; all treatment groups were combined. During the first 24 weeks of the trial, health-related quality of life (HRQoL) was measured by Short Form-36 Health Survey (SF-36) domain scores, the EuroQoL 5 Dimensions Visual Analogue Scale (EQ-5D VAS), and the Work Productivity and Activity Impairment-Specific Health Problem (WPAI-SHP) activity impairment domain. Change in HRQoL at Week 24 was modelled using a response surface model with duration of consecutive PASI and ACR responses and their interaction as independent variables. Missing data were imputed using last observation carried forward and non-responder imputation for continuous and categorical endpoints, respectively.

**Results:** Of the 679 placebo- and IXE-treated patients in the SPIRIT trials, 215 (31.7%) had baseline  $\geq 3\%$  BSA and  $\geq 1$  PASI75 and ACR20 response. Longer consecutive ACR20 responses correlated positively with greater HRQoL improvements, as measured by the EQ-5D VAS (figure 1). Patients with a longer consecutive number of both ACR20 and PASI75 responses had the highest improvements in EQ-5D VAS. This was consistent with 7 of 8 SF-36 domains, as well as the WPAI-SHP activity impairment domain (data not shown).

Abstract SAT0316 – Figure 1

**Response surface modelling of the contribution of skin and joint improvements to patient HRQoL.** (A) Three-dimensional scatterplot of skin (y-axis: PASI – consecutive response in weeks), joint (x-axis: ACR20 – consecutive response in weeks), and HRQoL (z-axis: EQ-5D – change from baseline) improvement at Week 24. A colour spectrum is applied to HRQoL improvements (blue [least improvement] to red [greatest improvement]). (B) Response surface of scatterplot estimated by smoothing spline method.

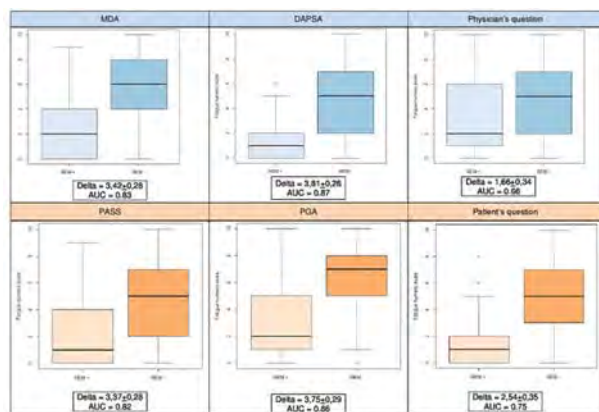

**Conclusions:** Early and sustained improvements in the symptoms of PSA correlated positively with improved HRQoL. The greatest HRQoL improvements were achieved when both skin and musculoskeletal symptoms improved early and were sustained.

DOI: 10.1136/annrheumdis-2018-eular.2331

**Conclusions:** Fatigue levels were relatively high in these PsA patients whose disease was often well-controlled. Fatigue was lower in patients in remission, according to all definitions of remission; the remission definition with best known-groups validity for fatigue was DAPSA remission. Moreover both composite measures perform better than the physicians opinion of remission. These elements may be important in a context of shared decision-making.

#### SAT0319 DESCRIPTION OF MUSCULOSKELETAL SYMPTOMS IN A COHORT OF PATIENTS WITH PSORIASIS

C. Magee<sup>1</sup>, F. Farkas<sup>1</sup>, N. Ikumi<sup>1</sup>, A. Szentpetery<sup>1</sup>, P. Gallagher<sup>1</sup>, B. Kirby<sup>2</sup>, O. Fitzgerald<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Dermatology, St. Vincent's University Hospital, Dublin, Ireland

**Background:** The BIOMarkers of COMorbidities (BIOCOM) in Psoriasis (Pso) study is a longitudinal study which aims to identify clinical, genetic or protein biomarker features associated with the development of co-morbidities, notably Psoriatic Arthritis (PsA) in patients with Pso. Pso usually precedes the development of PsA with an average interval of 10 years. Thus, Pso patients are an ideal group in which to study the early events in the evolution to PsA.

**Objectives:** Herein we describe the baseline clinical features in this BIOCOM cohort. Based on these features, we categorise patients into groupings which may be helpful during long-term follow-up.

**Methods:** Patients are being recruited from the dermatology clinics at St. Vincent's University Hospital, Dublin. Inclusion criteria included a diagnosis of Pso with disease duration of less than 10 years and an age of 18 years or older. Patients with another serious active medical illness, a previous diagnosis of inflammatory arthritis or those who were receiving systemic immunosuppressant therapy for Pso were excluded

Following recruitment, patients were assessed for musculoskeletal (MSK) signs or symptoms: questionnaire detailing history of any MSK complaints including inflammatory back pain, full physical examination including evidence of tender or swollen joints and enthesal tenderness (using the Leeds Enthesitis Index) and routine blood testing including inflammatory markers.

If patients had any MSK findings they underwent routine radiographs, MRI scanning or ultrasound scanning as indicated. Patients were then categorised using all information available as follows: Pso only; Pso+: MSK signs or symptoms but insufficient for diagnosis of PsA; PsA (CASPAR); Diagnosis of PsA meeting CASPAR criteria; Other Rheumatic Disease.

**Abstract SAT0319 – Table 1.** Breakdown of Features of Inflammatory Articular Disease

MSK Finding(s)	No. of Patients (total 96)
Tender or Swollen Joint(s) (T/S J) only	41
Enthesitis (E) only	12
Inflammatory Back Pain (IBP) only	10
T/S J and E	20
T/S J and IBP	3
E and IBP	2
T/S J, E and IBP	8

Of these 96 patients, 79 patients had some additional imaging studies.

**Results:** To date 190 patients with Psoriasis have been recruited. Of those, 9 were excluded due to a diagnosis of Pso >10 years previously. One was excluded due to a previous diagnosis of JIA

Of the remaining 180 patients: 106 were male (58.9%). Mean age was 41.5 ±14.8 years. Average duration of Pso: 6.1±2.9 years.

On examination: 126 (70%) had psoriatic nail disease (pitting, ridges or onycholysis).

84 patients had no musculoskeletal signs or symptoms. The remaining 96 patients had at least one musculoskeletal finding as outlined in table 1 below.

**Abstract SAT0319 – Table 2.** shows how patients were subsequently categorised based on their history, clinical examination, laboratory blood results and imaging.

Breakdown of Diagnoses of BIOCOM patients at baseline (180)

Pso only	84
Pso+	64
PsA (CASPAR)	7
Other Rheumatic Disease	25

**Conclusions:** Analysis of patients recruited to date for the BIOCOM-Pso study shows that at baseline at least one third of patients with Pso had non-specific MSK signs and symptoms. Previous studies suggest these patients may be more likely to subsequently develop PsA. By following this cohort prospectively, we hope to better characterise which features are predictive of the development of PsA in patients with Pso.

#### SAT0320 RELIABILITY ANALYSIS OF THE MADRID SONOGRAPHIC ENTHESIS INDEX (MASEI) AND DIFFERENT DOPPLER SUBGROUPS IN PSORIATIC ARTHRITIS

C. Macía Villa<sup>1</sup>, S. Falcao<sup>2</sup>, E. De Miguel<sup>3</sup>. <sup>1</sup>Rheumatology, Hospital Universitario Severo Ochoa, Madrid, Spain; <sup>2</sup>Rheumatology, CEDOC, NOVA Medical School, UNL, CHLO, EPE., Lisboa, Portugal; <sup>3</sup>Rheumatology, Hospital Universitario La Paz, Madrid, Spain

**Background:** Enthesitis is the cornerstone of spondyloarthritis, and ultrasound (US) indexes have emerged in the last years being the Madrid Sonographic Enthesis Index (MASEI) one of the more widely used.

**Objectives:** To evaluate the reliability of MASEI and different entheses power doppler (PD) definitions in Psoriatic Arthritis (PsA).

**Methods:** 27 consecutive non selected PsA patients were included. An US expert rheumatologist performed the MASEI examination using a MyLab 70 XVG machine, Esaote, Genova, Italy, with a greyscale (GS) 13 MHz probe and 7.1 MHz power Doppler (PD) frequency, PRF 750 Hz and 60 Gain. US images and 3–5 s videos were obtained in transversal and longitudinal views for further reliability analysis. The inter-reader reliability analysis was performed by three readers and true US result was the consensus of at least two of them. In addition to the PD item of MASEI (defined as signal in bone profile or intratendon or bursa on the entheses area), three other PD definitions were evaluated as present or absent: PD OMERACT (PD signal at entheses ≤2 mm to the bone profile), PD bursa (PD signal inside bursa) and PD tendon (PD signal in the entheses tendon >2 mm from the bone profile). Intraclass correlation coefficient (ICC) estimations and 95% confident intervals were calculated for the reliability analysis of MASEI and PD subgroups based on a mean-rating (k=3), absolute-agreement, two-way mixed effect model. Cohen's Kappa test was used for analysis of MASEI's items reliability. SPSS statistical package version 20 (SPSS Inc, Chicago, IL) was used.

**Results:** Inter-reader reliability of MASEI and PD subgroups is shown in table 1. PD bursa showed the lowest reliability. MASEI, PD MASEI, PD OMERACT and PD tendon showed good to excellent reliability, being PD tendon the best one. table 2 shows reliability data of each MASEI lesion in each entheses included in the index. Best agreement percentages and kappa values were found in erosions and PD with mainly good to excellent data, while the worst ones were found in calcifications with poor to moderate values.

**Abstract SAT0320 – Table 1.** Inter-reader reliability of MASEI and PD subgroups. Scores expressed as mean±SD for each reader.

	Reader 1	Reader 2	Reader 3	ICC	95% CI
<b>MASEI</b>	28,52 ±13,43	31,89 ±13,99	31,30 ±14,14	0922	0,852– 0962
<b>PD MASEI</b>	6,44±5,80	6,89±6,43	6,78±5,43	0921	0,851– 0962
<b>PD OMERACT</b>	1,25±1,32	1,41±1,65	1,11±1,39	0895	0,802– 0949
<b>PD BURSA</b>	0,30±0,67	0,18±0,56	0,11±0,42	0776	0,576– 0891
<b>PD TENDON</b>	1,96±1,74	2,15±2,09	2,22±1,82	0934	0,876– 0968

**Abstract SAT0320 – Table 2.** Inter-reader reliability and agreement analysis of MASEI components. All items were categorised as yes/no. N/A not applicable since one of the lectors offers the same result for all cases, so kappa can't be calculated in this item due to sparse differences between lectors. N/B enthesis without bursa.

		Abnormal tendon structure	Thickened tendon	Erosion	Enthesis calcification	Enthesis PD	Bursitis
Triiceps tendon enthesis	Mean kappa	0.68 ± 0.19	0.68 ± 0.19	0.68 ± 0.19	0.57 ± 0.19	0.62 ± 0.19	N/A
	Mean agreement	81.95%	86.42%	86.25%	80.25%	85.04%	
Quadriceps tendon enthesis	Mean kappa	0.52 ± 0.16	0.58 ± 0.16	0.60 ± 0.16	0.49 ± 0.15	0.61 ± 0.16	N/A
	Mean agreement	76.55%	79.01%	76.69%	70.69%	82.71%	
Proximal patellar ligament enthesis	Mean kappa	0.50 ± 0.14	0.47 ± 0.13	0.47 ± 0.13	0.23 ± 0.09	0.72 ± 0.11	N/A
	Mean agreement	77.77%	83.95%	88.89%	39.03%	93.83%	
Distal patellar ligament enthesis	Mean kappa	0.25 ± 0.13	0.49 ± 0.13	0.60 ± 0.13	0.43 ± 0.12	0.80 ± 0.09	N/A
	Mean agreement	60.25%	81.88%	100%	77.77%	85.04%	95.83%
Achilles tendon enthesis	Mean kappa	0.47 ± 0.14	0.79 ± 0.09	0.93 ± 0.04	0.49 ± 0.14	0.81 ± 0.08	0.78 ± 0.13
	Mean agreement	72.84%	91.64%	96.77%	81.48%	92.99%	83.83%
Plantar aponeurosis enthesis	Mean kappa	0.27 ± 0.11	0.52 ± 0.09	0.60 ± 0.10	0.11 ± 0.05	N/A	N/A
	Mean agreement	72.84%	87.04%	100%	45.68%	98.77%	

**Conclusions:** MASEI has demonstrated to be a reliable tool in PsA. Erosions and PD showed the best reliability values. Evaluating different definitions of enthesis PD, signal in the tendon was the most reliable one, followed with minimal differences by PD MASEI and PD OMERACT, and in last place PD bursa.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.4274

**Abstract SAT0321 – Table 1.** Enthesitis and Dactylitis Resolution from the Integrated SPIRIT-P1 and SPIRIT-P2 Dataset (Week 24)

	PBO	IXEQ4W	IXEQ2W
LEI=0	26/126 (21%)	53/136 (39%)*	49/141 (35%)*
Lateral epicondyle=0	24/79 (30%)	39/85 (46%)*	39/86 (45%)*
Medial femoral condyle=0	23/79 (29%)	41/92 (45%)*	45/100 (45%)*
Achilles tendon insertion=0	19/64 (30%)	37/75 (49%)*	38/74 (51%)*
LDI-B=0	10/42 (24%)	52/67 (78%)*	30/46 (65%)*

Data presented as n/N (%). N=patients with baseline enthesis (LEI>0), depicted enthesal points, or dactylitis (LDI-B=0); n=responding patients \*p<05,\*\*p<001

**Conclusions:** Treatment with IXE resulted in significant improvement in enthesitis and dactylitis in patients with pre-existing enthesitis or dactylitis. Resolution of enthesitis symptoms was associated with improvements in patients' function and HRQoL.

**SAT0321 IXEKIZUMAB TREATMENT SIGNIFICANTLY IMPROVES ENTHESITIS AND DACTYLITIS IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS: RESULTS FROM THE SPIRIT TRIALS**

D.D. Gladman<sup>1</sup>, A.-M. Orbai<sup>2</sup>, G. Gallo<sup>3</sup>, J. Birt<sup>3</sup>, S. Rathmann<sup>3</sup>, H. Marzo-Ortega<sup>4</sup>. <sup>1</sup>University of Toronto, Toronto, Canada; <sup>2</sup>Johns Hopkins University, Baltimore; <sup>3</sup>Eli Lilly and Company, Indianapolis, USA; <sup>4</sup>LBRC, LTHT, and LIRMM, University of Leeds, Leeds, UK

**Background:** Psoriatic arthritis (PsA) is a chronic inflammatory disease with heterogeneous musculoskeletal manifestations including enthesitis and dactylitis. Ixekizumab (IXE), an interleukin-17A antagonist, is approved in the USA for the treatment of PsA including patients with pre-existing enthesitis or dactylitis.

**Objectives:** To investigate the impact of IXE treatment on the resolution of enthesitis or dactylitis and whether such improvements were associated with improved function and health-related quality of life (HRQoL).

**Methods:** Patients with active PsA who were biologic-naïve (SPIRIT-P1; NCT01695239) or with prior inadequate response to tumour necrosis factor inhibitor(s) (SPIRIT-P2; NCT02349295) were randomised to placebo (PBO) or 80 mg IXE every 4 weeks (IXEQ4W) or 2 weeks (IXEQ2W), after a 160 mg starting dose. All patients who were inadequate responders at Week 16 received rescue therapy (changes in background therapy). Leeds Enthesitis Index (LEI), Leeds Dactylitis Index-Basic (LDI-B), Health Assessment Questionnaire Disability Index (HAQ-DI), and EuroQoL-5D Visual Analogue Scale (EQ-5D VAS) were measured at Week 24. Missing data or data from inadequate responders were considered non-response or imputed with last observation carried forward for categorical and continuous measures, respectively. Statistical comparisons between PBO and IXE treatment groups were performed with a logistic regression model using Wald's test with treatment and study as factors. In post hoc-analyses, associations between enthesitis and dactylitis with HAQ-DI and EQ-5D VAS are based on an ANCOVA model adjusting for study and Disease Activity of Psoriatic Arthritis (DAPSA).

**Results:** In the integrated SPIRIT-P1 and -P2 dataset (n=679), 403 patients (59% of total) had baseline enthesitis (LEI >0) with a mean 2.9 LEI score, and 155 patients (23% of total) had baseline dactylitis (LDI-B >0) with a mean 56.4 LDI-B score. Relative to PBO, IXE treatment resulted in significantly higher resolution of enthesitis (SPIRIT-P1) and dactylitis (SPIRIT-P1 and -P2) after 24 weeks.<sup>1,2</sup> In the integrated SPIRIT-P1 and -P2 dataset, both IXEQ4W and IXEQ2W had significantly higher enthesitis and dactylitis resolution than PBO treatment at Week 24 (Table). In ad-hoc analysis, IXE treatment had significantly higher resolution of enthesitis compared to PBO at the enthesal points comprising the LEI score (Table). For all PBO- and IXE-treated patients at Week 24, least squares mean (SE) HAQ-DI changes from baseline were -0.44 (0.05) and -0.25 (0.03); p<0.01 for patients who did and did not resolve enthesitis, and -0.41 (0.06) and -0.31 (0.07); p=0.34 for patients who did and did not resolve dactylitis. Corresponding EQ-5D VAS improvements were 12.3 (2.2) and 5.8 (1.5); p=0.02 for patients who did and did not resolve enthesitis, and 10.8 (2.8) and 9.8 (3.5); p=0.83 for patients who did and did not resolve dactylitis.

**SAT0322 THE EFFECT OF GUSELKUMAB ON DACTYLITIS: RESULTS FROM A PHASE 2 STUDY IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS**

Hsia<sup>7</sup>, C.S. Karyekar<sup>8</sup>, A. Deodhar<sup>9</sup>. <sup>1</sup>Krembil Research Institute, Toronto, Canada; <sup>2</sup>U of Geneva, Geneva, Switzerland; <sup>3</sup>NY Medical College, Metropolitan Hospital, New York, USA; <sup>4</sup>U of Leeds, Leeds, UK; <sup>5</sup>U of Queensland, Brisbane, Australia; <sup>6</sup>Janssen Research and Development, LLC, Spring House; <sup>7</sup>Janssen Research and Development, LLC/U Penn, Spring House/Phila; <sup>8</sup>Janssen Research and Development, LLC, Horsham; <sup>9</sup>Oregon Health and Science U, Portland, USA

**Background:** In a Phase 2 study, Guselkumab (GUS) was shown to be safe and effective in patients (pts) w/active psoriatic arthritis (PsA).

**Objectives:** To evaluate the effect of GUS on dactylitis in a subset of pts w/dactylitis at baseline (BL) in the phase 2 PsA study of GUS.

**Methods:** Pts w/active PsA and ≥3% body surface area of plaque psoriasis, despite current or previous treatment, were randomised 2:1 to receive 100 mg subcutaneous GUS at wks 0, 4 then every 8 weeks (wks, q8w) or placebo (PBO) during a 24wk double-blind treatment period. At wk16, pts w/<5% improvement in swollen and tender joint counts early escaped (EE). At wk24, the PBO group crossed over to receive GUS (wks 24, 28 then q8w) (PBO→GUS) and the GUS group continued receiving GUS (GUS→GUS) through wk44. Dactylitis was assessed by scoring each digit from 0–3 (0=absent, 1=mild, 2=moderate, 3=severe), for a combined score of 0–60. Sensitivity analysis of change from BL through wk24 in dactylitic digits was performed (combined score 20). Dactylitis scores during the 24-wk double-blind treatment was analysed using LOCF imputation for missing data and EE. Dactylitis after wk24 was evaluated using observed data.

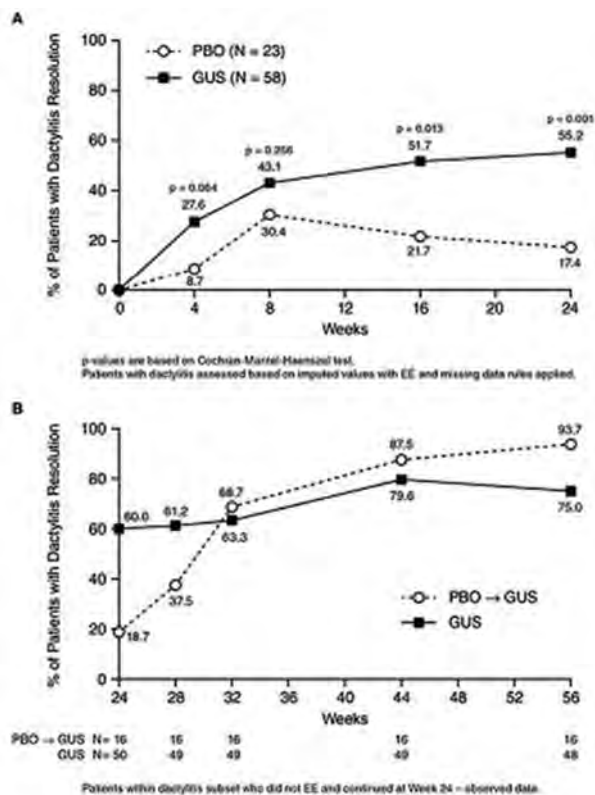

**Results:** Of 149 pts, 81 presented w/dactylitis at BL (PBO n=23, mean[SD]=3.9 [3.01]; GUS n=58, mean[SD]=6.5 [6.15]) and 66 continued to the active treatment period (PBO→GUS n=16; GUS→GUS n=50). The dactylitis subset was similar to the overall population in BL characteristics except for higher median values for # of swollen joints, # of tender joints, and CRP. At wks 16 and 24, the GUS group had a significantly greater reduction in the dactylitis score (wk24 mean [SD] change from BL, PBO: -0.4 [6.06]; GUS: -3.8 [4.93]; p=0.006) and a greater% of pts w/dactylitis resolution, compared to the PBO group (figure 1). Consistent results were obtained w/the # digits w/dactylitis (wk24 mean [SD] change from BL, PBO: -0.2 [3.04]; GUS: -2.1 [2.21]; p=0.003). Improvement in dactylitis seen at wk24 was maintained in the GUS→GUS group (wk56: mean[SD] change from BL=-5.5 [4.84], 75% of pts w/resolution) and the values for the PBO→GUS group (wk56: mean[SD] change from BL=-4.4 [3.50], 93.7% of pts w/resolution) approached those of the GUS→GUS group. Improvement in dactylitis was greater in ACR20/ACR50 responders vs non-responders in GUS-treated patients (Table

1) and was significantly correlated with improvement in TJC ( $R=0.38$ ,  $p=0.004$ ), SJC ( $R=0.50$ ,  $p<0.0001$ ), and HAQ-DI score ( $R=0.33$ ,  $p=0.013$ ).

**Abstract SAT0322 – Table 1.** Change in Dactylitis Score in ACR20/50 and PASI75 Responders and Non-responders

	Mean (SD) change from BL in Dactylitis Score at Wk24		
	Non-responders	Responders	p-value
ACR 20	-1.76 (7.595), n=21	-4.94 (4.666), n=36	0.044
ACR 50	-2.44 (6.213), n=36	-6.05 (5.133), n=21	0.027
PASI 75	-4.00 (2.858), n=13	-3.70 (6.736), n=44	0.924

**Figure 1.** Proportion of Patients with Dactylitis Resolution over Time

**Conclusions:** GUS is efficacious in resolving symptoms of dactylitis in pts w/ active PsA. This effect on dactylitis is correlated with improvement in joint symptoms and physical function.

### SAT0323 ADVERSE DRUG REACTIONS RELATED TO DISEASE-MODIFYING DRUGS (DMARD) IN PSORIATIC ARTHRITIS PATIENTS IN DAILY CLINICAL PRACTICE

D. Freitas Nuñez<sup>1,2,3</sup>, Z. Rosales<sup>1,2</sup>, L. León<sup>2</sup>, J. Font<sup>1</sup>, P. Lois<sup>1</sup>, C. Vellido<sup>1</sup>, E. Pato<sup>1</sup>, B. Fernández<sup>1</sup>, L. Rodríguez-Rodríguez<sup>1,2</sup>, J.A. Jover<sup>1</sup>, L. Abasalo<sup>1,2</sup>.  
<sup>1</sup>Rheumatology, Hospital Clínico San Carlos; <sup>2</sup>Fundación para la Investigación Biomedica; <sup>3</sup>Complutense University, Madrid, Spain

**Background:** Psoriatic arthritis (PsA) benefits from DMARDs and to know more about the adverse drug reactions (ADRs) represent an advance for the management and safety of these patients in clinical practice.

**Objectives:** To evaluate the discontinuation due to ADRs of DMARDs used in PsA patients and to analyse the possible associated factors.

**Methods:** Retrospective longitudinal observational study. **Subjects:** inception cohort of patients from January 2010 to December 2014 and followed up to December 2016, diagnosed with PsA according to ICD-10 code. **Main outcome:** discontinuation of conventional synthetic DMARDs (csDMARDs) and biological originator DMARDs (boDMARDs) due to ADR (moderate: drug suspension regardless of the repercussions, severe: hospital admission required or death). **Covariables:** sociodemographic and clinical. **Statistical analysis:** To estimate DMARDs discontinuation rates, survival techniques were used, expressing the incidence rate (IR) per 100patients\*year with their respective CI at 95%. Multivariate Cox regression models were performed to analyse the factors associated with DMARDs discontinuation due to ADRs and results were expressed in Hazard ratio(HR) and 95% CI.

**Results:** 191 patients were included, with a follow-up of 379.70 Patients\*year. 50.3% were male, mean age at diagnosis was 50±14.6 years old. 46.6% of the patients had a history of cutaneous psoriasis. HLA-B27 was positive in 20% of patients. Throughout the follow-up, all patients received csDMARDs and 23 used boDMARDs. Methotrexate(MTX) was the most used drug 69.7%. 30% were on combination therapy, the most frequent was antiTNF +MTX. There were 44 discontinuations due to ADRs, IR 11.59 [8.62–15.57] and 3 were severe, requiring hospital admission (two infections and one cancer), no deaths were recorded. Among the most frequent causes of discontinuation related to ADRs were digestive intolerance 32%, nonspecific manifestations 11%, infections 9% and abnormal transaminase levels 9%. Table1 shows the DMARDs discontinuation rates due to ADRs. In the final discontinuation model related with ADRs (Table2), we observed that distress, high disease activity, corticosteroids at diagnosis and combination therapy were associated with a higher rate of discontinuation.

Table1	Patients*years	Events (n)	IR	95% CI
MTX	243.46	23	9.45	
Salazopyrine	84.80	14	16.51	
Leflunomide	21.83	10	27.48	
Antimalarials	25.34	8	15.78	
boDMARDs	57.56	5	8.69	
Combination therapy	101.76	16	15.72	

Table2	HR	95% CI	P
Women	1.38	0.61–3.09	0.436
Age at diagnosis	0.97	0.94–1.00	0.103
Distress level	3.78	1.85–7.71	0.000
C Reactive protein ≥1.05 gr/dL	2.31	1.02–5.20	0.043
corticosteroids at diagnosis	2.66	1.10–6.40	0.029
Combination therapy	2.23	1.14–4.38	0.020
boDMARD	0.32	0.08–1.27	0.105
MTX vs rest of DMARD	0.42	0.19–0.92	0.032

**Conclusions:** The discontinuation rate due to ADRs was 11.59, although most of them did not have an important clinical impact. We have found some psychological, clinical and treatment factors that can modify the DMARDs survival on PsA patients. We also observed that MTX, seems to be safe in the treatment of PsA, presenting the lowest probability of suspension related to ADRs compared with the rest of treatments.

SAT0324

**CERTOLIZUMAB PEGOL PROVIDES SUSTAINED REMISSION AND MINIMAL DISEASE ACTIVITY IN PATIENTS WITH PSORIATIC ARTHRITIS OVER 4 YEARS' TREATMENT**

D. van der Heijde<sup>1</sup>, A. Deodhar<sup>2</sup>, O. FitzGerald<sup>3</sup>, R. Fleischmann<sup>4</sup>, D. Gladman<sup>5</sup>, A. B. Gottlieb<sup>6</sup>, L.C. Coates<sup>7</sup>, B. Hoepken<sup>8</sup>, L. Bauer<sup>9</sup>, L. Peterson<sup>9</sup>, M. Khraishi<sup>10</sup>, P. J. Mease<sup>11</sup>. <sup>1</sup>Leiden University Medical Centre, Leiden, Netherlands; <sup>2</sup>Oregon Health and Science University, Portland, OR, USA; <sup>3</sup>St Vincent's University Hospital and Conway Institute for Biomolecular Research, University College Dublin, Dublin, Ireland; <sup>4</sup>University of Texas Southwestern Medical Center, Dallas, TX, USA; <sup>5</sup>Centre for Prognosis Studies in The Rheumatic Diseases and Krembil Research Institute, Toronto Western Hospital, Toronto, Canada; <sup>6</sup>Department of Dermatology, New York Medical College at Metropolitan Hospital, New York, NY, USA; <sup>7</sup>Nuffield Orthopaedic Centre, Oxford, UK; <sup>8</sup>UCB Pharma, Monheim, Germany; <sup>9</sup>UCB Pharma, Raleigh, NC, USA; <sup>10</sup>Department of Medicine, Memorial University of Newfoundland, St John's, Canada; <sup>11</sup>Swedish Medical Center and University of Washington, Seattle, WA, USA

**Background:** Disease Activity Index for Psoriatic Arthritis (DAPSA)<sup>1</sup> and the minimal disease activity (MDA) criteria<sup>2</sup> are instruments recommended for evaluating disease activity in psoriatic arthritis (PsA). The RAPID-PsA trial (NCT01087788) has demonstrated the sustained efficacy of certolizumab pegol (CZP) across the spectrum of PsA symptoms.<sup>3,4</sup>

**Objectives:** To report the proportion of CZP-treated patients (pts) achieving DAPSA remission (REM), DAPSA low disease activity (LDA), MDA (fulfilling ≥5/7 MDA criteria), and very low disease activity (VLDA; fulfilling 7/7 MDA criteria) over 216 weeks (wks) in RAPID-PsA.

**Methods:** RAPID-PsA was double-blind and placebo-controlled to Wk24, dose-blind to Wk48, and open-label (OL) to Wk216. Pts had active PsA and had failed ≥1 disease modifying anti-rheumatic drug. Data for pts randomised to CZP at Wk0 (200 mg every 2 wks or 400 mg every 4 wks, following a 400 mg loading dose at Wks0, 2, 4), who continued their assigned dose in the OL period, are presented as observed case and with imputation (figure 1). Outcomes reported are DAPSA (the sum of tender and swollen joint counts [TJC 68; SJC 66], pt global and pain assessment [10 cm visual analogue scale], and C-reactive protein levels [mg/dL]), and pts achieving: 1) DAPSA LDA (DAPSA >4 and ≤14); 2) DAPSA REM (DAPSA ≤4); 3) MDA (fulfilling ≥5/7 MDA criteria); and 4) VLDA (fulfilling 7/7 MDA criteria), to Wk216. Pts withdrawing from the study between scheduled visits had their final observed assessment values assigned to the next scheduled visit timepoint.

**Results:** Of 409 pts randomised; 273 received CZP from Wk0, of whom 248 (90.8%) completed Wk24, 237 (86.8%) completed Wk48, and 183 (67.0%) completed Wk216. The mean (SD) baseline DAPSA was 44.8 (22.9). Of pts completing Wk24, 29.7% (74/249) achieved LDA; 25.3% (63/249) REM; 38.2% (95/249) MDA; and 14.9% (37/249) VLDA. At Wk216, 31.9% (59/185) achieved LDA; 44.3% (82/185) REM; 57.8% (107/185) MDA; and 29.0% (58/183) VLDA (figure 1).

**Figure: A) Patients with PsA achieving DAPSA LDA and REM over 4 years' CZP treatment**

**B) Patients with PsA achieving MDA and VLDA over 4 years' CZP treatment**

Data shown for the Randomized Set, for pts on either dose regimen. OC proportions are calculated as the number achieving the target relative to the number of pts assessed at that timepoint. Missing values were imputed using LOCF for DAPSA and NRI for MDA criteria. [a] Number of patients with an observed value at the scheduled visit timepoint; [b] The proportion of pts achieving MDA (≥5/7 criteria) shown includes those achieving VLDA (7/7 MDA criteria). CZP: certolizumab pegol; DAPSA: Disease Activity Index for Psoriatic Arthritis; DAPSA LDA: DAPSA low disease activity (>4 and ≤14); DAPSA remission: DAPSA REM (≤4); LOCF: last observation carried forward; MDA: minimal disease activity; NRI: non-responder imputation; OC: observed case; PsA: psoriatic arthritis; pt: patient; VLDA: very low disease activity.

**Abstract SAT0324 – Figure 1. A) Patients with PsA achieving DAPSA LDA and REM over 4 years' CZP treatment. B) Patients with PsA achieving MDA and VLDA over 4 years' CZP treatment**

**Conclusions:** A substantial proportion of pts who completed the 4 year study achieved disease inactivity targets: ~75% achieved DAPSA LDA or REM, almost 60% achieved MDA, and half of those also achieved VLDA.

SAT0325

**COMPARATIVE ANALYSIS OF GENDER DIFFERENCES, HLA-B27 STATUS AND SKIN LESION SEVERITY IN EARLY AXIAL AND PERIPHERAL PSORIATIC ARTHRITIS PATIENTS**

E.E. Gubar, E.Y. Loginova, T.V. Korotaeva, S.I. Glukhova, V.A. Nasonova  
Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Clinical features of axial involvement in psoriatic arthritis (PsA) had been studied before only at advanced stages. Skin lesion severity, HLA-B27 status and gender-specific differences in early PsA patients with axial involvement hadn't been sufficiently studied.

**Objectives:** To compare clinical features of two early peripheral PsA patient populations – with and without axial involvement.

**Methods:** 95 patients (pts) (M/F=47/48) with early PsA according to CASPAR criteria were included; all pts had peripheral arthritis for ≤2 years; no inflammatory back pain (IBP) pts were specially selected. Mean age 36.5±10.7 years, disease duration 12.2±10.3 mo, disease activity indexes DAS=4.0±1.4, DAS28=4.2±1.1, BASDAI=4.5±1.6 (in pts with axial involvement); patient's global disease activity (PGA) VAS 56.9±17.1. All pts were evaluated for the presence of inflammatory

back pain (IBP) by ASAS criteria. The examination included X-ray of sacroiliac joints (SIJs) (pelvic radiographs), HLA B27 antigen status; magnetic resonance imaging (MRI) of SIJs was performed in 79 pts, regardless of the presence of IBP, on Signa Ovation 0,35T. Bone marrow oedema on MRI (STIR) was considered as active MRI sacroiliitis (MRI-SI). Radiographic sacroiliitis (R-SI) was considered according to New York criteria (unilateral grade  $\geq 3$  or bilateral grade  $\geq 2$ ). X-ray and MRI results were evaluated by an independent reader. IBP was observed in 63 cases (66.3%), MRI-SI in 28 of 79 (35.4%) examined cases, R-SI in 29 cases (30.5%). Pts were split into two groups (gr.): those with axial involvement (axPsA), that is with IBP and/or R-SI and/or MRI-SI; and those without axial involvement (having only peripheral PsA [pPsA]). The axPsA gr. included 65 (68.4%) cases, the pPsA gr. – 30 (31.6%) cases. Skin lesion severity was evaluated in terms of body surface area (BSA) affected and Psoriasis Area Severity Index (PASI). When BSA was  $\geq 3\%$ , PASI was calculated.  $PASI \geq 11$  indicates moderate and severe psoriasis.

**Results:** The following significant differences were revealed between gr. axPsA and gr. pPsA: **gender-related ones:** in gr. axPsA men-to-women ratio was 60.0% to 40.0%, while in gr. pPsA it was 26.7% to 73.3% ( $p=0.003$ ); **age-related ones:** mean age of gr. axPsA was  $33.9 \pm 9.6$  years, while of gr. pPsA it was  $41.7 \pm 10.6$  years ( $p=0.0007$ ); **in disease duration:** in gr. axPsA it was  $10.3 \pm 8.7$  mo. which was less than gr. pPsA  $16.1 \pm 11.7$  mo. ( $p=0.008$ ); **in HLA-B27 antigen status:** in gr. axPsA it was positive in 47.6% of pts. while in gr. pPsA in 23.3% of pts. ( $p=0.02$ ); **in PGA:**  $58.4 \pm 17.3$  mm in gr. axPsA, and  $49.8 \pm 16.7$  mm in gr. pPsA ( $p=0.02$ ); **in skin lesions' severity:** it was higher in gr. axPsA: BSA median was 3.0 [1.0–9.0] in gr. axPsA and 1.0 [0.2–3.0] in gr. pPsA ( $p=0.007$ ), and PASI median was 15.6 [6.6–55.2] in gr. axPsA and 6.0 [0.0–7.2] in gr. pPsA ( $p=0.006$ ).

**Conclusions:** Axial involvement in early PsA patients is significantly more frequent in males and in pts with positive HLA-B27 antigen status. Axial involvement is associated with high patient-reported disease activity and severe skin lesion. These findings may have a positive impact on diagnosis of axial disease, as well as on the selection of the best therapeutic strategy.

SAT0326

#### DURATION OF REMISSION AND MINIMAL DISEASE ACTIVITY AFTER STARTING AND DISCONTINUATION OF BIOLOGIC (B) DMARDS IN EARLY PSORIATIC ARTHRITIS PATIENTS TREATED ACCORDING TO TREAT-TO-TARGET STRATEGY (RESULTS OF AN OPEN-LABEL REMARCA STUDY)

E. Loginova, T. Korotaeva, E. Gubar, S. Glukhova, E. Nasonov. *Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** The main goal of treat-to-target (T2T) strategy in psoriatic arthritis (PsA) is achievement of remission (REM) or minimal disease activity (MDA). There is limited data concerning the duration of REM/MDA after starting and discontinuation of bDMARDs in early (E) PsA patients (pts).

**Objectives:** to investigate the timing and duration of REM/MDA after starting and discontinuation of bDMARDs therapy in EPsA pts treated according to T2T strategy.

**Methods:** 34 (M-18/F-16) pts with active EPsA according to the CASPAR criteria non-responder to methotrexate (MTX) subcutaneous treatment, bDMARD-naïve were included; mean age  $38 \pm 11$  years, PsA duration  $12 \pm 10$  months (mon.), psoriasis duration  $89.8 \pm 91.1$  mon., median Disease Activity index for Psoriatic Arthritis (DAPSA)  $33.55 [28.34–41.77]$ . All pts started bDMARDs: Adalimumab (21 pts), Certolizumab pegol (3 pts), Etanercept (2 pts), Ustekinumab (8 pts)  $\pm$  MTX. The median duration of bDMARDs treatment was 9 [6.5–15], Min 3 mon. – Max 24 mon. The bDMARDs treatment was stopped due to an individual inefficiency, loss of efficacy or non-medical reasons. At baseline and every 3 mon. all pts underwent assessment of PsA activity by DAPSA and MDA criteria (tender joint count  $\leq 1$ , swollen joint count  $\leq 1$ , PASI  $\leq 1$  or BSA  $\leq 3$ , patient pain global assessment VAS  $\leq 15$ , patient's global disease activity VAS  $\leq 20$ , HAQ  $\leq 0.5$ , enthesitis count  $\leq 1$ ). The proportion of pts who achieved REM by DAPSA  $\leq 4$  and MDA (5 of 7 cutpoints) at least once, as well as timing and duration of REM/MDA after starting and cessation of bDMARDs were performed. Pts reports about a flare coming, close to the scheduled time of assessment, was taken into account.  $M \pm SD$ , Me [Q75; Q50], (%) were calculated. All  $p < 0.05$  were considered to indicate statistical significance.

**Results:** By the 24 mon. of the study REM by DAPSA and MDA was reached at least once by 27 (79%) and 28 (82%) out of 34 pts, accordingly. Mean timing of REM by DAPSA and MDA after starting of bDMARDs was  $5.8 \pm 3.2$  and  $4.0 \pm 1.9$  mon., accordingly. During the observation 19 out of 27 pts (70.4%) had stopped bDMARDs due to different reasons. 8 out of 27 pts (29.6%) continued the treatment and had REM according to DAPSA by the end of the study. After cessation of bDMARDs flares by DAPSA were seen in 12 out of 19 pts (63.2%) with the mean duration of REM  $5.8 \pm 2.3$  mon. (Fig 1.). The loss of MDA was seen in 12 out of 20 pts (60%) with the mean duration of MDA  $6.2 \pm 3.0$  mon. Pts reports about

the time of PsA symptoms flares was  $3.5 \pm 3.4$  mon. 5 out of 34 pts (15%) loss the efficacy after  $12.0 \pm 4.7$  mon. of bDMARDs treatment.

**Abstract SAT0326 – Figure 1.** Dynamics of DAPSA after starting and discontinuation of bDMARDs therapy in EPsA.

**Conclusions:** Most EPsA pts treated with bDMARDs according to T2T strategy achieved REM and MDA within 5 mon. Flares after bDMARDs discontinuation within 6 mon were found in more than a half of pts. according to PsA activity indices and within 3 mon. by pts reports. REM and flare timing after bDMARDs therapy discontinuation indicate that further studies concerning optimal management PsA pts by bDMARDs are needed.

"OO.RR. Foggia"; <sup>5</sup>UOC Reumatologia Universitaria, University of Foggia, Foggia; <sup>6</sup>Rheumatology Service, ASL Lecce – DSS Casarano and Gallipoli, Lecce; <sup>7</sup>Rheumatology Service, DSS4 Barletta ASL BT Andria, Andria; <sup>8</sup>UO of Rheumatology, ASL Taranto, Taranto; <sup>9</sup>Department of Rheumatology, University of Pavia, IRCCS Policlinico San Matteo Foundation, Pavia; <sup>10</sup>Hospital Outpatient clinic of Rheumatology, ASL BR, Brindisi, Brindisi; <sup>11</sup>Rheumatology, University of Messina, Messina; <sup>12</sup>DETO-Rheumatology Unit, University of Bari, Bari, Italy

**Background:** There are no real-world data for the profiling of patients with psoriatic arthritis (PsA) receiving the phosphodiesterase-4 inhibitor apremilast.

**Objectives:** To retrospectively evaluate the baseline characteristics and the reasons for apremilast prescription in a large Italian multicenter cohort of PsA cases (Real-life APremilast for Psoriatic arthritis Evaluation Registry, RAPPER).

**Methods:** Data were retrospectively extracted from the RAPPER registry which includes all PsA cases treated with apremilast in 11 Italian tertiary rheumatology centres between January 2017 and December 2017. Descriptive analysis of baseline characteristics of study population included demographics, previous treatments before apremilast, pattern of PsA involvement, disease activity indices, and prevalence of comorbidities (computed by the Rheumatic Disease Comorbidity Index [RDCl]). Reasons for apremilast choice were also analysed.

**Results:** We studied 97 patients with PsA (61% women; mean  $\pm$  standard deviation, SD) age  $56.7 \pm 11.9$  years; mean disease duration  $10 \pm 13.1$  years) who received apremilast as first-line targeted disease modifying drug (51.5%) or after the failure of at least one biologic agent (48.5%). In 75%, 33%, 11%, and 63% of patients there were articular (57% asymmetric oligoarthritis; mean Disease Activity in Psoriatic Arthritis [DAPSA]  $22.55 \pm 11.55$ ), enthesal (mean Leeds Enthesitis Index [LEI]  $2.63 \pm 1.42$ ), axial (mean Bath Ankylosing Spondylitis Disease Activity Index [BASDAI]  $6.02 \pm 2.40$ ), and skin/ungueal (mean body surface area [BSA]  $1.71 \pm 3.44$ ) involvement, respectively. Two thirds (64%) of patients had at least one comorbidity (mean RDCl  $1.20$ ) and the prevalence of conditions is reported in table 1. The main reasons for apremilast prescription were contraindication to biologic agents (66%), lack of poor prognostic factors (35%), comorbidities (34%),

risk of infections (33%), and history of malignancy (22.6%), whereas a preference for an oral drug drove the choice only in 7% of patients.

Abstract SAT0327 – Table 1. baseline prevalence of comorbidities

COMORBIDITY	PREVALENCE (n=97)
Hypertension	34%
History of malignancy	22%
Fibromyalgia	15%
Latent tuberculosis	14%
Liver disease	14%
Lung disease	13%
Dyslipidemia	12%
Diabetes	11%
Depression	10%
HBV/HCV infection	9%
Osteoporosis	8%
Hematological disorders	7%
Cardiovascular disease	7%
Gastrointestinal disorders	3%
Neurological disorders	3%

**Conclusions:** Based on our analysis, apremilast is mainly used in PsA with oligoarthritis, enthesitis, mild skin involvement, and low risk of disease progression, carrying comorbidities (especially history of infections and malignancies) with contraindications to the use of biologic drugs.

#### SAT0328 WEIGHT-LOSS IMPROVES DISEASE ACTIVITY IN OBESE PATIENTS WITH PSORIATIC ARTHRITIS

E. Klingberg<sup>1</sup>, A. Bilberg<sup>2</sup>, S. Björkman<sup>3</sup>, B. Eliasson<sup>4</sup>, I. Larsson<sup>3</sup>. <sup>1</sup>Department of Rheumatology and Inflammation Research, SAHLGRENSKA ACADEMY AT UNIVERSITY OF GOTHENBURG, Göteborg; <sup>2</sup>Institute of Neuroscience and Physiology, Section of Health and Rehabilitation, Physiotherapy, Sahlgrenska Academy at the University of Gothenburg; <sup>3</sup>Department of Gastroenterology and Hepatology; <sup>4</sup>Department of Endocrinology, Diabetology and Metabolism, Sahlgrenska University Hospital, Gothenburg, Sweden

**Background:** Obesity is over-represented in patients with psoriatic arthritis (PsA) and associated with increased risk of getting the disease, higher disease activity, poorer effect of treatment and in addition cardiovascular co-morbidity.

**Objectives:** The aim of this study was to determine the effects of weight-loss treatment on disease activity in patients with PsA and obesity

**Methods:** Patients with PsA (Caspar criteria) and obesity (body mass index BMI  $\geq 33$  kg/m<sup>2</sup>) were recruited from three Rheumatology clinics in the Western Sweden. Weight-loss treatment with Very Low Energy liquid Diet (VLED), which comprises a daily energy intake of 640 kcal, was given during 12–16 weeks, depending on BMI. The first strict period was followed by a structured reintroduction of an energy restricted diet during 18 weeks. The treatment was given within the framework of a structured program including support and medical follow-up at the Obesity Unit at Sahlgrenska University Hospital.

Treatment with DMARDs and biologics was held constant from 3 month before baseline until 6 months after baseline. The patients were assessed with 66/68 joints count, back-mobility tests, body surface area (BSA), questionnaires, ESR, CRP and BMI at baseline, 3 and 6 months. The number of patients reaching Psoriatic Arthritis Response Criteria (PsARC) and Minimal Disease Activity (MDA) was calculated.

**Results:** Totally 41 PsA patients, median age 54 (IQR 48–62) years, 63% women were included. The median weight-loss was 18.7 (IQR 14.6–26.5) kg. BMI decreased from median 35.2 (34.1–38.1) to 29.7 (26.2–31.5) kg/m<sup>2</sup>. A majority of the disease activity parameters improved significantly (Table). Totally 16 patients (39.0%) reached PsARC and the number of patients with MDA increased from n=12 (29%) to n=22 (54%), p<0.001 between baseline and the 6 months visit.

**Conclusions:** Weight-loss treatment with VLED had significant positive effects on disease activity in joints, entheses and skin in patients with PsA and obesity.

#### SAT0329 FIBROMYALGIA IN PATIENT WITH PSORIATIC ARTHRITIS: RELATIONSHIP WITH ENTHESOPATHY, SLEEP, FATIGUE AND QUALITY OF LIFE

E. Ulutatar<sup>1</sup>, C. Unal<sup>1</sup>, M.T. Duruoaz<sup>2</sup>. <sup>1</sup>PMR Department, <sup>2</sup>PMR Department, Rheumatology Division, Marmara University School of Medicine, Istanbul, Turkey

**Background:** Fibromyalgia is a syndrome characterised by musculoskeletal pain, sleep disturbance and fatigue. Fibromyalgia commonly accompanies rheumatic diseases. Enthesopathy seen in psoriatic arthritis (PsA) patients may have effect on fibromyalgia.

**Objectives:** To evaluate relationship of fibromyalgia with enthesopathy, sleep, fatigue and quality of life in patients with psoriatic arthritis.

**Methods:** The psoriatic arthritis patients according to CASPAR criteria were included into the study. Fibromyalgia diagnosis was based on 2010 ACR criteria. Demographic (age, gender, marital status, education, body mass index) and clinical parameters (disease duration, comorbidities, Moll-white classification of PsA) were noted. Disease activity and enthesopathy were evaluated with Disease Activity Score-28 (DAS-28) and Maastricht Ankylosing Spondylitis Enthesitis Score (MASES), respectively. Functional assessment scales in this study were Psoriatic Arthritis Quality of Life (PsAQoL), Pittsburgh Sleep Quality Index (PSQI), Multidimensional Assessment of Fatigue (MAF), Fibromyalgia Impact Questionnaire (FIQ) was used to assess functional status of fibromyalgia. The difference in mean scores between fibromyalgia and the patients without fibromyalgia were analysed with Mann-Whitney U test. Spearman correlation coefficient (rho) was used for correlations between functional parameters. p<0.05 was accepted as significant.

**Results:** We enrolled 50 PsA patients (32 female, 18 male) with a mean age 49.6 years (SD: 10.4) and mean disease duration 90.2 months (SD: 90.8). Thirty-two patients (64% of PsA patients) fulfilled ACR criteria for fibromyalgia. The mean scores of MASES, PSQI, MAF and PsAQoL were significantly higher in patients with fibromyalgia (p<0.05). The correlations between FIQ and other functional parameters were as follows; MASES (rho=0.73, p<0.0005), PSQI (rho=0.56, p<0.0005), MAF (rho=0.63, p<0.0005), PsAQoL (rho=0.69, p<0.0005). There was no significant correlation between FIQ and disease duration (p>0.05). Weak correlation was existing between FIQ and DAS-28 (rho=0.30, p=0.03).

Abstract SAT0329 – Table 1. Clinical characteristics of patients (n=50)

	Min-Max	Median (SD)	Lower-Upper Quartiles
DAS-28	1,20–5,60	2,60 <sup>1,18</sup>	1,99–3,50
MASES	0–13	3,00 <sup>4,84</sup>	0,00–10,00
PSQI	0–14	6,00 <sup>4,50</sup>	2,00–11,00
PSAQOL	0–20	6,00 <sup>5,79</sup>	1,75–11,25
MAF	1–45,80	27,25 <sup>14,98</sup>	10,75–37,75
FIQ	0–92,82	32,25 <sup>26,54</sup>	10,75–52,73

DAS-28: Disease activity score-28, MASES: Maastricht Ankylosing Spondylitis Enthesitis Score, PSQI: Pittsburgh Sleep Quality Index, PSAQOL: Psoriatic Arthritis Quality of Life, MAF: Multidimensional Assessment of Fatigue, FIQ: Fibromyalgia Impact Questionnaire, SD: Standart Deviation

**Conclusions:** Coexistence of fibromyalgia in PsA patients is associated with presence of enthesopathy, poor quality of life, sleep disturbance and fatigue. It is an important aspect to diagnose and treat fibromyalgia in PsA patients for comprehensive treatment.

**SAT0330 CHANGES IN LYMPHOCYTES AND LYMPHOCYTE SUBSETS IN TOFACITINIB-TREATED PATIENTS WITH PSORIATIC ARTHRITIS**

G. Burmester<sup>1</sup>, W.F.C. Rigby<sup>2</sup>, E. Choy<sup>3</sup>, P. Nash<sup>4</sup>, K. Winthrop<sup>5</sup>, P.J. Mease<sup>6</sup>, P. Young<sup>7</sup>, T. Hendrikx<sup>7</sup>, C. Wang<sup>8</sup>, S. Menon<sup>8</sup>, D. Graham<sup>8</sup>. <sup>1</sup>Charité – University Medicine Berlin, Berlin, Germany; <sup>2</sup>Geisel School of Medicine at Dartmouth, Lebanon, NH, USA; <sup>3</sup>Cardiff University School of Medicine, Cardiff, UK; <sup>4</sup>University of Queensland, Brisbane, Australia; <sup>5</sup>Oregon Health and Science University, Portland, OR; <sup>6</sup>Swedish Medical Center and University of Washington, Seattle, WA; <sup>7</sup>Pfizer Inc, Collegetown, PA; <sup>8</sup>Pfizer Inc, Groton, CT, USA

**Background:** Tofacitinib is an oral Janus kinase (JAK) inhibitor for the treatment of psoriatic arthritis (PsA). Cytokines involved in lymphocyte development, function and homeostasis signal through JAKs, and reductions in mean lymphocyte count over time have been reported in tofacitinib-treated patients (pts) with rheumatoid arthritis.<sup>1</sup>

**Objectives:** To characterise the effects of tofacitinib on absolute lymphocyte counts (ALCs) and lymphocyte subset counts (LSCs) in pts with PsA.

**Methods:** Data were pooled from 2 placebo (PBO)-controlled, double-blind, Phase 3 studies (OPAL Broaden [12 months; NCT01877668]; OPAL Beyond [6 months; NCT01882439]). Pts had active PsA and inadequate response to  $\geq 1$  conventional synthetic DMARD (OPAL Broaden) or to  $\geq 1$  tumour necrosis factor inhibitor (OPAL Beyond). Pts were randomised to tofacitinib 5 mg twice daily (BID), tofacitinib 10 mg BID, adalimumab 40 mg subcutaneous injection once every 2 weeks (active control; OPAL Broaden only) or PBO. PBO pts advanced in a blinded manner to tofacitinib 5 or 10 mg BID at Month (M)3. ALCs and LSCs were collected every 3 months as part of safety monitoring procedures in the Phase 3 studies (any abnormalities were confirmed upon retesting). Median ALCs and LSCs are reported up to M6. Incidence rates (pts with event/100 pt-years) for serious infections (SIs) were assessed by confirmed (two sequential measurements) ALC categories ( $\geq 2.0$ ,  $<2.0$ – $1.5$ ,  $<1.5$ – $1.0$  and  $<1.0$ – $0.5 \times 10^3/\text{mm}^3$ ) up to M12.

<sup>a</sup>OPAL Broaden only; <sup>b</sup>Placebo-controlled period was 3 months

ALC, absolute lymphocyte count; BID, twice daily; N, number of patients with observations at baseline; Q2W, once every 2 weeks; SC, subcutaneous

**Results:** The analysis included 816 pts: tofacitinib 5 mg BID, n=238; tofacitinib 10 mg BID, n=236; adalimumab, n=106; PBO, n=236. Up to M6, minimal decreases in median ALC were observed in pts who received tofacitinib 5 mg BID, tofacitinib 10 mg BID or PBO (up to M3 only) (Table). LSCs, including total T

cells (CD3+), cytotoxic T cells (CD8+) and NK cells (CD16 +56+), showed a similar trend to ALC for both tofacitinib doses and PBO (Table), with minimal decreases over 6 months. B cells (CD19+) showed numerical increases across treatments. Percentage changes from baseline in LSCs at M6 showed a generally similar pattern to absolute values. In adalimumab-treated pts, ALCs and all LSCs increased over 6 months. Up to M6, no pts receiving tofacitinib or adalimumab had confirmed ALC  $<0.5 \times 10^3/\text{mm}^3$ ; 1 pt receiving PBO had a confirmed ALC  $<0.5 \times 10^3/\text{mm}^3$  over 3 months, resulting in discontinuation from the study before advancing to active treatment. Up to M12, SIs were reported in 7 tofacitinib- (including 2 pts who advanced from PBO) and 1 adalimumab-treated pt; of these, 1 SI (PBO advanced to tofacitinib) occurred  $>6$  months after treatment initiation. There was no trend that suggested an increased risk of SIs in any ALC category (data not shown).

**Conclusions:** Up to M6 in tofacitinib-treated pts with active PsA, minimal changes in ALCs and LSCs were observed. Although incidence of SIs did not appear to be related to ALC, conclusions are limited by the small number of events.

**SAT0331 INFLAMMATORY MARKERS AND ADIPOKINES RELATED TO CARDIOVASCULAR RISK AND METABOLIC COMORBIDITIES IN PSORIATIC ARTHRITIS. IN VIVO EFFECTS OF APREMILAST**

I. Arias De La Rosa<sup>1</sup>, M.D. López-Montilla<sup>1</sup>, C. Pérez-Sánchez<sup>1</sup>, M.D.C. Ábalos-Aguilera<sup>1</sup>, M. Ruiz-Ponce<sup>2</sup>, Y. Jiménez-Gómez<sup>1</sup>, A. Escudero<sup>1</sup>, E. Collantes-Estévez<sup>1</sup>, C. López-Pedreira<sup>1</sup>, N. Barbaroja<sup>1</sup>. <sup>1</sup>Rheumatology service, IMIBIC/Reina Sofía Hospital/University of Córdoba; <sup>2</sup>Rheumatology service, IMIBIC/Reina Sofía Hospital/University of Córdoba, Córdoba, Spain

**Objectives:** 1) To evaluate the role of inflammatory mediators and adipokines in the cardiovascular risk profile and the metabolic comorbidities associated with psoriatic arthritis (PsA). 2) To evaluate the effect of apremilast in the adipocytokine pattern, metabolic components and endothelial dysfunction in patients with PsA and metabolic syndrome (MetSyn).

**Methods:** 55 PsA patients and 30 age and gender-matched healthy donors (HD) were analysed. An extensive clinical analysis including body index mass, lipid profile, HOMA-IR and intra-arterial blood pressure was performed. Endothelial function was measured through post occlusive hyperemia using Laser-Doppler. Different proinflammatory cytokines (TNF $\alpha$ , IL1b and IL6), vascular adhesion molecules (VEGF and E-Selectin) and adipokines (adiponectin, leptin, resistin and visfatin) were analysed on serum by ELISA. Ten biological-naïve patients with PsA having metabolic syndrome were given apremilast 30 mg twice daily for 6 months. All the measures were carried out at basal, week 4 and week 24 after apremilast treatment.

**Results:** The prevalence of metabolic comorbidities such as MetSyn, obesity and insulin resistance (IR) was significant higher in PsA compared to HD. PsA patients had impaired endothelial function showed by a reduced peak flow and hyperaemia area and increased levels of VEGF and E-Selectin in serum. The levels of

adipocytokines were significantly higher in PsA compared to HD. The body mass index values were significantly correlated with the clinical inflammatory parameters (CRP and ESR) and activity of the disease (swollen joints count and DAS28). Increased levels of HOMA-IR also correlated with DAS28, clinical and serological inflammatory markers, and diverse adipokines. Elevated levels of cytokines correlated with the activity of the disease and lipid alterations.

Significant improvements in efficacy outcomes, including DAS-28 using erythrocyte sedimentation rate (ESR), tender and swollen joint count, Visual Analogue Scale (VAS), enthesitis and morning stiffness severity, were observed with apremilast at week 4. No changes on BMI were noticed. A significant reduction of intra-arterial blood pressure was evidenced since the first 4 weeks. Serum levels of Apolipoprotein A and B, insulin and HOMA-IR values were also significantly reduced after 24 weeks of treatment. Endothelial dysfunction was significantly restored shown by an increase of the peak flow and hyperaemia area and decreased adhesion molecules in serum. Levels of interleukins and adipokines were also modulated after apremilast treatment.

#### Conclusions:

- PsA is associated with an increase in inflammatory cytokines and adipokines, alongside with an endothelial dysfunction. These alterations are related to the disease activity and the presence of metabolic comorbidities such as insulin resistance or obesity, contributing to the burden of cardiovascular disease risk.
- Apremilast might reduce IR, inflammation, hypertension, lipids and endothelial dysfunction, parameters strongly involved in cardiovascular disease.

SAT0332

#### A HIGH-DIMENSIONAL APPROACH TO DISSECTING THE ROLE OF THE TISSUE MICROENVIRONMENT IN SHAPING THE IMMUNE RESPONSE IN PSORIATIC ARTHRITIS

J.H.S. Chan<sup>1</sup>, Y.Y. Leung<sup>2</sup>, W. Fong<sup>2</sup>, Y.W.K. Yeo<sup>2</sup>, B. Paleja<sup>1</sup>, L. Lai<sup>1</sup>, S. Saidin<sup>1</sup>, C. Chua<sup>1</sup>, S. Nur Hazirah<sup>1</sup>, S.L. Poh<sup>1</sup>, H.L.A. Low<sup>2</sup>, S. Albani<sup>1</sup>. <sup>1</sup>Translational Immunology Institute (TII)/Singapore Health Services Pte Ltd; <sup>2</sup>Singapore General Hospital, Singapore, Singapore

**Background:** Psoriasis (Ps) currently inflicts 2%–3% of the population globally and one-third of patients have psoriatic arthritis (PsA). Up to 30% of PsA patients with active psoriasis (Ps) do not respond adequately to any treatment. Understanding the immune mechanisms contributing to the initiation and disease progression of PsA and Ps is crucial for devising novel therapeutic strategies.

**Objectives:** To address the current unmet clinical need and bridge the knowledge gap in the pathogenesis underlying PsA/Ps, we perform transcriptomic analyses of the skin microenvironment and deep immunophenotyping of immune cells from PsA patients with active disease. We hypothesise that the interaction between the tissue microenvironment and the peripheral immune system dictates the immune response that impacts upon the development and progression of PsA/Ps. This multi-dimensional strategy will also enable the distillation of immune cell subsets in the periphery that can potentiate pathogenic responses in the microenvironment.

**Methods:** Total RNA was extracted from skin punch biopsies of lesional and morphologically normal sites from 7 patients with active disease. RNASeq was performed to decipher the transcriptomes of the skin punch biopsies. Peripheral Blood Mononuclear Cells (PBMCs) from 17 PsA patients and 12 healthy donors were stimulated with PMA-Ionomycin, stained with 37 phenotypic T cells markers and interrogated with the CyTOF platform. Dimensional reduction and unsupervised clustering analyses were performed with Multi-dimensional Automated Reduction and Visualisation (MARVis).

**Results:** Transcriptomic analysis of skin punch biopsies of psoriatic and morphologically normal sites revealed a gene signature in lesional skin that promotes the infiltration of multiple immune cell subsets into the microenvironment. The expression of chemokine genes such as CXCL8, CCL4, and CCL20 suggests a role for the accumulation of neutrophils, monocytes, natural killer (NK) cells and lymphocytes in the establishment of a pro-inflammatory microenvironment that is perpetuated by the presence of TNF and IFN $\gamma$ .

Examination of the immune landscapes of PsA patients highlights multiple perturbations in various immune cell subsets. Specifically, we observed declines in CD8 +CD161+TCRV $\alpha$ 7.2+Mucosal Associated Invariant T (MAIT), CD4 +CD45RO+CXCR5+TFH as well as CD45RO+Tbet+IFN $\gamma$ +TNF $\alpha$ +IL17A +memory TH1 cells in PsA patients. This decline is potentially attributed to the trafficking of these immune cell subsets into the microenvironment in response to chemokine signals. Conversely, we observed enrichments of CD56 +Tbet

+GranB +IFN $\gamma$ +NK and activated CD4 +CD127+CCR7+CD69+effector T cells in PsA patients that can contribute to the pathogenic immune response.

**Conclusions:** Our multi-dimensional approach resolves the complex interactions between the tissue microenvironment and the peripheral immunome that shapes the immune response and dictates the cellular composition in lesional skin. These findings possess translational value and will facilitate the identification of novel immune therapeutic targets.

Pontevedra; <sup>5</sup>Rheumatology, CHU Arquitecto Marcide-Naval, Ferrol;

<sup>6</sup>Rheumatology, CHU Santiago, Santiago de Compostela; <sup>7</sup>Rheumatology, INIBIC-XXI A Coruña, A Coruña, Spain

**Background:** It is commonly accepted that additional methotrexate (MTX) does not increase efficacy for treatment with TNF in psoriatic arthritis (PsA) but concomitant MTX has been also associated with increased drug survival in register studies. However, the role of MTX comedication in PsA is still unclear.

**Objectives:** We aim was to evaluate TNF- $\alpha$  inhibitor (TNFi) persistence when used as first -line biologic therapy for the management of PsA naïve to biologic and determine features of patients as MTX comedication that are associated with TNFi persistence.

**Methods:** A ambispective longitudinal observational multi-centre cohort study was performed on all patients with PsA starting first TNFi therapy (etanercept, adalimumab, golimumab and infliximab) between 01/JUN/2003 and 01/12/2015. Demographic and clinical data, concomitant treatment with MTX, were compared with TNFi persistence, using Kaplan-Meier survival and Cox regression analysis.

**Results:** Were included 468 patients starting treatment with etanercept (242), adalimumab (120), golimumab<sup>31</sup> and infliximab (75); 235 receiving TNFi as monotherapy (50.2%) and 233 receiving concomitant MTX (49.8%). Mean age was 53.3 $\pm$ 12.6 years (men 53.3 $\pm$ 12.9 and women 53.2 $\pm$ 12.3, p=0.928) and 55.2% were men. Obesity (BMI  $\geq$ 30) was similar in patients with or without persistence on treatment: 30.39 (13.32) vs 29.20 (5.44), p=0.355). At 60 months of follow-up 50.6% of patients persisted with TNFi therapy (55.8% with etanercept, 50.0% with adalimumab, 29.3% with infliximab and 67.7% with golimumab). Infliximab had the lowest retention rate (p=0.006). Drug survival analyses had not differences between patients receiving co-medication or not (p=0.849). In the Cox regression analysis lack of concomitant MTX and gender female were predictors of discontinuation of TNFi (0.014).

**Conclusions:** At 60 months infliximab had the lowest percentage of treatment continuation compared with etanercept, adalimumab and golimumab. Patients with PsA who are female and have not concomitant treatment with MTX could have lower TNFi persistence.

#### CLINICAL AND SONOGRAPHIC ANALYSIS OF PSORIATIC PATIENTS WITHOUT MUSCULOSKELETAL COMPLAINTS. PRELIMINARY RESULTS OF A PROSPECTIVE STUDY: THE PRE-APS COHORT

J. Ramírez García<sup>1</sup>, A. Cuervo<sup>1</sup>, M. Alsina<sup>2</sup>, R. Celis<sup>1</sup>, V. Ruiz-Esqueda<sup>1</sup>,

R. Castellanos<sup>1</sup>, M.V. Hernández<sup>1</sup>, R. Sanmartí<sup>1</sup>, J.D. Cañete<sup>1</sup>. <sup>1</sup>Rheumatology;

<sup>2</sup>Dermatology, Hospital Clínic, Barcelona, Barcelona, Spain

**Background:** Early diagnosis in psoriatic arthritis (PsA) is mandatory in order to initiate early therapy and prevent disability. Around 20% of patients with Psoriasis (PsO) routinely visited in Dermatology departments have PsA previously undiagnosed.

**Objectives:** The aim of this study is to evaluate the presence of inflammation by clinical examination and ultrasound in joints and entheses of patients with PsO without musculoskeletal symptoms.

**Methods:** Patients with PsO under topic or PUVA therapy without musculoskeletal symptoms were referred to our Arthritis Unit. Clinical and demographic data were collected. The patients were evaluated for Body Surface Area (BSA), Swollen Joint Count (SJC) (66 joints), Tender Joint Count (TJC) (68 joints) and enthesitis (MASES). Psoriatic Arthritis Impact of Disease tool questionnaire (PsAID) and Psoriasis Epidemiology Screening tool questionnaire (PEST) were used to assess the impact of the disease. A comprehensive ultrasound evaluation of 46 joints and 12 entheses was made (ESAOTE MylabTwice, 12–18 Mhz probe). Enthesitis score was calculated using the Madrid Sonographic Enthesitis Index (MASEI) and a total score for synovitis (synovial hypertrophy and Power Doppler) was also calculated.

**Results:** 42 patients were included. 20 patients were female (48%), mean age (SD) was 48.3 y (14.6) and disease duration was 17.9 y (15.9). Mean BMI was 24.6 (5.2) and BSA 5 (8.7). 13 out of 42 (31%) had severe PsO (systemic treatment or BSA >10% at any time of evolution). 4 patients (9.5%) had Power Doppler signal and 2 (4.8%) fulfilled criteria for ultrasound-defined active synovitis (SH  $\geq 2$  + PD) despite no signs or symptoms of musculoskeletal disease. However, although structural alterations such as calcifications and enthesophytes were frequent, no PD was found at any entheses.

In the univariate analysis, higher BMI ( $p=0.013$ ), weight ( $p=0.010$ ), waist ( $p=0.033$ ) and hip ( $p=0.014$ ) circumferences were significantly associated with severe PsO. In the same way, CRP serum levels were also significantly higher in patients with severe PsO ( $p=0.027$ ). A strong trend was found between higher MASEI scores and onychopathy ( $p=0.09$ ).

pan>

**Conclusions:** Patients with PsO under topic or PUVA therapy without musculoskeletal symptoms have a low prevalence of findings in the joints and entheses ultrasound evaluation. Of note, 9.5% of PsO patients had subclinical synovitis defined as PD. No changes in those finding were found in a short follow-up (6 months) in these patients. A higher number of patients would be necessary to have strong results. These patients will be followed in order to confirm if they develop Psoriatic Arthritis.

### SECUKINUMAB PROVIDES RAPID AND SUSTAINED RESOLUTION OF ENTHESITIS IN PSORIATIC ARTHRITIS PATIENTS: POOLED ANALYSIS OF TWO PHASE 3 STUDIES, FUTURE 2 AND FUTURE 3

L.C. Coates<sup>1</sup>, D. McGonagle<sup>2</sup>, G. Schett<sup>3</sup>, P.J. Mease<sup>4</sup>, E. Quebe-Fehling<sup>5</sup>, D. L. Asquith<sup>6</sup>, L. Rasouliyan<sup>7</sup>, S. Mpofu<sup>8</sup>, C. Gaillez<sup>9</sup> on behalf of the FUTURE 2 and FUTURE 3 study groups. <sup>1</sup>University of Oxford, Oxford; <sup>2</sup>University of Leeds, Leeds, UK; <sup>3</sup>University of Erlangen-Nuremberg, Erlangen, Germany; <sup>4</sup>Swedish Medical Centre and University of Washington, Seattle, USA; <sup>5</sup>Novartis Pharma AG, Basel, Switzerland; <sup>6</sup>Novartis Pharmaceuticals UK Ltd., Camberley, UK; <sup>7</sup>RTI Health Solutions, Barcelona, Spain

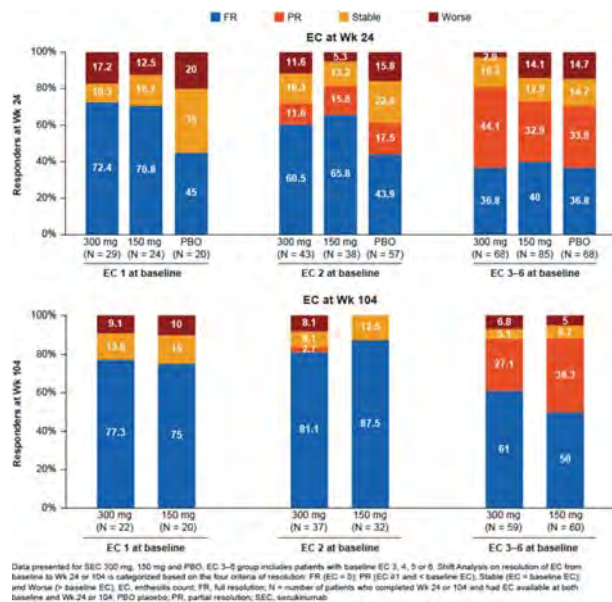

**Background:** Enthesitis, one of the key features of psoriatic arthritis (PsA), shows chronicity in 50–70% of affected patients (pts).<sup>1</sup> Secukinumab (SEC), a fully human monoclonal antibody that selectively neutralises IL-17A, provided significant and sustained improvement in the signs and symptoms of active PsA, with sustained resolution of enthesitis in Phase 3 studies.<sup>2,3</sup>

**Objectives:** Comprehensive *post-hoc* analysis to evaluate the effect of SEC on resolution of enthesitis count (EC; defined by Leeds Enthesitis Index) in PsA pts using pooled data from two Phase 3 studies, FUTURE 2 (NCT01752634) and FUTURE 3 (NCT01989468).

**Methods:** SEC and placebo (PBO) were administered weekly during the first 4 weeks (wks) followed by subcutaneous maintenance dosing every 4 weeks thereafter (PBO until Wk 16/24). The results are reported only for SEC 300 and 150 mg (approved doses). Pts with baseline (BL) enthesitis (BLE) or without BLE (No BLE) were included. Evaluation through Wk 104 included: time to first resolution of enthesitis (i.e. EC=0); shift analysis of BL EC (1, 2 or 3–6) to full resolution (FR) and partial resolution (PR; reduction of EC) at Wks 24 and 104; and number of new enthesitis sites developed in No BLE pts. Individual status over time with respect to resolution of EC was also determined by heat map analysis using last observation carried forward. Data are as observed in the overall population; time to first resolution of enthesitis was analysed in the overall population and by prior use of tumour necrosis factor inhibitor (TNFi-naïve and -inadequate responders [IR]).

**Results:** A total of 466 pts had BLE with a mean EC of 3.1±1.6, and 246 pts had no BLE. Median days to resolution of EC in BLE pts for SEC 300, 150 mg and PBO groups were 57, 85 and 167 in overall population; 57, 85 and 120 in TNFi-naïve pts; and 92, 82 and 169 in TNFi-IR pts, respectively. In pts with BL EC=1/2,

72%/61% (SEC 300 mg), 71%/66% (SEC 150 mg) and 45%/44% (PBO), respectively, achieved FR at Wk 24, with FR in SEC groups sustained or increased to 77%/81% (SEC 300 mg) and 75%/88% (SEC 150 mg) at Wk 104. In BL EC=3–6, 81% (SEC 300 mg), 73% (SEC 150 mg) and 71% (PBO) of pts achieved FR and PR at Wk 24, with an increase of FR and PR to 88% (in both SEC 300 and 150 mg) at Wk 104 (figure 1). A total of 89% of pts with No BLE did not develop enthesitis by Wk 104. Heat map analysis showed that SEC-treated pts at individual level had more resolution of EC than PBO pts at Wk 24.

Abstract SAT0335 – Figure 1. Shift Analysis of EC from Baseline to Wk 24 or 104

**Conclusions:** Time to resolution of enthesitis was earlier with SEC than PBO in the overall population, with faster resolution observed in TNFi-naïve than TNFi-IR pts. Majority of SEC-treated pts with BL EC=1/2 had FR by Wk 24, with further an improvement by Wk 104. In pts with BL EC=3–6, greater improvement was observed with SEC 300 mg vs PBO in the proportion of pts with FR and PR of enthesitis at Wk 24; further improvements were observed in both SEC groups at Wk 104.

SAT0336

### MEASUREMENT PROPERTIES OF THE MINIMAL DISEASE ACTIVITY CRITERIA FOR PSORIATIC ARTHRITIS

L.C. Coates<sup>1</sup>, V. Strand<sup>2</sup>, H. Wilson<sup>3</sup>, B.S. Stolshek<sup>4</sup>, A. Samad<sup>4</sup>, J. Chung<sup>4</sup>, D. D. Gladman<sup>5</sup>, P. Mease<sup>6</sup>. <sup>1</sup>NDORMS, University of Oxford, Oxford, UK; <sup>2</sup>Division of Immunology/Rheumatology, Stanford University, Stanford, CA; <sup>3</sup>Evidera, Seattle, WA; <sup>4</sup>Amgen Inc., Thousand Oaks, CA, USA; <sup>5</sup>University of Toronto, Toronto Western Hospital, Toronto, Canada; <sup>6</sup>Swedish Medical Center and University of Washington, Seattle, WA, USA

**Background:** Psoriatic arthritis (PsA) is a heterogeneous inflammatory joint disease, which generally occurs in combination with psoriasis. Key defining features include joint inflammation, psoriasis, nail changes, axial disease, dactylitis, and enthesitis. A composite endpoint that captures all aspects of the disease is critical to understanding disease activity. Recognising the need for a measure of acceptable disease status that equates to a clinically meaningful outcome for patients, the Group for Research and Assessment of Psoriasis and PsA followed methodology from Outcome Measures in Rheumatology to develop the Minimal Disease Activity (MDA) criteria.<sup>1</sup> Since initial publication of the MDA criteria, which consist of physician and patient-reported measures, they have been used in a number of randomised controlled trials (RCTs) and long-term observational studies (LOS). These studies provide an opportunity to systematically evaluate the measurement properties of the MDA.

**Objectives:** To examine evidence of the validity and the ability of the MDA to detect change in published PsA studies.

**Methods:** A targeted literature review was conducted in MEDLINE and EMBASE to identify publications that provided evidence of the validity or ability of the MDA criteria to detect change. LOS that reported data without a comparator and studies that examined the relationship between achievement of MDA and baseline variables were excluded. Abstracts of conference proceedings were included if they reported on phase 3 results not yet formally published. Relevant data were extracted and summarised in tabular format, and reviewed by an independent investigator.

**Results:** 20 publications were identified that met inclusion criteria. In both LOS and RCTs, patients in MDA consistently had decreased inflammatory markers (ie CRP), decreased radiographic joint erosions and progression of structural damage over time, and reported less disease impact on patient-reported outcomes. The consistency of these findings in both LOS and RCTs provide support for the validity of the MDA. Nine RCTs demonstrated superior efficacy to the respective comparator arm. All nine of these RCTs also reported a significantly greater percentage of patients in the active treatment arms met MDA criteria vs. Placebo. These results provide support for the ability of the MDA to detect between-subjects change. Two LOS were also identified that reported on the association with achievement in MDA following initiation of treatment with bDMARDs. demonstrated a significant likelihood of patients beginning treatment with bDMARDs to meet MDA after 4, 6, and 12 months of treatment, providing support for the MDA to detect change in a real-world setting.

**Conclusions:** Published evidence indicates that the MDA is a validated measure with the ability to detect change in PsA patients. The MDA criteria offer a practical, holistic, and clinically meaningful endpoint for patients and clinicians to assess the impact of specific treatment interventions on PsA disease activity.

Nasonova Research Institute of Rheumatology, Moscow, Russian Federation; <sup>8</sup>Hôpital Lariboisière and University of Paris Diderot, Paris, France; <sup>9</sup>Amsterdam Rheumatology and Immunology Center, VU University Medical Centre and Reade, Amsterdam, Netherlands; <sup>10</sup>University of Athens Medical School, Athens, Greece; <sup>11</sup>University of Glasgow, UK; <sup>12</sup>Janssen Pharmaceutica NV, Moscow, Russian Federation; <sup>13</sup>Janssen EMEA, Issy-les-Moulineaux, France; <sup>14</sup>Medical University of Vienna, Vienna, Austria

**Background:** The PsABio study (ClinicalTrials.gov Id: NCT02627768) was developed to evaluate the efficacy, tolerability and persistence of TNF inhibitors (TNFi) and ustekinumab (UST) for patients with psoriatic arthritis (PsA) starting 1 st, 2nd or 3rd line biologic disease-modifying antirheumatic drugs (bDMARDs) in real-world routine care.

**Objectives:** In this interim analysis, the objective was to describe the profile of patients starting either UST or TNFi in routine clinical care in 8 European countries.

**Methods:** Between Dec 2015 and, Aug 2017 patients were enrolled in Italy, Greece, Russia, France, United Kingdom, The Netherlands, Spain and Belgium and had valid baseline data available. Descriptive baseline characteristics for the UST and TNFi cohorts were compared.

**Results:** 563 consecutive patients were analysed (278 UST- and 285 TNFi-treated patients): mean (SD) age 49.3 (12.4) years, disease duration 7.2 (7.5) years; 49.6% were men and most had polyarticular disease (Table). Among comorbidities, cardiovascular disease (38.9%) and obesity (30.4%) were most frequent; 11.5% had anxiety or depression. 25.6% of patients were current smokers. TNFis were more often given as 1 st line bDMARD than UST (56.8% vs 39.2%). For patients receiving their 1 st bDMARD, the prevalence of concomitant conventional synthetic (cs) DMARDs at baseline was: UST: 46.8% (39.5% methotrexate [MTX]) and TNFi: 53.7% (39.5% MTX). Among 166 patients who received a 2nd or 3rd bDMARD and had no ongoing csDMARDs at baseline, 66.3% received UST and 33.7% received TNFi. The most prescribed TNFi were etanercept (34.0%), adalimumab (25.3%) and golimumab (19.6%); 12.6% were TNFi biosimilars. The majority of patients on UST received the recommended dose, although 27.8% (10/36) of patients >100 kg started with 45 mg every 3 months. Disease activity was moderate to high with more axial, skin and nail involvement in the UST group.

**Abstract SAT0337 – Table 1.** Baseline characteristics for all patients and by bDMARD in PsABio as of August 2017. Values are mean (SD), if not otherwise indicated.

	UST (n=278)	TNFi (n=285)	All (n=563)
Age, yrs	49.9 (12.2)	48.8 (12.6)	49.3 (12.4)
Disease duration since diagnosis, yrs	7.7 (7.6)	8.7 (7.4)	7.2 (7.5)
Sex (male), %	47.8	51.2	49.6
Comorbidities (all), %	62.9	55.4	59.1
Cardiovascular comorbidity, %	40.8	37.2	38.9
PsA subtype: %			
oligo	25.6	28.5	27.0
poly	63.0	61.6	62.3
axial (isolated or combined with other subtype)	35.1	27.8	32.6
Enthesitis present, %	47.6	47.9	47.8
Leads Enthesitis Index	2.6 (1.4)	2.5 (1.3)	2.6 (1.4)
Dactylitis present, %	20.1	21.8	21.0
BSA, %			
<3%	36.3	50.4	43.3
3%–10%	35.0	33.2	34.1
>10%	28.8	16.4	22.6
Nail disease, %	43.5	37.2	40.3
DAS28	4.3 (1.2)	4.1 (1.3)	4.2 (1.3)
DAPSA	33.6 (21.1)	31.9 (18.9)	32.7 (20.0)
Swollen Joint Count (66)	5.9 (7.8)	5.6 (6.3)	5.8 (7.1)
Tender Joint Count (68)	12.6 (12.7)	11.4 (10.2)	12.1 (11.5)
CRP (mg/dl), median (IQR)	0.7 (0.3, 1.6)	0.7 (0.3, 1.8)	0.7 (0.3, 1.6)

**Conclusions:** European PsA patients starting bDMARDs in 2016/2017 frequently presented with moderate to high disease activity, and overlapping subtypes of PsA, mainly polyarticular disease. Comorbidities, predominantly

cardiovascular, were common. Compared to patients treated with TNFi, UST was more often given as 2nd or 3rd line bDMARD and in patients with more axial and skin disease. Among patients who switched to a 2nd or 3rd line bDMARD, those not on concomitant csDMARDs preferentially received UST.

SAT0338

#### PREDICTION OF CARDIOVASCULAR EVENTS IN PATIENTS WITH PSORIATIC ARTHRITIS: PERFORMANCE OF FIVE RISK ALGORITHMS IN AN ITALIAN BICENTRIC STUDY

L. Navarini<sup>1</sup>, D.P.E. Margiotta<sup>1</sup>, F. Caso<sup>2</sup>, D. Currado<sup>1</sup>, M. Tasso<sup>2</sup>, S. Angeletti<sup>3</sup>, M. Ciccozzi<sup>3</sup>, R. Scarpa<sup>2</sup>, A. Afeltra<sup>1</sup>, L. Costa<sup>2</sup>. <sup>1</sup>Unit of Allergology, Immunology, Rheumatology, Department of Medicine, Università Campus Bio-Medico, Rome; <sup>2</sup>Rheumatology Unit, Department of Clinical Medicine and Surgery, University Federico II, Naples; <sup>3</sup>Unit of Clinical Laboratory Science, Department of Medicine, Università Campus Bio-Medico, Rome, Italy

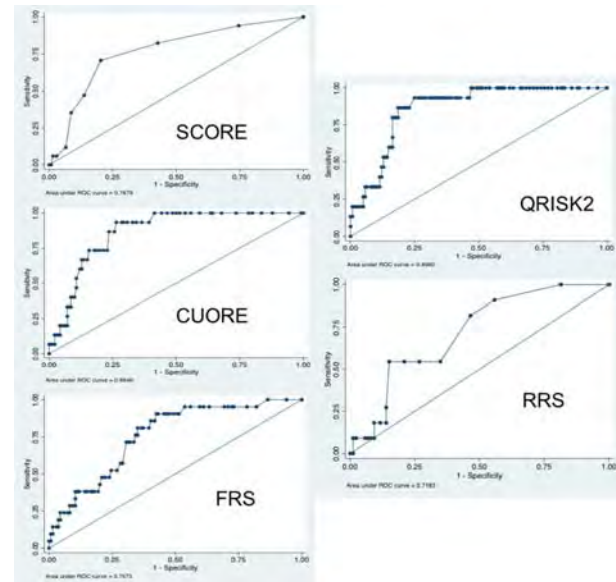

**Background:** The burden of cardiovascular (CV) risk in patients with psoriatic arthritis (PsA) is increased. Prediction of CV risk and consequent preventive strategies play a pivotal role in management of PsA. Recently, EULAR recommendations suggested to use a multiplication by the factor of 1.5 of original CV risk algorithms in patients with rheumatoid arthritis and other inflammatory arthritis.<sup>1</sup>

**Objectives:** To evaluate the performance and calibration of five original and adapted according to EULAR recommendations CV risk algorithms in PsA: SCORE, CUORE, Framingham Risk Score (FRS), QRISK2, and Reynold's Risk Score (RRS).

**Methods:** Prospectively collected data from two Central-Southern Italian cohorts of patients with an history of PsA of almost 10 years at November 2017 and without a personal history of CV disease (CVD) at baseline has been used. The primary outcome was the first CV event: sudden cardiac death, coronary artery diseases (CAD) (stable and unstable angina pectoris, myocardial infarction), cerebral vascular accident (CVA), transient ischaemic attack (TIA), peripheral artery disease (PAD) and heart failure (HF). Discriminatory ability for CV risk prediction was evaluated by the area under the receiver operating curve (ROC). Calibration between predicted risk and observed events was assessed by Hosmer-Lemeshow (HL) tests and calibration plots. Fisher's exact test has been used for analysis of contingency table 1, while Mann-Whitney test has been used to compare ranks. Sensibility, specificity, and odds ratio were calculated for low-to-intermediate risk cut-off (1% for SCORE, 10% for all the other algorithms) and for intermediate-to-high risk cut-off (5% for SCORE, 20% for all the other algorithms).

**Results:** 155 patients (57±10.57 years) were enrolled with an observation of 1550 patient/year. During follow-up, 21 patients had a CV event (1.35 events per 100 patient/years): 8 cases of myocardial infarction or unstable angina pectoris, 3 cases of stable angina pectoris, 2 cases of TIA, 4 cases of PAD, 4 cases of HF. No fatal events were reported. Area under the ROC were 0.7679 (95% CI 0.64768 to 0.88812), 0.864 (95% CI 0.79675 to 0.93278), 0.7575 (95% CI 0.65784 to

0.85708), 0.8660 (95% CI 0.79428 to 0.93772), and 0.7183 (95% CI 0.57795 to 0.85862) for SCORE, CUORE, FRS, QRISK2, and RRS, respectively, suggesting fair to good discriminative ability between patients with or without a CV event (figure 1). HL tests demonstrated poor model fit (p<0.05) for SCORE, CUORE, and RRS, but not for FRS and QRISK2 (p>0.05). Discriminative ability and calibration were not improved by adaption of the algorithms according to EULAR indications. A large amount of patients who experienced a CV event was at "low risk" (minimum 17.6% for SCORE and maximum 81.8% for RRS) or at "low-intermediate" risk (minimum 52.9% for SCORE and maximum 95.2% for FRS).

**Conclusions:** Adaption of the CV risk algorithms according to EULAR indications did not provide improvement in discriminative ability and calibration in patients with PsA from Centre and South of Italy. In PsA, an excess of CV events has been observed in patients at "low risk" or "low-intermediate risk".

#### IMPACT OF ALTERNATE MECHANISM OF ACTION BIOLOGICS ON TUMOUR NECROSIS FACTOR INHIBITOR (TNF) PRESCRIBING IN PSORIATIC ARTHRITIS: RESULTS FROM A NATIONAL PATIENT CHART AUDIT

J. Robinson, L. Price. Advanced Analytics Group, Spherix Global Insights, Exton, USA

**Background:** Tumour Necrosis Factor-inhibitor (TNF) therapy has long been the standard of care for adult patients diagnosed with moderate to severe psoriatic arthritis (PsA), though several new biologics and small molecules have recently received FDA approval for the treatment of PsA.

**Objectives:** This research sought to understand the extent to which biologics and small molecules with a different mechanism of action (MOA) have been adopted for the treatment of PsA and their impact on the use of well-established TNFs in the United States.

**Methods:** We conducted a retrospective chart review of patients diagnosed with PsA (n=1,008), who had switched from one biologic therapy or apremilast to another in the prior twelve weeks. Data were collected in April 2017 and included clinical and non-clinical patient demographics, as well as physician demographics and attitudinal survey responses. This study was a non-longitudinal trending analysis to a 2016 audit following the same methodology.

**Results:** 78% of the participating rheumatologists reported recent changes to the management of their patients with PsA. The two most commonly recalled treatment shifts were: more aggressive use of biologics in general and an increased use non-TNF agents for the treatment of PsA. With increased treatment options, US rheumatologists are switching patients more frequently and faster than previously recorded. In 2017, US rheumatologists reported that, over the course of a year, 29% of their biologic and apremilast treated patients are switched to a

different brand, a figure significantly up from 2016 (25%). Furthermore, a higher percent of the audited switched patients occurred within six months of initiating the prior agent compared to the prior year (56% vs. 40%).

In 2017, switching between TNF agents significantly decreased from 52% in 2016 to 41% in 2017, and switches from a TNF to an alternate MOA biologic significantly increased from 13% to 20%, respectively. The growth in the switching share of alternative MOAs was driven primarily by increased use of secukinumab, an Interleukin-17 inhibitor approved in January 2016. While most of the secukinumab patients originated from TNF inhibitors, ustekinumab switching share was also impacted. Indeed, rheumatologists indicated that 33% of the patients switched to secukinumab in 2017 would have been placed on ustekinumab if secukinumab had not been available.

**Conclusions:** Increased biologic and small molecule options for the treatment of PsA has resulted in US rheumatologists switching patients more frequently and faster than in the past. Though TNF inhibitors remain the predominant mechanism of action for the treatment of PsA, the introduction of secukinumab has had a direct impact on the PsA switching environment in 2017 and recent approvals in the form of tofacitinib, ixekizumab, and abatacept are hypothesised to further impact the PsA switching environment in 2018.

Valesini. <sup>1</sup>Department of system medicine, Rheumatology, Allergy and Clinical Immunology; <sup>2</sup>Department of system medicine, Dermatology, University of Rome Tor Vergata; <sup>3</sup>Dermatologia, IFO San Galliciano; <sup>4</sup>Istituto di Reumatologia e Scienze Affini; <sup>5</sup>Istituto di Dermatologia, Università Cattolica del Sacro Cuore - Fondazione Policlinico Universitario Agostino Gemelli - Presidio Columbus; <sup>6</sup>Reumatologia; <sup>7</sup>Dermatologia, ASL RM6, Frascati; <sup>8</sup>Reumatologia; <sup>9</sup>Dermatologia, Ospedale San Camillo-Forlanini; <sup>10</sup>Dermatologia; <sup>11</sup>Reumatologia, Università Sapienza Polo Pontino; <sup>12</sup>Reumatologia; <sup>13</sup>Dermatologia, Dipartimento di Medicina Interna e Specialità Mediche Policlinico Umberto I, Roma, Italy

**Background:** The assessment of joint disease in psoriasis (PsO) patients is paramount, particularly where consensus among dermatology and rheumatology specialists is necessary.

**Objectives:** To evaluate the prevalence of psoriatic arthritis (PsA) in PsO patients and assess how a novel 16-item visual instrument (PsA-Disk) correlates with the disease and its clinical manifestations.

**Methods:** Data were prospectively collected from 8 dermatological/rheumatological centres across Italy. During their first dermatological visit, patients completed both PEST (Psoriasis Epidemiology Screening Tool) and PsA-disk questionnaires. Rheumatological visit was performed in order to confirm presence/absence of PsA. Clinimetric and disease activity variables were recorded.

**Results:** From a total of 239 PsO patients, 120 (50.2%) patients were diagnosed with PsA. More PsA-positive patients had nail PsO (54.2% vs. 42%, p=0.05) and a PEST score  $\geq 3$  vs. PsA-negative patients (77.5% vs. 37.8%, p<0.001). PsA-positive patients presented with significantly higher ESR (21.9 $\pm$ 17.1 vs. 15.9 $\pm$ 10.2 mm/h, p=0.041), NAPS1-feet (10.2 $\pm$ 9.7 vs. 3.9 $\pm$ 7.8, p=0.002), NAPS1-(hands+feet; 9.3 $\pm$ 6.8 vs. 4.6 $\pm$ 7.9, p=0.007), and PsA-Disk scores (73.9 $\pm$ 32.1 vs. 58.1 $\pm$ 39.8, p<0.001) vs. PsA-negative patients. PsA-patients with axial involvement had higher PsA-Disk scores (86.7 vs. 72.5, p=0.088) as well as patients with knee arthritis (98.4 vs. 71.5, p=0.006). PsA-Disk scores were also positively correlated with number of swollen (r=0.2, p<0.05) and tender joints (r=0.24, p=0.021), patient- (r=0.4, p<0.001) and physician-pain-VAS (r=0.33, p<0.001), PGA-VAS (r=0.23, p=0.025), physician-HAQ (r=0.38, p=0.011), DAS-44 (r=0.25, p=0.023) and DAPSA scores (r=0.31, p=0.005) (figure 1A). Examples of the powerful visual use of this instrument can be seen in figure 1B.

#### EFFICACY AND SAFETY OF IXEKIZUMAB IN PATIENTS WITH ACTIVE PSORIATIC ARTHRITIS AND PREVIOUS INADEQUATE RESPONSE TO TNF INHIBITORS: 52-WEEK RESULTS FROM A PHASE 3 STUDY

M.C. Genovese<sup>1</sup>, B. Combe<sup>2</sup>, J. Kremer<sup>3</sup>, D. Adams<sup>4</sup>, C. Lee<sup>4</sup>, L. Kerr<sup>4</sup>, P. Nash<sup>5</sup>.

<sup>1</sup>Stanford University Medical Center, Palo Alto, USA; <sup>2</sup>Department of Rheumatology, CHU Montpellier and Montpellier University, Montpellier, France; <sup>3</sup>Albany Medical College and The Center for Rheumatology, Albany; <sup>4</sup>Eli Lilly and Company, Indianapolis, USA; <sup>5</sup>University of Queensland, Brisbane, Australia

**Background:** Ixekizumab (IXE) is a high affinity monoclonal antibody that selectively targets interleukin-17A. In patients with active psoriatic arthritis (PsA) who had an inadequate response to tumour necrosis factor inhibitors (TNFi), IXE was superior to placebo (PBO) in improving the signs and symptoms of PsA after 24 weeks of treatment (SPIRIT-P2; NCT02349295).<sup>1</sup>

**Objectives:** The objective of this study is to report the Week 52 interim efficacy and safety findings of IXE treatment during the Extension Period (EP) of SPIRIT-P2 (Weeks 24–156).

**Methods:** SPIRIT-P2 is a Phase 3, multicenter, double-blind study. All 363 patients had an inadequate response to one or two TNFi or were intolerant to TNFi. During the Double-Blind Treatment Period (DBTP; Weeks 0–24), patients were randomly assigned 1:1:1 to subcutaneous administration of either 80 mg IXE every 4 weeks (Q4W; n=122) or every 2 weeks (Q2W; n=123) following a 160 mg starting dose at Week 0, or PBO (n=118). Of these, 310 patients completed the DBTP and entered the EP (Weeks 24–156). Patients randomised to IXE at Week 0 continued the same dose regimen in the EP. PBO patients were re-randomised (1:1) to IXE Q4W or Q2W at Week 16 (inadequate responders) or 24. In this interim analysis, efficacy (up to Week 52) and safety (up to Week 156) were analysed using the EP population, defined as all patients who received at least 1 dose of study drug in the EP. Missing values were considered non-response for categorical data and were imputed by modified baseline observation carried forward for continuous data.

**Results:** In the DBTP, a significantly higher percentage of patients achieved ACR20 at Week 24 with IXE Q4W (53%) or Q2W (48%) than with PBO (20%).<sup>1</sup> For patients who entered the EP, the mean age was 52 years, 47% were male, the mean time since PsA onset was 12 years, and mean tender and swollen joint counts at baseline (Week 0) were 23 and 12, respectively. For EP patients who were initially randomised to IXE Q4W or Q2W during the DBTP, ACR20 responses at Week 52 were 68% and 59%, respectively. For patients treated with PBO during the DBTP and re-randomised to IXE Q4W or Q2W during the EP, ACR20 responses at Week 52 were 61% and 50%, respectively. Additional efficacy measures are depicted in the Table. The frequency of adverse events (AEs) in the EP is presented in the Table; the majority were mild or moderate in severity. Serious AEs occurred in 15 patients, and one death occurred in the EP population: a myocardial infarction in a PBO/IXE Q2W patient 502 days after starting IXE.

**Abstract SAT0341 – Table 1.** Efficacy and safety results of an interim analysis of the extension period population of SPIRIT-P2.

#### SAT0342 INFLAMMATORY BACK PAIN IN PSORIATIC ARTHRITIS IS SIGNIFICANTLY MORE RESPONSIVE TO CORTICOSTEROIDS COMPARED TO BACK PAIN IN ANKYLOSING SPONDYLITIS: A PROSPECTIVE, OPEN-LABELLED, CONTROLLED PILOT STUDY

M. Haroon<sup>1</sup>, M. Ahmad<sup>1</sup>, N. Baig<sup>2</sup>, O. Mason<sup>3</sup>, J. Rice<sup>2</sup>, O. FitzGerald<sup>4</sup>.  
<sup>1</sup>Rheumatology, <sup>2</sup>Orthopaedics, University Hospital Kerry, Tralee, County Kerry, <sup>3</sup>CSTAR (Centre for Support and Training in Analysis and Research), University College Dublin; <sup>4</sup>Rheumatology, St Vincent's University Hospital, Dublin, Ireland

**Background:** Inflammatory spinal disease is one of three inflammatory musculoskeletal manifestations which frequently occur in PsA. There is very limited data about the axial involvement in PsA, especially as regards treatment, with

treatment guidelines based largely on data from AS trials. The efficacy of corticosteroids in PsA patients with inflammatory back pain has not been studied to date. **Objectives:** In this controlled trial, we aimed to investigate the comparative performance of corticosteroids for active axial-PsA (AxPsA) versus those with active AS.

**Methods:** PsA patients (fulfilling CASPAR criteria), and AS as per the 1984 Modified New York Criteria, were suitable for inclusion. Among them, patients with active AxPsA and active AS (naïve to biologic therapies) were recruited. The active disease was defined as patients with inflammatory back pain, with spinal pain score of ≥4 and BASDAI score ≥4 despite taking NSAIDs. Furthermore, only those AxPsA and AS patients with an MRI proven sacroiliac joint bone marrow oedema (MRI of sacroiliac joints performed within the 6 months prior to recruitment) were considered for inclusion. Hence, all recruited patients with AxPsA and AS had not only clinically active disease, but also had bone marrow oedema on MRI of sacroiliac joints. Moreover, we recruited a control group of non-inflammatory lower back pain. All patients received a single, intra-muscular dose of depot corticosteroid injection (Triamcinolone Acetonide 80 mg) at baseline. The intra-muscular corticosteroid option was used to overcome any drug compliance issues. Clinical outcome assessments were made at following time points: baseline, week-2, and week-4. The primary efficacy end point was the mean change in Ankylosing Spondylitis Disease Activity Score (ASDAS) at week-2. Key secondary outcome were the mean change of BASDAI, BASFI and ASQoL at week-2 and week-4.

**Results:** In total, 40 patients were recruited – AxPsA=15, AS=15, control=10. At week-2 following corticosteroid treatment, patients with AxPsA had significantly higher improvements in the mean ASDAS compared to patients with AS (1.43 ±0.39 vs. 1.03±0.30, p=0.004), and the same was the case when compared to controls (p<0.001, table-2, figure-1). At week-4, AxPsA patients also showed significantly higher improvements in the mean ASDAS compared to both AS patients (1.09±0.32 vs. 0.77±0.27, p=0.007) and controls (p<0.001). Similarly, the mean BASDAI, VAS spinal pain score, ASQoL and BASFI improved significantly among AxPsA patients compared to AS patients and controls at week-2, with this trend also largely maintained at week-4

**Conclusions:** Axial inflammation in PsA potentially responds significantly better to corticosteroids than in patients with AS. This furthers the argument and adds to the growing evidence that AxPsA and AS are distinct entities. Future studies should further investigate the use of corticosteroids and of sDMARD usage among patients with active IBP in PsA.

#### SAT0343 CARDIOVASCULAR DISEASE RISK IN CLINICAL SUBTYPES OF PSORIATIC ARTHRITIS

N. Hassan<sup>1</sup>, M. Bradley<sup>2</sup>, R. Davies<sup>1</sup>, E. Choy<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Cardiff University School of Medicine, Cardiff, UK

**Background:** Patients with psoriatic arthritis (PsA) have been shown to be at increased risk of developing cardiovascular disease (CVD), with one recent meta-analysis demonstrating an increased CVD risk of 43% compared to the general population. However PsA is a heterogeneous disease consisting of five different clinical subtypes. It is not known whether the risk of CVD varies between different PsA subtypes.

**Objectives:** To determine whether particular subtypes of PsA are associated with an increased risk of cardiovascular disease.

**Methods:** 114 patients with PsA attending the University Hospital of Wales were asked to complete a questionnaire about their cardiovascular risk factors. Anthropometric and biochemical measurements, including blood pressure, body mass index (BMI), C-reactive protein (CRP) and cholesterol, were also performed. Patients were grouped into one of the five PsA subtypes as described by Moll and Wright. The QRISK2 algorithm was used to determine the 10 year risk of developing CVD for each patient. Multivariate analyses using linear and logistic regression with QRISK2 score and QRISK2 score >10% as dependent variables were conducted and adjusted for known cardiovascular risk factors.

**Results:** Symmetrical polyarthritis was the most common subtype, no patients had arthritis mutilans. There were no statistically significant differences between the subtypes with regards to age, gender, BMI, blood pressure, smoking status, cholesterol or CRP. Statistically significant differences were found between the subtypes using Chi-square (χ<sup>2</sup>) tests for QRISK2 score >10% (p=0.031) as well as the presence of existing cardiovascular disease, diabetes mellitus and cholesterol lowering treatment (p=0.021, 0.021 and 0.037 respectively). The table 1 below lists the number of patients by subtype and these variables.

	Asymmetrical/ oligo-articular	Distal interphalangeal (DIP) predominant	Spinal predominant	Symmetrical polyarthritis
n (out of 100)	24	9	13	68
Age (mean±SD)	51.3±15.0	61.4±7.8	58.8±13.7	50.7±15.2
Male (n,%)	14 (58.3)	5 (55.6)	6 (46.2)	32 (47.1)
Presence of cardiovascular disease (n,%)*	1 (4.2)	0 (0)	3 (23.1)	1 (1.5)
History of diabetes mellitus (n,%)*	6 (25.0)	2 (22.2)	3 (23.1)	3 (4.4)
On cholesterol- lowering treatment (n, %)*	4 (16.7)	1 (11.1)	6 (46.2)	9 (13.2)
QRISK2 risk score (mean±SD)	12±12.3	15.1±8.5	18.8±13.9	11.1±13.3
Those with QRISK2 risk score>10% (n,%)*	9 (37.5)	7 (77.8)	8 (61.5)	23 (33.8)

\*denotes p<0.05

**Conclusions:** PsA patients with symmetrical polyarthritis appear to have the lowest risk of developing CVD. This subtype also had a significantly lower proportion of patients with coexisting diabetes mellitus. Patients with the distal interphalangeal (DIP) subtype are more likely to have existing CVD and be on cholesterol-lowering medications. Patients with the DIP and spinal predominant subtypes of PsA are also more likely to have a QRISK2 score of greater than 10% compared to the other PsA subtypes, suggesting they are more likely to develop CVD and may consequently need closer monitoring and management of CVD risk factors.

**Background:** In a Phase 2 study, Guselkumab (GUS) was shown to be safe and effective in patients (pts) w/active psoriatic arthritis (PsA) w/meaningful improvements in enthesitis.

**Objectives:** To evaluate the effect of GUS on enthesitis in a subset of pts w/ enthesitis at baseline (BL) from the phase 2 PsA study of GUS.

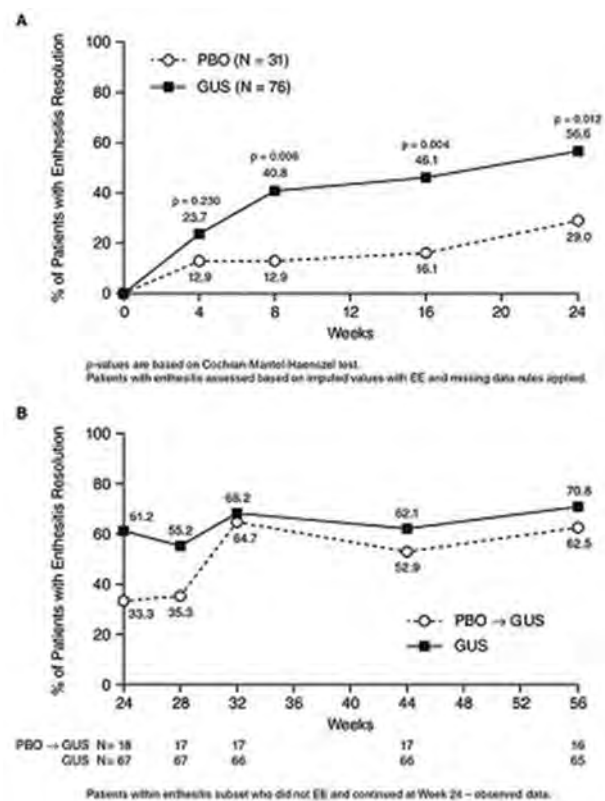

**Methods:** Pts w/active PsA and ≥3% body surface area of plaque psoriasis, despite current or previous treatment, were randomised 2:1 to receive 100 mg subcutaneous GUS or placebo (PBO) at weeks (wks) 0, 4, then every 8 wks (q8w) during a 24-wk double-blind treatment period. At wk16, pts w/<5% improvement in swollen and tender joint counts early escaped (EE) to open-label ustekinumab. At wk24, the PBO group crossed over to receive GUS at wks 24, 28 then q8w (PBO→GUS) and the GUS group continued receiving GUS (GUS→GUS) through wk44. Enthesitis was assessed using the Leeds enthesitis index (LEI). Enthesitis scores during the 24-wk double-blind treatment was analysed using LOCF imputation for missing data and EE. Enthesitis after wk24 was analysed using observed data.

**Results:** Of 149 total pts w/active PsA, 107 (72%) presented w/enthesitis at BL (PBO n=31, mean [SD] LEI=2.6 [1.48], median [range]=2.0;<sup>1</sup>; GUS n=76, mean (SD) LEI=2.7 [1.54], median [range]=2.0<sup>1</sup>; and 85 continued at Wk24 (PBO→GUS n=18; GUS→GUS n=67). Except for higher tender/swollen joint counts and CRP, BL characteristics of the enthesitis subset was similar to the overall population. GUS significantly reduced the LEI by wk8 (mean [SD] change from baseline, PBO: -0.4 [1.59]; GUS: -1.2 [1.65]; p=0.037), and through wk24

(mean [SD] change from baseline, PBO: -0.7 [1.53]; GUS: -1.5 [1.81]; p=0.045). GUS also significantly increased the% of pts w/enthesitis resolution (figure 1). After wk24, the PBO→GUS group achieved rapid, sustained resolution (wk56: mean[SD] change from BL=-2.1 [1.65]; 62.5% of pts w/resolution), similar to GUS→GUS group (wk56: mean[SD] change from BL=-1.9 [1.59], 70.8% of pts w/resolution). Improvement in enthesitis was observed at each enthesitis site assessed, and was greater in ACR20 (Table) responders vs non-responders in GUS-treated patients and was correlated w/improvement in tender (R=0.37, p=0.001) and swollen (R=0.27, p=0.020) joint counts, physician's (R=0.47, p<0.0001) and patient's global assessment of disease activity (R=0.32, p=0.005), and SF36 PCS (R=0.27, p=0.02) and MCS (R=0.35, p=0.002).

**Abstract SAT0344 – Table 1.** Change in LEI in ACR20/50 and PASI75 Responders and Non-responders

	Mean (SD) change from BL in LEI at Wk24		
	Non-responders	Responders	p-value
ACR 20	-0.93 (2.054), n=28	-2.06 (1.660), n=47	0.002
ACR 50	-1.55 (2.190), n=49	-1.81 (1.132), n=26	0.057
PASI 75	-1.25 (1.138), n=12	-1.71 (1.995), n=63	0.524

**Abstract SAT0344 – Figure 1.** Proportion of Patients with Enthesitis Resolution over Time

**Conclusions:** GUS treatment produces rapid and sustained improvement of enthesitis in pts w/active PsA, which correlates w/improvement in joint symptoms and patient-reported outcomes.

**SAT0345 QUALITY INDICATORS IN THE CARE OF PSORIATIC ARTHRITIS**

P. Helliwell<sup>1</sup>, G. Favier<sup>2</sup>, D. Gladman<sup>1</sup>, E. Soriano<sup>1</sup>, B. Kirkham<sup>1</sup>, L. Coates<sup>1</sup>, L. Puig<sup>1</sup>, W.-H. Boehncke<sup>1</sup>, D. Thaci<sup>1</sup>. <sup>1</sup>Group for Research and Assessment of Psoriasis and Psoriatic Arthritis, Seattle, USA; <sup>2</sup>Global Strategy Group, Healthcare and Life Sciences, KPMG LLP, London, UK

**Background:** In 2016, members of GRAPPA in collaboration with KPMG LLP (UK) conducted a study to benchmark care in psoriatic arthritis (PsA). Challenges in the care of patients with PsA were identified but a key finding was that centres do not usually have processes in place to measure the impact of improved quality of care.<sup>1</sup>

**Objectives:** To identify quality of care indicators to enable PsA caregivers to assess and monitor the outcomes of specific initiatives aimed at improving care in four focus areas. The focus areas are aligned to key patient pathway challenges: 1) Shorten time to diagnosis, 2) Improve multi-disciplinary collaboration, 3) Optimise disease management and 4) Improve disease monitoring.

**Methods:** 1. Structured review literature to obtain a longlist of 100 potential indicators across 4 focus areas. Search strategy used specific terms related to quality measures in PsA, adjacent and other chronic diseases. 80+publications were reviewed and rated based on relevance to four focus areas. 2. Survey expert rheumatologists and dermatologists representative of different healthcare systems to review the longlist and identify the most meaningful and feasible indicators for use in day to day practice. 3. Consensus discussion among the experts to identify shortlist of indicators based on pre-defined selection criteria. Key criteria for the Indicators were: <sup>1</sup> support improvement of patient care <sup>2</sup> evidence-based, <sup>3</sup> measurable, and <sup>4</sup> feasible. 4. Electronic group discussion among the experts to refine definitions of shortlisted indicators and targets.

**Results:** The expert group arrived at a consensus with a shortlist of 8 quality indicators across each focus area.

Domain (Indicator, Target). 1. *Shorten time to diagnosis* (a) Average duration from presentation to HCP to confirmed PsA diagnosis. Less than 6 months<sup>2</sup> (b)% of patients with Psoriasis who receive a PsA screening test Annually<sup>3</sup>. 2. *Improve multidisciplinary collaboration* (a) Multidisciplinary PsA assessment is available (Y/N)<sup>4</sup> (b) Does the centre provide suitable training for HCPs, nurses etc. to increase awareness of PsA disease symptoms (Y/N)<sup>5</sup> 3. *Optimise disease management* (a) Average number of PsA evaluations done by HCP per patient in a year<sup>6</sup> 1–2 annually (b)% PsA patients on whom T2T strategy is applied<sup>7</sup> 4. *Improve disease monitoring* (a)% of PsA patients who received full disease assessment for co-morbidities, e.g. co-morbidity index at least once every year<sup>8</sup> (b) Availability of short-term unscheduled appointments (Y/N)<sup>9</sup> Max. 2 weeks.

**Conclusions:** 8 quality indicators in 4 areas of practice have been defined. The respective targets are evidence based, feasible, measurable and meaningful for patients.

**SAT0346 CLINICALLY MEANINGFUL IMPROVEMENT IN SKIN AND NAIL PSORIASIS IN BIO-NAÏVE ACTIVE PSORIATIC ARTHRITIS PATIENTS TREATED WITH INTRAVENOUS GOLIMUMAB: RESULTS THROUGH WEEK 24 OF THE GO-VIBRANT STUDY**

P.J. Mease<sup>1</sup>, M.E. Husni<sup>2</sup>, S.D. Chakravarty<sup>3</sup>, S. Kafka<sup>4</sup>, D.D. Harrison<sup>5</sup>, D. Parenti<sup>4</sup>, L. Kim<sup>6</sup>, K.H. Lo<sup>6</sup>, E.C. Hsia<sup>7</sup>, A. Kavanaugh<sup>8</sup>. <sup>1</sup>Swedish Medical Center and U of Wash School of Medicine, Seattle; <sup>2</sup>Cleveland Clinic, Cleveland; <sup>3</sup>Janssen Scientific Affairs, LLC/Drexel U College of Med, Horsham/Phila; <sup>4</sup>Janssen Scientific Affairs, LLC; <sup>5</sup>Janssen Research and Development, LLC, Horsham; <sup>6</sup>Janssen Research and Development, LLC, Spring House; <sup>7</sup>Janssen Research and Development, LLC/U Penn, Spring House/Phila; <sup>8</sup>UCSD, San Diego, USA

**Background:** GO-VIBRANT was a Ph3 trial of IV golimumab (GLM) in adult pts w/active PsA.

**Objectives:** To evaluate improvement in skin, nail psoriasis and Dermatology Life Quality Index (DLQI) w/IV GLM.

**Methods:** Adult bio-naïve PsA pts w/active disease (≥5 swollen and tender joints, CRP ≥0.6 mg/dl, active plaque PsO or documented history, and despite treatment w/csDMARDs and /or NSAIDs) were randomised to IV GLM 2 mg/kg at wks0, 4, and q8wks thereafter or PBO at wks0, 4, 12, and 20 w/crossover to GLM at wk24. Pts w/≥3% body surface area (BSA) PsO at baseline (BL) were assessed using Psoriasis Area and Severity Index (PASI, 0–72) 75/90/100% and modified Nail Psoriasis Severity Index (mNAPSI, 0–130) at BL, wks14 and 24 (in pts w/ mNAPSI>0 at BL). DLQI was assessed at BL, wks8, 14 and 24.

**Results:** 394 pts (PBO:n=198;GLM:n=196) had ≥3% BSA PsO at BL; 76.5% had mNAPSI >0 at BL (mean 18.6). Pts on GLM achieved a greater PASI75 response vs PBO (59.2% vs 13.6%, p<0.001) at wk14 and wk24 (64.8% vs 13.1%, p<0.001). At wk14, pts on GLM achieved greater PASI 90/100 responses vs PBO (39.3/16.8% vs 6.6/4.5%; p<0.001 for all) and at wk24 (42.9/25.5% vs 7.6/5.6%; p<0.001 for all) (table 1). At wk14, similar proportions of pts in GLM grps, regardless of BL MTX use, achieved PASI 90/100 responses. At wk24, greater proportions of pts on GLM+MTX and GLM only achieved PASI100 vs PBO (+MTX:30.5% vs 7%, p<0.001; -MTX:15.4% vs 1.8%, p<0.010) (table 1). Mean decrease (improvement) from BL in mNAPSI score was greater in GLM vs PBO (-9.6 vs -1.9, p<0.001) at wk14 and wk24 (-11.4 vs -3.7, p<0.001). At wk8, mean decrease (improvement) from BL in DLQI was greater in GLM vs PBO (-7.2 vs -1.7, p<0.001), at wk14 (-7.7 vs -1.8, p<0.001) and wk24 (-8.1 vs -1.9, p<0.001). At wk14, 55.1% of pts treated w/GLM achieved a PASI50 response and improvement in DLQI ≥5 vs 7.1% treated w/PBO (p<0.001) and at wk24, 59.2% vs 8.1% (p<0.001).

### SAT0347 BASELINE CHARACTERISTICS OF PATIENTS WITH PSORIATIC ARTHRITIS INITIATED ON APREMILAST IN THE CORONA PSORIATIC ARTHRITIS/SPONDYLOARTHRITIS (PSA/SPA) REGISTRY

P.J. Mease<sup>1</sup>, E. Rosenstein<sup>2</sup>, H. Feng<sup>3</sup>, M. Liu<sup>3</sup>, B. Guette<sup>4</sup>, L. Teng<sup>4</sup>, S. Rebello<sup>3</sup>, A.R. Ogdie-Beatty<sup>5</sup>. <sup>1</sup>Swedish Medical Center and University of Washington School of Medicine, Seattle; <sup>2</sup>Institute for Rheumatic and Autoimmune Diseases, Overlook Medical Center, Summit; <sup>3</sup>Corrona, LLC, Southborough; <sup>4</sup>Celgene Corporation, Summit; <sup>5</sup>Department of Medicine, Division of Rheumatology, University of Pennsylvania, Philadelphia, USA

**Background:** Apremilast (APR) is an oral phosphodiesterase 4 inhibitor approved for the treatment of adult patients with active psoriatic arthritis (PsA) and psoriasis.

**Objectives:** To characterise demographics, disease activity and duration, concomitant therapy, quality of life, and prior comorbidities among patients with PsA who initiated APR in the Corona Psoriatic Arthritis/Spondyloarthritis (PsA/SpA) registry, an independent, prospective, US observational cohort.

**Methods:** Adult patients  $\geq 18$  years of age with PsA who were reported initiating APR in the Corona PsA/SpA registry between May 2014 and September 2017 were included in the analysis. Descriptive statistics were calculated for patients' clinical characteristics and disease assessments at the index visit. The index visit was defined as the Corona visit when APR initiation was reported. If the patient started a drug between 2 Corona visits, the measures/outcomes from a prior visit were imputed to replace the missing values.

Clinical Characteristics and Disease Assessments of PsA/SpA Patients at the Index Visit		
Characteristic	n*	Mean (SD)
Swollen joint count (0-66)	136	2.7 (4.43)
Tender joint count (0-68)	136	7.2 (11.56)
PhGA (VAS 0-100 mm)	135	22.1 (18.82)
PGA (VAS 0-100 mm)	134	54.2 (26.45)
Dactylitis count (1-20)	14/138	2.6 (2.21) <sup>‡</sup>
SPARCC/Leeds Enthesitis Index (1-16)	34/138	4.2 (3.05) <sup>‡</sup>
DAS-28 (CRP) (0-10)	67	3.1 (1.04)
CDAI (0-76)	128	13.9 (9.57)
cDAPSA (0-154)	128	20.7 (15.07)
HAQ-S (0-3)	135	0.95 (0.69)
BASDAI (0-10)	126	5.4 (2.53)
Morning stiffness (VAS 0-100 mm)	134	54.4 (28.26)

\*Number of patients with data for the given assessment. <sup>‡</sup>Assessed among patients with dactylitis (n=14) or enthesitis (n=34) at baseline.  
PhGA=Physician's Global Assessment of Disease Activity; PGA=Patient's Global Assessment of Disease Activity; VAS=visual analog scale; SPARCC=Spondyloarthritis Research Consortium of Canada; DAS-28-28=joint count Disease Activity Score; CRP=C-reactive protein; CDAI=Clinical Disease Activity Index; cDAPSA=Clinical Disease Activity Index for Psoriatic Arthritis; HAQ-S=Health Assessment Questionnaire for Spondyloarthritis; BASDAI=Bath Ankylosing Spondylitis Disease Activity Index.

**Results:** Among 138 patients included in the analysis, mean (SD) age was 56<sup>12</sup> years, mean (SD) BMI was 33,<sup>7</sup> 62% were female, 66% were previously on a non-biologic DMARD (nbDMARD) and 79% had prior biologic use; 62% were on APR monotherapy. Of the APR initiators, the number of patients receiving concomitant methotrexate, nbDMARD, TNF inhibitor, and non-TNF inhibitor were 32 (23%), 41 (30%), 6 (4%), and 4 (3%), respectively. Pertinent comorbidities included diabetes mellitus (22%), metabolic syndrome (22%), cancer (18%), cardiovascular disease (17%), and congestive heart failure (0.7%). Patients reported a mean (SD) of 13<sup>10</sup> years for PsA symptoms and a mean (SD) of 10<sup>9</sup> years since PsA diagnosis. Of the 94 patients with data available for evaluation, 14% met criteria for minimal disease activity while 1% met criteria for very low disease activity. Most patients had moderate or low levels of disease activity, respectively: CDAI (48% and 35%), cDAPSA (47% and 34%), and DAS-28 (CRP) (37% and 21%). Of note, 82% of patients had <5 swollen joints and 63% had <5 tender joints. Mean HAQ-S (0-3) was 0.95 and BASDAI (0-10) was 5.4 (Table). Patients demonstrated a substantial burden of disease with a mean fatigue score (0-100) of 55 and mean overall pain score (0-100) of 55, and 81% reported stiffness lasting >30 min. Additionally, mean baseline work productivity and activity impairment (WPAI) subscale scores

indicated limitations on absenteeism (8%), presenteeism (25%), work productivity loss (26%), and activity impairment (40%).

**Conclusions:** The population of patients with PsA treated with APR in the Corona PsA/SpA registry exhibited low to moderate disease activity and were substantially impacted, as evidenced by patient-reported outcomes (pain, fatigue, stiffness, and productivity). Future analyses on this cohort will provide more insight into patient characteristics and treatment patterns in this population, as well as long-term efficacy and safety information for PsA patients treated with APR.

### SAT0348 SAFETY OF IXEKIZUMAB IN PATIENTS WITH PSORIATIC ARTHRITIS: RESULTS FROM A POOLED ANALYSIS OF THREE CLINICAL TRIALS

P. Goupille<sup>1</sup>, E. Roussou<sup>2</sup>, G. Burmester<sup>3</sup>, P.J. Mease<sup>4</sup>, A.B. Gottlieb<sup>5</sup>, S. Garces<sup>6</sup>, O. Benichou<sup>7</sup>, D. Adams<sup>8</sup>, W. Xu<sup>9</sup>, P. Nash<sup>9</sup>. <sup>1</sup>University Hospital of Tours, Tours, France; <sup>2</sup>King George Hospital, Essex, UK; <sup>3</sup>Charité—University Medicine Berlin Free University and Humboldt University, Berlin, Germany; <sup>4</sup>Swedish Medical Center, and University of Washington, Seattle; <sup>5</sup>New York Medical College, New York; <sup>6</sup>Eli Lilly and Company, Indianapolis, USA; <sup>7</sup>Eli Lilly and Company, Paris, France; <sup>8</sup>University of Queensland, Brisbane, Australia

**Background:** Ixekizumab (IXE), a high affinity monoclonal antibody that selectively targets interleukin-17A, has been shown to be superior to placebo (PBO) in improving signs and symptoms of psoriatic arthritis (PsA) in Phase 3 trials<sup>1,2</sup>.

**Objectives:** To assess the safety of IXE in patients with active PsA using data pooled from 3 (SPIRIT-P1, -P2, and -P3) Phase 3 trials.

**Methods:** SPIRIT-P1<sup>1</sup> and -P2<sup>2</sup> are double-blind trials; patients were randomised to PBO, adalimumab (ADA; active reference arm; SPIRIT-P1 only),<sup>1</sup> or 80 mg IXE every 4 (Q4W) or 2 (Q2W) weeks. PBO and ADA patients were re-randomised to either IXEQ4W or IXEQ2W for the open-label extension period (Weeks 24–156); patients who initially received IXE remained on their original dose. SPIRIT-P3 is an open-label (Week 36–64) trial where patients received IXEQ2W followed by a randomised withdrawal period. In all the 3 trials, patients received a 160 mg loading dose of IXE. Safety data were integrated from all IXE-treated patients (defined as all patients receiving  $\geq 1$  dose of IXE) included in SPIRIT-P1, -P2, and -P3. Exposure-adjusted incidence rates (IRs) per 100 patient-years (PY) were reported for adverse events (AEs).

**Results:** Overall, 1118 patients received IXE (total exposure=1373.4 PY). Four deaths (0.3/100PY) were reported (cerebrovascular accident, cardio-respiratory arrest, drowning, and pneumonia) (Table). The most common treatment-emergent AEs (TEAEs) were injection-site reaction (ISRs), upper respiratory tract infection, and nasopharyngitis; IRs for TEAEs, including ISRs, decreased over-time. There was no clinically meaningful increase in IRs of serious AEs, infections, serious infections, hypersensitivity, and major adverse cardiovascular events (MACE) with longer IXE exposure (Table). IR for serious infections was low (1.2/100PY). Serious infections included pneumonia (0.2/100PY), lower respiratory tract infection, and esophageal candidiasis (0.1/100PY each). No case of active tuberculosis (TB) was reported, but 1 case of latent TB was deemed as serious due to hospitalisation for testing to exclude active TB. Opportunistic infections were limited to oral and esophageal *Candida* and localised herpes zoster. There were no reports of deep organ or bloodstream *Candida* infections. No anaphylaxis was reported, but 1 patient (0.1/100PY) experienced angioedema. No patient had infections temporally associated with Grade  $\geq 2$  neutropenia. Nine patients (0.7/100PY) had MACE. One case (0.1/100PY) each of Crohn's disease (with prior history of irritable bowel syndrome) and ulcerative colitis were reported. However, none of the 12 patients with pre-existing inflammatory bowel disease experienced an exacerbation with IXE.

**Abstract SAT0348 – Table 1.** Exposure-Adjusted Incidence Rate of TEAEs at 12-Week Intervals up to Week 96 (All PsA Ixekizumab Exposures Integrated Analysis Set: SPIRIT-P1, SPIRIT-P2, and SPIRIT-P3).

All data are IRs (95% confidence intervals) unless otherwise specified. \*Potential hypersensitivity events were defined by the adverse event within hypersensitivity SMOO excluding local injection site reactions.  
Abbreviations: DIP, inflammatory bowel disease; IR=incidence-adjusted incidence rates per 100 patient-years; ISR=injection site reactions; MACE=major adverse cardiac event; N=total number of patients analyzed at each time point; SAEs=serious adverse events; TEAEs=treatment emergent adverse events.

**Conclusions:** The safety profile of IXE in patients with PsA is consistent with previous reports as derived from the analysis of the three SPIRIT trials from a large cohort of patients. No new safety signals were identified with longer IXE treatment exposure.

**SAT0349 A NOVEL SCORING SYSTEM TO DIFFERENTIATE PSORIATIC ARTHRITIS FROM NODAL OSTEOARTHRITIS ON PLAIN-FILM RADIOGRAPHS**

R. Mandegaran<sup>1</sup>, E. Nikiphorou<sup>2</sup>, S. Bahadur<sup>3</sup>, C. Hughes<sup>3</sup>, B. Kirkham<sup>3</sup>, A. Zavareh<sup>1</sup>. <sup>1</sup>Radiology, Guy's and St Thomas' NHS Foundation Trust, <sup>2</sup>Academic Rheumatology Department, King's College London; <sup>3</sup>Rheumatology, Guy's and St Thomas' NHS Foundation Trust, London, UK

**Background:** Differentiating Psoriatic Arthritis (PsA) and Nodal Osteoarthritis (NOA) in patients with interphalangeal joint (IPJ) involvement is often challenging.<sup>1-3</sup> Yet, the distinction is important to make, especially as the treatment for these conditions is vastly different. Here we present a novel scoring system based on identifying often subtle but characteristic radiographic features of both conditions on bilateral hand plain-film radiographs.

**Objectives:** To describe the key radiographic discriminating features that underpin a new scoring system aimed primarily to differentiate PsA from NOA.

**Methods:** The initial scoring methodology was tested through blind analysis and scoring of 99 bilateral hand radiographs of patients with a confirmed clinical diagnosis of PsA, NOA and RA.<sup>4</sup> In this initial study, anonymised radiographs were read by a Musculoskeletal Radiologist blinded to all clinical information. The reader correctly identified the clinical diagnosis in 100% of radiographs. The analysis method was taught to 3 specialist trainees, in a 1 hour training session. They assessed the same radiograph series with an accuracy of 67%–88%.

We refined the radiograph analysis method to develop a scoring system by developing weighted scores for different PsA arthropathic features. These include peri-articular erosions and new bone formation (NBF), reduced joint space, soft tissue

oedema and asymmetry of findings. Osteoarthritis features included marginal osteophytes, subchondral sclerosis/cysts and reduced joint space.

**Results:** All bilateral interphalangeal joints and 1 st metacarpophalangeal (MCP) joint are assessed – (20 joints in total). First carpo-metacarpal joint changes were more common in NOA, but had little discriminatory value. Periarticular erosion and NBF are the key indicators and either feature must be present on the radiographs. Asymmetry of the findings and soft tissue oedema are also included.

Each radiographic feature is scored between 0 and 2 (0=normal, 1=mild/moderate, 2=severe). The scoring system allows the identification of PsA features, even in the presence of background NOA. This scoring system is currently undergoing validation.

**Conclusions:** This radiographic interpretation and scoring system provides a clear framework with key discriminators and relative major and minor weighting. Once validated, it could be taught and used as a readily available, low-cost imaging tool, by both radiologists and non-radiologists alike.

**SAT0350 CONTENT AND FACE VALIDITY AND FEASIBILITY OF FIVE CANDIDATE INSTRUMENTS FOR PSORIATIC ARTHRITIS RANDOMISED CONTROLLED TRIALS: RESULTS FROM THE PSA OMERACT CORE SET WORKSHOP AT THE GRAPPA 2017 ANNUAL MEETING**

R. Holland<sup>1</sup>, W. Tillett<sup>1</sup>, A. Ogdie<sup>1</sup>, Y.Y. Leung<sup>1</sup>, D.D. Gladman<sup>1</sup>, K. Callis Duffin<sup>1</sup>, L. C. Coates<sup>1</sup>, P. Mease<sup>1</sup>, L. Eder<sup>1</sup>, V. Strand<sup>1,2</sup>, M. Elmamoun<sup>1</sup>, P. Hojgaard<sup>1</sup>, I. Campbell<sup>1</sup>, J. Chau<sup>1</sup>, M. de Wit<sup>1</sup>, N. Goel<sup>1</sup>, C.A. Lindsay<sup>1</sup>, O. FitzGerald<sup>1</sup>, B. Shea<sup>2</sup>, D. Beaton<sup>2</sup>, A.-M. Orbai<sup>1</sup>. <sup>1</sup>Grappa-omeract PSA Core Set Working Group; <sup>2</sup>Outcome Measures in Rheumatology, International Organisation, -

**Background:** The Group for Research and Assessment of Psoriasis and Psoriatic Arthritis (GRAPPA) – Outcome Measures in Rheumatology (OMERACT) Psoriatic Arthritis (PsA) Core Set working group is developing a core instrument set to guide selection of outcome measures (instruments) for PsA randomised controlled trials (RCTs) and longitudinal observational studies (LOS). Candidate instrument measurement properties are being appraised in systematic literature reviews by working group members.

**Objectives:** Appraise the content and face validity (domain match) and feasibility of PsA instruments with GRAPPA stakeholders using the OMERACT Filter 2.1 instrument selection process<sup>1</sup>.

**Methods:** The PsA Core set workshop held at the GRAPPA 2017 annual meeting comprised an introductory plenary session and breakout group discussions. Working group members facilitated six breakout groups, with two patient research partners (PRPs) per group, discussing pre-selected domain-instrument pairs. Participants individually reviewed the instrument(s). After group discussion, they completed anonymised paper-based OMERACT questionnaires examining domain match and feasibility, with votes for each aspect of domain match and feasibility centralised by instrument. A final vote (show of hands) on whether the assigned instrument met the requirements for domain match and feasibility using the OMERACT traffic-light scoring system was taken. Consensus was defined as more than 70% agreement, and majority as more than 50% agreement within a group. Consensus represents stronger evidence than majority agreement.

**Results:** There were 145 participants across all breakout groups and 116 returned completed questionnaires. Anonymized votes are summarised across groups and instruments in figure 1. More than 70% in the respective breakout groups endorsed the PsA instrument 66 swollen and 68 tender joint count (66/68 SJC/TJC) as a good match with the target domain of arthritis, a subset of MSK disease activity, FACIT-Fatigue as a good match with fatigue, and PsAID12 as a good match with HRQoL. There was consensus or majority agreement for all feasibility questions for the 66/68 SJC/TJC, HAQ-DI and PsAID9 and PsAID12. For the SPARCC enthesitis index only one item in both domain match and feasibility did not reach majority agreement.

**Abstract SAT0350 – Figure 1.** GRAPPA stakeholders' ratings for OMERACT domain match and feasibility for 6 PsA instruments

**Conclusions:** The first two steps of the OMERACT Filter 2.1 instrument selection process for five candidate instruments have been completed. The first set of candidate instruments selected to undergo the next phase of the OMERACT Filter 2.1, construct validity and discrimination appraisal are 66/68 SJC/TJC, SPARCC enthesitis index, PsAID9, PsAID12, HAQ-DI and FACIT-Fatigue. Additional PsA instruments will undergo the OMERACT selection process.

#### SAT0351 VERY LOW DISEASE ACTIVITY, DAPSA REMISSION, AND PATIENT-ACCEPTABLE SYMPTOM STATE IN PSORIATIC ARTHRITIS

R. Queiro<sup>1</sup>, J.D. Cañete<sup>2</sup>, C. Montilla<sup>3</sup>, M.A. Abad<sup>4</sup>, S. Gómez<sup>5</sup>, A. Cabeza<sup>5</sup> on behalf of MAAPs study group. <sup>1</sup>Rheumatology, Hospital Universitario Central De Asturias, Oviedo; <sup>2</sup>Rheumatology, Hospital Clinic, Barcelona; <sup>3</sup>Rheumatology, HU. Salamanca; <sup>4</sup>Rheumatology, H. Virgen del Puerto, Plasencia; <sup>5</sup>Pfizer Medical Dpt., Madrid, Spain

**Background:** The goal of treatment in psoriatic arthritis (PsA) according to the T2T strategy is remission, or at least, a low disease activity state<sup>1</sup>. Currently there is no clear agreement on how to measure these treatment goals.

**Objectives:** To explore the relationship between very low disease activity (VLDA) state, according to the MDA 7/7 criteria<sup>2</sup>, and DAPSA remission<sup>3</sup>, as well as its association with the impact of the disease evaluated by the PsAID questionnaire<sup>4</sup>, in patients with PsA in routine clinical practice.

**Methods:** Post-hoc analysis of the MAAPs study<sup>5</sup>. We included patients who met CASPAR criteria, with at least one year of disease evolution, and treated with biological and/or synthetic DMARDs according to the usual clinical practice in Spain. Patients were considered in VLDA if they met 7/7 of the MDA criteria, and in DAPSA/cDAPSA remission (this last without CRP) if they had a value  $\leq 4$ . A PsAID  $< 4$  represented a patient-acceptable symptom state (PASS). The frequency of these states and kappa ( $\kappa$ ) agreement between them were analysed.

**Results:** Of the 227 patients included in the original study, 26 (11.5%), 52 (30.6%), 65 (36.9%) and 125 (55%) were in VLDA, DAPSA remission, cDAPSA remission, and PASS, respectively. There was a moderate agreement between VLDA and DAPSA remission ( $\kappa=0.52$ ) or the cDAPSA remission ( $\kappa=0.42$ ). Patients in VLDA had a lower impact of the disease measured by PsAID [mean total score (SD): VLDA 1.1 (1.2); DAPSA remission 1.3 (1.5); cDAPSA remission 1.7 (1.6)]. There was a moderate agreement between DAPSA remission or cDAPSA remission and PASS ( $\kappa=0.55$  and  $\kappa=0.58$  respectively), while fair agreement was found between VLDA and PASS ( $\kappa=0.18$ ).

**Conclusions:** About one third of this series reached DAPSA remission, while only 11.5% reached VLDA state. On the other hand, more than half were in PASS situation. Agreement between VLDA and DAPSA was moderate. Although the MDA 7/7 criteria seem to be more stringent criteria for assessing remission, DAPSA remission shows better agreement with PASS. DAPSA and VLDA would be adequate treatment targets in daily practice.

#### SAT0352 PREVALENCE AND CHARACTERISTICS OF CORONARY DISEASE AND CARDIOVASCULAR RISK FACTORS IN A COHORT OF PATIENTS WITH PSORIATIC ARTHRITIS

S.A. Rodríguez Montero, N. Plaza Aulestia, M.J. Pérez Quintana, M.L. Velloso Feijoo, J. L. Rheumatology, Valme Hospital, Seville, Spain

**Background:** We performed a descriptive study of our patients with psoriatic arthritis (PsA) over 40 years old, attending to the presence of coronary disease and cardiovascular risk factors in each group of treatment (DMARDs vs biologic therapy).

**Methods:** Patients older than 40 years, diagnosed with psoriatic arthritis attending clinics at the Department of Rheumatology were analysed to determine how many of them presented coronary disease. The following information was recorded: age, sex, disease duration and age at the coronary event, HLA-B27 positivity, hypertension, type II diabetes and hyperlipidemia, on medical records and discharge reports for each patient.

**Results:** All 137 patients were identified from an electronic database. We found a male predominance: 57% versus 43% of women. Mean age  $57.05 \pm 10.6$  years. Of the 137 patients, 82% had only peripheral arthritis, while 18% also showed axial involvement. With regard to the latter subgroup, 16% patients had a positive HLA-B27 test, 56% were HLA-B27 negative and 28% showed lack of HLA-B27 test. Almost all patients (87%) were in DMARDs therapy, while 31% received biologic therapy: etanercept 42%, secukinumab 16%, adalimumab 12%, ustekinumab 12%, infliximab 9.5%, golimumab 4.7% and certolizumab 2%. About 7% of patients didn't receive DMARDs neither biologic therapy, because of intolerance. Results regarding to cardiovascular risk factors, and coronary disease are as follows:

	DMARD therapy	Biologic therapy ( $\pm$ DMARDs)
Arterial Hypertension	43%	26%
Diabetes	19.5%	7%
Hyperlipidemia	47.5%	38%
Coronary disease	10.9%	2.4%

In DMARD subgroup, we found 6 myocardial infarction (all of them revascularized) and 3 angina, versus 1 myocardial infarction in biologic subgroup.

**Conclusions:** There is solid epidemiologic evidence linking PsA to cardiovascular risk factors and an increased risk of developing cardiovascular disease<sup>1</sup>. Furthermore, over the past two decades it has become increasingly clear that chronic inflammation is an independent risk factor for cardiovascular events. In our study the ratio of ischaemic heart disease for patients with PsA in DMARD therapy is four times higher than that of biologic treatment group. This may be due to the greater percentage of cardiovascular risk factors in the first group, although, the cardioprotective effect of biologic therapies, must be taken into account, as there are some studies that show association between anti-TNF and significant reduction in carotid IMT<sup>2</sup>. Proper management of cardiovascular risk requires aggressive control of disease activity.

**Background:** The environmental and genetic factors play a crucial role in the pathogenesis of psoriatic arthritis (PsA) which may cause a difference in disease characteristics for patients from different geographical regions.

**Objectives:** The aim of the study was to explore the disease characteristics, treatment choices and comorbidities in patients with PsA in different countries to see the impact of geographic factors.

**Methods:** PsArt-ID (Psoriatic Arthritis- International Database) is a prospective, multicentre registry in PsA, which was initially developed in Turkey in 2014, with participation of Canada since 2015 and Italy since 2017. Patients with PsA are consecutively registered to this registry with the aim of investigating the real-life data. Patient characteristics across Turkey (n=1283) and Canada (n=119) are compared for this analysis.

**Abstract SAT0353 – Table 1.** The demographics and clinical characteristics in two countries

	TURKEY	CANADA	p value
Female*	827/1283 (64.5)	60/119 (50.4)	<b>0.002</b>
Age (years)	47 (36–56.7)	49 (34–61)	<b>&lt;0.001</b>
BMI (kg/m <sup>2</sup> )	27.47 (24.5–31.2)	29 (23.7–33.5)	<b>0.013</b>
At onset age for PsA	36 (29–49.7)	39 (30–48)	0.058
Smoking (package/years)	10 (3–19.7)	14.5 (5–26.25)	<b>0.007</b>
Education years	8 (5–12)	15 (13–16)	<b>&lt;0.001</b>
SJC	2 (1–5)	2 (1–7)	0.461
TJC	4 (2–8)	6.5 (2–17)	0.340
TEP	2 (1–2)	1 (1–2)	<b>0.021</b>
BSA	5 (1–13.75)	1 (0–5)	<b>&lt;0.001</b>
BASDAI	37 (20–54)	38 (22–58)	<b>0.027</b>
PT GA	45 (20–60)	31 (12–70)	<b>&lt;0.001</b>
PGA	30 (20–50)	34 (18–66)	<b>&lt;0.001</b>
Pain VAS	40 (20–60)	33 (18–78)	<b>&lt;0.001</b>

TJC: tender joint counts; TEP: tender enthesal points; BSA: body surface area; PTGA: patient global activity; PGA: physician global activity. All data were given n/total n (percentage (%))\* or median (first-third percentiles).

**Abstract SAT0353 – Figure 1.** The distribution of the treatment choices in Turkey and Canada, excluding patients with new diagnosis at the time of recruitment. DMARD: Disease-modifying anti-rheumatic drug; anti-TNF: anti-tumour necrosis factor. All data were given n/total n (percentage (%)).

**Results:** Canadian patients were older at the time of recruitment (Table). They also were more frequently smokers, had higher duration of education and higher BMI than patients in Turkey. Patients in Canada had more frequent polyarthritis (66.7% vs 39.6%, p<0.001), DIP joint disease (34.2% vs 16%, p<0.001), dactylitis (38.1% vs 29%, p=0.037) nail involvement (55.9% vs 45.7%, p=0.008) and higher number deformed joints (29.3% vs 20.7%, p=0.035) whereas Turkish patients had oligoarthritis more often (37.6% vs 24.8%, p=0.016). For disease activity, tender and swollen joint counts were similar for whereas the skin activity was higher in Turkish patients. There were no major differences between countries regarding treatment choices with similar frequencies of patients on biologic therapies (34.5% vs 30.2%, p=0.339) (figure 1). Although the numbers were very low, there was more frequent cancer in Canada than Turkey (4.3% vs 1.4%, p=0.022) whereas all the other comorbidities were similar.

**Conclusions:** Geographical differences have impacts on the disease features in PsA, which may be due to genetic, environmental and cultural differences. The treatments are comparable suggesting a similar approach by the physicians.

**SAT0354 THE WORK PRODUCTIVITY AND ACTIVITY INDEX SPECIFIC HEALTH PROBLEM (WPAI-SHP) AND ITS ASSOCIATION WITH PSORIATIC ARTHRITIS (PSA) ACTIVITY BY DISEASE ACTIVITY INDEX FOR PSORIATIC ARTHRITIS (DAPSA) IN ROUTINE CARE: DATA OF THE RUSSIAN PSORIATIC ARTHRITIS REGISTRY (RU-PSART)**

T. Korotaeva<sup>1</sup>, E. Loginova<sup>1</sup>, A. Koltakova<sup>1</sup>, E. Gubar<sup>1</sup>, Y. Korsakova<sup>1</sup>, E. Nasonov<sup>1</sup>, A. Lila<sup>1</sup>, M. Sedunova<sup>2</sup>, T. Salnikova<sup>3</sup>, I. Umnova<sup>4</sup>, I. Bondareva<sup>5</sup>, G. Zagidulina<sup>6</sup>, P. Zemtsova<sup>7</sup> on behalf of the RU-PsART study group. <sup>1</sup>Nasonova Research Institute of Rheumatology, Moscow; <sup>2</sup>St. Petersburg Clinical Rheumatology Hospital No.25, St. Petersburg; <sup>3</sup>Tula Regional Hospital, Tula; <sup>4</sup>Omsk Regional Hospital, Omsk; <sup>5</sup>Kemerovo Regional Hospital, Kemerovo; <sup>6</sup>Kazan City Hospital No.7, Kazan; <sup>7</sup>Nizhny Novgorod Regional Clinical Hospital n. a. Semashko, Nizhny Novgorod, Russian Federation

**Background:** Psoriatic arthritis (PsA) can lead to impaired physical function and work productivity due to chronic inflammation. The goal of PsA treatment is minimal disease activity (MDA) or Remission/Low Disease Activity (REM/LDA) attainment by DAPSA. But there is limited data about the association between PsA activity and work productivity in routine care. The Russian Psoriatic Arthritis Registry (RU-PsART) collected data from 25 rheumatology clinics in the Russian Federation regions.

**Objectives:** evaluate the association between attainment of REM/LDA by DAPSA and the WPAI-SHP in PsA pts in routine care.

**Methods:** 294 (M/F=133/161) pts with PsA, diagnosed according to CASPAR criteria, mean age 41.2±1.9 (Min 21 – Max 72) years (yrs.), PsA duration 6.1±5.3 (Min 0 – Max 31) yrs., psoriasis duration 13.6±10.7 (Min 0.2 – Max 54.8) yrs. were included in the RU-PsART after signing consent participation forms. Pts underwent evaluation of PsA activity by DAPSA and considered REM≤4, LDA≤14, moderate disease activity (MDA) ≤28, high disease activity (HDA) >28 at baseline. 175 out of 294 pts fulfilled WPAI-SHP. DAPSA and WPAI-SHP at the same time were available in 135 out of 175 pts. 87 out of 135 patients were able to work and operate. At the time of evaluation 82 out of 135 pts were taking sDMARDs, 19 out of 135 pts were missing. Overall work impairment, daily activity impairment, absenteeism and presentism were calculated. M±SD,%, ORs with 95% CI were performed. All CI >1 were considered to indicate statistical significance.

**Results:** Daily activity impairment was found in 91 out of 135 pts (67%), overall work impairment – in 64 out of 87 pts (74%), presentism – in 47 out of 87 pts (49%), absenteeism – in 31 out of 87 pts (36%). 40 pts out of 135 (29.6%) had REM/LDA and 95 out of 135 pts (62.9%) had MDA/HAD by DAPSA accordingly at the time of the assessment. Among pts with MDA/HAD daily activity impairment, overall work impairment, presentism and absenteeism were seen in significantly more cases compared to pts with REM/LDA – in 69 out of 95 pts (73%) and in 22 out of 40 pts (55%), OR 2.17 [1.0–4.69]; in 54 out of 62 pts (87%) and in 10 out of 25 pts (40%), OR 10.13 [3.40–30.16]; in 38 out of 62 pts (38%) and in 9 out of 25 pts (36%), OR 2.81 [1.07–7.38]; in 30 out of 62 pts (48%) and in 1 out of 25 pts (4%), OR 22.5 [2.86–176.80] accordingly (Fig.1).

**Abstract SAT0354 – Figure 1.** Interrelation between WPAI-SHP and PsA activity by DAPSA. ORs with 95% CI.

**Conclusions:** Work disability is commonly found in PsA pts in routine care. REM/LDA status by DAPSA was associated with less disability and better work productivity.

## Crystal diseases, metabolic bone diseases and bone diseases other than osteoporosis

### SAT0355 THE VALIDITY OF GOUT DIAGNOSIS IN PRIMARY AND SECONDARY CARE – RESULTS FROM A PATIENTS SURVEY

A.J. Landgren, L.T.H. Jacobsson, U. Bergsten, M.I. Dehlin. *Department of Rheumatology and Inflammation Research, Institution of Medicine, Sahlgrenska Academy, University of Gothenburg, Gothenburg, Sweden*

**Background:** Gout affects 1%–2% of adults worldwide being the most common inflammatory arthritis and usually managed in primary care. The gold standard for definitive diagnosis of gout is the presence of monosodium urate crystals (MSU) in joints or tissues and the latest classification criteria from ACR-EULAR also have this as a central item. Microscopy is however seldom performed in primary care today. Although not intended as diagnostic there are several classification criteria, such as the Mexico and the Netherlands criteria that do not include microscopy.

**Objectives:** The aim of this study was to validate the diagnosis of gout in primary and secondary care according to the Mexico and the Netherlands criteria and items thereof through a patient survey.

**Methods:** All patients above 18 with an ICD10-diagnosis of gout at a visit in primary and secondary care<sup>Jan 2015</sup> through February 2017) were identified from 12 primary care centres and one rheumatology clinic within the Western Sweden Health Care Region. They were sent a questionnaire regarding comorbidities, demographics and gout characteristics. To test the validity of their gout diagnosis, questions of the two gout classification criteria Mexico and the Netherlands were posed. Self-reported knowledge about having gout, was included as an anchor point for the diagnosis. Positive predictive values (PPV) were calculated for these definitions. Structured telephone interviews collecting similar information were performed in 10% of non-responders. The ACR/EULAR criteria was not used, since it includes identification of MSU crystals and imaging as central items.

**Abstract SAT0355 – Table 1.** Positive predictive values for different classification criteria, anchor points for gout diagnosis and common items of classification criteria

Definitions used for gout diagnosis	Primary care (n=784)	Secondary care (n=84)
Netherlands $\leq$ 4, n(%)	57 (7.7)	3 (3.8)
Netherlands $\geq$ 8, n(%)	522 (70.7)	62 (78.5)
Mexico_score $\geq$ 4, n(%)	548 (74.2)	64 (82.1)
Self-reported gout diagnosis (%)	691 (90.2)	78 (94.0)
<b>Selected items (self-reported) from classification criteria</b>		
Hyperuricemia, n(%)	320 (41.8)	55 (66.3)
Men, n(%)	629 (80.2)	62 (73.8)
MI§ or Stroke or Hypertension, n(%)	598 (78.1)	70 (84.3)
Tophus, n(%)	107 (14.1)	26 (31.3)
Any MTP1 attack, n(%)	472 (62.4)	39 (47.6)
Swollen and red joint at attack, n(%)	583 (76.7)	77 (92.8)
Individual joints ever involved in attacks:		
1 joint, n(%)	205 (27.1)	3 (3.7)
>1 joints, n(%)	471 (60.1)	73 (86.9)

§ Myocardial infarction

**Results:** 1589 individuals with a gout diagnosis were identified. 868 (54.6%) individuals responded. Mean age was 71 years and the proportion of men was 80%.

89% of secondary care patients had ever been treated with Allopurinol compared to 71% in primary care. The PPVs ranged from 78.5% to 94%, in secondary care, being lowest for the Netherlands criteria and highest for self-reported gout (table 1). Corresponding PPVs were marginally lower in primary care (but still over 70% for all criteria). Similar results were found among those interviewed by telephone (not shown).

**Conclusions:** The majority of patients diagnosed with gout in both primary and secondary care have had clinical symptoms compatible with the Netherlands and Mexico criteria for gout. Diagnoses of gout identified through health care registers is therefore a valid and useful tool for epidemiological research. Patients with gout in secondary care reported more features of gout than patients in primary care.

### SAT0356 FACTORS INFLUENCING TOPHUS RESOLUTION IN PATIENTS WITH PERSISTENT URATE LOWERING RESPONSES TO PEGLOTICASE

B. Mandell<sup>1</sup>, A. Yeo<sup>2</sup>, P. Lipsky<sup>3</sup>. <sup>1</sup>Cleveland Clinic, Cleveland; <sup>2</sup>Horizon Pharma, Lake Forest; <sup>3</sup>AMPEL BioSolutions LLC, Charlottesville, USA

**Background:** Pegloticase is a recombinant mammalian uricase conjugated to polyethylene glycol approved for treatment of chronic refractory gout. It profoundly decreases serum urate levels and also causes rapid resolution of tophi. However, there is considerable heterogeneity in the velocity of tophus resolution.

**Objectives:** To assess factors that may influence the velocity of tophus resolution in subjects with persistent lowering of serum urate levels.

**Methods:** This analysis used results from two randomised controlled trials (RCT) of 6 months duration.<sup>1,2</sup> Tophus assessment was carried out using Computer-Assisted Photographic Evaluation in Rheumatology (CAPER) methodology.<sup>3</sup> Photographs of hands and feet and two other area of visually apparent tophi were taken and assessed for total tophus area and also resolution of tophi in response to therapy. Subjects were defined as responders based upon maintenance of serum urate <6 mg/dL during intensive monitoring periods after 3 and 6 months of treatment. Subject factors evaluated for a relationship with velocity of tophus resolution included age, body mass index, gender, race, and tophus location. Additionally, results for pegloticase responders were subdivided into tertiles on the basis of baseline tophus burden; low (total baseline tophus area <668 mm<sup>2</sup>), medium (baseline tophus burden 688–1690 mm<sup>2</sup>), and high (baseline tophus burden >1690 mm<sup>2</sup>), and the velocity of tophus resolution was determined for each of these groups.

**Results:** The mean measured total tophus area at baseline was 585.8 mm<sup>2</sup> for biochemical responders and complete resolution of all tophi photographed was achieved by 34.8% of this group during the RCT. The velocity of tophus resolution for the pegloticase responders was 60.1 mm<sup>2</sup> per month. Clinical features including age, body mass index, gender, race, and tophus location did not significantly influence the velocity of tophus resolution. The mean (standard deviation [SD]) baseline tophus areas at baseline were 419.4 mm<sup>2</sup> (202.4) for subjects with low baseline tophus burden, 1176.9 mm<sup>2</sup> (238.7) for those with moderate tophus burden, and 4260.4 mm<sup>2</sup> (2784.9) for those with high baseline tophus burden. The mean (SD) velocity of tophus resolution was 28.7 mm<sup>2</sup>/month (13.6) for patients with low baseline tophus burden, 60.2 mm<sup>2</sup>/month (53.5) for those with moderate baseline tophus burden, and 89.5 mm<sup>2</sup>/month (38.7) for those with high baseline tophus burden. Even though the velocity of resolution was greater for those with a larger tophus burden, the time required for complete tophus resolution was substantially less for those with a smaller tophus burden. The projected times to resolution of all visualised tophi determined by linear regression analysis were 6.98, 7.14 and 12.02 months for the subjects with low, medium and high baseline tophus burden (p<0.0001, p<0.0001, p=0.048), respectively.

**Conclusions:** Pegloticase treatment causes a rapid resolution of tophi in biochemical responders and the rate of decrease is not significantly associated with age, body mass index, gender, race, or tophus location. However, the rate of tophus resolution is inversely correlated with the total tophus burden at the beginning of treatment.

SAT0357

### COMPLIANCE AND PERSISTENCE TO URATE LOWERING THERAPY FOR THE TREATMENT OF GOUT AND HYPERURICEMIA: A RETROSPECTIVE ANALYSIS OF MEDICATION PRESCRIPTION RECORDS

C.A. Janssen<sup>1</sup>, M.A. Oude Voshaar<sup>1</sup>, H.E. Vonkeman<sup>1,2</sup>, M. Krol<sup>3</sup>, M.A. van de Laar<sup>1,2</sup>. <sup>1</sup>Arthritis Center Twente, Department of Psychology, Health and Technology, University of Twente; <sup>2</sup>Department of Rheumatology and Clinical Immunology, Medisch Spectrum Twente, Enschede; <sup>3</sup>Real World Evidence Solutions, IQVIA, Amsterdam, Netherlands

**Background:** Hyperuricemia is the predominant risk factor for gout, a common crystal-induced disease, manifested as an acute inflammatory arthritis. Urate lowering therapy (ULT) is an effective and recommended life-long treatment for lowering and managing serum urate levels in gout patients.<sup>1</sup> However, recurrent attacks of gouty arthritis are commonly observed in practice, even during long-term ULT.<sup>2</sup> This is often attributed to poor medication adherence and continuance.<sup>3</sup> Gaining insight into the dispensing patterns and medication adherence of ULT, provides a reflection of the current gout care delivered by health professionals.

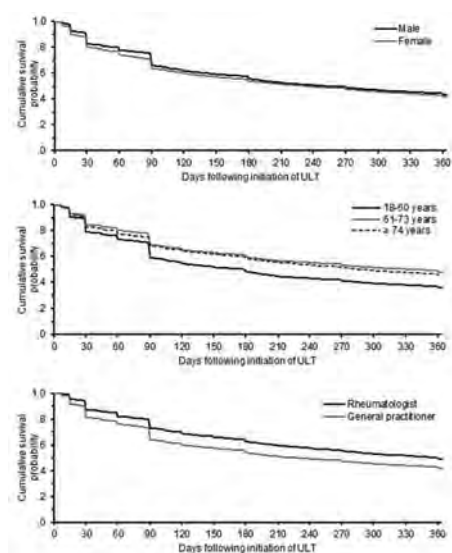

**Objectives:** To examine the levels of compliance and persistence to commonly prescribed ULT for the treatment of hyperuricemia and gout in the Netherlands.

**Methods:** Anonymous medication prescription records were obtained from IQVIA's longitudinal prescription database in The Netherlands, containing ULT dispensing data (allopurinol, febuxostat and benzbromarone) from November 2013 to July 2017. Compliance to ULT was determined by calculating the proportion of days covered (PDC) over a period of 12 consecutive months. Good compliance was defined as a PDC $\geq$ 0.80. Persistence over 12 months was evaluated by determining the time to discontinuation, without surpassing a refill gap of >30 days. The association of PDC and persistence with age, gender and first prescriber were examined using beta regression- and cox-regression models, respectively.

Abstract SAT0357 – Table 1. Variables associated with PDC

	Univariate analyses			Multivariate analyses <sup>1</sup>		
	Gender	Age	Prescriber	Gender	Age	Prescriber
$\beta$ -coefficient	-0.044*	0.011**	0.336**	-0.127**	0.012**	0.348**
SE	0.014	<0.000	0.015	0.014	<0.000	0.015
Pseudo R <sup>2</sup>	<0.000	0.011	0.011	0.024	0.024	0.024

<sup>1</sup> Model: PDC~gender+ age+prescriber. \*p<0.01; \*\*p<0.001; SE, standard error; PDC, proportion of days covered.

Abstract SAT0357 – Figure 1. Survival curves of persistence of ULT drugs one year after initiation of treatment.

**Results:** In total, 45 654 patients were identified meeting the enrollment criteria, of which 76.1% were male. The initial ULT drug prescribed most frequently among general practitioners and rheumatologists was allopurinol 100 mg, 75.9% and 72.1%, respectively. In total, 51.7% of the cases had good compliance after one year. The median time to discontinuation was 248 days, and after one year 42.7%

of the cases were still persistent. In general, men, older patients and patients whose first prescriber was a rheumatologist were more persistent, and had a higher PDC, although effect sizes were modest (table 1 and **Abstract SAT0357 – figure 1**).

**Conclusions:** Our results show that medication adherence to ULT after one year is suboptimal, considering that current guidelines recommend ULT as a life-long treatment. Future studies addressing the reasons for treatment cessation and improving treatment adherence are warranted.

SAT0358

### DIABETES AND GOUT: REAL-WORLD EVIDENCE EVALUATING PATIENT CHARACTERISTICS, TREATMENT PATTERNS, AND HEALTH CARE UTILISATION

D.C. Taylor<sup>1</sup>, A.-C. Fu<sup>1</sup>, R. Morlock<sup>2</sup>. <sup>1</sup>Ironwood Pharmaceuticals, Inc., Cambridge; <sup>2</sup>YourCareChoice, Ann Arbor, USA

**Background:** Gout and type 2 diabetes mellitus (T2DM) are common in the United States (US), but little is known about potential associations of T2DM and hyperuricemia/gout with clinical outcomes. This study examined variations in gout severity, management, and health care utilisation among gout patients with and without T2DM.

**Methods:** Data were assessed from a survey of US physicians and patient chart audits. Participating physicians managed the care of  $\geq$ 50 patients with gout annually; chart audits were of their last 5 consecutive adult patients with confirmed gout. Gout severity was measured by physician global assessment, flares, organ/joint damage, and tophi. Treatment characteristics, presence of clinician-confirmed T2DM, and socio-demographics were identified. Descriptive and multivariate (stepwise logistic regression) statistics analysed the differences among gout patients with and without clinician-confirmed comorbid T2DM and assessed urate-lowering therapy (ULT) use and gout control.

**Results:** Overall, 1159 charts of patients with gout were abstracted (246 with T2DM, 913 without T2DM; 81% male; 71% Caucasian); the proportion of patients aged  $\geq$ 61 with gout was greater for those with T2DM than without T2DM (69% vs 31%; p<0.01). Patients with gout and T2DM had longer mean duration of gout (63 vs 41 months), were more likely to have tophi (37% vs 20%), joint damage (24% vs 13%), and clinician-rated severe gout (27% vs 13%) than those without T2DM (all p<0.01). Patients with gout and T2DM were also more likely to receive ULT than those without T2DM (86% vs 71%; p<0.01), and among those patients with gout and T2DM receiving allopurinol, mean daily doses were not significantly different (321 mg vs 298 mg; p=0.17). Gout patients with T2DM were more likely to have additional comorbidities (cardiovascular disease, kidney disease, COPD, depression, diabetes, hyperlipidemia, hypertension, obesity, prostate problems [men]) and have chronic pain than those without T2DM (all p<0.05). On average, gout patients with T2DM vs. those without T2DM reported more office visits (4.1 vs 3.5), were more likely to have an emergency department visit (17% vs 9%) and were more likely to have a hospitalisation (5% vs 2%) (all p<0.01). In both groups, ULT use was associated with better gout control, but the specific factors predictive of ULT use and disease control varied between those with and without T2DM.

**Conclusions:** Gout patients with T2DM were more likely to have a greater impact on health system utilisation and spending, with additional comorbidities and more severe gout than those without T2DM. These data suggest that patients with gout and T2DM constitute a less healthy group in need of careful monitoring and more aggressive gout management.

### SAT0359 EVOLUTION OF RENAL FUNCTION IN GOUT AFTER NORMALISATION OF SERUM URIC ACID LEVEL

E. Gazaix-Fontaine<sup>1</sup>, A. Ostertag<sup>2</sup>, H.-K. Ea<sup>1</sup>, F. Lioté<sup>1</sup>. <sup>1</sup>Rheumatology Department, <sup>2</sup>INSERM UMR 1132 Bioscar, Centre Viggo Petersen, Hospital Lariboisière, Paris, France

**Background:** Chronic kidney disease (CKD) is one of the main causes of mortality in gout. In addition, hyperuricemia can contribute to the decrease of renal function.

**Objectives:** The aim of this study was to evaluate the evolution of renal function after reducing serum uric acid (sUA) level to therapeutic target in gout, and to identify the factors that might influence this evolution.

**Methods:** Patients with gout were followed at a single university-based hospital. They were free of urate lowering therapy (ULT) and had an estimated glomerular filtration rate (eGFR) higher than 15 ml/min. Renal function was measured at start of ULT and when sUA was reduced below 360 µmol/L (or 6.0 mg/dL). ULT was allopurinol or febuxostat at the choice of clinician.

**Results:** In this retrospective study, 63 patients (pts) were included with an initial mean sUA level of 541 µmol/l (±86). Overall 42 pts were treated with allopurinol and 21 with febuxostat for an average length of 278 days (±185). After ULT, mean eGFR differed significantly: +2.6 [IC95%: -0.279; 5.484; p=0.08], +3 [IC95%: 0.167; 5.794; p=0.04] and +2.7 [IC95%: 0.490; 4.960; p=0.02] ml/min/1.73 m<sup>2</sup> depending on the calculation method, Cockcroft-Gault (C-G), MDRD and CKD-EPI, respectively. eGFR improvement was statistically significant, p=0.04, 0.02 et 0.01, respectively. Initial eGFR >45 ml/min/1.73 m<sup>2</sup> was associated with a better outcome of eGFR expressed in percentage: +4.7% vs -7.3% (p=0.02), +6.3% vs -4.9% (p=NS), +6.2% vs -5.3% (p=0.03) according to the calculation method, C-G, MDRD and CKD-EPI, respectively. We also found a better evolution of renal function when patients were treated with allopurinol compared to febuxostat, but confounding bias might have occurred since their mean eGFR was also better. In contrast, neither sex, BMI, presence of hypertension nor diabetes showed any significant effect on eGFR improvement.

**Conclusions:** Renal function was significant different after normalisation of sUA in gout patients. We observed an improvement of eGFR which is consistent with recent studies. Interestingly, when initial renal function was at CKD IIIa level or higher (eGFR >45 ml/min/1.73 m<sup>2</sup>), renal outcome was even better. It strengthens the rationale to treat high sUA as soon as possible.

### SAT0360 A SUMMARY OF CLINICAL EVIDENCE FOR COMMONLY USED URICOSURICS FOR GOUT IN EUROPE

F. Perez-Ruiz<sup>1</sup>, P. Kandaswamy<sup>2</sup>, R. Karra Gurunath<sup>2</sup>, H. Burton<sup>3</sup>, T. Jansen<sup>4</sup>. <sup>1</sup>Rheumatology Division, Hospital Universitario Cruces, Bilbao, Spain; <sup>2</sup>Grunenthal GmbH, Aachen, Germany; <sup>3</sup>DRG Abacus, Bicester, UK; <sup>4</sup>Rheumatology, VieCuri MC, Venlo, Netherlands

**Background:** Uricosurics (benzbromarone, probenecid, or sulfipyrazone) are recommended for second-line treatment of gout if treatment target cannot be achieved with allopurinol or if allopurinol cannot be tolerated. While some uricosurics have been available since the 1970s, only two head-to-head trials have been conducted, both of which compared benzbromarone with probenecid. A new uricosuric, lesinurad, has recently been developed, but also has no head-to-head data against current uricosurics. There is therefore a need to compare the efficacy of uricosurics relative to each other via network meta-analysis (NMA), which requires high-quality evidence from well conducted trials, and also for evidence-based recommendations.

**Objectives:** To identify and assess the quality of the randomised controlled trial (RCT) evidence for uricosurics currently licensed for the treatment of gout, and to assess the feasibility of developing an NMA based on these trials.

**Methods:** A systematic review was conducted to identify RCT evidence for uricosurics, followed by an assessment of the quality of the comparisons possible based on this evidence using the GRADE system. This assessment was then used in a feasibility assessment for NMA based on the comparability of the trials in terms of population, comparators, and outcomes.

**Results:** In total, 21 publications reporting on 13 unique studies were identified by the SR, two of which had no common comparator arm with other trials and were excluded from further assessment. Eleven studies were included in the quality assessment informing comparisons between treatments for two outcomes: proportion of patients achieving sUA <6 mg/dL (or 0.36 mMol/L) and change from baseline in sUA. Issues with two or more elements of the methodological quality of the studies were present in all comparisons other than lesinurad plus allopurinol vs placebo plus allopurinol, including open-label design, incomplete reporting and sparse data mainly of safety assessment, and inadequate randomisation. The outcomes assessed in these RCTs were generally comparable across trials, but follow-up time ranged from 1 week to a mean of 19.6 months and few trials reported data at the same endpoint. In addition, line of therapy was unclear/not reported in four trials, with uricosurics used in a first-line population in two trials. The final GRADE quality rating was 5 (high) for lesinurad plus allopurinol vs placebo plus allopurinol and -1 to 1 (very low) for all other comparisons (febuxostat plus lesinurad was not included in comparisons). Based on this assessment, it was concluded that a NMA or other statistical comparison is not possible because of substantial heterogeneity between trials for methodological quality, outcomes, and population.

**Conclusions:** The quality of the randomised controlled trial evidence supporting the use of uricosurics other than lesinurad for gout is poor, and there is substantial heterogeneity in reported follow-up times and study populations. It is therefore not possible to make valid comparisons between these treatments based on this data, which may have implications for decision-makers in assessments of future treatments for gout.

### SAT0361 TRABECULAR BONE SCORE IN OSTEOGENESIS IMPERFECTA. IS IT USEFUL?

H. Florez<sup>1</sup>, A. Muxi<sup>2</sup>, E. Gonzalez<sup>3</sup>, A. Monegal<sup>1</sup>, N. Guañabens<sup>1</sup>, P. Peris<sup>1</sup>. <sup>1</sup>Metabolic Bone Diseases Unit, Department of Rheumatology; <sup>2</sup>Department of Nuclear Medicine; <sup>3</sup>Department of Immunology, HOSPITAL CLÍNICA, Barcelona, Spain

**Background:** The trabecular Bone Score (TBS) is a novel gray-level textural analysis measurement that can be applied to DXA images to estimate trabecular microarchitecture and has been shown to be related to direct measures of bone microarchitecture and fracture risk. Osteogenesis imperfecta (OI) is a congenital bone disease characterised by a low bone mineral density (BMD) and poor bone quality and strength. The usefulness of TBS in OI has been scarcely evaluated.

**Objectives:** To analyse the clinical usefulness of TBS determination in patients with OI and its relation with anthropometric and clinical features (especially concerning skeletal fractures and BMD results).

**Methods:** Twenty-four patients (18 F:6 M) with OI with a mean age of 38±15 years<sup>19-63</sup> attending a Metabolic Bone Disease Unit were included. The clinical reports of the patients were reviewed, with especial attention to the clinical features (weight, height and body mass index [BMI]), previous fractures, disease severity, associated mutations and treatments received. Lumbar spine (LS), total hip (TH), and femoral neck (FN) BMD were measured using DXA equipment (Lunar) in all patients. TBS was analysed in LS, and the results were classified in three categories<sup>1</sup>: TBS >1.310 (normal), TBS 1.230-1.310 (partially degraded microarchitecture), TBS <1.230 (degraded microarchitecture). TBS values were compared with a healthy control group of similar age and gender.

**Results:** 5/24 patients (21%) had a degraded microarchitecture, 4 (17%) a partially degraded microarchitecture and 15 (63%) normal TBS. All patients with TBS <1.230 were over 40 years old. 21/24 patients had a previous history of multiple fractures. Regarding BMD, 54% of the patients had osteoporosis, 42% osteopenia and one had normal values. Most patients had a mutation in the COL1A1 gene (63%). A correlation was observed between TBS and age (r=-0.5, p=0.006) and LS BMD (r=0.5, p=0.014), showing a trend to significance with BMI (r=-0.4, p=0.058). No significant differences were observed on comparing TBS in patients and controls (1.321 vs. 1.391, p=N .S.).

**Conclusions:** TBS measurement does not seem to be useful for evaluating bone strength in patients with OI. Despite most patients presenting a history of multiple fractures, only 21% showed degraded microarchitecture with TBS.

### PERFORMANCE OF THE 2015 ACR/EULAR CLASSIFICATION CRITERIA FOR GOUT IN KOREAN PATIENTS PRESENTING WITH ACUTE ARTHRITIS

I.A. Choi<sup>1</sup>, Y.-J. Ha<sup>2</sup>, E.H. Kang<sup>2</sup>, Y.J. Lee<sup>2</sup>, K. Shin<sup>3</sup>, E.Y. Lee<sup>4</sup>, E.B. Lee<sup>4</sup>, Y. W. Song<sup>4</sup>. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Chungbuk National University Hospital, Cheongju; <sup>2</sup>Division of Rheumatology, Department of Internal Medicine, Seoul National University Bundang Hospital, Seongnam; <sup>3</sup>Division of Rheumatology, Department of Internal Medicine, SMG-SNU Boramae Medical Center; <sup>4</sup>Division of Rheumatology, Department of Internal Medicine, Seoul National University Hospital, Seoul, Korea, Republic Of

**Background:** A definite diagnosis of gout requires the detection of monosodium urate (MSU) crystals in synovial fluid or tissue. However, the procedure involved is invasive and often not available in acute or primary care settings. Therefore, several alternate sets of classification criteria for gout have been developed.

**Objectives:** This study was undertaken to assess the performance of the 2015 American College of rheumatology (ACR)/European League Against Rheumatism (EULAR) classification criteria for gout and to compare its performance to previous sets of criteria including the New York, American Rheumatism Association (ARA) 1977 and Mexico criteria, in Korean patients presenting with acute arthritis.

**Methods:** Patients with acute arthritis who attended rheumatology clinics and underwent arthrocentesis were enrolled in the study, during February 2017 and December 2017. The gout group included patients with MSU crystals in synovial fluid or tissue, as assessed by an experienced rheumatologist or pathologist. Since the presence of MSU crystals alone is sufficient to fulfil the criterion for gout according to the 2015 ACR/EULAR classification, New York, ARA 1977 and Mexico criteria, this criterion is considered to have a 100% sensitivity in the gout group by our definition. Therefore, we excluded positive MSU crystal results in these four criteria sets to avoid a case of circular reasoning.

**Results:** A total of 116 gout patients (as determined by the presence of MSU crystals) and 71 non-gout patients participated in the study. The number of male patients in the gout group (94.8%) was higher than that in non-gout group (15.1%). The mean ( $\pm$ SD) age of the patients was 58.4 ( $\pm$ 15.0) and 64.5 ( $\pm$ 13.3) years in the gout and non-gout group, respectively.

The sensitivity, specificity, positive predictive value and negative predictive value of the criteria sets were 87.1%, 100%, 100% and 73.2% respectively (area under the curve, AUC 0.975) for the 2015 ACR/EULAR classification criteria, 71.5%, 97.2%, 97.6% and 67.6% (AUC 0.960) for the clinical-parameters-only version of the 2015 ACR/EULAR classification criteria, 68.1%, 81.7%, 85.9% and 61.0% (AUC 0.784) for the New York criteria, 77.6%, 81.7%, 87.4% and 69.0% (AUC 0.878) for the ARA 1977 criteria, and 87.9%, 63.4%, 79.7% and 76.3% (AUC 0.878) for the Mexico criteria.

To determine the performance of the existing criteria sets for gout without relying on the detection of MSU crystals, we also calculated the performance of the criteria assuming an absence of both positive and negative crystal test results. By this parameter, the sensitivity of the 2015 ACR/EULAR classification criteria was 77.6%, specificity was 84.8%, positive predictive value was 89.1%, and negative predictive value was 69.8% (AUC 0.918). The performance of the New York, ARA 1977 and Mexico criteria did not change.

**Conclusions:** The performance of the 2015 ACR/EULAR classification criteria for gout was better than that for the New York, ARA 1977 and Mexico criteria in Korean patients presenting with acute arthritis. When an MSU crystal identification test is not available, 2015 ACR/EULAR classification criteria for gout could be a useful option in the diagnosis of gout in Korean patients presenting with acute arthritis.

SAT0363

### ARE "TARGET-URATE" AND REMISSION CRITERIA POSSIBLE IN SEVERE GOUT? A REAL LIFE EXPERIENCE IN A COHORT

J. Vazquez-Mellado<sup>1</sup>, C. O. Lopez-Lopez<sup>2</sup>, E. Alvarez-Hernandez<sup>1</sup>, I. Pelaez-Ballestas<sup>1</sup>, C. Gomez-Ruiz<sup>1</sup>, A. Vazquez-Mellado<sup>1</sup>, R. Burgos-Vargas<sup>1</sup> on behalf of GRESGO cohort. <sup>1</sup>Rheumatology, <sup>2</sup>Rehabilitation and physical therapy, Hospital General De México, México, Mexico

**Background:** Gout remission, quality of life and disability improvement are the main objectives of chronic treatment. Gout T2T goal is to achieve and maintain target urate <6 mg/dL and <5 mg/dL (TU) in severe gout (SG).

**Objectives:** To determine in a cohort of gout patients, SG frequency, associated factors, percentage of patients achieving TU and remission criteria.

**Methods:** Patients with gout (ACR-EULAR) from GRESGO cohort were included and evaluated at baseline and bi-annually. At baseline visit, information about gout, life style changes and treatment were discussed with the patients and relatives. Prescription for gout and associated diseases was according to published guides and available drugs. Measures: demographic, clinical and biochemical. HAQ, EUROQoL, VAS-pain and global health. SG: $\geq$ 5 tophi and/or intradermal

tophi. TU:sUA <6 mg/dL and <5 mg/dL; remission according to published proposal (de Loutour H/2016). This protocol was approved by the local IRB, all patients signed informed consent. Statistical analysis: t test, X2, Friedman, multi-ple-correlation and multivariable analysis.

**Results:** At baseline visit 500 gout patients were included, (221/44% with SG and 279/56% non-SG). Males 97%, all received individualised ULT treatment (allopurinol and/or probenecid). The whole group, improved significantly during follow-up in urate, flares, tophus burden, HAQ, pain, EUROQoL and renal function. SG patients were significantly: younger at onset, with lower educational level, socioeconomic status, more laboral absenteeism. Also, had longer disease duration and significant differences in all clinical variables related to severity:>joint count, >index tophi size, >% lithiasis,>HAQ score,>EUROQoL and<MDRD, all these outcomes improved significantly during follow-up. In multivariate analysis, disease duration (p0.008) and flares/years (p0.055) persist significantly associated to SG at baseline. SG patients received significantly higher allopurinol doses (>600 mg/day) and required more frequently glucocorticoids. Eleven patients died, 1 year after baseline ~50% patients were lost. Among those that continued, target urate <6 mg/dL was possible in only 50%–70% of the patients followed for 3–5 years. Less than 50% of patients achieved TU<5 mg/dL during long follow-up. There were no significant differences in most percentages of TU 6 or 5 mg/dL between SG VS non-SG patients (see table 1). Although, both groups improved significantly in all clinical outcomes. Remission definition require none tophi and at least 12 months follow-up, it was observed in 9.4% of non-SG patients.

**Percentage of patients achieved TU:** (\*significant differences)

TU<6 mg/dL<5 mg/dL

	SG %	Non- SG %	SG %	Non- SG %	N
Baseline	12	16	1	8	500
6	21	24	11	15	329
12	35	44	16	22	254
18	53	55	28	26	208
24	58	52	37*	24	189
30	56	51	32	28	152
36	58	59	38	34	131
42	70	58	38	30	94
48	73*	50	35	27	81
54	63	54	0	0	53
60	53	43	42	19	40

**Conclusions:** In our population, SG is very frequent and associated with younger age at onset, low socioeconomic and educational level, longer duration and severe disease. Although they receive more intense treatment according to availability, TU and remission criteria are seldom observed and very difficult to achieve. Earlier diagnosis, intensive and adequate treatment should change these results.

SAT0364

### HIGH PREVALENCE OF ENTHESTOPATHIES IN PATIENTS WITH X-LINKED HYPOPHOSPHATEMIA

A. Salcion Picaud<sup>1</sup>, L. Lassalle<sup>1</sup>, V. Merzoug<sup>2</sup>, A. Usardi<sup>2</sup>, A. Rothenbuhler<sup>2</sup>, P. Kamenicky<sup>2</sup>, C. Roux<sup>1</sup>, A. Linglart<sup>2</sup>, K. Briot<sup>1</sup>. <sup>1</sup>Cochin Hospital, Paris; <sup>2</sup>Kremlin Bicêtre Hospital, Le Kremlin Bicêtre, France

**Background:** X-linked hypophosphatemia (XLH) is a rare genetic disease (incidence 1/20 000) due to mutations in the *PHEX* gene. The genetic defects is associated with high level of FGF23 leading to impaired renal phosphate reabsorption and 1,25(OH)vitaminD synthesis. Most patients are diagnosed at walking age because of lower limb deformities and rickets. In adulthood, patients complain of musculoskeletal pain in relation to bone lesions (pseudofractures, osteomalacia) and joint involvement but also ossification of entheses. The latter is a strong determinant of the altered quality of life in this population.

**Objectives:** The aim of this work was to describe the structural bone and joint involvement of the entire skeleton in a large cohort of adult patients with XLH.

**Methods:** The study was prospectively conducted in symptomatic adult XLH patients in the context of the systematic evaluation at the French reference centre for rare diseases of calcium and phosphate metabolism. 81 of the 136 patients included between June 2011 and December 2017 had full body x-rays performed with the EOS low-radiation system. Two trained readers performed a standardised analysis of radiographs with a reading grid including the collection of ossifications of the anterior and lateral vertebral ligament, iliac crests, ischial sites, cotyles and achilles tendons; osteophytes on the spine and hip osteoarthritis; and sacroiliac joint aspect.

**Results:** Of the 81 patients, 55 are women (68%), mean age 42.4 $\pm$ 13.6 years, diagnosed on average at the age of 11 years. 63 (78%) patients were treated during childhood with phosphate and/or vitamin D supplementation. At the time of study, 41 (50.6%) were still upon phosphate supplements and/or vitamin D

analogues, 32 (40%) were taking analgesics, although 65 (80%) suffered from pain (71% articular pain, 22% bone pain and 20% enthesitic pain). Of the 81 patients, 71 (88%) presented with structural damage including 44 (63%) with syndesmophytes or ossifications. The average number of syndesmophytes/ossifications was 4.1±2.6 per patient in this subgroup. Most of them were localised at the cervical spine (82%) and the lumbar spine (62%). In addition, these ossifications were fine in 59% (syndesmophytes-like) and coarse in 41%. The other localizations were the ischial region (40%), iliac crests (37%) and the cotyles (90%). Calcanei were visible on 52 radiographs and showed coarse ossifications for 22 of them (42%). 46 patients (65%) had already hip osteoarthritis and 26 (37%) had at least one osteophyte on the spine mainly on the thoracic spine (58%). We found complete ankylosis of sacro-iliac joints in 12 patients (17%).

**Conclusions:** This observational study shows that 88% of adult XLH patients have structural damages and at least one ossification on the spine and/or on periarthral joint (specially on the cotyles). Of importance, these ossifications were as frequent and as severe in patients not treated with phosphate and vitamin D analogues than in untreated patients. Knowing that this disease can be misdiagnosed and eventually diagnosed only at the adult age, attention must be paid to ossification of the entheses, in particular of the common anterior vertebral ligament and Achilles tendons. The mechanisms of formation of these enthesopathies remain to be determined.

### SAT0366 SECULAR TRENDS IN THE INCIDENCE AND PREVALENCE OF GOUT IN DENMARK FROM 1995–2015: A NATIONWIDE REGISTER-BASED STUDY

K. Zobbé<sup>1,2</sup>, D. Prieto-Alhambra<sup>3,4</sup>, R. Cordtz<sup>1,2</sup>, P. Højgaard<sup>1,2</sup>, J.S. Hindrup<sup>1</sup>, L. E. Kristensen<sup>2</sup>, L. Dreyer<sup>1,2,5</sup>. <sup>1</sup>Center for Rheumatology and Spine Diseases, Rigshospitalet/Glostrup, Hellerup; <sup>2</sup>The Parker Institute, Bispebjerg and Frederiksberg Hospital, Frederiksberg, Denmark; <sup>3</sup>Musculoskeletal Pharmaco- and Device Epidemiology, Centre for Statistics in Medicine, NDORMS, Oxford, UK; <sup>4</sup>GREMPAL Research Group, Idi Jordi Gol and CIBERFes, Universitat Autònoma de Barcelona and Instituto de Salud Carlos III, Barcelona, Spain; <sup>5</sup>Department of Rheumatology, Aalborg University Hospital, Aalborg, Denmark

**Background:** Gout is perceived as the most prevalent inflammatory arthritis in the western world – but with great regional and ethnical variation. The incidence and prevalence is thought to be increasing but it's based on few population studies with limited calendar time periods.<sup>[1]</sup> We took advantage of the unique Danish health registries to examine the incidence and prevalence of gout in a nationwide cohort covering the last two decades.

**Objectives:** To examine temporal trends in the incidence and prevalence of gout in the adult Danish population.

**Methods:** Using the nationwide Danish National Patient Registry (DNPR), we calculated the incident rate of hospitalised gout patients (per 1 000 000 person-years) within each 1 year period from 1995 to 2015, and prevalence of gout requiring hospitalisation in 2000 and 2015. Additionally, the age- and gender-specific incidence rates of gout from 1995 to 2015 were calculated. Incidence rates were standardised according to the NORDCAN standard population. Confidence intervals (CI) were calculated according to a Poisson distribution. Both incidence rates based on diagnosis from all specialties and rheumatologists, respectively, were calculated.

**Results:** In the 20 year study period we identified 45 685 newly diagnosed cases of gout. We found an increase in overall incidence, from 32.26/100,000 [95%CI 30.7 to 33.1] in 1995 to 57.5/100,000 [95%CI 55.6 to 59.5] in 2015 (p<0.001). The age and sex specific incidence rates increased progressively with increasing age among both sexes, most markedly in patients aged >60 years. Similar trends were observed for cases diagnosed at rheumatology departments. We likewise observed an increase in the prevalence of gout from 0.29% [95%CI 0.29 to 0.30] in 2000 to 0.68% [95%CI 0.68 to 0.69] in 2015.

**Conclusions:** We found a 1.8-fold increase in the incident rate of hospitalised gout patients in the period 1995–2015 in Denmark among both men and women. Similarly we found a 2.2-fold increase in the prevalence from 2000 to 2015. Further research is needed to elucidate the causes underlying the observed increase in the burden of gout in Denmark

### SAT0366 SERUM URIC ACID INCREASES AFTER ABROGATION OF SYSTEMIC INFLAMMATION BY TNF INHIBITION

L. Petru<sup>1,2</sup>, H. Hulejova<sup>1</sup>, A. Mahajan<sup>3</sup>, M. Herrmann<sup>3</sup>, J. Zavada<sup>1</sup>. <sup>1</sup>Institute of Rheumatology; <sup>2</sup>Department of Rheumatology, First Faculty of Medicine, Charles University, Prague, Czech Republic; <sup>3</sup>Department of Internal Medicine 3 – Rheumatology and Immunology, Friedrich-Alexander University of Erlangen-Nürnberg, Erlangen, Germany

**Background:** In patients with gout, the serum uric acid (SUA) is usually lower during acute gouty attacks than during intercritical periods. It has been suggested that systemic inflammatory response can cause this phenomenon.

**Objectives:** We aimed to investigate whether SUA levels are associated with levels of pro-inflammatory cytokines in patients with systemic autoimmune rheumatic diseases: rheumatoid arthritis (RA), ankylosing spondylitis (AS), psoriatic arthritis (PsA) and juvenile idiopathic arthritis (JIA) and whether the initiation of a therapy with TNF inhibitors (TNFi) would change levels of SUA.

**Methods:** A cohort of 128 patients with clinically active chronic inflammatory rheumatic disease (44 with RA, 45 with AS, 23 with PsA, 16 with JIA) and CRP ≥10 mg/L was recruited in the Institute of Rheumatology, Prague. SUA, CRP, creatinine, MCP-1, IFN-α2, IFN-γ, IL-1β, IL-6, IL-8, IL-10, IL-12, IL-17a, IL-18, IL-23, IL-33 and TNF-α were measured in serum before and after 3 months of treatment with TNFi. We employed bead-based immunoassays to quantify the cytokines and retrieved demographic data, BMI and co-medications. We present the data as mean ± standard deviation or mean and 95% CI.

**Results:** SUA was significantly lower before initiation of TNFi (288.5±78.7 μmol/l) than after 3 months of treatment (307.7±81.7 μmol/l, p=0.0002). The level of CRP (38.9±30.3 vs 5.0±7.6 mg/L, p<0.0001), IL-6 (172.8±339.0 vs 24.2±32.5 pg/ml, p<0.0001) and MCP-1 (1062±554.7 vs 959.2±508.9 pg/ml, p=0.015) significantly decreased during treatment. When we grouped our patients according to sex and diagnosis, the SUA levels significantly increased in the male patients (311.4±79.5 vs 343.9±74.3 μmol/l, p<0.0001), patients with AS (298.4±70.0 vs 326.4±73.1 μmol/l, p=0.0009) and with PsA (302.6±75.3 vs 334.6±74.3 μmol/l, p=0.033), but not in patients with RA or JIA. There was no correlation between the magnitude of the change of SUA, CRP and pro-inflammatory cytokines or the reported use of NSAIDs. However, when we classified our cohort according to increase or decrease of SUA after initiation of TNFi, we observed statistically significant differences in the changes of IL-1β (1.5, -10.8 vs 13.9, vs 29.4, 5.4 to 53.1 pg/ml, p=0.023), IL-23 (0.7, -40.0 to 41.3 vs 102.0, 5.5 to 198.6 pg/ml, p=0.023), IL-33 (-1.2, -26.7 to 24.3 vs 48.8, 3.8 to 93.9 pg/ml, p=0.039) and TNF-α (-0.8, -6.1 to 4.5 vs 10.5, -0.4 to 21.32 pg/ml, p=0.037) between these two groups.

**Conclusions:** We have shown that abrogation of systemic inflammation by TNFis results in an increase in the levels of SUA within 3 months, especially in male patients with AS or PSA. Our results support the hypothesis that systemic inflammation is associated with a decrease in SUA concentrations. The mechanism remains elusive. However, IL-1β, IL-23, IL-33 and TNF-α are candidate players. The difference between the male and female patients argue for a role of the sex hormones. We cannot exclude the possibility that an underreported differential in the use of NSAIDs, known for their uricosuric effect, may have partly biased our observations.

SAT0367

### PATIENTS HOSPITALISED WITH GOUT AS MAIN DIAGNOSIS: COSTS AND EFFICIENCY ACCORDING TO HOSPITAL DEPARTMENTS

M. Hernández Hurtado<sup>1</sup>, M. Á. Martínez Huedo<sup>2</sup>, A. Balsa Criado<sup>3</sup>, D. Peiteado López<sup>3</sup>, E. De Miguel Mendieta<sup>3</sup>. <sup>1</sup>Medical Student, Universidad Autónoma de Madrid; <sup>2</sup>Teaching and investigation unit., Hospital Universitario La Paz; <sup>3</sup>Rheumatology Department, Hospital Universitario La Paz-IdiPaz, Madrid, Spain

**Background:** Gout is the most common inflammatory articular disease in adults concerning a 1%–2% of the general population, and even a 4%–5% in older than 70 years. Recently, it has been reported an increase of the prevalence of gout, especially in developed countries.

**Objectives:** The main objective of this study is to describe the clinical and epidemiological characteristics of gout hospitalised patients in Spain (as the main reason of admission) and the economic outcomes of its management by the main care departments in charge when this disease is the principal diagnosis.

**Methods:** The main objective of this study is to describe the clinical and epidemiological characteristics of gout hospitalised patients in Spain (as the main reason of admission) and the economic outcomes of its management by the main care departments in charge when this disease is the principal diagnosis.

**Results:** From the whole 192.037 patients we have with gout diagnosis we performed a sub-analysis of 10.512 patients with gout as the main cause of hospitalisation, from which the 85.9% are males. The admission number for this cause has remained constant or with a slight increase, with an average of 956 patients per year (equivalent to a 5.5% of gout total admissions). The average male age was 64.02 years (standard deviation (SD) 14.43) and 73.9 years (SD 13.69) for women ( $p < 0.001$ ). When comparing patients with gout as main cause of admission against patients hospitalised by other causes, with gout as a secondary diagnosis. The former ones showed a significant lower percentage of comorbidities (type 2 diabetes, congestive heart failure, acute myocardial infarction and cerebrovascular disease).

Regarding the average of hospital stay of these patients, it was  $6.71 \pm 6.8$  days with an average cost of  $3471 \pm 2678$  €. Three medical specialities (Internal Medicine with 3852 hospital admissions (36.6%), Rheumatology with 2600 (24.7%) and Traumatology with 2033 (19.3%)), attended to an 80.6% of the total gout patients as main diagnosis for admission. It was noticed that the hospital stay was lower in the Traumatology Department with an average of  $4.85 \pm 6.78$  days compared with the Rheumatology and Internal Medicine departments, which had an average of  $6.52 \pm 5.65$  days and  $7.76 \pm 6.83$  days respectively. However, it was found the lowest cost in the Rheumatology Department, with an average of 2892 €.

**Abstract SAT0367 – Table 1.** Average stay and costs by clinical departments: in gout as main diagnosis hospitalised patients.

	Internal Medicin	Rheumatology	Traumatology
Number (%)	3852 (36.6%)	2600 (24.7%)	2033 (19.3%)
Average hospital (SD) days	7.76 (6.83)	6.52 (5.65)	4.85 (6.78)
Cost (SD) €	3549 (1796)	2892 (1806)	3715 (2541)

SD=standard deviation

**Conclusions:** Only 24.7% of hospitalised patients with gout as main diagnosis are attended by Rheumatology Departments. However, Rheumatology was the most efficient clinical department in the care of this pathology. This conclusion should be considered in order to improve the management of gout in the health system

### ROLE OF JOINT ULTRASONOGRAPHY IN PATIENTS WITH GOUT STARTING TREATMENT WITH FEBUXOSTAT

M. Novella-Navarro<sup>1</sup>, J.L. Cabrera-Alarcón<sup>2</sup>, E. Calvo-Aranda<sup>1</sup>, T. Rodríguez-Araya<sup>1</sup>, J.-J. González-Martín<sup>1</sup>, P. Alcocer-Amores<sup>1</sup>, F. Aramburu-Muñoz<sup>1</sup>, C. Marín-Huertas<sup>1</sup>, A. Gómez-Gómez<sup>1</sup>, I. Amil-Casas<sup>1</sup>, C. Vergara-Dangond<sup>1</sup>, M. Valero-Expósito<sup>1</sup>, S. Rodríguez-Rubio<sup>1</sup>, P. García de la Peña-Lefebvre<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Universitario Madrid Norte Sanchinarro; <sup>2</sup>Bionformatics, Molecular Biology Center, Severo Ochoa, Madrid, Spain

**Background:** Gout is the most prevalent arthritis globally, it is due to monosodium urate (MSU) crystals deposit on tissues, mainly in joints and periarticular structures. Although the main clinical pattern in gout is monoarticular, many patients suffer from oligo/polyarticular disease. Due to the information obtained

through imaging tests such as ultrasonography (US), we know that the extent of MSU deposits are greater than we expected in many occasions, affecting clinically silent joints. Musculoskeletal US is a key tool due to its accessibility and safety, it determines accurately the current extent of deposits and joint involvement in gout, which may condition therapeutic changes.

**Objectives:** To evaluate the influence of articular US for clinical practice in Rheumatology when initiating treatment with febuxostat in patients with gout, determining the degree of crystalline deposit and articular ultrasonographic involvement.

**Methods:** Observational cross-sectional study of 129 patients diagnosed with gout (ACR criteria), treated with febuxostat (14 due to renal disease, adverse reaction/intolerance to allopurinol, and 115 due to non-response to allopurinol). One month after the onset of treatment, US examination was performed following the protocol proposed by Peiteado *et al*<sup>1</sup>, determining the number of joints with signs of gout (double contour, hyperechoic aggregates) and acute inflammatory activity (Doppler). Other variables were analysed: age, sex, hypertension, diabetes, dyslipidemia, chronic kidney disease, time of disease evolution and clinical pattern of joint involvement.

**Results:** 115 patients with febuxostat (112 men and 3 women), with a mean age of  $57 \pm 13$  years and mean of disease evolution  $14 \pm 10$  years. 59 patients had monoarticular clinical pattern, 46 oligoarticular and 10 polyarticular. US involvement: we observed acute inflammatory activity by Doppler in 47 patients (40.86%), microcrystalline aggregates in 90 patients (78.26%) and double contour sign in 53 patients (42.08%). The mean uricemia at the time of the joint ultrasound examination was  $7.4 \pm 1.8$  g/dl. Of the 94 patients with uric acid levels  $> 6$  mg/dl, 72 presented extensive US involvement (76.59%), whereas of the 21 patients with levels  $\leq 6$  mg/dl, US involvement was observed in 18 (85.71%). From the observed variables, none was a risk predictor for joint involvement in binomial logistic regression model. Uricemia presented OR=0.83 CI (0.6–1.1)

**Conclusions:** US quantification of MSU deposits can significantly condition the intensity of uricemia-reducing treatment regardless of serum uric acid levels. In this study, patients with non-target uricemia did not present a greater joint affection evaluated by US, however, those with  $< 6$  mg/dl, did present more affection than might be expected. US examination of joints allows a more precise individualization of the treatment in gout and should be incorporated to the periodic evaluation of these patients to optimise their prognosis

### COMPARISON OF RISK FACTORS FOR CARDIOVASCULAR DISEASES IN PTS WITH CPPD GOUT AND OSTEOARTHRITIS

S. Vladimirov, M. Eliseev, O. Zhelyabina, M. Chikina. V. A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** The data on rates of comorbidities and risk factors for cardiovascular disease in CPPD is insufficient.

**Objectives:** To compare the rates of cardiovascular diseases, risk factors and the risk of death from cardiovascular disease in pts with CPPD, OA and gout.

**Methods:** The study included 488 patients: 232 CPPD (111 m and 121 f) pts, 60 OA (19 m and 41 f) pts and 196 (169 m and 27 f) gout pts. The OA diagnosis was established based on ACR criteria, the CPPD diagnosis – on McCarty criteria, and gout diagnosis – on the detection of monosodium urate crystals in synovial fluid. The mean age in CPPD pts was  $57.6 \pm 18.2$  y., OA pts –  $57.5 \pm 8.5$  y., and gout pts –  $52.7 \pm 12.2$  y. Serum levels of cholesterol, glucose, uric acid, and hsCRP were obtained in all pts, and thorough evaluation for cardiovascular diseases was performed as well as including SCORE (Systematic COronary Risk Evaluation) scale assessment. Statistica 10.0, and Biostatistics were used for statistical data processing. Differences were considered to be statistically significant at  $p < 0.05$ .

**Results:** Obtained data are presented in table 1. High or very high risk of cardiovascular death (SCORE scale) was identified in 47.8% of CPPD pts, was comparable to that in gout pts (48.9%) and exceeded the same in OA pts (33%) ( $p < 0.05$ ). Higher probability of myocardial infarction (MI), chronic heart failure (CHF), chronic kidney disease stage  $\geq 2$  (CKD) and higher mean serum CRP levels were established in CPPD and gout patients as compared to OA pts. There was no difference in rates of stroke, thrombosis, arterial hypertension (AH), ischaemic disease (ICD), diabetes mellitus (DM 2), or in average glucose and cholesterol levels between CPPD, OA and gout pts. Average serum levels of uric acid were higher in patients with gout.

**Abstract SAT0369 – Table 1.** Comparative rates of cardiovascular diseases, risk factors and SCORE values in patients with CPPD, gout and OA

Parameter	CPPD (n=232)	Gout (n=196)	OA (n=60)

SAT0370

**ASSOCIATION OF RENAL DYSFUNCTION AND DEVELOPMENT OF TOPHI IN SUBJECTS WITH CHRONIC REFRACTORY GOUT AND RESPONSE TO TREATMENT WITH PEGLOTICASE**N.L. Edwards<sup>1</sup>, J. Singh<sup>2</sup>, O. Troum<sup>3</sup>, A. Yeo<sup>4</sup>, P. Lipsky<sup>5</sup>. <sup>1</sup>University of Florida, Gainesville; <sup>2</sup>University of Alabama at Birmingham, Birmingham; <sup>3</sup>University of Southern California, Los Angeles; <sup>4</sup>Horizon Pharma, Lake Forest; <sup>5</sup>AMPEL BioSolutions LLC, Charlottesville, USA**Background:** Many, but not all patients with chronic refractory gout develop tophi; and the factors that govern tophus formation are not known. To address this question, we assessed subjects enrolled in the pivotal trials of pegloticase, a mammalian recombinant uricase conjugated to polyethylene glycol that is approved for the treatment of gout refractory to conventional oral urate lowering therapy.**Objectives:** To determine the factors associated with the presence of tophi in patients with chronic refractory gout.**Methods:** This analysis used results from two pivotal randomised controlled trials (RCTs)<sup>1,2</sup> to assess the clinical characteristics of subjects with chronic refractory gout and effects of treatment with pegloticase. Overall, 73% of the subjects in these trials had clinically apparent tophi at baseline and 27% did not. Demographic features of these subjects were assessed and renal function was evaluated by measurement of estimated glomerular filtration rate (eGFR). Subjects were treated with pegloticase, 8 mg every other week (q2w) in a 6 month RCT and then followed for up to 3 years in an open label extension (OLE).**Results:** The analysis included subjects with chronic refractory gout, 154 with tophi at baseline and 57 without tophi. Chronic refractory gout subjects in the two groups were generally similar at baseline, but with a difference in disease duration: 16.3 years for tophaceous subjects vs 11.7 years for subjects without tophi (p=0.007). There were no significant differences in most comorbidities for the two groups. However, eGFR was significantly lower in the subjects with tophi (85.2 mL/min) vs those without tophi (116.5 mL/min) (p=0.001). The frequency of tophi increased in subjects with lower eGFR values (Table). Six months of treatment with pegloticase (8 mg q2w) in a subgroup of subjects resulted in complete or partial resolution of at least one tophus with no increase in others in 74% of subjects, but had no significant effect on renal function measured by eGFR (78.8 mL/min vs 84.2 mL/min, n=51, p=0.7). Continued treatment with pegloticase in the OLE further decreased the burden of tophi, but had no significant effect on renal function measured by eGFR (75.7 mL/min, p=0.6).**Abstract SAT0370 – Table 1**

Baseline eGFR (mL/min)	Non-tophaceous (n=57)	Tophaceous (n=154)
≥90 (n=97)	33 (34.0%)	64 (66.0%)
60 to <90 (n=54)	16 (29.6%)	38 (70.4%)
30 to <60 (n=43)	5 (11.6%)	38 (88.4%)
15 to <30 (n=17)	3 (17.6%)	14 (82.4%)

p=0.0094, Cochran-Mantel-Haenszel chi square test

**Conclusions:** These results indicate that chronic refractory gout patients may present with or without clinically apparent tophi. A significant association was

noted between the presence of renal dysfunction measured by eGFR and the frequency with which chronic refractory gout patients manifested tophi. Pegloticase treatment markedly decreased the tophus burden, but in this analysis did not improve renal function. These results suggest that renal failure may predispose patients to tophus formation, whereas the resolution of tophi in this analysis did not appear to improve renal function.

SAT0371

**FACTORS ASSOCIATED WITH ALLOPURINOL ADHERENCE AND TREATMENT OUTCOME AMONG GOUT PATIENTS**

S. Asaiphanit, P. Narongroeknawin. Internal Medicine, Phramongkutklao Hospital, Bangkok, Thailand

**Background:** A serum uric acid (SUA) level of <6.0 mg/dL has been widely accepted as the therapeutic target for patients with gout. Recent studies implicate allopurinol nonadherence as a major barrier to achieving this target. However, factors that could affect this medication adherence are not clearly identified.**Objectives:** To identify factors associated with allopurinol adherence and SUA goal attainment in gout patients.**Methods:** This study identified patients aged 18 years or older with a diagnosis of gout by 1977 ARA classification criteria for gout, received at least 1 month of allopurinol, and attended out-patient clinics of Phramongkutklao hospital from Jul 2016–Sep 2017. Allopurinol adherence was defined as Medication Taking Behaviour for Thai patient (MTB-Thai) scores >21 points. Patient characteristics, comorbidities, concomitant medications, prescriber specialty, number of gout attack and SUA were examined. Multivariate logistic regression was used to examine factors associated with allopurinol adherence and SUA target, defined as SUA <6.0 mg/dL.**Results:** A total of 226 patients with gout was included. Approximately half of patients (43.4%) were adherent, whereas only one-third of them achieved SUA target (29.2%). Factors associated with allopurinol adherence in the multivariate analysis included disease duration (>1 year) (odds ratio [OR] 0.1, 95% confident interval [CI]: 0.05–0.21), history of gout attack (>2 times/year) (OR 0.14, 95% CI: 0.08–0.27), and prescriber specialty (rheumatologist) (OR 2.64, 95% CI: 1.28–5.43). Factors associated achieved SUA goal in the multivariable analysis included history of gout attack (>2 times/year) (OR 0.21, 95% CI: 0.1–0.42), prescriber specialty (rheumatologist) (OR 2.01, 95% CI: 1.31–4.13), allopurinol dose escalation (OR 2.11, 95% CI: 1.17–3.79), current allopurinol dosage (>100 mg/day) (OR 2.02, 95% CI: 1.11–3.65), and allopurinol adherence (OR 13.6, 95% CI: 6.52–28.39).**Conclusions:** Among patients with gout receiving allopurinol in our study, 70.8% did not reach the SUA goal and 56.6% of patients were non-adherent. Allopurinol adherence was strongly associated with SUA goal attainment. The only modifiable factor associated with allopurinol adherence was prescriber specialty, whereas, modifiable factors associated with SUA goal attainment were prescriber specialty, allopurinol dose escalation, and current allopurinol dosage. Appropriate dose escalation and rheumatology referral could be important factors to consider in efforts aimed at optimising gout treatment outcomes.**Disclosure of Interest:** None declared

SAT0372

### INCREASED CAROTID INTIMA-MEDIA THICKNESS IN HYPERURICEMIC INDIVIDUALS MAY BE EXPLAINED BY HYPERHOMOCYSTEINEMIA ASSOCIATED WITH RENAL DYSFUNCTION

S. Choi<sup>1</sup>, J.H. Park<sup>1</sup>, J.-S. Song<sup>1</sup>, E.-J. Kang<sup>2</sup>, K.-H. Lee<sup>3</sup>. <sup>1</sup>Internal Medicine, Chung-Ang University College of Medicine, Seoul; <sup>2</sup>Internal Medicine, Busan Medical Center, Busan; <sup>3</sup>Internal Medicine, Dongguk University College of Medicine, Goyang, Korea, Republic Of

**Background:** Both hyperuricemia and hyperhomocysteinemia are known to be associated with the deterioration of vascular endothelial function and are regarded as important risk factors for atherosclerotic vascular diseases. However, there has been no report about the relationship between homocysteine (Hcy) and atherosclerosis in patients with hyperuricemia.

**Objectives:** In this study, we evaluated the relationship between the carotid IMT and various clinical parameters including renal function and serum Hcy level in patients with hyperuricemia, and investigated the possible mechanism of how hyperuricemia is related with the increase of carotid IMT.

**Methods:** A total of 1228 subjects who visited the health promotion centre of hospital were enrolled in this study. All subjects completed both carotid ultrasonography and laboratory measurement, including serum Hcy levels and renal function. Serum Hcy levels were measured by a competitive immunoassay using direct chemiluminescent. Carotid IMT was evaluated by B-mode carotid ultrasonography.

**Results:** Hyperuricemic patients showed higher carotid IMT values compared with normouricemic patients (1.12±0.64 mm vs. 1.02±0.50 mm, p=0.043). The serum Hcy levels were significantly higher in the hyperuricemic group than in the normouricemic group (13.39±4.42 µmol/L vs. 11.69±3.65 µmol/L, p<0.001). In patients with hyperuricemia, serum uric acid levels were negatively correlated with estimated glomerular filtration rates (eGFR) ( $\gamma=-0.334$ , p<0.001), and eGFR were negatively correlated with serum Hcy levels ( $\gamma=-0.490$ , p<0.001). Carotid IMT was correlated with serum Hcy levels ( $\gamma=0.196$ , p=0.008), and atherosclerotic changes of carotid artery measured by carotid ultrasonography increased 1.09-fold (OR, 95% CI 1.006–1.185, p=0.036) per 1 µmol/L difference in serum homocysteine levels. In multivariate linear regression analysis, carotid IMT was affected by reduced eGFR ( $\beta=-0.263$ , p=0.002).

**Conclusions:** Carotid IMT was higher in patients with hyperuricemia than in normouricemic individuals. This study suggests that impairment of the renal function in patients with hyperuricemia may induce the increase in carotid IMT via increased serum Hcy levels.

SAT0373

### PREVENTING A LARGE MAJORITY OF INCIDENT GOUT CASES BY MODIFYING KEY RISK FACTORS: FINDINGS FROM A PROSPECTIVE COHORT OF 44,629 MEN OVER 26 YEARS

S.K. Raj<sup>1,2,3</sup>, N. Lu<sup>3</sup>, C. Yokose<sup>1</sup>, H.K. Choi<sup>1,3</sup>. <sup>1</sup>Division of Rheumatology, Allergy, Immunology, Massachusetts General Hospital, Harvard Medical School; <sup>2</sup>Department of Nutrition, Harvard T.H. Chan School of Public Health; <sup>3</sup>Channing Division of Network Medicine, Department of Medicine, Brigham and Women's Hospital, Harvard Medical School, Boston, USA

**Background:** Many modifiable risk factors have been found to be independently associated with the risk of developing gout, including dietary factors (e.g., intakes of red meat and fructose), adiposity, alcohol intake, and diuretic use. Conversely, healthy dietary patterns (e.g., Dietary Approaches to Stop Hypertension [DASH]) and a high intake of vitamin C have been shown to be independently associated with lower gout risk. However, the potential combined impact of these factors on the risk of developing gout is unknown.

**Objectives:** We aimed to estimate the proportion of incident gout cases that could theoretically be avoided through the simultaneous adoption of multiple low-risk behaviours, including low body mass index (BMI), consumption of a DASH-style eating pattern, no alcohol intake, vitamin C supplementation, and no diuretic use.

**Methods:** From 1986 to 2012, we prospectively followed 44 629 men free from gout at baseline in the Health Professionals Follow-up Study. Lifestyle, anthropometric, and medical information was collected at baseline and updated biennially. Dietary data were obtained using validated food frequency questionnaires at baseline and approximately every 4 years during follow-up. We ascertained incident cases of gout using the American College of Rheumatology survey criteria for gout. We defined low-risk groups according to combinations of the following

five factors: a low BMI (<25 kg/m<sup>2</sup>), adherence to a DASH-style diet, no alcohol intake, vitamin C supplementation ( $\geq 1500$  mg), and no diuretic use. Cox proportional hazard regression models were used to estimate the association of each risk factor with the development of gout and calculate the population attributable risk percent (PAR%).

**Results:** During 9 50 086 person-years of follow-up, incident gout developed in 1687 participants. All five modifiable risk factors were independently associated with incident gout. Obesity was the single most important predictor of gout; all other risk factors were also associated with a statistically significant increased risk of gout, even after adjustment for BMI. As compared with the rest of the cohort, men in the low-risk group (comprised of all five low-risk factors; 4.4% of men) had a relative risk of gout of 0.30 (95% confidence interval [CI], 0.12 to 0.72) (table 1). Accordingly, the PAR% for all five risk factors combined was 70% (table 1). The PAR% for four and three risk factors was 64% and 50%, respectively (table 1).

**Abstract SAT0373 – Table 1.** Relative and Population Attributable Risks of Gout for Groups Defined by Combinations of Modifiable Risk Factors

	Percentage of Men (%)	Number of Gout Cases	Relative Risk (95% CI)	PAR%
3 factors in low-risk category <sup>a</sup>	11.0	24	0.49 (0.33, 0.74)	50
4 factors in low-risk category <sup>b</sup>	10.3	15	0.35 (0.21, 0.59)	64
5 factors in low-risk category <sup>c</sup>	4.4	5	0.30 (0.12, 0.72)	70

Abbreviations: BMI, body mass index. CI, confidence interval. DASH, Dietary Approaches to Stop Hypertension. PAR%, Population attributable risk percent.

Relative risks were adjusted for total energy intake, coffee intake, and histories of renal failure and hypertension.

<sup>a</sup>Low BMI, highest quintile of DASH diet score, and no alcohol intake.

<sup>b</sup>Low BMI, highest quintile of DASH diet score, no alcohol intake, and no diuretic use.

<sup>c</sup>Low BMI, highest quintile of DASH diet score, no alcohol intake, no diuretic use, and vitamin C supplementation.

**Conclusions:** Five modifiable risk factors accounted for 70% of incident gout cases in this large prospective cohort of male health professionals. Assuming a causal relation, our findings support the hypothesis that the vast majority of cases of gout could be prevented by modifying key risk factors.

**Acknowledgements:** This study was supported by a grant from the National Institutes of Health (R01AR065944).

SAT0374

### LESINURAD (LESU) ADJUNCTIVE THERAPY WITH ALLOPURINOL (ALLO) IN PATIENTS NOT RESPONDING TO ALLO MONOTHERAPY: POOLED POST HOC SAFETY AND EFFICACY ANALYSIS IN A PATIENT SUBGROUP USING CONCOMITANT DIURETICS AT SUBLINE (BL)

T. Bardin<sup>1</sup>, R.G. Karra<sup>2</sup>, A. So<sup>3</sup>, A.-K. Tausche<sup>4</sup>, I. Wild<sup>2</sup>, H. Hagedorn<sup>2</sup>, P. Kandaswamy<sup>2</sup>, F. Perez-Ruiz<sup>2</sup>. <sup>1</sup>Rheumatology, Hôpital Lariboisière, Paris, France; <sup>2</sup>Grunenthal GmbH, Aachen, Germany; <sup>3</sup>Rheumatology, chuv, Lausanne, Switzerland; <sup>4</sup>University Clinic, Dresden, Germany; <sup>5</sup>Rheumatology, University of the Basque Country, Biscay, Spain

**Background:** LESU is approved as adjunctive therapy in combination with xanthine oxidase inhibitors (XOI) for gout PT not responding to XOI alone<sup>1</sup>. Gout PT often have hypertension (HT) for which diuretics especially thiazide and thiazide-like diuretics (TTLD) are prescribed. TTLD contributes to hyperuricemia<sup>2</sup> by acting on OAT4 transporter, which is inhibited by LESU.

**Objectives:** To assess the efficacy and safety of LESU+ALLO in the subgroup of PT using concomitant diuretics at BL in CLEAR 1 and CLEAR 2, two randomised, double-blind, placebo-controlled Phase 3 studies that evaluated LESU200/400 mg daily in combination with ALLO vs ALLO+placebo.<sup>3&4</sup>

**Methods:** Data from both trials of 1,213 PT, was pooled and PT group using diuretics at baseline was compared to non-users with respect to sUA target and TEAE.

**Results:** Totally 221 PT received diuretics, >90% due to HT and ~80% being TTLD. In both groups, LESU +ALLO doubled the number of PT reaching sUA target of <6.0 mg/dL vs ALLO +PBO at month 6 (m-6) and 12 (m-12) (table 1). At m-12, the response rate in PT receiving TTLD was 60.8%, 61.5% in the LESU 200 and 400 mg group, and 26.6% in the ALLO alone group, and 47.5%, 50.5%, and 25.7% in PT not receiving TTLD respectively. The safety profile was comparable

except for transient and reversible serum creatinine elevations in the LESU groups. (table 1).

Abstract SAT0374 – Table 1

Variable	Group receiving Diuretics			Group not receiving Diuretics		
	PBO	LESU	LESU	PBO	LESU	LESU
	+ALLO	200 mg	400 mg	+ALLO	200 mg	400 mg
	[n=64]	+ALLO	+ALLO	[n=343]	+ALLO	+ALLO
		[n=79]	[n=78]		[n=326]	[n=323]
<b>Efficacy</b> , proportion of PT achieving [number (%)]:						
sUA<6.0 mg/dL at m-6	19 (29.7)	48 (60.8)†	57 (73.1)*	85 (24.8)	174 (53.4)*	195 (60.4)*
sUA<6.0 mg/dL at m-12	17 (26.6)	48 (60.8)*	48 (61.5)*	88 (25.7)	155 (47.5)*	163 (50.5)*
<b>Safety</b> , proportion of PT reporting [number (%)]:						
Any TEAEs	45 (70.3)	62 (78.5)	65 (83.3)	239 (69.7)	237 (72.7)	252 (78.0)
←Serum creatinine by ≥1.5	2 (3.1)	2 (2.5)	11 (14.1)	5 (1.5)	17 (5.2)	47 (14.6)

† p=0.0003, \*p<0.0001 versus PBO+ALLO (Cochran-Mantel Haenszel test)

**Conclusions:** LESU +ALLO doubled the number of PT reaching sUA target of <6.0 mg/dL at m-6 and sustained at m-12, irrespective of TTLD use. Adjunctive therapy with LESU +ALLO is safe and efficacious even in PT subgroups using concomitant TTLD.

#### SAT0375 IMPACT OF FEBUXOSTAT ON RENAL FUNCTION AMONG GOUT PATIENTS WITH DIFFERENT RENAL FUNCTION

T.-T. Chung<sup>1</sup>, C.-F. Kuo<sup>1,2</sup>, J.-S. Chen<sup>1</sup>, M.-J. Chiou<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Allergy and Immunology, Chang Gung Memorial Hospital, Taoyuan, Taiwan, Province of China; <sup>2</sup>Division of Rheumatology, Orthopaedics and Dermatology, University of Nottingham, Nottingham, UK

**Background:** Febuxostat is a new xanthine oxidase inhibitor which is effective in the treatment of hyperuricemia. Its use in people with different levels of renal function has not been thoroughly assessed.

**Objectives:** To assess the risk of renal function deterioration in gout patients using febuxostat and compare it with patients using allopurinol and other uricosuric agents.

**Methods:** We included 5882 adult patients with gout diagnosed between 2012 and 2015. We divided patients into three groups by usage of urate-lowering drugs used (allopurinol, febuxostat and uricosuric agents including benzbromarone, probenecid and sulfipyrazone). The primary outcome was a progress of one chronic kidney disease (CKD) stage. The index date was the first date of urate-lowering drugs used. We follow each patient to the date of event, death, switch to other drug or the end of the study. The Cox proportional hazards model was used to estimate the adjusted hazard ratios (HRs), adjusted for age, sex, baseline eGFR, baseline serum urine acid, comorbidity, co-medication.

**Results:** The incident rate of the renal function deterioration was 2.37 (95% CI, 1.75–3.14) per 1000 person-days in allopurinol users, 1.54 (95% CI, 1.30–1.81) per 1000 person-days in febuxostat users and 1.43 (95% CI, 1.32–1.56) per 1000 person-days in uricosuric agent users. The HRs of progression of CKD stage in febuxostat and uricosuric agent users were 0.98 (95% CI, 0.70–1.38) and 0.80 (95% CI, 0.59–1.09) compared with allopurinol. Among febuxostat users, the HRs were 1.80 (95% CI, 0.85–3.98) in patients with an estimated glomerular filtration rate (eGFR) ≥90 ml/min/1.73 m<sup>2</sup>, 1.06 (95% CI, 0.56–2.03) for patients with an

eGFR 60–89 ml/min/1.73 m<sup>2</sup>, 0.78 (95% CI, 0.45–1.42) for patients with an eGFR 30–59 ml/min/1.73 m<sup>2</sup> and 0.73 (95% CI, 0.22–3.52) for patients with an eGFR 15–29 ml/min/1.73 m<sup>2</sup>. Among uricosuric agent users, the HRs were 0.94 (95% CI, 0.52–1.88) in patients with an eGFR ≥90 ml/min/1.73 m<sup>2</sup>, 0.88 (95% CI, 0.55–1.50) in patients with an eGFR 60–89 ml/min/1.73 m<sup>2</sup>, 0.71 (95% CI, 0.41–1.28) in patients with an eGFR 30–59 ml/min/1.73 m<sup>2</sup> and 0.71 (95% CI, 0.19–3.62) in patients with an eGFR 15–29 ml/min/1.73 m<sup>2</sup>.

**Conclusions:** Renal function deterioration is not uncommon after initiation of urate-lowering treatment and febuxostat has a similar renal safety profile as allo-purinols and uricosuric agents.

**Disclosure of Interest:** None declared

#### SAT0376 THE INCIDENCE, PREVALENCE AND USE OF URATE LOWERING AGENTS IN HONG KONG: A POPULATION STUDY FROM 2006 TO 2016

T.T. Cheung<sup>1</sup>, M.F. Tsoi<sup>1</sup>, M.H. Chung<sup>2</sup>, B.M.Y. Cheung<sup>1</sup>, W.C.S. Lau<sup>1</sup>. <sup>1</sup>Medicine, The University of Hong Kong; <sup>2</sup>Medicine, Queen Mary Hospital, Hong Kong, Hong Kong

**Background:** The prevalence of gout has increased significantly over the past decade, especially in developed countries and Oceanic populations. The estimated prevalence of gout in the US, Canada and European countries was 3%. Asian countries, except Taiwan, were considered to have a lower prevalence of gout due to differences in ethnicity and lifestyle.

Since there are no recent epidemiological data on gout in Hong Kong, we conducted this population study to determine the incidence and prevalence of gout in Hong Kong as well as the utilisation of urate lowering agents among patients with gout.

**Objectives:** To determine the incidence, prevalence of gout and use of urate lowering agents in Hong Kong

**Methods:** Data were retrieved from the Clinical Data Analysis and Reporting System (CDARS) of the Hospital Authority. The Hospital Authority is the only public healthcare provider in Hong Kong. Since treatment is heavily subsidised and available to all residents, it covers more than 90% of all medical care for the general population in Hong Kong.

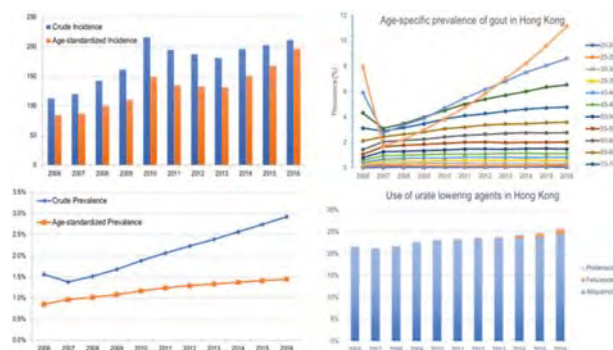

Clinical data including demographic, diagnosis of gout, serum urate levels and prescriptions of urate lowering agents were retrieved from CDARS from 2006 to 2016. For inclusion, subjects must have attended any out-patient clinics or accident and emergency department (with or without hospitalisation) in 2005. Subjects with a diagnosis of gout who died before 2006 were excluded. All subjects were followed until the cut-off date or death.

Gout was defined as the physician diagnosis and coding in CDARS. The serum urate levels achieved after prescribing urate lowering agents were the means of all serum urate levels 6 months after prescriptions.

Results were analysed by R statistics version 3.3.3. with package 'prevalence' version 0.4.0.

**Results:** 2741862 participants were included in the analysis. Both the incidence and prevalence of gout in Hong Kong have increased over the past 10 years. In 2016, the crude and age-standardised prevalence of gout were 2.92% and 1.44%, respectively. 6.26% of the general population aged 80 years or older was diagnosed to have gout.

Despite the increase in incidence and prevalence of gout in Hong Kong, the utilisation of urate lowering agents remained low. In 2016, only 25.55% of patients with gout were prescribed urate lowering agents. More importantly, only 35.8% of those could achieve the therapeutic target of serum urate level <6 mg/dL.

**Conclusions:** Population ageing has led to increases in incidence and prevalence of gout in Hong Kong. In 2016, the crude prevalence of gout in Hong Kong was 2.92%, which is similar to figures reported in western countries. Despite an

increase in prevalence of gout, the utilisation of urate lowering agents remained low. Only 1 in 4 patients with gout were prescribed urate lowering agents.

**Acknowledgements:** The Hospital Authority of Hong Kong

SAT0377

#### THE BURDEN OF MONOSODIUM URATE CRYSTALS ASSESSED BY DUAL-ENERGY CT AND ULTRASONOGRAPHY IS NOT CORRELATED TO CARDIOVASCULAR RISK

T. Pascari<sup>1</sup>, B. Capon<sup>2</sup>, A. Grandjean<sup>1</sup>, J. Legrand<sup>2</sup>, N. Namane<sup>2</sup>, E. Houvenagel<sup>1</sup>, L. Norberciak<sup>3</sup>, J.-F. Budzik<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Radiology; <sup>3</sup>Biostatistics, Hopital Saint Philibert, Lomme, France

**Background:** Gout is associated with higher cardiovascular risk and increases with disease severity. It is not clear if the monosodium urate (MSU) crystal burden is associated with traditional cardiovascular risk factors.

**Objectives:** The objective of this study was to explore the relationship between the extent of MSU deposition assessed with ultrasonography (US) and dual-energy CT (DECT) and cardiovascular risk.

**Methods:** Gout patients naive of urate lowering therapy were included in this cross-sectional study to undergo DECT scans for the assessment of total MSU volume deposition of the knees and feet, and US to evaluate the number of joints with the double contour (DC) sign among the femoro-patellar, talo-crural and first metatarsophalangeal joints. Participants were screened for traditional cardiovascular risk factors and levels of the ACC/AHA 10 year-risk for heart disease or stroke was calculated. The primary endpoint was the Spearman correlation coefficient  $\rho$  between DECT MSU volume and cardiovascular risk.

**Results:** A total of 50 patients predominantly male (46/50) aged 62.6 years ( $\pm 14.1$ ) were included. Participants had gout duration of 9.5 years ( $\pm 11.8$ ), had experienced 4.1 flares ( $\pm 6.3$ ) over the past year, had serum urate (SU) levels of 8.1 mg/dL ( $\pm 2.3$ ), and 35/50 had at least one US tophus of 1.5 cm<sup>3</sup> ( $\pm 1.8$ ). The volume of MSU deposits with DECT was 3.9 cm<sup>3</sup> ( $\pm 11.2$ ) for the feet and 2 cm<sup>3</sup> ( $\pm 4.4$ ) for the knees. Overall, 28 patients presented with the metabolic syndrome. Correlations between DECT volumes of MSU deposits of the knees, feet, and knees+feet were poor with  $\rho$  respectively of 0.23, 0.03 and 0.21. There was no correlation between the number of joints with the DC sign and cardiovascular risk ( $\rho$  of 0) and the correlation was poor with SU levels ( $\rho=0.09$ ). Patients with the metabolic syndrome had similar DECT volume of MSU deposits than those without ( $p=0.29$ ).

**Conclusions:** This study suggests that the association of gout with traditional cardiovascular risk factors is not related to the extent of the monosodium urate crystal burden.

**Disclosure of Interest:** None declared

SAT0378

#### THE TREND OF TREG AND TH17 CELLS CHANGES IN P2X7R-REGULATED ACUTE GOUTY ARTHRITIS MODEL RATS

X.-J. Dai<sup>1</sup>, J.-H. Tao<sup>1</sup>, X. Fang<sup>1</sup>, Q. Lin<sup>1</sup>, M.-Y. Li<sup>1</sup>, Y. Xia<sup>1</sup>, X.-M. Li<sup>1</sup>, X.-P. Li<sup>1</sup>, Y.-P. Wang<sup>2</sup>. <sup>1</sup>Rheumatology and Immunology, The First Affiliated Hospital of University of Science and Technology of China, Hefei, China; <sup>2</sup>Centre for Transplantation and Renal Research, Westmead Institute for Medical Research, The University of Sydney, NSW, Australia

**Background:** ATP may be the second causative signal for the onset of gout, which acts on P2  $\times$  7R to regulate the development of acute gouty arthritis.<sup>1</sup> Both regulatory T cells and Th17 cells are important in the development and progression of inflammatory diseases.<sup>2</sup>

**Objectives:** To investigate the effect of P2  $\times$  7R on Treg and Th17 cells in acute gouty arthritis model of rats and its role in acute gouty arthritis.

**Methods:** Eighty male SD rats were randomly divided into three groups: After establishment of acute gouty arthritis model, rats were given P2  $\times$  7R agonist ATP, P2  $\times$  7R inhibitor BBG and PBS, respectively. The rats were sacrificed at 6 hour, 12 hour, 24 hour, 48 hour and 72 hour after treatment. The spleens of the rats were grinded and the expression of Treg and Th17 cells were detected by flow cytometry. Comparison the levels and the ratio of Treg and Th17 cells at the different time points.

**Results:** (1) The expression levels of Treg and Th17 in the spleen: After treatment at 12 hour, The expression levels of Treg and Th17 in the ATP group were significantly higher than that in the BBG and control groups ( $p=0.001$ ,  $0.021$ ;  $p=0.01$ ,  $0.025$ ); The expression levels of Treg and Th17 in control group were higher than that in BBG group ( $p=0.021$ ,  $0.044$ ); There were no significant differences in the three groups at 72 hour after treatment ( $p=0.052$ ,  $0.116$ ). (2) The expression trend of Treg and Th17 in different time points: the level of Treg was increased at 6 hour, but decreased gradually at 12 h, 24 hour and then increased at 48 hour again; The level of Th17 was increased at 6 hour, 12 h and 24 hour, but decreased gradually at 48 hour, 72 hour. (3) The ratio of Treg/Th17 gradually decreased in the first three time points, increased at 48 hour and 72 hour in three groups. The ratio of Treg/Th17 in ATP group was lower than that in BBG group and control group at 12 hour, with significant difference ( $p<0.05$ ). But at other four time points, the ratios were no significant differences among the three groups.

**Conclusions:** Activation of P2  $\times$  7R decreased the ratio of Treg/Th17 in acute gouty arthritis rat model that showed an acute change trend along with the time, suggesting that P2  $\times$  7R-regulated the ratio of Treg/Th17 cells affected acute gouty arthritis.

#### VACUUM-ASSISTED CLOSURE VERSUS CONVENTIONAL WOUND CARE IN THE MANAGEMENT OF CHRONIC ULCERS IN PATIENTS WITH TOPHACEOUS GOUT: A PROSPECTIVE ANALYSIS

X. Pan, Z. Huang, M. Liu, D. Li, Z. Huang, Y. Huang, X. Huang, M. Liu, X. Li, X. Yao, Y. Wang, Q. Huang, X. Guo, S. Zheng, T. Li. *Department of Rheumatology and Clinical Immunology, Guangdong Second Provincial General Hospital, Guangzhou, China*

**Background:** With the rising epidemic of gout, an increasing number of patients suffer from chronic ulcers associated with tophaceous gout in China, causing poor quality of life and disability. Such ulcers are very difficult conditions to deal with. Vacuum-assisted closure (VAC) has been proved to be effective in treating a variety kinds of wounds such as diabetic foot ulcers. However, its use in chronic ulcers associated with tophaceous gout has seldom reported.

**Objectives:** In the present study, we evaluated the use of VAC in the treatment of chronic ulcers associated with tophaceous gout in comparison to conventional wound care (CWC).

**Methods:** We performed a 12 week prospective study that included 13 patients treated with VAC and 14 patients treated with CWC. We collected the clinical outcomes of these patients and data from a satisfaction survey. Chronic ulcers were treated until wound closure, or until the end of 12 weeks. Study will discontinue when the ulcer worsens or remains unchanged by the end of week 4.

**Results:** Granulation tissue appeared in 12 (92.31%) patients by the end of week 2 in the VAC group, while it appeared in 6 (42.86%) patients by that time in the CWC group ( $p=0.013$ ). 100% granulation was achieved in 11 (84.62%) patients by the end of week 8 in the VAC group as compared to 5 (35.71%) patients by that time in the CWC group ( $p=0.018$ ). By the end of week 12, decreasing in wound size was achieved in 12 (92.31%) patients in the VAC group, while it was achieved in 10 (71.43%) patients in the CWC group ( $p=0.326$ ). Among them, wound closure was achieved in 9 (69.23%) patients in the VAC group, while it was achieved in 3 (21.43%) patients in the CWC group ( $p=0.021$ ). None developed local infection in both groups during the treatment. More patients in the VAC group were satisfied with treatment as compared to the CWC group.

## PANLAR-ACCAR RECOMMENDATIONS ON DIAGNOSIS AND TREATMENT OF CHIKUNGUNYA-RELATED INFLAMMATORY ARTHROPATHIES IN LATIN AMERICA

P. Monge<sup>1</sup> on behalf of PANLAR-ACCAR Consensus Group in Chikungunya in Latin America, A.M. Sapag<sup>2</sup>, I.Y. Moreno<sup>3</sup>, R.A. Montúfar<sup>4</sup>, V. Khoury<sup>5</sup>, P. Camilo<sup>5</sup>, R.E. Rivera<sup>6</sup>, J.C. Rueda<sup>7</sup>, D. Jaramillo-Arroyave<sup>8</sup>, J. Londoño<sup>9</sup>, M.C. Ruiz<sup>10</sup>, F. Fernández-Castillo<sup>11</sup>, M. Quintero<sup>12</sup>, Y. Fuentes<sup>13</sup>, J.L. Aguilar<sup>14</sup>, C. V. Caballero-Urbe<sup>15</sup>, H. Sandoval<sup>16</sup>, C. Pineda<sup>16</sup> on behalf of Pan-American League of Associations for Rheumatology (PANLAR), in collaboration with the Central American, Caribbean and Andean Rheumatology Association (ACCAR by its Spanish acronym). <sup>1</sup>Asociación Costarricense De Reumatología, San Jose, Costa Rica; <sup>2</sup>Sociedad Boliviana de Reumatología, Santa Cruz, Bolivia, Plurinational State Of; <sup>3</sup>Sociedad Panameña de Reumatología, Panama City, Panama; <sup>4</sup>Asociación Salvadoreña de Reumatología, San Salvador, El Salvador; <sup>5</sup>Sociedad Dominicana de Reumatología, Santiago, Dominican Republic; <sup>6</sup>Asociación Guatemalteca de Reumatología, Guatemala City, Guatemala; <sup>7</sup>Asociación Colombiana de Reumatología, Chia; <sup>8</sup>Asociación Colombiana de Reumatología, Medellín; <sup>9</sup>Asociación Colombiana de Reumatología, Bogotá, Colombia; <sup>10</sup>Sociedad Venezolana de Reumatología, Maracay; <sup>11</sup>Sociedad Venezolana de Reumatología, Barquisimeto; <sup>12</sup>Sociedad Venezolana de Reumatología, Mérida; <sup>13</sup>Sociedad Venezolana de Reumatología, Ciudad Bolívar, Venezuela, Bolivarian Republic Of; <sup>14</sup>Sociedad Peruana de Reumatología, Lima, Peru; <sup>15</sup>Asociación Colombiana de Reumatología, Barranquilla, Colombia; <sup>16</sup>Instituto Nacional de Rehabilitación, México City, Mexico

**Background:** Although mortality rates related with Chikungunya (CHIK) outbreaks into Latin America's endemic-dengue rural and new urban regions are low, dealing with symptoms and sequelae can produce both a significant burden of disease and diminish quality of life — from many months to years — after the acute phase of infection, with a significant impact on public and individual health.

**Objectives:** The aim of this work was to establish a PANLAR-ACCAR consensus on diagnosis and treatment of CHIK-related inflammatory arthropathies transmitted by *Ae. Aegypti* and *Ae. Albopictus* in Latin America (LA).

**Methods:** Based on the Consensus Development Conference format, a panel of ACCAR rheumatologists (n=10) took part in this PANLAR initiative. Experts voted recommendations from a previous content analysis of the medical literature on CHIK, four subsequent topic's Conferences and a workshop. Consensus represents the majority agreement (≥80%) achieved for each recommendation.

**Results:** The panel reach four overarching principles: 1) CHIK virus (CHIKV) is a re-emergent virus transmitted by two species of mosquitoes: *Ae. Aegypti* and *Ae. Albopictus*; 2) CHIKV caused massive outbreaks in LA; 3) Chronic CHIKV infection produces an inflammatory joint disease that in some cases can last several months to years, and 4) Currently, there are no vaccines or antivirals available for CHIKV infections.

**Conclusions:** PANLAR-ACCAR achieve 13 recommendations on CHIK categorised in three groups: 1) epidemiology and clinical manifestations; 2) diagnosis, and 3) treatment, representing the consensus agreement from the panel's members.

Figure 1. A 57-years old man, who suffered from ulcers associated with tophaceous gout for around 3 months, was successfully treated with VAC therapy.

**Abstract SAT0379 – Figure 1.** A 57-years old man, who suffered from ulcers associated with tophaceous gout for around 3 months, was successfully treated with VAC therapy.

Figure 2. A 35-years old man, who suffered from ulcers associated with tophaceous gout for around 6 months, was successfully treated with VAC therapy.

**Abstract SAT0379 – Figure 2.** A 35-years old man, who suffered from ulcers associated with tophaceous gout for around 6 months, was successfully treated with VAC therapy.

**Conclusions:** Our preliminary study suggests that VAC therapy is effective and safe in treating chronic ulcers associated with tophaceous gout and appears to be superior to CWC therapy. Large-scale studies are needed to further evaluate the efficacy and safety of the VAC therapy in the treatment of chronic ulcers associated with tophaceous gout.

### NEUTROPHIL-RELATED BIOMARKERS DISCRIMINATE SEPTIC ARTHRITIS FROM OTHER INFLAMMATORY ARTHRITIDES: DATA FROM THE BOSSA TRIAL

A. Baillet<sup>1</sup>, C. Trocmé<sup>2</sup>, A. Courtier<sup>3</sup>, C. Nguyen<sup>3</sup>, B. Toussaint<sup>2</sup>, O. Epaulard<sup>4</sup>.  
<sup>1</sup>GREPI University Grenoble-Alpes (UGA) EA74 08, France; <sup>2</sup>TheReX/TIMC-IMAG (UMR 5525) Laboratory, UGA; <sup>3</sup>Laboratory of Biochimie des Enzymes et des Protéines, Centre Hospitalier Universitaire Grenoble Alpes, France; <sup>4</sup>Sinnoval SAS; <sup>5</sup>Infectious Disease department, Grenoble Hospital, Grenoble, France

**Background:** Septic arthritis is a life threatening purulent invasion of a joint by an infectious agent which produces arthritis. If untreated, septic arthritis causes structural damage to the joint. Unfortunately no relevant biomarkers are available for the diagnosis of this disabling condition. We aimed at determining whether calprotectin (S100A8/A9) and Human neutrophil alpha-defensins (HNP1-3) could discriminate septic from other inflammatory arthritides

**Objectives:** We aimed at determining whether calprotectin (S100A8/A9) and Human neutrophil alpha-defensins (HNP1-3) could discriminate septic from other inflammatory arthritides

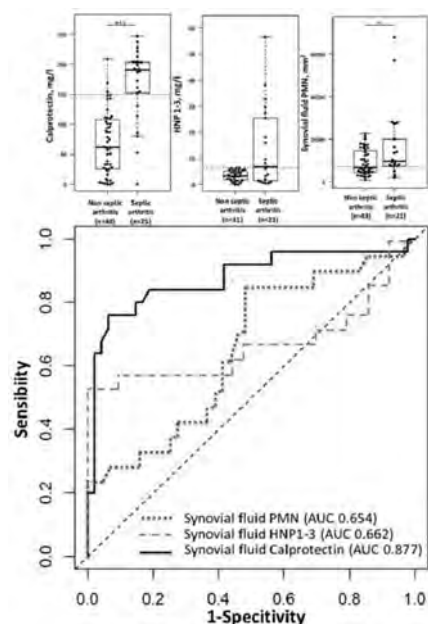

**Methods:** Patients joint effusions for which septic arthritis was suspected were prospectively collected in Grenoble Hospital. Patients with inflammatory synovial fluid (*i.e.* with white blood cell >2000/mm<sup>3</sup> and >80% polymorphonuclear neutrophils (PMN)) were included in this trial. Diagnosis of septic arthritis was retained if bacteria were cultured from inflammatory synovial fluid and/or blood samples. Diagnosis of pseudo gout was retained when pyrophosphate calcium crystals were observed in inflammatory synovial fluid. Diagnosis of rheumatoid arthritis was retained according to rheumatologist opinion.

C Reactive protein (CRP), both neutrophil-related proteins calprotectin and human neutrophil alpha-defensins (HNP1-3) levels were assessed in synovial fluids.

Threshold for biomarkers were determined by ROC curve analysis. Sensibility, Specificity, Positive (PPV) and Negative (NPV) Predictive Values at a pre specified threshold were calculated. Biomarkers with  $p \leq 0.05$  were included into a multivariate model. Multivariate logistic regression with stepwise selection was performed to build the final combined model.

**Results:** A total of 74 patients were included: septic arthritis (n=26), pseudo gout (n=28) and Rheumatoid arthritis (n=20). Patients with septic arthritis group were more likely to be male (69% vs. 31%,  $p=0.030$ ), were younger (median age (range) 65.5 (27-84) vs. 72.5 (33-91),  $p=0.047$ ), displayed higher synovial fluid PMN count (9,600 (1,800-68000) vs. 6560 (750-22500,  $p=0.047$ ), LR+12.2 and LR- 0.26.

Calprotectin was significantly increased in patients with septic arthritis (190 (0.1-247) vs. 62 (0-208) mg/L,  $p<0.001$ , figure 1) whereas only a trend of an HNP1-3 rise was shown in arthritis septic (6.8 (0.5-56.6) vs. 3.4 (0.1-6.4) mg/L,  $p=0.050$ ). Optimal Thresholds for calprotectin, HNP1-3, and synovial fluid PMN were respectively 150 mg/L, 6.5 mg/L and 7000/mm<sup>3</sup>.

In the multivariate model, including calprotectin, HNP1-3, synovial fluid PMN count and gender, calprotectin was the only biomarker discriminating septic arthritis from non-septic inflammatory arthritides with 76% sensitivity, 94% specificity, 86% PPV and 88% NPV.

**Conclusions:** Our data show here that synovial fluid calprotectin is a relevant biomarker to discriminate septic arthritis from other inflammatory arthritides. This biomarker should be tested in an independent cohort.

### UTILITY OF NEUTROPHIL CD64 & SERUM TREM-1 IN DISTINGUISHING BACTERIAL INFECTION FROM DISEASE FLARE IN SLE AND ANCA ASSOCIATED VASCULITIS

S. Ajmani<sup>1</sup>, H. Singh<sup>2</sup>, S. Chaturvedi<sup>2</sup>, R. Mishra<sup>2</sup>, M.K. Rai<sup>2</sup>, A. Jain<sup>2</sup>, D.P. Misra<sup>1</sup>, V. Agarwal<sup>2</sup>. <sup>1</sup>Clinical Immunology; <sup>2</sup>Sanjay Gandhi Post Graduate Institute, Lucknow, New Delhi, India

**Background:** Treating physician is challenged to differentiate between disease activity vs. infection as to the cause of fever in patients with SLE and ANCA associated vasculitis (AAV). Presently, there is no biomarker to reliably differentiate between them.

**Objectives:** We aimed to determine the usefulness of CD64 (FcγR1) expression on neutrophils and sTREM-1 (soluble triggering receptor expressed on myeloid cells) in serum in distinguishing bacterial infection from disease flare in SLE and AAV.

**Methods:** 20 healthy controls and patients of SLE and AAV admitted to our unit either with disease flare or bacterial infection were recruited over a period of 1 year. Neutrophil CD64 expression was measured by flow cytometry and sTREM-1 by ELISA from blood samples collected on the day of admission.

**Results:** Among the 76 patients included in the study 51 (SLE-35 and AAV-16) had disease flare while 25 (SLE-21 and AAV-4) had infection. 72% had fever at presentation. The percentage of neutrophils with CD64 expression and their mean fluorescence intensity in patients with infection were significantly ( $p<0.05$ ) higher as compared to those without infection and controls (Table-1). The sensitivity and specificity of CD64 expression on neutrophils to diagnose bacterial infection (using a cut off value of 30%) was 85% and 84%, respectively. Whereas, the sensitivity and specificity of procalcitonin was 75% and 85% respectively. There was no significant difference in soluble TREM-1 levels between the two groups. Total leucocyte count (TLC), ESR, CRP, C3, C4 levels were not significantly different between disease flare and infection group. On subgroup analysis (Table-2) patients of SLE with infection had a higher CRP, TLC and Procalcitonin compared to those with disease flare ( $p<0.5$ ). ROC curves are depicted in figure 1.

**Table-1-** Comparison of various parameters between healthy controls, patients with active disease and infection

Characteristic	Active disease (n=51)	Infection (n=25)	Healthy controls (n=20)
CD64 expression on neutrophils (%)	7.7 (2.6-13)	68.8 (56.9-86.5)*	7.05 (1.4-9.5)
Mean fluorescence intensity of CD64	456 (20-986)	1037 (229-1828)*	99.5 (54.7-140.7)
sTREM-1 (pg/ml)	1184 (717-1609)**	899 (531-1284)**	255.1 (95.1-634.8)
Procalcitonin (pg/ml)	157.7 (115.1-209.3)**	301 (141.8-339.3)*	77.6 (61-101.8)
Total leucocyte count (cells/mm <sup>3</sup> )	9700 (4600-12400)	10750 (6000-15000)	-
CRP (mg/L)	1.9 (0.86-6.05)	5.4 (1.83-8.9)	-
ESR (mm/hr)	70 (30-103)	75 (55-110)	-

\* $p<0.05$  vs. active disease group and healthy controls

\*\* $p<0.05$  vs. healthy controls

All values expressed as median (25th-75th Interquartile range)

**Abstract SAT0382 – Table 2.** Subgroup analysis of patients with SLE and ANCA associated vasculitis

Variable	SLE with active disease (n=35)	SLE with Infection (n=21)	AAV with active disease (n=16)	AAV with infection (n=4)
CRP (mg/dl)	1.3 (0.39-2.3)	5.54 (1.8-9.2)*	7.3 (2.64-10.5)	11.7 (2.08-20.85)
TLC (cells/mm <sup>3</sup> )	6400(3400-9500)	11 000(5925-16650)*	12 200(10550-20400)	12 000(10,300-20100)
nCD64 (%)	9.42 (3-13.7)	69.4 (59-87.1)*	4.25 (2.27-8.5)	76 (42.5-80.9)
Procalcitonin (pg/ml)	174 (101-204)	316 (231-345)*	172 (127-257)	104 (86-356)

\* $p<0.05$  vs. SLE with disease flare

All values expressed as median (25th-75th Interquartile range)

Abstract SAT0382 – Figure 1. ROC analysis of various parameters in patients with underlying SLE

**Conclusions:** CD64 expression on neutrophils is helpful in differentiating bacterial infection from disease flare in patients with SLE and AAV.

### SAT0383 RHEUMATOLOGICAL DISORDERS FOLLOWING CHIKUNGUNYA INFECTION – A RETROSPECTIVE STUDY OF 882 CASES FROM NEW DELHI

N. Gupta. *Clinical Immunology and Rheumatology, Max Super Speciality Hospital, Shalimar Bagh, New Delhi, DELHI, India*

**Background:** Chikungunya virus (CHIKV) is notoriously arthritogenic and is known to cause a wide spectrum of rheumatological disorders.

**Objectives:** To study the Rheumatological Manifestations of CHIKV Infection.

**Methods:** Record of 1641 consecutive patients who presented to the outpatient department (OPD) with history of chikungunya infection (fever, joint pains±rash) during the period of 1 st July 2016 to 31 st October 2016 were checked and recruited from private hospital, camps and clinic from urban and suburban population from 1 st February to 31 st December 2017. The study cohort was subjected to laboratory tests – serum IgM, IgG and RT-PCR for chikungunya virus. Those patients who tested positive for  $\geq 1$  lab tests were included in the study. Of the 1641 patients, 408 patients either refused the lab tests or were lost to follow up. Of the remaining 1233 patients, 882 (71.53%) patients tested positive for  $\geq 1$  lab tests and 351 (28.47%) tested negative for all the 3 lab tests. These patients were classified into rheumatological disorders as per validated criteria.

**Results:** We studied 882 consecutive patients of chikungunya infection with some rheumatological manifestations. Mean age of study cohort was 53.64  $\pm$  15.82 years with male:female of 398 (45.12%):484(54.88%). Mean disease duration of post CHIKV infection was 08.45 $\pm$ 3.64 months. Serologically, isolated serum IgM CHIKV was positive in 128 (14.51%) patients, IgG CHIKV in 340 (38.54%) patients and RT-PCR CHIKV in 223 (25.28%) patients. Combination of serum IgG and IgM CHIKV both were positive in 62 (7.03%), IgM and RT-PCR CHIKV 49 (5.55%) and IgG and RT-PCR CHIKV in 40 (4.54%) patients. All the 3 serum IgM, IgG and RT-PCR CHIKV were positive in 50 (5.67%) patients.

Of these 882 patients, 143 (16.21%) patients had rheumatological disorder prior to CHIKV infection which flared up after the infection. Of the 143 patients, 69 (48.25%) had osteoarthritis (OA) knee, 29 (20.27%) had mechanical low back ache, 12 (8.39%) cervical spondylitis, 10 (6.99%) had rheumatoid arthritis (RA), 7 (4.89%) each adhesive capsulitis and ankylosing spondylitis (AS), 3 (2.1%) psoriatic arthritis (PsA), 2 (1.4%) each had SLE, dequervian tenosynovitis and granulomatous with polyangitis.

Remaining 739 patients presented with various rheumatological disorders, most common of which was post chikungunya polyarthralgias in 568 (76.86%) patients. Of the 739 patients, 40 (5.4%) patients developed new onset OA knee, 38 (5.14%) met ACR/EULAR 2010 criteria for RA, 28 (3.78%) met modified New York criteria for AS, 29 (3.92%) developed undifferentiated arthritis, 17 (2.3%) patients developed various enthesitis and tenosynovitis, 1 (0.14%) patients fulfilled ACR 1997/SLICC 2012 criteria for SLE, 20 (2.7%) patients fulfilled ACR 2010 criteria for fibromyalgia, 5 (0.67%) patients fulfilled CASPAR criteria for PsA, 3 (0.4%) patients fulfilled 2015 classification criteria for Gout.

Family history of RA was present in 4 (10.52%) patients and AS in 9 (32.1%) patients. Co-morbidities as hypothyroid were present in 132 (17.86%) patients, hypertension in 88 (11.90%) and diabetes mellitus in 168 (22.73%) patients. Limitation of study – This study was not community based and only those patients who had persistent symptoms were recruited. Those patients whose symptoms of CHIKV infection subsided were not included.

**Conclusions:** CHIKV is a worldwide epidemic which precipitates chronic inflammatory rheumatological diseases.

K.M. Hayes<sup>1</sup>, R. Hayes<sup>2</sup>, J. Pope<sup>3</sup>. <sup>1</sup>Schulich School of Medicine, Western University, London; <sup>2</sup>Department of Genetics and Genome Biology, Hospital for Sick Children, Toronto; <sup>3</sup>Rheumatology, St. Joseph's Health Care London, London, Canada

**Background:** Reactive arthritis (ReA) seen by rheumatologists may be changing in frequency (less common) and severity (less than full triad of symptoms and less chronic ReA). Epidemiologic changes in ReA could be due to less food borne illness, cleaner water, and possibly more rapid treatment of sexually transmitted diseases or for other unknown reasons.

**Objectives:** To understand rheumatologists' perspectives about changes in frequency, severity, and manifestations of ReA.

**Methods:** After obtaining ethics approval, 548 members of the Canadian Rheumatology Association (CRA) were surveyed via email with a reminder email. There were 6 groups of questions: demographic information, views from respondents regarding the prevalence of ReA (including acute, recurrent, and chronic), tests ordered to investigate suspected ReA, treatments prescribed for ReA, causes of ReA in their practices, and perspectives on changes in the incidence, severity and causes of ReA over time. Descriptive statistics were used to analyse the data. Results were by physician report and were not confirmed by chart audits.

**Results:** Sixty-six rheumatologists completed the survey (15.5% response rate). The results of the survey indicated that 47% of rheumatologists believed that the incidence of ReA is declining, compared to 6% who thought it was increasing; and that the common causes may be changing (39% agreed/strongly agreed with a mean 3.4/5 on the Likert scale).

Acute, chronic, and recurrent ReA were all perceived to have similar frequencies in their practices. In terms of presentation, asymmetric oligoarthritis occurred in the majority of ReA seen by those surveyed (78%). Full triad ReA (arthritis, conjunctivitis, urethritis) was thought to occur in 21% of ReA cases, and patients with conjunctivitis were very likely to exhibit the rest of the triad. Similarly, patients with recurrent ReA were more likely to exhibit the full triad (43%) compared to acute or chronic ReA (14%). Rheumatologists believed that the infectious cause of ReA was found in only 35% of cases. The data indicate that the most common cause of ReA was 'unknown' infectious organisms, followed by gastrointestinal (GI) infections and sexually transmitted infections (STIs).

Multiple tests were ordered to investigate ReA. The three most common investigations ordered by respondents included testing for chlamydia (66%), C-reactive protein (CRP) (62%), and human leukocyte antigen (HLA-B27) (50%). Imaging was ordered by 39% of respondents with sacroiliac (SI) joint imaging ordered by 21%, X-rays of the affected joints by 15%, and other imaging by 7.5%. Figure 1 shows these results.

Treatments used for ReA varied, as shown in figure 2. The most common treatments for ReA were nonsteroidal anti-inflammatory drugs (NSAIDs) (97% frequently or always used), intra-articular corticosteroid injections (65% frequently or always used), and disease-modifying antirheumatic drugs (DMARDs) (45% frequently or always used). Sixty-six percent said they used tumour necrosis factor alpha inhibitors (TNFi) at least occasionally in chronic ReA.

Abstract SAT0384 – Figure 1

Abstract SAT0384 – Figure 2

**Conclusions:** Respondents tended to believe that ReA may be decreasing and the causes may be changing. In most cases the causative organism was thought to be unknown followed by GI and STIs. Interestingly, full triad ReA was thought to be linked with recurrent ReA. The results suggest several avenues for exploring clinical and epidemiological relationships in ReA.

**Objectives:** To characterise the etiologies and clinical features at diagnosis of patients with hemophagocytic lymphohistiocytosis (HLH) and correlate these baseline features with survival using an etiopathogenically-guided multivariate model.

**Methods:** The HLH Study Group of the Spanish Group of Autoimmune Diseases (GEAS) was formed in 2013 with the aim of collecting a large series of Spanish adult patients with HLH with substantial experience in the management of patients with systemic diseases. By October 2017, the database included 151 consecutive patients who fulfilled at least 5 of the 8 criteria proposed by the Histiocytosis Society in 2004.

**Results:** The cohort consisted of 151 patients (91 male, mean age 51.4 years). After a mean follow-up of 17 months, 80 (53%) patients died. With respect to the HLH-dependent variables, adenopathies (HR 0.63, p=0.040), low platelets (HR 3.39, p=0.008), leukopenia (HR 1.81, p=0.047), severe hyponatremia (HR 1.61, p=0.042), disseminated intravascular coagulation (HR 1.87, p=0.034), bacterial infection (HR 1.99, p=0.025), mixed microbiological infections (HR 3.42, p=0.008) and >1 infectious trigger (HR 2.95, p=0.003) were associated with death. Time-to-event analyses for death identified a worse survival curve for patients with neoplasia (p<0.001), mixed microbiological (p=0.019) and >1 (p=0.011) infections and glucocorticoid monotherapy (p=0.021). After adjusting for confounding variables, platelets<100,000/mm<sup>3</sup> (HR 2.64), severe hyponatremia (HR 1.88), >1 infectious trigger (HR 3.43) and mixed microbiological infection (HR 2.96) remained significant. Multivariate Cox proportional hazards regression analysis identified >1 infectious trigger (HR 2.60, 95% CI 1.16 to 5.84) as the only variable independently associated with death.

**Conclusions:** The mortality rate of adult patients diagnosed with HLH exceeds 50%. Infection with >1 microbiological agent was the only independent variable associated with mortality irrespective of the underlying disease, epidemiological profile, clinical presentation and therapeutic management.

**SAT0386** **ADJUDICATION OF INFECTIONS FROM THE PHARMACOVIGILANCE IN JUVENILE IDIOPATHIC ARTHRITIS PATIENTS (PHARMACHILD) TREATED WITH BIOLOGIC AGENTS AND/OR METHOTREXATE: UPDATE ON RESULTS WITH A FOCUS ON OPPORTUNISTIC INFECTIONS**

G. Giancane, J.F. Swart, E. Castagnola, A. Groll, G. Horneff, H.-I. Huppertz, D. J. Lovell, T. Wolfs, M. Hofer, E. Alexeeva, V. Panaviene, S. Nielsen, J. Antón López, F. Uettwiller, V. Staņevich, M. Trachana, F. De Benedetti, L.M. Ailioaie, E. Tsitsami, S. Kamphuis, T. Herlin, P. Doležalová, G. Susic, B. Flatö, F. Sztajnbock, E. Fueri, F. Bovis, F. Bagnasco, A. Pistorio, A. Martini, N. Wulffraat, N. Ruperto on behalf of PRINTO. *Clinica Pediatrica e Reumatologia – PRINTO, Istituto Giannina Gaslini, GENOA, Italy*

**Background:** Pharmachild is a pharmacovigilance registry on children with JIA treated mainly with biologics±methotrexate (MTX). Little evidence exists in literature about the role of JIA or its immunosuppressive therapy in determining infections, especially caused by opportunistic pathogens.

**Objectives:** To provide an update on opportunistic infections (OI) revised by an independent Safety Adjudication Committee (SAC) (3 paediatric rheumatologists and 2 paediatric infectious disease specialists).

**Methods:** The participating centres were asked to report all infections encountered by their JIA patients. PRINTO and the medical monitor (MM) classified events based on MedDRA dictionary. Moderate/serious/severe/very severe infections were then revised blindly by the SAC, who was asked to answer 6 questions. The events with consensus of at least 3/5 experts on the first 3 questions ('Is this an infection?', 'Is it common?', 'Is it opportunistic?') were retained for the analysis. With referral to the recommendations by Withrop *et al.*<sup>1</sup>, for the first time a list of OIs in children with JIA on immunosuppressive therapy was elaborated and approved by consensus, through three Delphi steps. Finally, we compared the OI list defined by the SAC to the list of OI approved by the specialists.

**Results:** A total of 772 safety events related to 634 patients were submitted to the SAC. 689 (89.2%) events received consensus among the experts on the 3 questions and, of these, 682 (99.0%) were considered as infections, corresponding to 153 different Preferred Terms (PT), according to MedDRA dictionary. Among the 682 infections, 603 (88.4%) were defined by the experts as common and 119 (17.4%) as opportunistic. For 92 (60%) of the 153 PT, the MM and SAC used the same PT, while the remaining 40% was adjudicated by a third examiner, who analysed again the case reports and assigned the PT which was the most appropriate taking into account the experts' opinion. Among the final number of infections emerged that herpes viral, respiratory and EBV infections were the most frequent (Table). Analysing the infections by PT (n=149), the experts adjudicated: 22 as OI, 119 as not OI, 8 discordant. Comparing the experts' adjudication with the approved list of OI by PT, there was full agreement for the 22 PT classified as OI, while 19/117 (16.2%) PT resulted in the list, but were not classified as OI by the experts.

Abstract SAT0386 – Table 1. The most frequent HLT for the 682 infections with agreement of at least 3/5 experts on the first questions. (N: number of infections)

HLT	N	%
Herpes viral infections	265	38.9
Lower respiratory tract and lung infections	49	7.2
Upper respiratory tract infections	44	6.5
Epstein-Barr viral infections	38	5.6
Abdominal and gastrointestinal infections	32	4.7
Tuberculous infections	29	4.3
Bacterial infections NEC	27	4
Infections NEC	19	2.8
Ear infections	18	2.6
Candida infections	17	2.5
Influenza viral infections	14	2.1
Streptococcal infections	14	2.1
Salmonella infections	9	1.3
Urinary tract infections	9	1.3
Cytomegaloviral infections	8	1.2
Molluscum contagiosum viral infections	7	1
Papilloma viral infections	7	1
Sepsis, bacteraemia, viraemia and fungaemia	7	1
Campylobacter infections	5	0.7
Staphylococcal infections	5	0.7
Viral infections NEC	5	0.7
Escherichia infections	4	0.6
Pneumocystis infections	4	0.6
Skin structures and soft tissue infections	4	0.6

**Conclusions:** Our analysis showed a significant number of OI in JIA patients on immunosuppressants and provided an approved document stating the most frequent OI in children with JIA. The most frequent opportunistic pathogens resulted herpes virus, excluding varicella, and mycobacteria, but the list of definite and probable OIs needs to be validated/revised with the analysis of future datasets.

SAT0387

**DESCRIPTIVE ANALYSIS OF LEISHMANIASIS CASES IN THE FUENLABRADA OUTBREAK (SPAIN) ASSOCIATED WITH THE USE OF BIOLOGICAL THERAPY**

M.P.M. Ahijado Guzmán<sup>1</sup>, R.M. Veiga Cabello<sup>2</sup>, M. Cantalejo Moreira<sup>1</sup>, J. Ruiz Ruiz<sup>3</sup>, A. Zapatero Gaviria<sup>3</sup>, L. Cebrian Méndez<sup>4</sup>. <sup>1</sup>Rheumatology Service, Htal Universitario de Fuenlabrada; <sup>2</sup>Rheumatology Service, Htal Central de la Defensa; <sup>3</sup>Internal medicine service, Htal Universitario de Fuenlabrada; <sup>4</sup>Rheumatology Service, Htal Universitario Infanta Leonor, Madrid, Spain

**Background:** Protozoan parasites of the genus Leishmania can cause opportunistic infections in patients using anti-tumour necrosis factor (anti-TNF) agents, and some authors recommend serological tests for leishmaniasis before using them. An outbreak of cutaneous and visceral leishmaniasis (CL,VL) occurred in the Fuenlabrada area (Spain) in 2010–2012. Some patients were on anti-TNF treatment.

**Objectives:** We aimed to explore leishmaniasis related to biological therapies in the literature, and to obtain data on leishmaniasis cases in patients using anti-TNFs referred to our Department of Infectious Diseases

**Methods:** Literature search of leishmaniasis cases in patients using biological therapies, and to realise descriptive analysis of the clinical features of patients treated with anti-TNFs in our outbreak.

**Results:** Cases detected in the literature, included our cases, are listed in table 1. In our outbreak of Leishmaniasis, 127 VL and 194 CL cases were detected. Six patients were using anti-TNFs: 2 presented with VL and were using etanercept (33.3%) and 4 using other anti-TNFs had CL (66.6%). (table 2) These results do not coincide with the total data (table 1): CL 55.2%, VL 44.8%, 17 ADA (44.7%), 16 IFM (42.1%), 4 ETN (10.5%), 1 CTZ (2.7%). There are not more cases described with another biologic therapies at the present time.

Abstract SAT0387 – Table 1

Pathology	Cutaneous Leishmaniasis	Visceral leishmaniasis
Rheumatoid Arthritis	4 ADA, 2 IFM, 1 CTZ	4 ADA, 4 IFM, 2 ETN
Psoaric Arthritis	4 ADA, 1 IFM	1 ADA, 2 ETN
Ankylosing spondylitis	3 IFM, 3 ADA	2 IFM
Undifferentiated Arthritis		1 IFM
Giant cell arteritis		1 IFM
Psoaric	1 ADA, 2 IFM	

Table 2

Hospital	Sex	Age	Condition	Anti-TNF	CL/VL	Other treatment	Clinical details
HUIL	M	47	RA	CTZ	CL	MTX, folate acid.	Prior anti-TNF agents: -
HUP	M	54	PSA	ETH	VL	MTX, SSZ (prior discontinued)	- Infliximab (secondary loss of efficacy)
HUP	F	51	PSA	ADA	CL	Prior: EFA, ETH, MTX, SSZ (prior discontinued)	Prior anti-TNF agents: EFA, ETH (diverse event)
HUP	F	54	RA	ADA	CL	MTX (discontinued)	Non-healing granulomatous disease
HUP	M	32	PSO (not rheum.)	IFM	CL	MTX, CSA, 4-cortem	
HUP	F	55	RA	ETH	VL	MTX, FRD	ETH and MTX discontinued 1 month before myelodysplasia diagnosis

HTL: Hospital Universitario; HUP: Hospital Universitario de Fuenlabrada; RA: Rheumatoid arthritis; CL: cutaneous leishmaniasis; VL: Visceral leishmaniasis; PSA: Psoriasis; ADA: adalimumab; CTZ: etanercept; EFA: efalizumab; ETH: etanercept; MTX: methotrexate; FRD: granulomatous fistulizing dermatitis; CSA: Cyclosporine A

**Conclusions:** This preliminary detection of leishmaniasis in patients using anti-TNFs is aimed at examining the safety of TNFα inhibitors in areas where Leishmania is endemic. This is a small series, but the largest described to date. Our preliminary results suggest that the use of either TNFα receptor or other anti-TNFs has the same probability of triggering the disease but etanercept seems to be associated with fewer, although more severe, cases of VL. Nevertheless, adding all the cases, Table number 1, ADA e IFM are the 86.8% of the Leishmaniasis, but perhaps will be due to this therapies are combined and of the most prevalent use. On the other hand, no leishmaniasis cases related to IBD treatment have been described in the literature, suggesting possible involvement of therapies concomitant with the use of anti-TNF with MTX. We detected 3 additional cases of VL and 1 CL using MTX without anti-TNFs. Serological tests for leishmaniasis before using anti-TNFs might not be useful.

### FACTORS ASSOCIATED WITH THE PERSISTENCE OF ARTICULAR SYMPTOMS IN PATIENTS WITH CHIKUNGUNYA FEVER – CHIKBRASIL COHORT

C. Marques<sup>1</sup>, A. Duarte<sup>1</sup>, A. Dantas<sup>1</sup>, A. Ranzolin<sup>1</sup>, N. Cavalcanti<sup>1</sup>, M. Medeiros<sup>2</sup>, M. Bezerra<sup>2</sup>, V. Marques<sup>2</sup>, L. Rocha Jr<sup>3</sup>, P. Melo<sup>3</sup>, L. Valadares<sup>4</sup>, C. da Fonte<sup>4</sup>, E. Freire<sup>5</sup>, A.K. Melo<sup>5</sup>, R.A. Ocea<sup>6</sup>. <sup>1</sup>Internal Medicine, Universidade Federal de Pernambuco, Recife; <sup>2</sup>Rheumatology, Universidade Federal do Ceará, Fortaleza; <sup>3</sup>Internal Medicine, Instituto de Medicina Integral Professor Fernando Figueira – IMIP; <sup>4</sup>Internal Medicine, Hospital Getúlio Vargas, Recife; <sup>5</sup>Internal Medicine, Universidade Federal da Paraíba, João Pessoa; <sup>6</sup>Internal Medicine, Universidade Federal de Sergipe, Aracaju, Brazil

**Background:** Chikungunya Fever (CHIK) may evolve chronically with joint impairment, often disabling, which leads to a functional and quality of life impact. The CHIK outbreak in Brazil began in 2015, reaching its peak in 2016, particularly in the Northeast of the country, with 2 35 136 reported cases. Since this is the first epidemic of CHIK in Brazil, data on persistent post-acute joint disease are scarce, and this knowledge is of fundamental importance in defining the long-term impact of the disease.

**Objectives:** To evaluate factors associated with persistence of the joint symptoms in CHIK patients.

**Methods:** The CHIKBRASIL cohort is a prospective, multicenter, observational study, conducted in six research rheumatology centres from the Northeast of Brazil, and has enrolled CHIK patients with joint manifestations since April 2016. Data from 207 patients followed up to December 2017 were analysed.

**Results:** The mean age was 54.7 years, most female (90.3%); 39.1% of the patients had a diagnosis of previous rheumatic disease (49.4% osteoarthritis). The most frequent initial clinical manifestations were arthralgia (98.1%), fever (95.6%), morning stiffness (92.3%) and arthritis (88.9%). The first evaluation with the rheumatologist occurred at a median time of 12 weeks after the onset of symptoms; at this time the median PGA of disease by the patient was 7 and by the physician was 6; the median number of painful joints was 8 and of swollen joints was 3% and 75.5% of the patients had arthritis. After a median follow-up time of 37 weeks, there was complete improvement of joint symptoms in 21.7% and 18.9% of cases reported little or no improvement. The persistence of arthralgia was reported by 76.7% and arthritis by 28.1% of the patients. A significant association was found between the persistence of arthritis and the physician's general VAS (p=0.02), number of painful (p=0.002) and swollen (p=0.001) joints, besides knees (p=0.009), proximal interphalangeal (p=0.07), metacarpophalangeal (p=0.022), elbow (p=0.026) and wrist oedema (p=0.003) at the first consultation). With regard to the persistence of joint pain, associations were found with a higher initial morning stiffness time (p=0.011), shoulder tendinopathy (p=0.019) and tarsal pain. The factors associated with no complete improvement after the follow-up period were tarsal pain (0.021) and shoulder tendinopathy.

**Conclusions:** In the Brazilian CHIK patients, the percentage of persistence of joint manifestations is high after 24 weeks, with a considerable number of patients maintaining arthritis, similar to other countries in Latin America.<sup>2</sup> Significant associated factors were more severe initial symptoms, polyarthritis, polyarthralgia, shoulder tendinopathy and tarsal pain.

### MRI PREDICTIVE FACTORS FOR POSITIVE CT-GUIDED BIOPSY IN SUSPECTED SEPTIC SPONDYLODISCITIS

E. Chotard<sup>1</sup>, H. Jacquier<sup>2</sup>, P. Rchette<sup>3</sup>, C. Rioux<sup>4</sup>, V. Joly<sup>4</sup>, E. Palazzo<sup>1</sup>, M. Forien<sup>1</sup>, G. Jelin<sup>1</sup>, Y. Yazdanpanah<sup>4</sup>, P. Dieudé<sup>1</sup>, S. Ottaviani<sup>1</sup>. <sup>1</sup>Service de Rhumatologie, Hôpital Bichat; <sup>2</sup>Service de Microbiologie, Hôpital Lariboisière; <sup>3</sup>Service de Rhumatologie, Hôpital Lariboisière; <sup>4</sup>Service de Maladies infectieuses et tropicales, Hôpital Bichat, PARIS, France

**Background:** Septic spondylodiscitis is an infection involving intervertebral disc and adjacent vertebral endplates that could lead to neurological complications. Magnetic resonance imaging (MRI) is the main imaging modality to suspect spondylodiscitis. However, MRI features predictive for septic spondylodiscitis are still lacking.

**Objectives:** To assess the MRI features associated with microbial pathogen detection by CT-guided biopsy among patients with suspected septic spondylodiscitis.

**Methods:** Between May 2007 and July 2017, we retrospectively analysed patients who underwent MRI and CT-guided biopsy for suspicion of septic spondylodiscitis. Baseline clinical and biological characteristics were collected. MRIs were analysed by one physician blinded to clinical data. The following MRI features were assessed when available: oedema or contrast-enhancement of intervertebral disk, adjacent vertebrae, epidural and paravertebral space, presence of abscess and paravertebral oedema size. A positive biopsy was defined by pathogen identification on culture or by direct microscopy examination.

**Results:** Fifty-one patients (54.9% of males, mean  $\pm$ SD age of 59.2 $\pm$ 19.1 years) were analysed. Lumbar spine (n=38) was the most affected site. A total of 26 (51%) patients had a CT-guided biopsy positive for a bacterial pathogen, mainly *mycobacterium tuberculosis* (n=7) and *staphylococcus aureus* (n=7). Disc size reduction, more than 50% of endplate oedema, loss of intradiscal cleft and abscess were the MRI findings associated with detection of bacterial pathogen by biopsy with a frequency of 100%, 92%, 81% and 50%, respectively. Size of paravertebral oedema was statistically higher in positive CT-guided biopsy than those negative (20.5 $\pm$ 12.6 vs. 11.0 $\pm$ 9.8 mm, p=0.004). The highest specific MRI finding for bacterial pathogen detection was the presence of paravertebral abscess (80%).

**Abstract SAT0389 – Table 1.** Characteristics of the patients (n=51)

Male sex, n (%)	28 (54.9)
Age, mean $\pm$ SD years	59.2 $\pm$ 19.13
Symptoms duration, mean $\pm$ SD days	91.7 $\pm$ 86.58
Fever, n (%)	12 (23.5)
Altered general health status, n (%)	21 (41.2)
Back pain, n (%)	45 (88.2)
Positive blood culture, n (%)	10 (19.6)
C-reactive protein, mean $\pm$ SD mg/L	79.6 $\pm$ 79.0
Neurological complications, n (%)	13 (25.5)

**Abstract SAT0389 – Table 2.** MRI features according to bacterial pathogen detection by CT-biopsy

	Positive CT-biopsy (n=26)	Negative CT-biopsy (n=25)	p
Endplate oedema, n (%)	26 (100)	24 (96)	0.98
>50% of endplate oedema, n (%)	24 (92)	17 (68)	0.029
Disc oedema (n=45) n (%)	25 (96.2)	20 (80)	0.145
Loss of intradiscal cleft (n=30) n (%)	21 (80.8)	9 (36)	0.001
Epiduritis (n=30) n (%)	19 (73.1)	11 (44)	0.067
Paravertebral oedema (n=46) n (%)	23 (88.5)	23 (92)	0.317
Paravertebral infiltrate size, mean $\pm$ SD mm	20.5 $\pm$ 12.6	11.0 $\pm$ 9.8	0.004
Abscess (n=17) n (%)	13 (50)	4 (16)	0.025
Endplate erosion (n=40) n (%)	23 (88.5)	17 (68)	0.528
Disc size reduction (n=47) n (%)	26 (100)	21 (84)	0.034

**Conclusions:** Our study showed that loss of intradiscal cleft, abscess and a large endplate oedema were the best predictive factors for a positive CT-guided biopsy. Size of paravertebral oedema is also associated with detection of bacterial pathogen. Physician must be aware of these MRI findings to better determine which patients should have a CT-guided biopsy.

### CLINICAL SPECTRUM OF CHIKUNGUNYA EPIDEMIC-OBSERVATIONAL STUDY FROM A TERTIARY REFERRAL CENTRE IN CENTRAL INDIA

A. Pandey<sup>1</sup>, V. Prakash<sup>2</sup>, M. Pandey<sup>3</sup>. <sup>1</sup>Rheumatology, Apollo hospitals Indore; <sup>2</sup>Internal Medicine, MGMMC; <sup>3</sup>Oral medicine and Radiology, My Dentist Indore, Indore, India

**Background:** Chikungunya virus is an alphavirus, family Togaviridae. Chikungunya fever is a mosquito born disease transmitted to humans by the bite of infected *Aedes aegypti* mosquitoes. An outbreak of chikungunya virus is currently ongoing in many Asian countries since January 2005. The recent outbreak and epidemic of Chikungunya fever in our state reflect the survival capability and tenacity of mosquitoes that continues to be man's biggest foes. An Observational study was conducted to evaluate epidemiological, virological and clinical features of chikungunya fever in patients presenting with acute febrile illness in our state of madhya pradesh.

**Objectives:** To observe the clinical features and laboratory parameters of patients coming with Chikungunya coming to our referral setup during the three months of epidemic presenting from 1 st July to 30th September 2017.

**Methods:** We included all patients (n=325) presenting to us from age 16 years with acute history (<7 days) of fever with joints pain. They were assessed for demographic characteristics, pattern of joints involvement, systemic manifestations, lab parameters, and chikungunya virus positivity. All these parameters were observed according to age and sex and both clinical as well as laboratory markers were studied. We excluded 29 patients, twenty one had past history of inflammatory joint pain and rest had positive virology for dengue virus.

**Results:** We included 325 patients in which Males (M) were 140 and Females (F) were 185, F:M ratio of 1:0.75). The distribution of patients according to age was quite similar across all age groups. Small joints involvement in total of 287 patients (M:40.4%, F:59.6%), axial involvement in 219 patients (M:36.1% and F:67.6%), knee joint involvement in 285 patients (M:41.1% and F:58.9%), ankle pain in 285 patients (M:42.8% and F:57.2%), early morning stiffness was seen in 308 patients (M:44.8% and F:55.19%), eyes involvement in 53 patients (M:35.8% and F:64.2%), Neurological manifestations in 134 patients (M:43.3% and F:56.7%), stomatitis and oral ulcers in 85 patients (M:45.9% and F:54.1%), retrobulbar pain occurred in 73 patients (M:45.2% and F:54.8%), rashes were seen in 47 patients (M:59.6% and F:40.4%). Forty two patients (12.9%) had history of Diabetes (F:73% and M:26%) and 31 patients (9.5%) were hypothyroid with female predominant (100%). Urea and creatinine was also raised (n=18). Rheumatoid factor was positive in 19 patients (M:42.1% and F:57.9%). IgM Chikungunya was positive in 202 patients (M:46.04% and F:53.96%), and out of those 65 patients in which it was negative, we did RT-PCR in 18 patients due to unaffordability being a major factor and we found that RT-PCR came out positive in 15 patients. The mean ESR in males was 41.76±19.98, in females it was 53.66±24.66, mean CRP in males was 29.84±19.61 and in females it was 40.74±25.94.

**Conclusions:** We conclude that Chikungunya is a multisystem disease affecting both genders. In our setup, we observed it affected females more and seropositivity for chikungunya was seen in around half of the patients presenting with signs and symptoms. PCR test is more reliable for confirmation. Skin rashes with neurological symptoms, severe pain causing disability and dependence on others for personal care were main complaints. No mortality was reported in our study.

### SAT0391 MUSCULOSKELETAL MANIFESTATIONS OF CHIKUNGUNYA FEVER IN ELDERLY PATIENTS – CHIKBRASIL COHORT

A. Dantas<sup>1</sup>, A. Duarte<sup>1</sup>, C. Marques<sup>1</sup>, A. Ranzolin<sup>1</sup>, N. Cavalcanti<sup>1</sup>, M. Medeiros<sup>2</sup>, M. Bezerra<sup>2</sup>, V. Marques<sup>2</sup>, L. Rocha Jr<sup>3</sup>, P. Melo<sup>3</sup>, L. Valadares<sup>4</sup>, C. da Fonte<sup>4</sup>, E. Freire<sup>5</sup>, A.K. Melo<sup>5</sup>, R.A. Ocea<sup>6</sup>. <sup>1</sup>Internal Medicine, Universidade Federal de Pernambuco, Recife; <sup>2</sup>Rheumatology, Universidade Federal do Ceará, Fortaleza; <sup>3</sup>Internal Medicine, Instituto de Medicina Integral Professor Fernando Figueira – IMIP; <sup>4</sup>Internal Medicine, Hospital Getúlio Vargas, Recife; <sup>5</sup>Internal Medicine, Universidade Federal da Paraíba, João Pessoa; <sup>6</sup>Internal Medicine, Universidade Federal de Sergipe, Aracaju, Brazil

**Background:** Elderly patients with Chikungunya virus (CHIKV) infection may exhibit atypical and more severe clinical manifestations in the acute phase,<sup>1</sup> but little is known about these patients progress in the chronic phase of the disease.

**Objectives:** To describe the chronic clinical course of CHIKV infection in Brazilian elderly patients.

**Methods:** The CHIKBRASIL is a prospective, multicenter, observational cohort, conducted in six research rheumatology centres from the Northeast of Brazil, and has enrolled CHIK patients with joint manifestations since April 2016.<sup>2</sup> Data from 353 patients followed up to December 2017 were analysed, divided into two groups: the elderly (age ≥60 years) and not elderly.

**Results:** Of the 353 cases, 124 were elderly (35,1%), mean age was 67.1 years (±5.6), 81.5% women. Patients in the elderly group had a higher frequency of comorbidities, such as systemic arterial hypertension (p<0.0001), diabetes mellitus (p<0.001) and hyperlipidemia (p=0.0003). The median time of disease was 26 weeks, most of them were in the chronic phase of the disease (61.3%). With respect to initial clinical manifestations, no significant differences were observed between the groups, except for fatigue, which occurred more often in the non-elderly group (p=0.036). In general, the elderly group presented a lower frequency of absence at work (0.000), lower limb oedema (0.006) and less prescription of methotrexate (p=0.048). In addition, it was also observed that older patients had a lower mean of the number of painful joints (10.2±1.7), but without statistical difference (p=0.0655). After a median follow-up time of 27.5 weeks, the number of patients who presented complete improvement was higher in the non-elderly group (p=0.07), but without differences between the number of tender and swollen joints, persistence of arthralgia or arthritis in the two groups. No association was observed between the presence of comorbidities and the clinical evolution of the patients.

**Conclusions:** Despite the risk of a more severe evolution at the onset of CHIKV infection, elderly patients present a similar clinical course to the non-elderly in the chronic phase, apparently with less severity. However, such group is a high-risk

population with an important number of comorbidities. In all stages of the disease, especially in the acute phase, strict clinical supervision is recommended regarding the use of drugs and increased risk of complications.

### SAT0392 THE RELEVANCE OF SERUM PROCALCITONIN QUANTIFICATION FOR DIFFERENTIAL DIAGNOSIS OF INFECTIONS AND RHEUMATIC DISEASES

A. Dilbaryan, B. Belov, G. Tarasova, D. Bukhanova, V.A. Nasonova *Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Assessment of procalcitonin (PCT) serum levels is of great interest in current rheumatology practice, due to clinical and laboratory similarity of acute systemic rheumatic diseases (RDs) and acute infectious process, and because of low diagnostic yield of conventional ESR, CRP and WBC in active RDs.

**Objectives:** To evaluate the relevance of PCT as a specific marker of generalised and local infections in patients with RDs.

**Methods:** Medical records of 134 in-hospital patients (mean age 40,6±19,5) admitted to VA Nasonova Research Institute of Rheumatology for examination and treatment were analysed in this retrospective study. Serum PCT concentration was measured using quantitative electrochemiluminescence method, Cobas E 411 analyzer (Roche, Switzerland). The infectious process was diagnosed in 75 pts, generalised – in 4, and local – in 71. Based on the severity of fever and intoxication local infections were divided into mild – 41 cases, and severe – 30 cases.

**Results:** The PCT level reached >2.0 ng/mL in 3 of 4 cases in generalised infection. In population with severe local infections (n=30) the PCT concentration exceeded the threshold and amounted to 0.60 ng/mL [0.19; 1.84], while in pts with mild infection (n=41) it was 0.13 ng/mL [0.08; 0.25] (table 1). PCT levels positively correlated with ESR, CRP, white blood cell count, and SLE activity according to SLEDAI index in this retrospective study. Maximal PCT levels were found in adult-onset Still's disease (ASD) pts with high activity of rheumatic process without underlying infection – 0.26 [0.10; 0.61] ng/mL. The test's sensitivity and specificity in generalised/severe local infections group (n=34) were 60% and 82,5%, respectively, with a threshold value of 0.4 ng/mL.

**Abstract SAT0392 – Table 1.** PCT values in different groups of patients, n (%)

PCT level, ng/mL	Generalised infection (n=4)	Local infection		No infection	
		Severe (n=30)	Mild (n=41)	Still's disease (n=6)	Totally (n=59)
≤ 0,05	-	1 (1,33)	4 (9,76)	-	12 (20,34)
0,05–0,1	-	2 (6,67)	13 (31,71)	1 (16,67)	19 (32,20)
0,1–0,25	-	5 (16,67)	13 (31,71)	2 (33,33)	16 (27,12)

Me [25-ii; 75-ii percentiles]	5,30 <sup>1,63; 9,06*</sup>	0,60 [0,19; 1,84] <sup>†</sup>	0,13 [0,08; 0,25] <sup>‡</sup>	0,26 [0,10; 0,61] <sup>§</sup>	0,09 [0,06; 0,19] <sup>¶</sup>

p < 0,05.

**Conclusions:** PCT quantification is a sensitive and specific method for differential diagnosis of serious bacterial infections in patients with different activity of systemic RD. ASD seems to be the exception, as it was associated with PCT increase in the absence any infection. Further studies are needed to determine PCT thresholds for different RDs.

**SAT0393 DEVELOPMENT OF A SCORE FOR THE DIAGNOSIS OF INFECTIOUS ARTHRITIS IN DIFFICULT TO PUNCTURE JOINTS**

C.A. Guillen-Astete, B. Blanco Cáceres. *Rheumatology Department, Ramon y Cajal University Hospital, Madrid, Spain*

**Background:** In previous studies, we have demonstrated the benefit of the determination of serum procalcitonin in the diagnostic discrimination between gouty and an infectious monoarthritis. On the other hand, the utility of this analyte has been suggested in the diagnostic study of monoarthritis in which the obtention of joint fluid for lab analysis is difficult or impossible in the immediate term.

**Objectives:** The objective of this study is to perform the validation of a score to determine the diagnosis of Native Joint Septic Arthritis (ASAN) in difficult to puncture joints.

**Methods:** A logistic regression study was conducted using 37 cases of ASAN (sternoclavicular, acromioclavicular, coxofemoral, intratarsal, and metatarsophalangeal) and 160 of non-infectious arthritis diagnosed as such between 2013 and 2016 by microbiological criteria, the presence of crystals or absence of both situations. The explanatory variables were: Three age strata, three CRP levels, three strata of PCT figure, immunomodulation/immunosuppression condition, two strata of time of evolution, the presence of fever and neutrophilia. After a forward modelling, a test validation study was performed using the modelling coefficients as a weight reference for each value of the score.

**Results:** The only variables that overcame the forward modelling were PCT, temperature, immunosuppression and time of evolution. Using the reference coefficients (table 1), validation tests were performed by means of the ROC curve. According to the presented curve, a sensitivity of 86.6% and specificity of 95.8% is reached if the total score reaches or exceeds 5pts (Strata of PCT 6, 4 and 2, and 2 points by any of the remaining three considerations). The total area under the curve was 0.926.

**Abstract SAT0393 – Table 1.** Results of the multivariable logistic regression backward modelling.

Variable	Coef.	E.E.	Wald	p-value	R
PCT > 1.4ng/ml.	5.8412	1.0231	32.5971	<0.0001	0.4010
PCT <1.0 – 1.4ng/ml.>	5.2632	1.9117	7.5798	0.0059	0.1712
PCT <0.5 – 1.0ng/ml.>	4.6626	1.7378	7.1985	0.0073	0.1653
Body temp > 38.0°C	2.1119	0.8883	5.6524	0.0174	0.1385
Immunomodulation	1.9623	0.9473	4.2911	0.0383	0.1097
Time of onset <72h	1.6565	0.7649	4.6897	0.0303	0.1189

**Conclusions:** Taking into account the high specificity achieved, we the authors propose the use of the present score to exclude ASAN in situations in which access to synovial fluid is difficult or technically not feasible.

**SAT0394 IMMUNOGENICITY AND SAFETY OF 23-VALENT PNEUMOCOCCAL VACCINE IN RA PATIENTS: RESULTS OF A 4- YEAR FOLLOW UP STUDY**

D. Bukhanova, M. Sergeeva, B. Belov, G. Tarasova, M. Cherkasova, Y. Muraviev, G. Lukina, N. Demidova. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Comorbid infections have significant impact on morbidity and mortality, especially in autoimmune diseases. Prevention of infection is an integral part of supervision of these patients.

**Objectives:** To investigate immunogenicity and safety of 23-valent polysaccharide pneumococcal vaccine in patients with rheumatoid arthritis (RA) treated with diseases modifying anti rheumatic drugs (DMARDs) and biologic diseases modifying anti rheumatic drugs (bDMARDs).

**Methods:** The study included 110 patients (females–81 (73.6%), males–29 (26.4%), aged 23–76 y), 79 RA pts and 31 controls with  $\geq 2$  recent episodes of upper respiratory tract infections (bronchitis, pneumonia). 52 RA pts were treated with methotrexate (MT), 14 – with leflunomide (Lef), 13– with TNF-  $\alpha$  inhibitors +MT. One dose (0,5 ml) of 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously without discontinuing MT/Lef or 28–30 days prior to initiation of TNF-  $\alpha$  inhibitors. Control visits were scheduled as follows: at baseline (Visit I), and in 1, 3, and 12 months after immunisation. 39 out of 110 pts were followed for 24 months, 23 pts – for 36 months, and 16 pts – for 48 months. Standard clinical examination and lab tests were performed at each visit. Levels of serum antibodies (AB) to Pneumococcal capsular polysaccharide were measured with VacciZyme™ PCP IgG 2 panels (The Binding Site Group Ltd, Birmingham, UK). Coefficient of post-immunisation response (CPR) was determined for each patient as the ratio of AB levels at Visits II, III, IV, V, VI and VII to AB level at Visit I.

**Results:** There were no documented clinical or radiological symptoms of bacterial pneumonia in a single patient during the FUP. CPR dynamics in RA pts on different therapeutic regimens and in the controls is shown in the table 1.

**Abstract SAT0394 – Table 1.** CPR dynamics in RA pts and the controls during 1-year FUP, M $\pm$  $\sigma$ .

	Visit II (1 month)	Visit IV (12 month)	Visit V (24 month)	Visit VI (36 month)	Visit VII (48 month)
RA patients	2,33* [1,6;3,8]	2,64* [2,03;6,39]	3,07* [1,56;6,18]	1029 [0,74;1,32]	2,08* [0,69;3,80]

\*p<0,05

Pronounced positive immune reaction to the study vaccine was documented in all RA patients on different therapeutic regimens as significant CPR incremental growth. The proportion of responders to the vaccine reached 61% among RA pts. *Significant* decrease of RA activity according to DAS28 scores in RA pts (4,32 and 3,31 at Visits I and IV, respectively, p<0,001) demonstrates absence of any negative effect of vaccination on disease activity. There was a trend to weakening of post-vaccination response in 3 years, although significantly high level of post-immunisation response still persisted after 4 years of FUP. Not a single case of pneumococcal infection was ever documented during 4 years FUP, although one case of interstitial viral pneumonia was registered in 6 month after immunisation. Not a single vaccination-related RA exacerbation episode was documented during the FUP.

**Conclusions:** Therefore obtained results are indicative of sufficient immunogenicity, good safety and efficacy of 23-valent pneumococcal vaccine in RA pts on different therapeutic regimens.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.1586

**SAT0395 ASSESSMENT OF EFFICACY AND SAFETY OF A TRIVALENT SPLIT-VIRUS INFLUENZA VACCINE IN PATIENTS WITH RHEUMATIC DISEASES**

D. Bukhanova, B. Belov, G. Trasova, S. Erdes, T. Dubinina, G. Lukina, N. Demidova, A. Volkov, N. Yudkina. *V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** In current rheumatology practice concurrent infections produce significant negative impact on patients' morbidity, mortality and quality of life, especially in cases of systemic connective tissue diseases. Based on WHO estimations the annual incidence of influenza in adult population amounts to 5%–10% worldwide. Influenza can lead to hospitalisation (3 to 5 million cases per year) and even death (250–500 thousand cases per year). Flu and its complications rates are higher in patients with rheumatic diseases (RD) as compared to general population. Therefore, prevention of influenza should be viewed as integral part of RD population management.

**Objectives:** To study the safety and efficacy of inactivated split-virus influenza vaccine in patients with rheumatoid arthritis (RA), ankylosing spondylitis (AS), and systemic sclerosis (SS) treated with diseases modifying anti rheumatic drugs (DMARDs) and biologic diseases modifying anti rheumatic drugs (bDMARDs).

**Methods:** 133 subjects (97 females and 36 males, aged 22–82 y) with recent acute respiratory viral infections (ARVI) and flu episodes in medical records were enrolled, including 52 RA patients, 34 AS patients, 7 SS patients and 40 healthy volunteers as the control group.

39 RA pts received methotrexate (MTX), 12 – TNF $\alpha$  inhibitors+MTX, 8 – leflunomide, 2 – abatacept, 2 – sulfasalazine, 1 – tofacitinib +MTX. 19 AS patients were treated with nonsteroidal anti-inflammatory drugs (NSAIDs), 15 –with TNF $\alpha$  inhibitors. The RD duration ranged from 2 months to 46 years. All participants were injected subcutaneously with one dose (0.5 ml) of the "Vaxigrip" vaccine containing the actual influenza virus strains with ongoing therapy. The control visits were scheduled at baseline, and in 1, 3 and 6 months after vaccination (Visits 0, 1, 2 and 3, respectively). Standard clinical and laboratory tests were performed during each visit.

**Results:** Vaccine tolerability was good in 103 participants (77.4%). Post-vaccination pain, swelling and redness of the skin up to 2 cm in diameter were registered in 20 cases (15%), low-grade fever, myalgia and malaise were documented in 10 cases (7.5%). There was no causal relationship between these reactions and principal therapy, therefore, no modifications of therapeutic regimens were required, and complete resolution occurred within 24 hours without additional interventions. No RD exacerbations or emergence of *de novo* autoimmune disorders were observed during the FUP. At baseline mean pts' DAS28 and BASDAI scores were 3.56 and 3.85, improving up to 1.99 and 3,09, respectively, 6 mo post-vaccination. For the entire FUP there were no cases of influenza or influenza-like illness registered.

**Conclusions:** Therefore, the preliminary results show good tolerability and efficacy of inactivated split-virus influenza vaccine in RA, AS, and SS patients. Future studies on larger patients' populations are warranted for more complete evaluation of vaccine safety and efficacy.

**Disclosure of Interest:** None declared

**DOI:** 10.1136/annrheumdis-2018-eular.1500

### SAT0396 THE RISK FACTORS OF SERIOUS INFECTION IN PATIENTS WITH RHEUMATOID ARTHRITIS

E. Hasegawa<sup>1,2</sup>, D. Kobayashi<sup>1</sup>, S. Ito<sup>1</sup>, I. Narita<sup>2</sup>, K. Nakazono<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Niigata Rheumatic Center, Shibata; <sup>2</sup>Division of Clinical Nephrology and Rheumatology, Niigata University Graduate School of Medical and Dental Sciences, Niigata, Japan

**Background:** Although life expectancy has improved for many rheumatoid arthritis (RA) patients, serious infection is one of the major causes of mortality. Undernutrition is widely known to be a risk factor for infection; however, the association between undernutrition and infection in RA patients is not well known.

**Objectives:** The aim of this study was to identify the risk factors associated with infection requiring hospitalisation in RA patients.

**Methods:** We retrospectively analysed data obtained from 74 patients with RA (male, n=21; female, n=53; age 74.7±12.6), who were admitted to our hospital between 2016 and 2017 for infection (infection group). Among the patients who experienced multiple infections during this time, only the first infection was included in this study. We also recruited control RA patients (n=222) who were matched for age, gender and disease duration, with a match ratio of 1:3 (non-infection group). The details of the patients' infections, clinical characteristics (including nutritional conditions), and RA treatment were obtained from their clinical records. The nutritional condition was assessed based on the body mass index (BMI), serum albumin (Alb) level, total lymphocyte count (TLC), haemoglobin (Hb) level, controlling nutrition status (CONUT) score, and prognostic nutritional index (PNI). Differences between each group were compared using a nonparametric Wilcoxon's rank sum test for continuous variables and Fisher's exact test for categorical variables. Multiple regression analyses were performed to determine the factors associated with the development of serious infection. We selected seven candidate factors: Steinbrocker's classification (Stage)≥III, BMI≥18.5, CONUT score ≥5, DAS28-ESR≥3.2, use of methotrexate, use of prednisolone, use of biologics.

**Results:** The respiratory tract was the most frequent site of infection (n=33, 44.6%), followed by the urinary tract (n=14, 18.9%), skin (n=13, 17.6%), bones and joints (n=5, 6.8%), and gastrointestinal tract (n=3, 4.1%). Seven patients died during hospitalisation for infection, in spite of treatment. Relative to the non-infection group, the BMI (20.9±4.1 vs. 22.0±3.4, p=0.036), Alb (3.3±0.7 vs. 3.9±0.4 g/dL, p<0.001), TLC (1190±574 vs. 1328±526/μL, p=0.008), Hb (11.1±1.9 vs. 12.3±1.5 g/dL, p<0.001), and PNI (55.4±8.0 vs. 60.4±8.0, p<0.001) values were significantly lower, and the CONUT score (4.1±2.7 vs. 1.9±1.5, p<0.001) was significantly higher in the infection group. In addition, the DAS 28-ESR (3.5±1.2 vs. 2.9±1.1, p=0.001), dose of prednisolone (4.6±3.4 vs. 2.3±2.3, p<0.001), and rate of biologics usage (33.8 vs. 21.2%, p=0.041) were higher, while the dose of methotrexate (1.6±3.2 vs. 3.2±4.0, p=0.002) was lower in the infection group. The multiple regression analysis revealed that the CONUT score (odds ratio [OR], 62.9; 95% credible interval [CrI], 7.9 to 500.0), use of prednisolone (OR, 6.7; CrI, 2.2 to 20.7), and use of biologics (OR, 3.9; CrI, 1.7 to 9.3) were significant risk factors for serious infection.

**Conclusions:** Multiple factors were found to be associated with infection in RA patients. The improvement of nutrition may have a beneficial effect with regard to the prevention of infection during the care of RA patients.

**Disclosure of Interest:** None declared

### SAT0397 SAFETY AND IMMUNOGENICITY OF 23-VALENT PNEUMOCOCCAL VACCINE IN SLE PATIENTS

G. Tarasova, B. Belov, D. Bukhanova, S. Soloviev, E. Aseeva, T. Popkova, M. Cherkasova. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** Immunisation with pneumococcal vaccine is the key prophylactic measure to protect patients with systemic lupus erythematosus (SLE) against severe respiratory infections.

**Objectives:** To study the efficacy and immunogenicity of 23-valent polysaccharide pneumococcal vaccine in SLE pts.

**Methods:** The study included 30 SLE pts, 27 females, 3 males, aged 19–62 y, the follow up (FUP) was 12 mo. Disease activity at vaccination was high – in 1 patient, moderate – in 4 pts, and low – in 20 pts; drug-induced remission – in 5. Therapy: 29 pts were on glucocorticoids (GCs), 23 – on hydroxychloroquine, 14 – on cytostatic (CS) drugs, 9 – on biologic diseases modifying anti rheumatic drugs (bDMARDs): 4 – on rituximab, and 5 – on belimumab. One dose (0,5 mL) of 23-valent polysaccharide pneumococcal vaccine was administered subcutaneously. Standard clinical examination and lab tests were performed, and vaccine immunogenicity was determined by measuring antibody (AB) levels against *Streptococcus pneumoniae* (VaccZyme™ PCP IG 2 panels (The Binding Site Ltd, Birmingham, UK)) at control visits.

**Results:** Local injection site reactions of varying intensity were registered in 19 (63,3%) pts, lasting from 2 to 7 days. One patient developed an immediate hypersensitivity reaction – the Arthus phenomenon-type. All accompanying symptoms completely resolved within 7 days with the intake of antihistaminic drug and local use of GCs. Mean (Me (25,75 percentiles)) SLEDAI scores for SLE activity prior to and 1 year after vaccination did not differ significantly: 2 (2;4) and 2 (0;4), respectively. Mean values of SLE immunological activity parameters (a-dsDNA, C3 and C4 components of the complement) also did not differ significantly, with a visible trend for a-dsDNA reduction and complement components increase: C3 (0,86 (0,81;1,07) and 0,93 (0,86;1,05)); C4 (0,16 (0,13;0,19) and 0,18 (0,13;0,19), respectively. (table 1)

**Abstract SAT0397 – Table 1.** Dynamics of immunological activity parameters (Me) and SLE SLEDAI (Me) scores prior to and after the vaccination (12 mo).

FUP	A-dsDNA <20	C3 0,9–1,8	C4 0,1–0,4	SLEDAI
Visit 1 (baseline)	21,3 (4,7; 48,4)	0,86 (0,81;1,07)	0,16 (0,13;0,19)	2 (2;4)
Visit 2 (1 mo)	25,0 (4,7; 48,4)	1,1 (0,9; 1,2)	0,17 (0,13; 0,19)	2 (0;4)
Visit 3 (3 mo)	20,9 (8,2; 34,5)	0,91 (0,8; 1,0)	0,17 (0,14; 0,2)	2 (2;4)
Visit 4 (12 mo)	18,7 (8,7;68,7)	0,93 (0,86;1,05)	0,18 (0,12;0,19)	2 (0;4)

There were no SLE exacerbations with definite casual relationship with the vaccination. Significant increase (≥2 fold vs the baseline values) of AB levels against *S.pneumoniae* polysaccharides was documented in 25 (83,3%) pts 1 mo post-vaccination. High AB titers still persisted 1 year post-vaccination in 19 (63,3%) pts (responders). More than 2-fold increase of anti-*S.pneumoniae* AB concentrations was not maintained by the end of FUP (12 mo) in 11 (36,7%) «non-responders». 7 (63,6%) out of them were treated with GEBA (4-rituximab, 3 – belimumab). 2 (10,5%) pts out of 19 «responders» were also treated with GEBA (belimumab). The difference was statistically significant, p=0008.

**Conclusions:** Obtained results demonstrate the safety and immunogenicity of 23-valent pneumococcal vaccine in SLE patients during one year FUP. The negative effect of bDMARDs on post-vaccination response was noticed. Future studies of vaccine efficacy and safety are needed in larger SLE populations.

### SAT0398 SPINE IMMOBILISATION AND NEUROLOGICAL COMPLICATIONS IN VERTEBRAL OSTEOMYELITIS: RESULTS FROM A MULTICENTER PROSPECTIVE STUDY

G. Bart<sup>1</sup>, G. Coiffier<sup>2</sup>, O. Merot<sup>3</sup>, M. Couderc<sup>4</sup>, E. Hoppe<sup>5</sup>, G. Cormier<sup>6</sup>, J.-M. Ziza<sup>7</sup>, B. Le Goff<sup>1</sup>. <sup>1</sup>CHU Nantes, Nantes; <sup>2</sup>CHU Rennes, Rennes; <sup>3</sup>Saint Nazaire Hospital, Saint Nazaire; <sup>4</sup>CHU Clermont, Clermont-Ferrand; <sup>5</sup>CHU Angers, Angers; <sup>6</sup>CHD Vendée, La Roche sur Yon; <sup>7</sup>GHDCCS, Paris, France

**Background:** Neurological complications of vertebral osteomyelitis (VO) can be serious. In a previous work,<sup>1</sup> we showed that they occur in up to 40% of the

patients. Bed rest and spine immobilisation by bracing is prescribed to decrease pain but also to prevent those complications. There is currently no consensus about the best immobilisation protocol to follow in VO. French guidelines recommend bracing for all patients whereas recently published American recommendations did not even mention spine immobilisation.

**Objectives:** To describe the type and duration of prescription of spine immobilisation during VO.

**Methods:** A prospective multicenter study was performed in 7 French centres. All patients with VO were followed prospectively: neurological complications, imaging findings, type and duration of immobilisation were reported. We present here the data of our study after 3 months of follow-up.

**Results:** To date, 79 patients completed 3 months follow-up. Median age was 67 ±15 years old with 66% of males. Median duration of symptoms before diagnosis was 27 days, IQR. 11–40 37 patients (47%) had staphylococcal infection.

35% of the patients had an abnormal neurological exam at baseline: 18 patients (23%) had minor neurological signs (sensory loss, radiculopathy or pyramidal syndrome), and 10 (12%) had major neurological signs (motor deficit or cauda equine syndrome). During hospital stay, 5 patient developed major neurological signs (median 5 days after diagnosis) and 7 minor neurological signs (median 6 days after diagnosis). Half of the patients with abnormal neurological exam at baseline had functional sequelae at 3 months. On MRI, 17% of patients had epidural phlegmon, 20% had anterior effacement of subarachnoid space, and 16% had involvement of cervical spine. All these MRI signs were significantly associated with major neurological complications ( $p=0.004$ ,  $p=0.004$  and  $p=0.002$ , respectively).

Median duration of bed rest was 9 days (IQR 7–18). Overall, only 60% of patients have been immobilised by bracing (90% of rigid bracing). Median duration of prescription was 8 weeks, IQR. 6–12 Patients who did not receive spine immobilisation had all a lumbar involvement, a normal neurological examination at baseline. None of them developed secondary neurological complications. They were no significant difference in age (72±16 versus 65±15 years old), sex or duration of the symptoms between patients who have been immobilised or not.

**Conclusions:** Neurological complications occurred in 35% of our patients as published in previous VO cohort. Interestingly, 40% of our patients were not treated with bracing. They all had lumbar involvement and normal initial neurological examination. None of them developed secondary neurological complications. Bed rest without bracing might be the best therapeutic option for these patients, preventing the morbidity associated with bracing.

#### SAT0399 CHIKUNGUNYA FEVER IN KARACHI: CLINICAL AND LABORATORY FEATURES AND FACTORS ASSOCIATED WITH PERSISTENT ARTHRALGIA

H. Alam, T.P. Umer, L. Nazir. *Rheumatology, Liaquat National Hospital, Karachi, Pakistan*

**Background:** Chikungunya virus (CHIKV) is an alphavirus transmitted by mosquito vectors.<sup>1</sup> Acute infection lasts for 1–10 days and is characterised by abrupt onset of fever and severe arthralgia. Painful polyarthralgia is the symptom causing serious economic and social impacts on individuals and the affected communities.<sup>2</sup> In a study conducted by Schilte C et al, 60% of CHIKV-infected patients suffered from arthralgia, 36 months after acute infection.<sup>3</sup> Non-salicylate analgesics and non-steroidal anti-inflammatory drugs (NSAIDs) are most commonly used for symptomatic relief.<sup>4</sup> There is lack of local data on CHIKV and its after effects. By determining the clinical and laboratory features associated with CHIKV and persistent arthralgia, it will help us in early diagnosis, and improved outcomes in our population.

**Objectives:** To study clinical and laboratory features associated with persistent arthralgia in patients with chikungunya fever

**Methods:** This observational study was conducted at the Rheumatology Clinic of Liaquat National Hospital, Karachi. It comprised of collected data of patients who presented with arthralgias and positive chikungunya serology. Detailed history, examination and laboratory investigations were recorded in a pre-designed structured proforma and SPSS21 was used for statistical analysis.

**Results:** We had 52 patients out of which 28.8% were males and 71.2% were female, mean age being 45±5 years. Mean duration of arthralgia was 2.6 months. Pre-existing rheumatologic conditions were RA in 1.9% while SLE in 1.9% of the patients. Out of the total 9.6% were hospitalised due to complications like encephalitis, septic arthritis. Symmetrical arthralgia and asymmetrical was described

in 76.9% and 23.1% of cases respectively. Small joint involvement was in 21.2%, large joint in 20.8% while both small and large involvement was seen in 48.1% of patients. Morning stiffness of greater than ½ hour was described in 63.5% of cases. Elevated ESR, CRP was seen in 69.2% and 59.6% cases, respectively. Patients were either given NSAIDs (34.6%), steroids (57.7%), or both (7.7%). Steroid was usually given in the form of a single intra muscular methylprednisolone 120 mg dose. In total 85.7% of patients improved after receiving steroids. While in group receiving NSAIDs only, improvement was seen 7.1% of total cases, and persistent arthralgia was seen in 88.9% of same group.

**Conclusions:** Chikungunya viral arthralgia has constituted a major disease and socioeconomic burden in our society in a relatively short span of time. Studies including our show it to be a great mimicker of inflammatory arthritis, and stresses the need to differentiate it, as history, clinical examination and lab parameters show quite similarity. Prompt treatments through steroids have shown great response in symptoms.

#### SAT0400 INFECTIOUS SPONDYLODISCITIS: 7-YEAR ANALYSIS OF CLINICAL AND PROGNOSTIC VARIABLES IN A TERTIARY HOSPITAL

J. Frago<sup>1</sup>, R. Gonzalez Mazario<sup>1</sup>, E. Labrador Sanchez<sup>1</sup>, E. Grau Garcia<sup>1</sup>, K. R. Arevalo Ruales<sup>1</sup>, M. de la Rubia Navarro<sup>1</sup>, C. Alcañiz Escandell<sup>1</sup>, L. Gonzalez Puig<sup>1</sup>, J. Ivorra Cortes<sup>1,2</sup>, I. Martinez Cordellat<sup>1</sup>, I. Canovas Olmos<sup>1</sup>, C. V. Inmaculada<sup>1</sup>, C. Najera Herranz<sup>1</sup>, C. Fedec Olmos<sup>1</sup>, R. Negueroles Albuixech<sup>1</sup>, J.E. Oller Rodriguez<sup>1</sup>, F.M. Ortiz Sanjuan<sup>1</sup>, V. Fornes Ferrer<sup>3</sup>, M. Tacias Pitarch<sup>4</sup>, E. Calabuig Muñoz<sup>4</sup>, M. Salavert Lletí<sup>4</sup>, J.A. Roman Ivorra<sup>1,2</sup>. <sup>1</sup>*Rheumatology, Hospital La Fe*; <sup>2</sup>*Rheumatology, UCV Medical School*; <sup>3</sup>*Biostatistics Unit, IIS La Fe*; <sup>4</sup>*Infectious Diseases Unit, Hospital La Fe, Valencia, Spain*

**Background:** Spondylodiscitis is an infectious disease of the vertebral body and intervertebral space, the early diagnosis and treatment are essential to give the patient the best chance of a good outcome, but these are often delayed because it tends to present nonspecific manifestations.

**Objectives:** To analyse cases of Spondylodiscitis and identify poor prognosis variables.

**Methods:** A retrospective observational study, included all adult patients with confirmed infectious spondylodiscitis between January 2010 and December 2017. Demographic features, concurrent disease, clinical history, laboratory findings, microbiological diagnosis, radiological data and clinical outcome were compiled from the clinical history management software. Statistical analysis was performed with the software R (version 3.3.2).

**Results:** We included 87 patients with a mean age of 62.05 (16.94) years old. Males predominated (69%). Almost 31% patients presented of a level of immunosuppression (immunosuppression treatment, cirrhosis, HIV infection, solid organ transplantation). The average time with axial pain was 74 (87.65) days. Mean length of hospital stay was 34.24 (34.3) days and readmission rate was 34.9%. Most of patients showed high CRP levels at their admission, with an average value of 88.92 (84.58) mg/L, it was not correlated with worse prognosis. Underlying endocarditis proportion was 11.5%. Blood cultures were positive in 29 patients (33,3%), it was correlated with hospital stay ( $p=0,03$ ). 51 patients had punction-aspiration and intervertebral biopsy with microbiologic findings diagnosis in 30 patients (58.8%): 42.5% patients had an identifiable gram +bacteria (37,8% *Streptococcus* genere), 13.7% a Gram- bacteria, *Mycobacterium tuberculosis* in 8% and fungi infection (all *Candida spp.*) in 3.4%. 38% of patients showed vertebral destruction on MRI; 17.4% cord compression and developed neurological complications (8 of them paraparesis). 18.4% of patients required further surgical procedures. Furthermore, vertebral destruction was statistically correlated with epidural abscess ( $p=0,006$ ). Almost 6% of patients died in the following year after diagnostic.

**Conclusions:** Delay in diagnosis is an important issue in Spondylodiscitis patients. Higher complications rates are mainly in relation to greater vertebral destruction. Underlying infectious endocarditis was described in a small proportion of patients in contrast to other studies. Presence of epidural abscess was also

correlated with vertebral destruction, for this reason, patients with this finding should be more carefully follow-up.

#### SAT0401 RISK OF HOSPITAL ADMISSION DUE TO SEVERE INFECTION IN PATIENTS UNDER TREATMENT WITH ANTI-TNF DRUGS: DATA FROM A LOCAL REGISTRY

J. Rosas<sup>1</sup>, M. Pucciarelli<sup>2</sup>, J.M. Senabre-Gallego<sup>1</sup>, J.A. García-Gómez<sup>3</sup>, J. Ena<sup>2</sup>, G. Santos-Soler<sup>1</sup>, X. Barber<sup>3</sup>, E. Salas<sup>1</sup>, A. Pons-Bas<sup>1</sup>, C. Cano<sup>1</sup>, E. Ivars<sup>1</sup>, M. Lorente<sup>1</sup> on behalf of AIRE-MB Group. <sup>1</sup>Rheumatology Department; <sup>2</sup>Internal Medicine Department, Hospital Marina Baixa, Villajoyosa (Alicante); <sup>3</sup>COI, Miguel Hernández University, Elche, Spain

**Objectives:** To Know characteristics of patients treated with anti-TNF, who suffered infections that forced hospital admission.

**Methods:** Prospective observational study in patients treated with anti-TNF, during 1/1/2000 to 12/31/2017, followed up in the Rheumatology Section. General data of patients (age, gender), of disease (diagnosis and time of evolution, type of anti-TNF, time in anti-TNF, concomitant treatment with DMARD), regarding the presence of severe infection, defined as infection that required hospital admission (time in anti-TNF to infection, location of infection, days of admission, mantoux/IGRAS and vaccinations prior to the start anti-TNF treatment) was collected. The admission decision was made by Emergency Department of centre or Rheumatology.

**Results:** Of 442 patients with anti-TNF, 44 (9.6%) patients had at least one hospital admission due to severe infection. 59% were women, with mean age 64±16.72 years,<sup>22-88</sup> 21.25±4.02 years of disease evolution. A mantoux/IGRAS was performed prior anti-TNF. Diagnosis was: rheumatoid arthritis (RA): 25 (57%), ankylosing spondylitis (AS): 12 (27%), psoriatic arthritis (PSA): 5 (11%) and juvenile idiopathic arthritis (JIA): 2 (5%). The mean time of treatment with anti-TNF is 5.6 ±4.5 years. Adalimumab received 24 (55%) patient, infliximab 8 (18%) patients, etanercept 6 (14%) patients, golimumab 5 (11%) and 1 (2%) certolizumab.

Of the 55 confirmed infections: non-pneumonic infection in 13 (24%) patients, pneumonia: 10 (18%), septic arthritis: 6 (11%), septic shock and/or bacteremia: 6 (11%), abscess: 4 (7%), urinary infections: 4 (7%), cellulitis: 3 (5%), cutaneous leishmaniasis: 3 (5%), acute gastroenteritis: 2 (4%), surgical wound infection: 1 (2%), cutaneous infection: 1 (2%), Septic bursitis: 1 (2%), gonorrhoea: 1 (2%). The mean time of hospital admission was 9.76 days. Three (7%) patients presented the infection within a year of starting treatment.

The rate of severe infection x100 patients/year of exposure is 2.01 (1.47–2.67). The odd ratio of admission for infection of 3.67 (1.11–4.87, p=0.03). The risk of admission for infection in patients with peripheral arthritis (RA, PSA, JIA) is 2.42 (1.21–3.11) times higher than in patients with AS (p=0.012).

In the table 1, the Odd ratio of income for infection distributed by anti-TNF drug is shown.

Anti-TNF	N° patients	Odds ratio (IC 95%)
Infliximab	101	8.01 (4.99–12.05)
Golimumab	82	5.68 (2.95–9.73)
Certolizumab	33	3.25 (0.54–10.03)
Adalimumab	239	3.03 (2.08–4.22)
Etanercept	188	2.44 (1.48–3.76)

**Conclusions:** 1. The severe infection rate x100 patients/year of exposure is 2.01 and the prevalence is 9.6%. 2. The majority of severe infection occurred late, after more than 1 year of treatment. 3. The most frequent infection were those of respiratory origin, followed by sepsis or bacteremia and septic arthritis. 4. Etanercept has presented the lowest rate of severe infection. 5. Patients with AS have a lower risk of severe infection than patients with chronic peripheral arthritis.

**Acknowledgements:** The study was supported with a research grant from the Association for Research in Rheumatology of Marina Baixa (AIRE-MB).

#### SAT0402 LEISHMANIASIS IN PATIENTS ON TUMOUR NECROSIS FACTOR INHIBITORS TREATMENT

L. Montolio Chiva<sup>1</sup>, E. Valls Pascual<sup>1</sup>, D. Ybañez García<sup>1</sup>, A. Martínez Ferrer<sup>1</sup>, M. Fernández Matilla<sup>2</sup>, J. Lluch Pons<sup>3</sup>, X. Juanola Roura<sup>3</sup>, J. Marcoval Caus<sup>4</sup>, M.-I. García Briz<sup>5</sup>, J.M. Paredes Arquiola<sup>6</sup>, I. López Cruz<sup>7</sup>, A. Salazar Cifre<sup>8</sup>, M. Aguilar Zamora<sup>1</sup>, A.V. Orenes Vera<sup>1</sup>, A. García Sendra<sup>1</sup>, V. Núñez Monje<sup>1</sup>, I. Torner Hernández<sup>1</sup>, J.J. Alegre Sancho<sup>1</sup>. <sup>1</sup>Rheumatology, Hospital Dr Peset; <sup>2</sup>Rheumatology, Hospital Arnau de Vilanova, Valencia; <sup>3</sup>Rheumatology; <sup>4</sup>Dermatology, Hospital de Bellvitge, Barcelona; <sup>5</sup>Dermatology; <sup>6</sup>Digestive; <sup>7</sup>Internal Medicine, Hospital Dr Peset; <sup>8</sup>Epidemiology, Public Health Center, Valencia, Spain

**Background:** Tumour necrosis factor (TNF) plays a major role in defense against leishmaniasis. Despite wide use of TNF $\alpha$  inhibitor (anti-TNF) for several diseases, leishmaniasis has been a rare infectious complication so far in these patients. Recently, an increased incidence has been noted.

**Objectives:** To describe a recent multicenter case series of leishmaniasis in patients with chronic inflammatory diseases treated with anti-TNF.

**Methods:** We reviewed the clinical history of a multicentric series of patients with chronic inflammatory diseases treated with anti-TNF, who were diagnosed with leishmaniasis between January 2013 and December 2017. Patients came from Rheumatology, Digestive and Dermatology departments of several hospitals in Valencia<sup>2</sup> and Cataluña<sup>1</sup> region. Demographic (age, sex) and clinical (inflammatory disease, comorbidities, current treatment, year of infection and leishmaniasis form) variables were collected. Anti-TNF withdrawal, subsequent reintroduction and recurrence rate were recorded in two hospitals. Biologic drug dispensation trends from 2013 to 2016 and epidemiological data published by the Regional Ministry of Health of Valencia for the area where cases were most incident were analysed.

**Results:** 25 cases of leishmaniasis in patients treated with immunomodulators were identified: 7 on DMARD, 1 on tocilizumab and 17 on anti-TNF (7 infliximab, 4 adalimumab, 3 golimumab, 2 certolizumab, 1 etanercept). Regarding patients on anti-TNF, 2 cases were collected in 2014, 4 in 2015, 4 in 2016 and 7 in 2017. Three patients developed the visceral form, 13 the cutaneous form and 1 presented visceral and cutaneous involvement. Seven patients were males and 10 females, with an average age of 50 (SD14) years. One patient presented rheumatoid arthritis, 4 psoriatic arthritis, 1 undifferentiated spondyloarthritis, 2 ankylosing spondylitis, 1 uveitis, 6 Crohn's disease and 2 ulcerative colitis. Six patients presented other chronic disease (1 latent tuberculosis, 1 pyoderma gangrenosum, 1 psoriasis and 3 diabetes mellitus). In two hospitals (15 patients), anti-TNF treatment was withdrawn in 10 cases, and it was reintroduced after treating the infection in 5 cases. No infection recurrences have been identified. Focusing on the area with the highest incidence of cases, despite the increase in anti-TNF use over the last years, its consumption was not parallel to the rise of leishmaniasis cases reported.

**Conclusions:** the disproportionate increase of leishmaniasis cases in patients with anti-TNF suggests the necessity to investigate and control other possible factors involved.

#### SAT0403 BLOOD B CELL SUBSET PROFILE DISTURBANCE IN WHIPPLE'S DISEASE

M. Le Goff<sup>1</sup>, D. Comec<sup>2</sup>, D. Guellec<sup>1</sup>, T. Marhadour<sup>1</sup>, V. Devauchelle-Pensec<sup>1</sup>, S. Jousse-Joulin<sup>1</sup>, M. Herbette<sup>1</sup>, J.M. Cauvin<sup>3</sup>, C. Le Guillou<sup>3</sup>, Y. Renaudineau<sup>4</sup>, J.-O. Pers<sup>4</sup>, A. Saraux<sup>1</sup>. <sup>1</sup>Rheumatology, CHU Brest and Université Bretagne Occidentale; <sup>2</sup>Rheumatology, CHU Brest and UMR 1227 Université Bretagne Occidentale; <sup>3</sup>DIM; <sup>4</sup>Immunology, CHU Brest and Université Bretagne Occidentale, Brest, France

**Background:** Technological advances have improved phenotypical characterisation of blood cells, and flow cytometry is currently used in haematology, infectious disease, systemic auto-immune diseases. Abnormalities of blood B cell subset profile might provide a useful diagnostic tool in systemic auto-immune diseases, especially for primary Sjögren's Syndrome<sup>1</sup> in which the activated B cells to memory B cells ratio is increased. Nevertheless, we observed that some patients suffering from chronic infection had lymphocytes disturbances similar to those observed in primary Sjögren's Syndrome.

**Objectives:** Whipple's disease (WD) is a rare, systemic, disease caused by intracellular gram positive bacterium, *Tropheryma Whipplei* (TW). No previous study evaluated the role of B cells in WD. The aim of this study was to analyse whether the circulating blood B cell subset disturbances is characteristic of WD.

**Methods:** We collected characteristics of all patients coming for inflammatory rheumatism in our rheumatology department between April 2010 and December 2016. All of them had systematically routine examination, immunological tests, lymphocyte subsets in peripheral blood by flow cytometric analysis. We selected among this population those patients who also had PCR for *TW* for suspicion of WD, and compared the distribution of lymphocyte subsets of those with and without WD. Then, we evaluated their diagnostic value for WD using a ROC curve.

**Results:** Among 3494 patients with inflammatory rheumatism, 121 patients (212 visits) had a suspicion of WD and the diagnosis of WD was retained by an expert rheumatologist for 9 (7.4%) (22 visits). T cells and NK cells were not different whereas percentage of circulating memory B cells (IgD<sup>+</sup>CD38<sup>low</sup>) was lower (18.0%±9.7% vs 26.0±14.2%,  $p=0.041$ ) and the ratio of activated B cells to memory B cells higher (4.4±2.0 vs 2.9±2.2,  $p=0.023$ ), in patients compared with controls. More precisely, the analysis of the frequency of peripheral blood B cells showed that IgD<sup>+</sup>CD27<sup>-</sup> naïve B cells were higher (66.2%±18.2% vs 54.6±18.4%,  $p=0.047$ ) and IgD<sup>+</sup>CD27<sup>+</sup> switched memory B cells lower (13.3%±5.7% vs 21.4±11.9%,  $p=0.023$ ), in patients compared with the controls. The best diagnostic value was obtained for the IgD<sup>+</sup>CD27<sup>-</sup> naïve B cells (cut off 70.5, sensitivity 73%, specificity 80%).

**Conclusions:** Our study provides data on blood B cells disturbances and a first step towards understandings of immunological abnormalities in WD. These disturbances provide guidance for diagnosis and allow physiopathological hypothesis.

#### SAT0404 CLINICAL CHARACTERISTICS AND OUTCOME AFTER TREATMENT OF A NATIONAL COHORT OF PCR-POSITIVE LYME ARTHRITIS

M. Scherlinger<sup>1,2</sup>, A. Grillon<sup>3</sup>, J. Sibilia<sup>4</sup>, L. Arnaud<sup>4</sup>, B. Jaulhac<sup>3</sup>. <sup>1</sup>Rheumatology, CHU de Bordeaux; <sup>2</sup>Immunoconcept, UMR-CNRS 5164, Bordeaux; <sup>3</sup>Centre National de Référence Borrelia; <sup>4</sup>Rheumatology, CHU de Strasbourg, Strasbourg, France

**Background:** Lyme arthritis (LA) is a disseminated *Borrelia* infection whose prevalence is lower in Europe than in the USA, probably because of difference in *Borrelia* species ecology. Few data concerning treatment efficacy and long-term outcome of LA in Europe are available.

**Objectives:** The aim of our study was to describe clinical characteristics and treatment outcomes of a national cohort of patients with LA confirmed with synovial fluid PCR.

**Methods:** We conducted a retrospective observational study using the French Borrelia reference centre database. Patients presenting with a PCR positive for *Borrelia* DNA in their synovial fluid between 2011 and 2016 were included. PCR-positive patients were offered by their referring physician to participate to a standardised telephonic interview. Patients' medical files were also retrieved. The main objectives were to describe patient characteristics, disease presentation and outcomes after antibiotic treatment.

**Results:** Between 2011 and 2016, among 358 synovial fluids tested at the national reference centre, 38 were positive for *Borrelia* DNA. Among these patients, 35 were contacted (3 missing contact information). Median age was 36 years with 31% minors and 63% men. Tick exposure was reported by 88% patients whereas tick bite and erythema migrans were only reported in 40% (10/25) and 14% (3/21), respectively. The presentation was monoarticular in 91% (32/35) cases and oligoarticular in others. The knee was involved in 97% (34/35) cases and 21% presented fever. The diagnosis was often delayed with a median time from symptom onset to diagnosis of 3 months (range 1 to 112). The serology performed before or at the time of the PCR testing was IgG positive in all cases but only in IgM positive in 40%. All positive IgG serologies were also positive with Western-Blot. In the synovial fluid, the identified species of *Borrelia* were *B. burgdorferi sensu stricto*, *B. garinii* and *B. afzelii* in 54%, 29% et 17% of cases, respectively. Antibiotics prescribed were mostly doxycycline and ceftriaxone in 17 and 9 patients, respectively, sometime in combination. Follow-up data were available for 26 patients with a median follow-up time of 27 months (range 1–73). Full recovery was reported by 62% patients whereas 6 presented persistent non-inflammatory articular pain of the affected joint. One patient reported a chronic pain syndrome without objective sign of persistent infection (including a negative synovial fluid PCR). Three patients developed chronic inflammatory arthritis leading to the introduction of DMARDs.

**Conclusions:** Our study reports original data on Lyme arthritis in France. Treatment outcomes are usually good but a significant proportion of patients may develop chronic inflammatory arthritis.

**Acknowledgements:** All clinicians participating the study.

**Disclosure of Interest:** None declared

#### SAT0405 FINDINGS OF A COHORT OF PATIENTS WITH CHIKUNGUNYA IN A COLOMBIAN POPULATION

M.A. López<sup>1</sup>, R. Badillo<sup>1,2</sup> on behalf of Association Colombian of Rheumatology, E. Rojas<sup>1</sup>, M. Gelvez<sup>1</sup>, Y. Santamaria<sup>1</sup> on behalf of Association Colombian of rheumatology. <sup>1</sup>Santander, Industrial University of Santander; <sup>2</sup>Santander, Association Colombian of Rheumatology, Bucaramanga, Colombia

**Background:** Chikungunya virus is a Togaviridae family virus transmitted by mosquitoes, which generates febrile syndrome with joint pain. It has been widely studied for the findings of chronic inflammatory polyarthropathy similar to rheumatoid arthritis. In Colombia, an epidemic occurred between 2014 and 2015, which was studied in several cities. International meta-analyses have shown a prevalence of 32.13% in the follow-up cohorts greater than 18 months. At present, this issue has gained a new opportunity due to the appearance of new outbreaks in Italy and France, after 10 years of the first epidemic.

**Objectives:** To compare the clinical findings of a cohort of patients with Chikungunya in the subacute phase and the chronic phase.

**Methods:** Follow-up of 70 patients who attended Chikungunya in a Colombian population who were evaluated in person by a rheumatologist, initially at 40 days after the disease and after two years.

**Results:** The average age of the study participants was 59.88 years, being more frequent in women with 78.6% of the cases. 40% of the cases were older than 65 years, with the older adult population being a representative part of the cases. The history of osteoarthritis occurred in 11.7% of cases. There was no history of systemic lupus erythematosus.

The most frequent symptoms presented at the first visit (outbreak context) were as follows, in order: Joint pain (71.4%), morning stiffness (48.6%), Metacarpophalangeal compression test (51.2%). The most frequent symptoms in the second visit (two years after the outbreak) were: joint pain (74.2%), morning stiffness (21.4%) and metacarpophalangeal compression test (17.1%).

At the time of the second visit, the clinical findings were classified by diseases, according to the rheumatologist's assessment as follows: Post-Chikungunya polyarthropathy (17.1%), Fibromyalgia (10%), Carpal tunnel syndrome (17.1%), Osteoarthritis of knees (32.8), osteoarthritis of distal interphalangeal (20%), painful shoulder syndrome (17.1%), tenosynovitis (18.6%), gout (1.4%), sequelae of fracture of hip (1.4%), lateral epicondylitis (1.4%). 28.5% of the cases had no diagnosis of rheumatological pathology. Of the total cases, only 24.3% (17 people) had symptoms for more than 6 weeks.

**Conclusions:** Chikungunya virus infection increases the prevalence of joint and extra-articular rheumatological diseases in the Colombian population evaluated.

#### SAT0406 CHIKUNGUNYA VIRUS AND THE RHEUMATOLOGY: OBSERVATION OF 76 CASES DURING AN EPIDEMIC IN BRAZIL

M. C. D. F. Salgado, Y. D. F. B. Chagas, J. L. P. Vaz, F. C. Freire, V. Vigneron, A. Vaz. *General Medicine, Federal University of Rio de Janeiro State, Rio de Janeiro, Brazil*

**Background:** Chikungunya fever is caused by a virus of the family Togaviridae and the genus Alphavirus. The first epidemic occurred in Africa in 1952, transmitted by mosquitoes of the genus *Aedes*. In Brazil, the first cases were registered in 2014. Clinical manifestations include fever, polyarthralgia, joint oedema, arthritis and morning stiffness.

Diagnosis is confirmed by IgM/IgG serology for Chikungunya. The persistence of joint symptoms for a long time is an important feature of the disease.

**Objectives:** To evaluate the prevalence of rheumatologic manifestations in 76 patients with Chikungunya infection, during an epidemic occurred in 2016 in the city of Rio de Janeiro, Brazil.

**Methods:** To evaluate the prevalence of rheumatologic manifestations in 76 patients with Chikungunya infection, during an epidemic occurred in 2016 in the city of Rio de Janeiro, Brazil.

**Results:** Females were the most prevalent: 65 patients (85,5%); male sex: 11 (14,5%). The mean age of the patients was 57,17 years, The youngest at age 24 and the oldest 87 years old. The time between the onset of symptoms and the first consultation with a rheumatologist ranged from 11 days to the highest period of 40 weeks. Among articular symptoms, polyarthralgia occurred with higher prevalence (39 patients, 51,31%), affecting wrists, ankles, shoulders, knees and hands. Twenty six patients had arthritis (34,21%), Tendinopathy in 27 regions, being more common in shoulders, ankles and wrists and including De Quervain. Paresthesias occurred in 7 patients, prevailing carpal tunnel syndrome and one patient presented dactylitis. Symptoms persisted for months in all patients.

**Conclusions:** Chikungunya is an endemic disease in Brazil, with severe joint manifestations and chronic symptoms. Often there is delay in starting treatment with rheumatologist, resulting in worsening of the clinical picture.

#### SAT0407 MYCOBACTERIAL INFECTIONS IN A RHEUMATOLOGY UNIT OF A TERTIARY HOSPITAL

M. Espinosa Malpartida<sup>1</sup>, C. Ramos Giráldez<sup>1</sup>, C. Merino Argumániz<sup>1</sup>, O. Rusinovich<sup>2</sup>, M. García Moreno<sup>3</sup>, C. Barbadillo Mateos<sup>1</sup>, J. Campos Esteban<sup>1</sup>, H. Godoy Tundidor<sup>1</sup>, J. Sanz Sanz<sup>1</sup>, C.M. Isasi<sup>2</sup>, M. Jiménez Palop<sup>2</sup>, J.L. Andreu Sánchez<sup>1</sup>, L.F. Villa<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>H. U. Puerta de Hierro Majadahonda, Madrid, Spain; <sup>3</sup>Microbiology, H. U. Puerta de Hierro Majadahonda, Madrid, Spain

**Background:** Many treatments for rheumatic diseases, especially the new ones such as anti-TNF or anti-IL6 therapies, are known to increase the risk of tuberculosis (TB) and nontuberculous mycobacterial (NTM) infections.

**Objectives:** To determine the incidence of mycobacterial infections in patients of the rheumatology unit in our hospital.

**Methods:** We retrospectively reviewed the results of microbiological studies for the detection of mycobacteria requested for patients of the Rheumatology service in our hospital from January 1, 2008 to October 1, 2017. We reviewed the clinical histories of the patients in whom a positive result was obtained. Different clinical and microbiological parameters were collected: age, gender, type of sample, isolated germ, infection location, antimicrobial treatment, main basal disease and immunosuppressive treatment received at the time of sampling.

**Results:** We reviewed 719 samples from 311 patients. The 28 samples that were positive for mycobacteria corresponded to 16 patients (50% males, with a mean age of 58.6 years). *M. avium complex* (MAC) was isolated in 10 patients, *M. tuberculosis complex* (MTB) in 4 patients and *M. goodii* in two cases. Seven clinical infections occurred (5% of the total studied patients), 4 due to MTB and 3 to MAC. The predominant involvement was pulmonary (5 patients, one of them also with spondylodiscitis); one patient had infectious oligoarthritis with cutaneous involvement and another patient lymph node involvement. Six of the 7 patients with mycobacterial infection were receiving chronic treatment with prednisone (or equivalent dose of corticosteroids)>5 mg/day (85.71%). In two of them adalimumab was associated, and methotrexate in other two.

**Conclusions:** The incidence of mycobacterial infections in patients with rheumatic diseases has increased, coupled with prolonged corticosteroid therapy – sometimes at high doses – and biological therapies. In our unit, an incidence of mycobacterial infections of 5% has been observed in the last 10 years. Most of the patients with clinical infection were under treatment with prednisone (or equivalent dose of corticosteroids)>5 mg/day. We conclude that the need for chronic corticosteroid therapy should be balanced carefully in each patient, trying to reduce the dose and/or suspend it as soon as possible.

**Disclosure of Interest:** None declared

#### SAT0408 SAFETY OF CONCOMITANT TREATMENT WITH DENOSUMAB AND OTHER BIOLOGICAL DRUGS

M. Garijo Bufort<sup>1</sup>, M. Guerra González<sup>2</sup>, C. Moriano Morales<sup>1</sup>, C. Iñiguez Ubiaga<sup>1</sup>, A. Crespo Golmar<sup>1</sup>, I. González Fernández<sup>1</sup>, A. López Robles<sup>1</sup>, E. Díez Álvarez<sup>1</sup>, C. Álvarez Castro<sup>1</sup>, M. Martín Martínez<sup>1</sup>, M.E. Vallejo Pascual<sup>3</sup>, T. Pérez Sandoval<sup>1</sup>. <sup>1</sup>Rheumatology Department of the University Health Care Complex of León; <sup>2</sup>Hospital Pharmacy of the University Health Care Complex of León; <sup>3</sup>University of León, León, Spain

**Background:** Denosumab (DB) is a monoclonal antibody to RANK ligand that, like all biological drugs, can be associated with an increased risk of infections. However, there are few studies concerning the risk of infection in these patients treated concomitantly with DB and other biologic drugs.

**Objectives:** This study aims at determining whether the treatment with biological drugs and DB combined is associated with an increased risk of adverse effects in patients with autoimmune diseases.

**Methods:** Retrospective observational study of patients treated with DB combined with other biological drugs at the Hospital of León between 2010–2017. For proper patient selection, the data obtained from the medical prescription program of primary care and the data from the registry of outpatients and walk-in patients of hospital pharmacy were cross-referenced.

To determine the increased risk, a control group of patients treated both with bisphosphonates (BF) and with biological agents was selected.

The data collected in both groups were: age, sex, diagnosis, comorbidities and other prescribed drugs. Infection, tumour or other adverse effects appeared three months, six months, one year and two years after starting the concomitant treatment. When performing the statistical analysis, it was analysed the time elapsed until the first adverse effect appeared.

**Results:** A total n of 28 patients was registered. 16 were treated with BF and biological agents, and 12 were treated with DB and other biological drugs. The prevalence of women was higher in both groups (87.5% BF, 91.7% DB). The mean age at the beginning of the concomitant treatment was similar, being 69.1±8.5 years in the BF group and 69.7±7.1 years in the DB group. All patients treated with DB were diagnosed with RA. Regarding the comorbidities, it seems that those patients treated with DB had fewer CVRF than those treated with BF (68.8% HBP in BF versus 50% in DB, 37.5% dyslipidaemia in BF versus 33.3% in DB). The biological drugs prescribed to be used concomitantly with DB were: 49.7% anti-TNF $\alpha$ , 33.3% rituximab, 8.3% abatacept and 8.3% tocilizumab.

In addition, there were no significant differences regarding the application time of the concomitant treatment with biological agents in the BF (35.7±26.7 months) and DB (58.6±43.7 months) groups; being in both groups similar. By comparing both groups, it is observed that those patients treated concomitantly with DB and other biological drugs, have more infections and these appear earlier in time than in patients treated with BF and biological agents (p<0.005). Only one patient in the DB group had a tumour of pulmonary nature as an adverse effect.

There were no differences in the appearance of adverse effects in patients with other comorbidities or concomitant treatments.

**Conclusions:** It seems that the treatment of DB combined with other biological drugs is associated with a greater number of adverse effects, mainly caused by infections, and having an earlier appearance.

More studies and a larger sample would be necessary to confirm this association and to be able to prove the relationship between comorbidities and the use of other concomitant drugs with the appearance of adverse effects.

#### SAT0409 AEROCOCCUS URINAE: FIRST REPORT OF SEPTIC OLIGOARTHRITIS AND SYSTEMATIC REVIEW OF AN EMERGING GERM IN MUSCULOSKELETAL INFECTIONS

M. Greco<sup>1</sup>, Í. Rúa-Figueroa<sup>1</sup>, S. Ghigione<sup>2</sup>, E. Santana Medina<sup>3</sup>, J.C. Quevedo Abeledo<sup>1</sup>, C. Rodríguez-Lozano<sup>1</sup>, I. Altabás<sup>1</sup>. <sup>1</sup>Rheumatology Department, Hospital Universitario de Gran Canaria Dr. Negrín; <sup>2</sup>Radiology Department, Complejo Hospitalario Universitario Insular Materno Infantil; <sup>3</sup>Radiology Department, Hospital Universitario de Gran Canaria Dr. Negrín, Las Palmas, Spain

**Background:** Aerococcus are a bacteria not generally included in lists of musculoskeletal infections (MSK-I). They have been misidentified using standard techniques and can be detected by the sequencing of 16S rRNA (16S rDNA-PCR). Matrix-assisted laser desorption ionisation time-of-flight mass spectrometry (MALDI-TOF MS) has shown to be reliable.<sup>1</sup>

**Objectives:** To describe and analyse all documented cases of musculoskeletal infections caused by *Aerococcus* *urinae* and other *Aerococcus* sp.

**Methods:** In the framework of the study of a 63-years-old man with septic oligoarthritis caused by *Aerococcus* *urinae* (AU) (isolated in 2 synovial fluid samples), a systematic review was conducted to analyse all documented cases of aerococcal MSK-I (until December 2017); other manifestations of interest present in our case were also considered.

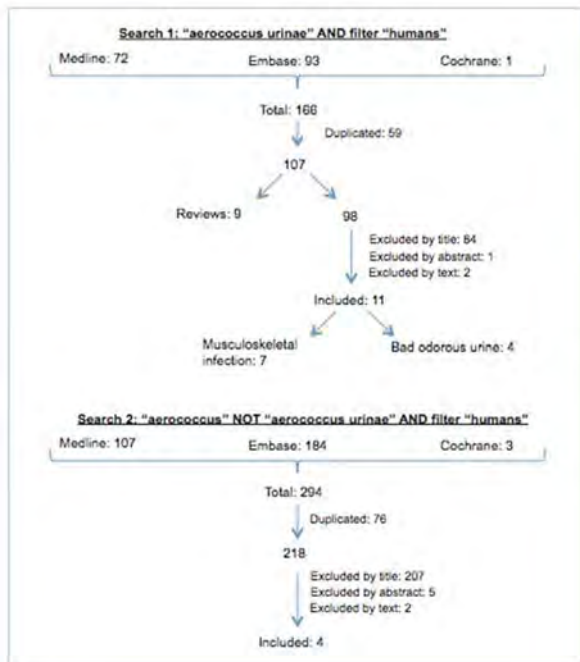

**Results:** A total of 166 articles were obtained for the term "Aerococcus urinae" and 294 for "Aerococcus" NOT "Aerococcus urinae" (both with filter "humans") (figure 1). Of them, 15 articles (16 cases) were selected and analysed:

- 8 AU MSK-I cases (our case is the 9th involving a MSK-I):
- 6 cases of spondylodiscitis (66%), 1 hip abscess, 1 septic arthritis in a prosthetic hip and our case with septic oligoarthritis.
- 66% were male and 77% were 60 years or older.
- 77% presented previous urinary tract disease, 55% previous urinary tract invasive procedures and 44% prostatic disease.
- AU was isolated in 4 of 6 cases that reported blood cultures and 2 of 4 cases with reported echocardiography presented infectious endocarditis.
- AU was not isolated in any of the 5 cases that reported urine cultures.
- 100% of cases were diagnosed after 2002 and 78% after 2010; 56% of them were diagnosed by **16 s rDNA PCR or MALDI-TOF MS** while a 33% did not provide enough information on the identification method used.

4 cases of AU with bad odorous urine (symptom present in our case): all were healthy paediatric boys that presented AU in urinary cultures without other associated symptoms; 100% were diagnosed after 2010 and 75% of them by **16 s rDNA PCR or MALDI-TOF MS**.

4 cases of *Aerococcus viridans* MSK-I: 2 spondylodiscitis, 1 knee arthritis and 1 case of hip septic arthritis; none was diagnosed via the methods previously described.

The analysed cases and previous reviews that report other AU invasive infections describes good response to beta-lactams and a synergistic effect with aminoglycoside. Our case was treated with intravenous Ampicillin (4 weeks) followed by oral Ciprofloxacin (7 weeks), due to a better bone penetration than oral beta-lactams.

Abstract SAT0409 – Figure 1. Flowchart.

**Conclusions:** – Similarly as in other invasive infections, AU **MSK-I** are more frequent in older males with previous urinary tract disease.

- The recent increased identification of AU **MSK-I** may well correlate with an increasing use of **MALDI-TOF MS** in clinical laboratories.<sup>1</sup>
- Despite its limitations, this systematic review summarises the only data available to date on aerococcus MSK-I and also suggest the likelihood of more frequent diagnosis in the near future.

#### SAT0410 CHARACTERISTICS OF ABSCESSES DURING BRUCELLAR SPONDYLODISCITIS

O. Saidane, I. Oueslati, I. Mahmoud, A. Ben Tekaya, R. Tekaya, L. Abdelmoula. *rheumatology department, Charles Nicolle hospital, Tunis, Tunisia*

**Background:** Spondylodiscitis is a frequent and important complication of brucellosis. The occurrence of abscesses is common

**Objectives:** The aim of this study was to determine the characteristics of these collections and if there is an association between the diagnostic delay and their occurrence

**Methods:** we conducted a retrospective study of 27 patients admitted for Brucella spondylodiscitis over a period of 17 years [2000 and 2016]. Etiological diagnosis was made on a positive Wright agglutination test. All patients underwent a cross sectional imaging: spinal CT (13 cases) and/or spinal MRI (24 cases).

**Results:** twenty seven patients were included. Ten women and 17 men aged from 33 to 75 years. The most common symptoms were spinal pain (96,3%) and radiculargia (44,4%). The most frequently involved segments were the lumbar spine (59,3%) and the dorsal spine (18,5%). Three patients (11,1%) suffered from cervical spondylodiscitis. The physical examination showed no paravertebral swelling or neurological abnormalities. Seventeen patients had abscesses on the cross sectional imaging (63%). Epidural fluid collections were revealed in 10 cases (37%). Nine patients had psoas abscesses (33,3%) with a bilateral involvement in 3 cases (11,1%). Less frequently, a prevertebral (18,5%), peri-vertebral (18,5%) and intradiscal collections (3,7%) were detected. A statistically significant positive association was found between a longer diagnosis delay and the presence of abscess on spinal MRI (p=0.036).

**Conclusions:** Epidural and paravertebral abscesses during Brucellar spondylodiscitis are frequent, especially if the diagnosis is delayed. However, they are rarely associated with neurological damage and must be sought consistently on the MRI

**Disclosure of Interest:** None declared

#### SAT0411 INVESTIGATIONS FOR THE DIAGNOSIS OF SEPTIC ARTHRITIS IN THE ACUTE SETTING. RESULTS FROM A SINGLE TERTIARY CENTRE OVER 5 YEARS

P. Shamdassani<sup>1</sup>, D. Liew<sup>1,2</sup>, C. McMaster<sup>1</sup>, A. Foote<sup>1,3</sup>, A. Hardidge<sup>4</sup>, R. Buchanan<sup>1,2</sup>. <sup>1</sup>Department of Rheumatology, Austin Health; <sup>2</sup>Department of Medicine, University of Melbourne; <sup>3</sup>Department of Rheumatology, Northern Health; <sup>4</sup>Department of Orthopaedic Surgery, Austin Health, Melbourne, Australia

**Background:** Septic arthritis is a rheumatologic emergency associated with significant morbidity and mortality<sup>1</sup>. Timely and accurate diagnosis in the emergency department is essential for early medical and surgical involvement.

**Objectives:** To examine the predictive value of investigations used to diagnose septic arthritis in the acute setting.

**Methods:** A retrospective chart review was conducted on all patients referred from the emergency department to the orthopaedic surgery service with a potential diagnosis of septic arthritis between June 2010 and December 2015 at the Austin Hospital in Melbourne, Australia. Data was collected regarding demographic details, risk factors, pathology results, antibiotic prescribing, joint aspirate and theatre samples.

**Results:** The study included 126 patients with 132 emergency department presentations involving 141 joints. The median age of patients was 70 (IQR 52.3–79.8); 86 (68.3%) were male. The most common joints involved were the knee (49.6%) and hip (17.7%). In 88 of the 132 presentations (67%), culture of the synovial fluid was positive. 19 of these 88 (22%) culture positive presentations had no classical risk factors for septic arthritis (joint prosthesis, previous septic arthritis, immunosuppressed, previous joint disease, intravenous drug use). 12 of the 88 (13%) culture positive patients had symptoms for longer than 4 weeks on presentation in contrast to 2 of the 44 (5%) in culture negative group. There were 8 presentations with multiple joints involved. None of these presentations were in the culture positive group. There was no evidence of a relationship between WCC and culture status (p=0.56) or CRP and culture status (p=0.64), either singly or when combined. There were 94 joint aspirations performed in 132 presentations. 30 (32%) joint aspirations required ultrasound guidance. 42 (45%) joint aspirations had antibiotics administered prior to sample collection. In the culture positive presentations 25 (28.4%) did not have a joint aspirate performed prior to surgical washout. Crystals were seen in 19 (30.2%) culture positive patients. 26 (29.5%) culture positive presentations had no growth on aspirate culture but had positive theatre cultures.

**Conclusions:** While septic arthritis is a common emergency presentation, there are few useful non-invasive diagnostic tests. Although risk factors aid in stratifying risk, duration of symptoms and inflammatory markers are poor differentiators. Neither the presence of crystals nor the absence of growth on aspirate culture exclude septic arthritis.

**SAT0412 TUBERCULOSIS REACTIVATION DURING BIOLOGICAL THERAPY**

R. Carlan<sup>1</sup>, S.P. Simon<sup>1,2</sup>, L. Muntean<sup>1,2</sup>, M.M. Tamas<sup>1,2</sup>, L. Damian<sup>1</sup>, I. Felea<sup>1</sup>, I. Filipescu<sup>1,2</sup>, S. Rednic<sup>1,2</sup>. <sup>1</sup>Rheumatology, County Clinical Emergency Hospital, <sup>2</sup>Rheumatology, "Iuliu Hatieganu" University of Medicine and Pharmacy, Cluj-Napoca, Romania

**Background:** With the increasing use and wide variety of biological therapies, there is a concomitant increase in concern for associated opportunistic infections, especially for *Mycobacterium tuberculosis*.<sup>1</sup>

**Objectives:** The aim of this study was to identify patients who have developed tuberculosis (TB) reactivation during treatment with a biological agent.

**Methods:** We included patients treated with biological agents in a tertiary Department of Rheumatology who had developed TB and were registered in the national registry for biological therapy. Demographic (urban or rural environment), clinical, therapeutic (biologic agent used) and comorbidities data were retrieved from the database.

**Results:** The database included 505 patients: 314 patients with rheumatoid arthritis (RA), 129 patients with ankylosing spondylitis (SA) and 62 patients with psoriatic arthritis (PsA).

Prior to the start of biological therapy, tuberculosis screening for latent infection was conducted in all patients. Eight patients (1,58%) were identified as being diagnosed with TB reactivation during biological therapy: 5 RA and 3 SA patients. Two had positive tuberculin test (TST) at baseline and required chemoprevention therapy prior to the initiation of the biological agent (respecting the preexisting guidelines).

Demographic data shows 62.5% patients from urban areas, 50% female and 50% male. Regarding comorbidities, one patient had biapical pachypleuritis (probably TB sequelae), antiphospholipid syndrome and pulmonary hypertension; one had chronic kidney failure and inflammatory bowel disease. The other six patients had minor comorbidities.

62,5% of patients were treated with oral corticosteroids combined with DMARDs. Four patients have been treated with infliximab, three with adalimumab and one with etanercept.

The average time to TB reactivation was 19.6 months (range 2 months to 52 months). Patients who had TB reactivation after two months of biologic therapy were treated with infliximab.

Four patients had developed pulmonary TB; one case was described as a miliary complicated with bacillary peritonitis (peritoneal biopsy). One patient had developed lymph node TB (lymph node biopsy) and one TB of the wrist (switch therapy was not chosen yet).

One particular case was of a patient that had developed TB meningitis with lymphadenitis and a compressible tuberculoma with spastic paraparesis. Switching of biological agent was chosen in 5 patients without another reactivation of tuberculosis. The biological agents chosen in 40% was rituximab, 20% was etanercept, 20% was adalimumab and 20% was infliximab.

**Conclusions:** Pulmonary and extrapulmonary TB reactivation equally occurred during anti TNF therapy. In some cases, reactivation of tuberculosis occurred even with chemoprevention.

**SAT0413 THE TREND OF INCIDENCE RATE, FREQUENCY, OUTCOMES AND HLA PHENOTYPE OF REACTIVE ARTHRITIS AND UVEITIS IN JAPANESE PATIENTS WITH BLADDER CANCER FOLLOWING INTRAVESICAL BCG THERAPY: A 20-YEAR, TWO-CENTRE RETROSPECTIVE STUDY**

Y. Nakatani<sup>1</sup>, Y. Taniguchi<sup>2</sup>, S. Inotani<sup>2</sup>, H. Nishikawa<sup>2</sup>, T. Karashima<sup>3</sup>, Y. Yoshinaga<sup>4</sup>, Y. Terada<sup>2</sup>. <sup>1</sup>Center for the Support and Development of Medical Professionals; <sup>2</sup>Department of Endocrinology, Metabolism, Nephrology and Rheumatology; <sup>3</sup>Department of Urology, Kochi Medical School Hospital, Nankoku; <sup>4</sup>Rheumatic Disease Center, Kurashiki Medical Center, Kurashiki, Japan

**Background:** Intravesical instillation of Bacillus Calmette-Guerin (iBCG) is used as an effective immunotherapy of bladder cancer. However it may have, as adverse event, a reactive arthritis (ReA) and the frequencies are known as about 0.5% to 1% in Western countries.

**Objectives:** To evaluate the trend of incidence rate, frequency and HLA phenotype of reactive arthritis (ReA), uveitis and other adverse events in Japanese patients with bladder cancer following iBCG therapy.

**Methods:** The clinical findings of Japanese patients who received iBCG (n=555 [250 and 305 in Kochi Medical School Hospital and Kurashiki Medical Centre, respectively]) for bladder cancer from March 1997 to February 2017 were retrospectively assessed, with specific attention to patients with ReA and uveitis. HLA phenotypes of patients with ReA were also looked. Moreover, iBCG-induced ReA diagnosed from 1997 to 2007 were compared with that from 2007 to 2017. Finally, outcomes of ReA patients were also evaluated.

**Results:** Patients' mean age was 72±10 years and male/female ratio was 438/117. Fever, haematuria, and dysuria were presented in 91/555 (16.4%), 121/555 (21.8%), and 196/555 (35.3%), respectively of all enrolled patients. Of the 555 cases, ReA and uveitis were revealed in 11/555 (2.0%) and 4/555 (0.7%). The protocol of iBCG therapy was stable over the 20 years. Notably, HLA-B27, -B35, -B39 and -B51 positivity was more frequent in ReA patients (9.1%, 36.3%, 36.3% and 63.6%, respectively) (p<0.05) than in healthy subjects without ReA (0.3%, 8.3%, 4.0% and 9.1%, respectively). All 4 cases with uveitis had ReA, and showed positive HLA-B27 (25%), -B39 (50%) and -B51 (25%). Moreover, the overall incidence of iBCG-ReA was not different between from 1997 to 2007 and 2007 to 2017. Finally, all ReA patients did not progress to chronic type and spondyloarthritis (SpA) as outcomes.

**Conclusions:** The 2.0% iBCG-induced ReA frequency in Japanese patients exceeds that in Western countries, and its incidence has been stable and all ReA did not progress chronic type and SpA over the last 20 years. HLA phenotype, especially HLA-B51 and -B39 alleles in addition to -B27, may be a risk factor in iBCG-induced ReA in Japanese patients.

SATURDAY, 16 JUNE 2018

**SLE, Sjögren's and APS – clinical aspects (other than treatment)**

**SAT0414 DEVELOPMENT OF MALIGNANCY IN KOREAN SJÖGREN'S SYNDROME PATIENTS; WHOLE NATIONAL HEALTH INSURANCE DATA BASED ANALYSIS**

C.H. Lee<sup>1</sup>, J.S. Park<sup>1</sup>, H.S. Lim<sup>2</sup>, H.Y. Pak<sup>2</sup>. <sup>1</sup>Dept. Internal medicine, Div. Rheumatology; <sup>2</sup>Research and analysis team, NHIS Ilsan Hospital, Goyangsi, Korea, Republic Of

**Background:** Though ocular and oral dryness are the main symptoms of Sjögren's syndrome, extraglandular manifestations including lymphoma were also developed. However, prevalence of Sjögren's syndrome was too low, most studies about lymphoma and malignancy were done on a small-scale.

**Objectives:** For more large-scale research about development of malignancy in Sjögren's syndrome, we analysed this with whole Korean National Health Insurance data which include more than 95% of the population of the Republic of Korea.

**Methods:** We compared the incidence of malignancy in newly diagnosed Sjögren's syndrome patients from 2004 to 2015 with age-sex matched controls and calculated hazard ratio (HR) with multiple Cox's model.

**Results:** Among 198,872 Sjögren's syndrome patients, cancer developed in 9883 patients (5% of newly diagnosed Sjögren's syndrome patients) after diagnosed Sjögren's syndrome. The duration from diagnosis of Sjögren's syndrome to development of malignancy was 5.4 year and their mean age was 55.2 years old. Malignancy incidence was higher in men, increased with age from the forties. It was also higher in patients who smoking or smoked, drinking more than 3times a week, and having history of malignancy (HR; 1.588, 95% CI; 1.405–1.794). The

most common malignancy in patients with Sjogren's syndrome was thyroid cancer. The risk of overall malignancy was not higher than that of the control. However, the incidence of prostate cancer (HR; 1.339, 95% CI; 1.076~1.667), thyroid cancer (HR; 1.320, 95% CI; 1.093~1.594) and lymphoma (HR; 1.620, 95% CI; 1.066~2.462) were higher and hepatocellular carcinoma (HR; 0.591, 95% CI; 0.455~0.767) was lower than that of control. Lymphoma developed in 305 patients (3.1% of total malignancy); 10 cases of Hodgkin lymphoma, and 290 cases of non-Hodgkin lymphoma. Gender, age, smoking, drinking, body mass index, fasting blood glucose, and proteinuria were not significantly different from the control group in lymphoma development.

**Conclusions:** Sjogren's syndrome patients' overall malignancy risk was not higher than that of control group. However, risk of lymphoma, prostate cancer, and thyroid cancer was higher than control group.

**SAT0415 THE MRZ REACTION HELPS TO DISTINGUISH RHEUMATOLOGIC DISORDERS WITH CENTRAL NERVOUS INVOLVEMENT FROM MULTIPLE SCLEROSIS**

N. Venhoff<sup>1</sup>, J. Thiel<sup>1</sup>, A.C. Venhoff<sup>1</sup>, S. Rauer<sup>2</sup>, D. Huzly<sup>3</sup>, M.-T. Schleyer<sup>1</sup>, C. Hentze<sup>1</sup>, R.E. Voll<sup>1</sup>, M. Rizzi<sup>1</sup>, U. Salzer<sup>1</sup>, T. Hottenrott<sup>2</sup>. <sup>1</sup>Department of Rheumatology and Clinical Immunology; <sup>2</sup>Department of Neurology and Neurophysiology; <sup>3</sup>Institute of Virology, University Medical Center Freiburg, Freiburg, Germany

**Background:** Some rheumatologic disorders (RD) may initially manifest with central nervous system (CNS) affection, mimicking the clinical, magnetic resonance imaging, and cerebrospinal fluid (CSF) findings of multiple sclerosis (MS). Vice versa MS might be difficult to separate from some RD because of the presence of autoantibodies (e.g. ANA) in up to 50%. The MRZ reaction (MRZR), composed of the three respective antibody indices (AI) against measles, rubella, and varicella zoster virus, has been found positive frequently in MS patients. However, it is unclear whether the MRZR is helpful to distinguish rheumatologic disorders with CNS involvement (RDwCNS) from MS.

**Objectives:** To investigate the MRZ reaction as a diagnostic tool to distinguish patients with RDwCNS from patients with MS.

**Methods:** The MRZR was evaluated in 35 patients with RDwCNS and compared to 70 sex- and age- matched MS patients. An AI result  $\geq 1.5$  was indicative for intrathecal IgG production against the respective pathogen. Two previously established stringency levels, MRZR-1 ( $\geq 1$  of 3 AIs positive) and MRZR-2 ( $\geq 2$  of 3 AIs positive), were applied. CNS involvement of RDwCNS was defined as clinical manifestation with neurological symptoms and signs of inflammation in CSF analysis and/or cerebral/spinal magnetic resonance imaging (MRI). MRZR results were compared using the Fisher's exact test with  $p < 0.05$  for statistical significance.

**Abstract SAT0415 – Figure 1.** Frequency of positive MRZ reaction (MRZR-1 and MRZR-2) in patients with RDwCNS compared to MS patients.

**Results:** Within the RDwCNS group, 31 patients suffered from systemic lupus erythematosus, four had a small vessel vasculitis. In both groups 77.1% were female, mean age ( $\pm$ SD) was 43.2 years ( $\pm$ 18.7) in RDwCNS and 47.5 years

( $\pm$ 7.8) in MS ( $p = .n.$ ). All RDwCNS patients showed clinical symptoms indicative for CNS involvement and signs of inflammation in CSF analyses and/or MRI of the brain. In 52 MS patients autoantibody screening was performed. 42% were positive for ANA ( $n=20$ ) or ANCA ( $n=2$ ) in indirect immunofluorescence. Only 14.3% of RDwCNS patients had a positive MRZR-1 compared to 85.7% within the MS group ( $p < 0.0001$ ). The more specific MRZR-2 was positive in 60% of the MS patients compared to only 8.5% of the RDwCNS patients ( $p < 0.0001$ ). By using a higher threshold of  $>2.0$  for a positive AI, the prevalence of positive MRZR-2 dropped to 5.7% ( $n=2$ ) in the RDwCNS group compared to 54.3% ( $n=38$ ) in the MS group ( $p < 0.0001$ ). Oligoclonal bands were found in 94.3% of the MS and 28.6% of the RDwCNS patients ( $p < 0.0001$ ).

**Conclusions:** Considering the high specificity of the MRZR-2 for MS confirmed in this study, this laboratory test may be a helpful diagnostic tool to distinguish RDwCNS from MS.

**Objectives:** To analyse the clinical features and outcomes of patients presenting with life-threatening systemic disease in a large cohort of Spanish patients with primary Sjogren syndrome (SjS).

**Methods:** The GEAS-SS multicenter registry was formed in 2005 with the aim of collecting a large series of Spanish patients with primary SS. By January 2018, the database included 1535 consecutive patients fulfilling the 2002/2016 criteria. Life-threatening systemic disease was defined as an activity level scored as "High" in at least one ESSDAI domain.

**Results:** 209 (14%) were classified as presenting with a life-threatening systemic disease: 194 presented one ESSDAI domain classified as high, 14 two domains and only one presented three high activity domains. The high-ESSDAI domains included lymphadenopathy in 78 (37%) cases, CNS in 28 (13%), PNS in 25 (12%), pulmonary in 25 (12%), renal in 22 (10%), cutaneous in 18 (9%), articular in 18 (9%), haematological in 7 (3%) and muscular in 4 (2%); the most frequent clinical presentations in each domain were, respectively, parotid lymphoma ( $n=41$ ), focal neurological deficit ( $n=20$ ), ganglionopathy ( $n=11$ ), usual interstitial pneumonitis ( $n=9$ ), renal failure ( $n=11$ ), ulcerated cutaneous vasculitis ( $n=9$ ), symmetric polyarthritis ( $n=17$ ), severe thrombocytopenia ( $n=3$ ) and severe myositis ( $n=3$ ). With respect to therapeutic approach, 144 (69%) required glucocorticoids, 65 (31%) immunosuppressive agents and 42 (20%) biological therapies. During the follow-up, 36 (17%) patients died, mainly due to lymphoma ( $n=16$ ), pulmonary fibrosis ( $n=5$ ), end-stage renal failure ( $n=4$ ), CNS progressive disease ( $n=3$ ) and systemic vasculitis ( $n=3$ ).

**Conclusions:** A 14% of patients with primary SjS develop a potentially life-threatening systemic disease (mainly lymphoma, but also severe internal organ involvements including nervous system, the lungs and the kidneys). This subset of patients requires intensive therapeutic management with a mortality rate of nearly 20% of cases.

**SAT0417 PREDICTIVE VALUE OF FETAL UMBILICAL ARTERY DOPPLER IN PRETERM BIRTH IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS**

Z. Zhan<sup>1</sup>, D. Chen<sup>1</sup>, Q. Qiu<sup>1</sup>, X. Wang<sup>2</sup>, Y. Zhan<sup>3</sup>. <sup>1</sup>Department of Rheumatology, The First Affiliated Hospital of Sun Yat-sen University; <sup>2</sup>Department of Ultrasound, The First Affiliated Hospital, Traditional Chinese Medicine University Of Guangzhou; <sup>3</sup>Department of Obstetrics and Gynecology, The First Affiliated Hospital of Sun Yat-sen University, Guangzhou, China

**Background:** Pregnancies in women with systemic lupus erythematosus (SLE) resulted in an increase of preterm birth. The predictive value of fetal umbilical artery Doppler examinations for adverse pregnancy outcomes has been reported, while not widely be assessed in SLE pregnant women.

**Objectives:** To examine the predictive value of the fetal umbilical artery Doppler on preterm birth in pregnant women with SLE.

**Methods:** A fetal Doppler ultrasound examination was performed on all fetuses during the third trimester (28–36 weeks of gestation). The Doppler flow parameters of umbilical arteries were recorded, including pulsatility parameter (PI), resistance index (RI), the peak value of umbilical arteries at end-systole (Vmax, also abbreviate as S) and the peak value of umbilical arteries at end-diastole (Vmin, also abbreviate as D). The value of S/D was automatically calculated. The clinical data from 160 live births of SLE patients were analysed retrospectively.

**Results:** The mean age of SLE patients at pregnancy was (29.7±3.7) years old (20–37). Totally, 52 patients (32.5%) were preterm births and 76 (47.5%) were fullterm births without any other adverse pregnancy outcomes. The rate of preterm birth before 34 weeks was 26.9% and the number changed to 73.1% for those preterm deliveries after 34 weeks. Iatrogenic preterm birth was the most common cause of preterm birth (30 cases), followed by spontaneous preterm birth (12 cases) and preterm premature rupture of membranes (10 cases). The pulsatility index (PI), resistance index (RI) as well as S/D value of SLE patients with pre-term delivery was higher than that of patients with full-term delivery ( $p < 0.05$ ). The area below the ROC curve for PI, RI and S/D was 0.6 (95%CI 0.5–0.7), 0.7 (95%CI 0.6–0.8) and 0.6 (95%CI 0.5–0.7), respectively. PI with cut-off value of 1.0 indicated the highest risk of preterm birth, with sensitivity of 34.6% and specificity of 84.2%. Regarding 0.7 as the cut-off value for RI to predict preterm birth, the sensitivity was 50.0% and the specificity was 81.6%. The optimal cut-off value for S/D was 2.8, at which sensitivity (50.0%) and specificity (81.6%) had the best combination.

**Conclusions:** Pregnancies in lupus still had an increased risk of preterm birth. Umbilical artery Doppler was a useful monitoring measure for preterm birth in lupus pregnancies.

**SAT0418 CAN THE AUTOMATED NEUROPSYCHOLOGICAL ASSESSMENT METRICS (ANAM) PREDICT COGNITIVE IMPAIRMENT COMPARED TO A COMPREHENSIVE NEUROPSYCHOLOGICAL BATTERY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)?**

Z. Touma<sup>1</sup>, D. Beaton<sup>2</sup>, C. Tartaglia<sup>3</sup>, L. Ruttan<sup>4</sup>, S. Lombardi<sup>4</sup>, J. Su<sup>5</sup>, J. Wither<sup>6</sup>, M. Fritzer<sup>7</sup>, R. Green<sup>8</sup>. <sup>1</sup>Internal Medicine, Division Of Rheumatology, University of Toronto; <sup>2</sup>St. Michael's Hospital; <sup>3</sup>University of Toronto, Krembil Neurosciences Centre; <sup>4</sup>Toronto Rehabilitation Institute; <sup>5</sup>Krembil Research Institute, University Health Network; <sup>6</sup>University of Toronto, Toronto Western Hospital, Toronto; <sup>7</sup>University of Calgary, Calgary; <sup>8</sup>University of Toronto, Toronto Rehabilitation Institute, Toronto, Canada

**Background:** The diagnosis of cognitive impairment (CI) is often delayed requiring use of a comprehensive battery (CB). The Automated Neuropsychological Assessment Metrics (ANAM) is a computerised tool that can be used to screen for CI.

**Objectives:** To determine the ability of ANAM (v4) GNS Battery to predict CI in patients with systemic lupus erythematosus (SLE).

**Methods:** SLE patients (n=98), aged 18–65 years, attending a single centre between July 2016–April 2017 were recruited. Participants were administered the ANAM and CB on the same day. ANAM throughput scores were used to provide an estimate of cognitive efficiency. Patient scores on the ANAM and CB were compared to a normative sample of age and gender-matched healthy controls. The CB evaluates the following major cognitive domains: manual motor speed and dexterity, simple attention and processing speed, visual-spatial construction, verbal fluency, learning and memory (visuospatial and memory), and executive

functioning (untimed and timed). ANAM evaluates the following major cognitive domains: attention and processing speed, memory, visual-spatial processing, executive functioning, abstract language function and fine motor processing. CI was operationalized on the CB and ANAM as a z-score of  $\leq -1.5$  on  $\geq 2$  domains or a z-score  $\leq -2.0$  on  $\geq 1$  domains, or either.

The performance of ANAM was compared against the CB using different CI definitions. Descriptive analysis was used to determine prevalence, sensitivity (Sn), specificity (Sp), Positive Predictive Value (PPV) and Negative Predictive Value (NPV).

**Results:** Of the 98 patients (90.8% female), the mean age at SLE diagnosis was 28.5±10.2 and disease duration at enrolment was 15.5±10.0 years. Prevalence of CI using CB ranged between 40.0%–44.8% ( $z \leq -1.5$  on  $\geq 2$  domains and  $z \leq -2.0$  on  $\geq 1$  domains, respectively) and 55.2% for either. Prevalence of CI using the ANAM ranged between 30.8%–39.3% ( $z \leq -1.5$  on  $\geq 2$  domains and  $z \leq -2.0$  on  $\geq 1$  domains, respectively) and 43.0% for either.

ANAM Sn/Sp was 52/73% and PPV/NPV was 70/55% [based on  $z \leq -1.5$  on  $\geq 2$  domains or  $z \leq -2.0$  on  $\geq 1$  domains for ANAM and CB (corresponding for A+B and E+F in table 1)].

**Abstract SAT0418 – Table 1.** Performance of ANAM against the CB

	Definitions of CI	Comprehensive Battery (CB)			
		$z \leq -1.5$ on $\geq 2$ domains		$z \leq -2.0$ on $\geq 1$ domains	
		E Sn/Sp PPV/NNV	F Sn/Sp PPV/NNV	E+F Sn/Sp PPV/NNV	
ANAM	$z \leq -1.5$ on $\geq 2$ domains	A	45/81%	37/76%	37/80%
		B	62/68%	55/61%	69/51%
	$z \leq -2.0$ on $\geq 1$ domains	B	55/76%	49/72%	50/80%
		A	61/71%	58/65%	75/57%
	+B	55/69%	51/67%	52/73%	
			55/64%	55/64%	70/55%

Sn sensitivity; Sp specificity; PPV Positive Predictive Value/NPV Negative Predictive Value

**Conclusions:** ANAM is a promising tool for the assessment of CI in SLE. Future studies are required to determine if the sensitivity of the ANAM can be improved against the current CB.

**Disclosure of Interest:** None declared

**SAT0419 RENAL AND OVERALL SURVIVAL ANALYSIS IN A COHORT OF PATIENTS WITH LUPUS NEPHRITIS WITH UP TO 40 YEARS OF FOLLOW UP**

F. Farinha<sup>1</sup>, R. Pepper<sup>2</sup>, B.S. Bernstein<sup>1</sup>, D.A. Isenberg<sup>1</sup>, A. Rahman<sup>1</sup>. <sup>1</sup>Centre for Rheumatology; <sup>2</sup>Centre for Nephrology – Royal Free Campus, UCL, London, UK

**Background:** Although the prognosis has improved in the last decades, Lupus patients still have a 3-fold increase in mortality, compared with the general population. Lupus nephritis (LN) is one of the most severe manifestations of this complex systemic disease, occurring in up to 60% of patients.

**Objectives:** 1) To obtain the overall and renal survival curves for a LN cohort; 2) To investigate factors affecting survival; 3) To identify the causes of death in this cohort.

**Methods:** Single-centre retrospective observational study, including all patients with biopsy-proven LN, followed at UCLH Rheumatology department from 1975 to 2017. Individual clinical files were reviewed to obtain demographic, clinical, laboratory and pathological data. We also recorded data on treatment with corticosteroids, immunosuppressants and antimalarials. We analysed overall survival and renal survival through the Kaplan-Meier method. COX regression analyses were conducted to investigate possible predictors of shorter survival. Significance level was defined at 0.05.

**Results:** 209 patients were included (table 1). Cumulative survival at 5, 10, 15 and 20 years after the diagnosis of LN was 92%, 86%, 81% and 76%, respectively. Main causes of death were infection (29%), malignancy (21%) and cardiovascular (21%). Regarding progression to end-stage renal disease (ESRD), cumulative renal survival at 5, 10, 15 and 20 years was 94%, 86%, 79% and 72%, respectively. Table 2 shows the predictors of shorter survival identified for this

cohort. Image 1 represents the Kaplan-Meier curves according to the factors affecting renal survival.

**Abstract SAT0419 – Table 1.** Characterisation of the UCLH cohort of Lupus Nephritis patients

		ISN/RNP 2003 classification						Total
		I	II	III	IV	V	VI	
Total, N		2	18	38	97	38	2	209
Sex	F, N (%)	2	18	35	88	33	2	189 (90.4)
	M, N (%)	0	0	3	9	5	0	20 (9.6)
Ethnicity	Caucasian, N (%)	1	8	19	48	12	1	92 (44)
	Afro-Caribbean, N (%)	1	7	9	26	18	1	68 (32.5)
	Asian, N (%)	0	3	10	23	8	0	49 (23.4)
ESRD, N (%)		0	0	8	26	3	1	40 (19)
Deaths, N (%)		0	2	9	21	4	1	38 (18)
Age LN diagnosis, mean±SD		28.68±11.81						
Time FU since LN, mean±SD		12.95±8.96						

ISN/RNP: International Society of Nephrology and Renal Pathology Society; F: females; M: males; ESRD: end-stage renal disease; LN: Lupus nephritis; FU: follow-up.

**Abstract SAT0419 – Table 2.** Final models for predictors of shorter survival.

Multivariable COX regression	HR [95% CI] p
<b>Overall survival</b>	3.002 [1.461–6.171] 0.003
ESRD	
No antimalarials	2.942 [1.430–6.052] 0.003
Ethnicity (Afro-Caribbean)	2.656 [1.250–5.642] 0.011
Age at LN diagnosis	1.039 [1.012–1.067] 0.004
<b>Renal survival</b>	4.424 [1.542–12.695] 0.006
Histological class (III, IV or VI)	
Ethnicity (Afro-Caribbean)	3.727 [1.691–8.218] 0.001
No antimalarials	2.482 [1.237–4.982] 0.011

HR: hazard ratio; ESRD: end-stage renal disease; LN: Lupus nephritis

**Conclusions:** Cumulative survival rates and causes of death for this cohort are comparable with other cohorts of LN. ESRD confers the higher risk for death; African or Caribbean ethnicities and not taking antimalarials predict shorter overall and renal survival among these patients.

#### SAT0420 INCREASED RESISTANT HYPERTENSION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS: A RETROSPECTIVE COHORT STUDY

J.S. Gandelman<sup>1</sup>, M. Shuey<sup>2</sup>, O. Khan<sup>3</sup>, J. Neal<sup>4</sup>, A. Dickson<sup>5</sup>, A. Barnado<sup>5</sup>, L. Wang<sup>4</sup>, W. Dupont<sup>4</sup>, C.M. Stein<sup>5,6</sup>, C.P. Chung<sup>5,6</sup>. <sup>1</sup>School of Medicine; <sup>2</sup>Department of Pharmacology, Vanderbilt University; <sup>3</sup>Department of Biostatistics, Vanderbilt University Medical Center; <sup>4</sup>Department of Biostatistics, Vanderbilt University School of Medicine; <sup>5</sup>Department of Internal Medicine; <sup>6</sup>Department of Clinical Pharmacology, Vanderbilt University Medical Center, Nashville, USA

**Background:** Resistant hypertension (RHTN) is characterised by blood pressure that remains  $\geq 140/90$  mmHg despite concurrent use of 3 antihypertensive drugs. In the general population, RHTN is associated with a 47% increased risk of cardiovascular events.<sup>1</sup> Patients with systemic lupus erythematosus (SLE) have increased cardiovascular risk; however, no research has addressed the incidence, prevalence, or risk factors associated with RHTN in patients with SLE.

**Objectives:** To compare the risk of RHTN in patients with SLE and frequency-matched controls without SLE; to define factors associated with RHTN in patients with SLE.

**Methods:** We used a validated algorithm (94% PPV) to identify patients with SLE from the electronic health records (EHR) at an academic medical centre.<sup>2</sup> We established a control cohort matched by age, race, and sex with a 5:1 control-case ratio. Follow-up began at first ICD9 code for SLE (cases) or first ICD9 code (controls) and continued until RHTN diagnosis or last note. RHTN diagnosis required either the simultaneous use of 3 antihypertensive drugs and a mean blood pressure  $\geq 140/90$  mm Hg in the following 6 months, or the use of  $\geq 4$  antihypertensive drugs simultaneously. We used logistic regression and Cox proportional hazards (CPH) models to compare risk of RHTN between groups, with CPH performed on incident cases only.

**Results:** We studied 1044 patients with SLE and 5241 controls (median age 42, [31–54] 90% female and 70% Caucasian). Of the total cohort, RHTN developed in 106 SLE patients (10%) and 278 controls (4%). The incidence rate of RHTN was 14.7 cases/1000 person-years in SLE patients compared to 7.4 in controls [HR 1.66, 95% CI, 1.25–2.21] (figure 1). In logistic regression models, RHTN was associated with older age, black race, male gender and end stage renal disease (ESRD). Patients with SLE had a higher risk of RHTN when adjusted for age, sex, race, calendar year, and ESRD [HR 1.53, 1.15–2.05]. In an analysis among SLE patients, RHTN was associated with mortality in an unadjusted model [HR 3.38, 2.20–5.18]. This association remained when age, sex and race were added to the model [HR 2.58, 1.65–4.03], but when ESRD, calendar year and creatinine were included, the association was no longer significant [HR 1.51, 0.91–2.51].

**Abstract SAT0420 – Figure 1.** Cumulative Incidence of RHTN in SLE versus Control Cohort

Log rank test:  $p=0.000391$

**Conclusions:** Patients with SLE have a higher risk of RHTN compared to frequency-matched controls. RHTN is an important comorbidity for clinicians to recognise in SLE, as it is associated with a 3.3-fold higher risk of mortality.

#### SAT0421 LONG-TERM IMMUNOGENICITY OF A QUADRIVALENT HUMAN PAPILLOMAVIRUS VACCINE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

C.C. Mok<sup>1</sup>, L.Y. Ho<sup>1</sup>, C.H. To<sup>2</sup>. <sup>1</sup>Medicine, Tuen Mun Hospital; <sup>2</sup>Medicine, Pok Oi Hospital, HK, Hong Kong

**Objectives:** To report the 5 year immunogenicity of a quadrivalent human papillomavirus (HPV) vaccine (GARDASIL) in patients with systemic lupus erythematosus (SLE).

**Methods:** Female SLE patients and healthy controls, aged 18–35 years, who received GARDASIL in the year 2011 and sero-converted 12 months post-vaccination were followed for the persistence of immunogenicity at 5 years. Antibodies to HPV serotypes 6,11,16,18 were repeated at 5 years using an IgG immunoassay developed on a Luminex microsphere platform (total IgG LIA; Merck Research Laboratory). The rate of sero-reversion was compared between

patients and controls. Factors associated with sero-reversion of the anti-HPV antibodies were studied by statistical analyses.

**Results:** 50 SLE patients (age 25.8±3.9 years) and 50 controls (25.8±3.9 years) were vaccinated with Gardasil in 2011. The sero-conversion rates of anti-HPV serotypes 6,11,16 and 18 in patients and controls were 82%, 89%, 95%, 76%, and 98%, 98%, 98%, 80%, respectively, at month 12 post-vaccination. Among those subjects who sero-converted and were available for follow-up, persistence of the antibodies to HPV serotypes 6,11,16 and 18 at 5 years was present in 24/27 (89%), 26/31 (84%), 32/34 (94%), 24/25 (96%) of the SLE patients and 32/33 (97%), 32/33 (97%), 32/32 (100%) and 23/24 (96%) of the controls, respectively. Moreover, antibody titers to HPV serotypes 6 and 16 at 5 years were significantly lower in SLE patients than controls. Seven (21%) SLE patients had sero-reversion of any one of the four anti-HPV antibodies (6,11,16 or 18) at year 5 post-vaccination. Patients who sero-reverted had received a significantly higher cumulative dose of prednisolone (13.0±5.34 vs 4.63±4.59 grams;  $p=0.002$ ), mycophenolate mofetil (1050±1180 vs 238±49.5 grams;  $p=0.007$ ) and tacrolimus (375±580 vs 268±1180 mg;  $p=0.03$ ) during the 5 year follow-up than those with persistence of immunogenicity. These sero-reverted patients had also received a non-significantly higher cumulative dose of cyclophosphamide (1.97±5.22 vs 0.43±2.24 grams;  $p=0.27$ ). In addition, sero-reverted patients had more SLE flares in the 5 year follow-up period compared to those with persistence of immunogenicity (3.14±1.21 vs 1.89±1.28;  $p=0.03$ ). Among 64 flares in patients with persistent anti-HPV antibodies and 26 flares in those with sero-reversion, renal flares occurred more frequently in the latter group of patients (16% vs 38%;  $p=0.02$ ).

**Conclusions:** Immunogenicity of the quadrivalent HPV vaccine was retained in 79% of SLE patients at 5 year post-vaccination. Antibody titers to HPV serotypes 6 and 16 were significantly lower in SLE patients than controls. Patients who had more SLE flares, especially renal flares, and had received higher cumulative doses of glucocorticoids, mycophenolate mofetil and tacrolimus were more likely to have sero-reversion of one or more anti-HPV antibodies. Re-vaccination of these patients should be considered.

**SAT0422** **INDIRECT PATHOGENIC ROLES OF CEREBROSPINAL FLUID ANTI-U1RNP ANTIBODIES IN THE PRESENCE OF ANTI-NR2 ANTIBODIES IN PATIENTS WITH NEUROPSYCHIATRIC SYSTEMIC LUPUS ERYTHEMATOSUS**

T. Fujii<sup>1,2</sup>, S. Kondo-Ishikawa<sup>3</sup>, N. Ishigooka<sup>2</sup>, H. Yoshifuji<sup>2</sup>, K. Ohmura<sup>2</sup>, T. Mimori<sup>2</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Wakayama Medical University, Wakayama; <sup>2</sup>Rheumatology and Clinical Immunology, Kyoto University School of Medicine; <sup>3</sup>Rheumatology, National Hospital Organization Utano Hospital, Kyoto, Japan

**Background:** Autoantibodies (auto Abs) and inflammatory mediators (IMs) in cerebrospinal fluid (CSF) may be involved in the pathogenesis of neuropsychiatric systemic lupus erythematosus (NPSLE). Previous studies indicated that anti-N-methyl *D*-aspartate receptor NR2 subunit (NR2) Abs have a pathogenic role in NPSLE by BBB disruption.<sup>Hirohata S, et al. Arthritis Res Ther. 2014</sup> We also reported the association between NPSLE and CSF-anti-U1RNP Abs (Sato, et al, A and R, 2010).

**Objectives:** In the present study, synergistic effects of these auto Abs, their associated IMs, and blood brain barrier (BBB) permeability are determined in NPSLE patients.

**Methods:** CSF samples were collected from 69 of NPSLE patients at their acute phase and 13 of non-NPSLE control after obtaining the written informed consent. CSF anti-NR2 and anti-U1RNP Abs were determined by ELISA. CSF IL-6, IL-8, and monokine induced by IFN- $\gamma$  (MIG) were measured by quantitative multiplex cytokine analysis. BBB permeability was evaluated by albumin quotient (Qalb).

**Results:** 1) CSF IL-6 levels were higher in CSF anti-NR2 Ab +ve (70±178 pg/mL) than in -ve (11±32,  $p=0.02$ ) patients and in controls (16±40,  $p=0.003$ ) and positively correlated with anti-NR2 Ab titer ( $r=0.42$ ,  $p=0.003$ ). Anti-U1RNP Ab positivity was not associated with CSF IL6 elevation. 2) CSF IL-8 levels were higher in CSF anti-U1RNP Ab +ve than in -ve (270±862 vs. 52±177 pg/mL,  $p=0.04$ ) patients. Anti-NR2 Ab positivity was not involved in CSF IL8 elevation. 3) CSF MIG levels were more elevated in both CSF anti-NR2 +ve (4483±11845 pg/mL,  $p=0.04$ ) and anti-U1RNP Ab +ve (5519±13504,  $p=0.03$ ) patients than in controls (115±125). 4) All the patients were divided into 4 groups: CSF anti-NR2 +ve/anti-U1RNP+ve (double positive [DP], n=9), anti-NR2 +ve/anti-U1RNP -ve (aNr2, n=15), anti-NR2 -ve/anti-U1RNP+ve (aU1RNP, n=9), and anti-NR2 -ve/anti-

U1RNP -ve (double negative [DN], n=36). In comparison between DP and aNr2 groups, anti-U1RNP Abs had a synergistic effect on CSF IL-6 elevation (150±260 vs. 18±44 pg/mL,  $p=0.03$ ) that is not directly associated with anti-U1RNP Ab positivity. In comparison with aNr2 group, both CSF IL-8 (543±1198 vs. 43±102 pg/mL,  $p=0.04$ ) and MIG (10104±17 748 vs. 1111±2584 pg/mL,  $p=0.03$ ) levels, which were positively correlated with CSF anti-U1RNP Ab titer, were more elevated in DP group. 5) Qalb was positively correlated with CSF IL-8 ( $r=0.51$ ,  $p<0.0001$ ) and MIG ( $r=0.44$ ,  $p=0.0003$ ), suggesting that CSF anti-U1RNP Ab positivity is involved in the BBB disruption. Actually, Qalb ( $\times 10^3$ ) tended to be higher in DP than in aNr2 group (13±9 vs. 9±8,  $p=0.06$ ) and CSF anti-NR2 Ab titer appeared to be more elevated in DP than in aNr2 group (81±47 vs. 57±21,  $p=0.06$ ).

**Conclusions:** The present study suggested that anti-NR2 and U1RNP Abs have synergistic effects on CSF IL-6 elevation in patients with NPSLE. CSF IL-6 level was associated with anti-NR2 Ab titers, which depend on BBB permeability. CSF anti-U1RNP Ab-mediated IL-8 and MIG elevation may induce BBB disruption followed by anti-NR2 Ab penetration into CSF.

**SAT0423** **MOLECULAR PROFILES ASSOCIATE WITH CLINICAL DISEASE ACTIVITY AND INFORM PATIENT SUBSETTING IN ADULT SYSTEMIC LUPUS ERYTHEMATOSUS**

J.M. Guthridge, R. Lu, C. Arriens, T. Aberle, S. Kamp, M.E. Munroe, T. Gross, W. DeJager, S.R. Macwana, R.L. Bourn, S. Apel, H. Chen, E.F. Chakravarty, A. Thanou, J.T. Merrill, J.A. James. Arthritis and Clinical Immunology, Oklahoma Medical Research Foundation, Oklahoma City, USA

**Background:** Systemic lupus erythematosus (SLE) is characterised by remarkable clinical and pathophysiological diversity, hindering diagnosis, treatment and treatment development. Subsetting of patients based upon clinical presentations alone has not identified homogeneous groups of patients best treated with a directed therapeutic.

**Objectives:** To cluster SLE patients into more homogeneous subsets with common molecular pathway signatures, and to assess the clinical, therapeutic, and demographic features enriched in each cluster.

**Methods:** Serial or single plasma, serum and RNA samples (n=290) were collected from 198 SLE patients who met ACR classification. Disease activity was assessed by modified SLEDAI-SLEDAI at an average of 17 visits per patient. Transcriptional co-expression signature module scores were calculated from Illumina Beadchip Microarray gene expression data for 29 immune pathway related modules. Plasma soluble mediators (n=23) and 12 antinuclear autoantibodies (anti-dsDNA, chromatin, ribosomal P, Sm, Sm, SmRNP, RNP, Ro/SSA, La/SSB, centromere B, Scl-70 and Jo-1) were assessed by multiplex bead-based assay and ELISA. Spearman correlations were used for univariate and multivariate analysis using R. Patients were clustered on module signature scores and soluble mediators using random forest and tSNE.

**Results:** SLEDAI scores strongly correlated with interferon modules and were modestly correlated with plasmablast and select cell cycle signatures in this adult lupus collection. SLEDAI scores also correlated with soluble levels of IFN $\alpha$ , IL21, IL1 $\alpha$ , IL17A, IP10 and MIG. Random forest defined seven clusters of SLE patients with unique molecular phenotypes based upon gene co-expression module signatures and soluble mediators. Inflammation and interferon (IFN) signatures were elevated in Clusters 1 (moderately) and 4, with decreased T cell signatures in Cluster 4. The other clusters had lower IFN and inflammation signatures, but differed in their monocyte, plasmablast and T cell signatures. Clusters 1 and 4 had the highest SLEDAI scores, with high rates of anti-dsDNA, low complement, proteinuria and hematuria; these features were also prominent in Cluster 3, which lacked the IFN and inflammation signatures. Cluster 6 had the highest plasmablast module score, highest IL1 $\alpha$  levels, and SLEDAI scored rashes, but only moderate IFN and inflammation module scores. Cluster 2 had higher rates of SLEDAI scored alopecia, a slightly elevated inflammation signature, but lower interferon signature and lower soluble mediator levels.

Abstract SAT0423 – Figure 1. Modular transcriptional score profiles of seven SLE clusters

**Conclusions:** SLE subsets can be distinguished by a range of molecular profiles encompassing IFN, T cell, neutrophil, plasmablast, and inflammation co-expression signatures, as well as soluble mediators that vary with disease activity. Prospective longitudinal studies of these molecular profiles may inform clinical trial design and personalised disease management.

**SAT0424** **COMPLEMENT C4 GENE COPY NUMBER VARIATIONS BESTOW LARGE RANGES OF SERUM C4 PROTEIN LEVELS IN CHINESE PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS (SLE) AND CONTRIBUTE TO ORGAN AND CARDIOVASCULAR DAMAGES OVER TIME**

C.C. Mok<sup>1</sup>, E. King<sup>2</sup>, B. Zhou<sup>2</sup>, G. Yu<sup>2</sup>, Y.L. Wu<sup>2</sup>, C.Y. Yu<sup>2</sup>. <sup>1</sup>Medicine, Tuen Mun Hospital, HK, Hong Kong; <sup>2</sup>Pediatrics, Nationwide Children's Hospital, Columbus, Ohio, USA

**Background:** Human SLE is characterised by fluctuating serum levels of complement proteins. There are frequent copy number variations (CNVs) of complement C4A and C4B genes among different individuals. Previously, we demonstrated that C4A deficiency is a strong genetic risk factor for SLE.

**Objectives:** To investigate how CNVs of C4 contribute to the great variability of C4 serum levels and how deficiencies of C4A or C4B modulate the clinical presentations, including organ damage, of SLE.

**Methods:** Our study population included 499 patients from Hong Kong, who fulfilled  $\geq 4$  of the 2013 ACR/SLICC criteria for SLE. Among them 93% were women, the mean age of SLE onset was  $32.8 \pm 13.0$  years, and SLE duration was  $14.4 \pm 7.6$  years. Gene copy numbers (GCNs) of total C4 (C4T), C4A and C4B were determined by real-time PCRs. Serial serum levels over the past 5 years for C4 and C3 of each patient were retrieved through the laboratory data registry system. Serum C4 and C3 levels are shown as mg/100 ml (unit). Clinical manifestations and organ damage of SLE were correlated with CNVs of C4 genes and serum levels. Continuous data between groups were compared by t-tests and categorical data by  $\chi^2$  analyses. Logistic regression was used to calculate odds ratios (ORs) and 95% confidence intervals for effects of C4 CNVs on cumulative clinical manifestations of SLE and accrued organ damage, adjusted for durations of disease.

**Results:** Serum levels for C4 varied from 1–84 units (Median: 17) and for C3 from 8–314 units (Median: 86). There was a very strong correlation between C4 and C3 protein levels ( $R=0.70$ ,  $p=5.3 \times 10^{-75}$ ). The GCN of C4T varied between 2 and 9 with a median of 4 copies (54%), followed by 2 and 3 copies (21%). Each additional gene copy correlated to an increase of 4 and 6 units for the mean and maximum serum C4 levels, respectively. A higher GCN of C4T ( $\geq 3$  vs  $<3$ ) was protective against the development of neuropsychiatric disorder over time [OR 0.45 (0.21–0.98),  $p=0.04$ ]. A high GCN of C4L ( $\geq 3$  vs  $<3$ ), or the absence of C4S (GCN=0), was negatively associated with the occurrence of thrombocytopenia

[OR 0.64 (0.42–0.97),  $p=0.04$ ]. A high GCN of C4B was associated with damage to any organ [OR 1.76 (1.05–2.93),  $p=0.03$ ], but a high GCN of C4A ( $\geq 3$  vs  $<3$ ) was associated with cardiovascular damage [OR 2.30 (1.06–5.00),  $p=0.04$ ]. Among the SLE patients studied, 18.3% had persistently low levels of C4 (mean  $\leq 10.0$  units). These patients mostly had GCNs of C4T=2 or 3 [OR 4.02 (2.47–6.56),  $p=4.7 \times 10^{-8}$ ], or C4B=0 or 1 [OR 3.06 (1.89–4.96),  $p=9.0 \times 10^{-6}$ ]. Patients with persistently low C4 levels had increased prevalence of mucosal ulceration [OR 2.09 (1.15–3.78),  $p=0.02$ ], lymphopenia [OR 1.76 (1.01–3.05),  $p=0.045$ ] and gastrointestinal disorders [OR 2.52 (1.31–4.84),  $p=0.005$ ].

**Conclusions:** CNVs of C4 genes confer great variability of serum C4 levels among SLE patients. While C4A deficiency contributes to genetic predisposition of SLE, persistently low levels of serum C4 among patients were strongly correlated with low GCN of total C4 and C4B deficiency. Elucidating C4-CNVs may have prognostic significance of SLE as high GCNs of C4B and C4A appeared to correlate with organ damage and cardiovascular disease, respectively.

**SAT0425** **PHENOTYPING PRIMARY SJÖGREN'S SYNDROME (PSS) BY USING SALIVARY GLAND ULTRASONOGRAPHY: A STEP FORWARD TO INDIVIDUALISED THERAPIES**

C. Baldini<sup>1</sup>, F. Ferro<sup>1</sup>, N. Luciano<sup>1</sup>, E. Calabresi<sup>1</sup>, E. Elefante<sup>1</sup>, V. Donati<sup>2</sup>, M. Mosca<sup>1</sup>, S. Bombardieri<sup>1</sup>. <sup>1</sup>Rheumatology Unit, University of Pisa; <sup>2</sup>Pathologic Anatomy II, Pisa, Italy

**Background:** Salivary gland ultrasonography (SGUS) has recently appeared as a useful tool to non invasively assess major salivary glands inflammation and damage in primary Sjögren's syndrome (pSS). To date, relatively few studies have evaluated the usefulness of SGUS in characterising different disease phenotypes ultimately providing information on which patients might be most likely to benefit from specific interventions.

**Objectives:** to explore whether SGUS may be useful in identifying different clinical-serological and histopathological phenotypes of pSS, ultimately allowing individualised treatments.

**Methods:** Sonographic data were retrieved from a large monocentric cohort of pSS patients. The echostructure of each gland on B-mode images was graded on a 5-point scale (0–4), and a SGUS score  $\geq 2$  was defined as pathological. Hypo-anechoic areas in the glands were defined as isolated ( $<25\%$  of the surface), localised (25%–50%) and diffuse-scattered ( $>50\%$ ). The biggest hypo or anechoic area in each gland was measured. SGUS was repeated in 150 pSS patients at least twice over a median follow up of 24 months. All the patients received a complete rheumatological assessment: disease activity was measured by the EULAR Sjögren's Syndrome Disease Activity Index (ESSDAI), histopathological evaluation included the assessment of the focus score (FS) and the reporting of the number of germinal centre (GC)-like structures.

**Results:** We included in this study 311 patients (300 F: 11 M; median age=58 years (IQR, 49–69)) and median disease duration of 3 years (IQR 0–9). Out of them 136/311 (43.7%) had a SGUS score  $<2$  with none or isolated hypo-anechoic areas in their glands. Localised areas were detected in 87/311 (28%) pSS patients and diffuse-scattered areas in 88/311 (28.3%). Patients with none or isolated hypo-anechoic areas tended to be older ( $p=0.06$ ) and presented a significantly lower FS, a lower ESSDAI and a higher unstimulated salivary flow rate when compared to the other pSS patients ( $p<0.001$ ). Patients with localised or diffuse-scattered echographic pattern were more frequently seropositive for anti-Ro/SSA, anti-La/SSB and rheumatoid factor, presented more frequently hypergammaglobulinemia and low C3/C4 levels and had a higher frequency of GC-like structures in their biopsies ( $p<0.001$ ). Patients with diffuse-scattered hypo-anechoic areas presented the highest disease activity, in particular in the ESSDAI glandular, cutaneous and haematological domains. Notably, the SGUS score did not change over the time in patients who underwent repeated SGUS evaluations. Out of 136 patients with a SGUS score  $<2$ , 58 underwent additional SGUS evaluations over the follow-up. The SGUS was unchanged in all the cases and still associated with a low systemic disease activity.

**Conclusions:** This study highlighted the potential usefulness of SGUS in phenotyping pSS subsets. Patients with none or isolated hypoechoic areas in their glands are likely to present a low systemic disease activity during the disease course, being therefore candidate to less aggressive treatments. By contrast, patients with highest SGUS scores tend to present a more active systemic involvement and are candidate to receive a more aggressive therapy.

**SAT0426 SERUM URIC ACID LEVELS PREDICT DAMAGE ACCRUAL IN SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS**

C. Elera-Fitzcarrald<sup>1,2</sup>, C. Reategui-Sokolova<sup>1</sup>, R.V. Gamboa-Cárdenas<sup>1,3</sup>, M. Medina<sup>1</sup>, F. Zevallos<sup>1</sup>, V. Pimentel-Quiroz<sup>1</sup>, J.M. Cucho-Venegas<sup>1</sup>, J.L. Alfaro-Lozano<sup>1</sup>, Z.J. Rodríguez-Bellido<sup>1,3</sup>, C.A. Pastor-Asurza<sup>1,3</sup>, R.A. Perich-Campos<sup>1,3</sup>, G. Alarcón<sup>4</sup>, M.F. Ugarte-Gil<sup>1,2</sup>. <sup>1</sup>Rheumatology, Hospital Guillermo Almenara Irigoyen, EsSalud; <sup>2</sup>Universidad Científica del Sur; <sup>3</sup>Universidad Nacional Mayor de San Marcos, Lima, Peru; <sup>4</sup>School of Medicine, The University of Alabama at Birmingham, Birmingham, AL, USA

**Background:** Serum uric acid levels have been reported as predictors of cardiovascular and renal morbidity,<sup>1</sup> and, of increasing the risk of renal damage in systemic lupus erythematosus (SLE) patients.<sup>2</sup> However, their role as predictors of global damage accrual in SLE patients has not been determined.

**Objectives:** To determine whether uric acid levels predict new damage in SLE patients.

**Methods:** This is a longitudinal study of SLE patients from a single centre cohort which started in 2012. Visits were performed every six months. Patients with at least two visits were included. Demographic and clinical characteristics as well as treatment were recorded at every visit. Disease activity was ascertained with the Systemic Lupus Erythematosus Disease Activity Index (SLEDAI), and damage with the Systemic Lupus International Collaborating Clinics (SLICC)/American College of Rheumatology (ACR) damage index (SDI). Prednisone use was recorded as current daily dose and time of exposure. Immunosuppressive drugs and antimalarial use was recorded as current, past or never. All variables were ascertained at baseline, with the exception of new damage which was assessed at the subsequent visits. Univariable and multivariable Cox-regression models were performed to determine the impact of uric acid levels on the risk of new damage. Multivariable models were adjusted for age at diagnosis, disease duration, socioeconomic status, SLEDAI, SDI, comorbidities and use of prednisone, immunosuppressive drugs and antimalarials.

**Results:** Two hundred and thirty-seven patients were evaluated. The mean (SD) age at diagnosis was 35.9 (13.1) years, 220 patients (92.8%) were female, nearly all were Mestizo, disease duration was 7.3 (6.6) years. The mean SLEDAI and SDI were 5.1 (4.2) and 0.9 (1.3), respectively. The Charlson comorbidity index was 0.5 (0.9). Uric acid levels were 4.5 (1.4) mg/dl. The mean current prednisone dose 7.1 (6.4) mg/d. The duration of exposure to prednisone was 6.9 (6.2) years. Follow-up time was 3.1 (1.3) years. One hundred and twelve (47.3%) patients accrued damage during the follow-up. In univariable and multivariable analyses, uric acid levels predicted new damage [HR=1.14 (95% CI 1.01–1.28); p=0.026 and HR=1.16 (95% CI 1.00–1.34); p=0.043, respectively].

**Conclusions:** Higher uric acid levels predicted the development of new damage in our SLE patients.

**SAT0427 PREDICTIVE VALUE OF FETAL UMBILICAL ARTERY DOPPLER IN ADVERSE PREGNANCY OUTCOMES IN PATIENTS WITH LUPUS NEPHRITIS**

D. Chen, Z. Zhan. *Rheumatology, The first affiliated hospital of Sun Yat-sen University, guangzhou, China*

**Background:** Compared with the general population, patients with lupus nephritis (LN) are still at high risk of adverse pregnancy outcomes (APOs), including fetal loss, preterm birth and intrauterine growth retardation (IUGR). Umbilical artery is particularly important for placental perfusion and fetal development. Increased umbilical artery resistance could be traced by Doppler velocimetry, which could be used as a screening tool for placenta-related diseases. However, the predictive value in HDP of lupus pregnancies has not been widely assessed.

**Objectives:** To examine the predictive value of the fetal umbilical artery Doppler on adverse pregnancy outcomes (APOs) in pregnant women with lupus nephritis (LN).

**Methods:** The clinical data of 158 LN pregnant patients from the First Affiliated Hospital of Sun Yat-sen University were analysed retrospectively.

**Results:** Totally, 119 were diagnosed before pregnancy and 39 were newly diagnosed during pregnancy. One or more APOs occurred in 74.7% of patients with LN and 40 (25.3%) were without any APOs. Fifty-four of pregnancies (12.3%) resulted in fetal loss. A total of 55 pregnancies were preterm birth, 24 were IUGR, 14 were fetal distress and 9 were neonatal lupus. Doppler pulsatility index (PI), resistance index (RI) as well as S/D value were significantly higher in the APOs groups than in the patients without APOs (p<0.05). The area below the receiver operating characteristic (ROC) curve for PI, RI and S/D all was 0.7 (95%CI 0.6–0.8). PI with cut-off value of 0.9 indicated the highest risk of APOs, with sensitivity of 28.3% and specificity of 97.2%. Regarding 0.6 as the cut-off value for RI to predict APOs, the sensitivity was 45.7% and the specificity was 80.6%. The optimal cut-off value for S/D was 2.5, at which sensitivity (39.1%) and specificity (90.0%) had the best combination.

**Conclusions:** Pregnancies in LN were more prone to pregnancy loss and preterm birth. Umbilical artery Doppler was a useful monitoring measure for APOs in pregnancies of LN.

**Disclosure of Interest:** None declared

**SAT0428 ASSOCIATION BETWEEN ORGAN DAMAGE AND HEALTH-RELATED QUALITY OF LIFE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE): A SYSTEMATIC REVIEW**

E.R. Hammond<sup>1</sup>, D.H. Lin<sup>2</sup>, I.B. Murimi<sup>2</sup>, H. Nab<sup>3</sup>, H. Kan<sup>2</sup>, O. Onasanya<sup>2</sup>, J. C. Tierce<sup>2</sup>, X. Wang<sup>1</sup>, B. Desta<sup>1</sup>, G.C. Alexander<sup>2</sup>. <sup>1</sup>AstraZeneca, Gailthersburg, MD; <sup>2</sup>Johns Hopkins Bloomberg School of Public Health, Baltimore, MD, USA; <sup>3</sup>AstraZeneca, Cambridge, UK

**Background:** Organ damage in SLE is associated with increased morbidity and mortality. The comorbid burden of SLE involves various organ systems and may be associated with pain, fatigue, difficulty with daily activities (including school and work), and emotional well-being, all contributing to high rates of disability.

**Objectives:** We conducted a systematic literature review evaluating association between SLE-related organ damage and health-related quality of life (HRQOL).

**Methods:** A systematic literature search (January 2000–February 2017) of PubMed, EMBASE, Cochrane Library, and Latin American and Caribbean Health Sciences Literature was conducted to identify studies evaluating association between organ damage (measured by SLICC/ACR Damage Index [SDI]) and HRQOL for adults with SLE. Instruments examined include the Short Form 36 (SF-36: Physical Component Summary [PCS] and Mental Component Summary [MCS], 15 studies); EuroQol 5 Dimensions Questionnaire (EQ-5D) and Fatigue Severity Scale (FSS, 2 studies each); and the LupusQoL, Multidimensional Fatigue Inventory (MFI), Quality of Life Questionnaire of the European Foundation for Osteoporosis (QUALEFFO), and WHO Quality of Life Scale (WHOQOL-BREF) (1 study each).

**Results:** From 10 420 articles screened, 20 studies were included (3 prospective cohort studies, 17 cross-sectional studies). The 3 prospective studies evaluated HRQOL by the SF-36, 2 of which modelled SDI as a binary variable. For patients without damage at baseline, any damage accrual over 2 years was associated with a 5.5-fold increased risk of decreased HRQOL compared with those who did not develop new damage (SF-36 overall relative risk [RR] 5.5 [95% CI: 1.1–26.6; p=0.03]). A similar trend toward increased risk of decreased HRQOL was observed with PCS: RR 2.5 (95% CI: 0.6–10.0; p=0.19); and MCS: RR 4.6 (95% CI: 0.9–22.8; p=0.06). Any damage at baseline was associated with 67% decreased odds of achieving minimum clinically important improvement in SF-36 PCS: odds ratio [OR] 0.33 (95% CI: 0.13–0.85; p=0.02). However, no association was observed for MCS. When SDI was modelled as a continuous variable, increasing damage was associated dose-dependently with decreased SF-36 PCS compared with SDI=0; SDI 1: –2.64, p<0.001; SDI 2: –2.86, p=0.003; SDI 3: –5.94, p<0.001; SDI 4: –6.35, p<0.001; and SDI 5+: –8.11, p<0.001. In cross-sectional evaluations, increasing SDI was modestly correlated with decreased HRQOL: SF-36 correlation coefficient score range: –0.12 to –0.30; SF-36 regression coefficient score range: –0.011 to –4.65; LupusQoL correlation coefficient –0.31, p<0.01; and WHOQOL-BREF regression coefficient –0.06, p=0.57. Increasing fatigue displayed weak correlation with damage: FSS correlation coefficient range: 0.04 to 0.15.

**Conclusions:** Organ damage was associated with decreased HRQOL in most studies evaluated. This review determined heterogeneity in HRQOL instruments and methodology across studies. Improving construct validity of instruments and

consistent evaluation will improve the ability to estimate the burden of SLE and enhance efforts to improve HRQOL in SLE.

#### HOW PHENOTYPE OF THE SMALL FIBRE NEUROPATHY (SFN) IN PRIMARY SJÖGREN SYNDROME (PSS) DIFFERS FROM OTHERS CAUSES OF SMALL FIBRE NEUROPATHY?

E. Descamps<sup>1</sup>, J. Henry<sup>1</sup>, C. Labeyrie<sup>2</sup>, D. Adams<sup>2</sup>, D. Aiello<sup>2</sup>, X. Mariette<sup>1</sup>, R. Seror<sup>1</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Neurology, Hopitaux Universitaires Paris Sud, Kremlin Bicêtre, France

**Background:** Small fibre neuropathy (SFN) is a peripheral neuropathy characterised by neuropathic pain associated with normal routine nerve conduction study but rarefaction of intraepidermal nerve fibres (IEFN). Primary Sjögren Syndrome (pSS) is one of the many etiology of SFN.

**Objectives:** To compare phenotype of SFN in pSS, transthyretin (TTR) familial amyloidosis and idiopathic SFN. To describe evolution of SFN in pSS.

**Methods:** All patients referred since October 2012 with a biopsy-proven SFN associated with either pSS (ACR/<sup>EULAR</sup> 2016 criteria), TTR-amyloidosis or idiopathic were included in this monocentric retrospective study. Diagnosis of SFN was confirmed by normal nerve conduction study and abnormal lower limb skin biopsies. All patients undergo standardised diagnosis procedures during an out-patient day-clinic, pSS patients were further followed and undergo a second evaluation. Characteristics of SFN were compared between 3 groups: pSS, TTR-amyloidosis and idiopathic, and outcome of pSS associated SFN was analysed.

**Results:** We included 15 patients with pSS (13 (86.7%) women, median age: 56 years [IQR:46.5–63.5], 7 (46.7%) anti-SSA positive, 12 (80%) focus score  $\geq 1$ , 17 with TTR-amyloidosis (7 (41.2%) women, median age: 47 years<sup>35–56</sup>) and 11 with idiopathic SFN (7 (63.6%) women, median age: 47 years [36–56.5]). Patients with pSS had a median ESSDAI of 5.5–8. One had monoclonal gammopathy, 5/13 (38.5%) rheumatoid factor, 2/13 (15.4%) hypergammaglobulinemia and none had cryoglobulin. Time from first neurologic symptoms to diagnosis of SFN was significantly higher for pSS (29 months [8.5–65]) and idiopathic group (35 months [11.5–65]) than for TTR group (6 months [0–15]). Clinical presentation was length dependant in only 2 (13.3%) patients with pSS compared to 10 (58.8%) in TTR amyloidosis ( $p=0.01$ ) and 2 (18.2%) in idiopathic group ( $p=1$ ). A “patchy” presentation (defined by asymmetrical and/or proximal symptoms involving limb, trunk and/or face), was significantly more frequent in pSS than in TTR amyloidosis (7 (43.7%) vs. 1 (5.9%);  $p=0.01$ ). This more frequent non-length dependant course was confirmed on skin biopsies with an IEFN at proximal site <IEFN at distal site in 7/14 (50%) pSS patients compared to 2/15 (13.3%) in TTR ( $p=0.05$ ) and 1 (9.1%) in idiopathic ( $p=0.04$ ) groups. Lauria score was significantly higher in pSS than in TTR, (5 [4–7.5] vs. 2.2–5  $p=0.007$ ), mainly due to items of sicca symptoms ( $n=14/15$ ) and peripheral limb pain ( $n=13/15$ ). Ten patients with pSS have been reassessed with a median follow up of 31 months [16.5–53.5]. At reassessment, the Lauria score did not significantly differ (6<sup>5–7</sup>) from initial score, patchy presentation was still predominant 5 (50%). Patients did not evolve through large fibre neuropathy, except one patient who had received a neurotoxic chemotherapy by platin for ovarian cancer, between the 2 evaluations.

**Conclusions:** pSS patients with SFN had a low frequency of serum B cell activation biomarkers. Compared to other causes of SFN, in pSS SFN was characterised by a more frequent non-length dependant and patchy presentation and a higher Lauria score. After a median follow-up of 31 months, SFN in pSS were stable in the time and did not evolve through large fibre neuropathy.

Lau<sup>13</sup>, A. Hoi<sup>1</sup>, M. Nikpour<sup>14</sup>, E. Morand<sup>1</sup>. <sup>1</sup>School of Clinical Sciences at Monash Health, Monash University, Clayton, Australia; <sup>2</sup>Chiang Mai University Hospital, Chiang Mai, Thailand; <sup>3</sup>Chang Gung Memorial Hospital, Taipei; <sup>4</sup>Chang Gung Memorial Hospital, Keelung, Taiwan, Province of China; <sup>5</sup>National University Hospital, Singapore, Singapore; <sup>6</sup>University of Malaya, Kuala Lumpur, Malaysia; <sup>7</sup>University of Santo Tomas Hospital, Manila, Philippines; <sup>8</sup>University of Padjadjaran, Bandung, Indonesia; <sup>9</sup>Tokyo Women's Medical University, Tokyo, Japan; <sup>10</sup>Tan Tock Seng Hospital, Tan Tock Seng, Singapore; <sup>11</sup>Liverpool Hospital, Liverpool; <sup>12</sup>Royal Adelaide Hospital and Flinders Medical Centre, Adelaide, Australia; <sup>13</sup>University of Hong Kong, Pok fu lam, Hong Kong; <sup>14</sup>St. Vincent's Hospital, Melbourne, Australia

**Background:** Patients with systemic lupus erythematosus (SLE) are commonly assessed using the classification criteria developed by the American College of Rheumatology (ACR), or more recently by the Systemic Lupus International Collaborating Clinics (SLICC). Although SLE is highly prevalent and severe in Asians, no comparison of patients meeting these criteria in predominantly Asian SLE patients has been performed.

**Objectives:** To compare patients meeting the ACR and SLICC classification criteria in the Asia Pacific Lupus Collaboration (APLC) cohort.

**Methods:** All patients fulfilled either the ACR (1997) criteria ( $\geq 4$  of 11 items) or SLICC criteria ( $\geq 4$  of 17 items, including  $\geq 1$  clinical and  $\geq 1$  immunologic criteria, or biopsy-proven lupus nephritis (LN) +  $\geq 1$  immunological criterion), evaluated at enrolment. Demographic and clinical data were compared using Kruskal Wallis (for medians) chi-squared (proportions) tests.

**Results:** 1735 patients were studied with a median (IQR) (range) follow up of 795 [532, 1087] (0, 1443) days. 1716 (98.9%) and 1668 (96.1%) patients met SLICC and ACR criteria respectively. 1649 (95%) patients met both criteria, 67 (3.9%) patients met SLICC criteria only and 19 (1.1%) patients met ACR criteria only. Patients in ACR-only and SLICC-only groups were significantly older than those who met both criteria (ACR-SLICC group); ACR-only patients had longer observation period (table 1), 15/67 SLICC-only patients had non-scarring alopecia, which is not an ACR item, and 14 had LN with  $\geq 1$  immunologic criterion. Discrepancies between the 19 ACR-only patients and the ACR-SLICC group were predominantly observed in the immunological criteria. Both ACR-only and SLICC-only patients had lower SLEDAI-2k score at recruitment when compared to ACR-SLICC group, and a fewer SLICC-only patients were in flare (table 1). During the observation period, SLICC-only patients had the lowest time-adjusted mean (TAM) SLEDAI-2k and prednisolone dose; lowest proportions of flares and damage accrual, and highest proportion of patients achieving Lupus Low Disease Activity State (LLDAS) at least once. In contrast, ACR-only patients had the highest proportion of patients experiencing flares and least proportion of achieving LLDAS (table 1).

	ACR & SLICC n=1649	ACR only n=19	SLICC only n=67	p-value
<b>Demographics</b>				
Age at enrolment (years)	40 (31, 50)	50 (37, 59)	46 (34, 55)	0.003
Study observation period (years)	2.2 (1.5, 3.0)	3.4 (2.4, 3.5)	2.1 (1.7, 2.8)	0.005
Females, n (%)	1533 (93.0%)	18 (94.7%)	64 (95.5%)	0.7
<b>Clinical indications at recruitment</b>				
PGA	0.5 (0.2, 1.0)	0.5 (0.2, 0.8)	1.0 (0.3, 1.2)	0.09
SLEDAI-2k score	4.0 (2.0, 6.0)	2.0 (0.0, 4.0)	2.0 (1.0, 4.0)	0.03
Mild/mod./severe flare, n (%)	272 (16.5%)	4 (21.1%)	3 (4.5%)	0.03
Organ damage, n (%)	679 (41.2%)	10 (52.6%)	25 (37.3%)	0.5
In LLDAS, n (%)	769 (46.7%)	7 (36.8%)	39 (58.2%)	0.12
<b>Longitudinal clinical indications</b>				
Time adjusted mean PGA	0.4 (0.2, 0.8)	0.4 (0.2, 0.6)	0.5 (0.2, 0.9)	0.7
Time adjusted mean SLEDAI	3.4 (1.5, 5.4)	2.6 (1.0, 5.3)	2.0 (1.3, 4.0)	0.009
Time adjusted mean prednisolone (mg)	5.0 (2.1, 8.9)	4.1 (2.5, 8.9)	3.0 (0.0, 6.6)	0.004
Mild/mod./severe flare ever, n (%)	954 (57.9%)	12 (63.2%)	21 (31.3%)	<0.001
Damage accrual, n (%)	241 (14.6%)	3 (15.8%)	6 (9.0%)	0.4
LLDAS ever, n (%)	1282 (77.7%)	12 (63.2%)	58 (86.6%)	0.07

**Conclusions:** We observed a high overlap between the two classification criteria, but the use of both criteria captured a larger cohort overall. In this cohort, patients meeting SLICC but not ACR criteria had less active disease.

**Disclosure of Interest:** None declared

### THE ACR-EULAR CLASSIFICATION CRITERIA IN PRIMARY SJÖGREN'S SYNDROME: THE CONTRIBUTING ROLE OF ULTRASOUND

E. Mossel<sup>1</sup>, J.F. van Nimwegen<sup>1</sup>, M.S. van Ginkel<sup>1</sup>, K. Delli<sup>2</sup>, A.J. Stel<sup>1</sup>, F. G. Kroese<sup>1</sup>, F.K. Spijkervet<sup>2</sup>, A. Vissink<sup>2</sup>, S. Arends<sup>1</sup>, H. Bootsma<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Oral and Maxillofacial Surgery, University Medical Center Groningen, Groningen, Netherlands

**Background:** Salivary gland ultrasound (SGUS) is cheap, non-invasive and easy to perform in an outpatient setting. The ACR-EULAR criteria were recently developed to reach international consensus regarding the classification of primary Sjögren's syndrome (pSS), but SGUS is not yet included as a classification item.

**Objectives:** To assess the performance of the ACR-EULAR criteria when salivary gland ultrasound (SGUS) replaces current items, in a large cohort of patients clinically suspected or diagnosed with pSS in daily clinical practice.

**Methods:** Included were all consecutive outpatients who underwent SGUS between October 2014 and July 2017 and had a complete data-set on all ACR-EULAR items. Classification according to the criteria was determined separately in patients who were subjected to a labial or parotid gland biopsy. For SGUS, the average score for hypoechogenic areas in the parotid and submandibular glands on one side was applied (range 0–3)<sup>1</sup>. The optimal cut-off value for our SGUS score was determined using ROC analysis. Clinical diagnosis by the treating physician was used as gold standard. Area under the curve (AUC), absolute agreement, sensitivity and specificity of the original and adjusted ACR-EULAR criteria sets were determined.

**Results:** Of the 363 consecutive patients, 243 patients had a complete data-set, of whom 147 patients were diagnosed with pSS. Accuracy of SGUS to predict clinical diagnosis was good, with an AUC of 0.860 and optimal cut-off value of  $\geq 1.5$ . When applying a weight of 1 point for a positive SGUS, the cut-off value of the ACR-EULAR criteria to discriminate between pSS and non-pSS remained 4, irrespective of the type of biopsy used.

In patients who underwent a labial gland biopsy (n=124), the original ACR-EULAR criteria showed an AUC of 0.965 (figure 1A). Absolute agreement with clinical diagnosis was 94.4%, sensitivity was 95.9% and specificity was 92.2%. When SGUS replaced the labial gland biopsy, absolute agreement was 87.9%, sensitivity was 82.2% and specificity was 96.1%. When SGUS replaced anti-SSA antibody status, absolute agreement was 89.5%, sensitivity was 86.3% and specificity was 94.1%. When SGUS replaced the ocular staining score (OSS), Schirmer's test or unstimulated whole saliva flow (UWS), absolute agreement varied between 89.5%–93.5%, sensitivity varied between 90.4%–95.9% and specificity varied between 88.2%–92.2%. In patients who underwent a parotid gland biopsy (n=198), similar results were found (figure 1B).

**Abstract SAT0431 – Figure 1.** Ultrasound replacing current ACR-EULAR items in patients who underwent a labial gland biopsy (A) or a parotid gland biopsy (B).

**Conclusions:** SGUS cannot be used as a replacement for salivary gland biopsy or anti-SSA antibody status in the ACR-EULAR criteria because of a substantial reduction in sensitivity. For diagnostic purposes, a high sensitivity is preferred over a high specificity.

Replacement of the OSS, Schirmer's test or UWS by SGUS only resulted in negligible changes in accuracy of the ACR-EULAR criteria. With SGUS being able to replace one of these function tests, clinicians are offered more options that could lead to fulfilment of the ACR-EULAR criteria.

### MEMBRANOUS VERSUS PROLIFERATIVE LUPUS NEPHRITIS: TWO DIFFERENT DISEASES?

F. Farinha<sup>1</sup>, B.S. Bemstein<sup>1</sup>, R. Pepper<sup>2</sup>, D.A. Isenberg<sup>1</sup>, A. Rahman<sup>1</sup>. <sup>1</sup>Centre for Rheumatology; <sup>2</sup>Centre for Nephrology – Royal Free Campus, UCL, London, UK

**Background:** Lupus nephritis (LN) is currently classified according to the 2003 International Society of Nephrology/Renal Pathology Society (ISN/RPS) classification system, which is based on histology. Most patients have proliferative lupus nephritis (PLN), which has been the most studied type of LN. Membranous lupus nephritis (MLN) is less frequent, accounting for 10%–20% of the cases. In some patients there is a combination of the two types.

**Objectives:** To compare MLN and PLN with respect to demographic, clinical and laboratory characteristics.

**Methods:** Single-centre retrospective observational study. All patients with biopsy-proven proliferative (class III and IV), membranous (class V) and mixed (class III or IV+V) LN (according to the 2003 ISN/RPS classification), followed at UCLH Rheumatology department from 1975 to 2017, were included. Individual clinical files were reviewed to obtain demographic, clinical, laboratory and pathological data. We also recorded data on treatment with corticosteroids, immunosuppressants and antimalarials. We compared groups using Pearson's chi-squared test for qualitative variables and Mann-Whitney test for quantitative variables. Renal survival was analysed through the Kaplan-Meier method. Significance level was defined at 0.05.

**Results:** 187 patients were included (table 1). Age at diagnosis was not significantly different between groups (p=0.474). The groups differ regarding ethnicity – higher proportion of Caucasians with PLN versus higher proportion of Afro-Caribbeans with MLN. Patients with MLN present with higher C3 levels and significantly lower anti-dsDNA levels than the ones with proliferative changes. Thirty-four patients with PLN, 3 with MLN and 2 with mixed nephritis, progressed to end-stage renal disease. Cumulative renal survival rates at 5, 10, 15 and 20 years were 91, 81, 75% and 66% for PLN and 100, 97, 92% and 84% for MLN, respectively (Image 1).

**Abstract SAT0432 – Table 1.** Comparison between the three groups of patients

#### APPLICATION OF THE DORIS ALGORITHM FOR THE DEFINITION OF DISEASE REMISSION OVER A 2-YEAR PERIOD IN A COHORT OF ITALIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

F. Dall'ara<sup>1</sup>, L. Andreaoli<sup>1</sup>, G. Armentaro<sup>1</sup>, F. Migliorati<sup>1</sup>, M. Frassi<sup>1</sup>, F. Franceschini<sup>1</sup>, S. Calza<sup>2</sup>, A. Tincani<sup>1</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Department of Clinical and Experimental Sciences, Spedali Civili and University of Brescia; <sup>2</sup>Department of Translational and Molecular Medicine, Biostatistics Unit, University of Brescia, Brescia, Italy

**Background:** Systemic Lupus Erythematosus (SLE) is characterised by a fluctuating course. To achieve sustained remission is the ultimate goal of maintenance treatment. However remission is difficult to define in SLE. In 2014, an international Task Force named DORIS proposed four definitions of remission.<sup>1</sup>

**Objectives:** Aim of this study was to evaluate the performance of the DORIS algorithm in comparison to the remission status as defined by clinical judgement and to identify the frequency of remission as determined by DORIS for each clinical disease pattern.

**Methods:** Monocentric retrospective study. Among all SLE patients followed at the Lupus Clinic between 2014 and 2016, we enrolled patients fulfilling the SLICC<sup>2012</sup> criteria who were visited at least once in 2016 and who had at least 5 biannual medical examinations in the previous 2 years. Definitions of remission according to DORIS, Clinical Remission, and disease patterns are reported in table 1.

**Results:** 101 SLE patients were enrolled for this study (94% female, mean age 45 years). 17.8% of patients were in remission in all the 5 time-points, vice versa 29.7% of patients never got into remission. 17.8% of patients have been in remission for 24 months, while 21.8% of patients less than 6 months. Mean duration of DORIS remission was 7.96 months. The most prevalent disease pattern were RR (41.6%) and CQ (41.6%), while CA pattern was present in 16.8% of patients. DORIS remission was most frequently achieved in CQ pattern (65.2% of visits), less frequently in CA (5.9%). 294 visits out of 505 (58%) were defined as "non-remission" according to DORIS. cSLEDAI above zero was the item that most frequently accounted for "non-remission", particularly urinary and haematological (as reported in figure 1). In 229 (43.3%) visits there was a disagreement between DORIS and clinical judgement: the reasons for discordant results were respectively: a) self-management of steroids dosage and precautionary increase of steroids in the suspect of a flare in 7.1%; b) cSLEDAI >0 in 27.2%, PGA ≥ 0.5 in 12.6%, more than one of these items in 53.1%.

**Abstract SAT0433 – Table 1.** Definition of Remission according to Doris, Definition of Clinical Remission according to Clinical judgement; Definition of disease pattern. PGA: Physician Global Assessment; cSLEDAI: clinical SLEDAI

Definition of Remission	Clinical Items		Treatment		
	cSLEDAI	PGA	Daily dose of prednisone	Antimalarials	Immunosuppressants/ Biologics
Remission "off treatment"	= 0	< 0.5	0	yes	no
Remission "on treatment"	= 0	< 0.5	≤ 5 mg	yes	yes
No Remission	≠ 0	≥ 0.5	≥ 5 mg	yes	yes
<b>Definition of Clinical judgement of Remission</b>	Absence of any increase in corticosteroids dosage or any change in immunosuppressants				
<b>Definition of disease patterns</b>					
Chronic active (CA)	Persistent disease activity over time with a cSLEDAI ≥ 1 in each visit for at least one year				
Relapsing-remitting (RR)	Characterised by periods of disease activity with cSLEDAI ≥ 1 interspersed with periods of disease inactivity with cSLEDAI = 0 in different visits for at least one year				
Clinical quiescent (CQ)	Defined as absence of disease activity with a cSLEDAI = 0 for at least one year				

**Abstract SAT0433 – Figure 1.** Items are responsible of disagreement between DORIS and Clinical definition of Remission

**Conclusions:** Nearly 40% of the visits displayed a disagreement between clinical judgement of remission and DORIS remission. This may be attributable mainly to a different approach in evaluating patients: longitudinal by clinical judgement and cross-sectional by DORIS. As compared to clinical judgement of remission, the DORIS definition is not designed to capture "low disease activity", particularly patients who carry a PGA between 0.5 and 1 and those who require a medium dosage of steroids in the frame of a CA pattern.

SAT0434

#### PARTICIPATION IN SYSTEMIC LUPUS ERYTHEMATOSUS – A CROSS-SECTIONAL ANALYSIS OF THE LULA-COHORT IN GERMANY 2015

G. Chehab<sup>1</sup>, J.G. Richter<sup>1</sup>, R. Fischer-Betz<sup>1</sup>, R. Brinks<sup>1</sup>, B. Winkler-Rohlfing<sup>2</sup>, M. Schneider<sup>1</sup>. <sup>1</sup>Policlinic of Rheumatology and Hiller Research Unit Rheumatology, Medical Faculty, Heinrich-Heine-University, Duesseldorf; <sup>2</sup>German Lupus Self-Help Community, Wuppertal, Germany

**Background:** Participation of chronically ill patients can be permanently and severely impaired. In a heterogeneous disease like systemic lupus erythematosus (SLE), various influencing factors such as disease activity, damage, concomitant diseases, but also detrimental effects due to the psychological burden must be considered.

**Objectives:** Our objective was to assess the current state of participation in a representative sample of German patients with SLE and evaluate the impact of demographic and clinical factors.

**Methods:** The Lupus erythematosus long-term study (LuLa-Study), a nationwide longitudinal study among German Caucasian patients with SLE, is being

conducted annually by a self-reported questionnaire since 2001. Inclusion criteria are a diagnosis of SLE and returning the completed paper questionnaire. Amongst others medication, comorbidities, health-related quality of life (HRQoL, Short-Form-12), and disease activity (Systemic Lupus Activity Measure) are surveyed. In the year 2015 we additionally inquired about participation using the "Index zur Messung von Einschränkungen der Teilhabe" (IMET; Index for measuring limitations of participation) that was developed on the basis of the International Classification of Functioning, Disability and Health (ICF), as well as depression (Centre for Epidemiologic Studies Depression Scale), and pain coping (Pain Related Self statements scale).

A multiple linear regression was run to predict overall impairment and impairment in the individual subdomains (dependent variables). Age, disease duration, number of comorbidities, pain, disease activity, catastrophizing, coping, depression, physical functioning, and physical and mental HRQoL were entered into our model as candidates for the independent variables. Variable selection was accomplished by a stepwise approach based on Akaike information criterion (AIC).

**Results:** The questionnaire was completed by 579 patients (response rate 89.2%). Only 48 (8.3%) reported no impairment of participation by their disease. Most limitations were reported in the domains 'stress and extraordinary strains' (56.3% reported moderate to high impairment) and 'sex life' (48.7%), whereas 'common activities of daily life' (21.1%) and 'close personal relationships' (26.5%) seemed to be limited less frequently.

Depression, physical functioning, and physical and mental HRQoL predicted overall participation (F-test,  $p < 0.0001$ ).

Depression, physical functioning, and physical HRQoL predicted also most of the participation subdomains whereas age, disease duration, no. of comorbidities, disease activity, pain, and pain coping behaviour impacted only individual subdomains.

**Conclusions:** Limitations of participation are common in SLE patients and affect different areas of life. In order to improve participation, it is of great importance to maintain, respectively improve physical and mental quality of life, physical functioning, and depression. The direction of causality cannot be proved beyond reasonable doubt in this cross-sectional analysis. Additional longitudinal studies are necessary.

**Background:** Systemic lupus erythematosus (SLE) is an autoimmune disease characterised by a variable involvement of multiple organs and tissues. Acute and/or chronic vascular inflammation is not uncommon in patients with SLE and can significantly affect patient quality of life and survival. Specific markers of vascular inflammation in SLE are lacking. Pentraxin-3 (PTX3) is an evolutionarily conserved pattern recognition receptor expressed by multiple cell lines and is growingly recognised as a marker of the vessel response to injury. Glucocorticoids are known inducers of PTX3 in most tissues. The role of PTX3 as a biomarker in SLE is discussed.

**Objectives:** To assess the potential informative role of PTX3 as a biomarker in patients with SLE with and without current or previous vasculitic manifestations and with active or quiescent disease.

**Methods:** We enrolled 55 adult patients with SLE for a total of 60 samples. Samples were classified as taken from patients with active disease (SLE disease activity index, SLEDAI,  $\geq 4$ ) with or without active vasculitis and from patients with quiescent disease (SLEDAI  $< 4$ ). Further stratification was performed according to a history of lupus vasculitis. Five patients were bled twice under different conditions. Plasma PTX3 was measured by ELISA. Non-parametric tests were employed to compare PTX3 levels among groups.

**Results:** PTX3 plasma levels were slightly but not significantly more elevated in patients with active vasculitis. PTX3 levels correlated with SLEDAI in the whole set of patients ( $p = 0.007$ ) and in those who were off corticosteroids ( $p < 0.001$ ), but

not in patients receiving prednisone. PTX3 levels correlated with the dose of prednisone ( $p < 0.001$ ). Patients with  $> 1$  moderately-to-highly active (A, B) British Isles Lupus Assessment Group (BILAG) domain had significantly higher PTX3 levels than those with more limited disease activity extent ( $p = 0.041$ ). PTX3 also correlated with a 0.0–3.0 physician global assessment scale (PGA), with patient-reported visual analogue scale, and inversely with C4 levels ( $p = 0.004$ ,  $p = 0.013$ ,  $p = 0.001$  respectively). There was no significant correlation with age or disease duration nor with C-reactive protein (CRP). Similar to PTX3, CRP was higher in patients with  $> 1$  A/B BILAG domain ( $p = 0.004$ ), but did not correlate with SLEDAI or prednisone dose. Repeated samples showed a high intra-individual variability for PTX3, which unpredictably correlated with disease activity and prednisone dosage.

**Conclusions:** Our data suggest that PTX3 is a marker of active disease extent rather than vascular inflammation in SLE and it shares this behaviour with CRP, another member of the pentraxin family. Nonetheless, PTX3 also specifically correlate with monoparametric indexes of activity such as SLEDAI. A high intra-individual variability and the effect of corticosteroids constitute potential limitations to future diagnostic applications of PTX3 in SLE.

Amoura<sup>1,2,3</sup>. <sup>1</sup>French national reference center for systemic lupus erythematosus and antiphospholipid antibody syndrome, service de Médecine interne 2, Institut E3M, Assistance Publique-Hôpitaux de Paris (AP-HP), Groupement Hospitalier Pitié-Salpêtrière (GHPS); <sup>2</sup>U1135, Centre d'Immunologie et des Maladies Infectieuses (CIMI-Paris), INSERM; <sup>3</sup>Université Pierre et Marie Curie, Université Pierre et Marie Curie; <sup>4</sup>service de néphrologie, Assistance Publique-Hôpitaux de Paris (AP-HP), Groupement Hospitalier Pitié-Salpêtrière (GHPS); <sup>5</sup>Service d'Anatomie et Cytologie Pathologiques, Assistance Publique-Hôpitaux de Paris (AP-HP), Groupement Hospitalier Pitié-Salpêtrière; <sup>6</sup>Département d'imagerie cardiovasculaire et de radiologie interventionnelle, Assistance Publique-Hôpitaux de Paris (AP-HP), Groupement Hospitalier Pitié-Salpêtrière (GHPS), Paris, France

**Background:** Renal biopsy is the cornerstone of Lupus nephritis (LN) management. However, transcutaneous renal biopsy (TCRB) is hampered by the antithrombotic treatment frequently prescribed in Systemic Lupus Erythematosus (SLE) and Antiphospholipid Antibody Syndrome (APS). Transjugular renal biopsy (TJRB) offers an attractive alternative for patients at increased risk of bleeding.

**Objectives:** The primary objective of the study was to describe the safety and the diagnostic performance of TJRB in SLE and APS.

**Methods:** A retrospective review of SLE and/or APS patients who consecutively underwent a renal biopsy in our department between January 2004 and October 2016 was performed. Biopsies were divided into four groups: TCRB, TJRB with aspirin treatment (aspirin TJRB), TJRB with anticoagulant treatment (anticoagulant TJRB), and TJRB without anti-thrombotic drug (no-antithrombotic TJRB). Major complications were defined as decrease, haemostasis nephrectomy, renal artery embolization, blood transfusion, sepsis and vascular thrombosis. Minor complications were defined as gross haematuria, renal hematoma and arteriovenous fistula.

**Results:** Fifty-four TCRB and 256 TJRB were analysed – 69 aspirin TJRB, 68 anticoagulant TJRB and 119 no-antithrombotic TJRB. Major complications rate was 1.9% for TCRB and 2.0% for TJRB ( $p = 1$ ). One patient in the TJRB group suffering from catastrophic antiphospholipid syndrome (CAPS) died suddenly 6 weeks after the biopsy. No patient died of bleeding complication. One patient in the anticoagulant TJRB group required a renal artery embolization and blood transfusion. Four other patients required blood transfusion (1 in the TCRB group, 1 in the aspirin TJRB group and 2 in the anticoagulant TJRB group). Minor complications rate was 1.9% for TCRB and 7.8% for TJRB ( $p = 0.2$ ).

Among the 256 TJRB, the rate of complication (major or minor) was higher for patients with glomerular filtration rate CKD-EPI  $< 30$  mL/min (6/24 [25%]) compared to patients with GFR  $> 30$  mL/min (16/232 [7%],  $p < 0.01$  using the Chi-2 test). Age over 40, blood pressure  $> 140/90$  mmHg, APS or positive

antiphospholipid biology without APS, Prothrombin Time<50%, activated Partial Thromboplastin Time ratio >1.2, platelets<50 G/L and biopsied kidney size were not associated with a higher rate of complications.

The number of glomeruli sampled and the performance of the biopsy to establish a histologic diagnostic were similar in the 4 groups.

**Conclusions:** TJRB provides diagnostic yield and safety similar to those of TCRB. It should be considered as a first intention procedure for SLE and APS patients at risk of bleeding.

SAT0437

#### INITIAL MANIFESTATIONS OF CHILDHOOD-ONSET SYSTEMIC LUPUS ERYTHEMATOSUS: RESULTS OF SINGLE CENTRE RETROSPECTIVE STUDY

M.I. Kaleda, E.A. Aseeva, I.P. Nikishina, S.K. Soloviev. *Pediatrics, V.A. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation*

**Background:** Approximately 10%–20% of patients (pts) with SLE develop lupus before 18 years old. Childhood-onset SLE (cSLE) usually has more aggressive course. The achievement of medication-free remission in adulthood is extremely rare in cSLE and quality of life remains compromised.

**Objectives:** To establish the specific features of cSLE at disease onset by the retrospective study in single centre.

**Methods:** 216 pts with cSLE who were hospitalised in our centre from 1992 to 2017 were included in retrospective study. Diagnosis of SLE was reviewed according to 2012 SLICC criteria. Clinical, haematological and immunological manifestations of SLE were evaluated. SLEDAI 2K was used for disease activity assessment.

**Results:** 12.9% of cSLE pts were boys (girls to boys ratio was 6.7:1). The triggering factor was found in 29% pts: solar exposure – in 51%, previous infection – in 19%, stressful situation – in 12%, vaccination – in 10%, menarche – in 5%, high physical activity – in 3%. Only 9.2% of patients initially had SLE diagnosis, 1.4% had discoid lupus erythematosus as an initial diagnosis, 21% – different infections, 11.2% – allergic diseases, 6.3% – nephritis, 33.6% – various rheumatic diseases (16.8% – juvenile idiopathic arthritis), in remaining 17.3% cases the information about initial diagnosis was missing. The median age at the onset was 13.7 y (10.8; 15.05); the median disease duration at the time of cSLE verification was 6 months.<sup>2; 14</sup> In 33.4% pts cSLE was verified after 1 year disease duration, in 15.3% – after 3 years. The most common feature was arthritis – in 71.4%. Fever observed in 68.5% pts at the onset, significant weight loss – in 29.4%. 64% pts had acute cutaneous lupus at the onset, 42.4% – chronic cutaneous lupus, 17.7% – oral and nasal ulcers, 22.2% – non-scarring alopecia, 31% – serositis, 56.6% – renal involvement, 21.2% – neuropsychiatric disorder. The Coombs' positive hemolytic anaemia was found in 15.8% pts, leucopenia/lymphopenia – in 52.2%, thrombocytopenia – in 23.6%. ANA were detected in 100% pts, anti-dsDNA – in 83.3%, anti-Sm – in 29.2%, antiphospholipid antibodies – in 7.3%, hypocomplementemia – in 49.0%, positive direct Coombs test out of hemolytic anaemia – in 13.5%. Macrophage activation syndrome at the onset was documented in 3.4% pts. Median disease activity by SLEDAI at the time of cSLE verification was 13.7 scores,<sup>8;20</sup> maximum – 42.

**Conclusions:** cSLE presentation with non-specific general and constitutional manifestations in the majority of cases misled to erroneous interpretation of the condition as infectious or allergic disease in 1/3 of all cases. A monosymptomatic manifestation at the onset, such as arthritis, skin lesion or hematologic disorders, can lead to late diagnosis and very high activity at the moment of start therapy. Specific features of cSLE must be suspected in all cases of arthritis with skin lesions and/or any haematological manifestations, even non-specific.

SAT0438

#### INCREASED RISK OF DEPRESSION IN PATIENTS WITH CUTANEOUS LUPUS ERYTHEMATOSUS AND SYSTEMIC LUPUS ERYTHEMATOSUS: A DANISH NATIONWIDE COHORT STUDY

J.H. Hesselvig<sup>1</sup>, A. Egeberg<sup>1</sup>, K. Kofoed<sup>1</sup>, G. Gislasen<sup>2</sup>, L. Dreyer<sup>3</sup>. <sup>1</sup>Department of Dermatology and Allergy; <sup>2</sup>Department of Cardiology; <sup>3</sup>Department of Rheumatology, Herlev and Gentofte University Hospital, Copenhagen, Denmark

**Background:** Quality of life is considerably impaired in patients with systemic lupus erythematosus (SLE) as well as in patients with cutaneous lupus erythematosus (CLE). In patients with SLE, prevalence estimates of depression ranges considerably,<sup>1</sup> while the prevalence of depression in CLE remains severely understudied. Data on the actual risk of depression in adults after being diagnosed with CLE or SLE remain scarce.

**Objectives:** To examine whether patients with SLE or CLE have increased risk of depression.

**Methods:** In this nationwide observational cohort study, we included patients ≥18 years with a first-time diagnosis of SLE or CLE between 2000–2015 identified in the Danish National Patient Register matched with people from the general population in Denmark in a 1:10 ratio. After linkage to various national Danish health registers analyses of risk for depression and antidepressant use were performed in Cox regression models adjusted for age, sex, socio-economic status, smoking, alcohol abuse, prior depression, and prior antidepressant use.

**Results:** A total of 3489 patients with lupus erythematosus and 34 890 people from the general population were included. The adjusted hazard ratios (HRs) of depression were 1.87 (95% CI, 1.37–2.55) and 2.15 (95% CI, 1.66–2.77) for patients with CLE and SLE, respectively, compared to the general population. The adjusted HRs of antidepressant use were 1.36 (95% CI 1.22–1.51) and 1.76 (95% CI 1.62–1.91) for patients with CLE and SLE, respectively. The risk of depression was more pronounced in patients diagnosed <50 years of age; adjusted HR=2.88 (95% CI, 1.77–4.69) for CLE and HR=2.33 (95% CI, 1.56–3.49) for SLE. Also a high risk of depression was observed for men with CLE (HR 2.59, 95% CI, 1.24–5.42) and SLE (HR 2.23, 95% CI, 1.11–4.48). Neither CLE or SLE were associated with increased risk of death from suicide.

**Abstract SAT0438 – Table 1.** Crude and adjusted hazard ratios for depression and antidepressant use in patients with lupus erythematosus compared with the general population

	Crude HR	(95% CI)	P-value	Adjusted HR*	(95% CI)	P-value
<b>Depression</b>						
CLE	2.34	(1.71–3.18)	<0.0001	1.87	(1.37–2.55)	0.0001
SLE	2.33	(1.81–3.01)	<0.0001	2.15	(1.66–2.77)	<0.0001
<b>Antidepressant use</b>						
CLE	1.61	(1.45–1.79)	<0.0001	1.36	(1.22–1.51)	<0.0001
SLE	1.94	(1.78–2.10)	<0.0001	1.76	(1.62–1.91)	<0.0001

\* Adjusted for age, sex, smoking, alcohol abuse, socio-economic status, prior depression, and prior antidepressant use.

CI, confidence interval; CLE, cutaneous lupus erythematosus; HR, Hazard Ratio; SLE, systemic lupus erythematosus.

**Conclusions:** The risk of depression was significantly increased in patients with SLE or CLE. We recommend that rheumatologists and dermatologists are aware of the increased risk of depression in patients with SLE or CLE.

#### DIFFERENTIAL LEVELS OF NOVEL AND CLASSIC ANTIPHOSPHOLIPID ANTIBODIES AMONG PATIENTS WITH PRIMARY ANTIPHOSPHOLIPID SYNDROME AND SYSTEMIC LUPUS ERYTHEMATOSUS

J.A. Gómez-Puerta<sup>1,2</sup>, T. Urrego<sup>3</sup>, A. Hernández<sup>4</sup>, S. Ruiz<sup>4</sup>, S.M. Osorno<sup>2</sup>, C. Rúa<sup>4</sup>, J. Duque Botero<sup>5</sup>, A.L. Vanegas-García<sup>6,7</sup>, C.H. Muñoz<sup>6,7</sup>, L. A. González<sup>6</sup>, G. Vásquez<sup>3,6</sup>. <sup>1</sup>Rheumatology, Hospital Clínic, Barcelona, Spain; <sup>2</sup>Dinámica IPS; <sup>3</sup>Grupo de Inmunología Celular e Inmunogenética; <sup>4</sup>Medicina Interna; <sup>5</sup>Grupo de Investigación en Trombosis; <sup>6</sup>Grupo de Reumatología, Universidad de Antioquia; <sup>7</sup>Servicio de Reumatología, Hospital San Vicente Fundación, Medellín, Colombia

**Background:** High levels of antiphospholipid antibodies (aPL) are associated predominantly with a higher risk of thrombosis, however, information about differential levels according underlying diagnosis is less well known.

**Objectives:** Our aim was to compared serum levels of 2 novel aPL (anti-phosphatidylserine/prothrombin (PS/PT) antibodies and anti domain 1 against β2 glycoprotein I (anti-D1 B2GP1)) and "classic" (anticardiolipin, aCL and anti B2GP1 antibodies) among patients with primary APS, SLE with and without thrombosis

**Methods:** In this cross-sectional study, Anti-D1 B2GP1 antibodies were tested using a chemiluminescent immunoassay (QUANTA Flash, Inova Diagnostics). In

addition, anti PS/PT (IgG and IgM), aCL (IgG and IgM) and anti B2GP1 (IgG and IgM) were measured at the same time by ELISA techniques (QUANTA Lite, Inova Diagnostics). Lupus anticoagulant was detected according to the guidelines of the International Society on Thrombosis and Haemostasia. Differences in mean values between groups were analysed with the Mann-Whitney U test for comparison of 2 groups

**Results:** One hundred and seventy three patients were included, 87% of patients were female with a mean age of 33±12 years. 150 patients had SLE and 23 patients primary APS. Fifty five (31%) out of 177 had history of thrombosis and 41 (23%) of pregnancy losses. Levels of IgM aCL, IgM B2GP1, IgM Anti PS/PT and total antibodies against Anti-D1 B2GP1 were significantly higher in patients with primary APS than in patients with SLE and thrombosis (see figure 1). IgG anti PS/PT (75.9±91.3 vs 27.4±39.3 IU, p<0.001) and total anti-D1 B2GP1 (65.2±152 vs 16.4±65.1 IU, p<0.001) were significantly higher in patients with SLE with thrombosis than in patients with SLE without thrombosis. Obstetric morbidity (66.7% vs 21.7%, p=0.016) and *livedo reticularis* (22% vs 0%, p>0.07) were more common in patients with primary APS than SLE with thrombosis. No significant differences were found in terms of thrombotic events among both groups

**Abstract SAT0439 – Figure 1.** aPL levels according diagnosis (IgM for aCL, anti B2GP1 and anti PS/PT and total antibodies against Anti-D1 B2GP1)

**Conclusions:** Patients with primary APS have significant higher serum levels of anti PS/PT and anti-D1 B2GP1 antibodies and “classic” aPL (aCL and anti B2GP1) antibodies than patients with SLE with thrombosis. Whether if these titers are useful to differentiate patients with primary and secondary APS requires further analysis in prospective studies.

**SAT0440 PHENOTYPIC FEATURES AND PREDICTORS OF THE CLINICAL SEVERITY OF KERATOCONJUNCTIVITIS SICCA AND SALIVARY GLAND DYSFUNCTION IN PATIENTS WITH SJÖGREN'S SYNDROME: A LONGITUDINAL ANALYSIS OF THE KISS COHORT**

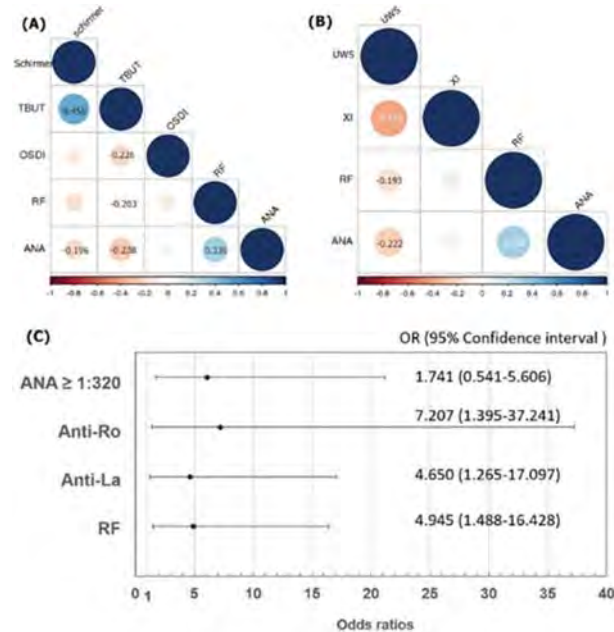

J.H. Koh<sup>1</sup>, Y.S. Suh<sup>2</sup>, J. Lee<sup>3</sup>, S.-K. Kwok<sup>4</sup>, S.-H. Park<sup>3</sup>. <sup>1</sup>Division of Rheumatology, Department of internal medicine, Pusan National University Hospital, Pusan; <sup>2</sup>Division of Rheumatology, Department of internal medicine, Gyeongsang National University Changwon Hospital, Changwon; <sup>3</sup>Division of Rheumatology, Department of Internal medicine; <sup>4</sup>Division of Rheumatology, Departement of Internal medicine, Seoul St.Mary's hospital, the Catholic University of Korea, Seoul, Korea, Republic Of

**Background:** Hyposecretion of tears and saliva is the main phenotype of primary Sjögren's syndrome (PSS). However, the prevalence and degree of ocular and oral involvement in PSS is highly variable.

**Objectives:** The aims of this study were 1) to investigate oral and ocular signs and changes in primary SS patients, and 2) to explore possible predisposing factors for moderate to severe oral or ocular signs in primary SS.

**Methods:** We analysed 140 participants from the Korean Initiative of PSS cohort who completed a two-year follow-up oral and ocular sign test. The severity of keratoconjunctivitis sicca (KCS) was determined by the Schirmer I test (Moderate-to-severe [MS], ≤5 mm/5 min; mild [Mi], >5 mm/5 min). Salivary gland dysfunction (SGD) was determined by unstimulated whole salivary flow rate (UWS) (MS, UWS <0.1 ml/min; Mi ≥0.1 ml/min). Subgroups were divided into three groups according to the severity of KCS and SGD: MS-KCS/MS-SGD, MS-KCS/Mi-SGD, and Mi-KCS/MS-SGD group. We analysed the severity of changes in KCS and SGD during the follow-up period.

**Results:** Among the 140 participants enrolled in this study, 108 (61%) were placed in the MS-KCS/MS-SGD group, 17 (24%) were in the MS-KCS/Mi-SGD, 15 (16%) were in the Mi-KCS/MS-SGD at the two-year follow-up. The MS-KCS/Mi-SGD group was younger than the other two groups, had a lower xerostomia inventory, and lower level of β2 microglobulin. Participants in the Mi-KCS/MS-SGD group had less hyperimmunoglobulinemia, rheumatoid factor (RF), antinuclear antibodies, anti-Ro, and anti-La antibodies. Older patients and those with positive RF, anti-Ro, or anti-La antibodies at baseline were more likely to have moderate to severe KCS at the two-year follow-up.

**Conclusions:** Patients with PSS and positive RF, anti-Ro, or anti-La antibodies at baseline may benefit from regular ophthalmology exams, even if they do not have KCS at baseline or dry eye symptoms.

**SAT0441 PREDICTIVE VALUE OF ANTIPHOSPHOLIPID ANTIBODIES IN THE ACUTE PHASE OF DEEP VEIN THROMBOSIS**

K. Perdan Pirkmajer<sup>1</sup>, A. Boc<sup>2</sup>, S. Čučnik<sup>1</sup>, A. Mavri<sup>3</sup>, P. Žigon<sup>1</sup>, E. Podovšovnik<sup>4</sup>, M. Štalc<sup>5</sup>, N. Vene<sup>3</sup>, A. Ambrožič<sup>1</sup>. <sup>1</sup>Department of Rheumatology, University Medical Centre Ljubljana; <sup>2</sup>Institute of Anatomy, Faculty of Medicine; University of Ljubljana; <sup>3</sup>Department of Vascular Diseases, University Medical Centre Ljubljana; <sup>4</sup>Faculty for Tourism Studies University of Primorska, Capodistria; <sup>5</sup>Department of Nuclear Medicine, University Medical Centre Ljubljana, Ljubljana, Slovenia

**Background:** Deep vein thrombosis (DVT) is frequent and potentially life threatening disease with tendency to recur. Anticoagulant treatment of the first episode of DVT usually lasts 3 months. Antiphospholipid syndrome (APS) is an important cause of DVT. However, the APS can be confirmed only 24 weeks after DVT according to the current APS classification criteria.<sup>1</sup> Thus, undiagnosed APS patients, who cease anticoagulant therapy after 3 months, might be exposed to a greater risk for recurrent venous thromboembolism. Studies evaluating the significance of positive antiphospholipid antibody (aPL) test in the acute phase of DVT are lacking.

**Objectives:** To evaluate whether positive aPL test at the time of acute DVT diagnosis is predictive of APS.

**Methods:** Patients with acute DVT were included into a 24 month prospective study. All patients were given anticoagulants. aCL IgG/IgM and anti-β2GPI IgG/IgM/IgA antibodies were determined by our in-house ELISA<sup>2</sup> at inclusion and then every 4 weeks for the first 24 weeks. The last aPL measurement was performed 24 months after inclusion into the study. APS was confirmed if a patient tested positive (medium or high positive aCL and/or presence of anti-β2GPI) 12 and 24 weeks after DVT. Lupus anticoagulants (LA) were tested after cessation of anticoagulation.

**Results:** 196 patients (111 male, 85 female, age 54±2 years) included in the study had aPL titer assessed at least 5 times. Ultimately, 20/196 (10.2%) patients fulfilled APS classification criteria. Among these, 15/20 (75%) patients had medium or high titer aPL at the time of acute DVT (1 of them had double positive aPL and 2 of them had multiple positive aPL at first aPL determination). Two patients (10%) had low positive aCL IgG and one had low titer aCL IgM. Two patients (10%) were negative for aPL, but had later fulfilled APS criteria due to positive LA. APS was not established in 176/196 (89.8%) patients. Among these, 146/176 (83%) patients were negative for aPL at inclusion, while 30/176 (17%) had low titer aCL IgM or aCL IgG. Altogether, diagnostically important aCL IgG/IgM and/or anti-β2GPI titer at the time of acute DVT had 83% specificity and 90.5% sensitivity for APS. Isolated low titer aCL IgG were more frequent in patients with APS than in patients without APS ( $\chi^2=125.6$ ;  $p<0.001$ ). Completely negative aCL IgG/IgM and anti-β2GPI in the acute phase of DVT had a negative predictive value of 98.6%.

**Conclusions:** Here we show that in acute phase of DVT, positive medium or high titer aCL IgG/IgM or anti-β2GPI is suggestive of APS. In these patients continuation of anticoagulation beyond the initial 3 months should be considered. Patients with negative aPL in the acute phase of DVT do not need further aPL testing; however, LA should be determined. Low aPL titre at the time of acute DVT deems further testing imperative.

**SAT0442 RISK FACTORS FOR HEART VALVE DISEASES IN PATIENTS WITH ANTIPHOSPHOLIPID SYNDROME**

K. Hiramoto, J. Kikuchi, Y. Kaneko, T. Takeuchi. *Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine, Tokyo, Japan*

**Background:** Antiphospholipid syndrome (APS) patients are known to be at a high risk of heart valve diseases (HVDs), however, risk factors of HVDs in APS patients is unclear.

**Objectives:** The purpose of this study is to elucidate risk factors for HVDs in patients with APS.

**Methods:** We reviewed consecutive APS patients diagnosed according to the Sydney criteria in 2006 who had been followed in Keio University Hospital in October 2017. The presence of HVDs was identified by the latest transthoracic and/or transesophageal echocardiography. HVDs were defined any kind of valve diseases such as mitral valve regurgitation (MR) and stenosis more than mild degree, aortic valve regurgitation (AR) and stenosis more than mild degree and Libman-Sacks endocarditis. Antiphospholipid antibodies (aPLs) included lupus

anticoagulant (LA), anticardiolipin antibodies (aCL), and anticardiolipin β2-glycoprotein I complex antibodies (aCL-β2GPI). We divided the patients into two groups by the presence of HVDs, and evaluated the risk factors of them.

**Results:** Fifty-five APS patients were identified. Among them, 43 patients underwent echocardiography and enrolled in the analysis. Six patients were primary APS, 36 were secondary APS with systemic lupus erythematosus, and one with Sjögren syndrome. HVDs were detected in 26 (60.5%) patients including 20 patients with MR, 8 patients with AR and a patient with Libman-Sacks endocarditis. The use of prednisolone, miscarriage episodes and the presence of arterial or venous thrombosis in patients with HVDs did not differ from those without HVDs. Immunologically, there was no significant difference in anti-double-stranded DNA antibody, anti-Smith antibody, anti-ribonucleoprotein antibody, anti-SSA/La antibody and anti-SSB/Lo antibody between patients with or without HVDs. While the positivity of aCL or aCL-β2GPI was not different between patients with HVDs and those without, positive LA was much higher in patients with HVDs and in patients with MR than those without (88.5% vs 35.3%,  $p<0.01$ ; 85.0% vs 52.2%,  $p=0.027$ , respectively). In addition, patients with HVDs had double and triple positive tests of aPLs significantly more frequently than those without HVDs ( $p=0.010$  and  $p=0.023$ , respectively[Y1]). Hospitalisation risk in patients with HVDs because of heart failure or syncope were 0.011/patient year.

**The proportions of positive aPLs in APS patients with HVDs and without them.**

**Conclusions:** Positive LA test and positivity for 2 or more tests of aPLs are risk factors for HVDs in patients with APS. Regular monitoring cardiac ultrasonography is needed in those patients.

**SAT0443 DIAGNOSTIC AND PREDICTIVE EVALUATION USING SALIVARY GLAND ULTRASONOGRAPHY IN PRIMARY SJOGREN'S SYNDROME**

K.-A. Lee, S.-H. Lee, H.-R. Kim. *Konkuk University Medical Center, Seoul, Korea, Republic Of*

**Background:** There is an increasing need for alternative, non-invasive and reliable diagnostic tools with the potential to improve and simplify the diagnostic process for primary Sjogren's syndrome (pSS). The main advantage of salivary gland ultrasonography (SGUS) is the direct visualisation of structural abnormalities of the salivary glands. Despite these advantages of SGUS, a number of obstacles remain. Different SGUS scoring systems in B-mode were used in previous studies. The diagnostic usefulness of Doppler analysis and glandular size measurement has not been established. Indeed there is no proven prognostic factor for glandular damage in pSS, although a number of studies have revealed the risk factors for lymphoma.

**Objectives:** We aimed to assess the diagnostic value of SGUS as a single test for the detection of pSS in an integrated manner. We assessed the diagnostic accuracy of three SGUS parameters: the ultrasound (US) grey-scale scoring system, glandular volume measurement, and intraglandular power Doppler US. The secondary aim was to examine the prognostic factors for severe structural changes in major salivary glands based on the SGUS scoring system.

**Methods:** Patients with pSS (n=94) and idiopathic sicca syndrome (n=44) were evaluated using the SGUS 0–48 scoring system, which comprises five parameters: parenchymal echogenicity, homogeneity, hypoechoic areas, hyperechoic reflections, and clearness of posterior borders (figure 1). The salivary gland volume and intraglandular power Doppler signal (PDS) were also assessed. A multivariate linear regression analysis was performed to determine the factors associated with SGUS score.

**Results:** Patients with pSS showed a significantly higher SGUS score than controls [median (IQR): 24.5 (13.0) vs 6 (3.75),  $p < 0.001$ ]. An SGUS cut-off of  $\geq 14$  had a sensitivity of 80.9% and a specificity of 95.5% for the diagnosis of pSS. There were no significant differences in the measured volumes and PDS between pSS patients and controls. The SGUS score correlated with unstimulated salivary flow rate (USFR), serum rheumatoid factor and IgG. Double seropositivity with anti-Ro/SS-A and anti-La/SS-B ( $\beta = 6.060$ ,  $p = 0.001$ ) and USFR ( $\beta = -1.913$ ,  $p < 0.001$ ) were independently associated with the SGUS score.

**Conclusions:** The SGUS scoring system is a valuable diagnostic method for pSS. Double seropositivity of anti-Ro/SS-A and La/SS-B is an independent predictive factor for structural damage of the salivary glands.

#### INCIDENCE AND PREDICTORS OF IMMUNOSUPPRESSANT DISCONTINUATION AND RISK OF SUBSEQUENT FLARE IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS

M. Zen, F. Saccon, M. Gatto, M. Larosa, L. Iaccarino, A. Doria. *Department of Medicine, Division of Rheumatology, University of Padova, Padova, Italy*

**Background:** Prolonged treatment with immunosuppressants (IS) has been associated with long-term complications in Systemic Lupus Erythematosus (SLE); however, few data on IS discontinuation in remitted patients are available to date.

**Objectives:** We conducted an observational study to describe the proportion of SLE patients who discontinued IS and to assess the potential predictors of a subsequent flare.

**Methods:** We used data from Padua Cohort, which includes 454 SLE patients followed up from 1990 to 2017. Patients treated with IS over the disease course who discontinued IS and seen at least once in 2017 were studied. Reasons for discontinuation were: remission (defined by clinical SLE disease activity Index=0) or poor compliance/intolerance. Flares were defined according to SLEDAI Flare

Index. Predictors of a subsequent flare were analysed by multivariate logistic regression analysis.

**Results:** Eligible patients who were ever treated with IS were 297. IS were discontinued in 106 patients (35.7%): mycophenolate (50, 47.2%), azathioprine (27, 25.5%), cyclophosphamide (11, 10.4%), methotrexate (10, 9.4%), cyclosporine (8, 7.5%). Mean  $\pm$ SD follow-up duration after IS withdrawal was  $82 \pm 64$  months (range 6–320).

83 out of 106 patients (78.4%) discontinued IS due to remission (mean remission duration at IS discontinuation  $39 \pm 28$  months), and 23 (21.6%) due to poor compliance/intolerance. Among remitted patients, 18 (78.3%) experienced a flare after IS discontinuation (9/55 patients with nephritis, 5/10 with arthritis, 2/9 with skin involvement, 1/3 with neuroSLE, 1/4 with haematological involvement) after a mean of  $65 \pm 52$  months (range 6–180). Conversely, in patients with poor compliance/intolerance, 17 relapsed (73.9%) after a mean of  $22 \pm 16$  months. Flare-free 10 year-survival rate was higher in patients who discontinued IS due to remission than to poor compliance/intolerance ( $p < 0.001$ , figure 1).

In patients who discontinued IS due to remission, a shorter duration of remission at IS discontinuation was associated with disease relapse ( $p = 0.006$ ). Patients who were on IS due to nephritis had a lower risk of flare after IS discontinuation compared with patients with other manifestations (16.4% vs 32.1%, OR 0.58, 95% CI 0.32–0.98,  $p = 0.049$ ); patients with arthritis were those who were more likely to flare (OR 4.61, 95% CI 1.16–18.29,  $p = 0.035$ ). Positive anti-SSA/SSB (OR 0.45, 95% CI 0.26–0.78,  $p = 0.012$ ) and antimalarials intake after IS discontinuation (OR 0.22, 95% CI 0.07–0.73,  $p = 0.015$ ) were associated with a lower risk of flare. No clinical features over the disease course were associated with flare occurrence.

At multivariate analysis, antimalarial use was the strongest protective factor against flares after IS discontinuation (OR 0.22, 95% CI 0.05–0.85,  $p = 0.029$ ).

**Abstract SAT0444 – Figure 1.** Free-flare 10 year survival in the cohort.

**Conclusions:** In our cohort, one third of patients treated with IS discontinued the drug during the follow-up, in most cases due to a prolonged remission. Patients who discontinued IS due to remission had a higher free-survival rate than those who discontinued these drugs due to poor compliance/intolerance. The use of antimalarials after IS discontinuation was independently associated with a significant decrease in the risk of flare. IS discontinuation in patients with arthritis requires particular caution.

SAT0445

#### THE CORRELATION BETWEEN THE TYPE OF CELLS IN MINOR SALIVARY GLANDS INFILTRATES AND THE SELECTED IMMUNOLOGICAL, CLINICAL AND LABORATORY PARAMETERS, IN PRIMARY SJOGREN'S SYNDROME PATIENTS WITH HISTORY OF EPSTEIN – BARR VIRUS INFECTION

M. Maślińska<sup>1</sup>, M. Prochorec-Sobieszek<sup>2</sup>, B. Kwiatkowska<sup>1</sup>. <sup>1</sup>Early Arthritis Clinic, National Institute of Geriatrics, Rheumatology and Rehabilitation; <sup>2</sup>Department of Hematology Diagnostics, Institute of Hematology and Transfusion, Warsaw, Poland

**Background:** The number of inflammatory mononuclear cell foci is crucial in primary Sjogren's syndrome (pSS) diagnosis, with their cellular composition changing in subsequent inflammation stages. The Epstein -Barr virus (EBV) infection is believed to play a role in the pathogenesis of pSS.

**Objectives:** Establishing the correlation of selected clinical, immunological and laboratory parameters with cellular composition of minor salivary glands infiltrations.

**Methods:** 41 pSS patients, 34 female (83%), 7 men (17%), average age 52 y.o, SD=15, with history of EBV infection, divided into two age groups (45<:>45). The diagnostics: white blood count (WBC), rheumatoid factor (RF), erythrocyte sedimentation rate (ESR), CRP, serum concentration of  $\gamma$ -globulins, antinuclear antibodies ANA(IF); anti-SS-A and anti-SS-B antibodies (semi-quantitative immunoblotting evaluation), standard ELISA assays of serum cytokines levels (BAFF, APRIL, FLT-3L, LT- $\alpha$ , IL-21), minor salivary gland biopsy with the histopathological evaluation (focus score-FS), immunochemistry assessment of the CD3 +, CD4 +, CD19 +, CD21 +, CD35 +cells presence, ocular tests: Schirmer's test and ocular staining score (OSS); ELISA assay of antibodies against EBV specific proteins (viral capsid antigen, early antigen and Epstein-Barr nuclear antigen), ESSDAI evaluation. The Bioethics Committee approval was obtained. Statistic: U Mann-Whitney test and Spearman correlation coefficient with statistical significance set at  $p < 0.05$ .

**Results:** In infiltrates CD3 +, CD4 +and CD19+cells dominated, WBC negatively correlated with CD 35+cells ( $\rho = -0.323$ ). CD3 +and CD4+absolute cell count correlated positively with anti-SS-A antibodies, but not with ANAs and anti-SS-B antibodies. The CD19 +, CD3 +and CD4+absolute cell count correlated positively with the serum LT- $\alpha$  concentration (respectively  $\rho = 0.349, 0.488, 0.483$ ) and moderately negatively with Schirmer test, but not with OSS. There were no differences in FS grade between age groups. In the younger group all cell types were found, including CD21 + ( $p = 0.042$ ) and CD35 + ( $p = 0.036$ ); the older subgroup lacked dendritic cell markers. The ESSDAI positively correlated with CD3 +, CD4 +, CD19 +and CD21+cells (respectively  $\rho = 0.320, 0.329, 0.28, 0.241$ ).

**Conclusions:** a) Leukopenia may be associated with the dendritic cells (CD35 +) presence in the disease subsequent stage. b) The positive correlation of mononuclear cells with LT- $\alpha$  confirms the LT- $\alpha$  effect on the immune response in peripheral lymphatic organs and on T and B lymphocytes. c) The presence of CD21 +and CD 35+cells observed in younger group, may indicate an active and early phase of inflammation and the activity of both T and B-lymphocytes and dendritic cells. d) The positive correlation ESSDAI with all studied cell types confirms the observation, that organ-related complications correlate with inflammatory activity expressed in mononuclear cell infiltrates. e) The effect of EBV reactivation/previous infection on FS, CD3 +, CD4 +, CD19 +, CD21 +, CD35 +was not demonstrated.

#### SERUM CONCENTRATIONS OF 25-HYDROXYVITAMIN D AND METABOLIC SYNDROME AND ITS COMPONENTS IN NONDIABETIC SYSTEMIC LUPUS ERYTHEMATOSUS PATIENTS

M. García-Carrasco<sup>1,2</sup>, C. Mendoza Pinto<sup>1,2</sup>, M. Cabrera-Jiménez<sup>1</sup>, S. Méndez-Martínez<sup>1</sup>, I. Etcheagaray-Morales<sup>2</sup>, I. Zamora-Guinez<sup>2</sup>, A. Ruiz-Arguelles<sup>3</sup>, R. Cervera<sup>4</sup>. <sup>1</sup>Systemic Autoimmune Diseases Research, HGR36-CIBIOR IMSS; <sup>2</sup>Immunology and Rheumatology, Medicine School BUAP; <sup>3</sup>Immunology Laboratory, Laboratorios Clínicos de Puebla, Puebla, Mexico; <sup>4</sup>Systemic Autoimmune Diseases Department, Hospital Clinic, Barcelona, Spain

**Background:** Increasing evidence has suggested a protective role of vitamin D in the metabolic syndrome (MetS). However, studies addressing this issue are limited in systemic lupus erythematosus (SLE).

**Objectives:** We examined the relationship between serum 25-hydroxyvitamin D (25(OH)D) status and MetS in nondiabetic SLE patients.

**Methods:** Cross-sectional analyses of the relationship between concentrations of 25(OH)D, MetS, and its components were made in 160 nondiabetic SLE women. MetS was defined according to the NCEP-ATP III criteria. Serum 25(OH)D was measured by chemiluminescent immunoassay. Serum 25(OH)D levels were categorised into quartiles (<16.6, 16.6–21.1, 21.2–26.3,  $\geq 26.4$  ng/ml).

**Results:** A total of 79 (49.3%) of SLE women had MetS. Without adjusting for BMI or smoking, the odds of having MetS decreased according to increasing quartiles of vitamin D levels ( $P$  for trend=0.036). The odds ratio (OR) of having MetS was 0.39 (95% confidence interval: 0.16–0.97,  $p = 0.043$ ) for the highest vs. the lowest quartile of vitamin D levels when adjusted by age. The crude OR of having elevated hypertriglyceridemia decreased according to increasing quartiles of

vitamin D levels ( $P$  for trend=0.036). However, further adjustments for BMI and smoking removed the inverse association between vitamin D status and MetS and its individual components (Table).

**Table.** Multivariable-adjusted OR (95%) for metabolic syndrome according to categories of serum 25(OH)D

	Quartiles of 25(OH) ng/ml				P value

Adjusted OR (95% CI) ‡	1.0	1.07 (0.40–2.85)	0.58 (0.21–1.58)	0.49 (0.18–1.32)	0.492

\* Adjusted by age, † Adjusted by age and BMI, ‡ Adjusted by age, BMI and smoking

**Conclusions:** In nondiabetic SLE women with mild activity, the potential inverse relationship between vitamin D status and MetS may be attributable to the joint effects of individual obesity and smoking. Prospective studies are necessary to better determine the role of 25(OH)D in the incidence of MetS in SLE patients.

SAT0447

#### VALIDATION OF THE 2017 ACR/EULAR CLASSIFICATION CRITERIA OF SYSTEMIC LUPUS ERYTHEMATOSUS

M. Suda, H. Yanaoka, R. Rokutanda, T. Tsuda, M. Kishimoto, K. Yamaguchi, M. Okada. *Immuno-Rheumatology Center, St. Luke's International Hospital, Tokyo, Japan*

**Background:** Two major classification criteria have been used in the clinical trials of systemic lupus erythematosus (SLE). One is American College of Rheumatology (ACR) criteria first developed in 1982 and revised in 1997 (1997 criteria)<sup>1</sup>, and the other is Systemic Lupus International Collaborating Clinics (SLICC) criteria developed in 2012 (2012 criteria)<sup>2</sup>. In the ACR annual meeting on November 2017, the new classification criteria of SLE (2017 criteria) were proposed, aiming for better specificity and sensitivity. They were made based on the agreement of expert panel<sup>3</sup>, and have not been validated in the real-world practice.

**Objectives:** The objective of the study is to evaluate the sensitivity of 2017 criteria when applied to real SLE cases.

**Methods:** We retrospectively reviewed the electronic medical record of the consecutive 100 patients who visited St. Luke's International Hospital, a tertiary care centre in Tokyo, Japan, searching back from November 13, 2017. Patients were included if they are clinically diagnosed as having SLE with board-certified doctors, and excluded if they complicated with other autoimmune disease or if they

are under 18-year-old. Each patient was evaluated if he or she satisfied the 1997, 2012, or 2017 criteria.

**Results:** Among the 100 cases, 9 were male and 91 were female, with wide range of age;<sup>18-88</sup> mean 44.5-year-old). Asian accounted for 98%, with Hispanic 1%, and Caucasian 1%.<sup>†</sup> The sensitivity of 1997, 2012, 2017 criteria are, 97%, 99%, 87% respectively. The positivity rate of each domain in the 2017 criteria was shown in table 1. The total score that the patients got in the 2017 criteria ranged from 12 to 44 (mean: 27.3). All the cases who were classified as non-SLE in the 2017 criteria had anti-nuclear antibody (ANA) <80; all of them scored more than 10 points.

**Abstract SAT0447 – Table 1.** Validation of the 2017 SLE classification criteria using clinically diagnosed 100 SLE cases.

Item (point)	Positivity (%)
<b>Entry Criteria</b>	
ANA ≥80 (required: no point)	87.0

†N/A in 3, ‡N/A in 1.  
 Abbreviations: ACLE, acute cutaneous lupus erythematosus; ANA, anti-nuclear antibody; anti-CL, anti-cardiolipin antibody; DLE, discoid lupus erythematosus; N/A, not available; SCLÉ, sub-acute cutaneous lupus erythematosus; SLE, systemic lupus erythematosus.

†N/A in 3, ‡N/A in 1.  
 Abbreviations: ACLE, acute cutaneous lupus erythematosus; ANA, anti-nuclear antibody; anti-CL, anti-cardiolipin antibody; DLE, discoid lupus erythematosus; N/A, not available; SCLÉ, Sub-acute cutaneous lupus erythematosus; SLE, systemic lupus erythematosus.

**Conclusions:** 2017 criteria for SLE accomplished modestly high sensitivity in the real-world practice, but not as high as 1997 and 2012 criteria. They possibly miss-classify the real SLE cases as non-SLE, especially if patients have low titer (<80) of ANA.

**Background:** Cardiac neonatal lupus is due to placental transfer of maternal anti-Ro/SSA and anti-La/SSB autoantibodies to the fetus and mainly includes congenital heart block (CHB) and dilated cardiomyopathy. The prevalence of CHB has been estimated as 1%–2% in anti-Ro/SSA women while the recurrence rate is 16%–19%.<sup>1</sup> This condition is associated with a high rate of fetal/neonatal mortality and in the majority of cases requires pacemaker pacing.<sup>2–6</sup>

**Objectives:** The rarity of this condition requires the establishment of collaborative registries in order to improve our knowledge. Here we report the data of the ongoing Italian Registry of the autoimmune congenital heart block (Lu.Ne), which was created in 2016

**Methods:** The aim was to collect retrospective and prospective pregnancies complicated with CHB in patients with antibodies. Data regarding demography, treatment, maternal and neonatal outcome and follow-up were collected through an online electronic datasheet prepared in a Research Electronic Data Capture platform.

Later Pacemaker implantation	23 (32.4)
Infant/childhood death	2 (3.2)

**Results:** Eighty-six cases of CHB were collected in 82 women with 85 pregnancies that occurred between 1969–2016. CHB was mostly detected in utero (81

cases, 90.6%) with 5 neonatal CHB. Demographic description of the mothers, pregnancy outcomes and treatment are reported in table 1. Child mortality was observed in 22 (25.5%) cases: 12 fetal, 5 termination of pregnancy and 5 postnatal. Maternal and fetal risk factors for fetal mortality were analysed and, at univariate analysis, factors associated with death were an earlier detection of CHB (20.9  $\pm$  0.9 weeks vs 24.8  $\pm$  5.4 weeks;  $p=0.007$ ), hydrops ( $p=0.002$ ; OR=11.3; CI95% 1.84–69.2) and pericardial effusion ( $p=0.025$ ; OR >100; CI95% 2.88 > 100).

**Conclusions:** The Lu.Ne registry is an ongoing project aiming at collecting all Italian CHB. Our data showed similar rate of fetal/neonatal death and of PM implantation previously reported. We confirmed that hydrops and pericardial effusion are risk factors for fetal death. A peculiarity of our cohorts is that the majority of the mothers (59%) had an established diagnosis of systemic autoimmune disease at CHB detection. This is in contrast with other registries showing that usually CHB was incidentally detected in healthy women and related to the recruiting Centres all belonging to Rheumatology Society. The collection of cases from Gynaecological and Paediatric Centres, planned in the next months, will complete our analysis

#### SAT0449 JUVENILE ONSET SYSTEMIC LUPUS ERYTHEMATOSUS OUTCOME IN ADULTHOOD: A MONOCENTRIC RETROSPECTIVE COHORT

M. Pha<sup>1</sup>, A. Mathian<sup>1</sup>, J. Haroche<sup>1</sup>, F. Cohen Aubart<sup>1</sup>, M. Hié<sup>1</sup>, D. Lê Thi Huong<sup>1</sup>, M. Pineton de Chambrun<sup>1</sup>, T. Kwon<sup>2</sup>, Z. Amoura<sup>1</sup>. <sup>1</sup>French Referral Center for Systemic Lupus Erythematosus, Antiphospholipid Antibody Syndrome and Rare Autoimmune Diseases, Service de Médecine Interne 2, Groupement Hospitalier Pitié-Salpêtrière, Assistance Publique–Hôpitaux de Paris (APHP); <sup>2</sup>Pediatric Nephrology Department, Robert Debré Hospital Assistance publique–Hôpitaux de Paris (APHP), PARIS, France

**Background:** Outcome of juvenile-onset SLE (j-SLE) during adulthood is poorly described.

**Objectives:** To report adult outcome of j-SLE and compare SLE course during childhood and adulthood.

**Methods:** j-SLE was defined as a SLE fulfilling ACR criteria and diagnosed before the age of 16 years. Mac Nemar test for paired nominal data and Wilcoxon signed rank test for paired data were used.

**Results:** One hundred and six patients j-SLE (88 women and 18 men, female to male ratio: 4.9), mean age at diagnosis: 12.3 years were followed during a mean duration of 13.8 years, from childhood (mean: 4 years) to adulthood (mean: 10.3 years). 97.2% patients received corticosteroids (with intravenous pulses for 50.9%) and 77.3% immunosuppressant drugs. 105 (99%) patients received anti-malarial drugs.

Clinical manifestations of the first flare were: arthritis (67.9%), cutaneous (57.5%), nephritis (23.6%), fever (17.9%), hematologic: ITP, AIHA (15%). Neuropsychiatric manifestations were found in 6.6%. Digestive involvement was only present in 6% of cases. According to the revised SELENA FLARE INDEX (SFI), the first flare was severe for half of the patients (n=55).

Disease course during adulthood had two patterns: 82 patients (77.3%) had at least one SLE flare and 24 (22.6%) a sustained remission. Mean follow up was however significantly higher in the relapsing group (15 years vs 9.8 years,  $p=0.0014$ ). No difference was found between these 2 groups for first flare severity and clinical manifestations during childhood.

Significantly more cutaneous (61.3 vs 42.4%,  $p=0.003$ ), musculoskeletal (75.5 vs 59.4%,  $p=0.007$ ), neuropsychiatric (10.4 vs 3.8%,  $p=0.035$ ), or hematologic manifestations like AIHA (9.4 vs 2.8%,  $p=0.039$ ) or ITP (26.4 vs 10.4%,  $p=0.001$ ), and fever (32.1 vs 3.7%,  $p<0.001$ ) were observed during childhood than during adulthood. Nephritis occurred at similar frequencies in childhood and adulthood (34.9% and 30.2% respectively). Half of adulthood nephritis were relapses of j-SLE nephritis.

At the end of the survey mean global SLICC damage index (SDI) was 0.64. Mean childhood SDI was lower than mean adulthood SDI (0.21 vs 0.45,  $p=0.016$ ). However mean adult follow up was significantly longer. Mean SDI increase per year was similar during childhood and adulthood (0.053 vs 0.049 respectively,  $p=0.563$ ).

13 patients (12.3%), had musculoskeletal damage occurring more frequently during adulthood than childhood (11 vs 2,  $p=0.022$ ), specially avascular necrosis (8 vs 0,  $p=0.008$ ). 5 (4.7%) patients had a renal damage that occurred mostly during adulthood (n=4). Ocular damage was present for 9 (8.5%) patients. Premature gonadal failure occurred for 5 women (5.7%). Among the 88 women 19 had 32 pregnancies, leading to 22 births.

**Conclusions:** Damage accrual seems to increase at the same pace during childhood and adulthood. SDI was low at the end of the survey. This could reflect a protective role for HCQ, more immunosuppressant use with lower dose of steroids. Juvenile SLE nephritis are at high risk of relapsing during adulthood raising the issue of duration of immunosuppressive treatment.

#### SAT0450 ESTIMATING DURATION OF RESPONSE IN SYSTEMIC LUPUS ERYTHEMATOSUS TRIALS

M. Kim<sup>1</sup>, J. Merril<sup>2</sup>, K. Kalunian<sup>3</sup>, L. Hanrahan<sup>4</sup>, P. Izmirly<sup>5</sup>. <sup>1</sup>Epidemiology and Population Health, Albert Einstein College of Medicine, Bronx; <sup>2</sup>Medicine, Oklahoma Medical Research Foundation, Oklahoma; <sup>3</sup>Clinical Medicine, UC San Diego, San Diego; <sup>4</sup>Lupus Foundation of America, Washington DC; <sup>5</sup>Medicine, NYU Medical Center, New York, USA

**Background:** The primary endpoint in SLE trials is usually response to therapy at a landmark visit. However, during a trial, patients may alternate between response and non-response states. Duration of response would therefore be important to assess, but the optimal approach for estimating response duration has not been determined. Analysing response duration only among responders at a landmark visit can result in selection bias. Drop-outs and missed visits further complicate estimation of response duration.

**Objectives:** To quantify response duration and assess baseline predictors of transitions into and out of response in SLE patients receiving standard of care (SoC) by fitting a multi-state Markov (MSM) model.

**Methods:** Data on 759 SLE patients with active disease (SLEDAI  $\geq 6$  at entry) randomised to SoC in 52 week trials was obtained from the Collective Data Analysis Initiative (CDAI) database of the Lupus Foundation of America. The following monthly response endpoints (without medication stipulations) were analysed: SRI-4, SRI-5, SRI-6, and BICLA. A MSM model allowing for bi-directional transitions between response and non-response states was fit to estimate the probability of being in response at 52 weeks, average duration of response (sojourn time) and mean total time in response. Predictors of attainment and loss of SRI-5 response were also identified.

**Results:** Based on the MSM model, the probability of being in response at 52 weeks ranged from 42% (SRI-6) to 61% (SRI-4), higher than conventional 52 week landmark response rates that assume non-response for missing data. The estimated mean duration of response ranged from 20.4 weeks (BICLA) to 31.5 weeks (SRI-4). Mean total time in response over 52 weeks based on all patients was 16.4–24.8 weeks. After adjusting for baseline SLEDAI score, patients with lower anti-dsDNA titers were more likely to achieve and maintain SRI-5 response ( $p<0.001$ ). Younger age ( $p<0.001$ ) and higher protein/creatinine ratio ( $p<0.001$ ) were associated with higher frequency of SRI-5 response but also shorter response duration. Response duration was also shorter in patients who were non-White ( $p<0.001$ ), had longer history of disease ( $p=0.03$ ), and lower lymphocyte count ( $p=0.001$ ) at baseline.

Responder index	Landmark response rate at 52 weeks	Probability in response at 52 weeks from MSM (95% CI)	Mean sojourn time in response (95% CI)	Mean total time in response (95% CI)
SRI-4	45.5% (95% CI 42.3%–49.5%)	61.0% (95% CI 58.3%–63.5%)	31.5 weeks (95% CI 28.5–34.6)	24.8 weeks (95% CI 23.7–25.9)
SRI-5	33.6% (95% CI 30.2%–37.1%)	43.0% (95% CI 40.8%–46.3%)	25.7 weeks (95% CI 23.1–28.7)	17.7 weeks (95% CI 16.1–19.1)
SRI-6	32.5% (95% CI 29.2%–36.0%)	41.7% (95% CI 38.8%–44.7%)	24.3 weeks (95% CI 21.9–27.1)	16.4 weeks (95% CI 15.3–17.5)
BICLA	38.9% (95% CI 33.4%–47.7%)	50.2% (95% CI 47.1%–53.5%)	20.4 weeks (95% CI 18.1–23.0)	21.3 weeks (95% CI 19.7–22.5)

**Conclusions:** Factors associated with greater disease severity were consistently associated with shorter response duration on SoC, despite exhibiting variable effects on the probability of achieving response at a given time. Response duration might therefore provide a more discriminating measure to distinguish effective investigational treatments from background SoC, although this remains to be tested. Multi-state models make better use of complex longitudinal clinical trial data and provide a more comprehensive view of the response profile and the role of patient characteristics in different aspects of response.

**SAT0451 DISEASE COURSE PATTERNS IN SYSTEMIC LUPUS ERYTHEMATOSUS**

K. Tselios, D. Gladman, Z. Touma, J. Su, N. Anderson, M. Urowitz. *Rheumatology, Toronto Western Hospital, University of Toronto, Toronto, Canada*

**Background:** Previous studies described three patterns of disease activity over time in systemic lupus erythematosus (SLE), namely long quiescent, relapsing remitting and persistently active. However, they enrolled prevalent patients, many of whom in the late stages of the disease. As such, the patterns of disease course since diagnosis are not known.

**Objectives:** The aim of the present study was to assess the prevalence and characteristics of such patterns over 10 years of follow-up in an inception cohort.

**Methods:** The inception patients of a large lupus cohort (enrolled within 18 months of diagnosis, n=883), with at least 10 years of follow-up and no time interval >18 months between consecutive visits, were investigated. Monophasic (M) pattern was defined as a clinical SLEDAI-2K=0 [serology (anti-dsDNA antibodies and C3/C4 levels) excluded], achieved within five years since enrollment and maintained for ≥10 years after that. Relapsing-remitting (RR) pattern was defined based on ≥2 remission periods (a remission period equals two consecutive visits with a clinical SLEDAI-2K=0), while patients with no remission were categorised as persistently active (PA). Descriptive and regression analyses were used to compare the different groups regarding cumulative damage at 10 years, mortality and flare rate beyond 10 years.

**Results:** Of 267 patients who fulfilled the inclusion criteria, 27 (10.1%) were monophasics, 180 (67.4%) RR and 25 (9.4%) PA. Thirty-five patients (13.1%) had only one remission period ("hybrid"). There were no significant differences regarding the demographic, clinical, immunological and therapeutic characteristics among groups at enrollment. At 10 years, PA patients had received significantly more glucocorticosteroids [39.4±24.3 g vs. 16.6±10.7 g and 27.3±18.4 g for the M and RR groups, p<0.001] and accumulated significantly more damage [SLICC/DI=2.36±1.6 vs. 0.93±1.07 and 1.22±1.33, respectively, p<0.001]. A trend for higher mortality was observed in the PA patients [24% vs. 13.3% and 11.1% for the RR and M patients respectively, p=0.22] whereas death occurred earlier [18.4±4.4 vs. 20.1±7.2 and 24±4.1 years, p=0.11]. Beyond 10 years, the annual flare rate was higher for the PA and RR patients as compared to the monophasics [0.50±0.40 vs. 0.47±0.57 vs. 0.10±0.18 respectively, p<0.001]. Multinomial regression analysis for group membership showed Black race [OR=2.78, 95% CI=1.05–7.31, p=0.039] and higher adjusted mean SLEDAI-2K over the first two years [OR=1.21, 95% CI=1.11–1.32, p<0.0001] to be associated with a more severe disease course.

**Conclusions:** Approximately 70% of lupus patients followed a relapsing remitting course from diagnosis onwards, while 10% displayed a monophasic and another 10% a persistently active course. Black race and more severe disease over the first two years were associated with a worse disease course.

**SAT0452 ENDOTHELIUM DYSFUNCTION IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS WITH AND WITHOUT NEPHRITIS**

N. Mohannad<sup>1</sup>, A.I. El Zawawy<sup>2</sup>, M. Elbordeny<sup>3</sup>, D. Emara<sup>4</sup>, S. Ibrahim<sup>5</sup>. <sup>1</sup>Internal Medicine department, *Rheumatology Unit, Alexandria University Hospitals;* <sup>2</sup>Internal Medicine department, *Rheumatology Unit;* <sup>3</sup>Department of Clinical and Chemical Pathology; <sup>4</sup>Department of Radiodiagnosis, *Alexandria University;* <sup>5</sup>Internal Medicine, *Ministry of Health, Alexandria, Egypt*

**Background:** Organ-specific manifestations in systemic lupus erythematosus (SLE) are highly influenced by the inherent characteristic of the vasculature<sup>(1)</sup> Endothelial dysfunction might have significant roles in the pathogenesis of glomerular diseases. CD31 or platelet endothelial cell adhesion molecule-1 is known to have roles in angiogenesis, platelet function, thrombosis, and regulation of leukocyte migration through vascular walls<sup>(2)</sup>

**Objectives:** to assess the endothelium dysfunction in SLE patients (pts) and to determine its association with lupus nephritis (LN)

**Methods:** Study included 60 pts with SLE fulfilling the SLICC criteria for classification of SLE: 30 with(LN), 30 SLE without LN and 10 matched healthy controls. Routine laboratory tests, lipid profile, renal functions, titres of autoantibodies [ANA, anti ds-DNA, anticardiolipin antibodies ACL(IgM, IgG), flowcytometry to detect PECAM-1/CD31, doppler ultrasound to detect FMD of the brachial artery and SLEDAI were done to all SLE pts. Pts with diseases known to affect endothelial function: smoking, DM, essential HTN, known CAD were excluded

**Results:** Correlation between FMD% and different parameters are shown in table 1. There was a statistical significant positive relation between CD31 and urea in LN(p=0.014), non LN(p=0.014), total SLE pts(p<0.001), creatinine in non LN group

(p=0.025), 24 hour protein in LN(p<0.001), non LN(p<0.001) and total SLE pts (p<0.001), cholesterol in LN(p<0.001), non LN(p=0.001) and total SLE pts (p<0.001), LDL in LN(p=0.001), non LN(p=0.009) and total SLE pts(p<0.001), TG in total pts(p=0.048), anti-dsDNA in LN(p=0.024) and total SLE pts(p=0.008), SLEDAI in LN(p=0.001) and total SLE pts(p<0.001).

**SAT0453 ASSOCIATION OF COMORBID PULMONARY CONDITIONS WITH PATIENT-REPORTED OUTCOMES IN SYSTEMIC LUPUS ERYTHEMATOSUS**

P. Katz<sup>1</sup>, S. Pedro<sup>2</sup>, E. Alemao<sup>3</sup>, J. Mukherjee<sup>3</sup>, K. Michaud<sup>2</sup>. <sup>1</sup>University of California, San Francisco; <sup>2</sup>National Data Bank for Rheumatic Diseases, Wichita; <sup>3</sup>Bristol-Myers Squibb, Princeton, USA

**Background:** Risk of chronic obstructive pulmonary disease (COPD) and allergic conditions, including asthma (AM), is elevated among SLE patients.<sup>1</sup> Both AM and COPD negatively affect quality of life measured through patient-reported outcomes (PROs). Little research has examined the impact of AM and COPD on PROs in SLE, independent of SLE disease status.

**Objectives:** Determine the impact of AM/COPD on PROs in SLE, concurrently and longitudinally.

**Methods:** Data from 2 large, longitudinal, observational cohorts were examined (Lupus Outcomes Study, LOS: n=796; National Data Bank for Rheumatic Diseases, Forward: n=2804). AM and COPD were determined at study entry by self-report. PROs included validated scales or items measuring physical functioning, fatigue, pain, cognitive function, depressive symptoms and global severity, although the cohorts included different PROs (Table). Multiple regression analyses examined differences between subjects with and without AM/COPD cross-sectionally, controlling for age, sex, race, lupus duration, education, income, obesity, smoking, other comorbid conditions, and presence or history of renal involvement, clotting disorder or seizures. Longitudinal analyses examined PROs at 3 years (yrs) of follow-up, controlling for covariates above as well as baseline PRO values.

**Results:** LOS cohort was 92% female, mean age 47 years, 70% white, 42% ever smokers, mean lupus duration 13 years. Forward cohort was 94% female, mean age 51 years, 87% white, 38% ever smokers, mean lupus duration 16 years. 36% of LOS and 30% of Forward reported AM/COPD at study entry, compared to COPD prevalence of 7%<sup>2</sup> and AM prevalence of 9.7%<sup>3</sup> among US women. In cross-sectional analyses (Table), AM/COPD were associated with significantly worse scores on all PRO measures, except depressive symptoms (LOS). Longitudinal results were similar: AM/COPD were associated with worse scores on all PROs except SF-36 PF and Fatigue in LOS.

Table. Multivariate Regression Analyses

	PRO variables	Cross-sectional	Longitudinal
LOS	SF-36 Physical Function (PF) <sup>†</sup>	-9.2 (<0.0001)*	-1.8 (0.26)
	SF-36 Fatigue	6.6 (<0.0001)	2.4 (0.09)
	CESD	1.5 (0.10)	1.7 (0.04)
Forward	MOS Cognitive <sup>†</sup>	-6.6 (<0.0001)	-3.3 (0.01)
	HAQ II	0.2 (<0.0001)	0.2 (<0.0001)
	Fatigue (0-10)	0.7 (<0.0001)	0.8 (<0.0001)
	PHQ8	2.0 (0.01)	1.9 (0.006)
	Pain (0-10)	0.8 (<0.0001)	0.8 (<0.0001)
	Trouble thinking or remembering	1.5 (1.2-1.8)	1.2 (1.0-1.5)
	Global severity (0-10)	0.5 (<0.0001)	0.6 (<0.0001)

\*Beta (p value) from multiple linear regression analyses, except Forward 'trouble thinking or remembering', which is odds ratio (95% CI)

<sup>†</sup>Lower scores=worse status. Otherwise, higher scores=worse status  
CESD=Centre for Epidemiologic Studies Depression scale; HAQ=Health Assessment Questionnaire; PHQ8=Patient Health Questionnaire depression inventory

**Conclusions:** AM/COPD are more common in SLE than the general population and are independently associated with worse outcomes on a wide range of PROs, even after controlling for sociodemographic and lupus characteristics. Findings suggest that physicians should screen for pulmonary comorbidities and ensure adequate treatment for these conditions. Future analyses of PROs in SLE should include AM/COPD as important comorbid conditions.

**SAT0454 IN PRIMARY SJÖGREN'S SYNDROME BLOOD CD180-NEGATIVE B CELLS ARE INCREASED IN PATIENTS WITH HIGH SYSTEMIC DISEASE ACTIVITY**

R. Felten<sup>1</sup>, C. Mayeur-Rousse<sup>2</sup>, L. Miguet<sup>2</sup>, L. Arnaud<sup>1</sup>, E. Chatelus<sup>1</sup>, R.-M. Javier<sup>1</sup>, H. Petit<sup>1</sup>, J. Sibilia<sup>1</sup>, C. Sordet<sup>1</sup>, L. Fornecker<sup>2</sup>, L. Mauvieux<sup>2</sup>, J.-E. Gottenberg<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Hematology, Hautepepiere, Strasbourg, France

**Background:** CD180, a related member of the Toll-like receptor family, seems to be underexpressed at the plasma membrane in circulating B cells of auto-immune disease (systemic lupus especially),<sup>1</sup> and is lost in various B-cell lymphomas except marginal zone lymphomas (MZL), the most severe complication of primary Sjögren's Syndrome (pSS).<sup>2</sup>

**Objectives:** To define the expression of CD180 at the plasma membrane of circulating B cells of pSS and determine its association with systemic disease activity.

**Methods:** The expression of CD180 at the plasma membrane of circulating B cells was studied by flow cytometry, in 69 successive patients with pSS, in comparison to patients with systemic lupus (SLE) (n=7) and healthy controls (n=28).

**Results:** The cohort of pSS was composed of 65 women for 4 men, median age of 59 years.<sup>25-89</sup> Median clinESSDAI was 2 [0-18], 46 patients with a clinESSDAI >0 (low disease activity), 18 patients with a clinESSDAI >5 (moderate disease activity) and 6 patients ≥14 (high disease activity). The more frequently involved domains of the ESSDAI were biological (39%, n=27), glandular (32%, n=22), articular (20%, n=14), and peripheral neurological (9%, n=6) domains. Forty patients were anti-SSA+, 16 anti-SSA and anti-SSB+. 18 had a hypergammaglobulinemia, 17 a hypocomplementemia, 7 a cryoglobulinemia, 18 a rheumatoid factor and 9 a lymphopenia.

**- CD180-negative B cells in pSS, SLE and controls**

The proportion of total lymphocytes, B cells, T cells, NK cells or CD180-negative B cells (0.85% vs 0.95%, p=0.64) was not significantly different between pSS patients and healthy controls.

Patients with SLE had significantly fewer lymphocytes (860 vs 1544, p=0.0012), B cells and T cells than those with pSS (p=0.023 and p=0.0016); CD180-negative B cells tended to have a higher proportion in SLE than in pSS patients (1.9% vs 0.85%, p=0.055).

**- Increase of CD180-negative B cells in patients with pSS and high systemic disease activity**

CD180-negative B cells subset was significantly higher in patients with high systemic disease activity (2.55% CD180-negative B cells in patients with clinESSDAI ≥14 vs 0.8% in patients with clinESSDAI <14, p=0.036). CD180-negative B cells subset was also significantly higher in patients with anti-SSA and anti-SSB+ (1.9% vs 0.8%, p=0.0082) and in patients with markers of B-cell activation: hypergammaglobulinemia (1.7% vs 0.75%, p=0.034), hypocomplementemia (2.1% vs 0.8%, p=0.0021), cryoglobulinemia (4.6% vs 0.8%, p=0.0097), presence of rheumatoid factor (1.7% vs 0.7%, p=0.015).

**Conclusions:** Blood CD180-negative B cells are increased in pSS patients with high systemic disease activity or in immunologically active pSS. Functionality of CD180 and the prognostic interest of CD180 staining on blood B cells to predict lymphoma in pSS patients, have now to be studied.

**SAT0455 CLINICAL AND IMMUNOLOGICAL CHARACTERISTICS OF PATIENTS WITH SUSPECTED SJÖGREN SYNDROME AND ANTI-RO52 POSITIVE ANTIBODIES**

R. Solans-Laque<sup>1</sup>, J. Loureiro<sup>1</sup>, A. Marin<sup>2</sup>, F. Martinez-Valle<sup>1</sup>, M. Alberola<sup>3</sup>, J. J. Puig<sup>4</sup>, J. Mestre<sup>1</sup>, S. Bujan<sup>1</sup>. <sup>1</sup>Autoimmune Diseases Unit, Internal Medicine Department; <sup>2</sup>Immunology; <sup>3</sup>Pathology; <sup>4</sup>Ophthalmology, Vall Hebron University Hospital, Barcelona, Spain

**Background:** Anti-Ro52 antibodies have been described in patients with Sjögren syndrome (SS) but there are limited data on their significance, and they are not included in the diagnostic criteria of SS.

**Objectives:** To analyse the clinical and immunological characteristics of patients with suspected SS and positive anti-Ro52 antibodies, and to assess the diagnostic value of this antibodies.

**Methods:** retrospective study of all patients evaluated at our Department between January 2000 and January 2016 for possible SS in which anti-Ro52 abs. were determined. Patients were classified as having SS, according to the 2002

European-American Consensus Group (EACG) criteria. Statistical analysis was performed using the SPSS vs.20 package

**Results:** 348 patients (331 women), mean age at diagnosis 56.12±14.19 years (range 22–92), with possible SS were analysed. All patients met the European criteria for SS diagnosis, and 242 the EACG criteria. AAN were positive in 345 (99.4%) patients, RF in 169 (48.4%), anti-Ro60/SSA in 188 (54%), and anti-La/SSB in 11 (32%). Anti-Ro52 abs. were positive in 173 (49.7%) patients: 162 women, 11 men. Of these patients, 154 (89%) also had anti-Ro60/SSA positive abs., 103 (59.5%) anti-La/SSB abs., and 117 (67.6%) positive RF. Anaemia, leukopenia, lymphocytopenia and hypergammaglobulinemia, were significantly more frequent in patients with anti-Ro52 positive abs. The presence of anti-Ro52 abs. was significantly related to the development of lung fibrosis (OR 2.42, 95% CI 1.23–4.75, p=0.007), peripheral neuropathy (OR 2.53, 95% CI 1.1–5.95, p=0.022), arthritis (OR 1.95, 95% CI 1.2–3.35, p=0.016) and parotitis (OR 3.04, 95% CI 1.75–5.3, p<0.001). A total of 160/173 (92.5%) patients with anti-Ro positive abs. met the EACG criteria. When we analysed the 13 patients with anti-Ro52 positive abs., which did not meet the AECG criteria, these patients presented severe salivary gland scintigraphic involvement, positive ocular test for dry eyes, more hypergammaglobulinemia (OR 6.67, 95% CI 1.95–22.8, p=0.003), more peripheral neuropathy (OR 13.8, 95% CI 2.1–92.7, p=0.0012), more lung fibrosis (OR 13.95, 95% CI 2.1–93.7, p=0.012), and more risk of lymphoma development (OR 16.72, 95% CI 1.4–199.8, p=0.039), than patients with suspected SS who did not meet the AECG criteria and who had negative anti-Ro52 abs.

**Conclusions:** in our series most patients with anti-Ro52 positive antibodies had also anti-Ro60/SSA positive antibodies and met the AECG criteria. However, there were 13 patients with positive anti-Ro52 abs., which did not meet the AECG criteria. These patients showed similar characteristics to those with positive anti-Ro52 abs. and AECG criteria, and had more risk to develop peripheral neuropathy, lung fibrosis and lymphoma. Our results support that anti-Ro52 antibodies should be included in the diagnostic criteria for SS.

## SAT0456

**THE INCIDENCE OF CARDIOVASCULAR EVENTS IN ITALIAN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IS LOWER THAN IN NORTH EUROPEAN AND AMERICAN COHORTS: IMPLICATION OF DISEASE-ASSOCIATED AND TRADITIONAL RISK FACTORS AS EMERGED BY A 16-YEAR RETROSPECTIVE GIRRCS STUDY**

S. Fasano<sup>1</sup>, D.P. Margiotta<sup>2</sup>, R. Gualtierotti<sup>3</sup>, A. Corrado<sup>4</sup>, O. Berardicurti<sup>5</sup>, D. Iacono<sup>1</sup>, L. Pierro<sup>1</sup>, A. Riccardi<sup>1</sup>, R. Giacomelli<sup>5</sup>, F.P. Cantatore<sup>4</sup>, P. Meroni<sup>3</sup>, A. Afeltra<sup>2</sup>, G. Valentini<sup>1</sup> on behalf of GIRRCS= Gruppo Italiano di Ricerca in Reumatologia Clinica e Sperimentale. <sup>1</sup>Division of Rheumatology, Department of Clinical and Experimental Medicine, Università della Campania Luigi Vanvitelli, Naples; <sup>2</sup>Clinical Medicine and Rheumatology Department, Campus Bio-Medico University of Rome, Rome; <sup>3</sup>Division of Rheumatology, ASST Pini, Department of Clinical Sciences and Community Health, University of Milan, Milan; <sup>4</sup>Rheumatology Clinic, Department of Medical and Surgical Sciences, University of Foggia Medical School, Foggia; <sup>5</sup>Division of Rheumatology, Department of Biotechnological and Applied Clinical Science, University of L'Aquila, L'Aquila, Italy

**Background:** Cardiovascular (CV) disease is the leading cause of premature death among Systemic Lupus Erythematosus (SLE) patients<sup>1</sup>. Several studies have analysed the incidence of CV events in SLE patients. However, the majority of them have been conducted in American and North European countries 2–7. At the best of our knowledge, no studies in Italy have considered cumulative incidence and incidence rate of CV events in Italy.

**Objectives:** The present study is devoted to estimate the incidence of a first ever CV event in Italian lupus patients from five rheumatologic tertiary units from North, Centre and South Italy and to search for features associated with and potentially causative of the detected differences.

**Methods:** Clinical charts of SLE patients consecutively admitted to five Italian rheumatologic centres from November 1 st 2000 and December 31 st 2016 were retrospectively studied. Patients selected were free of CV events at baseline. CV cumulative incidence was evaluated as the proportion of patients who experienced a new CV event over the follow up period. CV incidence rate was expressed as the number of events in the cohort divided by the total number of

years at risk. Our incidence was compared with that detected in the Italian general population and those reported in SLE cohorts from other countries.

**Results:** The median duration of follow-up was 6 years (IQR=3–11). During the observational period, 39(cumulative incidence=7.6%) of the 511 patients had a first CV event with an incidence rate of 10.4/1000 person-years i.e. 12 times higher than in the general population. The CV cumulative incidence detected in our Italian cohort was similar to that reported in the Spanish cohort, but lower than those from North European and American cohorts. The Italian cohort differed from other SLE cohorts in some traditional risk factors (smoke, hypertension, dyslipidemia) and treatment with aspirin and hydroxychloroquine.(table1)

First CV event	Yes	Yes	Yes	Yes	Yes	No	
Mean follow-up (years)	6	-	8.3	-	6.4	7.7	
Person-years	3721	-	-	9485	-	540	
Incidence rate (1000p-y)	10.4	-	-	14.1	-	31.4	

**Conclusions:** Our study confirmed the increased CV risk in SLE compared with the general population. However, the incidence of CV events in our SLE series was lower than that detected in North European and American lupus cohorts. These disparities could be ascribed to the differences in the prevalences of traditional CV risk factors among the distinct cohorts. Nevertheless, our CV cumulative incidence was very similar to that detected in the Spanish cohort, despite their higher frequency of traditional risk factors. For this evidence, the geographic (Mediterranean) origin deserve to be considered. On the other hand, the slight difference detected between our series and Baltimore cohort<sup>2</sup>(where patients were examined every 3 months) underlines the need of a strict follow-up of the SLE patient.

**Objectives:** To take a "high-definition" picture of the main features of primary Sjögren syndrome (SjS) following a worldwide data-sharing cooperative merging of international clinical SjS databases.

**Methods:** The Big Data Sjögren Project Consortium is an international, multi-centre registry created in 2014 including leading clinical centres in SjS of the 5 continents that shared a harmonised data architecture and conducted cooperative online efforts to refine collected data of primary SjS patients fulfilling the 2002 classification criteria.

**Results:** By January 2018, the participant centres had included 10 475 patients from 22 countries, including 7637 (73%) patients from Europe, 1420 (14%) from America, 1186 (11%) from Asia, 167 (1.4%) from Australia and 65 (0.6%) from Africa. The cohort included 9781 (93%) women and 694 (7%) men, with a mean age at diagnosis of primary SjS of 53 years. The frequencies of fulfilment of the 2002 criteria were 92% for dry eye, 94% for dry mouth, 83% for abnormal ocular tests, 82% for positive minor salivary gland biopsy, 78% for abnormal oral diagnostic tests and 76% for positive anti-Ro/La antibodies. The frequency of positive immunological markers at diagnosis was 79% for ANA, 73% for anti-Ro, 49% for RF, 45% for anti-La, 13% for low C3 levels, 14% for low C4 levels and 7% for cryoglobulins.

**Conclusions:** International data sharing-based projects merging disperse clinical registries may be essential tools to increase current knowledge and to improve patient care in specific systemic autoimmune diseases.

**SAT0458 URINE SOLUBLE UROKINASE PLASMINOGEN ACTIVATOR RECEPTOR AS A POTENTIAL BIOMARKER OF LUPUS NEPHRITIS ACTIVITY**

S. Burcsár<sup>1</sup>, G. Toldi<sup>2</sup>, B. Szalay<sup>3</sup>, B. Vászárhelyi<sup>3</sup>, L. Kovács<sup>1</sup>, A. Balog<sup>1</sup>.  
<sup>1</sup>Department of Rheumatology and Immunology, Faculty of Medicine, Albert Szent-Györgyi Health Center, University of Szeged, Szeged, Hungary; <sup>2</sup>Neonatal Unit, Birmingham Women's and Children's Hospital, Birmingham, UK; <sup>3</sup>Department of Laboratory Medicine, Semmelweis University, Budapest, Hungary

**Background:** Over the recent years, soluble urokinase plasminogen activator receptor (suPAR) has been described as a valuable indicator of the activation state of the immune system. Our previous work supported that suPAR might be an objective marker for identifying systemic lupus erythematosus (SLE) patients with active disease. Urokinase plasminogen activator receptor (uPAR) expression is also induced in podocytes during renal diseases such as focal segmental

glomerulosclerosis (FSGS). In addition, levels of suPAR were found to be elevated in paediatric and adult patients with FSGS. Current noninvasive laboratory and clinical measures of lupus nephritis (LN) activity are not sensitive or specific enough to reliably measure the course of LN. Improved, noninvasive biomarkers are needed to accurately detect LN activity.

**Objectives:** To evaluate suPAR in urine as a potential biomarker of renal system-specific disease activity in SLE.

**Methods:** A prospective follow-up study was designed. 14 SLE patients with newly diagnosed LN and 31 healthy individuals were enrolled in this study. LN was the leading symptom of all SLE patients. Further organ involvements including arthritis, leucopenia, serositis, fever and rash also occurred at the time of LN diagnosis. 12 out of 14 LN were confirmed by renal biopsy. Urine samples were taken before the initiation of LN induction therapy, and monthly thereafter (6 to 11 times). Global and renal disease activity were defined using the SLE Disease Activity Index 2000 (SLEDAI-2K) and the SLEDAI-2K renal domain score. suPAR concentrations in the urine were measured with the suPARnostic Flex ELISA assay. Non-parametric testing was used for statistical analysis, including the Kruskal-Wallis test and the Mann-Whitney U test.

**Results:** All urine suPAR levels were elevated in SLE patients with active LN compared with patients with resolved LN and healthy controls (21.75 vs 4.93 and 5.09 ng/mL, respectively, p<0.0001). suPAR levels were higher measured before than after the initiation of LN induction therapy in patients before resolution of active LN (29.46 vs 21.07 ng/mL, p=0.0122). Prospective follow-up measurements also suggested that urine suPAR levels raised again in patients with a relapse of LN according to SLEDAI-2K renal domain score (n=3; 5.45 vs 15.19 ng/mL, p=0.0127).

**Conclusions:** Urine suPAR is a promising LN activity biomarker, given its isolated elevation in urine in active LN and pronounced decrease with LN improvement. It may potentially become a more convenient alternative to renal biopsy, the current gold standard of LN activity monitoring.

**Background:** Patients with systemic lupus erythematosus (SLE) are at higher risk than the general population of developing lymphoma. Relatively little is known about the risk factors, the treatment and the outcome of lymphoma in SLE.

**Objectives:** We aimed to describe a cohort of patients suffering from lymphoma in the setting of SLE and to study the risk factors of developing this complication.

**Methods:** We collected clinical data of SLE patients with confirmed lymphoma in a multicentric and retrospective study. SLE patients were eligible for the study if they fulfilled at least 4 of the 1997 ACR criteria for SLE. Exclusion criteria were HIV or C hepatitis infection.

**Results:** We included 38 patients (34 women and 4 men) coming from 10 different French University Hospitals. The lymphoma occurred after the diagnosis of SLE for 35 patients, with a median (range) time of 8.8 years (0–39). In their past or present medical history, 11 (29%) had a haematological involvement (5 immune thrombocytopenias, 4 autoimmune hemolytic anemias and 2 patients with both). Nine patients (24%) had associated Sjögren syndrome. 22 patients (58%) had a polyclonal hypergammaglobulinemia. Before the occurrence of the lymphoma, 18 patients (47%) had received an immunosuppressant during a median (range) period of 67 months. 6–195 17 patients had an indolent B cell lymphoma (IBCL), 14 a high-grade B cell lymphoma (11 diffuse large B cell lymphoma [DLBCL]; 2 a primary DLBCL of the central nervous system; and 1 an iatrogenic immunodeficiency-associated lymphoproliferative disorder), 5 a Hodgkin's disease (HD), and 2 a T cell lymphoma. The EBER *in situ* hybridization stain was positive in 7 of the 13 patients assessed (3/3 HD, 3/7 DLBCL and 1/2 IL) and was not associated with the immunosuppressant prescription. The median (range) of the survey after the lymphoma was 28.5 month (0–235.1). The 14 DLBCL patients except 1 were treated with chemotherapy: 4 died, 9 were in complete remission and 1 was in progression. Regarding the 17 IBCL, 9 patients were treated with chemotherapy, 2

patients with surgery, 1 patient with radiotherapy and 5 patients were not treated: 3 patients had to short follow-up or were lost, 1 died, 2 developed a DLBCL, 4 were stable and 7 were in complete remission. The 5 HL were treated with chemotherapy and all were in complete remission.

**Conclusions:** IBCL and DLBCL were the most common type of lymphomas in SLE patients. Data suggest a role for EBV but not for exposition to immunosuppressant in the pathogenesis of SLE-associated lymphoma. The outcome of lymphoma in the setting of SLE seems not different from the outcome of lymphoma in the general population. A case-control study is ongoing to study the risk factors associated with the occurrence of lymphoma in SLE

#### LONG-TERM IMMUNE PROTECTION FOLLOWING PNEUMOCOCCAL 13-VALENT/23-VALENT POLYSACCHARIDE VACCINE IN SYSTEMIC LUPUS ERYTHEMATOSUS (SLE)

T. Goulenok<sup>1</sup>, M. Bahuau<sup>2</sup>, C. Francois<sup>1</sup>, J.-F. Alexandra<sup>1</sup>, P. Aucouturier<sup>3</sup>, M. Hurtado-Nedelec<sup>1</sup>, H. Moins<sup>4</sup>, F. Batteux<sup>2</sup>, T. Papo<sup>1</sup>, K. Sacre<sup>1</sup>. <sup>1</sup>PARIS-7 University, Aphp, Bichat Hospital; <sup>2</sup>PARIS-5 University, Aphp, Cochin Hospital; <sup>3</sup>PARIS-6 University, Aphp, St Antoine Hospital; <sup>4</sup>PARIS-7 University, Aphp, St Louis Hospital, Paris, France

**Background:** Systemic lupus erythematosus (SLE) patients are at increased risk for *Streptococcus pneumoniae* infection. Although pneumococcal vaccination is an attractive method to prevent invasive pneumococcal infection, vaccination coverage remains dramatically low in SLE. Moreover, the efficacy of vaccination may be reduced in SLE patients and sequential pneumococcal vaccination using new conjugated pneumococcal vaccines in combination with 23-valent pneumococcal polysaccharide vaccine (PPV23) is now advocated.

**Objectives:** We aimed to determine the efficacy of the prime-and-boost vaccination strategy using the 13-valent pneumococcal conjugate (PCV13) and 23-valent polysaccharide (PPV23) vaccines in SLE.

**Methods:** Consecutive SLE patients admitted from April to December 2015 in our daycare hospital unit (Paris, France) were enrolled to receive PCV13 vaccine followed by PPSV23 vaccine 8 weeks later. Immune protection, defined by an antigen-specific IgG concentration  $\geq 1.3$   $\mu\text{g/mL}$  for at least 70% of 7 pneumococcal serotypes (4, 6 B, 9 V, 14, 18 C, 19 F, 23 F), was assessed at baseline, 2 and 12 months. The primary endpoint was immune protection 12 months (long-term) after PCV13 shot.

**Results:** 37 consecutive adult SLE patients admitted in our daycare hospital unit (Department of Internal Medicine, Bichat Hospital, Paris, France) were screened for pneumococcal vaccination. Among them, 8 patients refused to be vaccinated, 7 patients accepted the vaccination but refused to complete the 12 months immune response follow up and 1 patient had already been vaccinated against pneumococcal infection. Eventually, 21 (40<sup>25-75</sup> years; 85.7% female) SLE patients were included in the study and received the sequential PCV13/PPV23 pneumococcal vaccines. Only 12 patients (57.1%) reached the primary endpoint. Nine patients had no long-term protection with a seroconversion that never (n=4, not protected, NP) or only transiently (n=5, short-term protected, STP) occurred. B-cells defects and immunosuppressive treatment were associated with the NP status. A lower IgG2 serum level and a higher ratio of pre-germinal/post-germinal centre B cells were associated with the STP status. The serotype 19 F IgG titer measured 2 months after PCV13 had the best ability (sensitivity of 100% [95% CI: 47.8–100]; specificity of 91.7% [95% CI: 61.5–99.8]) to predict long-term protection.

**Conclusions:** The benefit of sequential PCV13/PPV23 vaccination in SLE is limited. Several factors are associated with long-term immune protection and may help to design selective schedule strategy and/or new vaccines.

#### ULTRASONOGRAPHY OF SALIVARY GLANDS IN PRIMARY SJOGREN'S SYNDROME AND ASSOCIATION WITH DISEASE ACTIVITY, SEROLOGICAL MARKERS AND BIOPSY OF MINOR SALIVARY GLANDS

V. Milic<sup>1</sup>, G. Radunovic<sup>1</sup>, J. Marinkovic<sup>2</sup>, N. Damjanov<sup>3</sup>. <sup>1</sup>Institute of rheumatology, Medical School, University; <sup>2</sup>Institute of Social Medicine and Informatics, School of Medicine, University of Belgrade; <sup>3</sup>Institute of rheumatology, Medical School, University, Belgrade, Serbia

**Background:** Parenchymal inhomogeneity of the salivary glands (SG) is the most relevant ultrasonographic (US) feature for diagnosis primary Sjogren's syndrome (pSS).

**Objectives:** To analysis parenchymal echostructure of SG in patients with established pSS and association USSG score with disease activity, serological markers and biopsy of minor salivary glands (MSG).

**Methods:** This study included 205 pSS patients (mean age 53.9 $\pm$ 11.5, disease duration 5.6 years) and 87 healthy controls (mean age 52.3 $\pm$ 14.7). All pSS patients fulfilled the AECG diagnostic criteria. The disease activity was evaluated by EULAR SS disease activity index (ESSDAI), Sjögren's Syndrome Disease Damage Index (SSDDI) and EULAR Sjogren's syndrome patient reported index (ESSPRI). The presence of ANAs assessed by indirect immunofluorescence assay on Hep-2 cells, anti SSA and anti SSB (commercial ELISA kit) and RF (nephelometry). The parotid and submandibular glands on both sides were examined by US using a GE LogiqE9 with a linear high-frequency transducer (6–15 MHz). Inhomogeneity of the SG were graded according to the De Vita scoring system. Grading 0 was for a homogeneous gland, 1 for mild inhomogeneity, 2 for evident inhomogeneity and 3 for a grossly inhomogeneous gland. The global SGUS score (0–6) was the sum of the scores of each pair of SG. Statistical analysis was performed by SPSS v19. Data were compared using *t*-test,  $\chi^2$  test and Mann-Whitney U test. The diagnostic accuracy of inhomogeneity was evaluated by area under the receiver operating characteristics curves (AUC-ROC). A multivariate linear regression analysis was performed to determine the factors associated with SGUS score.

**Results:** Xerophthalmia and xerostomia were presented in 185/205 (90.2%) and 186/205 (91.2%), respectively. According to ESSDAI, the majority of pSS patients 88/205 (43%) had moderate disease activity. Seventy-eight per cent of pSS patients were anti-SSA positive, 44% anti-SSB positive. Biopsy of MSG was positive in 140/172 (81.4%) pSS patients. US abnormalities were established in 197/205 (96%) pSS patients and in 16/85 (18%) controls ( $p < 0.0001$ ). The median SGUS was significantly higher in pSS patients in comparison with control group [median (range) 4 (0–6) vs. 0 (0–2),  $p < 0.0001$ ]. The diagnostic accuracy of parenchymal inhomogeneity was high, AUC-ROC 0.89 (0.02) with cut-off  $\geq 2$  (Sp 89.5%, Sn 89.3%). Out of 197 pSS patients with abnormal findings, the most patients had US score 4 (47%), while 81% in control group had score 0. After adjustment for potential confounders variables, dry mouth ( $B=1.192$ ,  $\beta=1.542$ ;  $p=0.04$ ), ESSDAI ( $B=0.184$ ,  $\beta=1.203$ ;  $p=0.008$ ) and biopsy of MSG ( $B=1.006$ ,  $\beta=2.735$ ;  $p=0.05$ ) were significantly associated with advanced US changes of SG. Dry eyes, SSDAI, ESSPRI and serological markers were not associated with USSG score ( $p > 0.05$ ).

**Conclusions:** Our findings confirmed that parenchymal inhomogeneity of the salivary glands is the reliable feature for primary Sjogren's syndrome. Presence of xerostomia, objective disease activity assessed by ESSDAI and pathological findings of biopsy of minor salivary glands had predictive value for advanced US change of salivary glands.

SAT0462

#### PD-1+CXCR5-CD4+ T CELLS MAY PLAY AN IMPORTANT ROLE IN THE SEVERITY OF SYSTEMIC ERYTHEMATOSUS LUPUS

W. Chen, Y. Yu, J. Lin. The First Affiliated Hospital, College of Medicine, Zhejiang University, Hangzhou, China

**Background:** CD4<sup>+</sup> T cells are central mediators in specific autoimmune diseases; however, it remains challenging to define their key effector functions in systemic erythematosus lupus (SLE), a chronic immune-mediated damage to the whole system. Programmed death 1 (PD-1), a negative T cell regulator to maintain peripheral tolerance, induces negative signals to T cells during interaction with its ligands. PD-1<sup>+</sup>CD4<sup>+</sup>T cells could be divided into PD-1<sup>+</sup>CXCR5<sup>+</sup>CD4<sup>+</sup>T peripheral helper cells and PD-1<sup>+</sup>CXCR5<sup>+</sup>CD4<sup>+</sup>T (Tfh) cells according to CXCR5 expression. PD-1<sup>+</sup>CXCR5<sup>+</sup>CD4<sup>+</sup>T peripheral helper (Tph) cells were proven to promote B cell responses and antibody production in rheumatoid arthritis Rao DA, Nature, 2017.<sup>1</sup> Tfh cells were required for the generation of most memory B cells and long-lived plasma cells in SLE. However, what the role of Tph cells in the pathogenesis of SLE was unknown.

**Objectives:** We assessed that whether Tph cells were associated with clinical profiles of patients with SLE.

**Methods:** This cohort study included 36 patients with SLE from the Division of Rheumatology, the first Affiliated Hospital, college of medicine, Zhejiang University. All SLE patients fulfilled the American College of Rheumatology revised classification criteria. 26 Age- and sex-matched healthy individuals had no connective tissue disorders, neoplasms or current infections. Here we used flow cytometry to analyse PD-1<sup>+</sup>CXCR5<sup>+</sup>CD4<sup>+</sup>T cells in peripheral blood from patients with SLE. Correlation between Tph cells and other parameters was investigated by Spearman's correlation coefficient test, and comparisons between groups were performed using nonparametric Mann-Whitney test.

**Results:** Firstly, we revealed a markedly expanded population of Tph cells (8.95  $\pm$  6.35 vs. 2.67  $\pm$  1.22,  $p < 0.0001$ ) in the circulation of patients with SLE (n=36),

compared to healthy controls ( $n=26$ ) (figure 1a, b). And Tph cells were much higher in active group than those in inactive group ( $13.21\pm 5.96$  vs.  $4.19\pm 1.59$ ,  $p<0.0001$ ) (figure 1a, c). Secondly, like Tfh cells ( $r=0.611$ ,  $p<0.0001$ ), Tph cells ( $r=0.829$ ,  $p<0.0001$ ) were significantly associated with SLEDAI scores (figure 1d). Tph cells were associated with IgG ( $r=0.650$ ,  $p<0.001$ ) (figure 1e), C3 ( $r=-0.528$ ,  $p=0.001$ ) (figure 1 f), C4 levels ( $r=-0.561$ ,  $p=0.001$ ) (figure 1 g), but not ESR, CRP, IL-2, IL-6, TNF- $\alpha$ , IFN- $\gamma$ , and IL-17A levels. Furthermore, Tph cells were much higher in lupus patients with arthritis ( $17.71\pm 10.05$  vs.  $11.14\pm 6.84$ ,  $p=0.045$ ), in skin mucous group ( $18.71\pm 6.08$  vs.  $10.32\pm 7.32$ ,  $p=0.004$ ), in pleuritis ( $20.60\pm 8.87$  vs.  $11.40\pm 7.24$ ,  $p=0.025$ ), in pericarditis group ( $26.65\pm 0.21$  vs.  $11.58\pm 7.25$ ,  $p=0.006$ ), in group with haematological involvement ( $15.51\pm 7.76$  vs.  $8.97\pm 6.58$ ,  $p=0.010$ ), when compared to patients without relevant symptoms.

**Conclusions:** Our data suggest that increased Tph cell proportions seem to have an important role in lupus disease development.

#### OLFACTORY IMPAIRMENT IN PATIENTS WITH PRIMARY SJÖGREN'S SYNDROME AND ITS CORRELATION WITH ORGAN INVOLVEMENT AND IMMUNOLOGICAL ABNORMALITIES

X. Xu, L.-Y. Geng, Z.-Y. Chen, J. Liang, L.-Y. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nan jing, China*

**Background:** Recent findings suggest that autoimmune disorders predispose to a diminished capacity to smell. This has been shown for patients with systemic lupus erythematosus as well as for patients with rheumatoid arthritis. However, this problem has not received much attention in primary Sjögren's syndrome (pSS).

**Objectives:** The aim of the study was to assess the olfactory functions of patients with primary Sjögren's syndrome and to correlate these findings with their disease activity.

**Methods:** Fifty-two patients with primary SS and 52 age- and sex-matched healthy control subjects underwent clinical and laboratory examination. Olfactory functions were evaluated using olfactory function assessment by computerised testing including the three stages of smell: threshold, identification and memory of the different odours. The disease activity was assessed by the EULAR SS Patient Reported Index (ESSPRI) and the EULAR SS Disease Activity Index (ESSDAI).

**Results:** All the olfactory scores (odour threshold, odour memory and identification) in patients with pSS were significantly below the scores in the control group (all  $p<0.001$ ). Multivariable regression analysis revealed that smell threshold score correlated negatively with ESSPRI and ESSDAI (adjusted  $R^2=0.381$ ,  $p<0.05$ ). Smell threshold score was decreased in pSS patients with anti-SSA antibody compared with those without ( $p<0.05$ ). Total smell scores were significantly reduced in patients with thyroid involvement ( $p<0.01$ ).

**Conclusions:** Our findings indicate that olfactory functions are impaired in pSS patients. There was close correlation between olfactory dysfunction with disease severity and serological abnormalities. Therefore, imperative that physicians should make their patients to be aware of these sensory dysfunctions and educate them on methods to cope with it for better quality of life.

#### COMPARISON OF DISEASE ACTIVITY SCORES PREDICTING MORTALITY IN PATIENTS WITH SYSTEMIC LUPUS ERYTHEMATOSUS IN COLOMBIA

Y. Santamaria-Alza<sup>1</sup>, J.D. Sánchez-Bautista<sup>2</sup>, J. Fajardo-Rivero<sup>1</sup>, C.L. Figueroa-Pineda<sup>1</sup>. <sup>1</sup>*Internal medicine, Industrial University of Santander, Bucaramanga, Colombia;* <sup>2</sup>*Center for infection and inflammation Imaging Research, Centre for Tuberculosis Research, Johns Hopkins University., Baltimore, USA*

**Background:** Systemic lupus erythematosus (SLE) is a disease with multisystem involvement. Throughout history, different activity indices have been developed trying to identify patients who have the flare of the disease. These indexes measure different aspects of the disease. Among the most recognised score is SLEDAI 2 K. Others that had been evaluated is the SLEDAI MEX and the ECLAM. The performance of the measurement of the SLEDAI 2 K is more expensive because of the number of variables evaluated. ECLAM score and the SLEDAI MEX have less number of variables and therefore costs are minor. <sup>1, 2, 3</sup>

**Objectives:** To compare the predictive capacity of mortality of three different scores of disease activity (SLEDAI 2 K, SLEDAI MEX, and ECLAM) in a Colombian population with SLE.

To compare the predictive capacity of mortality of three different scores of disease activity (SLEDAI 2 K, SLEDAI MEX, and ECLAM) in a Colombian population with SLE.

**Methods:** Cross-sectional study, in which descriptive analysis with measures of frequency, central tendency and dispersion were made. Subsequently, mortality prediction analysis of the three scales was performed through the evaluation of the ROC curve. Analysis of classification statistics was done.

**Results:** A total of 200 patients with SLE were included, with mortality of 11%. The averages of disease activity were: for SLEDAI 2 K was 14.5 with standard deviation (SD) of 9.7, for SLEDAI MEX 9.26 with SD of 5.93 and for ECLAM 4.39 with SD of 2.28. The area under the curve of the ROC curves was 0.9082, 0.9206 and 0.8917 for the scales SLEDAI 2 K, SLEDAI MEX and ECLAM respectively. Regarding classification statistics, a sensitivity of 36.3% was found for the SLEDAI 2 K scale, specificity was 97.7%, positive predictive value 66.6, negative predictive value 92.5% and correct classification of 91%. For the SLEDAI MEX scale were: Sensitivity 50%, specificity 96.6%, positive predictive value 64.7%, negative predictive value 93.9% and correct classification of 91.5%. Finally, for the ECLAM scale, it was obtained the following results: sensitivity 9.09%, specificity 98.88%, positive predictive value 50%, negative predictive value 89.8% and correct classification in 89%.

**Conclusions:** It can be observed that the predictive capacity for mortality in the patients evaluated is good with the three different scales. The sensitivity found for the three scales is not optimal for making a promptly medical decision, so later it will be necessary the formulation of a new index in which higher number of patients with SLE can be detected with death risk. An additional relevant result is that the SLEDAI MEX activity index has a similar performance than the SLEDAI 2 K activity index for predicting mortality, with the advantage of being a practical index easy to apply and a lower cost of the evaluation.

**CLINICAL MANIFESTATIONS AND PROGNOSIS OF SLE WITH CLINICALLY SIGNIFICANT ANTIPHOSPHOLIPID ANTIBODIES**

Y. Zhang, X. Feng, L. Sun. *Department of Rheumatology and Immunology, The Affiliated Drum Tower Hospital of Nanjing University Medical School, Nanjing, China*

**Background:** Antiphospholipid antibodies (aPLs) have been described in 20% >40% of SLE patients, with 50%>70% of patients with SLE and aPL showing the clinical features of APS after 20 years of follow-up<sup>1</sup>. It assumes that aPLs-positive SLE patients would have a more severe clinical phenotype and worse prognosis than those without aPLs.

**Objectives:** We decided to investigate the clinical manifestations and prognosis of SLE with clinically significant aPLs in a multiple centre SLE cohort.

**Methods:** A follow-up study to investigate the prognosis of SLE, has been conducted in 26 centres across Jiangsu province as described before<sup>2</sup>. SLE patients fulfilled ACR/SLICC criteria. Patients who had ever recorded first admissions and detected aPLs during the 1999±2009 decade were followed and checked for their survival status in 2015. Clinically significant aPL were defined as: positive LA test, aCL IgG/IgM antibodies>99 th percentile and/or aβ2GPI>99 th percentile on two or more occasions at least 12 weeks apart.

**Results:** 1) Among 1372 SLE patients, 495 patients was reported the aPLs minutely, and 146 cases was with clinically significant aPLs. Compared with aPLs negative SLE patients, the proportion of men, and the rates of oral ulcer, neuropsychiatric involvement, dsDNA, antinuclear antibody and C3 were significantly higher in aPLs positive SLE. (table 1)

	aPLs positive n=146	aPL negative n=349	P
Gender (male)	5	32	0.017
Oral ulcer	29	44	0.047
Thromboembolism	16	18	0.031
Neuropsychiatric	14	20	0.000
C3 decrease	119	248	0.015
Anaemia	109	214	0.005
ANA positive	138	317	0.048
Anti dsDNA positive	83	169	0.009

2) There were 20 deaths in aPLs positive SLE group and 52 deaths in aPLs negative SLE group during the average follow up of 7.38±0.56 years and 7.54±0.0.47 years respectively. There was no significant difference in survival curves by Kaplan Meier survival analysis (p=0.776). (Picture 1)

3) Multivariate Cox regression analysis revealed that long time of diagnosis (HR 4.205, p<0.05), SDI>1 in admission (HR 11.982, p<0.01), neuropsychiatric involvement (HR 2.826, p<0.05), and increased serum creatinine (HR 8.403, p<0.01) were independent predictors of mortality. (table 2)

factors	Univariate			Multivariate		
	HR	95% CI	P	HR	95% CI	P
Time of diagnosis>1 year	5.26	2.24–12.32	0	4.20	1.06–16.56	0.04
SDI≥1 on admission	4.37	1.67–11.40	0.003	11.98	2.85–50.25	0.001
Neuropsychiatric	4.52	1.89–10.84	0.001	2.82	1.01–7.85	0.048
Increased serum creatinine	4.39	1.87–10.30	0.001	8.40	2.20–32.04	0.002

**Conclusions:** In this study, we observed that around one-third of patients had clinically significant aPLs, and such autoantibody positivity was associated with a different clinical and serological profile. However, the mortality between aPLs

positive and negative SLE patients had no significant difference. SLE patients presented with vital organ damages rather than active disease at initial hospitalisation are likely to have a poor outcome, especially neuropsychiatric involvements and renal insufficiency.

**SERUM VITAMIN D DEFICIENCY IS ASSOCIATED WITH ACTIVE RENAL DISEASE IN SYSTEMIC LUPUS ERYTHEMATOSUS**

Y.-J. Park<sup>1</sup>, I.-W. Baek<sup>2</sup>, K.-J. Kim<sup>1</sup>, W.-U. Kim<sup>3</sup>, C.-S. Cho<sup>2</sup>. <sup>1</sup>Internal Medicine, ST Vincent Hospital, The Catholic University of Korea, Suwon; <sup>2</sup>Internal Medicine, Yeouido St. Mary's Hospital, The Catholic University of Korea; <sup>3</sup>Internal Medicine, St. Mary's Hospital, The Catholic University of Korea, Seoul, Korea, Republic Of

**Objectives:** 25-hydroxyvitamin D (25(OH)D) deficiency is common in systemic lupus erythematosus (SLE) as well as chronic kidney disease. In this study, we investigated the association of 25(OH)D deficiency and renal involvement in SLE patients.

**Methods:** Two hundred seventy-two SLE patients and 138 control subjects were enrolled; 102 patients with active nephritis, 42 patients with inactive nephritis, and 128 patients with non-renal disease. Serum 25(OH)D levels were measured, and clinical and laboratory data were obtained from medical records.

**Results:** Mean serum 25(OH)D levels were significantly lower in SLE patient than control subjects (19.6 ng/ml versus 21.7 ng/ml, p=0.006). Out of 272 patients, 61.8% were vitamin D deficient (defined as <20 ng/ml). Patients with active nephritis had lower serum 25(OH)D levels (16.9 ng/mL) than patients with inactive nephritis (20.2 ng/mL) and without nephritis (21.5 ng/mL) (p=0.030, p<0.001), but there was no difference between the inactive nephritis and non-renal disease. Moreover, serum 25(OH)D levels were positively correlated with complement C3 ( $\gamma=0.135$ , p=0.026) and C4 ( $\gamma=0.159$ , p=0.009), but inversely with anti-dsDNA antibody level ( $\gamma=-0.156$ , p=0.010). Analysis of receiver operating characteristic curve for differentiating active nephritis and non-renal disease revealed an area under the curve (AUC) of 0.676, which is better than those of anti-dsDNA antibody (AUC=0.585, p=0.038) and complement C3 (AUC=0.509, p=0.001), C4 (AUC=0.538, p=0.008).

**Conclusions:** Vitamin D deficiency is more common in SLE patients with active nephritis, and its level could be a potential marker for active renal disease in SLE. A prospective cohort study is needed to further elucidate the causal relationships over time.

**CEREBRAL VENOUS THROMBOSIS OCCURRENCE IN SYSTEMIC LUPUS ERYTHEMATOSUS WITHOUT ANTIPHOSPHOLIPID ANTIBODY SYNDROME: A MONOCENTRIC SERIE OF 10 CASES**

Z. Lepine<sup>1,2</sup>, A. Mathian<sup>1</sup>, M. Pineton De Chambrun<sup>1</sup>, F. Cohen<sup>1</sup>, J. Haroche<sup>1</sup>, M. Hie<sup>1</sup>, M. Pha<sup>1</sup>, Z. Amoura<sup>1</sup>. <sup>1</sup>Service de Médecine Interne 2, Centre National de Référence Maladies Auto-Immunes et Systémiques Rares – Lupus et Syndrome des Anticorps Antiphospholipides, Pitié-Salpêtrière Hospital, Paris; <sup>2</sup>Neurology, Purpan Hospital, Toulouse, France

**Background:** Cerebral venous thrombosis (CVT), which includes cerebral vein and dural sinus thrombosis, is a rare disorder that can lead to significant morbidity and mortality. Its occurrence in SLE in the absence of APS has been rarely reported. In this study we aimed to describe a cohort of SLE patients suffering from CVT without APS.

**Methods:** We collected retrospectively clinical and biological data of patients with confirmed CVT in the Pitié-Salpêtrière cohort of SLE (n=1352 patients). Patients fulfilled ACR SLE criteria. The diagnosis of CVT was confirmed by brain imaging studies. Exclusion criteria were patient with a lupus anticoagulant or IgG/IgM anti-cardiolipin antibodies or anti-β2 glycoprotein-1 abs. We searched on PUBMED database for case report of this association published in English until 31 August 2017. Lupus flares were defined according the SELENA Flare instrument.

**Results:** We included 10 patients (8 women and 2 men). The median (range) age at diagnosis of CVT was 28 years.<sup>9-53</sup> The CVT occurred with a median delay of 4

years (0–11) after the diagnosis of SLE. At the time of the CVT diagnosis: no patients had a past medical history of thrombotic event or miscarriage or foetal loss; 7 patients had a lupus flare (5 lupus nephritis [1 class I, 1 class V, 2 class IV and 1 class III+V], 4 immune thrombocytopenia, 2 autoimmune hemolytic anaemia, 3 cutaneous lupus, 1 serositis and 1 arthritis); 7 patients were treated with corticosteroids, 4 with hydroxychloroquine and 4 with immunosuppressive drugs. Other potential precipitating factors of CVT were: 2 nephrotic syndromes, 2 anaemia and 1 hyperhomocysteinemia. CVT was symptomatic for 9 patients: 8 headaches, 3 epilepsy and 1 sensitive-motor deficit. The diagnosis of CVT was confirmed by magnetic resonance imaging (MRI) for 9 patients and cerebral angiography for 1 patient. The median delay between the onset of clinical symptoms and the diagnosis of thrombosis was 10 days.<sup>3–37</sup> Nine patients presented a single localisation of CVT (superior longitudinal or lateral or cavernous sinus, or cortical cerebral vein). Only 1 patient had thrombosis of both lateral and sigmoid sinus. Cerebral infarction or haemorrhage was seen for 2 patients. Corticosteroids and immunosuppressant treatment were increased or introduced because of a concomitant lupus flare for 2 patients. All patients were treated with heparin followed by vitamin K antagonists for 7 patients or apixaban for 2 patients. One patient received long-term heparin. After a median survey of 19.5 (1–120) months: anti-coagulant drugs were stopped for 6 patients; recanalisations were complete in 7 of the 7 patients assessed on brain MRI; no patient had a residual neurological damage; only 1 patient had a new vascular event in the form of a brain haemorrhage. In addition to these 10 cases we found 17 cases from a literature review.

**Conclusions:** CVT is a rare event in SLE in absence of APS. In our cohort SLE was often active at the time of the CVT occurrence. Most of the CVT were limited in extension and severity. The outcome on anticoagulant treatment was favourable without residual neurological damage. The occurrence of CVT in SLE is not an indication by itself to increase or to introduce corticosteroids or immunosuppressive drug.

## Scleroderma, myositis and related syndromes

### SAT0468 SCLERODERMA -INTERSTITIAL LUNG DISEASE: DOES MAINTENANCE THERAPY MAKE A DIFFERENCE

S.K. Sharma, A. Chattopadhyay, S. Naidu, V. Dhir, S. Jain. *Internal Medicine, post graduate institute of medical education and research, Chandigarh, Chandigarh, India*

**Background:** Interstitial lung disease (ILD) is the commonest cause of death among Scleroderma (SSc) patients. The evidence regarding efficacy of cyclophosphamide (CYC) in SSc-ILD results mainly from two high-quality RCTs.<sup>1,2</sup> In the scleroderma lung study 1, after 12 months of therapy with oral CYC, a significant difference in mean forced vital capacity (FVC) was noted favouring CYC group. However, the effect waned off by the end of 24 months of follow up, indicating that maintenance therapy might help in preserving the initial benefits.<sup>3</sup>

**Objectives:** To study the long-term effect of maintenance therapy in SSc related interstitial lung disease (SSc-ILD)

**Methods:** This is a retrospective data analysis of forty-three patients with SSc-ILD divided into two groups, those who received maintenance therapy with either mycophenolate (MMF) or azathioprine (AZA) and the other group without any maintenance therapy following CYC induction. Response to treatment was classified as improved ( $\geq 10\%$  increase in FVC from baseline), stable (change in FVC of 0%–10% from baseline) and worsened ( $\geq 10\%$  decrease in FVC or fall of FVC to  $< 40\%$  of predicted). Results were expressed as percentages for categorical variables and mean with standard deviation (SD) for continuous variables. Chi square test was used for comparison of responses between two groups of patients. Following induction patients were divided into groups: those They were assessed at three years.

**Results:** Baseline characteristics of the study population are shown in table 1. Maintenance therapy was given in 29 (67.4%) patients and among them favourable outcome (improve +stable) was noted in 23 (79.3%) patients and unfavourable outcome was noted in 6 (20.7%) patients. Fourteen (32.6%) patients did not receive maintenance therapy and among them, favourable outcome was noted in 4 (28.6%) patients and unfavourable outcome in 10 (71.4%) patients. This difference in the rates of favourable outcome between both the groups was statistically significant ( $p=0.001$ ). Figure 1 summarises the response rates of the patients of these two groups.

**Abstract SAT0468 – Table 1.** Baseline characteristics of the patients (n=43)

Characteristic	Maintenance group (n=29)	No maintenance group (n=14)
Females (%)	93	85.7
Mean age in years(SD)	40.9 ( $\pm 10.9$ )	42 ( $\pm 10.5$ )
Type of Scleroderma		
Limited cutaneous (%)	44.8	57.1
Diffuse cutaneous (%)	55.1	42.9
ANA positivity (%)	75.9	78.6
PAH (%)	34.5	28.6
Mean FVC (SD)	57.6 ( $\pm 13$ )	55.6 ( $\pm 15.2$ )

**Conclusions:** Maintenance therapy up to 3 years (either with AZA or MMF) following IV-CYC induction, resulted in a favourable outcome and helps in preserving the initial beneficial effects achieved with IV CYC.

### SAT0469 “INTERSTITIAL LUNG DISEASE IN IDIOPATHIC INFLAMMATORY MYOPATHIES: ULTRASOUND ASSESSMENT OF PLEURAL IRREGULARITIES AND COMPARISON WITH HIGH RESOLUTION COMPUTED TOMOGRAPHY”

E. Cioffi<sup>1</sup>, S. Barsotti<sup>1</sup>, C. Romei<sup>2</sup>, C. Giovanetti<sup>1</sup>, C. Roncella<sup>2</sup>, F. Ferro<sup>1</sup>, E. Perrone<sup>2</sup>, M. Mosca<sup>1</sup>, F. Falaschi<sup>2</sup>, R. Neri<sup>1</sup>. <sup>1</sup>Rheumatology Unit, University of Pisa; <sup>2</sup>Radiology Unit, Pisa University Hospital, Pisa, Italy

**Background:** Interstitial Lung Disease (ILD) is one of the most frequent and significant extra-muscular manifestations in Idiopathic Inflammatory Myopathies (IIM). Although high resolution computed tomography (HRCT) remains the gold standard technique for the evaluation of ILD, during the last years several authors proposed ultrasound (US) quantification of pleural irregularities (PIs) as a possible method to detect lung involvement in IIM patients.

**Objectives:** The objective of our study was to evaluate the prevalence of PIs and to compare the results obtained to the data provided by HRCT.

**Methods:** Thirtyseven patients (24 females, 13 males, mean duration of the disease 5.21 $\pm$ 7.6 and median age 62.24 $\pm$ 1.8 years) with a diagnosis of IIM according to Bohan and Peter criteria (17PM, 16DM, 1MCI, 3overlap syndromes) who required HRCT evaluation were enrolled. All patients underwent rheumatological clinical evaluation, including dyspnoea measurement by means MRC scale and disease activity assessment according to IMACS criteria (muscle enzymes, MMT8, VAS, HAQ, MYOACT). Patients were also asked to complete Patient Reported Outcome (PRO) questionnaires as Leicester Cough Questionnaire (LCQ). All the patients underwent a thoracic US evaluation in 53 anterior and posterior thoracic areas by Esaote MyLab Gold ultrasound device with 8–18 MHz

linear probe. We evaluated the aspect of the pleural profile assigning each space a score according to a 3 points scale (regular=0, mild irregularity=1, irregularity=2) and summed the score in each space to obtain the PIs total score. HRCT was assessed by an expert radiologist to obtain a semiquantitative evaluation of parenchymal involvement by Warrick score. In a subgroup of patients, thoracic US was repeated by the same operator after two days from the first evaluation and by a second operator to evaluate the intrareader and interreader agreement of the technique.

**Results:** The PIs total score obtained with lung US ( $24.70 \pm 13.66$ ) was higher in patients with thoracic crackles at clinical examination ( $p=0.008$ ) and in patients with positivity for antisynthetase autoantibodies, particularly anti-Jo1 ( $p<0.001$ ). A positive correlation was found between PIs total score and MYOACT total score ( $r=0.36; p=0.027$ ), instead a negative one was found with LCQ score ( $r=-0.56; p=0.009$ ). Interestingly, a good correlation between PIs total score and the Warrick score ( $r=0.65; p<0.001$ ) was found. From the analysis of ROC curve, we demonstrated that a cut-off of PIs total score  $<18.5$  might be able to identify all patients with HRCT abnormalities (sensitivity 100%). Lung US was repeatable (inter-reader reliability:  $\alpha=0.916$ ) and reproducible (intra-reader reliability:  $\alpha=0.945$ ).

**Conclusions:** The US PIs total score is strictly correlated to clinical, serological and HRCT parameters and as the lung US is a non-invasive and relatively inexpensive technique, the results of our study suggest a possible role of this method in the screening of lung involvement in IIM patients. Follow up studies in a larger cohort of IIM patients are required.

#### SAT0470 MYOSITIS, OFTEN SUSPECTED, IS ACTUALLY RARE IN PRIMARY SJÖGREN'S SYNDROME: DATA FROM THE FRENCH COHORT ASSESS

R. Felten<sup>1</sup>, R. Seror<sup>2</sup>, O. Vittecoq<sup>3</sup>, E. Hachulla<sup>4</sup>, A. Perdriger<sup>5</sup>, P. Dieude<sup>6</sup>, J.-J. Dubost<sup>7</sup>, A.-L. Fauchais<sup>8</sup>, V. Le Guern<sup>9</sup>, C. Larroche<sup>10</sup>, E. Dernis<sup>11</sup>, D. Guellec<sup>12</sup>, D. Corne<sup>12</sup>, J. Sibilla<sup>1</sup>, J.-E. Gottenberg<sup>1</sup>, A. Meyer<sup>1</sup>. <sup>1</sup>Rheumatology, CHU, Strasbourg; <sup>2</sup>Kremlin-Bicêtre, Paris; <sup>3</sup>CHU, Rouen; <sup>4</sup>CHU, Lille; <sup>5</sup>CHU, Rennes; <sup>6</sup>Bichat, Paris; <sup>7</sup>CHU, Clermont-Ferrand; <sup>8</sup>CHU, Limoges; <sup>9</sup>Cochin, Paris; <sup>10</sup>Avicenne, Bobigny; <sup>11</sup>CH, Le Mans; <sup>12</sup>CHU, Brest, France

**Background:** Myositis prevalence in primary Sjögren's syndrome (pSS) and whether it is associated with peculiar extra-muscular involvement and/or a biological profile is unknown.

**Objectives:** To refine prevalence and characteristics of patients with pSS and myositis.

**Methods:** In the national multicenter prospective cohort ASSESS (395 patients with pSS with a 5 year-prospective follow-up), patients with suspected myositis were identified. Their charts were reviewed and the patients were compared with the rest of the cohort.

**Results:** Myositis was suspected in 38 patients (2 men, 36 women, 58<sup>29-78</sup> yr old) because of myalgia and/or exercise intolerance ( $n=38$ ) along with high blood CK level ( $n=28$ ). As compared with the rest of the cohort, they had higher patient-reported signs including pain VAS, dryness VAS and patient reported index ESSPRI (6.3 vs 5.3,  $p=0.007$ ). In contrast, proportion of systemic involvements (76.3% vs 70.9%,  $p=0.57$ ) and systemic disease activity measured by the ESSDAI, without taking the muscular domain into account (2 vs 3,  $p=0.93$ ), were not different from patients without suspected myositis. Demographic characteristics and disease duration were also similar.

Electromyographic recording and/or muscle histology performed in these 38 patients objective muscular involvement in only 4 patients (1% of the cohort).

- Three patients were diagnosed with inclusion body myositis (sIBM). Accordingly, age at first sign was 49 years, 49-60 muscle disease had progressive onset as suggested by the 11 years<sup>1-28</sup> delay between first muscle sign and diagnosis. CK level was  $<1000$  U/L. Immunomodulatory drugs had no effect on myositis, even though methotrexate, IVIg and rituximab were most frequently given than in patient without myositis (respectively 50% vs 12.4%; 75% vs 1.8% and 75% vs 4.9%;  $p<0.0001$ ).

- One pSS patient with myositis was a 39 years old woman with polymyositis. She developed proximal muscle weakness, CK was 750U/L and muscle biopsy found endomyosial infiltrate. Muscle force and CK level normalised with immunomodulatory drugs.

Compared to the rest of the cohort, patient with myositis had longer disease duration at inclusion (15 vs 5 year,  $p=0.01$ ) and tended to be younger at pSS diagnosis (41.5 vs 53 year,  $p=0.07$ ). They had more frequent history of systemic manifestations (100% vs 65.0%,  $p=0.011$ ) but ESSDAI at baseline (2 vs 3,  $p=0.56$ ) and the

biological characteristics were not different from patients without myositis. In contrast with the patients with suspected but not confirmed myositis, patient-reported signs (i.e. fatigue, pain, dryness and ESSPRI score) were similar to patients without myositis.

**Conclusions:** Myositis is frequently suspected in patients with pSS, especially when patients-reported signs are particularly disabling. Myositis occurs very infrequently (1% of the cohort), in patients with longer disease duration. sIBM was the most predominant subset of myositis in the present study.

#### SAT0471 ABNORMAL NAILFOLD CAPILLAROSCOPIC PATTERNS ARE COMMON IN UNDERWEIGHT SUBJECTS WITH RAYNAUD'S PHENOMENON

A. Eman Abdulle<sup>1</sup>, A.M. van Roon<sup>1</sup>, M.M. Habing<sup>1</sup>, A.J. Stel<sup>2</sup>, A.J. Smit<sup>1</sup>, H. van Gooij<sup>3</sup>, D.J. Mulder<sup>1</sup>. <sup>1</sup>Dept. of Internal medicine, div. Vascular Medicine; <sup>2</sup>Dept. of Rheumatology and Clinical Immunology; <sup>3</sup>Dept. of Pathology and Medical Biology, Section Pathology, University of Groningen – University Medical Centre Groningen., Groningen, Netherlands

**Background:** Despite the extensive research on this subject, the exact pathogenesis of RP still remains incompletely understood. The current view on this rather complex phenomena is that the imbalance between vasoconstriction and vasodilatation is purely functional and that structural vascular changes do not occur in PRP patients. Although RP is a frequently occurring problem in underweight patients, microvascular changes have never been (structurally) investigated.

**Objectives:** The aim of the current study was to investigate the relationship between microvascular abnormalities and body mass index (BMI) in subjects with Raynaud's phenomenon (RP), without an underlying connective tissue disease.

**Methods:** Nailfold capillaroscopic patterns (NCP) were retrospectively assessed in 352 RP patients, without an underlying systemic disease (e.g. negative serology tests, and no signs of organ involvement). Patient characteristics were obtained and patients were divided by BMI category: underweight (BMI  $<18.5$  kg/m<sup>2</sup>), normal weight (BMI 18.5–24.99 kg/m<sup>2</sup>), and overweight (BMI  $\geq 25$  kg/m<sup>2</sup>). Patterns were deemed abnormal if the mean capillary count was  $<20$  per 3 mm, or mean number of dilated capillaries per finger was  $>3$ , or any giant capillaries were observed.

**Results:** Approximately 70% of the underweight patients showed an abnormal NCP. This was irrespective of age and smoking behaviour. Underweight RP patients had the highest mean count of dilated capillaries (5.14 for BMI  $<18.5$  kg/m<sup>2</sup>; 4.17 BMI for 18.5–24.99 kg/m<sup>2</sup>; 2.61 for BMI  $\geq 25$  kg/m<sup>2</sup>,  $p=0.002$ ) and giant capillaries (1.01 for BMI  $<18.5$  kg/m<sup>2</sup>; 0.48 BMI 18.5–24.99 kg/m<sup>2</sup>; 0.23 BMI  $\geq 25$  kg/m<sup>2</sup>,  $p=0.024$ ). However capillary loss was not found to be significantly different ( $p=0.458$ ). Furthermore, mean number of capillaries ( $r=0.260$ ,  $p<0.001$ ), mean number of dilated capillaries ( $r=-0.225$ ,  $p<0.001$ ) and mean number of giant capillaries ( $r=-0.221$ ,  $p<0.001$ ) were found to be associated with BMI.

**Conclusions:** Our findings indicate NCP abnormalities are more frequently observed in underweight individuals, indicating that microvascular changes may occur independently of an underlying connective tissue disease. These findings may alert clinicians that (perivascular) adipose tissue may play a crucial role in the occurrence of Raynaud's phenomenon.

SAT0472

### ULNAR OCCLUSION IS A MARKER OF GLOBAL VASCULAR DAMAGE IN SYSTEMIC SCLEROSIS: RESULTS FROM A MONOCENTRIC PROSPECTIVE STUDY OF 99 PATIENTS

C.M. Yelnik<sup>1</sup>, D. Elodie<sup>2</sup>, C. Lamotte<sup>1</sup>, V. Sobanski<sup>1</sup>, S. Morell-Dubois<sup>1</sup>, H. Maillard<sup>1</sup>, M. Lambert<sup>1</sup>, P.-Y. Hatron<sup>1</sup>, D. Launay<sup>1</sup>, E. Hachulla<sup>1</sup>. <sup>1</sup>Département de Médecine Interne et d'Immunologie Clinique, Centre National de Référence Maladies Systémiques et Auto-immunes Rares, European Reference Network on Rare Connective Tissue and Musculoskeletal Diseases Network, Univ. Lille, CHU Lille; <sup>2</sup>Univ. Lille, CHU Lille, EA 2694 – Santé publique: épidémiologie et qualité des soins, Département de Biostatistique, Lille, France

**Background:** Macrovascular damages of systemic sclerosis (SSc) were poorly investigated, and the link between macrovasculopathy and microvasculopathy of SSc, cardiovascular disease, and mortality remain unclear.

**Objectives:** To evaluate if macrovascular damage in SSc predicts the occurrence of new digital ulcers (DU), cardiovascular events and mortality, and to further assess the relationship between micro and macrovascular damages in SSc.

**Methods:** All consecutive SSc patients followed in our SSc National Reference Centre, who underwent an arterial doppler ultrasonography (aDUS) of the upper limbs, were included and prospectively followed up until October 2017. Inclusion criteria were: 1) adults; 2) a diagnosis of SSc according to 2013 ACR/EULAR criteria; 3) aDUS performed in our vascular exploration department.

**Results:** Ninety-nine SSc patients were included. Median follow-up duration was 35 (IQR, 21 to 39) months. Macrovascular damages mainly affected ulnar arteries, with ulnar artery occlusion (UAO) in 28 (28.3%) patients (bilateral 60.7%). New DU occurred in 26 (27.1%) patients, new cardiovascular event in 10 (10.4%) patients, and 11 patients died during the study period. Interestingly, UAO was not associated with traditional cardiovascular risk factors (except dyslipidemia) nor with history of cardiovascular diseases, and was not predictive of new cardiovascular events. Conversely, UAO was associated with makers of microvascular damages, such as late nailfold capillaroscopy pattern (33.3% vs 6.8%; OR=6.88, 95% CI=1.76 to 26.82; p=0.03) and was predictive of new ischaemic DU (44.5% vs 24.8%; HR=2.23, 95%CI=1.02 to 4.86; p=0.037), pleading for a SSc specific vasculopathy.

**Conclusions:** Our study confirms that macrovascular damages are frequent in SSc patients and mainly affect ulnar arteries. Interestingly, UAO was associated with severe microvasculopathy, but not with markers of cardiovascular diseases.

### CLINICAL AND ECHOCARDIOGRAPHIC ASSOCIATES OF ALL-CAUSE MORTALITY AND CARDIOVASCULAR OUTCOMES IN PATIENTS WITH SYSTEMIC SCLEROSIS

S.E. van Wijngaarden<sup>1</sup>, M. Boonstra<sup>2</sup>, B. Bloem<sup>1</sup>, D. Cassani<sup>3</sup>, F.C. Tanner<sup>3</sup>, S. Jordan<sup>4</sup>, O. Distler<sup>4</sup>, V. Delgado<sup>1</sup>, J.J. Bax<sup>1</sup>, J.K. de Vries-Bouwstra<sup>2</sup>, N. Ajmone Marsan<sup>1</sup>. <sup>1</sup>department of Cardiology, Heart Lung Center, Leiden University Medical Center; <sup>2</sup>department of Rheumatology, Leiden University Medical Center, Leiden, Netherlands; <sup>3</sup>department of Cardiology, University Heart Center, University Hospital Zurich; <sup>4</sup>department of Rheumatology, University Hospital Zurich, Zurich, Switzerland

**Background:** Cardiac events are an important cause of mortality in Systemic Sclerosis (SSc), but its diagnosis remains challenging. Left ventricular global longitudinal strain is a novel parameter derived from speckle tracking echocardiographic analysis which has been proposed to identify patient at higher risk of cardiac events.

**Objectives:** We aimed to identify clinical and echocardiographic (including GLS) parameters associated with all-cause mortality and cardiovascular events in SSc patients.

**Methods:** 408 SSc patients (344 females, age 54±14 years.) were prospectively evaluated at baseline and follow-up (FU time 3.3 years. [IQR 1.8 to 5.5]). Cardiovascular events included: heart failure, cardiac infarction, coronary interventions, device implantation, arrhythmias, cerebral infarction, peripheral ischaemic vascular disease.

**Results:** All-cause mortality (n=37) or cardiovascular events (n=57) occurred in 84 patients. At baseline, these patients were older (59±14 vs. 53±14 years., p<0.001), more often male (24 vs. 13%, p=0.018), more often had skin pigment changes (21 vs. 5%, p=0.011), coronary artery disease (11 vs. 3%, p=0.001), holter abnormalities (45 vs. 24%, p≤0.001), increased ESR (24 [IQR 14 to 46] vs. 11 [IQR 6 to 25], p<0.001), worse NT-proBNP (151 [IQR 60 to 644] vs. 82 [IQR 51 to 145] ng/L, p<0.001), worse lung function test results (FVC 92±19 vs. 104%±21%,

p<0.001; DLCO 55±17 vs. 70%±19%, p<0.001), worse left ventricular diastolic function (E/E-prime ratio 9.9 [IQR 6.7 to 10.2] vs. 7.8 [IQR 6.4 to 9.7], p<0.001), higher systolic pulmonary artery pressure (31±12 vs. 25±7 mmHg, p<0.001) and lower GLS (-18.8 [IQR -20.3 to -19.5] vs. -21.1 [IQR -22.1 to -20.0]%, p<0.001). In a multivariate cox-regression analyses, age (HR 1.029, 95% CI 1.006 to 1.052), female sex (HR 0.527, 95% CI 0.302 to 0.922), NT-proBNP (HR 1.000, 95% CI 1.000-1.001), DLCO (HR 0.973, 95% CI 0.961-0.986) and GLS (HR 1.281, 95% CI 1.172-1.399) were independently associated with outcome. After dividing patients into groups according to median GLS (-20.9%) and elevated NT-proBNP (>200 ng/L), survival rates were lower and cardiovascular events increased when GLS was impaired and worsened when NT-proBNP was elevated (Log-rank p<0.001).

**Conclusions:** In SSc patients, next to age, DLCO and NT-proBNP, GLS strongly associates with all-cause mortality and cardiovascular events, indicating that these parameters reflect relevant cardiac involvement in SSc, and as such can contribute to risk stratification and patient management.

### RACIAL DIFFERENCES IN SSC DISEASE PRESENTATION: A EUROPEAN SCLERODERMA TRIALS AND RESEARCH GROUP STUDY

V.K. Jaeger<sup>1</sup>, E. Siegert<sup>2</sup>, E. Hachulla<sup>3</sup>, P. Airò<sup>4</sup>, G. Valentini<sup>5</sup>, M. Matucci-Cerinic<sup>6</sup>, O. Distler<sup>7</sup>, F. Cozzi<sup>8</sup>, Y. Allanore<sup>9</sup>, M. Li<sup>10</sup>, M. Tikly<sup>11</sup>, U.A. Walker<sup>1</sup> on behalf of EUSTAR co-authors. <sup>1</sup>University Hospital Basel, Basel, Switzerland; <sup>2</sup>University Hospital Charité, Berlin, Germany; <sup>3</sup>Université de Lille, Lille, France; <sup>4</sup>Spedali Civili, Brescia; <sup>5</sup>University of Campania, Naples; <sup>6</sup>University of Florence, Florence, Italy; <sup>7</sup>University Hospital Zurich, Zurich, Switzerland; <sup>8</sup>University of Padova, Padova, Italy; <sup>9</sup>Cochin Hospital, Paris, France; <sup>10</sup>Peking Union Medical College Hospital, Beijing, China; <sup>11</sup>Chris Hani Baragwanath Hospital, Johannesburg, South Africa

**Background:** Genetic and environmental factors play a significant role in systemic sclerosis (SSc). African Americans are known for a higher SSc incidence, an earlier age of onset, and a greater frequency of interstitial lung disease and pulmonary hypertension (PH) compared to white patients. Data on blacks mostly stem from African Americans and studies on SSc in Asians are mostly from outside Asia and lack direct comparison with other racial groups.

**Objectives:** We aimed to evaluate differences of SSc presentations between white, Asian and black patients.

**Methods:** Characteristics of self-reported white, Asians or black SSc patients from the EUSTAR cohort were compared across racial groups; survival and multiple logistic regression analyses were used to adjust for age, sex, disease duration and antibody status.

**Results:** 9162 white, 341 Asian and 181 black patients were included. Of the Asian patients 208 stem from within Asia and 133 from 34 centres outside Asia; of the black patients 65 stem from within Africa and 116 from 35 centres outside Africa.

Asian and black patients were on average 10 years younger than white patients (p<0.001). Black patients developed the first non-Raynaud's phenomenon (RP) feature of SSc faster than Asian and white patients (all p<0.01; figure 1) also after adjustment (hazard ratio (HR)[blacks] 1.4, p<0.001; HR[Asians] 1.1, p=0.13 vs whites).

Among ANA specificities, ACA predominated in white patients (whites: 40%, Asians: 16%, blacks: 10%; p<0.001) and Scl-70 in Asian patients (whites: 34%, Asians: 46%, blacks: 32%; p<0.001). The prevalence of diffuse skin involvement was similar in Asian (28%) and white patients (27%), but more common in black patients univariately (59%; p<0.001); however in multivariable analysis Asian patients were less likely to have diffuse SSc than white patients (OR 0.6, p=0.001) while black patients were more likely (OR2.9, p<0.001).

The prevalence of PH (defined as PAPsys >40 mmHg as estimated by echocardiography) was similar in the three groups (whites: 13%, Asians: 17%, blacks: 14%; p=0.10); however multivariably, Asians were more likely to have PH (OR [Asians] 2.0, p<0.001, OR[black] 1.5, p=0.13 vs whites). Asians had a higher prevalence of an impaired diffusing capacity for carbon monoxide (DLCO;<80% of predicted; 84%) than black (72%) or white patients (69%, p<0.001) also in multivariable analysis (OR[Asians] 3.0, p<0.001; OR[blacks] 1.2, p=0.36 vs whites). Both, Asians (43%) and black patients (58%), had a higher prevalence of a reduced forced vital capacity (FVC;<80% of predicted) compared to white patients (23%, p<0.001) univariably and multivariably (OR[Asians] 2.4, p<0.001; OR[blacks] 4.0, p<0.001 vs whites).

**Abstract SAT0474 – Figure 1.** Kaplan-Meier curves with 95% CI of the first non-RP feature after RP onset according to racial group.

Patients who experienced their first non-RP feature of the disease before the onset of RP were included with a simultaneous onset.

**Conclusions:** Several clinical and serological differences were evident between the three racial groups. Asians had high prevalences of Scl-70, PH and of a reduced FVC. Black patients in contrast had fast disease onset and a high prevalence of diffuse skin involvement.

SAT0475

**ANTI-MDA5 (+) CLINICALLY AMYOPATHIC DERMATOMYOSITIS-ASSOCIATED RAPIDLY PROGRESSIVE INTERSTITIAL LUNG DISEASE: ROLE OF HEMOPERFUSION WITH POLYMYXIN**

A. Selva-O'callaghan<sup>1</sup>, C. Vizcaino<sup>2</sup>, J.C. Ruiz-Rodriguez<sup>2</sup>, E. Trallero-Araguás<sup>3</sup>, N. Ramos<sup>4</sup>, C. Berastegui<sup>5</sup>, A. Gil Vila<sup>6</sup>, M.A. Martinez<sup>7</sup>, X. Solanich<sup>8</sup>, R. Ferrer<sup>2</sup>.

<sup>1</sup>Medicine, Universitat Autònoma de Barcelona, Autoimmune Systemic Diseases Unit, Vall d'Hebron General Hospital; <sup>2</sup>Critical Care Department; <sup>3</sup>Rheumatology; <sup>4</sup>Nephrology; <sup>5</sup>Pneumology; <sup>6</sup>Internal Medicine, Vall d'Hebron General Hospital; <sup>7</sup>Immunology, Sant Pau Hospital; <sup>8</sup>Internal Medicine, Hospital Universitari de Bellvitge, Barcelona, Spain

**Background:** Patients with clinically amyopathic dermatomyositis (CADM) with MDA5 positive autoantibodies may develop a severe pulmonary syndrome with rapidly progressive interstitial lung disease (RP-ILD) with a bad prognosis and high mortality.

**Objectives:** To analyse the efficacy of a therapeutic protocol that includes hemoperfusion with polymyxin B (PMX-HP) in addition to immunosuppressive treatment with tacrolimus and glucocorticoids, plasmapheresis and intravenous immunoglobulin (IVIG).

**Methods:** We retrospectively analysed 12 (10 male) patients diagnosed with anti-MDA5 (+) CADM associated RP-ILD between 1983 and 2018. Anti-MDA5 antibodies were determined by ELISA and confirmed by blot. RP-ILD was defined as a worsening of radiologic interstitial changes with progressive dyspnoea and hypoxemia within 1 month after the onset of respiratory symptoms. From 2014 to 2018, patients (Group 1) were treated with the following protocol: pulses of methylprednisolone (500 mg/day for 3 consecutive days), tacrolimus 2 mg/12 hour, PMX-HP (Toraymyxin 20R, Toray Medical Co., Tokyo, Japan) at a flow of 100 ml/

h for 3 hour once daily on two successive days, and a plasmapheresis scheme with replacement of 3.5 l of seroalbumin 5% followed by IVIG infusion (0.4 mg/kg) during 3 consecutive days and then in alternate days for 7 days more. A comparison was performed with anti-MDA5 (+) CADM associated RP-ILD patients from a historical group (Group 2). PaO<sub>2</sub>/FiO<sub>2</sub> (P/F) ratio was measured before and after PMX therapy. A composite endpoint that included mortality due to respiratory failure or lung transplantation was defined. Differences between pre- and post-PMX P/F values were evaluated using paired sample t-test.

**Results:** Mean (SD) age at diagnosis was 49 (3.5) yrs, with a mean (SD) follow-up of 13 (3.9) months. Comparison between both Groups showed that 3 out of 6 (50%) patients from the Group 1 in comparison with 5 out of 6 (83.3%) from the historical group (Group 2) reached the composite endpoint. Mean (CI 95%) values of P/F after PMX treatment showed a significantly improvement when compared with the pre-PMX values (240 [85–396] vs. 125, <sup>60–189</sup> p=0.038)

**Conclusions:** Our protocol seems to be useful at some extent in anti-MDA5 (+) CADM associated RP-ILD patients. A transient but significant improvement can be attributed to PMX-HP. Adsorption and elimination of inflammatory cytokines, mediators and activated leukocytes, as well as anti-MDA5 antibodies could be the rationale of its efficacy.

SAT0476

**INCIDENCE, PREVALENCE, MORTALITY AND PERFORMANCE OF THE ACR/EULAR 2013 CLASSIFICATION CRITERIA IN PHYSICIAN DIAGNOSED SYSTEMIC SCLEROSIS: RESULTS FROM A POPULATION BASED US COHORT (1980–2016)**

A.S. Sandhu<sup>1</sup>, C.S. Crowson<sup>1</sup>, P.R. Bauer<sup>2</sup>, E.L. Matteson<sup>1</sup>, A. Makol<sup>1</sup>.

<sup>1</sup>Rheumatology; <sup>2</sup>Pulmonary and Critical Care, MAYO CLINIC, Rochester, USA

**Background:** Systemic Sclerosis (SSc) is a complex and heterogenous chronic inflammatory disease characterised by widespread fibrosis of the skin and visceral organs, microvascular injury and evidence of immune system activation. Diagnosis can be challenging in the absence of specific laboratory markers or diagnostic criteria.

**Objectives:** To determine the incidence, prevalence and mortality of physician diagnosed SSc in a population based US cohort and evaluate the performance of the ACR/EULAR 2013 Classification criteria in comparison to the 1980 ACR criteria in classifying patients with SSc.

**Methods:** Medical records of patients with a diagnosis or suspicion of SSc in Olmsted County, Minnesota from January 1, 1980 to December 31, 2016 were reviewed to identify incident cases of SSc (defined by physician diagnosis). Prevalent cases of SSc in Olmsted County on January 1, 2015 were also identified. Incidence and prevalence rates were age and sex adjusted to the 2010 US white population. Survival rates were compared with the expected rates in the population of Minnesota. Fulfilment of the 1980 and 2013 classification criteria was ascertained.

**Results:** A total of 79 incident cases of SSc from 1980 through 2016 and 49 prevalent cases on Jan 1, 2015 were identified. Of these, 71 (90%) were females, 68 (87%) were caucasians, age at diagnosis 55.8±15.9 years (mean ±SD). The overall age- and sex- adjusted annual incidence for 1980–2016 was 2.7 (95% C.I. 2.1–3.3) per 1 00 000 population. The age-adjusted incidence was 4.6 (95% CI: 3.5–5.7) per 1 00 000 for females and 0.6 (95% CI: 0.2–1.1) per 1 00 000 for males, with no change in incidence over time. The age- and sex-adjusted prevalence on January 1, 2015 was 47.4 (95% CI: 34.1–60.7) per 1 00 000 population.

64 of 79 (81%) patients fulfilled the 2013 classification criteria, while only 48% fulfilled the 1980 criteria. All but 1 patient that fulfilled the 1980 criteria, also fulfilled the 2013 criteria. All 79 patients had Raynaud's, 38 had cardiopulmonary involvement (pulmonary artery hypertension and/or interstitial lung disease), 33 had digital ulcers/pitting scars, 66 had telangiectasias and 69 had sclerodactyly. 66 patients had limited cutaneous SSc, 11 had diffuse cutaneous SSc and only 2 had Sine scleroderma. 39 patients had a positive autoantibody for SSc: anti-centromere in 29, anti Scl-70 in 8 and anti RNA-polymerase III in 2.

Mortality among SSc patients was significantly higher in comparison to the general population (standardised mortality ratio, 2.24; 95% C.I., 1.52–3.18). Figure 1 demonstrates survival of 79 Olmsted County residents with incident SSc compared to expected rates from Minnesota life tables (observed: solid line; expected dashed line).

**Conclusions:** The average incidence of SSc in this population-based US cohort was 2.7 per 1 00 000 population with no change in incidence over the 36 year period of study. The new 2013 classification criteria perform significantly better than the 1980 criteria, but failed to classify 19% of patients in this cohort. Overall survival of patients with SSc is worse than the general population with no evidence of improved survival over time, indicating an unmet need for early diagnosis and more aggressive management.

SAT0477

#### INTENSIFIED B-CELL DEPLETION THERAPY IN PROGRESSIVE SYSTEMIC SCLEROSIS PATIENTS: 24 MONTHS FOLLOW-UP

D. Rossi, I. Cecchi, S. Sciascia, M. Radin, E. Rubini, D. Roccatello. *Center of Immunopathology and Rare Diseases, University of Torino, Torino, Italy*

**Background:** Systemic sclerosis (SSc) is a connective tissue autoimmune disease with systemic involvement and a serious medical condition with a high rate of mortality, especially due to interstitial lung disease (ILD). The exact pathophysiology is still unclear, but B cells seem to play a crucial role in the initiation and the progression of the disorder.<sup>1</sup> Therefore, the use of Rituximab (RTX) might have a rational in the treatment of SSc.

**Objectives:** We aimed to investigate the outcomes of SSc patients treated with RTX after a follow-up of 24 months.

**Methods:** We retrospectively collected data from SSc patients<sup>2</sup> resistant or intolerant to previous therapies, treated with intensified B-depletion therapy, between 2013 and 2016. Therapeutic protocol comprehends: RTX 375 mg/sm on days 1, 8, 15, 22, and two more doses after one and two months, associated with two intravenous administrations of 10 mg/kg of cyclophosphamide and three methylprednisolone pulses (15 mg/kg) followed by oral prednisone (0.8 mg/kg/day, rapidly tapered to 5 mg/day by the end of the 3rd month after RTX).

**Results:** The study included 20 SSc patients (18 females and 2 males; mean age 66.7±11.0 years). Patients presented with severe multiorgan involvement: ILD (19/20, 95%), pulmonary hypertension (12/20, 60%), and skin thickening (17/20, 85%). After a follow-up of 24 months, we observed a decrease in the levels of NT-proBNP (mean baseline: 385.4±517, mean at 24 months: 283±648, p<0.05), and in the Modified Rodnan Skin Score (mRSS) (mean mRSS baseline: 14.4±10.5, mean after 24 months of follow-up: 12.9±10, p<0.05). Four out of 19 (21%) patients experienced a significant improvement of ILD, as assessed by high-resolution computed tomography, while in 12/19 (63%) patients the intensified B-cell depletion therapy was associated with a stabilisation of the imaging features with no sign of progression. Three out of 19 (16%) patients showed a deterioration of the ILD.

Patients showed no significant decrease in forced vital capacity (FVC) (mean baseline FVC: 93.6±19.3, mean after 24 months of follow-up: 92.2±23.3), no significant decrease in forced expiratory volume in one second (FEV1) (mean baseline FEV1: 89.5±15.6, mean FEV1 at 24 months: 87±21.2), no significant decrease in diffusing capacity (DLCO) (mean baseline DLCO values: 58.8±8.6, mean at 24 months: 60.3±14), no significant change in the ejection fraction (EF)

(mean baseline EF values: 62.8±6.4, mean EF values at 24 months: 58.6±7.1) and in pulmonary artery pressure (PAP) (mean baseline PAP: 30.2±10.5, mean at 24 months: 31.1±11.05).

**Conclusions:** Despite recent advances in the treatment of SSc, ILD heavily affects prognosis and life expectancy of these patients. Our data suggest that the intensified B-depletion therapy protocol might represent a promising tool for the management of SSc in terms of controlling the progression of the disease, especially when considering pulmonary and skin manifestations. Further prospective studies are needed in order to confirm our results.

#### DISEASE-SPECIFIC AUTOANTIBODIES ASSOCIATE WITH REMARKABLY DIFFERENT RISK OF DEVELOPMENT OF SIGNIFICANT LUNG FIBROSIS IN SYSTEMIC SCLEROSIS

A. Sari, S.I. Nihtyanova, A. Gill, V.H. Ong, C.P. Denton. *Rheumatology, Royal Free Hospital, University College London, London, UK*

**Background:** Pulmonary fibrosis (PF) is an important complication of systemic sclerosis (SSc), being a leading cause of disease related death. Some studies suggest that the timing of PF development differs between patients with different autoantibodies.

**Objectives:** We set out to assess a large single-centre SSc cohort, focusing on the timing of clinically significant PF (csPF), and to compare this within subgroups with different disease-specific autoantibodies, in particular anti-centromere antibody (ACA), anti-topoisomerase I antibody (ATA) and anti-RNA polymerase antibody (ARA).

**Methods:** Patients with confirmed SSc and information on autoantibodies were included. PF was confirmed on high-resolution CT and defined as clinically significant based on at least one of the following: FVC <70%; a drop in FVC >15%; DLCO<70% with no pulmonary hypertension (PH) present; or a drop in DLCO>15% with no PH. Only subjects who had first available lung function test result within the first 3 years from onset were included. 1-Kaplan-Meier (1 KM) estimation was used to calculate cumulative incidence of csPF. To assess the timing of highest rates of csPF development, hazard rates were calculated within intervals of 12 months over the follow-up.

**Results:** A total of 450 subjects, 75 (16.7%) male, mean age of onset 47.4 years, were included in the study. Of those 225 (50%) had diffuse cutaneous SSc, 105 (23.3%) carried ACA, 113 (25.1%) ATA and 72 (16%) ARA. Mean follow-up was 12 years, interquartile range 8–16 years. Over the entire follow-up period, 196 (43.6%) of the subjects developed csPF.

Using 1 KM estimation, for the whole cohort, over the first 20 years of disease, approximately half of the patients developed csPF. Three quarters of the patients who developed csPF had reached this endpoint by 5 years (38.2%) with much lower incidence thereafter (at year 10, 15 and 20%—43%, 47% and 49.6%, respectively).

Analysis within subgroups showed that, ACA was associated with a very low risk of csPF development (cumulative incidence of 5.9%, 8.1%, 9.8% at 5, 10 and 15 years from SSc onset). On the other hand, ATA +patients had a remarkably high risk of csPF development, which ultimately occurred in the majority of cases, with cumulative incidence of 77.6% at 5 years, 82.7% at 10 years and 87.1% at 15 years. Rates of csPF development among ARA+patients were higher than those in ACA+, but still much lower than ATA+, and even after 20 years of follow-up, the cumulative incidence of csPF among them was less than a half of that among ATA +patients (23.7%, 33% and 41% at years 5, 10 and 15, figure 1).

The hazard of csPF among ACA +patients was highest in the second year from SSc onset (3%) and in the subsequent years varied between 0% and 1.8%. On the other hand, among ATA +patients hazard of csPF was 28.3% in year 1, 44.9% in year 2, peaked at 52.5% in year 3 and went down sharply thereafter. Although hazard was much lower among ARA+patients, this still peaked at year 3 (2.8%, 6.1% and 12.1% at year 1, 2 and 3 respectively) and declined after.

**Conclusions:** Our analysis demonstrates that csPF is a complication that tends to develop early in the disease course. Although the overall risk of csPF differs by antibodies, it is highest at around 3 years from disease onset and goes down thereafter. This can be used to inform organ disease monitoring and clinical trials recruitment.

**SAT0479 LASER SPECKLE CONTRAST ANALYSIS: A PILOT STUDY AND SYSTEMATIC LITERATURE REVIEW OF RELIABILITY OF THE QUANTITATIVE ASSESSMENT OF PERIPHERAL BLOOD PERFUSION IN SYSTEMIC SCLEROSIS**

A. Vanhaecke<sup>1,2</sup>, M. Cutolo<sup>3</sup>, B. Ruaro<sup>3</sup>, L. Deroo<sup>1</sup>, C. Ickinger<sup>4</sup>, K. Melsens<sup>1,2</sup>, Y. Piette<sup>2</sup>, F. De Keyser<sup>1,2</sup>, V. Smith<sup>1,2</sup> on behalf of the EULAR study group on microcirculation in Rheumatic diseases. <sup>1</sup>Department of Internal Medicine, Ghent University; <sup>2</sup>Department of Rheumatology, Ghent University Hospital, Ghent, Belgium; <sup>3</sup>Research Laboratory And Academic Division Of Clinical Rheumatology, Department Of Internal Medicine, Irccs San Martino Aou, University Of Genoa, Genoa, Italy; <sup>4</sup>Division of Rheumatology, Faculty of Health Sciences, University of the Witwatersrand, Johannesburg, South Africa

**Background:** Microvasculopathy is an important feature of systemic sclerosis (SSc), making its assessment a key issue in SSc clinical research. Nailfold videocapillaroscopy (NVC) is a valuable tool to detect and classify microvascular structural alterations. In contrast, laser speckle contrast analysis (LASCA), a non-invasive microvascular imaging tool, has been proposed as an objective technique to dynamically evaluate the peripheral blood perfusion (PBP).

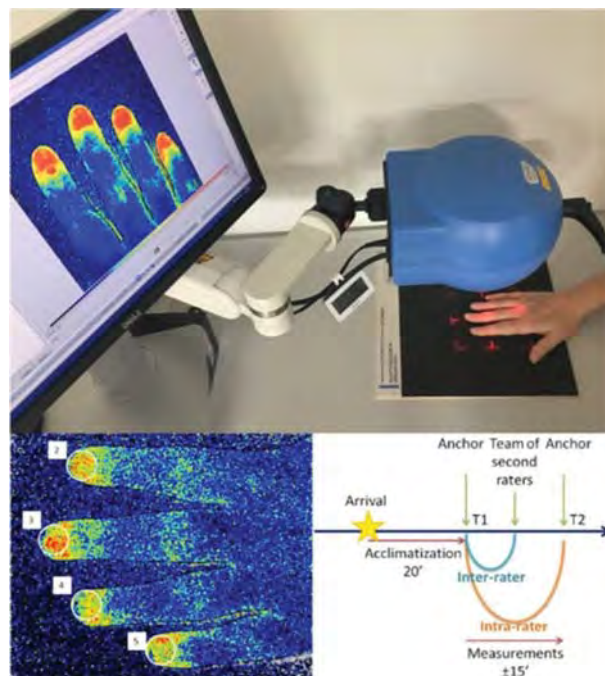

**Objectives:** The specific objectives were 1) to perform a pilot study to investigate as first both the intra- and inter-rater reliability of LASCA in an unselected SSc cohort and descriptively in healthy subjects (HS) and 2) to identify the available literature on the reliability of LASCA in SSc by a systematic literature review.

**Methods:** First, a pilot study was performed to assess the reliability of LASCA to measure the PBP at the level of the fingers in an unselected cohort SSc patients and descriptively in HS. Intra-rater reliability was assessed by having a first anchor rater performing the measurements at 2 time-points (within 15 min) and inter-rater reliability by subsequently having the first anchor rater and a team of 3 s raters performing the measurements in 15 SSc and 30 HS (see figure 1). As external validation, the measurements were repeated with a second anchor rater in a distinct cohort of 15 SSc patients. Reliability was described by calculating the intraclass correlation coefficient (ICC).

The systematic search was performed to identify relevant full-text articles in PubMed, EMBASE and Web of Science. All retrieved articles were screened on title, abstract and full-text level, reference lists were additionally searched.

**Results:** Thirty SSc patients (5 men, 25 women; mean age 52±17 y; 1LSSc, 25LcSSc, 4DcSSc; 14 vasodilatory therapy) and 30 HS (8 men, 22 women; mean age 33±11 y) underwent LASCA measurements. ICC for intra-rater reliability of the first anchor was 0.95 (95% CI 0.86–0.98) in SSc and 0.93 (95%CI 0.83–0.97) in HS, the ICC for inter-rater reliability was 0.97 (95%CI 0.90–0.99) in SSc and 0.93 in HS. Intra- and inter-rater reliability of anchor 2 was 0.78 (95%CI 0.46–0.92) and 0.87 (95%CI 0.67–0.96) respectively.

The systematic search identified 64 unique articles, of which 12 were eligible for full-text review. Two additional references were identified through a reference search of retrieved articles. Only 1 of the 14 selected references that met the inclusion criteria documented reliability as outcome and was included in the final analysis. This pilot study by Lambrecht et al measured the PBP at the level of the fingertips and reported ICC values varying from 0.82–0.91 for the dorsal and 0.74–0.86 for the volar fingertips.

**Conclusions:** The body of knowledge regarding intra- and inter-rater reliability of LASCA in SSc is very limited. Only one manuscript reporting very good inter-rater reliability of PBP measurements of the distal fingertips by LASCA could be withheld. These results could be confirmed by our pilot study. In addition, we demonstrated excellent intra-rater reliability of LASCA measurements for the evaluation of the PBP of the hands in SSc patients and HS.

**SAT0480 EVALUATION OF STANDARDISED TEACHING OF MODIFIED RODNAN SKIN SCORE ASSESSMENT IN SYSTEMIC SCLEROSIS**

A.H. Low<sup>1,2</sup>, S.-A. Ng<sup>1,2</sup>, V. Berrocal<sup>3</sup>, B. Brennan<sup>3</sup>, G. Chan<sup>4</sup>, S.-C. Ng<sup>1,2</sup>, D. Khanna<sup>5</sup>. <sup>1</sup>Rheumatology and Immunology, Singapore General Hospital; <sup>2</sup>Duke-National University of Singapore, Singapore, Singapore; <sup>3</sup>Biostatistics, University of Michigan, Michigan, USA; <sup>4</sup>Rheumatology, Allergy and Immunology, Tan Tock Seng Hospital, Singapore, Singapore; <sup>5</sup>Scleroderma Program, University of Michigan, Michigan, USA

**Background:** The modified Rodnan skin score (mRSS) is a standard outcome measure for skin involvement in systemic sclerosis (SSc) clinical trials. Training assessors reduces variability in mRSS measurement.

**Objectives:** Our objective is to report the inter- and intra-observer variability of mRSS scoring using newly developed standardised training guidelines by the Scleroderma Clinical Trials Consortium (SCTC).

**Methods:** Two SSc experts (DK/AL), 2 facilitators, 52 rheumatology trainees and 8 SSc patients fulfilling the 2013 American College of Rheumatology criteria participated in a SSc skin scoring workshop. Eight SSc patients were examined by 2 SSc experts and facilitators together and consensus scores reached. All trainees attended a talk on mRSS skin scoring by an SSc expert (DK), followed by a video and live demonstration by an expert examining a patient exhibiting different aspects of skin scoring. Each trainee subsequently performed mRSS scoring on 4 SSc patients independently. This concluded the teaching session for mRSS scoring. The mRSS scoring for each trainee was compared to the consensus expert mRSS, and a score of ≤5 in 3 out of 4 patients is considered acceptable inter-observer variability, as determined by SCTC guidelines.

Two days after training, 12 trainees, 2 facilitators and 2 experts re-assessed independently the mRSS of 2 SSc patients whom they had examined previously. The repeat day 2 mRSS score for each trainee was compared to the baseline mRSS score, and a score of ≤3 is considered acceptable intra-observer variability.

We computed the inter- and intra-observer variability using a linear mixed model with an intercept term and random effects for patient, rater and patient by rater with the following values representing the degrees of agreement: <0 –poor; 0–0.20 –slight; 0.21–0.40 –fair; 0.41–0.60 –moderate; 0.61–0.80 –substantial; and 0.81–1.00 –almost perfect agreement.

**Results:** For the first group of assessors involving 52 trainees, 65.4% of them achieved acceptable inter-observer variability, with inter-observer variability of

activity and depression. Full names of questionnaires are listed in the table 1. Data are presented as mean  $\pm$  SEM.

**Results:** Compared to HC, patients with SSc had significantly higher prevalence and greater severity of sexual dysfunction (FSFI, BISF-W: in all subscales as well as total scores), dysfunction of pelvic floor (PISQ-12, PFIQ7), and worse sexual quality of life (SQoL-F) (table 1). Worse scores in SSc patients were associated with higher disease activity [ESSG activity index: SQoL-F ( $r=-0.364, p=0.0443$ ), PFIQ7-gynaecological subscale ( $r=0.492, p=0.0036$ )], greater fatigue [all three questionnaires FSS/FIS/MAF correlated negatively with FSFI, BISF-W], more severe depression [BDI-II: FSFI ( $r=-0.553, p=0.0002$ ), BISF-W ( $r=-0.514, p=0.0007$ ), PFIQ7 ( $r=0.495, p=0.0010$ )], deteriorated quality of life [SHAQ: FSFI ( $r=-0.536, p=0.0003$ ), BISF-W ( $r=-0.563, p=0.0001$ ), SQoL-F ( $r=-0.338, p=0.0382$ ), PISQ-12 ( $r=0.563, p=0.0051$ ), PFIQ7 ( $r=0.380, p=0.0142$ )], and worse ability to perform physical activities [HAP: FSFI ( $r=0.407, p=0.0082$ ), BISF-W ( $r=0.409, p=0.0078$ )].

Questionnaire: score range	Systemic sclerosis (n=41)	Healthy controls (n=41)	p-value
FSFI: Female Sexual Function Index: 2(worst)–36(best)	15.2 $\pm$ 1.7	25.0 $\pm$ 1.7	$p<0.0001$
BISF-W: Brief Index of Sexual Function for Women: –16(worst)–75(best)	17.5 $\pm$ 2.8	29.7 $\pm$ 2.8	$p=0.0027$
PISQ-12: Pelvic Organ Prolapse/Urinary Incontinence Sexual Questionnaire short form: 0(best)–48(worst)	13.9 $\pm$ 0.9	8.5 $\pm$ 0.7	$p<0.0001$
PFIQ7: Pelvic Floor Distress Inventory Questionnaire – short form 7: 0(best)–300(worst)	26.4 $\pm$ 5.9	7.1 $\pm$ 2.2	$p=0.0092$
SQoL-F: Sexual Quality of Life Questionnaire – Female: 0(worst)–100(best)	56.7 $\pm$ 3.9	78.8 $\pm$ 3.3	$p<0.0001$
FSS: Fatigue Severity Scale: 9(best)–63(worst)	40.7 $\pm$ 2.2	6.9 $\pm$ 1.0	$p<0.0001$
FIS: Fatigue Impact Scale: 0(best)–160(worst)	59.2 $\pm$ 4.9	28.8 $\pm$ 4.3	$p<0.0001$
MAF: Multidimensional Assessment of Fatigue Scale: 1(best)–50(worst)	26.0 $\pm$ 1.6	13.6 $\pm$ 1.3	$p<0.0001$
BDI-II: Beck's Depression Inventory II: 0(best)–63(worst)	14.2 $\pm$ 1.3	4.8 $\pm$ 0.8	$p<0.0001$
HAP: Human Activity Profile–adjusted activity score: 0(worst)–94(best)	49.4 $\pm$ 3.7	81.1 $\pm$ 1.5	$p<0.0001$
HAQ: Health Assessment Questionnaire: 0(best)–3(worst)	0.9 $\pm$ 0.1	0.1 $\pm$ 0.0	$p<0.0001$

**Conclusions:** Women with SSc reported significantly impaired sexual function, sexual quality of life and pelvic floor function than age-matched healthy controls. Worse scores in SSc were associated with disease activity, physical activity, fatigue, depression and quality of life.

#### SAT0484 PERFORMANCE OF THE 2017 EULAR/ACR CLASSIFICATION CRITERIA FOR INFLAMMATORY MYOSITIS AND THEIR MAJOR SUBGROUPS IN THE REMICAM (REGISTRY OF INFLAMMATORY MYOPATHIES IN THE MADRID COMMUNITY)

E. Rabadán<sup>1</sup>, B.E. Joven<sup>1</sup>, F. Lozano<sup>1</sup>, L. Nuño<sup>2</sup>, F.J. López-Longo<sup>3</sup>, J. Martínez-Barrios<sup>3</sup>, C. Larena<sup>4</sup>, M. Blazquez<sup>4</sup>, C. Barbadillo<sup>5</sup>, I. Llorente<sup>6</sup>, A. Pérez<sup>7</sup>, T. Cobo<sup>8</sup>, R. Almodovar<sup>9</sup>, L. Lojo<sup>10</sup>, R. Calvo<sup>1</sup>, M.J. García de Yébenes<sup>11</sup>, P. E. Carreira<sup>1</sup> on behalf of REMICAM group. <sup>1</sup>H 12 Octubre; <sup>2</sup>H La Paz; <sup>3</sup>H Gregorio Marañón; <sup>4</sup>H Ramón y Cajal; <sup>5</sup>H Puerta de Hierro; <sup>6</sup>H La Princesa; <sup>7</sup>H Príncipe de Asturias; <sup>8</sup>H Infanta Sofía; <sup>9</sup>H Fundación Alcorcón; <sup>10</sup>H Infanta Leonor; <sup>11</sup>Instituto musculoesquelético, Madrid, Spain

**Background:** A collaborative EULAR/ACR Project has developed new criteria for inflammatory myopathies(IM) and their subgroups<sup>1</sup>

**Objectives:** To analyse agreement between the 2017 IM classification criteria and the Bohan and Peter(BP) criteria in REMICAM cohort<sup>2</sup>

**Methods:** All patients were included. New criteria were applied to obtain classification as: possible(Pos), probable(Pro) and definitive(Def) IM, and subclassification in 6 subgroups: polymyositis(PM), dermatomyositis(DM), juvenile DM(JDM), amiodopathic DM(ADM), inclusion body myositis(IBM) and juvenile myositis(JM). The 7 subgroups in REMICAM were harmonised to fit the 6 subgroups of the 2017 criteria. Agreement between 2017 and BP criteria was analysed in classification/subclassification, calculating the weighted kappa value (k). Subanalysis including only patients with available data on the muscle strength items required for the 2017 criteria, and in those having also muscle biopsy data, were conducted.

**Results:** From 479 REMICAM patients, 477 (99.6%), fulfilled BP criteria (5.9% Pos, 26.8%Pro, 67.4%Def) and 431 (89.9%) 2017 criteria (2.5%Pos, 21.8%Pro, 65.7Def). Global agreement between both criteria was 89.5%. Agreement

between subtypes (Pos, Pro, Def) was low ( $k=0.15$ ). When 399 patients with muscle strength data, and 243 with muscle biopsy data were analysed, results were similar ( $k=0.17$ ). Disagreement was mainly seen in Pos/Pro subtypes with BP criteria, since 60% classified as Def when the 2017 criteria were applied. Agreement in the different subgroups of IM (PM, DM, JDM, ADM, IBM, JM) between both criteria was very high ( $k=0.94$ ).

**Conclusions:** The new 2017 EULAR/ACR criteria for IM classification show good agreement with BP criteria in the REMICAM cohort. New criteria classify 60% of Pos/Pro patients by BP criteria, as Def, and show very high agreement between IM subgroups. Validation studies are needed, but our results in this large cohort suggest the 2017 criteria might be useful for clinical trials and research in IM.

#### SAT0485 WHAT IS THE EFFECT OF CYCLOPHOSPHAMIDE IV PULSE THERAPY IN PATIENTS WITH DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS ON SKIN INVOLVEMENT: AN OBSERVATIONAL STUDY

B. Kersten, N. den Broeder, F. van den Hoogen, E. van den Ende, M. Vonk. *Rheumatology, Radboud University Medical Center, Nijmegen, Netherlands*

**Background:** Patients with systemic sclerosis who have proximal skin involvement are classified as diffuse cutaneous systemic sclerosis (DcSSc). Patients with progressive skin involvement have worse prognosis due to internal organ involvement. Treatment options of these patients consist among others of cyclophosphamide iv pulse therapy (iv CYC).<sup>1</sup> Recent studies show significant improvement of skin thickening in patients treated with CYC orally,<sup>2</sup> but the effect of iv CYC on skin involvement remains unclear.

**Objectives:** To examine the extent of skin involvement during 12 monthly iv CYC (750 mg/m<sup>2</sup>) in DcSSc and to identify factors that predict response to therapy.

**Methods:** Patients with DcSSc receiving iv CYC between 2004 and 2016 were included if they received at least 6 pulses. Skin involvement was assessed with the modified Rodnan Skinscore (mRSS) at baseline, month 6, 12, 24 and 36 by the same trained rheumatologist as part of routine care. Data of patients with the baseline measurement and at least one follow up measurement were included in the study. Missing mRSS data were imputed using multiple imputation by chained equation. Patients were classified as responders if the mRSS decreased at least 5 points and 25% from baseline at month 12. A prediction model for response at 12 months was created using backwards logistic regression considering baseline variables and response at 6 months as possible predictors.

**Results:** A total of 99 patients were included. The mean improvement of mRSS over time was  $-4.05$  (95% CI  $-5.53$  to  $-2.55$ ) (figure 1). 43% of patients had a response according to the response criteria.

**Abstract SAT0485 – Table 1.** Demographic and clinical characteristics of responders and non-responders

	Responders at 12 months (n=40)	Non-responders at 12 months (n=51)
Age, mean (sd)	52 (14)	54 (13)
Female gender, n (%)	19 (48%)	19 (37%)
Baseline mRSS, median (IQR)	13 (9–21)	19 (15–24)
Disease duration (months), median (IQR)	3 (1–12)	6 (2–18)
infusions completed, n (%)	37 (93%)	37 (73%)
12	3 (8%)	14 (27%)
$\geq 6$ and $<12$		
Antibodies	12 (30%)	19 (37%)
-ANA	24 (60%)	29 (57%)
-Anti-topoisomerase		
Response at 6 months	17 (46%)	1 (2%)

In univariate prediction models, baseline mRSS (OR 1.06,  $p=0.024$ ), response at 6 months (OR: 37.45,  $p<0.001$ ) and completed treatment (yes/no) (OR: 4.108,  $p=0.033$ ), were significant predictors of response at 12 months. For the last variable it should be mentioned that some patients who did not achieve a response at month 6 did not continue iv CYC for that reason.

Abstract SAT0485 – Figure 1. mRSS course of all patients during iv CYC

**Conclusions:** This study shows that only 43% of the treated DcSSc patients experienced clinical important improvement of skin involvement following iv CYC. Response at month 6 is the best predictor for response on month 12. This could imply that at this time point, counselling about other available treatment options, should be considered in those patients.

#### SAT0486 MYELOABLATION FOLLOWED BY AUTOLOGOUS STEM CELL RESCUE LEADS TO NORMALISATION OF SERUM IL-6 LEVELS IN PATIENTS WITH SYSTEMIC SCLEROSIS

C. Bellocchi<sup>1,2</sup>, K. Sullivan<sup>3</sup>, E. Goldmuntz<sup>4</sup>, J. Ying<sup>1</sup>, L. Keyes-Elstein<sup>5</sup>, J. Varga<sup>6</sup>, M.E. Hinchcliff<sup>6</sup>, P. McSweeney<sup>7</sup>, D.E. Furst<sup>8</sup>, R. Nash<sup>7</sup>, L.J. Crofford<sup>9</sup>, B. Welch<sup>4</sup>, A. Pinckney<sup>5</sup>, M.D. Mayes<sup>1</sup>, S. Assassi<sup>1</sup>. <sup>1</sup>University of Texas Health Science Center at Houston, Houston, TX, USA; <sup>2</sup>Scleroderma Unit, Referral Center for Systemic Autoimmune Diseases, Fondazione IRCCS Ca' Granda Ospedale Maggiore Policlinico di Milano, Milan, Italy; <sup>3</sup>Duke University, Durham, NC; <sup>4</sup>National Institute of Allergy and Infectious Diseases, Bethesda, MD; <sup>5</sup>Rho Federal Systems Division, Chapel Hill, NC; <sup>6</sup>Northwestern University, Chicago, IL; <sup>7</sup>Colorado Blood Cancer Institute, Denver, CO; <sup>8</sup>University of California Los Angeles, Los Angeles, CA; <sup>9</sup>Vanderbilt University, Nashville, TN, USA

**Background:** In the randomised Scleroderma: Cyclophosphamide or Transplantation (SCOT) trial, myeloablation followed by autologous hematopoietic stem cell transplantation (HSCT) led to improved clinical outcomes compared to monthly cyclophosphamide (CYC) treatment in systemic sclerosis (SSc).<sup>1</sup> Moreover, there is emerging evidence on the role of the Th2 cytokine, interleukin 6 (IL-6) in SSc pathogenesis, and clinical trials targeting the IL-6 pathway have been completed.<sup>2</sup>

**Objectives:** To investigate the association of IL-6 with baseline clinical features and to examine its longitudinal changes in the treatment arms of the SCOT trials.

**Methods:** The SCOT trial enrolled 75 subjects with diffuse SSc, 65 (HSCT=31, CYC=34) subjects with a mean disease duration of 2.2 years were analysed; 65 age and gender matched controls were also investigated. All available serum samples at the baseline (n=65), 8- (n=55) and 26- (n=45) month visits were included. IL-6 was determined using ultra-sensitive Simoa assay. For purposes of comparison, prominent, pro-inflammatory Th1 cytokines, Interleukin 1 $\beta$  (IL-1 $\beta$ ), interleukin 12 (IL-12), and interferon gamma (IFN- $\gamma$ ) were determined by Rule

Based Medicine multiplex assays. The serum IFN- $\gamma$  levels were in undetectable range in the majority of patient and control samples. Therefore, the comparative analysis focused on IL-1 $\beta$  and IL-12.

**Results:** Serum IL-6 was higher in SSC patients than controls (fold change=1.62,  $p<0.001$ ). At the baseline visit, IL-6 positively correlated with hsCRP ( $r_s=0.56$ ,  $p<0.001$ ) and modified Rodnan Skin Score ( $r_s=0.26$ ,  $p=0.037$ ) and showed an inverse relationship with disease duration ( $r_s=-0.26$ ,  $p=0.037$ ), while it did not have a significant correlation with forced vital capacity ( $r_s=-0.19$ ,  $p=0.126$ ). Moreover, no significant correlations were observed with IL-1 $\beta$  and IL-12.

A comparison of regression lines revealed a significant decrease in serum IL-6 levels in the HSCT arm relative to CYC ( $p=0.0004$ ). By 26 months, the HSCT arm no longer showed upregulation of serum IL-6 relative to controls while the CYC arm remained upregulated. In contrast, time trends for IL-1 $\beta$  and IL-12 did not differ significantly between arms ( $p$ -values=0.161 and 0.456, respectively). (figure 1).

**Conclusions:** The Serum IL-6 levels decreased significantly 26 months after HSCT, while the two Th1, proinflammatory cytokines did not show similar

changes. This finding supports the notion that this treatment modality normalises specific serum protein imbalances implicated in SSc pathogenesis.

SAT0487

#### A COHORT STUDY OF MACROVASCULAR INVOLVEMENT IN PATIENTS WITH SYSTEMIC SCLEROSIS

C. Caimmi<sup>1</sup>, S. De Marchi<sup>2</sup>, G. Astorino<sup>1</sup>, E. Bertoldo<sup>1</sup>, P. Caramaschi<sup>1</sup>, M. Rossini<sup>1</sup>. <sup>1</sup>Rheumatology Unit, <sup>2</sup>Angiology Unit, University of Verona, Verona, Italy

**Background:** It is well known that systemic sclerosis (SSc) affects microvessels, but data on macrovascular involvement are still lacking or debatable.

**Objectives:** Aim of this study was to estimate the prevalence of atherosclerotic plaques and their possible determinants in a large cohort of SSc patients.

**Methods:** One-hundred and four outpatients with SSc were enrolled. Data about disease characteristics and cardiovascular risk factors (diabetes, hypertension, dyslipidemia, smoke) were collected and patients underwent a full ecocolor Doppler ultrasonography of arteries of the neck and lower limbs (LL).

**Results:** Mean age of our cohort was 62±13 years and 17 (16.3%) patients were male. Seventy patients (67.3%) had a limited subset and the mean disease duration was 12.7±6.8 years. A previous history of digital ulcers was found in 27 cases (26.0%). Thirty-eight patients (36.5%) were on ongoing or previous treatment with immunosuppressive drugs.

Regarding cardiovascular risk factors, 22 (21.2%) had hypertension, 7 (6.7%) diabetes, 52 (50%) dyslipidemia and 45 (43.3%) were active or past smokers. Fifty-seven (54.2%) patients had plaques at carotids, 1 (1%) at LL and 37 (35.9%) at UL. Prevalences were higher in older patients, as expected.

Patients with carotid plaques were older ( $p<0.001$ ), with hypertension ( $p=0.057$ ), a limited disease subset ( $p=0.005$ ), a more severe disease according to Medsger severity score (0.048), worse renal function ( $p=0.012$ ), higher glucose blood levels ( $p<0.001$ ), homocysteinemia ( $p=0.006$ ) and ESR ( $p=0.004$ ) and less often on immunosuppressors ( $p=0.048$ ) but more often on steroids ( $p=0.050$ ). Patients with LL plaques were older ( $p<0.001$ ), male ( $p=0.003$ ), treated with statins ( $p=0.056$ ), with a worse renal function ( $p=0.001$ ), higher glucose blood levels ( $p=0.038$ ) and homocysteinemia ( $p=0.006$ ).

In multivariate analysis with all variables with a  $p<0.010$  in univariate, patients with carotid plaques were found to be older ( $p=0.003$ ) and with a limited disease subset ( $p=0.012$ ; OR 5.6, CI95% 1.5 to 21.5). These data were confirmed even after correcting also for other well-known risk factors for atherosclerosis. No variables were found to be statistically different between patients with and without LL plaques.

**Conclusions:** in this study we performed one of the most complete evaluation of macrovascular involvement in one of the most numerous cohort of SSc patients present in literature. The prevalence of carotid and LL plaques did not seem to be higher in SSc patients as compared to what reported in healthy subjects. Intriguing is that patients with limited disease have an increased risk of having carotid plaques even after correcting for possible confounders.

SAT0488

#### ORGAN INVOLVEMENT AND ILD PROGRESSION IN SCLERODERMA PATIENTS WITH ANTI-TOPOISOMERASE I SPECIFICITY AND LIMITED CUTANEOUS FORM

E. Zanatta, P. Polito, F. Ometto, M. Felicetti, M. Tonello, A. Scanu, L. Punzi, F. Cozzi. *Rheumatology Unit, Department of Medicine – DIMED, Padova University, Padova, Italy*

**Background:** The great variability of clinical manifestations in systemic sclerosis (SSc) yields the need of defining prevalence and progression of organ

involvement in the different subsets of the disease. Despite the classical association between anti-topoisomerase-I (SCI70) positivity with diffuse cutaneous SSc (dSSc), and anti-centromere (ACA) with limited cutaneous SSc (lSSc), a population of patients with anti-SCI70 and lSSc has been described.<sup>1</sup> Interstitial lung disease (ILD) is nowadays the leading cause of mortality in SSc; its progression can range from a self-limiting form to a rapidly progressive lung involvement, despite immunosuppressive treatment.

**Objectives:** The aim of our study was to evaluate the prevalence of different organ involvement in three groups of patients: ACA-lSSc, SCI70-dSSc e SCI70-lSSc. Our second endpoint was to investigate possible differences in ILD onset and progression between SCI70-lSSc and SCI70-dSSc patients.

**Methods:** Consecutive 260 patients attending the Rheumatology Unit of Padova University of Padova were included and retrospectively evaluated. Clinical, biochemical and functional parameters concerning pulmonary, cardiac and articular involvement were collected in all patients, with an average follow-up time of 15 years. As for lung involvement, spirometric indices (FVC e DLCO) and HRCT at ILD onset and at last follow up were considered (median ILD duration 8 years<sup>4,12</sup>). Time between SSc onset and ILD first evidence was defined as "scleroderma free ILD". ILD grading was determined according to Kazerooni score. ILD progression was defined as either an HRCT score worsening of at least 2 points, or as a significant progression of spirometric indices (10% and 15% for FVC and DLCO respectively).<sup>2</sup>

**Results:** 150 patients with ACA-lSSc, 58 with SCI70-dSSc and 52 with SCI70-lSSc were included in the study. SCI70-lSSc patients presented more often with pulmonary and articular involvement with respect to ACA-lSSc patients (50% vs 6.9% and 42.9% vs 23.6% respectively), and less often compared to SCI70-dSSc. In SCI70-lSSc, cardiac and gastrointestinal involvement, BEV and digital ulcers were less prevalent with respect to SCI70-dSSc ( $p<0.05$ ). SCI70-lSSc patient had a longer "scleroderma free-ILD" compared to SCI70-dSSc. At ILD onset pulmonary function was worse in SCI70-dSSc group than in SCI70-lSSc group ( $p=0.02$  e  $p=0.009$  for FVC e DLCO respectively), even in the absence of a significant difference between HRCT scores (12.73±5.25 vs 10.25±4.93,  $p=0.284$ ). Total ILD progression was significantly higher in SCI70-dSSc ( $p<0.0001$ ).

**Conclusions:** Our study shows that SCI70-lSSc patients appeared to have a different prevalence of targeted organ involvement and ILD progression with respect to both SCI70-dSSc and ACA-lSSc. Since the correct classification of SSc patients is extremely important in view of a tailored treatment, our data suggest that it could be worth to identify patients with SCI70 and limited cutaneous form as a different and specific subset.

#### ASSESSMENT OF PERSISTENT ORGAN DAMAGE ACCORDING TO IMACS (INTERNATIONAL MYOSITIS ASSESSMENT AND CLINICAL STUDIES) MYOSITIS DAMAGE INDEX IN 92 PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOSITIS

E. Oguz<sup>1</sup>, E. Sahin<sup>2</sup>, M. Erdugan<sup>1</sup>, B.A. Esen<sup>1</sup>, A. Gul<sup>1</sup>, L. Ocal<sup>1</sup>, M. Inanc<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology; <sup>2</sup>Department of Internal Medicine, Istanbul Faculty of Medicine, Istanbul University, Istanbul, Turkey

**Background:** Number of work regarding long term organ damage caused by idiopathic inflammatory myopathies (IIM) and risk factors associated with organ damage have been understudied and never reported from Turkey; recently a new tool as developed for that purpose.

**Objectives:** In this study we aimed to evaluate by long term organ damage and risk factors, associated with these prospectively in IIM patients.

**Methods:** IIM patients (n=110) who has been followed up for at least six month by our clinic and fulfilling Bohan and Peter criteria were recruited. Demographic data, clinical and serological features, treatment and final clinical tatus was recorded. IMACS Myositis Damage Index (MDI) was determined twice in 92 patients (71% female) at the time of diagnosis from the records and at the at last clinical visit prospectively.

**Results:** Mean age of the 92 patients during the diagnosis was 46±14.7. Out of 92 patients 69% had dermatomyositis, 23% had polymyositis, 8% had necrotizing

autoimmune myopathy and inclusion body myositis. Mean follow up was 82 months. Frequencies of dysphagia, respiratory muscle involvement and interstitial lung disease were 29.5;34% respectively. Twenty-one percent of the patients had associated malignancy. The mean daily prednisolone dosage and total amount was 7.5 mg/day and 9000 mgs. Mortality was 13%. Initial mean MDI at the time of diagnosis was 1.6±3.0 (range, 0–14) and the last DMI score recorded was 6.1±4.7 (range, 0–21). After the last assessment the proportion of patients without damage was 8% and whose score was 4 were 37%. The last DMI score was significantly higher than the first DMI score ( $p<0.001$ ). The last DMI in females and patients with calcinosis were significantly high ( $p=0.002$ ;  $p=0.007$ ). The last DMI score and disease duration were weakly correlated ( $r=0.35$   $p=0.001$ ). A moderately significant correlation was found between the last DMI score, the duration of glucocorticoid use and the total dose used ( $r=0.48$   $p<0.001$ ;  $r=0.45$   $p<0.001$ ).

**Conclusions:** Our long term follow up data showed that persistent organ damage assessed by DMI and mortality were high in patients with IIM and over half of patients developed severe damage. Organ damage was detected in some patients at presentation and DMI scores were significantly increased during the follow up. DMI scores were found high in females and in patients with calcinosis. There were significant correlation between disease duration, the duration of glucocorticoid use, the total dose used and DMI scores. Current treatments and strategies have been insufficient at improving the prognosis of patients with IIM and new treatment strategies and drugs are needed.

#### SAT0490 INCIDENCE AND PREVALENCE OF SYSTEMIC SCLEROSIS IN AN ITALIAN ALPINE VALLEY DURING A 18-YEAR LONG PERIOD

F. Dall'ara<sup>1</sup>, A. Premoli<sup>1</sup>, S. Zingarelli<sup>2</sup>, M.G. Lazzaroni<sup>1</sup>, A. Tincani<sup>1</sup>, M.G. Fenini<sup>3</sup>, F. Inverardi<sup>4</sup>, R. Furloni<sup>4</sup>, M. Scarsi<sup>4</sup>, P. Airò<sup>2</sup>. <sup>1</sup>Rheumatology and Clinical Immunology, Department of Clinical and Experimental Sciences, Spedali Civili and University of Brescia; <sup>2</sup>Rheumatology and Clinical Immunology, Spedali Civili of Brescia, Brescia; <sup>3</sup>Clinical Pathology Laboratory; <sup>4</sup>Rheumatology, Internal Medicine Department, ASST Valcamonica, Ospedale di Esine, Esine, Italy

**Background:** Not much information is available on the variations in the incidence and prevalence of Systemic Sclerosis (SSc) over time.

**Objectives:** To investigate the epidemiology of SSc in Valcamonica, an Alpine valley in northern Italy (Brescia Province, Lombardy region), during a 18-year-long period.

**Methods:** All patients with diagnosis of SSc living in Valcamonica between 1999 and 2016 were identified by capture/recapture method using: 1) clinical databases of the only secondary Rheumatology Unit present in the valley (Esine Hospital), and of the only tertiary referral centre for this area (Spedali Civili, Brescia); 2) administrative data (ASST Valcamonica, Esine), extracting all records with the ICD-10 code for SSc (710.1). Clinical charts were reviewed and patients included in the analysis when either the 1980 ARA or the 2013 ACR/EULAR classification criteria for SSc were satisfied. Incidence was calculated using the number of new cases observed as the numerator, and the Valcamonica population as the denominator for each year; to study temporal changes, mean yearly incidence during 3 different 6 year intervals was calculated (table 1). Prevalence rates were estimated at 4 different time points dividing the number of living patients by the number of individuals in the population (table 2). Survival, incidence and prevalence rates were expressed with 95% confidence intervals. Incidence and prevalence rates observed in different periods were compared using ANOVA test. Demographic data were expressed as the medians (IQR).

**Results:** General population with age over 14 years living in Valcamonica varied during the evaluated period between 85 168 (1999) and 91 245 inhabitants (2011). Fifty-six patients with SSc fulfilling the 2013 ACR/EULAR criteria, and in 68% of them also the 1980 ARA criteria were identified (Female 85.7%, Male:

14.3%; Caucasian: 96.4%, African 3.6%; age at diagnosis: 58;<sup>47–80</sup> deaths: 13 (8 because of SSc); survival: at 5 years: 89.4% (76.2–95.5), at 10 years: 84.4% (69.9–92.3); diffuse SSc: 17.9%, limited SSc: 82.1%; anticentromere: 62.3%, anti-topoisomerase I (topo I): 20.8%, anti-RNA polymerase III (RNAP3): 5.4%; anti-topo I and RNAP3: 1.9%; Anti-Th/To: 1.9%; interstitial lung disease: 23.1%; group 1 pulmonary arterial hypertension 19.6%; renal crisis 5.4%). No significant variation of incidence was observed during the period of time evaluated in the study (table 1). Analysis of prevalence revealed a continuous increase of the disease using both the 1980 ARA criteria or 2013 ACR/EULAR criteria ( $p<0.001$  for both comparisons; table 2). The prevalence on 2016 was 50.9 per 1 00 000 persons aged >14 years, one of the highest ever recorded by SSc epidemiology studies. However, notably, the prevalence in Valcamonica during the first years of the 21 st century was similar to that reported by previous other studies performed in Italy in the same years.<sup>1–2</sup>

**Abstract SAT0490 – Table 1.** Incidence of SSc in Valcamonica expressed as cases per 100,000 adults aged over 14-years

SEX	STUDY PERIOD	MEAN POPULATION >14 YEARS	NEW CASES	INCIDENCE (CI 95%)
MALE AND FEMALE	1999-2004	86,205.5	12	2.3 (1.2-4.1)
	2005-2010	89,448.5	14	2.6 (1.4-4.4)
	2011-2016	90,843	16	2.9 (1.7-4.8)

**Abstract SAT0490 – Table 2.** Estimates of the prevalence of SSc in Valcamonica expressed as cases per 100,000 adults aged over 14-years

SEX	YEAR	POPULATION >14 YEARS	LIVING CASES	PREVALENCE (CI 95%)
MALE AND FEMALE	1999	85168	14	16.4 (9-27.6)
	2005	88011	26	29.5 (19.3-43.3)
	2011	91245	37	40.6 (28.6-55.9)
	2016	90441	46	50.9 (37.2-67.8)
FEMALE	1999	43755	13	29.7 (15.8-50.8)
	2005	44751	22	49.2 (30.8-74.4)
	2011	46149	31	67.2 (45.7-95.3)
	2016	45868	42	91.6 (66-123.8)
MALE	1999	41413	1	2.4 (0-13.5)
	2005	43260	4	9.3 (2.5-23.7)
	2011	45096	6	13.3 (4.9-29)
	2016	44573	4	9 (2.5-23)

**Conclusions:** Although the incidence of SSc did not change significantly over time in this area, the disease prevalence constantly increased, with recruitment of new cases exceeding the number of deaths.

**Background:** Anti-MDA5 antibodies are a known set of antibodies observed mainly in dermatomyositis, typically associated with cutaneous involvement, presence and often rapid progression (RP) of interstitial lung disease (ILD) and amyopathic muscle involvement. Despite the increased attention, described cohorts involves only a limited number of cases

**Objectives:** to define clinical characteristics of a large cohort of anti-MDA5 antibodies positive patients

**Methods:** Retrospective assessment of anti-MDA5 positive patients from centres referring to our group

**Results:** 82 anti-MDA5 positive cases (56 females) were collected. In median: onset age was 44 Y (IQR 22.57), diagnostic delay 4 Mo (IQR 1–10), follow-up 13 Mo (IQR 3–43). Fifty-three patients had ILD, that was RP in 24 cases (15 at ILD onset, 9 after ILD onset). Fifteen ILD patients were admitted in Intensive Care Unit (ICU): 4 were treated with Extracorporeal-Membrane-Oxygenation, 7 with mechanical-invasive and 2 with mechanical-non-invasive ventilation. Forty-nine patients had muscle involvement (39 symptomatic), 42 arthritis, 54 cutaneous involvement, 9 history of malignancy. Twelve patients died (ILD=7, ILD and sepsis=3, neoplasia=1, not specified=1), 7 of those in ICU

**Conclusions:** In our cohort, ILD was the most frequent finding. A RP of ILD was common, occurring also in ILD with symptomatic/chronic onset. The low rate of survival in ICU raised the problem of follow up and early treatment of ILD. In our cohort arthritis was common and muscle involvement mainly symptomatic. Finally, the high percentage of observed malignancies suggests a careful neoplastic screening and follow up

SAT0492

### PREVALENCE OF THE METABOLIC SYNDROME IN PATIENTS WITH SYSTEMIC SCLEROSIS

G. Cuomo, F. Danzo, F. Masini, R. Ferrara, E. Pinotti, C. Romano, L.E. Adinolfi. *UOC Medicina Interna, Universita Degli Studi Della Campania, Napoli, Italy*

**Background:** The metabolic syndrome is an independent risk factor for ischaemic heart disease. Patients with systemic lupus erythematosus have an increased prevalence of the metabolic syndrome.<sup>1</sup> There are no controlled studies of the metabolic syndrome in patients with SSc.

**Objectives:** To compare the prevalence of the metabolic syndrome in patients with SSc and controls and to evaluate its relationship to activity and severity of disease.

**Methods:** Methods: 50 consecutive patients with SSc (45 female, median age 48; range 20–72) and 50 controls (patients with fibromyalgia) (45 female, median age 46; range 25–72) were studied. The prevalence of the metabolic syndrome was compared in patients and controls using the National Cholesterol Education Program Adult Treatment Panel III (NCEP-ATPIII): central obesity: waist: 102 cm in men and 88 cm in women;<sup>2</sup> hypertriglyceridaemia:>150 mg/dl;<sup>3</sup> low HDL, 40 mg/dl in men and 50 mg/dl in women;<sup>4</sup> high blood pressure:>130/85 mm Hg or use of drugs for high blood pressure; and<sup>5</sup> high fasting glucose >110 mg/dl, and associations with activity and severity of the disease were examined.

**Results:** The metabolic syndrome was present in 24% of patients and in 30% of controls subjects (p>0.05). Among patients with SSc, the metabolic syndrome was significantly associated with higher value of ESR (ESR >30) (5/7 vs 4/34; p=0.027). Neither disease activity nor severity scores were associated with the metabolic syndrome

**Conclusions:** Patients with SSc have a lower prevalence of the NCEP-ATPIII-defined metabolic syndrome than controls. This result may help to justify the coronary prevalence in SSc patients similar to that of the general population.<sup>2–3</sup>

### PLASMA LEVELS OF HSP90 ARE INCREASED IN INTERSTITIAL LUNG DISEASE AND SKIN FIBROSIS IN PATIENTS WITH SYSTEMIC SCLEROSIS

H. Storkanova<sup>1</sup>, S. Oreska<sup>1</sup>, M. Spiritovic<sup>1,2</sup>, B. Hermankova<sup>1,2</sup>, K. Pavelka<sup>1</sup>, J. Vencovsky<sup>1</sup>, J.H. Distler<sup>3</sup>, L. Senolt<sup>1</sup>, R. Becvar<sup>1</sup>, M. Tomcik<sup>1</sup>. <sup>1</sup>Department of Rheumatology, 1st Medical Faculty, Charles University, Institute of Rheumatology; <sup>2</sup>Department of Physiotherapy, Faculty of Physical Education and Sport, Charles University, Prague, Czech Republic; <sup>3</sup>Department of Internal Medicine III and Institute for Clinical Immunology, University of Erlangen-Nuremberg, Erlangen, Germany

**Background:** Our previous study demonstrated that Heat shock protein 90 (Hsp90) is overexpressed in the skin of patients with systemic sclerosis (SSc), in cultured SSc fibroblasts and preclinical models of SSc in a TGF- $\beta$  dependent manner. We showed that Hsp90 is a regulator of TGF- $\beta$  signalling and its inhibition prevents the stimulatory effects of TGF- $\beta$  on collagen synthesis and dermal fibrosis in three preclinical models of SSc<sup>1</sup>.

**Objectives:** The aim of this study was to evaluate Hsp90 in the circulation of SSc patients and characterise its potential association with skin changes and SSc-related features.

**Methods:** A total of 91 patients (78 females; mean age 52.7; disease duration 6.0 years; diffuse cutaneous (dc)SSc/limited cutaneous (lc)SSc=38/53) who met the ACR/EULAR 2013 classification criteria for SSc and 85 age-/sex- matched healthy individuals were included. Plasma Hsp90 was measured by ELISA (eBioscience, Vienna, Austria). Data are presented as median (IQR, 25.–75. percentile).

**Results:** Plasma Hsp90 levels were increased in SSc patients compared to healthy controls [12.5 (9.6–17.9) vs. 9.9 (7.9–12.6) ng/mL, p=0.001], but no difference between lcSSc and dcSSc was detected [13.1 (9.4–18.1) vs. 11.5 (9.5–17.5) ng/mL, p=0.316]. Hsp90 levels in all patients positively correlated with CRP

( $r=0.313$ ,  $p=0.006$ ). Furthermore, Hsp90 was increased in patients with interstitial lung disease (ILD) compared to those without ILD [12.8 (10.2–17.9) vs. 10.3 (8.6–16.6) ng/mL,  $p=0.045$ ] and was negatively associated with functional parameters of ILD: FVC ( $r=-0.299$ ,  $p=0.011$ ), FEV1 ( $r=-0.256$ ,  $p=0.031$ ), DLCO ( $r=-0.303$ ,  $p=0.009$ ) and SpO<sub>2</sub> ( $r=-0.317$ ,  $p=0.038$ ). In addition, only in patients with dcSSc, Hsp90 levels positively correlated with the mRSS ( $r=0.437$ ,  $p=0.006$ ). Hsp90 concentrations were not significantly affected by other main clinical parameters of SSc.

**Conclusions:** We demonstrated higher plasma levels of Hsp90 in SSc patients compared to healthy controls. Concentrations of extracellular Hsp90 increase with higher inflammatory activity, with deteriorated lung functions in ILD and also with the extent and severity of the skin involvement in patients with diffuse cutaneous SSc. These data further highlight the role of Hsp90 as a significant regulator of fibroblast activation and tissue fibrosis in SSc.

#### CLINICAL AND ELECTROPHYSIOLOGICAL DIAGNOSIS OF SYMMETRICAL POLYNEUROPATHY IN SYSTEMIC SCLEROSIS: STUDY FROM A SINGLE TERTIARY CENTRE IN MALAYSIA

T. Balaikerisnani<sup>1</sup>, K.J. Goh<sup>2</sup>, L.P. Ramanaidu<sup>2</sup>, J. Raja<sup>1</sup>. <sup>1</sup>Division of Rheumatology, Department and Faculty of Medicine; <sup>2</sup>Division of Neurology, Department and Faculty of Medicine, University of Malaya, Kuala Lumpur, Malaysia

**Background:** Peripheral neuropathy (PN) in systemic sclerosis (SSc) is an under recognised non-lethal burden with its prevalence between 0.01% to 28%<sup>1</sup>. Previous studies have been limited by small sample size, variable diagnostic criteria and different populations studied.

**Objectives:** The aim of this study is to determine the prevalence of symmetrical PN in SSc patients and to identify the associated factors that can predispose to PN in SSc.

**Methods:** 59 SSc patients from University Malaya Medical Centre participated in this cross-sectional study. Clinical symptoms/signs of PN were assessed using modified Total Neuropathy Score (TNS). Nerve conduction studies (NCS) were carried out on the upper and lower limbs. Diagnosis of symmetrical polyneuropathy was defined as combined TNS score  $\geq 2$  and abnormal NCS parameters in at least 2 nerves including the sural<sup>2</sup>. Focal neuropathy was defined as abnormal NCS of a nerve other than the sural nerve (radial, median, ulnar, common peroneal).

**Results:** Majority were females (54, 91.5%) and had limited cutaneous SSc (44, 74.6%). Mean age was 55.7 (SD  $\pm 13.1$ ) years while mean duration of disease (non-Raynaud's disease onset) was 8.74 years (SD  $\pm 8.09$ ) (range 1 to 44 years). Out of 59 patients, 38 (64.4%) had TNS  $\geq 2$ . On NCS, 17 (31.5%) and 12 (22.2%) had findings of symmetrical polyneuropathy and focal neuropathy respectively. A total of 14 (23.7%) SSc patients were diagnosed to have symmetrical polyneuropathy. Lower haemoglobin level was significantly associated with symmetrical polyneuropathy ( $p=0.047$ ) after adjustment for potential confounding variables. Serum vitamin B12 was normal in all subjects with symmetrical polyneuropathy. No correlation was seen in SSc related comorbidities (diabetes mellitus and kidney disease), serum fasting blood sugar, creatinine and MCV, as well as disease markers such as skin fibrosis (MRSS skin score), specific organ manifestations, Raynaud's or vasculopathy, SSc specific auto-antibodies and treatment received.

Demography	No polyneuropathy n=45 (76.3%)	Polyneuropathy n=14 (23.7%)	p value
Mean age (y.o $\pm$ )	53.6 $\pm$ 13.22	62.57 $\pm$ 10.69	<b>0.025</b>
Sex			0.325
Female	45 (76.3)	14 (23.7)	
Male	5 (100)	0 (0)	
BMI kg/m <sup>2</sup> (mean)	22.9 $\pm$ 5.94	21.0 $\pm$ 5.13	0.736
Diffuse SSc	10 (22.2)	4 (28.5)	0.722
Limited SSc	35 (77.7)	10 (71.4)	0.316
MRSS score (mean)	10.29 $\pm$ 8.02	8.36 $\pm$ 4.23	0.594
SSc duration (mean)	8.97 $\pm$ 8.78	8.00 $\pm$ 5.51	0.803
Haemoglobin (mean) (g/L)	12.36 $\pm$ 1.33	11.2 $\pm$ 1.25	<b>0.010</b>
MCV <sub>&gt;97</sub> (fl)	4 (8.9)	3 (21.4)	0.175
Creatinine (median) (umol/L)	55 $\pm$ (IQR 45–60)	61.5 $\pm$ (IQR 49–75)	0.111

Fasting blood sugar (mean) (mmol/L)	4.32 $\pm$ 1.16	5.67 $\pm$ 2.46	0.095
ESR (mean) (mm/hr)	33.7 $\pm$ 20.65	44.23 (19.6)	0.068

**Conclusions:** The prevalence of PN in a Malaysian SSc cohort is similar to other studies (23.7%). Lower haemoglobin level was significantly associated with symmetrical polyneuropathy in SSc.

SAT0495

#### PLASMA D-DIMER CONCENTRATION, MACROVASCULAR DISEASE AND MORTALITY IN PATIENTS WITH SYSTEMIC SCLEROSIS

J.J. Alegre-Sancho, M. Robustillo-Villarino, M. Aguilar-Zamora, L. Montolio-Chiva, E. Valls-Pascual, D. Ybáñez-García, Á. Martínez-Ferrer, I. Tomer-Hernández, V. Núñez-Monje, A.V. Orenes-Vera, A. Sendra-García. *Rheumatology, Hospital Universitario Doctor Peset, Valencia, Spain*

**Background:** Plasma d-dimer (DD) has proven to be a reliable marker of a systemic prothrombotic state and its measurement might be helpful in predicting cardiovascular events and even mortality across a broad variety of diseases. An association between high levels of DD and macrovascular disease, diffuse cutaneous involvement and active disease has been suggested in patients with SSc.

**Objectives:** To determine the usefulness of DD measurement as a marker of macrovascular disease and mortality in patients with SSc. To explore its relation with other features and biomarkers of SSc.

**Methods:** Descriptive ambispective observational study. We included, consecutively from 2010 to 2015, SSc patients controlled in a tertiary hospital. We gathered demographic, clinical, and analytical variables, including DD levels measured by turbidimetric immunoassay (ACL TOP 700 CTS, Werfen Spain). Other variables were collected retrospectively from the electronic medical record. We explored the extracranial branches of the carotid artery (ESAOTE MyLab XV70, 7–12 MHz linear probe, software <sup>RF</sup>QIMT) measuring intima media thickness (IMT) by radiofrequency, and the presence of atheroma plaques, as per the Mannheim consensus, was registered. The *ankle-brachial index (ABI)* was measured by a Vascular Surgeon. We considered an IMT > 900  $\mu$  and/or presence of atheroma plaque and/or an ABI < 0.9 as macrovascular damage. We prospectively collected mortality until dec-2017. Statistical analysis was performed using SPSS 17.0 software.

**Results:** 115 patients were included consecutively, of which finally 100 were studied (91 women, 9 men), with a mean age of 60.2 years (SD 15). Mean SSc evolution time was 13.9 years (SD 11.2). LSSc was most frequently diagnosed (50%), followed by DSSc (18%), SSc without scleroderma (17%), overlap syndrome (9%) and pre-SSc (6%). 37% of patients were hypertensive, 45% dyslipidemic, and 7% were diabetic. Overall, 40% had macrovascular damage. The mean values of DD were 437.6 ng/mL (SD 683.5), 60% of the patients having levels of DD (>250 ng/mL). During follow up, there were 16 deaths, 50% due to vascular events. Baseline high levels of plasma DD were associated to macrovascular damage and ischaemic digital ulcers, together with advanced age, arthritis, inflammation biomarkers, HTA, sPAP, lower DLCO% and coexistence of

an inflammatory disease (overlap, infection, neoplasia), and showed a tendency to an association with mortality. This association became statistically significant when considering DD plasma levels as a quantitative variable ( $p < 0.001$ ) and remained significant after adjustments (age, coexistence of an inflammatory disease) ( $p = 0.003$ ).

**Conclusions:** DD plasma levels are associated with macrovascular involvement and can be helpful in predicting medium-term mortality in our SSC patients. Levels of plasma DD can be modified by systemic inflammation.

#### SAT0496 INCIDENCE, CARDIOVASCULAR EVENTS AND MORTALITY OF ADULT INFLAMMATORY MYOPATHIES IN SOUTH KOREA: A NATIONWIDE POPULATION-BASED STUDY

K.H. Jung<sup>1</sup>, H.J. Kim<sup>2</sup>, W. Park<sup>1</sup>, S.R. Kwon<sup>1</sup>, H.S. Ahn<sup>2</sup>. <sup>1</sup>Rheumatology, INHA University, Incheon; <sup>2</sup>Preventive medicine, Korea University, Seoul, Korea, Republic Of

**Background:** The inflammatory myopathies (IMs), including dermatomyositis (DM) and polymyositis (PM), are rare autoimmune diseases characterised by progressive proximal muscle weakness, elevated muscle enzyme and various organ involvement. Studies on epidemiology and mortality of IMs at the national level are rare.

**Objectives:** We conducted a nationwide population study of incidence, cardiovascular events (especially acute myocardial infarction, ischaemic stroke, haemorrhagic stroke) and survival of IMs in South Korea over the course of 11 years.

**Methods:** We used data from the Rare Intractable Disease (RID) registry and Health Insurance Review and Assessment (HIRA) service, which include information on all IMs patients diagnosed based on uniform criteria between 2005 and 2015. Survival data from Statistics Korea linked to HIRA-RID database were used in our survival analysis.

**Results:** In this study, total incident cases between 2005 and 2015 were 3014 (1,860 DM patients, 1,154 PM patients) and the mean annual incidence rate was  $7.16/10^6/\text{year}$  (DM was  $4.42/10^6/\text{year}$ , PM was  $2.74/10^6/\text{year}$ ). The female to male ratio of DM was 2.2:1 and that of PM was 1.9:1. Cardiovascular events occurred in 155 patients during the study period. Of the patients with DM, 25 were diagnosed with AMI (SIR 1.3, 95% CI 0.9–1.9), 39 with ischaemic stroke (SIR 1.4, 95% CI 1.0–1.9), 18 with haemorrhagic stroke (SIR 1.3, 95% CI 0.8–2.0). The results of PM were similar with those of DM. Of 155 patients, 63 (40.6%) died and had a high mortality rate. 640 of 3014 patients with IMs died during the study period; 290 and 350 were male and female, respectively. The survival curve for IMs is shown in Fig.1. The DM patients showed a 5 year survival rate (YSR) of 76.8%, and a 10-YSR of 68.9%, and the PM patients showed a 5-YSR of 79.3% and a 10-YSR of 68.3%.

**Abstract SAT0496 – Figure 1.** Survival curves of dermatomyositis and polymyositis

**Conclusions:** This is the first study of incidence and mortality of IMs over 3000 cases by the national registry in South Korea. In this nationwide population-based study of IMs, we found still high mortality and low survival and increased cardiovascular events related mortality compared than general population.

#### SAT0497 FOLLOW-UP OF DISEASE ACTIVITY IN HUNGARIAN PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHY

L. Bodoki<sup>1</sup>, M. Nagy-Vincze<sup>2</sup>, Z. Griger<sup>2</sup>, Z. Szekanez<sup>1</sup>, K. Dankó<sup>2</sup>. <sup>1</sup>University Of Debrecen, Faculty Of Medicine, Department Of Internal Medicine, Department Of Rheumatology; <sup>2</sup>University Of Debrecen, Faculty Of Medicine, Department Of Internal Medicine, Department Of Clinical Immunology, Debrecen, Hungary

**Background:** Assessing disease activity in patients with myositis is an important goal. A method called Disease Activity Core Set Measures was established by International Myositis Assessment and Clinical Studies Group (IMACS) for evaluating activity of myositis. This assesses the manifestations of myositis which are thought to be reversible that result directly from the inflammatory process.

**Objectives:** In this prospective study authors aimed to monitoring disease activity in Hungarian myositis patients treated at the Autoimmune Outpatient Clinic, Department of Clinical Immunology, University of Debrecen. First, disease activity data of poly (PM) – and dermatomyositis (DM) patients were compared. Secondly, by patients with active disease, the correlations between the components of Disease Activity Core Set Measures were studied.

**Methods:** During the three-year follow-up period, at every single visit, authors evaluated disease activity using factors of Disease Activity Core Set Measures and patients filled Health Assessment Questionnaire (HAQ). Only those patients who appeared at least three times during the follow-up period were selected. Statistical analysis was made using SPSS 17.0 statistical software.

**Results:** Collection of data from 219 patients (age: 44.93 years, female: male ratio 2.98:1) happened in a total of 1101 outpatient visits. The 107 PM patients had statistically significant higher physician and patient visual analogue (VAS) and myositis disease activity assessment tools scores than the 61 DM patients, with the exception of cardiovascular disease activity. Activity of skin lesions was significant higher in DM patients. By the 44 patients, who had an active disease, the MMT scores gave significant negative correlations with HAQ scores ( $R = -0.536$  and  $p < 0.001$ ) and CK levels ( $R = -0.387$  and  $p < 0.001$ ). The physician and patient VAS gave strong negative correlations with MMT scores ( $R = -0.714$  and  $p < 0.001$  and  $R = -0.730$  and  $p < 0.001$ , respectively) and positive correlations with HAQ scores and CK levels (physician VAS vs. HAQ  $R = 0.691$  and  $p < 0.001$ ; patient VAS vs. HAQ  $R = 0.629$  and  $p < 0.001$ ; physician VAS vs. CK  $R = 0.622$  and  $p < 0.001$ ; patient VAS vs. CK  $R = 0.615$  and  $p < 0.001$ ).

**Conclusions:** As far as we know, this is the first study which compares the activities of PM and DM patients based on the IMACS system. According to our data, we can conclude that PM patients had more severe muscle symptoms and extra-muscular manifestations. Secondly, as seen in other previous studies, calculations in patients with active myositis showed a clear correlation between the most important components of Disease Activity Core Set Measures.

#### SAT0498 ABNORMAL ELECTROCARDIOGRAPHIC FINDINGS IN A SCANDINAVIAN COHORT OF PATIENTS WITH IDIOPATHIC INFLAMMATORY MYOPATHIES

S.S. Korsholm<sup>1</sup>, M. Dastmalchi<sup>2</sup>, A.C. Diederichsen<sup>3</sup>, D.C. Andersson<sup>4</sup>, I. E. Lundberg<sup>2</sup>, N. Witting<sup>5</sup>, M.E. Krogager<sup>5</sup>, T. Friis<sup>6</sup>, S. Jacobsen<sup>7</sup>, J.B. Knudsen<sup>1</sup>, L.P. Diederichsen<sup>1</sup>. <sup>1</sup>Department of Rheumatology, Odense University Hospital, Odense C, Denmark; <sup>2</sup>Department of Rheumatology, Karolinska University Hospital, Stockholm, Sweden; <sup>3</sup>Department of Cardiology, Odense University Hospital, Odense C, Denmark; <sup>4</sup>Dept. of Physiology and Pharmacology, Karolinska Institute, Stockholm, Sweden; <sup>5</sup>Department of Neurology, Copenhagen University Hospital; <sup>6</sup>Dept. of Autoimmunology and Biomarkers, Statens Serum Institut; <sup>7</sup>Department of Rheumatology, Copenhagen University Hospital, Copenhagen, Denmark

**Background:** Idiopathic inflammatory myopathies (IIMs) are characterised by progressive muscle weakness and muscle fatigue. IIMs frequently appear with other organ involvement, e.g. the heart. Cardiac affection is often subclinical but associated with poor prognosis which makes early detection critical.

Presence of autoantibodies is common in IIMs and autoantibodies are important biomarkers to confirm the diagnosis of IIMs. Autoantibodies may even predict organ involvement, e.g. the common myositis specific autoantibody anti-Jo1, which is a marker of lung involvement. So far, an autoantibody predicting cardiac involvement has yet to be identified.

**Objectives:** The aim of this study was to identify and estimate presence of cardiac involvement detected by electrocardiography (ECG) and to evaluate possible associations between ECG changes and autoantibodies in a Scandinavian cohort of patients with IIMs.

**Methods:** In a Scandinavian cross-sectional study, 241 patients with polymyositis (PM), dermatomyositis (DM), or inclusion body myositis (IBM) and 48 healthy controls (HCs) were investigated by ECG, basic cardiovascular assessments, and

autoantibody profile including myositis specific autoantibodies (MSAs) and myositis associated autoantibodies (MAAs).

**Results:** Compared to HCs, patients with IIMs more frequently had prolongation of QTc ( $p=0.037$ ) and QRS ( $p=0.031$ ). All patient groups had significantly longer QTc and QRS duration than HCs. In multivariate regression analysis of patients with IIMs, increased CRP ( $p=0.006$ ) was associated to increased QTc. Pooled data for patients with IIMs and HCs showed an association between diagnosis of IIM and increased QTc duration ( $p<0.001$ ). An association between presence of any MAA and QRS duration appeared in patients with IIMs ( $p=0.019$ ). In pooled data for patients with IIMs and HCs, diagnosis of IIM was associated with QRS duration ( $p=0.001$ ).

Table: Multivariate regression analyses of explanatory factors for QTc duration (ms)

Risk factor	OR	95% CI	P-value	OR	95% CI	P-value
Gender, male	0.46	0.28 0.75	0.002	0.46	0.29 0.72	0.001
Age at inclusion, per year	1.02	0.99 1.04	0.068	1.02	1.00 1.04	0.047
Hypertension, no vs. yes	1.63	0.93 2.86	0.086	1.58	0.97 2.60	0.069
Former/present smoker, no vs. yes	1.35	0.84 2.17	0.213	1.57	1.02 2.41	0.041
Increased CRP, no vs. yes	2.17	1.25 3.75	0.006	1.98	1.15 3.40	0.013
BMI, kg/m <sup>2</sup>			NS			NS
Dyspnea (NYHAI-IV), no vs. yes			NS			NS
Presence of MSAs/MAAs, no vs. yes			NS	NA	NA	NA
HAQ (Health Assessment Questionnaire), 0–3			NS	NA	NA	NA
IIM, no vs. yes	NA	NA	NA	4.11	2.21 7.63	<0.001

**Conclusions:** Patients with IIMs, no matter of clinical subgroup, had a higher occurrence of cardiac abnormalities detected by ECG than HCs. Increased CRP and presence of any MAA were associated with increased QTc and QRS duration, respectively. These results support our notion of possible associations between inflammation and autoimmunity and cardiac affection in patients with IIMs. There is now a pressing need to set up a larger prospective study to validate the present findings.

#### SAT0499 ASSOCIATION BETWEEN SYSTEMIC SCLEROSIS AND OTHER SYSTEMIC AUTO-IMMUNE DISEASES: STUDY IN TWO UNIVERSITY HOSPITALS COHORTS

M. Scherlinger<sup>1</sup>, J. Lutz<sup>2</sup>, J. Sibilia<sup>2</sup>, E. Chatelus<sup>2</sup>, M.-E. Truchetet<sup>1</sup>.

<sup>1</sup>Rheumatology, CHU de Bordeaux, Bordeaux; <sup>2</sup>Rheumatology, CHU de Strasbourg, Strasbourg, France

**Background:** Association between systemic sclerosis (SSc) and another autoimmune systemic disease (AISD) in the same patient seems to be more frequent than each disease's prevalence would explain.

**Objectives:** The aim of our work was to describe patients presenting an overlap syndrome from 2 french cohorts and to compare their characteristics with patients presenting SSc alone.

**Methods:** This was a retrospective observational study conducted in two french auto-immune diseases reference centre (Strasbourg and Bordeaux). Patients responding to the 2013 ACR-EULAR scleroderma classification criteria for SSc were screened for concomitant AISD. Patients satisfying 2010 ACR-EULAR diagnostic criteria for rheumatoid arthritis (RA) and/or 2016 ACR-EULAR classification criteria for Gougerot-Sjögren syndrome (GSS) and/or 2012 SLICC systemic lupus erythematosus (SLE) classification criteria were included in our study. Patient, disease, and treatment characteristics were retrospectively retrieved from medical records and were compared to a SSc control cohort for Bordeaux University Hospital.

**Results:** A population of 534 SSc patients was studied. Thirty-four (6.4%) patients were identified as having overlap syndrome. There was 21 (62%, prevalence 3.9%) patients with RA, 14 (41%, prevalence 2.6%) with GSS and 4 (12%, prevalence 0.7%) with SLE (5 patients had 2 AISD).

There were 24 (71%) patients with limited cutaneous SSc. Median Rodnan was 6 (extreme 0–42), 13 (38%) patients had interstitial pneumonia and 9 (26%) presented lung fibrosis. Three patients had pulmonary arterial hypertension (PAH) confirmed with catheterism. Seventeen patients (50%) had anti-centromere Ab, 11 (32%) had anti-Scl70 Ab whereas none had anti-RNA-polymerase III Ab (investigated in 24 patients).

Concerning RA patients, 17 (81%) were ACPA-positive and 17 (81%) had erosive disease. Only 6 (29%) were in remission according to Boolean criteria and 13 (62%) had a DAS28-CRP $\leq$ 3.2 suggesting difficult-to-treat RA. Patients with GSS

all presented sicca syndrome, 8 (57%) had a Chisholm grade  $\geq$ 3 on accessory salivary gland biopsy and 12 (86%) had positive anti-SSA Ab. In patients with SLE, 3 (75%) had positive anti-DNA Ab and one had a grade IV kidney disease. Three (75%) patients with SLE had a SLICC organ-damage score  $\geq$ 5 suggesting severe SLE.

Compared with our control cohort, patients with overlap syndrome had higher frequency of corticosteroid, immunosuppressive and biologic therapy use (85.3% vs 45%; 70.6% vs 31.3%; 52.9 vs 3.8%;  $p<0.0001$  for all comparisons).

**Conclusions:** Association of SSc and another auto-immune systemic disease is present in more than 6% of patients. These patients might have a more severe disease than usual SSc patients requiring prompt diagnosis and adequate treatment.

#### SAT0500 MYOCARDIAL INVOLVEMENT AT MAGNETIC RESONANCE IN PATIENTS WITH SYSTEMIC SCLEROSIS AND MINOR ARRHYTHMIAS: ASSOCIATION WITH CLINICAL FEATURES AND IMPACT OF TREATMENT

M. De Santis<sup>1</sup>, L. Monti<sup>2</sup>, M. Briani<sup>3</sup>, E. Indolfi<sup>3</sup>, E. Generali<sup>1</sup>, N. Isailovic<sup>1</sup>, A. Ceribelli<sup>1</sup>, G.M. Guidelli<sup>1</sup>, M. Caprioli<sup>1</sup>, M. Meroni<sup>1</sup>, C. Selmi<sup>1,4</sup>. <sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Radiology; <sup>3</sup>Cardiology, Humanitas Research Hospital, Rozzano; <sup>4</sup>Biometra Department, University of Milan, Milan, Italy

**Background:** Systemic sclerosis (SSc) is an autoimmune fibrotic disease characterised by variable clinical manifestations based on the predominant organ involvement. With the exceptions of acute fulminant myocarditis with pericardial effusion and heart failure, myocardial involvement in SSc is clinically silent until arrhythmias appear, while representing the major cause of sudden death or atrio-ventricular (AV) blocks in SSc. There are no reliable screening algorithm to discriminate myocardial involvement nor established treatments.

**Objectives:** To identify early/clinically silent myocardial involvement in SSc and define a possible treatment.

**Methods:** We used Holter electrocardiography (ECG) to investigate our cohort of patients with SSc ( $n=221$ , all fulfilling the ACR classification criteria) for ventricular ectopic beats (VEB)/AV blocks/unexplained tachycardia as sensitive signs of myocardial involvement. In 24 patients (women 23%–95.8%, anti-centromere-ACA 16%–66.6%, anti-topoisomerase-aScl70 3%–12.5%, anti-RNA polymerase III 3%–12.5%, anti-Ku 2%–8.3%, limited skin disease-ISSc 12%–50%, diffuse skin disease 5%–20.8%, *sine scleroderma* 7%–29.2%, median age 66.5 years, IQR 57.8–72.5), never treated with anti-fibrotic agents, we performed heart magnetic resonance (hMR) searching for myocardial oedema (on T2 STIR sequences, using the signal ratio between myocardium and skeletal muscle with a cut-off value of  $\geq 1.9$  for oedema) or fibrosis (presence of any late gadolinium enhancement (LGE) with intramyocardial or subepicardial pattern). Patients with myocardial oedema at hMR were treated with mycophenolate mofetil (MMF) 2 g/day or with azathioprine (AZA) 100 mg/day and underwent a control hMR after six months.

**Results:** In 10/24 (42%) of the SSc cases with Holter ECG alterations (8 VEB, 1 tachycardia, 1 type II AV block) we observed SSc myocardial involvement at hMR. In more detail, 6 patients had myocardial oedema at T2 STIR sequences (including cases as follows: 1 aScl70-positive with ISSc and lung fibrosis, 2 ACA-positive with ISSc, 3 ACA-positive *sine scleroderma*), and 4 only fibrosis (1 Scl70-positive with ISSc and lung fibrosis, 1 ACA-positive with ISSc, 1 ACA-positive *sine scleroderma*, 1 anti-Ku-positive *sine scleroderma*). At 6 months of medical treatment, myocardial oedema disappeared in 3 patients treated with AZA and in 1 treated with MMF, the additional 2 patients are still receiving MMF treatment at the time of analysis.

**Conclusions:** We observed that 42% of patients with SSc and minor arrhythmias on 24 hour Holter ECG have clinically silent myocardial involvement at hMR; those with potential reversible disease (oedema rather than fibrosis) favourably respond to immunosuppressants. Detectable serum ACA and the absence of skin involvement are over-represented in this subgroup of patients.

#### SAT0501 EARLY VERSUS LATE-ONSET SYSTEMIC SCLEROSIS: ARE THERE CLINICAL AND IMMUNOLOGICAL DIFFERENCES?

M. Luís<sup>1</sup>, F. Costa<sup>1</sup>, A. Carmo<sup>2</sup>, J. Ferreira<sup>3</sup>, T. Santiago<sup>1</sup>, R. Cunha<sup>2</sup>, M. J. Salvador<sup>1</sup>, J. da Silva<sup>1</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Clinical Pathology; <sup>3</sup>Cardiology, Centro Hospitalar e Universitário de Coimbra, Coimbra, Portugal

**Background:** The clinical course of Systemic Sclerosis (SSc) depends on subtype, organ involvement and age. Peak age at onset of SSc is between 30 and 50

years, although SSc may also start in both young and elderly patients. Few data have been reported on patients suffering from late-onset SSc.

**Objectives:** To characterise clinical and immunological features of early and late-onset SSc in a tertiary referral hospital.

**Methods:** We analysed data from 178 patients followed at our SSc clinic. All the patients fulfilled the ACR/EULAR 2013 classification criteria for SSc or the LeRoy's criteria for the classification of early SSc.

Based on the mean of age of onset of the whole series (50±15 years), ages extremes were defined as younger than 35 versus older than 65 years of age at onset. Disease characteristics as well as clinical and immunological features were evaluated.

**Results:** The early and the late-onset groups included 35 and 31 patients, respectively. Patients' current mean age was 42.8±14.1 vs. 75.8±6.2 with a mean disease duration of 14.5±14.7 vs. 4.3±4.6 years. The most common first manifestation of disease was Raynaud phenomena followed by arthritis/inflammatory arthralgia, in both groups. However, the time between clinical onset and SSc diagnosis was higher in the late-onset group (p=0.034). A higher number of diffuse and pre-SS was observed in the early group but this difference didn't prove statistically significant. There was a higher prevalence of centromere antibodies in the late-onset group (p=0.001). Clinical manifestations and target-organ damage didn't differ between groups, except for a higher prevalence of heart conduction abnormalities in the late-onset group (p=0.02). In multivariate analyses, age alone (OR=1.04; 95% CI 1.0, 1.1), but not disease duration (OR=0.99; 95% CI 0.9–1.0), was an independent predictor for the presence of heart conduction abnormalities.

**Abstract SAT0501 – Table 1.** Demographic, clinical and immunological features of Early and Late-Onset SSc Patients. Abbreviations: yr = years; SSc = Systemic Sclerosis. \* confirmed by esophageal manometry. \*\* Based on pulmonary function tests with diffusing capacity of lung for carbon monoxide. \*\*\* Diagnosed with echocardiography and confirmed by right heart catheterization wherever available.

	Early-Onset Group (≥ 35 yr), n=35	Late-Onset Group (≥ 65 yr), n=31	P
Sex (male:female)	6:29	5:26	0.912
Age at diagnosis (yr)	28.3 ± 5.4	71.4 ± 4.7	<0.001
Time until diagnosis (yr)	4.3	8.5	0.034
First manifestation (%)			
- Raynaud	82.9	82.1	0.061
- Arthritis/Arthralgia	14.3	20.7	0.499
Type of SSc (%)			
- Pre-SSc	37.1	25.8	0.324
- Limited	34.3	41.9	0.523
- Diffuse	22.9	12.9	0.295
Capillaroscopy pattern (%)			
- SSc specific	51.7	52.9	0.936
- Unspecific	31.0	41.2	0.486
- Normal	17.2	5.9	0.270
Raynaud phenomena (%)	100	92.9	0.113
Digital ulcers (%)	48.5	30.8	0.169
Arthritis/arthralgia (%)	63.6	44.4	0.137
Esophageal involvement (%) <sup>*</sup>	31.2	33.3	0.865
Interstitial lung disease (%) <sup>**</sup>	28.1	26.9	0.919
Pulmonary arterial hypertension (%) <sup>***</sup>	12.5	29.6	0.103
Heart conduction alteration (%)	18.8	48.1	0.016
Anticentromere antibodies (%)	45.7	87.1	<0.001
Anti-Scl 70 antibodies (%)	17.1	3.2	0.067
Anti-nuclear antibodies (%)	94.3	100	0.401

**Conclusions:** In line with findings from other studies, late-onset SSc shows a distinct clinical and immunological presentation. The present study confirms that late-onset is associated with longer diagnostic delay, positive centromere and heart conduction abnormalities. These observations may be due to age and potential age-associated confounders, rather than the disease itself. Knowledge of these different characteristics can help to improve the management of the disease.

SAT0502

#### COMPARISON OF THE CREATININE-BASED AND THE CYSTATIN C-BASED ESTIMATED GLOMERULAR FUNCTION (EGFR) IN PATIENTS WITH SYSTEMIC SCLEROSIS PATIENTS

M. Krusche, T. Kubacki, R. Osei-Davies, I. Kötter. *Rheumatologie, klinische Immunologie und Nephrologie, AK Altona, Hamburg, Germany*

**Background:** Kidney involvement is common in systemic sclerosis (SSc) and proteinuria or renal crisis are associated risk factors for increased mortality in SSc.

For the measurement of the kidney function (glomerular filtration rate, GFR) the creatinine-based estimation formula of the Chronic Kidney Disease Epidemiology Collaboration (CKD-EPI) and the Modification of Diet in Renal Diseases (MDRD)-formula are commonly used.

Cystatin C has a higher diagnostic sensitivity to show a reduction of GFR. As it is not being influenced by muscle mass or diet it has advantages over the creatinine-based measurements.

**Objectives:** Comparison of the creatinine-based and cystatin C-based eGFR in systemic sclerosis patients.

**Methods:** Single-centre, retrospective analysis of SSc patients between 2015–2017 which were parallel tested for serum creatinine and cystatin C.

108 patients (78 females, 30 males), 21 patients with diffuse systemic sclerosis (dcSSc), 76 patients with limited systemic sclerosis (lcSSc) and 11 patients with overlap syndrome. Medium age 58,8 (±16,1 years), age span 17–83 years.

For the calculation of the estimated glomerular filtration rate (eGFR) the following formulas were used: MDRD-Study Equation, CKD-EPI Creatinine Equation 2009. CKD-EPI Cystatin C Equation 2012

**Results:** The mean eGFR according to the CKD-EPI Creatinine Equation was 84,4 ml/min (±23,5), according to the MDRD formula it was 80,24 ml/min (±22,8) (p<0,001) and 65,3 ml/min (±21,7) (p<0,001) when the CKD-EPI Cystatin C Equation was used. According to the KDIGO stages of chronic renal impairment a stage G2 (eGFR <90 ml/min) was present in 39,8% of the patients (43/108) using the CKD-EPI Creatinine Equation, in 47,2% (51/108) using MDRD and in 48,1% (52/108) using the CKD-EPI Cystatin C Equation.

A relevant chronic kidney impairment stage G3 (eGFR <60 ml/min) or higher was present in 14,8% of the patients (16/108) calculated by CKD-EPI Creatinine Equation, in 17,6% (19/108) of the patients according to MDRD Equation and in 38,8% (42/108) according to CKD-EPI Cystatin C Equation.

Patients with a higher difference (>18 ml/min) between creatinine-based and cystatin C-based eGFR did not differ in age, body mass index (BMI) or disease subset from patients with a lower difference but a higher difference occurred significantly more often in men (p=0,012).

**Conclusions:** Many patients with SSc showed a significant difference using cystatin C for the calculation of GFR compared to the creatinine-based formulas. As reduced muscle mass is common in SSc this could be due to sarcopenia in the context of the underlying disease. Early detection of impaired kidney function might be useful to monitor disease progress and is important for the management of immunosuppressive drugs like methotrexate and cyclophosphamide which are commonly used in the disease but need to be adjusted to the renal function.

A prospective study with measurement of GFR and comparison of different formulas in this patient population seems necessary.

SAT0503

#### ASSESSMENT OF PROSTANOIDS (ILOPROST, ALPROSTADIL) EFFICACY IN TREATMENT OF ULCERS IN PATIENTS WITH SYSTEMIC SCLEROSIS

M. Starovoytova, O. Desinova, O. Koneva, O. Ovsyannikova, L. Garzanova, VA Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** The prostanoids are currently regarded as the most effective agents in treatment of ischaemic lesions in patients with rheumatic diseases. However, the efficacy of Alprostadil is underexplored, especially in comparison with Iloprost.

**Objectives:** To evaluate the efficacy of Alprostadil (Vazaprostan®) and Iloprost (Ilomedin®) in treatment of digital ulcers in SSc pts using modern assessment tools (questionnaires and designated forms) of digital ulcers.

**Methods:** This 1 year study included 42 patients with systemic scleroderma (SSc) aged >18 y, having digital ulcers. Standard evaluation procedures and questionnaire to assess therapy, as well as scales and questionnaires for assessment of digital ulcers were used at baseline and after 12 months. The therapeutic regimens were as follows: Alprostadil at 20 mg/kg i/v drip rate infusion during 10 days, 1 course in 6 mo (totally 2 courses). Iloprost at 20 mg/kg i/v via infusion pump during 5 days each 3 months (totally 2 courses).

The following questionnaires/forms to evaluate the therapy of digital ulcers were used: 1/VAS for pain assessment, 2/SSc-HAQ, 3/Cochin hand function scale, 4/ the total hand pain score, 5/global patient's assessment of ulcers, 6/global

physician's assessment of ulcers, 7/patient's evaluation of changes in ulcers, 8/ physician's evaluation of changes in ulcers 9/number of digital ulcers.

The patients were evaluated after the drug infusion and 1 year later. Clinical and demographic characteristics of patients treated with vasoactive drugs are presented in table 1.

**Results: Table 1.** Clinical and demographic characteristics of patients with digital ulcers

	llovedin <sup>®</sup>	Vazaprostan <sup>®</sup>
N	22	20
Females (%)	100	90
Age	46.7 (±9.9)	41.9 (±12.9)
Diffuse SSc (%)	36.4	14.3
SSc duration (yy)	12.9	10.8
N of ulcers (baseline)	3.3 (±2.2)	1.7 (±1.03)

\*Mean ±SD

**Results:** The results obtained show improvement of ischaemic lesions in both groups.

The comparison of results speaks in favour of Vasoprostan vs llovedin in terms of significant pain reduction, table 2.

**Abstract SAT0503 – Table 2.** Comparative characteristics of scores and values from different assessment tools in groups treated with Vasoprostan and llovedin (post-treatment).

	llovedin <sup>®</sup>	Vazaprostan <sup>®</sup>
HAQ-SSc	1.49	1.18
HAQ	1.22	1.18
Cochin score	16.38	22
VAS	46.61*	27.12*
Physicians Global assessment	3.8	3.5
patients Global assessment	4.61	3.75
Ulcers N	3.07	1.16

\*p<0.05

**Conclusions:** It should be noted that certain degree of positive dynamics in healing of ulcers was established by practically all assessment tools. VAS looks like the most sensitive tool in evaluation of pain. Of importance is the fact, that despite marked ischaemic lesions and digital ulcers, the Cochin score reflecting hand functional capacity did not exceed average values at baseline and did not change significantly post-treatment.

Ku	0	0	0	0	0	0	0	0	0

**Objectives:** To study the prevalence of Myositis specific and Myositis Associated antibodies (MSA and MAA respectively) in Indian patients with AIM and to correlate these antibodies with clinical features.

**Methods:** All consecutive patients with Inflammatory myositis (satisfying the Bohan and Peter criteria, 1975 attending the Rheumatology and Clinical Immunology department of Medanta hospital from November 2016 to October 2017 were included prospectively and divided into groups as Dermatomyositis (DM), Polymyositis (PM), CTD associated myositis (CTD-M), Cancer associated myositis (CAM) and Juvenile Myositis (JM). Their clinical data and sera were collected after obtaining informed consent. Sera was analysed for IgG antibodies against Jo-1, PL-7, PL-12, E.J, SRP, Mi-2, MDA-5, TIF1 $\gamma$ , SAE1, SAE2, NXP2 and SSA/RO52kD using the microELISA technique (BlueDriver Dot Myositis<sup>12</sup> SAE IgG kit). Their ENA was also recorded (Blue DriverQuantrix-ANA25 Screen IgG kit d-tek). Results were read by the BlueScan scanner and value  $\geq 10$  were considered positive. The study was approved by the Ethics committee of Medanta hospital.

**Results:** There were 48 patients in the cohort (M:F=12:36) with the mean age of 41.3 years and a median disease duration of 30 months. Nineteen of them were DM, 19 were PM, 5 were CTD-M, 2 were CAM and 3 were JM. 58.3% were ANA positive and MSA were positive in 37.5% of the cohort, MSA being mutually exclusive. Antibodies against Mi-2 were present in 6 patients (12.5%), Jo-1 antibodies in 5 (10.4%), 2 (4.1%) patients each had PL-7 and SRP antibodies. One patient (2%) each had MDA-5, NXP2 and Tif1 $\gamma$  antibodies. MAAs were seen in 39.5% of the cohort with antibodies against Ro, RNP and PM- Scl seen in 16 (33.3%), 2 (4.1%) and 1 (2%) respectively. Mi-2 antibodies were seen only in DM and JM group. The lone patient who had MDA-5 antibody had amyopathic DM. Malignancy screening was negative in NXP2 and TIF1 $\gamma$  antibody positive patients.

**Conclusions:** MSA were present in almost 40% of the cohort. Mi-2 antibodies were associated with rash and none had ILD whereas Jo-1 antibodies were associated with mechanic hands, arthritis and ILD. With further recruitment of patients in this ongoing study, we hope to get more robust data in future.

**Disclosure of Interest:** None declared

#### SAT0505 COMPARISON OF LONG-TERM CYCLOPHOSPHAMIDE (CY) AND MYCOPHENOLATE MOFETIL (MMF) EFFICACY AND SAFETY IN PATIENTS WITH SYSTEMIC SCLEROSIS (SSC) AND INTERSTITIAL LUNG DISEASE (ILD)

O. Koneva, O. Ovsyannikova, O. Desiniva, L. Garzanova, L. Ananieva, M. Starovoytova. Nasonova Research Institute of Rheumatology, Moscow, Russian Federation

**Background:** CY is considered to be the drug of choice for ILD therapy in patients with SSc. However, based on published evidence, only temporary and modest improvement of pulmonary fibrosis is usually achieved, therefore search for new more effective and safe agents is ongoing, with specific attention given to MMF.

**Objectives:** To compare CY and MMF effects on SSc clinical manifestations and activity, and safety of both agents in an open prospective non-randomised study.

**Methods:** The study included patients with a documented SSc diagnosis and ILD signs based on HRCT data. All patients were treated with immunosuppressants in combination with low and medium doses of glucocorticoids. 36 pts (mean age 47  $\pm$  12 years, m/f 1/1,1, SSc duration 5.0 $\pm$ 4.8 years, diffuse/limited – 1/1,6) were administered parenteral CY during 12 $\pm$ 6 months, with a cumulative dose of 10.6  $\pm$  5 g. 45 pts (mean age 49 $\pm$ 13 years, m/f – 1/10, SSc duration 7.6 $\pm$ 6.3 years, diffuse/limited – 1/1,3) were administered MMF at 2 g/day during 13 $\pm$ 2 months. The

following parameters were monitored during the study: FVC%, DLC%, modified skin score (), activity index (EScSG), gastrointestinal tract symptoms, left ventricle ejection fraction, presence of diastolic ventricle dysfunction, PASP (Echo-CG), heart rhythm and conduction disorders (ECG), count of digital ulcers and necroses.

**Results:** MMF therapy led to a significant reduction of the mRSS (7.5±6.9 and 4.8±3.9, p=0.0006), EScSG (1.9±1.5 and 1.22±0.9, p=0.005), number of patients with heart conduction disorders (13/29% and 5/11%, p=0.03).

The FVC improvement by ≥10% was documented in 6 (13%) pts, and DLCO – in 3 (7%); while worsening was observed in 4 (9%), and 2 (4%) cases, respectively. Mean FVC (90.3±20.8 and 92.2±21, p=0.09), and DLCO (52.2±17.4 and 51.9 ±17, p=0.86) values did not change significantly.

CY therapy resulted in significant FVC increase (80.5±20.1 and 85.9±20.5; p=0.034), reduction of EScSG (2.8±2 and 1.4±1.2, p=0.0002) and mRSS (11,2 ±9,8 and 7.9±6,8, p=0.009). ≥10% FVC increase was observed in 11 (31%) pts, which was significantly more than in MMF group (p=0.043). FVC loss was noticed in 2 (5.6%) cases. The median FVC increase was 5.4% (25th%=-0.6, 75th% =12.3). ≥10% DLCO improvement and worsening was observed in 2 (6.7%) pts. The mean DLCO values (53,5±16,2 and 54.4±15,5) did not change significantly.

The other parameters monitored did not show significant deviations during the observation period.

Drug tolerability was better in MMF group: the rate of adverse drug reactions was significantly lower in MMF group (12/27%), compared to CY group (19/53%), p=0.03.

**Conclusions:** Both drugs effectively reduced mRSS and EScSG in SSc patients. However, CY more often led to a clinically significant increase in FVC, in contrast to MMF, mostly contributing to stabilisation of FVC. The obtained results justify a differentiated approach to SSc pharmacotherapy depending on disease severity. A CY induction therapy should be considered as appropriate practice in patients with more severe pulmonary disease. A MMF induction therapy should be considered in SSc patients with cardiomyopathy and mild pulmonary disease, with poor CY tolerability. In other cases, MMF should be used for maintenance therapy after induction with CY.

**Background:** Systemic sclerosis (SSc) is a very heterogeneous multisystem connective tissue disease. The majority of affected patients develop initial clinical symptoms between the age of 30 to 50 years. It is not known whether an ageing population affects the clinical phenotype of SSc.

**Objectives:** To investigate the relationship of the age at disease onset and clinical characteristics in SSc patients using the registry of the German Network for Systemic Scleroderma.

**Methods:** Clinical data of the patient registry, currently including 4021 patients, were evaluated. Three age ranges at disease onset (<40 years, 40–60 years, and >60 years) were correlated with clinical characteristics.

**Results:** Among all SSc patients, 27% of patients developed first non-Raynaud symptoms at the age <40 years, while 44% developed SSc between 40–60 years, and 29% were older than 60 years of age. In particular, SSc patients with disease onset >60 years developed significantly (p<0.001) more often the lcSSc subtype (71.1%), anti-centromere antibodies (45.8%), had a significantly lower modified Rodnan Skin Score (mRSS) (7.8±8.1), more often pulmonary hypertension (PH) (17.4%), a significantly lower mean DLCO level (69.7%±21.5) and less often digital ulcerations (20.2%). However, a significant difference for lung fibrosis, heart or kidney involvement could not be observed. The more progressive subsets (dcSSc

and SSc overlap syndromes) are found significantly more often at younger ages (p<0.001).

**Conclusions:** In this registry, nearly one third of patients developed SSc at an age above 60 years. These are mostly of the limited cutaneous subtype with frequent PH. These findings have an important influence on recommendations on diagnosis and therapy of SSc.

#### SAT0507 IMPLANTABLE LOOP RECORDER CAN SCREEN FOR INCIDENTAL SIGNIFICANT ARRHYTHMIAS IN SCLERODERMA, WITH CARDIAC MRI ECV AND TROPONIN BIOMARKER, USEFUL FOR RISK STRATIFICATION

R. Dumitru<sup>1,2</sup>, L.-A. Bissell<sup>1,2</sup>, G. Abignano<sup>1,2</sup>, B. Erhayiem<sup>3</sup>, G. Fent<sup>3</sup>, H. Donica<sup>4</sup>, A. Burska<sup>1,2</sup>, F. Del Galdo<sup>1,2</sup>, J. Greenwood<sup>3</sup>, S. Plein<sup>3</sup>, L. Graham<sup>3</sup>, M.H. Buch<sup>1,2</sup>. <sup>1</sup>Leeds Institute of Rheumatic and Musculoskeletal Medicine, University of Leeds; <sup>2</sup>NIHR Biomedical Research Centre; <sup>3</sup>Leeds Institute of Cardiovascular and Metabolic Medicine, University of Leeds, LEEDS, UK; <sup>4</sup>Department of Biochemical Diagnostics, University of Poland, Lublin, Poland

**Background:** Cardiac involvement and in particular conduction abnormalities represent a significant cause of morbidity and mortality in patients with systemic sclerosis (SSc). No studies assessed the value of implantable loop recorder (ILR) for early detection of arrhythmias in asymptomatic patients with SSc; or whether cardiac magnetic resonance (CMR) features associate with arrhythmias.

**Objectives:** To assess the prevalence of conduction abnormalities over a 3 year period using an ILR (REVEAL) and evaluate relationship with disease phenotype, cardiac biomarkers and CMR in SSc patients.

**Methods:** 20 patients (pts) with ACR/EULAR criteria for SSc, with no history of cardiovascular (CV) disease and ≤1 CV risk factor had 3T CMR with late gadolinium enhancement (LGE) and T1 mapping for ECV quantification. An ILR was then inserted, for 3 years follow-up. ILR data were downloaded every 3 months. Serum cardiac biomarkers were also measured at the initial visit.

**Results:** 19 pts had available ILR data; 12 (63%) females, median (SD) age 53 (12, 6 (32%) diffuse SSc(dcSSc), 6 (32%) ACA+, 4 (21%) Scl70+, 8 (42%) history of interstitial lung disease (ILD) and 7 (36%) history of digital ulcers (DU). 14/19 had any ILR abnormalities, 8/14 significant arrhythmias: 1 complete heart block; 2 non-sustained ventricular tachycardia (NSVT), and 5 atrial arrhythmias (1 atrial flutter, 1 AF, 1 SVT, 1 AF and SVT and 1 AF followed by atrial flutter and SVT). Of these 8 pts, 4 had dcSSc, 2 Scl70+, 4 ACA+, 3 with ILD and 3 DU history. All 3 patients with severe arrhythmias (NSVT/CHB) were dcSSc, 2 Scl70+, 2 males. Management comprised 1 permanent pacemaker implantation, 3 antiarrhythmic treatment, 1 anticoagulation. 15 pts had CMR. The 8 pts with significant arrhythmia appeared to have higher ECV, LV mass, and LVEF% (table 1). LGE was observed in 1 (NSVT), of a total of 5/15 with LGE. HsTnI was considerably higher in those with significant arrhythmias (mean diff. (95% CI) 117 (-10, 245)). NTproBNP [(mean diff. (95% CI) 92 (-30, 214)] also appeared greater in those with significant arrhythmias. There was no difference in CK levels between the two groups.

CMR baseline	ILR significant arrhythmias, all years n=6 Mean(SD)	ILR no significant arrhythmias n=9 Mean(SD)	Mean difference [95% CI]
ECV%	32 <sup>(2)</sup> n=5	29 <sup>(4)</sup> n=9	2 [-2,6]
LVEDV/BSA (ml/m <sup>2</sup> )	84 <sup>(16)</sup>	83 <sup>(20)</sup>	1 [-21, 22]
LVEF%	62 <sup>(4)</sup>	59 <sup>(5)</sup>	2 [-3,8]
LV mass/BSA(g/m <sup>2</sup> )	46 <sup>(7)</sup>	44 <sup>(14)</sup>	2 [-10, 15]
LVSV/BSA(ml/m <sup>2</sup> )	51 <sup>(8)</sup>	49 <sup>(11)</sup>	2 [-9, 13]
LVESV/BSA(ml/m <sup>2</sup> )	33 <sup>(9)</sup>	34 <sup>(10)</sup>	-2[-13, 9]
Distensibility (10 <sup>-3</sup> mmHg <sup>-1</sup> )	5 (4)	4 (2)	0.4 [-3, 4]
Torsion °	12 <sup>(6)</sup> n=5	14 <sup>(5)</sup> n=8	-2[-8, 5]
LGE	N 1/5	N 4/9	

**Conclusions:** This pilot study demonstrates the ability of ILR to detect life-threatening arrhythmia in asymptomatic SSc pt. The data suggest CMR ECV (but not LGE) and cardiac biomarkers, in particular hsTnI (indicating subclinical myocardial injury) may be able to identify at risk pts that would benefit from ILR screening. Future studies can inform a risk model, and provide insight into the pathogenesis of SSc associated arrhythmias.

### ACE-INHIBITORS IN ARTERIAL HYPERTENSION IN SSC PATIENTS DISPLAY A RISK FACTOR FOR SCLERODERMA RENAL CRISIS – A EUSTAR ANALYSIS

S. Adler<sup>1</sup>, P.A. Varisco<sup>2</sup>, O. Distler<sup>3</sup>, L. Buetikofer<sup>4</sup>, O. Kowal-Bielecka<sup>5</sup>, Y. Allanore<sup>6</sup>, G. Riemekasten<sup>7</sup>, P.M. Villiger<sup>8</sup>. <sup>1</sup>Rheumatology, University Hospital Bern; <sup>2</sup>Regional Medical Service, Bern; <sup>3</sup>University Hospital Zurich, Zurich; <sup>4</sup>Clinical Trials Unit, Bern, Switzerland; <sup>5</sup>Warsaw Medical University, Warsaw, Poland; <sup>6</sup>Cochin Hospital, Paris, France; <sup>7</sup>University Hospital Schleswig-Holstein, Luebeck, Germany; <sup>8</sup>University Hospital Bern, Bern, Switzerland

**Background:** Scleroderma renal crisis (SRC) represents a rare but life-threatening manifestation in systemic sclerosis (SSc). Survival remains poor despite therapeutic use of ACE inhibitors (ACEi). Factors influencing the risk of SRC are not well characterised. In particular, ACEi are discussed as promoting but also as protecting SRC.

**Objectives:** To investigate the effect of ACEi on SRC incidence in prospectively collected data of a cohort of SSc patients.

**Methods:** EUSTAR database analysis with focus on arterial hypertension, antihypertensive medication and glucocorticoids. Subgroup analysis of a dataset with defined documentation of medication from January 2009 until November 2017.

**Results:** Out of 14'524 patients in the database we identified 7'648 patients with at least one follow-up after 2009. 102 patients developed SRC in 27'450 person-years (py), representing an incidence of 3.72 (3.06–4.51) per 1'000 py. In a multi-variable time-to-event analysis adjusted for age, sex, disease severity and onset, arterial hypertension, tendon friction rubs, SCL70 and ACA positivity, 78 of 6083 patients developed SRC. Herein, use of ACEi displayed an increased risk for the development of SRC with a hazard ratio (HR) of 2.07 (95% confidence interval (CI):1.28–3.36). Calcium channel blockers (CCB), angiotensin receptor blockers, endothelin receptor antagonists and glucocorticoids did not influence SRC incidence. Medication strategies were not altered after renal crisis. Cumulative mortality 5 years after renal crisis was 18.6% (95% CI: 13.0%–26.3%).

Figure (A) Cumulative incidence plots for scleroderma renal crisis (SRC) depending on whether patients have arterial hypertension (AH), or are treated with ACE inhibitors (ACE), Calcium channel blockers (CCB) or Glucocorticoids (GC).

**Conclusions:** This EUSTAR analysis supports the notion that ACEi should be avoided in arterial hypertension in SSc patients. Alternative antihypertensive drugs as CCB might be preferred.

### HOW MONEY SHOULD BE SPENT: PATIENTS PERSPECTIVES ON SCLERODERMA RESEARCH FUNDING

S. Divani<sup>1</sup>, J. Patel<sup>2</sup>, R. Stratton<sup>3</sup>. <sup>1</sup>University College London Medical School; <sup>2</sup>Homerton University Hospital; <sup>3</sup>Royal Free Hospital, London, UK

**Background:** Scleroderma (systemic sclerosis, SSc) is an autoimmune disease that can affect blood vessels, skin and various organs, causing Raynaud's phenomenon, thickening of skin, gastro-oesophageal reflux and lung fibrosis. Despite remarkable improvements and innovations in management for SSc, leaders in the field continue to believe there is scope for more.<sup>1</sup> Patients' opinions on future research into the condition and its management, can provide valuable insight on how to shape its prospects and improve outcomes, and how research funding should be best directed.<sup>2</sup>

**Objectives:** To determine if doctors and patients with scleroderma agree on where future scleroderma research should be focussed.

**Methods:** 25 patients with scleroderma and 10 doctors were given questionnaires that asked them to rank 12 issues in order of importance, with a view to directing future Scleroderma research and funding. The highest ranked issue was appointed a score of 12, and the lowest ranked appointed a score of 1. The mean scores were calculated, and compared for concordance using ANOVA testing.

All patients had been admitted for elective Iloprost infusions at Royal Free Hospital and varied in age and gender. The clinicians were of varied levels from FY1-consultant, and all worked in the Rheumatology team at Royal Free.

**Results:** Patients ranked the issue of "managing Raynaud's symptoms" as the most important, which is significantly different to how clinicians viewed it – patients gave it a ranking 9.8 compared to only 4.9 from clinicians ( $p < 0.005$ ). However, doctors placed more value on "avoiding organ involvement" (10.4 from clinicians and 7.67 from patients ( $p < 0.005$ )).

Patients and clinicians, however, agreed about the least important issues, scoring "medication side effects" 3.6 and 3.1 respectively, "social and psychological support" 3.7 and 4.0, and "family planning and genetics" 3.8 and 3.6. They also agreed that research should be targeted at finding "new treatments that stop disease progression" which scored highly in both groups (9.7 in patients, 10.5 in clinicians).

**Conclusions:** Patients appear to feel that Raynaud's symptoms are affecting their quality of life in a way that is not being appreciated as important by clinicians. This may be due to ineffective communication between them, perhaps due to the time constraints of appointments.

Contrastingly, doctors are more concerned about avoiding organ involvement compared to patients, perhaps as they are more aware that organ involvement has a much greater effect on prognosis. However, both patients and clinicians were equally committed to investigating mechanisms of this disease.

Overall, these findings between doctors and patients should not just be a point of focus for future funding and research. It can be used to identify where there are differences in expectations during clinical encounters, and therefore allow us as clinicians to tailor our agenda to better meet the needs of our patients, which would likely improve the patient-doctor relationship, enhancing communication in clinic appointments.

**Background:** Calcinosis is a cutaneous manifestation that produces disability and complications in patients with idiopathic inflammatory myopathies (IIM). Studies about associated factors are limited.

**Objectives:** To investigate cutaneous manifestations and factors associated with calcinosis in patients with IIM from the REMICAM registry.

**Methods:** A multicenter retrospective study (1980–2014) was performed. Patients were classified as primary dermatomyositis (DM), primary polymyositis (PM), cancer associated myositis (CAM), overlap myositis (OM), inclusion body myositis, immune-mediated necrotising myopathy (IMNM) and juvenile myositis (JuM). A description of the cutaneous manifestations in each subgroup of IIM was done. The associations between calcinosis and demographic data, clinical characteristics, antibodies and treatments were analysed independently for JuM and adult IIM.

**Results:** 479 patients were included, of whom 49 (10%) had calcinosis with the following distribution: 27 JuM (55%), 9 DM (18%), 9 OM (18%), 3 PM (6%) and 1 IMNM (2%). Non-characteristic cutaneous manifestations were more prevalent in DM, OM, CAM and IMNM. At multivariate analysis, disease duration (OR=2; p=0.016), immunoglobulin treatment (OR=5.68; p=0.036) and immunosuppressants (OR=8.94; p=0.01) were associated with calcinosis in JuM. In addition, dysphagia (OR=21.3; p=0.008), positivity for anti-PM-Scl (OR=34.1; p=0.01), baseline ESR (OR=1.05; p=0.04) and interstitial lung disease (OR=10.2; p=0.039) were associated with calcinosis in adult.

**Conclusions:** Our results suggest that factors associated with calcinosis might be different in adult and juvenile myositis, but in both cases, they are related to more severe disease.

**Disclosure of Interest:** None declared

Matucci-Cerinic<sup>13,14</sup>. <sup>1</sup>Rheumatology, ASST Pini-CTO; <sup>2</sup>Dept Clinical Sciences and Community Health, Univ Milan, Milan, Italy; <sup>3</sup>Cochin Hospital, Rheumatology A dept, Univ Paris Descartes, Paris, France; <sup>4</sup>Div Rheumatology, Univ Pavia, IRCCS S. Matteo Foundation, Pavia; <sup>5</sup>Rheumatology, Univ Modena and Reggio Emilia, Modena, Italy; <sup>6</sup>Dept Rheumatology, Univ Hospital Zurich, Zurich, Switzerland; <sup>7</sup>UCLA, Los Angeles; <sup>8</sup>Univ Washington, Seattle, USA; <sup>9</sup>Univ Florence, Florence, Italy; <sup>10</sup>Dept Dermatology, Univ Cologne, Cologne, Germany; <sup>11</sup>DETO-Section of Rheumatology, Bari, Italy; <sup>12</sup>Univ Michigan, Ann Arbor, USA; <sup>13</sup>Dept Experimental and Clinical Medicine, Univ Florence; <sup>14</sup>Div Rheumatology, AOUC Careggi, Florence, Italy

**Background:** Raynaud's phenomenon (RP) and digital ulcer (DU) are prominent features of SSc. According to the 2017 EULAR recommendations, intravenous (IV) iloprost (ILO) may be used for RP and DU after failure of oral therapies. Where available, IV ILO is indicated in RP secondary to systemic sclerosis (SSc) for 3–5 days with no other advice about the regimen (dosage, duration and frequency).

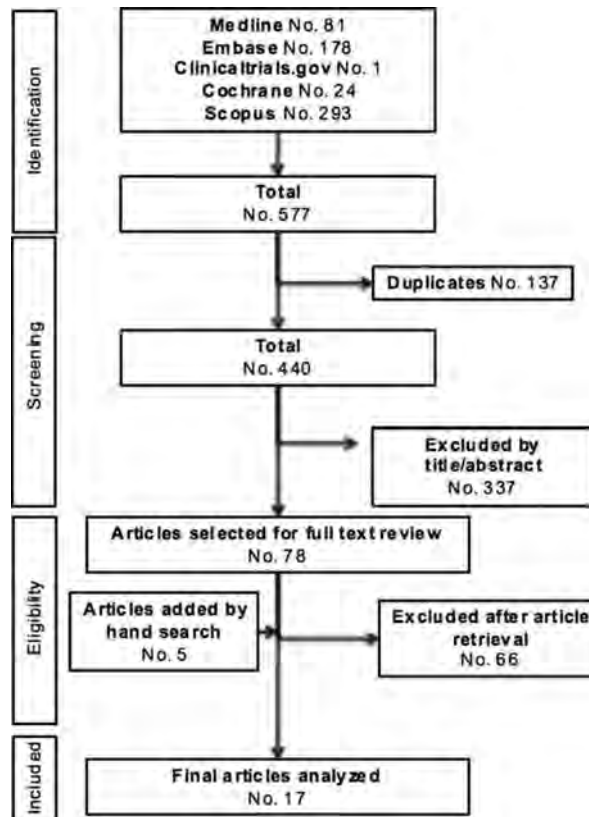

**Objectives:** To provide a systematic review focused on IV ILO use in SSc RP and DU and to perform a meta-analysis. In the case of lack of data, a Delphi consensus was performed to provide practical suggestions about ILO usage in SSc RP and DU and to propose a research agenda for future studies.

**Methods:** The systematic review of the literature on IV ILO in SSc patients complicated by DU and RP was performed according to PRISMA guidelines and the meta-analysis to the GRADE system. A three-step web-based Delphi consensus was designed if not enough data were available from the literature.

**Results:** The review flow process is outlined in figure 1. The meta-analysis could not be performed due to insufficient literature data about dosage, regimen and frequency of IV ILO. Therefore, a three-round Delphi exercise was performed to

identify and establish a consensus about IV ILO use in SSc RP and DU. Expert consensus was reached at the third step for the following items:

- Severe or refractory to oral therapy RP, IV ILO 0.5 and 2.0 ng/kg/min, 1–3 days monthly.
- DU healing, IV ILO 0.5 and 2.0 ng/kg/min up to the maximum tolerated dose the first day of therapy, 1–3 days monthly.
- DU prevention, IV ILO 0.5 and 2.0 ng/kg/min, 1 day monthly.
- Research agenda: trials for head-to-head comparison and for regimen assessment.

**Conclusions:** IV ILO is currently available in some countries with the approved indication only for RP-SSc for 3–5 days. Our data, based on expert consensus, suggest a 1–3 days monthly regimen for RP and DU healing and 1 day monthly for DU prevention. These suggestions may allow clinicians to decide how to personalise the IV ILO therapy according to patients' needs. Although these suggestions are intended for clinical setting use, it will be necessary to formally validate the present suggestions in future clinical trials.

**Acknowledgements:** The consensus meeting has been supported by Italfarmaco.

**SAT0512 SAFETY AND EFFICACY OF LENABASUM IN REFRACTORY SKIN-PREDOMINANT DERMATOMYOSITIS SUBJECTS TREATED IN AN OPEN LABEL EXTENSION OF TRIAL JBT101-DM-001**

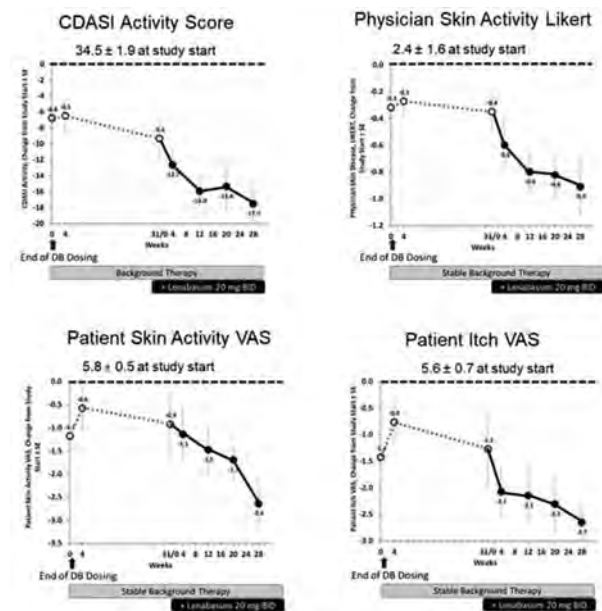

V.P. Werth<sup>1,2</sup>, B. Patel<sup>1,2</sup>, J.S. Concha<sup>1,2</sup>, J. Okawa<sup>1,2</sup>, D. Pearson<sup>1,2</sup>, E. Hejazi<sup>1,2</sup>, R. Feng<sup>1,2</sup>, C. Cornwall<sup>3</sup>, N. Dgetluck<sup>3</sup>, S. Constantine<sup>3</sup>, A. Aggarwal<sup>3</sup>, B. White<sup>3</sup>. <sup>1</sup>Philadelphia Veteran Affairs Medical Center; <sup>2</sup>University of Pennsylvania, Philadelphia; <sup>3</sup>Corbus Pharmaceuticals, Inc., Norwood, USA

**Background:** Lenabasum (aka anabasum, JBT-101) is a selective cannabinoid receptor type 2 agonist that activates resolution of innate immune responses. It is a synthetic, oral, non-immunosuppressive small molecule. Lenabasum showed acceptable safety and tolerability and evidence of clinical benefit in 22 subjects with refractory, skin-predominant dermatomyositis (DM) in Phase 2 trial JBT101-DM-001 (NCT02466243).

**Objectives:** This study evaluated safety and efficacy of open-label dosing of lenabasum in moderately-to-severely active skin-predominant DM in subjects who were refractory to or intolerant of hydroxychloroquine treatment.

**Methods:** Subjects who completed the double-blind placebo-controlled (DBPC) part of JBT101-DM-001 with 12 weeks of active dosing and 4 weeks of safety follow-up were eligible to receive lenabasum 20 mg BID in an open-label extension (OLE). Safety and efficacy evaluations were done at Week 4 after the start of OLE, then every 8 weeks thereafter.

**Results:** 20/22 (91%) eligible subjects enrolled in the OLE and 17/20 (85%) were on baseline immunosuppressive drugs. There was a mean interval of 31 weeks (range 4–92 weeks) from the end of active DBPC dosing and the start of the OLE, during which time subjects remained on background medications prior to adding lenabasum in the OLE. At the time of OLE data cut-off, no subjects had discontinued, all 20 subjects in the OLE completed visits through Week 12 and 11 subjects completed visits through Week 28. During the 28 weeks of OLE dosing, adverse events (AEs, n=30) occurred in 14/20 (70%) subjects. Only 1 subject had a moderate AE, all other AEs were mild. Four (20%) subjects had AEs considered related to lenabasum. The only AE that occurred in more than 1 subject was DM flare (n=2, 10%). During the OLE, there was improvement from the beginning of the OLE dosing and from the study start in Cutaneous Dermatomyositis Activity and Severity Index (CDASI) Activity score and physician Likert assessments of global disease activity, skin disease activity and extramuscular disease activity. Similarly, there were improvements in multiple patient-reported outcomes, including patient 10 cm VAS scores of global disease activity, skin disease activity, itch and pain, as well as the Skin-dex-29 symptoms domain and PROMIS-29 physical function, fatigue, pain interference, and anxiety domains. Selected efficacy outcomes are shown in figure 1 as change from study start during two periods: 1) "off treatment" from the end of active DBPC dosing to the start of OLE, dotted line; and 2) OLE dosing, solid line.

Abstract SAT0512 – Figure 1. Mean change from Baseline ± SE in Selected Efficacy Outcomes

**Conclusions:** Lenabasum continues to have a favourable safety and tolerability profile in the OLE of the Phase 2 trial JBT101-DM-001 with no severe or serious AEs or study discontinuations related to lenabasum. The CDASI activity score and multiple other physician and patient-reported outcomes improved from study start and start of the OLE, although open-label nature of dosing with lenabasum is acknowledged. These data support further testing of lenabasum for the treatment of DM.

**SAT0513 PROGRESSIVE SKIN FIBROSIS IS ASSOCIATED WITH A DECLINE IN LUNG FUNCTION AND POORER SURVIVAL IN PATIENTS WITH DIFFUSE CUTANEOUS SYSTEMIC SCLEROSIS: A EUROPEAN SCLERODERMA TRIALS AND RESEARCH (EUSTAR) ANALYSIS**

W. Wu<sup>1</sup>, S. Jordan<sup>1</sup>, N. Graf<sup>2</sup>, J. Pena<sup>3</sup>, J. Curram<sup>4</sup>, Y. Allanore<sup>5</sup>, M. Matucci-Cerinic<sup>6</sup>, J.E. Pope<sup>7</sup>, C. Denton<sup>8</sup>, D. Khanna<sup>9</sup>, O. Distler<sup>1</sup> on behalf of EUSTAR coauthors. <sup>1</sup>University Hospital Zurich, Zurich, Switzerland; <sup>2</sup>Graf Biostatistics, Winterthur, Switzerland; <sup>3</sup>Bayer US LLC, Parsippany, NJ, USA; <sup>4</sup>Bayer Plc, Reading, UK; <sup>5</sup>Cochin Hospital, Paris Descartes University, Paris, France; <sup>6</sup>University of Florence, Florence, Italy; <sup>7</sup>University of Western Ontario, St. Joseph's Health Care, London, ON, Canada; <sup>8</sup>University College London, Royal Free Hospital, London, UK; <sup>9</sup>University of Michigan, Ann Arbor, MI, USA

**Background:** Short disease duration and low baseline modified Rodnan skin score (mRSS) have been identified as independent predictors of progressive skin fibrosis in patients with diffuse cutaneous systemic sclerosis (dcSSc) using the EUSTAR database.<sup>1</sup> However, whether worsening of skin fibrosis is an appropriate surrogate marker for new-onset or deterioration of visceral organ disease and overall survival in dcSSc has been questioned.

**Objectives:** To determine whether progressive skin fibrosis is associated with visceral organ progression and mortality in dcSSc patients during follow-up.

**Methods:** We performed a survival analysis of the EUSTAR database including patients with dcSSc, fulfilling the ACR 1980<sup>2</sup> criteria, with baseline mRSS ≥ 7 in 2009 or later, valid mRSS at 12±3 months after baseline and ≥ 1 available annual follow-up visit. Progressive skin fibrosis was defined as an increase in mRSS >5 units and ≥25% from baseline to 12±3 months later. Disease outcome was defined as occurrence of one of the following new events during follow-up based on expert group consensus: relative decrease in forced vital capacity (FVC) ≥10%; left ventricular ejection fraction (LVEF) <45% or relative decrease in LVEF >10% for patients with baseline LVEF <45%; pulmonary hypertension globally judged on echocardiography by the treating physician; renal crisis; all-cause death. The association between skin progression and disease outcomes over follow-up was evaluated by Kaplan–Meier analysis, log-rank test and multivariate Cox regression. Multiple imputation was used to handle missing values.

**Results:** Among 1021 eligible dcSSc patients, 78 (7.6%) had progressive skin fibrosis within 1 year (defined as progressors). The median follow-up period was 3.4 years. Survival analyses indicated that skin progressors had a significantly higher probability of FVC decline ≥10% (53.6% vs 34.4%; p<0.001) and all-cause death (15.4% vs 7.3%; p=0.003) than non-progressors (figure 1). These significant associations between skin progression and FVC decline and all-cause death were also observed in the subgroup of patients with either baseline mRSS ≤22/51 or disease duration ≤15 months. Multivariate Cox regression confirmed that skin progression was independently associated with FVC decline ≥10% (HR 1.79, 95% CI 1.20 to 2.65) and all-cause death (HR 2.58, 95% CI 1.31 to 5.09).

Abstract SAT0513 – Figure 1. Kaplan-Meier survival plots for A) pulmonary progression and B) all-cause death during follow-up for skin progressors and non-progressors

**Conclusions:** In patients with dcSSc, progressive skin fibrosis within 1 year is associated with a decline in lung function and worse survival over follow-up. This evidence-based finding is helpful for cohort enrichment in clinical trials for both skin and lung fibrosis, and for risk stratification in clinical practice.

#### SAT0514 MRI – GUIDED THERAPY FOR SYSTEMIC SCLEROSIS ASSOCIATED MYOSITIS

Y. Braun-Moscovici<sup>1</sup>, D. Militianu<sup>2</sup>, N. Puchkov<sup>2</sup>, D. Markovits<sup>1</sup>, M. Braun<sup>3</sup>, M. A. Nahir<sup>1</sup>, A. Balbir-Gurman<sup>1</sup>. <sup>1</sup>Rheumatology department, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion; <sup>2</sup>Department of Medical Imaging, Rambam Health Care Campus, Rappaport Faculty of Medicine, Technion, Haifa; <sup>3</sup>Liver Institute, Beilinson Hospital, Sackler School of Medicine, Tel Aviv University, Petach Tikva, Israel

**Background:** Muscle involvement in systemic sclerosis (SSc) has a significant impact on morbidity, functional capacity, and mortality. The muscle histopathology is heterogeneous including inflammatory and fibrotic changes. Currently there are no satisfactory means to diagnose inflammatory myopathy in SSc pts with normal creatine kinase (CK) and to assess the response to therapy.

**Objectives:** Our aim was to evaluate whether muscle magnetic resonance imaging (MRI) might be a tool to diagnose inflammatory myopathy in SSc patients (pts) and to assess the effect of muscle oriented- immunomodulatory therapy.

**Methods:** We retrospectively analysed the clinical data of 290 consecutive SSc pts seen at our centre between the years 2012–2017. Our cohort is part of the EUSTAR registry (centre 042). Pts with muscle weakness as defined by the Medsger muscle severity score of  $\geq 1$  and at least one MRI study were included. Clinical data analysis included SSc subtype, disease duration, modified Rodnan skin score (mRSS), Medsger muscle severity score, CK, autoantibody profile, MRI and immunomodulatory treatment.

**Results:** 26 pts with muscle weakness answered the criteria of Medsger muscle severity score of  $\geq 1$  MRI data were available, in 17 of the pts. Muscle oedema and fasciitis were seen in MRI in 13 pts (10 diffuse subset, median: age 40, disease duration 1.25 years, mRSS 13.5). MRI was normal in 4 pts (2 diffuse SSc, median: age 50 years, disease duration 6 years, mRSS 4). CK was normal in 10 pts with pathologic MRI. Anti-topoisomerase was positive in 6 pts, RNA polymerase 3 – in 3 pts, anti-centromere – in 2 pts and 6 pts were only ANA positive. Muscle biopsy results were available in 4 pts: Biopsy was compatible with myositis in 3 pts with pathologic MRI and revealed fibrosis in 1 pt with normal MRI. 14 pts received immunomodulatory treatment: rituximab (3 pts), rituximab and intravenous immunoglobulins (IVIG) (3 pts), IVIG and methotrexate/azathioprine/mycophenolate mofetil.<sup>8</sup> A second MRI was performed in 6 pts with first pathologic MRI, after 12 months of treatment. Significant regression of muscle oedema and per fasciitis was observed in 5 pts and correlated with clinical amelioration, with improvement of muscle strength. No clinical and imaging improvement occurred in one patient, despite the treatment. No change in muscle strength was seen in the patient with normal MRI and evidence of fibrosis on muscle biopsy, although the skin score improved.

**Conclusions:** MRI might serve as a non-invasive tool for diagnosis of inflammatory myopathy in SSc pts with early disease, Medsger muscle severity score of  $\geq 1$  and normal CK and for assessment of treatment efficacy.

**Disclosure of Interest:** None declared

Sato<sup>9</sup>, M. Kuwana<sup>10</sup> on behalf of JAMI investigators. <sup>1</sup>Division of Rheumatology, Department of Internal Medicine, Keio University School of Medicine; <sup>2</sup>Department of Rheumatic Diseases, Tokyo Metropolitan Tama Medical Center, Tokyo; <sup>3</sup>Department of Endocrinology, Metabolism, Nephrology and Rheumatology, Kochi Medical School Hospital, Kochi; <sup>4</sup>Department of Environmental Immuno-Dermatology, Yokohama City University Graduate School of Medicine, Kanagawa; <sup>5</sup>Department of Allergy and Rheumatology, Nippon Medical School Graduate School of Medicine, Tokyo; <sup>6</sup>Department of Anesthesiology, National Defense Medical College School of Medicine, Saitama; <sup>7</sup>Department of Immunology and Rheumatology, Nagasaki University Graduate School of Biomedical Sciences, Nagasaki; <sup>8</sup>Institute of Rheumatology, Tokyo Women's Medical University, Tokyo; <sup>9</sup>Division of Rheumatology, Department of Internal Medicine, Tokai University School of Medicine, Kanagawa, Japan

**Background:** Cancer-associated myositis (CAM) is believed to be rarely complicated by interstitial lung disease (ILD), and, thus, detailed clinical characteristics of CAM in patients with polymyositis (PM)/dermatomyositis (DM)-associated ILD are not well known.

**Objectives:** To clarify the incidence, risk factors, and impact on survival of malignancy in patients with PM/DM-associated ILD, using a large cohort data.

**Methods:** We used 497 patients with PM/DM-associated ILD enrolled in a multi-centre retrospective cohort of incident cases from 44 institutions across Japan (JAMI). CAM was defined as malignancy diagnosed within 3 years before or after PM/DM diagnosis. Demographic data and clinical characteristics were recorded at the time of diagnosis, and follow-up survival and malignancy data were collected prospectively.

**Results:** Thirty-two patients with CAM (6.4%) were identified. Patients in the CAM group were older (64.3 vs 55.1 years,  $p < 0.001$ ), had shorter disease duration at onset (4.1 vs 7.0 months,  $p = 0.01$ ), and presented with arthritis less frequently (24.1 vs 48.5%,  $p = 0.01$ ), in comparison with those with non-CAM group. All patients with CAM were older than 40 years, and the proportion of CAM increased along with the age. Patients who were  $\geq 59$  years at diagnosis and lacked arthritis were at 12 times higher risk for concomitant malignancy than those without such features (figure 1). Frequencies of autoantibodies, including anti-MDA5, anti-ARS, and anti-TIF1gamma, were not different between the groups. In 19 patients (59%), malignancy was diagnosed within 3 months before or after PM/DM diagnosis. Eleven CAM patients were died, and cause of deaths included ILD in 6 and malignancy in 5. Survival analysis by Kaplan-Meier method demonstrated that CAM patients had a poorer survival than did non-CAM patients ( $p = 0.016$ ).

**Conclusions:** In patients with PM/DM-associated ILD, older age at diagnosis and lack of arthritis are predictors for concomitant malignancy, which leads to a reduced survival.

#### Vasculitis

#### SAT0516 TWO DISTINCT SUBSETS OF LOW DENSITY GRANULOCYTES IN ANCA ASSOCIATED VASCULITIS

A. Endo, Y. Komagata, K. Yamagishi, N. Ikegaya, K. Fukuoka, M. Karube, Y. Arimura, S. Kaname. Division of Nephrology and Rheumatology, First Department of Internal Medicine, Kyorin University School of Medicine, Tokyo, Japan

**Background:** Low density granulocyte (LDG), a proinflammatory population of neutrophils, was first described in systemic lupus erythematosus (SLE) and has

been shown to contribute to lupus pathogenesis. It has been suggested that LDGs have a pathogenic role in ANCA associated vasculitis (AAV) based on the data of gene expression signature in AAV and the ability of excessive neutrophil extracellular traps (NETs) formation by LDGs in AAV. However, more detailed analysis of LDG in AAV patients has not been reported.

**Objectives:** In this study we investigated the characteristics of LDG in AAV patients using flow cytometry and proteomics approach and examined the correlations with disease activity.

**Methods:** We examined the presence of LDGs in peripheral blood of 10 AAV patients before treatment and followed them for 4 months with immunosuppressive therapy. Normal-density granulocytes (NDGs) were isolated by dextran sedimentation and PBMCs were isolated by Ficoll gradient. LDGs were assessed using cell surface expression of CD14 and CD15 by flow cytometry and isolated by magnetic bead procedure from PBMCs. We performed comparative proteomic analysis among LDGs and autologous NDGs and healthy controls (HC)-NDGs.

**Results:** LDG frequencies were 9.8-fold higher in AAV patients before treatment relative to HC. There were two distinct populations of LDGs showing different cell surface expressions of CD10, CD14, and CD15 in AAV patients. One population of LDGs was mainly CD10 positive and another one was CD10 negative. Although the frequency of CD10 positive-LDG decreased along with decrease of disease activity, the frequency of CD10 negative-LDG increased in 4 months (17.9-fold higher than before treatment). Comparative proteomic analysis revealed these two populations of LDGs were distinct from each other and had common differences from autologous NDGs and HC-NDGs.

LDG frequencies were 9.8-fold higher in AAV patients before treatment relative to HC. There were two distinct populations of LDGs showing different cell surface expressions of CD10, CD14, and CD15 in AAV patients. One population of LDGs was mainly CD10 positive and another one was CD10 negative. Although the frequency of CD10 positive-LDG decreased along with decrease of disease activity, the frequency of CD10 negative-LDG increased in 4 months (17.9-fold higher than before treatment). Comparative proteomic analysis revealed these two populations of LDGs were distinct from each other and had common differences from autologous NDGs and HC-NDGs.

**Conclusions:** We identified two distinct subsets of LDGs in AAV. It is possible that they play different roles in the pathogenesis of AAV.

SAT0517

#### GENDER DIFFERENCES INFLUENCES CLINICAL PRESENTATION AND VASCULAR PATTERN IN PATIENTS WITH TAKAYASU ARTERITIS: AN ITALIAN MONOCENTRIC STUDY

*A. Tomelleri, C. Campochiaro, S. Sartorelli, A. Cariddi, G. Cavalli, E. Baldissera, L. Dagna. Unit of Rheumatology, Immunology, Allergy and Rare Diseases (UnIRAR), San Raffaele Scientific Institute, Milan, Italy*

**Background:** Takayasu arteritis (TA) is a large-vessel vasculitis affecting aorta and its major branches<sup>1</sup>. Vascular inflammation may cause luminal narrowing, occlusion or aneurysms<sup>2</sup>. TA affects more frequently young women, but occurrence in patients >40 years is not rare. Female:male ratio is 9:1<sup>3</sup>

**Objectives:** To compare age at disease onset, age at diagnosis and diagnostic delay between male and female Italian TA patients from our cohort. To compare symptoms presentation and vascular involvement

**Methods:** Data from 10 male and 104 female TA patients (fulfilling ACR criteria) from our tertiary centre were retrospectively collected. Age at diagnosis, age at first symptom onset, diagnostic delay, signs and symptoms subsequently attributed to TA, and arteries involved before the diagnosis were compared. Non-parametric statistical tests were used

**Results:** In male patients mean age at diagnosis was 33.5±14.64 years and mean age at onset was 25.8±13.01 years. In female patients mean age at diagnosis was 36.26±12.6 years and mean age at onset was 31±13.1 years. The differences not being statistically significant. The highest percentage of male patients disease onset was <18 years (40%), in female patients it was between 18–40 years (61.5%). Mean diagnostic delay was 92.9±80.78 months in male and 63.03

±85.63 in female patients (p=0.050). Features at disease onset are summarised in table 1. Frequency of limbs claudication was not significantly different in the two groups (50% vs 56.7%), 10% of male patients had upper limbs claudication, compared to 43.3% of female patients, p=0.047. Arterial hypertension was more frequent in male patients (70% vs 35.6%, p=0.044). Acute coronary syndrome was more frequent in male patients (30% vs 5.8%, p=0.031). Frequency of cardiovascular risk was not significantly different in the two groups (40% vs 32.7%). Coronary angiography was more frequently performed in male patients (30% vs 2.9%, p=0.009). At disease onset, compared to female patients, male patients coronary (30% vs 6.7%, p=0.042), iliac (50% vs 15.4%, p=0.018) and femoral arteries (40% vs 6.6%, p=0.008) were more frequently involved. In female patients subclavian arteries were more frequently involved (72% vs 40%, p=0.066).

Signs/symptoms	N°male patients (%)	N°female patients (%)	P-value
Constitutional symptoms	5 (50)	61 (58.7)	0.740
Arthralgias	3 (30)	28 (26.9)	1
Carotidynia	1 (10)	25 (24.0)	0.451
Syncope/vertigo	2 (20)	22 (21.2)	1
Neurological signs	1 (10)	8 (7.7)	0.576
Overall limbs claudication	5 (50)	59 (56.7)	0.746
Upper limbs claudication	1 (10)	45 (43.3)	<b>0.047*</b>
Lower limbs claudication	5 (50)	25 (24.0)	0.125
Arterial hypertension	7 (70)	37 (35.6)	<b>0.044*</b>
Discrepancy in BP	1 (10)	29 (27.9)	0.287
Reduced/absent pulses	3 (30)	46 (44.2)	0.511
Vascular bruits	4 (40)	32 (30.8)	0.723
Angina abdominis	0 (0)	16 (15.4)	0.353
Chest pain	3 (30)	9 (8.7)	0.071
Acute coronary syndrome	3 (30)	6 (5.8)	<b>0.031*</b>
Serositis	0 (0)	7 (6.7)	1

**Conclusions:** Male patients with TA have more frequent involvement of the coronary arteries and of the iliac and femoral arteries. As a consequence, they suffer more frequently acute coronary syndrome and lower limbs claudication. Besides, they have more frequently arterial hypertension

SAT0518

#### THE ROLE OF LEFLUNOMIDE IN THE TREATMENT OF GIANT CELL ARTERITIS

*A. Hocevar, R. Ješe, Ž. Rotar, M. Tomšič. Dpt. of Rheumatology, University Medical Center Ljubljana, Ljubljana, Slovenia*

**Background:** Glucocorticoids (GC) have been the mainstay treatment in giant cell arteritis (GCA) for decades. Recently tocilizumab and abatacept have been proven to be effective alternatives to glucocorticoids. However, not all GCA patients are eligible for a biologics.

**Objectives:** We aimed to evaluate the role of leflunomide (LEF) as a steroid sparing agent in GCA.

**Methods:** This prospective observational study included newly diagnosed GCA patients followed at least 48 weeks at a single secondary/tertiary rheumatology centre.

Patients were treated with GC in line with the EULAR recommendations.<sup>1</sup> In short, patients with uncomplicated GCA initially received oral methylprednisolone (MP) 32–48 mg qd, while those with ischaemic complications or large vessel disease first received MP 250 mg on 3 consecutive days intravenously, followed by oral MP. MP tapering was started 2–4 weeks after treatment initiation slowly to 4 mg qd which was continued for at least 6 months. At week 12, LEF 10 mg qd was recommended as an add-on therapy to those GCA patients without contraindications for it. The final decision to add LEF was patient dependent. Follow-up visits with predetermined clinical and laboratory tests were performed 4, 12, 24, 48, 96 and 144 weeks after diagnosis. In patients who relapsed during the MP tapering unscheduled visits were arranged and treatment was adjusted (GC dose was

increased and LEF 10 mg or LEF dose increase to 20 mg or alternative steroid sparing agent in case of LEF ineffectiveness recommended). The number of relapses and a cumulative GC dose during follow-up were recorded.

**Results:** Between July 2014 and December 2016 we identified 76 (65.8% female, median (IQR) age 73.7 (66.1–78.8) years) new GCA cases with a follow-up of at least 48 weeks (median (IQR) 75<sup>51–104</sup> weeks). 30/76 patients (39.5%) received LEF at W12 ("LEF" group), the others continued with GC only. During the follow-up 22 patients relapsed, 4 in "LEF" group (13.3%) and 18 (39.1%) in "GC only" group. The difference was statistically significant ( $p=0.02$ ; NNT 3.9 (95%CI 2.2–17.4)). Furthermore, 17/30 GCA cases (56.7%) in "LEF" group managed to stop GC at W48 (with 1 relapse (5.9%) shortly afterwards), but none in GC only group. Patients tolerated LEF relatively well. Adverse events (AEs) were usually mild. 8/30 patients (26.7%) discontinued LEF (1 due to ineffectiveness and 7 due to one/more AEs – hair loss developed in 4/7 cases, diarrhoea in 2/7 patients, weight loss in 2/7 cases, and elevated transaminases in 1/7). The occurrence of infections requiring antibiotics and/or hospital admission was lower in LEF group compared to "GC only" group (10% vs. 26.5%).

**Conclusions:** We found in our prospective observational study in GCA a steroid sparing action and a rather good tolerability of LEF.

SAT0519

### INTERSTITIAL LUNG DISEASE IN ANCA-ASSOCIATED VASCULITIS PATIENTS: COMPARISON WITH IDIOPATHIC PULMONARY FIBROSIS AND INTERSTITIAL PNEUMONIA WITH AUTOIMMUNE FEATURES

A. Abri<sup>1</sup>, M. Kwon<sup>2</sup>, C. Rojas<sup>3</sup>, A. Khoo<sup>4</sup>, I. Mira-Avendano<sup>2</sup>. <sup>1</sup>Rheumatology; <sup>2</sup>Pulmonary medicine; <sup>3</sup>Radiology; <sup>4</sup>Pathology, Mayo Clinic, Jacksonville, FL, USA

**Background:** Patients with ANCA-positive vasculitis may develop interstitial lung disease (ILD), it is an uncommon but increasingly recognised manifestation. Clinical characteristics and prognosis are not well known in these patients. The largest report to date is from East Asia describing microscopic polyangiitis (MPA) as the most common association with ILD.

**Objectives:** To describe the clinical manifestations and response to therapy of patients with AAV and ILD compared with patients with idiopathic pulmonary fibrosis (IPF) and interstitial pneumonia with autoimmune features (IPAF)

**Methods:** We conducted a retrospective 10 year chart review at the Mayo Clinic Florida, including patients with confirmed diagnoses of both AAV and ILD done by expert rheumatology and pulmonology clinical evaluations. Clinical characteristics of ANCA-ILD in 24 patients were compared to 29 patients with idiopathic pulmonary fibrosis (IPF) and 22 patients with interstitial pneumonia with autoimmune features (IPAF), which were confirmed by applying the IPF diagnostic criteria based on the most recent ATS guidelines and IPAF criteria defined by Fischer and colleagues, respectively.

**Results:** We identified 24 ANCA-ILD patients. 14 patients had MPA, 12 patients had granulomatosis with polyangiitis (GPA), and 2 patients had eosinophilic granulomatosis with polyangiitis (EGPA). 54% were female and mean age was 70. In half of the ANCA-ILD patients, vasculitis presented prior to ILD, mainly MPA, 36% of patients presented with ILD first, most of them with GPA. The rest presented with ILD and vasculitis at the same time. Usual interstitial pneumonia (UIP) was the most common radiographic pattern. Honeycombing was more common in MPA compared to GPA patients. Ground glass opacity was present in 5 (63%) of GPA and in 5 (36%) of MPA patients. Most MPA patients had positive anti-MPO antibody and p-ANCA. Only one GPA patient had positive anti-MPO antibody and two were p-ANCA positive. The majority of the GPA patients were positive for anti-proteinase-3 antibody and c-ANCA. The mainstay of treatment was corticosteroids. Rituximab was used in 14 patients. The decline in functional vital capacity (FVC) and diffusing capacity (DLCO) was most marked in IPF group, followed by ANCA-ILD and then the IPAF group ( $\Delta$  FVC,  $-0.5$ ,  $-0.5$ , and  $0.3$  L/s;  $\Delta$  DLCO,  $-3.7$ ,  $-3.6$ , and  $-0.1$ , respectively). In a similar manner, survival was poorest in IPF, followed by ANCA-ILD and was best in the IPAF group.

**Conclusions:** This is, to our knowledge, the largest case series of clinically confirmed AAV with ILD in North America. Sizable number of GPA with c-ANCA positive patients presenting concomitant ILD is a novel observation for the clinical characteristics of ANCA-ILD that contradicts previous epidemiology of ANCA-ILD. Our data is also of value by adding prognostic information in an era of newer therapeutics, such as rituximab. In addition, the intermediate prognosis of ANCA-ILD, between IPF and IPAF, is very interesting especially after the new classification IPAF.

**Objectives:** To assess the efficacy of Tocilizumab (TCZ) in refractory uveitis associated to extraocular manifestations due to Behçet's disease (BD).

**Methods:** Multicenter study of patients with BD refractory to standard systemic treatment (conventional immunosuppressive drugs and/or anti-TNF- $\alpha$  agents).

**Results:** We studied 11 patients (7 men/4 women) (20 affected eyes); mean age 38.4 $\pm$ 20.4 years. Uveitis was bilateral in 9 patients. The pattern of ocular involvement was: panuveitis (n=8; with retinal vasculitis in 4), anterior uveitis (n=2) and posterior uveitis (n=1). Cystoid macular oedema (CME) was present in 7 patients. The clinical course was recurrent (n=7) or chronic (n=4). Apart from the visual complications, at TCZ onset the following extraocular manifestations were present: oral and/or genital ulcers (n=7), arthritis (n=4), folliculitis/pseudofolliculitis (n=4), erythema nodosum (n=2), livedo reticularis (n=1), intestinal affection (n=1), and neurological involvement (n=2).

Before TCZ, they had received systemic corticosteroids, conventional immunosuppressive drugs and biologic agents, adalimumab (n=8), infliximab (n=4), golimumab (n=3), canakinumab (n=1), or etanercept (n=1). TCZ was used in monotherapy or combined with conventional immunosuppressive drugs at 8 mg/kg/iv/4 weeks (n=10) or 162 mg/sc/week (n=1). TCZ yielded rapid and maintained improvement in all ocular parameters (TABLE). After a mean follow-up of 9.5 $\pm$ 8.05 months using TCZ, all patients experienced ocular improvement, with complete remission in 8 of them. However, TCZ was only effective in 3 of the patients with extraocular manifestations. This biologic agent had to be withdrawn in 2 cases, 1 due to a severe infusion reaction and 1 due to arthritis impairment.

**Abstract SAT0520 – Table 1.** Epidemiological and clinical characteristic of the sample.

Case	Sex / Age (years)	Ocular pattern and course	Extraocular manifestations	Extraocular manifestations with no response to TCZ
1	Male/27	Anterior posterior uveitis + unilateral CME	Oral ulcers, arthropathy, white nodules (nodules on skin, ankles, elbows)	---
2	Female/32	Anterior uveitis + unilateral CME	Oral and genital ulcers, erythema nodosum	Oral and genital ulcers, erythema nodosum
3	Male /33	Anterior uveitis/papillitis + unilateral CME	Psoriasis, arthritis	---
4	Male /38	Anterior uveitis + retinal vasculitis	Oral ulcers, skin ulcers	Oral ulcers, skin ulcers
5	Female/37	Anterior uveitis + retinal vasculitis + bilateral CME	Oral ulcers	Arthropathy
6	Male /33	Anterior uveitis + retinal vasculitis + unilateral CME	Oral ulcers, skin ulcers, folliculitis	Oral and genital ulcers, folliculitis
7	Female/22	Anterior uveitis + bilateral CME	None	---
8	Male /39	Anterior uveitis + retinal vasculitis + unilateral CME	Oral and genital ulcers, white, skin ulcers	Oral and genital ulcers, skin ulcers
9	Male /30	Anterior uveitis	Oral and genital ulcers, hemorrhagic stroke, erythema nodosum	Hemorrhagic stroke
10	Female/41	Anterior uveitis	Oral and genital ulcers, arthritis, erythema nodosum, arthropathy, erythema nodosum, arthropathy	Oral and genital ulcers, arthritis, erythema nodosum, arthropathy
11	Male /38	Anterior uveitis	Oral ulcers, arthritis	Oral ulcers, arthritis

Abbreviations: CME, cystoid macular oedema; MRI, magnetic resonance imaging; TCZ, tocilizumab.

#### Abbreviations:

CME, cystoid macular oedema; MRI, magnetic resonance imaging; TCZ, tocilizumab.

**Conclusions:** TCZ appears to be useful in highly refractory BD-related uveitis. However, there are controversial results regarding its efficacy in the treatment of extraocular manifestations of BD.

SAT0521

**A PROSPECTIVE OBSERVATIONAL STUDY ON THE SAFETY AND EFFICACY OF INFliximab-BIOSIMILAR IN PATIENTS WITH TAKAYASU'S ARTERITIS (TAKASIM): PRELIMINARY DATA**

C. Campochiaro, A. Tomelleri, S. Sartorelli, C. Sembenini, G. Cavalli, E. Baldissera, L. Dagna. *Unit of Rheumatology, Immunology, Allergy and Rare Diseases (UnIRAR), San Raffaele Scientific Institute, Milan, Italy*

**Background:** Takayasu arteritis (TA) is a large-vessel vasculitis<sup>1</sup>. Treatment is mainly based on steroids, but in approximately 50% of patients a disease-modifying antirheumatic drug (DMARD) is required<sup>2</sup>. Anti-TNF $\alpha$  agents are recommended for steroid tapering despite DMARDs<sup>3</sup>. Infliximab-originate (IFX-O) is a chimeric monoclonal antibody against TNF $\alpha$  effective in TA patients. Infliximab-biosimilar (IFX-B) is an immunoglobulin-G1 chimeric human-murine monoclonal antibody biosimilar to IFX-O.

**Objectives:** To assess safety and efficacy of IFN-B in TA patients requiring anti-TNF $\alpha$  therapy.

**Methods:** 30 TA patients, diagnosed according to ACR criteria at our tertiary centre, will be recruited from our cohort. Both biological therapy-naïve and IFX-O treated patients will be eligible. Disease activity will be assessed 6-monthly by means of magnetic resonance angiography (MRA) and 18 F-fluorodeoxyglucose (FDG) PET/CT. ITAS2010 and ITAS-ESR/CRP will be obtained 6-monthly. Baseline was defined as the time of IFX-B start. Non parametric statistical tests were used.

**Results:** At January 2018, 19 patients (18 female, 1 male) were included. 12 patients have been on IFX-B for at least 6 months. Median age at baseline was 45 years (range 25–70). At recruitment median disease duration was 52 months (range 24–180), all patients were on IFX-O. Median time on IFX-O at baseline was 35 months (range 14–150). 3 patients had been previously treated with other biologics: tocilizumab,<sup>1</sup> adalimumab.<sup>1</sup> 18/19 patients (94.7%) were on concomitant steroid therapy (mean dose 5 $\pm$ 1.8 mg). It was significantly reduced to a mean dose of 4 $\pm$ 1.7 mg (p=0.043) at month 6. 15/19 patients (78.9%) were also on DMARDs, kept unchanged throughout treatment. 1 patient on IFX-B was switched to a different therapy because of poor disease control with both IFX-O and IFX-B. Mean IFX-B dose at baseline was 6.92 $\pm$ 1.76 mg/kg. Mean IFX-B dose at month 6 was 7.42 $\pm$ 2.19 mg/kg. IFX-B dose was increased in 5 patients. Mean time interval between IFX-B infusions was kept unchanged (5.79 $\pm$ 0.63 weeks). Mean CRP and ESR were 3.28 $\pm$ 2.64 mg/L and 19.68 $\pm$ 9.94 mm/1 hour at baseline and 3.4 $\pm$ 3.12 mg/L and 20.53 $\pm$ 14.06 mm/1 hour at month 6, the difference not being statistically significant. Mean ITAS2010 and ITAS-ESR/CRP were 7.6, 8.2 and 8 at baseline and 6.1, 6.8 and 6.3 at month 6, the difference not being statistically significant. At month 6 PET/CT showed no disease progression in all patients and MRA disclosed disease stability in 8/12 (66.7%), progression in 3/12 (25%) and improvement in 1 (8.3%) patient. No patient experienced side effects during infusion. 11/19 patients (57.9%) experienced low-grade side effects related to TNF $\alpha$  blockade. 6 patients experienced upper airway infection, 3 herpes simplex reactivation, 1 viral gastroenteritis, 1 vaginal candidiasis. No modification of IFX-B therapy was required.

**Conclusions:** Our preliminary data suggest that IFX-B is as effective and safe as IFX-O in TA patients.

SAT0522

**VASCULAR AND JOINT INFLAMMATION ARE NEGATIVELY CORRELATED IN PATIENTS WITH POLYMYALGIA RHEUMATICA, GIANT CELL ARTERITIS AND FEVER OF UNKNOWN ORIGIN**

D. Camellino<sup>1,2</sup>, M. Bauckneht<sup>3</sup>, S. Morbelli<sup>4</sup>, M. Marchiano<sup>2</sup>, G. Pesce<sup>2</sup>, D. Saverino<sup>2</sup>, M. Bagnasco<sup>2</sup>, M.A. Cimmino<sup>5</sup>. <sup>1</sup>Division of Rheumatology, Musculoskeletal System Department, Azienda Sanitaria Locale 3 Genovese, Arenzano; <sup>2</sup>Autoimmunology Laboratory, Department of Internal Medicine; <sup>3</sup>Nuclear Medicine Division, Department of Health Sciences; <sup>4</sup>University of Genoa, Genoa, Italy; <sup>5</sup>Rheumatology Clinic, Department of Internal Medicine, University of Genoa, Genoa, Italy

**Background:** 18 F-Fluorodeoxyglucose positron emission tomography (PET) reveals the presence of large vessel vasculitis (LVV) in 30%–40% of patients with apparently isolated polymyalgia rheumatica (PMR), in 70%–80% of patient with giant cell arteritis<sup>1</sup> and in about 20% of patient with fever of unknown origin (FUO)<sup>2</sup>, suggesting that these conditions may be different clinical manifestations of the same entity.

**Objectives:** To evaluate and compare the patterns of vascular and joint uptake in patients with PMR, GCA, and FUO.

**Methods:** Consecutive patients with a diagnosis of PMR, GCA or FUO underwent a thorough clinical examination and a PET/CT scan. Arterial and joint uptake of FDG were scored relative to liver uptake with a 4-point scale. The values of each district examined were summed to obtain a total vascular score (TVS) and a total joint score (TJS). A semi-quantitative analysis of FDG uptake was carried out. Arterial FDG uptake was quantified by calculating the mean standardised uptake value (SUV) within each region of interest (ROI) and the results expressed as the ratio between mean SUV value of each ROI and the blood-pool (SUV/BP). To assess joint metabolism, CT-based ROIs were bilaterally drawn on joint and bursal spaces.

**Results:** One hundred and thirty-one patients were included, 89 females and 42 males, with a median age of 74 years (range 47–92). Ninety-seven patients were diagnosed as PMR, 13 as GCA, 16 with both PMR and GCA and 5 patients presented with FUO. FUO patients showed a higher mean arterial SUV in comparison to PMR (0.77 vs. 1.15, p=0.004) and GCA patients (0.81 vs 1.15, p=0.052). Similar and more striking results were obtained using visual scoring. FUO patients showed always increased uptake in the large vessels. PMR patients showed statistically lower TVS than GCA +PMR, GCA and FUO patients. Patients with PMR showed a statistically significant higher mean joint SUV than GCA patients (p=0.01). The highest mean articular uptake was shown by PMR patients and the lowest by FUO patients. Mean TJS of PMR patients was significantly higher than that of GCA and FUO patients (p<0.001). TVS and TJS correlated negatively (p=0.01), as did mean vascular SUV and mean joint SUV (p=0.001).

**Conclusions:** Although patients with diseases different from PMR were few, our PET/CT study support the view that there is a continuum in the intensity of inflammation, with FUO >GCA>PMR+GCA> PMR for vessels, and the opposite for joints. Vascular and joint inflammation were negatively correlated. Our data support the view that similarities exceed differences in these conditions, with clinical features depending from the relative contribution of vessel and joint involvement.

**Background:** Giant cell arteritis (GCA) is a large vessel vasculitis that has a special predilection for extracranial branches of the external carotid artery. Among its most fearsome complications is visual affectation. Tocilizumab (TCZ) is a monoclonal antibody directed against the interleukin 6 receptor that has shown utility in the treatment of GCA.

**Objectives:** Our aim was to assess the evolution of visual clinic in patients with GCA treated TCZ.

**Methods:** Retrospective multicentre study of 20 GCA patients with visual involvement treated with TCZ. The efficacy of this drug on visual symptoms was evaluated.

**Results:** We evaluated 20 patients (14 women and 6 men) with a mean age  $\pm$ SD of  $73.7 \pm 10.1$  years with GCA and visual symptoms. In total there were 23 affected eyes. The symptoms reported were: unilateral blindness (n=6), unilateral blurred vision (n=6), unilateral amaurosis fugax (n=3), unilateral hemianopsia (n=2), bilateral blindness (n=1), bilateral blurred vision (n=1), bilateral hemianopsia (n=1). Before starting treatment with TCZ all patients had received high doses of prednisone, with a mean  $\pm$ SD of  $54.2 \pm 13.8$  mg/day (range of doses: 40–80 mg/day). In addition, 9 of them also received intravenous corticosteroid boluses. In addition, 13 patients received traditional immunosuppressants: methotrexate (MTX) (n=12), cyclophosphamide (n=2), leflunomide (n=1) and azathioprine (n=1). Regardless of corticosteroids, TCZ was administered as monotherapy in 14 patients, while in 6 it was administered in combination with MTX. The TABLE shows the evolution of the visual affectation of these patients. Throughout a median follow-up [RIC] of 9<sup>4</sup>–18 months, none of the 7 patients who had a blindness regained vision. The 2 patients who presented unilateral hemianopsia recovered vision. The patient with bilateral hemianopsia and the patient with bilateral blurred vision experienced a partial improvement. The rest of the patients achieved a complete recovery.

	Month 1 n=20	Month 3 n=14	Month 6 n=10	Month 12 n=5
<b>Visual improvement after starting TCZ, n (%)</b>				
Complete improvement:	6 (30)	5 (35.7)	5 (50)	1 (25)
Partial improvement:	2 (10)	3 (21.4)	0 (0)	0 (0)
No improvement:	12 (60)	6 (42.8)	5 (50)	4 (75)

**Conclusions:** Although TCZ seems to be also useful in the treatment of visual manifestations of ACG, once blindness is established, it does not seem to be effective.

**Disclosure of Interest:** None declared

## THE ROLE OF POLYMORPHISMS OF HEMOSTASIS GENES IN VENOUS THROMBOEMBOLIC EVENTS IN ANCA-ASSOCIATED VASCULITIDES

E. Makarov<sup>1</sup>, N. Bulanov<sup>2</sup>, P. Novikov<sup>2</sup>, T. Krasnova<sup>1</sup>, A. Balatskiy<sup>3</sup>, L. Samokhodskaya<sup>3</sup>, S. Moiseev<sup>1</sup>. <sup>1</sup>Department of internal diseases, Lomonosov Moscow State University, E.M. Tareev Clinic Of Nephrology, Internal And Occupational Diseases; <sup>2</sup>Rheumatology department, I.M. Sechenov First Moscow State Medical University, E.M. Tareev Clinic Of Nephrology, Internal And Occupational Diseases; <sup>3</sup>Lomonosov Moscow State University, Medical Scientific And Educational Center, Moscow, Russian Federation

**Background:** The role of polymorphisms of hemostasis genes in venous thromboembolic events in ANCA-associated vasculitides.

**Objectives:** To evaluate the role of polymorphisms of hemostasis genes in the risk of VTEs in AAV patients and to the clinical features of AAV.

**Methods:** We studied 85 patients with AAV [69 with granulomatosis with polyangiitis (GPA), 11 with microscopic polyangiitis (MPA), 5 with eosinophilic granulomatosis with polyangiitis (EGPA)] diagnosed according to CHCC 2012 classification. There were 34 males and 51 females, aged of 55<sup>45;63</sup> years. Duration of follow-up was 74.0 (36.5;120.3) months. Coagulation genes polymorphisms MTHFR 677 C/T (rs1801133), FV 1691 G/A (rs6025), FII 20120 G/A (rs1799963), FGB 455 G/A (rs1800790), PAI-1 675 5G/4G (rs1799889), ITGA2 807 C/T (rs1126643), ITGB3 1565 T/C (rs5918), FVII 10976 G/A (rs6046), FXIII 103 G/T (rs5985) were evaluated by real time polymerase chain reaction. VTEs (deep vein thrombosis, pulmonary embolism) were identified by ultrasonography and chest computed tomography, respectively. We used score system, according to which the presence of each minor allele was assigned one point.

**Results:** We retrospectively detected 12 (14.1%) VTEs in 85 patients with AAV, including 5 (7.2%) in GPA, 4 (36.4%) in MPA and 3 (60.0%) in EGPA. There were no significant differences in the prevalence of alleles of the each gene in patients with and without VTE (figure 1). However, the combination of integrin A2 (ITGA2 807 C/T), plasminogen activator inhibitor-1 (PAI-1 675 5 G4G), fibrinogen (FGB 455 G/A) and FV<sup>FV 1691</sup> G/A) polymorphisms was associated with a significantly higher occurrence of VTE in patients with AAV (p=0.007) (table 1).

**Abstract SAT0524 – Table 1.** The prevalence of minor alleles of ITGA2 807 C/T, PAI-1 675 5G/4G, F5 1691 G/A, FGB 455 G/A in patients with and without VTE

Minor allele sum score	VTE (n=12)	No VTE (n=73)
0	0 (0%)	4 (5.5%)
1	1 (8.3%)	17 (23.3%)
2	3 (25.0%)	34 (46.6%)
3	8 (66.7%)	18 (24.7%)
4	0 (0%)	0 (0%)
Median sum score*	3.0 (2.0;3.0)*	2.0 (1.0;2.5)*

\*p=0.007

We observed a higher risk of lung involvement in carriers of methylenetetrahydrofolate reductase gene (MTHFR 677 C/T) polymorphism (p=0.007, OR 4.305 (95% CI 1.55 to 11.98), and an earlier AAV onset in patients with FXIII 103 G/T polymorphism (47.0 vs 50.0 years, p=0.049)

**Abstract SAT0524 – Figure 1.** Rates of minor alleles in patients with and without VTE

**Conclusions:** The combination of several genetic polymorphisms of hemostasis system is associated with an increased prevalence of VTE in AAV patients. The association between MTHFR 677 C/T and FXIII 103 G/T alleles and clinical features of AAV warrants further studies in the larger cohorts of patients.

### AN UPDATE ON PULMONARY ARTERY INVOLVEMENT IN BEHCET'S SYNDROME: MORE PULMONARY ARTERY THROMBOTIC DISEASE AND A BETTER OUTCOME

Y. Ozguler<sup>1</sup>, E. Dincses<sup>1</sup>, S. Bakan<sup>2</sup>, G. Hatemi<sup>1</sup>, M. Melikoglu<sup>1</sup>, S. Ugurlu<sup>1</sup>, S. Yurdakul<sup>1</sup>, H. Yazici<sup>1</sup>, E. Seyahi<sup>1</sup>. <sup>1</sup>Department of Internal Medicine Division of Rheumatology; <sup>2</sup>Department of Radiology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

**Background:** Pulmonary artery involvement (PAI) is the most common form of arterial involvement in Behçet's syndrome (BS) and is a well-known cause of mortality and morbidity. A previous survey<sup>1</sup> by our group had analysed the clinical characteristics and outcome of 47 pts with PAI registered between 2000–2007 and shown that: 1. the overwhelming male predominance was decreasing; 2. 1/4th of the pts had isolated pulmonary artery thrombosis (PAT); and 3. the mortality rate was 26% after a mean follow-up of 7 years. Recently we had the impression that female/male ratio was perhaps increasing, we are becoming to see more pts with isolated PAT and that we started to use more biologics.

**Objectives:** This survey was done to look at these assumptions formally in a recent group of BS pts with PAI.

**Methods:** We reviewed the records of about 3390 pts with BD who were registered at our multidisciplinary BS clinic between Jan 2008 and Jan 2018. From this group we identified 47 (42 M/5 F) pts who were diagnosed with PAI and recorded all information regarding clinical characteristics, outcome, radiological studies and medical or surgical treatment.

**Results:** The prevalence of pts with PAI decreased from 1.9% to 1.4% in the recent cohort. The M/F ratio, the mean age at the onset of PAI were similar across 2 cohorts. The frequencies of other vascular involvement were almost similar to that observed in the previous cohort. However, there were more pts with neurological disease (parenchymal) in the recent cohort. As usual, PAT or PAA were mostly bilateral and involved descending lobar arteries. On the other hand, types of PAI involvement at presentation had changed substantially: those with isolated PAT reached a share of 45%. Forty-five (96%) pts received cyclophosphamide (Cy) pulses for a mean of 6±4 courses, which was significantly shorter compared to that observed in the previous cohort. A total of 23 (49%) pts received infliximab because of relapsing course, side effects or unresponsiveness to Cy for a mean follow-up of 8±4 mo while only 2 pts received anti-TNF's in the older cohort. 4 pts had lung surgery. These were lobectomies in 3 pts due to giant rapidly progressing aneurysms and cavectomy in 1. Bronchial artery embolization was done in 3 pts because of refractory hemoptysis. By Jan 2018 the outcome of information was available on 45/47 pts: 4 pts (all male) (8%) had died, 2 were lost to follow-up after 12 and 16 mo of follow-up and the remaining were alive after a median follow-up of 5 [IQR:3–9] years. The causes of deaths were massive hemoptysis in 3, severe pulmonary hypertension in 1. As shown in the figure, the survival has improved significantly in the recent yrs.

**Conclusions:** The surveys of 2 consecutive cohorts showed that the prevalence of PAI perhaps mildly decreased, isolated PAT type of involvement was with considerably higher frequency and the outcome was getting better. Cy is still the first agent in these pts however its duration of use became much shorter and anti-TNF's mainly infliximab was used in about half of the cohort. The survival seems to have improved significantly. This could have been due to a decreased severity of the type of PAI, with isolated PAT becoming the most frequent type, or a better management.

**Objectives:** Corticosteroids (CS) are accepted as the standard first-line treatment for giant cell arteritis (GCA). However, controlled trials of tocilizumab and abatacept demonstrated relapse rates of up to 70%–80% in patients on CS-only protocols in 12–24 months. Though level of evidence is low and not suggested by guidelines (except for methotrexate), conventional immunosuppressives (ISs) are also commonly used. We aimed to assess the relapse rates in patients with GCA in routine practice, retrospectively.

**Methods:** We assembled a retrospective cohort of patients with GCA from Turkey. All data was abstracted from records. Relapse was defined as any new manifestation or increased acute-phase response leading to the change of the CS dose or use of a new therapeutic agent by the treating physician.

**Results:** The study included 156 (F/M: 95/61) patients with GCA (table 1). The mean age at disease onset was 67.8±9.1 years. Polymyalgia Rheumatica was also present in 48 (30.8%) patients. Diagnosis was proven histopathologically in 99 patients. All patients received 1 mg/kg/day CS for remission induction, additional CS pulses were given to 36 (23.1%) patients. Conventional ISs including methotrexate and azathioprine were used in 89 (56.1%) and 26 (16.6%) patients respectively, while 10 (6.4%) patients received biologic treatments (8 tocilizumab, 2 etanercept). Forty-four (28.2%) patients used only CS during follow-up. Follow-up of at least 6 months was available for 132 patients, and median follow-up duration was 35 (6–268) months. Relapses occurred in 27 (20.5%) patients during follow-up. Mortality rate was 7.5% (n=10) during follow-up. VDI score was 2.4±1.7. Main causes of damage were related to CS treatments such as cataract, osteoporosis and diabetes mellitus.

	Giant Cell Arteritis (n=156)
Manifestations of systemic inflammation, n/156 (%)	
Anemia (<12 mg/dl for female, <13 mg/dl for male)	94 (60.2%)
Erythrocyte Sedimentation Rate (mm/hour) *	84.6 ± 30.1
C-reactive protein (mg/l) *	84.8 ± 65.3
Malaise	132 (84.6%)
Weight loss	72 (46.1%)
Fever	35 (22.4%)
Stiffness and/or pain muscles and joints	48 (30.8%)
Manifestations of Vascular Ischemia, n /156 (%)	
Headache	144 (92.3%)
Scalp Tenderness	78 (50%)
Jaw Claudication	57 (36.5%)
Ocular Symptoms	72 (46.2%)
Extremity Claudication	14 (8.9%)
Neurological Manifestations	14 (9%)

**Conclusions:** In this first multi-centre series of GCA from Turkey, we observed that only one fifth of patients had relapses during a mean follow-up of 35 months. This lower relapse frequency suggests a different clinical spectrum in routine

practice compared to patients included in controlled trials. Our results also suggest that there is a clear need for a steroid sparing agent in patients with GCA, that is a older aged population prone to CS side effects.

SAT0527

### RITUXIMAB PRESCRIPTION PATTERNS AND EFFICACY IN THE INDUCTION TREATMENT OF ANCA-ASSOCIATED VASCULITIS IN A BELGIAN MULTICENTRIC COHORT

F. Vanderghyest<sup>1</sup>, P. Chasseur<sup>1</sup>, J.-B. Nicolas<sup>2</sup>, C. von Frenczell<sup>3</sup>, D. Blockmans<sup>4</sup>. <sup>1</sup>Internal Medicine, Erasme Hospital, Brussels; <sup>2</sup>Internal Medicine, CHU Mont-Godinne, Yvoir; <sup>3</sup>Rheumatology, CHU Sart-Tilman, Liège; <sup>4</sup>Internal Medicine, UZ Gasthuisberg, Leuven, Belgium

**Background:** The RAVE trial has revolutionised the induction treatment of ANCA-Associated Vasculitis (AAV, including GPA, granulomatosis with polyangiitis and MPA, microscopic polyangiitis), by demonstrating non-inferiority of rituximab compared with cyclophosphamide<sup>1</sup>.

**Objectives:** To study AAV patients' characteristics, rituximab prescription practices and efficacy in AAV induction treatment in 4 Belgian university hospitals. The patient population, selected according to the Belgian reimbursement criteria, is relatively homogeneous and comparable to the one of RAVE trial.

**Methods:** 57 patients, receiving rituximab as AAV induction therapy since May 2014, were enrolled in an observational retrospective multicenter trial involving 4 Belgian university hospitals. We have focused on the type of AAV (GPA/MPA), ANCA specificity (anti-PR3/MPO), prescriber's speciality, used reimbursement criteria, organ involvements, severity of the flares (according to BVAS-WG definition) and finally rituximab efficacy in AAV induction treatment by considering the RAVE primary (complete remission without prednisone) and secondary (complete remission with prednisone <10 mg, rates of relapses) outcomes at 6, 12, 18 and 24 months.

**Results:** The most frequent subtype of AAV was GPA (84%). The main indication was relapsing disease (54.4%), followed by contra-indication to cyclophosphamide (38.6%). 66.7% of the patients reached complete remission with prednisone <10 mg at 6 months, and 55.3% at 12 months, 40% at 18 months, 25% at 24 months respectively. In the "severe disease" subgroup, 73% reached complete remission with prednisone <10 mg at 6 months, 58.8% at 12 months, 50% at 18 months and 32% at 24 months. The rates of complete remission without steroids were very low at 6, 12, 18 and 24 months (between 0%–6%) but our patients were not asked to follow a glucocorticoid tapering scheduled for complete withdrawal of prednisone after 6 months and were usually maintained under low-dose prednisone. Relapse rates were high between 18 and 24 months both in the total group and in the severe disease subgroup (due to the fact that rituximab is not reimbursed for maintenance treatment in Belgium). The subtype of ANCA was not predictive of the risk of relapse.

**Conclusions:** Our results confirm – in a "real-life" cohort of patients selected according data of RAVE trial – those of RAVE regarding complete remission rates at 6 months with prednisone 10 mg/j. The high prevalence of relapses – in particular after 18 months – underlines the need to optimise maintenance treatment after an induction treatment with rituximab.

### EFFECTIVENESS OF REMISSION-INDUCTION THERAPY WITH CONCOMITANT CYCLOPHOSPHAMIDE AND GLUCOCORTICOID FOR MICROSCOPIC POLYANGIITIS AND GRANULOMATOSIS WITH POLYANGIITIS IN JAPAN: A PROPENSITY SCORE MATCHED ANALYSIS OF TWO NATIONWIDE PROSPECTIVE COHORT STUDIES

H. Watanabe<sup>1</sup>, K.-E. Sada<sup>1</sup>, Y. Matsumoto<sup>1</sup>, M. Harigai<sup>2,3</sup>, H. Makino<sup>4</sup> on behalf of Japan Research Committee of the Ministry of Health, Labour, and Welfare for Intractable Vasculitis (JPVAS). <sup>1</sup>Department of Nephrology, Rheumatology, Endocrinology and Metabolism, Okayama University Graduate School of Medicine, Dentistry and Pharmaceutical Sciences, Okayama; <sup>2</sup>Department of Pharmacovigilance, Graduate School of Medical and Dental Sciences, Tokyo Medical and Dental University; <sup>3</sup>Division of Epidemiology and Pharmacoepidemiology of Rheumatic Diseases, Institute of Rheumatology, Tokyo Women's Medical University, Tokyo; <sup>4</sup>Okayama university, Okayama, Japan

**Background:** Although concomitant use of cyclophosphamide (CYC) with glucocorticoids (GC) is considered to be one of the standard remission-induction therapies for antineutrophil cytoplasmic antibody (ANCA) associated vasculitis over 30 years, there are few reports about clinical efficacy or effectiveness of CYC.

**Objectives:** To evaluate effectiveness and safety of concomitant CYC as remission induction therapy in Japanese patients with microscopic polyangiitis (MPA) and granulomatosis with polyangiitis (GPA) using data sets from two nationwide prospective cohort studies.

**Methods:** Newly diagnosed MPA and GPA patients treated with GC with or without CYC for remission-induction therapy were enrolled. The patients treated with other immunosuppressants or plasma exchange were excluded. A propensity score for the use of CYC was estimated using age, types of AAV, serum creatinine level, Birmingham Vasculitis Activity Score (BVAS), and initial GC dosage at baseline. After propensity score matching at 1:1, remission, overall survival, and end-stage renal disease (ESRD)-free survival rates, Vasculitis Damage Index (VDI), and incidence of serious infection within 6 months were compared between patients treated with and without concomitant CYC.

**Results:** Of enrolled 327 patients, concomitant CYC was used in 119 (36%) patients during the initial 3 weeks of treatment. After propensity score matching, 95 patients with concomitant CYC (CYC group) and 95 controls (non-CYC group) were selected. Demographics, baseline characteristics and treatments were balanced between the two groups except for myeloperoxidase ANCA positivity (Table). The remission within 6 months was achieved in 85% in both groups. The survival and ESRD-free survival rates were also similar between the two groups (log-rank test;  $p=0.77$  and  $1.0$ , respectively). Median VDI at the time of last observation did not differ between the two groups (CYC, 3 [interquartile {IQR}: 2–4]; non-CYC, 2 [IQR:1–3],  $p=0.26$ ). The accumulated GC dosage of the CYC-group from 3 to 24 months was lower than the non-CYC group, the GC-related damage did not differ (CYC, 1 [IQR: 0–2]; non-CYC, 0 [IQR:0–2],  $p=0.69$ ).

**Table.** Comparison of patients treated with concomitant cyclophosphamide and with glucocorticoid alone

Variables at baseline and treatments	Cyclophosphamide users (n=95)	Non-users (n=95)	p-value
Male/female, n	51/44 (46%)	60/35	0.24
Age, years	70 (65–78)	71 (62–75)	0.92
GPA/MPA	26/69	27/68	1.0
Myeloperoxidase ANCA, n (%)	78 (82)	89 (94)	0.02*
Proteinase-3 ANCA, n (%)	17 (18)	8 (8)	0.15
Serum creatinine, mg/dL	1.2 (0.8–3.2)	1.1 (0.7–2.5)	0.39
C-reactive protein, mg/dL	7.5 (2.3–12.6)	7.2 (2.1–11.7)	0.35
BVAS	15 (12–20)	16 (12–21)	0.99
Interstitial lung disease, n (%)	38 (40)	37 (49)	0.55
Glucocorticoid (mg/kg/day) <sup>d</sup>	0.83 (0.72–0.97)	0.83 (0.67–0.99)	0.89

Values expressed as a number of patients (%) or median (interquartile). \* $p<0.05$ .

**Conclusions:** In Japanese patients with MPA and GPA, concomitant CYC could not show any benefits on clinical outcomes within 24 months. Dosage and treatment duration of CYC, as well as tapering methods of GC, could be confounding factors. Longer observation may be necessary to confirm the effectiveness of CYC as GC sparing agent.

SAT0529

**SHORT-TERM EFFICACY AND SAFETY OF BIOSIMILAR RITUXIMAB IN PATIENTS WITH SYSTEMIC VASCULITIDES**

I. Smitienko<sup>1</sup>, P. Novikov<sup>2</sup>, S. Moiseev<sup>2</sup>, A. Zykova<sup>3</sup>, T. Shevtsova<sup>3</sup>. <sup>1</sup>Medical center K+31; <sup>2</sup>Sechenov First Moscow State Medical University; <sup>3</sup>Lomonosov Moscow State University, Moscow, Russian Federation

**Objectives:** To study efficacy and safety of biosimilar (intended copy) rituximab (Acellbia, BIOCAD) in patients with systemic vasculitides.

**Methods:** We enrolled in our case series all consecutive patients with systemic vasculitides diagnosed according to CHCC2012 and ACR criteria (if applicable) who were treated with biosimilar rituximab since 2015. Activity of vasculitis was evaluated using BVAS3. CD19+ B-cells count was measured by standard method. Patients received intravenous rituximab at a 500 mg dose (four weekly infusions for remission induction or two weekly every 6 months infusions for maintenance treatment).

**Results:** In total, 45 patients were treated with biosimilar rituximab (29 GPA, 12 MPA, 1 EGPA, 2 cryoglobulemic vasculitis, 1 rheumatoid vasculitis). In 12 patients (7 GPA, 3 MPA, 1 CryoVas, 1 RheumVas), rituximab was administered for induction of remission due to high activity and relapsing course of vasculitis and low efficacy of previous treatment. 33 patients (22 GPA, 9 MPA, 1 EGPA, 1 CryoVas) received rituximab for maintenance of remission. Median duration of follow-up was 12 months.<sup>6-26</sup>

At 1 and 3 months, all patients achieved B-cell depletion. At 6 months, B-cell repopulation was shown in 9 patients (20%). Remission induction therapy with rituximab resulted in decrease of median BVAS from 16 10–24 to 1 (0–4) at 3 months and to 0 (0–2) at 6 months. At 3 and 6 months, median prednisone dose was tapered from 50 mg 35–80 to 25 mg 15–40 and 10 mg, 5–20 respectively.

In patients who received rituximab for maintenance treatment, median BVAS showed no disease activity (0–1) both at baseline and at 3 or 6 months. At baseline and at 3 months median doses of prednisolone were 5 mg (0–7.5) and 5 mg (0–5). At 6 months, it was reduced to 2.5 mg (0–5). Biosimilar rituximab had acceptable safety profile. Adverse events included mild infusion reaction,<sup>2</sup> urinary<sup>3</sup> and bronchopulmonary<sup>5</sup> infections which required intravenous antibiotics (median 4 months after infusions), hypogammaglobulinemia<sup>2</sup> that persisted for at least 12 months and 1 case of late-onset neutropenia in 8 months.

**Conclusions:** Biosimilar rituximab showed high efficacy and acceptable safety in patients with systemic vasculitides.

**CLINICAL FEATURES ASSOCIATION WITH HLA-B ALLELIC TYPES (B27, B51) IN KOREAN PATIENTS OF BEHCET'S DISEASE**

J.H. Kim, J.H. Jung, S.J. Choi, Y.H. Lee, J.D. Ji, G.G. Song. *Internal medicine, KOREA University Medical Center, Seoul, Korea, Republic Of*

**Background:** The recurrent oral ulcer frequently occur as a first clinical manifestation of Behcet's disease (BD), but BD is characterised by considerable phenotypic variation, comprising a myriad of manifestations, e.g. recurrent genital ulcers and skin, joint, eye, vascular and/or CNS involvement. BD is well known to be associated with HLA-B51 antigen. HLA B27 antigen is famous for association with spondyloarthritis. But BD is also observed in HLA B27 positive patients.

**Objectives:** The aim of this study was to clarify the clinical features association with HLA-B antigens (B27, B51) in Korean patients of Behcet's disease.

**Methods:** We genotyped HLA-B alleles in 433 patients who showed recurrent oral ulcer. The diagnosis of BD was determined according to revised international study group criteria. Among them, 126 patients of BD were included. The genotyping was performed using 66 sets of sequence specific DNA probe (PCR-SSP). The clinical feature was assessed according to HLA B allele in the patients diagnosed with BD.

**Results:** HLA-B51 allele frequency was more frequent in both 126 BD patients and 433 total patients and the frequency was 40 (31.7%) and 110 (25.4%) respectively. Among the HLA B51 +BD patients (n=40), similar gender ratio was observed (Male 52.5%, Female 47.5%) and clinical features of diagnostic criteria were dominant. Among the HLA B27 +BD patients (n=17), genital ulcer and skin lesions were dominant. HLA B27 +B51+BD patient was one and clinical features were genital ulcer, skin lesion and arthritis.

**Conclusions:** The specific clinical features of BD were observed in HLA-B51 +BD patients. In HLA B27 +BD patients, genital ulcer and skin lesions were

more observed. The study about clinical features associated with HLA-B allele (B27, B51) in spondyloarthritis patients is also needed.

Dasgupta<sup>8</sup>, J. Rech<sup>9</sup>, C. Salvarani<sup>10</sup>, H. Schulze-Koops<sup>11</sup>, G. Schett<sup>12</sup>, R. Spiera<sup>13</sup>, S.H. Unizony<sup>1</sup>, N. Collinson<sup>3</sup> on behalf of GiACTA Investigators. <sup>1</sup>Massachusetts Gen Hosp Rheumatol Unit, Harvard Med School, Boston; <sup>2</sup>Genentech, South San Francisco, USA; <sup>3</sup>Roche Products Ltd, Welwyn Garden City, UK; <sup>4</sup>Abteilung für Rheumatologie, Dresden, Germany; <sup>5</sup>University Hospitals Gasthuisberg, Leuven, Belgium; <sup>6</sup>University of Groningen, University Medical Center, Groningen, Netherlands; <sup>7</sup>University of Barcelona, Institut d'Investigacions Biomèdiques August Pi i Sunyer, Barcelona, Spain; <sup>8</sup>Southend University Hospital, NHS Foundation Trust, Westcliff-on-Sea, UK; <sup>9</sup>Friedrich-Alexander-U Erlangen-Nürnberg, Erlangen, Germany; <sup>10</sup>Arcispedale Santa Maria Nuova-IRCCS, Reggio Emilia, Italy; <sup>11</sup>University of Munich, Munich; <sup>12</sup>Universitätsklinikum Erlangen, Erlangen, Germany; <sup>13</sup>Hospital for Special Surgery, Cornell, USA

**Background:** The relationship between acute phase reactant levels and giant cell arteritis (GCA) disease flares is not known, particularly in the era of interleukin-6 receptor blockade with tocilizumab (TCZ). Prednisone doses at which GCA flares can occur have not been studied thoroughly in prospective clinical trials.

**Objectives:** Investigate prednisone doses and acute phase reactant levels at the time of disease flare in patients with GCA.

**Methods:** Secondary analyses of prednisone doses, C-reactive protein (CRP) levels, and erythrocyte sedimentation rate (ESR) were performed for patients who experienced GCA flare after achieving remission during 52 weeks of treatment with TCZ-weekly or -every-other-week+26 week prednisone taper (TCZ-QW or TCZ-Q2W) or placebo +26 week or 52 week prednisone taper (PBO+26 or PBO+52). The last CRP and ESR values before first disease flare were used if values on the day of first flare were missing. Analyses are descriptive and were performed post hoc.

**Results:** GCA flare after remission was reported in 23% (23/100) of TCZ-QW patients, 26% (13/50) of TCZ-Q2W patients, 68% (34/50) of PBO +26 patients, and 49% (25/51) of PBO +52 patients.<sup>1</sup> Median CRP levels and ESR at the time of flare were lower in the TCZ groups than in the PBO groups (Table). In the TCZ groups, 92% (33/36) of flares were associated with normal CRP levels ( $\leq 1$  mg/dL) and 89% (32/36) were associated with normal ESR values ( $< 30$  mm/h). In the PBO groups, 34% (20/59) of flares were associated with normal CRP values and 31% (18/59) with normal ESR. Median (min–max) prednisone doses at the time of disease flare in the combined TCZ and combined PBO groups were 5.5 (0.0–310.0) and 9.0 (0.0–55.0) mg/day, respectively. Among 149 patients in the TCZ groups, 10 (7%) had disease flares while receiving prednisone doses greater than 10 mg/day, accounting for 28% of all disease flares in the TCZ groups. Among 101 patients in the PBO groups, 23 (23%) had disease flares while receiving prednisone doses  $> 10$  mg/day, accounting for 39% of all disease flares in the PBO groups. Thus, 33 of the 95 disease flares in GiACTA (35%) occurred while the patient was receiving  $\geq 10$  mg/day prednisone.

**Abstract SAT0531 – Table 1.** Prednisone doses and acute phase reactants at GCA flare

	TCZ-QW N=100	TCZ-Q2W N=49	PBO+26 N=50	PBO+52 N=51
Patients who experienced flare, n (%) <sup>a</sup>	23 (23)	13 (27)	34 (68)	25 (49)
Median (min-max) prednisone dose at flare, mg	7.0 (0.0–30.0)	2.0 (0.0–310.0)	6.5 (0.0–55.0)	10.0 (2.0–40.0) <sup>a</sup>
Patients who experienced first flare while on prednisone dose, mg/day, n (%) <sup>a</sup>				
0	5 (5.0)	4 (8.0)	9 (18.0)	0
1–5	5 (5.0)	4 (8.0)	7 (14.0)	5 (9.8)
>5–10	5 (5.0)	3 (6.0)	4 (8.0)	10 (19.6)
>10–20	5 (5.0)	1 (2.0)	9 (18.0)	8 (15.7)
>20–30	3 (3.0)	0	2 (4.0)	0
>30–40	0	0	2 (4.0)	1 (2.0)
>50–60	0	0	1 (2.0)	0
>60	0	1 (2.0)	0	0
Median (min-max) CRP, <sup>b</sup> mg/L	0.4 (0.2–93.2)	1.0 (0.2–18.1)	23.1 (1.4–119.0)	17.3 (0.2–122.0)
Flare patients with elevated CRP, <sup>c</sup> n (%) <sup>c</sup>	1 (4)	2 (15)	22 (65)	17 (68)
Median (min-max) ESR, <sup>d</sup> mm/h	5.0 (0.0–80.0)	5.0 (1.0–43.0)	51.0 (8.0–140.0)	39.0 (4.0–138.0)
Flare patients with elevated ESR, <sup>e</sup> n (%) <sup>e</sup>	1 (4)	3 (23)	27 (79)	14 (56)

<sup>a</sup>Percentage based on N. <sup>b</sup>Normal  $\leq 10$  mg/L. <sup>c</sup>Percentage based on n who experienced flare. <sup>d</sup>Normal  $< 30$  mm/h. <sup>e</sup>n=24

**Conclusions:** Acute phase reactants are not reliable correlates of disease flare in TCZ-treated patients, but approximately one-third of all PBO +prednisone patients also had normal acute phase reactants at the time of disease flare. Median prednisone dose at the time of disease flare for TCZ-treated patients was numerically lower than that of patients treated with PBO +prednisone. One-third of all disease flares in GACTA occurred while the patient was receiving  $>10$  mg/day prednisone.

### SAT0532 TREATMENT WITH METHOTREXATE AND RISK OF ISCHAEMIC RELAPSES IN PATIENTS WITH GIANT CELL ARTERITIS IN CLINICAL PRACTICE

J. Font Urgelles<sup>1</sup>, Z. Rosales Rosado<sup>1</sup>, D.D. Freitas Núñez<sup>2</sup>, P.M. Lois Bermejo<sup>1</sup>, L. León Mateos<sup>2</sup>, I.C. Morado Quiñoa<sup>1</sup>, E. Pato Cour<sup>1</sup>, J.A. Jover Jover<sup>1</sup>, L. Abásolo Alcázar<sup>2</sup>. <sup>1</sup>Rheumatology, Hospital Clínico San Carlos; <sup>2</sup>Instituto De Investigaciones Sanitarias San Carlos, Madrid, Spain

**Background:** Clinical trials show the efficacy of Methotrexate (MTX) in giant cell arteritis (GCA). It is necessary to corroborate these results in real life.

**Objectives:** To assess the incidence and the risk of ischaemic relapses in GCA patients treated with and without Methotrexate (MTX) in clinical practice.

**Methods:** Retrospective longitudinal observational study. **Subjects:** patients treated at the Rheumatology Service of the Hospital Clínico San Carlos with the diagnosis of GCA. They were included from the date of diagnosis (January 1991 to September 2013) and followed-up until lost of follow up or Sept-2014. **Main outcome:** relapses by isquem event (RIE): Presence of mandibular claudication, visual manifestations (blurred vision, diplopia, transient or permanent loss of vision), cerebrovascular accident, ischaemic heart disease or claudication of limbs, after having achieved an objective improvement, associated with an

increase in the erythrocyte sedimentation rate (ESR) and the need to increase corticosteroids (at least 10 mg over the previous dose). **Independent variable:** exposure to MTX over time. **Secondary variables:** sociodemographic, clinical and treatment. **Statistical analysis:** RIE rates were assessed by survival techniques, expressing the incidence per 100 patients\*year with their 95% confidence interval [CI]. The influence of MTX on the RIE was analysed by multivariate Cox regression models. Results were expressed as Hazard ratios (HR) with their respective CI.

**Results:** 168 patients were included with a follow-up of 675.59 patients\*year. 80.36% were women (mean age: 76.77 $\pm$ 7 years). The most prevalent comorbidities were arterial hypertension (64%), dyslipidemia (34%), cardiovascular pathology (30%) and polymyalgia rheumatica (13.77%). The most common clinical symptom at diagnosis was headache (87.43%), systemic involvement (55%) and polymyalgia rheumatica (49.70%). The ESR was 78 $\pm$ 30.85 mmHg and Hb of 12.06 $\pm$ 1.58 mg/dL. 46.39% had a positive biopsy. 64% were on MTX (mean dose: 10 mg) at any time during the follow-up, from those 68% started MTX in the first 4 weeks after diagnosis. The mean dose of corticosteroids was 50.72 $\pm$ 15.46 mg. There were 21 relapses by ischaemic events (12.5%), with an incidence of 3.1 [2.02–4.77]. The median time to first RIE was 0.4 [p25–75: 0.4–5.1] years. The incidence of RIE in patients exposed to MTX was 1.92 [0.8–4.62], whereas in those without MTX was 3.84 [2.36–6.28]. The incidence of RIE in women was 3.44 [2.17–5.46] and in men was 1.97 [0.6–6]. In the multivariate analysis after adjusting for age, sex, disease activity and calendar time, exposure to MTX had less risk of relapse by ischaemic event compared to those without MTX (HR 0.3 [0.096–0.99]; p=0.048).

**Conclusions:** The frequency of RIE was 12.5%. The incidence of RIE was 3% patients-year. With the results observed in this study, the use of MTX seems to decrease the risk of relapses by ischaemic event.

### SAT0533 POLVAS – RETROSPECTIVE REGISTRY OF POLISH PATIENTS WITH ANCA-ASSOCIATED VASCULITIDES

K. Wójcik<sup>1</sup>, J. Kur-Zalewska<sup>2</sup>, A. Masiak<sup>3</sup>, A. Dębska-Ślizień<sup>3</sup>, J. Jeleniewicz<sup>4</sup>, K. Jakuszkó<sup>5</sup>, P. Glusko<sup>6</sup>, M. Wisłowska<sup>7</sup>, I. Brzosko<sup>8</sup>, A. Hawrot-Kawecka<sup>9</sup>, J. Musiał<sup>1</sup> on behalf of POLVAS. <sup>1</sup>Jagiellonian University Medical College, Kraków; <sup>2</sup>Military Institute of Medicine, Warszawa; <sup>3</sup>Medical University of Gdańsk, Gdańsk; <sup>4</sup>Medical University of Lublin, Lublin; <sup>5</sup>Wrocław Medical University, Wrocław; <sup>6</sup>National Institute of Geriatrics, Rheumatology and Rehabilitation; <sup>7</sup>Central Clinical Hospital MSWiA, Warszawa; <sup>8</sup>Pomeranian Medical University, Szczecin; <sup>9</sup>Medical University of Silesia, Katowice, Poland

**Background:** Vasculitides are a heterogeneous group of rare diseases with unknown etiology and the clinical spectrum ranging from life-threatening systemic disease to minor isolated skin changes. Present nomenclature and definitions of systemic vasculitides have been proposed in 2012 at the International Chapel Hill Consensus Conference.<sup>1</sup> Antineutrophil cytoplasmic antibody (ANCA)-associated vasculitides (AAV) belong to the small to medium-size vessel systemic diseases comprising granulomatosis with polyangiitis (GPA), microscopic polyangiitis (MPA) and eosinophilic granulomatosis with polyangiitis (EGPA).

**Objectives:** We decided to retrospectively analyse a large cohort of Polish AAV patients coming from referral centres – members of the Scientific Consortium of the Polish Vasculitis Registry (POLVAS).<sup>2,3</sup>

**Methods:** We conducted a systematic multicenter retrospective study of adult patients diagnosed with AAV between Jan 1990 and Dec 2016. Patients were enrolled to the study by 9 referral centres (14 clinical wards: – rheumatology – 10, nephrology – 2, metabolic diseases – 1, clinical immunology – 1) from 7 Voivodships populated by 22.3 mln inhabitants (58.2% of the Polish population). Patient data have been collected according to the uniform protocol in the POLVAS registry.

**Results:** Distribution of AAV in the Polish population resembles that of north European cohorts.<sup>4</sup> In POLVAS registry 417 (66.7%) patients were diagnosed with GPA, 106 (17.0%) with MPA and 102 (16.3%) with EGPA. Male-to-female ratios were almost 1:1 for GPA (210/207) and MPA (54/52), but EGPA was twice more frequent among women (34/68). Clinical manifestations and organ involvement were analysed both by clinical phenotype (GPA, MPA, EGPA) and ANCA specificity (anti-PR3+, and anti-MPO+). Analysis by ANCA specificity showed no apparent difference as compared to phenotype analysis. Clinical manifestations

of different AAV in the Polish population seems very similar to other European countries.

SAT0534

#### ANNUAL INCIDENCE OF GIANT CELL ARTERITIS IN URBAN AND RURAL AREAS IN WESTERN NORWAY 1972–2012

L.K. Brekke<sup>1</sup>, B.-T. S. Fevang<sup>2</sup>, G. Myklebust<sup>3</sup>. <sup>1</sup>*Hospital for Rheumatic Diseases, Haugesund*; <sup>2</sup>*Dept. of Rheumatology, Haukeland University Hospital, Bergen*; <sup>3</sup>*Dept. of Rheumatology, Hospital of Southern Norway, Kristiansand, Norway*

**Background:** Giant cell arteritis (GCA) is the most common vasculitis in adults. The etiology is not fully understood, and environmental factors which may influence the incidence are poorly investigated.

**Objectives:** To determine the potential influence of rural or urban residence on the incidence of GCA during a 41 year period.

**Methods:** Hospital-based retrospective cohort study including patients diagnosed with GCA in Bergen Health Area during 1972–2012. Patients were identified through computerised hospital records using the International Classification of Diseases (ICD)-coding system. Clinical information was extracted by review of the patients' medical journals. The patients' residential address was obtained from the population register in Norway. Municipalities were classified as urban (code 1 and 2) or rural (code 3 thru 6) using the <sup>Statistics Norway 2017</sup> classification of centrality. The background population data was obtained from Statistics Norway ([www.ssb.no](http://www.ssb.no)). Wilcoxon signed-rank test was used for statistical comparison.

**Results:** The inclusion process have been published previously.<sup>1</sup> For the computing of incidence 743 patients were included. Among these there were 536 (72%) females (mean age 73.4 years, SD 8) and 207 (28%) males (mean age 72.6, SD 9). 493 patients (66%) had a positive temporal artery biopsy. 484 patients (65%) had a residential address in a municipality classified as urban and 259 (35%) in a rural municipality. The number of inhabitants (aged ≥50 years) in urban areas (i.e. city of Bergen) was 60 910 in 1972 and 81 972 in 2012. The corresponding number of inhabitants in rural areas was 30 320 and 51 401.

The overall annual cumulative incidence of GCA was 16.7 (95% CI 15.5–18.0) per 100 000 persons ≥50 years. The mean annual incidence for urban municipalities was 17.1 (95% CI 15.9–18.4) per 100 000 ≥50 years. The corresponding incidence for rural areas was 16.1 (95% CI 14.9–17.3), p=0.46. With regards to biopsy-proven GCA, the overall annual incidence was 11.2 (95% CI 10.2–12.3). In urban and rural areas, the incidence of biopsy-proven GCA was 11.7 (95% CI 10.6–12.7) and 10.4 (95% CI 9.4–11.4) respectively, p=0.10. There were large fluctuations in annual incidence in both urban and rural areas (figure 1).

**Conclusions:** Annual cumulative incidence of GCA was slightly higher in urban than in rural areas in our study, but the difference was not statistically significant. This is in contrast to a previous study, which found GCA more prevalent in urban than in rural populations.<sup>2</sup> Further studies are required to determine whether there is a true difference in incidence of GCA in urban versus rural populations, and whether or not exposures to environmental factors may be involved in GCA pathogenesis.

**Background:** Giant cell arteritis (GCA) represents the most common form of primary vasculitis and can be associated with severe and potentially life-threatening complications. Due to its low prevalence, systematically collected data on course and outcome of this disease are scarce.

**Objectives:** The aim of this EULAR Task Force was to identify a core set of data items which can easily be collected from clinicians and facilitates examination of disease course and outcome.

**Methods:** A multidisciplinary EULAR task force group of 20 experts including rheumatologists, epidemiologists and patient representatives was assembled and breakout groups formed for a meeting at which items from a previously compiled collection of core parameters for a GCA registry were evaluated. Results were presented to the other group members following a structured process for discussion and consensus finding. The meeting was followed by several rounds of discussions to achieve consensus.

**Results:** A total of 95 items were identified, subdivided into the following categories: General, Demographics, GCA-related signs and symptoms, Other medical conditions, and Treatment. Suitable instruments and assessment intervals were determined for documentation of each item. To facilitate implementation of the recommendations in both primary care and scientifically oriented registers, a minimum core set of parameters was distilled, with supplemental items that can be added optionally depending on the designated purpose of individual registers.

**Abstract SAT0535 – Table 1.** A minimum core set of parameters to be collected in giant cell arteritis registries and databases

Item	Instrument
<b>General</b> <sup>1,2</sup>	
visit date	date
<b>Demographics</b>	
age <sup>3</sup>	date of birth
<b>GCA-related Signs &amp; Symptoms</b> <sup>4,5</sup>	
cranial <sup>6</sup>	
ocular involvement	
permanent partial visual loss / blindness	y/n (examination)
transient visual loss (amaurosis fugax)	y/n (interview)
scotopia	y/n (interview)
headache	y/n (interview)
<b>Treatment</b> <sup>7</sup>	
glucocorticoids <sup>8,9</sup>	
current GC use	mg per day in prednisone equivalent; route of administration
tapering ongoing	y/n
recent GC use	
continuous (> 3 months) intake	y/n (interview)
immunosuppressants	
conventional synthetic DMARDs	current medication <sup>10,11</sup>
biological DMARDs	historical treatment <sup>12</sup>
	current medication <sup>13,14</sup>

<sup>1</sup> record at baseline  
<sup>2</sup> record during follow-up  
<sup>3</sup> report with date in case it occurs  
<sup>4</sup> record every 3-6 months; acute changes need to be recorded whenever they occur (e.g. new medication, imaging finding, osteoporotic fracture)  
<sup>5</sup> record every 6-12 months; acute changes need to be recorded whenever they occur (e.g. new medication, imaging finding, osteoporotic fracture)  
<sup>6</sup> record annually; acute changes need to be recorded whenever they occur (e.g. new medication, imaging finding, osteoporotic fracture)

**Conclusions:** This core set intends to ensure that data from different GCA registries and databases can be compared for the dual purposes of clinical research and improving clinical care, thereby facilitating collaborative analyses.

#### SAT0536 MULTIPLE RELAPSES IN PATIENTS WITH GIANT CELL ARTERITIS

M. Banjari, E. LIOZON, S. Dumonteil, G. Gondran, S. Palat, H. Bezanahary, S. Nadalon, A.-L. Fauchais, K.H. Ly. *Internal Medicine, CHU Dupuytren Limoges, Limoges, France*

**Background:** Glucocorticoids (GC) remain the mainstay of treatment for patients with GCA. However, relapses and recurrences (events) occurred in 34% to 74.5%

of the patients.<sup>1-3</sup> Most studies compared mainly patients with disease relapses/recurrences to whom without any.

**Objectives:** To compare patients who had multiple events to those who presented only one in order to identify characteristics and predictive factors of multiple events in patient with GCA

**Methods:** From 1976 to 2016, we collected prospectively clinical, laboratory, and pathological data, and the treatments and outcomes, of consecutive patients who were diagnosed to have GCA based ACR classification criteria. We compared these data in patients who had more than one event (group 1), either a relapse or a recurrence, to those who had only one (group 2). Relapse was defined as occurrence of clinical symptoms and/or inflammatory parameters, attributable to GCA, which required increased medication during follow-up i.e. under GC therapy while new disease activity after a period of remission was defined as a recurrence.

**Results:** We included 494 patients for whom data was collected. Forty-seven patients were excluded from our cohort due to lack of data. Among the 447 patients, 228 (51%) presented at least one event. Mean age of this population was 73,3±7 years with female predominance (70%). The median follow-up was 75±55 months. Among these patients 139 (61%) had only one event while 89 (39%) presented more than one. The total number of events was 477 of which 89 recurrences. Events occurred during the first year of treatment in 74% of patients. The majority of these events occurred with a mean prednisone dose of 12.8 ±9 mg/day (median dose 10 mg/d). In univariate analysis, significant differences between both groups is illustrated in table 1. Multivariate analysis showed that ear pain and an elevated ESR were predictive factors of multiple events (OR: 2,45 and 1,93; p=0,04 and p=0,03 respectively). We also found that this risk is lower in patients over 80 years-old (OR: 0,35, p=0,008)

**Abstract SAT0536 – Table 1**

Characteristic	Group 1 (>1; n=89)	Group 2 (=1; n=139)	P
Age (years)	72,67	75,34	0.011
Cough (%)	20,7	10,9	0.042
Ear pain (%)	19,5	9,4	0.029
PMR (%)	11,3	4,3	0.041
Duration of CS (m)	53,7	26,3	0.0001
Complications of CS(%)	28,4	16	0.024
Steroid sparing treatment (%)	30,7	17,8	0.024
Remission(%)	35,6	62,1	0.0001
Death(%)	23,8	36,4	0.046

**Conclusions:** Patients with more than 1 event represent 7% to 46% of patients with event<sup>1-3</sup> which is consistent with our study (39%). The event occurred most often during the first year of GC therapy in our cohort (74% of patients) while it affects 24% to 50% of patients in other series for the same period.<sup>1-3</sup> This difference could be explained by the heterogeneity of GC protocols. We did not found any positive correlation with hypertension, diabetes, and deep vein thrombosis that seemed to be more frequent in patients with multiple events.<sup>2</sup> In our study, this group of patients appeared younger and presented more often with cough, ear pain, and polymyalgia rheumatica that preceded GCA. Logically, in these patients, corticosteroid therapy was longer and the use of GC-sparing agent was more common. Although getting remission was more difficult in these patients, the long-term prognosis is not poor.

#### SAT0537 IS BALANCE AFFECTED IN BEHCET'S DISEASE AND WHAT ARE THE FACTORS THAT EFFECT THE BALANCE?

A. Ceilk, M. A. Meilkoğlu. *Department of Physical Medicine and Rehabilitation, Faculty of Medicine, Ataturk University, Erzurum, Turkey*

**Background:** Behcet's Disease (BD) is a multisystem vasculitis that has a broad range of manifestations. Balance as a complex task may be affected in BD and this may cause postural instability and fall risk.

**Objectives:** The aim of this study was to determine the fall risk in cases with BD with an objective computerised technique and to evaluate the potential related risk factors for falls in these cases.

**Methods:** After calculating sample size as 24 (with%95 confidence interval and± %5 standard deviation), 30 patients with BD (according to The Behcet's

Syndrome International Study Group Criteria) and 30 healthy controls were included. Cases who were not able to tolerate posturography, with a history of orthopaedic surgery and with known balance problems were excluded. The age, gender, disease duration, anamnesis of falls (last 12 months), fear of falling (yes/no) and drugs used were recorded. Also disease activity (with Behçet's Disease Current Activity Form; BDCAF) and fall efficacy (with Tinetti's Falls Efficacy Scale) were evaluated. Fall risk analysis was performed by Tetrax Interactive Balance System which is a computerised posturography device. By this method, fall risk is obtained as a numeric value (0–100) and as ranges indicating low, moderate or high risk of fall. We investigated age, gender, disease duration, fall anamnesis, fear of falling, drug usage, fall efficacy, disease activity as possible related factors to fall risk. Mann–Whitney U, chi square and Spearman correlation tests were used for statistical analysis.

**Results:** The mean ages of the cases and controls were 35,17±9,48 and 33,03±11,813 years, respectively. Symptom duration of the cases was 7,70±6,613 years. 7 cases (23,3%) had anamnesis of falls during the last 12 months, whereas only 8 control (26,7%) had this anamnesis ( $p>0.05$ ). Fear of falling was reported by 43,3% of the cases and 40% of the controls ( $p>0.05$ ). There was no significant difference between case and control groups in terms of FES-I scores (15,97±9,257 and 12,53±3048 respectively;  $p=0,599$ ). With the computerised system used, significantly higher fall risk results were recorded in patients with BD than the controls (50,40±24 710 and 23,13±11,811, respectively;  $p<0,001$ ). Low, moderate and high fall risks were recorded as 30%, 33,3% and 36,7% of the cases and 70%, 30% and 0% of the controls and this distribution was also significantly worse in cases than controls ( $p<0,05$ ). No significant correlation was found between fall risk and other factors including age, gender, disease duration, fall anamnesis, fear of falling, drug usage, disease activity except arthralgia which was significantly correlated with fall risk assessment in cases ( $p<0,05$ ).

**Conclusions:** With an objective computerised technique, fall risk was found to be higher in cases with BD than controls in our study. The higher fall risk in these patients seems to be affected by joint involvement. An increased awareness of the potential fall risk and future studies investigating the possible coexisting balance problems in BD may contribute to the management.

SAT0538

#### AORTIC INVOLVEMENT IN RELAPSING POLYCHONDRIITIS: A SYSTEMATIC REVIEW

M. Erdogan, S.N. Esatoglu, G. Hatemi, V. Hamuryudan. *Internal medicine division of Rheumatology, Cerrahpaşa Medical Faculty, Istanbul, Turkey*

**Background:** Aortic involvement (AI) is an important complication of relapsing polychondritis (RP). Current literature is based on case reports and small case series.

**Objectives:** To delineate the clinical characteristics and outcome of AI in RP through a systematic literature review (SLR).

**Methods:** The SLR covered all English articles retrieved with relevant keyword combinations listed in PubMed until October 2017. Initially the titles and abstracts were screened by two investigators and articles considered to be relevant (involvement of the aorta and the aortic valve) were identified. Data extraction was done by the same investigators.

**Results:** The SLR revealed 352 papers of which 162 were discarded at the first step and a further 114 after full reading. After excluding 5 articles reporting on the same patient, we finally had 71 papers reporting 97 patients. The sex distribution was identifiable in 79 patients of whom 39 were men and 40 were women. The median age at the first symptom of RP was 31.5 years [IQR:24–43 years], the median age at RP diagnosis was 36 years [IQR: 28–43 years]; median age at the diagnosis of AI was 37 years [IQR:29–49 years]. Median duration from first RP diagnosis to AI diagnosis was less than 1 year [Range:0–21]. AI was the presenting symptom in 3 patients.

Seventy patients (73%) had involvement of thoracic aorta and 16 (23%) had involvement of the abdominal aorta. Other involved arteries were: coronary (8 patients), subclavian (5 patients), renal (3 patients), iliac (3 patients) and others (8 patients). Two patients had neurologic and renal involvement, respectively.

The most common symptoms were dyspnea (40%), followed by chest pain (13%), abdominal pain (13%) and fever (9%).

The diagnosis of AI was made during surgery in 6 patients and with different radiologic methods ranging from chest x-ray to PET-CT.

All patients excluding 1 received corticosteroids either alone or in combination with classical immunosuppressives (cyclophosphamide, azathioprine, methotrexate, mycophenolate-mofetil) or biologics (infliximab, tocilizumab, adalimumab).

The majority of the patients (53/87 patients (61%) underwent surgery including aortic graft replacement, coronary by-pass, aortic valve or mitral valve replacement operations.

16 patients died after a median follow up of 24 [IQR:11–43] months. The reasons for deaths were mainly vascular (acute myocardial infarction, heart failure,

cardiovascular operation, abdominal aorta dissection, aortic rupture and acute aortic valvular dysfunction).

Information on follow-up was known in 30 patients for a median of 18.5 months [IQR 10–48 months].

**Conclusions:** AI is less frequently recognised but prognostically important complication of RP. Thoracic aorta is the most frequently involved site. Surgery is needed in the majority of patients. Medical treatment is empirical and is based on glucocorticoids and immunosuppressives including biologic agents. Despite treatment, mortality is high (18% during a median of 24 months).

SAT0539

#### THE FREQUENCY OF RECURRENT ORAL ULCERS IN FAMILY MEMBERS OF PATIENTS WITH BEHÇET'S DISEASE

N. Çakır<sup>1</sup>, B. Çelik Yıldırım<sup>1</sup>, N. İmeryüz<sup>2</sup>. <sup>1</sup>Rheumatology, Medeniyet University School of Medicine, Department of Rheumatology; <sup>2</sup>Gastroenterology, Marmara University School of Medicine, Istanbul, Turkey

**Background:** It is unknown whether the observed geographic disparities in Behçet's Disease (BD) occurrence reflect primary genetic susceptibility or environmental influences within specific populations. Family aggregation studies may help to discriminate between environmental and genetic components but there are no large family surveys.

**Objectives:** The aim of this study was to contribute to a better understanding of the genetic aspect of familial aggregation studies in Turkey.

**Methods:** The study group consisted of siblings and children of 133 unrelated consecutive patients followed up at the BD outpatient clinic in FSM Hospital, Istanbul. Surveyed individuals were interviewed via telephone regarding if they had ever suffered from recurrent oral ulcerations (ROU). Children less than ten years old were surveyed via discussion with their parents. Symptoms and signs of Behçet's disease in family members were also interviewed via telephone. Subjects experience ROU, at least three episodes in one year, were invited to attend further examination, and also were asked whether anyone in their family had BD.

**Results:** Total 133 patients with BD (86 F, 47 M, respective mean ages: 39.9±11.7, 43.9±10.4 years) had 271 children (137 F, 134 M) and 642 siblings (319 sisters, 323 brothers, respective mean ages: 42.1±13.6, 40.7±14.4 years). All 642 siblings were contacted by telephone: 62 siblings (33 F, 29 M, respective mean ages: 17.9±9.8, 18.2±9.9 years) and 84 children (63 F, 21 M) had positive ROU history. All probands were invited, only 36% family members attended. Apart from patients with BD, 146 family members had ROU (14%). The estimated ROU rate among siblings and children was 9.6%, and 31% respectively. Among members there were 13 patients with BD (2 fathers, 1 mother, 2 children, 3 brothers, 5 sisters). Eleven of these were diagnosed at another centre. We identified 2 additional patients who met ISG criteria during the survey. Only five spouses had ROU (0.5% of members).

**Conclusions:** In a study from Istanbul, ROU was reported as 9.5% in the general population. In our previous study, that was conducted in an area that was reported as having the lowest prevalence rate of BD, this was estimated as 2.1% in the general population. The ROU rate in the current study for total family members was 16%, and 31% for children, which was higher than in the general population. The rate of patients with BD in the studied cohort, apart from previously diagnosed patients, were 140 per 10,000 while the reported prevalence rates changed regionally between 20 per 10,000 and 42 per 10,000 in Turkey. These findings suggest that BD risk is primarily influenced by genetics rather than environmental conditions. Familial aggregation supports a genetic background for BD

SAT0540

#### TREATMENT WITH INTRAVENOUS IMMUNOGLOBULIN IN THE VASCULITIS ANCA POSITIVE. 27 CASES STUDIED IN A SINGLE REFERENCE CENTRE

N. Aviles Mendez, V. Calvo Rio, J. Loricera, B. Atienza Mateo, J.L. Martin Varillas, J. Blanco, R. Blanco, M.A. Gonzalez-Gay. *1Rheumatology. Hospital Universitario Marqués de Valdecilla. IDIVAL, Santander, Spain*

**Objectives:** Intravenous immunoglobulins (IGIV) is a therapeutic alternative in vasculitis ANCA+ specially in cases of refractory or superinfection. We study the efficiency and safety in the short and long term of the IGIV in the vasculitis ANCA.

**Methods:** Descriptive and observational study of 27 patients with vasculitis ANCA from a reference tertiary hospital. We analysed the treatments received, the clinical and analytical variables and the indexes of activity and evolution (TABLE). Birmingham Vasculitis Activity (BVAS) was the activity index used, and for prognosis Five Factory Score (FFS). Results are indicated as mean ±SD when

there is a normal distribution, or as median [25–75 IQR] when there is an usual one.

**Results:** 27 patients were analysed (14 W/13 M). At the beginning of the IGIV the average age was 57.8±15.98 and the vasculitis average development was 1.29 ±0.68. The vasculitis ANCA subtypes were: **a)**granulomatosis with polyangiitis (n=14; 51.8%), **b)**microscopic polyangiitis (n=9; 33.3%), **c)**eosinophilic granulomatosis with polyangiitis (n=2; 7.4%), **d)**pulmonary-renal syndrome with ANCA positive (n=1; 3.7%) and **e)** indeterminate vasculitis ANCA positive (n=1, 3.7%). Previously to the treatment with IGIV, apart from steroids, they also received: cyclophosphamide (n=12, 44.4%), metotrexate (n=6, 22.2%), infliximab (n=5, 18.5%), rituximab (n=4, 14.8%), azathioprine (n=3, 11.1%), mycophenolate (n=3, 11.1%) and plasmapheresis (n=1; 3.7%).

Refractionness (n=18) and suspicious of infection (n=9) were the reasons for the application of IGIV. The IGIV guideline was 0.4 g/kg/day for 5 consecutive days. 66.6% received methylprednisolona IV concomitant (0.5–1 g/day for 3 days). After a follow-up of 80±68.4 months we observed clinical and analytical improvement, as well as, in the activity indexes (TABLE). The majority of the side effects were lower and IGIV was suspended in just one patient due to severe effects of congestive heart disease.

**SAT0541** **INCIDENCE OF LARGE VESSEL GCA IN NORTHERN ITALY DURING A 12-YEAR PERIOD (2005–2016)**

P. Macchioni<sup>1</sup>, L. Boiardi<sup>1</sup>, G. Restuccia<sup>1</sup>, F. Muratore<sup>1</sup>, P. Mancuso<sup>2</sup>, M. Catanoso<sup>1</sup>, C. Salvarani<sup>1</sup>. <sup>1</sup>Ospedale Santa Maria Nuova; <sup>2</sup>Epidemiology, Ausl Regg Emilia, Reggio Emilia, Italy

**Background:** There are no studies regarding the incidence of large vessel GCA (LV GCA).

**Objectives:** To investigate the incidence of LVGCA in the Reggio Emilia Area from 2005 through to 2016.

**Methods:** All patients with incident large vessel GCA diagnosed between 1 January 2005 and 31 December 2016 and living in the Reggio Emilia area, were identified by capture and re-capture checking of computerised discharge diagnosis codes (ICD10) and using outpatients databases from rheumatology, internal medicine, surgery, pathology, imaging departments of Reggio Emilia Hospital as well as by examining the Reggio Emilia district database for rare diseases. To be included in the study, patients must satisfy the following 2 criteria: Age at disease onset ≥50 years; evidence of large-vessel vasculitis by angiography, MRA, CTA, PET/CT and/or ultrasonography. We included in the study also patients associating biopsy proven GCA with evidence of LVV. We also evaluated the incidence of biopsy proven GCA without LV in same time period.

**Results:** There were 93 incident cases of LV GCA (66 women, 71%) during the 12 year study period; Mean ±SD age at diagnosis was 72±9 years. Incidence per 1 00 000 persons aged ≥50 years was 3.78 (95% confidence interval [95% CI 3.01, 4.55]). In particular incidence was 1.60 in LV GCA with biopsy proven GCA and 2.18 in LV GCA not biopsy proven GCA (pts biopsy negative and pts in which the biopsy had not been performed). Incidence was significantly higher in women (4.89 [95% CI 3.69, 6.09]) than in men (2.50 [95% CI 1.56, 3.45]) (p<0.0006). The highest incidence in women was observed in the 70–79 years age group (7.72 [95% CI 4.89, 11.58]) while in men the peak of incidence was in the 80–89 age group (4.23 [95% CI 2.50, 8.45]). A progressive increase in total incidence rates was observed during the 4 three years periods from 3.13 (2005–2007) to 4.85 (2014–2016). The incidence per 1 00 000 persons aged ≥50 years of GCA

biopsy proven without LV during the 12 year study period was 4.48 [95% CI 2.22, 9.45].

**Conclusions:** The incidence of LV GCA in the Reggio Emilia area 100.000/aged >50 was 3.78 and it was lower than that of patients with biopsy proven GCA without LV; the incidence of LV GCA was significantly higher in women and increased during the study period.

**SAT0542** **INTERLEUKIN-12 AND INTERLEUKIN-23 ARE KEY PATHOGENIC PLAYERS IN GIANT CELL ARTERITIS**

R. Conway<sup>1</sup>, L. O'Neill<sup>1</sup>, P. Gallagher<sup>1</sup>, G. McCarthy<sup>2</sup>, C. Murphy<sup>3</sup>, D. Veale<sup>1</sup>, U. Fearon<sup>4</sup>, E. Molloy<sup>1</sup>. <sup>1</sup>St Vincents University Hospital; <sup>2</sup>Mater Misericordiae University Hospital; <sup>3</sup>Royal Victoria Eye and Ear Hospital; <sup>4</sup>Trinity College Dublin, Dublin, Ireland

**Background:** Giant cell arteritis (GCA) is the most common form of systemic vasculitis; the pathogenesis is unclear. Current evidence suggests both the T<sub>H</sub>1 and T<sub>H</sub>17 pathways are important but the proximal initiators and effector cytokines are unknown. IL-12 and IL-23 secreted by dendritic cells are hypothesised as stimulators of these pathways. We have previously reported the efficacy of IL-12/23 blockade with ustekinumab in refractory GCA in a prospective clinical trial.

**Objectives:** To assess the role of IL-12 and IL-23 in GCA pathogenesis.  
**Methods:** IL-12 and IL-23 were quantified by immunohistochemistry in temporal artery (TA) biopsies. TA explant, peripheral blood mononuclear cell (PBMC) and myofibroblast outgrowth culture models were established from patients with GCA and disease controls. PBMCs and TA explants were cultured for 24 hours in the presence or absence of IL-23 (10 ng/ml) or IL-12 (50 ng/ml). Gene expression was quantified by Real-time PCR and cytokine secretion by ELISA. Myofibroblast outgrowths were assessed following 28 days culture and quantified by counting the number of outgrowths/high-power field (hpf).

**Results:** Immunohistochemistry demonstrated IL-12p35 and IL-23p19 in inflammatory cells in TA biopsies (n=33). IL-12p35 and IL-23p19 were only detected in positive TA biopsies. IL-12p35 was increased in those with cranial ischaemic complications (p=0.026) and those with large vessel vasculitis (p=0.006). IL-23p19 was increased in those with two or more relapses (p=0.007). In cultured PBMCs, IL-12 stimulation increased IL-6 (n=17, p=0.009), IL-22 (n=16, p=0.003), and IFN-γ (n=14, p=0.0001) secretion and decreased IL-8 (n=15, p=0.0006) secretion, while IL-23 stimulation increased IL-6 (n=40, p=0.029), IL-22 (n=16, p=0.001), IL-17A (n=16, p=0.0003) and IL-17F (n=9, p=0.012) secretion. In the TA explant culture model, IL-23 stimulation increased gene expression of IL-8 (n=13, p=0.0001) and CCL-20 (n=9, 0.027) and protein expression of IL-6 (n=61, p=0.002) and IL-8 (n=60, p=0.004). IL-12 stimulation (n=14) had no effect; however, IFN-γ and IL-17A were not detectable in this model. IL-12 (n=20, p=0.0005) and IL-23 (n=33, p<0.0001) stimulation increased the quantity of myofibroblast outgrowths from TA biopsies. In all experiments there were no significant differences between biopsy positive GCA, biopsy negative GCA, and disease controls.

**Conclusions:** IL-12 and IL-23 play central and distinct roles in stimulating inflammatory and proliferative pathways in GCA. Our results were consistent in patients with biopsy positive and negative GCA, and in disease controls, suggesting that IL-12 and IL-23 play proximal roles in inducing these pathways.

**SAT0543** QUALITY OF LIFE IN BEHÇET'S SYNDROME: THE ROLE OF PATIENT REPORTED OUTCOME

R. Talarico, A. d'Ascanio, R. Neri, C. Tani, C. Baldini, M. Mosca. *Department of Clinical and Experimental Medicine, University of Pisa, Rheumatology Unit, Pisa, Italy*

**Background:** Behçet's syndrome (BS) is a systemic vasculitis, typically characterised by recurrent oro-genital ulcers, ocular inflammation and skin manifestations; articular, vascular, gastro-enteric and neurological involvement may also occur. The complex pattern of BS profile can effect negatively on patients' quality of life.

**Objectives:** The primary aim of this study was to explore the role of quality of life in BD patients by means of patient reported outcome (PRO); the secondary aim was to study any correlation between disease activity and quality of life.

**Methods:** The study enrolled 130 patients (71 M, 59 F), all fulfilling the International Study Group (ISG) criteria for BS. Their mean age was 42±8 years, 18–77 while the mean age at disease onset was 11±4 years 5–18 and the mean follow-up of 8±2 years. Disease activity was evaluated by means of the Behçet's Disease Current Activity Form (BDCAF), while Short-form-36 (SF-36) was used to evaluate quality of life. Disease activity was compared with the global SF-36 score and with each dimension, that includes: physical functioning, physical disability, body pain, general health, vitality, social functioning, emotional disability, mental health. The statistical analysis was performed using Student t-test, Mann-Whitney-U test, ANOVA and Pearson correlation

**Results:** At time of evaluation, according BDCAF, 51 BS patients (39%) had clinically active disease (36 muco-cutaneous involvement, 21 ocular involvement 10 joint involvement, 6 neurological involvement, 4 gastro-enteric). As expected, the overall SF-36 scores were significantly lower in patients with clinically active disease. Moreover, female BS patients had statistically significant lower scores in all SF-36 domains compared with male patients. When each domain of SF-36 was evaluated, we found that physical disability (p=0.004), body pain (p=0.006), general health (p=0.001), and vitality (p=0.001) were significantly lower in patients with disease activity. Notably, vitality (p=0.001), physical disability (p=0.004), social functioning (p=0.001), emotional disability (p=0.003) and mental health (p=0.001) were significantly lower in patients with muco-cutaneous active disease, compared with the other patients with active disease.

**Conclusions:** The clinicians who take care of any chronic disease would like to correctly know the current status of a patient to manage him properly. In this regard, the combination data of PRO measures and disease activity have been demonstrated to add more information compared to the evaluation of disease activity alone. These consideration suggest that the correct assessment of BS needs a multi-dimensional approach, that fairly includes disease activity, disease damage and quality of life

**SAT0544** COMPARING THE CLINICAL PROFILE OF ADULTS AND CHILDREN WITH BEHÇET'S SYNDROME IN THE UK

S. Myers<sup>1</sup>, E. Makmur<sup>1</sup>, L. Hanns<sup>1</sup>, D. Huskard<sup>2</sup>, P. Brogan<sup>1</sup>, N. Ambrose<sup>1</sup>.

<sup>1</sup>University College London; <sup>2</sup>Imperial College London, London, UK

**Background:** Behçet's syndrome (BS) is a rare multi-system inflammatory disorder and most commonly presents in young adults. Clinical phenotypic variance across geographical regions is recognised but there has been no UK publication assessing UK BS patients' variance by age groups. BS is primarily a clinical diagnosis, and there is significant diagnostic delay in the UK. Exploration of the phenotype in UK adults and children may help clinicians diagnose BS more effectively.

**Objectives:** Describe and compare the clinical features of adults and children with BS in a UK population.

**Methods:** We examined and compared two cumulative databases of clinical features of BS patients. The paediatric database was collected Great Ormond Street Hospital for Children, London (n=46). The adult database was collected at the Hammersmith Hospital, London (n=560).

**Results:** Oral ulcers were common for both paediatric (97.8%) and adult (96.6%) populations. Genital ulceration also did not differ between paediatric (73.9%) and adult (75.7%) groups. Eye involvement was rare in children (4.3%) versus adults (37%) (p<0.001). Skin involvement was more common in the adult cohort (55.4% vs. 21.7%, p<0.001). There was a trend towards increased vascular involvement in adults (17.5%) versus children (6.5%). The children had higher gastrointestinal involvement compared to adults (21.7% vs. 4.5%, p<0.001)

**Conclusions:** Paediatric BS patients displayed less ocular and skin manifestations compared to the adult BS patients. The BS UK phenotype differs from international cohorts. This information will be valuable in helping clinicians diagnose BS in UK adult and paediatric populations.

**SAT0545** GIANT CELL ARTERITIS AND HEMATOLOGIC MALIGNANCIES: A REAL-LIFE EXPERIENCE

S. Tiosano<sup>1,2</sup>, L. Dar<sup>1,2</sup>, O. Gendelman<sup>1,2</sup>, D. Comaneshter<sup>3</sup>, A. Wata<sup>1,2</sup>, A. D. Cohen<sup>3,4</sup>, H. Amital<sup>1,2</sup>. <sup>1</sup>Internal Medicine 'B', Sheba Medical Center, Tel-Hashomer, Ramat-Gan; <sup>2</sup>Sackler School of Medicine, Tel-Aviv University; <sup>3</sup>Chief Physician's office, Clalit Health Services, Tel-Aviv; <sup>4</sup>Siaal Research Center for Family Medicine and Primary Care, Faculty of Health Sciences, Ben-Gurion University of the Negev, Beer-Sheva, Israel

**Background:** Giant cell arteritis (GCA), also known as temporal arteritis, is a vasculitis of large and medium-sized vessels, which commonly involves the extracranial branches of the carotid artery. There are conflicting evidence regarding the association between GCA and both solid and hematologic malignancies.<sup>1-4</sup>

**Objectives:** To assess the coexistence rate of GCA and hematologic malignancies.

**Methods:** This cross-sectional study was performed utilising the database of Israel's largest healthcare association, Clalit Health Services (CHS). All patients with previously documented diagnosis of GCA were included, as well as age- and sex-matched controls without GCA. The proportions of Hodgkin's lymphoma, Non-Hodgkin's lymphoma and multiple myeloma were compared between patients and controls. Univariate analysis was compared using chi-square test for categorical variables and student's t-test for continuous variables. A multivariable logistic regression model was built to assess the covariates associated with each Non-Hodgkin's lymphoma, the hematologic malignancy with the highest number of patients.

**Results:** The study included 5,663 GCA patients and 28 308 controls with a mean age of 71 and 68.3, respectively. Both groups consisted of 69.8% females. Multiple myeloma was observed in 27 GCA patients (0.48%) and 53 controls (0.19%), crude OR=2.56 p<0.001. Hodgkin's lymphoma was observed in 19 GCA patients (0.34%) and 41 controls (0.14%), crude OR=2.33 p=0.004. Non-Hodgkin's lymphoma was observed in 64 GCA patients (1.13%) and 164 controls (0.58%), crude OR=1.96 p<0.001. Multivariable logistic regression model adjusting for age and gender found GCA as independently associated with Non-Hodgkin's lymphoma (adjusted OR 1.96, p<0.001).

Characteristic	No GCA n=28 308	GCA n=5663	OR	p.ratio
Age	68.3±27.4	71.0±15.6	1.00	<0.001
Gender: Female	19 767 (69.8%)	3954 (69.8%)	1.00	0.991
BMI	28.2±5.91	28.1±5.60	1.00	0.081
Socioeconomic status:				
Low	5443 (36.8%)	1970 (34.9%)	Ref.	Ref.
Medium	6241 (42.2%)	2339 (41.4%)	1.04	0.330
High	3093 (20.9%)	1336 (23.7%)	1.19	<0.001
Multiple Myeloma	53 (0.19%)	27 (0.48%)	2.56	<0.001
Hodgkin's Lymphoma	41 (0.14%)	19 (0.34%)	2.33	0.004
Non-Hodgkin's Lymphoma	164 (0.58%)	64 (1.13%)	1.96	<0.001

**Conclusions:** GCA patients have higher rate of hematologic malignancies compared to controls. The association with Non-Hodgkin's lymphoma is the most prominent, and proper screening methods should be applied for early detection and treatment.

**SAT0546** **SENSORINEURAL HEARING LOSS IN TAKAYASU'S ARTERITIS**

U. Kimyon<sup>1</sup>, S.N. Esatoglu<sup>1</sup>, E. Kara<sup>2</sup>, A. Atas<sup>2</sup>, E.E. Gunay<sup>2</sup>, E. Karaman<sup>2</sup>, E. D. Gozen<sup>2</sup>, V. Hamuryudan<sup>1</sup>, H. Yazici<sup>1</sup>, E. Seyahi<sup>1</sup>. <sup>1</sup>Istanbul University, Cerrahpasa Medical School, Department of Internal Medicine, Division of Rheumatology; <sup>2</sup>Istanbul University, Cerrahpasa Medical Faculty, Department of Otorhinolaryngology, Istanbul, Turkey

**Background:** Sensorineural hearing loss has been reported to be increased in several chronic autoimmune and non-autoimmune diseases such as systemic lupus erythematosus (SLE), progressive systemic sclerosis, rheumatoid arthritis, small vessel vasculitides, ankylosing spondylitis and Behçet's syndrome. We had sporadically noted several degrees of sensorineural hearing loss among our Takayasu's arteritis (TA) patients. While some revealed this in their past history, others had relapsing attacks of hearing loss independent of or associated with vascular relapses.

**Objectives:** We formally investigated the frequency and type of hearing loss among TA patients and suitable controls.

**Methods:** The study was done in two parts. In the first part, consecutive TA and SLE patients seen at outpatient clinic along with apparently healthy controls were administered a standardised questionnaire that assessed hearing loss, tinnitus, and episodic vertigo. In the second part, previously registered TA and SLE patients for another study were called to specifically for otological examination and audiometry tests that included pure-tone air and bone conduction, speech audiometry and acoustic reflex threshold test.

**Results:** In the first part, 73 patients with TA, 107 patients with SLE and 133 healthy controls were studied as shown in table 1. The frequency of those with hearing deficit/loss, tinnitus and vertigo were significantly more common among both TA and SLE patients (table 1). While the frequency of those with hearing deficit/loss was similar in TA and SLE, those with tinnitus and vertigo were significantly more common in TA.

In the second part, 50 patients with TA, 22 patients with SLE and 32 healthy controls were studied as shown in table 2. Audiometry tests revealed that several degrees of hearing loss were present in 36% of the patients with TA, 18% of the patients with SLE and 6.3% of the healthy controls ( $p < 0.05$ ). This was mostly due to sensorineural hearing loss in TA patients (13/18) and high-frequency type was the most common pattern. Moreover, those TA patients with sensorineural hearing loss did not show any specific vascular pattern.

**Abstract SAT0546 – Table 1.** Results of the questionnaire survey

	Takayasu's arteritis (n=73)	SLE (n=107)	Healthy controls (n=133)	p value
Mean age	43.7±11.0	44.0±10.3	42.5±8.3	
Disease duration, med [IQR]	7 <sup>3-12</sup>	8 <sup>3-11</sup>	NA	
Hearing deficit/loss, n (%)	20 (27.4)	21 (19.6)	4 (3.0)	<b>0.001</b>
Tinnitus, n (%)	37 (50.7)	34 (31.8)	16 (12.0)	<b>0.001</b>
Vertigo, n (%)	39 (53.4)	38 (35.5)	19 (14.3)	<b>0.001</b>

	Takayasu's arteritis (n=50)	SLE (n=22)	Healthy controls (n=32)	p value
Mean (SD) age	41.3±8.9	42.1 ±10.3	41.1±0.8	NS
Disease duration, med [IQR]	6 <sup>4-11</sup>	7 <sup>3-11</sup>	-	NS
Hearing loss, n (%)	18 (36.0)	4 (18.1)	2 (6.3)	<0.05
Sensorineural type, n (%)	13 (26.0)	2 (9.0)	1 (3.1)	
Conductive type, n (%)	5 (10.0)	2 (9.0)	1 (3.1)	

**Conclusions:** We are unaware of previous surveys of sensorineural hearing loss in TA. Our study shows that audiovestibular system is considerably affected in TA, similar to that observed in SLE. The fact that there was no clear vascular pattern among patients with hearing loss, suggest that small vessel vasculitis was probably the cause of this hearing loss.

**SAT0547** **PROGNOSTIC NUTRITIONAL INDEX FOR ESTIMATING BIRMINGHAM VASCULITIS ACTIVITY SCORE IN ANCA-ASSOCIATED VASCULITIS**

S.S. Ahn, J. Yoo, S.M. Jung, J.J. Song, Y.-B. Park, S.-W. Lee. Division of Rheumatology, Department of Internal Medicine, Yonsei University College of Medicine, Seoul, Korea, Republic Of

**Background:** The prognostic nutritional index (PNI), which was first introduced by Onodera et al., is calculated based on the serum albumin level and total lymphocyte count in the peripheral blood. It is proposed to be a parameter to reflect immunonutritional status, however, it is also known that albumin and lymphocyte count may decrease in proportion to inflammatory burdens in autoimmune diseases.

**Objectives:** We investigated whether PNI at diagnosis can be used for estimating BVAS at diagnosis in antineutrophil cytoplasmic antibody (ANCA) associated vasculitis (AAV) patients.

**Methods:** We retrospectively reviewed the medical records of 160 patients with AAV. We calculated Birmingham vasculitis activity score (BVAS). We collected laboratory results including erythrocyte sedimentation rate (ESR), C-reactive protein (CRP), while blood cell, lymphocyte and platelet counts and serum albumin. Prognostic nutritional index (PNI) was calculated by  $(10 \times \text{serum albumin (g/dl)} + 0.005 \times \text{lymphocyte count (mm}^3))$ . The association was assessed linear regression analyses. The optimal cut-off of PNI for predicting relapse was set at 36.6. Comparison of cumulative relapse free survival was analysed by the Kaplan-Meier survival analysis.

**Results:** The mean age at diagnosis was 55.2 years and 48 patients were male. Eighty-five patients had MPA, 41 patients had GPA and 34 patients had EGPA. The mean BVAS and PNI at diagnosis were 11.9 and 43.4. Forty-three patients experienced relapse of AAV. In univariable linear regression analysis, BVAS was positively correlated with ESR and CRP and was negatively correlated with lymphocyte count, serum albumin level and PNI. In multivariable analysis, BVAS was the most significantly associated with only PNI (standardised  $\beta = -0.296$ ). Patients having PNI at diagnosis  $\leq 36.6$  exhibited significantly lower cumulative relapse free survival rate than those having PNI at diagnosis  $> 36.6$  ( $p = 0.002$ ).

**Abstract SAT0547 – Table 3.** Univariable linear regression analysis of BVAS and continuous variables in 160 patients with AAV

	Univariable analysis		
	Regression Coefficient (Crude B)	Correlation Coefficient (R=β)	p value
<b>Demographic data at diagnosis</b>			
Age (year old)	0.027	0.053	0.504
<b>Acute reactants at diagnosis</b>			
ESR (mm/hr)	0.044	0.218	0.006
CRP (mg/L)	0.023	0.169	0.033
<b>Laboratory results reflecting inflammation at diagnosis</b>			
White blood cell count (/mm <sup>3</sup> )	0.000	0.104	0.189
Lymphocyte count (/mm <sup>3</sup> )	-0.002	-0.214	0.007
Platelet count (x1,000/mm <sup>3</sup> )	0.003	0.060	0.449
Serum albumin (g/dL)	-2.557	-0.262	0.001
<b>PNI</b>	<b>-0.252</b>	<b>-0.307</b>	<b>&lt;0.001</b>

BVAS: Birmingham vasculitis activity score; ANCA: antineutrophil cytoplasmic antibody; AAV: ANCA associated vasculitis; ESR: erythrocyte sedimentation rate; CRP: C-reactive protein; PNI: prognostic nutritional index.

**Abstract SAT0547 – Figure 2.** The association of PNI at diagnosis with relapse of AAV during the follow-up. We selected the optimal cut-off of PNI at 36.6, divided patients into two groups according to the cut-off and conducted Kaplan-Meier survival analysis. Patients having PNI at diagnosis  $\leq 36.6$  exhibited significantly lower cumulative relapse free survival rate than those having PNI at diagnosis  $> 36.6$  ( $p = 0.002$ ). PNI: prognostic nutritional index; AAV: antineutrophil cytoplasmic antibody.

**Conclusions:** PNI at diagnosis can be used to estimate BVAS at diagnosis and PNI at diagnosis  $\leq 36.6$  may predict relapse during the follow-up in AAV patients.

#### PROGNOSTIC FACTORS FOR INTERSTITIAL LUNG DISEASE WITH MICROSCOPIC POLYANGIITIS

T. Shoda<sup>1,2</sup>, T. Takeuchi<sup>2</sup>, K. Isoda<sup>1,2</sup>, J. Komma<sup>1,2</sup>, T. Kotani<sup>2</sup>, S. Makino<sup>2</sup>.

<sup>1</sup>Clinical Immunology and Rheumatology, Yodogawa Christian Hospital;

<sup>2</sup>Department of Internal Medicine (IV), Osaka Medical College, Osaka, Japan

**Background:** Many cases of interstitial lung disease (ILD) complicated by microscopic polyangiitis (MPA) show the UIP pattern on chest HRCT, being similar to idiopathic pulmonary fibrosis (IPF/UIP), and the associated prognosis is poor compared with that of MPA without ILD.<sup>1</sup> However, the details have not been fully clarified.

**Objectives:** Prognostic factors of MPA-ILD sufficiently treated with immunosuppressive therapy were investigated.

**Methods:** Of consecutive patients with MPA who received inpatient treatment at our hospitals between 2001 and 2016, MPO-ANCA-positive patients who met the 2007 EMEA classification criteria and had concomitant ILD on HRCT were selected as the subjects. Using the clinical data and HRCT fibrosis score,<sup>2</sup> the outcome and prognostic factors were retrospectively investigated.

**Results:** The subjects were 65 patients with MPA-ILD, 31 and 34 patients were male and female, respectively, and the median age (interquartile range) was 73<sup>67–76</sup> years old. At the time of treatment initiation, MPO-ANCA was 129 (50.9–359) EU; KL-6, 461 (289–665) U/mL; Aa-DO2, 25.1 (15.6–34.2);%FVC, 81.2 (67.8–93.9)%; and%DLco/VA, 62.7 (45.3–73.2)%. On HRCT, the UIP and non-UIP patterns were observed in 44 and 21 patients, respectively. In treatment, prednisolone was administered to 63 patients, immunosuppressants were used in 55 patients, and blood purification therapy was concomitantly administered to 9 patients. MPO-ANCA on the final follow-up was lower than the detection sensitivity in 56 patients. The outcome was death in 23 patients, and the 5- and 10 year survival rates after treatment initiation were 69.8% and 51.1%, respectively (acute exacerbation of interstitial pneumonia: 5 patients, infection and alveolar haemorrhage: 3, infection: 1, pneumothorax: 1, lung cancer: 2, pulmonary hypertension: 1, sudden death: 4, heart failure: 2, renal failure: 2, cerebral haemorrhage: 1, intestinal haemorrhage: 1). Regarding lung disease-related death, the age (p=0.018),%FVC (p=0.026), HRCT fibrosis score (p<0.001), CPFE (p=0.004), decreased lung volume (p=0.041), and honeycombing (p=0.051) were extracted on univariate analysis, and the HRCT fibrosis score was significant on multivariate analysis (p=0.001): The prognosis of patients with a fibrosis score of 19% or higher was significantly poor.

**Conclusions:** Many MPA-ILD patients showed the UIP pattern, but their prognosis was better than that of previously reported IPF/UIP patients, suggesting that early immunosuppressive therapy is effective. However, expansion of fibrosis was included in the factors indicating a poor prognosis, suggesting the limit of immunosuppressive therapy.

#### AUTOLOGOUS HEMATOPOIETIC STEM CELL TRANSPLANTATION (HSCT) FOR ANTI-NEUTROPHIL CYTOPLASMIC ANTIBODY (ANCA)-ASSOCIATED VASCULITIS (AAV) – A EBMT RETROSPECTIVE SURVEY

T. Alexander<sup>1</sup>, C. Samuelson<sup>2</sup>, T. Daikeler<sup>3</sup>, J. Henes<sup>4</sup>, L. Skagerlind<sup>5</sup>, M. Akil<sup>2</sup>, G. Ehninger<sup>6</sup>, E. Jantunen<sup>7</sup>, D. Farge<sup>8</sup>, J. Snowden<sup>9</sup> on behalf of EBMT Autoimmune Diseases Working Party. <sup>1</sup>Rheumatology, University Medicine Berlin, Berlin, Germany; <sup>2</sup>Childrens Department, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK; <sup>3</sup>Rheumatology, University Hospital, Basel, Switzerland; <sup>4</sup>Rheumatology, Medizinische Universitätsklinik Abt. II, Tübingen, Germany; <sup>5</sup>Hematological Department, University Hospital of Umeå, Umeå, Sweden; <sup>6</sup>Hematology Department, Universitätsklinikums Dresden, Dresden, Germany; <sup>7</sup>Department of Medicine, University of Eastern Finland, Kuopio, Finland; <sup>8</sup>Internal Medicine, St. Louis Hospital, Paris, France; <sup>9</sup>Hematology Department, Sheffield Teaching Hospitals NHS Foundation Trust, Sheffield, UK

**Background:** ANCA-associated vasculitides (AAV) are chronic autoimmune diseases, which can present with life-threatening multi-system involvement. Despite the use of rituximab and other available modern biologic therapies some patients with AAV develop severe and refractory courses of disease.

**Objectives:** The aim of this study was to analyse outcomes of autologous hematopoietic stem cell transplantation (HSCT) for refractory AAV

**Methods:** Adults receiving HSCT for AAV and whose data were registered within the EBMT Autoimmune Disease Working Party (ADWP) were identified retrospectively through the EBMT database. Treating physicians were surveyed to produce a retrospective evaluation of outcomes.

**Results:** 7 patients underwent HSCT primarily for AAV between 1999–2014 in 6 centres across Europe. 5 females and 2 males were transplanted; 6 had a diagnosis of granulomatosis with polyangiitis (GPA) and 1 eosinophilic granulomatosis with polyangiitis (EGPA). Median age was 39 years (range 32–55 years). Patients had received 4–6 prior lines of therapy, including cyclophosphamide (CYC, with median cumulative dose of 80 g) and steroids in every case, and rituximab in 4 cases. Stem cell source was peripheral blood in every case; CD34-selection was performed in 4 cases, mean CD34<sup>+</sup> cell dose was 4.2 × 10<sup>6</sup>/kg (range 0.6–7.9 × 10<sup>6</sup>/kg). Conditioning regimen was CYC/ATG in 5 patients and CYC in 2 patients. Median follow-up was 86 months (range 1–204 months). Transplant-related mortality (TRM) occurred in 2 causes. All but one patient went into remission but 3 later relapsed at 6, 12 and 36 months, respectively, and required further treatment for disease control. At time of last clinical follow-up, 3 patients had drug-dependent partial response; 1 had drug-dependent complete remission and 1 had drug-free complete remission.

**Conclusions:** Outcomes of HSCT for these heavily pre-treated AAV patients were variable. Only 1 patient achieved drug-free complete remission and TRM was observed in a quarter. Nevertheless, HSCT had the potential to stabilise AAV in patients who initially failed to respond to conventional therapies. These data do not support HSCT for advanced stage ANCA-positive vasculitis, although it may have a place as salvage treatment in otherwise refractory patients. As for other autoimmune diseases, HSCT may provide better outcomes when performed at early stage of disease. Overall, HSCT should only performed in clinical trial settings in experienced centres.

#### HEALTH-RELATED QUALITY OF LIFE IN PATIENTS WITH GIANT CELL ARTERITIS TREATED WITH TOCILIZUMAB IN A PHASE 3 RANDOMISED CONTROLLED TRIAL

V. Strand<sup>1</sup>, S. Dimonaco<sup>2</sup>, K. Tuckwell<sup>3</sup>, M. Klearman<sup>3</sup>, N. Collinson<sup>2</sup>, J. H. Stone<sup>4</sup> on behalf of GiACTA Investigators. <sup>1</sup>Division of Immunology/Rheumatology, Stanford University, Palo Alto, USA; <sup>2</sup>Roche Products Ltd, Welwyn Garden City, UK; <sup>3</sup>Genentech, South San Francisco; <sup>4</sup>Massachusetts General Hospital Rheumatology Unit, Harvard Medical School, Boston, USA

**Background:** Superior rates of sustained glucocorticoid (GC)-free remission were shown in patients with giant cell arteritis (GCA) treated with weekly or every-other-week (wk) subcutaneous tocilizumab (TCZ) 162 mg +26 wk GC taper for 52 wks compared with placebo +26 wk or 52-wk GC taper (PBO +26 or PBO +52) in the GiACTA trial. Statistically significant improvements in SF-36 Physical Component Summary (PCS) scores were reported for weekly TCZ vs PBO +52 and in patient-reported global assessment of disease activity for both TCZ groups vs both PBO groups.<sup>1</sup>

**Objectives:** To report further analysis of patient-reported outcomes (PROs) in GiACTA.

**Methods:** Analyses of SF-36 PCS and Mental Component Summary (MCS), SF-36 domains, and Functional Assessment of Chronic Illness Therapy (FACIT)-fatigue compared patients treated with weekly TCZ (n=100) vs PBO +26 (n=50);

not shown) or PBO +52 (n=51) for 52 wks based on reported data, including all responders as well as patients with post-escape data following flare.  
**Results:** Improvements in SF-36 PCS and MCS scores, 6 of 8 SF-36 domains, and FACIT-Fatigue at wk 52 were significantly greater with weekly TCZ vs PBO +52 (p<0.01) (table 1, figure 1). At wk 52, mean scores met or exceeded age/gender (A/G)-matched normative scores in the weekly TCZ group; higher proportions of patients reported scores exceeding A/G norms in SF-36 PCS and MCS, all SF-36 domains, and FACIT-Fatigue (Table) compared with PBO groups. The median cumulative prednisone dose over 52 wks was lower with weekly TCZ (1862.0 mg) vs PBO +26 (3296.0 mg) or PBO +52 (3817.5 mg) (p<0.01).

Table. Change From Baseline to Wk 52; mean score (% ≥A/G norms)

	Weekly TCZ+26 n=100			PBO+52 n=51

**SAT0551 LEG ULCERS IN BEHCET'S SYNDROME: AN OBSERVATIONAL SURVEY IN 24 PATIENTS**

Y. Ozguler<sup>1</sup>, Z. Kutlubay<sup>2</sup>, A.S. Dikici<sup>3</sup>, M. Melikoglu<sup>1</sup>, C. Mat<sup>2</sup>, H. Yazici<sup>1</sup>, E. Seyahi<sup>1</sup>. <sup>1</sup>Department of Internal Medicine, Division of Rheumatology; <sup>2</sup>Department of Dermatology; <sup>3</sup>Department of Radiology, Istanbul University Cerrahpasa Medical Faculty, Istanbul, Turkey

**Background:** Formal experience with leg ulcers in Behçet's syndrome (BS) is limited. It is a rare complication that can be seen during the course of mainly pts with the post-thrombotic syndrome. They can be difficult to manage and may cause disability leading to unemployment and severe impairment in quality of life.

**Objectives:** In this observational survey, we aimed to describe clinical characteristics of pts with leg ulcers.

**Methods:** A total of 24 pts (23 M/1 F) that were seen at our multidisciplinary BS clinic between May 2016-Jan 2018 were evaluated with the help of a standardised questionnaire. Venous Doppler US and if necessary abdominal CT were used to evaluate localization of venous involvement. Biopsies were done if needed. Medical and other interventional treatments were recorded.

**Results:** The mean age at disease onset was 27.5±7.1 years. The median duration between the disease onset and ulcer development was 4.0 [2.5–11.5] years. The median follow-up was 7.8 [IQR: 2.9–14.2] years. Eleven (46%) were unemployed due to the leg ulcer. Venous involvement was present in 20 pts (83%). Lower extremity vein thrombosis was shown in all these 20 pts. It was mostly bilateral (15/20). Femoral veins were the most commonly involved (18/20), followed by popliteal veins (14/20), v. saphena magna or v. saphena parva (7/20), iliac veins or inferior vena cava (8/20). The same 9/20 pts had other large vessel involvement such as pulmonary artery (n=5) or dural sinus thrombosis (n=3). Four pts did not have any venous thrombosis or insufficiency. Histopathologic studies could be done in 3 and showed necrotizing vasculitis in 2 and venous stasis in the 3rd. Twelve pts (50%) had solitary ulcers and 12 had 2 or more. We observed a total of 34 ulcers in 24 pts. They were mostly found around the medial malleolus (15/34) and anterior surface of the tibia (14/34). Five pts had leg ulcers at unusual places such as lateral malleolus (n=2), popliteal fossa (n=1) and posterior surface of the tibia (n=2). Immunosuppressive agents including azathioprine, cyclophosphamide, interferon alpha, infliximab, and corticosteroids were used. Bed rest was advised to almost all. Iloprost infusions were given in 13 (54%) for a median duration of 6 mo. Additionally, larvae of *Lucilia sericata* were tried in 9 pts. Skin graft insertion was used in 2 pts, however, was successful in 1. We observed that in 11 (46%) pts 17 ulcers healed in median 24 mo [IQR:9–78]. In the remaining 13 (54%) pts 17 ulcers stayed as unhealed for a median 7 years [IQR:5–11], despite all interventions and medical treatment. We saw the mean age at BS onset was significantly younger (24.4±5.4 vs 30.4±7.3 years; p<0.05) and the median time between disease onset and ulcer development was significantly shorter (3 [IQR:1–4.5] vs 10 [IQR:4–14] years, p<0.05) in pts with healed ulcers compared to those with unhealed ulcers. There were no apparent associations with the type of management and the severity of venous involvement.

**Conclusions:** Leg ulcer develops mainly due to venous disease in the lower extremities. Peripheral arterial occlusive disease seems to be rarely involved. It may cause unemployment in 46% and be resistant to treatment in 54% of the cases. Ulcers that appear early during the disease course heal faster and is more responsive to treatment.

## Osteoarthritis

SAT0552

### BASILINE PREDICTORS OF UPPER LEG MUSCLE STRENGTH OVER 2 AND 4 YEARS IN SUBJECTS WITH KNEE OSTEOARTHRITIS: DATA FROM THE OSTEOARTHRITIS INITIATIVE

A.H. De Zwart<sup>1</sup>, M. van der Leeden<sup>1,2</sup>, L.D. Roorda<sup>1</sup>, M. van der Esch<sup>1</sup>, J.W. R. Twisk<sup>3</sup>, W.F. Lems<sup>1,4,5</sup>, J. Dekker<sup>2,6</sup>. <sup>1</sup>Reade Rehabilitation Center Amsterdam; <sup>2</sup>Dept of Rehabilitation Medicine, VU University Medical Center (VUmc), Amsterdam Public Health research institute; <sup>3</sup>Department of Epidemiology and Biostatistics, VU University Medical Center, VU University; <sup>4</sup>Dept of Rheumatology, VU University Medical Center (VUmc); <sup>5</sup>Jan van Breemen Research Institute; <sup>6</sup>Dept of Psychiatry, VU University Medical Center, VU University, Amsterdam, Netherlands

**Background:** Muscle weakness is common in patients with knee osteoarthritis (OA). Muscle weakness negatively impacts future functional status, and has been linked to symptomatic and radiographic progression of knee OA. Limited information is available on the course of muscle strength over time in these patients.

**Objectives:** The aim of the present study is to (i) analyse the course and (ii) to identify baseline predictors for upper leg muscle strength over time in subjects with knee OA.

**Methods:** Data were obtained from the progression cohort of the Osteoarthritis Initiative (OAI) database. Upper leg muscle strength (in N/kg) was measured at baseline, 24 months and 48 months. Potential baseline predictors were demographic factors (age, gender, race, body height, body weight), metabolic factors (body mass index (BMI)), nutrition and vitamin related factors (dietary protein intake, dietary energy intake, vitamin D use, glucosamine use), lifestyle related factors (alcohol consumption, smoking, physical activity), OA-specific factors (KL grade, knee alignment, effusion, pain, pain medication use) and health related factors (comorbidities and depression). Univariable and multivariable mixed model analyses were performed to analyse the course and to identify baseline predictors for muscle strength over time.

**Results:** A total of 1390 subjects with knee osteoarthritis were included. The majority of the subjects were female (57.1%), mean  $\pm$ SD for age was 61.4  $\pm$ 9.1 and mean  $\pm$ SD for body mass index was 30.2  $\pm$ 4.9. All subjects had frequent knee symptoms and radiographic tibiofemoral knee OA (Kellgren en Lawrence score  $\geq$  2) at baseline. Muscle strength was significantly lower at 24 months and 48 months compared to baseline; there was no difference between 24 and 48

months. Older age, being female, higher BMI, being non-Caucasian, lower protein intake (g/kg bodyweight), higher dietary energy intake, alcohol consumption, less physical activity valgus malalignment, higher score on the WOMAC pain subscale and the use of pain medication at baseline were predictors of lower muscle strength over time.

**Conclusions:** Muscle strength decreased over time between baseline and 24 months, but not between 24 and 48 months, which may be attributed to reaching a plateau or to other reasons. In the present study a number of demographic factors, metabolic factors and factors related to nutrition and vitamins, lifestyle and knee OA were found to be predictive for decreased muscle strength over time. This set of baseline factors can be used to identify patients with knee OA at risk for decline of muscle strength over time. External validation of our model is needed.

### CHONDROCALCINOSIS OF THE KNEE AND THE RISK FOR KNEE OR HIP OSTEOARTHRITIS PROGRESSION: DATA FROM THE KHOALA COHORT

A. Latourte<sup>1,2</sup>, A.C. Rat<sup>3,4</sup>, W. Ngueyon Sime<sup>3</sup>, C. Roux<sup>5</sup>, F. Guillemin<sup>3</sup>, P. Richette<sup>1,2</sup>. <sup>1</sup>Rheumatology Department, Lariboisière Hospital, Assistance Publique-Hôpitaux de Paris; <sup>2</sup>Inserm U1132, Paris Diderot University, Paris; <sup>3</sup>Inserm CIC 1433 Epidemiologie Clinique, Université de Lorraine; <sup>4</sup>Rheumatology Department, CHRU Nancy, Nancy; <sup>5</sup>Rheumatology Department, CHU Pasteur 2, Lamhess EA6309, UMR7277 iBV CNRS, University of Nice Sophia Antipolis, Nice, France

**Background:** Cross-sectional studies repeatedly found that chondrocalcinosis (CC) is associated with osteoarthritis (OA). However, whether CC worsens pre-existing knee or hip OA is unclear.

**Objectives:** We conducted this study to assess the impact of knee CC on the risk of 1) incident joint replacement surgery, 2) worsening of pain or function and 3) radiographic progression in patients with symptomatic knee OA.

**Methods:** The KHOALA cohort is a French multicenter population-based cohort of 878 patients with symptomatic knee and/or hip OA (ACR criteria), aged 40–75 years. Patients were followed annually by self-reported questionnaires and by clinical examination and radiography at baseline (year 0), years 3 and 5. Only patients with knee OA were kept for this analysis. CC, defined by the presence of calcium deposits within hyaline or fibro-cartilage on knee radiograph (anteroposterior view), was recorded as present or absent. We used Cox proportional-hazard regression modelling to estimate the local or systemic impact of CC at one knee (index knee) on the 5 year risk of incident total knee replacement (TKR) at the index knee or incident total hip or knee joint replacement (TJR), respectively. In the subgroup of patients without incident TJR during follow-up, logistic regression was performed to assess whether CC was associated with the worsening of Western Ontario and McMaster Universities Arthritis Index (WOMAC) for OA pain or function, or with radiographic progression as defined by a change in Kellgren and Lawrence (KL) grade, between years 0 and 5.

**Results:** Among the 656 patients included (mean  $\pm$ SD age 62.2 $\pm$ 8.5 years; 70.3% females), 93 (14.2%) had CC in at least one knee at baseline. As compared with patients without CC, those with CC were older (64.3 $\pm$ 9.6 vs 61.9 $\pm$ 8.2 years; p=0.009), had longer disease duration (16.4 $\pm$ 10.5 vs 13.0 $\pm$ 7.6 years; p<0.001) and lower body mass index (29.1 $\pm$ 5.3 vs 30.5 $\pm$ 6.3 kg/m<sup>2</sup>; p=0.047). Patients with/without CC did not differ in baseline pain (7.1 $\pm$ 4.3 vs 6.6 $\pm$ 3.8; p=0.26) and function (22.2 $\pm$ 14.7 vs 20.7 $\pm$ 13.5; p=0.32) scores, or KL grade (p=0.69). Overall, 105 (16.0%) and 91 (13.9%) patients underwent TJR and TKR of the index knee, respectively, during follow-up. The presence of CC at one knee did not affect the risk of TKR in the same index knee (HR=1.0; 95% CI 0.6 to 1.8), or risk of TJR (HR=0.9; 95% CI 0.5 to 1.6). In patients without incident TJR surgery (n=551), the presence of CC did not affect the risk of worsened WOMAC pain/function scores or KL grade at year 5.

**Conclusions:** In a population-based cohort of symptomatic knee OA, the presence of CC in the knee did not affect the risk of subsequent TKR or TJR, nor clinical or radiographic outcomes at 5 years. These results suggest that CC is not a risk factor for worsening clinical or structural outcomes in knee OA.

SAT0554

### PREOPERATIVE PHYSICAL FUNCTION INFLUENCES ON STAIR CLIMBING ABILITY 1 MONTH AFTER TOTAL KNEE ARTHROPLASTY

B.R. Kim. Jeju National University Hospital, Jeju, Korea, Republic Of

**Objectives:** This study was undertaken to identify preoperative physical performance factors predictive of stair climbing ability 1 month following total knee arthroplasty.

**Methods:** In this prospective cohort study, we assessed a total of 84 patients (8 males and 76 females; average age 72.0±6.0 years) who underwent a primary unilateral total knee arthroplasty (TKA). Before and 1 month after TKA, patients completed physical performance tests including stair climbing test (SCT), 6 min walk test (6MWT), timed up and go test (TUG), isometric knee flexor and extensor strength of the surgical and non-surgical knees, and instrumental gait analysis for spatiotemporal parameters. Self-reported disease-specific physical function measured by using the Western Ontario McMaster Universities Osteoarthritis Index (WOMAC) and self-reported quality of life measured by using Euro QOL five dimensions (EQ-5D) questionnaire.

**Results:** In the bivariate analyses, the postoperative SCT-ascent had a significant positive correlation with the SCT-ascent ( $r=0.29$ ,  $p=0.01$ ), SCT-descent ( $r=0.28$ ,  $p=0.01$ ), TUG ( $r=0.37$ ,  $p<0.01$ ), preoperative age ( $r=0.25$ ,  $p=0.02$ ), and a significant negative correlation with the preoperative 6MWT ( $r=-0.33$ ,  $p<0.01$ ), peak torque (PT) extensor of surgical knee ( $r=-0.29$ ,  $p=0.01$ ), PT flexor of surgical knee ( $r=-0.26$ ,  $p=0.02$ ), PT extensor of the non-surgical knee ( $r=-0.26$ ,  $p=0.02$ ), PT flexor of the nonsurgical knee ( $r=-0.25$ ,  $p=0.02$ ). The postoperative SCT-descent had a significant positive correlation with the SCT-ascent ( $r=0.28$ ,  $p=0.01$ ), SCT-descent ( $r=0.40$ ,  $p<0.01$ ), TUG ( $r=0.38$ ,  $p<0.01$ ), preoperative age ( $r=0.27$ ,  $p=0.01$ ), WOMAC function ( $r=0.30$ ,  $p<0.01$ ), and a significant negative correlation with 6-MWT ( $r=-0.33$ ,  $p<0.01$ ), PT extensor of surgical knee ( $r=-0.23$ ,  $p=0.04$ ), PT flexor of surgical knee ( $r=-0.24$ ,  $p=0.03$ ), PT extensor of the nonsurgical knee ( $r=-0.25$ ,  $p=0.03$ ), PT flexor of the nonsurgical knee ( $r=-0.23$ ,  $p=0.03$ ). In the linear regression analyses, the postoperative SCT-ascent had a significant positive correlation with the preoperative TUG ( $\beta=0.28$ ,  $p<0.01$ ), PT extensor of surgical knee ( $\beta=-0.23$ ,  $p=0.03$ ) and the postoperative SCT-descent had a significant positive correlation with preoperative SCT-descent ( $r=0.28$ ,  $p=0.01$ ), and the age ( $\beta=0.20$ ,  $p=0.04$ ).

**Conclusions:** This study demonstrated that preoperative physical function influenced on postoperative stair climbing ability 1 month after TKA. Using variables easily measured before surgery, it may be possible to predict with good accuracy for postoperative stair climbing ability. In addition, these results could be of importance in determining variable preoperative rehabilitation strategies to improve stair climbing ability, especially focusing on balance, endurance and strengthening exercises.

**SAT0555 ON THE WAY TO KNEE REPLACEMENT: TRAJECTORY AND CORRELATION OF KNEE OA MRI CARTILAGE THICKNESS, RADIOGRAPHIC JOINT SPACE WIDTH, AND WOMAC KNEE PAIN IN THE OAI**

C.K. Kwok<sup>1</sup>, E.L. Ashbeck<sup>1</sup>, M.J. Hannon<sup>2</sup>, S. Wax<sup>3</sup>, J. Kraines<sup>3</sup>. <sup>1</sup>University of Arizona Arthritis Center, University of Arizona, Arizona; <sup>2</sup>Medicine, University of Pittsburgh, Pittsburgh; <sup>3</sup>EMD Serono, Inc, Billerica, USA

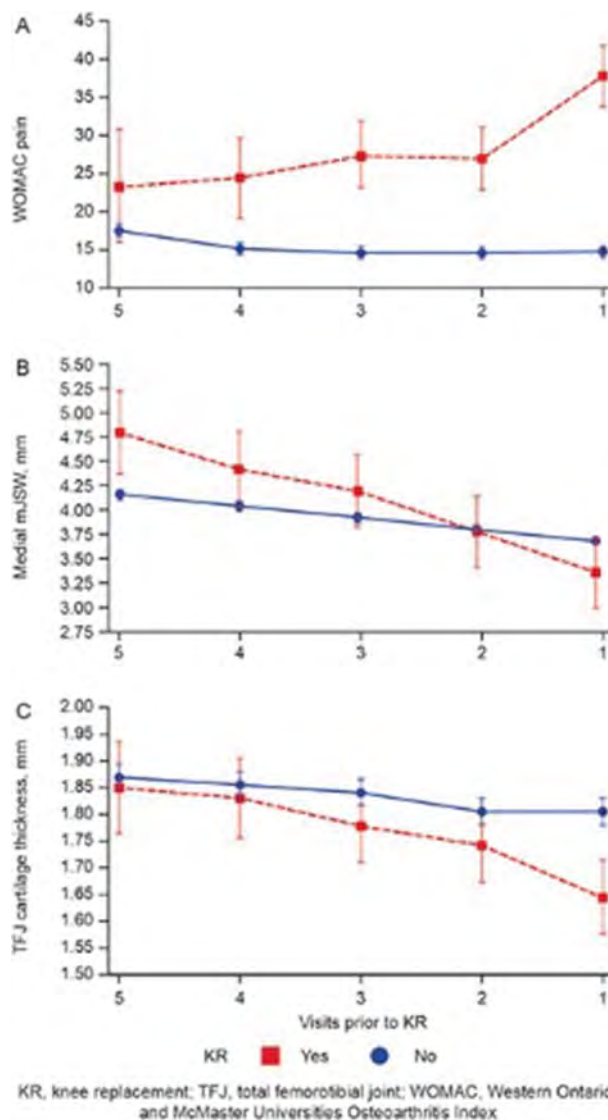

**Background:** Symptoms and structure are both important outcomes in osteoarthritis. However, prior knee osteoarthritis studies have found either poor or no correlation between structural and symptom outcomes.

**Objectives:** 1) Estimate the trajectory of mean WOMAC pain scores, medial minimum JSW (mJSW), and quantitative total tibiofemoral joint (TFJ) cartilage thickness in the five years leading up to knee replacement (KR), in KR case and control knees; 2) Estimate the correlation between change in WOMAC pain scores and change in structural measures prior to KR.

**Methods:** Osteoarthritis Initiative participants with at least one knee that met common eligibility criteria for DMOAD RCTs up to the 4 year follow-up visit were selected for analysis. Eligibility criteria included Kellgren and Lawrence grade of 2 or 3, medial mJSW  $\geq 2.5$  mm, and knee pain at its worst in the past 30 days (4–9 on a 10-point scale, or 0–3 with pain medication). Quantitative MRI (qMRI) cartilage thickness across the TFJ was measured on 3 Tesla MRI. Medial mJSW was measured on fixed flexion weight-bearing radiographs. WOMAC questionnaires were administered annually, and pain scores were scaled 0–100. Mean pain scores and structural measures at each annual visit were estimated with 95% confidence intervals (CI) using mixed effects models. Correlations between changes in structure and WOMAC pain scores were estimated using Spearman correlation coefficients ( $r$ ), with negative coefficients indicating a correlation between loss of cartilage and increase in pain.

**Results:** WOMAC scores and medial mJSW measures were available for 91 cases (KR knees) and 1833 controls, with knees contributing an average of 4.5 WOMAC observations and 3.7 medial mJSW observations to the longitudinal analysis. TFJ cartilage thickness measures were available in 86 cases and 524 controls, with knees contributing an average of 3.1 observations. Over 4 years of

observation, among knees that went on to KR, the greatest annual change in mean WOMAC pain (10.8; 95% CI: 7.2, 14.4) and cartilage thickness ( $-0.100$  mm; 95% CI:  $-0.118$ ,  $-0.082$ ) occurred between the two visits most proximal to KR, while the decrease in mean medial mJSW in the final year ( $-0.408$ ; 95% CI:  $-0.545$ ,  $-0.270$ ) was similar to the rate of loss in prior years (figure 1). Average pain and structure was relatively stable among knees that did not undergo KR. Estimated correlation was moderate between one year change in WOMAC pain and TFJ cartilage thickness among case knees over the year prior to KR ( $n=52$ ,  $r=-0.46$ ), with lower correlations at earlier time points based on a more limited sample. Among control knees, the estimated correlation between annual change in WOMAC pain and structure was negligible at all time points ( $r<0.1$ ).

**Conclusions:** Loss of TFJ cartilage thickness and pain progression were most pronounced over the year prior to knee replacement. Over this time frame, pain progression was moderately correlated with loss of TFJ cartilage, though not with loss of medial mJSW.

### COST-EFFECTIVENESS OF A BLENDED PHYSIOTHERAPY INTERVENTION IN PATIENTS WITH HIP AND/OR KNEE OSTEOARTHRITIS: A CLUSTER RANDOMISED CONTROLLED TRIAL

C. Kloek<sup>1,2,3</sup>, J.M. van Dongen<sup>4</sup>, D. Bossen<sup>5,6</sup>, J. Dekker<sup>7</sup>, C. Veenhof<sup>8</sup>.

<sup>1</sup>TRANZO, Tilburg University, Tilburg; <sup>2</sup>Netherlands Institute for Health Services Research (Nivel); <sup>3</sup>Research Group Innovation of Mobility Care, HU University of Applied Sciences, Utrecht; <sup>4</sup>Department of Health Sciences and EMGO+ Institute for Health and Care Research, VU University Medical Center Amsterdam; <sup>5</sup>ACHIEVE Centre of Expertise, Amsterdam University of Applied Sciences; <sup>6</sup>Coronel Institute of Occupational Health, Academic Medical Center, University of Amsterdam; <sup>7</sup>Department of Rehabilitation Medicine and Department of Psychiatry, VU University Medical Center Amsterdam, Amsterdam; <sup>8</sup>Department of Rehabilitation, Physiotherapy Sciences and Sports, Brain Center Rudolf Magnus, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** Physiotherapy, consisting of education, graded activity and exercises, is effective in improving levels of physical functioning and pain in patients with osteoarthritis (OA) of hip and/or knee. Blended physiotherapy, in which physiotherapy sessions and an online application are integrated, might support patients in taking an active role in the management of their condition and may reduce disease related costs. Recently, the blended physiotherapy intervention e-Exercise was developed.<sup>Bossen 2016</sup> E-Exercise is an integration of five face-to-face physiotherapy sessions with an online application consisting of information-, exercise-, and a graded activity module.

**Objectives:** To evaluate the cost-effectiveness of e-Exercise compared to usual physiotherapy in patients with OA of hip and/or knee, from the societal as well as the healthcare perspective.

**Methods:** This economic evaluation was conducted alongside a 12 month cluster randomised controlled trial, in which 108 patients received e-Exercise and 99 patients received usual physiotherapy. Clinical outcome measures were quality-adjusted life years (QALYs) according to the EuroQol (EQ-5D-3L), physical functioning (HOOS/KOOS) and physical activity (Actigraph Accelerometer). Costs were measured using self-reported questionnaires. Missing data were multiply imputed and bootstrapping was used to estimate statistical uncertainty.

**Results:** Total societal costs and total healthcare costs did not significantly differ between groups. Intervention costs ( $\Delta C$  € -202; 95% CI: -286 tot -120) and medication costs ( $\Delta C$  € -151; 95%: -340 tot -52) were significantly lower in e-Exercise compared to usual physiotherapy. No significant differences in effectiveness were found between groups (QALYS (0-1): B=0.01; 95% CI: -0.03 till 0.04; HOOS/KOOS (0-100): B=1.49; 95% CI: -4.70 till 0.69; Accelerometer (min/dag): B=-3.46; 95% CI: -11.66 till 4.73). For physical functioning and physical activity, the maximum probability of e-Exercise being cost-effective compared to usual physiotherapy was moderate (<0.82) from both perspectives. For QALYs, the probability of e-Exercise being cost-effective compared to usual physiotherapy was 0.68/0.84 at a willingness to pay of € 10.000,- and 0.70/0.80 at a willingness to pay of € 80.000,- per gained QALY, from respectively the societal and the healthcare perspective.

**Conclusions:** E-Exercise itself was significantly cheaper compared to usual physiotherapy in patients with hip and/or knee OA, but not cost-effective from the societal- as well as healthcare perspective. The decision between both interventions can be based on the preferences of the patient and the physiotherapist.

### 10-YEAR TRAJECTORIES OF PAIN IN EARLY KNEE AND HIP OSTEOARTHRITIS; THE CHECK STUDY

J. Runhaar<sup>1</sup>, J. Waarsing<sup>2</sup>, D. Schiphof<sup>1,1</sup>, W. van Spij<sup>3</sup>, M. van Middelkoop<sup>1</sup>, S. Bierma-Zeinstra<sup>4</sup>. <sup>1</sup>Department of General Practice; <sup>2</sup>Department of Orthopedics, ERASMUS MC, Rotterdam; <sup>3</sup>Department of Rheumatology and Clinical Immunology, UMC Utrecht, Utrecht; <sup>4</sup>Department of General Practice and Department of Orthopedics, ERASMUS MC, Rotterdam, Netherlands

**Background:** Osteoarthritis (OA) is one of the leading causes of chronic pain worldwide. Yet, relatively little is known about the trajectories of pain in early knee and hip OA.

**Objectives:** To determine subgroups of patients with homogenous patterns of pain over 10 years follow-up, among patients with early hip and/or knee complaints in primary care.

**Methods:** Data from the CHECK cohort (Cohort Hip and Cohort Knee) were used. For this cohort, 1002 patients between 45 and 65 years at or within 6 months from their first consultation at a general practitioner for symptoms of their hips and/or knees, were included and followed for 10 years. A numeric rating scale (NRS) for perceived pain was obtained at baseline and after 2, 5, 8 and 10 years, or until total joint replacement. Using these longitudinal data, subgroups of patients with comparable trajectories over time were identified using Latent Class Growth Analysis (LCGA). Models with 3 to 6 classes when using linear, cubic and quadratic trajectories were evaluated using Mplus software.

**Results:** At baseline, the 998 subjects (79% women) with  $\geq 2$  NRS data points available had a mean age of 55.9 $\pm$ 5.2 years and a mean BMI of 26.2 $\pm$ 4.0 kg/m<sup>2</sup>. In total, 410 patients reported knee pain only (41%), 173 hip pain only (17%), and 415 reported both knee and hip pain (42%) at baseline. On a joint level, 156 knees and 160 hips had KL-grade  $\geq 2$  at baseline.

The by LCGA derived models of 3 groups with a linear trajectory and of 6 groups with a cubic trajectory resulted in comparable goodness of fit indicators (Bayesian Information Criteria 17 991 vs. 17927, Akaike Information Criteria 17 927 vs. 17761, and entropy 0.694 vs. 0.683 for the 3 and 6 group models, respectively). Both models and the corresponding trajectories are presented in the figure 1. In the 3 group model, the 'high pain trajectory' (group 2, blue line, n=206) contained most patients with knee and hip complaints (53%), females (84%), TJR (21%), and the highest mean BMI (27.6 $\pm$ 4.6). The 'low pain trajectory' (group 3, green line, n=441) contained most patients with only hip (19%) and only knee (48%) complaints, and the lowest mean BMI (25.3 $\pm$ 3.6).

In the 6 group model, the 'always high pain trajectory' (group 1, red line, n=176) contained most females (86%) and TJR (24%), and the highest mean BMI (27.7 $\pm$ 4.7). The 'always low pain trajectory' (group 5, brown line, n=289) contained most patients with only knee complaints (51%) and the lowest mean BMI (25.0 $\pm$ 3.4). The 'decreasing pain trajectory' (group 2, blue line, n=37) contained most patients with only hip complaints (22%). The 'fluctuating high pain trajectories' (groups 3 (n=88) and 4 (n=142), green and pink lines) contained most females (3:83% and 4:86%), and patients with knee and hip complaints (3:61% and 4:44%).

**Conclusions:** The 6 group model identified more extreme groups with lower minimal and higher maximal prevalence of the presented clinical characteristics. In the end, the conclusion drawn from the two models appear similar; Patients presenting with both knee and hip complaints had less favourable pain trajectories over the following 10 years and the number of total joint replacements was the highest in the groups always reporting high pain scores.

SAT0558

### PHARMACOTHERAPY OF OBESITY IN PATIENTS WITH KNEE OSTEOARTHRITIS AND METABOLIC SYNDROME

E. Strebkova, L. Alekseeva. Nasonova Research Institute Of Rheumatology, Moscow, Russian Federation

**Background:** Osteoarthritis (OA) is one of most common diseases of locomotor system. Different OA phenotypes are currently identified, including metabolic OA associated with meta-inflammation induced by obesity and metabolic syndrome.

**Objectives:** To assess orlistat pharmacotherapy in patients with knee OA (KOA) and metabolic syndrome.

**Methods:** 50 female patients with Kellgren-Lawrence stage II-III KOA were randomised into 2 equal groups in a 6 months study. All pts were administered lifestyle

changes by increasing physical activity and limiting calories (1200 kcal), and patients from Group 1 were additionally treated with orlistat 120 mg 3 times a day. WOMAC and EQ-5D scores and anthropometric data were regularly obtained during the study; biochemistry panel (lipid profile, glucose, CRP), leptin and interleukin-6 were assessed at baseline and at Mo 6.

**Results:** Metabolic syndrome (MS) was diagnosed at baseline in 41 patients. Following orlistat therapy pts from Group 1 managed to reduce their body weight by 10,07% ( $p<0,05$ ; Fig 1), and waist circumference (WC) by 7,5% ( $p<0,05$ ), improving the clinical course of OA: total WOMAC score was reduced by 55% ( $p<0,05$ ; Fig 2), and EQ-5D quality of life was improved by 44% ( $p<0,05$ ). Patients from Group 2 lost only 0,88% of their body weight versus the baseline, and reduced WC by 1%, without changes in EQ-5D scores. MS lab parameters – lipid profile and glucose – did not change significantly after orlistat treatment in Group 1. Patients from Group 2 showed significant increase in total cholesterol ( $p<0,05$ ) after 6 months of dieting and exercising, revealing direct correlation between raised LDL and triglycerides levels and total WOMAC scores. CRP dropped by 23,74% ( $p>0,05$ ) in Group 1. More pronounced decrease of CRP was observed in pts losing more than 10% of their body weight ( $p=0,07$ ). Statistically significant decrease in leptin and IL-6 levels was documented in pts with orlistat-induced significant weight loss ( $p<0,05$ ).

Abstract SAT0558 – Figure 1. Body mass reduction (kg,  $p<0,05$ ).

Abstract SAT0558 – Figure 2. Dynamics of total WOMAC score ( $p<0,05$ ).

**Conclusions:** Abdominal obesity is considered to be the major component of MS and key risk factor for the development and progression of knee OA. Our study demonstrates that induced by orlistat, diet and exercise weight loss by >10% improves the clinical course of KOA and patient’s quality of life, reduces activity of inflammation and improves key parameters of metabolic syndrome. Therefore, KOA and MS therapeutic strategies should include pharmacotherapy of obesity in patients who fail to lose weight with the diet and physical exercise only.

**SAT0559 SYSTEMATIC LITERATURE REVIEW (SLR) FOR THE 2018 UPDATE OF THE EULAR MANAGEMENT RECOMMENDATIONS FOR HAND OSTEOARTHRITIS (OA)**

F. Kroon<sup>1</sup>, M. Kloppenburg<sup>1,2</sup>, J. Schoones<sup>3</sup>, L. Carmona<sup>4</sup>. <sup>1</sup>Rheumatology, <sup>2</sup>Clinical Epidemiology, <sup>3</sup>Walaeus Library, Leiden University Medical Center, Leiden, Netherlands; <sup>4</sup>Instituto de Salud Musculoesquelética, Madrid, Spain

**Background:** As part of the update of the EULAR management recommendations an SLR of available evidence for hand OA treatment was performed.

**Objectives:** To inform the task force of an overview of available evidence for the efficacy and safety of all non-pharmacological, pharmacological and surgical interventions for hand OA.

**Methods:** We searched Medline, EMBASE, Cochrane Central, and 2016–2017 conference abstracts until June 2017 for (randomised) controlled trials or Cochrane reviews. Observational studies with a comparator were included to assess safety, or effects of surgical interventions. Main efficacy outcomes were pain, function, and hand strength. Risk of bias was assessed. Meta-analysis was performed if possible.

**Results:** Of 7036 records, 127 references were included, of which 50 studies concerned non-pharmacological, 64 concerned pharmacological, and 12 concerned surgical interventions. Most trials were published after 2007. Many studies were at high risk of bias, mainly due to inadequate randomisation or lack of blinding. Overall, effect sizes of effective therapies were small. Beneficial non-pharmacological treatments for pain relief include hand exercise, and prolonged splinting of the thumb base (Table). A single trial showed that assistive devices had no effect on pain, but led to functional improvements (mean difference (MD) –0.3, 95% confidence interval (CI) –0.6;0.01 on AUSCAN function, range 1–5). Topical and oral non-steroidal anti-inflammatory drugs (NSAIDs) proved equally effective for pain relief (Table), while topical NSAIDs led to less adverse events (e.g., risk ratio for withdrawals due to adverse events 0.15, 95% CI 0.03;0.63). Single trials demonstrated beneficial effects for other pharmacological interventions, including chondroitin sulphate, and intra-articular (i.a.) glucocorticoid injections in interphalangeal joints (Table). Compared to placebo, no beneficial effects were demonstrated for i.a. glucocorticoid or hyaluronic acid injections in the thumb base, hydroxychloroquine, or tumour necrosis factor inhibitors (Table). In two trials, structure modification was the primary outcome measure, though no disease-modifying properties were found in these studies. In a Cochrane review no surgical intervention for thumb base OA appeared more effective than another, although in general, more complex procedures led to more complications.

Abstract SAT0559 – Table 1. Effect on pain of main non-surgical interventions for hand OA from controlled trials.

Intervention	Control	N patients (studies)	Duration	OA type or location	RoB	Difference?	Effect estimate [95% CI]
<b>Non-pharmacological interventions</b>							
Hand exercise	No exercise	381 (5)	12 w	-	High	Intervention better	SMD -0.27 [-0.47, -0.07]
Joint protection	No joint protection	257 (1)	26 w	-	High	No	MD -0.79 [-1.7, 0.12] on AUSCAN pain (range 0-20)
Thumb splint	Usual care or no intervention	221 (4)	4-8 w	CMC	High	No	MD -2.9 [-12.2, 6.3] on 100 mm VAS

**Conclusions:** The number of trials in hand OA has steeply increased over the last decade, providing evidence for several therapeutic options for symptom relief, though no disease-modifying drugs have yet been found. High-quality trials investigating often used analgesics like paracetamol are needed.

**Disclosure of Interest:** None declared

### FROM A 2-YEAR MULTICENTRE CLINICAL TRIAL IN KNEE OSTEOARTHRITIS, A METABOLOMIC ANALYSIS REVEALS THAT OVER ACTIVATION OF THE CONVERSION PATHWAY OF PHOSPHATIDYLCHOLINE TO LYOPHOSPHATIDYLCHOLINE IS ASSOCIATED WITH KNEE CARTILAGE VOLUME LOSS OVER TIME

G. Zhai<sup>1</sup>, J.-P. Pelletier<sup>2</sup>, M. Liu<sup>1</sup>, E. Randell<sup>3</sup>, J. Martel-Pelletier<sup>2</sup>. <sup>1</sup>Discipline of Genetics, Memorial University of Newfoundland, St. John's, NL; <sup>2</sup>University of Montreal Hospital Research Centre, Montreal; <sup>3</sup>Department of Laboratory Medicine, Memorial University of Newfoundland, St. John's, NL, Canada

**Background:** While progression of osteoarthritis (OA) is variable, no tools yet exist to predict disease course.

**Objectives:** To identify, using a metabolomic approach, serum marker(s) for predicting knee cartilage volume loss over time measured by magnetic resonance imaging (MRI) in a 24 month Phase III clinical trial in patients with symptomatic knee OA.

**Methods:** 139 knee OA patients who completed the clinical trial according to protocol were selected from a 24 month DMOAD trial studying the effect of licofelone versus naproxen. MRI was performed at baseline and 24 months. Targeted metabolomic profiling was performed on serum collected at baseline. Metabolite ratios as proxies for enzymatic reaction were calculated and used in the analysis. The levels of 186 metabolites were measured and 152 met the quality control requirements. The metabolite concentrations were standardised using the Z-score. 21 952 pair wise metabolite ratios were analysed. A metabolome-wide significance level of  $\alpha=2.3 \times 10^{-5}$  was defined after correcting multiple testing with the Bonferroni method. Univariable and multivariable analyses adjusted for age, sex, BMI and treatment were performed. Gene expression analysis of human OA articular cartilage (n=32) and subchondral bone (n=39) tissues from total joint replacement, and controls (non-OA) from individuals having a fracture (n=21; n=9, respectively) was done to further explore the potential metabolic pathway(s).

**Results:** Data revealed that the baseline ratio of the metabolite lysophosphatidylcholine 18:2 (lysoPC 18:2) to phosphatidylcholine 44:3 (PC44:3) was associated with the cartilage volume loss in the lateral compartment (univariable,  $b=-0.21 \pm 0.04$ ,  $p=8.53 \times 10^{-7}$ ; multivariable,  $b=-0.18 \pm 0.04$ ,  $p=9.5 \times 10^{-6}$ ). Further experiments demonstrated that the lysoPC 18:2/PC44:3 ratio was also significantly ( $r=0.31$ ,  $p=0.0002$ ) correlated with an articular degradation marker, COMP. The data of the increased lysoPC 18:2 to PC44:3 ratio involve a conversion pathway of PC to lysoPC which is catalysed by a phospholipase A2 (PLA2), suggesting a higher activity of PLA2. Data demonstrated that in both human cartilage and subchondral bone tissues, a PLA2, PLA2 group 5 (PLA2G5), was markedly over-expressed in OA cartilage and subchondral bone compared to these non-OA tissues (445% and 158% increase, respectively, all  $p<0.02$ ). Interestingly, in these tissues TNF- $\alpha$  was also upregulated ( $p=0.007$ ;  $p=0.06$ , respectively), and positively correlated with PLA2G5 ( $r=0.71$ ,  $p=0.02$ ).

**Conclusions:** Our data suggest that the ratio of lysoPC 18:2/PC44:3 is predictive of greater risk of cartilage loss in OA. We speculate that this specific conversion pathway may produce a bioactive molecule like oleoylethanolamide (OEA), which has been demonstrated to bind to a novel cannabinoid receptor, GPR119, thus could be a novel therapeutic target for OA treatment.

**Acknowledgements:** This work is supported by Canadian Institutes of Health Research. The metabolomic profiling was done at Translational Metabolomics Innovation Centre. The original clinical trial was supported in part by grants from Merckle GmbH (Ulm, Germany) and ArthroLab Inc. (Montreal, Quebec, Canada).

### MITOCHONDRIAL BACKGROUND INFLUENCES THE JOINT EVOLUTION IN A CONPLASTIC MOUSE MODEL OF AGEING

I. Rego-Pérez<sup>1</sup>, A.V. Lechuga-Vieco<sup>2</sup>, M. Scotece<sup>1</sup>, P. Filgueira-Fernández<sup>1</sup>, S. Pértiga<sup>3</sup>, J.A. Enríquez<sup>2</sup>, F.J. Blanco<sup>1</sup>. <sup>1</sup>Servicio de Reumatología, INIBIC – HOSPITAL UNIVERSITARIO A CORUÑA, A Coruña; <sup>2</sup>Grupo de Genética funcional del sistema de fosforilación oxidativa, Centro Nacional de Investigaciones Cardiovasculares (CNIC), Madrid; <sup>3</sup>Unidad de Epidemiología Clínica y Bioestadística, Inibic – Hospital Universitario A Coruña, A Coruña, Spain

**Background:** Several studies showed interesting associations between mtDNA haplogroups and different OA-related features, including prevalence, incidence or progression of the disease<sup>1-3</sup>. The use of conplastic animals-individuals with the same nuclear genome but different mtDNA variants-provides an accurate tool to study the influence of the mitochondrial background in the ageing process<sup>4</sup>.

**Objectives:** To study the influence of mtDNA variation in the degree of joint deterioration of the knees of aged animals using a conplastic mouse model of ageing

**Methods:** mtDNAs from C57BL/6 and NZB/OlaHsd mice were used. These mtDNAs differ by 12 missense mutations, 4 tRNAs mutations, 8rRNAs mutations and 10 non-coding region mutations. Then, a conplastic mouse strain was developed with the C57BL/6 nuclear genome and the NZB/OlaHsd mtDNA (BL/6<sup>NZB</sup>) to compare with the original C57BL/6 strain (BL/6<sup>C57</sup>) in animals of 25 and 75 weeks. A total of 38 limbs from 19 mice were processed to perform histologic analyses: 8 BL/6<sup>NZB</sup>25 w, 10 BL/6<sup>NZB</sup>75 w, 10 BL/6<sup>C57</sup>25 w and 10 BL/6<sup>C57</sup>75 w.

**Results:** Mankin score data showed significantly increased values in all knees from both strains at 75 w compared with 25 w ( $p<0.001$ ), confirming the ageing of the joint. When 75 w mice were selected (table 1), the BL/6<sup>C57</sup> strain showed a significantly increased score in whole joint ( $p=0.038$ ), femoral condyles ( $p=0.021$ ) and medial femoral condyle ( $p=0.015$ ) than BL/6<sup>NZB</sup> strain. Safranin-O/Fast-green ratio value at 75 w was higher in the medial compartment of BL/6<sup>NZB</sup> compared with BL/6<sup>C57</sup> (both tibial plateau and femoral condyle); however, only the differences detected in the medial compartment of the tibial plateau reached the statistical significance ( $p<0.001$ ), whilst the differences detected in the femoral condyle borderline the statistical significance ( $p=0.091$ ).

The width of the epiphyseal plate was analysed in both tibia and femur bones. The results showed significantly decreased values in BL/6<sup>C57</sup> at 75 w compared with the same strain at 25 w in tibial plateau ( $p<0.001$ ) and femoral condyle ( $p=0.049$ ); however, these differences were not observed in animals belonging to BL/6<sup>NZB</sup> strain. In addition, the BL/6<sup>C57</sup>75 w strain also showed significantly lower values in tibial plateau than BL/6<sup>NZB</sup> strain at the same age ( $p=0.032$ )

**Abstract SAT0561 – Table 1.** Mankin score grading of cartilage destruction in conplastic mice BL/6<sup>C57</sup> and BL/6<sup>NZB</sup> at 75 w

### HIP SHAPE PREDICTS KNEE OSTEOARTHRITIS OUTCOMES OVER A DECADE IN OLDER-ADULTS

I.P. Munugoda<sup>1</sup>, H.G. Ahedi<sup>1</sup>, R.M. Aspden<sup>2</sup>, K. Wills<sup>1</sup>, S.E. Graves<sup>3</sup>, M. Lorimer<sup>4</sup>, F. Cicuttini<sup>5</sup>, J.S. Gregory<sup>2</sup>, G. Jones<sup>1</sup>, M.L. Callisaya<sup>1</sup>, D. Aitken<sup>1</sup>. <sup>1</sup>Menzies Institute for Medical Research, University of Tasmania, Hobart, Tasmania, Australia; <sup>2</sup>Aberdeen Centre for Arthritis and Musculoskeletal Health, Institute of Medical Sciences, University of Aberdeen, Aberdeen, UK; <sup>3</sup>Australian Orthopaedic Association National Joint Replacement Registry (AOANJRR); <sup>4</sup>South Australian Health and Medical Research Institute (SAHMRI), Adelaide, South Australia; <sup>5</sup>Department of Epidemiology and Preventive Medicine, Monash University Medical School, Melbourne, Victoria, Australia

**Background:** Various hip shapes may be important as a risk factor for development and progression of knee osteoarthritis, due to the biomechanical link between the two joints.

**Objectives:** This study aims to identify the relationship between hip morphology and structural and clinical osteoarthritis outcomes in the knee over 10.7 years, in older-adults.

**Methods:** 377 community-dwelling older-adults aged 50–80 years were studied. At baseline, dual-energy X-ray absorptiometry images of the left hip were obtained and hip shapes were described using mode scores from an 85-point statistical shape model. MRI scans were conducted at baseline and a mean follow-up of 10.7(SD:0.67) years later, to assess right knee tibial cartilage volume and bone-marrow lesions(BMLs). Knee pain was assessed using Western Ontario and McMaster Universities Osteoarthritis Index(WOMAC). Knee replacement(KR) data were obtained by data linkage to the Australian Orthopaedic Association National Joint Replacement Registry. Linear mixed-effects, log-binomial models

and survival analysis, were used to investigate associations between hip shape modes and change in cartilage volume, incident BMLs, worsening knee pain and left KR respectively. All models were adjusted for baseline age, sex, BMI, knee injury or surgery and hip radiographic osteoarthritis (ROA), while the KR model was additionally adjusted for WOMAC pain and knee ROA.

**Results:** Ten hip shape modes were identified, describing 78% of the total shape variance in descending order from mode 01 (31% variance) to mode 10 (1.82% variance). Hip shapes with a larger greater trochanter (mode 07) were associated with lower knee cartilage volume loss (Beta:2.14, 95% CI:0.07,4.21), while a shorter and narrower femoral neck shape (mode 09) was related to increased volume loss (Beta:-3.86, 95% CI:-6.16,-1.56). Increasingly non-spherical femoral head (mode 04) was associated with an increased risk of incident BMLs (RR:1.19, 95% CI:1.07,1.34). Those with a longer, wider femoral neck and a larger femoral head (mode 01) had an increased risk of worsening knee pain (RR:1.33, 95% CI:1.09,1.61), whereas those with a smooth curving upper femoral neck (mode 09) had a lower risk of worsening knee pain (RR:0.78, 95% CI:0.67,0.90). A larger greater trochanter and wider femoral neck shape (mode 08) was associated with an increased risk of KR (RR:1.73, 95% CI:1.18,2.52), while increasing acetabular coverage (mode 10) was associated with a lower risk of KR (RR:0.54, 95% CI:0.36,0.8).

**Conclusions:** Hip shape variations were associated with significant MRI-based and clinical outcomes in knee over 10.7 years, possibly due to biomechanical, lifestyle or other factors related to both joints. These results suggest that hip shape may play an important role in the onset and progression of knee osteoarthritis over time.

#### IDENTIFICATION AND VALIDATION OF PHYSICAL ACTIVITY PHENOTYPES FOR KNEE OSTEOARTHRITIS: A POPULATION-BASED COHORT STUDY

I.P. Munugoda<sup>1</sup>, F. Pan<sup>1</sup>, K. Wills<sup>1</sup>, F. Cicuttini<sup>2</sup>, S.E. Graves<sup>3</sup>, M. Lorimer<sup>4</sup>, G. Jones<sup>1</sup>, M.L. Callisaya<sup>1</sup>, D. Aitken<sup>1</sup>. <sup>1</sup>Menzies Institute for Medical Research, University of Tasmania, Hobart, Tasmania; <sup>2</sup>Department of Epidemiology and Preventive Medicine, Monash University Medical School, Melbourne, Victoria; <sup>3</sup>Australian Orthopaedic Association National Joint Replacement Registry (AOANJRR); <sup>4</sup>South Australian Health and Medical Research Institute (SAHMRI), Adelaide, South Australia, Australia

**Background:** The identification of phenotypes to reduce heterogeneity of characteristics is important in understanding the development and progression of knee osteoarthritis.

**Objectives:** This study aimed to identify physical activity (PA) phenotypes and to investigate the association of these phenotypes with tibial cartilage volume, bone marrow lesions (BMLs) and knee replacements (KR) over 10.7 years.

**Methods:** 1046 community-dwelling older adults aged 50–80 years were studied. At baseline, PA was measured by pedometers (steps/day), knee pain was assessed using Western Ontario and McMaster Universities Osteoarthritis Index (WOMAC) and body mass index (BMI) was determined utilising objective weight and height measures. MRI scans were conducted at baseline and 10.7 years to assess tibial cartilage volume and BMLs. The incidence of KR was determined by data linkage to the Australian Orthopaedic Association National Joint Replacement Registry. Latent class analysis was used to determine 'PA phenotypes' based on PA, BMI and WOMAC pain at baseline. Linear mixed-effects models and log-binomial models were used to estimate the associations between the identified PA phenotypes with change in cartilage volume, incident BMLs, and KR surgery over 10.7 years. All models were adjusted for age, sex, and history of knee injury or surgery, while the KR model was additionally adjusted for the prevalence of knee radiographic osteoarthritis.

**Results:** Three PA phenotypes were identified: Class 1: Normal/overweight participants with low levels of PA and low pain (42%); Class 2: Obese participants with low levels of PA and high pain (26%); Class 3: Normal/overweight participants with high levels of PA and low pain (32%). Mean cartilage volume loss over 10.7 years was 465±231 mm<sup>3</sup>. 221 participants had an incident BML while 74 had an incident KR. Class 2 participants had greater cartilage volume loss over 10.7 years (Beta: -79.9, 95% CI -135.8,-23.9) and, had a higher risk of KR (RR 2.36, 95% CI 1.20, 4.67) compared to Class 1 participants. Class 3 was not associated with cartilage volume loss (Beta: -36.2, 95% CI -86.6, 14.1) or risk of KR (RR 0.86, 95% CI 0.40, 1.84) compared to Class 1. Similarly, PA phenotypes were not associated with incident BMLs (Class 2: RR 1.15, 95% CI 0.88, 1.50; Class 3: RR 1.19, 95% CI 0.93, 1.54; compared to Class 1).

**Conclusions:** Our findings support the existence of homogeneous PA profiles, and suggest that PA interacts with body weight and knee pain and has long-term impacts on osteoarthritis outcomes.

SAT0564

#### EFFECTS OF EDUCATION AND INCOME ON PREVALENCE, INCIDENCE, AND PROGRESSION OF RADIOGRAPHIC KNEE OSTEOARTHRITIS: AN ANALYSIS OF THE OSTEOARTHRITIS INITIATIVE DATA

I. Shirinsky, V. Shirinsky. Research Institute Of Fundamental And Clinical Immunology, Novosibirsk, Russian Federation

**Background:** Low socioeconomic status (SES) is one of the strongest predictors of morbidity and mortality from many chronic diseases including cardiovascular diseases, obesity, and diabetes.<sup>1</sup> There is insufficient data regarding impact of SES on knee osteoarthritis (OA).

**Objectives:** To evaluate the associations between education, income levels and prevalence, incidence, and progression of radiographic knee OA

**Methods:** For the current analysis we used data from the publicly available Osteoarthritis Initiative (OAI) database. The education status of the participants was dichotomized into either low/moderate or high educational attainment. The income status was dichotomized using 50 K US threshold. A baseline sample was used to analyse the impact of SES on knee OA prevalence (prevalence sample). To evaluate the effects of SES on knee OA incidence and progression we analysed the samples of OAI participants with KL <2 at baseline (incidence sample) and OAI participants with JSN <3 at baseline (progression sample), respectively. We used logistic regression models to assess the association between SES and prevalence and incidence of radiographic knee OA (defined as KL2 and JSN or joint replacement), and disease progression (defined as increase in semiquantitative JSN or a new knee replacement). Generalised estimating equations (GEE) were used to adjust for the correlation between knees. The models were adjusted for multiple covariates including age, race, and body mass index.

**Results:** Prevalence, incidence, and progression samples consisted of 4371 participants (8741 knees), 2268 participants (4535 knees), and 3950 participants (4013 knees), respectively.

Higher education attainment and higher income were associated with decreased prevalence of the knee OA in the crude analyses. After adjustment for confounders these associations became insignificant (Table). There was no effect of SES on incidence and progression of the knee OA.

Table

	Prevalence			
	Unadjusted OR (95% CI)	P value	Adjusted OR (95% CI)	P value
Education	0.8 (0.7–0.9)	<0.001	1.05 (0.9–1.18)	0.48
Income	0.71 (0.64–0.8)	<0.001	1 (0.87–1.4)	0.97

OR – odds ratio, CI – confidence interval

**Conclusions:** Higher levels of education and income are linked with decreased prevalence of radiographic knee OA. Lack of this association after adjustment suggests confounding or mediating effects of other risk factors. Future studies are needed to delineate the precise mechanisms of how SES impact knee OA.

SAT0565

#### ADJUSTING FOR THE INTRA-ARTICULAR PLACEBO EFFECT IN KNEE OSTEOARTHRITIS THERAPIES

I. Simsek<sup>1</sup>, T. Phalen<sup>1</sup>, A. Bedenbaugh<sup>1</sup>, M. Phillips<sup>2</sup>, J. Tambiah<sup>1</sup>. <sup>1</sup>Samumed, LLC, San Diego, USA; <sup>2</sup>McMaster University, Ontario, Canada

**Background:** Currently, there is a large debate regarding the appropriateness of intra-articular (IA)-saline injection as a "placebo" comparator in knee osteoarthritis (OA) trials and meta-analyses. There is substantial evidence to suggest that the injection of saline into the joint is not without treatment effect.

**Objectives:** This study aimed to assess the current literature's estimates of the IA-saline treatment effect against a range of appropriate minimal clinically important difference (MCID) values to identify if IA-saline provides a therapeutic effect that is not indicative of a null-effect.

**Methods:** The treatment effect estimates of IA-saline and topical placebo for knee OA pain, relative to oral placebo, were derived from a published network meta-analysis Bannuru et al, 2015 and compared across a range of plausible

MCID values. Effect estimates of pharmacologic knee OA treatments were also extracted from recent high-quality meta-analyses, and the effect of IA-saline or topical placebo was used as an adjustment for meta-analyses that used IA-saline or topical placebo as a comparator, respectively. This was done to estimate the therapeutic effect of these treatment options when compared to a truly null treatment option, as IA-saline has been shown to not be a null-effect intervention. The unadjusted and adjusted treatment effect values were compared across an MCID value range of 0.2 to 0.5 standard deviation units representing an effect size range. This range was used to determine if the adjustment for the effect of IA-saline would affect the potential clinical interpretation of the previously published meta-analysis results.

**Results:** IA-saline provides a therapeutic benefit that is potentially clinically meaningful to patients based on a range of MCID values (figure 1). Across the same range of MCID values, the effects of high molecular weight IA-hyaluronic acid products and IA-corticosteroid treatments were not conclusively clinically significant. However, when reassessing these treatments while accounting for the treatment effect of IA saline, they were found to have a clinically significant effect at the strictest MCID value (figure 2).

**Figure 1.** Effects of Topical Placebo and IA-Saline in Comparison to the MCID Threshold Range

**Figure 2.** Pain Effect Estimates Adjusted for Placebo Effect Estimate (from Bannuru et al [2015])

**Conclusions:** The use of IA-saline as a placebo treatment within RCTs of IA injectable therapies is inappropriately underestimating the true effect of these treatments. When the potential therapeutic effect that IA-saline demonstrates is accounted for, these IA therapies show a considerably larger therapeutic effect.

**SAT0566 ASSOCIATIONS OF OSTEOCLASTS AND MACROPHAGES IN SUBCHONDRAL BONE WITH SYMPTOMS IN PEOPLE WITH KNEE OA**

K. Aso<sup>1</sup>, M. Shahtaheri<sup>1</sup>, R. Hill<sup>2</sup>, D. Wilson<sup>2</sup>, D.A. Walsh<sup>1</sup>. <sup>1</sup>Arthritis Research UK Pain Centre and NIHR Nottingham BRC, University of Nottingham; <sup>2</sup>Sherwood Forest Hospitals NHS Foundation Trust, Nottingham, UK

**Background:** Knee pain is a major source of disability and reason for hospital visits in patients with knee OA, but the pain pathophysiology is incompletely

understood. Recent accumulating clinical evidence indicates that subchondral bone plays a role in generating joint pain in OA<sup>1</sup>. Subchondral bone marrow lesions (BMLs) detected on magnetic resonance imaging (MRI) in knee OA are strongly associated with pain<sup>1</sup>. In human OA histology, bone turnover and osteoclast numbers in subchondral bone were increased<sup>2</sup>. Inflammatory CD68-positive macrophages have been detected in bone marrow compartments of subchondral bone tissue from tibial plateaux of OA knees<sup>3</sup>. However, the relevance of osteoclasts and macrophage infiltration in subchondral bone to knee OA symptoms has not been clarified.

**Objectives:** To identify osteoclast and macrophage infiltration in subchondral bone associated with symptomatic knee OA, by comparing cases with similar macroscopic chondropathy, half of whom had sought help for knee pain and undergone total knee replacement (TKR) surgery (symptomatic chondropathy), the other half of whom had not sought help for knee pain but had died from unrelated illness (asymptomatic chondropathy).

**Methods:** Medial tibial plateaux were obtained from people undergoing TKR for OA (symptomatic chondropathy), and from post-mortem (PM) cases matched for similar macroscopic chondropathy scores (asymptomatic chondropathy). Samples were histologically graded for chondropathy, subchondral fibrovascular or macrophage infiltration, and TRAP-positive osteoclasts were quantified (figure 1).

**Results:** Patient demographics are shown in table 1. Total Mankin score showed similar values between the two groups (Table 2). The number of osteoclasts in symptomatic chondropathy cases was significantly higher than in asymptomatic chondropathy cases (table 2). This difference remained significant (p<0.05) after adjusting for age by logistic regression analysis. However, there was no significant difference in macrophage densities between symptomatic and asymptomatic chondropathy groups (Table 2).

**Abstract SAT0566 – Figure 1.** Representative photomicrographs of TRAP-positive osteoclasts and CD68-positive macrophages in subchondral bone.

\* : p<0.05 by Mann-Whitney U test

\*; p<0.05 by Mann-Whitney U test

**Conclusions:** Our results showed that not macrophages but osteoclast infiltration in subchondral bone were associated with symptomatic knee OA. Osteoclasts release protons that generate a local acidosis, which might be a potent activator of nociceptors leading to increased pain signaling<sup>4</sup>. Increased osteoclast activity might be key features associated with bone pain in knee OA.

SAT0567

#### THE LEADING RISK FACTORS FOR DEVELOPING INTENSIVE PAIN SYNDROME IN THE KNEE JOINTS IN PATIENTS WITH OSTEOARTRITIS

L.I. Alekseeva, E.A. Taskina, N.G. Kashevarova, S.G. Anikin, E.P. Sharapova, E. A. Strebkova, T.A. Korotkova, A.U. Feklistov. V.A. Nasonova Research Institute of Rheumatology, Moscow, Russia, Moscow, Russian Federation

**Background:** Intensive pain is one of key predictors of OA progression, although it remains unclear which key factors are responsible for the development of intensive pain.

**Objectives:** To study the risk factors for developing intensive knee pain in OA pts in a multicenter prospective study.

**Methods:** A prospective 5 year study included 185 female-patients from 6 RF territorial entities aged 40–75 y. with confirmed knee OA (ACR criteria), stages I-III (Kellgren J.-Lawrence J), who signed an informed consent. Mean age was 59 ± 8,1 y., the age at knee pain onset was 49 ± 8,7 y., and average OA duration was 11 ± 8,4 y. Individual annual medical file included patient's anthropometric parameters, case history, clinical examination findings, evaluation of knee pain intensity by VAS, WOMAC scale, the knee joint status, comorbidities and therapeutic modalities used during the follow up period. Instrumental diagnostic methods included plain radiography of knee joints, dual energy X-ray absorptiometry (DEXA) of the lumbar spine, femoral neck and of subchondral bone of the hip and tibia, ultrasonography (US) and MRI examination of knee joints. Stage II of knee OA was documented in 135 (73%) out of 185 pts, and stage III – in 50 (27%). Statistica 10.0 and SPSS 15.0 packages were used for statistical analysis.

**Results:** Based on pain intensity pts were divided into two groups: Group I – pts with more intensive pain (>70 mm VAS) – 16,8%, and Group II – pts with less intensive knee pain (<70 mm VAS) – 83,2%. Both groups were comparable in terms of age 58,8 ± 7,68 vs 61,06 ± 5,91 y., and disease duration 10<sup>(5–17)</sup> vs 12<sup>(6–18)</sup> y. Although, pts from Group I had statistically significantly higher body weight 82,7 ± 13,8 vs 74,8 ± 12 kg ( $p=0,002$ ), higher pain estimations by WOMAC 374<sup>(348–382)</sup> vs 225<sup>(172–268)</sup> mm ( $p<0,0001$ ), stiffness 100<sup>(80–125)</sup> vs 80<sup>(60–110)</sup> mm ( $p=0,01$ ), FI 1102 (970–1238) vs 820(646–935) mm ( $p<0,0001$ ) and total WOMAC 1541 (1462–1702) vs 1130(880–1291) mm ( $p<0,0001$ ). Besides, pts from Group I had greater percentages of varus knee deformity – 80,6% vs 29,2% (RR=2,76, 95% CI 2,04–3,73,  $p<0,0001$ ) and of H.valgus 87,1% vs 59,1% (RR=1,47, 95% CI 1,22–1,78,  $p=0,002$ ). MRI showed higher rate of bone marrow oedema in medial tibia in Group I: 51,9% vs 31,1% (RR=1,67, 95% CI 1,07–2,59,  $p=0,03$ ) compared to pts from Group II with less pronounced pain. A multivariate (discriminant) analysis showed that the most important risk factors for developing intensive knee pain in OA pts were: significant functional impairment, presence of knee varus deformity and Heberden's nodes, cartilage abnormalities (MRI finding) in medial tibial compartment, familial OA. A model capable of predicting development of intensive knee pain in an individual patient with high accuracy (area under the ROC-curve 0910 (95% CI 0,860–0,961) has been developed based on identified RF and their coefficients. Model accuracy is 87%.

**Conclusions:** In a prospective multicenter study, using comprehensive instrumental modalities (knee radiography, ultrasonography, MRI and BMD of peripheral bones and subchondral hip and tibia) it has been demonstrated that intensive knee pain (>70 mm VAS) is caused by excessive functional impairment, presence of knee varus deformity, Heberden's nodes, OA in parents, and cartilage destruction in the medial tibial compartment.

SAT0568

#### EFFECT OF DIACERIN VS GLUCOSAMINE-CHONDROITIN ON DISEASE PROGRESSION, AND MEASURES OF FUNCTION IN PERSONS WITH KNEE OSTEOARTRITIS: A 2-YEAR RANDOMISED, DOUBLE-BLIND, PLACEBO-CONTROLLED TRIAL

M.A. Khan, M. Chinoy, S. Iftikhar, D. Siddiqui, S. Ashfaq. *The Indus Hospital, Karachi, Pakistan*

**Background:** Globally, the incidence of knee osteoarthritis (KOA) is increasing. The treatments available for many years have included both pharmacological and non-pharmacological modalities.

**Objectives:** To examine whether Diacerein is more effective than glucosamine-chondroitin or a placebo in slowing disease progression, physical functioning and/or pain in patients with mild-moderate knee osteoarthritis

**Methods:** In a double-blind RCT, 322 Pakistani patients between 40–65 years with mild to medium KOA (Kellgren-Lawrence Grading 2 or 3) and a history of knee pain >6 months were randomised to receive Diacerein (50 mg twice daily) or Glucosamine-chondroitin (1200 mg twice daily) or a placebo (twice daily) for 2 years. All groups received exercise, diet and pain management counselling. Participant's general health and knee condition was assessed at baseline, 6-, 12-, 18- and 24 months using Short Form<sup>36</sup> Health Survey (SF 36) and WOMAC Index respectively. The Cartilage Oligomeric Matrix Protein (COMP) test was carried out at baseline, 12- and 24 months to assess progression of Knee OA. Improvement was considered at least a 10 point increase in SF36 score from baseline; a 10 point decrease in WOMAC and a 1 unit decrease in COMP.

**Results:** Participants with complete data at the end of year 1 (n=226) and year 2 (n=191) were analysed. At baseline, no significant differences were found in the distribution of gender, age, BMI, COMP levels, SF36, WOMAC scores as well as KL grade levels. Compared to baseline, at year 1 and 2 follow-up, participants in the Diacerein group had statistically significant improvement in their ability to work and other physical activities in comparison with those in the other 2 groups. By the end of year 2, social functioning improved in the Diacerein group as compared to those in the Glucosamine-Chondroitin (GC) group. Compared to placebo group, social functioning improved in the Diacerein group. A greater proportion of GC and placebo group participants reported reduction in their fatigue levels than those in the Diacerein group ( $p$  value=0.007). Using the SF36 scale, in comparison to baseline, improvements were made in all the groups albeit with no between group differences for physical functioning, emotional well-being, and general health. Using the WOMAC index, improvement occurred in all its domains of pain, stiffness and physical functioning, but statistically larger proportion of stiffness reduction took place in the GC group.

**Abstract SAT0568 – Table 1.** Status (% of patients) of functionality in participants at end of Year 1 and Year 2 compared to baseline

	Yr compared to BL	Diacerein <sup>a</sup>	Glucosamine-Chondroitin <sup>b</sup>	Placebo <sup>b</sup>	P-value
<b>General Health - SF-36 Scales</b>					
Role limitation due to physical health	Yr1	Improved (89.6%) <sup>c,c'</sup>	Improved (75.3%)	Improved (75%)	0.04 <sup>c</sup>
	Yr2	Improved (91.8%) <sup>c,c'</sup>	Improved (75%)	Improved (80.3%)	0.04 <sup>c</sup>
Fatigue	Yr1	Decreased (66.2%)	Decreased (80.8%) <sup>c'</sup>	Decreased (86.8%) <sup>c'</sup>	0.007 <sup>c</sup>
	Yr2	Decreased (73.8%)	Decreased (78.1%)	Decreased (69.7%)	0.55
Social functioning	Yr1	Improved (70.1%) <sup>b</sup>	Improved (92.2%)	Improved (72.4%)	0.20
	Yr2	Improved (67.2%) <sup>b</sup>	Improved (45.3%)	Improved (60.6%) <sup>b</sup>	0.04 <sup>c</sup>
Pain	Yr1	Decreased (58.4%)	Decreased (71.2%) <sup>c'</sup>	Decreased (53.9%)	0.08
	Yr2	Decreased (54.1%)	Decreased (45.3%)	Decreased (48.5%)	0.61

Pain <sup>d</sup>	Yr1	Decreased (83.1%)	Decreased (88.6%)	Decreased (80.8%)	0.33
	Yr2	Decreased (81.8%)	Decreased (91.7%) <sup>c,c'</sup>	Decreased (78.9%)	0.09
Stiffness	Yr1	Decreased (68.9%)	Decreased (71.9%)	Decreased (69.7%)	0.93
	Yr2	Decreased (68.9%)	Decreased (71.9%)	Decreased (69.7%)	0.93
Physical functioning	Yr1	Improved (97.4%)	Improved (97.2%)	Improved (98.7%)	0.80
	Yr2	Improved (98.4%)	Improved (98.4%)	Improved (98.5%)	0.99
Biochemical Criteria: Comp	Yr1	Decreased (45.5%)	Decreased (53.4%)	Decreased (60.5%) <sup>c</sup>	0.17
	Yr2	Decreased (47.5%)	Decreased (43.5%)	Decreased (50%)	0.76

Significant differences between groups in superscript where a)Diacerein, b)Glucosamine-Chondroitin, c)Placebo  
<sup>c</sup>p-value<0.05; <sup>c'</sup>p-value<0.10; Chi-square/Fisher-exact test  
<sup>b</sup>At yr 2 patients showed a 100% decrease in pain levels

**Conclusions:** In the first placebo-controlled trial assessing the effect of Diacerein versus GC, improvements occurred for all 3 criteria: general health, clinical and biochemical. A larger proportion of Diacerein participants improved their physical role limitation and social functioning in comparison to the other groups. Fatigue reduction was not the highest in the Diacerein group but that could be attributed to their increased physical and social functioning. Using the WOMAC scale, improvement in pain, stiffness and physical functioning occurred in all the groups indicating that perhaps the role of non-pharmacological interventions such as diet, exercise and pain management needs to be further explored. Biochemical COMP levels decreased in half the participants in comparison to baseline in all groups.

## SAT0569 IMPACT OF BARIATRIC SURGERY ON RHEUMATIC DISEASES: A SYSTEMATIC REVIEW AND META-ANALYSIS

M. Moly<sup>1</sup>, B. Combe<sup>1</sup>, T. Barnetche<sup>2</sup>, C. Daien<sup>1</sup>, C. Gaujoux-Viala<sup>3</sup>, C. Lukas<sup>1</sup>, J. Morel<sup>1</sup>, C. Hua<sup>3</sup>. <sup>1</sup>Rheumatology, Montpellier University Hospital, Montpellier; <sup>2</sup>Rheumatology, FHU ACRONIM Bordeaux University Hospital, Bordeaux; <sup>3</sup>Rheumatology, Nîmes University Hospital EA2415 Montpellier University, Nîmes, France

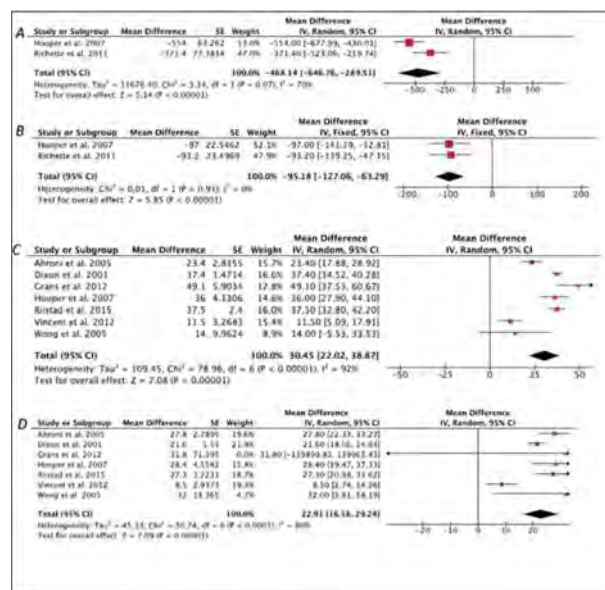

**Background:** Obesity increases the incidence of rheumatic diseases.<sup>1-3</sup> Bariatric surgery (BS), is known to improve obesity-related comorbidities.<sup>4</sup>

**Objectives:** The aim of our study was to assess current literature on the impact of BS on rheumatic diseases.

**Methods:** We systematically searched literature (via Pubmed, Embase, Cochrane library and abstracts from recent ACR and EULAR meetings) for studies evaluating the effects of BS on musculoskeletal disorders and, more precisely, on auto-immune inflammatory rheumatic disorders (AIRD), osteoarthritis and gout. Whenever methodologically feasible and relevant, a meta-analysis was performed with Review Manager Software, with random effects models in case of heterogeneity. Data were extracted by one investigator and independently checked by another.

**Results:** The literature search revealed 399 articles of potential interest, and further examination resulted in 119 studies included in systematic review (SR) and 24 studies fulfilling required criteria for preplanned meta-analysis. According to SR, BS seems to improve AIRD outcomes with notably 1 study on rheumatoid arthritis showing improvement in disease activity scores after BS and 2 studies showing a reduced incidence of psoriatic arthritis in patients who had BS compared to either general population or patients with psoriasis. Studies on patients

with musculoskeletal disorders (mainly osteoarthritis but also undefined musculoskeletal pain) showed an improvement of physical function and pain after BS with pooled mean difference of -468.1 (95% confidence interval [95% CI] -646.8; -289.5) for WOMAC function score, -95.2 [-127.1; -63.3] for WOMAC pain score, 30.5 [22.0; 38.9] for SF36 physical function score, 22.9 [16.6; 29.2] for SF36 bodily pain score (figure 1). Meta-analysis on osteoarthritis surgical management (hip or knee arthroplasty) did not show significant differences between patients who had undergone BS and obese patients without previous BS: pooled Odds ratio (OR) for incidence of orthopaedic reoperation was 1.4 [0.88; 2.3] and pooled OR for incidence of post-operative prosthesis infection was 0.91 [0.53; 1.6]. Hyperuricemia frequency (effect size 0.83 [0.79; 0.87]) and uric acid levels (mean difference -1.5 [-2.0; -0.94]) were significantly decreased after BS. Two studies showed a decrease in gout flares after BS.

**Abstract SAT0569 – Figure 1.** Forest plot for the mean difference between before and after BS for WOMAC function (A), WOMAC pain (B), SF36 physical function (C) and SF36 bodily pain (D) in musculoskeletal disorders

**Conclusions:** Despite heterogeneity, our study supports the benefit of BS on several parameters for obese patients presenting with rheumatic diseases.

**SAT0570 RESTING-STATE FMRI BRAIN CONNECTIVITY IN HAND OSTEOARTHRITIS**

M.D. Russell<sup>1</sup>, F.A. Howe<sup>2</sup>, T.R. Barrick<sup>2</sup>, N. Sofat<sup>1</sup>. <sup>1</sup>Institute of Infection and Immunity; <sup>2</sup>Molecular and Clinical Sciences Research Institute, St George's, University of London, London, UK

**Background:** Studies indicate brain grey matter volumetric changes are associated with chronic pain. In people with painful hand osteoarthritis (OA), grey matter volume reductions have been identified in the anterior cingulate cortex (ACC): a key pain-processing region.<sup>1</sup>

**Objectives:** We hypothesised that people with hand OA would have alterations in resting-state functional connectivity networks involving the ACC and other pain-processing brain regions relative to non-OA controls. Furthermore, we hypothesised that treatment with centrally-acting analgesics (pregabalin or duloxetine) would result in connectivity changes in these brain regions.

**Methods:** Resting-state functional MRI (fMRI) of the brain was performed on hand OA participants (n=28) before and after 12 weeks of treatment with duloxetine, pregabalin or placebo, and compared to non-OA participants (n=11) from the same age range (40–75 years). Scans of 7 hand OA participants and 1 control were excluded due to excessive movement artefact. Seed-based correlation analyses were performed using the CONN toolbox<sup>2</sup> to evaluate differences in functional connectivity of networks involving the ACC, insular cortices and thalami between patients and controls, and between pre- and post-treatment states.

**Results:** Relative to non-OA controls, hand OA participants had increased functional connectivity at baseline between the ACC and the cuneil, occipital poles, lateral occipital cortices and precuneus ( $p=0.00054$ , FDR-corrected for multiple comparisons; MNI coordinates  $x=-4$ ,  $y=-86$ ,  $z=+40$ ; 513 voxels) (figure 1). No differences in baseline functional connectivity were seen in the insular cortices or thalami. After treatment, altered functional connectivity was identified between the left thalamus and the ACC and paracingulate gyri ( $p_{FDR}=0.038$ ; MNI coordinates  $x=+2$ ,  $y=+36$ ,  $z=+24$ ; 138 voxels). Pairwise comparisons between treatment cohorts suggested that this represented a reduction in connectivity with pregabalin relative to duloxetine, without reaching statistical significance ( $p_{FDR}=0.062$ ). No significant treatment-associated connectivity changes were evident between duloxetine and placebo, or pregabalin and placebo.

**Abstract SAT0570 – Figure 1.** Seed-based correlation analysis demonstrating increased baseline functional connectivity between the ACC and the cuneil, occipital poles, lateral occipital cortices and precuneus in hand OA participants, relative to non-OA controls.

**Conclusions:** We have shown that people with painful hand OA have altered functional connectivity networks involving the ACC. In conjunction with previous findings of volumetric changes in this pain-processing brain region, this strongly supports the role of maladaptive neuroplasticity and central sensitisation in hand OA pain. Larger studies are required to better confirm if treatment with centrally-acting analgesics leads to connectivity changes in these brain regions.

**Objectives:** To evaluate the radiological, clinical and functional properties of hand osteoarthritis and to assess their relationship in a Turkish population.

**Methods:** The subjects with hand OA recruited into the study from the multi-centre national osteoarthritis cohort by the Turkish League Against Rheumatology (TLAR-OA). The demographic characteristics, body mass index (BMI), smoking, finger ratio, (2nd to 4th finger length), grip strengths with Jamar dynamometer, hand pain duration (month), hand pain severity (visual analogue scale; 0–100 mm) were evaluated. The radiological stage of hand OA was assessed according to the Kellgren Lawrence OA staging. The highest stage among the joints involvement was noted as the OA stage of the hand. The functional disability concerning to hand involvement was assessed with Duruöz Hand Index (DHI). The SPSS 24.0 statistical package was used for analysis. The descriptive analysis was performed for all parameters. Spearman's correlation coefficient was used to assess the relation between quantitative variables.

**Results:** A total of 364 subjects (330 female, 34 male) from 15 centres with mean of age 62.96 (SD: 10.22) were recruited into the study. The mean of BMI was 29.54 (SD: 4.51) and the percentage of smoking person was 6.3%. The mean of 2nd finger to 4th finger ratio of the patients was 0.96 (SD: 0.05). The mean of grip strengths of the right hand and left hand were respectively 15.55 kg (SD: 12.88) and 14.13 kg (SD: 11.39), which is lower than normal population.<sup>1</sup> The median pain duration of hand was 24 months (min-max: 1–480 months). The mean VAS score of pain was 5.05 (SD: 2.33). The mean DHI score was 16.82 (SD: 15.53). The patients' radiological OA involvement stages (2,3 and 4) of right and left hands were respectively 26.1% and 23.6% (stage 2); 22.5% and 20.9% (stage 3); 13.2% and 12.4% (stage 4) according to the Kellgren Lawrence scoring. The radiological stages of right and left hands respectively had poor correlation with VASpain ( $\rho=0.152$ ,  $p=0.010$ ;  $\rho=0.158$ ,  $p=0.009$ ); low but significant correlations with Duruöz Hand Index ( $\rho=0.257$ ,  $p<0.0001$ ;  $\rho=0.267$ ,  $p<0.0001$ ) and low but significant correlations with the duration of pain ( $\rho=0.231$ ,  $p<0.0001$ ;  $\rho=0.181$ ,  $p=0.003$ ). There were no significant correlations between the radiological stage of hand OA and BMI, finger ratio, grip strength ( $p>0.05$ ).

**Conclusions:** Although the subjects with hand OA had pain, low grip strength and hand disability; the radiological findings had meaningful relations with only functional involvement and pain duration in our population.

SAT0572

### INITIAL STRUCTURAL RESPONSE PREDICTS LONG-TERM SURVIVAL OF KNEE JOINT DISTRACTION AS A TREATMENT FOR KNEE OSTEOARTHRITIS

M. Jansen<sup>1</sup>, G. Van der Weiden<sup>1</sup>, R. Custers<sup>2</sup>, S. Mastbergen<sup>1</sup>, F. Lafeber<sup>1</sup>.<sup>1</sup>Rheumatology and Clinical Immunology; <sup>2</sup>Department of Orthopedics, University Medical Center Utrecht, Utrecht, Netherlands

**Background:** In relatively young patients with end-stage knee osteoarthritis (OA), total knee arthroplasty (TKA) comes with the risk of revision surgery<sup>1</sup>. Knee joint distraction (KJD) is a joint preserving surgery technique, which has been shown to provide clinical and structural improvement for at least five years<sup>2</sup> and postpones the need for TKA.

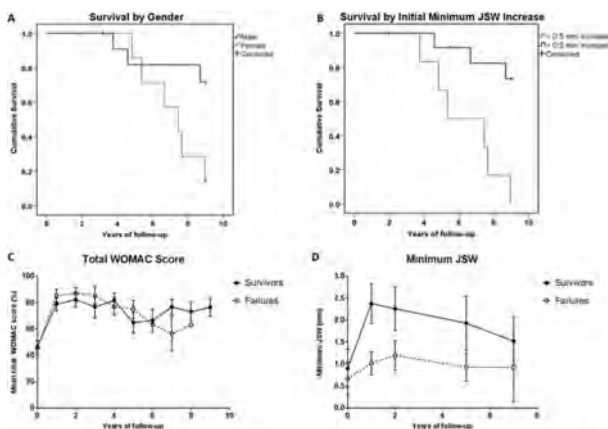

**Objectives:** To evaluate long-term clinical and structural results and identify characteristics predicting survival of the native knee joint after KJD.

**Methods:** End-stage tibiofemoral OA patients (n=20; age <60 years) indicated for TKA were treated with KJD. WOMAC questionnaires (100 best) and VAS pain scores (0 best) were used for clinical evaluation at baseline and every year after treatment, up to 9 years. Minimum and mean joint space width (JSW) and mean bone density of the most affected compartment (MAC) were measured using KIDA software on standardised radiographs (baseline and 1, 2, 5 and 7 years after treatment). The mean cartilage thickness of the MAC was measured on MRI scans (baseline and 1, 2 and 5 years after treatment). Survival after treatment was analysed (failure defined by TKA). Prediction of KJD survival was studied by logistic regression analyses.

**Results:** Three patients withdrew consent. Survival 9 years after treatment was 48%. Survival percentages differed significantly for gender (women 14%, men 70%; p=0.035; figure 1A) and for increase in minimum JSW in the 1st year (<0.5 mm increase 0%, >0.5 mm increase 72%; p=0.002; figure 1B).
